Various other peculiarities distinguish the horse from most other animals; some of these are shared by other hoofed animals. The two long bones of the fore-arm (*radius* and *ulna*) are separate in the greater number of animals, but in the horse, and in many other hoofed animals, they are consolidated into a single bone. The same consolidation is seen in the bones of the lower leg (*tibia* and *fibula*). The lengthening of the foot and stepping on the end of the toe raises the heel in the horse, as in many other animals, to a considerable height above the ground, where it forms the hock joint, bending backward, as the knee bends forward. In these as in various other ways the legs of the horse are especially fitted for swift running over hard and level ground, just as its teeth are for grinding the wiry grasses which grow on the open plain.

The zebra and the ass have the same peculiar structure of teeth and feet as the domestic horse, and differ only in the color of the skin, proportions of various parts of the body, etc.

Fossil Horses of the Age of Man.— In the early part of the Age of Man, or Quaternary Period, wild species of horse were to be found on every continent except Australia. Remains of these true native horses have been found buried in strata of this age in all parts of the United States, in Alaska, in Mexico, in Ecuador, Brazil and Argentina, as well as in Europe, Asia and Africa. All these horses were much like the living species, and most of them are included in the genus *Equus*. A complete skeleton of one of them (*Equus scotti*) was found by the American Museum expedition of 1899 in northern Texas. The difference between it and the domestic horse is chiefly in proportions, the skull shorter with deeper jaws, the legs rather short and feet small in proportion to the body. In these characters this fossil horse resembles an overgrown zebra rather than a domestic horse. We know nothing of its coloring. It may have been striped, and in this case would have been very zebra-like; but there are some reasons for believing that it was not prominently striped. The bones are petrified, brittle and heavy, the animal matter of the bone having entirely disappeared and having been partly replaced by mineral matter. They are not much changed in color, however, and are so perfectly preserved that they look almost like recent bone.

All the remains of these native horses which have been found in America have been petrified more or less completely; this means that they have been buried for many thousands of years, for petrifaction is an exceedingly slow process.

It serves as an easy method of distinguishing them from bones of the domestic horse, found buried in the earth. These cannot in any case have been buried for more than four or five centuries, and have not had time to petrify. Remains of these fossil horses are found in various parts of the United States, chiefly on the Niobrara River in Nebraska, and in central Oregon. Many separate teeth and bones have been found in the phosphate mines near Charleston, S. C.; other specimens have come from central Florida, from southern Texas, Arizona, Kansas, Louisiana and even from Alaska. They are, in fact, so often found in deposits of rivers and lakes of the latest geological epoch (the Pleistocene) that the formation in the western United States has received the name of Equus Beds.

In South America, in strata of the Pleistocene Epoch, there occurs, besides several extinct species of the genus *Equus,* the *Hippidium,* a peculiar kind of horse characterized by very short legs and feet, and some peculiarities about the muzzle and the grinding teetch. The legs were hardly as long as those of a cow, while the head was as large as that of a racehorse or other small breed of the domestic horse. All these horses became extinct, both in North and South America. It may have been that they were unable to stand the cold of the winters, probably longer continued and much more severe during the Ice Age than now. It is very probable that man — the early tribes of prehistoric hunters — played a large part in extinguishing the race. The competition with the bison and the antelope, which had recently migrated to America — may have made it more difficult than formerly for the American horse to get a living. Or, finally, some unknown disease or prolonged season of drought may have exterminated the race.

In Central Asia, two wild races persist to the present day; others were domesticated by man in the earliest times, and their use in Chaldæa and Egypt for draught and riding is depicted in the ancient mural paintings. In Africa the larger species became extinct in prehistoric times, as in America, but the smaller zebras still survive in the southern part of the continent (one species, the quagga, abundant 50 years ago, is now probably extinct), and the African wild ass is found in the fauna of the northern part. The wild horse of prehistoric Europe, a small race, short-legged and shaggy-haired, was domesticated by man, a fact that is known from the rude drawings scratched on bone or ivory by men of the Neolithic or Polished Stone Age. But the domestic horse now in use is derived chiefly from the Asiatic race, although it is probable that in some breeds there is a considerable strain of this shaggy, short-legged European race, and it is possible also that African races may have been domesticated and to some extent mixed with the Asiatic species. The domesticated ass is a descendant of the African species.

The Evolution of the Horse.— The history of the evolution of the horse through the Tertiary Period or Age of Mammals affords the best known illustration in existence of the doctrine of evolution by means of natural selection and the adaptation of a race of animals to its environment. The ancestry of this family has been traced back to nearly the beginning of the Tertiary without a single important break. During this long period of time, estimated at nearly 3,000,000 of years, these animals passed through important changes in all parts of the body, but especially in the teeth and feet, adapting them more and more perfectly to their particular environment, namely the open plains of a great plateau region with their scanty stunted herbage, which is the natural habitat of the horse. In the series of ancestors of the horse we can trace every step in the evolution of those marked peculiarities of teeth and feet which distinguish the modern horse from an ancestor which so little suggests a horse that, when its remains were first found 40 years ago, the animal was named by the great palæontologist Richard Owen, the *Hyracotherium* or "Coney-like Beast." Its relation to the horse was not at that time suspected by Prof. Owen, and was recognized by scientific men only when several of the intermediate stages between it and its modern descendant had been discovered. On the other hand, this first ancestor of the horse line is very difficult to distinguish from the contemporary ancestors of tapirs and rhinoceroses, and indicates how all the modern quadrupeds have diverged from a single type, each becoming adapted to the needs of its especial mode of life.

The earliest known ancestors of the horse were small animals not larger than the domestic cat, with four complete toes on each forefoot and three on each hindfoot. There is reason to believe that the still more ancient ancestors of this and all other mammals had five toes on each foot. In the forefoot of the earliest known stage we find a splint-bone or small, slender rudiment representing the missing first digit or thumb, which no longer appears on the surface of the foot, while in the hindfoot there is a similar rudiment representing the outer or fifth digit, but no trace is left of the innermost or first digit. The proportions of the skull, the short neck and arched back and the limbs of moderate length, were very little horse-like; recalling, on the contrary, some modern carnivorous animals, especially the civets (*Viverridæ*). The teeth were short-crowned and covered with low rounded knobs of enamel, suggesting those of monkeys and of pigs or other omnivorous animals, but not at all like the long-crowned complicated grinders of the horse.

Commencing with the *Hyracotherium,* 12 stages have been recognized from as many successive formations, showing the gradual evolution of the race into its modern form, and each stage is characteristic of its particular geological horizon. Some of the stages have been found in several parts of the world, but by far the most complete and best known series comes from the Tertiary Bad Lands of the Western States. Besides the main line of descent which led into the modern horses, asses and zebras, there were several collateral branches which have left no descendants. Of some stages all parts of the skeleton have been found, of others, only the jaws, or jaws and feet, are known. We can mention only the more important stages.

1. The *Hyracotherium* is the most primitive stage known, but only the skull has been found, so that it has not been determined exactly what the feet were like. The teeth display six rounded knobs or cusps on the upper molars and four on the lower ones, and these are just be-

THE EVOLUTION OF THE HORSE.

ginning to show signs of fusing into cross-crests. The premolar teeth have only one main cusp, except the third and fourth premolars (next the molars) in each jaw, which have two and three, respectively. The only specimens which have been found were in the London Clay or Lower Eocene of England and are preserved in the British Museum.

2. The *Eohippus* is much better known. It comes from the Lower Eocene of Wyoming and New Mexico, and is very like the *Hyracotherium* except that the molar teeth have the cusps more clearly fusing into cross-crests, and the last premolar is beginning to look like one of the true molars. The forefoot of this animal has four complete toes and the splint of a fifth. The hindfoot has three complete toes and the splint of another.

3. *Protorohippus.* In these animals the splint of the first digit in the forefoot and the splint of the fifth digit of the hindfoot have disappeared, but there are still four complete toes in the fore- and three in the hindfoot. The crests on the molars are a little clearer and the last premolar has become almost like the molars, while the next to the last premolar is beginning to become so. A skeleton of *Protorohippus* shows an animal of the size of a small dog, and proportioned much like the breed known as the *whippet.* The *Protorohippus* was found by Dr. J. L. Wortman in 1880 in the Wind River Bad Lands of Wyoming, and was described by Prof. Cope and others under the name of the "Four-Toed Horse."

4. Of *Orohippus* we have only parts of jaws and teeth. A specimen of the forefoot is exhibited in the Museum of Yale University.

5. *Epihippus* (*Upper Eocene*).—Of this stage of the evolution of the horse only incomplete specimens have been found. The molar teeth have the once round cusps almost completely converted into crescents and crests, while another tooth of the premolar series has become like the molars. The toes are still four in the forefoot and three in the hindfoot, but the central toe in each foot is becoming much larger than the side toes. (This species happens to be somewhat smaller than those found in the Middle Eocene stage, but no doubt there were others of larger size living at the same time). *Palæotherium* and *Paloplotherium* of the Upper Eocene of Europe form a side branch. They were very abundant in Europe, but have not been found in the New World. On each foot they had three toes of nearly equal size, and the teeth show a rather peculiar pattern. One of these animals was thought by Prof. Huxley to be a direct ancestor of the horse, but it now is considered to be merely a collateral relative. Some species of *Palæotherium* were of large size, equal to a tapir. They were first described in the year 1804 by the celebrated Baron Cuvier from remains found in the gypsum quarries of Montmartre, Paris.

6. *Mesohippus. Oligocene* (*White River Formation*). In this stage there are three toes on each foot, a splint representing the fifth digit of the forefoot of the Eocene ancestors. The middle toe is now much larger than the side toes, which bear very little of the weight of the animal. Three of the premolars have now become entirely like the molar teeth, the crests on the crown are completely formed, and the outside crest in the upper molars has taken the shape of two crescents. In the Middle Oligocene is found *Mesohippus bairdi* about the size of a coyote, while in the Upper Oligocene occurs *Mesohippus intermedius* as large as a sheep. Of both these animals all parts of the skeleton are known.

7. *Anchitherium* (*Lower Miocene*).—This stage has been found both in Europe and in America. It is much like its predecessor, but is larger and has the crests of the teeth somewhat higher and more complete. It probably is not in the direct line of descent of the horses, but is on a side branch.

8. *Parohippus* and *Hypohippus* (*Middle Miocene*).—In *Parahippus* the tooth-crests are much higher, and the transverse ridges on the upper molars are beginning to change shape so as to become a second pair of crescents inside the outer pair. *Hypohippus* is off the direct line of descent; its teeth are like those of *Anchitherium,* by which name it has been generally called, but the animal was much larger, equaling a Shetland pony in size. A complete skeleton of the *Hypohippus* was found near Pawnee Buttes, Colorado, in 1901 by Barnum Brown, of the Whitney expedition. In the forefoot of *Hypohippus* small rudiments still remain representing the first and fifth digits, but there is no splint of the fifth, as in *Mesohippus.* The second and fourth digits still touch the ground, though lightly. The feet of *Parahippus* were much like those of *Hypohippus,* but the side toes were smaller.

9 and 10. *Protohippus* and *Pliohippus* (*Middle* and *Upper Miocene*).—In this stage the crowns of the upper molars have become much longer, the two pairs of crescents on the upper molars are complete, with two half-separated cusps within the inner pair. And the valleys between the crests have become filled with cement, so that with the wear of the teeth the edges of hard enamel are backed inside by dentine and outside by cement. In this way the surface of the tooth has a series of enamel ridges always projecting a little above the grinding surface, because the softer material on each side wears down into hollows, yet never breaking off, because they are braced so thoroughly on each side. This is a very efficient instrument for grinding hard grasses. In *Protohippus* and *Pliohippus,* especially in the former, the crowns of the teeth are by no means as long as in the modern horses; they must therefore wear more slowly or wear out at an earlier age. The feet in these two genera have but one toe touching the ground. The side toes (second and fourth digits) are complete, but much more slender than in the earlier stages, and are apparently useless, as they cannot reach the ground. In some species of *Pliohippus* they have almost disappeared. The forefoot of *Protohippus* still retains tiny nodules of bone at the back of the "wrist" (sometimes improperly called in the horse the "knee-joint"), which are the remains of the first and fifth digits.

11. *Hipparion* (*Pliocene*).—This genus, probably also a side branch of the genealogical tree of the horse family, is much like *Protohippus,* but larger and with more complication about the tooth pattern. It is common in the

European Pliocene beds and has been found in America also. The feet are still three-toed, the side toes as large as those of the older *Protohippus.*

12. *Equus* (*Pleistocene* and *Recent*).— In this stage, that of the modern horse, the side toes have entirely disappeared and are represented by splints on the fore- and hindfoot. No trace remains on the forefoot of the little nodules which in *Protohippus* represented the first and fifth digits. The crowns of the teeth are much longer than in the last stage, and of the two half-separated inner columns on the upper molars, one has disappeared, the other has increased in size and changed in form. The skull has lengthened and the animal is much larger.

13. *Hippidium* (*Pleistocene. South America*).— The feet are like those of *Equus,* except that they were short and stout. The teeth are like those of *Pliohippus,* from which it is supposed to be descended. The skull is large and long, with very long slender nasal bones. Casts of the skull and limbs presented by the Museo Nacional of Buenos Ayres, Argentine Republic, are exhibited here.

The Change in Feet and Teeth.— Along with the disappearance of the side toes in the evolution of the horse there is a considerable increase in the proportionate length of the limbs, and especially of the lower part of the leg and foot. The surfaces of the joints, at first more or less of the ball-and-socket kind, which allows free motion of the limbs in all directions, become keeled and grooved like a pulley-wheel, permitting free motion forward and backward, but limiting the motion in all other directions and increasing considerably the strength of the joint. By this means the foot is made more efficient for locomotion over a smooth regular surface, but less so for traveling over very rough ground, and it becomes of little use for striking or grasping or the varied purposes for which the feet of polydactyl animals are used.

The increased length in the lower leg and foot increases the length of the stride without decreasing its quickness. The heavy muscles of the leg are chiefly in the upper part, and to increase the length of the lower part changes the centre of gravity of the limb very little. Consequently the leg swings to and fro from the socket nearly as fast as before, since in an ordinary step the action of the leg is like that of a pendulum, and the speed of the swing is regulated by the distance of the centre of gravity from the point of attachment, as that of a pendulum is by the height of the bob. To increase the length of lower leg and foot therefore gives the animal greater speed; but it puts an increased strain on the ankles and toe-joints, and these must be strengthened correspondingly by converting them from ball-and-socket joints to "ginglymoid" or pulley joints. Additional strength, likewise at the expense of flexibility, is obtained by the consolidation of the two bones of the fore-arm (*ulna* and *radius*) and of the leg (*tibia* and *fibula*) into one, the shaft of the smaller bone practically disappearing, while its ends become fused solidly to its larger neighbor.

The increase in length of limb renders it necessary for the grazing animal that the head and neck should increase in length in order to enable the mouth to reach the ground. An example of these changes is the modern horse, in which we find the neck and head much elongated when compared with the little *Hyracotherium,* and this elongation has taken place *pari passu* with the elongation of the legs. The reduction and disappearance of the side toes and the concentration of the step on the single central toe serve likewise to increase the speed over smooth ground. The soft yielding surface of the polydactyl foot is able to accommodate itself to a rough irregular surface, but on smooth ground the yielding step entails a certain loss of speed. A somewhat similar case is seen in the pneumatic tire of a bicycle; a "soft" tire accommodates itself to a rough road and makes easier riding, but a "hard" tire is faster, especially on a smooth road. Similarly, the hard, firm step from the single toe allows of more speed over a smooth surface, although it compels the animal to pick its way slowly and with care on rough, irregular ground.

The change in the character of the teeth from "brachydont" or short-crowned to "hypsodont" or long-crowned enables the animal to subsist on the hard, comparatively innutritious grasses of the dry plains, which require much more thorough mastication before they can be of any use as food than do the softer green foods of the swamps and forests.

All these changes in the evolution of the horse are adaptations to a life in a region of the level, smooth and open grassy plains which are now its natural habitat. At first the race was better fitted for a forest life, but it has become more and more completely adapted to live and compete with its enemies or rivals under the conditions which prevail in the high dry plains of the interior of the great continents. The great increase in size, which has occurred in almost all races of animals whose evolution we can trace, is dependent on abundance of food. A large animal, as may be shown on ordinary principles of mechanics, requires more food in proportion to its size than does a small one, in order to keep up a proper amount of activity. On the other hand a large animal is better able than a small one to defend itself against its enemies and rivals. Consequently, as long as food is abundant, the larger animals have the advantage over their smaller brethren, and by the laws of natural selection the race tends to become continually larger until a limit is reached when sufficient food becomes difficult to obtain, the animal being compelled to devote nearly all its time to getting enough to eat.

Cause of the Evolution.— The evolution of the horse, adapting it to live on the dry plains, probably went hand in hand with the evolution of the plains themselves. At the commencement of the Age of Mammals the western part of the North American continent was by no means as high above sea-level as now. Great parts of it had but recently emerged, and the Gulf of Mexico still stretched far up the valley of the Mississippi. The climate at that time was probably very moist, warm and tropical, as is shown by the tropical forest trees, found fossil even as far as Greenland. Such a climate, with the low elevation of the land, would favor the growth of dense forests all over the country, and to such conditions of life the animals of the beginning of the Mammalian period must have been adapted. During the Tertiary the continent was steadily rising above the ocean-level, and at the

SKELETON FROM MIDDLE MIOCENE BEDS, NEAR PAWNEE BUTTE, COLORADO.

same time other influences were at work to make the climate continually colder and drier. The coming on of a cold, dry climate restricted and thinned the forests and caused the appearance and extension of open, grassy plains. The ancient forest inhabitants were forced either to retreat and disappear with the forests, or to adapt themselves to the new conditions of life. The ancestors of the horse, following the latter course, changed with the changing conditions, and the race became finally as we see it to-day, one of the most highly specialized of animals in its adaptation to its peculiar environment. At the end of the Age of Mammals the continents stood at a higher elevation than at present, and there was a broad land connection between Asia and North America, as well as those now existing. At this time the horse became cosmopolitan, and inhabited the plains of all the great continents, excepting Australia.

It is a question whether the direct ancestry of the modern horse is to be searched for in western America or in the little known interior plains of eastern Asia. It is also unknown why the various species which inhabited North and South America and Europe during the early part of the Age of Man should have become extinct, while those of Asia (horse and wild ass) and of Africa (wild ass and zebra) still survive. Man, since his appearance, has played an important part in the extermination of the larger animals; but there is nothing to show how far he is responsible for the disappearance of the native American species of horse.

Parallel Evolution in Other Races.—It is interesting to observe that while the evolution of the horse was progressing during the Tertiary Period in North America another group of hoofed animals, the *Litopterna*, now extinct, in South America evolved a race adapted to the broad plains of Argentina and Patagonia and singularly like the horse in many ways. These animals likewise lost the lateral toes one after another, and concentrated the step on the central toe; they also changed the form of the joint-surfaces from ball-and-socket to pulley-wheel joints; they also lengthened the limbs and the neck; and they also lengthened the teeth, and complicated their pattern. Unlike the true horse, they did not form cement on the tooth, so that it was by no means so efficient a grinder. This group of animals native to South America became totally extinct, and were succeeded by the horses, immigrants from North America, which in their turn became extinct before the appearance of civilized man.

Many of the contemporaries of the horse in the northern hemisphere were likewise lengthening the limbs, lightening and strengthening the feet, elongating the tooth-crowns to adapt themselves to the changing conditions around them, but none paralleled the horse evolution quite so closely as did the pseudo-horses of South America. But the camels in America, the deer, antelope, sheep and cattle in the Old World, progressed on much the same lines of evolution, although their adaptation was not to just the same conditions of life.

William D. Matthew,
American Museum of Natural History.

Horse, the French Coach. The prevailing characteristic of a Frenchman is his devotion to those things that make life pleasant. From an artistic standpoint he leads the world. Pleasure and horses go together. A Frenchman is instinctively a horseman. The French cavalry is without an equal in the world. Since the time of Napoleon the French government has taken charge of the breeding of horses that are best adapted for cavalry uses, and in accomplishing this purpose the government has contributed to the production of a very high-class coach horse. The cavalry horse of France is usually selected after the committee has finished their work of picking out the very best stallions for breeding purposes. Nearly every French coach stallion that stands for public service in France is owned by the French government. The French have been willing to advertise and sell their other breeds of horses, but they have been loath to part with their coach horses. The instinct of self-preservation causes the French government and the French people to keep their French coach horses at home in order to have better horses than can be found in any other country.

The breed of French coach horses has its origin from the same source as the English thoroughbred. On the one hand, the English thoroughbred surpasses in speed, while the French coach horse is superior in all of those qualities that go to make up a high-class carriage horse. Like the Percheron, the French coacher is developed in its highest state of perfection in Normandy, but he comes from the northern part, while the Perche is in the south of Normandy.

The French coach horse is about 16 hands high; his average weight is between 1,200 and 1,300 pounds. His color is as a rule bay, brown or chestnut. His outline is most pleasing. He is a fast trotter, and under the conditions of horse racing in France under saddle over a turf track a distance of 4,000 metres he holds the record. The French method of developing their trotters cultivates a very high, attractive style of action. Not only is the French coacher seen in every French city hauling the most gorgeous equipages over the boulevards surrounding Paris, but he is to be seen in the best stables throughout all of the capitals of Europe, especially in London.

The French coacher supplies the English royalty with their most useful and most attractive carriage horses.

For more than 20 years French coach stallions have been brought to America very sparingly. Where they have been crossed with the best road mares, trotting bred mares, the result has been most satisfactory. High-grade carriage horses that go into our best markets and sell for the highest prices usually have a strain of French coach blood flowing through their veins.

A perfect type of the French coach horse when standing or in action is impossible to describe in words. To fully realize his superiority, to appreciate and admire his style and magnificent high action, one must actually see him. Words are inadequate to describe him, and the most perfect picture falls far short of the most perfect horse.

John R. McLaughlin.

Horse, the Percheron. The Percheron horse is the production of the most patient care and the application of the best scientific principles of breeding. From the dawn of his-

tory the French breeders of draft horses have been most successful, and the horses they have raised have been renowned the world over.

In the 16th, 17th and 18th centuries the same rules of selection in breeding have been applied that prevail to-day. The good horses were permitted to reproduce themselves and multiply. The inferior and unsound ones were never permitted to breed. The result of this most careful selection, based on scientific principles, has given the French the best draft horse that the world produces.

In a very small portion of Normandy called the "Perche" the highest result has been attained. From this district the Percheron horse has been sent to all parts of the world with such satisfactory results that the word Percheron to-day means the ideal draft horse the world over. From the very beginning up until the present time the object of the Percheron breeders has been to produce the kind of horse that would move the greatest weight with the greatest speed.

In making their selections for breeding purposes the Frenchmen have not only picked out stallions and mares that would make the best horses, but comely appearance and pleasing outline have also in a measure been their guide, and as a result the Percheron horse to-day is not only the best draft horse in the world, but he is one of the most attractive. He is indeed a handsome horse. The prevailing color of the Percheron horse is from black to white, including all of the various gradations from black, dark gray, dapple gray, gray and white.

About 50 years ago the first Percheron stallions were imported from France to America, and those that became most famous came to Ohio. One, called Louis Napoleon, owned in Union County, Ohio, and afterwards sold to go to Normal, Ill., both here in Ohio and in his new home in Illinois, was admired by all. In a few years, when his colts began to appear, the reputation of the Percheron breed in America was so well established that hundreds and even thousands of them have been imported to America each year.

During the past hundred years the government in France has maintained a system of supervision over the horse-breeding industry. The government does not own every Percheron stallion, but every Percheron stallion must be approved by the government inspectors and must receive a certificate of approval before he can be used for breeding purposes in France. Many of the best stallions belong to the government. Many of those owned by private individuals receive a subsidy from the government if their owner will offer their services to the public.

On account of the very high tariff laws the French breeders supply nearly all of the horses used in France. The ups and downs of prosperity and depression do not affect the horse-breeding industry in that country. During the period of depression that prevailed in the United States ten years ago American breeders became very much discouraged. Most of the stallions were castrated and the best mares were disposed of, but in France these conditions did not prevail.

In '97, '98 and '99, when more prosperous conditions were brought about in this country, the demand for horses was very greatly increased. The French were able to supply the deficiency. Good stallions and mares could be found there in abundance when a surplus could not be found anywhere else in the world. Instinctively the French breeders keep their best stallions and mares, no matter what the foreign demand may be, and as long as they pursue this policy the best Percheron horses will be found in France and the best breed of draft horses in the world will be the Percheron.

JOHN R. MCLAUGHLIN.

Horse Bot-fly, a bot-fly (*Gastrophilus equi*) parasitic in horses. The adult is about .75 inch long; the wings transparent with dark spots forming an irregular band toward the centre; the body brown and very hairy, the head whitish in front, and the abdomen dark-spotted. The females (males are rarely seen) have an elongated tapering abdomen. The oblong light yellow eggs are glued, one by one, to the hairs of the forepart of the body, where they are likely to be licked off by the animal. The moisture of the tongue causes the developed larvæ to break through the shell almost instantly, and to be carried into the mouth and thence to the stomach. Many curious facts have been observed in connection with these eggs and their development, and may be found fully discussed by Osborn in his 'Insects Affecting Domestic Animals,' issued by the United States Department of Agriculture (1896). Reaching the stomach, the larvæ fasten themselves to its walls by hooks in the posterior end of the body, and great masses sometimes accumulate, seriously obstructing the pyloric outlet. They remain there, absorbing nourishment and interfering with digestion through the winter, and on the return of warm weather let go their hold, pass out through the intestines, enter the ground, pupate there for a few days, and then emerge as flies. This pest chiefly affects horses out at pasture, and can be prevented only by removing the eggs, which can easily be seen. The attempt to remove the bots from the stomach by turpentine or other drugs is a dangerous proceeding which should only be attempted under direction of a veterinarian.

Horse-chestnut, or **Buckeye,** a tree of the small family *Hippocastanaceæ* and genus *Æsculus*, represented in Europe by the horse-chestnut (*Æ. hippocastanum*), now cultivated in all parts of the world, but native to Greece, Turkey, and southwestern Asia; and three indigenous American species known as buckeyes, from the appearance of the fruit. These trees are shapely, have leaflets diverging from the stalk like fingers, and bear white or tinted flowers in large erect panicles, turning the whole tree into the semblance of a big bouquet. The fruit of the horse-chestnut much resembles a huge chestnut, and is prickly when young. In this respect the common or Ohio buckeye (*Æ. glabra*) agrees with it, but has only five leaflets in each leaf and its flowers are small and not showy. The unpleasant odor exhaled by the bark and leaves in all this genus is especially strong in this species. A more southern species, developed into fine trees in the southern Alleghanies, is the sweet or yellow buckeye (*Æ. octandra*) which with the red buckeye (*Æ. pavia*) bears smooth fruit. Though so hand-

some, rapid in growth and serviceable as ornamental or shade trees, they are otherwise of little value. The wood is light colored, soft, and useful mainly for paper pulp and small articles; it contains a large quantity of saponaceous material, so that country people use the mucilaginous sap as soap. The leaves and roots of the Ohio buckeye are poisonous. The seeds are bitter but are eaten by cattle and sheep, with the preparation of boiling in alkaline water which is necessary in Europe; and from them a flour is made especially adapted to bookbinders' and shoemakers' paste, as, besides having great tenacity, it will not be attacked by insects. In France starch is produced from horse-chestnut seeds on a large scale. The seeds are also used in the southern United States to impart a flavor of age to raw whiskey. The red buckeye has been naturalized in Europe as a park tree. California has a species of its own, Japan another, and a third grows on the Himalaya Mountains.

Horsefield, Thomas, American naturalist and explorer: b. Bethlehem, Pa., 12 May 1773; d. London, England, 1866. He was graduated in medicine at the University of Pennsylvania, and served as "medical apprentice" in the Pennsylvania Hospital from 1794–99, being the fifth interne in the hospital in the order of appointment. In October 1799 he accepted service as surgeon on the "China," about to sail for Java. He returned in the latter part of 1800, but in 1801 went again to Java for the purpose of thoroughly exploring the island, and was commissioned as regimental surgeon by the Dutch Colonial Government. From 1802 he devoted himself to the thorough examination of the flora, fauna, and geology of the island, at first under the auspices of the Dutch government, and, when possession of Java was taken by the English, under the especial patronage of Sir Thomas Stamford Raffles, the lieutenant-governor. A warm friendship, due to kindred tastes, sprang up between Horsefield and his celebrated patron, and, when the English tenure of Java ceased and Sir Stamford Raffles returned to England, Horsefield accompanied him, bringing with him the collections he had made, which were placed in the museum of the East India Company in London, of which he was presently made the curator, a position which he held for nearly fifty years until his death. Horsefield, by his explorations and writings, laid foundations for our knowledge of the natural history of the far East. He contributed while in Java many important papers to the publications of the Batavian Society of Arts and Sciences. In 1824 he gave to the world his great work entitled 'Zoological Researches in Java and the Neighboring Islands,' and from 1838–52 issued in folio parts the 'Plantæ Javanicæ Rariores.' Both works are sumptuously illustrated by colored plates. In 1856–58 he published the 'Catalogue of the Birds in the Museum of the East India Company,' and in 1857–59, with Frederic Moore, the 'Catalogue of the Lepidopterous Insects in the Museum of the East India Company.' Besides these larger works he was the author of a multitude of papers published in the 'Transactions' and 'Proceedings' of societies.

To him perhaps more than to any other single naturalist are we indebted for the first correct account of the botany and zoology of the regions with which he became familiar in his early life.

W. J. Holland,
Director Carnegie Museum, Pittsburg.

Horse-fly, Gad-fly, or **Deer-fly,** any species of the family *Tabanidæ,* usually large, robust, flies, with a broad head pointed in front and concave behind, with immense eyes, and fitting closely to the thorax. The legs are long and stout; sometimes hairy, but without stiff bristles. The females are provided with a long sharp proboscis with which they pierce the skin of animals, and are especially annoying to such short-haired kinds as horses and deer. No poison is injected into the wound, but injurious bacilli may be introduced, causing bad sores. One of the most widely distributed in the United States is the large black *Tabanus americanus.* These flies attach their eggs to grass and sticks in wet places. The larvæ find their way into water or wet earth, and are carnivorous, feeding on other insects, snails, etc. They pass the winter before pupating and emerge as flies in the early summer. To the same family belong many smaller green or yellow species of the woods more usually called deer-flies.

Horse-mackerel. The horse-mackerel, tuna or tunny (*Thunnus thynnus*), is the largest member of the mackerel family (*Scombridæ*), attaining a length of 10 feet or more and a weight of 1,000 to 1,500 pounds. It is found in all warm seas, both of the Atlantic and Pacific oceans, and wanders as far north as Newfoundland, appearing on our shores with the menhaden and mackerel. See Tunny.

Horse-power, the power of an ordinary horse or its equivalent, the force with which a horse acts when drawing. The mode of ascertaining a horse's power is to find what weight he can raise and to what height in a given time, the horse being supposed to pull horizontally. From a variety of experiments it is found that a horse, at an average, can raise 160 pounds weight at the velocity of 2½ miles per hour. The power of a horse exerted in this way is made the standard for estimating the power of a steam-engine. Thus we speak of an engine of 60 or 80 horse-power, each horse-power being estimated as equivalent to 33,000 pounds raised one foot high per minute, but this estimate is considered much too high, 17,400 foot-pounds per minute being generally considered nearer the truth. As it matters little, however, what standard be assumed, provided it be uniformly used, that of Watt has been generally adopted. The general rule for estimating the power of a steam-engine in terms of this unit is to multiply together the pressure in pounds on a square inch of the piston, the area of the piston in inches, the length of the stroke in feet, and the number of strokes per minute, the result divided by 33,000 will give the horse-power deducting one tenth for friction. As a horse can exert its full force only for about six hours a day, one horse-power of machinery is equal to that of 4.4 horses.

The motive power used in the manufacturing establishments of the United States in 1900, according to the census report, aggregated 11,300,081 horse-power, as compared with 5,954,655 horse-power in 1890, 3,410,837 horse-power in 1880 and 2,346,142 in 1870. Of the total power used in manufactures during the census

year, steam-engines furnished 8,742,416 horse-power, or 77.4 per cent of the aggregate; water wheels supplied 1,727,258 horse-power, or 15.33 per cent; electric motors, 311,016 horse-power, or 2.7 per cent; gas and gasoline engines, 143,850 horse-power, or 1.3 per cent, and other forms of mechanical power 54,490 horse-power, or five tenths of 1 per cent. Rented power was used to the extent of 321,051 horse-power, or 2.8 per cent of the total. Of this rented power 183,682 horse-power was electric and 137,369 horse-power was from other sources of energy. See POWER.

Horse-racing, a national pastime, which has been called the sport of kings because it has been one of their amusements since the earliest dawn of civilization. The racing horse is of three distinct types, the running horse, the pacing horse, and the trotting horse. For many centuries the running race has been the traditional turf sport in Great Britain and on the continent, with many varieties, such as flat racing, or racing on level ground; steeple-chasing, or racing over ground not specially prepared for the purpose, and hurdle-racing, in which the horses have to leap over obstacles purposely placed in the way. Trotting is primarily an American institution, the outcome of thoroughbred development. Late in the 19th century horse-racing made a wonderful advance in the United States and easily became the great national pastime of the country.

Early History.— Thothmes I., of the 18th Egyptian dynasty, left a papyrus letter telling of his conquest of Mesopotamia, and priding himself upon the acquisition of the racing horse (the Arab) and being the first to introduce him in Africa. Somewhat later the records tell of King Solomon buying horses from Egypt, and paying as much as $3,000 for some of them. Among the Greeks it was introduced into the Olympic games in the 33d Olympiad (648 B.C.). From Greece it was introduced into Rome, where it gained a place as one of the games of the circus. The institution of horse-races in England, where the sport has become a great national pastime, belongs to a very remote period. The first regular horse-races, however, did not take place till the reign of James I. The successors of James I. down to Queen Anne were all more or less attached to the sport. In the reign of the latter, in 1711, the York Plates were founded, and about that date the passion for betting on the turf began to be general. Under George I., the successor of Queen Anne, horse-racing became more flourishing. The two most celebrated horses of that period were Flying Childers (foaled in 1715) and Eclipse (foaled in 1764), which long had the reputation of being the fleetest horses that ever ran. From the latter are descended many of the first-class thoroughbreds of the present day. None of the English sovereigns was more devoted to horse-racing than George IV. Between 1784 and 1792, while yet Prince of Wales, he gained 185 prizes, including the Derby of 1788. Horse-racing was introduced into France from England during the reign of Louis XIV., and under Louis XV. was pursued with the utmost enthusiasm.

Breeding and Training.— The training of a running horse begins with its second year, and is a slow process, requiring great care and attention. During the period of training the horse is under the charge of a stable-boy. In the first part of the training the exercise to which the horse is subjected is comparatively gentle, but in the latter part a gallop of half or three quarters of a mile is taken every other day. Before a race takes place the powers of the horse are put to the test by its being made to run over about half a mile against an older horse, which is weighted to make up for the difference in age. The breeding of thoroughbred horses, that is, of horses which can trace an unbroken pedigree through the best sires and the best dams, is when well conducted a very profitable business. The prices given for stallions are sometimes enormous. In 1900, when the Duke of Westminster's racing stud was sold, the average price reached the high level, and the world's record price of $187,500 was brought by Flying Fox, which had won the Derby the year before. Before this, Ormonde, another Derby winner, had sold for $150,000. The large sums now given for the use of stallions in breeding studs are the cause of race-horses being withdrawn much earlier than they used to be from the turf, for as soon as they have acquired a reputation the owner of a good race-horse can make much larger sums by hiring it out for breeding purposes than he could by entering it for races. The pedigrees of all thoroughbred horses are registered in the stud-book, so that if any particular animal is omitted in that register the inference is that its pedigree is not without some blemish more or less remote. The effects of a careful system of breeding in improving the quality of horses are very marked. No pure Arabian horse can be compared in point of speed with a thoroughbred. In size and shape, too, the horses of the present day surpass those of former times, the average height of a thoroughbred now being 15 hands 3 inches, while formerly it seldom reached 15 hands. See also HORSES, AMERICAN THOROUGHBRED.

Race Meetings.— In Great Britain the chief race meetings are those at Epsom, Newmarket, Ascot in Berkshire, Doncaster, Goodwood, Liverpool, Manchester, and Leicester. Those at Newmarket are the oldest of all, dating from the reign of Charles II. The Ascot races are considered the most fashionable, being largely attended by the aristocracy, and sometimes honored with the presence of royalty. The Goodwood races, which are held in the Duke of Richmond's park in Sussex, are also a favorite rendezvous of the aristocracy. But the most popular meeting throughout the year is the Epsom, which owes its popularity partly to the proximity of Epsom to London and partly also to its being the meeting at which the Derby and the Oaks are run. At the Oaks the ladies are the chief bettors, and the bets are not thousands of pounds, but dozens of Paris gloves. The principal racing meetings in France are those held in spring and autumn at Chantilly and the Bois de Boulogne.

In the United States the season opens at the Bennings track at Washington early in the spring and closes there in the fall. Following Bennings comes the Aqueduct, and Morris Park, Gravesend and Sheepshead, the latter track being the show track of this country, occupying the same position as the Ascot of the English

turf, which is also named "The Ladies Meet." Then follows the Brighton Beach season during July and August. Although the classic events of England and France are of longer standing they cannot be said to outrank or outinterest the famous Brooklyn Handicap, founded in 1887; the Suburban (1884); the Futurity (1888); the Realization (1889), and numerous other events. There are racing parks and tracks in nearly every city in the country, and there are many famous meetings in the West and South, like the Latonia in Kentucky, the Harlem and Washington Park in Chicago, Saratoga and others.

Racing Rules.— The conditions under which the most of the races are run are the following: Every horse that takes part in a running race must be entered as a yearling, that is, before the close of the year in which it is foaled, for a horse's age is always reckoned from the 1st of January of the year in which its birth takes place. On being entered a certain sum is paid by the owner, which is called a forfeit, because it is forfeited if the horse is afterward withdrawn, or, in the language of the turf, "scratched." The racing is conducted under association rules, and in England under regulations laid down by the Jockey Club, a body instituted in 1750. The stewards of the Jockey Club have power to grant and to withdraw licenses to racing officials, jockeys, and race-courses; to fix the dates on which all meetings shall be held, and to make inquiry into and deal with all matters relating to racing. At every regular race-meeting there must be at least two stewards, with a clerk of course, a handicapper, a stake-holder, a clerk of the scales (since the jockeys of course must be carefully weighed), a starter, and a judge, each of these officials being licensed by the club.

Handicapping.— Formerly all running races were what is called weight-for-age races, that is, all the horses entered to compete were of the same age and bore equal weights, or if in certain cases there was an inequality in point of age there was also a fixed difference in the weight carried. But it was found that when races were conducted on this plan the best horses came to be known, and the inferior ones withdrew, not venturing to compete with them, so that the race resulted in a walk-over. Hence arose the practice of handicapping, that is, of adjusting as nearly as possible the weight to be carried to the previously ascertained powers of the horse, so as to reduce the chances of all the horses entered to an exact equality. In England the principal weight-for-age race for two-year-olds is the Middle Park Plate, and for the three-year-olds the principal for both colts and fillies are the Two Thousand Guineas, the Derby, and St. Leger, and for fillies only the One Thousand Guineas and Oaks. The most important handicap races are the Great Northampton Stakes, the City and Surburban and Metropolitan Stakes at Epsom, the Northumberland Plate, the Goodwood Stakes, the Ascot Stakes, the Ebor Handicap (run at York), the Great Yorkshire Stakes (run at Doncaster), the Liverpool Spring, Summer, and Autumn Cups, the Cesarewitch, Cambridgeshire, and Newmarket Handicaps (run at Newmarket).

Betting and Book-making.— The prevalence of the practice of betting in connection with horse-racing is a fact so well known that it is needless to enlarge upon it, although it will be of interest to some to explain in what manner it is conducted. Bettors are divided into two classes — the backers of horses, and the book-makers, or professional bettors, who form the betting ring, and make a living by betting against horses according to a methodical plan. Backers of horses may be again divided into those who have special information about the qualities of the horses which are to engage in a race, which enables them to back a particular horse with a certain amount of confidence; and those who have no such means of information, and accordingly back horses pretty much at random. The former class, if their information is good, have a very fair chance of success in their speculations, and the horse that wins any great race usually brings in to his owner vast sums in payment of bets, compared with which the stakes, considerable as they often are, are insignificant; but the latter class are pretty certain in the long run to lose. By the method adopted by the professional bettor the element of chance is as far as possible removed. Instead of backing any particular horse, the professional bettor lays the same sum against every horse that takes the field, or a certain number of them, and in doing so he has usually to give odds, which are greater or less according to the estimate formed of the chance of success which each of the horses has on which the odds are given. In this way, while in the event of the race being won (as is usually the case) by any of the horses entered in the betting-book of a professional bettor, the latter has always a certain fixed sum (say $5,000) to pay, he receives from the backers of the losers sums which vary in proportion to the odds given. Thus, if a book-maker is making a $5,000 book, and the odds against some horse is 4 to 1, he will, if that horse wins, have to pay $5,000, while, if it loses, he will receive $1,250. If the sum of the amounts to which the horses in a particular race have been backed in some professional bettor's book is $6,500, and if the odds against the first favorite were 5 to 2 (or $5,000 to $2,000), then the total sum received by the book-maker, in the event of the race being gained by the first favorite, would amount to $6,500, $2,000 or $4,500, so that he would suffer a loss of $500; while if a horse had won that had long odds against him (say 200 to 1, or $5,000 to $25), his total receipts would amount to $6,475, and his gains to $1,475. Very frequently the receipts of the book-maker are augmented by sums paid on account of horses which have been backed and never run at all.

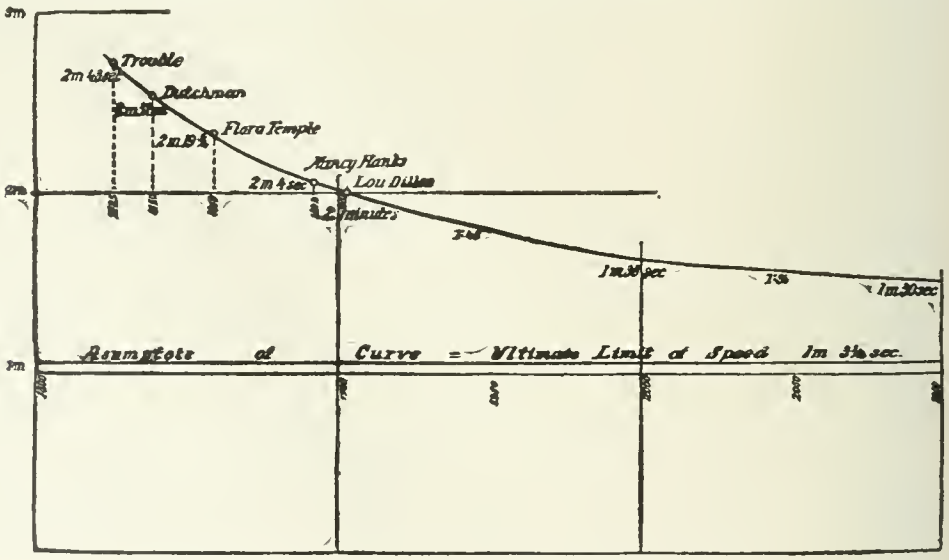
Americans Abroad.— In 1855 an American horse had never won a race abroad and an American jockey had never ridden in an English race. The first American to go to England with a stable of thoroughbreds was Richard Ten Broeck, who sailed for England in 1856, taking with him Lexington, Lecompte, the only horse that ever beat Lexington: Pryor, and Prioress. Lecompte died of influenza the first year, and Pryor soon followed. It was left for Prioress to retrieve the fortunes of the stable. Her great victory was in the Cesarewitch, a race at 2 miles, 2 furlongs, and 28 yards. There were 37 starters, the very best horses on the English turf. After one of the most exciting races ever run, Prioress, El Hakim, and Queen Bess finished in a dead heat. In the run off, the American horse won by a length in 4 minutes and 15

seconds. American successes really began in 1878, when Pierre Lorillard and James R. Keene shipped stables to England. The former's Parole won the Newmarket Handicap, defeating the English favorite, Isonomy, a horse that was called the best ever foaled on English soil. The American gelding next took the great Metropolitan, the Great Cheshire, and the Epsom Gold Cup in quick succession. Iroquois followed Parole, winning four important stakes in 1880, including the St. Leger. The subsequent invasion of England by W. C. Whitney, Clarence A. Mackey, Richard Croker and others with famous winning horses, and the successes of Sloan, Reiff, Martin and other American jockeys, have brought renown to the American turf. In 1902, American horses ridden by American jockeys took part in 561 races in England, of which they won 85, were second in 80, third in 52, and unplaced 344 times. The stakes and purses won amounted to $234,120. In 1903, up to 15 September the Americans have done even better proportionately, starting in 453 races, winning 74, second in 81, third in 47, and unplaced 251 times. The winnings amount to $259,000. American horses were second in the Oaks and third in the Derby.

Trotting.— The evolution of the trotting horse in America, and the gradual reducing of the one mile record, is a history coincident with the improvement and progress made in breeding. Beginning with the record of Trouble, who trotted a mile in 2.43 in 1826, of Dutchman (2.32) in 1839, and Flora Temple (2.19¾) in 1859, the evolution proceeds to George Wilkes, Dexter, Goldsmith Maid and the others who followed. In 1818, at a Jockey Club dinner, discussion drifted to the trotter, and a wager was made that no horse could be produced which could trot a mile in three minutes. Boston Blue was named at the post by Maj. William Jones, and the old chronicle says that he "won cleverly and gained great renown." The New York Trotting Club was organized in 1825, for the purpose of improving the speed of road-horses. The initial purses were for races of two-mile and three-mile heats. In 1835 trotting was in almost daily vogue in New York. It was not until 1845 that a mile was trotted in less than 2.30. In 1863, the American trotting horse was an unknown quantity abroad, while in 1903, American trotting stock was in demand throughout Europe. Germans, French, Russians, and Austrians have bought some of our best bred animals.

The National Trotting Association was formed in 1870 as a result of a meeting of breeders and track owners the previous year. In 1887 the American Trotting Association was formed with headquarters in Chicago, and it works with the National Trotting Association to detect and punish fraud. Some of the ablest men in the country sit on the boards of appeals, and the decisions command respect and are accepted as final. The careers and records of famous trotters like George Wilkes; Dexter; Harrietta; Axtell (2.12); St. Julian (2.11¼); Sunol (2.10½); Maud S. (2.08¾); Kremlin (2.07¾); Stamboul (2.07½); Beuzetta (2.06¾); Directum (2.05½); Nancy Hanks (2.04); Alix (2.03¾); The Abbot (2.03¼), and the mile of Major Delmar (2.00¼), Cresceus (1.59¾), and Lou Dillon (1.58½) in 1903, tell the brief but wonderful story of the trotting horse in America. See also HORSES, TROTTING.

Record Possibilities.— The gradual lowering of the trotting record from a mile in three minutes to the 1.58½ record of Lou Dillon on 24 Oct. 1903 has led many to question if a limit is ever to be reached. The mathematician has a rule to guide him in a guess at the answer to such questions, and the 'Scientific American' has prepared the accompanying chart which is of vast interest. The vertical lines represent the years in which the record has been lowered, the spaces between the lines indicating the time interval, the length of each vertical line indicating the record for that year. A curve is next sought that will pass through as many of the points as possible, or close to them, and the continuation of this curve across lines indicating future years shows the best answer to the main question that the facts warrant. If the curve



Equilateral Hyperbola Showing the Law of Trotting Improvement.

proves to be a hyperbola, it will afford confidence in the accuracy of the solution, for a peculiar property of the hyperbola is that it constantly approaches but never reaches a straight line called an asymptote, and this asymptote represents the ultimate rate of speed. With Lou Dillon at the two minute mark, a point is indicated on the chart showing this hyperbolic curve as the law of improvement. It is now possible to pass the curve of a hyperbola through the record points of Trouble in 1826, Dutchman in 1839, Nancy Hanks in 1892 and Lou Dillon in 1903. This curve will be within a few seconds of many other records in which the time was notably reduced.

The hyperbola is represented by the equation $xy = 10.000$, in which x equals the number of years since 1726, y equals the number of seconds over 63½ seconds to trot a mile. The notable records of Maud S. in 1881 and 1885, with the high-wheel sulky, are 2¼ to 3¼ seconds above the curve, which would indicate that the change to the pneumatic sulky will account for this measurement of the improvement. This curve places the ultimate limit of trotting speed at a mile in 63½ seconds, which, though constantly approached, will never be reached actually, and it indicates the minute and a half mark as two centuries away.

Horse-radish, a species of water-cress (*Roripa armoracia*), native to Europe, but now cultivated everywhere, and becomes naturalized in most parts of the world. Its basal leaves are oblong, finely crenelate and irregular in outline, and its flowers are white and showy. The roots furnish the highly pungent ingredient of a well-known sauce, prepared by grating them, adding vinegar and sealing. They have also some medical use.

Horse-radish-tree. See Ben, Oil of.

Horsefoot Crab, Horse-shoe Crab, or King Crab. This marine animal (*Limulus polyphemus*) was formerly regarded as a crustacean, and is the sole survivor of an extinct group of arthropods intermediate between the trilobites and arachnids. It belongs to the order *Xiphosura,* class *Merostomata,* and phylum *Palæopoda.* By some English authors it is regarded as an arachnid allied to the scorpion. This difference of opinion regarding its affinities is due to the generalized structure of the animal, and to the fact that its nearest allies are extinct.

The body of the horsefoot crab is sometimes two feet in length, and consists of a head and a hind-body or abdomen, the latter ending in a long spine (telson), which is elevated by the creature in defense. The head is in shape somewhat like a horse's hoof, and in burrowing it acts as a shovel, being bent down at nearly right angles to the hind-body. There are a pair of compound and of simple eyes; the mouth is on the under side, nearly surrounded by six pairs of walking legs, while on the hind-body are six pairs of broad swimming legs. There are no antennæ, jaws, maxillæ, or foot-jaws, as in the lobster. The horsefoot crab breathes by means of gills attached to the under side of the last five pairs of abdominal legs, which consist of a pile of about 100 thin broad sacs growing out, one pile on each side, from the base of the legs. The nervous system is peculiar from the nature of the brain, and the œsophageal ring; while the entire system behind the brain is enveloped by the arteries, the latter ending in remarkably fine branches. The heart is large, tubular, the liver very voluminous, and the kidneys are represented by four pairs of excretory red glands, arising from a stolon-like base. The animal is bisexual, the male differing from the female in the second pair of legs ending not in a forceps, but in a sort of hand, with an opposing thumb. The ovaries and testes are voluminous, and the sexual products, eggs and sperm, pass out through a pair of papillæ situated on the under side of the first pair of abdominal legs.

The female lays her large round eggs loosely in the sand between high and low water, spawning in May and June; in about a month they hatch, and the young, after passing late in embryonic life through a trilobite stage, assumes the form of the parent, differing in the short rudimentary caudal spine. It molts frequently, and during the process the front edge of the carapace or head splits open, enabling the animal to draw itself out of the old shell. The recently hatched Limulus is strikingly like a trilobite, but while in the latter new segments are added after birth, in Limulus no new ones are added. The young horsefoot is about 4 millimetres in length. Specimens an inch long are about a year old, and it probably requires several years to grow to the length of a foot or more.

Limulus polyphemus inhabits the eastern coast of North America from Boothbay, Maine, to the West Indies and Honduras, but is most abundant in shallow, retired, sandy, or muddy bays on the coast of New Jersey, Virginia, and North Carolina. Several other species inhabit the seas of the Eastern Archipelago, China, Philippines, and southern Japan. In the United States it is used as a fertilizer, while in the Malayan markets the animals are sold as food.

The Limuli date from the Devonian. An allied group, in shape and structure approaching scorpions, is the Eurypterida (q.v.), one of which (*Stylonurus laccoanus*) of the Devonian of New York and Pennsylvania was about five feet in length, while the British *Pterygotus anglicus* is estimated to have been about six feet in length and two feet across. It is now thought that the scorpions have descended from some merostome, which became adapted for a terrestrial life.

Alpheus S. Packard,
Late Professor of Zoology, Brown University.

Horse'heads, N. Y., village, in Chemung County; on the Erie & Central N. Y., and branches of the Delaware, L. & W. and the Northern C. R.R.'s; about six miles north of Elmira. It is in a fertile agricultural region. Its chief manufactures are creamery products, bricks, screens, doors, blinds, men's clothing, cigars, cattle-feed, shoes, and hardware. Pop. (1900) 1,901.

Horsemanship. See Riding.

Horses, American Thoroughbred. The American thoroughbred is the production of pure breeds imported from England, first during the 17th and 18th centuries. They first found their way into the Old Dominion of Virginia, where they founded a tribe of early racehorses, to which trace to-day many of the most fashionable pedigrees. From Virginia the thorough-

breds finally found their way into the Carolinas and as far south as Mississippi and Louisiana, and, upon the formation of Tennessee and Kentucky as States, the breeding of thoroughbreds became with them what might be termed an industry.

The early part of the 20th century finds Kentucky in the lead in the production of thoroughbred horses, followed next by California and then by Tennessee. Missouri and Illinois have recently greatly increased their thoroughbred holdings, while both New York and New Jersey produce a goodly number. Many of the other States take rank as fair producers of thoroughbreds, and, in fact, the breed has found its way into every section of the country, even as isolated a State as Oregon annually producing a number of thoroughbred horses.

The requirements of an American thoroughbred horse are that the pedigree contains five uncontaminated crosses, but the average pedigree traces through 16 to 18 crosses, some having as many as 25. Those reaching an origin of a Natural Barb source are considered the most fashionable, but many great racehorses have descended from lines unknown to early English or Arabian pedigrees.

Diomed, the winner of the first English Derby, imported to this country in 1799, when he was 20 years old, is classed as the greatest of early importations, and he has left a marked impress upon American pedigrees. The most successful importation of the 19th century was unquestionably Glencoe (imported in 1836), and in later days Leamington ranks the highest. In more recent years, the ranks of the American thoroughbred have been greatly increased by almost unlimited importations from England, France, Australia, and other foreign countries, and horses are produced in this country now that are of entirely foreign pedigrees, while there are numerous instances where the first few crosses are strictly foreign lines.

The average height of the early thoroughbred horse was something less than 15 hands, but at this time they average over 15 hands 2 inches, and weigh 150 pounds more than they did a half century ago. In individuality, too, the improvement is very marked, the types now being far superior in form to the horses of early times.

In soundness and general service the American thoroughbred has no superior, this being the result of judicious breeding and favorable rearing conditions. The statistics of the American turf (commonly known as Turf Guides) extend over a period of about 30 years, and in this time these records show that the thoroughbred horse has improved some 30 pounds, which is an equivalent of from 5 to 6 seconds to the mile. This marked improvement can be attributed to an accepted theory of breeding that like begets like, to intelligent methods of training, and to superior riding.

The most favorable condition which has proved so successful in raising the thoroughbred in this country is that he is housed less and has, at all times, access to lands covered by the finest of grasses, which brings his feet constantly into contact with moisture. The frog of the foot, being like a sponge, absorbs this moisture, thus creating a gentle pressure which spreads the hoof. A horse having bad feet naturally favors them, which has a tendency to make bad ankles and tendons on account of their not being freely used, and it is a conceded fact that "no foot, no horse."

In America the horse has been bred more for business than pleasure. The invention of the elliptic spring and the use of American hickory in the production of light vehicles for pleasure and business, together with the invention of macadam and Telford roads, turned the demand from the running to the trotting horse. The first private coach was introduced into New York in 1745; but coaches were scarce until after the Revolutionary War, and not until after 1840, when the light one-horse vehicle came into use, did the changed conditions of travel develop a harness-horse for purposes of business and pleasure. Along with the change in vehicles incident to the evolution of the trotter came as great a change in the style of harness and trappings.

About the beginning of the 19th century there came from the lines of breeding of the thoroughbred, traceable to Flying Childers, Byerly Turk, and the Darley Arabian, Messenger, a gray, stoutly built horse, of wonderful power and stamina, with a slashing, open gait, fitted to found a race of trotters. He was foaled in 1780, and became the progenitor of the trotting families in America. In 1793 Justin Morgan was foaled, sired by one believed to be thoroughbred. Three of his sons, Bulrush, Sherman, and Woodbury, became noted as the sires of horses of intelligence, courage, and speed, and the get of some of them excelled as roadsters and stage horses. From Black Hawk Morgan, sired by Sherman out of a fast trotting English mare, has come the beautiful, useful, and courageous line of Morgans. The original horse (2.40) died in 1856 at the age of 23. In 1849 was foaled Rysdyck's Hambletonian, the founder of the most noted family of trotters, sired by Abdallah, who traced to Messenger by both the sire and dam, out of a dam by Bellfounder, with Messenger crosses on the dam's side. As early as 1876 the interest in breeding and rearing trotters had become so great that fabulous prices were paid for colts, simply on the strength of their breeding. Two fillies, untrained, sold for $13,000. The three-year-old colt Steinway was sold for $13,000 in 1879. Maud S., bred at Alexander's noted stock farm in Kentucky, was sold to Mr. Bonner for $21,000 when four years old, with a record of 2.10¼, and the title "Queen of the Turf." Smuggler sold for $40,000, Pocahontas for $45,000, Goldsmith Maid for $36,000, Dexter for $36,000, and so on, until we come to Axtell, who sold for $100,000 after he had eclipsed the time of all stallions, and retired to the stud, where his service fee was $1,000. The stallion, Rysdyck's Hambletonian, was purchased with his dam for $125, and earned in the stud $205,750. Thirty-six of his get trotted in 2.30 or better, and the prices for which they could have been sold in their best days amounted to $325,000. Among them were Sentinel, George Wilkes, Jay Gould, and Administrator, all noted sires. Their united progeny was worth many thousands for stud and track uses. Some of his sons, without a 2.30 record, became successful in the stud. Alexander's Abdallah was sold for about $3,500, but he got Goldsmith Maid, who made a record of 2.14, and won on the turf close to $250,000; Almont sired 22 2.30 trotters; Bel-

mont got nine with records better than 2.30. So the descendants of Alexander's Abdallah have been worth to their owners hundreds of thousands of dollars. Volunteer was another who ranked among the most successful of the noted Hambletonian sires, having to his credit 23 2.30 performers. Electioneer, bought by Gov. Stanford, proved a noted sire, getting the fastest yearling, 2.36½; the fastest two-year-old, 2.21; the fastest three-year-old, 2.19½; and the fastest four-year-old, 2.18¾. The bracing climate of Palo Alto, and the methods of handling peculiar to Gov. Stanford's breeding farm, aided in these accomplishments. These are but a few of the thousands of good horses that owe success to the Hambletonian blood. The value of trotters has been measured largely by their speed, taken as a measure of ability to win future races, or as evidence of blood lines that will make the animal valuable in the stud. Success in campaigning is undoubted evidence of pluck and stamina; and the breeding and training of the trotter, and his contests on the track, have developed these qualities in so high a degree that no other class can equal him. The evolution of the trotting horse has also shown the value of a training peculiar to America as a factor in breeding.

It is pertinent to notice that in the first years of the last century running races became common in the Middle and Southern States, while a strong sentiment against racing prevailed in the Northern States. In 1820, Pennsylvania, for example, not only forbade racing, but also enacted that no person should "print or cause to be printed, set up or cause to be set up, any advertisement mentioning the time and place for the running, trotting, or pacing of any horses, mares, or geldings," etc. A similar law was in the statutes of Connecticut until within 30 years. New York passed an act to prevent horse-racing 19 March 1802, which was amended 30 March 1821, permitting the "training of pacing, trotting, and running horses" in Queens County for five years. The sheriff was required to be on hand to witness these "trials of speed," as called in the statute. This amendment was re-enacted 3 April 1826, without a time limit. In 1825 the New York Trotting Club was organized, with a view of "improving the speed of road horses." This track was probably the first trotting course in the world. The Hunting Park Association was formed in Philadelphia in February 1828, and the next year a trotting club was organized in Baltimore. These facts show a changing public sentiment, and the records begin to fall. The keeping of records became an established custom as early as 1829, when the 'American Turf Register' began. The English had not then begun to keep records, but the American custom has enabled us to mark the development of speed and establish well-defined breeds during the threescore and more years it has been in use. Wallace's 'American Trotting Register' was started in 1871 by J. H. Wallace, New York, since which time the business of breeding trotters has increased, until now it is estimated by good authority that the number of registered standard-bred trotters exceeds 120,000. In the early history of the record many animals were admitted to registry that are not now classed as standard-bred. The term "standard" indicates to-day ability of one or more ancestors to trot within 2.30.

Before the days of macadam roads and light vehicles, saddle-horses were as common as trotters are to-day. They were of no particular breeding, but traced to the thoroughbred, the Narragansett pacer, or the Scottish Galloway. Herbert suggests that they were of Spanish origin, their ancestors coming from Cuba. There is now a revival of interest in the saddle-horse as a luxury, the demand being beyond the supply. From the ideal set up, especially in Kentucky, it is safe to predict that there will soon be an improved breed of American saddle-horses.

Prior to the introduction of railroads Vermont had what Herbert called a distinct breed of cart-horses. He described them as "the models of what draft-horses should be, combining immense power with great quickness, a very respectable turn of speed, fine show, and good action." They had "none of the shagginess of mane, tail, and fetlocks which indicates descent from the black horse of Lincolnshire," and none of the curliness of mane and tail which marks the Canadian or Norman blood, and were characterized by short backs, close ribbing up and round barrels. The only other breed of American horses we have to notice is the Conestoga, which before the days of the Pennsylvania Railroad was common on the farms and highways of Pennsylvania. It seems to have descended from the stock brought by emigrants from Flanders, Denmark, and Germany. It was a mixture of several breeds, resulting in a large, patient burden bearer, held in high esteem by the Germans of that State. Although we have not originated and permanently established any American breed of draft-horses, the number of heavy horses has greatly increased, and the quality has improved. The increasing heavy business of factories, jobbers, importers, and transfer and express companies in our well-paved cities has called for a great number of powerful horses. This demand has led to the importing of heavy horses from France, England, Scotland, and Germany. The Vermont cart-horse and Conestoga draft-horse excelled the types of foreign heavy horses, as a rule; and it is to be regretted that our pride in American animals has not led our people to perpetuate and further develop these useful horses. Tens of thousands of dollars have been sent abroad since the fad of importing heavy elephantine horses became common in the Western States. The enterprising importers scoured France, England, Scotland, and Germany for the heaviest animals. They imported more than they could sell, and then adopted the plan of leasing stallions for a term of years. Since 1890 there have been many disastrous failures among this class of importers. There were, however, several importers who imported the best type of the draft and heavy coach breeds to be found abroad, establishing breeding farms not excelled in the world. The earliest importer of high-class draft-horses was Edward Harris, of Moorestown, N. J. In 1839 he imported two mares and the stallion Diligence, who was in many respects similar to the McNitt horse, but heavier and more compactly built, being a little over fifteen hands high. The next valuable importation was made by Charles Fullington, of Union County, Ohio, in the spring of 1851. He bought and brought home from France the famous Louis Napoleon, a "short-legged, closely ribbed, blocky, and compact gray, three years old." In 1853 he was sold

to A. P. Cushman, of De Witt County, Illinois, and after his colts in Union County proved his worth, a company was formed for importing other horses of his type. The author of the 'Percheron-Norman Stud-Book' says of him that he was undoubtedly the best-known and most popular French horse ever brought to America. The first importations west of the Wabash were made in 1868 by W. J. Edwards, of Chicago, in the great stallions Success and French Emperor. The latter went to Iowa as the property of Hon. J. B. Grinnell. Success was sold to the Fletcher Horse Company, of which M. W. Dunham, of Wayne, Ill., was an active member. In 1874 he purchased the entire interest of the company, establishing his celebrated importing and breeding farm at Wayne. Success's colts at the average age of two years and eight months sold at the average price of $450 per head, and in 1874 alone the sales of his get amounted to $36,000. The Clydesdale has been the strong rival of the Percheron-Norman; is popular in Canada, and has numerous representatives in the Northwest. The secretary of the American Clydesdale Association, Alexander Galbraith, says: "No importations into the United States appear to have been made until about 1870 and 1872, when John Reber, of Lancaster, Ohio, and the Fullingtons, of Union County, began the work. From that date small importations were made by various parties, the most prominent being the Powell Brothers, of Shadeland, Pa. Importations steadily increased up to 1888. To-day the largest breeder in America is Col. Holloway, of Illinois; N. P. Clarke, of Minnesota, and R. B. Ogilvee, of Wisconsin, coming next. These three breeders have among them about 175 brood-mares, and have the very cream of Scotland both in blood and individual merit. As high as $10,000 has been paid for one Clyde. Eight volumes of the 'American Clyde Stud-Book' have been published, containing 8,000 entries." The Shire horse is little esteemed in Canada, but in the American craze for heavy horses he finds admirers. There is an American stud-book of three volumes, with 4,100 entries, 3,500 of which represent imported horses. See HORSE-RACING; HORSES, TROTTING AND PACING.

Lexington, Ky.

Horses, Military. The relative importance of the horse as a factor in the progress of civilization has been somewhat reduced by the introduction of steam and electricity, but mechanical devices such as the bicycle and automobile are not likely to wholly supplant the indispensable ally of man for war purposes. The value of cavalry has not, within the century, been so fully recognized as during the recent South African campaigns, where the supply of horses reached enormous proportions. The kind of horse for cavalry and artillery use is controlled by the character of service for which he is to be used. Hardy range horses are desirable in a campaign where the question of forage supply is a difficult one, but, if fully armed and equipped men of average size are to be transported and held in readiness for mounted combat with opposing cavalry, then larger and better trained horses are desirable.

The source from which cavalry horses are obtained differs in various countries. Some European nations breed and raise their remounts, while others provide the services of selected stallions gratuitously to breeders, the foals being held subject to purchase by the state. The American plan differs from the European practice and involves only the inspection of such animals as are presented by contractors. This encourages all farmers to breed a fair class of horses, and whenever the requirements of the markets increase the breeding usually increases until prices sometimes fall below a level at which colts can be profitably reared. Only a small percentage of horses raised in the United States are adapted to the requirements of cavalry service. This arises from the existence of a special and narrowly defined object to be attained, and which requires animals of particular conformation and character. The inspection of remounts for soundness and conformation is a very important duty, demanding technical training and intelligence. It requires judgment, much instruction and long practice to correctly estimate the relative value of various points of the horse and to determine whether the good qualities counterbalance the existing defects. Contractors do not usually present ideal animals, but the market from which they draw is so large that there is no serious difficulty in supplying the remounts annually required for the United States cavalry.

In European armies horses are accepted at four years of age, and sometimes under that age. It has been found in practice in the United States preferable to buy no horses under six years of age for immediate use in field service. Younger horses may be accepted during peace when there is no likelihood of immediate hard service, but they are subject to influenza or shipper's fever to a degree which often renders them unserviceable for many months. Good points in a cavalry horse are not mere matters of beauty, but shapes which, on mechanical principles, are likely to answer required ends. Cavalry horses must have certain qualifications, the most important of which are the possession of sufficient mobility to execute tactical maneuvers at varying degrees of speed and the ability to stand hard service while carrying great weight. The weight of trooper and equipment averages about one fourth the weight of the horse. Ability to carry flesh under stress of short rations is a commendable quality in a cavalry horse, since it enables him to stand hard work and to avoid a sore back. As a result of many years of experience the requirements demanded in the cavalry horse of the United States are laid down in the regulations in this language:

"The cavalry horse must be sound and well bred; gentle under the saddle; free from vicious habits; with free and prompt action at the walk, trot, and gallop; without blemish or defect; of a kind disposition; with easy mouth and gait, and otherwise to conform to the following description:

"A gelding of uniform and hardy color; in good condition; from fifteen and one fourth to sixteen hands high; weight not less than 950 nor more than 1,150 pounds; from four to eight years old; head and ears small; forehead broad; eyes large and prominent; vision perfect in every respect; shoulders long and sloping well back; chest full, broad, and deep; fore legs

straight and standing well under; barrel large and increasing from girth toward flank; withers elevated; back short and straight; loins and haunches broad and muscular; hocks well bent and under the horse; pasterns slanting, and feet small and sound." See also HORSES, RIDING AND DRIVING.

W. H. CARTER,
Brigadier-General, U. S. Army.

Horses, Riding and Driving. In the latter days of this country one can hardly go to even an insignificant town or village without finding that a number of its residents spend time and money in raising, training, and driving as good horses as their means will afford. Another striking feature of this country horsemanship is the rivalry and constant vying of each horse-fancier to excel among his fellows, and the interest manifested to-day in buying, selling and "swapping" horseflesh is typical of the American.

The county and state agricultural fairs, which now make the exhibition of horses a special feature, are largely the outgrowth of this far-reaching interest in horses. Nearly every country fair has, besides trotting and perhaps running races, a department for harness horses and breeders' competitions. As freight and passenger rates are commonly commuted by the railroads or the fair corporations, these meetings enable the farmer to see the best the country for miles around can produce, raise his standards and teach him the results to be attained by proper breeding.

The horse shows, held annually in many of our large cities, at regular seasons throughout the year, and so arranged that they may not conflict as to dates, invite competitors from all parts of the country, who exhibit what they have with fair prospects of making their expenses from the prize money won. These horse shows are fostered both as sporting and business institutions, and the best horsemen in the country form their directorates and act as judges. These large shows do much to establish the types of animals that meet with favor, and their growth and popularity has cultivated the taste and interest of the general public in horses more than any other factor.

The types of horses highly valued in the large cities and in the country are, of course, similar to a large extent. A good horse is good anywhere. Nevertheless, the requirements of a metropolitan market are much more exacting and extend to the many qualities which we will try to outline in this article. While the country is often satisfied with mere "getting there" qualities in the horse, regardless of how it is done, or perhaps a mere combination of speed and endurance, the standard of a large city calls for certain definite requisities and qualifications — "points"— which are well nigh indispensable if the horse is to command a good price.

To fill the requirements of the affluent class it is estimated that not more than 5 per cent of the horses throughout the country, including those raised with this object solely in view, can be utilized. Indeed, taste has become so fastidious that the right kind can only be found by diligent search, and prices verge into sums that 10 years ago would have been unbelievable. It must not be thought that the general run of horses in this country, or indeed that the quality of our native bred horses, has deteriorated in the past few years. Such, in the writer's opinion, is not the case. The fact is, that to fill the high requirements of the metropolitan market has become the recognized goal of all horse breeders; and it is now generally understood throughout the country that the market for the inferior horse is limited to those who can afford to pay so little that the breeder is not compensated for his care and outlay in breeding anything but the best. The general introduction of trolleys and electric vehicles has been an important factor in curtailing the market for horses that are merely "serviceable" and has reduced it to a competitive point that is unprofitable.

The high qualifications for the metropolitan market have reduced the available horses to such a small number that expert buyers search this country and the Dominion of Canada from one end to the other. Buying as cheaply as possible, so thorough has been the scouring of the country that the prices paid would seem fabulous to the seller if the cost alone of raising the horse were taken into consideration. The buyer must also assume the risk and expense of transportation to market.

The "points" for which the breeder is striving are well defined, but the individual may vary so much in combining them that the interesting feature of personal taste remains as the determining factor in selecting horses for personal use.

Heavy-Harness Horse.— The term "heavy-harness horse" is a general one. Under it may be classed anything from the 12 hand pony for basket-phaeton or village cart, through the various types suitable for the runabout, gig, brougham, victoria and other vehicles that fashion prescribes for various uses, to the 16–1 hand carriage horse for pulling the capitalist's omnibus.

The importation into this country, since 1883, of English hackneys and the exhibition of them has undoubtedly done much to educate the public to a type of carriage horse. While no disparagement is intended to the standard bred trotting horse, whose origin, indeed, is allied to the hackney — although his later history is somewhat different — the serviceable, short-backed, straight-legged and intelligent horse now the standard for metropolitan use is nevertheless nearer the hackney type than the old style American trotter. It should be stated, however, that very few either of the trotters or hackneys of 25 years ago would generally fill the requirements of the harness horse to-day. A type having been once well established, however, horses filling the requirements can be selected from carefully bred trotters as well as from hackneys, and one breed is often mistaken for the other, such is their closeness in resemblance and the result of breeding with particular ends in view. The elements to be taken into consideration in the harness horse are as follows: Conformation, manners, action, speed, color, size and age. Conformation ranks first in point of importance, but manners are an absolute essential also. These two although somewhat variable must be present in any horse required for harness; the others vary considerably according to the type and weight of the vehicle to which the horse is to be harnessed and the purchaser's personal taste.

The elements in the order of their importance from a purely selling point of view are:

1. Conformation as to head and neck. This is probably the first feature the average purchaser will look for. The horse should possess a small head, delicately molded nostrils and a small tapering muzzle. His jaw-bones should be well apart so that when the head is reined in they will not interfere with his breathing. He should have good sized eyes, well separated; a narrow forehead or small eyes being general indications of lack of intelligence, nervousness or a tendency to fright or bad temper. The ears should be small and well apart. The neck should be gently tapering and well cut out in the throat, and the so-called "crest" from which the mane grows should have the slight convexity which indicates strength, maturity and condition. The neck should be set on sloping shoulders, so that the head will be naturally held erect, turning upward from the forward line of the trunk nearly perpendicular. A tapering neck is an indication of breeding and fineness as distinguished from the coarseness of draft blood and the common horse in ordinary use.

2. Conformation as to legs. The general requirements are that all four legs shall be approximately straight and not too long. A moderately short-legged horse is generally preferred, both for looks and service, to one that depends upon long legs for height. The forelegs should be perpendicular when the horse is standing erect, bones flat, but not heavy or coarse. The hind legs, when in a natural position, should be so formed that a plumb line dropped from posterior point of the haunch will be nearly tangent at the point of the hock, the rear line of the leg below the hock being approximately parallel to the plumb line. The thighs should be moderately heavy at the height of the lower line of the trunk. The modern idea is that the horse's buttocks should be round and muscular viewed from behind. The pasterns of all four legs should be springy and long rather than short.

3. In general. The horse should be "close-coupled"; in other words, there should not be too much space between the last rib and the quarter. His trunk should be round and just fleshy enough so that his ribs may be felt — not seen. Standing on level ground the height of his withers and croup should be about the same. The trunk, directly under the withers, should be deep and the chest from the front view broad, giving room for the heart and lungs and an appearance of power. The belly should be well picked up beneath the kidneys with a gentle, convex, upward curve from between the front legs — not enough, however, to produce the waspy effect sometimes seen in horses otherwise well formed. The back should be short, lending to the trunk an appearance of compactness and solidity. The quarters should not fall away back of the kidneys more than an inch or so to the root of the tail. The tail, if set well forward of the posterior line of the horse's haunches, is generally admired, and in this position will be carried at the proper angle naturally.

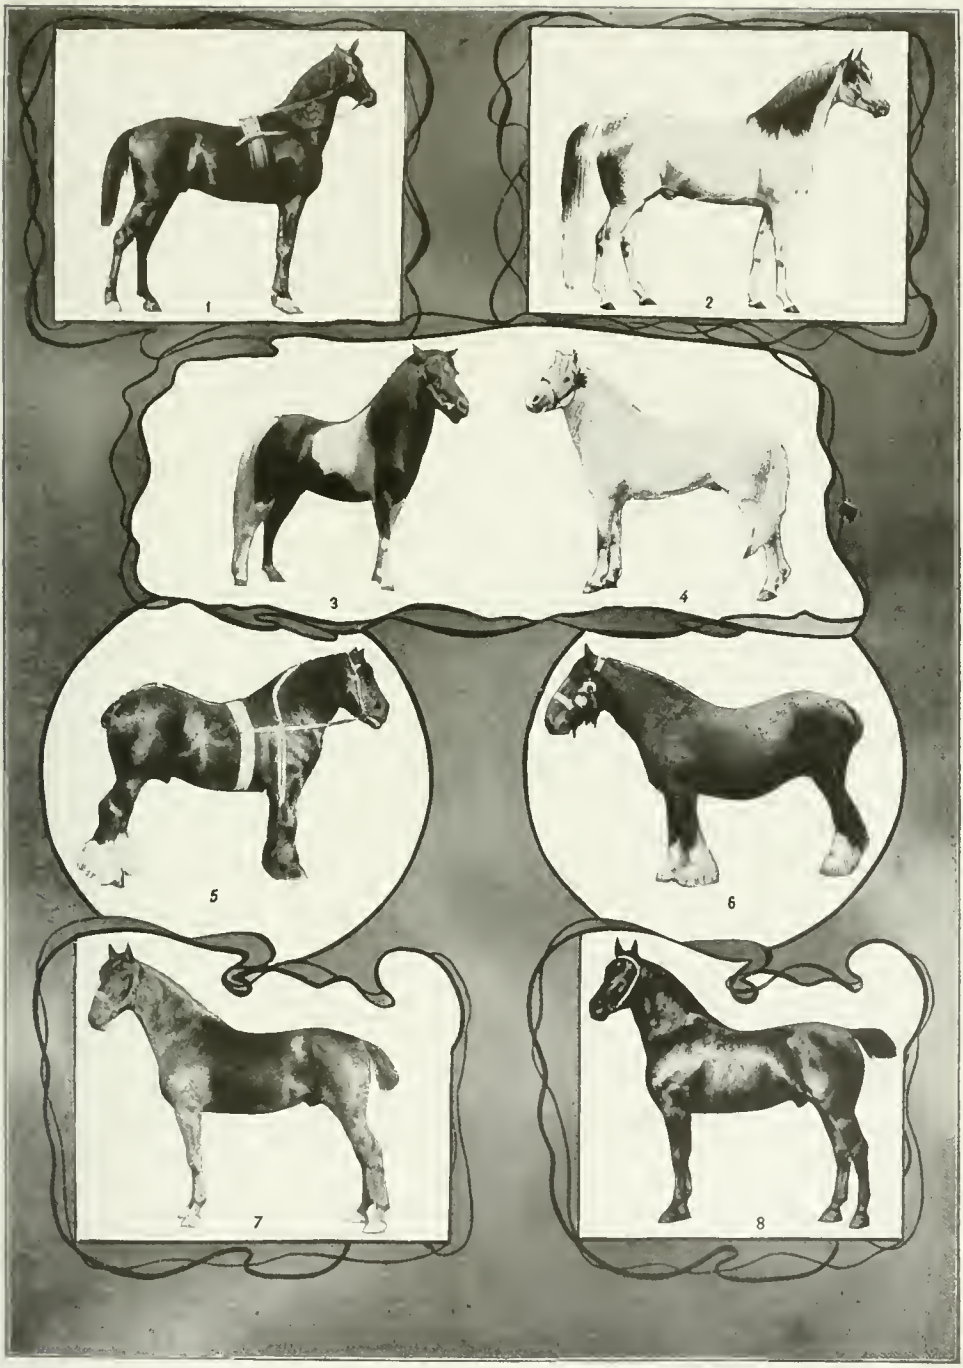
Under the subject of *Manners*, full technical treatment should be sought in various books relating to horse training and breaking. We will endeavor to point out, however, to what extent manners in a harness horse is supplemental to ordinary training; to treat the subject fully being like attempting to describe what a gentleman should do under all circumstances. A few salient points will perhaps give a fair indication of the general subject.

The well-mannered horse should be so trained that when bitted his head is carried almost vertical, and close to his neck, which will be gently curved; the head and neck taken together being straight with the line of direction in which he is traveling. This position is not only graceful but gives the driver the utmost command over him. He should "fill his collar" without urging, but be light mouthed and susceptible to the slightest hint from the reins, voice or whip. He should be afraid of nothing and possess sufficient intelligence so that after first acquaintance with motor vehicles, railroad trains and other startling objects, he will pay no attention to them.

Into this subject therefore the question of natural disposition necessarily enters, as without a sensible but willing and high-strung disposition, it is impossible to produce a fashionable carriage horse. The horse should be trained to back and turn for the voice or with the slightest pressure of the reins without manifesting any disposition to shake his head or bore upon the bit. Plunging, rearing or trickiness must be absolutely eliminated, so that he is safe for a lady to drive through crowded city streets. He should be broken single, double and tandem, and to the saddle for convenience sake, and should be ready at any moment to serve in any one of these capacities.

All this mannering constitutes a supplemental or post-graduate education, for the horse as delivered from the country is broken, but commonly utterly devoid of manners. To accomplish this a training extending over a period of as much as three months is often necessary even with a horse that would be considered thoroughly broken in the country; and after mannering him as to how he shall carry his head and respond to the driver, it is necessary, so perfectly must the horse be trained to suit the metropolitan purchaser to spend a week or more in thoroughly accustoming him to city pavements and sights. It is almost superfluous to state that many horses cannot be brought to this high state of perfection, but the question of manners enters very largely into the price consideration, and the schooling should be carried on to as high a point as the disposition of the individual will admit.

While *Action* is not absolutely indispensable, it is nevertheless the feature that many amateur horsemen will look for first, often neglecting much more important points to secure the flashiness of the high actor. Many dealers say, "Give me action and I can sell anything." Without going to this extreme, it is undoubtedly true that high action will cover many sins, and if a horse will only "get his head up and act" he is apt to be salable. Without action speed seldom attracts the city purchaser, and while it is undeniable that high action, except with careful driving and stable attention, will often cripple a horse on hard pavements who might otherwise go sound for years, the average high-price buyer not only asks for clean, straight action, but verges to the danger point in its height. The expert will seek horses having action both in



1. Pure Arabian.
2. Arabian Stallion.
3. Shetland Pony.
4. Welsh Mountain Pony.
5. English Shire Stallion.
6. Clydedale Gelding.
7. French Coach Horse.
8. English Hackney.

front and behind, as he knows that without hock action, little, if any, speed will be produced, the propelling force lying in the power of the thighs. He will look at the horse going, coming and sideways, first to see that the horse neither toes in, paddles or interferes in front; second, to see that he keeps his hocks close together as they pass, and consequently does not "straddle" or place his hind legs at the extreme forward stride outside of the line taken by his fore legs, or interfere by brushing either fetlock joint; third, that he does not forge and that his action is even when looked at from the side, each leg advancing at a stride the same distance and height as the corresponding leg on the other side.

The only gait admissible in the heavy harness horse is a trot. Pacing, racking, single-footing, or any gait other than a square line trot, by whatever term it may be called, have no place in the metropolitan market. The horse should strike out straight from the shoulder in front, the whole leg straightening at the instant the hoof touches the ground, the hoof striking flat. The straightened foreleg then passes under the body of the horse and is rolled up when it leaves the ground, the hoof nearly touching in extreme cases the point of the elbow joint. While still "folded" the arm bone reassumes the position for the next forward stride. As indicated above, the action of any single leg and hoof should be in a single longitudinal vertical plane. Some writers have endeavored to demonstrate, by projecting upon a longitudinal vertical plane the arc described by the forward point of the hoof from the time the horse picks up his foot from the ground until he touches it again, that the ideal action thus projected would form a symmetrical arc of an ellipse. While it is conceivable that such may be the case, it is practically impossible to determine slight variations from this ideal, and if the horse acts high, clean and straight without interference or forging he will not generally be open to criticism.

The modern buyer looks more and more nowadays for strong hock action, which means that the horse will cover ground and retain much of his action regardless of the amount of weight behind him.

While *Speed* is not a very important element in horses for carriage use, it would be a truism to state that people like to go fast, and of two individuals equal in other respects, the purchaser will prefer the horse that has the most "step." A discriminating dealer will commonly aim to secure horses that can go a mile under ordinary circumstances in 3½ minutes, and if possible in 3 minutes. This is, ordinarily, quite fast enough for salability, and the horse that will "road" steadily at 10 to 12 miles an hour and can increase the speed a little for a short spurt, fills the market requirements pretty fully.

In *Color*, modern fashion prescribes bays, chestnuts and browns, a dark seal brown being perhaps the most popular. Golden chestnuts are also popular, and blood bays are in high favor. Very few purchasers will consider a white or black horse, regardless of any number of other good qualities. Grays, except of the dark dapple variety, are rarely used, except in a cross-matched pair, and then only as a matter of personal fancy. In a road coach four, however, they are approved by the best authorities.

The amount of white on a horse is a matter of personal taste, many people liking white fetlocks and a star, stripe or blaze on a chestnut or bay's head, others preferring solid color. Bays are generally most popular with black points, but in general it may be stated that the horse possessing too much white will not please. One or two white legs, with white extending a short way to the knee or hock, will not be objected to, but it can be stated positively that, except for a leader or wheeler in a road coach team, where a showy effect is desired, there should be no white upon the body of the horse.

A sleek, shiny coat is a recommendation for any horse, as it usually bespeaks condition and breeding.

The question of *Size* is one that is a matter of personal taste primarily, and secondly, one of suiting the vehicle to which the horse is to be harnessed. The salable horse for ordinary city use is rarely under 14½ hands, and in the opinion of most judges should not exceed 16¼ hands. For a lady's phaeton a small team with considerable substance and not usually less than 14½ hands in height is required, and for a heavy omnibus sufficient weight and strength are usually secured in the horse whose height does not exceed 16 hands. The most salable size for horses in general use is about 15–2½ hands. Most buyers will restrict their purchases to horses between 15–1 and 16 hands, unless the animal is very remarkable in other respects, because customers for extremes in size are few in number, and such horses are consequently less readily salable.

A word should be said as to the *Age* of the marketable horse. It is pretty well understood that colts suitable for heavy harness do not attain maturity and maximum strength until they reach the age of five or six years, and the ordinary purchaser will prefer the six-year-old horse. From seven to 10 years the horse is at his best. While some horses hold their good qualities and are serviceable up to an extreme age of perhaps 20 years,—in the city horses rarely stand the strain of travel on hard pavements for many years without showing signs of usage sufficient to render them unsalable, except at small prices.

Horses kept for the show-ring and therefore not subject to usage on hard pavements exemplify the fact that there is little or no advantage *per se* in the young horse. Indeed, the horse may be at his best at the age of 10 years, and many of the blue ribbon winners of the past few years are even somewhat older.

The Saddle Horse.— Neglecting the subject of chargers and hunters, the former having but a limited market and being generally subject to army specifications, and the latter constituting too large a subject for discussion in an article of this character, and of more interest abroad, especially in England and Ireland, than in America, we shall say a few words of the saddle horse, presenting as briefly as possible some of the facts which should be borne in mind in supplying the market.

The conformation of the saddle horse will not be found to differ very materially from the carriage horse, and many private owners, who do not feel able or warranted in stabling horses for saddle purposes only, will find a combination horse for saddle and harness use a possi-

bility. A saddle horse is not improved in gait by being harnessed to a vehicle, particularly a heavy one, in fact is impaired thereby, but moderate driving to light vehicles will not incapacitate him wholly for the saddle.

In a "park hack" we should look for somewhat substantial conformation. As in a carriage horse, depth of girth should be sought and the back should be short, all the distance possible, however, separating the forelegs from the hind, the horse having much of his length in his shoulders and quarters. The croup should be long, so that, taken in combination with high and prominent withers and heavy shoulders, the saddle will have a good seat and be prevented from slipping forward. As in the hind legs reside the seat of propelling power the thighs should be long and muscular, and some people prefer the hocks well bent. The pasterns should be somewhat longer and have more spring than in the harness horse.

As in the harness horse the saddle horse should be about the same width in front as behind. Many will not object, however, to a horse slightly wider behind than in front, as the claim is made that, in a gallop, the hind legs will better pass outside of the forelegs; but, under no conditions should the horse be wider in front than behind. He should have a moderately long and upright neck and a prominent crest, as this is the muscle that supports his head, and the neck should be arched. With this combination a horse will usually carry his head erect without support from the reins, and the rider will have better control and feel that he has something in front of him.

The manners of a saddle horse is an element worthy of particular notice. Besides the qualities and disposition valuable in a harness horse, primarily he must possess a high degree of intelligence and be absolutely fearless; and he needs a further education to make him "bridle wise." By this term is indicated response to the slightest pressure of the rein on either side of the neck, so that the horse turns readily by the lateral movement of the rein hand. This allows the rider one hand free for use or emergency.

As to gait and action, the horse should have a fast walk, so that when ridden in company he will keep up without breaking into a jog. The trot should be even, springy and regular, so as not to jolt the rider. Extreme action is not a necessary feature, but the horse should possess enough action to be noticeable in company; and high action is not a detriment if unaccompanied by pounding. An easy canter and gallop are necessities, and particularly is this true of the horse intended for long rides or to be used in the country. These gaits should be accomplished with a maximum of forward motion and a minimum of rocking.

Types and sizes of saddle horses vary greatly according to personal taste and the weight to be carried. Some desire a short-legged, thick-set cobby horse for weight-carrying, while those of lighter build may prefer a taller horse of less substance and more speed. Above all things the horse should be free and willing, as no man desires, or will tolerate, a horse needing constant urging.

Breeding.— A word or two as to breeding may not be inappropriate, as the requirements of the market are so exacting that every breeder should take them into consideration, in order to produce and raise as large a percentage of marketable horses as possible.

Much has been written upon the subject of horse breeding and genealogy in America, and careful investigation reveals much shallow erudition. The results of recent research have shed sufficient light upon this subject to show that much of the published matter as to the ancestry of the American trotter will not bear close investigation. Heretical as it may seem, the history and origin of the Hambletonian strain of blood, which for years has been held in high esteem among breeders throughout the country, we believe is open to reasonable doubt as to its authenticity. It does not seem unlikely that some of the breeders, in their desire to create a lineage for their horses, drew on their imagination for the breeding of the ancestors. After many years of assumption that the published facts were correct, grave doubt is now cast upon the breeding of some of the original stock. Perhaps, therefore, the less we attempt to demonstrate results by referring to the lineage of the standard bred trotting horse the safer.

Of the other breeds of this country perhaps the best known are the Morgans and Clays, but generally speaking, such numerous and often careless crosses have been tolerated that these breeds in anything like purity of blood have mostly disappeared. In the author's opinion, up to a recent date, the breeder in America has sought speed to the detriment of action, even going so far as to make conformation a secondary element.

A word should be said about the Hackney. Much confusion has resulted temporarily, and probably only temporarily, from the placing on the market of so-called Hackneys, which are such only in conformation and not in the action and speed which are characteristic of the Hackney of honest blood. This breed lends itself exceedingly well to the requirements of the heavy harness horse when proper individuals are used in the stud. Although at present there are but few such individuals in this country, the Hackney dates back in England to the 18th century. It was originally a cross between the shire or English cart horse, an animal somewhat coarse but of much substance, power and action, and the sleeker thoroughbred of delicate conformation and high strung temperament. So well has this breed been cultivated, to the elimination of the coarser individuals by a few reputable breeders in this country, that it is not difficult for the careful judge to discriminate.

Recently, American breeders have achieved extremely satisfactory results by crossing hackney stallions with clean-limbed, nicely turned trotting-bred mares, and while this cross is one that breeders claim should not be carried beyond one generation for fear of the infusion of cold blood in the offspring, a single cross certainly produces a large percentage of good marketable stock. This cross commonly combines high action and much substance with speed and breedy appearance.

As most scientific breeders now acknowledge, the main fact of all breeding is that it is a matter primarily of individuals, good lineage counting for little in the produce if the breeding stock do not themselves fill all the requirements

desired. Not only should care be taken to use proper individuals, but if a slight fault exists in either parent — no horse being absolutely perfect — the other should be selected especially proficient in what the one lacks.

Back of the standard bred trotting horse, Morgan, Hackney and French coach horse — another imported breed — stand practically the same Arabian ancestors, and as all are to-day bred with one end in view, the choice of one breed as against the others is a matter of selecting the individual best filling requirements.

If the main purpose be to breed for that market which is the most profitable, that of the heavy harness horse, it seems to the author that, instead of horses becoming standard by performance on the track if they became standard by performance in the show-ring all the qualities desired as well as speed would be more properly conserved. Of course, many practical difficulties, some of which would defeat the very ends sought, stand in the way of such a movement unless it were conducted by the government. A stud book formally conducted by the government and authentically recording the lineage and performances of stock, so that the history of a strain and the results of crosses might be generally published and read, would be of immense value to the horse breeder and to the government itself by raising the quality and value of the horses raised both for domestic use and export.

An interesting commentary on the subject of the harness horse and an evolution well worth notice is the gradual elimination of the unreliable small dealer in the metropolis; in fact, the market is fast falling into the hands of the comparatively few reputable dealers who endeavor to conduct their business on broad commercial lines. The purchasing public are beginning to recognize that it is best for their interests to patronize such dealers as can rather afford to take a loss on an unsound or unsafe animal by giving him away than to sell him under a misrepresentation and make a financial gain at the expense of reputation. This fact is not only an assurance that the interest manifested in the horse in our large cities will not decrease, but the business being in good hands that many who have in the past been slow to venture into this field of pleasure and sport can now enter into it as beginners without a long, unsatisfactory and expensive experience as a preliminary. See also Horses, American Thoroughbred.

Arthur Man,
Sec'y Standard Coach Horse Co., New York.

Horses, Trotting and Pacing. The harness racing horse has two gaits, namely, the trot aand the pace. They were both originally the connecting link between the walk and the gallop, but by development and careful training have come to take the place of the latter so far as extreme speed in harness is concerned. The term "diagonal gait" is applied to trotting because the horse employing it raises simultaneously a front and hind foot at opposite sides of the body. In pacing the front and hind feet on the same side move together, and this is best expressed as the "lateral gait." No one has yet been able to explain why a horse goes at one or other of these gaits when urged from the walk and guided by the rein to keep from the gallop.

The history of harness racing in America is practically contemporaneous with that of the Republic of the United States. After the Revolution the development of speed in the horse had its attractions here as in Europe. At first the running gait was the only one considered, but the importation of an English sire called Messenger marked the beginning of a new era. He was brought over in 1788 and landed at Philadelphia. Though descended from stock that inclined to the gallop and practically a thoroughbred, this horse was more inclined to the trot. What is more remarkable he transmitted this habit or instinct to so marked a degree that he made a great reputation in the New World through the superiority of his progeny over all other breeds. So "Imported Messenger," as he was popularly known, was the patriarch of the American trotter, and nearly all of the immense troop of harness racers in this country to-day trace descent to him. His death in 1808 near Oyster Bay, N. Y., was looked upon as a national calamity, and he was buried with military honors, the funeral being attended by prominent horsemen from all the neighboring States. As this horse was the founder of a notable family and represents a type in some respects separate and distinct from others of the *genus equus* it seems unfortunate that no portrait or drawing of him was ever made. There is a pen picture which in some measure atones for this, and is worth quoting. It describes Messenger as of a gray color, standing full 15 hands 3 inches in height, with a thin mane and tail, ears larger than most well bred horses, but erect and lively.

At the time of Messenger's death the limit of speed at the trot was in round numbers a mile in three minutes. The saddle was chiefly in vogue for this gait as well as running, but the employment of a vehicle with two wheels followed the building of better roads. According to J. H. Wallace, an authority on the thoroughbred, a chestnut horse trotted at Philadelphia in a sulky 25 Aug. 1810, one mile in 2:48½ for $600. The horse was fourteen years old and barely 15 hands high. There is an earlier feat now accepted as authentic of a horse called Yankee, trotting a mile in 2:59 in 1806 on Harlem Lane, a favorite driving place for New Yorkers. The breeding of these first champions of the sulky remains in obscurity, but it was not long before the descendants of Imported Messenger began to do greater things. Topgallant, who is credited with three miles in 8:11 and easily the best trotter of his day, was inbred to Messenger, his sire and dam both being by the potent English stallion. Screwdriver, who went three miles to saddle in 8:02 a year before this, was another of the stars descended from Messenger, as was Dutchman, another long distance trotter, who went his three miles under saddle in 7:32½; but the most famous of the Messenger brood in the nearer generations was Lady Suffolk. She was the first queen of trotters, her reign being a long and undisputed one from 1838 to 1852. She enjoys the special distinction of being the first trotter to score as fast as 2:30 for a mile in harness. Following Lady Suffolk there were a few lesser lights that improved slightly on her best record, but her real successor as a conqueror of time was Flora Temple. She was foaled in 1845, her turf career

beginning in 1852. Five times this wonderful mare reduced the figures that represented the speed limit, her greatest effort being 2:19¾. Then came the mighty Dexter, who reduced the record to 2:17¼. His public career was cut short when Robert Bonner purchased him and took him to New York for his private driving on the road. Goldsmith Maid came out in 1871 and clipped a fraction from Dexter's mark. She was foaled in 1857, made her debut at 10 years and continued to fill engagements in races and against time up to 1877. Rarus managed to improve Goldsmith Maid's record a trifle during a very creditable career. The gelding St. Julien eclipsed him a year after by a full second. Then a new queen appeared in Maud S., and between this fleet pair was a lively duel for the championship. The figures were improved by fractions of a second until the mare reached 2:10¾ in 1880, which proved too much for the gelding. After his surrender another candidate appeared in Jay Eye See. Meantime Maud S. had got down to 2:10¼, but Jay Eye See enjoys the distinction of being the first to touch the even 2:10. This was in 1884, and then the mare showed that she was the better horse by compassing the track in 2:09¾, and again in 2:08¾.

The greatest mechanical aid to the harness horse that has yet been devised came into use during 1892. This was the application of the ball-bearing axle first applied to the bicycle, with the pneumatic tire and a wheel of about 28 inches diameter. Its first public trial was in a race at Worcester, Mass., early in May, where its manifest advantage enabled a slow horse to fairly play with a field of faster competitors. None of the prominent trainers had seen this new contrivance, and it was not until well along in July when they awoke to a full realization of its merits. The writer was privileged to see and try this sulky with its frictionless gear before it had come into general use, and on exploiting it with a conservative opinion that a horse could go at least two seconds faster than if hitched to the high wheel sulky, was informed by Budd Doble, the leading reinsman of that day, that he was the victim of a hoax. Less than three months after this same Doble had driven Nancy Hanks to one of these smooth running machines a mile in 2:04, or nearly five seconds faster than the record of Maud S. This material reduction was only the beginning of a new era in speed, as four other trotters have taken advantage of this appliance and earned the championship in turn. Alix only clipped a quarter of a second from the mark set by Nancy Hanks, but she did this after a hard race campaign that took away from her real ability. It was six years before this resolute overworked mare had to surrender the crown, when in 1900 the Abbot trotted in 2:03¼. He had previously won his spurs in several creditable races, but his successor and conqueror, Cresceus, proved to be a much more remarkable representative of his kind. Starting at three years this Hercules among trotters met and defeated older and more seasoned campaigners in his colthood, scoring 2:11¼ in the eighth heat of a winning race. Then each successive season found Cresceus able to add to his laurels until in 1901 he earned the championship twice. His record of 2:02¼ was followed by the famous match against The Abbot at Brighton track, Brooklyn, N. Y., 15 August, when, in the presence of an immense crowd, many of whom came hundreds of miles to see this battle of the giants, Cresceus was the victor. It was no light task at first, as The Abbot forced him to go in 2:03¼, the fastest mile by nearly two seconds ever scored in a trotting race. Besides these feats Cresceus has lowered many other records, including the one for two miles which he placed at 4:17 late in 1902. During the season of 1903 he again battled against time, and after his previous championship record had been several times beaten by Lou Dillon and Major Delmar this stout warrior trotted in 1.59¾ at Wichita, Kan., in October 1903.

Before this great feat his star was momentarily eclipsed by the advent of the long expected and much desired two-minute trotter. So suddenly has this new marvel appeared, and so rapidly has she reached the goal that hitherto seemed unattainable that the world at large cannot fully appreciate the merit of what Lou Dillon has accomplished. To begin with, she is the youngest of all the champions, being but five years old. What is even more remarkable, her turf life extends over little more than 12 months, and up to last June she had never filled a public engagement. Yet within a few weeks this marvelous mare has smashed records and on 22 Aug. 1903 she electrified the country by a mile in two minutes. This was done over the track at Readville, near Boston, where six years before the pacer Star Pointer scored the first mile ever made faster than "even time." An analysis of Lou Dillon's unparalleled flight for a trotter shows that she was rated with great skill. At the Brighton track just a week before she had gone a first quarter in 28¾ seconds, and a half mile in 59 seconds, a killing rate, which destroyed any chance she had of finishing in time to break the record. Profiting by this experience her driver and those who handled the two gallopers hitched to separate carts that accompanied her as pace makers, did much better work at Readville. This is shown by the time at the various quarters, which was 30¼, 30½, 30¼, and 29 seconds, respectively. While a full meed of praise is always due to the man or horse that does something better than what has previously been achieved, it is only fair to state that Lou Dillon has enjoyed special advantages in her preparation for record breaking. She was first trained in the winter of 1902 on the track at Pleasanton, California, her native State, and on the death of her breeder and owner this year was brought to Cleveland and sold at auction. The purchaser, C. K. G. Billings, of Chicago, got a rare bargain at $12,500, and being strictly an amateur he promptly canceled all engagements previously made for this promising mare. She then received special training for miles against time, and not only astonished the world by her mile in even time at Boston, but a few days later drew the old-style sulky with high wheels, in 2:05 at Cleveland, clipping three seconds and three quarters from the record Maud S. made nearly 20 years before. Later on, at Memphis, Lou Dillon added to her fame by another mile in 1:58½ to sulky, and one to wagon in exactly 2 minutes. She also defeated Major Delmar in a race for the Memphis Gold Cup, and being only in the heyday of her power,

it is within the realm of possibility that she will pass the mark for pacers. This now stands at 1:56¼, made by Dan Patch at Memphis, 22 October 1903.

The following table gives the names of all the record makers among the trotters, and shows how the figures have been reduced from 2:30 to 2:00:

Lady Suffolk, gr. m. foaled 1833, by Engineer 2d, dam by Don Quixote. Driven by David Bryan, Beacon Course, Hoboken, N. J., Oct. 13, 1845, 2:29½.

Pelham, b. g. foaled 1837, pedigree not traced. Driven by William Whelan, Centreville, N. Y., July 2, 1849, 2:28.

Highland Maid, b. m. foaled 1847, by Saltram; dam Roxanna, by Hickory. Driven by F. J. Nodine, Centreville, N. Y., June 15, 1853, 2:27.

Tacony, ro. g. foaled 1844; by Sportsman; dam not traced. Union Course, N. Y., July 14, 1853, 2:27.

Flora Temple, b. m. foaled 1845, by Bogus Hunter; dam Madam Temple, by Terry Horse. Driven by Hiram Woodruff, Union Course, East New York, N. Y., Sept. 2, 1856, 2:24½.

Flora Temple. Driven by James D. McMann, Centreville, N. Y., Aug. 9, 1859, 2:23½.

Flora Temple. Driven by James D. McMann, Centreville, N. Y., Aug. 9, 1859, 2:22.

Flora Temple. Driven by James D. McMann, Cincinnati, Ohio, Oct. 7, 1859, 2:21½.

Flora Temple. Driven by James D. McMann, Kalamazoo, Mich., Oct. 15, 1859, 2:19¾.

Dexter, br. g. foaled 1858, by Hambletonian; dam Clara, by American Star. Driven by Budd Doble, Riverside Park, Boston, Mass., July 30, 1867, 2:19.

Dexter. Driven by Budd Doble, Buffalo, N. Y., Aug. 14, 1867, 2:17¾.

Goldsmith Maid, b. m. foaled 1857, by Alexander's Abdallah; dam Ab. by Abdallah. Driven by Budd Doble, Milwaukee, Wis., Sept. 6, 1871, 2:17.

Goldsmith Maid. Driven by William H. Doble, Mystic Park, Boston, Mass., June 9, 1872, 2:16¾.

Occident, br. g. foaled 1863, by Doc; dam Mater Occidentis, pedigree not traced. Driven by George Tennet, Sacramento, Cal., Sept. 17, 1873, 2:16¾.

Goldsmith Maid. Driven by Budd Doble, East Saginaw, Mich., July 16, 1874, 2:16.

Goldsmith Maid. Driven by Budd Doble, Buffalo, N. Y., Aug. 7, 1874, 2:15½.

Goldsmith Maid. Driven by Budd Doble, Rochester, N. Y., Aug. 12, 1874, 2:14¾.

Goldsmith Maid. Driven by Budd Doble, Mystic Park, Boston, Mass., Sept. 2, 1874, 2:14.

Rarus, b. g. foaled 1867, by Conklin's Abdallah; dam Nancy Awful, by Telegraph. Driven by John Splan, Buffalo, N. Y., Aug. 3, 1878, 2:13¾.

St. Julien, b. g. foaled 1869, by Volunteer; dam Flora, by Harry Clay. Driven by Orrin Hickok, Oakland, Cal., Oct. 25, 1879, 2:12¾.

Maud S., ch. m. foaled 1874, by Harold; dam Miss Russell, by Pilot Jr. Driven by W. W. Bair, Rochester, N. Y., Aug. 12, 1880, 2:11¾.

St. Julien. Driven by Orrin Hickok, Rochester, N. Y., Aug. 12, 1880, 2:11¾.

St. Julien. Driven by Orrin Hickok, Hartford, Conn., Aug. 27, 1880, 2:11¼.

Maud S. Driven by W. W. Bair, Chicago Driving Park, Chicago, Ill., Sept. 18, 1880, 2:10¾.

Maud S. Driven by W. W. Bair, Homewood Park, Pittsburg, Pa., July 13, 1881, 2:10½.

Maud S. Driven by W. W. Bair, Rochester, N. Y., Aug. 11, 1881, 2:10¼.

Jay Eye See, bl. g. foaled 1878, by Dictator; dam Midnight, by Pilot Jr. Driven by Edwin Bither, Providence, R. I., Aug. 1, 1884, 2:10.

Maud S. Driven by W. W. Bair, Cleveland, Ohio, Aug. 2, 1884, 2:09¾.

Maud S. Driven by W. W. Bair, Lexington, Ky., Nov. 11, 1884, 2:09¼.

Maud S. Driven by W. W. Bair, Cleveland, Ohio, July 30, 1885, 2:08¾.

Sunol, b. m. foaled 1886, by Electioneer; dam Waxana, by Gen. Benton. Driven by Charles Marvin, Stockton, Cal., Oct. 20, 1891, 2:08¼.

*Nancy Hanks, br. m. foaled 1886, by Happy Medium; dam Nancy Lee, by Dictator. Driven by Budd Doble, Chicago, Ill., Aug. 17, 1892, 2:07¼.

Nancy Hanks. Driven by Budd Doble, Independence, Ia., Aug. 31, 1892, 2:05¼.

Nancy Hanks. Driven by Budd Doble, Terre Haute, Ind., Sept. 28, 1892, 2:04.

Alix, b. m. foaled 1888, by Patronage; dam Atlanta, by Attorney. Driven by Andy McDowell, Galesburg, Ill., Sept. 19, 1894, 2:03¾.

The Abbot, b. g. foaled 1893, by Chimes; dam Nettie King, by Mambrino King. Driven by Ed. Geers, Terre Haute, Ind., Sept. 25, 1900, 2:03¼.

Cresceus, ch. h. foaled 1894, by Robert McGregor; dam Mabel, by Mambrino Howard. Driven by George H. Ketchum, Cleveland, Ohio, July 26, 1901, 2:02¾.

Cresceus. Driven by George H. Ketchum, Columbus, Ohio, Aug. 2, 1901, 2:02¼.

Lou Dillon, ch. m. foaled 1898, by Sidney Dillon; dam Lou Milton, by Milton Medium. Driven by Millard F. Sanders, Readville, Mass., Aug. 24, 1903, 2:00.

Lou Dillon. Driven by M. F. Sanders to high wheel sulky, Cleveland, Ohio, September 12, 1903, 2:05.

Cresceus. Driven by George H. Ketchum, Wichita, Kan., Oct. 19, 1903, 1:59¾.

Lou Dillon. Driven by M. F. Sanders, Memphis, Tenn., Oct. 24, 1903, 1:58½.

*First champion mile to bicycle sulky.

The progress and development of the lateral or pacing gait has kept side by side with trotting. Before Lady Suffolk had opened the door for the 2:30 list, the pacer Drover had gone a mile in 2:28. For over a century the lateral gait has kept a second or more ahead of the diagonal one. Dividing the century, since speed in harness for a mile was first considered, into two decades we are able to compare the two gaits and note the progress of each by the following table. The names of pacers are in italics:

	1800-1810.		
Yankee, b. g.		Harlem, N. Y.	2:59
	1810-1820.		
Boston Horse, ch. g.		Philadelphia, Pa.	2:48½
Bolton Blue, bl. g.		Jamaica, N. Y.	3:00
	1820-1830.		
Topgallant, b. g.		1829—3 miles	8:11
Bowery Boy.		1829—2 miles	5:04½
	1830-1840.		
Edwin Forrest, bl. g.	(to saddle)	1834	2:31½
Sally Miller, b. m.		1834	2:37
Drover, b. g.		1839	2:28
	1840-1850.		
Lady Suffolk, gr. m.		1845	2:29½
Moscow, b. g.		1845	2:30
Pelham, b. g.		1849	2:28
James K. Polk, ch. g.		1845	2:27
	1850-1860.		
Flora Temple, b. m.		1859	2:19¾
George M. Patchen, b. h		1859	2:26¼
Ethan Allen, b. h.		1858	2:28
Pocahontas, ch. m.		1855	2:17¼
Pet, ro. g.		1852	2:18½
	1860-1870.		
Dexter, br. g.		1867	2:17¼
Goldsmith Maid, b. m.		1869	2:19½
George Wilkes, br. h.		1868	2:22
George M. Patchen, b. h.		1860	2:23½
Ethan Allen, b. h.		1860	2:25½
Billy Boyce, b. g.	(to saddle)	1868	2:14¼
	1870-1880.		
St. Julien, b. g.		1879	2:12¾
Rarus, b. g.		1878	2:13¼
Goldsmith Maid, b. m.		1874	2:14
Smuggler, br. h.		1876	2:15¼
Sleepy Tom, ch. g.		1879	2:12¼
Rowdy Boy, bl. g.		1879	2:13¾
	1880-1890.		
Maud S., ch. m.		1885	2:08¾
Jay Eye See, bl. g.		1884	2:10
St. Julien, b. g		1880	2:11¼
Axtell (3 yrs.), b. h.		1889	2:12
Maxie Cobb, b. h.		1884	2:13¼
Phallas, b. h.		1884	2:13¾
Johnston, b. g.		1884	2:06¼
Gold Leaf (4 yrs.), ch. m.		1889	2:11¼
Little Brown Jug, b. g.		1881	2:11¾
Brown Hal, br. h.		1889	2:12½
	1890-1903.		
Lou Dillon, ch. m.		1903	2:00
Cresceus, ch. h.		1903	1:59¾
Major Delmar, b. g.		1903	2:00¼
Cresceus, ch. h.		1901	2:02¼
The Abbot, b. g.		1900	2:03¼
Alix, b. m.		1894	2:03¾
Nancy Hanks, br. m.		1892	2:04
Azote, b. g.		1895	2:04¾
Directum, bl. h.		1893	2:05¼
Stamboul, br. h.		1892	2:07½
Arion, b. h.		1893	2:07¾
Kremlin, b. h.		1892	2:07¾
Martha Wilkes, b. m.		1892	2:08
*Lou Dillon,		1903	2:05

*Sunol, b. m.	1891	2:08¼
*Palo Alto, b. h.	1891	2:08¾
*Direct.	1891	2:06
Dan Patch, br. h.	1903	1:56¼
Prince Alert	1903	1:57

*Made to high wheel sulky.

In the matter of breeding, reference has already been made to the fact that the imported horse Messenger, who played so important a part in the generation of harness horses, was of running stock. His descendants that have influenced this type more than any others were Rysdyck's Hambletonian and Mambrino Chief. The former was the son of Abdallah, whose sire Mambrino was by the English Messenger. This same Mambrino was also the grandsire of Mambrino Chief, so that his blood more than that of any of the get of Messenger has been potent in the production of the numerous fast exponents of the two harness gaits. Bellfounder, another English horse, brought over to Boston in 1823, had also much to do in founding the American trotter. His origin seems to be obscure, but he was probably of the type known as the Norfolk Roadster, from which the hackney has sprung. The most famous of his progeny in the first generation was the Charles Kent Mare, the dam of Rysdyck's Hambletonian. At least 75 per cent of what are called "Standard bred" trotters trace to this sire, and as none of the rest of Abdallah's get amounted to much there is every reason to believe that this daughter of imported Bellfounder had the inherent quality which made the Hambletonian strain so valuable. Every one of the champion trotters that succeeded Flora Temple are descended directly from this horse, Dexter himself being one of his sons.

To show how the "fast list," as it is called, has increased since the day of Lady Suffolk and Drover, it may be stated that up to the close of 1902 there were 18,548 trotters with records of 2:30 or better, and 9,713 pacers credited with marks of 2:25 or better. In each case these figures represent what is known as "standard" speed at the respective gaits. See HORSE-RACING.

Secretary New York Trotting Association.

Horseshoe Falls. See NIAGARA FALLS.

Horstmann, Ignatius F., American Roman Catholic prelate: b. Philadelphia, Pa., 16 Dec. 1840. In 1857 he was graduated from the Central High School, and afterward attended Saint Joseph's College, Philadelphia. Desirous of studying for the priesthood, he went to the Preparatory Seminary of Glen Riddle in 1859, and in 1860 entered the American College, Rome, where, after completing his course, he was ordained priest by Cardinal Patrizzi, 10 June 1865. In 1866 he took in Rome the degree of doctor of theology, and in the same year returned to Philadelphia and accepted the chair of mental philosophy in the diocesan seminary of Saint Charles Borromeo, continuing to hold the same position in the new seminary at Overbrook. In 1877 he became pastor of Saint Mary's Church, Philadelphia, and in 1885 was named chancellor of the archdiocese. On 29 Nov. 1891 Leo XIII. appointed him to the vacant see of Cleveland, Ohio, and he was consecrated bishop 25 Feb. 1892. The diocese now (1905) has a Catholic population of 300,000; 296 priests; 287 churches; 1 seminary; 166 parochial schools; 7 orphanages; 9 hospitals, and several charitable institutions.

Horticulture, the art of growing plants, flowers, and vegetables for aiding in sustaining life, maintaining health, and for ornamental purposes. While as an art it is the highest type of work which pertains to the cultivation of the soil, its principles are based on many branches of science. Plant physiology, chemistry, and physics play important roles in every branch of this work and the application of their laws, directly and indirectly, constitutes the more essential features of the art.

Adopting Bailey's plan of division (Annals of Hort., 1891), horticulture may be discussed under four heads: (1) Pomology or fruit-growing; (2) olericulture or vegetable-growing; (3) floriculture or the growing of flowers and plants for ornamental and other purposes; (4) landscape gardening, or the growing of plants and the grouping of them for the purpose of enhancing the beauty and value of landscape.

In no country in the world has pomology or fruit-growing made such advances as in America. In the early history of the country fruit-growing was of necessity given minor attention. The clearing of the wilderness and the opening of new territory always involve attention to purely utilitarian projects first; hence there is little record of systematic or extensive fruit planting in this country prior to the beginning of the 19th century. Naturally, fruit was planted by the very earliest settlers, but this was done more as an effort to supply individual needs than as a means of profit. Thus, in the middle of the 16th century the early Spanish settlers made plantings of fruits in Florida and elsewhere, and early in the 17th century the English did considerable in the matter of planting fruits in Maryland and Virginia and elsewhere in what is now the eastern United States. Grapes especially received early attention, and numerous attempts were made to establish vineyards of European sorts in different parts of America. None of these early attempts, however, was very successful; and when it was found that the European kinds were so poorly adapted to the conditions of the regions then occupied by settlers, attention was turned to the improvement of our native forms. There is probably no more striking example of what can be accomplished by careful horticultural work than the results secured in the improvement of our native forms of American grapes. From the wild types so abundant in our native woods have come practically all of the fine table and wine varieties that are grown in the United States and Canada east of the Rocky Mountains to-day. The work mentioned did not involve any questions of fruit-growing on an extensive scale such as we find now. Nearly every farm in those early times had fruit grown upon it, partly for home use and partly for sale if there was produced more than was required for home consumption. With varying changes caused by the increase in population, the improvement in living conditions, and the demand for more fruits, fruit-growing progressed, until about 50 or 60 years ago it began to take on a new aspect. It

was at this time that fruit culture in its broadest sense showed marked development as an independent commercial industry; hence in looking back we find the beginning of such important lines of work as commercial apple, pear, peach, and grape growing, commercial small-fruit-growing, etc. With the advancement of this work came the gradual development of horticultural sections or the localization of horticultural work in certain special localities where experience had shown that the best results were secured in the matter of production, marketing, etc. The peach districts of Delaware, Maryland, New Jersey, Michigan, Connecticut, and Georgia, the grape districts of New York and Ohio, and the apple region of western New York are examples of this movement toward centralization or specialization. With the further increase of population, especially in cities, the improvement in transportation facilities and better knowledge as to climatic and soil conditions, more and more centralization and specialization resulted. With the growth of the fruit interest of the Pacific coast and of Florida and other portions of the South, new features were added to the entire work. Thus has been developed commercial pomology as we find it to-day in this country, involving (1) the production of fruits of high quality, and (2) the harvesting, packing, storing, and transportation of such fruits to market so as to secure the highest prices with a minimum expenditure of outlay for the work. Still further involved in these questions are, of course, other important ones, such as tillage, pruning, spraying, etc., which it is not necessary to discuss here.

According to the figures of the 12th census, the value of all fruits produced in the United States for 1899 was, in round numbers, $131,000,000. Of this amount the orchard fruits had a value of $83,000,000, grapes $14,000,000, small fruits $25,000,000, and sub-tropical fruits $8,000,000. The great fruit districts are shown by the fact that of the $131,000,000 of fruit produced, California furnished $28,000,000 worth, New York $15,000,000, Pennsylvania $10,000,000, Ohio $9,000,000, Michigan $6,000,000, Illinois $5,500,000, Missouri $4,500,000, and Indiana $4,500,000, all in round numbers. The exportation of American fruits to foreign countries is rapidly assuming important proportions. For the fiscal year 1902 the total value of fresh, dried, and canned fruits and nuts exported from the United States was $8,719,344. With the rapid development of fruit-growing in this country there has been felt the need for careful systematic studies of the many varieties in cultivation and offered for cultivation. Systematic pomology, therefore, is an important branch of the work, and is being given special attention by the General Government and by the various State experiment stations and agricultural colleges.

Olericulture or vegetable gardening is an important branch of horticulture, and from time immemorial the art has been practised both for pleasure and for profit. Vegetable gardening proper does not include the growing of such crops as Irish potatoes, sweet potatoes, sugar-beets, shell beans, etc., where the same are produced in large quantities and are handled as ordinary farm produce. Vegetable gardening proper, as we understand it, embraces market gardening, truck-growing, and the growing of vegetables under glass. No sharp lines can be drawn between any of these industries, as they merge in many cases one into the other. Growing vegetables, as already indicated, has long been practised and was a feature in nearly every home in the early days of the country. With increasing population and the consequent demand for more luxuries and more variety, gardens began to expand, and thus was developed the work of market gardening in the vicinity of the larger cities. Although market-gardening and truck-farming merge closely into each other, market-gardening proper, as a rule, is held to apply to the growing of vegetables for the local market, while truck-growing and truck-gardening imply the shipment of produce to a considerable distance, either by rail or in other ways. Truck-growing proper, on a large commercial scale, has developed practically within the last 25 years and owes its rapid growth largely to the improved transportation facilities and the rapid extension of railroads north and south along the Atlantic coast. The trucking interests proper were an outgrowth from the market garden work in the vicinity of New York. Gradually this work was pushed out to Long Island, and thence it spread to the lands adjacent to Chesapeake Bay, where fast sailing boats made it possible to bring the produce quickly into the markets of the larger cities. The work at first centralized at points where good harbors made regular steamship service available, but rapidly extended south along the lines of the Atlantic coast railways, and now has reached important developments in Virginia, North Carolina, South Carolina, Florida, and other Southern States. There is also another important truck region which has developed along the lines of the Illinois Central Railway in the Mississippi Valley, the crops grown in this region being shipped to the cities north and from them disseminated to large towns and cities, both east and west. More recently there have been large developments in this line in eastern Texas and southern and central California, each region now shipping early vegetables northward and eastward to the extent of thousands of carloads annually. The development of the winter growing of vegetables in the South and elsewhere has to some extent modified the methods of producing crops in the North, especially where glass is used. There is still, however, important work of this nature in progress in the vicinity of all large cities, particular attention being given to the growth of vegetables in greenhouses and under frames. According to figures secured by the writer in 1899, there were at that time 4,500,000 square feet of glass devoted to the growing of vegetables. The value of the establishments aggregated $2,250,000; the wholesale value of the annual product amounted to $2,250,000, and the retail value to $4,500,000. The number of men employed in this work — that is, the growing of plants under glass — was 2,250. According to the figures of the 12th census there were devoted to the growing of vegetables for market in 1899, 1,175,200 acres, and the market value of the product was $67,399,348. There were devoted to the production of vegetables for home use 940,370 acres, yielding a product valued at $46,477,087. This includes only miscellaneous vegetables, and does not cover such crops as Irish potatoes, sweet potatoes, onions, sugar-beets, etc. Thus it appears that, exclusive of glass, there were devoted to the growing of vegetables for the market and for

the home 2,115,570 acres, giving an annual product valued at $113,876,435.

The development of floriculture in America has been coincident with that of vegetable gardening and pomology, excepting, of course, that flowers, being more or less of a luxury, were the last to receive special attention. Flower gardens, to a certain extent, formed a part of nearly all the home surroundings of the early settlers. See article Floriculture in America.

Landscape gardening literally means the creation of landscape pictures with plants. The pictures may be formal or they may be natural; that is, they may deviate widely from the bits of beautiful scenery which nature so lavishly bestows, or they may attempt to copy these bits of nature or perchance improve upon them by modifying them to meet the immediate surroundings. The picture created may be a matter of taste. Hence, in one country and in one place we find extreme formality, grotesque figures, and various-colored foliage beds forming a part of these pictures, while monstrous forms carved from shrubs and evergreen trees may form another part. Again we see the true lover of nature copying as closely as possible nature's own landscape, which is, after all, true landscape gardening. A bit of lawn, a fringe of foliage, and a clustering group of trees may be all that is required to form this picture, but it is a natural picture, and if harmony is kept in view the results are always charming. The art has long been practised, and its various types and modifications are to be found in our public parks and in private grounds throughout the country. There has been a growing interest in landscape gardening in America in recent years, owing chiefly to the advanced ideas set forth by such men as Downing and Olmsted, who have done much to create an appreciation and love for the purely natural in this work. More recently a still broader conception has been given to landscape effort, and work in this direction has been made to cover important matters connected with the relation of landscape surroundings to buildings, the proper arrangement of roads, etc. Thus we have had developed the field of landscape architecture, which is a broader term than landscape gardening. The landscape architect makes a study of his problem and works out a scheme of operation involving everything that may be connected with it. The landscape gardener may be called upon to carry out part of this scheme, but the architect proper will also be involved.

The literature on horticulture is exceedingly voluminous, covering many writings and textbooks, special papers, reports, etc. The more important standard American pomological works are Downing's 'Fruit and Fruit Trees of America,' Barry's 'Fruit Garden,' and Thomas's 'American Fruit Culturist.' In vegetable culture, Henderson's 'Gardening for Profit,' Bailey's 'Forcing Book,' and Rawson's 'Market Gardener' are standard works. Of the American publications on landscape gardening may be mentioned: Downing, 'Landscape Gardening'; Parson, 'Landscape Gardening'; Long, 'How to Plant the Home Grounds'; Waugh, 'Ornamental Gardening.' The most useful work on horticulture recently issued is Bailey's 'Cyclopedia of American Horticulture,' published in four volumes, the last of which appeared in 1902.

B. T. Galloway,
U. S. Department of Agriculture.

Hor'ton, Robert Forman, English Congregational clergyman and author: b. London 18 Sept. 1855. He was educated at New College, Oxford, and in 1879 he was made a fellow of New College, and lecturer on history. In 1880 he became the pastor of the Congregational church at Hampstead, and in 1893 pastor of the Lyndhurst Road church there. In 1893 he delivered the Lyman Beecher lectures at Yale; in 1903 he was chairman of the Congregational Union of England and Wales. His writings include 'History of the Romans' (1885); 'Inspiration and the Bible' (1887); 'The Teaching of Jesus' (1895); 'Oliver Cromwell' (1897); 'Women of the Old Testament' (1897); 'The Commandments of Jesus' (1898); 'England's Danger' (1898); 'The Pastoral Epistles' (1901); 'The Trinity' (1901).

Horton, Samuel Dana, American publicist: b. Pomeroy, Ohio, 16 Jan. 1844; d. Washington, D. C., 23 Feb. 1895. He was graduated from Harvard in 1864, and from the law school in 1868, and also studied abroad. He began the practice of law in Cincinnati, but devoted himself mainly to the study of monetary questions, spending much time abroad; he was one of the first to advocate the establishment and maintenance of an international ratio between gold and silver. He was a recognized authority on all questions concerning coinage, was secretary of the international monetary conference at Paris in 1871, and a delegate from the United States at the conference of 1881; shortly before his death he went to Washington at the request of the administration for a conference concerning the financial situation. His writings include 'Silver and Gold and their Relation to the Problem of Resumption' (1876); 'The Silver Pound and England's Monetary Policy since the Restoration' (1887); 'The History of the Guinea' (1887); 'Silver in Europe' (1890).

Hosack, hŏs'ak, **David,** American physician and author: b. New York 31 Aug. 1769; d. there 23 Dec. 1835. He was graduated from Princeton College in 1789, and concluded his medical studies in Philadelphia in 1791. In 1795 he was appointed professor of botany in Columbia College. In 1796 the chair of materia medica was assigned to Hosack, who held it with that of botany until 1807, when he accepted the department of materia medica and of midwifery in the College of Physicians and Surgeons. He held at different times several public trusts, as physician to the New York hospital, and the Bloomingdale asylum, resident physician of the city of New York, etc. He was among the original projectors of the New York Historical Society, of the Horticultural Society, and of the New York Literary and Philosophical Society. He was the author of 'Annals of Medicine' (1793); 'Hortus Elginesis' (1808); and numerous papers on medical subjects.

Hosea, hō-zē'a, the first in order among the minor prophets of the Old Testament, but more probably the third in order of time. Nothing is known of his life, except what can be gathered from the introduction to his prophecies, namely, that he was the son of Beeri, and that his ministry belonged to the reigns of Uzziah,

Jotham, Ahaz, and Hezekiah, kings of Judah, beginning probably about the end of the reign of Jeroboam II., king of Israel. His prophecies are addressed almost equally to both kingdoms. His book was admitted into the canon after the Babylonish captivity. He has represented in the three first chapters of his book, the guilty violation of their covenant with God by an allegory, very common among the Hebrew poets, of a marriage covenant which the wife has violated, referring to the covenant which God had concluded with the Israelites. The remaining chapters treat of the same subject, under different figures, with reproaches, exhortations, and threats; he predicts the approaching exile of his countrymen, and the consoling promise of the final return of an improved people forms the conclusion of this prophetical book. He is remarkable for his laconic style, hastening from image to image, and from reflection to reflection. The stream of a powerfully excited fancy forces him irresistibly onward. Hence he does not exhibit the roundness, grace, and harmony which characterize the other prophets.

Hosiery, hō'zhėr-ĭ, a word properly applied only to the making of hose or stockings, but used as a general term for all kinds of knitted articles. The materials used for the purpose are cotton, linen, and wool, the last of which is sometimes mixed with cotton or silk. Silk is also frequently used alone. Since 1841 the Jacquard loom, and similar looms have been employed in the manufacture of articles of hosiery. See *Knitting; Textiles,* under KNIT-GOODS,

Hos'mer, Harriet, American sculptor: b. Watertown, Mass., 6 Oct. 1830. She early showed skill as a modeler in clay, and after receiving a general education studied anatomy in a medical college at St. Louis. Her first work, a reduced copy of Canova's Napoleon, was followed by an ideal head of Hesper (1852). She went to Rome in 1852 and studied under John Gibson, the English sculptor. About this period she produced ideal busts of Daphne and Medusa, and in 1855 completed her first life-size figure, Œnone. To the same year belongs Puck, which gained her a great reputation in the United States, and the next year she executed a Will-o'-the-Wisp. The statue of Beatrice Cenci in the public library of St. Louis was finished in 1857, and her colossal statue of Zenobia in 1859. Her next work was a statue of Benton, the Missouri statesman, a bronze cast of which was erected in Lafayette Park, St. Louis. Other works are: Sleeping Faun, exhibited at Dublin in 1865 and at Paris in 1867; a statue of the Queen of Naples as the Heroine of Gaëta; a monument to Abraham Lincoln; and Waking Faun.

Hosmer, James Kendall, American librarian and biographer: b. Northfield, Mass., 29 Jan. 1834. He was a professor in Antioch College, Ohio, and the University of Missouri, in 1874–92, was professor of English and German literature in Washington University (St. Louis, Mo.), and in 1892 became librarian of the public library of Minneapolis. Among his works are: 'The Color Guard' (1864), a record of experiences as a private in the Civil War; 'The Thinking Bayonet' (1865), a novel; 'History of German Literature' (1879); 'Life of Samuel Adams' (1885); 'Life of Sir Henry Vane' (1888); 'A Short History of Anglo-Saxon Freedom' (1890); 'How Thankful was Bewitched' (1894); and a 'Life of Thomas Hutchinson' (1896).

Hos'pital, an institution for the treatment of sick, injured or infirm persons, supported in most cases by voluntary contributions, but in special instances from the funds of the government, state or civic municipalities. Hospitals are of various kinds: medical; surgical; for the reception of incurables; for consumptives; for the deaf, dumb, and blind; for the aged and infirm; for the care and treatment of the insane; emergency and field hospitals for the care of wounded in battle, etc. Modern hospitals are so constructed and their interior is so arranged as to enable a limited staff of physicians and nurses to attend to the wants of the greatest possible number of patients with a view to the most speedy recovery.

The site selected for a hospital should be on high ground; the soil should be clean and dry, free from damp ravines and undrained marshy ground, and the drainage should be ample. If possible it should not be surrounded by other buildings than those belonging to the hospital itself. The structural arrangements should be such as to secure perfect, free circulation and sunshine. The size of the wards depends on the number of patients to be therein maintained and having a capacity of 3,000 cubic feet for each inmate. The disciplinary and economical disposition in a hospital requires that each nurse should have the patients allotted to her under constant observation and personal supervision and that the arrangements are so constructed that the greatest number of patients can be attended and nursed by a given number of nurses. From 20 to 32 beds have been taken as a basis for ward construction. In some hospitals there are wards of one and two beds for cases of unusual gravity. The general form of ward construction is governed by the question of renewal of air and the superficial area allowed to each patient, for on this depends the distance of the sick from each other, the facility of changing the beds, cleanliness and many other important features. In a ward 24 feet wide, with a window for every bed or two, a 7 foot 6 inch bed space along the outer walls is sufficient. That would give 90 superficial feet per bed, which must however be increased in pernicious fevers, surgery and lying-in cases. In the Herbert hospital the smallest allowance is 99 feet per bed. The ceilings should be 12 to 14 feet high. With a view to economize heat in winter and to keep the wards cool in summer the walls should be hollow and all walls ceiled. The walls should be of an impervious polished surface, easily cleansed with soap and water. All corners should be rounded off and no cracks are to be tolerated, since they fill with impurities. Plaster, wood, paint and varnish all absorb organic impurities. The safest arrangement for walls is plaster, lime-whited or painted, which should often be scraped off or renewed.

The floors and woodwork throughout should be of oak, closely jointed, oiled and waxed, rubbed and polished. Confine the woodwork to absolute necessity. The forms of windows must be adapted to facilitate the entrance of light, as a factor to promote health, to promote ventilation, to facilitate nursing and to allow the patient to read in bed. In order to give cheerfulness to the ward and to renew the air easily,

the windows should be inserted opposite each other; should extend to 2 feet 6 inches from the floor to within a foot of the ceiling. One cubic foot of window glass to every 50 or 55 cubic feet of space will afford a well lighted, cheerful ward.

The ward offices are those necessary for facilitating the nursing and administration, as the nurses' rooms, ward scullery, bath-rooms and lavatories.

They should all be well ventilated and lighted and all fittings finished in light color so that dirt can be at once detected. The nurses' room should command a view over the whole ward. The lavatory table should be constructed out of an impervious material, as slate or marble, with a row of sunk porcelain basins supplied with hot and cold water. The bathtubs should be porcelained iron. The toilets and urinals should invariably be placed against an outer wall, supplied with a siphon carrying a sufficient water capacity to thoroughly flush the basins. For the floor of these quarters, cement, marble or slate is preferable, and the walls are to be lined with glass, white-glazed tiles, marble, slate or Parian cement.

The administration building, that is, for offices, reception rooms, lodging the staff, operating rooms, kitchen, store-rooms, dispensary, etc., should always be subordinate to the question of the accommodation of the sick. In hospitals where a school is to be established, the necessary lecture rooms, laboratories and amphitheatre should be kept entirely separate from the sick; the morgue and dissecting rooms should be as far removed as possible. The consensus of professional opinion is opposed to the present plan of constructing large edifices for hospital purposes; that the benefits they confer are greatly diminished by the risk of hospital diseases — fevers of certain forms, erysipelas, pyæmia, etc., and which when once installed are most difficult and often impossible to eradicate. A system of cottage and hut construction, any of which could easily be destroyed and replaced, should the emergency demand, has been seriously advocated, but found impracticable because of the great expense and administrative difficulties. The profession to-day favors a system of construction known as the "pavilion plan," which can be called a compromise measure between the large block edifice and the cottage and huts. According to this system the wards are separate and distinct from the administration building and should be arranged to form pavilions, one story high, never more than two, and they should always surround the administrative blocks. This mode of construction is both applicable to large and small establishments. The Royal Infirmary of Edinburgh, the Herbert hospital of Woolwich, the New York hospital, the United States Marine hospital of San Francisco are among the best examples of the pavilion style. There should be free circulation of air between the pavilions, and the space between them should be exposed to the sunshine. The arrangements should be of a character to allow a covered communication between the wards, and each pavilion should have its own broad stairway.

The pavilion and general construction of the administrative building should be made quite subservient to the accommodation for the sick and should never interfere with the light and air of the wards.

Hospitals or asylums for inebriates, likewise hospitals for those addicted to the use of opium and other narcotics, have lately been established throughout the United States. Fever hospitals are maintained in all communities to secure isolation in infectious diseases, and hospital ships and floating hospitals are extremely valuable to promote complete isolation in cases of virulently infective disorders, such as smallpox (q.v.), etc. Children's hospitals are often provided with swimming tanks, indoor and outdoor playing, large ball and tennis grounds and in fact any and everything to promote healthy exercise and pastime for the inmates.

Military and naval hospitals, establishments for the care of sick and wounded soldiers and seamen, exist in all civilized nations. They are either temporary or permanent and if the former located in the immediate vicinity of the scene of operation. Hospital ships are ships fitted out as hospitals in all expeditions beyond the sea. They serve either as stationary hospitals or, if the sick accumulate sail home, or to the nearest station. See also QUARANTINE; RAILROAD HOSPITALS.

Hospitallers, charitable brotherhoods who devote themselves to tend the sick in hospitals. The name is specially applied to an order of knights, the Knights of Saint John. See ORDERS, RELIGIOUS.

Host, or **Hosta Sacra** (sacred host), in the liturgy of the Roman Catholic Church, the body of Christ present in the sacrifice of the Mass under the appearance of bread. The Latin word *hostia* denotes that which is offered in sacrifice; hence in the Mass, where the victim is the same who offered himself on the cross, "the cup" is no less the *hostia* than is "the bread"; but usage has sanctioned the appropriation of the word host to the latter. In the canon of the Mass, the priest, in offering the consecrated elements to God the Father, speaks of both the "bread" and the "cup" as *hostia*; and in the ancient Spanish missal (the Mozarabic) occurs the phrase "this host of bread and wine." But the word *hostia* is also employed to signify specially the bread before consecration; and this usage has its sanction in the Roman liturgy itself and in the rubrics of the Missale Romanum. In the rubric of the *ordo missæ* the altar-bread before consecration is called *hostia,* and after consecration it is called *hostia consecrata.* "Host" in the former sense, that is, the "altar-bread," is, in the Latin Church, a circular wafer made of fine wheaten flour mixed with water only, and it is unleavened. Usually the wafers are stamped either with an image of Christ crucified or with the letters I H S. They are of two sizes, a larger one which the celebrant himself receives (a host of this size is also reserved for the benediction (q.v.) of the Blessed Sacrament); and a smaller size for administration to those who may communicate at the Mass, or to the sick in their houses. The hosts destined for this use are kept in the pyx (called also *ciborium*), a silver vase gilt inside, and deposited in the tabernacle of the altar. As long as the host is thus reserved in the tabernacle the sanctuary lamp is kept alight before it. The Eastern churches in communion with the See of

Rome, except the Maronite and Armenian churches, retain the use of leavened bread in the Eucharist.

Hostage (French, *ôtage;* Latin, *obses;* Low Latin, *obstagius*), a person left as pledge or surety for the performance of the articles or conditions of a treaty. The taking or giving of hostages is now scarcely known in the relations of modern communities, but was formerly almost universal, and many questions in the law of nations arose out of the practice. Writers on international law have discussed how far the rights of conquerors extend over hostages, what circumstances may release them from their obligation, and what effect their escape will produce on the treaty proposed by the contracting parties. In modern civilized warfare hostages are not usually interchanged.

Hos'telry. See HOTEL.

Hot-bed. See HORTICULTURE.

Hot Springs, Ark., city and county seat of Garland County, and one of the most famous sanatoriums of the United States; in the southern centre of the State, 55 miles southwest of Little Rock and 397 miles from Saint Louis; on the Choctaw, O. & G., and Little Rock & H. S. W. R.R.'s. The location is 600 feet above sea-level and lies principally at the easterly base of the mountain complex known as the Ouachita Range, the nearby peaks of which are oftentimes called the Ozark Range — in a valley between two rocky and heavily wooded ridges called West Mountain and Hot Springs Mountain, 400 feet higher — and in its sheltered situation has a mild and pleasant climate. Lat. 34° N.; lon. 93° W. Through the valley runs the Hot Springs Creek starting two miles above; and into this the water from 47 hot mineral springs — originally 73, but many merged artifically or run dry — springing from vents in the gray volcanic tufa near the base of the Hot Springs Mountain on the east. Forty-four are in use or usable; the others rise in the bed of the creek. The former yield 830,000 gallons a day; contain large amounts of calcium and magnesium carbonates, and the presence of lithium, iodides and bromides, etc.; the total mineral matter in solution is between 275 and 280 parts per million and the results, as to the percentage composition of the mineral matter in each hot spring, are very much the same. The waters are prescribed for bathing and drinking and have remarkable curative properties. De Soto, it is said, sought to explore them as the veritable fountain of youth. The ordinary tub bath is the principal feature of treatment, but vapor, shower and plunge baths are also used. People suffering with consumption of the lungs; those afflicted with dilation of the heart; very old people, whose arteries are atheromatous; and paralytics, when their condition is the result of organic central lesions, should not bathe. Relief or cure may be expected in rheumatic, syphilitic, and numerous other conditions. The surgeon-general of the United States army, in an official circular of information issued by the War Department, says:

> The various forms of gout and rheumatism, after the acute stage, or inflammatory stage, neuralgia, especially when depending upon gout or rheumatism, metallic or malarial poisoning; paralysis, not of organic origin; the earlier stages of locomotor ataxia; chronic Bright's disease (the earlier stages only), and other diseases of the urinary organs; functional diseases of the liver; gastric dyspepsia, not of organic origin; chronic diarrhœa; catarrhal affections of the digestive and respiratory tracts; chronic skin diseases, especially of the squamous varieties, and chronic conditions due to malarial infection.
>
> In all forms of dyspepsia and in ulcers of the stomach and intestines the actual bathing which the diseased surfaces receive from the hot water drank materially aids in hastening cures.

As many as 90,000 patients and pleasure seekers visited here in 1902–3. The temperature of the springs varies from 97° to 147°. All issue from a space something over a quarter of a mile long and 200 to 300 feet up the slope, some 10 acres in all. By treaty with the Quapaw Indians in 1818 and by act of Congress in 1832, four sections (2,529 acres) became a reservation, and the springs are in the centre. Dunbar and Hunter of the Lewis and Clark expedition visited the place in 1804 and settlement was made in 1807. After 1832 numerous attempts were made to enter the lands, and title to property involved many years of contention and "shot-gun right." In 1870 Congress authorized suits against the United States in the court of claims. In 1876 title was held to be in the United States by the Supreme Court. Justice Field of the Supreme Court, in an opinion, said: "From the protracted litigation to which it has given rise the Hot Springs reservation is famous in the history of land titles of the country." And Justice Bradley: "The title to a well-known watering place in the State of Arkansas, called the Hot Springs, has been contested by a number of claimants for nearly half a century." In 1877 Congress created a commission to adjudicate squatter rights, giving right of purchase from the United States and to lay off the town. Under this act the Hot Springs were reserved by the United States to prevent monopoly or injury, and 911 acres are used as permanent parks. The government has expended nearly a million dollars in arching the creek, erecting the Army and Navy hospital (open to soldiers and sailors of the Civil War), and in developing and beautifying a system of parks not yet finished. These parks are covered with forest trees, and some are thoroughly fitted up for public enjoyment. Large sums have been spent on boulevards, walks, artificial lakes, landscape gardening, and handsome marble hot-water fountains scattered plentifully through the city. The grand entrance to Hot Springs Mountain, from Central Avenue, is a noble architectural feature, and the initial point of 15 miles of fine drives around the summits of Hot Springs, North and West Mountains.

With one exception, the springs are all enclosed in solid masonry, and the water is conducted by protected pipes into reservoirs near the base of Hot Springs Mountain or to the 23 bath-houses on and off this reservation. The exception is left open and accessible to the public. The government maintains a free bathing establishment for the indigent at which over 10,000 bathe annually, over 90 per cent being benefited. The prices of baths and fees of attendants are fixed by the Department of the Interior, with severe penalties for deviation. A rental of $30 per annum is collected for each tub; 716,053 baths were administered in 1902–3. A handsome city has grown up to house the guests and permanent residents. Along the front of the reservation bath-houses and on the slope of Hot

Springs Mountain is a fine park of 100 acres, with the most elegant buildings facing it. The creek is covered in, and sidewalks and roadways built over it. Several of the hotels, as the Arlington, Eastman, Park and Majestic, are among the largest and best appointed in the country.

Hot Springs received its city charter in 1876. It has a biennial mayor and a council. Being a pleasure resort, as well as a health resort, it has a large itinerant population. Large quantities of novaculite rock, "Arkansas" and "Ouachita," are quarried in the surrounding mountains, and 5,000 bales of cotton are marketed annually. The country abounds in cold springs, some of which have remarkable curative properties, notably Mountain Valley and Potash-Sulphur, 10 and 7 miles distant from Hot Springs; these are efficacious in conditions affecting the kidneys and intestinal tract. Pop. (1870) 1,276; (1880) 3,554; (1890) 8,086; (1900) 9,973.

CHAS. D. GREAVES,
Prest. School Board, Hot Springs, Ark.

Hot Springs, S. D., city, county-seat of Fall River County; on Fall River, the Fremont, E. & M. V. and the B. & M. R.R.'s; about 100 miles south of Deadwood. It is the trade centre for stock, lumber, and mining interests. The water-power is used for several manufactories, a stucco-mill, board and planing-mills, and machine shops. It has thermal and medicinal springs, and is the seat of the Black Hills College (M. E.), opened in 1890, and the State Soldiers' Home. Pop. (1900) 1,319.

Hotch'kiss, Benjamin Berkely, American inventor: b. Watertown, Conn., 1 Oct. 1826; d. Paris, France, 14 Feb. 1885. He was in early life a machinist and turned his attention to the invention of deadly weapons, among them the Hotchkiss magazine gun and the Hotchkiss machine gun, adapted for use in the fighting-tops of warships. In 1870 he established a factory at Paris. His guns were widely used by navies and armies until supplanted by other devices. He also improved heavy ordnance and projectiles.

Hotchkiss Gun. See MACHINE-GUN; ORDNANCE.

Hotel, or Hostelry, an inn or public tavern. The palatial hotels that have sprung up since the introduction of railways are too well known to require notice. One point of difference between the European and the American systems is that under the former, except in the case of a *table d'hôte*, the charge is for each dish ordered, while under the American plan a fixed price is charged for every meal. The modern French word is still used for the house of a rich or distinguished man, or for a public building, such as the *Hôtel de Ville*. See HOTELS IN AMERICA.

Hotels in America. The public house, or hotel, was established in the early days of the colonies to afford accommodation for those who might be compelled to journey from one place to another. As roads were poor, in those days, and stage transportation was slow, many of these houses were opened along the principal roads, or turnpikes, and the majority of these so-called inns bore such names as "King's," "Queens," "The Red Lion," etc. As public opinion changed, however, and the colonies inaugurated their revolt against the Crown, there was a corresponding change in the names of these hotels which brought them into closer harmony with the spirit of the times. From being mere public houses, wherein beds and food might be obtained by travelers, they became the meeting places of patriots, so it was but natural that the portrait of Washington, or of some other great American, should have taken the place of that of George III., and other royal personages, on the swinging signs before these doors. As time passed and the patriotic spirit rose to greater heights, these inns became the scenes of many events that brought them into the closest relation with the progress of the Revolutionary period and with the formative days which followed the declaration of peace. There was, for example, the City Tavern, in Philadelphia (1775), at which General Washington was frequently a guest; the Bunch of Grapes Tavern, Boston, where he enjoyed that "elegant dinner provided at public expense, while joy and gratitude sat on every countenance and smiled in every eye" (28 March 1776); the True American Inn, at Trenton (1777); Arnold's Tavern, Morristown; Sufferin's Tavern, Smith's Clove, N. Y.; the Buck Tavern, near Philadelphia; Smith's Tavern, Smith's Clove, N. Y. (1779); the tavern at East Chester, N. Y., where he was ill (1780); the Fountain Inn, Baltimore (1781); Day's Tavern, Harlem, where he stopped with Governor Clinton (1783); Fraunces Tavern, New York, where, in the assembly-room, he bade farewell to the men who had followed his fortunes so faithfully; Mann's Hotel, Annapolis, from which he proceeded to Congress on the day when he resigned his commission, and the City Hotel, Alexandria, where he was afterward entertained by the Alexandria Lodge, of which he was a member. The tavern at East Chester, where Washington stayed, during his illness, was erected soon after the beginning of the 17th century. At one time Lafayette was entertained in the house, and, for a season, it was practically the seat of the national government, President John Adams having taken refuge at East Chester during the yellow fever epidemic at Philadelphia, then the federal capital. This tavern now stands within the New York city limits, and the rooms which have the greatest historic interest still preserve the same appearance which they had in those old days.

Among the other taverns of the country which are rich in historic memories, but which were not directly associated with the career of the first President, were the Catamount Tavern, at Bennington, Vt.; George Burn's Coffee-House, in New York, long the lounging place of the British officers, although privately frequented by the Sons of Liberty during the occupation of the city by the British; the Tun Tavern, Philadelphia, the house in which the first Masonic lodge in America was organized; the City Tavern and the Bird in Hand, at Richmond, Va., and the Rose Tree Inn, at Media, Pa.

The first hotels in this country were conducted on the so-called American plan, which provided a fixed price for a day and for each fraction of a day. In those times $1 a day was considered a "good round price," and taverns were ordinarily so small that one which was provided with 20 rooms was regarded as a most commodious house. The rooms were usually comfortable, however, and were neatly, if

plainly furnished with strongly-made furniture. Carpets were rarely found, although hand-woven rag-rugs frequently appeared on the floors. Meals, which were served at fixed hours only, were announced by the ringing of a bell or gong, and all guests were expected to respond as quickly as possible. The table was abundantly supplied with dishes that were both substantial and palatable, the cooking being done by the wife of the landlord, with such assistants as the patronage of the inn might authorize, and while meat dishes predominated, game was so plentiful that its appearance attracted no comment.

At this time in the history of the American public house there were comparatively few inns that made an extra charge for wines. Instead decanters of liquors and of some favorite wine, like Madeira, port, or sherry, frequently stood upon the tables, and from these the guests served themselves freely. There were no printed bills of fare in these days, but practically all the food to be served was placed on the table at one time. Guests helped themselves, some slight assistance being given by the waiter who stood at hand. When Congress met in New York, in 1789, the members found accommodations chiefly in the boarding-houses which abounded in the neighborhood of the Battery — on lower Broadway, in Cedar street, and in Maiden Lane. It is rather amusing to note that people from other parts of the country complained about the "high prices" that were charged at the taverns and boarding-houses in New York, for that was the time when the "board of the Congressmen was paid out of the common treasury, to which every citizen of the United States contributed his share." In reply to this charge of exorbitant prices it was stated that board in New York "ranges from $3 to $7 per week," and one house was cited as furnishing "from 7 to 9 dishes a day, with 4 sorts of liquor."

The most important American taverns in 1795 were located in New York, Philadelphia, Baltimore, and Boston. The best New York taverns were Fraunces', opened in 1762, and formerly known as the Queen Catherine, one of the largest inns during the Revolutionary period, as it contained some 30 rooms; the City Hotel, which was erected on the site of the George Burns' Coffee House, in 1793, and which was not only the meeting place of the fashionable City Assembly, but was patronized by the so-called "Three Hundred" of that day; Bunker's, the Washington Tavern, and the Tontine Coffee House, on Wall street.

The National Hotel, in Washington, which was for many years the home of the most eminent public men of the nation, was opened in 1827. In 1829, the Tremont House was opened in Boston, and for years it was noted as being the grandest hotel in the land, if not the most elegant public house in the world. Prior to that time the principal hotels in Boston had been the Eastern Stage House, Doolittle's City Tavern, and the Lamb Tavern.

It was about that time, or, to be exact, in 1830, that Delmonico opened the first high-class restaurant in New York. High as his prices were, when compared to those which prevailed elsewhere, epicures and persons of fashion flocked to his support and the enterprise prospered from the day of its inception. In 1833, the United States Hotel, in New York was opened; in 1834, the Louisville Hotel, and, in 1835, the Galt House, also at Louisville, all of which immediately became noted as fine houses. The United States Hotel, at Boston, which has since been greatly enlarged and is still standing, was opened in 1835, while, about this time, the old Washington Hotel, at Portland, Me., which had been established since 1823, also took the name of the United States. The Rockingham, at Portsmouth, N. H., once the home of Governor Langdon, was opened in 1834, but, like other hotels of that time it was not particularly commodious in the modern sense of the word. In fact, up to 1836, there were comparatively few hotels in the United States that were capable of accommodating as many as 200 persons. In 1836, the Astor House, in New York, was opened. Built of massive granite, and furnished with all the conveniences of that day, it was a fitting rival to Boston's Tremont House. Barnum's Hotel, at Baltimore, which was opened at about this time, eclipsed the best houses which had hitherto been built in that city, while the opening of the St. Charles Hotel, at New Orleans, in the same year, was an event which was heralded from one end of the land to the other. Situated in the centre of the "American" portion of the city, its stately portico built in the style of a Corinthian temple, made it, next to the Capitol, at Washington, the most imposing structure in the land. It was also one of the best appointed and most commodious houses in America, having accommodations for more than 700 persons. The original buildings were burned in 1851, but it was almost immediately rebuilt, and it continued to enjoy its position as the centre of southern hotel life, until the outbreak of the Civil War. In 1894, the structure was once more burned, but it has since been rebuilt, and still ranks as one of the best hotels in America.

The Charleston Hotel, at Charleston, had the distinction of being the only hotel in the country that had been burned to the ground on the same day on which it was opened. This was in 1839, but as it was rebuilt at once, it was again opened in 1840, and afterward becoming the favorite resort of Calhoun and other great southern statesmen. When the Planter's House, at St. Louis, was opened in 1841, it justly prided itself upon being "the largest hotel west of the mountains." It had 215 well-furnished rooms, a classic ball-room with a floor-space "8,911 square feet more than the celebrated Tremont House, in Boston," while the china and cutlery, all of which was made in England, bore the name of the house. Charles Dickens, who stopped there in 1842, spoke favorably of the hospitality of this hotel in his "American Notes." The Massassoit House, at Springfield, Mass., one of the celebrated New England hotels, and the New York Hotel, were both opened in 1848. The Delevan House, at Albany, was opened in 1845. The year 1847 will always be a memorable one in the history of the American hotel, for it marks the date of the opening of the Revere House, Boston, a house which, under the management of Paran Stevens, soon became the pattern which all other hotels in this country sought to imitate.

Up to 1855, the principal hotels in Philadelphia were the Mansion House, the United States,

the Washington City, and the Girard House, and it was in that year that the Burnett House, at Cincinnati, was opened with 250 bed-rooms, besides many drawing-rooms, and especially spacious corridors. The Eagle Hotel, at Richmond, where Lafayette had stopped in 1824, was burned in 1840, and the Exchange and Ballard's were afterward opened. The Clarendon and the Irving House, in New York, were opened about 1850. The first Tremont House, at Chicago, which for some time was the leading hotel in that city, was opened about this time, while the Battle House, at Mobile, the St. Louis Hotel, at New Orleans, and the St. Nicholas and the Metropolitan, in New York, were opened about 1852. All were large houses, and were conducted upon an expensive scale, while the two New York houses were particularly conspicuous in having introduced "bridal chambers" and other novelties.

In 1854, the Brevoort and the Everett were opened, on the European plan, in New York; the famous Parker House, in Boston, also on the European plan, was opened in 1855, while the Fifth Avenue Hotel, in New York was finished in 1859. It was the first hotel to introduce a passenger elevator.

Willard's Hotel, at Washington, was the focus of many thrilling scenes and events during the Civil War, and among the houses that were opened during the next few years were the Lindell and Southern hotels, at St. Louis; the Albemarle, Hoffman, St. James, and Grand, in New York, and the Arlington, at Washington. The Gilsey House, which was opened in 1871, in New York, at once took rank as one of the best European-plan hotels, while the Windsor House, in New York, began the successful career that ended so disastrously in the fire of 1899, in 1873. The Brunswick, in Boston, and the Palmer and Grand Pacific, both in Chicago, were opened about this time, while the Palace Hotel, at San Francisco, one of the most famous and palatial houses in the far west, began to receive guests in 1875.

The last two decades of the 19th century were conspicuous, not only for the sudden increase of new and more splendid hotels, but also for the enlargement and improvement of those already built, in every part of the country, while, in such a brief review of the hotel business, it is impossible to name all the hotels worthy of mention that have been built during the past 25 or 30 years, it may justly be said that the revival of interest in the making of new and better houses extended from the Atlantic to the Pacific, and from our northernmost boundary to the Gulf. Beginning with the Vendome and Young's, at Boston, the list would include the Narragansett, at Providence; the Grand Union, Park Avenue, and Murray Hill, in New York; the Lafayette and Stratford, at Philadelphia; the Rennet, at Baltimore; the De Soto, at Savannah; the Kimball, at Atlanta; the Iroquois, at Buffalo; the Hollenden, at Cleveland; the Grand, at Cincinnati, and the Cadillac and Russell, at Detroit. Later came the Auditorium, at Chicago; the Plankinton, at Milwaukee; the Ryan, at St. Paul; the West, at Minneapolis; the Coates House, at Kansas City; Brown Palace Hotel, at Denver; the Portland, at Portland, Oregon, and the Tacoma, at Tacoma. The impetus to the hotel business, which began some 30 years ago, however, has continued up to the present time for the last few years have witnessed the construction of many new and finer hotels than any that had hitherto been built, among them being the Imperial, the Savoy, the Holland, the Waldorf, the New Astor, and the St. Regis, while one of the most unique experiments in the hotel line was the establishment of the Martha Washington, a hotel exclusively for women, which is now being successfully operated, also in New York.

The watering-place and summer-resort hotels also represent an important and rapidly increasing branch of the business. At the beginning of the 19th century there were a few inns at places like Saratoga, while a tavern at the White Mountains was built by Crawford in 1803. In 1822, the Catskill Mountain House was opened, and, by 1840, there were good houses at Trenton Falls and Delaware Water Gap. Twenty years later, Newport, Nahant, the White Mountains, Lake George, Satatoga, Niagara, Cape May, Old Point Comfort, and the Virginia springs, all had good hotel accommodations, but, since that time this branch of the business has grown to such an extent that splendid hotels are now located on almost every available spot on the coast from Maine to Florida, while the Adirondacks, the Catskills, and many interior resorts have accommodations for guests that can compare favorably with the best hotels in the country. At such hotels the American plan usually prevails, as it does to a considerable extent throughout the smaller cities and towns. In the large cities, however, the European plan, which fixes a price for the room, and which charges for extra service and for each item on the bill of fare, has become more popular, for while, in some instances, the two plans are combined, it is the European plan that is generally followed by the large hotels. Moreover the charges at the best hotels are about twice as great as they were in 1850.

When compared with the palatial hotels of to-day even the fine houses like the Tremont and the Astor House were primitive in their construction and management. The modern hotel is equipped with running water and set basins in every room; many rooms also have water-closets and baths with exposed plumbing; everywhere there are open grates and steam heat, improved ventilation, elevators for both passengers and baggage, electric bells, telephones, and every possible device to prevent fire, or to assure the safe escape of guests in case of a conflagration. Utensils and machinery have also multiplied greatly during the past few years, for the best hotels now run a thoroughly up-to-date laundry, an electric lighting plant, apparatus for the distilling of water, and the most elaborate cold-storage conveniences, often including an individual ice-making plant, while, among the other necessary conveniences of every well-equipped hotel one may mention the reading, writing, and music rooms; the coat, package, and baggage rooms; the barber shop, with its manicuring, boot-blacking, and other accessories; the billiard-room; telephone, telegraph, and ticket offices; the book and newsstand; the stenographers and typewriters, and the carriage and messenger services, not to mention a score of other details that are just as imperative a necessity. It is no uncommon

thing to-day to find single hotel structures valued at $3,000,000 or $4,000,000, equipped with furnishings costing many hundred thousand dollars.

A conservative estimate of the number of hotels in the United States, in 1905, exclusive of those in process of erection, places the number at 44,250. Of these about 3,750 are summer or winter resort hotels, 3,000 are family, or private hotels, while the balance are commercial houses. These hotels now give employment to no less than 3,250,000 persons, and the amount of capital invested in the business is undoubtedly in excess of $6,000,000,000.

Hottentots, hŏt'ĕn-tots, an African race, the aboriginal occupants of the south end of that continent, near the Cape of Good Hope. The name now given to the whole race was that of the tribe in the immediate vicinity of the Cape of Good Hope, with which the Dutch settlers first became acquainted. The origin of the name is unknown. They are, when young, of remarkable symmetry; but their faces are ugly, and this ugliness increases with age. The complexion is a pale olive, the cheek-bones project, the chin is narrow and pointed, and the face consequently is triangular. The lips are thick, the nose flat, the nostrils wide, the ears large and lobeless, the hair woolly, and the beard scanty. The women in early life are often models of proportion, and their gait by no means deficient in grace. Their bloom, however, is transient, for, marrying at twelve or thirteen, after the first child they lose their grace and proportion, and soon become hideous. Both sexes are distinguished by excessive incurvation of the spine. When the Dutch first settled at the Cape the Hottentots were a numerous nation, and occupied a territory of 100,000 square miles. They had abundance of horned cattle and sheep; and it is supposed that the seven tribes into which they were divided made up together a population of at least 200,000. At the present day this race is nearly extinct within the wide territory which formerly belonged to it. They may amount to about 20,000. The Koras or Korannas (shoe-wearers), south of the Kalahari Desert, still remain a favorable specimen of the Hottentot race. They are taller, stronger, and more cleanly than some of the other tribes. Most of them possess cattle; those who do not, soon degenerate into Bushmen. On the eastern frontier of the colony are still some remnants of the Gona or Gonaqua tribe; but they have nowhere preserved their ancient usages and purity of blood, but are much mixed with the Amakosa Kafirs. The Namas, who are the purest type of Hottentots now existing, dwell in Namaqualand, in German Southwest Africa. The Namas are a pastoral people almost exclusively. Their dwellings are low, rude huts, surrounded by fences. Many of them have been Christianized. The Hottentots generally are very indolent and lethargic.

Hottentot's-bread. See ELEPHANT'S-FOOT.

Houdon, Jean Antoine, zhŏn ăn-twăn oo-dŏn, French sculptor: b. Versailles 20 March 1741; d. Paris 15 July 1828. Having gained the first prize for sculpture in the royal academy at Paris, he visited Italy, passed 10 years in Rome in the study of the antique, and finished, among other works, the statue of St. Bruno in the church of St. Maria degli Angeli. Returning to Paris, he executed admirable busts of Rousseau, Diderot, D'Alembert, Franklin, Turgot, Mirabeau, Gluck, and many other distinguished men; statues of Voltaire and Tourville; the celebrated 'Diana' for the empress of Russia; and other works, which placed him in the first rank of French sculptors. In 1785 he accompanied Franklin to the United States, to prepare the model for the statue of Washington ordered by the State of Virginia, and passed two weeks at Washington's residence at Mt. Vernon for that purpose. The statue, bearing the sculptor's legend, "*Fait par Houdon, citoyen Francais,* 1788," now stands in the hall of the capitol of Virginia at Richmond. Among Houdon's later works is the celebrated statue of Cicero in the palace of the Luxembourg.

Hough, hŭf, Emerson, American author: b. Newton, Ia., 28 June 1857. He was graduated from the State University of Iowa in 1880, traveled extensively in the wild portions of the West, was for several years a writer in Chicago, and there became in 1899 western manager of the New York periodical 'Forest and Stream.' His publications are: 'The Singing Mouse Stories' (1895); 'The Story of the Cowboy' (1895); 'The Girl at the Half-way House' (1900); and 'The Mississippi Bubble' (1902).

Hough, George Washington, American astronomer: b. Montgomery County, N. Y., 24 Oct. 1836. He was graduated at Union College in 1856; appointed astronomer at the Cincinnati Observatory in 1859, and the following year became astronomer and director of the Dudley Observatory, Albany, N. Y. In 1879 he became director of the Dearborn Observatory and professor of astronomy at the Chicago University; and later accepted a similar position at the Northwestern University. He has invented several astronomical instruments and has discovered more than 600 double stars. He has written 'Annals of the Dudley Observatory' (1866–71).

Hough, Walter, American ethnologist: b. Morgantown, W. Va., 23 April 1859. He was graduated from the West Virginia University in 1883 and since 1885 has been connected with the ethnological department of the United States National Museum, becoming in 1895 assistant curator. He has published several important professional monographs.

Hough, Warwick, American jurist: b. Londoun County, Va., 26 Jan. 1836. He was graduated from the University of Missouri in 1854, subsequently studied law and was admitted to the bar in 1859. In January 1861 he was appointed adjutant-general of Missouri, as such issuing the general order under which the State military organizations went into camp on 3 May. He was for a short time secretary of state in Missouri, resigning in 1863 to enter the Confederate service, and serving on the staffs of General Polk and other Confederate commanders. For a few years after the war he practised law in Memphis, Tenn., but afterward returned to Missouri, establishing himself in Kansas City. He was a judge of the Missouri supreme court 1874–84, for two years of that period serving as chief justice of the State. In 1884 he removed to St. Louis, where he has continued in the active practice of his profession.

Houghton, hō'tŏn, **Henry Oscar,** American publisher: b. Sutton, Vt., 30 April 1823; d. North Andover, Mass., 25 Aug. 1895. He was apprenticed to a printer in Burlington, Vt., and later entered the University of Vermont, where he was graduated in 1846. Going soon after to Boston he became a member of the printing firm of Bolles & Houghton at Cambridge in 1849, and founded later the 'Riverside Press.' In 1864 he entered the book publishing firm of Hurd & Houghton, now the widely known house of Houghton, Mifflin & Co.

Houghton, how'tŏn, **Richard Monckton Milnes,** Baron, English poet: b. Fryston Hall, near Pontefract, Yorkshire, 19 June 1809; d. Vichy, France, 11 Aug. 1885. He was educated at Oxford and was long prominent in Parliament as a moderate Conservative. He was raised to the peerage in 1863. He was the author of several volumes of verse and prose, including a 'Life of Keats' (1848).

Houghton, hō'tŏn, Mich., a village and the county-seat of Houghton County, 94 miles northeast of Marquette; on the south bank of Portage Lake, and on the Copper Range, Mineral Range, and Duluth, S. S. & A. R.R.'s. Portage Lake is connected with Lake Superior at the south by the Portage River and at the north by a ship-canal by means of which steamers avoid the detour around Keweenaw Point.

Industries, etc.— Houghton is the centre of the rich mineral district in the peninsula of Keweenaw, the total output of which was in 1901 nearly 150,000,000 pounds. The larger part of the copper export of the region is shipped from this port. There is also considerable lumbering, manufacture, and commerce, and the shipping interests are important. The various industries have about 1,000 employees.

Public Institutions, Buildings, etc.— It is the seat of the Michigan College of Mines, which was founded in 1885 and occupies a fine structure. There are Episcopal, Methodist Episcopal, Catholic, and Presbyterian churches. Mention should also be made of the county court-house. The two banks have a combined capital of $250,000 and deposits of about $3,000,000.

History and Government.— Houghton was first settled in 1851. Its government is by a president and a council of six members elected biennially, three in each year. Pop. (1903) 4,000.

Horace J. Stevens,
Editor of the 'Copper Handbook.'

Houlton, hōl'tŏn, Maine, town, county-seat of Aroostook County, in the eastern part of the State; on the Canadian P. and the Bangor & A. R.R.'s; about 145 miles northwest of Eastport. It is the trade centre for a large lumbering region, and in the near vicinity there is quite an acreage of good agricultural lands. The chief manufactures are flour, butter, starch, foundry and machine-shop products, lumber, woolen goods, and furniture. It has a large slaughter-house and planing- and molding-mills. It is the seat of Ricker Classical Institute, a Baptist school. It has a town public library. Pop. (1900) 4,686.

Houma, hoo'ma, La., town, parish-seat of Terrebonne Parish; on the Bayou Terrebonne, and the Southern Pacific R.R.; about 72 miles southwest of New Orleans. It is situated in an agricultural region where the principal crops are rice, sugar-cane, and grain. The canning of oysters is one of the important industries; it has a large moss-factory and lumber yards. From 1890 to 1900 the increase in population was over 100 per cent. Pop. 4,686.

Hound, a dog that hunts by scent, a definition which excludes the greyhound (q.v.). It is difficult to determine from what stock the English hound has originally sprung, but the old "Southern hound" or talbot was most probably the source of the various hounds now known, among which the bloodhound, foxhound, beagle, harrier, dachshund, turnspit, otterhound and boarhound (now known as Great Dane) are the principal varieties. The mastiff (q.v.) ought also to be included in this group. See Dog.

Hour-glass, a species of chronometer or instrument for measuring time. It consists usually of two hollow bulbs placed one above the other, and having a narrow neck of communication. Dry sand is introduced in quantity sufficient nearly to fill one of the bulbs and fine enough to pass freely through the orifice of the connecting neck. The quantity of sand is adjusted to the time which the glass has been constructed to indicate. In the case of an hour-glass the sand in the upper bulb takes an hour to pass into the lower bulb; and so on for any other definite division of time. This instrument is always subject to slight error in its indications of time, owing to the expansion and contraction of the glass by changes of temperature, and by the variations of dryness in the sand. The hour-glass was commonly used in churches during the 16th and 17th centuries to regulate the length of the sermon, and in some places it continued in use down to the beginning of the 19th century.

Houris, hoo'- or how'rĭz, the "black-eyed" nymphs of Paradise, whose company, according to the Koran, is to be one of the rewards of the faithful. They are described as most beautiful virgins endowed with perpetual youth. They dwell in beautiful gardens, by flowing streams, and the very meanest of the faithful will have at least 72 of them.

Housatonic, hoo-sa-tŏn'ĭk, a river which has its rise in the Berkshire Hills, in the western part of Massachusetts, and flows south, through Connecticut, into Long Island Sound. Its course of about 155 miles is through a hilly, mountainous country, noted for its scenic beauty.

House, a place of abode of a family or individual. The common expression, "a man's house is his castle," is in most instances true. Except in criminal cases a man can hold his house against all comers. No sheriff can break open his door to arrest him, or seize his goods for debt, except by a writ, affidavit, or search-warrant. But the house is no protection where there has been a criminal offence. Breaking into a house with the intent to rob is burglary, and to set fire to a house constitutes arson. A man may defend his house against trespassers and thieves attempting forcible entrance, even to the killing of the intruder, if it can be shown that he has used no greater force than was absolutely necessary.

House-boat, a combination of boat and house, used largely as pleasure craft on rivers, canals, and lakes, in Great Britain and the United States. The houseboat had its origin in England about 1860. Its growth there has been comparatively slow. It was transplanted to this country late in the 19th century, and at first found favor with only a select few; but as soon as its advantages became manifest it began to develop rapidly, and advanced to a most remarkable state of perfection. A "house-boat" is not a boat with two, three or four decks and a number of staterooms, but a commodious, comfortable craft arranged for the accommodation of a family party, a company of bachelors or any suggestible combination of people. It might be likened to a suite of apartments afloat.

The house-boat in England has been particularly a Thames attraction and is seen to the best advantage at Henley. In 1903 there were several hundred of these floating houses on the water of the Thames. The price of a house-boat ranges from $300 to $25,000. But a comfortable craft, containing saloon, kitchen and four bed-rooms, may be purchased for $2,000. The Thames season lasts from June to September, and is at its height in July and August. A large house-boat may be hired for the season, including Henley, for $1,000.

In the United States the house-boat is seen most frequently during the summer months on the Hudson River, the St. Lawrence River, and Long Island Sound. The American vessels are even larger than the English boats and more expensive. They are constructed on approved plans, and contain every possible comfort and convenience that may be found in the best equipped dwelling or suite of apartments ashore. There are spacious sleeping rooms, larger than the staterooms on ocean steamers, a cosy sitting-room, a parlor, a library, a reception room, all the necessary storerooms, a lavatory, a cook's galley and, in fact, everything that a well-ordered household might demand. The properly constructed house-boat has a promenade deck and a high rail encloses it so that children may play about the deck with the utmost freedom and safety. The more pretentious are lighted with gas supplied from a naphtha gas-making machine, or electric light, with the energy supplied by storage batteries.

The great charm of the house-boat is the power that its occupants possess to move it from one place to another. On dry land when a man or a family does not fancy a place he or they move away and leave the house behind. On the house-boat they take their house along with them, and they can go wherever navigable water exists. The boat can be anchored in mid-stream or moored to a pier. No persons can interfere with the privacy of those on board. It is their own floating castle. When they are tired of one place they can go to another, and they have the advantage over their land-living friends that they not only take their house along, but all their belongings, and without the aid of the baggage master.

A typical American house-boat is the Idler, owned by a New York gentleman and used about Alexandria Bay, in the St. Lawrence River. The cabin has a dozen or more windows of goodly size; there is a saloon and opening from it a dining-room. The kitchen, store-rooms and quarters for a servant or two are "aft." The promenade deck has hammocks, steamer chairs, camp stools, rugs, tables, books, work baskets, and flowers; here the family live, move, and have their being for three quarters of the time spent on the boat. Among the well known house-boats on the St. Lawrence, are the Nydia, Mavis, River God, Bohemia, Amaryllis, Merrivale, and Summerholme.

On the Mississippi River, Ohio River and other large streams in the Western States the house-boat is utilized for business as well as for pleasure, and floating grocery stores, photograph galleries, and dry goods and notion shops are not uncommon. There is on the Mississippi at least one floating theatre built on the house-boat plan, and hundreds of small families have adopted a rudely constructed inexpensive type of boat for permanent residences.

House-Boat on the Styx, A, a humorous book by John Kendrick Bangs (q.v.) published in 1895. It purports to be an account of the doings and conversations of a company of literary ghosts assembled in a house-boat managed by Charon. Among the ghostly personages represented are Shakespeare, Raleigh, Dr. Johnson, and many more of various degrees of renown.

House-cricket. See GRYLLIDÆ.

House-finch, A familiar garden finch (*Carpodacus frontalis*) of California, grayish, with the head, neck and breast scarlet-carmine. It represents a group of beautiful and interesting Pacific Coast and Mexican finches also known as linnets and burions.

House-fly. See FLIES.

House Industry, a modern system of labor in which the workmen carry to their homes raw materials and other goods to be manufactured within their own houses. In New York and other large cities this form of labor particularly applies to the Polish Jews, who are employed to the number of many thousands by the manufacturers of coats, cloaks, and other wearing apparel. The abuses of house industry have become notorious under the name of the sweat-shop system, which will be found described more in detail in the article FACTORIES AND FACTORY INSPECTION.

House of Lords. See PARLIAMENT.

House of Representatives, the branch of most State legislatures, and of Congress, which has the more numerous members, elected from smaller districts, and in some cases for shorter terms. It is very commonly termed the "lower house" or "popular branch," implying a misunderstanding at once of its origin and functions. The House, for instance, is commonly supposed to be related to the Senate as the British House of Commons is to the House of Lords, and to have been modeled on that relation; the former is wholly untrue and the latter largely so. The House of Commons represents popular constituencies, the House of Lords represents only itself; the former is the less dignified theoretically, in practice it has not only more power but all the power; the individual members of the former have mostly less power than those of the latter, but as a body they are incomparably more powerful. None of these things is true about the House and Senate of Congress. Both rep-

resent constituencies and the public equally; both are not only theoretically but practically equal — the Senate's power of confirming appointments and treaties being fully balanced by the House's power of impeachment, of originating revenue bills, and electing a President if the electors fail of a choice. Nor are the members of either as individuals presumptively superior in power to those of the other. The actual superiority of the Senate is due to the longer terms, which give the older members a parliamentary experience before which the mass of raw members of the House bow; to the seats being the subject of eager competition among the ablest politicians, so that the average public position is higher; and to the lesser membership and smaller number of new bills, which enable it to preserve more independence of the chairman's tyranny than the House. Still, a certain glamour always surrounds the latter as the "popular branch"; partly due to the fact that, owing to its great number and short terms, popular movements are more quickly transformed into legislative action than in the Senate. In this respect alone the idea is correct: a party intrenched in the Senate has often boasted that no matter what the majority of the people wished it could not be dislodged for at least eight years, or the time of two presidential elections, in which anything might happen.

In its formation, the model in the State legislatures was simply to follow the old colonial form of council and assembly, itself not copied from Parliament but an independent development; and in Congress the model was partly those legislatures and doubtless partly Parliament — the political theory of "checks and balances" being more potent, however, in defining the distribution of powers than in creating the forms of the houses. The actual form of Congress was a compromise, without which the Union could not have been formed. The large States were averse to being outweighed by the small, and wished for a two-chambered body, with representation in each proportionate to population; the small ones were determined on a single-chambered one, with each State having one vote. The present arrangement was the suggestion of the Connecticut members; a final item of the compromise was that the senators should vote individually and not by States, so that a State should only have its power on condition of keeping its members in place. For the general functions of the House, and its relations present and prospective to the Senate, see CONGRESS.

The members of the House, according to the Constitution, must be 25 years of age, seven years citizens of the United States, and residents of the States which send them; by act of 25 June 1842 they must be chosen from districts formed of contiguous territory (but see GERRYMANDER for the observance of this). This put an end to electing on general ticket, but there is no provision that the representatives shall be residents of their districts, and the people have a perfect right to choose them in the British fashion, from any part of the State. What prevents this is not law, but the intense local particularism which, even in State senatorial districts made up of several towns, insists on passing the office around among the towns; at bottom, the American conviction that public office demands no training. The number of members is fixed by Congress after each new census.

A quorum of members is a majority of those actually chosen. The House organizes by having the clerk of the last House call the new members to order, and if a quorum is present he calls the roll for a vote on choice of Speaker. The members choose their seats in turn as their numbers are drawn by lot. The principal officers are the Speaker, clerk, sergeant-at-arms, doorkeeper, postmaster, and chaplain. (For the Speaker's powers, see CONGRESS.) The sergeant-at-arms is the constable. The symbol of his authority is the mace, made on the pattern ordered by the House 14 April 1789; a Roman device, ebony fasces, of which each rod ends in a spear-head, bound at the ends and in the middle with silver bands, and on the end a globe surmounted by an eagle with outspread wings. The House is governed by Jefferson's Manual of Parliamentary Practice, plus its standing rules and orders and the joint rules of the two houses.

House of the Seven Gables, The, a novel by Nathaniel Hawthorne (q.v.).

House Snake, or **Milk Snake,** a variety of *Lampropeltis doliatus,* the corn-snake (q.v.) of the South, found abundantly in most parts of the northern half of the United States westward to the Rocky Mountains. The dorsal scales are not at all keeled and the ventral plates often exceed 200 in number; the ground-color is gray with three series of rounded black-bordered brown blotches, and the belly checkered with black and white; a length of 4 feet is sometimes attained. This is a handsome and mild-tempered colubroid snake, very abundant in farming districts, where it frequently enters houses, but probably in search of mice rather than for the purpose of drinking milk, as is popularly believed. It is an expert climber, often ascending porches and vines attached to the walls of houses. As usual, the eggs are deposited in a hole dug in a sandy field.

House Sparrow. From the circumstances of the chief importations into this country having been from England this species, the *Passer domesticus* of ornithologists, is almost exclusively known in the United States as the English sparrow, although it is distributed quite as plentifully throughout most parts of Europe. The appearance and general habits of this familiar and ubiquitous bird require no description. The presence of the house-sparrow in America is a most noteworthy instance of the folly of disturbing the proper "balance of Nature" by the thoughtless introduction into new regions of vigorous species which are relieved from the restraining influences of those checks that usually operate in their original habitats. The motives which led to its importation seem to have been two-fold: the desire to combat the plague of measuring-worms (*geometridæ*), with which the parks of many of the eastern cities were affected, and the sentiment which moved many of our foreign born citizens to look with favor upon the introduction of a familiar bird of the fatherland. The importations began in 1850, when the directors of the Brooklyn Institute, led by the Hon. Nicolas Pike, liberated 8 pairs in that city, followed by larger numbers in 1852

and 1853. The following year saw their introduction into Portland, Me. Within the next 15 years direct importations were made to the eastern seaboard, the city of Philadelphia liberating 500 pairs in 1869 in her parks, which were carefully nurtured by a paid caretaker. During the next decade small lots were set free in nearly every State of the Union, including those on the Pacific coast. Thus, purposely distributed by man, carried in grain cars on the railroads and aided by its remarkable hardiness, fecundity, boldness and adaptability, the house-sparrow has in 50 years spread to practically all parts of this country, except a few remote and isolated regions, and to many parts of British America. It keeps close to the abodes of man and has become extraordinarily abundant in many large cities and towns, where it acts as a scavenger and befouls the buildings with its droppings and slovenly nests. Because of its presence and pugnacity many smaller native birds have withdrawn from the parks and open spaces, and it has in many other ways become a nuisance, though it does not altogether lack virtues. In its relation to agriculture little that is favorable can be said of the English sparrow. About three fourths of its food consists of grain, much of which is obtained by raids on the fields and store houses; serious injury is also done by its attacks on flower and leaf buds and on all kinds of fruits. On the credit side may be mentioned the relatively small quantity of insects and the considerable quantity of weed seeds devoured. Consult, Gentry, 'The House-Sparrow at Home and Abroad' (1878); Barrows, 'The English Sparrow in North America' (1889).

Housing Problem. See TENEMENT HOUSE, *Reform.*

Hous'man, Laurence, English author and illustrator: b. London 14 July 1867. He has illustrated 'The Goblin Market'; 'Weird Tales'; 'The Were Wolf'; 'Jump to Glory Jane'; and other books, his work being mostly engraved on wood by his sister Clemence. He is the author of 'The Writings of William Blake' (1858); 'A Farm in Fairyland' (1894); 'The House of Joy' (1895); 'Green Arras' (1896); 'All Fellows' (1896); 'Gods and Their Makers' (1897); 'The Field of Clover' (1898); 'The Little Land' (1899); 'Rue' (1899); 'The Seven Young Goslings' (1899); 'Bethlehem' (1902), and 'Love Letters of an Englishwoman' (1901), which appeared anonymously and was attributed to various writers of the day.

Houssa, how'sä, or **Haussa,** Central Soudan, a former important negro kingdom, north of the junction of the Benue and Niger rivers. After internecine divisions it was succeeded by a Mohammedan Fulah empire in 1802, and is now incorporated in Nigeria. The name is perpetuated by a negritic race and language distributed far beyond the ancient Houssa boundaries. The race is distinguished as able traders and craftsmen, and the language, for its euphony, simplicity and literary adaptability.

Houssaye, Henri, ŏñ-rē oo-sā, French historian: b. Paris 24 Feb. 1848. He was educated at the Lycée Napoléon, fought with distinction in the Franco-German war, became an editor of the 'Revue des Deux Mondes' and the 'Journal des Débats,' and was chosen president of the Société des Gens de Lettres. In 1864 he obtained election to the French Academy, which in 1873 awarded the Thiers prize to his 'Histoire d'Alcibiade.' He published in three parts—'1814,' and '1815' (2 vols.)—a study of Napoleon's downfall, which enjoyed wide sale in France, and is considered one of the best extant works on the subject.

Houston, hūs'tŏn, **Sam,** American soldier and statesman: b. Lexington, Va., 2 March 1793; d. Huntsville, Tex., 25 July 1863. Leaving home when a boy he crossed the Tennessee River and took up his abode with the Indians, by whom he was kindly received, and with whom he lived after their own fashion for several years. Oolooteka, one of their chiefs, adopted him as his son. In 1811 he returned to his family, and to maintain himself opened a school. In 1813 he enlisted as a common soldier in the United States army, was promoted ensign, and fought under Gen. Jackson against the Indians at the battle of Tallapoosa, in March 1814. In November 1817 he was appointed a subordinate Indian agent to carry out the treaty with the Cherokees just ratified. In the following winter he conducted a delegation of Indians to Washington. On arriving he found that complaints had been made against him to the government on account of the zeal with which he had exerted himself to prevent the unlawful importation of African negroes through Florida, then a Spanish province, into the southern States. He was acquitted of all blame, but conceiving himself to be ill treated he resigned his commission in the army, and returning to Tennessee settled in Nashville and began the study of law. In 1819 he was elected district attorney, and in 1821 was chosen major-general of militia. Two years later he was elected to Congress; re-elected in 1825, and in 1827 was chosen governor of Tennessee.

In 1829, for reasons unknown, he resigned his office, separated from his family, and deserting civilization, went to Arkansas, where his former Indian friends, the Cherokees, had removed. He was kindly received and for years remained with the Indians. In 1832 he went to Texas and at the outbreak of the Mexican war was elected commander-in-chief of the Texan army.

After the massacre of the Alamo, the Mexican President-general Santa Anna was defeated by Houston at the battle of San Jacinto, 21 April 1836. Santa Anna was captured by the Texans and the independence of Texas was achieved. On 23 July a general election for president, vice-president, and members of Congress of the republic of Texas was ordered to take place on the first Monday of the following September. Houston was solicited to be a candidate, but declined; but as the day of election approached the popular feeling in his favor became so manifest that he had no alternative but to accept. He was elected by a large majority and was inaugurated 22 Oct. 1836. One of his first acts was to liberate Santa Anna, who had been kept in captivity, and to send him to Washington to confer with the president of the United States. He next opened negotiations with the United States government for the annexation of Texas to the Union, but the measure encountered such strong opposition in the United States that it did not succeed till several years later.

Texas became one of the United States in

1845, and Houston and Rusk were the first senators sent to Washington. Houston was re-elected at the end of his term in 1853, and remained in the Senate till March 1859. As a senator he was opposed to the Kansas and Nebraska bill, against which he made one of his most elaborate speeches, in which he declared that the repeal of the Missouri Compromise was a flagrant breach of faith, which would involve the country in interminable agitation and difficulty. He was prominently mentioned in 1854 as a presidential candidate of the "Know-Nothing" party. He was elected governor of Texas 1 Aug. 1859, but was deposed for adherence to the Union in 1861. See Williams, 'Sam Houston and the War of Independence in Texas' (1893).

Houston, Texas, city and county-seat of Harris County, at the junction of White Oak and Buffalo bayous; the highest inland point in the State permanently accessible by water from the Gulf of Mexico. Buffalo Bayou, which furnishes an outlet to the sea, 50 miles distant, has been navigated from the earliest days of the city's history, and is being widened and deepened by the Federal government at a cost of $4,000,000 so as to admit of the passage of the largest ocean-going craft.

Houston was settled shortly after the battle of San Jacinto, which was fought on 21 April 1836, within a few miles of its location. The city was named after Gen. Sam Houston (q.v.). It was made the seat of government for the Republic of Texas, and so remained until 1840.

Government.— Houston was first incorporated under an act of the Texas Congress passed 29 Dec. 1837. It now has a charter granted by special act of the legislature in 1903. Under the charter a mayor is its chief executive officer, and 12 aldermen (two for each of the six wards into which the city is divided) constitute the legislative division of its government. The mayor and the aldermen are elected for two years as are also the city treasurer, the city tax assessor and collector, the city attorney, the city health officer, the street commissioner, the chief of police and the judge of the corporation court, which has jurisdiction of police cases. The cost of Houston's city government, including the amount appropriated out of the general revenue fund for the public schools, ranges between $600,000 and $650,000 per annum. The city owns a sewer system with 37½ miles of conduits. The city has about 36 miles of paved and otherwise improved streets. The city maintains a paid fire department at a cost on an average of $60,000 per annum. The cost of police protection averages about the same.

Public Buildings.— Houston's chief buildings are the city-hall and market-house, the Central fire station, the Binz office building, the Commercial National Bank building, the Stowers building, the Houston Post building, the High School building, the Mason building, the Carnegie Library building, the First Presbyterian Church house, the Christ Episcopal Church house, the Waddell building, the Kiam building, and a provided-for Federal building to cost $500,000 and the Rice Institute building for the erection and maintenance of which an endowment of between $4,000,000 and $5,000,000 has been left. The William M. Rice Institute was founded in the year 1892 by the late William Marsh Rice, of New York. This institute contemplates the establishment and maintenance of an industrial or polytechnic school for males and females, designed to give instruction on the application of science and art to the useful occupations of life. It establishes and maintains a free library and reading rooms, and galleries of art.

Education.— The city has 20 public schools (including a high school for whites and one for negroes), and 26 private schools — and one Carnegie library building. The city's school affairs are managed by a board of seven trustees appointed by the mayor with the approval of the city council. The schools are maintained by direct appropriation from the general revenue fund and get from $80,000 to $1,000,000 from that source annually. In addition they receive each year from the State a per capita apportionment of the State school fund which runs from $4.50 to $5.00 for each pupil between the ages of 7 and 17.

There are 5 Baptist, 5 Catholic, 3 Christian, 2 Christian Science, 3 Episcopalian, 2 German Methodist (North), 5 Methodist (South), 1 Methodist (North), 1 Cumberland Presbyterian, 5 Presbyterian and 2 non-denominational churches for whites, besides one Episcopalian chapel and two missions, a Salvation Army barrack and a Spiritualist association. The negroes have 29 churches of all denominations. The city's eleemosynary institutions consist of the Bayland Orphans' Home, the De Pelchin Faith Home, the Florence Crittenton Rescue Home, the Sheltering Arms Home of Christ's Episcopalian Church and an Infants' Home for foundlings. The city has one public park and zoological garden valued at $80,000.

The city has six national banks with a combined capital stock of $1,450,000; an average surplus of $900,000 and average undivided profits of $500,000. Their deposits range around $11,000,000 in amount and their loans around $7,000,000. In addition there are three private banks with combined resources of $3,000,000. Bank clearings in excess of $600,000,000 are annually effected through the city's clearing house.

Trade and Commerce.— In point of trade and commerce Houston distributes more groceries, hardware and machinery than any other city in the State. It is the most important spot cotton market in the world, barring Liverpool, 1,927,607 bales, or a little less than 19 per cent of the entire crop of the United States, constituting the volume of its transactions in the staple for the year 1903, said transactions involving an approximate outlay of $86,742,315. Houston is also the principal lumber market of the Southwest. In sugar Houston is second to New Orleans only, while in rice, a comparatively new industry in Texas, it ranks as one of the four principal markets west of the Mississippi.

More produce, fruit and feed stuff is consumed and distributed in Houston than in any other city in the Southwest.

Transportation.— Houston's pre-eminence as a commercial centre is due to its supply of transportation facilities. In 1856 these consisted, aside from a navigable outlet to the sea, of 56 miles of railroad. In 1861 its rail lines extended a distance of 357 miles, there being but 462 miles of railroad in the entire State at that time. And this ratio has been pretty well preserved until 1903 when 6,500 miles of rail-

SAMUEL HOUSTON.

road, or more than one half the State's mileage were operated by 14 lines for which Houston is an initial point and which during that year moved 16,000,000 tons of freight, or about three fifths of the tonnage which went toward making up the total of the State's railroad business. These 14 lines with their immediate system connections give Houston 30,000 miles of direct rail facilities. In addition to this Houston enjoys direct rail and barge connection with a second steamship line to New York which has tri-weekly sailings from Galveston. By reason of its location at the head of ocean navigation on Buffalo Bayou, Houston enjoys water rates on freight from defined territories as well as from the Atlantic seaboard and finds itself in a most advantageous position for the distribution of merchandise of all classes. Freight to the value of $25,000,000 is annually exported and imported on barges and other craft navigating Buffalo Bayou and plying between Houston and Galveston.

Manufactures.— Houston has 507 industrial plants in operation in the city, an increase of 141 per cent during the last decade. There are $8,000,000 invested in manufacturing enterprises with products to the value of $12,000,000 in 1903. Manufacturing has been stimulated to a great extent by the discoveries of petroleum and the development of the rice industry. The rapid growth of the sawmill and lumber products business — the most important in the State — 85 per cent of which is carried on within easy reach of Houston and in a section for which the city is the natural market has also contributed to the same end. Chief among Houston's manufacturing concerns are the cotton oil refineries of which there are five. These represent an investment of $1,250,000 and annually, on an average, convert 144,000 tons of cotton seed into products bringing $3,168,000 in the markets of the world, in the aggregate. Here are also the general car shops of the Atlantic division of the Southern Pacific and allied lines and the division car shops of three other railroad companies. The city has 35 miles of electric street car lines.

Population.— (1890) 27,557; (1900) 44,663; (1903) 65,000.

R. M. Johnston,
Houston Daily Post.

Hovey, Alvin Peterson, American soldier: b. Mount Vernon, Ind., 1821; d. Indianapolis 23 Nov. 1891. He studied law, and was admitted to the bar in 1843; was appointed successively circuit judge, judge of the supreme court, and United States district attorney. He was a major of Indiana volunteers, and afterward major-general during the Civil War. In 1866 he was made minister to Peru; was elected to Congress in 1886, and became governor of Indiana in 1888.

Hovey, Charles Mason, American horticulturist: b. Cambridge, Mass., 26 Oct. 1810; d. Boston 2 Sept. 1887. He was the first to introduce a pistillate strawberry, known as "The Hovey," a variety that marks the beginning of strawberry culture in the United States. He edited the 'Magazine of Horticulture' for many years, and was the author of 'Fruits of America' (1880).

Hovey, Richard, American poet: b. Normal, Ill., 4 May 1864; d. New York 24 March 1900. He was graduated at Dartmouth 1885, went abroad and led a bohemian life, being in turn actor, journalist, dramatist and poet, and finally lecturer on English literature in Barnard College, New York. His verse was of the idealistic school and marked with the influence of Ibsen and Maeterlinck. His works are: 'Launcelot and Guenevere' (1880); 'Taliesin: a Masque' (1900); 'Seaward: an Elegy' (1893); 'The Laurel' (1897); 'Along the Trail' (1898); and with Bliss Carman (q.v.) wrote 'Songs from Vagabondia' (1893); and 'More Songs from Vagabondia' (1896).

Howard, Blanche Willis. See Teuffel, Blanche Willis Howard, Baroness Von.

Howard, Bronson, American playwright: b. Detroit, Mich., 7 Oct. 1842. Preparing for college he turned to journalism instead of entering Yale, and from 1867 to 1872, was employed on the New York *Tribune, Evening Mail* and other newspapers. In 1864 he had written a dramatic piece called 'Fantine,' which was produced in Detroit, but his first important play was 'Saratoga,' produced by Augustin Daly in 1870, and the first of a long list of successes, which gave him a foremost position among American playwrights. Among his plays are: 'The Banker's Daughter' (1878); 'Young Mrs. Winthrop' (1882); 'The Henrietta' and 'Met by Chance' (1887); 'Shenandoah' (1889); 'Aristocracy' (1892); 'Peter Stuyvesant' (with Brander Matthews); etc.

Howard, Catharine, fifth queen of Henry VIII.: b. about 1520; d. 13 Feb. 1542. She was a granddaughter of the second duke of Norfolk.

Howard, Guy, American soldier: b. Augusta, Maine, 16 Dec. 1855; d. 21 Oct. 1899. He was a son of Gen. O. O. Howard (q.v.) and entered the United States army in 1876 as a second lieutenant. He was promoted chief quarter-master, with rank of lieutenant-colonel 11 Aug. 1898; was assigned to duty in Manila under Gen. Lawton; and had charge of the transportation for Lawton's advance movement. While on the gunboat Oceania he was attacked by Filipino insurgents, and fatally shot.

Howard, John, English philanthropist: b. probably Hackney 2 Sept. 1726; d. Kherson, Russia, 20 Jan. 1790. In 1773 he was appointed high sheriff of Bedfordshire, when the subject of prison discipline came under his notice; and finding many abuses in the management of jails, he resolved to devote his time to investigation of the means of correcting them. With this view he visited most of the English county jails and houses of correction, and in March 1774 laid the result of his inquiries before the House of Commons. In 1781 and 1782 he made a tour through the northern parts of Europe, including Denmark, Sweden, Russia, and Poland. In 1783 he visited Spain and Portugal, and again surveyed the prisons of his own country. At the same time was published a complete edition of his 'State of the Prisons,' with all the supplementary matter. A new subject now engaged his attention, namely, the management of lazarettos, and the means of preventing the communication of the plague and other contagious diseases. In 1789 he published 'Account of the Principal Lazarettos in Europe.' In 1789 he proceeded through

Germany to St. Petersburg and Moscow. Prisons and hospitals were everywhere thrown open for his inspection as a friendly monitor and public benefactor. Consult: Howard's 'Correspondence' (1855); and 'Lives' by Dixon (1849); Stoughton (1853).

Howard, John Eager, American soldier: b. Baltimore County, Md., 4 June 1752; d. 12 Oct. 1827. He joined the army under Washington at Middlebrook, N. J., in the spring of 1777, and subsequently fought at Germantown and Monmouth. In 1780 he joined the army under Greene, and in the battle of Cowpens (1781) he displayed great gallantry, and the bayonet charge of the Maryland troops under his command, whereby the enemy were thrown into confusion, turned the fortune of the day and secured victory to the Americans. For his services in this battle he received from Congress a silver medal. In 1788 was elected governor of Maryland, a position which he filled for three years. From 1796 to 1803 he represented Maryland in the United States Senate. He was a candidate for the Vice-Presidency in 1816.

Howard, Oliver Otis, American general: b. Leeds, Maine, 8 Nov. 1830. He was graduated from Bowdoin in 1850, and from West Point in 1854. He was then assigned to the ordnance department of the regular army, served in Florida against the Seminoles, and was professor of mathematics at West Point 1857–61. At the outbreak of the Civil War he entered the volunteer service as colonel of the 3d Maine regiment. He was in over 20 important battles; in 1861 he was at the battle of Bull Run, and was afterward made brigadier-general of volunteers; in 1862 he served in the Virginia campaign, and at the battle of Fair Oaks lost his right arm. He commanded at the battles of Antietam and Fredricksburg; in 1863 was appointed to the command of the 11th Army Corps and led them at the battles of Chancellorsville and Gettysburg. When the 11th Corps was united with the 12th he was given command of the 4th Corps of the Army of the Cumberland, but was shortly afterward transferred to the command of the Army of the Tennessee, which was the right wing of Sherman's army on his "march to the sea." In 1864 he was appointed brigadier-general in the regular army, and in 1865 made commissioner of the Freedmen's Bureau, which he conducted very efficiently; 1869–73 he was president of Howard University (q.v.), established in Washington for the higher education of the negro. In 1874 he was placed in command of the Department of the Columbia, and there conducted four campaigns against the Indians, including that against the Nez Percés tribe. In 1881 he was superintendent at West Point, and subsequently in command of the Departments of the Platte and of California; in 1886 he was promoted to the rank of major-general, and assigned to the Department of the East, where he remained until his retirement in 1894. In 1895 he founded the Lincoln Memorial University, Cumberland Gap, Tenn. He has written: 'Donald's School Days' (1879); 'Chief Joseph, or the Nez Percés in Peace and War' (1881); 'General Zachary Taylor' (1892); 'Isabella of Castile' (1894); 'Fighting for Humanity'; and 'Henry in the War.' Consult: L. C. Holloway, 'Life of General Howard.'

Howard Memorial Library, established in 1889 in New Orleans, La., is one of the few complete reference libraries in the United States. It was founded by Annie Turner Howard, whose gift of site, building, and endowment amounted to nearly $350,000. The plans for the building were made by Henry Hobson Richardson (q.v.). In addition to the 45,000 volumes of the best books on all subjects, it contains special and nearly complete collections on the history, description, and literature of Louisiana and the Gulf States. It has a dictionary card catalogue.

In the spacious and handsome reading-room are many fine bronzes, including the Houdon bust of Washington, from a life mask. This bronze is on a pedestal which brings the face to the correct height. This library is of great service to students of all the educational institutions of the Southern States, and also to writers on special subjects pertaining to the Gulf States.

WILLIAM BEER,
Librarian of Howard Memorial Library.

Howard University, a coeducational institution, situated in Washington, D. C., established by the United States government in 1867. It was named for Gen. O. O. Howard, who was head of the Freedmen's Bureau, and had much to do with the foundation of the school. The university is supported by Congressional appropriation, except the medical department, which is maintained by tuition fees, and this is the only department in which tuition is charged. The departments are preparatory, collegiate, medical, agricultural, dentistry, pharmacy, pedagogy, theology, law, music, and agriculture. An industrial department provides instruction in trades for students in the preparatory and English courses. The pupils in this department have practice under competent workmen, in printing, carpentry, bookbinding, and tinsmithing. The university is well known for its work in the higher education of the negroes of the United States. The school has property valued at about $1,000,000, and a general endowment fund of $175,000.

Howe, Andrew Jackson, American eclectic surgeon and author: b. Paxton, Mass., 14 April 1825; d. Cincinnati, Ohio, 16 Jan. 1892. Educated in Leicester Academy and Harvard College, from which he graduated in 1853. Attended medical lectures at Jefferson Medical College, Philadelphia; College of Physicians and Surgeons, and the New York Medical College of New York city, and Worcester Medical Institute, graduating from the latter in 1855. He was demonstrator of anatomy in his alma mater in 1855–6; professor of surgery in Cincinnati College of Eclectic Medicine and Surgery, 1856–9; demonstrator and professor of anatomy in Eclectic Medical Institute of Cincinnati, 1859–61; professor in same of surgery, from 1861 to 1892. He wrote 'A Treatise on Fractures and Dislocations' (1873); 'Manual of Eye Surgery' (1874); 'Art and Science of Surgery' (1876); 'Operative Gynæcology' (1890); 'Conversations on Animal Life,' and 'Miscellaneous Papers,' published in 1894, after his death. He was president of the National Eclectic Medical Association in 1882–3.

ELIAS HOWE,

INVENTOR OF THE SEWING MACHINE.

JULIA WARD HOWE.

Howe, Edgar Watson, American novelist and editor: b. Treaty, Ind., 3 May 1854. At the age of 12 he entered a printing office, and when only 19 was publisher of the 'Golden Globe' in Golden, Col. Ten years later he became proprietor and editor of the Atchison (Kan.) *Daily Globe.* He has written: 'The Story of a Country Town' (1883), which attracted considerable attention; 'The Mystery of the Locks' (1883); 'A Moonlight Boy' (1887); 'A Man Story' (1888); 'An Ante-Mortem Statement'; 'The Confession of John Whitlock'; etc.

Howe, Elias, American inventor: b. Spencer, Mass., 9 July 1819; d. Brooklyn, N. Y., 3 Oct. 1867. He lived with his father, who was both farmer and miller, till 1836, working upon the farm and in the mill and attending the district school during the winters. He then learned the trade of a machinist, and experimented in inventing a sewing-machine. The model was completed and the patent issued 10 Sept. 1846. A patent was also taken out in England, but from this the inventor realized nothing. After constructing four machines in the United States, he visited England in 1847, remaining two years. He returned to Boston entirely destitute, and resumed his trade for the support of his family. From this period until 1854 he was involved in expensive lawsuits, when the principal infringers of his patents acknowledged his rights, and arranged to manufacture sewing-machines under licenses from him. He served as a private in the 17th Connecticut volunteers during the Civil War. He was the recipient of the Legion of Honor cross and many medals.

Howe, Henry, American publisher and historian: b. New Haven, Conn., 16 Oct. 1816; d. 1893. He entered the publishing business in 1839, and while conducting this business began historical researches in New Jersey and New York. He later moved to Ohio, where he continued his historical studies, and published subscription books. His writings include: 'Memoir of Eminent Mechanics' (1839); 'The Great West' (1851); 'Travels and Adventures of Celebrated Travelers' (1853); 'Adventures and Achievement of Americans' (1858); 'Our Whole Country' (1861); 'Over the World' (1883); and 'Historical Collections' of three States, New Jersey, New York and Ohio.

Howe, John, English Puritan divine: b. Loughborough, Leicestershire, 17 May 1630; d. London 2 April 1705. He was frequently styled "The Platonic Puritan" and is ranked as the greatest of the Puritan clergymen. He was an eloquent preacher and a powerful controversialist, but fortunately free from animosity or theological bitterness. Among his works, 'The Living Temple'; 'The Blessedness of the Righteous'; and 'The Oracles of God' have been especially valued. See 'Life' by Rogers (1836).

Howe, John Ireland, American inventor: b. Ridgefield, Conn., 20 July 1793; d. Birmingham, Conn., 10 Sept. 1876; was at first a physician, but in 1830 invented a pin-making machine. This he perfected later and it was the means of revolutionizing the pin manufacture.

Howe, Joseph, Canadian statesman: b. near Halifax, Nova Scotia, 13 Dec. 1804; d. Halifax, 1 June 1873. He learned printing and in 1827 became connected with the 'Acadian' and in 1828 editor and proprietor of the 'Nova Scotian.' He contributed several remarkable articles to this paper, called "Western and Eastern Rambles" and the papers "Legislative Reviews." He was elected to the Provincial Parliament in 1836. He favored free common schools, one Provincial University and complete, responsible government and it was mainly due to his efforts that Nova Scotia finally received such government. He was a member of the Executive Council in 1840 and Speaker of the Assembly the same year. In 1846 he succeeded in making himself a popular power in the province and turned it over to the Liberals. Howe opposed confederation in the old assembly and even went to London to lay a petition before the throne against "the assertion of Federal supremacy," but lost his fight. He served as secretary of state for the provinces in the Dominion cabinet and superintendent of Indian affairs (1869–72), and later was a member of the Dominion Parliament for Hants County, Nova Scotia. He returned to Halifax in 1873 as lieutenant-governor, but only lived a few months to enjoy it.

Howe, Julia Ward, American author and philanthropist: b. New York 27 May 1819. In 1843 she married S. G. Howe (q.v.) of Boston, and immediately became active in philanthropical work. With her husband she edited the 'Boston Commonwealth,' one of the ablest anti-slavery papers, to which she contributed leading articles, essays, poems, letters, and witty comments. At the same time she also wrote for the New York *Tribune,* and the 'Anti-Slavery Standard.' Since the Civil War she has been active as writer and speaker in other social and philanthropic work, particularly in the agitation for woman's suffrage and for prison reform. She was one of the founders of the New England Women's Club, the first organization of its kind in America; she was delegate to the World's Prison Reform Congress in London (1872); and was president of the women's branch of the New Orleans Exposition (1884). She has also preached occasionally in Unitarian pulpits. She has been president of the Boston Authors Club from its foundation in 1899. Her writings include: 'Passion Flowers' (1854); 'Words for the Hour' (1856); 'Later Lyrics' (1866); 'A Trip to Cuba,' and 'From the Oak to the Olive,' two books of travel: 'The World's Own' (1855), a drama; 'Sex and Education' (1874); 'Modern Society' (1881); 'Is Polite Society Polite?'; 'Life of Margaret Fuller' (1883); and 'Reminiscences' (1899). Her best known poem is 'The Battle Hymn of the Republic' (in 'Later Lyrics'), written early in the Civil War, while she was visiting the camps around Washington. It was set to the music of 'John Brown's Body,' and immediately became popular with the soldiers.

Howe, Mark Antony de Wolfe, American editor and author: b. Bristol, R. I., 28 Aug. 1864. He was educated at Lehigh and Harvard universities, and on leaving college entered the editorial office of 'The Youth's Companion,' Boston. In 1893–5 he was assistant editor of the 'Atlantic Monthly,' and since 1899 has been corresponding editor of 'The Youth's Companion.' He has published: 'Shadows,' verse (1897); 'American Bookmen' (1898); 'The Memory of

Lincoln' (edited) (1899); 'Phillips Brooks' (1899); 'Boston: the Place and the People' (1903). He has edited the series of 'Beacon Biographies' from 1899.

Howe, Richard, Earl, English admiral: b. London 8 March 1726; d. 5 Aug. 1799. At 14 he shipped as a midshipman on board the Severn in which he sailed with Anson for the Pacific, and passed through the usual gradations of the service under that admiral till 1745, when he obtained the command of the Baltimore sloop-of-war, in which he took part in the siege of Fort William, during the last Jacobite rebellion. In 1756 he served in the Channel fleet; in 1758 reduced Cherbourg. In 1759 he defeated a French squadron under De Conflans, and for two years (1763–5) occupied a seat in the board of admiralty. In 1776, as commander-in-chief in North America, he acted against the American forces and against D'Estaing, who commanded a superior French fleet. He sailed to the relief of Gibraltar in 1782 and was successful in spite of the combined fleets of France and Spain. On the outbreak of war with France in 1793 he took the command of the British fleet, and on 1 June 1794, obtained a decisive victory off Ushant for which he received the thanks of Parliament. He was made admiral of the fleet in 1796. His name is one of the highest among those of the famous naval commanders of Great Britain. He greatly improved the service by the introduction of a new system of tactics.

Howe, Robert, American colonial soldier: b. Brunswick County, N. C., 1732; d. there 12 Nov. 1785. He was a member of the assembly and of two provincial congresses, and took a prominent part in the preparation for the Revolution. At the outbreak of the war he was given a command and aided in driving the British out of Virginia; was promoted to the rank of major-general and commanded in the South. In 1778 he was repulsed by the British and compelled to evacuate Savannah; though then deprived of command he was afterward acquitted by the court-martial by which he was tried for the loss of the city. In 1780 he commanded at Charleston; in 1783 assisted Washington in putting down a mutiny; and in 1785 was elected to the North Carolina legislature, but died before he took his seat.

Howe, Samuel Gridley, American philanthropist: b. Boston 10 Nov. 1801; d. there 9 Jan. 1876. He was graduated from Brown University in 1821, and from the Harvard Medical School in 1824. Immediately after completing his studies he joined the Greek army at the time of the war for independence; he created an excellent surgical corps for the Greeks, and was also distinguished as a brave commander in battle; at the declaration of peace he established an industrial colony of Greeks on the Isthmus of Corinth. He returned to the United States for a short time, but becoming interested in the work for the blind, went back to Europe in order to study the schools for the blind there; while in Paris he was chairman of the committee for the relief of the Poles in the time of the Polish uprising; he went to Prussia to distribute the funds collected, and was imprisoned by the Prussian authorities. In 1832 he returned to Boston, and founded the Perkins Institution for the Blind, of which he became superintendent; in this position he did much to improve the methods in the instruction of the blind, and to found similar schools throughout the United States. His greatest success was in the training of Laura Bridgman. (See Defectives, Education of.) He also assisted in organizing the Massachusetts School for Idiots. He was active in the anti-slavery cause; was candidate of the Conscience Whig Party for Congress, but was defeated; and was editor of the anti-slavery paper, the 'Boston Commonwealth,' assisted by his wife, Julia Ward Howe (q.v.). At the close of the Civil War he joined in the work of the Freedmen's Bureau (q.v.). He was always active in many lines of philanthropic work, organized the Massachusetts State Board of Charities and went to Greece in 1867 with supplies for the Cretans. In 1870 he was one of the commission appointed by President Grant to visit Santo Domingo and report upon the advisability of its annexation. He wrote: 'Historical Sketches of the Greek Revolution' (1828); 'Reader for the Blind' (1839). Consult: The 'Life,' by Julia Ward Howe, and Sanborn, 'S. G. Howe, the Philanthropist.'

Howe, Timothy Otis, American statesman: b. Livermore, Maine, 24 Feb. 1816; d. Kenosha, Wis., 25 March 1883. He received a common school education, studied law, was admitted to the bar, and sat in the Maine legislature in 1845. He removed in that year to Wisconsin, entered politics, and in 1861 was chosen United States Senator, serving till 1879. He declined a Supreme Court judgeship on the death of Salmon Chase, but in 1881 became postmaster-general in President Arthur's cabinet.

Howe, Sir William, English general: b. 10 Aug. 1729; d. 12 July 1814. He was a brother of Admiral Richard Howe (q.v.) and was the successor of Gen. Gage in command of the British forces in America. He had previously served under Wolfe at the battle of Quebec. He commanded at the battle of Bunker Hill (1775), in which he lost one third of his men present in the action, and in August 1776, gained the battle of Long Island and took New York city. He won the battle of Brandywine in September 1777, in consequence of which Philadelphia was occupied by his army. At his own request he was recalled in 1778, and was succeeded by Sir Henry Clinton, who repulsed Washington at Germantown in the October following. He succeeded to the Irish peerage as viscount in 1799.

How'ell, Clark, American journalist and politician: b. Barnwell County, S. C., 21 Sept. 1863. He was graduated from the University of Georgia in 1883, entered journalism, became managing editor in 1889 of the Atlanta *Constitution,* and editor-in-chief 1897. He was a member of the Georgia House of Representatives 1890–1 and has been a member of the Georgia Senate from 1900.

Howell, Mich., village, county-seat of Livingston County: on the Pere M. and the Ann A. R.R.'s; about 50 miles northwest of Detroit. It is located in a rich agricultural section of the State. The chief manufactures are flour and condensed milk; and it has a large sash, door,

and blind factory, and a planing-mill. Pop. (1900) 2,518.

Howells, William Dean, American novelist, poet and critic: b. Martin's Ferry, Ohio, 1 March 1837. During his boyhood his father owned and published daily papers in Hamilton and Dayton, Ohio, successively, and he learned the printer's trade and gradually the whole business of conducting a newspaper. In 1851 he was working in Columbus as a compositor; in 1856 he became Columbus correspondent of the Cincinnati *Gazette;* and in 1859 was appointed news editor of the *Ohio State Journal.* At this time he published a small volume of poems, and also some poems in the 'Atlantic Monthly.' In 1860, when Lincoln was nominated, Howells wrote his life, and in 1861 was appointed United States consul at Venice, where he remained till 1865. The impressions of his stay there were embodied in 'Venetian Life' (1866), and 'Italian Journeys' (1867). On his return to the United States, he was for a time connected with the staff of the New York *Tribune,* the *Times,* and the 'Nation.' In 1866 he became assistant editor of the 'Atlantic Monthly,' and editor-in-chief in 1872. In 1886–92 he conducted the critical department of 'Harper's Monthly' called "The Editor's Study"; and in 1892 was editor of the 'Cosmopolitan' for a short time.

His first novel 'Their Wedding Journey,' was published in 1871; his other novels include: 'A Chance Acquaintance' (1874); 'A Foregone Conclusion' (1875); 'The Lady of the Aroostook' (1879); 'The Undiscovered Country' (1880); 'Doctor Breen's Practice' (1882); 'A Modern Instance' (1882); 'A Woman's Reason' (1883); 'The Rise of Silas Lapham' (1885); 'Indian Summer' (1886); 'The Minister's Charge' (1886); 'April Hopes' (1887); 'A Hazard of New Fortunes' (1889); 'The Shadow of a Dream' (1890); 'An Imperative Duty' (1892); 'The Quality of Mercy' (1892); 'The World of Chance' (1893); 'The Coast of Bohemia' (1893); 'A Traveller from Altruria' (1894); 'The Landlord at Lion's Head' (1897); 'An Open-Eyed Conspiracy' (1898); 'The Story of a Play' (1898); 'Ragged Lady' (1899); and 'Their Silver Wedding Journey' (1900). Howells has also written farces and comedies, including: 'The Sleeping-Car' (1883); 'The Mouse-Trap' (1897); 'The Unexpected Guests' (1898); and 'The Albany Depot' (1898); etc., and the following volumes of verse: 'Poems of Two Friends' (1860), with J. J. Piatt; 'No Love Lost, a Romance of Travel' (1868); and 'Poems' (1873). His other works include: 'Tuscan Cities' (1885); 'Modern Italian Poets'; 'Essays and Versions' (1887); 'Criticism and Fiction' (1891); and 'Impressions and Experiences' (1896); 'Literary Friends and Acquaintances' (1899); and 'Heroines of Fiction.'

In American literature, Howells is the leader of the realistic school; his novels portray the average, everyday American life; he has a true and sympathetic understanding of the "common people" of the United States, and types of the American "self-made" man appear and reappear in his stories. His latest phase, that in which he seeks to understand and set forth the American social problems, — the meaning of socialism, the relations of labor and capital, and, more broadly, the mystery of poverty and of human suffering, — is typified in a book like 'A Hazard of New Fortunes'; and 'A Traveller from Altruria,' a picture of an ideal commonwealth. The absence of idealism in Howells' writings has been cited as their gravest defect; but it is by no means true that he entirely excludes the ideal sides of life from treatment. His work is marked by carefulness and thoughtfulness in style and construction, and by fidelity to a high ideal of artistic excellence. His essays, like his novels, have always that indefinable charm which is the enduring note in good literature, and to the charm are added the broad outlook and the deep ethical interest which are typical of the man.

How'ison, George Holmes, American philosopher: b. Montgomery County, Md., 29 Nov. 1834. He was graduated from Marietta College, Ohio, in 1852, and from Lane Theological seminary, Cincinnati, in 1855, and after holding various college professorships elsewhere became Mills professor of philosophy at the University of California in 1884. He has published 'Treatise on Analytic Geometry' (1869); 'Limits of Evolution' (1901); 'The Conception of God' (1897).

Howison, Henry Lycurgus, American rear-admiral: b. Washington 10 Oct. 1837. He was graduated from the United States Naval Academy in 1858. He served in various important engagements, becoming lieutenant-commander in 1865. In 1899 he became rear-admiral and was retired 19 Oct. 1899. In 1901 he was appointed a member of the Schley court of inquiry, but on being challenged, was relieved from service.

How'itt, William and **Mary,** English authors commonly named together. William (b. Heanor, Derbyshire, 18 Dec. 1792; d. Rome, Italy, 3 March 1879), showed such a bias to literature that he published verses at 13. In 1821 he married Mary Botham (b. Uttoxeter 12 March 1799; d. Rome 30 Jan. 1888), who wrote both by herself and with her husband. Their first joint work, a volume of poems, 'The Forest Minstrel,' was published in 1823, and in 1827 appeared 'The Desolation of Eyam.' The best lines in these are by Mrs. Howitt. Howitt himself having no great poetic gift. In 1871, however, he published a volume entitled 'The Mad War Planet and Other Poems.' William and Mary Howitt settled first in Staffordshire. In 1823 they removed to Nottingham, where they resided till 1837, and in 1840 visited Germany, where they resided for three years. Results of their residence in Germany appeared in 'Student Life of Germany' (1841) and 'Rural and Domestic Life of Germany' (1842), which, being translated into German, acquired flattering popularity. While at Heidelberg Mrs. Howitt set herself to translate the tales of Frederika Bremer into English, and later the works of Hans Andersen. Their most ambitious work is 'The Literature and Romance of the North' (1852). Howitt's best works are those in which English history and life are treated of in connection with English scenery. The earliest of these was the 'Book of the Seasons' (1831), which acquired great popularity; 'Rural Life in England' (1838) was also well received. Still others are: 'Visits to Remarkable Places' (1840); 'Homes and Haunts of

the British Poets' (1847); 'The Year Book of the Country' (1850); and 'The Northern Heights of London' (1869). With his wife he published volumes on 'The Ruined Abbeys and Castles of Great Britain.' Mrs. Howitt's books for young people were long popular in the United States, and 'The Pet Lamb' and a few other unpretending verses of hers have become familiar to thousands of juvenile readers.

How'itzer. See ORDNANCE.

How'land, Alfred Cornelius, American painter: b. Walpole, N. H., 12 Feb. 1838. As an art student he began in the studios of Schultz and Eppindale at Boston, and subsequently went to Düsseldorf and Paris, in which latter place he painted under Lambinet. He excels in genre and landscape, and among his favorite works are 'Ford's Glen' (1878); 'Rendezvous of the Veterans' (1884); and 'The Coming Circus' (1886).

Howland, Gardiner Greene, American journalist: b. New York 1834; d. there 9 May 1903. He was the intimate and confidential friend of the elder James Gordon Bennett, held the same relations with the younger Bennett, was general manager of the *Herald* for more than twenty-five years, and one of the corporators named under the incorporation of the newspaper.

Howley, Michael Francis, Canadian ecclesiastic: b. 1843. In 1857 he entered Saint Bonaventure's College, and in 1863 went to Rome, entering Propaganda as an ecclesiastical student. In 1868 he was ordained a priest and went to Scotland as secretary to Most Rev. Dr. Ayre, but in 1870 returned to Rome with Dr. Ayre and was present on the occasion of the declaration of the dogma of papal infallibility by Pope Pius IX. He accompanied the Rt. Rev. Thomas J. Power to Newfoundland in 1870, and for over 30 years he has labored with great success for the spiritual and ecclesiastical advancement of Newfoundland. In 1886 he was made prefect apostolic of Saint Georges, in 1892 was consecrated bishop in Saint John's and made vicar apostolic of Saint Georges, in 1902 appointed bishop of Saint John's in succession to Rt. Rev. Dr. Power, and in 1904 he was named by the Holy See archbishop of the ecclesiastical province of Newfoundland. Archbishop Howley is not only distinguished as a theological scholar and thinker, a devoted missionary and able preacher, but also as a poet, lecturer, and antiquary. He has also contributed much to the historical study of Newfoundland (q.v.).

Howorth, how'ërth, **Henry Hoyle, SIR,** English author and politician: b. Lisbon, Portugal, 1 July 1842. He was a Conservative member of Parliament for South Salford 1886–1900. In recognition of his works on Eastern history and other subjects, he was created K. C. I. E. in 1892. Besides very many scientific memoirs, he has published: 'History of the Mongols'; 'The Mammoth and the Flood'; 'The Glacial Nightmare and the Flood'; 'Genghis Khan and his Ancestors,' etc.

Howrah, how'rā, India, an independent municipality, suburban to Calcutta (q.v.). Pop. (1901) 157,847.

Hox'ie, Vinnie Ream, American sculptor: b. Madison, Wis., 23 Sept. 1846. She was educated at Christian College, Columbia, Mo., and going to Washington, D. C., studied art, executed busts of Grant, Sherman and others, and a statue of Lincoln for the National Capitol. She then went abroad, where she designed medallions of Doré, Liszt, Buchanan, Read, and others. Among other works of hers are ideal statues of 'Sappho'; 'The Spirit of the Carnival'; and the statue of Admiral Farragut in Farragut Square, Washington. She was married to Major R. L. Hoxie of United States Engineers.

Hoyle, Edmond, English writer on games: b. 1672; d. London 29 Aug. 1769. It is said that he was educated for the law, but nothing definite is known of his career except that he was for many years in London a writer on and instructor in games. His 'Short Treatise on Whist' (1742), a compendium of the laws of the game and many rules for play, sold largely and has been the basis of all subsequent manuals of the kind. So generally has his authority been accepted in the game that "according to Hoyle" has attained a proverbial significance.

Hoyt, Charles Hale, American dramatist: b. Concord, N. H., 1860; d. 1900. He was at one time musical and dramatic critic of the *Post* of Boston. His works comprise 'A Midnight Bell' (1887), and a long series of farce-comedies, such as 'A Trip to Chinatown' (1890).

Hoyt, Henry Martyn, American lawyer and soldier: b. Kingston, Pa., 8 June 1830; d. Wilkesbarre, Pa., 1 Dec. 1892. He was graduated from Williams College in 1849, read law, was admitted to the bar in 1853, practised at Wilkesbarre, at the opening of the Civil War was appointed lieutenant-colonel of 52d Pennsylvania regiment, served during the Peninsular campaign in 1862, and was captured in a night attack on Fort Johnson during the siege of Morris Island. Mustered out with the grade of brevet brigadier-general; he practised his profession until 1867, and was then appointed additional law-judge of the Luzerne County courts. In 1879–83 he was Republican governor of Pennsylvania. His administration was particularly characterized by a wise financial policy, by means of which the State debt was reduced to $10,000,000 and refunded at three per cent. He published: 'The Controversy between Connecticut and Pennsylvania' (1879); 'Protection *v.* Free-Trade' (1885).

Hoyt, John Wesley, American educator: b. near Worthington, Ohio, 13 Oct. 1831. He was graduated at Ohio Wesleyan University in 1849, and later studied both medicine and law. He has had charge of educational exhibits in several international expositions, and was made chairman of the National Committee to Promote the Establishment of the University of the United States. He was the first president of the University of Wyoming, and was governor of Wyoming 1878–83. He has published 'Progress of University Education'; 'Studies in Civil Service'; etc.

Hoyt, Wayland, American Baptist clergyman and author: b. Cleveland, Ohio. He was educated at Brown University and studied for the Baptist ministry at the Rochester Theological Seminary. Since then he has held pas-

torates at Pittsfield, Mass., Cincinnati, Brooklyn, Minneapolis, and Philadelphia. Among his published works are 'Hints and Helps for the Christian Life' (1880); 'Gleams from Paul's Prison' (1882); 'Light on Life's Highway' (1890).

Huaina Capac, wä-ē'nä kä'päk, or **Huayna Capac,** 11th Peruvian Inca: b. Cuzco, Peru, about 1450; d. Tumibamba, Ecuador, November 1525. He began his reign in 1480, or, according to some authorities, 1491, and made many conquests, even subduing the country as far south as Chile. By his will he divided the empire between two of his sons, Huascar and Atahualpa (q.v.).

Huamanga, wä-män'gä, or **Guamanga,** gwä-män'gä, Peru, the former name of Ayacucho (q.v.).

Huanaco, hwä-nä'kō, the most numerous and widely distributed of the two species of the genus *Lama* (*L. guanaca*), of the camel family, resident in South America. It is somewhat like a large goat in form, but with a much longer neck, surmounted by a small camel-like head, and long, pointed, alert ears, but no weapons. A large male is about four feet tall at the withers, a female somewhat less. The coat is of long, woolly, reddish-gray hair, the improvement of which by selective breeding in domestication has formed the alpaca breed (see ALPACA). It roams the open plains of Argentina and Patagonia, serving as the principal game animal of that region, and furnishing the scattered natives with food, clothing and shelter. In the autumn it gathers into large herds, and behaves in general like the antelopes of the similar arid plains of other parts of the world. Consult Darwin, Hudson, Spears, and other writers on Patagonia. See LLAMA.

Huascar, wäs'kär, Peruvian Inca, son of Huaina Capac (q.v.). See ATAHUALPA.

Hub'bard, hŭb'ard, Elbert, American author: b. Bloomington, Ill., 1859. After working on a farm as a boy, he went to Chicago, where he entered a printing-office, and later was employed in a soap factory In the latter business he rose to be manager, and finally partner of the firm; selling out his interest, he devoted himself for a time to study and travel, and finally settled at East Aurora, where he established the Roycroft shop, devoted mainly to the artistic printing and binding of books. The organization of the shop is co-operative, and its ideal is for every worker to do that which best expresses his own individuality. Hubbard is editor of the 'Philistine,' a "magazine of protest," and has written 'Little Journeys' (biographical sketches); 'No Enemy but Himself'; 'Message to Garcia' (1898); and 'Time and Chance' (1901); 'The Man of Sorrows' (1904).

Hubbard, Joseph Stillman, American astronomer: b. New Haven, Conn., 7 Sept. 1823; d. there 16 Aug. 1863. He was graduated from Yale in 1843, and accompanied Frémont as observer of latitude and longitude in the latter's transcontinental journey. From 1845 until his death he was stationed at the Washington observatory as professor of mathematics in the United States navy. He made important investigations regarding comets, was at two different periods editor of the 'Astronomical Journal,' and was a member of the National Academy of Sciences.

Hubbard, Leonidas, Jr., American journalist, writer, and explorer: b. Waldron, Mich., 12 July 1872; d. Labrador 18 Oct. 1903. He was a teacher in the public school at Angola, Mich., while still in his teens, and early in life showed keen interest in writing, exploration, and athletics. Graduated from University of Michigan in 1897. He at once began reportorial work in Ann Arbor, and later on the Detroit *Evening News.* He came to New York in the summer of 1899 and attached himself to the staff of the *Daily News,* but early in 1902 became associate editor of 'Outing,' in which work he was much interested. He conceived the idea of exploring into the wilds of Labrador, and 20 June 1903, accompanied by Dillon Wallace, a New York lawyer, and George Elson, a Cree Indian guide, he left New York, going by steamer from Saint Johns, N. B., to Rigolette, a Hudson Bay trading post on the Grand River. From this point Hubbard and his friends traveled by canoe and on foot, mapping correctly for the first time Grand Lake; then penetrating the interior in a westerly and northwesterly direction, mapping the course of the Beaver River from its source to the point where it flows into the southeast bay of Lake Michikamau; and locating and mapping several large lakes in the interior. The party penetrated some 250 miles farther into new territory than any previous expedition. Notes on the geology and general observation of the topography of the country were also made. Among Mr. Hubbard's most noted writings are: 'The Moonshiner at Home' (1902); 'Barataria' (1902); 'Children of the Bush' (1903); and 'Where Romance Lingers' (1904).

Hubbard, Oliver Payson, American physician: b. Pomfret, Conn., 31 March 1809; d. New York 9 March 1900. Graduated from Yale in 1828, he was assistant to Silliman the elder in the laboratory there in 1831–6, and aided Goodyear in experiments connected with the vulcanizing of India rubber. In 1836–66 he was professor of chemistry, pharmacy, mineralogy, and geology at Dartmouth, in 1866–71 lectured on those subjects, and from 1871 until his retirement as professor emeritus in 1883 was professor of chemistry and pharmacy. He was a founder of the American Association of Geologists and Naturalists in 1841, and its secretary in 1844. He contributed to the 'American Journal of Science,' and published 'A History of Dartmouth Medical College' (1880), etc.

Hubbard, Richard William, American artist: b. Middletown, Conn., 15 Oct. 1810. He was educated at Yale, set up his studio in New York, was elected to the National Academy in 1858, and painted numerous American landscapes, such as: 'Mansfield Mountain at Sunset'; 'Showery Day, Lake George'; 'Glimpse of the Adirondacks'; and 'Lake Cazenovia.'

Hubbard, William, American colonial clergyman and historian: b. Tendring, Essex, England, 1621; d. Ipswich, Mass., 14 Sept. 1704. He was graduated at Harvard College in 1642, and was ordained about 1656 as minister at Ipswich, where he continued during the remainder of his life. He is the author of 'A Narrative of the

Troubles with the Indians from 1607 to 1677, with a Discourse' (1677), the map accompanying which is supposed to be the first executed in America. He left in manuscript a 'General History of New England,' for which the colony paid him £50, and which has been consulted with advantage by Mather, Hutchinson, Holmes, and other American historians and annalists. It was published by the Massachusetts Historical Society in 1815.

Hubbardton, hŭb'ard-tŏn, Vt., town in Rutland County; 13 miles from Castleton, its nearest railroad station. It is in an agricultural region, and has but little manufacturing; its raw products are sent direct to the markets. On 7 July 1777 a battle took place here between the Americans under Colonels Francis and Warner, and a British and Hessian force under Generals Riedesel and Fraser, in which the British were successful. The Americans, the rearguard of Gen. St. Clair's army, who were retreating from Ticonderoga, lost in killed, wounded, and prisoners 324 men; and the British loss was 183 men. A monument in memory of the American soldiers who were killed in this battle, occupies a prominent position. Pop. 500.

Huber, Johannes, German philosopher and theologian: b. Munich 18 Aug. 1830; d. there 19 March 1879. He was educated at the University of Munich, became professor of philosophy there in 1859, and was one of the leaders of the Old Catholic party and an active opponent of the Ultramontanes. He vigorously attacked the definition of the dogma of papal infallibility. Among his works were 'Studies' (1867); 'Das Papsttum und der Staat' (1870); 'Der Jesuitenarden' (1873); and 'Zur Philosophie der Astronomie' (1877).

Huber, Victor Aimé, German publicist and author: b. Stuttgart 10 March 1800; d. Wernigerode 19 July 1869. Educated at Würzburg and Göttingen, he became professor of the history of literature and of modern history at Rostock in 1833, of the languages of western Europe at Marburg in 1836, and at Berlin in 1843. He retired in 1850. Huber was one of the most profound of German scholars in the Spanish language and literature. Among his publications were: 'Die Geschichte des Cid' (1829); 'Crónica del Cid' (1844); and 'Skizzen aus Spanien' (1828–35).

Hubert de Burgh, English statesman: d. London 12 May 1243. He held office under Richard Cœur de Lion, and was made castellan of Falaise by King John, with whom he sided in the struggle with the barons, though advising the granting of Magna Charta. In the year of Runnymede (1215) he was made justiciar (chief-justice) of England. On 24 Aug. 1217 he won a distinguished victory over a French fleet bringing reinforcements to the army besieging Dover Castle; the treaty of Lambeth was concluded (11 September) and the enemy evacuated England. After 1219 he was co-regent with Langton, archbishop of Canterbury, for Henry III. He vigorously opposed the foreigners who were endeavoring to obtain control of the government, and sought to end the exactions of the clergy. In 1232 he was dismissed, owing largely to his failures in the conflict with the Welsh, and thereafter he had no part in the government.

Hubert, hū'bert (Fr. ü-bār), Saint, apostle of Ardennes, the patron of huntsmen; d. about 727. Legend says that he was a keen hunter, and that being once engaged in the chase on Good Friday, in the forest of Ardennes, a stag appeared to him having a shining crucifix between its antlers, and he heard a warning voice. He was converted, entered the church, and became bishop of Maestricht and Liège. He worked many miracles, and his body, at first deposited in the church of St. Peter at Liège, was in 817 conveyed to the Benedictine convent of Andain, in the Ardennes, which received the name St. Hubert's of Ardennes. The day of the saint is 3 November, and was formerly celebrated at many courts by a solemn chase.

Hübner, Joseph Alexander, Count, Austrian diplomat: b. Vienna 26 Nov. 1811; d. there 30 July 1892. He was educated at Vienna, and, having entered the service of the government, became in 1849 minister at Paris, and in 1865–8 was ambassador at Rome. In 1879 he became a member of the clerical-conservative wing in the upper house of the Reichsrat. Among his published works are: 'Sixte-Quint-D'après des Correspondances Diplomatiques Inédites' (1870, new ed. 1883); 'Ein Spaziergang um die Welt' (1872, 7th ed. 1891); and 'Durch das Britische Reich' (1886, 2d ed. 1891).

Hübner, Julius, German painter: b. Oels, Silesia, 27 Jan. 1806; d. Loschwitz, Saxony, 7 Nov. 1882. He studied at the Berlin Academy and was also a pupil of Schadow at Berlin and Düsseldorf. In 1841 he became professor in the Dresden Academy of Arts. He was an historical painter of the Düsseldorf School, his works including 'Disputation between Luther and Eck' and 'Charles V. at Saint Just.'

Hübnerite, a native tungstate of manganese, $MnWO_4$. It always contains some ferrous iron and as its percentage increases it graduates toward wolframite (q.v.), which it often much resembles, but from which it is distinguished by its brown color and pleochroism. It occurs in monoclinic crystals, often bladed and deeply striated. It has easy pinacoidal cleavage, is brittle, has a hardness of 5. to 5.5 and is very heavy, its specific gravity being 7.2 to 7.5. Its lustre is sub-metallic or resinous, and its streak yellowish-brown or greenish-gray. It occurs in considerable quantities near Silverton, Colo., in New Mexico, Nevada, Arizona and elsewhere.

Huck'leberry, a name of uncertain derivation applied to a variety of shrubs, especially to species of the genus *Gaylussacia*, and to those belonging to the order *Vacciniaceæ* and the genus *Vaccinium*. The principal species are found mainly in the northern hemisphere, throughout North America, Northern Britain and Europe. The fruit of *Vaccinium* is a many-sided berry with four or five cells. *V. Pennsylvanicum* is a small plant about six inches in height. Other species range widely in size, *V. corymbosum* sometimes attaining a height of nearly 10 feet. In many places in the United States huckleberries are a valuable product, the fields in which they grow are preserved, and the berries are secured either for household use or for profitable marketing.

Huckleberry Finn, The Adventures of, a story by Samuel L. Clemens ("Mark Twain"), published in 1884. It is a sequel to, and fol-

lows the fortunes of the leading characters of the same author's 'Tom Sawyer.' In this book the author not only preserves to us a valuable record of a rapidly disappearing social order, but throws light upon some questions of moment to the student of history.

Hudibras, hū'dĭ-brăs, Sir, the hero of a famous satirical poem by Samuel Butler (q.v.), published 1663–78.

Hud'son, H. Lindsay, "Harry Lindsay," English novelist; b. Belfast, Ireland, 10 April 1858. He has been a journalist and schoolmaster by turns, and among his writings published under the signature "Harry Lindsay" are 'Methodist Idylls' (1897); 'An Up-to-Date Parson' (1899); 'Judah Pyecroft: Puritan' (1902).

Hudson, Henry, English navigator. The time and place of his birth appear to be lost. We only know that he had earned, perhaps by the time he was 40, sufficient reputation as a bold and skilful navigator to be placed in command of the ship Half Moon of Amsterdam. Early in 1609 he made a contract with a party of Dutch merchants to act as captain of their private exploring expedition, and in the written agreement between them he was described as "Henry Hudson, Englishman." This settles the honor of his birth country, though nothing more. At that time the one great commercial demand was for a shorter and better, all-sea trade route to the Far East. It was known that there was land to the west of Europe and it was believed that a passage could be found through these lands directly westward to the East. It is clear that Hudson believed that the western route was the most promising and, no doubt, he suggested it to his employers, but they evidently had more faith in a sea passage north and then east, round Europe and Asia to China. Thus it happened this English sea captain sailed from the Dutch port of Amsterdam in the small ship "Half Moon bound for China by the way of the North Cape. The ship's company of Dutch and English was fortunate in having as mate one Robert Juet (perhaps also of England), and the mate could read and write. Juet kept the ship's log, and in this log book on the first page are these words: "On Saturday, the five and twentieth of March, 1609, after the old account (style), we set sayl from Amsterdam, and by the seven and twentieth day we were down at the Texel; and by twelve of the clock we were off the land, it being east of us two leages off."

Once "off the land" the ship was free to go where the captain pleased and it certainly did not please the crew to face the arctic cold of the attempted voyage round Europe. Solid pack ice and the open mutiny of the crew decided Hudson to turn back and he steered south — and west. It is evident that he felt free to carry out his own plans and reach China by another route. His owners' plans had failed and, while his plan might fail, his success would justify his action. Hudson's decision was almost as bold as that of Columbus for, while he had, no doubt, some knowledge of the lands to the west, he evidently had no conception of the shape or size of North America nor of the width of the Pacific.

The Half Moon was a slow sailer, and four months passed before she made the land along the eastern coast of what is now the United States. The log book described the land as "low white sandy ground" — exactly describing all the shore line south of Sandy Hook. The book might also have described parts of Long Island or Cape Cod and it is clear it did not describe the coast of Maine, and it is more than probable the first land mentioned in the book was south of Sandy Hook for, on reaching the land and finding no passage westward, Hudson steered "northeast by north" until, about two weeks later, he came to a great bay. The log book, which does not give the name of the month, and which must have been September, says, "And from that lake or bay the land lyeth north by east, and we had a great streame out of the bay." The Half Moon had found the "great stream" described by Verrazano, and with the flood tide sailed into New York Bay and headed for the Narrows and, as the log book says, "came to three great rivers." And it continues: "So wee stood along to the northmost, thinking to have gone into it." The Half Moon was off Manhattan. It was true Verrazano, in 1524, had entered New York Bay and left a record of a high hill and a great bay out of which flowed a large river, but Verrazano had not the courage to pass the Narrows, except in a small boat. Other explorers may have looked into the bay. The Half Moon was the first ship to pass up the "great stream" and to Hudson belonged the entire honor of discovering and exploring the river that now bears his name.

The pages of Juet's journal tell nothing of Hudson's own hopes, fears and anticipations. Yet, it is fair to think that Juet's enthusiasm over the beauty and value of the great valley was shared by his captain and that the ship's log was, in a sense, a reflex of Hudson's own views. There is no hint of Hudson's belief that he could reach China by this route, yet it is reasonable to suppose he entered New York Bay in the hope that the "great stream" would lead through the land to the Pacific. The great size of the bay and river and the fact that the tide flowed far into the land and that for the first few days' sail the water remained salt, no doubt encouraged him to keep on through this most promising opening in the land. Favored by "fairer weather" and a favorable breeze he steered northerly over the wide salt arm of the sea until the apparent strait became a river and the sea water became fresh. At the Highlands all hope of a road to China must have faded away. Still, he would sail on, push through the mountains and see what manner of country lay beyond.

The items of the log book plainly show that Hudson, after passing the Highlands, began to recognize the transcendent importance of his discovery. He had found a new land of surpassing beauty and fertility and everywhere clothed in splendid forests. Hudson clearly recognized the commercial value of his discovery, for the log book enumerates all the potential wealth of the river and valley in fish, game, lumber, fruits, vegetables, grains and peltry. It even mentions the fact that Hudson, while the ship was at anchor somewhere near the present city of Hudson, sent the ship's carpenter ashore to fashion a new forearm out of one of the primeval trees — the first bit of lumbering done by white men in the valley.

Hudson seems to have decided, after reaching the upper river and sailing to a point opposite the Catskills, that the best way to mollify his owners on his return would be to report as fully as possible the potential wealth he had discovered and he sent a boat up the river to explore the country. The boat party appears to have been absent several days, for they rowed up stream about nine leagues or perhaps beyond Albany where, as the log book says, the boat found "it bee at an end for shipping to goe in — with but seven foot water and unconstant soundings." Meanwhile Hudson evidently traded with the Indians for peltry, no doubt regarding the furs as something that would demonstrate to his merchant owners the value of his discovery.

Three weeks after the Half Moon entered "the great streame" she again passed Sandy Hook and steered away for Amsterdam. There is no record of the return voyage nor is there any record of Hudson's report to the merchants of Amsterdam, yet it is evident that his story and perhaps the exhibit of peltry created a tremendous sensation in the commercial cities of Holland. Hudson appears not to have cared much about this side of the affair. He seems to have considered his voyage a failure. He had tried to reach China and failed, and wished to sail again, but the merchants seem to have been wholly occupied in fitting out new ships under more commercial captains and would not listen to him. At last, after some delay, he did secure a second ship and set forth once more to find a sea path through America. He appears to have thought there might be a passage round by the north of America and he steered for Baffin's Bay. Once more he found a great passage leading westward into the land, once more a salt water strait seemed to promise success, but it only led to an inland sea. His miserable crew, ignorant, frightened at the arctic cold and gathering ice, rose in mutiny, and putting their great captain in an open boat, with his son, a boy of seven, and some invalid sailors, set them adrift in the vast waters of Hudson Bay and left them there to perish.

CHARLES BARNARD,
Lecturer, Board of Education, New York.

Hudson, Henry Norman, American Shakespearian scholar and Episcopal clergyman: b. Cornwall, Vt., 28 Jan. 1814; d. Cambridge, Mass., 16 Jan. 1886. He served as chaplain in the Civil War, was professor of Shakespeare at Boston University, and for a time editor of the 'Churchman.' He published 'Lectures on Shakespeare' (1848); 'Campaign with General Butler' (1865); 'Shakespeare, his Life, Art, and Characters' (4th ed. 1883); 'Essays on Education' (1883). He edited the Harvard and the University edition of Shakespeare.

Hudson, Thomson Jay, American philosophical writer: b. Windham, Ohio, 22 Feb. 1834; d. Detroit, Mich., 1903. After studying law and being admitted to the bar in Cleveland, Ohio, in 1857, he practised three years, was engaged in journalism in Michigan 1860–76, and was principal examiner in the United States Patent Office 1886–93. He has published 'The Law of Psychic Phenomena' (1893); 'A Scientific Demonstration of the Future Life' (1895); 'The Divine Pedigree of Man' (1899); 'Law of Mental Medicine' (1903).

Hudson, William Henry, American educator and critic: b. London, England, 2 May 1863. He was five years private secretary to Herbert Spencer (q.v.) and coming to America was assistant librarian of Cornell University, 1890–2. He has been an assistant professor of English literature at Leland Stanford University from 1892, and has published 'The Church and the Stage' (1886); 'An Introduction to the Philosophy of Herbert Spencer' (1893); 'Studies in Interpretation' (1896); 'Idle Hours in a Library' (1897); 'The Study of English Literature' (1898); 'The Sphinx and Other Poems' (1900); 'The Meaning and Value of Poetry' (1901); 'Life of Sir Walter Scott' (1901); 'Famous Missions of California' (1901); etc.

Hudson or Hudson's Bay, Canada, an extensive bay or inland sea extending between lat. 51° and 64° N., and lon. 77° and 95° W. Its greatest length north to south is about 800 miles, greatest breadth, 600 miles. It is connected with the Atlantic Ocean by Hudson Strait and with the Arctic Ocean by Fox and other channels. Hudson Bay is navigable in summer from the middle of June to the end of October, being obstructed by drift-ice during the rest of the year. There are many islands, reefs and sand banks. The white whale is found in its waters, and there is a considerable summer fishery. Numerous rivers flow into the bay, the chief being the Nelson and Churchill on the east. The shores on the east are high and bold; those on the west are low and level, and much of the land is favorable for stock and dairy farming, while valuable deposits of iron ore, galena, and plumbago exist. With the exception of a few fur trading stations on the west and south coast, there are, however, no settlements.

Hudson, Mass., town, Middlesex County, on the Assabet River, and on the Boston & M. and the Fitchburg R.R.'s; about 17 miles northwest of Worcester. The town is situated in an agricultural region, but it is particularly noted for its manufactures, especially of articles made from leather and rubber. The chief manufactures from rubber are gossamer clothing, webbing, goring, and boots and shoes. Some of the other manufactures are paper and wooden boxes, leather, and leather boots and shoes. The town owns and operates the electric-light plant and the waterworks. Pop. (1900) 5,454.

Hudson, N. Y., city, port of entry, county-seat of Columbia County; on the Hudson River, and on the New York Central & H. R. and the Boston & A. R.R.'s; about 30 miles south of Albany. Area of the city, one square mile. Hudson was settled in 1783 and was called Claverack Landing; but the year following the name was changed to Hudson. In 1785 it was chartered as a city, and in 1790 it was made a port of entry. From the first it was a trading station of importance and a whaling port. After the Revolution a large foreign trade was established, but the commerce of the city was injured by the destruction of its shipping in the War of 1812. The surrounding country is devoted largely to agriculture, and the city has a number of manufacturing establishments. The chief manufactures are foundry products machinery, knit goods, car-wheels, and creamery products. It has a large sash and blind factory

and several small manufacturing establishments. Some of its prominent buildings are the State Volunteer Firemen's Home, the State House of Refuge for Women, an orphanage, hospital, and the city public buildings. The city owns and operates the waterworks. The government is vested in a mayor, who holds office two years, and a city council. Pop. (1900) 9,528.

Hudson, Ohio, town in Summit County, on the Pennsylvania railroad, 20 miles south of Cleveland. This was one of the earliest settled towns on the Ohio Western Reserve, and prior to the Civil War was an abolition stronghold. The Western Reserve College, before its removal to Cleveland, was located here. Pop. (1900) 2,240.

Hudson, Wis., city, county-seat of Saint Croix County; on Lake Saint Croix, an expansion of the Saint Croix River, and on the Chicago, St. P., M. & O. railroad; about 65 miles northwest of Eau Claire and 20 miles east of St. Paul, Minn. The chief manufactures are flour, finished lumber, furniture, railroad cars, machinery, beer, and brooms. The city has a large cold-storage plant and ample facilities for shipping butter, poultry, vegetables, and fruits. It has a large sanatorium. The electric-light plant and the waterworks are owned and operated by the city. Pop. 3,259.

Hudson, the largest river in the State of New York, has its head waters in Hamilton and Essex counties, and flows southwest into Saratoga County, then nearly directly east to Sandy Hill in Washington County, and from this point south through New York Bay into the Atlantic Ocean. It is fed by several of the Adirondack lakes, a number of small streams, and by Schroon River, Batten Kill, Hoosick, Wappingers and Croton from the east, and the Sacondaga, Mohawk, Wallkill, and Esopus Creek from the west. The Mohawk (q.v.), which flows into the Hudson at Cohoes, is the largest tributary; the Rondout enters the Wallkill near the Hudson. The head waters of the Hudson and the sources of several of the streams which flow into the Saint Lawrence are very near each other in the Adirondack Mountains. At Troy, three miles below the mouth of the Mohawk, the Hudson becomes a navigable tidal stream. There is a tidal rise of about one foot at Albany. Above Troy there are a number of rapids and long falls in the river; but below, the navigation is uninterrupted. At one time there were a few obstacles, the largest of which was "Overslaugh", or Castleton Bar, at Castleton. This hindrance to navigation has been almost wholly removed by the Federal and State government. The Catskill Mountains, on the west side, begin about 25 miles below Albany. Lower down are the Highlands, averaging about 1,100 feet in height, which extend along the shore for a distance of about 20 miles. The Highlands of the Hudson are noted for their beautiful scenery. On the west bank are the famous Palisades (q.v.) about 13 miles long, their southern extremity being near Fort Lee, in New Jersey, and the northern extremity near Piermont, New York. This remarkable arrangement of rock rises from near the water's edge, almost perpendicularly, from 350 to 550 feet. Below Verplanck and Stony Point is an expansion in the river the upper part of which is called Haverstraw Bay and the lower part Tappan Sea. Many small islands in the river serve as foundations for lighthouses, or for the erection of dredging platforms. Iona, on which there is now a naval station, Constitution, and Beeren Islands have all figured in history. Below Albany the Hudson is more an estuary or fiord than a river, which accounts for the great depth of water. The area drained by the Hudson above where the Mohawk enters is about 30,000 square miles. The river is noted for its beautiful scenery from the source to the mouth. Along the lower part of its course there are many fine residences, as a large part of the country on both banks from New York to Albany is now a residential section. The Hudson is fittingly called the "Rhine of America."

Hudson River was discovered by Verrazano, an Italian navigator, in 1524; but it was explored by Henry Hudson in 1609. The Indian name for the river was Shatemuc, and the first colonists called it North River, as the Delaware was then called South River. The part of the river west of New York city is still called North River; but it was given the name Hudson in honor of its first explorer. The history of the country since its discovery by Europeans occupies an important place in the history of the United States. The almost unbroken waterway from the Atlantic Ocean through what is now the State of New York, to the Saint Lawrence River, made this an important route for missionaries, traders, and for the armies in the various wars. From the mouth of Lake Champlain to Lake George, across the portage from Lake George to the Hudson, and the Hudson to the ocean, was all disputed territory, and the scene of many a contest of the Revolutionary War. What a change in the map of America if Burgoyne had succeeded in his plan of 1777 "to cut the nation in two" by getting possession of Lake Champlain and the Hudson. See CHAMPLAIN, LAKE; CROWN POINT; HAVERSTRAW; TICONDEROGA.

The river is navigable for ships of the first class for about 117 miles from the ocean. Its whole length is about 300 miles. Before the introduction of railroads, the navigable waters of the Hudson, connecting New York with a large section of country, gave the city great opportunities for development. A canal built along the Mohawk Valley, in 1817–25, connected the Hudson with Lake Erie, and the Champlain Canal completed the water route from the Hudson to Lake Champlain. Later the Erie and the Delaware and Hudson railroads brought the coal of Pennsylvania to the Hudson River for transportation by water to markets in the interior. The New York Central and Hudson River Railroad is on the east side of the river and the West Shore on the west side. In 1807 Robert Fulton made on this river the first successful experiment with steam navigation. The Hudson is now a thoroughfare for an immense amount of freight, and elegant passenger steamers ply daily between New York and Albany. The government has erected and maintains 21 lighthouses and lighted beacons. Navigation ceases in winter because the river is frozen nearly its whole length. The ice crop harvested each winter on that part of the river between Albany and the Highlands is shipped, when navigation opens, chiefly to New York city. Shad fishing is one of the important Hudson River industries. Many of the cities on the Hudson were at first

only trading posts or ferry towns, but nearly all have kept pace in development with the rest of the State. The principal cities and towns on the river from north to south are Glens Falls, Sandy Hill, Fort Edward, Mechanicsville, Cohoes, Troy, Albany, Hudson, Catskill, Kingston, Poughkeepsie, Newburg, West Point, Peekskill, Haverstraw, Ossining, Nyack, Tarrytown, and Yonkers. At the mouth of the river are New York and Jersey City, with the suburbs, which are important shipping ports, Hoboken and Weehawken. The only bridge crossing the river between New York and Albany is the one which extends from Poughkeepsie on the east side to Highland on the west. There are 14 public ferries. The use of the water-power of the Hudson as an aid in developing electrical power for the mechanical arts is most important. From Mechanicsville the power of the Hudson is transmitted to the general electric shops of Schenectady. At Spiers Falls, at the foot of Mount McGregor, about forty miles above Albany, there has been constructed a dam,—a stone wall over 1,800 feet long, 100 feet high, and containing 1,800,000 cubic feet of masonry. The Hudson is raised 50 feet above its former river bed, then its waters fall 80 feet, and the power developed is (1904, 30,000 horse-power), transmitted for electrical machinery, to Schenectady, Albany, Troy, Amsterdam, and other places. The electric motors at Spiers Falls get some of their power from the older plant at Mechanicsville, about 20 miles distant. At other points storage plants will be constructed, more power will be developed, the current will be sent at a high pressure to sub-stations at Saratoga, Schenectady, Ballston, Glens Falls, Fort Edward, and Watervliet. This will mean running cars, lighting streets, driving machinery by power developed hundreds of miles away. This power development of the waters of the Hudson combined with development of like power of the waters of the Saint Lawrence at Massena (q.v.), keeps the two rivers, as in early years of our country, of vast importance to the State. Many industries are affected by this great new power, not the least of which are the coal-mining of Pennsylvania and the preservation of the Adirondack forests.

The Hudson occupies an important place in the historical, commercial, and mechanical development of the nation, also in its literary and artistic progress. Washington Irving who lived at "Sunny Side" and was laid to rest in Tarrytown, introduced to the world many of the places along the Hudson. Cro' Nest is associated with Joseph Rodman Drake and his poem, 'Culprit Fay'; West Park and the country around have been practice observation ground for the naturalists John Burroughs and Ernest Ingersoll; Cornwall-on-the-Hudson was the home of N. P. Willis and E. P. Roe. Artists who have received inspiration from Hudson's scenery and history have become sufficiently numerous and their works of importance enough to be called "The Hudson School of Painters." Consult Ingersoll, 'Guide to the Hudson River'; Cooper, article in 'Magazine of American History,' Vol. IV.

Hudson's Bay Company, incorporated 1670, the great fur-trading and later landholding and administrative company of Northwest Canada. It originated in the dissatisfaction of two French Protestant employees of the French fur-trading monopoly at Quebec, Groseilliers and Radisson, with its unwillingness to extend the trade to Hudson Bay, after vainly trying to induce Boston merchants and the French court to take up their scheme for so doing. They gained the ear of a company of London merchants and Prince Rupert, cousin of Charles II., brought a load of furs from the bay, and on 2 May 1670 Rupert and 17 associates received from Charles a charter for "The Governor and Company of Merchants-Adventurers trading into Hudson's Bay." It had the monopoly of the right to trade in the bay or on its coasts, and could expel any one entering the territory without its license; could build forts, send out ships of war and privateers, and declare war and make peace with any non-Christian people. Its capital was £10,500, divided into 34 shares with an extra one for Prince Rupert, and in 1676 it imported some £19,000 worth of furs, sending in return £650 worth of goods to the Indians. The profit was high on the petty capital paid in, but the gross amount was not large for a century. In 1748 the trade was carried on with four ships, and employed about 120 men in all, including the garrisons at its forts. The furs and other imports amounted to over £30,000, the exported goods to £5,000, and the costs of business over £17,000. The average profit was 40 per cent. on capital, but the sum was trivial. Moreover, the company had great losses and tribulations from the French rivalry and assaults, especially in the national wars. The French laid claim to the territory on the strength of a mythical expedition of Jean Bourdon in 1656, and in 1682 and 1686 captured several of the company's forts, the two countries' trading posts shared in the long war ended by the Peace of Ryswick in 1697, captured each others' forts, and the peace yielded Port Nelson to the French, to the great damage of the company. The War of the Spanish succession inflicted frightful hardships on both sides: the company claimed a loss of over £100,000, hundreds of trappers and employees starved to death, and the Indians turned cannibals. The Treaty of Utrecht in 1713 finally resigned all French claim to the Hudson's Bay territory, and thence till the cession of French Canada in 1763, the monopoly gave the company an easy life and good profits, though still on a small scale. But when that cession opened up access to Hudson's Bay from both land and sea, the possibilities of trade were incalculably enlarged. Despite the clandestine rivalry of Montreal traders who intercepted their boats, the gross volume increased manifold, and it was not crippled by the ravages of France in 1782, as part of the war begun in 1778, when they captured and partly ruined the massive stone Fort Prince of Wales at the mouth of Churchill River, and altogether destroyed property valued by the company at half a million pounds. But a much worse rivalry was at hand, organized and powerful: the Northwest Company (q.v.), started on a co-operative plan in 1784 by an association of Scotch merchants in Montreal. The Declaration of Rights having guaranteed free and open trade to all British subjects, this company invaded its rival's territory, and the trade competition for many years merged into actual war. In 1821 they had done each other so much harm that they consolidated, and Parliament in view of the evils of competi-

2. Looking northward from the battery.

tion empowered the crown to issue licenses for the "Indian territories," which was exercised in favor of the new company. Meantime exploration had been steadily enlarging the territory: Samuel Hearne for the old company had reached the Arctic in 1771, Alexander Mackenzie for the new one reached the Pacific in 1793. With the United States, its rivalry for the far Northwest was strenuous and persistent: it planted posts in the Oregon district, repelled settlers, and there was much danger of war till the boundary settlement of 1846 quieted the dispute. In 1849 it secured a grant of Vancouver Island. This was the time of its palmiest growth. In 1846 it had 513 employees and 35 officers, in 1856 it had over 3,000 employees and officers together, with 152 posts. Its trade monopoly expired by limitation in 1859, but there was also a great desire to settle the Northwest Territories, with which the fur-trade and administrative rights of the company were incompatible. The company, liable to be dispossessed by force if it refused to come to terms, agreed in 1869 to transfer its territorial rights to the Dominion of Canada for £300,000 and one twentieth of the lands set out for settlement by the government for the next 50 years. It retained its posts and its rights of trade. The transfer to Canada, and the survey of lands for settlement, was immediately followed by the Riel rebellion (q.v.). The company, despite its lapse of administrative powers, remains the most potent influence for law and order in the unsettled parts, through its relations with the Indians. Consult Bryce, 'History of the Hudson's Bay Company' (1900); Willson, 'The Great Company' (1900); Cawston and Keane, 'Early Chartered Companies' (1896). For the Northwest Company, see also Irving, 'Astoria.'

Hué, hoo-ā', the capital of Anam, on the river Truong, 10 miles from its mouth in the Gulf of Tonking. It is surrounded by Vaubanian fortified walls, five miles in circumference, the internal city being built on a rectangular plan with wide and straight streets. The chief building is the royal palace. Hué is the seat of a French political resident, and at Thuan-an, the port at the river mouth, there is a French garrison. Pop. estimated at 100,000, of whom less than 400 are Europeans.

Huelen, wā'lān, Chilean hero: b. about 1540; d. 1603. He attained the command of the native forces in Araucania, and was for a time successful in repelling the invading Spaniards, whose methods of warfare he copied. He defeated the enemy at Valdivia, near Concepción, and near Bio-Bio, but died at the siege of Osorno.

Hueppe, hüp'pē, **Ferdinand**, German hygienist: b. Heddesdorf, Rhine Province, 24 Aug. 1852. He studied at the Friedrich Wilhelms Institut of Berlin, and in 1890 became professor of hygiene in Prague University (German). His researches in bacteriology and disinfection have been extensive and important. He wrote 'Die Methoden der Bakterienforschung' (1885); 'Naturwissenschaftliche Einführung in die Bakteriologie' (1896); 'Handbuch der Hygiene' (1899), and other works.

Huger, ū-jē', **Benjamin**, American soldier: b. Santee, S. C., 22 Nov. 1805; d. Charleston, S. C., 7 Dec. 1877. He was graduated from West Point, served in the United States army during the Civil War and was brevetted colonel. He resigned his commission in 1861 and entering the Confederate army became a major-general.

Huger, Francis Kinloch, American soldier: b. Charleston, S. C., September 1773; d. there 14 Feb. 1855. He was a nephew of I. Huger (q.v.). His father, Major Benjamin Huger, was killed before the lines of Charleston in 1780. He joined with Dr. Eric Bollman of Philadelphia in a visit to Europe for the purpose of attempting the rescue of Lafayette from the dungeons of Olmütz, his father having been the first to receive that general on his arrival in Georgetown in 1777. The enterprise resulted in their imprisonment for eight months. Huger became a captain in the United States army in 1798, was a colonel in the war of 1812, and served in both branches of the legislature of his State.

Huger, Isaac, American general: b. Limerick Plantation, S. C., 19 March 1742; d. 17 Oct. 1797. He was one of five patriot brothers active in the revolution. Promoted to the rank of brigadier-general in 1777, he took a conspicuous part in the engagements connected with the siege of Savannah in 1778, commanded a force of cavalry at the siege of Charleston in 1780 which was surprised and dispersed by Tarleton, and commanded the Virginia brigade which formed the right wing in the battles of Guilford Court-House, and Hobkirk's Hill.

Huggins, hŭg'ĭnz, **Sir William**, English astronomer: b. London 7 Feb. 1824. In 1852 he was elected a member of the Microscopical Society, and in 1856 erected an observatory at Tulse Hill, in northeastern Surrey. When in 1859 Professor Kirchoff of the University of Heidelberg announced the true interpretation of the dark Fraunhofer lines in the solar spectrum, Huggins at once saw the possibility of using his practical knowledge of chemistry and physics in the service of astronomy. With W. A. Miller, professor of chemistry at King's College, London, he at once set about the task of constructing a star-spectroscope. The two then began the observation of stellar spectra. A full statement of their results was read before the Royal Society in 1864, the essence of the statement being, in Huggins' own words, that the chemistry of the solar system prevails, essentially at least, wherever a star twinkles. In August 1864 Huggins directed his star-spectroscope toward a planetary nebula in Draco, and found its spectrum to be a monochromatic one, thus proving that the nebula consists of a luminous gas. In 1868 he was able to announce to the Royal Society the results of his first measurements of the motion of stars in the line of sight. He began his observations of comet spectra with that of Winnecke's comet in 1868, and in 1868–9 made spectroscopic observations of the solar prominences. About 1876 he resumed his abandoned efforts to photograph stellar spectra, using the gelatine dry plate process then recently introduced, and this time he was completely successful. His photographs of the invisible ultra-violet portions of stellar spectra have proved extremely valuable, providing, for example, the only reliable data for determining the relative ages of the stars. He was elected a fellow of the Royal Society in 1865, and

awarded by that body a Royal Medal (1866), the Rumford Medal (1880), and the Copley Medal. He was president of the Royal Astronomical Society in 1876–8. With Lady Huggins he published in 1900 a valuable 'Atlas of Representative Stellar Spectra.'

Hugh Capet, king of France, founder of the Capetian dynasty. See CAPET.

Hughes, hūz, **Ball,** American sculptor: b. London 19 Jan. 1806; d. Boston, Mass., 5 March 1868. He early exhibited a decided taste for modeling, and at 12 years of age made out of wax candle ends a bas-relief copy of a picture representing the wisdom of Solomon, which was afterward cast in silver. He was then placed in the studio of Edward Hodges Bailey, where he remained seven years. At this time he successfully competed for the prize awarded by the Royal Academy, winning the large silver medal for the best copy in bas-relief of the Apollo Belvidere; also the silver medal from the Society of Arts and Sciences for a copy of the Barberini faun, the large silver medal for the best original model from life, and a gold medal for an original composition, "Pandora brought by Mercury to Epimetheus." He emigrated in 1829 to New York, where his first work of importance was a marble statue of Hamilton, for the Merchants Exchange, which was destroyed by fire in 1835. He subsequently removed to Boston, Mass. Among later works of his are the bronze statue of Bowditch at Mount Auburn Cemetery, a bust of Washington Irving, and a statuette of General Warren at Bunker Hill.

Hughes, David Edward, English-American inventor: b. London 16 May 1831; d. there 22 Jan. 1900. When very young came with his parents to the United States. He was educated at Bardstown College, Kentucky, where he was appointed professor of music (1850), and later of natural philosophy. In 1855 he patented his first important invention, that of the well-known printing telegraph which bears his name. It was at once adopted in America, and by 1876 by practically every European country. In 1878 Hughes announced to the Royal Society his invention of the microphone, an ingenious instrument which not only transmits sound, but so magnifies faint sounds as to make them distinctly audible. The microphone is now in universal use in the telephone. Another important invention, that of the induction balance, was completed by Hughes in 1879, and in 1880 he was elected a fellow of the Royal Society.

Hughes, Hugh Price, English Wesleyan clergyman: b. Caermarthen 1847; d. London 17 Nov. 1902. He was educated at University College, London, and the Wesleyan Theological College, Richmond, was appointed to Dover in 1869, and was afterward at Brighton; Stoke-Newington; Mostyn Road, London; Oxford; Brixton Hill; and the West London Mission. From 1885 he was editor of the Methodist 'Times,' and he was also at one time president of the national council of Evangelical free churches. He was prominently identified with reform work in London, and with the Anti-gambling League. Among his writings are: 'Social Christianity' (1889); 'The Atheist Shoemaker' (1889); 'The Philanthropy of God' (1890); and 'Ethical Christianity' (1892).

Hughes, John, American Roman Catholic prelate: b. Annaloghan, County Tyrone, Ireland, 24 June 1797; d. New York 3 Jan. 1864. His parents were poor but made sacrifices to give him the opportunity of acquiring an elementary education; and by his own efforts he continued his studies so that when he came with his parents to America in 1817 he was prepared for college. However, for lack of means he had to defer entering any school, and instead began work as a day laborer, in which occupation he continued for three years, but at 23 entered the Roman Catholic theological seminary, Mount Saint Mary's, Emmittsburg, Md. As a student, his remarkable power of reasoning and his ability in argument attracted attention. He was ordained priest in 1826, and for a time was stationed at Bedford, Pa., from which he was transferred to Philadelphia. Here he had charge of Saint Joseph's parish and later Saint Mary's parish. In 1838 he was consecrated titular bishop of Basileopolis and appointed coadjutor to the bishop of New York. In 1842, after the death of Bishop Du Bois, he was made bishop of New York. In 1850 the diocese of New York became an archdiocese, and on 19 July 1850 he was raised to the dignity of first archbishop of New York, which office he held until his death.

He was an active and effective worker. As a speaker or writer he was ever ready to defend the Church which he represented. When a student at Mount Saint Mary's, he wrote the pamphlet, 'An Answer to Nine Objections against the Catholic Church.' When in Philadelphia, he wrote the replies to Dr. Breckenridge, a Presbyterian clergyman. The articles on both sides are issued in book form, 'Hughes and Breckenridge.' Before asking his priests to collect money to build schools and churches, he had set the example. He collected money for the rebuilding of Mount Saint Mary's after it had been burned. He established St. John's orphan asylum in Philadelphia, and a number of charitable institutions in New York. He settled decisively the "trustee system" question which was agitating New York when he came there; and he defended the Church property against the attacks of the "Knownothing" element. The "school question" was to him all important. One of his first undertakings was to establish a theological seminary at La Fargeville in Jefferson County, N. Y.; the distance from New York caused the abandonment of this plan, and Saint John's College (q.v.) was founded at Fordham instead. In 1858 he laid the corner stone of Saint Patrick's Cathedral. In 1861, during the Civil War, he was sent by the United States government to Europe, to present the cause of the Union, and counteract any adverse sentiment which might exist against the attitude of the North. His diplomatic mission was most successful in France, Italy, and Ireland. Consult: Brann, 'John Hughes,' in the 'Makers of America Series'; Hassard, 'Life of John Hughes'; Sadlier, 'Archbishop Hughes,' in the 'Ave Maria' magazine.

Hughes, Rupert, American author: b. Lancaster, Mo., 31 Jan. 1872. He was graduated from Adelbert College of the Western Reserve University in 1892, was for a time assistant editor of the New York 'Criterion,' and in 1900 entered editorial work in London. In addition

to many contributions to periodicals, he wrote: 'The Lakerim Athletic Club' (1898); 'One Dozen from Lakerim' (1899); 'American Composers' (1900); 'Guide-Book to the World of Music' (1901); and, in verse, 'Gyges' Ring' (1901).

Hughes, Thomas, English author: b. Uffington, Berkshire, 20 Oct. 1823; d. Brighton, Sussex, 22 March 1896. He was educated at Rugby and Oxford, later studied law at Lincoln's Inn, was called to the bar of the Inner Temple in 1848, and began practice at once. In 1869 he was appointed queen's counsel, in 1882 county court judge. Throughout his long public career, as advanced Liberal in Parliament (1865–74), as founder with Canon Kingsley and Frederick Maurice of the Christian Socialists, as creator of Rugby, a socialistic community in the mountains of Tennessee (1880), he tried most earnestly to exercise a helpful influence upon English working-people. He early essayed journalism, writing many sketches for the London 'Spectator,'— chiefly accounts of traveling experiences. These sketches served as his apprenticeship in writing, and afterward were collected in book form with the title 'Vacation Rambles' (1895). But authorship was a secondary interest until 'Tom Brown's School Days,' first appearing in 1856, made him famous. This work is largely a presentation of the influence of Dr. Thomas Arnold (q.v.) in the great public school. 'The Scouring of the White Horse' (1858), a spirited account of a vacation trip, had a respectful although less cordial reception. The great success of the first story led him to continue his hero's career with 'Tom Brown at Oxford' (1861), first published serially in 'Macmillan's Magazine.' This second volume, which is much the longer, although often fine and spirited, sometimes waxes prolix, and has never been so popular as the earlier story. At the time of the American Civil War, Hughes was a decided abolitionist, and thus established a friendship with James Russell Lowell. Among other works of his are 'Alfred the Great' (1869); 'Life of Livingston'; 'Memoir of a Brother'; 'Life of Bishop Fraser' (1887).

Hughes, Thomas Patrick, American Protestant Episcopal clergyman: b. Ludlow, England, 26 March 1838. He was educated at Islington College, was ordained priest in 1864, in 1865–85 was missionary and chaplain at Peshawar, Afghanistan, in 1885–9 rector at Lebanon Springs, N. Y., and from 1889 of the Church of the Holy Sepulchre, New York. In 1875–85 he was also examiner in Oriental languages to the British government. Among his writings are: 'Notes on Mohammedanism'; 'The Poems of Abdur Rahman'; 'A Dictionary of Islam'; 'Heroic Lives in Foreign Fields.'

Hugo, hū'gō (Fr. ü'gō), **Victor Marie,** French poet and novelist: b. Besançon 26 Feb. 1802; d. Paris 22 May 1885. Major Hugo, his father, having entered the service of Joseph Bonaparte, king of Italy and afterward of Spain, Victor's earlier years were partly spent in these countries. At the age of 12 he was already writing verses, and in 1823 his first novel, 'Han d'Islande,' appeared, followed in 1825 by 'Bug Jargal.' In 1828 a complete edition of his 'Odes et Ballades' appeared. In these productions Hugo's anti-classical tendencies in style and treatment of his subject had been very visible, but the appearance of his drama, 'Cromwell' (1827), with its celebrated preface, gave the watchword to the anti-classical or romantic school. 'Cromwell' was too long for representation, and it was only in 1830 that 'Hernani,' over which the great contest between Classicists and Romanticists took place, was brought on the stage. Other dramas followed — 'Marion Delorme' (1831); 'Le Roi s'amuse' (1832); 'Lucrèce Borgia' (1833); 'Marie Tudor' (1833); 'Angelo' (1835); 'Ruy Blas' (1838); 'Les Burgraves' (1843). During those years he had also published a novel, 'Notre Dame de Paris' (1830), and several volumes of poetry, 'Les Feuilles d'Automne' (1831); 'Les Chants du Crépuscule' (1835); 'Les Voix intérieures' (1837); 'Les Rayons et les Ombres' (1840). The poetry of this period has a melody and grace superior perhaps to any that he afterward wrote, but wants that deep and original sense of life characteristic of his later poems. During the same period he also wrote critical essays on Mirabeau, Voltaire, and a number of articles for the 'Revue de Paris.' In 1841, after having been four times previously rejected, he was elected a member of the French Academy; made shortly afterward a tour in the Rhineland, of which he wrote a brilliant and interesting account in 'Le Rhin' (1842). In 1845 he was made a peer of France by Louis Philippe. The revolution of 1848 threw Hugo into the thick of the political struggle. At first his votes were decidedly Conservative, but afterward whether from suspicion of Napoleon's designs or from other reasons, he became one of the chiefs of the democratic party. After the *coup d'état,* 2 Dec. 1851, he was one of those who kept up the struggle in the streets against Napoleon to the last. He then fled to Brussels, where he published the first of his bitter satires on the founder of the Second Empire, 'Napoléon le Petit.' In August 1852 he went to live in Jersey, and finally settled in Guernsey, where he bought an estate called Hauteville House. In the following year (1853) the famous volume 'Les Châtiments,' a wonderful mixture of satirical invective, lyrical passion, and pathos, appeared. It was in the comparative solitude and quietness of the Channel Islands that he wrote most of the great works of his later years. 'Les Contemplations' (1856); 'La Légende des Siècles,' 1st series (1859); 'Chansons des Rues et des Bois' (1865), and his celebrated series of social novels, 'Les Misérables' (1862); 'Les Travailleurs de la Mer' (1866); and 'L'Homme qui Rit' (1869). In 1870, after the fall of the Empire, Victor Hugo returned to Paris, where he spent his remaining years in occasional attendances at the senate, and in adding to the already long list of his literary works. Among these latest productions may be cited, 'Quatre-Vingt-Treize' (1873); 'L'Art d'être Grand-père' (1877); 'L'Histoire d'un Crime' (1877); 'Le Pape' (1878); 'La Pitié Suprême' (1879); 'Religions et Religion' (1880); 'Les Quatre Vents de l'Esprit' (1881); 'La Légende des Siècles' (last series, 1883); 'Torquemada' (1882). If not the greatest writer that France has produced, certainly he is her greatest poet. But he had grave defects and limitations, the chief being an entire want of humor, a too frequent straining after effect through the abnormal and

bizarre, an overweening belief in his own infallibility, and an ever-present conviction that he was a sage, all of whose sayings might be regarded as priceless teachings, to be eagerly caught up by a listening world. An edition of his complete works in 40 vols. appeared at Paris in 1886. The house in which Victor Hugo lived, on the Place des Vosges, has recently been transferred to the city of Paris, and now forms a Victor Hugo Museum, full of interesting relics of the poet. Consult: Swinburne, 'Study of Victor Hugo' (1886); Barbou, 'Victor Hugo et son Temps' (1882); Mabilleau, 'Victor Hugo' (1893); Nichol, 'Victor Hugo, a Sketch of his Life and Work' (1894); Dupuy, 'Victor Hugo, l'Homme et le Poète' (1887); Bire, 'Victor Hugo après 1852' (1894).

Huguenots, hū'gē-nŏts, a term of unknown origin, believed to be derived from a personal name, applied to the Protestants of France during the religious struggles of the 16th and 17th centuries. During the early part of the 16th century the doctrines of Calvin, notwithstanding the opposition of Francis I., spread widely in France. Under his successor Henry II., 1547–59, the Protestant party grew strong, and under Francis II. became a political force headed by the Bourbon family, especially the King of Navarre and the Prince of Condé. At the head of the Catholic party stood the Guises. The contest between the two parties was as much political as religious. The result was that a Huguenot conspiracy headed by Prince Louis of Condé was formed for the purpose of compelling the king to dismiss the Guises and accept the Prince of Condé as regent of the realm. But the plot was betrayed, and many of the Huguenots were executed or imprisoned. In 1560 Francis died, and during the minority of the next king, Charles IX., it was the policy of the queen mother, Catharine de Medici, to encourage the Protestants in the free exercise of their religion in order to curb the Guises. In 1562 an accidental conflict between the followers of the Duke of Guise and some Protestants at a church meeting precipitated a series of religious wars which desolated France almost to the end of the century. Catharine, however, began to fear that Protestantism might become a permanent power in the country, and suddenly making an alliance with the Guises, with their help she projected and carried out the massacre of St. Bartholomew's (q.v.). The Protestants fled to their fortified towns and carried on a war with varying success. On the death of Charles IX., Henry III., a feeble sovereign, found himself compelled to unite with the King of Navarre, head of the house of Bourbon and heir-apparent of the French crown, against the ambitious Guises, who openly aimed at the throne, and had excited the people against him to such a degree that he was on the point of losing the crown. After the assassination of Henry III. the King of Navarre was obliged to maintain a severe struggle for the vacant throne; and not until he had, by the advice of Sully, embraced the Catholic religion (1593), did he enjoy quiet possession of the kingdom as Henry IV. Five years afterward he secured to the Huguenots their civil rights by the Edict of Nantes (q.v.) which confirmed to them the free exercise of their religion, and gave them equal claims with the Catholics to all offices and dignities. They were also left in possession of the fortresses which had been ceded to them for their security. This edict afforded them the means of forming a kind of republic within the kingdom, which Richelieu, who regarded it as a serious obstacle to the growth of the royal power, resolved to crush. The war raged from 1624 to 1629, when Rochelle, after an obstinate defense, fell before the royal troops; the Huguenots had to surrender all their strongholds, although they were still allowed freedom of conscience under the ministries of Richelieu and Mazarin. But under Louis XIV. a new persecution of the Protestants commenced. They were deprived of their civil rights, and bodies of dragoons were sent into the southern provinces to compel the Protestant inhabitants to abjure their faith. The Edict of Nantes was revoked in 1685, and by this act about 50,000 Protestant subjects were driven out of France to other countries. (See HUGUENOTS IN AMERICA.) In the reign of Louis XV. a new edict was issued repressive of Protestantism, but so many voices were raised in favor of toleration that it had to be revoked. The Code Napoléon and later enactments place Protestants in France on an equality with their Catholic compatriots.

Huguenots in America. The French Protestant settlements in the New World divide themselves into two classes: those of choice (or at least with time and opportunity to make choice) and those of necessity. The former extend from the middle of the 16th century down to the capture of New York by the English in 1664; the latter comprise all those dating from the increasing severity of repression that heralded the Dragonnades and the Revocation of the Edict of Nantes to the end. The former were deliberate organized colonizations, of the same stamp as the English and from the same motives; the latter were the desperate and generally hurried resource of crowds of ruined exiles. The former were complete failures, and were soon suppressed, absorbed, or exterminated; the latter sought only life and livelihood and welcomed absorption. The former include the abortive attempts in Brazil and Florida, the earliest settlements in Acadia and Canada, the first settlement of New York, and the settlement of some of the West Indies; the latter include the feeble attempts at settlements in New England, the flood of accessions to the French element in New York, the founding of New Rochelle, the migrations to Pennsylvania, Delaware, and Maryland, the promising but aborted attempt in Virginia and, greatest of all, the tide of immigrants that created South Carolina.

The first attempt at creating a New-World Huguenot asylum and magazine of supplies was undertaken in 1555; Nicholas Durand de Villegagnon (q.v.) pretended to undertake it for Coligny, and settled a colony in Rio Janeiro harbor. But it was half Catholics; Villegagnon was a scamp, persecuted and scattered the Protestants, and finally deserted the colony; and the Portuguese slaughtered it out in 1567. A more honest attempt was made by Jean de Ribault in 1562, at Port Royal, S. C., but failed. In 1564 René de Laudonnière founded a colony on the St. John's in Florida (q.v.), at Fort Caroline; but the next year Pedro Menendez de Avilés butchered

the entire settlement. St. Bartholomew and the religious wars intervened; and no further efforts were made till after the accession of Henry of Navarre, who had imbibed the ardor for colonization from Coligny. In 1604, under his commission, Sieur de Monts planted a settlement to be on the basis of perfect religious equality, the first in the New World — at Port Royal, N. S.; French mercantile jealousy had the commission revoked, and it perished; but two years later it was refounded by Poutrincourt, and De Monts and Champlain founded Quebec. In 1613 Sir Samuel Argall (q.v.) destroyed Port Royal, but the French stayed and bands of Protestants came to reinforce them at intervals. A small settlement was made on Newfoundland, but was broken up by the government except for a few who would turn Catholics. The founding of New Amsterdam, usually supposed to be by the Dutch, was in fact by Huguenots under Dutch auspices. The Huguenots — largely French-speaking Walloons — who had crowded into the Netherlands to escape persecutions, had tried to gain permission to found settlements in the English colonies; rebuffed in this, they engaged with the Dutch, and the first shipload of emigrants that came to the future New York were entirely Huguenot. Peter Minuit himself being a Walloon. French families had been there already for years, the first white child born on Manhattan Island being French. For three generations the French element continued to be a highly important factor in the city, and composed much of the business aristocracy; even after the English occupation, all official documents were printed in both Dutch and French as well as English. Of the first shipload of emigrants, a number went up the Hudson and founded Fort Orange (Albany). In 1660 a number of Walloon and Vaudois exiles, who had taken refuge in the Lower Palatinate, settled near Kingston, N. Y.; later, the Vaudois founded New Paltz in the Wallkill Valley. In 1677 a French town was founded at Hackensack, but the fast-breeding Dutch soon swamped it. Small French groups settled in various parts of New Jersey.

Of the second class, the refugee emigration, too scattered and hurried in general to found separate French settlements, the first beginning from the north was at Boston. From 1660 on, small numbers had come from the Channel Islands and Rochelle, but after the Dragonnades 200 or 300 families came over, including some of the most notable names in Boston history. A settlement at Oxford, Mass., was made in 1687, primarily to convert the Nipmuck Indians, but that tribe joined hands with the Canadian tribes in league with the French, and inflicted such horrors on them — one whole summer besieging them in their blockhouse — that the settlement broke up in despair, many of them taking refuge in Milford, Conn. Many small groups settled in Rhode Island; the largest had a miserable history, being defrauded by a New England company organized expressly to sell to innocent foreigners a tract of land to which it had no title. In Connecticut Hartford and Milford received the greatest number. In New York the arrivals strengthened the French element, but soon melted into the general mass. In Pennsylvania, Delaware, and Maryland, many hundreds settled, but as scattered members of the population, and left no outward trace. In Virginia, whose southern climate was congenial to them, the Huguenots had settled in considerable numbers for many years, but in 1690 William III. sent over some 300 Huguenots who had followed him from Holland, and they made a settlement named Monacantown, from an extinct Indian tribe. In 1700, after long negotiations, four shiploads more came over under Marquis de La Muce; about half of them settled at Jamestown, Va., and in South and North Carolina, the rest at Monacantown. Several hundred more came over at different times, and the settlement seemed to have struck enduring roots; but furious religious dissensions broke it in two, and the pastor led part of them to the Trent in North Carolina, whence in fear of Indian massacre they finally went to South Carolina, the Canaan of the Huguenots, settling at Jamestown there. This South Carolina French immigration, due to the latitude and soil fitting their habits, began in 1670 in small numbers. In 1680 the city of Charleston was founded, largely under French auspices; the same year Charles II. sent over about 90 Huguenots to raise wine, oil, and silk. After the Revocation the great tide began to flow in; in 1687 there were four wholly or largely French settlements — Jamestown on the Santee, the "Orange Quarter" on the Cooper, St. John's Berkeley, and Charleston. In 1732 a band of 360 French-Swiss Protestants settled Purysburg on the Savannah; and in 1764 the last French colony was founded — New Bordeaux in Abbeville County. In the intervals there was a steady stream, very large for many years after 1685. Some of the greatest names in Southern history are French, and the entire character and action of the State have been deeply molded by this fiery, impulsive, gallant strain. It is pitiful to record that after all the sacrifice and courage of these exiles, religious persecution forced them to close their churches. All but members of the Church of England were disfranchised in 1706, and the Huguenots were bribed into submission by government support of the churches and having the liturgy translated into French.

The Huguenot settlements in the West Indies — St. Christopher, Martinique, Guadeloupe, and some smaller ones — belong in origin to the former group, that of voluntary colonization; their later history and the flight from them belongs to the latter. They were colonized by a trading company under Richelieu's patronage from 1626 on; there was nominal prohibition of public worship, but actually the law was a dead letter, as there would have been no trade but for the Huguenots; the Walloon Synod of Holland supplied ministers, and the life was one of prosperity and content. Then as the Revocation approached, atrocious penal laws were passed, but still not enforced. But the Revocation changed everything into a scene of misery. The first result was the using of the islands as a penal settlement for the Huguenots of France; the latter were sold into service, sometimes of the worst character, and the horrors of the passage rivaled the worst of the slave-trade. Then the governor-general was ordered to extirpate heresy at all hazard, and threatened a dragonnade if the inhabitants did not recant.

The effect was a general flight; next a stern order from the governor-general to stop or he would carry out the government orders in all their severity, which produced a still greater stampede, assisted by the Catholics themselves. In a few months the islands were half depopulated and their trade nearly ruined. The king then modified his orders; the flight ceased and a few returned; but most of the refugees remained in the English colonies or Bermuda. Several score at least removed to New York, and some of them founded New Rochelle; a few to New England, and the Southern colonies naturally received the largest quota. This immigration had an important effect on the United States trade with the West Indies, as the Huguenot merchants, from their familiarity with the region and their family ties, took the lead in and greatly developed it.

The "dead-line" of the French churches in America, the test of that element's separate existence, is about the middle of the 18th century; beyond that, according to Baird, few existed and fewer kept their language. French instinct was to blend, and of course it was much the best that it should do so. The element was absorbed soon and utterly, but its blood and its ideas have been very valuable to the United States. Consult Baird, 'History of the Huguenot Emigration to America' (1885).

Huichol (wē'chōl) **Indians.** See INDIANS, AMERICAN.

Hull, Edward, Irish geologist: b. Antrim 21 May 1829. As a member of the Geological Survey of Great Britain for 20 years, he geologically mapped a large portion of the central counties of England. In 1869 he became professor of geology at the Royal College of Science, Dublin; and in 1883 commanded an expedition under the auspices of the Palestine Exploration Society to Arabia Petræa and Palestine. Among his important works are: 'The Coal-Fields of Great Britain' (1865); 'Building and Ornamental Stones' (1872); 'A Text-Book of Physiography' (1888); 'Mount Seir, Sinai, and Southern Palestine' (1885); 'Volcanoes, Past and Present' (1892); 'Our Coal Resources at the Close of the 19th Century' (1897).

Hull, Isaac, American commodore: b. Derby, Conn., 9 March 1775; d. Philadelphia 13 Feb. 1843. He commenced his career in the merchant service, and was commissioned as lieutenant in the navy at the commencement of hostilities with France in 1798. In 1800 when first lieutenant of the Constitution, he cut out a French privateer from under a strong battery in the harbor of Port Platte, San Domingo. During the war with Tripoli (1802–5) Hull served with distinction in the squadrons of Commodores Preble and Barron, in command of the schooner Nautilus and brig Argus, participating in the several attacks on the city of Tripoli in July, August, and September 1804, and subsequently co-operating with Gen. Eaton in the capture of the city of Derne. In May 1804, he was promoted to the rank of master commandant, and in April 1806, to that of captain. At the opening of the War of 1812 between the United States and Great Britain he was in command of the frigate Constitution, and in July of that year, while cruising off New York, fell in with a British squadron, which chased the Constitution closely for nearly three days and nights. The wind was light and baffling, but Hull handled his vessel with superior seamanship, and finally escaped without injury; at one time he resorted to a novel and successful expedient; the boats were lowered, and all the spare rope on board was bent to a kedge anchor which was carried out nearly a mile ahead and let go. The ship was warped up to this kedge, which was weighed while another was carried out. In this way she left her pursuers before they discovered the manner in which it was done. After this remarkable escape, Hull went into Boston for a few days, whence he sailed 3 August, and 19 August met the English frigate Guerrière, which after a short conflict he reduced to a complete wreck, and forced the English to surrender. (See CONSTITUTION, THE.) As this was the first naval action of the war, it was regarded as a very important one; Capt. Hull was enthusiastically received, and Congress at its next session presented him with a gold medal. After the war his principal services were in command of the navy yards at Boston and Washington, of the squadrons in the Pacific and Mediterranean, and as a member of the board of navy commissioners.

Hull, William, American soldier: b. Derby, Conn., 24 June 1753; d. Newton, Mass., 29 Nov. 1825. He was graduated at Yale College in 1772, studied law at Litchfield, Conn., and was admitted to the bar in 1775. He entered the army of the Revolution at Cambridge in 1775 as captain of a Connecticut company of volunteers; was promoted to the rank of major in the 8th Massachusetts regiment in 1777, and to that of lieutenant-colonel in 1779. He was in the battles at White Plains, Trenton, Princeton, Stillwater, Saratoga, Monmouth, and Stony Point. His services throughout the war received the approbation of his superior officers, and neither his courage nor patriotism was ever doubted. He was governor of Michigan Territory from 1805 till 1812, when he was appointed as brigadier-general to the command of the northwestern army. He marched his troops to Detroit, heard of the declaration of war, and of the fall of Michilimackinac, which let loose the Indians of the Northwest upon him, crossed into Canada, but found his communications cut off, recrossed, and on the arrival of Gen. Brock surrendered to that officer the post of Detroit and the territory. For this he was tried two years after by a court-martial, and sentenced to be shot. The execution of the sentence was remitted by the President in consideration of his age and Revolutionary services. Historians are now agreed that the difficulties which surrounded Gen. Hull were so great that we need not ascribe his surrender either to treason or to cowardice. In 1824 he published a series of letters in defense of his conduct in this campaign which had a wide circulation. Consult 'Life,' by his daughter, Maria Campbell, and his grandson, James Freeman Clarke (1848).

Hull, Canada, town and county-seat of Ottawa County, Quebec, on the Ottawa River, at the junction of the Gatineau River, opposite the city of Ottawa, and on the Canadian Pacific railway. It is connected with its important neighbor by a fine suspension bridge spanning the Chaudière Falls. Iron mining is carried on

in the neighborhood, and the Falls afford immense water-power. Lumbering is the chief industry of the district; and Hull has vast lumber yards, saw- and planing-mills, and manufactories of pulp, paper, matches, pails, woodenware, woolens, axes, etc. It has 5 churches, a college, a convent, many fine residences, and French and English newspapers. The population is chiefly French Canadian. The town has been rebuilt since its almost total destruction by fire, 26 April 1900. Pop. (1901) 13,993.

Hull, Kingston-upon-, England, a large river port, municipal and parliamentary borough, city and county of itself, situated in the East Riding of York, on the north shore of the estuary of the Humber, where it is joined by the Hull, 34 miles east-southeast of York. Its buildings of note are the town-hall, the exchange, the corn exchange, market-hall, post-office, the custom-house, Trinity House, dock offices, public rooms, royal institution (containing the rooms of the Philosophical Society, etc.), art gallery, technical schools, central library, Hymers College, grammar-school, the jail, royal infirmary, borough asylum, hospitals, crematorium, and dispensary. The town possesses three well-laid-out public parks. The industries are varied. There are several ship-building yards, iron-foundries, machine-shops, and steam flour-mills; the other principal branches of industry comprehend seed-crushing, color-making, paper-making, canvas, rope, and cable making, tobacco manufacturing, and oil boiling. Hull ranks as the third port in the kingdom, and has extensive ship accommodation, docks, quays, etc. The principal exports are machinery, coal, metal goods, and woolen and cotton goods, the total value in 1900 being £16,933,078 (besides £5,516,723 of foreign and colonial produce); imports — timber, corn, iron, wool, flax, hemp, tallow, hides, pitch, tar, rosin, bones, etc.; in 1900 £31,168,579. The name of Kingston-upon-Hull was given by Edward I., who erected a fortress, and constituted it a chartered town and port. When Edward III. invaded France in 1359 Hull contributed 16 ships and 470 mariners. During the civil war Hull was besieged unsuccessfully by the Royalists twice. Pop. (1901) 240,618.

Hul'lah, John Pyke, English musical composer: b. Worcester 27 June 1812; d. London 21 Feb. 1884. In 1833 he entered the Royal Academy of Music. His first important composition, an opera entitled 'The Village Coquettes,' of which the words were by Charles Dickens, was successfully produced at St. James' Theatre in 1836. Early in 1841 he opened classes in Exeter Hall for the instruction in vocal music of schoolmasters and the general public, and from 1849 to 1860 continued them in St. Martin's Hall, built for him by his friends and supporters. His classes were remarkably successful despite much adverse criticism of his method of teaching. In 1858 he succeeded Horsley as organist at the Charterhouse, and in 1872 received the appointment of musical inspector of training schools for the United Kingdom. He conducted the Philharmonic concerts at Edinburgh 1866–7, and those of the Royal Academy of Music 1870–3. He also held professorships in King's College, Queen's College, and Bedford College. Hullah's best-known compositions are songs, of which several, such as 'The Sands of Dee,' 'Three Fishers,' 'The Storm,' and 'O that We Two Were Maying,' have become very popular. He issued many excellent collections of songs and other musical pieces, among which are: 'Part Music,' in three series (1842–5); 'Vocal Scores' (1846 onward); 'School Songs' (1851); 'Sea Songs'; 'Singer's Library of Concerted Music' (1859); and 'Song Book' (1866). Dr. Hullah was the author of the following among other works on the history and theory of music: 'Grammar of Vocal Music' (1843); 'On Vocal Music' (1849); 'Grammar of Musical Harmony' (1852); 'The History of Modern Music' (1862); 'Grammar of Counterpoint' (1864); 'Music in the House' (1877). See the 'Life' by his wife (1886).

Hulme, Frederick Edward, English botanist: b. Hanley, Staffordshire, 1841. He has long been prominent as a writer upon natural history, art, heraldry, etc., and among his numerous works are: 'Plant Form' (1868); 'Familiar Wild Flowers' (7 vols. 1878–1902); 'Art Instruction in England' (1882); 'History, Principles and Practice of Symbolism in Art' (1891); 'History, Principles and Practice of Heraldry' (1892); 'Cryptography' (1898); 'History of the Flags of the World' (1897).

Humaita, oo-mä-ē'tä, Paraguay, town and fort; on the Paraguay River, near the mouth of the Paraná River; in the southwestern part of the republic. Its situation made its possession of importance during the war of the "Triple Alliance." It withstood a siege for a whole year, the attacking forces being Argentine and Brazil soldiers, but finally, in 1868, surrendered. At the close of the war, in 1870, the fortifications were destroyed. It is surrounded by a fertile agricultural country. There is but little local manufacturing, but there is an extensive trade in coffee, sugar, cotton, tobacco, hides, and live stock. Pop. 4,000.

Humane Association, American, a consolidation of various societies, formed at Cleveland, Ohio, in 1877, becoming a national organization for the prevention of cruelty to animals and children. The initial work of the society was to regulate the abuses in cattle-transportation by the railroads, and to secure the passage of State laws looking to this end. It offered a prize of $5,000 for the best model of a cattle car that would make possible the feeding, watering and resting of cattle in transit, and many improved cattle cars were brought into use. See ANIMALS, CRUELTY TO; CHILDREN, SOCIETY FOR THE PREVENTION OF CRUELTY TO.

Humane Society, Royal, formed in London, in 1774, for the purpose of resuscitating those who had been immersed in water and were apparently drowned. At the present time it distributes rewards, consisting of medals, clasps, testimonials, and sums of money to those who save or attempt to save life from drowning. Also "all cases of exceptional bravery in rescuing or attempting to rescue persons from asphyxia in mines, wells, blast-furnaces, or in sewers where foul gas may endanger life, are recognizable by the society." It likewise gives prizes for swimming to the pupils of public schools and of training-ships.

Hu'manists, the name assumed at the revival of learning by those who looked upon

the cultivation of classical literature as the most valuable instrument of education, in opposition to those who clung to the ancient methods of the Scholastics. In their modes of thought also the tendency of the humanists was to exalt paganism at the expense of Christianity. In the 18th century the name became a word of reproach for those who showed a blind zeal for the classics as the sole educational subject, opposing the Philanthropists, who asserted the value of mathematics, science, modern languages, and history.

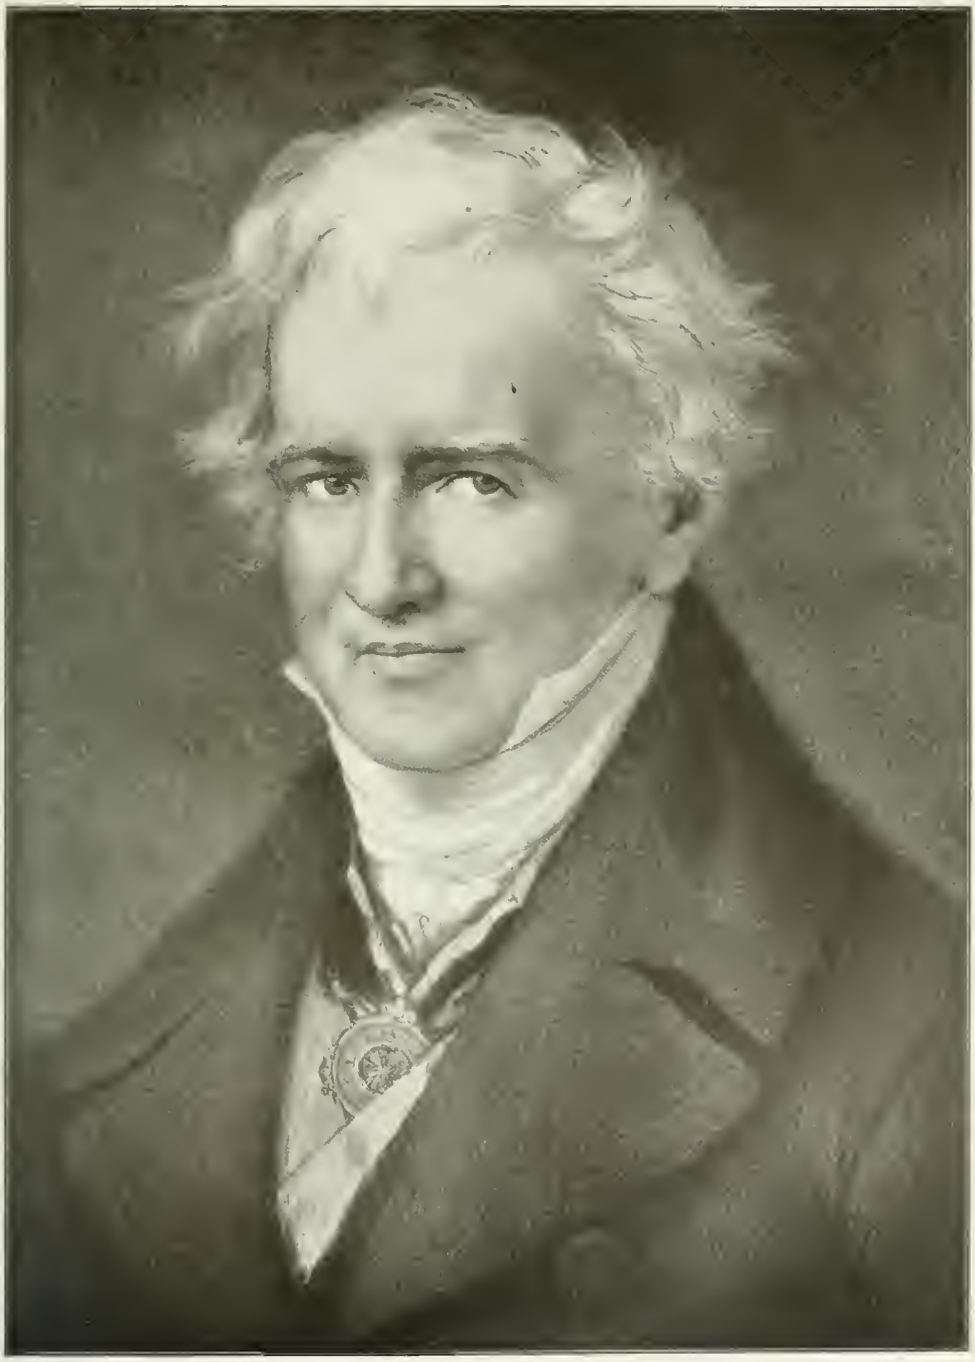
Humanita'rians, a term applied to the various classes of anti-Trinitarians, who regard Christ as a mere man. The earliest known author of the purely humanitarian theory is Theodotus of Byzantium, who lived in the second century. A contemporary of his, Artemon, taught the same doctrine, and asserted that such had been the universal belief of Christians up till the beginning of the 3d century. See UNITARIANISM.

Hum'bert I., RANIERI CARLO EMANUELE GIOVANNI MARIA FERDINANDO EUGENIO, king of Italy: b. Turin 14 March 1844; d. Monza, near Milan, 29 July 1900. He was eldest son of Victor Emmanuel II. and Queen Marie Adelaide, daughter of the Archduke Regnier of Austria. He took part as a youth in the war of independence, and in 1866 was in command of a division at Custozza. On 22 April 1868 he married his cousin, Princess Margherita of Savoy, daughter of the Duke of Genoa. On the death of his father he succeeded to the throne of Italy 9 Jan. 1878 as Humbert I. During his reign he carefully regarded constitutional limitations, and directing his choice of prime-ministers according to parliamentary conditions, selected but one, Rudini, from the Conservatives. In foreign policy he was evidently desirous of an active part in European affairs. In 1891 was concluded the "Triple Alliance" with Germany and Austria, a compact which necessitated the maintenance of a large army and navy, and the oppressive taxation of an already burdened country. Humbert also believed in colonial expansion, which he inaugurated by the occupying of Massowah, on the Red Sea. The Italian troops suffered reverses in 1887 and 1888, when they were defeated by the Mahdi, and 1 March 1896 when they lost the battle of Adowa to the Abyssinians. Humbert's attitude toward the Vatican was one of firmness, respecting all guarantees to the Pope, but insisting on the permanence of the Italian possession of Rome. His private munificence — it is said that he expended not less than $500,000 yearly in benefactions — and his personal interest and courage in the rescue work after the earthquake at Ischia (28 July 1883), and in visits to Busca and Naples during the cholera epidemic (1884), made him greatly respected by the Italians, to whom he was known as "Humbert the Good." He was thoroughly a soldier and eager in the interests of the army. Two unsuccessful attempts were made upon his life, one at Naples 17 Nov. 1878 by Passanante, a fanatic, and another near Rome 22 April 1897 by Acciarito, an anarchist. On 29 July 1900 he was shot and killed at Monza, near Milan, by the anarchist Bresci. See ITALY, *History.*

Humbert Swindle, The, one of the most daring and extensive frauds on record, perpetrated by a Mme. Humbert of Paris with the aid of various accomplices. It was alleged by Mme. Humbert that a certain Robert Henry Crawford, American millionaire, had left to her his fortune of $20,000,000. A subsequent will divided the estate between her younger sister, Marie Daurignac, and Henry and Robert Crawford, nephews of the testator, while a third document bound the heirs to the preservation of the title-deeds and securities, and placed these in the keeping of M. and Mme. Humbert until Marie should attain her majority. Without examination the alleged title-deeds and securities were deposited and sealed in a safe by the authorities. On this wholly fictitious basis Mme. Humbert obtained extensive loans. She is thought to have netted $10,000,000, while the amount of notes in the form of original loans and renewals equaled $140,000,000. The fraud was at last discovered, and Mme. Humbert and other parties to it were tried and condemned.

Humble-bee. See BUMBLEBEE.

Humboldt, hŭm'bōlt (Ger. hoom'bōlt), **Friedrich Heinrich Alexander,** BARON VON, German traveler and naturalist: b. Berlin 14 Sept. 1769; d. there 6 May 1859. His father was chamberlain to the king of Prussia. He studied at the universities of Frankfort-on-the-Oder, Berlin, and Göttingen, and in 1790 traveled along the Rhine to Holland, France, and England. This journey gave rise to his 'Observations on the Basalt on the Rhine,' published in 1793. In 1791 he studied mining and botany at the mining school in Freiberg, where his acquirements, his attractive and instructive conversation, his wit, and goodness of heart gained him universal esteem and affection. In 1792 he was appointed assessor in the mining and smelting department, and soon afterward removed to Baireuth, as overseer of the mines in Franconia. Here he introduced many improvements, among which was the establishment of the mining school at Steben; he likewise made valuable galvanic experiments, the results of which were published in 1796, in two volumes. But in 1797 he gave up this office from a desire to travel. Owing to the disturbed state of the Continent, however, it was not easy for him to carry out his project. For some time he resided in various parts of Germany, particularly at Jena, where he became intimately acquainted with Goethe and Schiller. In 1797 he went, in company with his brother, Karl Wilhelm, a Prussian minister of state, to Paris, where he became acquainted with Aimé Bonpland, a pupil of the medical school and botanic garden in Paris. He then went to Madrid, and having obtained permission from the crown to travel through the Spanish colonies in America, immediately sent for his friend Bonpland, and sailed with him from Corunna. They landed at Teneriffe, where they ascended to the crater in Pico, in order to analyze the atmospheric air, and to make geological observations. In July they arrived at Cumana in South America. For five years they were occupied incessantly in traveling through tracts of the earth rich in all that could interest the scientific observer, and till then never scientifically described. They explored the regions of South America watered by the Orinoco and the upper part of the Rio Negro, fully tracing the connection between the Orinoco and the Amazon; then returned to the coast and sailed



FRIEDRICH HEINRICH ALEXANDER VON HUMBOLDT.

for Cuba, where they remained some months. Leaving Cuba in 1801, they returned to the South American continent, sailed up the Magdalena as far as they could, pursued their route by land to Popayan and Quito, and thence as far south as Lima, crossing the Andes no fewer than five times in the course of their journey, and, besides other mountain ascents, climbing Chimborazo (23 June 1802) to an elevation of 19,300 feet, being the highest point of the Andes then reached by man; from Lima they sailed to Guayaquil, and thence to Acapulco, Mexico (January 1803). Some months were spent in examining the city of Mexico and the surrounding country, and in a visit to the United States; and in January 1804, they set sail for Europe, taking Cuba again on their way. On 3 Aug. 1804, they arrived at Bordeaux, bringing with them, as the result of their labors, an immense mass of fresh knowledge in geography, geology, climatology, meteorology, botany, zoology, and every branch of natural science, as well as in ethnology and political statistics. Humboldt selected Paris as his residence, no other city offering so many aids to scientific study, or having so many distinguished savants, and remained there till March 1805, arranging his collections and manuscripts, and experimenting with Gay-Lussac, in the laboratory of the polytechnic school, on the chemical elements of the atmosphere. He was accompanied by Gay-Lussac, who exerted a lasting influence on his chemical studies, in a visit to Rome and Naples, and also by Von Buch on his return through Switzerland to Berlin, where, after an absence of nine years, he arrived in November 1805. As the condition of Germany made it impracticable to publish there his large scientific works, he was permitted by King Frederick William III., as one of the eight foreign members of the French Academy of Sciences, to remain in Paris, which was his residence, excepting brief periods of absence, from 1808 to 1827. There appeared his 'Voyage aux Régions équinoxiales du Nouveau Continent' (with Atlas, 1809–25; German edition, Stuttgart 1825–32; new edition, edited by Hanff, four vols., 1859–60). When in 1810 his elder brother resigned the direction of educational affairs in Prussia to become ambassador at Vienna, the former post was urged upon Humboldt by Hardenberg; but he declined it, preferring his independence. He had also already decided upon a second scientific expedition, through Upper India, the region of the Himalaya, and Tibet, in preparation for which he was diligently learning the Persian language. The political events between the Peace of Paris and the Congress of Aix-la-Chapelle gave him occasion for several excursions. He went to England in the suite of the King of Prussia in 1814; again in company with Arago, when his brother was appointed ambassador to London; and again in 1818 with Valenciennes from Paris to London, and from London to Aix-la-Chapelle, where the king and Hardenberg wished to have him near them during the congress. He also accompanied the king to the Congress of Verona, and thence to Rome and Naples; and in 1827, at the solicitation of the monarch, gave up his residence in Paris, and returned by way of London and Hamburg to Berlin, where in the following winter he delivered a series of public lectures on the cosmos. Under the patronage of the Czar Nicholas he undertook in 1829 an expedition to northern Asia, to explore the Ural and Altai Mountains, the Chinese Dsoungaria, and the Caspian Sea. In this expedition he was accompanied by Ehrenberg and Gustav Rose. Their course lay through Moscow, Kazan, and the ruins of Old Bulghari to Ekaterinburg, the gold mines of the Ural, the platinum mines of Nijni Taghilsk, Bogoslovsk, Verhoturye, and Tobolsk, to Barnaul, Schlangenberg, and Ustkamengorsk, in the Altai region, and thence to the Chinese frontier. From the snow-covered Altai Mountains the travelers turned toward the southern part of the Ural range, and traversed the great steppe of Ischim, passed through Petropavlovsk, Omsk, Miask, the salt lake of Ilmen, Zlatousk, Taganay, Orenburg, Uralsk (the principal seat of the Uralian Cossacks), Saratov Dubovka, Tzaritzin, and the Moravian settlement of Sarepta, to Astrakhan and the Caspian Sea. They visited the Kalmuck chief Sered Jaab, and returned by Voronesh, Tula, and Moscow. The entire journey of over 10,000 miles was made in nine months; its results are given in Rose's 'Mineralogischgeognostische Reise nach dem Ural, Altai und dem Kaspischen Meere' (1837–42); and Humboldt's 'Asie Centrale, Recherches sur les Chaines de Montagnes et la Climatologie comparée.' It extended the knowledge of telluric magnetism, since in consequence of it the Russian Imperial Academy established a series of magnetic and meteorological stations from St. Petersburg to Peking, which was followed, on Humboldt's application to the Duke of Sussex, by the establishment of similar stations in the southern hemisphere by the British government. The convulsions of 1830 gave a more political direction to Humboldt's activity for several years. On the news of the French revolution, and the accession of Louis Philippe, he was selected to convey to Paris the Prussian recognition of the new monarch, and to send political advices to Berlin. The latter office fell to him again in 1834–5, and he was called upon to fulfil it five times in the 12 following years, residing four or five months in Paris on each mission. To this period belongs the publication of his 'Examen critique de la Géographie du Nouveau Continent' (1835–8). He accompanied the king of Prussia in visits to Denmark, England, etc. (1841–5), and resided for several months in Paris in 1847–8, from which time he lived in Prussia, usually in Berlin, occupying a high position at the court until his death. His last great work, 'Cosmos' (1845–58), has been unanimously recognized as one of the most valuable contributions to science ever published. It explains the physical universe according to its dependencies and relations, grasps nature as a whole, moved and animated by internal forces, and by a comprehensive description shows the unity which prevails amid its variety. It has been translated into all languages in which a book of science is required, and has been without an equal in giving an impulse to natural studies. See Bruhns, 'Alexander von Humboldt, eine Wissenschaftliche Biographie' (Eng. trans., 1873); Klenke, 'Alexander von Humboldt, ein biographisches Denkmal' (1859).

Humboldt, Karl Wilhelm, Baron von, German statesman and philologist, brother of

the preceding: b. Potsdam 22 June 1767; d. Tegel near Spandau, 8 April 1835. He studied law at Berlin, at Frankfort-on-the-Oder, and at Göttingen, and at the same time devoted equal attention to antiquities, æsthetics, and the philosophy of Kant. In 1789–90 he lived in Erfurt and Weimar, where a friendship commenced with Schiller, continued without interruption till the poet's death. A valuable memorial of his friendship with Schiller is the correspondence between them (Briefwechsel zwischen Schiller und Wilhelm von Humboldt, 1830). In 1801, at the request of the Prussian government, he accepted the situation of ministerial resident at Rome. From 1806–8 he was here minister plenipotentiary, but, having been called from Rome to fill the office of minister of the interior in connection with ecclestiastical and educational matters, had a most important share in the educational progress which Prussia has since made; more especially is the erection of the Berlin University to be ascribed to him. He exchanged this situation in 1810 for that of extraordinary ambassador and minister plenipotentiary to Vienna. He took an active part during the armistice of 1813 in the peace congress at Prague; in 1814 at the Congress of Chatillon, and the conclusion of the first Paris peace; in 1815 at the Congress of Vienna; and in 1816 at Frankfort-on-the-Main, in all matters connected with the German diet. He was afterward appointed ambassador to London, and in 1818 attended the Congress of Aix-la-Chapelle. In 1819 he was an active member of the Prussian ministry, but sent in his resignation the same year, in favor of a freer and more constitutional system. His collected works (1841–52), include poems, essays on subjects of taste, and in particular numerous valuable disquisitions in regard to the origin and progress of language.

Humboldt, a river which has its rise in the northeastern part of the State of Nevada, flows west and southwest, a distance of about 350 miles into Humboldt Lake, in the eastern part of the State. The stream is narrow, the waters saline, and the whole course is through a barren region, destitute of large trees and but few shrubs, except a few clusters of willows. The fields are covered with sage brush. The only east and west pass through the mountains of Nevada is the valley of the Humboldt. The Central Pacific railroad, in its course through the State, follows this river. Humboldt Lake has no outlet; but the waters evaporate so rapidly that sometimes its bed is dry, but when the water is high it overflows the banks. A dam built a few years ago prevents the overflow from falling in Carson Sink.

Hume, David, Scottish historian and metaphysician: b. Edinburgh 27 April 1711; d. there 25 Aug. 1776. He appears to have entered the University of Edinburgh at 12, and to have left at 14 or 15 without taking a degree. He began the study of law, but abandoned it in order to devote himself to the "pursuits of philosophy and learning." His first work, the 'Treatise of Human Nature,' was published partly in 1739 and partly in 1740; the books entitled 'Of the Understanding' and 'Of the Passions' appearing in the former, and that entitled 'Of Morals' in the latter year.

The 'Treatise of Human Nature' is the final and most complete exposition of the fundamental principles of the old school of empirical philosophy,—the school to which belonged Bacon, Locke, and Berkeley. According to Hume, the contents of the mind are embraced in the term "perceptions." Perceptions consist of sensuous impressions and ideas. Ideas are merely images of sensuous impressions. Knowledge is the cognition of the relation between two perceptions. There is no necessary connection between cause and effect. The idea of cause depends on the habit of the mind which expects the event that usually follows another. Mind is but a series or succession of isolated impressions and ideas. As knowledge is dependent on experience derived through the senses, and as the senses frequently deceive, one can have no absolute knowledge of things, but only of one's impression of them. Hence, to give the conclusion later arrived at in the famous 'Essay on Miracles,' a miracle even if genuine is incapable of proof.

The 'Treatise of Human Nature' is clear, forcible, and untechnical. Its most striking characteristics are its spontaneity and individuality. Hume owed little to academic training, and wrote his earlier works at a distance from centres of learning, without access to large libraries. The literary beauties of the 'Treatise,' however, are marred by its structural defects. It is a series of brilliant fragments rather than a well-rounded whole, and is concerned more with criticism of metaphysical opinions from the point of view of Hume's theory of knowledge than with the construction of a complete system of philosophy.

In 1741 appeared the first volume of the 'Essays, Moral and Political,' the second volume coming out in the following year. These, with some additions and omissions, were republished in 1748 under the expanded title, 'Essays, Moral, Political, and Literary,' which has been retained in the many subsequent editions. Hume's essays are models of their kind, full of sparkle, interest, and animation. Hume accompanied General Sinclair in 1746 and 1747 in his expedition against France and in a military embassy to Vienna and Turin. He now published a recasting of his 'Treatise upon Human Nature,' under the title 'An Inquiry Concerning the Human Understanding' (1747). In 1752 he published his 'Political Discourses,' which were well received, and his 'Inquiry Concerning the Principles of Morals.' The same year he obtained the appointment of librarian of the Advocates' Library at Edinburgh, and began to write his 'History of England,' of which the first volume appeared in 1754. It was, like most of the succeeding volumes, severely attacked both for its religious and political tendencies; but, in spite of adverse criticism, after its completion in 1761, was recognized as a standard work. Its merits are chiefly clearness and force of narrative and philosophical breadth of view in the judgment of men and events. In 1763 he accepted an invitation from the Earl of Hertford, then proceeding as ambassador to Paris, to accompany him, and was enthusiastically received by Parisian circles in his character of philosopher and historian. After the departure of Lord Hertford in 1756, he remained as *chargé d'affaires,* and returned to England in 1766, bringing with him Rousseau, for whom he pro-

cured a pension and a retreat in Derbyshire. But the morbid sensitivity of Rousseau brought about a disagreement which put an end to the friendship. In 1767 Hume was appointed under-secretary of state, a post which he held till 1769. As a philosopher, in which quality his reputation is perhaps greatest, Hume's acute skeptical intellect did great service by directing research to the precise character of the fundamental conceptions on which our knowledge and our beliefs are based. His acute negative criticism of these conceptions (for example, his reduction of the ideas of personal identity, conscience, causality, to mere effects of association) compelled philosophy either to come to a dead halt or to find, as Kant did, a new and profounder view of the nature of human reason. See Burton, 'Life and Correspondence of David Hume' (1840); Jodl, 'David Humes Lehre von der Erkenntnis' (1871); Gizyck, 'Die Ethik David Humes' (1878); Huxley, 'Hume' (1879); Knight (1886), and Hume, 'My Own Life.'

Hume, Fergus, English novelist: b. 24 July 1862. He was educated at the University of Otago, New Zealand, became a barrister, and in 1888 removed to London. His first long work, 'The Mystery of a Hansom Cab,' published in Melbourne (1887), and later in London, achieved a phenomenal circulation. Later publications are: 'The Piccadilly Puzzle' (1889); 'Miss Mephistopheles' (1890); 'A Creature of Night' (1891); 'An Island of Fantasy' (1894); 'The Bishop's Secret' (1900); 'The Turnpike House' (1902); 'The Mandarin's Fan' (1904).

Hume, Martin Andrew Sharp, English historian: b. London 8 Dec. 1847. He was educated in Madrid and was attached to the Turkish army 1878–9. He is editor of Spanish State Papers in the Public Record Office and examiner of Spanish in the University of London, and has published: 'Chronicle of Henry VIII.' (1889); 'Courtships of Queen Elizabeth' (1896); 'The Year after the Armada' (1896); 'Sir Walter Raleigh' (1897); 'Philip II. of Spain' (1897); 'The Great Lord Burghley' (1898); 'Spain: Its Greatness and Decay' (1898); 'Modern Spain' (1899); 'History of the Spanish People' (1901); 'Treason and Plot' (1901); 'The Love Affairs of Mary, Queen of Scots' (1903).

Humidity. See RAINFALL.

Hum'mel, Abraham H., American lawyer: b. Boston, Mass., 27 July 1849. He went to New York city in his youth, was educated in the public schools there and entered the law office of William F. Howe as an office boy. He early showed an unusual aptitude for the law, was admitted to the bar of New York in 1870, and subsequently was admitted to practice in the United States courts. In 1870 he founded the law firm of Howe & Hummel, of which he has been ever since a member, and has attained distinction as a divorce lawyer, in theatrical litigation, and important will contests. He represents nearly every important theatre in the United States, many prominent theatrical managers, and leading American and European actors. He is counsel in the United States for the Société des Auteurs Français — organized at Paris, France, for the purpose of protecting all foreign plays produced in the United States and elsewhere.

Hummel, hoom'mĕl, **Karl,** German landscape painter: b. Weimar 31 Aug. 1821. In 1841 he studied painting with Preller. His more idealistic pictures belong to the earlier part of his career, and his later work consists largely of German landscapes. Among his most noted works are: 'The Gardens of Armida' (1888); 'Keller Lake in Holstein' (1884); 'Wooded Landscape near Michaelstein' (1888).

Humming-birds, a family of small birds, the *Trochilidæ*, closely allied to the swifts, peculiar to America and almost exclusively tropical. They are distinguished by small size, iridescent plumage, long slender bill and the peculiar form of the tongue, which consists of a double tube tapering and separating at the tip into two externally lacerated sheaths, which contain the extensile portion. "The horns of the hyoid apparatus are greatly elongated, and pass round and over the back of the head, meeting near the top, and thence stretching in an ample groove to terminate in front of the eyes. This arrangement, analogous to that found in woodpeckers, allows the tongue to be suddenly protruded to a considerable distance, and withdrawn again in an instant." This is a modification of parts adapted to food-getting habits, and is accompanied by others equally characteristic. Humming-birds feed almost entirely upon minute living insects, especially those which gather about flowers and loiter in the corollas, feeding upon the nectar; or dwell on the leaves and bark of plants and trees. Such honey as may be taken with them seems to be gratefully accepted, but the birds do not seek for, nor "suck" the nectar from flowers, as has been popularly supposed. They will dart from a perch and capture an insect like a flycatcher, but ordinarily they obtain them by poising upon their wings about leaves and in front of tree-trunks, picking up morsels, not with the mandibles, but with the tongue; and still more frequently by searching flowers. As it is in the deep, tubular, sweet corollas of trumpet-creepers, orchids, and similar great blossoms of tropical shrubs and vines that insects most abound so there does the humming-bird find its richest hunting-ground; and the long curved beaks of most species have been developed in the constant effort to penetrate to the nectarous depths of these deep blossoms; in truth, the head and half the tiny body may often be pushed into the flower, and in so doing gather and dispense pollen from flower to flower, so that humming-birds are important if not exclusive agents in the cross-fertilization of certain large-flowered plants. This method of obtaining food requires the power of sustaining themselves in the air in a fixed position while they explore leaves or blossoms, since no perch is available for their feet, which are small and weak at best. Hence humming-birds have developed lightness of body coupled with extraordinary muscularity and extent of wings, which in most species reach far beyond the root of the tail. These long narrow wings are operated by pectoral muscles which proportionately exceed in size those of any other bird,— even those of the chimney-swifts; and these huge muscles actuate remarkable short wing-bones, so that extreme rapidity of movement is possible, but it is accompanied by a loss of that power secured by the relatively

longer alar bones of other birds. By this apparatus the humming-birds are able to beat the air with a rapidity which enables them to stand still, or to dart and dodge in pursuit of some agile insect, or in escaping danger, with a speed which defies human sight to trace; the moving wings at such times, indeed, appear only as a misty halo about the body of the bird, and make a loud humming noise. Most species have very long bills — frequently exceeding, and sometimes twice as long as the head; but some have short, owl-like beaks, with which they pierce the base of such flowers as are too deep for them.

A characteristic of humming-birds is that flashing beauty of plumage which long ago led to calling them the gems of the air, and is due mainly to the quality of the feathers, upon the surface of which are small scales that reflect the light in prismatic hues, giving an iridescent or metallic sheen to certain parts, especially the throat (gorget), comparable only to the shards of some beetles. Such brilliance, however, belongs only to the males, the females being uniformly more plainly dressed, though still highly colored. In many species, also, the males are further adorned with fanciful crests, mustaches, tufts, pendants of the chin and throat, "puffs" upon the legs, and especially with ornamental developments of the tail-feathers; and these they seem to take great delight in displaying for the admiration of the female, and the exasperation of rivals. They are extremely pugnacious, especially in the nuptial season, when constant and bitter fighting occurs, and their courage is so great that neither sex has any hesitation in attacking any bird which offends them or comes too near the nest,— even hawks and crows often flee ignominiously before the impetuous onslaughts of these little furies. On the other hand no bird is more fearless of man and easily tamed.

The nests of humming-birds are small cups of downy materials, sometimes resting upon the limb of a tree (as is the method with the common ruby-throat of the eastern United States; sometimes fastened in a crotch of a bush or of large leaves; or fastened to the tip of a pendant leaf, or in a bunch of hanging moss or foliage. The materials are adapted to the place in color and appearance, and further concealment is gained by coating the structure with lichens, or bits of bark, or with cone-scales, as is the habit of the familiar Calliope hummer of California, which nests in pine trees. The eggs of all species are only two in number, and purely white.

The family is exclusively American, and is represented from Labrador and southern Alaska to Patagonia; but the more vagrant species are few, and withdraw in winter toward the equator. About 125 genera with some 500 species, are recognized by ornithologists. Nine tenths of them belong to the Amazon and Orinoco valleys, or to the lowlands of Central America; yet some species habitually spend the summer on high mountains. The variety decreases northward, but nearly 20 species reach the boundary of the United States, and several are regularly present in summer west of the great plains, as far north as southern Alaska. One species wanders over the whole country, and is abundant in the Eastern States. This is the ruby-throat (*Trochilus colubris*). It is about 3½ inches long. The whole upper part, sides under the wings, tail coverts, and two middle feathers of the tail, are rich golden green; the tail is forked, and, as well as the wings, of a deep brownish purple; the bill and eyes black; but what constitutes their chief ornament is the splendor of the feathers on the throat of the male, which are ruby-red, and gleam like a great jewel. The females and immature young lack this gorget.

Consult: Jardine, 'Naturalists' Library,' Vols. I and II (Edinburgh 1833); Lesson, 'Histoire Naturelle des Colubris' (1830); Gould, 'Monograph of the Trochilidæ' (5 vols. 1850–9); Mulsant and Verreaux, 'Histoire Naturelle des Oiseaux-Mouches ou Colubris' (4 vols. 1876); Ridgway, 'The Humming-birds' (Am. Rept. U. S. National Museum for 1890 (Washington 1892).

ERNEST INGERSOLL,

Hu'mor, a fluid of the living body, of which Hippocrates enumerated four, namely, blood, phlegm, yellow bile, and black bile. These were considered to be the principal seats of disease in man. In modern medicine humor is a term generally applied to the thinner fluids, whether natural or morbid, limpid, serous or sanious, such as the humors of the eye or the watery matter in a blister of the skin caused by heat, etc.

Hump'back Salmon, Whitefish, etc., several kinds of fishes are said to be "humpbacked" because of an unusually raised dorsal outline. The humpback salmon of the Pacific coast is a commonly known, but little valued species (*Oncorhynchus gorbuscha*), whose flesh is styled in market "pink" salmon. (See SALMON.) The common whitefish (q.v.) is known locally as humpback or bowback; and the curious razor-backed sucker (*Xyrauchen cypho*), is locally called the humpback.

Humpback Whale, one of the baleen whales or rorquals (q.v.) of the genus *Megaptera,* characterized by a low hump in place of the inconspicuous dorsal fin and a tuberculous head. The genus is world-wide, and an undetermined number of species exist, of which the best known is the northern *M. longimanus,* the specific name referring to the elongated pectoral fin, with which the animal beats the water, itself and often its playmates. These whales reach 50 or 60 feet in length, and go about in small schools. See WHALE.

Humped Cattle. See INDIAN HUMPED CATTLE.

Humperdinck, Engelbert, ĕng'ĕl bĕrt hoom'pĕr-dĭnk, German composer: b. Siegburg, near Bonn, 1 Sept. 1854; after studying music at Cologne and elsewhere he taught in the conservatoriums of Barcelona and Cologne, and was musical adviser to a publishing firm in Mainz. Wagner asked him to assist in the production of the latter's only symphony; and he prepared and coached the first cast of 'Parsifal' at Baireuth (1882). He subsequently became famous as the author of the phenomenally successful children's musical fairy play, 'Hänsel und Gretel' (1894); followed by 'Schneewittchen' (The Snow Maiden) and 'The Royal Children.'

1. Double-crested (T. cornutus). 2. Ruby-throat (Trochilus colubris). 3. White-collared (T. melivorus). 4. Tufted-neck T. ornatus). 5. Delande's (T. delandii). 6. Cora's (T. cora). 7. Golden-green (T. prasina). 8. Vieillot's (T. chalybeus). 9. Evening (T. vesper). 10. Avocet-billed (T. avocetta). 11. Curve-bill (T. curvirostris). 12. Harlequin (T. multicolor). 13. Natterer's (T. scutatus).

Humphrey, hŭm'frĭ, **Charles Frederick,** American soldier: b. New York. He served in the 5th artillery in the Civil War, became 1st lieutenant of the 4th artillery in 1868, was transferred to the quartermaster's department in 1879 as assistant-quartermaster with captain's rank, and in 1897 attained the post of deputy quartermaster-general with grade of lieutenant-colonel. In 1898 he entered the volunteer service, participated in the Cuban expedition, and was promoted brigadier-general of volunteers. In 1899–1900 he was chief-quartermaster of the division of Cuba, in 1900 of the United States China relief expedition. In 1903 he was appointed quartermaster-general, United States army, with rank of brigadier-general.

Humphrey, Heman, American Congregational clergyman and college president: b. West Simsbury, Conn., 26 March 1779; d. Pittsfield, Mass., 3 April 1861. He was graduated from Yale in 1805, was pastor of the Congregational church at Fairfield, Conn., 1807–17, and of that at Pittsfield, Mass., 1817–23 while from 1823 to 1845 he was president of Amherst College. He published several works, including a popular 'Tour in France, Great Britain, and Belgium,' but is best known by a famous pamphlet called 'Parallel Between Intemperance and the Slave Trade.' See Tyler, 'History of Amherst College.'

Humphreys, hŭm'frĭz, **Alexander Combie,** American engineer: b. Edinburgh, Scotland, 1851. He entered business in New York in 1866; in 1877–81 studied at Stevens Institute of Technology (Hoboken, N. J.). He then held various posts first in a lighting, and then in a gas improvement, company, in 1892 became connected with a gas company of London, and in 1894 established a branch business in New York. During this time he did much to improve the manufacture of commercial water-gas. In 1902 he was elected president of Stevens Institute.

Humphreys, Andrew Atkinson, American soldier: b. Philadelphia, Pa., 2 Nov. 1810; d. Washington, D. C., 27 Dec. 1883. He was graduated at West Point 1831, receiving a commission in the artillery. Resigning in 1836 he was associated with Major Hartman Bache as a civil engineer in government work. He re-entered the army in 1838, and was engaged in several government surveys. In the Civil War he was topographical engineer to the Army of the Potomac. In 1862 he was made brigadier-general and commanded the Fifth corps of the Army of the Potomac at the battles of Fredericksburg and Chancellorsville. He commanded a division in the battle of Gettysburg and earned promotion to a major-generalship in the volunteer forces. He commanded the Second corps of the Army of the Potomac in the campaign which closed with Lee's surrender. After his services at Sailor's Creek, he was brevetted major-general in the regular army and was subsequently placed in command of the engineer corps with the regular rank of brigadier-general. He has written: 'The Virginia Campaigns of 1864 and 1865' (1882); 'From Gettysbury to the Rapidan' (1882).

Humphreys, David, American poet: b. Derby, Conn., 1753; d. New Haven 21 Feb. 1818. He was educated at Yale, entered the army at the beginning of the Revolutionary War, and in 1780 became a colonel and aide-de-camp to Gen. Washington. In 1784 he accompanied Jefferson to Europe as secretary of legation, in 1786 was elected to the legislature of Connecticut, and was soon associated with the "Hartford Wits," Hopkins, Trumbull, and Barlow, in the composition of the 'Anarchiad,' being thus one of "the four bards with Scripture names" satirized in London. He was minister to Lisbon 1791–7, minister plenipotentiary to Spain in 1797–1802, and on his return imported from Spain 100 merino sheep, the first introduced into the United States, and engaged in the manufacture of woolens. He held command of the Connecticut militia in the War of 1812. His principal poems are: an 'Address to the Armies of the United States' (1772); 'On the Happiness of America'; a tragedy, entitled the 'Widow of Malabar,' translated from the French of Le Mierre; and 'On Agriculture.' His 'Miscellaneous Works' (1790 and 1804) contain beside his poems 'An Essay upon the Life of Gen. Israel Putnam,' and several orations and other prose compositions.

Humphreys, Frank Landon, American Protestant Episcopal clergyman: b. Auburn, N. Y., 16 June 1868. He was educated at Columbia and Oxford universities. He was precentor and minister in charge of the Cathedral of the Incarnation, Garden City, L. I., 1885–90, and is now canon in the Cathedral of St. John the Divine, New York. Among his writings are: 'The Evolution of Church Music' (1896); 'The Mystery of the Passion' (1898); 'Men of Understanding' (1897); 'Christmas Carols and Caroling' (1900); and 'Clerical Education' (1896).

Humphreys, Joshua, American shipbuilder: b. 1751; d. 1838. He was the first builder of war vessels for the American colonists, and is therefore often called the "father of the American navy." Among the ships constructed by him were the Chesapeake, Congress, United States, Constellation, and the famous Constitution.

Hundred Years' War, the name given to the prolonged struggle between France and England which began in 1337 and ended in 1453. Among the chief of the immediate causes of the war was Edward III.'s claim to the French throne, but the keen rivalry of the two nations rendered conflict inevitable. It lasted during the reigns of five English kings, from Edward III. to Henry VI., and of five French kings, from Philip VI. to Charles VII., ending in the expulsion of the English from France.

Hu'neker, James Gibbons, American musical and dramatic critic: b. Philadelphia 31 Jan. 1859. In Paris he was a pupil of Barili, Ritter, and Dontreleau, and subsequently became an instructor in piano at the National Conservatory of New York. He was musical and dramatic critic of the New York *Recorder* in 1891–5, and of the *Morning Advertiser* in 1895–7. Subsequently he was musical editor, and from 1902 dramatic editor of the New York *Sun*. Among his writings are 'Mezzotints in Modern Music,' essays (1899); 'Chopin, as Man and Musician' (1900), an interesting study; and 'Melomaniacs' (1902), clever but often extravagant stories satirizing the musical profession.

Hungarian Language and Literature. See HUNGARY.

Hungary (Hungarian, Magyar-Ország, "Land of the Magyars"), a kingdom in the southeast of Europe, forming with Austria (q.v.), the Austro-Hungarian monarchy. It includes, in its widest acceptation, Hungary proper, Transylvania on the east, Slavonia and Austrian Croatia on the southwest, extending in this direction so far as to comprise a strip of coast on the Adriatic Sea, together with the former military frontiers, a long strip of territory on the southern borders. Total area, 125,039 square miles, with a population (1900) of 19,254,599. The capital is Budapest. In a more restricted sense Hungary proper is limited to the territory encircled from the east round the north to the northwest by the Carpathian Mountains; bounded west by the river March and some offsets of the Noric Alps; southwest by the Drave; south and southeast by the Danube and the Transylvanian Alps (a continuation of the Carpathian range); with an area of 109,007 square miles, and a population (1900) of 16,721,574. Hungary proper may be considered as a large basin surrounded by mountains on every side except the south; but even there the natural boundaries of this geographical basin are completed at no great distance from the frontier by the highlands of Croatia, Bosnia, and Servia, that meet those of Wallachia and Transylvania at the "Iron Gate", a pass formed by the abrupt divisions of the mountains on either side of the Danube, which there forms a celebrated rapid. From that point the Carpathians proceed by various ranges at first east, but afterward successively northwest and southwest. Several of their summits rise to between 8,000 and 9,000 feet above the sea. The Carpathians are richly wooded in many parts, and their branches are interspersed with numerous romantic and fertile valleys. On the west the Leitha Mountains, a spur of the Alps separating Hungary from Styria and Austria, progressively decline toward the Danube. The Bakonywald (Bakony Forest), another Alpine spur, upward of 2,000 feet in height, and clothed with dense forests of oak, beech, and other trees, intersects the southwest region of Hungary in a northeast direction to near Waitzen, where the Danube bends south, and with the Matra Mountains, beyond that river, divides Central Hungary into a greater and a smaller plain, respectively about 21,000 and 4,000 square miles in extent. The Danube and Theiss rivers traverse the south half of the country in parallel streams about 60 miles apart, the former previously flowing from the west, and the latter from the east or northeast to near the latitude of the capital. Near Eszek, in Slavonia, the Danube, met by the Drave, turns suddenly again to the east, and forms all the rest of the south frontier of Hungary, receiving in this part of its course the Theiss and several minor affluents. The March, Waag, Neutra, Gran, and Ipoli, in Upper Hungary, flow to the Danube from the north; the Bodrog, Schajo, Hernad, and Zagyva, flowing from the same direction, unite with the Thesis; and the Szamos, Körös, Maros, etc., join that river from the east. The Poprad, in the north, flows into Galicia, and is tributary to the Vistula, it being the only Hungarian river not belonging to the basin of the Danube. The Drave forms the southwest frontier on the side of Croatia and Slavonia, and is joined in Hungary by the Mur from Styria. Excepting these two, the Raab, which joins the Danube near the town of its name, is the only river of much magnitude in the southwest quarter of the country; but in that division of Hungary are its two principal lakes, on either side of the Bakonywald—Balaton, in the great plain, and the Neusiedler-See (Hungarian, *Fertö Tava*), close to the border of Austria. In the Carpathians are several smaller lakes, between 4,000 and 5,000 feet above the sea. In the lower courses of the Danube and Theiss are extensive marshes and swamps, especially along the Theiss. The total area of the morasses in Hungary has been estimated at 1,500,000 acres, or upward of 2,300 square miles; within the 19th century enough marsh-land was drained to furnish subsistence for 500,000 inhabitants. Mineral springs are numerous; the most celebrated are those which form the baths of Mahadia in the Banat. Among the minerals are gold, silver, copper, iron, lead, zinc, cobalt, antimony, sulphur, arsenic, salt, soda, saltpeter, alum, vitriol, marble, coals, peat; among the precious stones the opal and chalcedony are remarkably beautiful.

Hungary, including Transylvania, used to yield nearly a half of all the gold annually obtained in Europe. Its principal localities are Kremnitz, Chemnitz, and other places in the north, and Nagy Banya on the Transylvanian frontiers. Silver is found in independent localities, though more frequently in connection with the gold. They are sometimes found pure, but generally in combination with copper. Mining is not yet carried on to a great extent; but the production of coal and iron is rapidly increasing. Hungary is one of the healthiest countries in Europe. Owing to the variety of its surface it possesses a great diversity of climate, which, combined with the fertility of the soil, abundantly supplies her with natural productions.

The Hungarian has a natural inclination to agriculture and the breeding of cattle. Both are however, still in a backward state, though making rapid advances. But the inexhaustible fertility of nature supplies every deficiency of industry and skill, and Hungary is now one of the chief corn-growing countries of Europe, much wheat and flour being exported. Hungarian wheat is well known for its excellent quality. All kinds of grain, a species of maize, rice, kitchen vegetables, and garden plants of every description, melons (which are cultivated in open fields), Turkish pepper, fruits (particularly plums, for the sake of the brandy prepared from them, called *Slivovitza*), wines of different kinds, wood, gall-nuts, potash, tobacco, hemp, flax, hops, saffron, woad, madder, sumach, cotton, and rhubarb are among the products of Hungary.

Many improvements are made by individual proprietors, and Hungary has a large number of technical institutes in which students are thoroughly trained in agriculture. Next to France, Hungary is the chief wine-producing country of Europe, both as regards the quantity and the variety of the product. The annual produce of Hungary and the connected territories is estimated at between 26,000,000 and 27,000,000 eimers, of about 15 gallons each. The finest variety is the Tokay, which is produced in the Hegyallya, in the county of Zemplin.

Horses, cattle, sheep, hogs, game (in the north bears), poultry, fish (among which the sturgeon and salmon, *Salmo dantex*, are the principal), bees, and silkworms are among the productions of the animal kingdom.

The principal artisans are tanners, furriers, manufacturers of *tschism* (cordovan boots), lace-makers, harness-makers, makers of wooden wares, of straw-plait work, etc. There are few extensive manufactures in Hungary. There are numerous iron and steel works, some iron-foundries, tin-plate and wire works; also potteries, glass manufactories, sugar-refineries and beet-root sugar works, soap-works, tallow, stearine, and wax-candle works; soda, saltpeter, and potash works, and brandy distilleries. Trade is almost exclusively in the hands of the Germans, Greeks and Jews. Internal commerce is promoted by the railways and rivers, the Temes and Francis canals (the former 75, the latter 60½ miles long), the fairs (which amount to 2,000), and the complete absence of tolls. The railways in 1901 had a total length of 10,794 miles, 4,876 miles being state lines; 3,439 worked by the state, and the rest private commercial lines. The total length of navigable rivers and canals in the monarchy is over 3,000 miles. The Danube is the most important highway of traffic, but the foreign trade by it is comparatively small. Inland navigation and roads are given careful attention.

The great number of distinct races with entirely different habits which is found in Hungary is remarkable. According to the census of 1900 on the basis of language, the races inhabiting Hungary including Croatia and Slavonia were divided as follows:

Magyars	8,679,014
Rumanians	2,785,265
Germans	2,114,423
Slovaks	2,008,744
Croatians	1,667,377
Servians	1,045,550
Ruthenians	427,825
Various	526,401
	19,254,599

The Magyars, who are the dominant race, are located for the most part in the centre of the kingdom. They are high-spirited, brave, warlike and generous, and, according to travelers, more sincere than their Servian and Wallachian neighbors; impatience of control, pride, indolence, and ignorance are their besetting faults. Their general deportment is serious; and in many respects they resemble the Turks, who followed them out of Asia, and belong to the same great family of mankind. The Magyar costume is remarkable for its picturesque elegance. Most of the Hungarian nobles are Magyars; and it is by this section of the population that the constitutional form of government and municipal institutions have been mainly, if not wholly, upheld. The Slovaks are among the people apparently the earliest settled in Hungary; they inhabit the northwest, and are similar in race, customs, and language to the adjacent Moravians, to whose extensive empire they belonged before the Magyar conquest. The Ruthenians or Rusniaks dwell beneath the north and northeastern Carpathians. The Rumanians (Wallachians) occupy a tolerably wide tract of country on both sides of the west and north boundaries of Transylvania. They are far behind the Slovaks, and, indeed, nearly all the other nations of Hungary, in education and civilization. They appear to be the descendants of Italian colonists, placed in Dacia during the Roman dominion there, and have been accordingly called Daco-Romans — an epithet to which their classic features, easy manners, language, and antique costume seem to give them a claim. They call themselves *Romouni;* and speak a dialect of Latin, but they write it with the Cyrillian or Russian character. In this last particular they unite with their Servian neighbors inhabiting the Banat on their southwest. The Croats people nearly all Slavonia and Croatia, and stretch into seven of the counties of Hungary proper as far as the county of Pesth. The Wends (Vandals) inhabit two counties of Hungary proper as far as the county Theresianopel, and a few other parts of the Banat; the Montenegrins a part of the county Temes; and the Armenians portions of three of the eastern counties. The Germans appear, in the first instance, to have emigrated into the country during or before the 7th century, subsequently to which many successive immigrations took place, especially under Geysa, king of Hungary, who ascended the throne 1141 A.D. and who established large numbers of German colonists from Franconia, Thuringia, and Alsace in several of the northern counties, and in Transylvania. They speedily became dispersed in detached settlements over all Hungary; and early in the 13th century Pesth was described as a "large and rich German town." In the 18th century other Teutonic immigrants, with some French refugees, settled in the kingdom. The Germans are marked by their industry and thrifty condition, but also, it is said, by their litigious and avaricious propensities. They people the greater part of the western frontier, from Presburg and around the shores of Lake Neusiedler south nearly to the limit of Croatia; elsewhere they are most numerous in the county of Zips, the mining districts, the Banat, and especially in the towns, where they compose the bulk of the trading population.

With regard to popular education, attendance in elementary schools is compulsory from the completion of the sixth year (in Croatia and Slavonia the seventh) till the completion of the twelfth, and also in continuation-schools up to the age of 15. Every parish or commune is also bound to maintain an infant school. The great bulk of the schools are supported by the denominations. Besides gymnasiums and real-schools there are numerous technical schools for arts and industries of all kinds. There are universities at Budapest, Klausenburg, and Agram, attended by over 6,000 students. Over two thirds of the periodicals issued are in the Magyar language. The various religious bodies have long enjoyed equal rights in Hungary and Transylvania.

The civil population according to religion, on the basis of the census of 1900, comprised Roman Catholics 9,846,533, over 51 per cent; Greek Catholics 1,843,634; Greek Oriental 2,799,846; Evangelical Augsburg, 1,280,070; Evangelical Helvetian 2,423,818; Unitarians 68,005; Jews, 846,254; others 14,180.

The Roman Catholic clergy are powerful by reason of their large landed property, and the influence they possess over the appointments to many offices. There are three Roman Catholic

archbishops and 17 suffragan bishops, with a Greek (United) Catholic archbishop and five suffragan bishops. Among the Protestants, laymen and clergymen united manage the affairs of the different congregations under the direction of superintendents. Lutherans and Calvinists have each four superintendents in Hungary and one in Transylvania.

A sketch of the Hungarian constitution has already been given in the article AUSTRIA. Hungary is divided into counties and districts, according to a very old division of the country. These have the right to administer their own internal affairs. At the head of each is an *Obergespann* (or lord-lieutenant) and two *Vice gespanne*. There are three county courts in civil cases, according to the importance of the subject in question, consisting either of a judge with a jury, or of the vice-officer of the county with a judge and jury, or of the supreme tribunal of the county (*Sedes Judicaria, Sedria*), which also revises the decisions of the two other courts and of the seignorial courts. The courts of appellate jurisdiction are the Royal Table (which, however, in several cases has original jurisdiction) and the Table of the Seven. The former sits in Budapest and the latter in Agram. They are both comprised under the name of *Curia Regia*, the sentences of which have the force of law in case there is no positive law.

History.— The nations which occupied parts of Hungary before its conquest by the Magyars were the Dacians, Bastarnæ, Illyrians, Pannonians, Sarmatians, Vandals, Bulgarians, Jazyges, Alans, Huns, Marcomanni, Longobards, etc. The Romans held the southwest part of the country under the name of Pannonia, while the southeast belonged to their province of Dacia. Various Slavic tribes, together with Wallachians, Bulgarians, and Germans, were the chief occupants at the time of the Magyar invasion. The Magyars, a warlike people of Turanian race, had made various migrations, and long dwelt in the vicinity of the Caucasian Mountains, and afterward in the region between the Don and the Dniester, before they approached and crossed the Carpathians (about 887) under the lead of Almos, one of their seven chiefs (*vezér*), and elected head (*fejedelem*) or duke. Arpád, the son of Almos, conquered the whole of Hungary and Transylvania, organized the government, and also made various expeditions beyond the limits of these countries. These incursions were extended under his son Zoltán (907–46) and grandson Taksony (946–72), as far as the German Ocean, the south of France and Italy, and the Black Sea. These formidable enemies were first defeated by Henry I., the German emperor, at Merseburg in 933; they then invaded Franconia in 937, and Saxony in 938, were defeated at Stederburg, and also on the river Ohre. Their last incursion into Bavaria (954 and 955) terminated with their complete overthrow on the Lech, where Otho I., king of the Germans, conquered them. They gradually learned from the Slavonians and Germans whom they conquered, and from the prisoners whom they had taken in their incursions, the arts of peace, agriculture, and manufactures. The hospitality of Geysa (972–97), and the religious zeal of Sarolta his wife, did much to attract strangers from different countries and of all classes into Hungary. The Hungarians violently opposed the introduction of Christianity, and Geysa was obliged to leave the extension of it to his son Stephen (997–1038), who finally prevailed by the assistance of Latin monks and German knights. King Stephen granted a constitution, the principal features of which were never lost, but the unsettled state of the succession to the crown, and the consequent interference of neighboring princes and of the Roman court in the domestic concerns of Hungary, long retarded the prosperity of the country. The religious zeal and bravery of St. Ladislaus (1077–95),) and the energy and prudence of Coloman (1095–1114), shine amid the darkness of this period.

The introduction of German colonists from Flanders and Alsace into Zips and Transylvania by Geysa II. (1141–61) had an important influence on those districts. In 1186 Hungary became connected with France by the second marriage of Béla with Margaret, sister to Henry, king of France, and widow of Henry, king of England, who introduced French elegance at the Hungarian court. The reforms of Béla IV. (1235–70) were interrupted by the invasions of the Mongols (1241), and the kingdom was in a most deplorable condition. With Andrew III. (1290–1301) the male line of the Arpád dynasty became extinct, and the royal dignity became purely elective. Charles Robert of Anjou, by his mother a descendant of the extinct dynasty, was the first elected (1309). The reign of his descendant Sigismund (1387–1437) is interesting from the invasion by the Turks (1391) and the war with the Hussites. From their first appearance the Turks constantly disturbed the tranquillity of Hungary, which served as a bulwark to the rest of Europe. The death of Ladislaus I., in the unfortunate battle of Varna (1444) is to be regretted, as the plan of the hero John Huniades, for driving the Turks from Europe, failed through the coldness of the Christian courts and the intrigues of his enemies.

Matthias Corvinus (1458–90), son of Huniades, held the reins of government with a firm hand, and gained the love and confidence of the nation, notwithstanding the severe measures which he was often compelled to adopt.

During the reigns of Ladislaus II. (1490–1516) and Louis II. (1516–26) the ambition and rapacity of the optimates, headed by Stephen Zapolya, and afterward by his son John, excited domestic troubles and caused an insurrection of the peasants, which was only suppressed by the severest measures (1514), while they destroyed the foreign influence of the kingdom. The battle of Mohács (1526), in which Louis II. lost his life, and which for 160 years made a great part of Hungary a Turkish province, was the natural consequence of this state of things. The rest of the country was in dispute between the rivals Ferdinand of Austria and John Zapolya. The contest was decided by the Protestants, who, fearing the persecution of Zapolya, declared for Ferdinand. Their adherence gave him the superiority, and Zapolya was compelled to rest satisfied with the possession of Transylvania and some counties of Upper Hungary; but this division of the kingdom caused continual disputes with the descendants of Zapolya, instigated by the Turks and the French, gave rise to civil commotions, which were quicted by the treaties

of Vienna with Stephen Botskay (1606), of Nikelsburg with Gabriel Bethlen (1622), and of Lintz with George Rakoczy (1645). These circumstances delayed the expulsion of the Turks, in which Leopold I. finally succeeded so far that he took Buda (1686), and by the Peace of Carlowitz (1699) recovered the rest of Hungary (except the Banat) and Transylvania.

The Congress of Passarowitz (1718) restored the Banat to Hungary, and the Peace of Belgrade (1739) terminated hostilities with the Porte for a long time. Charles VI. (1711–40) by the pragmatic sanction secured the inheritance of the Hungarian crown to the female descendants of the house of Hapsburg, and improved the administration of the kingdom by giving the royal chancery and the vice-regal office an organization better suited to the age. He also formed a standing army for Hungary, and established the military contribution for its support. Joseph II. (1780–90), one of the greatest sovereigns of his age, was influenced by the best intentions in the changes which he undertook in the Hungarian constitution; but his zeal made him forget the necessity of proceeding gradually in such reforms, and the nation, far from entering into his views, opposed them.

The subsequent history of Hungary — the adoption of the Magyar language in its diet; the resistance against the encroachments of Austria; the heroic struggles for independence, and the noble work of Batthyani, Deak, Kossuth, and Klauzal, along these lines; the disastrous war of 1848 and the reduction of Hungary to the position of an Austrian crown-land; its rehabilitation to independence in 1867 and the constitution of the dual Austro-Hungarian Empire, are described under Austria. See paragraphs *Austria under the House of Hapsburg-Lorraine*, and *Recent Politics*.

Hungarian Language.— The language of the Magyars, as spoken and written at present in Hungary, is a phenomenon in philology, disclosing rich stores for the philosophical historian and philologist. It is classed in the Ugric branch of the northern division of the Turanian family of languages, and as such is most closely allied to the Ostiak, Vogulic, and Mordvinic, though it is also nearly akin to the Finnish and the Turkish. Differing from all the cultivated languages of Europe in internal structure and external form, the Hungarian nevertheless was obliged to express with the Roman alphabet, adopted with Christianity, all the Asiatic shades of sounds. The alphabet contains the following 26 simple and 6 compound sounds, pronounced as in Italian, except where otherwise marked:— 8 vowels: *a* (like *a* in what, swallow), *e* (=*é* French), *i* and *y*, *o*, *u*, *ö* (= French *eu* or German *ö*), *ü* (French *u*); 18 consonants: *b*, *d*, *f*, *g*, hard *h* (German), *j* (German), *k*, *l*, *m*, *n*, *p*, *r*, *s* (English *sh*), *t*, *v* (also *w*), *z* (French), *sz* (English *s*), *zs* (or *ś*, French *j*); 4 compounds with *y*: *gy* (pronounced *dy*, *gyar*, factory, pronounced *dyar*, in one syllable), *ly* (French liquid sound as in *fille*), *ny* (French and Italian *gn*), *ty*; and two compound sibilants: *cs* (written also *ch* and *ts* = English *tch*), and *cz* (English *ts*). If we add the long vowels, marked with the acute accent, *á*, *í*, *ó*, *ő* (long *ö*), *ű*, *ü* (long *ü*), we have 38 sounds in all, besides *x*, which is used in foreign names. The Hungarian has adopted a good many Slavic, Latin, German, Greek, and other foreign words; but it still retains the essential characteristics of its grammar and phonology. As in the other Turanian languages the root is never obscured in words, whatever changes they undergo. Determining or modifying syllables are placed at the end, and have a double form, always taking a different vowel when attached to a sharp-vowel root from what they have when attached to a flat-vowel root. This is a general characteristic of the Turanian languages. These suffixes represent the case-endings of nouns and the conjugations of verbs in other languages, and are very numerous. Hungarian is destitute of diphthongs. At the beginning of a syllable the Hungarian never allows more than one consonant; in foreign words which begin with two consonants, the consonants are made to go with different syllables by putting a vowel before them (for example, of *schola* they make *iskola*), or a vowel is put between (as from *král* they make *király*). In common with the other languages allied to it, it has no distinction of sex whatever. Family names are considered as adjectives, from which they mostly originated, and hence are put before the baptismal name; for instance, Bátori Gábor (Gabriel Bátori), as if it were the Batorish Gabor, the Gabor of the Batori family. The beautiful proportion between vowels and consonants, the accurate shadowing and full articulation which every syllable requires (the Hungarian suffers no mute vowels), and the fixed succession of vowels, give to the Hungarian language a character of masculine harmony, in which it will bear a comparison with any other. The richness and expressiveness of its various forms give it great energy; the regularity of its inflections and compositions, in which it is to be compared with the Sanskrit, makes it clear and distinct, and its infinite power of composition gives it the means of increasing its stores beyond almost any western language.

Hungarian Literature.— The preference given to Latin over the national language, not only in the church, but in judicial proceedings, legal documents, and forms prevailed until past the middle of the 19th century. The use of a dead language in common life, as well as on all scientific subjects, could neither be advantageous to the language itself, to the general improvement of the people, nor to the national literature. Despite these disadvantages, some buds of literature from time to time unfolded themselves, and native genius, notwithstanding its chains, would sometimes attain distinction. Though with the introduction of Christianity into Hungary the Latin language acquired the ascendency in the church, in schools, and public affairs; yet Hungarian was used in commerce, in the camp, and even the resolutions of the diet were first drawn up in Hungarian. When the missionaries addressed the people in Latin an interpreter was usually present; and there are several relics of poetry, sacred eloquence, and state papers extant in Hungarian. A new impulse was given to this language on the accession of the house of Anjou to the throne of Hungary. The Latin was indeed still the language of church and state; but the Hungarian became the language of the court. Documents were drawn up in Hungarian, and the Hungarian oath, in the Corpus Juris Hungariæ, dates from this time. The Holy Scriptures were translated into Hungarian; in the imperial

library, Vienna, there is a manuscript translation of 1832; and several other translations were published. In 1465 Janus Pannonius wrote a Hungarian grammar, which is lost. The 16th century was favorable to Hungarian literature, through the religious disputes in the country, the sacred, martial, and popular songs, as well as by the histories written and published for the people, and the multiplied translations of the Bible. It then reached a degree of perfection which it retained until the latter part of the 18th century. Among writers of ballads or metrical tales belonging to the 16th century may be mentioned Tinódi, Kákonyi, Tsanádi, Valkai, Tserényi, Szegedi, Illésfalvi, Fazékas, Balassa, etc. A higher aim was manifested by the epic poems of Count Niklas Zrinyi (1652), Ladislaus Lissthi (1653), Christopher Paskó (1663), Count Stephen Koháry (1699), and in particular the numerous and excellent productions of Stephen von Gyöngyösi (1664–1734), as well as the lyric poems of Rimai, Balassa, Benitzky, etc. In 1653 an encyclopædia of all the sciences, and in 1656 a work on logic, were drawn up in the Hungarian language by John Tsere (Apátzai). A large number of grammars and dictionaries were printed from the 16th century to the 18th. But the hopes of the further development of Hungarian literature were not realized; a Latin period again succeeded, from 1700 to 1780, during which time numerous and finished works were composed in Latin by Hungarian writers. In 1721 a Latin newspaper was established, and the state calendar, which commenced in 1726, was regularly published in Latin. In 1781 the first Hungarian newspaper was printed in Presburg.

After Joseph II. died (1790) many violent yet bloodless changes were made in the Hungarian constitution, and several laws were passed in favor of the Hungarian language. It was required to be used in all public proceedings. Courses of lectures were delivered in Hungarian in some of the schools, and it was taught in all of them. Several periodicals were established, Hungarian theatres erected in Buda and Pesth, many works were written both in poetry and prose. The modern period of Hungarian literature may be said to date from the time of Joseph II. The epic poem of Arpád was written by Andrew Horváth, and published at Pesth in 1830. The brothers Alexander and Charles Kisfaludy acquired a great and deserved reputation as poets and dramatists, and did much toward developing the national language and literature. The latter (who died in 1830) may be looked upon as the founder of the modern drama in Hungary. The most celebrated works of the former are his lyrical masterpiece, 'Himfy Szerelmei' (Himfy's Love, 1807), his 'Regék a Magyar elöidöböl' (Tales of the Early Hungarian Times), and his historical tragedies, which were partly modeled on those of Schiller. The development of the Hungarian literature owes much to the influence of the periodical press, which spread abroad a taste for literature at the same time as it intensified the sentiment of nationality among the people. In this department the name of Kossuth deserves honorable mention. Previous to the troubles of 1848–9, which checked for a time the natural growth of the literature, almost every species of composition was successfully practised. Works on politics and narratives of travel were written by Eötvös, Szechényi, Szalay, Szemere, etc.; on history by Stephen and Michael Horváth, Szalay and Jaszay; on philology by Fogarassy and Bloch; works on the exact sciences, however, were confined to translations from the German, French, and English. Novels and romances were written by Baron Jósika, Eötvös, Kemény, Kuthy, Nagy, Pálffy, etc., which, though of no great originality, showed considerable artistic skill, and helped to diffuse a more correct style. The dramatic pieces of Eötvös, Obernyik, Vörösmarty, and the prolific Szigligeti — who for a long time had almost the exclusive possession of the national stage — have greater value and originality. It is in poetry, strictly so called, however, that modern Hungarian literature shines. Many of the poems (songs, ballads, etc.) of Czuczor, Vörösmarty, Bajza, Garay, Bachot, Szász, Erdélyi, Kerény, and others, are among the finest things that modern literature has produced. In this field the palm must be awarded to Alexander Petöfi, who completely freed Hungarian poetry from its dependence on foreign models and subjects, and inspired it with a life drawn fresh from nature and national feeling; and who, in artistic skill and masterly handling of his mother tongue, ranks as a model. Tompa, Hiador, Lisznyai, and others, have copied him with more or less success. The collection of ancient Hungarian national poetry, compiled and edited by John Erdélyi, at the instance of the Kisfaludy Society (three vols., Pesth, 1845–7), contributed greatly toward bringing back the modern poetry to nature and originality, and to impress upon it the stamp of nationality. The ill success of the revolutionary struggle seemed for a time to have dealt a heavy blow to the progress of Hungarian literature, the most gifted writers having either fallen in battle (as Petöfi), or been imprisoned or banished. Time, however, opened the prisons and brought back the exiles; to the writers already mentioned others were added, and an active literary life again began. The greatest recent Hungarian poet is John Arany, who surpasses even Petöfi in artistic feeling, and whose national epic, 'Toldi,' is looked upon as a masterpiece. Baron Jósika holds the first place among the novelists; Jokai, Kuthy, Bérczy, Pálffy, Miksrath, and Dobzsa are also favorite fiction writers. Narratives of travel have been written by Count Andrassy, Ladislaus Magyar, Vámbéry, etc.; on politics by Esengery, Szalay, Pákh, and Eötvös. National history has attracted much attention; and besides the works of Szalay and Horváth, we should mention Teleki's 'Age of Hunyad,' Jászay's 'Hungary after the Battle of Mohács,' Salomon's 'The Rule of the Turks in Hungary,' etc. Many excellent translations of modern foreign works have been made, some of which, such as Esengery's translation of Macaulay's 'History of England,' and Somssich's translation of Guizot's 'Histoire de la Révolution d'Angleterre,' rival the originals in style. The best works on Hungarian literature are those of Toldy, some of which have been translated into German.

Hunger. See APPETITE; DIGESTION; FASTING; FOOD.

Hungerford, hŭng'gėr-fōrd, **Margaret Hamilton Wolfe Argles** ("The Duchess"), Irish novelist: b. Ross, Ireland; d. Bandon, County Cork, 24 Jan. 1897. She was the daughter of a vicar choral of Cork Cathedral and the death of her first husband, Edward Argles, left her with a young family to support, whereupon she took to writing novels, using the pseudonym "The Duchess." Later she was married to T. H. Hungerford. Her more than 30 novels were widely popular both in America and England and without possessing a large amount of literary value are cleverly written, entertaining fictions. Among them may be cited: 'Phyllis' (1877); 'Molly Bawn' (1878); 'Airy Fairy Lillian' (1879); 'Beauty's Daughters' (1880); 'Mrs. Geoffrey' (1881); 'Portia' (1882); 'O Tender Dolores' (1885); 'Green Pastures and Gray Grief' (1886); 'A Modern Circe' (1887); 'The Duchess' (1887); 'Undercurrents' (1888); 'Hon. Mrs. Vereker' (1888).

Hunk'ers (supposably from Dutch *honk*, "post" or "station;" "stick-in-the-muds"), in American politics, at present a contemptuous nickname, like "moss-backs," for the unprogressive elements of a party, which detest change. Originally, a name given about 1844 to the section of the New York State Democrats which opposed new issues: the points for which it then stood, however, had become party tenets from about 1835. Thence till 1840 the Hunker faction was in opposition to the Locofoco wing (q.v.) which opposed bank charters; but was obliged to yield in 1838. From 1840 to 1846 they oposed the Radicals, who wished a revised State constitution, elective judges, and cessation of State canal building. Thence till 1852 they opposed the Barnburners (q.v.), who, at first separately and then in alliance with the Free-Soil Party (q.v.), fought the national Democratic Party for recognition of its State power. After the election of Pierce in 1852, it divided into "hards" and "softs"; the first under Daniel S. Dickinson opposed the administration, the second under William L. Marcy supported it. The former made up the bulk of the "War Democrats" after 1861. Besides those named, Horatio Seymour is the best remembered Hunker leader; while the opposition has the familiar names of Martin Van Buren, Silas Wright, and John A. Dix, besides others remembered by the older generation.

Hunneus, ŭn-nā'ŭs, **George,** Chilean statesman: b. Santiago, Chile, 1831. He was graduated at the university of his native town in 1857, and became professor of political economy and jurisprudence at the same institution the following year. Montt, president of Chile, drove him out of the country on account of his liberal opinions, which he found carried into actuality in the government of the United States, where he spent his time of banishment. He was recalled to his native land in 1861, was elected to the House of Representatives and became its speaker. He was also appointed secretary of public instruction and is now rector of Santiago University, while holding from time to time high positions in the Chilean administration.

Hun'newell, James Frothingham, American bibliographer, and historical writer: b. Charlestown, Mass., 3 July 1832. He has written: 'Historical Monuments of France' (1884); 'The Imperial Island: England's Chronicle in Stone' (1886); 'A Century of Town Life' (1886); 'The Lands of Scott' (1871).

Huns, a people who make their appearance in authentic history about 375 A.D. Ethnologists identify them with a Mongolian people of Northern Asia, who invaded the Chinese Empire about 200 B.C., and after various migrations entered Europe. They appear afterward to have sided with the Goths of Mœsia against the Romans, and sometimes in alliance with the emperors, who purchased their services, and sometimes in hostility with them, they continued to extend their dominion along the Danube until the time of Attila (434), their greatest leader, whose reign constitutes the best-known period of their history. See Attila.

Hunt, Helen. See Jackson, Helen Fiske Hunt.

Hunt, Henry Jackson, American soldier: b. Detroit, Mich., 14 Sept. 1819; d. Washington, D. C., 11 Feb. 1899. He was graduated from West Point in 1839, receiving a commission in the artillery. He saw service in the Canadian rebellion 1837–8; afterward in the Mexican War. In General Scott's advance on the city of Mexico he distinguished himself as officer of the artillery at Contreras (18 Aug. 1847) and Churubusco (20 Aug. 1847) and subsequently received the brevet rank of major for his gallantry. In 1856 he was placed on the board engaged in revising the system of light artillery tactics. At the outbreak of the Civil War he was stationed at Fort Pickens, Fla., 1861, and the same year commanded the artillery at the battle of Bull Run, and in the defense of Washington during the summer of the same year. The September following he served on General McClellan's staff with the rank of colonel. He subsequently organized and commanded the reserve artillery of the Army of the Potomac. As commander of artillery he was present at the battle of Malvern Hill (1 July 1862) where his disposition of the artillery was especially commended, and he also took part in the battle of South Mountain, after which he maintained his position as commander of artillery in the Army of the Potomac until the end of the war. He was brevetted brigadier-general of volunteers in 1862, and was present at the battles of Antietam, Fredericksburg, Chancellorsville, and Gettysburg, where the fire of his artillery rendered futile the stubborn valor of the Confederate troops, and turned to flight the brilliant charge of Pickett. He served with distinction in the Wilderness campaign and at the end of the war retired from his position with the rank of brigadier-general in the United States army. In 1866 he received the commission of colonel in the reorganized army, and in 1883 became governor of the National Soldiers' Home at Washington. Among his writings are: 'Instruction for Field Artillery' (1860); 'Battles and Leaders of the Civil War'; 'The Battle of Gettysburg.'

Hunt, James Henry Leigh, English poet and essayist: b. Southgate, Middlesex, 19 Oct. 1784; d. Putney, Surrey, 28 Aug. 1859. He was educated at Christ Church Hospital, entered the office of his brother, an attorney, and afterward obtained a situation in the war office. In 1808,

with his brother John, he started the 'Examiner' newspaper, which soon became prominent for the fearlessness with which public matters were discussed. Ere long official resentment took shape in two prosecutions of the brothers, the second of which, occasioned by an article in the paper of 22 March 1812, reflecting on the character of the prince regent, resulted in the brothers being sentenced to pay a fine of £500 each, and to suffer two years' imprisonment. During this time Hunt wrote several works, among which are the 'Feast of the Poets'; the 'Descent of Liberty'; and the 'Story of Rimini.' In 1818 appeared 'Foliage,' a collection of original poems and translations from Homer, Theocritus, Bion, etc.; and in 1819 the 'Indicator' was started, a weekly journal on the model of the 'Spectator,' which contained some of Hunt's best essays. In 1822 he proceeded to Italy, having received an invitation thither from Byron and Shelley, and, with the former, carried on a newspaper called the 'Liberal,' but it proved unsuccessful. On his return to England Hunt published 'Recollections of Lord Byron and some of his Contemporaries' (1828). Among his subsequent works may be mentioned, 'A Legend of Florence,' a play presented with some success at Covent Garden in 1840; 'Stories from the Italian Poets' (1846); 'Men, Women, and Books' (1847); 'A Jar of Honey from Mount Hybla' (1847); 'The Town, its Memorable Characters and Events' (1848); 'Autobiography' (1850); 'Table Talk' (1850). In 1847 a government pension of £200 a year was bestowed on him.

Hunt, Leigh. See HUNT, JAMES HENRY LEIGH.

Hunt, Richard Morris, American architect: b. Brattleboro, Vt., 31 Oct. 1828; d. Newport, R. I., 31 July 1895. He began the study of architecture in Europe at an early age, attended the Ecole des Beaux-Arts in Paris, traveled in Germany, Italy, Asia, and Egypt, and under his former teacher, Lefuel, was clerk of the works on the buildings that were erected to connect the Tuileries with the Louvre. In 1855 he returned to the United States and immediately proceeded to signalize himself by a remarkable series of noble architectural creations, such as the Capitol extension at Washington, the Lenox Library, New York, the Yorktown Monument, Va., etc. He also designed the pedestal for Bartholdi's colossal statute of 'Liberty Enlightening the World' on Bedloe's Island, New York harbor. Some of the finest private houses in the country were built by him on a truly palatial scale of magnificence, such as that of W. K. Vanderbilt's in New York; the country house of George Vanderbilt, at Biltmore, N. C.; the so-called 'Marble House' and the 'Breakers' at Newport. He was one of the founders and served as president of the Institute of Architects, and through his artistic and structural faculty exercised a profound influence over American architecture, which is still felt in the traditions he has bequeathed to many distinguished pupils.

Hunt, Theodore Whitefield, American Presbyterian clergyman and educator: b. Metuchen, N. J., 19 Feb. 1844. He was graduated from Princeton 1865 and from Princeton Theological Seminary 1869, was instructor in English at Princeton 1868–71 and has been professor of English there from 1873. He has published 'The Principles of Written Discourse' (1884); 'English Prose and Prose Writers' (1887); 'Studies in Literature and Style' (1890) 'Ethical Teachings in Old English Authors' (1892); etc.

Hunt, Thomas Sterry, American chemist and geologist: b. Norwich, Conn., 5 Sept. 1826; d. New York 12 Feb. 1892. In 1845 he became an assistant to the elder Silliman at Yale College; was chemist and mineralogist to the Canadian Geological Survey 1847–52, professor of chemistry at Laval University 1856–62, and at McGill University 1862–68, and professor of geology in the Massachusetts Institute of Technology 1872–8. In organic chemistry his name is identified with a system his own to all intents, and his researches into the structure of rocks were of the greatest value. In 1859 he invented the green ink with which greenbacks (q.v.) are printed. He was made an officer of the Legion of Honor in 1867, Fellow of the Royal Society in 1859, and was president of the Royal Society of Canada in 1884. Among his published books are 'Chemical and Geological Essays'; 'New Basis for Chemistry'; etc.

Hunt, William Henry, American lawyer: b. New Orleans, La., 5 Nov. 1857. He was educated at Yale, became attorney-general of Montana in 1884; and held various public offices there after Montana became a State. He was for a time United States agent before the Chilean Claims Commission, but resigned that post in 1900 to become secretary of Porto Rico, and in July 1901 succeeded Charles H. Allen as governor of that island. On 1 July 1904 he was succeeded by Gov. Winthrop.

Hunt, William Holman, English Pre-Raphaelite painter: b. London 2 April 1827. He entered the schools of the Royal Academy in 1845, and next year he exhibited his first picture, 'Hark!' representing a child holding a watch to her ear. About 1848 Hunt, D. G. Rossetti, and J. E. Millais formed the Pre-Raphaelite Brotherhood, afterward enlarged by the admission of other painters and writers, and which attained a position of great influence through the eloquent support of Ruskin. Each of the three founders exhibited in 1849 a picture painted in strict accordance with the principles of the Brotherhood. Hunt's picture represented 'Rienzi Vowing to obtain Justice for the Death of his Younger Brother Slain in a Skirmish between the Colonna and Orsini Factions,' and was exhibited at the Royal Academy. The exhibition of 1854 included two of his greatest pictures, one of them the well-known 'Light of the World.' Both it and 'The Awakening Conscience' are characterized by the careful draughtsmanship and attention to detail which form notable features of the best Pre-Raphaelite work, but their full meaning is far from clear to the average spectator. In 1854 Mr. Hunt went to Palestine in order to obtain a living acquaintance with the scenes of the Biblical stories, and the first fruits of his study of Eastern life was 'The Scapegoat' (1856), one of his most original and most poetical works; but much finer is his 'Finding of the Saviour in the Temple,' exhibited in 1860. Among subsequent works of Hunt's are: 'A Street Scene in Cairo — the

Lantern-Maker's Courtship' (1861); 'Portrait of D. G. Rossetti' (1850); 'Fairlight Downs' (1858); 'The After-Glow in Egypt' (1865), "that modern masterpiece of technical art"; 'Isabella, or the Pot of Basil' (1868), based on the well-known story from Boccaccio utilized by Keats, and in respect of coloring, the finest of the artist's works; 'The Shadow of Death' (1873), showing a prevision of the Crucifixion in the carpenter shop where Jesus is working beside his mother; 'The Triumph of the Innocents' (1885), one of his masterpieces; 'Christ among the Doctors' (1860). See biography by Farrar and Meynell (1893); Williamson, 'Life of Holman Hunt.'

Hunt'er, David, American soldier: b. Washington, D. C., 21 July 1802; d. there 2 Feb. 1886. He was graduated at West Point in 1822, became captain in 1833, and resigning from the army in 1836 settled in Chicago. He, however, re-entered the army in 1842 as paymaster with the rank of major, and in May 1861 was appointed brigadier-general of volunteers, and a few months later major-general. He recruited and organized in South Carolina the first negro regiment in the Union army. He defeated the Confederates at Piedmont, 5 June 1864, and was chairman of the military commission which tried the conspirators engaged in the assassination of President Lincoln. He was brevetted major-general United States army, 13 March 1865, and retired on account of age in 1886.

Hunter, John, British surgeon and physiologist: b. Long Calderwood, Lanarkshire, 13 Feb. 1728; d. London 16 Oct. 1793. He was a younger brother of William Hunter (q.v.) In 1749 and 1750 he studied surgical pathology at Chelsea Hospital, London, and already began to make original observations, which his subsequent experience confirmed. In 1751 he attended St. Bartholomew's Hospital and in 1754 entered as a surgeon pupil at St. George's Hospital. In 1754 or 1755 he was admitted to a partnership in his brother's school of anatomy, and continued to lecture there till 1759. He served as staff-surgeon in France and Portugal 1760–3, and then returned to London and commenced practice as a surgeon. In 1767 he received an unexpected proof of the high estimation in which he was held by men of science in being elected a member of the Royal Society, and in 1768 he was appointed surgeon to St. George's Hospital. His investigations at this time extended over every branch of natural history, particularly pathology, comparative anatomy, and physiology, to which he devoted his entire leisure time. In 1790 he was appointed inspector-general of hospitals and surgeon-general to the army. Hunter left at his death a museum which he had built for himself, and filled with upward of 10,000 preparations illustrative of the departments of science to which his attention had been devoted. It was afterward purchased by government, and presented to the Royal College of Surgeons. In addition to papers contributed to the 'Transactions' of learned societies, his leading works are the 'Natural History of the Human Teeth' (1771); 'Treatise on the Venereal Disease' (1786); 'Observations on Certain Parts of the Animal Economy' (1786); 'Treatise on the Blood, Inflammation, and Gun-shot Wounds' (1794).

Hunter, Robert Mercer Taliaferro, American statesman: b. Essex County, Va., 21 April 1809; d. 18 July 1887. He was graduated at the University of Virginia, and, choosing the law for his profession, commenced practice in 1830. He soon began to take an active part in politics and at 24 was elected to the house of delegates, where he remained until 1837, when he was elected to Congress. In the discussions growing out of the commercial convulsion of that year, he at once took his stand on the side of the administration in favor of the independent treasury bill, and in his first speech developed those principles of free trade to which he consistently adhered throughout his public career. In the succeeding Congress he was elected to the speakership; and at the close of his term of service, the usual vote of thanks was passed without a dissenting voice, in a House of Representatives strongly marked by partisan bitterness. At the election in the spring of 1843 for members of the 28th Congress, Hunter was defeated by a small majority, mainly on account of his adherence to that clause of the independent treasury scheme requiring all dues to the government to be paid in specie. At the next congressional election in 1845, he was successful. In 1846 Hunter, in common with other southern representatives, resisted the application of the Wilmot Proviso. He voted for all the measures necessary to prosecute the war to a just and honorable conclusion, but altogether opposed the project, favored by some, of incorporating the whole of the Mexican states into our political system. During the winter of 1846–7 he was chosen by the legislature of Virginia to the United States Senate, and took his seat in December 1847, remaining there until 1861. He was active in framing the tariff act of 1857 and after leaving the Senate became the Confederate secretary of state. At a later period he was a Confederate senator and in 1865 commissioner of peace. He became treasurer of Virginia in 1877 and retired from public life in 1880.

Hunter, William, British anatomist: b. Long Calderwood 23 May 1718; d. London 30 March 1783. After studying at Glasgow University 1732–7, and subsequently medicine at Edinburgh, he went to London in 1741, and in 1746 received the appointment of lecturer on anatomy to a society of naval surgeons. In 1747 he became a member of the College of Surgeons, and practised surgery and midwifery, but at length confined himself entirely to that branch, and was appointed accoucheur to the British Lying-in Hospital. In the first volume of 'Observations and Inquiries,' published by the Medical Society in 1757, appeared Hunter's 'History of an Aneurism of the Aorta.' In 1762 he published 'Medical Commentaries,' and in 1764 was appointed physician-extraordinary to the queen. Hunter was elected a fellow of the Royal Society in 1767; and in 1768, on the establishment of the Royal Academy of Arts, he was appointed professor of anatomy. He was made a foreign associate of the Royal Medical Society at Paris in 1780, and of the Royal Academy of Sciences in 1782. The most elaborate of his publications, the 'Anatomy of the Human Gravid Uterus,' appeared in 1774. In 1770 he purchased and completed a house and theatre, in which he constituted a splendid museum. At

first he only contemplated a collection of preparations in human and comparative anatomy, but added a collection of shells, corals, and other objects of natural history, paintings and ancient coins and medals. He bequeathed the whole of his splendid museum, valued at £150,000, to the University of Glasgow, with the sum of £8,000 in cash to be expended in an appropriate building for its reception, and a further sum of £500 per annum to bear the charges of its preservation.

Hunter, Sir **William Wilson,** English statistician and author: b. Glasgow 15 July 1840. He was educated at the University of Glasgow and foreign universities, and appointed to the Bengal Civil Service in 1862. As director-general of statistics he made a statistical survey of India, the results of which are embodied in the well-known 'Imperial Gazetteer of India' (1881; 1885–7). He is also the author of 'Annals of Rural Bengal' (1868; 5th ed. 1872), continued in 'Orissa' (1872); 'The Life of the Marquess of Dalhousie'; 'A Dictionary of the Non-Aryan Languages of India and High Asia'; 'Brief History of the Indian Peoples,' which has been translated into five languages, and is the editor of the series of biographies known as 'The Rulers of India.' He was knighted in 1887.

Hunting, the sport or recreation of pursuing game, is a very ancient amusement. Alexander the Great is said to have paid a large sum of money for a treatise on hunting by Aristotle. The true sportsman rarely kills game for any other purpose than eating. The hunting of large game, as bear, deer, tigers, lions, leopards, etc., will be found treated under the titles by which they are described. In Europe the various methods of shooting game are known as open shooting, covert shooting, river and pond shooting, and salt-water wild fowl shooting. Deer-stalking (q.v.) and wild-boar hunting are favorite amusements of royalty in Europe; in India boar-hunting is commonly known as "pig-sticking." See Fox Hunting; Game Laws; Game Preserves, etc. Consult Dodge, 'Hunting Grounds of the Great West' (1877); Gasper, 'The Complete Sportsman' (1893); Mills, 'The Sportsman's Library'; Long, 'American Wild-Fowl Shooting' (1874); Murphy, 'American Game Bird Shooting' (1892); Pringle, 'Twenty Years' Snipe Shooting' (1899); Ramsford, 'Hunting' (1896); Roosevelt, 'Big Game Hunting' (1899); Ward, 'Records of Big Game' (1896).

Hunting-dog. See Hyena-dog.

Hun'tingdon, Selina Shirley, Countess of, English religious leader: b. 24 Aug. 1707; d. 17 June 1791. She was married in 1728, to the Earl of Huntingdon and on his death in 1746 became very devout, appointing the famous George Whitefield (q.v.) her private chaplain. Adopting the principles of the Methodists, she was long considered, owing to her rank and fortune, as the head of the Calvinistic Methodists, her followers being known as the "Countess of Huntingdon's Connection." She founded a College at Trevecca in Wales, for the education of ministers, built some 64 chapels, and contributed liberally to the support of the clergy.

Huntingdon, Pa., borough, county-seat of Huntingdon County; on the Juniata River, and on the Pennsylvania railroad; about 200 miles west of Philadelphia. Where Huntingdon is located was once a famous council ground for the Indians of the central part of Pennsylvania. It was first settled by white people in 1760, and was chartered in 1796. The country around is a fertile agricultural region, with valuable mineral deposits and quite extensive forests. The chief manufactures are boilers, machinery, radiators, sewer-pipe, flour, furniture, stationery, knit goods, and stoves. The trade is in the manufactures, and grain and fruits. Huntingdon is the seat of the State Industrial School, and of Juniata College, an institution opened in 1876 under the auspices of the German Baptist Brethren. The original charter is still in force and provides for a chief burgess, who holds office three years, and a council. Pop. (1900) 6,053.

Huntingdon's Disease, hereditary chorea. Chorea, or St. Vitus' dance, sometimes attacks adults, most frequently pregnant women. In such cases it is hard to distinguish from locomotor ataxia. The offspring of adults thus affected are likely to have congenital or hereditary chorea.

Hun'tington, Collis Potter, American capitalist: b. Harwinton, Conn., 22 Oct. 1821; d. Pine Knot Camp, near Lake Raquette, N. Y., 13 Aug. 1900. He worked on his father's farm, until his 14th year. In his 16th year he procured credit in New York for $3,000 worth of clocks, and peddled them through the South and West. He shipped goods to California in 1848; followed them in person in 1849 and began to make his fortune in the hardware business. In 1860 he matured a plan for a transcontinental railroad in conjunction with Leland Stanford, Charles Crocker, and Mark Hopkins. The Central Pacific was finished in 1869. This was the crowning achievement of his life, and at his death the railroad system known as the Southern Pacific, of whose managing board he was president, comprised 26 corporations, with more than 9,000 miles of tracks and 5,000 miles of steamship line. He was one of the largest landholders in the country and his fortune was estimated at $35,000,000. He built a granite church, to the memory of his mother, in his native town; gave C. W. Peale's portrait of Washington to the New York Metropolitan Museum; a library and reading-room to Westchester, N. Y., materially aided in building and equipping Hampton (Va.) Normal Agricultural Institute; and gave $50,000 for the endowment of Tuskegee (Ala.) Normal and Industrial Institute.

Huntington, Daniel, American painter: b. New York 14 Oct. 1816; d. there 18 April 1906. He was educated at Hamilton College, where he made the acquaintance of Charles L. Elliott, from whom he received a decided bias for his art. In 1835 he entered the studio of Professor Morse, president of the National Academy of Design, and soon after produced the 'Bar-room Politician'; 'A Toper Asleep,' besides some landscapes and portraits. In 1839 he went to Europe and in Florence painted the 'Sibyl' and the 'Florentine Girl.' Removing to Rome soon after, he painted the 'Shepherd Boy of the Campagna,' and 'Early Christian Prisoners,' both of which were

purchased by New York collectors. He became a member of the National Academy in 1840 and was its president in 1862 and 1869, and continuously from 1877 to 1899. He devoted himself mainly to portraits and among portraits by him of well known people are those of Presidents Lincoln and Van Buren, and of Sir Charles Eastlake. His noted 'Mercy's Dream' is now in the Corcoran Gallery at Washington.

Huntington, Frederic Dan, American Protestant Episcopal bishop: b. Hadley, Mass., 28 May 1819; d. Hadley, Mass., 11 July 1904. He was graduated at Amherst in 1839, and studied three years in the divinity school of Cambridge. In 1842 he was ordained pastor of the South Congregational (Unitarian) church in Boston, which he left in 1855 to become Plummer professor of Christian morals at Harvard. In 1860 he resigned and took orders in the Episcopal Church, founding Emmanuel Church, Boston, and serving as its rector 1861–9. In April 1869 he was consecrated bishop of Central New York. He has published: 'Sermons for the People' (1856); 'Christ in the Christian Year'; 'Helps to a Holy Lent' (1872); 'The Gospel and the People'; etc.

Huntington, Jedidiah Vincent, American author, brother of Daniel Huntington (q.v.): b. New York 20 Jan. 1815; d. Pau, France, 10 March 1862. He was educated as a physician, but in 1839 entered the Episcopal ministry, officiating for a short time as rector of an Episcopal church in Middlebury, Vt. In 1849 he became a Roman Catholic. His published works are: 'Poems' (1843); 'Lady Alice, or the New Una,' a novel (1849), which is the most popular of his works; 'Alban' (1850); 'The Forest,' a sequel to 'Alban' (1852); etc.

Huntington, Samuel, American jurist: one of the signers of the Declaration of Independence: b. Windham, Conn., 3 July 1732; d. Norwich, Conn., 5 Jan. 1796. He was educated to the law, and previous to 1775 held the offices of king's attorney and associate justice of the superior court of Connecticut. In January 1776 he entered the Continental Congress as a delegate from his native State. In September 1779 he succeeded John Jay as president of Congress, and discharged the functions of that office until July 1780, when he resumed his seat on the Connecticut bench. He served again in Congress from May to June, 1783, and in the succeeding year was appointed chief justice of the superior court of Connecticut. In 1785 he was elected lieutenant-governor of Connecticut, and in 1786 he succeeded Roger Griswold as governor, to which office he was annually re-elected until his death.

Huntington, William Reed, American Episcopal clergyman: b. Lowell, Mass., 20 Sept. 1838. After graduation from Harvard in 1859 he took orders in the Episcopal Church, was assistant at Emmanuel Church, Boston, 1861–2, rector of All Saints, Worcester, Mass., 1862–3, and since 1883 has been rector of Grace Church, New York. He has long been prominent in the councils of the Episcopal Church and is an acknowledged leader of the Low Broad Church school of thought.

Huntington, Ind., city, county-seat of Huntington County; on the Little River, and on the Chicago & E. and the Wabash R.R.'s; about 20 miles southwest of Fort Wayne and 70 miles southeast of South Bend. It was settled in 1834, incorporated as a town in 1834, and received its charter in 1873. The city has excellent water power. Its chief manufactures are bicycles, boots and shoes, pianos, plows, barrels, lime, and cement. It has railroad shops, and wood-working factories. The trade, in addition to the manufactures, is in coal and lime from the coal fields and lime-kilns nearby, and agricultural products. It is the seat of the United Brethren College. The public library has about 12,000 volumes. The city owns and operates the electric-light plant and the waterworks. Pop. (1900) 9,491.

Huntington, N. Y., town in Suffolk County on Long Island. It is on Long Island Sound and on the Long Island Railroad. Huntington originally included the village of Babylon and other adjoining places. As first laid out, the area was 150 square miles. The first settlement was made in 1653, and the first deed of land given to actual settlers was made on 2 April 1653, on behalf of the Matinecock tribe of Indians, and conveying to the whites six square miles between Cold Spring and Northport. The consideration paid was six coats, six kettles, six hatchets, six "howes," six shirts, 10 knives, six fathoms of wampum, 30 "muxes," and 30 needles. Additional lands were purchased in 1656–8. The early settlers were nearly all Puritans from England. The inhabitants of Huntington were among the first of the colonists to protest against "taxation without representation." From the first agriculture was the chief occupation; but trade with the West Indies began at an early date. In 1675 Thomas Fleet was listed as owning 40 vessels. Whales were often caught along the south coast. Nathan Hale (q.v.) was captured in Huntington. The place of capture is marked by a boulder, a shaft, and a drinking fountain. The town celebrated its 250th anniversary on 4 July 1903. The chief manufactures are pottery, brick, and dairy products. Large market gardens are in parts of the town, but much of it is a favorite residential suburb of New York. Pop. (1900) 9,483.

Huntington, W. Va., city, the capital of Cabell County, on the Ohio River, just below the confluence of the Guyandotte River, 18 miles above Ironton, 52 miles west of Charleston and on the Chesapeake & O., the Guyandotte Valley, and the Ohio River R.R.'s. The city, named after the late Collis P. Huntington, was founded and incorporated in 1871. It is an important commercial and industrial centre, has steamship communication with all the important river ports, and among its industrial establishments are the car manufacturing shops of the Chesapeake & Ohio railroad, foundry and machine shops, lumber and planing mills, manufactures of woodwork, paints, glass, stoves, bricks, and ice, bottling and meat-packing establishments, etc. The city is regularly laid out, has electric lights and street railways, two national banks, and is noted for its educational establishments which include Marshall College (the State Normal School), the Douglas High School for col-

ored students, and a Carnegie library. The West Virginia Asylum for Incurables is situated here. Pop. (1890) 10,108; (1900) 11,923.

Huntsville, Ala., city and county-seat of Madison County, on the Nashville, C. & St. L. and the Southern R.R.'s; 96 miles due north of Birmingham; 97 miles due west of Chattanooga; 125 miles south of Nashville, and 210 miles east of Memphis. The city is located in the heart of the famous Tennessee Valley, and is surrounded by a large and fertile agricultural, cotton, fruit, and stock-raising country, making it the most important commercial centre of this entire valley territory. In manufacturing it is fast reaching a position among the most important in the south. As a cotton manufacturing point it is to-day without a rival in all this section, and in spindles leads the South, and is second only to Lowell, Mass. Its nine cotton mills have 203,000 spindles, with 4,374 looms, the annual product of which amounts to $4,775,000. Besides these, Huntsville has machine and foundry shops, cottonseed-oil mills, hoop and heading factory, fibre factory, spoke and handle factories, saw and planing mills, brick plants, gas and electric plants, electric car lines, paid fire department, waterworks owned and operated by the city and supplied from a magnificent spring of purest water with a daily capacity of 2,400,000 gallons. The first settler here was John Hunt, a Virginian, and a soldier of the Revolution, who came to the "Big Spring" in 1805, built his cabin, the first, near by, and in 1806 went back to Tennessee and brought his family, having lived in that State before coming to Alabama. In 1811 the town was incorporated by the Territorial Legislature as "Huntsville." The first State constitutional convention sat here and framed the first constitution of the State, the convention convening 5 July 1819. The first legislature sat here and assembled on the first Monday in August 1820, and this was the first capital of Alabama. The city is well supplied with a number of private schools, and an excellent public city school with a new modern building erected at a cost of $25,000. Four miles north of the city is located the "Alabama Agricultural and Mechanical College for Negroes." The government of the city, under a new charter of 1897, is composed of a mayor and board of aldermen of eight, and it controls all of the city's affairs, including the waterworks. Pop. 16,000.

BENJAMIN POWEL HUNT.

Hunts'ville, Mo., city, county-seat of Randolph County; on the Wabash railroad; 130 miles northwest of Saint Louis and 145 miles northeast of Kansas City. It is situated in an agricultural and coal-mining region. Its principal industrial establishments are flour mills, machinery shops, rake and stacker factory. Its trade is chiefly in agricultural and mining implements, live stock, and farm products. Pop. (1900) 1,805.

Huntsville, Texas, city, county-seat of Walker County; on the International & G. N. railroad; about 200 miles southeast of Austin and 68 miles north of Houston. The first settlement was made about 1835. It is in a fertile agricultural region in which cotton is one of the large crops. The chief manufactures are cotton goods, cottonseed oil, cigars, steam-engines, foundry-products, agricultural implements, furniture, ice, corn-meal, and wagons. Here are the home and grave of Sam Houston, which are of historic interest; the main State Penitentiary, and the Sam Houston State Normal School are located in this city. Huntsville has an extensive trade in cotton. Pop. (1890) 1,509; (1900) 2,484.

Hurlbut, hėrl'bŭt, **Stephen Augustus,** American soldier and politician: b. Charleston, S. C., 29 Nov. 1815; d. Lima, Peru, 27 March 1882. He was admitted to the bar in 1837 and removing to Illinois became prominent in State politics, being a member of the Illinois Legislature 1859, 1861, and 1868. At the opening of the Civil War he became a brigadier-general of volunteers, and he commanded a corps in the expedition to Meridian in 1864. He was United States minister to the United States of Colombia, 1869–73; Republican member of Congress from Illinois, 1873–7; and United States minister to Peru.

Hur'ley, Wis., town, capital of Iron County, on the Montreal River, at the State boundary, opposite Ironwood, Mich. It is 49 miles by rail east by south of Ashland, on the Chicago & N. W., the Milwaukee, L. S. & W., and the Wisconsin C. R.R.'s. It is in a rich iron mining district and has saw-mills and considerable lumbering interests. Pop. (1900) 1,823.

Huron, hū'rŏn, an Indian tribe. See WYANDOT; INDIANS, AMERICAN.

Huron, S. Dak., city, county-seat of Beadle County; on the Chicago & N. W. and the Great N. R.R.'s; about 115 miles northwest of Yankton. It is situated in an agricultural and stock-raising region, where there is a large acreage of wheat and from which many cattle are shipped annually to market. Its manufactures are flour, bricks, dairy products, carriages, and wagons; and it has the Chicago & Northwestern railroad repair-shops, and grain elevators. Pop. (1900) 2,793.

Huron, Lake, one of the Great Lakes on the boundary between the United States and Canada. Canada is on the north and east, Canada and Michigan on the south, and Michigan on the west. It receives the waters of Lake Superior through the Saint Mary's River, and the waters of Lake Michigan through Straits of Mackinac, and discharges its waters through Saint Clair River into Lake Saint Clair (q.v.). Its general direction is northwest and southeast. Its length is about 250 miles, its average width about 155 miles, and its area, 22,322 square miles. This area includes Georgian Bay and North Channel. It is 581 feet above the sea, the same as Lake Michigan, 21 feet below the level of Lake Superior. The depth of the waters beyond the land shelf is from 200 to 750 feet; and along the coast, from 20 to 60 feet. The waters of the whole lake are remarkably clear, and in the northern part cold. In summer the temperature of the surface varies from 52° to 58° and of the bottom from 42° to 52°.

The chief arm of the Lake on the east coast is Georgian Bay, which indents Ontario; and on the west, Saginaw Bay, in Michigan. Other indentations on the west coast are Thunder,

Presque Isle, and Hammond bays. A number of short streams flow into the lake from Michigan, the largest of which are Thunder Bay, Au Sable, and Black rivers. The Lake receives from Canada a large amount of water from lakes Nipissing, Simcoe, Muskoka, and several other small bodies which discharge their waters through short rivers into Georgian Bay.

There are no large islands in the main body of the Lake, but on the north and northeast shores are a number of small islands, composed chiefly of glacial deposits and limestone. Grand Manitoulin and Cockburn islands, together with several small islands, belong to Canada. Drummond, Mackinac, and Bois Blanc islands belong to the United States. The long group of islands in the northeast are separated from the mainland of Ontario by North Channel. The greater part of the shore line is low and at one time the country on the west was well-wooded. Regular terraces showing different water levels, deposits of fine sand and clay containing freshwater shells, extend inland fully 20 miles and at heights above the Lake to 100 and 200 feet. These wide beaches show that at one time this Lake, as the other Lakes, must have been much larger than at present. The area of the whole basin of the Lake, including the surface of the water, is about 74,000 square miles. Some picturesque cliffs along the southeastern coast rise to a height from 80 to 150 feet. The harbors are nearly all protected by breakwaters. The chief ports on the west coast are Cheboygan, Alpena, Tawas City, Bay City (at the head of Saginaw Bay), and Sandbeach. Mackinaw and Saint Ignace, at the entrance to the Straits of Mackinac, are important ports. A railroad line from Detroit to Mackinaw is almost parallel with the west coast. There is an abundance of fish in this Lake, one kind, the whitefish, is most important.

Violent storms, to which the Lake is subject, make navigation dangerous. During the summer months, from the first of May to December, there are but few storms. Lake Huron as a factor in commercial enterprises is most important; it is one of the great waterways of the world, and the shipping on its waters is growing in amount and importance. The great bulk of the iron ore from the Lake Superior district is now brought to the Cleveland and Pittsburg districts; the wheat and flour from the Northwest comes east, and nearly all are carried over Lake Huron; and a large proportion of the products of the east which are sent to the Northwest pass over this same Lake. The Saint Mary's Falls Canal or "The Sault Canal," has been the means of greatly increasing the travel and traffic on Lake Huron.

As early as the 17th century this Lake was crossed by the French missionary, Père Marquette, who, in 1668, established a mission at Sault Sainte Marie, Saint Mary's Falls. In 1673 he was in charge of the mission at Mackinaw, from which place, on 17 May 1673, he departed with Joliet and others in search of the "Big River." For amount of tonnage see GREAT LAKES.

Huronian Series, the name (now largely abandoned) first given by Sir William Logan to a series of strata lying in the vicinity of Lake Huron. They are about 18,000 feet thick, and consist chiefly of quartzite with great masses of greenish chloritic schist, sometimes containing pebbles derived from the Laurentian rocks. No organic remains have yet been found in them, and limestones are rare. They are believed to be of Lower Cambrian age, and lie unconformably on the Laurentians. They occupy the same relative position as the upper parts of the Archæan rocks of Great Britain.

Hurricane. See CYCLONE; STORMS; TORNADO; TYPHOONS.

Hurst, hêrst, **Hal,** English artist: b. London 25 Aug. 1865. He started on his artistic career by drawing eviction scenes in Ireland. He emigrated to the United States, and joined the staff of the Philadelphia *Press;* afterward at New York, Paris, and London he contributed to various journals and periodicals. He became a painter, studying at the Art League in New York and under Julian at Paris. Among his paintings are 'The Siren' (1896); 'The Capture' (1898); and 'The First Court of Henry VII.'

Hurst, John Fletcher, American Methodist bishop: b. near Salem, Md., 17 Aug. 1834; d. Washington, D. C., 4 May 1903. He was graduated from Dickinson College, Carlisle, Pa., in 1854, studied theology in Halle and Heidelberg, Germany, and after holding pastorates in New Jersey and Staten Island became bishop in 1880, and chancellor of the American University in 1891. He was one of the leading men in his denomination and of much prominence as a writer. Among his many works may be cited: 'Literature of Theology'; 'History of Rationalism' (1865); 'Martyr to the Tract Cause' (1873); 'Life and Literature in the Fatherland' (1874); 'Outline of Church History' (1875); 'Our Theological Century' (1876); 'Bibliotheca Theologica' (1883); 'Short Histories of the Church' (1888–90); 'Short History of the Christian Church'; 'Indika: the Country and People of India and Ceylon' (1891); 'History of the Christian Church' (1897); translations of theological works and histories; etc.

Husband and Wife. See LAW OF HUSBAND AND WIFE.

Husbandry, Patrons of. See GRANGERS.

Huskisson, hŭs'kĭ-sŏn, **William,** English statesman and financier: b. Birch-Moreton, Worcestershire, 11 March 1770; d. 15 Sept. 1830. He was sent to Paris in 1783 to study medicine. In 1789 he became an enthusiastic sympathizer with the French Revolution, was present at the taking of the Bastille, and joined the Club of 1789, instituted the following year. He made a speech at the club against the proposed creation of paper money, and withdrew from it when the assembly decreed the issue of assignats. His views of the Revolution afterward underwent a change. In 1790 he was appointed secretary to the British ambassador; and when the ambassador was recalled in 1792 he returned to England, and in 1795 he became under-secretary for war and the colonies. In 1796 he was elected member of Parliament for Morpeth. He resigned in 1801, and returned in 1804. In Pitt's administration formed in this year he became secretary of the treasury, and during the Whig ministry that succeeded Pitt's death was an active member of the opposition. In 1807 he re-

sumed his post as secretary of the treasury, which he resigned in 1809. In 1823 he was elected M.P. for Liverpool, and appointed president of the board of trade, and treasurer of the navy. In 1827 he became secretary of state for the colonies. He was killed at the opening of the Liverpool and Manchester railway 15 Sept. 1830. He seldom spoke in Parliament except on commercial or financial subjects, on which he was an authority. He also anticipated Peel in his advocacy of a free-trade policy. A collective edition of his speeches appeared in 1831.

Huss, Henry Holden, American composer: b. Newark, N. J., 21 June 1861. In 1882 he entered the Munich Conservatory, Germany, and studied music, in theory and practice, under Rheinberger, Giehrl, and Abel. In 1885 he settled in New York, where he has had a successful career as composer, performer, and teacher. He has composed 'Cleopatra's Death,' a scene for soprano and orchestra, as well as songs, anthems, and charming chamber music.

Huss, or Hus, John, Bohemian religious heresiarch: b. Husinec, Southern Bohemia, about 1369; d. Constance, Switzerland, 6 July 1415. He studied at the University of Prague and in 1398 began to lecture on theology and philosophy. In 1401 he was made dean of the faculty of philosophy, and was made rector of the university (1400). Since 391 he had been acquainted with the writings of Wickliffe, and his denunciations of the indulgences, of masses for the dead, of auricular confession, etc., alarmed Archbishop Stynko of Prague, who had 200 volumes of Wickliffe's writings burned (1410) in the archiepiscopal palace, and the preaching of his doctrines in Bohemia prohibited. Huss appealed to the Pope John XXIII., who summoned him to appear at Bologna. Huss refused to appear and was in consequence excommunicated, and Prague threatened with an interdict as long as Huss should remain in it. Wenceslaus, the king, alarmed by this menace, thought to bring about peace; and at his demand, Huss made an orthodox profession of faith in 1411. But the quarrel broke out again when Huss and his friend Jerome publicly condemned the papal indulgences granted for the crusade against Ladislaus of Naples. Huss was again excommunicated and Prague interdicted. He now retired to Husinec to the protection of his feudal lord and here he wrote his books 'On the Six Errors' and 'On the Church,' in which he attacks transubstantiation, the belief in the papal primacy and the saints, the efficacy of the absolution of a vicious priest, unconditional obedience to earthly rulers, and makes the Scriptures the only rule of matters of religion. In the meantime the Council of Constance had convened in 1413. Huss was summoned to this council to render an account of his doctrines. The emperor Sigismund granted him a safe conduct to the council. After several examinations of his doctrines, and his persistent refusal to retract the points which were regarded as heretical, he was sentenced to death and burned 6 July 1415.

Husted, James William, American politician: b. 1833; d. Peekskill, N. Y., 25 Sept. 1892. He was graduated at Yale in 1854, studied law, and in 1869 was elected to the New York Assembly. He was re-elected 15 times, and was chosen speaker in 1874, 1876, 1878, 1886, and 1887. He also served in such varied capacities as superintendent of public schools, deputy superintendent of insurance, harbor master, deputy captain of the port of New York, judge-advocate of the Seventh brigade, and major-general of the Fifth Division, National Guard.

Hutcheson, hŭch'ĕ-sŏn, Francis, Irish philosopher: b. Drumalig, Ireland, 8 Aug. 1694; d. Dublin 8 Aug. 1746. He was educated at the University of Glasgow, taught in Dublin 1717–29, and in 1729 became professor of philosophy at Glasgow. In 1725 the first edition of his celebrated 'Inquiry into the Ideas of Beauty and Virtue' appeared without his name. In 1728 he published his 'Treatise on the Passions,' often reprinted, and admired even by those who dispute the soundness of its philosophy. In 1775 was published from his MSS. a 'System of Moral Philosophy.' The philosophy of Hutcheson is based primarily on that of Locke. His particular theory of conscience as a distinct sense was attacked by Richard Price in a celebrated work, 'Principal Questions and Difficulties in Morals.' The views of Hutcheson and Price are reviewed in Jouffroy's 'Cours de Droit Naturel.' Hutcheson was a writer of considerable originality, and justly regarded as the precursor of Reid, and the founder of the Scottish school in philosophy. An admirable résumé of his works is contained in Cousin's 'Philosophie Ecossaise.'

Hutch'ins, Thomas, American geographer: b. Monmouth, N. J., 1730; d. Pittsburg, Pa., 28 April 1789. In early life he enlisted in the English army, and saw active service in the French and Indian war. He was in England in 1779, and was arrested in London, and thrown into prison as an advocate of American independence. He escaped to France, from which country he sailed to America, and joined the Continental army and was appointed geographer-general by Gen. Greene. Among his published works are: 'Topographical Description of Virginia, Pennsylvania, Maryland, and North Carolina' (1778); 'History, Narrative and Topographical Description of Louisiana and Western Florida' (1784).

Hutch'inson, Anne, American religious leader, the founder of the Antinomian party in the New England colonies: b. Lincolnshire, England, about 1590; d. Westchester County, N. Y., August 1643. She was the daughter of a Lincolnshire clergyman. In England she was interested in the preaching of John Cotton and her brother-in-law John Wheelwright, and it was her desire to enjoy the ministry of the former which induced her to follow him to New England. She arrived in Boston with her husband, 18 Sept. 1634, was admitted a member of the Boston church 2 November, and rapidly acquired esteem and influence. She instituted meetings of the women of the church to discuss sermons and doctrines, in which, with a ready wit, bold spirit, and imposing familiarity with the Scripture, she gave prominence to peculiar speculations which even on her voyage had attracted the attention and caused the displeasure of her fellow passengers. Such were the tenets that the person of the Holy Spirit dwells in every believer, and that the inward revelations of the Spirit, the conscious judgments of the

mind, are of paramount authority. She had been two years in the country before the strife between her supporters and her opponents broke out into public action. Among her partisans were the young governor Vane, Cotton, Wheelwright, and the whole Boston church with the exception of five members, one of whom was the associate pastor, Wilson, while the country clergy and churches were generally united against her. "The dispute," says Bancroft, "infused its spirit into everything; it interfered with the levy of troops for the Pequot war; it influenced the respect shown to the magistrates, the distribution of town lots, the assessment of rates; and at last the continued existence of the two opposing parties was considered inconsistent with the public peace." The peculiar tenets of Mrs. Hutchinson were among the 82 opinions condemned as erroneous by the ecclesiastical synod at Newtown 30 Aug. 1637; and in November she was summoned before the general court, and after a trial of two days sentenced, with some of her associates, to banishment from the territory of Massachusetts, but was allowed to remain during the winter at a private house in Roxbury. She joined the larger number of her friends, who, led by John Clarke and William Coddington, had been welcomed by Roger Williams to his vicinity, and had obtained through his influence from the chief of the Narragansetts the island of Aquidneck, subsequently called Rhode Island. There a body politic was formed on democratic principles, in which no one was to be "accounted a delinquent for doctrine." The church in Boston, from which she had been excommunicated, vainly sent a deputation of "four men of a lovely and winning spirit" to the island with the hope of reclaiming her. After the death of her husband in 1642 she removed with her surviving family into the territory of the Dutch, probably from apprehensions that Rhode Island might not be a safe place of refuge from the encroachments of Massachusetts. The precise locality where she settled has been a matter of dispute, but according to the latest authorities it was near Hell Gate, Westchester County, N. Y. The Indians and the Dutch were then at war, and in an invasion of the settlement by the former her house was attacked and set on fire, and herself and all her family, excepting one child who was carried captive, perished either by the flames or by the weapons of the savages.

Hutchinson, Horatio Gordon, English golfer: b. 16 May 1869. He was educated at Charterhouse School, London, and graduated with classical honors in the University of Oxford. He was golf champion in England 1886–7. He has published 'Hints on Golf'; 'Golf' (in Badminton Library); 'Creatures of Circumstance'; 'Peter Steele the Cricketer'; 'My Wife's Politics'; 'Cricketing Laws and Stories'; 'The Book of Golf and Golfers' (1899); 'Little Lady Mary' (1900); 'Dreams and Their Meanings'; 'A Friend of Nelson' (1902).

Hutchinson, John, Puritan English soldier: b. Nottinghamshire 1617; d. Sandown castle, Kent, 11 Sept. 1664. Being of a religious turn of mind, he devoted much time to the study of divinity, from which his attention was soon diverted by the serious political questions which agitated the kingdom. A careful investigation of the matters at issue between the king and the parliament satisfied him of the justice of the latter's cause, and after the commencement of the civil war he declared for the parliament and was appointed governor of Nottingham castle, which he held until the close of the war. He afterward represented Nottingham in parliament, and, as a member of the high court of judiciary appointed for the trial of the king concurred in the sentence pronounced on him. The subsequent course of Cromwell, however, met with the disapproval of Hutchinson. At the restoration he was comprehended in the general act of amnesty, but was subsequently arrested on a suspicion of treasonable conspiracy, and after a detention of ten months in the Tower was removed to Sandown castle, where he died of fever.

Hutchinson, John, English philosopher; founder of a mystical school of philosophy and theology: b. Spennithorne, Yorkshire, 1674; d. 28 Aug. 1737. In 1724 appeared the first part of his 'Moses' Principia,' in which he disputed the Newtonian theory of gravitation. In the second part (1727) he continued his criticisms of Newton, and maintained on Biblical authority the doctrine of a *plenum* in opposition to that of a *vacuum*. From this time one or more of his uncouthly written volumes, containing a sort of cabalistic interpretation of the Hebrew Scriptures, appeared annually. His leading idea is that the Scriptures contain the elements of all rational philosophy as well as of general religion. The Hebrew language has not only its literal but its typical sense, every root of it being significant of hidden meanings. With this elastic principle of exegesis he deduces a system from which the occult powers of attraction, gravitation, magnetism, and electricity are excluded, but according to which the whole mechanism of the heavens is the result of the agency of fire, light, and spirit, the three material elements which were set to work in the beginning, and which typify the three persons of the Trinity.

Hutchinson, Thomas, American colonial governor: b. Boston 9 Sept. 1711; d. Brompton, near London, 3 June 1780. He was the son of a merchant of Boston who was long a member of the council, and graduated at Harvard College in 1727. He represented Boston for 10 years in the general court, of which he was for three years speaker; became judge of probate in 1752, was a councillor from 1749 to 1766, lieutenant-governor from 1758 to 1771, and appointed chief justice in 1760, thus holding four high offices at one time. In the disputes which led to the Revolution he sided with the British government. His brother-in-law, Andrew Oliver, was appointed distributor of stamps under the law which was to go into effect 1 Nov. 1765, but was compelled by mobs to resign the office before that time. The mansion of Hutchinson was also twice attacked in consequence of a report that he had written letters in favor of the act, and on the second occasion (Aug. 26), when the rioters were maddened by liquor, his house was sacked, the furniture burned in bonfires in the street, and many manuscripts relating to the history of the province, which he had been 30 years in collecting and which could not be replaced, were lost. The inhabitants of the town on the following day in public meeting voted their abhorrence of the proceedings; but though many of the actors were well-known, no one

was punished. He, however, received compensation for his losses. When in 1769 Gov. Bernard was transferred to Virginia, the government of Massachusetts fell to Hutchinson. The popular excitement had already been increased by the arrival of the British troops, and after the so-called Boston massacre a committee of citizens, headed by Samuel Adams, obliged him to consent to the removal of the regiments. The popular indignation against Hutchinson became so great that he at last obtained leave of absence and sailed for England 1 June 1773. The privy council investigated his official acts, and decided in favor of "his honor, integrity, and conduct," which decision was approved by the king. He was rewarded with a pension. He published 'History of the Colony of Massachusetts Bay, from the First Settlement Thereof, in 1628, until the Year 1750' (2 vols., 1760–7, vol. 3, 1828); 'Brief State of the Claim of the Colonies' (1764); 'Collection of Original Papers Relative to the History of the Colony of Massachusetts Bay' (1869). His diary and letters appeared (1804–6). The sober judgment of later times has reversed the prejudiced accusations of his American contemporaries and he is now seen to have been a conscientious man, zealous in the performance of duty but sorely perplexed between the claims of loyalty to the king and his natural inclinations in favor of the colony. See Hosmer, 'Life of Thomas Hutchinson' (1896); Fiske, 'Historical Essays, Vol. I.' (1902).

Hutchinson, Kan., city and county-seat of Reno County; on the Arkansas river, and on the Atchison, T. & S. F., the Chicago, R. I. & P., the Hutchinson & S. and the Missouri P. R.Rs.; 40 miles west of Wichita. The city has one of the largest salt interests in the world, producing about 6,000 barrels per day. It is also an important meat packing and shipping centre; and has manufactures of lumber, machinery, boilers, etc., and the railroad shops of the Hutchinson & Southern railroad. It has a public library, high school, state reformatory, electric lights, a national bank, and an assessed property valuation of $1,500,000. Pop. (1900) 9,376.

Hutch'ison, John, English sculptor: b. Edinburgh, Scotland, 1832. He served his apprenticeship in his native town at the trade of wood carving. Meanwhile he attended an art school, visited Rome and chose as his profession that of a sculptor. He exhibited in the London Royal Academy for the first time in 1862. He is best known for his statues of Robert Bruce and John Knox, and his busts of Norman McLeod, Queen Victoria, and the Prince Consort, as well as for the four figures he contributed to Scott's monument at Edinburgh (Baron Bradwardine, Hal-o'-the-Wynd, the Glee Maiden, Flora MacIver. Among his imaginative works are 'Greek Torch Racer'; 'Roman Dancing Girl.'

Hut'son, Charles Woodward, American educator: b. McPhersonville, S. C., 23 Sept. 1840. He was graduated from South Carolina College in 1860; served in the Confederate army, 1861–5; was professor of Greek in Louisiana State University, 1869–81; of modern languages in the University of Mississippi, 1881–9, and of English and history in the Texas Agricultural and Mechanical College from 1893. He has published 'Out of a Besieged City' (1887); 'The Beginning of Civilization' (1888); 'French Literature' (1889); 'The Story of Language' (1897).

Hutten, hoot'tĕn, **Philip von,** German adventurer; cousin of Ulrich von Hutten (q.v.): b. Birkenfeld about 1490; d. Venezuela 1546. In 1528 the Emperor Charles V. made a grant of the province of Venezuela to the Welsers, a firm of Augsburg merchants; and Hutten sailed with one of the companies sent out by them. He accompanied the viceroy, Georg Hohemut, in a journey (1536–8), in which they reached the headwaters of the Rio Japura, near the equator. In 1541 he set out in search of the Golden City. After several years of wandering, harassed by the natives and weakened by hunger and fever, he and his followers came on a large city, the capital of the Omaguas, in the country north of the Amazons; where they were routed by the Indians, and Hutten himself severely wounded. He led those of his followers who survived back to Coro in 1546, where Juan de Caravajal had in the meantime usurped the office of viceroy; and by him Hutten and his lieutenant, Bartel Welser, were seized and beheaded. Eight years later the Welsers' grant was taken from them, and the German rule in Venezuela was concluded. Hutten left an account of his journeyings which was published under the title 'Zeitung aus Indien' (1765). See Von Langegg, 'El Dorado' (1888).

Hutten, Ulrich von, ool'rĭH fŏn, German knight, distinguished for his poems and satires, and for the influence which his writings exercised upon the Reformation: b. Steckelberg on the Main 21 April 1488; d. Ufnau, an island in the Lake of Zürich, 23 Aug. 1523. His father placed him at Fulda, in order to educate him for a monk. The monastic school there was one of the most famous in all Germany, and he received an excellent education. Here he lost his faith and the declared enemy of Christianity fled to Erfurt in 1504, where he became intimately acquainted with several scholars and poets. In 1511 he went to Wittenberg, where he published a work on versification. Ulrich, duke of Würtemberg, having murdered a cousin of Hutten, Hutten gave free course to his indignation in poems, letters, and addresses, which made him known throughout Germany. He distinguished himself no less in the Reuchlinian controversy with the Dominican Hogstraaten in Cologne.

Hutten severely criticized the monastic life, and was so much the enemy of the clergy, that by his edition of Laurentius Valla, 'De falso credita et ementita Donatione Constantini,' he declared war upon the Church and prepared the way for Luther. In 1518 he entered the service of Albert, archbishop of Mayence, and made several official journeys to Paris. He also accompanied the archbishop to the diet at Augsburg, where Luther held his well-known discussion with Cajetan, and Hutten, in a Demosthenic oration, urged the German princes to a war against the Turks. He took the field with the Swabian League in 1519, against his hereditary enemy, Ulrich of Würtemberg, and then retired to the solitude of his paternal castle of Steckelberg, to engage anew in the controversy with the monks. Here he published work after work, violently assailing the Church,

the clergy and the state. Leaving Steckelberg in 1822 he went first to Basel and thence to Zürich, where he died. He was a savage and violent controversialist during his life and was unsparing in the vehemence of his invective.

Hutton, hŭt'n, **Charles,** English mathematician: b. Newcastle-upon-Tyne 14 Aug. 1737; d. 27 Jan. 1823. The destruction of the old bridge at Newcastle having attracted his attention to the subject of the construction and properties of arches, he was led to the production of a small work on the 'Principles of Bridges' (1772), which laid the foundation of his future fame. He was in 1773 appointed professor of mathematics at Woolwich Academy, elected a fellow of the Royal Society in 1774, and in 1785 published his 'Mathematical Tables,' preceded by an introduction, tracing the progress and improvement of logarithms from the date of their discovery. Later works were: 'Tracts, Mathematical and Philosophical' (1786); 'Elements of Conic Sections'; 'Mathematical and Philosophical Dictionary' (1795–6); 'Course of Mathematics' (1798–1811).

Hutton, Frederick Remsen, American mechanical engineer: b. New York 28 May 1853. He was graduated from Columbia in 1853 and is professor of mechanical engineering there. He has published: 'Mechanical Engineering of Power Plants' (1897); 'Heat and Heat Engines' (1899); 'Machine Tools.'

Hutton, James, Scottish geologist: b. Edinburgh 3 June 1726; d. there 26 March 1797. He studied medicine at Paris and Leyden, but on his return (1754) devoted himself to agricultural pursuits and to chemistry, from which he was led to mineralogy and geology. In 1768 he removed to Edinburgh, and there spent his time in scientific investigations. He published 'A Theory of the Earth' (1795) and 'A Theory of Rain' (1784); 'Dissertations in Natural Philosophy' (1792); 'Considerations on the Nature of Coal and Culm' (1777); and other works. See HUTTONIAN THEORY.

Hutton, Laurence, American editor and critic: b. New York 8 Aug. 1843; d. Princeton, N. J., 10 June 1904. He was privately educated, for some time devoted himself to the study of literature and to foreign travel, in the early 70's became a dramatic critic, and began contributions to periodicals of many sorts. From 1886 to 1898 he was literary editor of 'Harper's Magazine,' and subsequently he became lecturer in English literature at Princeton University. He was a well-known collector, possessing among various things a famous series of death-masks of historical personages. He was also an organizer and founder of the Authors' Club, and of the American Copyright League. Among his numerous writings were: 'Plays and Players' (1875); 'Literary Landmarks' (1885–1903), etc.

Hutton, Richard Holt, English essayist and journalist: b. Leeds 2 June 1826; d. Twickenham 7 Sept. 1897. The son of a Unitarian clergyman, he was educated at University College, London, and in Germany, for the Unitarian ministry, but, coming under the influence of F. D. Maurice, he entered the English Church. In 1861 he became editor of the 'Spectator,' which owed its prominence largely to him. Hutton's best work is in the critical 'Essays, Theological and Literary' (1871), and 'Essays on Some Modern Guides of English Thought' (1887), and in the biography of Sir Walter Scott in the 'English Men of Letters' (1878).

Hutton, William Holden, English Anglican clergyman and historian: b. Gate Burton, Lincolnshire, 24 May 1860. He was educated at Oxford where he was select preacher 1898–1900 and Bampton lecturer for 1903. He has published 'The Misrule of Henry III.'; 'Simon De Montfort'; 'St. Thomas of Canterbury'; 'William Laud'; 'Sir Thomas More'; 'Short History of the Church in Great Britain'; 'Constantinople'; etc.

Huttonian Theory, a view of geological processes first published by James Hutton (q.v.) in 1788, in his 'Theory of the Earth,' and developed in 1795. He was the first to distinguish between cosmogony and geology, believing the latter to be in no way concerned with "questions as to the origin of things." His view was that the upraised land of the globe must be worn away by atmospheric influences and the débris be finally deposited in the bed in the sea, where it is consolidated under great pressure; it is then forced upward by subterranean heat, acting with an expansive power, and thereby split and cracked, the fissures at the same time filling with molten mineral matter; and so the process goes on. Hutton was the precursor of Sir Charles Lyell, whose views were essentially the same, and who procured for them large acceptance among geologists. See UNIFORMITARIANISM.

Huxley, hŭks'lĭ, **Thomas Henry,** English biologist: b. Ealing, Middlesex, England, 4 May 1825; d. Eastbourne, Sussex, 29 June 1895. When he was 12 or 13, he wished to become a mechanical engineer; but a medical brother-in-law (Dr. Salt) took him in hand, and he commenced at this early age the study of medicine. Eventually he went to Charing Cross Hospital, and passed the first M. B. examination of the University of London. Stern necessity compelled him, as soon as his medical course was over, to seek at once, even before he was of age, some post or employment. At the suggestion of a fellow student, Huxley in 1846 applied for admission to the medical service of the navy, was admitted, and was in attendance at the naval hospital at Haslar. The next year he was appointed assistant-surgeon of the Rattlesnake, which was sent on an exploring and surveying cruise in the seas on the east and northeast of Australia. The voyage lasted four years, and gave Huxley an opportunity of gaining an almost unrivaled knowledge of marine zoology. Various papers on this subject were contributed by him to the Linnæan and the Royal Society (one of them gaining a medal from the latter body, of which he was elected a member in 1851), and a further result of his investigations was the important work published in 1859, entitled 'The Oceanic Hydrozoa.'

The Rattlesnake returned to England at the end of the year 1850 and Huxley found that the scientific papers he had sent home had already made him famous. By the aid of those who valued the promise given by his published work, he was allowed by the admiralty for

three years to draw pay as a navy surgeon whilst devoting himself to the working up of the results of his observations when at sea. In 1854 he was appointed lecturer or professor of natural history in the Royal School of Mines, a post long combined with that of naturalist to the geological survey. In 1855 he was appointed Fullerian professor of physiology to the Royal Institution, and delivered four courses of lectures in as many years; while he was also an examiner for seven years to the University of London. The posts of Croonian lecturer to the Royal Society and Hunterian professor in the College of Surgeons were likewise filled by him.

There is no doubt that Huxley was fortunate to obtain at 27 a post, worth nearly a thousand a year, in London, and unburdened with any excessive duties. He had to give during winter (October to end of February) a course of lectures on five days of the week, and attend in his study at the Museum in Jermyn Street, but had not the cares of a laboratory. He carried out his researches alone, and consequently was able to arrange the employment of his day in his own way. He wrote largely for the press upon such topics as belonged to his branch of science; lectured frequently in other places besides Jermyn Street; and took an active and important part in various government commissions, to which his official position rendered it proper that he should be appointed. His lectures to workingmen, in 1860, on the 'Relation of Man to the Lower Animals,' gave rise to much discussion, and led him to treat the subject in his 'Evidence as to Man's Place in Nature' (1863). By this time the Darwinian theory had given rise to much excited controversy, and Huxley's thorough-going Darwinism brought many a bitter attack upon him. In 1862 he was appointed by government to assist in inquiring into the effects of the acts regarding trawling for herring; and his labors and advice had much influence in determining the course of fishery legislation and administration. In 1870 his name became more prominent than ever on the publication of his collection of papers entitled 'Lay Sermons, Essays, and Reviews,' which met with fierce denunciation in many quarters. In this year he presided over the Liverpool meeting of the British Association, and was also elected a member of the first London School Board. In 1872 he was elected Lord Rector of Aberdeen University; in 1875–6 lectured on natural history in Edinburgh University.

In 1883 Huxley received the crowning honor of his life, being elected president of the Royal Society. But ill health soon compelled him to give up his official work. In 1885 he retired from his professorship, from his fishery post, and from the presidency of the Royal Society, and confined himself to such work as he could perform in his study at Eastbourne (where in 1890 he built himself a house), or in the Engadine, where he usually spent the summer.

He produced between 1885 and his death in 1895 a large series of brilliant and interesting essays, especially on the relation of science to Hebrew and Christian tradition, and on the evolution of theology and of ethics. During this period he was president of the Marine Biological Association, in the founding of which he took an active part, and in 1892 was made a member of the Privy Council.

In 1888 Huxley received the Copley medal of the Royal Society, and in 1894 the Darwin medal. Huxley was one of the first scientists of his time; his chief and most valuable work was in the direction of the popularization of science, particularly of the Darwinian theory; he was active also in lines of social and political reform, and in the development and organization of scientific education. His works include 'Oceanic Hydrozoa' (1859); 'Evidence as to Man's Place in Nature' (1863); 'Elementary Physiology' (1866); 'Anatomy of Vertebrated Animals' (1871); 'Elementary Biology' (with Dr. H. N. Martin); 'Anatomy of Invertebrated Animals' (1877); 'Physiography' (1877); 'Hume' (1878); 'The Crayfish' (1880); and numerous essays and addresses on scientific and sociological subjects. Consult: the 'Life,' by Mitchell; 'Life and Letters,' by L. Huxley; and Clodd, 'Thomas Henry Huxley.'

Huygens, hoi'gĕns or hī'gĕnz, **Christian,** Dutch mathematician and physicist: b. The Hague 1629; d. there 8 June 1695. He studied at Leyden, and at Breda, where he went through a course of civil law from 1646–8. Among his most important contributions to science are his investigations on the oscillations of the pendulum, and his 'System of Saturn,' in which he first proved that the ring completely surrounds the planet, and determined the inclination of its plane to that of the ecliptic. In 1690 he published important treatises on light and on weight. His 'Traité de la Lumière' was founded on the undulation theory, but in consequence of the prevalence of the Newtonian theory was long neglected till later researches established its credit.

Huygens' Principle. See LIGHT.

Huysmans, hīs-mäns, **Jorris Karl,** French novelist: b. Paris 5 Feb. 1848. He studied law and entered the French civil service, but abandoned it for literature. At first a pronounced realist, he turned to idealism and even mysticism. He first attracted notice by the story 'Pack on Back'; then followed 'Martha' (1876); 'The Vatard Sisters' (1879); 'The Ménage' (1881); 'Down There' (Là-bas) (1889).

Hwang or **Hoang-ho,** hwäng'hō, or **Yellow River,** China, a large river which rises in the mountains of north Tibet, in the Koko-Nor territory, about lat. 34° 30′ N., and lon. 97° 30′ E. It derives its name from the vast quantities of yellow mud continually carried down by its waters. After a winding course, north, east, and south, of about 2,600 miles, it flows since 1853 into the Gulf of Pe-chi-li, prior to that year its outlet being in the Yellow Sea. It is a turbulent, turbid, and impracticable stream, but little used for navigation and subject to disastrous floods, to prevent which and the former frequent changes in its bed and outlet, great expense is incurred maintaining artificial embankments.

Hy'acinth (1) A genus (*Hyacinthus*) of lilies with corolla-like, bell-shaped, six-cleft perianth, six stamens fixed in the tube of the perianth, and dry capsular fruit. The Oriental hyacinth (*H. orientalis*), one of the chief favorites of florists' flowers, is a native of Asia Minor, Syria, and Persia. It is now naturalized in some parts of the south of Europe. It has broad linear leaves,

THOMAS HENRY HUXLEY.

and a scape with a raceme of many flowers pointing in all directions. The flowers in cultivation exhibit great variety of color, chiefly blue, purple, and white. They are very beautiful and very fragrant. The fragrance is strongest about or after 11 o'clock at night. Among cultivated hyacinths are many with double flowers. The hyacinth has been cultivated from a remote period. It was introduced into Europe, probably by the Dutch, about the beginning of the 16th century. The grape-hyacinth is a somewhat different plant of the genus *Muscari*, of which *M. racemosum* is common in gardens. (2) See ZIRCON.

Hyacinthe, Père, pār ē-ä-sänt. See LOYSON, CHARLES.

Hyænodon, hī-en'ō-dŏn, a genus of primitive carnivorous mammals (creodonts), fossil in the upper Eocene and lower Miocene rocks of Europe and the western United States, of which several species are known by well preserved skeletons. The skull was relatively very large and long, with great canines and strong hyena-like molars, but the brain-cavity was very small. The feet were fully five-toed, had powerful claws, and the animal, which must have somewhat resembled a small, cat-like bear, was partly plantigrade. The remains of *H. cruentus* are numerous in the White River beds of North Dakota.

Hyams, Henry Michael, American lawyer and politician: b. Charleston, S. C., 1805; d. 1875. In 1828 he went to New Orleans, studied law, and after 15 years of country practice in Alexandria, La., resumed his residence in New Orleans, where his investments in landed property made him wealthy. In politics he was originally an old line Whig, but on the outbreak of Know-Nothingism joined the Democratic party. In 1855 he was elected to the State Senate; in 1859 he was chosen lieutenant-governor; the first Israelite to hold such an honor in the United States. He was devoted to the Southern cause, sent his sons to fight in the Confederate army, and after the war found his large fortune vanished. Prepared to begin life anew, he resumed the practice of law until his death.

Hyatt, Alpheus, American naturalist: b. Washington 5 April 1838; d. Cambridge, Mass., 15 Jan. 1902. He was graduated from the Lawrence Scientific School at Harvard in 1862, then entered the army and served during the war in the 47th Massachusetts regiment, being promoted to the rank of captain. After leaving the army, he resumed his studies under the instruction of Agassiz, and later studied abroad. In 1867 he went to Salem, where he was one of the founders of the Peabody Academy of Sciences and one of the curators of the Essex Institute. In 1870 he was made custodian of the collections of the Boston Society of Natural History, becoming curator in 1881. He was also connected with Boston University, was manager of the Teacher's School of Science, had charge of a laboratory of natural history founded by the Women's Educational Society at Annisquam, and was for several years professor of zoology and palæontology at the Massachusetts Institute of Technology. In his later life he had charge of invertebrate fossils in the Museum of Comparative Zoology at Cambridge. He was a member of the American Academy of Arts and Sciences, of the National Academy of Sciences, and of the American Society of Naturalists. He was one of the founders of the last mentioned society and its first president (1883); he was also one of the founders and editors of the 'American Naturalist.' His most distinctive work was the investigation of the development of the fossil *Cephalopoda* and of the fossil and semi-fossil *Planorbis* on Steinheim Lake, Germany, from which investigations he deduced laws of growth very important to the evolutionary theory. His works include 'Observations on Polyzoa' (1866); 'Fossil Cephalopods of the Museum of Comparative Zoology' (1872); 'Revision of North American Poriferæ' (1875–7), the only work on North American commercial sponges; 'Genesis of Tertiary Species of Planorbis at Steinheim' (1880); 'Genera of Fossil Cephalopoda' (1883); 'Larval Theory of the Origin of Cellular Tissue' (1884); 'Genesis of the Aretidæ' (1889); 'Bioplastology and the Related Branches of Biologic Research' (1893); 'Phylogeny of an Acquired Characteristic' (1894); 'Cephalopoda' (1900).

Hy'att, John Wesley, American inventor: b. Starkey, N. Y., 28 Nov. 1837. After an education in the common schools he became a printer and then an inventor. He perfected a composition billiard ball (1865), secured a "bonsilene" compound (1878), a water-purifying system, and a method of dissolving pyroxylin. He has secured about 200 patents for his inventions.

Hybridity, the crossing of two individuals of distinct species. The result of the intercrossing of species is a hybrid, for example, the mule, which is the result of breeding the horse with the ass. As the mule is invariably sterile, the infertility has always been supposed to be a test of species. But this is not an invariable rule, as not a few so-called "good" species have been crossed with one another. It may be set down as a general proposition that the difficulty of crossing increases the more distant the systematic relationship of the species experimented with. Also these difficulties are, says Hertwig, by no means directly proportional to the systematic divergence of the species.

Nature tends to keep species separate, in the higher animals, as well as among insects, etc.; mating is usually prevented by the structure of the parts concerned with sexual union; also the principle of preferential mating comes into play among mammals as well as insects, as often between males and females, even of closely allied species, or varieties. When there is no structural differences there may exist an aversion which prevents any union of the sexes.

Artificial Hybridization.— Many experiments have recently been made on the lower marine animals in which the eggs are fertilized in the sea without sexual union, by placing the eggs of starfish and sea-urchins, etc., in a watch-glass and adding the sperm of the males, thus securing artificial fertilization. In this way hybrids have been obtained from species belonging to quite different genera, while it has been found that in some cases closely related species will not cross. For example, among the sea-urchins the spermatozoa of *Strongylocentrotus lividus* readily fertilize the eggs of a species of Echinus,

but only rarely those of the more closely allied *Sphærechinus granularis*. Hybrids have been obtained from different genera of fishes, as those between the salmon and brown trout. It appears that salmon eggs have been fertilized by trout sperm, but not trout eggs by salmon sperm. According to Hertwig eggs have been fertilized by sperm belonging to species of different families, orders, and possibly classes. For example, the eggs of a flounder (*Pleuronectes platessa*) and of *Labrus rupestris* have been fertilized by the sperm of the cod; frog's eggs (*Rana arvalis*) by sperm of a triton, and even, it is said, the eggs of a starfish by milt from a sea-urchin; in such cases, however, the hybrids die during or at the close of segmentation of the yolk.

Fertility of Hybrids.— While the mule and many other hybrids are sterile, there are some known exceptions. Hybrids of hares and rabbits have continued fruitful for generations, and also hybrids obtained from the wild buck and she-goat, from the Chinese goose (*Anser cygnoides*) and the common goose (*A. domesticus*); from *Salmo salvelinus* and *S. fontinalis; Cyprinus carpio* and *Carassius vulgaris*, as well as between the two silkworm moths, *Philosamia cynthia* and *P. ricini*, the Arrhindy worm. In this country Caton has hybridized the common Virginian deer with the Ceylon deer and the Acapulco deer, and states that the hybrids seemed perfectly healthy and prolific. Ewart states that the Indian buffalo and the American bison produce fertile hybrids with the European wild ox.

In the human species it is a well-established fact that marriages between remote varieties or races tend to sterility, while crossing between allied races are fertile, and such unions are most beneficial. Thus the most mixed white races are the most fertile and vigorous. Ewart thinks that as there are no definite limits between species and varieties, there can be "no fundamental difference between a hybrid and a cross, nor yet any *a priori* reason why any given hybrid should be sterile, or any given cross fertile." He also states that sterility has in some cases been slowly acquired, in others abruptly, but how it has been acquired is not known.

As the result of breeding thousands of moths Standfuss states that in no case observed by him has the female of a true hybrid been shown to be fertile. On the other hand, the occurrence of undoubted cases of fertility in male hybrids has been proved by crossing the male hybrids with the females of both parent species.

Ewart's Experiments with crossing the Zebra and Horse, and the Wild Ass and Horse. — A Burchell's zebra stallion, "Matopo," became the father of nine zebra hybrids by mares of various sizes and breeds. The hybrids exhibited a curious blending of characters, which seemed to have been derived partly from their actual and partly from their remote ancestors; some of the hybrids strongly suggest their zebra sire, others their respective dams, "but even the most zebra-like in form are utterly unlike their sire in their markings."

According to 'Nature,' August 1903, he succeeded in 1902 in securing a male wild ass (kiang) from Central Asia and a couple of Mongolian pony mares, one a yellow dun and the other a chestnut. The wild ass was mated with the dun Mongol mare, a brownish-yellow Exmoor pony, and a bay Shetland-Welsh pony. The kiang hybrid in its long legs, slender joints and speed took after its kiang parent. The mane and tail "are exactly what one would expect in a mule." This kiang hybrid also differs from the wild horse (Przewalsky's horse) in not neighing like a horse. The result is to prove that the wild horse is not a kiang-pony male, but a "good" species. Also in accordance with Mendel's law (see under HEREDITY) the kiang proved to be dominant, the Exmoor pony recessive.

Hybridity in Plants.— The method of hybridizing hermaphroditic flowers is to cut away their stamens before they are ripe, and then enclose the flower in a paper bag. After the stigma has ripened the pollen is placed on it, the bag is again tied over the flower and not removed until the seed begins to form. Great advantages and improvements have resulted from hybridizing plants, chief among which are many new varieties of cultivated plants, increased size and vigor, hardiness, or adaptation to warmer climates, and increased resistance to disease, as well as increase in odor of flowers and the quality and flavor of fruits.

Thus far the cause of infertility in animals is unknown, but botanists attribute the frequent sterility of plants to the imperfect formation of the pollen. Standfuss' experiments with moths agree with Focke's statement as to the great variability of the offspring resulting from the crossing of a plant hybrid with one of the parent species. In plants, as discovered by Mendel, the proportion of the pure races is constantly increasing in the successive generations descended from a hybrid. Malformations and sports are much more frequent, especially in the floral organs in hybrids, than in individuals of a pure descent. Double flowers appear to be formed especially easily in hybrids. Recent experiments and results in the study of hybridity show how intimately the subject bears on heredity (q.v.) and the origin of species.

Consult: Bailey, 'Plant Breeding' (New York 1896); De Vries, 'Die Mutationstheorie' (Leipsic 1901–3); Bateson, 'Mendel's Principles of Heredity' (Cambridge, England, 1902) contains a bibliography of the subject.

ALPHEUS S. PACKARD,
Late Professor of Zoology, Brown University.

Hydatid, hī'dā-tĭd. See BLADDERWORM; TAPEWORM.

Hyde, Edward, British colonial governor in America: b. England about 1650; d. North Carolina 8 Aug. 1712. In 1710 he arrived as governor of the Albemarle district of North Carolina province. The provincial governor, by whom he was to be commissioned, was dead, and Thomas Carey, formerly a deputy-governor, had undertaken an armed insurrection. Hyde, at the request of the better class of the population, took office as governor, and, assisted by Spottswood, governor of Virginia, crushed the revolt. Not long after massacres by the North Carolina Indians compelled him to seek aid from Virginia and South Carolina.

Hyde, Edward Wyllys, American mathematician: b. Saginaw, Mich., 17 Oct. 1843. He was graduated from the civil engineering school

of Cornell University in 1872, was instructor in civil engineering there in 1871–3, assistant professor of mathematics in the University of Cincinnati in 1875–8, and professor from 1878. Besides extensive contributions to mathematical journals, he wrote: 'Skew Arches' (1875); 'Directional Calculus' (1890); 'A Portion of Higher Mathematics' (1896).

Hyde, William Dewitt, American college president: b. Winchendon, Mass., 23 Sept. 1858. He was graduated from Phillips Exeter Academy in 1875, from Harvard in 1879, and studied theology at Union and Andover. After completing his theological studies he was pastor for a time at Paterson, N. J. In 1885 he became president of Bowdoin College; at that time he was the youngest college president in the United States, and was not widely known. He has since won a high reputation as a scholar and an able executive, the college having grown largely in numbers and resources during his administration. He has written 'Practical Ethics' (1892); 'Social Theology' (1895); 'Practical Idealism' (1897); 'The Evolution of a College Student' (1898); 'God's Education of Man' (1899); 'The Cult of Optimism' (1900).

Hyde Park, London, a park in the West End, adjoining Kensington Gardens. It derived its name from having been the manor of the Hyde belonging to the Abbey of Westminster, and contains nearly 400 acres. It was opened to the public shortly after the Restoration in 1660, and abounds with fine trees and pleasing scenery. The sheet of water called the Serpentine River was made between 1730 and 1733 by order of Queen Caroline. It is much frequented in summer for bathing, and during frosts for skating. Other attractive features of the park are the fashionable drive, bridle path, and promenade of Rotten Row, the Ladies' Mile, and Marble Arch.

Hyde Park, Mass., town in Norfolk County; on the Neponset River, and on the New York, N. H. & H. railroad; about four miles southeast of Boston. The town contains four small villages. It was incorporated as a town in 1868. The chief manufactures are rubber goods, paper, morocco, cotton and woolen goods, curled hair, chemicals, dyestuffs, looms, and machinery. It is a residential suburb for many of the Boston business men. It has good schools and a free library which contains about 14,200 volumes. Pop. (1890) 10,193; (1900) 13,244.

Hyde Park, Vt., village in the town of Hyde Park; county-seat of Lamoille County; on the Lamoille River and on the Boston & M. railroad; about 31 miles northeast of Burlington and 23 miles north of Montpelier. The stone-quarries nearby are a source of industrial wealth. The manufactures are flour, lumber, dairy products, and leather. Pop. village (1900) town, 1,472.

Hyder Ali, hī'dėr ä'lē, Indian Mohammedan prince: b. Bangalore about 1728; d. Chittore, 7 Dec. 1782. Having deposed Kandih Rao, he was chosen rajah of Mysore in 1762, and he so greatly extended his dominions, that in 1766 they contained 84,000 square miles, and afforded an immense revenue. His reign was passed in wars with the English and with the Mahrattas. A treaty which he made with the East India Company in 1769, was violated in 1780, and, forming an alliance with the Mahrattas, he obtained the services of French officers, and took Arcot on the 31st October of the same year. He was defeated by Sir Eyre Coote, 1 June 1781. He was succeeded by his son Tippoo Saib (q.v.).

Hyderabad, hī-dėr-ạ-bäd', or **Haidarabad,** hī-dạ-rạ-bäd', India. (1) One of the largest native states occupying the greater part of the Deccan plateau of southern India, in possession of the Nizam, a Mohammedan prince, and frequently called the NIZAM'S DOMINIONS. It is bounded north by Berar, northeast by the central provinces, southeast by Madras, and west by Bombay. Area, 82,698 square miles; pop. (1901) 11,141,142. The chief rivers are the Godavery in the north and the Kistnah in the south. The soil generally is fertile but poorly cultivated; the principal crops are rice, wheat, maize, sugarcane, tobacco, cotton, and fruits. Indigo is manufactured, and the forests yield valuable timber; there are coal and iron deposits as yet little exploited, and diamonds and other gems are found. The ruler belongs to the dynasty founded by Asaf Jah, a distinguished soldier, whom the Emperor Aurungzebe made viceroy of the Deccan in 1713 with the title of Nizam or Regulator.

(2) HYDERABAD, the capital, is on the Musi River, at an elevation of 1,672 feet above the sea, about 400 miles in a direct line southeast of Bombay, with which it is connected by rail. It is wall-girt, and its chief buildings are the extensive nondescript palace of the Nizam, the handsome British Residency, the Charshinar, or Four Minarets, built about 1590 as a Mohammedan college, but now used for warehouses; and the Jumma Musjid or cathedral mosque, a reproduction of that at Mecca. Pop. (1901) 448,466. (3) HYDERABAD, the capital of a district of Sindh, British India, on the east bank of the Indus, is a well fortified town connected by rail with Karachi, 105 miles to the southwest. Pop. (1901) 69,378.

Hy'dra, a minute fresh-water polyp, living on the stems and underside of submerged leaves. The body is a club or vase-shaped sac, the mouth at the upper end surrounded by a crown of from five to eight long tentacles armed with lasso or nettling cells buried in the skin. The hydra feeds on minute crustacea, etc., which become paralyzed when swimming in contact with the arms of the hydra, thus being easily drawn by the creature into its stomach. The body is very retractile, and the hydra can slowly move from one place to another, by detaching the end of the body. The sexual cells are, during the reproduction season, developed in the skin, appearing as circular swellings, one (male) just below the tentacles, the other mass, corresponding to the ovary of higher animals, farther down the body. The hydra is famous from its power of regenerating parts of its body. Trembly in 1744 experimented upon this animal; he cut them in two, also into slices, and found that each bit became a new hydra, finally he turned one inside out, the stomach-lining becoming the skin, this experiment having recently been successfully repeated. This is due

to the lack of differentiation in the tissues and organs of the body, there being no distinct nervous, or circulatory system, the hydra being the most generalized member of its class, except the Protohydra, which has no tentacles.

Hydrangea, hī-drăn'jē-a, a genus of shrubby plants of the order *Saxifragaceæ*, with about 30 species indigenous to eastern Asia and temperate America. They have large simple leaves and very large cymes of flowers, the outer ones being infertile. The *H. vulgaris* grows on the Alleghanies, and in other parts of the United States. *H. nivea*, a more ornamental shrub, is most abundant in the region of the southern Alleghanies, but is found as far north as Pennsylvania. The *H. quercifolia*, distinguished by its lobate leaves, inhabits the country bordering on the Gulf of Mexico. The best-known species is *H. hortensis*, the Japan rose. The fruit is a multilocular capsule.

Hy'drants. See VALVES AND HYDRANTS.

Hydras'tis, an herb, the rhizome and rootlets of which are used as a bitter stomachic tonic and a tonic to the uterus in various diseases. In poisonous doses it stops the heart-action.

Hy'drate, in chemistry, a compound containing one or more molecules of the radical "hydroxyl" (OH). In these compounds, the water may be considered as playing the part of an acid, and the compounds themselves are entirely analogous to salts. Thus water, H_2O, combines with sodium oxid, Na_2O, according to the equation $Na_2O + H_2O = 2NaOH$; the reaction being accompanied by the liberation of considerable heat. The sodium hydrate (NaOH) that is produced is quite a different substance from the simple oxid, Na_2O, and it cannot be resolved into Na_2O and water by the action of heat alone. In organic chemistry hydrates are met with very frequently. The large and exceedingly important class of substances collectively known as the alcohols, for example, are hydrates of organic radicals. (See ALCOHOL.)

The word "hydrate" is also used in a less definite manner, to signify any compound which contains water, or from which water can be expelled by the action of heat. Thus salts or minerals which are associated with water of crystallization are said to be "hydrated." When an aqueous solution of a salt, containing an excess of the salt in the free state, is cooled until it freezes, a mechanical mixture of ice and of the precipitated salt is obtained, which is known as a "cryohydrate," although it is not a definite chemical compound.

Hydraulic (hī-drâ'lĭc) **Cement.** See CEMENT.

Hydraulic Crane. See HOISTING APPARATUS.

Hydraulic Engine, or Hydraulic Motor, an engine or motor driven by water under pressure. The water is admitted at a high pressure at the beginning of the stroke, and exhausted at a low pressure at the end of the stroke, thus giving a reciprocating motion to the plunger. The velocity of the piston has to be kept low to avoid injurious shocks in suddenly bringing the column of water to rest. Working under greater pressure than steam-engines — 700 pounds to the square inch is not an uncommon pressure — the hydraulic pressure engine can be built much smaller than an equivalent steam-engine. An additional advantage of the hydraulic engine for intermittent work is the comparative ease with which it may be started or stopped; hence it is commonly used for capstans, winches, cranes, and drawbridges. Single action in the hydraulic engine avoids shock at dead centres; and the three-cylinder single-acting form is in common use, since the three cranks make the turning force uniform and make it possible to start the engine from any position. Another form, of very recent development, is the turbine (q.v.).

Hydraulic Engineering, that branch of civil engineering which deals with the application to the use and convenience of man of the natural laws governing liquids. A liquid is a substance appreciable to the senses of sight and touch, and the particles composing which are incompressible and offer no resistance to interchange of position from any external force applied to them. The typical liquid is water, and the generic term hydraulics, used to denote the science and practice of handling liquids, is derived from a Greek word which means "pertaining to water." There are three distinct sets of laws or principles of science which have to be considered: hydrostatics, which relates to liquids at rest; hydraulics, which relates to liquids in motion; and hydrodynamics or hydromechanics, which relates to the mechanical effects produced upon other substances by liquids when acted upon by external forces.

The science of hydraulics is entirely modern. There is no evidence, either traditional or documentary, that the principles governing the action of liquids either at rest or in motion were studied and formulated at all prior to the days of Archimedes, 2,200 years ago. A few of the facts of both hydrostatics and hydraulics were established experimentally, so that aqueducts to convey water long distances were built by the Romans, and possibly before them by the Phœnicians and the Greeks; but no record remains of any elucidation of principles or formulation of laws. After the destruction of Rome in 475 A.D. even what had been known seems to have been lost for more than 1,000 years. As late as 1630 Galileo said that the laws governing the motions of the stars were better understood than those controlling the movement of water on the earth.

Hydrostatics.— It was Galileo who discovered and formulated the important law of hydrostatics that the pressure exerted by a column of fluid on any square unit of the surface which confines it is equal to the weight of a column of one unit square and of the height of the surface of the liquid above the point at which the pressure is measured, no matter whether the horizontal area of the column at that point is greater or less than at other points in its height. If the confining walls of the column are horizontal at any point, or if they are inclined to the perpendicular, the pressure of the liquid at that point is the same, whether upward or downward, as it is laterally against a vertical wall, and the wall at that point must be of such thickness that it will resist that pressure.

Where the pressure is upward the resisting force of the wall is increased by its own weight, and where the pressure is downward the resisting force is diminished by the weight of the wall itself. It is essential therefore to the stability of a wall which is surrounded by a liquid mass that the adjacent liquid should be excluded from passing under the wall so as to permit of an upward pressure which would tend to lift the wall from its base.

In all mechanical problems there are three units of comparison needed: the units of time, of distance, and of weight. The unit of time in modern science is the second, or $\frac{1}{86400}$ part of the average day. The unit of distance which is generally used in England and America is the foot, which is subdivided into twelfths, called inches, or into thousandths, while the unit of weight is the pound, which is arbitrarily fixed by law. In France and Germany the unit of distance is the metre, which is supposed to be one ten-millionth part of the distance from the pole to the equator, and is 3.28 feet long, and is subdivided into thousandths, while the unit of weight is the gram or cubic centimetre, which is the $\frac{1}{1000000}$ part of the weight of a cubic metre of pure water. Efforts are making by scientists to secure the universal adoption of the metric system of measures and weights, but in the English-speaking countries the foot and the pound are the only standards generally used and understood. In hydraulic science the basic hydrostatic facts are that a cubic foot of pure water weighs 62.417 pounds, and that to exert a pressure of one pound on every square inch of surface a column of water must be 2.307 feet high.

Hydraulics.— The instant that an orifice is made in the barrier confining a volume of liquid the particles of the liquid begin to move in the direction of the orifice. The theoretical velocity with which they issue from the orifice was discovered in 1644 by Torricelli, a pupil of Galileo, to be equal to that acquired by a cubic unit of the liquid in falling through the height between the surface of the liquid and the orifice. It was not until 1738 that Bernoulli formulated the fundamental expression for the acceleration of gravity, $v = \sqrt{2gh}$, in which v represents the speed per second of time, h represents the distance of the orifice below the surface of the liquid, and g is a quantity determined by experiment to be the velocity acquired by any body in falling freely in a vacuum, from a state of rest, in one second of time. Taking the foot as the unit of distance, $g = 32.16$ and $\sqrt{2g} = 8.020$, while if the metre is the unit, $g = 9.80$ and $\sqrt{2g} = 4.427$.

The students of hydraulic problems soon discovered that the conditions under which the movements of fluid take place modify materially the theoretical results obtained from the formulæ based on the laws of gravitation only. For 260 years they have been striving by a combination of reasoning and experimentation to formulate the laws which govern the movements of water under varying conditions of form and character of material composing the enclosing channels in which the movements occur. The value of v, as found to exist in practice, is only a fractional part of the theoretical value, and is designated by the expression $v = c\sqrt{2gh}$, in which c is a numerical coefficient which varies with the form of the orifice or channel through which the water passes, and with the character of the material through which the orifice is made. The reason of this is that the particles of the liquid which are in contact with the restraining solid material are retarded in their fall by the solid, and they in turn retard the next adjacent particles of fluid, the amount of retardation decreasing as the distance from the immovable solid increases. This retarding effect varies also with the roughness of the limiting solid, and with the velocity at which the initial movement, due entirely to the force of gravity, takes place. The quantity of water discharged is equal to the product of the velocity by the area of the orifice or $q = ac\sqrt{2gh}$. The value of c under the most favorable conditions has been found from numerous carefully conducted experiments to be about 0.60, or in other words, only about 60 per cent of the amount of water which the theoretical calculation of the velocity due to the head indicates as possible to be passed through an orifice in the side or bottom of a vessel or reservoir containing a mass of water, can be actually so passed. After passing the orifice of entry to a long channel, a new set of conditions is encountered in conveying water for long distances, as in a pipe or open canal. Gravity is the impelling force as before, and to ensure flow there must be a difference of elevation between the extremities of the channel, but the retarding forces are numerous, consisting of variations in the slope of the channel, in the proportion which the length of the wetted perimeter of the channel bears to the area of the waterway, and in the irregularity of the surface over which the water flows.

The fundamental formula for the velocity of the flow in channels of all kinds which is now accepted was suggested by Chézy in 1775 and is

$$v = c\sqrt{rs}$$

in which v represents the mean velocity of the fluid, r represents the hydraulic radius, as it is termed, or the area of waterway divided by the length of the wetted boundary of the channel, and s represents the slope of the surface, or the difference of elevation of the two ends of any section of channel, divided by the length of the section. The value of c is determined by experiments on the discharge of channels of different forms, materials, and dimensions. It is purely experimental. In the last 100 years numerous carefully conducted series of observations have been made by hydraulicians with the object of determining an exact mathematical expression for this coefficient under different conditions. The formula which so far seems to approach most nearly to the obtaining of a definite result is that proposed by Kutter, a German scientist, about 1868, in which the dominant element is a variable quantity designated as n, the value of which depends solely on the degree of irregularity in the wet surface bounding the cross section of the channel. In applying this formula to any channel the engineer must assume that value for n which has been determined by experiment to belong to a channel most nearly approaching in roughness the one under consideration, and from this he will be able to deduce with a very con-

siderable degree of accuracy the value of *c*, and use this to determine the velocity and discharge.

Hydrodynamics or Hydromechanics.— These are terms applied to the science which treats of the dynamic effect produced upon other substances by the arrest of the movement of fluids coming in contact with them. A stationary column of water exerts a pressure only; a moving column exerts a dynamic pressure proportional to the velocity with which the mass is moving. If an obstacle is interposed to water flowing in a channel of any kind, the force exerted by the water in removing that obstacle can be utilized in such a way as to produce a mechanical energy or work. The simplest form of this is the undershot wheel, where the pressure of the water flowing in a stream causes vanes or paddles attached to a shaft to revolve the shaft, and from this, by mechanical appliances, the circular motion can be directly utilized to exert energy either by revolving or reciprocating movement of machines. The breast-wheel and the overshot wheel utilize the power generated by a fall or head of water of from one half to two thirds of the diameter of the wheel. The turbine wheel invented in France by Fourneyron in 1833 revolutionized water-power engineering, utilizing as it does nearly the entire energy of any great head or fall of water by discharging the fluid from a pipe against revolving vanes so shaped as to afford the greatest resistance to the attacking current and the least to the discharging current. When the impulse of movement of machines. When the impulse of the moving liquid, which is that due to the product of its weight by its velocity, is at right angles to the interposing surface, it is equal to double the pressure exerted by the fluid in a state of rest. As the angle between the current and surface becomes oblique the pressure diminishes. The same rule holds good with reference to submerged surfaces exposed to the impact of waves and currents in deep water, so that the hydrodynamic forces present to the naval architect, as well as to the hydraulic engineer, innumerable problems delicate and difficult of solution.

Hydraulic Engineering.— The improvement of natural watercourses on the face of the earth is the most ancient and the most extensive of the works which have called for the exercise of hydraulic engineering. The remains of works for restraining the flood-waters of rivers, antedating all historical records, have been discovered in Egypt and China. In countries where the rainfall is so distributed throughout the year that alternate periods of extreme wetness and drought of long continuance occur, the retention of the excess of water in the wet season and its gradual delivery for irrigation purposes during the season of drought was extensively carried on at an early date. In Egypt, 2,320 years before the Christian era, Lake Mœris was constructed as a storage reservoir for retaining the waters of the Nile, and the prosperity of that country has ever since depended upon the maintenance and progressive improvement of its system of irrigation. The earlier works, while remarkable for their extent and magnitude, were not characterized by any particular skill in design or economy in construction. During the latter part of the 19th century and since the beginning of the present, under the control of French engineers, some very fine examples of dams and irrigation canals have been constructed. The Assuan dam is 90 feet high at the deepest point of the valley it crosses; 6,400 feet long, of granite, founded on solid rock; and it impounds water for the irrigation of 2,500 square miles of land 350 miles farther down the stream, where another dam, 48 feet high and 3,930 feet long, diverts the water on to the lands to be benefited.

In India, from very early ages, irrigation has been practised on an extensive scale, and enormous reservoirs were constructed for the storage of water at least as far back as 500 B.C. There are about 90,000 such reservoirs or their remains which were constructed before the British occupation of India, and 2,000 were built by English engineers in the last half of the 19th century. In Italy about 4,000,000 acres of land are under irrigation, and it is to the Italian engineers of the 18th century that hydraulic engineering is largely indebted for the elucidation of principles and the application of the same to practice so as to produce the greatest efficiency at the least expense.

For the successful conduct of irrigation works there is needed not only a knowledge of the laws of hydraulics, but also a thorough study of the meteorological conditions which have prevailed in the region under consideration for a long series of years, and likewise of the topography and geology of the region.

In the United States the importance of this has been fully recognized only within the last 20 years; but during that period the general government has devoted a good deal of attention to the subject, and has caused surveys, both topographical and geological, to be made of the arid region lying west of the 100th meridian of longitude; while a series of measurements of the rainfall and the run-off of the streams is being instituted, which will furnish the engineer with data necessary to an intelligent designing of irrigation works. This will undoubtedly prove of great benefit, inasmuch as not more than 7 per cent of the 70,000,000 acres in the United States susceptible and in need of irrigation are now supplied with it. In the works so far constructed are seen numerous efforts at improvement in design and methods of construction, some of which have not yet stood the test of time long enough to determine whether they will be effective. The careful observations which have been made and are still being made have resulted in a decided advance in knowledge of hydraulic principles.

In passing to the consideration of the next oldest class of hydraulic works, that for the regulation of rivers to protect and reclaim the riparian lands, the questions to be considered by the hydraulic engineer are materially changed. Large storage reservoirs are needed as in irrigation projects, but their capacity and arrangement with reference to the fluctuations of the natural flow of the stream must be very different. The channels, too, for the conveyance of the water are differently proportioned, and are likely to be required to be constructed of different material. In irrigation canals a low velocity of flow is desirable to avoid abrasions of the banks, and the sizes of the channel are proportioned to convey definite quantities of water steadily. In river regulation the channels must be designed

to carry constantly varying quantities of water at different speeds of current, and the banks must be fortified against injury from sudden fluctuations of level in the water surface and from abrasion by floating material or accretion by deposit. The construction of levees or embankments along the banks of a river and parallel to its current is the earliest and simplest of the methods of river improvement; but it is only within the last 200 years that this has been reduced to a science, and the most effective and economical methods of design and construction formulated. If the stream improved is of sufficient size to be navigable, the conditions of the problem are again changed. The course of the channel in places may have to be altered to avoid rapids of too steep descent for passage of boats, and a sufficient depth of water must be maintained at all times and in all places for boats of definite dimensions and draft. Where such artificial channels are necessary it is important that they should be so proportioned that the passage of the largest boat at the maximum permissible speed should not create a wave which would injure the banks or retard the progress of the boat.

River improvements of this class led to the construction of entirely new artificial channels or canals connecting different navigable streams or bodies of water. There are some very ancient examples of such structures. The Royal Canal of Babylon was built 650 B.C., and about 102 B.C. the Fossa Mariana, connecting the River Rhone and the Mediterranean Sea, was built. In the 8th century was built the Grand Canal of China, about 650 miles long, utilizing several canalized rivers on its way, and thus creating an inland navigation system of 1,000 miles. On this canal there were several inclined planes, up and down which loaded boats were passed from one level to another. Locks were first invented in 1439 by Philip Visconti, an Italian engineer. Prior to this time there was but one method of overcoming differences of elevation in navigable channels which had been constructed so as to afford long and nearly level stretches on which boats could pass in either direction, with approximately the same motive power, and with sudden changes of elevation at the ends of such levels. That method was the transhipment of cargoes, the Chinese method of inclined planes not being economical in the then state of the mechanic arts. Between 1750 and 1830, however, a number of inclined planes were built in England and America in cases where the lift of locks was so great as to necessitate a great wastage of water and loss of time. Since 1876 several vertical lifts have been constructed where very great heights had to be overcome, compressed air being the power medium. The invention of locks gave a great impetus to canal construction, and all over Europe large systems of internal navigation were constructed. Indeed the improvement of river channels was neglected for a long time, and canals were built parallel to rivers, and the opinion was expressed by an eminent English engineer, near the end of the 18th century, that «rivers were created for the purpose of feeding canals.»

During the first half of the 19th century about 3,000 miles of canals were constructed in the United States. Much experience in hydraulic construction was thus had, and many improvements in methods of construction were introduced; but there cannot be said to have been much advance in hydraulic science in this direction. In the matter of river improvement, however, the work done by the United States government on the Mississippi, and the records kept of the results attained, were of great scientific value, and enabled the Mississippi River Commission of 1879 to formulate the principles which should be observed in the regulation of large rivers of that class. Both in Europe and America during the last 30 years there has been great advance made in careful observation of the phenomena of rainfall, evaporation, seepage, and infiltration as affecting the run-off of rivers and the fluctuations in their flow at different seasons of the year and for periods of years. The action of flowing water on different materials and modes of construction has been also observed more systematically than ever before, with the result of a decided advance in hydraulic science and its practical application to the economical and effective improvement of river regulation in the interest of water transportation.

The question of the regulation of smaller non-navigable streams, so as to prevent injury to the territory along them from escaping floods, has of late been receiving attention. It is considered by some engineers that it will be practicable, by the construction of large storage reservoirs with restricted outlets, so to restrain the discharge at points along the course of a stream that sudden and great floods may be prevented. Experience has not yet proved the practicability of such an automatic regulation of the flow, but there is little question that before long efforts will be made to accomplish this object, or at any rate to acquire data from which a practicable scheme may be devised.

It is in the application of hydraulic science to the comfort and convenience of the individual rather than of the community that the most striking progress has been made during the last few generations. The fostering of agriculture and the improvement of means of transportation of heavy freights are of benefit to the public at large, but the furnishing of pure and wholesome water for household consumption in large quantities and at reasonable cost affects the health, the comfort, and the general condition of the individual directly. There are remains of structures which were evidently designed to supply water to large communities in the oldest partly civilized nations, but these are of crude design and display evidences of lack of knowledge of hydraulic principles. The Romans, about 500 B.C., built numerous aqueducts to convey water from distant sources, not only to the Imperial City itself, but also to the larger cities in their provinces; but for several hundred years after the fall of the Roman empire there did not appear to have been any works built for supplying water to communities. It was not until 1582 that London was furnished with water by Peter Morrys, who pumped it from the Thames and supplied a portion of the city. The grant under which he did so is still held by his successors.

There has been steady progress in the art of supplying water to towns during the last 300 years and now the questions which the

hydraulic engineer is required to consider in the design and construction of any waterworks embrace a great variety of subjects. It is necessary to consider:

1. The quantity of water likely to be needed. There is not yet any consensus of opinion among engineers on this point, the estimates varying from 100 to 150 gallons per day for each resident of the district to be supplied, at the expiration of 20 years from the inauguration of the supply. The prospective population is estimated from the records of the past growth of the district and the growth of districts of similar character of occupation.

2. The possible sources whence the required quantity of water can be obtained.

3. The character of the water obtainable from each source, as regards its chemical constituents, in order to judge of its economical as well as its sanitary value. It sometimes happens that a water otherwise acceptable is so charged with certain chemicals that the amount of soap required for washing with it is greatly in excess of that required by another water more difficult to procure, so much so that the cost to individual consumers for its constant use will be greater than the cost to the community of the introduction of the other supply.

4. The character of the water biologically; the number and nature of the organisms which are found in it. This is most important from the sanitary point of view. The identification of certain organisms as pathogenic or disease-producing is of recent origin; it marks a decided advance in sanitary science and is of great interest to the hydraulic engineer, since it is found that the removal of the injurious organisms from water can be effected by filtration, and it is the engineer's function to design or construct works for filtration through sand or other material which experiment proves to be adapted to the purpose.

5. The quantity of water obtainable from each source which appears generally suitable, the area of the watershed, the amount of annual rainfall upon it, the distribution of the rainfall through the year, the geological and topographical features of the surface, the range of temperature of the air, and the amount of evaporation must all be taken into consideration. Whenever the minimum rate of daily run-off from the watershed exceeds the maximum daily consumption to be provided for, reservoirs must be constructed to retain the stream-water in times of excessive flow, and deliver the excess gradually as required. The location of such reservoirs requires a thorough acquaintance with the topography of the district, and their construction demands a high order of both theoretic and practical acquaintance with the action of water on various materials and with the form and method of their collocation. The construction of dams of earth and masonry has been the subject of careful study within the last few years, and the general principles have been pretty well established; but there still remain a number of unsettled problems due largely to the progress of the mechanical arts and the introduction of new modes of construction. Just how far, for instance, combinations of metal and masonry, which assure strength with a reduction in amount of material and cost, can be depended upon for durability under the action of water in motion, can only be learned after the lapse of more time from the introduction of this class of construction.

6. The means of conveying the water from the source to the point where it is to be used. The conditions of this problem are unlike those which are encountered in rivers, or in canals for either irrigation or navigation. A nearly uniform quantity of water must be continuously carried a long distance at as great a velocity as is consistent with safety and economy. It must be protected from loss by evaporation and by leakage of the channels, and protected from pollution on its route. These conditions are best fulfilled by an enclosed conduit or pipe of masonry or metal, with a smooth interior surface, laid on a uniform grade so that there will not be any upward pressure tending to lift the covering of the conduit. The relations between different values of n, which can be obtained by using different classes of material and of construction, and values of c, obtainable by using different grades and alignments, have been for more than 30 years the subject of carefully conducted experiments by scientists, and it is the function of the hydraulic engineer to apply to the special case he has in hand the use of the materials which are available and the mode of construction practicable in the case, in accordance with the latest results of scientific research. Up to the present time the best form and material for large conduits seem to be masonry conduits of horseshoe form, with smoothly plastered interior surface; or steel-plate circular pipes with as few irregularities caused by rivet-heads as possible, laid on uniform grades, which will ensure a velocity of two miles per hour in the water flowing in the conduit.

7. On reaching the point of distribution an entirely different set of conditions is encountered. The water heretofore concentrated in large masses has to be distributed over a wide area in a great number of small pipes in which orifices are opened and shut at irregular intervals of time, these pipes, moreover, being under a great head of water producing a pressure of 50 to 100 pounds per square inch, and consequently a high velocity of efflux from any orifice. The problem to be solved is so to arrange the connections and sizes of these pipes that, under the ordinary conditions of use, the pressure in the pipes will not be materially altered at any time, and a constant supply may be kept up in the entire system. As illustrating the magnitude and complication of the distribution system in a large city, the conditions existing on Manhattan Island alone, in the city of New York, may be cited. There were there, in 1900, an area of 12,576 acres, 682 miles of pipes for the delivery of water, with 130,000 taps or orifices from which water is drawn at irregular intervals. The development of such a system as this involves the exercise of not only theoretical knowledge of the principles governing the flow of water under all conditions, but also a thorough acquaintance with materials of construction and the methods of using them to produce the best results at the least expenditure.

An interesting and important branch of hydraulic engineering is that which deals with larger masses of water than any of those so

far considered. The water of the ocean, when agitated by the winds and by terrestrial forces not thoroughly comprehended as yet, exerts a dynamic force which must sometimes be restrained and sometimes guided so as to produce results in a desired direction. Along the seacoasts of all countries there are places where the conformation of the shore and the nature of the contiguous lands render the creation of harbors desirable, but where the tidal waves and littoral currents come in conflict in such a way as to make the approach from the sea dangerous to vessels. To lessen the destructive effects of the great masses of water in motion, impelled by either the wind or the tidal currents, breakwaters or piers of stone projecting from the shore are built with good results. The massiveness which such structures are required to possess may be judged from the fact that it has been learned that the foundation for a breakwater must extend out to where there is from 18 to 20 feet of water at low tide; that the height of the waves by which it is likely to be assailed may be from 10 to 20 feet; and that the impact of the wave on the opposing structure may be as high as 6,000 pounds to the square foot. In the open sea it is not likely that waves as high as this are formed, or that the force exerted by them is nearly as great, but the problem of the form and resisting power of the hull of ships has to be considered from the standpoint of the dynamic effect of the water which is impelled by the wind and waves against the hull, as well as the resistance offered by the water to the passage of the hull through it.

The problem of the resistance of the water to a vessel passing through it enters into the consideration of the navigation of canals and inland waters as much or possibly even more than it does into ocean navigation. The more rapidly a vessel passes through a small channel, the greater is the work to be done in the displacement of the bulk of water occupied by the hull. The displaced water is prevented from flowing off by the adjacent banks and shallow bottom, and the pressure required to propel the boat is so increased that it is found that a greater velocity than three miles per hour is not economical.

Hydromechanics, as already stated, relates to the mechanical effects which may be produced by utilizing the force exerted by water in motion to generate power. In hydraulic works, distinctively so called, the effort is constantly made to diminish the mechanical effect of the moving water so as to avoid injury to surfaces and substances unprepared to resist it. In hydrodynamic works the effort is made to concentrate all the power obtainable from the moving water and transmit it to machines which do effective work. The difficulty of transmitting the power long distances without great loss has hindered utilization in many cases where a great head of water is available in some out-of-the-way spot, but recent improvements in electrical transmission have made such water-powers available for use, and many developments of hydraulic generation of electricity have been made, while others are now in course of construction. The utilization of Niagara Falls is a prominent instance of work of this class, and the latest installation in progress there is noteworthy for its boldness and promise of economical effectiveness, the head on the turbine wheels being obtained by sinking a vertical shaft on the shore a short distance above the falls and discharging the water through a tunnel run under the bed of the river to the precipice behind the Horseshoe Fall.

In the present state of hydraulic science more attention is being paid than ever before to the obtaining of closely accurate results of experiments conducted by skilled observers, in which the aid of electricity is used to register all phenomena in a manner never possible heretofore. Great as the advances have been during the last 25 or 30 years, equal or greater progress in the elucidation and practical application of principles may be expected within the next quarter of a century.

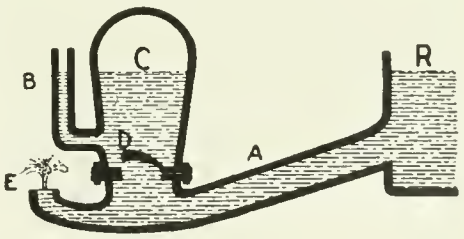
Hydraulic Press. See Hydrostatic Press.

Hydraulic Ram, a machine for raising water, the force being a greater body of water at a lower level. It consists primarily of two pipes, one, A, leading from the reservoir, spring, pond or other source of supply into C, an air-vessel, the opening being by a valve D; and the other pipe, B, leading out of this air-vessel. In the pipe A, or an extension of it is a ball valve E, smaller than the inside of the pipe. This ball valve E is forced shut by the free flow through A; the growing pressure forces D the valve into the air-vessel open; and the water flows into C the air-vessel and, to a less degree because of the smaller diameter of the pipe, into the discharge pipe B. The greater pressure on the air in C counteracts the force of the liquid column from A and the valve D closes. The force of the compressed air in C is then exerted to drive water from the air-vessel into the discharge pipe B. The efficiency of a hydraulic ram is seldom more than two thirds, so that 150 units of water falling 15 feet will lift 15 units only 100 feet, instead of 150 feet, as it theoretically should. The ram was invented in 1797 by Montgolfier and is commonly used where there is no regular waterworks but a plentiful supply of water.



Hydraulics, the branch of mechanics dealing with liquid flow in pipes and channels. The particles of fluids flow over each other with less friction than over solid substances; and as each particle is under the influence of gravitation no quantity of homogeneous fluid having its surface free can be in a state of rest unless every part of the surface is level. When water flows in a current, as in rivers, it is in consequence of the inclination of the channel, but all such motion is affected by the form of the channel and the friction of its sides. Experi-

mental investigation gives various coefficients, whereby the resistance to the flow of water in pipes or channels can be calculated. As water in descending follows the same laws as other falling bodies its motion is accelerated; in rivers, however, the velocity and quantity discharged at different depths is not as the square roots of those depths, the friction against the bottom diminishing the rapidity of the flow. But the law of the proportionality of the velocity of discharge to the square root of the depth applies, however, to the spouting of water through jets. Thus, if a hole be made in the side of a vessel of water, the water at this orifice, which before was only pressed by the simple weight of the perpendicular column above it, will be pressed by the same force as if the water were a solid body descending from the surface to the orifice.

Machines to raise water may be divided into four classes. Machines in which water is lifted in vessels by the application of some mechanical force to them were the earliest hydraulic engines; a type is the Persian wheel, a large vertical wheel, turned by animal power or by running water, and having buckets attached to the rim, and moving in a reservoir of water. The buckets are filled at the bottom and emptied at the top, so that the water is raised a height equal to the diameter of the wheel. The common dredges for rivers and harbors are modifications of this kind of machine. The Archimedian screw, the screw-pump and the bucket-engine or chain-pump are all on the same principle. The chain-pump usually consists of a succession of long links of metal rods revolving like an endless rope over two wheels, one under water. On this chain, between each joint, is fixed a flat piece of wood or metal, usually square, supported and kept in place by the projecting arms of the wheels; the wheel not under water is turned by a winch, which causes the whole chain to move, one side of it passing upwards, while the other side is continually descending in the same direction. The ascending side of the chain is made to pass through a box or pipe, one end of which is immersed in the water, the other end nearly reaching the upper wheel; this box corresponds in shape with the size of the plates, which fit pretty closely and form the pump. The succession of plates passing upward through the trunk forms a succession of cavities which are filled with water and are constantly discharged at the top. This pump will only work in deep water, and cannot drain a reservoir to the bottom; but it has the advantage of not becoming choked with sand or weeds. If the top and bottom wheels of this machine be retained, while the tube or trunk is taken away, and a number of small boxes or buckets be attached to the chain instead of the plates the machine then becomes a bucket-engine, which is only another form of the Persian wheel already described.

In the next class, more commonly called pumps, the water is raised by the pressure of the atmosphere. These act by removing the air from the surface of the water, which may thus be raised to the height of about 32 feet. Whenever it becomes necessary to raise water to greater heights, the third class of machines, or those which act by pressure on the water, are employed. The common suction-pump consists of a hollow cylinder A, of wood or metal, which contains a piston B, stuffed so as to move up or down in the cylinder easily, and yet be air-tight: to this piston there is attached a rod which reaches at least to the top of the cylinder when the piston is at the bottom. In the piston there is a valve C, and at the bottom of the cylinder there is another valve D also rising upwards, which covers the orifice of a tube fixed to the bottom of the cylinder, and reaching to the well from whence the water is to be drawn. This tube is commonly called the suction-tube, and the cylinder the body of the pump. When the piston is at the bottom of the cylinder there can be no air, or very little between it and the valve D. But the air in the cylinder being very much rarefied, the pressure of the valve D on the water at the bottom will be much less than that of the external atmosphere on the surface of the water in the well; therefore the water will be pressed up the pump

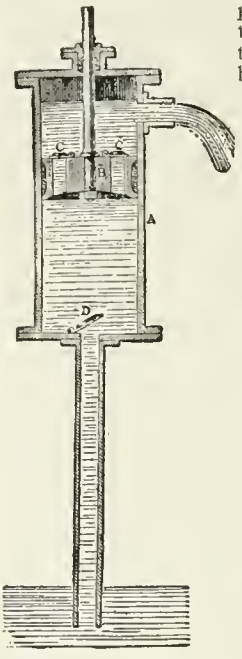


Fig. 1.—Suction Pump.

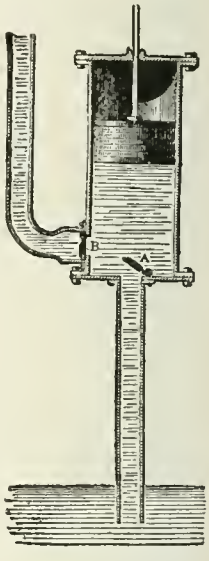

Fig. 2.—Forcing Pump.

to a height not exceeding 32 feet. As the valves shut downward, the water is prevented from returning. The quantity of water discharged in a given time is determined by considering that at each stroke of the piston a quantity is discharged equal to a cylinder whose base is the area of a cross section of the body of the pump, and height the play of the piston. Thus if the diameter of the cylinder of the pump be 4 inches, and the play of the piston 3 feet, then by mensuration we have to find the content of a cylinder 4 inches diameter and 3 feet high, the area of the cross section of the cylinder will be .08733 square feet; hence $.08733 \times 3 = .26199$ the content of the cylinder in cubic feet and the quantity of cubic feet of water discharged by one stroke of the piston.

The lifting-pump, like the suction-pump, has two valves and a piston, both opening upwards; but the valve in the cylinder, instead of being placed at the bottom of the cylinder, is placed

in the body of it, and at the height where the water is intended to be delivered. The bottom of the pump is thrust into the well a considerable way, and when the piston is at the bottom as its valve opens upwards, there will be no obstruction to the water rising in the cylinder to the height which it is in the well, for water will always endeavor to come to a level. Now when the piston is drawn up the valve in it will shut, the water in the cylinder will be lifted, the valve in the barrel will be opened, and the water will pass through it, and cannot return as the valve opens upward; another stroke of the piston repeats the same process, and in this way the water is raised from the well. But the height to which it may be raised is not in this, as in the suction pump, limited to 32 feet. To ascertain the force necessary to work this pump, we are to consider that the piston lifts a column of water whose base is the area of the piston, and height the distance between the level of the water in the well and the spout at which the water is delivered.

The forcing-pump constitutes the third class. It can raise water to any height. The piston of this pump has no valve, but there is a valve at the bottom of the cylinder, as is shown at A. In the side of the cylinder, and immediately above the valve A, there is another valve B opening outward into a tube, which is bent upward to the height at which the water is to be delivered. When the piston is raised the valve in the bottom of the pump opens, and a vacuum being produced, the water is pressed up into the pump on the principle of the suction-pump. But when the piston is pressed down the valve A at the bottom shuts, and the valve B at the side which leads into the ejection-pipe opens, and the water is forced up the tube. When the piston is raised again the valve B shuts and the valve A opens. In this form the discharge is not continuous. To make it so an air-vessel is fastened to the top of the eduction pipe. The air-vessel is a box, with a valve opening upwards into it and covering the top of the pipe. A tube is fastened into the top of the box, and reaches nearly to the bottom; it rises out of the box, and is furnished with a stop-cock. If the stop-cock be shut, and the water be sent by the action of the pump into the air-vessel, it cannot return because of the shutting of the valve at the bottom of the box; and because of the space occupied by the water, the air in the box is condensed, and will consequently exert a proportionate pressure on the water in the air-vessel, and force it up through the tube. The stream of water issuing will therefore be continuous, the pressure being continuous.

The fourth class of hydraulic machines for raising water consists of such engines as act either by the weight of a portion of the water which they have to raise, or of any other water that can be used for such purpose, or by its centrifugal force, momentum, or other natural powers. The centrifugal pump consists of a drum or wheel containing a series of curved vanes; this wheel is encased in a circularly-shaped casing, gradually enlarging toward the outlet. The wheel with its vanes being rapidly rotated causes the water to be impelled outward into the casing and ultimately discharged from the outlet. This machine is very similar in form to the vortex-wheel or turbine, the direction of flow of the water being, however, in the reverse direction.

An ingenious form of pump called the *pulsometer* has lately been devised and extensively employed. It consists essentially of a double chamber, having a ball-valve at top, and clack-valves at bottom. Steam is admitted to one of the chambers and presses out the water contained there. Condensation then taking place a vacuum is formed, and the ball falls over and closes the opening through which the steam entered, and water flows up through the clack-valves and again fills the chamber. The steam in the meantime acts upon the water contained in the adjoining chamber. Condensation then taking place there the ball falls back to that side, and the operations go on alternately, the result being a steady stream of water sucked into one chamber after another, and then forced out and upward by the steam pressure. The water is drawn into the machine from the centre. To the fourth class also belongs the hydraulic ram (q.v.).

Water-wheels are either vertical or horizontal. The former class is undershot, overshot, or breast-wheel, as the water is fed to it from below, above or at the middle of the wheel.

The undershot wheel, the oldest form, acts chiefly by the momentum of the water, the weight of the water being scarcely called into action, and so can be used where there is a great supply of water always in motion. It is the cheapest of all water-wheels, and is more applicable to rivers in their natural state than any other form of the wheel; it is also useful in tide-currents, where the water sets in opposite directions at different times, because it receives the impulse equally well on either side of its floats. In the overshot wheel the circumference is furnished with a series of buckets, into which the water is delivered from above. The buckets on one side being erect, will be loaded with water, and the wheel will be thus set in motion; the mouths of the loaded buckets being thus turned downwards by the revolution of the wheel, will be emptied, while the empty buckets are successively brought under the stream by the same motion and filled. The breast-wheel differs from this in receiving the water a little below the level of the axle, and in having floats instead of buckets. In these two wheels the weight of the water is used as well as its momentum, and a much greater power is therefore produced with a less supply of water than is necessary for the undershot wheel. In order to permit these wheels to work with freedom, and to the greatest advantage, it is necessary that the back or tail water, which is discharged from the bottom of the wheel, should have an uninterrupted passage off; otherwise it accumulates and forms a resistance to the float-boards.

Turbines or horizontal water-wheels are very suitable for high falls of water, as the action of such wheels depends upon the impulse of the water and not upon its direct weight as in the overshot wheel. Turbines have been divided into three classes: parallel-flow, where the water is supplied and discharged vertically; outward-flow, where the water acts from the centre outward; and inward-flow, where the water acts from the outside, the currents flowing inward toward the centre. In all cases the greatest effi-

ciency is obtained when the water acts upon the blades of the wheel without causing a shock, and leaves the wheel without having any whirling motion. See HYDRODYNAMICS; HYDROSTATICS.

Hy'drazine, or Di-Amidogen, a substance having the formula N_2H_4 (or $H_2N.NH_2$), obtained (together with oxalic acid, $H_2C_2O_4$,) by heating an aqueous solution of the complicated substance known as triazoacetic acid $(C_3H_3N_6)_3(COOH)_3$. It is a gas with a peculiar penetrating odor, but the properties of the pure substance are imperfectly known, on account of the avidity with which it combines with water to form the hydrate, $N_2H_4.H_2O$, and the consequent difficulty of isolating it. Hydrazine is a powerful base, combining with acids to produce numerous definite crystalline salts. Among these the sulphate, $N_2H_4.H_2SO_4$, and the two hydrochlorids, $N_2H_4.2HCl$ and $N_2H_4.HCl$, are important. The hydrate may be prepared by boiling the sulphate with a solution of caustic soda. It is a fuming liquid, somewhat oily in appearance, and boiling at 245° F. The hydrate reduces cold ammoniacal solutions of silver nitrate, and also reduces Fehling's solution. It attacks glass, cork and india rubber, but may be kept in silver vessels.

(2) The substances derived from hydrazine by replacing one or more of its hydrogen atoms by compound radicals are also called "hydrazines." If only one hydrogen atom is replaced the hydrazine is said to be "primary." If two hydrogen atoms are replaced, the hydrazine is said to be "secondary." The radical which replaces the hydrogen may belong to the fatty series, or to the aromatic series. One or more of the hydrogen atoms may also be replaced by a metal, such as sodium. The most important of the organic hydrazines is phenyl hydrazine, in which one of the hydrogen atoms is replaced by the aromatic radical phenyl, C_6H_5. This substance, which has the formula $(C_6H_5)HN.NH_2$, is an oily liquid, which solidifies to monoclinic tablets at 73° F. It mixes with alcohol, ether, benzene and chloroform, but hardly at all with water. It reduces Fehling's solution in the cold, and is very poisonous. A secondary hydrazine is "symmetrical" when the two substituted radicals are attached to different nitrogen atoms; it is "unsymmetrical" if they are attached to the same nitrogen atom. Thus $(C_6H_5)HN.NH(C_2H_5)$ is the symmetrical secondary hydrazine of phenyl (C_6H_5) and ethyl (C_2H_5), while $(C_6H_5)(C_2H_5)N.NH_2$ is the unsymmetrical secondary hydrazine of the same radicals.

Hy'dride, a chemical substance consisting of hydrogen combined with a metal, or some simple or compound metallic base.

Hydriod'ic Acid, an acid composed of hydrogen in combination with iodine, and having the formula HI. Hydriodic acid is analogous to the more familiar hydrochloric acid, both in its chemical structure and in its general properties. It may be prepared by the direct union of hydrogen and iodine at a red heat. A more convenient method, however, consists in passing sulphuretted hydrogen gas (H_2S) through water in which a little pulverized iodine is suspended. The reaction is $H_2S + 2I = 2HI + S$. Fresh supplies of iodine are added from time to time, and the liberated sulphur is finally removed by agitation and filtration, the sulphuretted hydrogen remaining in solution being also removed by the application of a gentle heat. The aqueous solution so prepared possesses strongly acid properties, and combines with bases to form salts called iodides. From it, or by other methods that are given in the larger treatises on chemistry, pure hydriodic acid, free from water, may be prepared. The pure acid is a colorless gas, with an odor similar to that of hydrochloric acid gas. It has a density about 63 times as great as that of hydrogen, and at a temperature of 32° F. it condenses to a liquid when subjected to a pressure of four atmospheres; the liquid so obtained freezing to a solid mass at about 67° F. below zero. The specific heat of the gas, at ordinary temperatures, is about 0.055 (at constant pressure), and the ratio of its specific heat at constant pressure to its specific heat at constant volume is 1.397. It dissolves freely in water, the specific gravity of a saturated aqueous solution, at 32° F., being about 2.00. The aqueous solution is colorless when pure, but it is slowly decomposed by sunlight, becoming dark from the liberation of iodine.

Hydriodic Ether (more correctly known as "iodide of ethyl"), a heavy, colorless liquid with a sharp, pungent taste and a penetrating ethereal odor, obtained by acting upon pure ethyl alcohol ($C_2H_5.OH$) by iodine, in presence of phosphorus. It has the formula C_2H_5I, boils at 162° F. (under ordinary atmospheric pressure), and has a specific gravity of about 1.946. When not quite pure it becomes brownish upon exposure to light, from the liberation of iodine. In chemistry, hydriodic ether (or ethyl iodide) is largely used as a fundamental substance in the preparation of the various other compounds of ethyl.

Hydrobro'mic Acid, or **Hydrogen Bromide,** a compound having the formula HBr, and analogous in its general properties to hydrochloric and hydriodic acids. Hydrogen and bromide do not combine directly, even in strong sunlight; but when hydrogen that is charged with bromine vapor is burned, hydrobromic acid and water are formed. Hydrogen and bromine may also be made to combine by electric sparks, or by passing the mixed gases over hot platinum. The most convenient way of preparing the acid, however, is by the action of bromine upon water, in the presence of phosphorus, the reaction being $4H_2O + 5Br + P = 5HBr + H_3PO_4$. Phosphoric acid, it will be seen, is formed at the same time; but the two are easily separated by heat. Pure hydrobromic acid, when free from water, is a colorless gas, having a density about 39.1 times as great as that of hydrogen. Under ordinary atmospheric pressure it condenses into a liquid at 99° F. below zero, and at a slightly lower temperature it crystallizes. It dissolves freely in water, a saturated solution, at 32° F., having a specific gravity of 1.78. A concentrated aqueous solution of hydrobromic acid fumes strongly in the air, but does not decompose. Hydrobromic acid is a powerful acid, forming, with metallic bases and with organic radicals, definite salts called "bromides." The bromides of the alkalies are greatly used in medicine as sedatives. Bromide of silver is also extensively used in photography, in the manufacture of sensitive dry-plates.

Hydrocar'bons, compounds consisting solely of carbon and hydrogen. They are exceedingly numerous, and many of them occur in nature, both in petroleum, asphaltum, and other similar minerals, and in the essential oils of plants. The hydrocarbons can be broadly divided into two general classes, according to the way in which the carbon atoms that they contain are connected to one another. In the fatty series, the atoms are all connected in open chains, while in the aromatic series the carbon atoms are connected with one another in such a manner as to form closed rings. (See FATTY COMPOUNDS and AROMATIC COMPOUNDS.) As a class, the hydrocarbons are insoluble in water; they cannot be saponified; and they are neutral, and do not combine with acids to form salts.

The classification of the hydrocarbons is as yet incomplete; but the greater number of those that are known can be included in one or another of the following groups:

1. The *Paraffins,* having the general formula C_nH_{2n+2}. The lowest member of this series is methane, or marsh gas, CH_4, and many other members of the series are known, each containing one carbon atom and two hydrogen atoms more than its immediate predecessor. (See PARAFFINS.)

2. The *Olefines,* having the general formula C_nH_{2n}. Ethylene, C_2H_4, is the simplest member of this series.

3. The *Acetylene* series, having the general formula C_2H_{2n-2}. Acetylene gas, C_2H_2, is the simplest representative of this series.

The foregoing all belong to the fatty subdivision. To them we may add:

4. The *Benzene* series, having the general formula C_nH_{2n-6}, and

5. The *Terpenes,* a class of substances having the general formula $C_{10}H_{16}$. Both of these latter series belong to the aromatic subdivision of the general hydrocarbon group.

The known hydrocarbons having any one general formula may be ranged in a series, whose members exhibit a sort of regular progression in their properties. For example, the first eight members of the normal paraffin group may be arranged as follows:

		Boiling point.
Methane	CH_4	(Gaseous)
Ethane	C_2H_6	"
Propane	C_3H_8	"
Butane	C_4H_{10}	34° F.
Pentane	C_5H_{12}	100° F.
Hexane	C_7H_{16}	158° F.
Heptane	C_8H_{14}	210° F.
Octane	C_8H_{18}	255° F.

A series of this sort is said to be "homologous."

The paraffins are said to be "normal" when they contain but two methyl groups, (CH_3). Thus normal propane, C_3H_8, has the constitutional formula $CH_3.CH_2.CH_3$; and it is not possible to arrange its atoms in any other way. In proceeding from this hydrocarbon to the next in the same series (that is, butane, C_4H_{10},) we may substitute the methyl group, CH_3, for a hydrogen atom in the CH_2 of the propane, or for a hydrogen atom in one of the CH_3 groups. Hence we may have either of the two following constitutional formulas for the hydrocarbon butane:

or

$$CH_3—CH_2—CH_2—CH_3.$$

The latter compound, which contains only two CH_3 groups, is called "normal butane"; while the former, which contains three such groups, is known as "isobutane." Two butanes, each having the empirical formula C_4H_{10}, are therefore possible, and both are actually known. When we pass to the higher members of the paraffin group we find that a far greater number of isomeric forms can exist, according to the way in which the new CH_3 group is introduced, in generating the new hydrocarbon from the one next below it in the general series. Thus octane, C_8H_{18}, can exist in 18 different isomeric forms, and tridecane, $C_{13}H_{28}$, in no less than 802.

Hydrochlo'ric Acid, an important compound of hydrogen and chlorine, which under the names "spirit of salt" and "muriatic acid," has been known in aqueous solution from very early times. It has the chemical formula HCl, and may be formed by exposing a mixture of equal volumes of hydrogen and chlorine to diffuse daylight, the combination taking place quietly under these circumstances, but explosively under the influence of direct sunlight. A more convenient and usual method of preparing hydrochloric acid is by treating common salt ("sodium chlorid," NaCl) with strong sulphuric acid (H_2SO_4). The reaction is as follows: $NaCl + H_2SO_4 = HNaSO_4 + HCl$. Pure hydrochloric acid is a colorless gas, 1.269 times as heavy as an equal volume of air at the same temperature and pressure. At a temperature of 50° F. it condenses, under a pressure of 40 atmospheres, to a colorless liquid, which boils, under ordinary atmospheric pressure, at 171° F. below zero, and solidifies at a temperature about 6° below the boiling point. The specific heat of the gas at constant pressure (compared with water) is about 0.19; and the ratio of its specific heat at constant pressure to its specific heat at constant volume, at ordinary temperatures, is 1.389. Hydrochloric acid gas was first prepared, in an approximately pure state, by Priestley, in 1774; but it was believed to be an oxid of a new element (provisionally called "murium") until Davy, in 1810, showed that it is a compound of hydrogen and chlorine.

Hydrochloric acid gas is exceedingly soluble in water. If a dry glass flask, which is completely filled with the dry gaseous acid, be brought mouth downward under water, and the stopper is then removed, solution takes place with such extreme rapidity that the water is often drawn into the flask suddenly enough to break it. By passing a stream of the gaseous acid into water, an aqueous solution may be prepared which has a specific gravity, when saturated, of 1.21. The commercial acid is commonly known, to the present day, as "muriatic acid." Large quantities of it are obtained as a by-product in the manufacture of sodium carbonate from common salt; but the acid so produced is not entirely pure, and the traces of iron and other impurities that are present give it a yellowish tinge. Aqueous hydrochloric acid is largely used in the laboratory, and also in the

arts in the manufacture of a great variety of substances.

Hydrochloric acid combines with metallic bases to form salts which are known as "chlorids." Common salt (chlorid of sodium, NaCl) is the most familiar and the most abundant example, in nature, of this class of substances. The chlorids of silver, gold, mercury, barium, aluminum, platinum, and ammonia are also important, and are described under MERCURY, ALUMINUM, etc.

Hydrocyan'ic Acid, or **Prussic Acid,** an exceedingly poisonous substance, discovered by Scheele in 1782. It has the chemical formula HCN, and may be formed by passing a series of electric sparks through a mixture of nitrogen and acetylene (q.v.). The reaction in this case is $2N + C_2H_2 = 2HCN$. The pure acid is more conveniently prepared by passing sulphuretted hydrogen gas, H_2S, over dry mercuric cyanide, $Hg(CN)_2$, hydrocyanic acid and mercuric sulphid being formed, according to the equation $Hg(CN)_2 + H_2S = 2HCN + HgS$. As thus prepared, hydrocyanic acid is a volatile liquid, boiling at 80° F. and freezing at 5° F., and possessing a peculiar smell of bitter almonds. It is so intensely poisonous that a single drop of the anhydrous acid produces instant death when swallowed, and its vapor, even when mixed with considerable quantities of air, is also exceedingly poisonous. It mixes readily with water, ether, and alcohol. Although it is called an acid, and forms salts that are known as "cyanides," it is very weak in its acid properties. It does not redden litmus paper, and its salts are readily decomposed by other acids.

Among the more important compounds of hydrocyanic acid are potassium cyanide and mercuric cyanide. Potassium cyanide, KCN, may be formed by passing nitrogen gas over a white-hot mixture of charcoal and potassium carbonate, the reaction being:

$$K_2CO_3 + 2N + 4C = 2KCN + 3CO.$$

It is more conveniently prepared, however, by strongly heating potassium ferrocyanide (see below), which breaks up into potassium cyanide, carbide of iron, and free nitrogen. Potassium cyanide is a white salt, soluble in water and in alcohol, and exceedingly poisonous. It is much used in electroplating as a solvent for gold and silver, and also in the extraction of gold from certain ores by the process known as "cyaniding." It melts without decomposition, and in the molten state it is a powerful reducing agent. For this reason it is often used as a flux in welding, and in other metallurgical operations.

Mercuric cyanide, which is also very poisonous, is used in medicine, and is prepared by dissolving mercuric oxid in an aqueous solution of hydrocyanic acid.

Allied to hydrocyanic acid are two other acids, known respectively as "ferrocyanic acid," $H_8Fe_2(C_3N_3)_4$, and "ferricyanic acid," $H_6Fe_2(C_3N_3)_4$, which are not of any importance in the arts in the free state, but whose potassium salts are much used. Potassium ferrocyanide, or yellow prussiate of potash, $K_8Fe_2(C_3N_3)_4 + 6H_2O$, is prepared on a large scale by heating a mixture of nitrogenous organic matter and caustic potash, and treating the mass with freshly prepared ferrous carbonate. Crude cyanide of potassium is formed in the first instance, and this combines with the ferrous carbonate to form the yellow prussiate of potash and potassium carbonate, from which the yellow prussiate may be obtained in large crystals, by evaporation. When pure, the yellow prussiate is not poisonous. It is used, in the arts, as a source of Prussian blue, and also for the manufacture of potassium cyanide, which is liberated when the yellow prussiate is strongly heated.

Potassium ferricyanide, or red prussiate of potash, $K_6Fe_2(C_3N_3)_4$, is prepared by passing chlorine gas through a solution of the yellow prussiate, two molecules of potassium being thereby abstracted from it, with the formation of potassium chlorid as a secondary product. The red prussiate is used in the manufacture of sensitive paper for making blue-prints.

Hydro-ferricyanic (fĕr-ō-sī-ăn'ĭk) **Acid, and Hydro-ferrocyanic Acid.** See HYDROCYANIC ACID.

Hydrocele, hī'drō-sēl, a collection of serous fluid forming tumors around the testicle or spermatic cord. During fœtal life the testicle pushes the peritoneum before it as it descends from the abdomen into the scrotum. Along the spermatic cord the sac is usually obliterated, but if it is not it may become distended with fluid. The pouch of the peritoneum normally remains alongside of the testicle, and is called the tunica vaginalis. Distentions of these pouches may be congenital, but ordinarily they begin after maturity and probably are due to some fault in the blood-vessels, allowing the escape of the serum. Symptoms are due to the weight of the tumor, and the only danger lies in the possibility of the injury and rupture of the sac. Aspiration of the fluid, followed by the injection of a few drops of carbolic acid, may accomplish a cure, but partial removal of the sac may be necessary.

Hydrodynamics (ὕδωρ, water; δύναμις, force), or *Hydromechanics*, is that part of Dynamics which treats of the motion or rest of fluids under the action of forces. A perfect fluid is defined as a body whose parts are perfectly free to move under the action of the smallest forces, or otherwise, as a body such that the reactions between any two portions of it are normal to the surface separating them. If there is any tangential drag tending to prevent the one portion of the substance from slipping past the other, the fluid is said to be *viscous*. A perfect fluid is an abstraction, like the material particle or the rigid body, but many of the ordinary fluids, like water, alcohol, air, and other gases, are so slightly viscous that for many purposes they may be considered as perfect. The normal reaction, which alone we suppose to be present, is called the *pressure*, and is measured by the limit of the ratio of the force exerted on an element of surface to the area of the element, when both diminish without limit. The usual gravitational unit of pressure is the pound-weight per square inch, the usual scientific, absolute unit (see MECHANICS), is the dyne per square centimeter. The pressure of the atmosphere may be considered as equal to one million dynes per square centimeter.

The fundamental theorem of hydrodynamics is that the pressure on an element of surface is independent of the direction of the normal to the surface. This may be proved by consider-

ing the equilibrium of a small tetrahedron, $ABCD$, Fig. 1, and resolving the forces on its

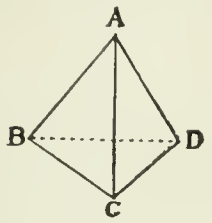

FIG. 1.

faces in the direction BD. The pressure being normal, the forces on ABD, BCD have no component along BD, while if the pressures on ABC, ACD, and the areas of those sides are respectively p_1, p_2, S_1, S_2, their normals n_1, n_2, we have for equilibrium $p_1S_1 \cos(n_1, BD) = p_2S_2 \cos(n_2, BD)$. But $S_1 \cos(n_1, BD)$, $S_2 \cos(n_2, BD)$ are the projections of the areas on a plane perpendicular to BD, which are equal, therefore $p_1 = p_2$. If there are other forces applied to the fluid besides the pressure, such, for instance, as its weight, these will be proportional to the volume of the tetrahedron, and when its size is diminished indefinitely, the volume vanishes to the third order of small quantities, and may thus be neglected in comparison with the area, which is of the second order, so that the result is not affected.

HYDROSTATICS.—We will first consider hydrostatics, or that part of our subject which deals with fluids at rest. Suppose that the fluid is subject to the action of forces whose components along the coordinate axes are equal to X, Y, Z per unit of mass. These we call bodily forces. Now consider the equilibrium of an infinitesimal rectangular parallelopiped, Fig. 2, whose edges, parallel to the coor-

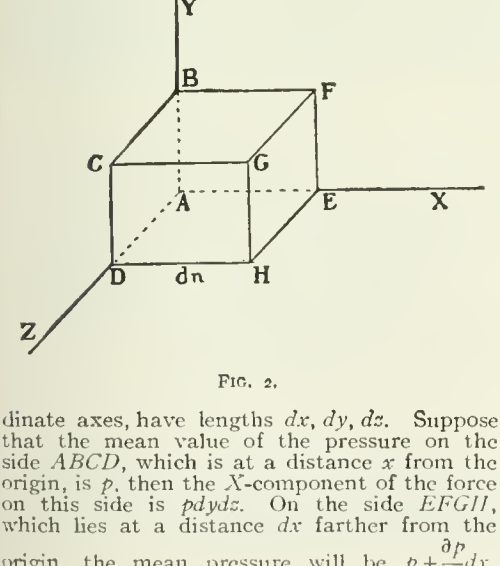

FIG. 2.

dinate axes, have lengths dx, dy, dz. Suppose that the mean value of the pressure on the side $ABCD$, which is at a distance x from the origin, is p, then the X-component of the force on this side is $pdydz$. On the side $EFGH$, which lies at a distance dx farther from the origin, the mean pressure will be $p + \frac{\partial p}{\partial x}dx$, and the component on the face $EFGH$, acting on the parallelopiped, being in the opposite direction will be $-\left(p + \frac{\partial p}{\partial x}dx\right)dydz$. Now if the density of the fluid is ρ, the amount of matter in the parallelopiped, being the product of the density and volume, will be $\rho dxdydz$, and the force exerted upon it in the X-direction will be $X\rho dxdydz$. We must therefore have for equilibrium

$$pdydz - \left(p + \frac{\partial p}{\partial x}dx\right)dydz + \rho X dxdydz = 0,$$

and passing to the limit by decreasing the dimensions, p will be the pressure at any point, and dividing by $dxdydz$, we have

$$\rho X = \frac{\partial p}{\partial x}.$$

In a similar manner we have

$$\rho Y = \frac{\partial p}{\partial y}, \qquad \rho Z = \frac{\partial p}{\partial z}. \tag{1}$$

Thus the fluid can be in equilibrium only under the influence of bodily forces such that the components of the bodily forces, multiplied by the density, are the derivatives of the same function of the coordinates. Now there is in general a physical relation between the pressure of a fluid and the density at any point. If we put

$$P = \int \frac{dp}{\rho}, \quad \frac{dP}{dp} = \frac{1}{\rho},$$

we have

$$\frac{\partial P}{\partial x} = \frac{dP}{dp}\frac{\partial p}{\partial x} = \frac{1}{\rho}\frac{\partial p}{\partial x}, \quad \frac{\partial P}{\partial y} = \frac{dP}{dp}\frac{\partial p}{\partial y} = \frac{1}{\rho}\frac{\partial p}{\partial y},$$
$$\frac{\partial P}{\partial z} = \frac{dP}{dp}\frac{\partial p}{\partial z} = \frac{1}{\rho}\frac{\partial p}{\partial z},$$

and our equations (1) become

$$X = \frac{\partial P}{\partial x}, \quad Y = \frac{\partial P}{\partial y}, \quad Z = \frac{\partial P}{\partial z}. \tag{2}$$

Now this is the condition that the bodily forces are *conservative* (see MECHANICS). In that case the potential energy for unit mass is called the *potential* of the forces, and will be denoted by V. Thus we shall have $P = -V$ + const., and $dV = -dP = -\frac{dp}{\rho}$. If two fluids of different densities are in contact, we have at their common surface

$$-dp = \rho_1 dV = \rho_2 dV,$$

so that

$$(\rho_1 - \rho_2)dV = 0,$$

and since $\rho_1 - \rho_2$ is not zero we must have $dV = 0$, $dp = 0$. Consequently the surface of separation is a surface of constant potential and constant pressure. In the case of gravity we have, if the Z-axis is measured vertically upward, $V = gz$, so that the surfaces of constant V are horizontal planes, and a surface where water is in contact with the atmosphere must be a horizontal plane, or level surface, the pressure being the constant atmospheric pressure. If

we suppose the fluid to be incompressible, we have ρ constant, $P=p/\rho$,

$$(3) \qquad \frac{p}{\rho} = -V + \text{const.} = -gz + \text{const.},$$

$$(4) \qquad p = -g\rho z + \text{const.},$$

so that, if we neglect the atmospheric pressure, and count the depth from the plane $z=0$, we have the fundamental theorem for heavy liquids, namely, that the pressure is proportional to the depth. This may be proved experimentally by placing a well-fitting plate under a tube, Fig. 3, communicating with a

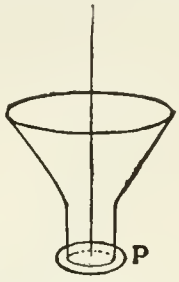

FIG. 3.

vessel of any shape, and holding the plate up by a wire hung from a balance, while water is poured in above. The weight required to hold the plate up is found to be independent of the shape of the vessel, and to depend only on the depth and the area of the plate. The vase and plate may also be immersed in liquid, while, instead of liquid within, weights are placed on the plate; the weight supported will then be proportional to the depth.

Consider now a gas, or compressible fluid, satisfying the law of Boyle and Mariotte,

$$p = a\rho.$$

Accordingly,

$$(5) \qquad P = \int \frac{dp}{\rho} = \int \frac{a\,d\rho}{\rho} = a \log \rho + \text{const.},$$

and

$$(6) \qquad V = gz = c - a \log \rho,$$

$$(7) \qquad \rho = \rho_0 e^{-\frac{gz}{a}}.$$

Thus as we ascend to heights in arithmetical progression the density decreases in geometrical progression, becoming zero at an infinite height. From equation (7) the barometric formula is obtained by which heights are found from barometer readings. The law of Boyle assumes constant temperature. It is, however, more likely that the temperature varies in accordance with what is called convective equilibrium, so that if a portion of air is hotter than the stratum in which it lies it will rise, and, cooling and expanding, will eventually find a layer of the same density and temperature as its own. The principles of thermodynamics give us the relation between pressure and temperature when the rarefaction is adiabatic, that is, when no heat is lost or gained by the air,

$$p = b\rho^{\kappa},$$

where κ is a constant for the gas, whose value is about 1.4. We then have

$$(8) \qquad V = gz = -\int b\kappa\rho^{\kappa-2}d\rho = c - \frac{b\kappa\rho^{\kappa-1}}{\kappa-1}.$$

Since $\kappa > 1$, ρ diminishes as z increases, and is equal to zero when $gz=c$, so that on this hypothesis the atmosphere has an upper limit.

Let us now consider the equilibrium of a solid body floating in a liquid. If we consider the body removed and the space that it occupied filled with water, since this water is in equilibrium, its weight is borne up by the pressure of the surrounding water, the effect of which is accordingly to apply to each portion of the water in question an upward force just equal to its weight. Now just the same forces must be the resultant of the pressures on the solid when it is substituted for the displaced water, so that it is borne up by a force equal to the weight of the displaced water. This is the Principle of Archimedes. Since the resultant of the weight of all the displaced water is a single force applied at its center of mass, the resultant upward thrust on the floating body is applied at a point coinciding with the center of mass of the displaced water. This point is called the *center of buoyancy* of the body. If the body is to be in equilibrium, according to the principles of statics of a rigid body, its weight must be equal to that of the displaced body, and its center of mass and center of buoyancy must be in the same vertical line. If the first condition is satisfied, but not the second, the body will float, but will be subject to a turning couple.

Suppose the body floats without being wholly immersed. A plane which cuts off from the body a volume equal to the volume of water having an equal weight is called a *plane of flotation*, and if we draw all such planes they will envelop a surface called the *surface of flotation*. For every plane of flotation there will be a center of buoyancy, and the locus of all these points is called the *surface of buoyancy*. Suppose the floating body is displaced from its position of equilibrium by rotation through a small angle $\delta\theta$ about an axis OX through O, Fig. 4, and let WL, $W'L'$ be the original and

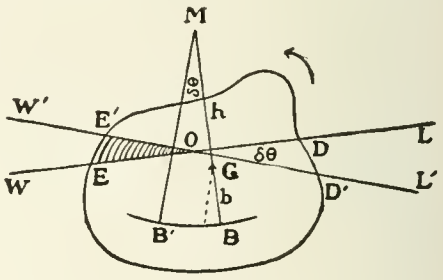

FIG. 4.

final planes of flotation. By turning the figure until either is horizontal both positions of the body may be shown. Let B be the original center of buoyancy, G the center of mass of the floating body. Then if B were the center of buoyancy in the second position,

the body would be acted on by the couple of which either arm would be the weight $W=mg$, and the arm the horizontal projection of BG, $b\delta\theta$, where $b=BG$. The moment of the couple tending to further displace the body will then be $Wb\delta\theta$. But this is not the only couple, for the immersed part is not the same as before, the volume of the wedge EOE' having become immersed, giving rise to an upward thrust, and the wedge DOD' having emerged and lost its buoyancy, both these causes giving rise to a turning moment in the same direction, and opposite to that previously found. Since the volume under water is to be the same in both positions, the volume of the wedges of immersion and emersion must be equal. Since the wedges are infinitely thin, the thickness at any point x, y in the plane of flotation is $s=y\delta\theta$. The condition for equality of volumes is then

$$\iint z\,dx\,dy=\delta\theta\iint y\,dx\,dy=0, \tag{9}$$

the integral being taken over the plane of flotation. This will be the case if the axis passes through the center of mass of the area of flotation. The thrust on any element of volume $d\tau=z\,dx\,dy$ being $g\rho\,d\tau$, the moment about the X-axis will be

$$L'=\iiint g\rho y\,d\tau=g\rho\delta\theta\iint y^2\,dx\,dy=g\rho\delta\theta S\kappa_x^2, \tag{10}$$

where κ_x is the square root of the mean of the squares of the distances of the elements from the X-axis, or the so-called radius of gyration of the area of flotation about the X-axis, and S is the area of flotation. In like manner the moment about the Y-axis is

$$M'=-\iiint g\rho x\,d\tau=-g\rho\delta\theta\iint xy\,dx\,dy. \tag{11}$$

There are always two axes at right angles to each other, called *principal axes*, for which the integral above vanishes, and for such an axis a displacement about it gives rise only to a couple about that axis. Subtracting this couple L' from the one previously found we obtain for the magnitude of the *righting couple*

$$L=g\delta\theta(\rho S\kappa_x^2-mb). \tag{12}$$

If is evident that in moving the point of application of the thrust from the center of mass of one wedge to that of the other, the center of buoyancy will be moved in a parallel direction, so that, in the limit, this direction being that of the plane of flotation, the line BB' will be parallel to that plane, or the tangent to the surface of buoyancy is parallel to the corresponding plane of flotation. It is also evident that the body is under the same forces that it would be if the surface of buoyancy were material and rested on a horizontal plane, for the reaction would be vertical and equal to the weight of the body.

If B' be the new center of buoyancy, and we draw verticals from B and B', they will be normals to the surface of buoyancy and will intersect at M, the center of curvature of the section of the surface of buoyancy. This point is called the *metacenter*, and its distance h_x above G the *metacentric height*. Evidently for stable equilibrium, or a positive righting couple, M must be above G. The arm of the couple being the horizontal projection of MG is equal to $h_x\delta\theta$ and we have $L=mgh_x\delta\theta$. Inserting this in equation (12) we obtain for the metacentric height

$$mh_x=\rho S\kappa_x^2-mb, \tag{13}$$

and dividing by m and writing $V=m/\rho$ for the volume of displaced liquid,

$$h_x=\frac{S\kappa_x^2}{V}-b. \tag{14}$$

The equilibrium is stable or unstable according as this is positive or negative.

For the displacement about the Y-axis we have in like manner a couple proportional to the angle of displacement, with a new metacentric height,

$$h_y=\frac{S\kappa_y^2}{V}-b, \tag{15}$$

where κ_y is the radius of gyration about the Y-axis. It is evident that the metacentric height is greater for a displacement about the shorter principal axis of the plane of flotation. Thus it is easier to roll a ship than to tip it endwise. The above theorems concerning the surfaces of flotation and buoyancy are due to Dupin.

If the floating body is totally submerged, like a submarine boat, only the first moment $mgb\delta\theta$ comes into play, S being zero, and the center of buoyancy becomes the metacenter. The stability is in this case only secured by placing the center of gravity low.

HYDROKINEMATICS.—We will now consider the motions possible to a fluid, without regard to the forces causing them. Let the velocity at a point be the vector q, with components u, v, w, and let us consider the quantity of fluid entering or leaving any closed surface in the unit of time. The amount of fluid which crosses the element of surface dS, Fig. 5,

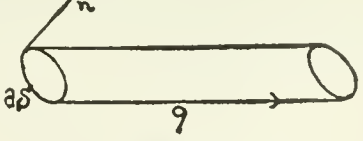

FIG. 5.

with a velocity q would in unit time, if q were constant, fill a prism on the base dS with a slant height q. If n is the normal to dS, the volume of this prism is $dSq\cos(qn)$, and the mass of fluid in it $dS\rho q\cos(qn)$, or using the formula for the projection of q on n (see MECHANICS, equation (12)),

$$dS\rho q_n=dS\rho\{u\cos(nx)+v\cos(ny)+w\cos(nz)\}.$$

Consequently if we consider any closed surface, whose outward normal is n, we have for the whole outflow in unit time the surface integral

$$\Phi=\iint\rho q_n\,dS=\iint\rho[u\cos(nx)+v\cos(ny)+w\cos(nz)]\,dS. \tag{16}$$

But we may find a different expression for the same quantity, by considering the ele-

ments of volume. Consider the parallelopiped of Fig. 2, and let u be the mean velocity on the side $ABCD$, $u+\frac{\partial u}{\partial x}dx$ on the opposite side $EFGH$. Then the inflow on the first side will be $\rho u dydz$, while the outflow through the second will be $\left\{\rho u+\frac{\partial(\rho u)}{\partial x}dx\right\}dydz$. The total outflow will thus be

$$\frac{\partial(\rho u)}{\partial x}dxdydz.$$

In a similar manner we find the outflow through the two remaining pairs of sides to depend on the other two components. From the whole surface we accordingly have the outflow

$$\left\{\frac{\partial(\rho u)}{\partial x}+\frac{\partial(\rho v)}{\partial y}+\frac{\partial(\rho w)}{\partial z}\right\}dxdydz,$$

and for the outflow per unit volume we have

$$\frac{\partial(\rho u)}{\partial x}+\frac{\partial(\rho v)}{\partial y}+\frac{\partial(\rho w)}{\partial z}. \tag{17}$$

On account of this kinematical interpretation, if we have any vector F, whose components X, Y, Z are functions of the coordinates of a point, the expression

$$\frac{\partial X}{\partial x}+\frac{\partial Y}{\partial y}+\frac{\partial Z}{\partial z} \tag{18}$$

is called the *divergence* of the vector, and will be abbreviated div F. Summing up the outflow for all the elements of volume inside the surface S, it is evident that the volume integral thus found must be equal to the surface integral Φ. Thus we have

$$\int\int \rho\{u\cos(nx)+v\cos(ny)+w\cos(nz)\}dS \tag{19}$$
$$=\int\int\int\left\{\frac{\partial(\rho u)}{\partial x}+\frac{\partial(\rho v)}{\partial y}+\frac{\partial(\rho w)}{\partial z}\right\}dxdydz.$$

This may be taken as a kinematical proof of the *Divergence Theorem*, due to Gauss and Green, in which, for any vector function which is continuous and has a definite value at every point in the volume within S,

$$\int\int\{X\cos(nx)+Y\cos(ny)+Z\cos(nz)\}dS \tag{20}$$
$$=\int\int\int\left\{\frac{\partial X}{\partial x}+\frac{\partial Y}{\partial y}+\frac{\partial Z}{\partial z}\right\}dxdydz,$$

or in more abbreviated notation,

$$\int\int F_n dS=\int\int\int \operatorname{div} F\cdot d\tau. \tag{20}$$

The surface-integral in (20) is called the *flux* of the vector F through the surface S. If we have any continuously distributed vector-function F, that is, one whose components X, Y, Z are continuous functions of the point x, y, z, we may draw curves having the property that at every point on a curve its tangent has the direction of the vector F. The differential equations of these curves are

$$\frac{dx}{X}=\frac{dy}{Y}=\frac{dz}{Z}=\frac{ds}{F},$$

and the curves are called *lines* of the vector F. For instance, lines of the vector q are called *lines of flow*. If we draw all the lines of the vector passing through a closed contour, we shall obtain a tubular surface called a *tube* of the vector, Fig. 6.

If the fluid is incompressible, as much fluid must flow out from as into any volume, so

FIG. 6.

that the total outflow is zero. The density is then constant, and we have, dividing (17) by ρ,

$$\operatorname{div} q=\frac{\partial u}{\partial x}+\frac{\partial v}{\partial y}+\frac{\partial w}{\partial z}=0. \tag{21}$$

A vector whose divergence is zero is said to be *solenoidal* ($\sigma\omega\lambda\acute{\eta}\nu$, a tube), for its tubes have the property that the flux across a cap, or portion of a surface bounded by the tube, is the same wherever the surface be drawn. Analytically, applying the divergence theorem to the portion of space bounded by a portion of such a tube and two caps forming ends, since along the sides of the tube the normal component vanishes that portion of the flux in (20) is zero. Accordingly the flux through both ends is zero, or the flux out through one is equal to that in through the other. Or, looking in the direction of the vector-lines, the flux across any cap is the same. If we consider a tube of infinitesimal cross-section, and S is the area of a right section, since the flux is FS, which is constant for the tube, the magnitude of the vector F is inversely proportional to the area of the cross-section.

If the liquid is not incompressible the total outward flux is equal to the time-rate of decrease of the mass inside the surface S, so that, the mass in an element of volume $d\tau=dxdydz$ being $\rho d\tau$, we have

$$-\frac{\partial m}{\partial t}=-\frac{\partial}{\partial t}\int\int\int\rho d\tau=\int\int\rho q_n dS \tag{22}$$
$$=\int\int\int\operatorname{div}(\rho q)d\tau.$$

Now since the volume over which we integrate is independent of the time, we may differentiate under the integral sign; also, both integrals being taken over the same volume, we may combine them into one,

$$\int\int\int\left\{\frac{\partial\rho}{\partial t}+\operatorname{div}(\rho q)\right\}d\tau=0. \tag{23}$$

This equality holding for any volume whatever, the integrand must vanish, so that we have

$$\frac{\partial\rho}{\partial t}+\frac{\partial(\rho u)}{\partial x}+\frac{\partial(\rho v)}{\partial y}+\frac{\partial(\rho w)}{\partial z}=0. \tag{24}$$

This is the so-called *equation of continuity*, the term arising from the continuity of existence of mass, none being created or destroyed, but being conveyed without change from place to place.

Beside the surface- and volume-integrals dealt with above, we need to consider certain

line-integrals. If we resolve the vector q along the direction of the tangent to a curve running from A to B, and multiply by the length of the arc ds, and integrate from A to B along the curve, the line-integral

$$\int q_s ds = \int (u dx + v dy + w dz) \tag{25}$$

is called the *circulation* along the curve. If we describe the curve in the reverse direction, the integral changes sign. If the curve is a closed one, we shall prove the line-integral to be equal to a certain surface-integral over any surface S which has the contour in question as a boundary. Suppose first the contour is a plane curve and the surface is a plane. Let us divide the area up into infinitesimal rectangles by lines parallel to the axes of X and Y, Fig. 7. If we then find the circulation

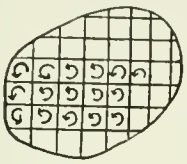

FIG. 7.

around each of the rectangles in the same direction, we shall have gone around all the sides common to two adjacent rectangles twice in opposite directions, so that those parts of the circulation will have destroyed each other, and there will remain only those parts which belong to the original contour. Accordingly the integral around the contour is equal to the sum of all these around the infinitesimal rectangular contours. Consider one of these, $ABCD$, Fig. 8. Along AC the

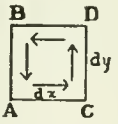

FIG. 8.

tangential component is u, and the contribution to the integral $u dx$. Along BD the value of u is $u + \frac{\partial u}{\partial y} dy$, and since we are going in the opposite direction the contribution to the integral is $-\left(u + \frac{\partial u}{\partial y} dy\right) dx$. Along AB the tangential component is v, and, since we are moving from B to A, the contribution to the integral is $-v dy$. Along CD the tangential component is $v + \frac{\partial v}{\partial x} dx$ and the contribution $\left(v + \frac{\partial v}{\partial x} dx\right) dy$. Adding these four we have

$$\left(\frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}\right) dx dy,$$

and summing for all the rectangles,

$$\int q_s ds = \int\int \left(\frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}\right) dx dy, \tag{26}$$

which is a particular case of our theorem.

If the contour is not a plane curve, so that the surface S is not plane, let us by drawing a series of planes parallel to one of the coordinate planes divide it into infinitesimal strips, Fig. 9, and then by drawing planes alternately

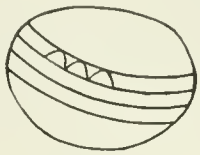

FIG. 9.

parallel to the two other coordinate planes divide each strip into infinitesimal triangles each having one side parallel to each coordinate plane. As before, the sum of the circulations around all the triangles is equal to the circulation around the contour. Let us consider one of these triangles, BCD, Fig. 10, and let A

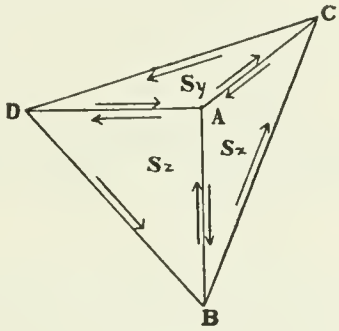

FIG. 10.

be the point from which lines drawn parallel to the coordinate axes will pass through B, C, D. Again, circulation around BCD is equivalent to the sum of the circulations around the triangles ABC, ACD, ADB, the projections of BCD parallel to the coordinate planes. Let the areas of these four triangles be respectively dS, $dS_x = dS \cos(nx)$, $dS_y = dS \cos(ny)$, $dS_z = dS \cos(nz)$, n being the normal to S. Then we have, applying (26) to the three contours,

$$\int_{ABCA} q_s ds = \left(\frac{\partial w}{\partial y} - \frac{\partial v}{\partial z}\right) dS_x,$$

$$\int_{ACDA} q_s ds = \left(\frac{\partial u}{\partial z} - \frac{\partial w}{\partial x}\right) dS_y,$$

$$\int_{ADBA} q_s ds = \left(\frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}\right) dS_z,$$

and consequently

$$\int_{BCDB} q_s ds = \left\{ \left(\frac{\partial w}{\partial y} - \frac{\partial v}{\partial z}\right) \cos(nx) + \left(\frac{\partial u}{\partial z} - \frac{\partial w}{\partial x}\right) \cos(ny) + \left(\frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}\right) \cos(nz) \right\} dS.$$

Summing up for all the infinitesimal triangles, we find the surface-integral over the surface S to be equal to the circulation around the contour.

$$(27)\quad \int (u\,dx + v\,dy + w\,dz) =$$
$$\iint \left\{ \left(\frac{\partial w}{\partial y} - \frac{\partial v}{\partial z}\right)\cos(nx) + \left(\frac{\partial u}{\partial z} - \frac{\partial w}{\partial x}\right)\cos(ny) + \left(\frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}\right)\cos(nz) \right\} dS.$$

This is known as Stokes's theorem.

If we define a vector ω with the components ξ, η, ζ,

$$(28)\quad 2\xi = \frac{\partial w}{\partial y} - \frac{\partial v}{\partial z},\qquad 2\eta = \frac{\partial u}{\partial z} - \frac{\partial w}{\partial x},\qquad 2\zeta = \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y},$$

we have the integrand in the surface-integral in (27),

$$2[\xi\cos(nx) + \eta\cos(ny) + \zeta\cos(nz)] = 2\omega_n,$$

as the component of 2ω normal to the surface S. The vector 2ω is called the *curl* of q, for the reason that if the lines of the vector «curl» about in any region, so that the tangential component along a closed curve always has the same sign, the surface-integral, and hence the curl, cannot vanish. We may write Stokes's theorem in the abbreviated form

$$(27)\quad \int q_s\,ds = \iint (\text{curl } q)_n\,dS.$$

As an example of the kinematical significance of the curl, let us consider a portion of fluid which revolves like a rigid body about the Z-axis. We then have $u = -ay$, $v = ax$, where a is a constant representing the angular velocity. We thus have

$$2\zeta = \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} = 2a.$$

Or applying Stokes's theorem to a circle with center on the axis of rotation, since $q = ar$,

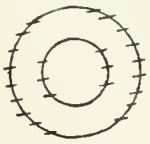

Fig. 11.

the line-integral is $2\pi r \cdot q = 2\pi r^2 a$, which is equal to the area of the circle multiplied by $2a$, which must represent the curl. Thus we

Fig. 12.

find that the curl of the velocity is twice the angular velocity with which an element of fluid is revolving. On this account the vector ω has received the name of *vorticity*, and fluid moving so that ω is not zero is said to move vortically. As the difference between vortical and non-vortical motion is very important, we may illustrate it as follows: It is possible that fluid may circulate in a region either vortically or non-vortically. Suppose that the fluid is filled with short straws represented by the short lines in Figs. 11 and 12; if, as the fluid moves about, these all remain parallel to their original direction, the flow is non-vortical, Fig. 11; if they turn, the flow is vortical, Fig. 12. Thus it is impossible to tell by merely looking at a diagram of stream-lines whether the flow is vortical or not.

It will be shown later that the divergence and curl of a vector function are characteristic of it, and that if they are known everywhere the complete nature of the vector is known. They are quite independent of each other, as is illustrated in Fig. 13, which shows regions where the divergence and curl are zero or not, independently.

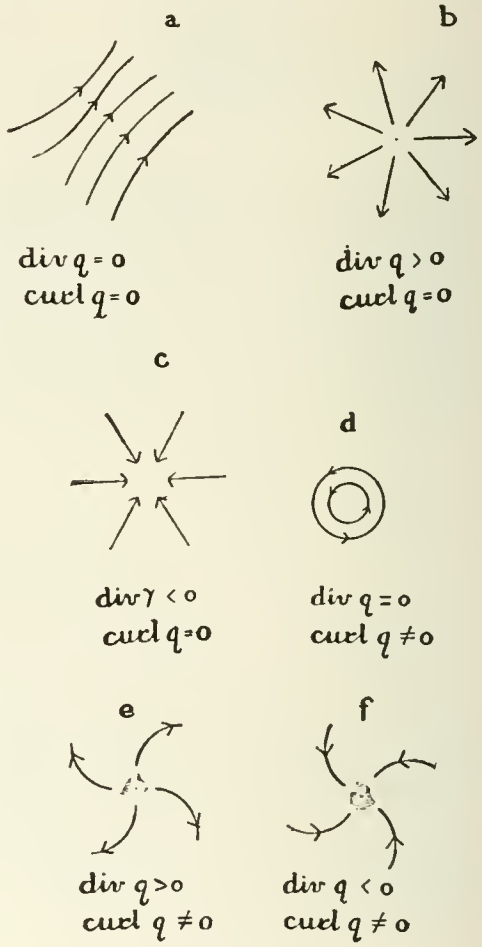

Fig. 13.

Non-vortical Motion.—Let us first examine non-vortical motion, that is, where curl $q = 0$ everywhere. If we connect A and B by any two curves ACB, ADB, the circulation around the

closed path $ACBD.1$ will be zero, hence the circulation from A to B will be the same by either path. Thus the circulation does not depend on the path, but only on the position of its ends, so that we have

$$(29) \qquad \int_A^B q_s ds = \phi_B - \phi_A,$$

which necessitates

$$q_s ds = u dx + v dy + w dz = d\phi$$
$$= \frac{\partial \phi}{\partial x} dx + \frac{\partial \phi}{\partial y} dy + \frac{\partial \phi}{\partial z} dz,$$

and therefore

$$(30) \qquad u = \frac{\partial \phi}{\partial x}, \quad v = \frac{\partial \phi}{\partial y}, \quad w = \frac{\partial \phi}{\partial z}.$$

The function ϕ is called the *velocity-potential*. The direction of the velocity q is everywhere normal to the equipotential surfaces $\phi = \text{const.}$, for if we move along the equipotential we have

$$d\phi = u dx + v dy + w dz = 0,$$

which is the condition that the vectors u, v, w, the velocity, and dx, dy, dz, the displacement, are perpendicular. According to the relation $q_s ds = d\phi$, we have the component of velocity in any direction $q_s = \frac{\partial \phi}{\partial s}$, equal to the space-rate of variation of potential in that direction; and since the velocity itself is equal to the rate of change of ϕ in the direction of the normal to the surface $\phi = \text{const.}$, a vector related to a function ϕ by the relations (30) is called the *gradient* of the function. A vector which is thus derived from a potential function is called a *lamellar* vector.

As an example of lamellar flow, let us take the case in which the velocity is directed radially outwards from a given point a, b, c with a value depending on the distance $r = \sqrt{(x-a)^2 + (y-b)^2 + (z-c)^2}$ from that point, $q = f(r)$. The equipotential surfaces are concentric spheres, and we easily find the potential to be $\phi = \int f(r) dr$. For, since the direction cosines of r are $\cos(rx) = \frac{x-a}{r}$, $\cos(ry) = \frac{y-b}{r}$, $\cos(rz) = \frac{z-c}{r}$, we have the components of the velocity,

$$(30) \qquad u = f(r)\frac{x-a}{r} = \frac{d\phi}{dr}\frac{\partial r}{\partial x} = \frac{\partial \phi}{\partial x},$$
$$v = f(r)\frac{y-b}{r} = \frac{d\phi}{dr}\frac{\partial r}{\partial y} = \frac{\partial \phi}{\partial y},$$
$$w = f(r)\frac{z-c}{r} = \frac{d\phi}{dr}\frac{\partial r}{\partial z} = \frac{\partial \phi}{\partial z}.$$

The flux out through any of the concentric spheres is $M = 4\pi r^2 q$, so that if the fluid is incompressible we must have

$$(31) \qquad q = \frac{M}{4\pi r^2}, \quad \phi = -\frac{M}{4\pi r},$$

where M is constant. The vector q is then solenoidal as well as lamellar, and the equation of continuity becomes

$$(32) \quad \text{div } q = \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} = \frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} + \frac{\partial^2 \phi}{\partial z^2} = 0.$$

This equation for ϕ is known as Laplace's equation, and the sum of the three partial derivatives of second order, which will be abbreviated as $\Delta\phi$, is called the *Laplacian* of q. Obviously the above flow cannot extend as far as $r = 0$, for there the velocity would be infinite. Suppose that in a small region of volume τ at the center liquid is being created just fast enough to supply the outflow, so that the volume M is created per unit of time. Such a region is called a *source*, and the whole system of flow is called a *squirt*. The quantity M is called the *strength* of the source, and the strength per unit of volume $M/\tau = \sigma$ the *source-density*. If we have several sources, and add their potentials, the resultant velocity will be obtained as the gradient of the sum. Thus a complicated vector-field may be represented by its potential function. The sources may be continuously distributed through a portion of space, then σ, the source-density, will be a function of the position of the point, and the total strength will be

$$(33) \qquad M = \iiint \sigma d\tau,$$

while the total potential will be

$$(34) \qquad \phi = -\frac{1}{4\pi} \iiint \frac{\sigma d\tau}{r},$$

where r represents the distance from the element $d\tau$ to the point where ϕ is calculated. The total flux through any closed surface will be

$$(35) \quad \iint q_n dS = \iint \frac{\partial \phi}{\partial n} dS = \iint (\text{grad } \phi)_n dS,$$

or by the divergence theorem,

$$(36) \quad \iint q_n dS = \iiint \text{div } q \cdot d\tau = \iiint \Delta\phi \cdot d\tau$$
$$= \iint (\text{grad } \phi)_n dS.$$

Since this flux must be equal to the strength of all the sources within the surface of integration, we must have

$$(37) \qquad \iiint \Delta\phi \cdot d\tau = \iiint \sigma d\tau.$$

Now as this equality holds for any volume whatsoever, the integrands must be equal; accordingly we have

$$(38) \qquad \Delta\phi = \sigma,$$

as a consequence of equation (34). The equation (38) is called Poisson's equation. We may also prove the converse, namely, that if σ is given as a function of the point, the integral of equation (38) is given by (34). This is done by means of Green's theorem.

In the divergence theorem (20) let us put for the vector F the value $U \cdot \text{grad } V$, where U and V are two functions, both of which, with their derivatives, are finite, singly-valued, and continuous in the region of integration. Then we have

$$X = U\frac{\partial V}{\partial x}, \quad Y = U\frac{\partial V}{\partial y}, \quad Z = U\frac{\partial V}{\partial z},$$

$$\frac{\partial X}{\partial x} + \frac{\partial Y}{\partial y} + \frac{\partial Z}{\partial z} = U\Delta V + \frac{\partial U}{\partial x}\frac{\partial V}{\partial x} + \frac{\partial U}{\partial y}\frac{\partial V}{\partial y} + \frac{\partial U}{\partial z}\frac{\partial V}{\partial z},$$

$$(39)\quad \int\int F_n dS = \int\int U(\text{grad } V)_n dS$$
$$= \int\int U\frac{\partial V}{\partial n} dS$$
$$= \int\int\int \left\{ U\Delta V + \frac{\partial U}{\partial x}\frac{\partial V}{\partial x} + \frac{\partial U}{\partial y}\frac{\partial V}{\partial y} + \frac{\partial U}{\partial z}\frac{\partial V}{\partial z} \right\} d\tau.$$

Interchanging the functions U and V and subtracting from (39), we have

$$(40)\quad \int\int \left\{ U\frac{\partial V}{\partial n} - V\frac{\partial U}{\partial n} \right\} dS = \int\int\int \left\{ U\Delta V - V\Delta U \right\} d\tau.$$

The equations (39) and (40) are known as Green's Theorem. Let us apply it to two functions, one of which, U, is the reciprocal distance from a fixed point P, $U = 1/r$. Let us apply the theorem to the whole extent of space, bounded by the infinite sphere, with the exception of a portion bounded by a small sphere with center at P, which we exclude, on account of the infinite value of U at P. We must thus take the surface-integrals over the large and small spheres, the normals being in each case drawn away from the volume considered, or out in the first case, in in the second. Since the direction of the normal coincides with that of the radius of the sphere,

$$\frac{\partial(1/r)}{\partial n} = \pm\frac{\partial(1/r)}{\partial r} = \mp\frac{1}{r^2},$$

in the two cases respectively, while $dS = r^2 d\omega$, where $d\omega$ is the element of area of a sphere of radius unity, cut out by a cone of vertex P, having as base the element dS. Accordingly on either sphere

$$(41)\quad \int\int V\frac{\partial(1/r)}{\partial n} dS = \mp\int\int V d\omega,$$

and if V vanishes at $r = \infty$, the integral over the infinite sphere vanishes. If we now let the radius of the small sphere diminish without limit, the value of V to be taken is the value at P, so that

$$(42)\quad -\int\int V\frac{\partial(1/r)}{\partial n} dS = -V_P\int\int d\omega = -4\pi V_P.$$

On the other hand the surface-integral

$$\int\int \frac{1}{r}\frac{\partial V}{\partial n} dS = r\int\int \frac{\partial V}{\partial n} d\omega,$$

over the spheres vanishes for $r = \infty$, on account of the vanishing of $\frac{\partial V}{\partial n}$ to the second order, and for the small sphere in the limit, on account of the factor r. As for the volume-integrals we have seen in (31), (32), that any multiple of $1/r$ satisfies Laplace's equation, hence $\Delta(1/r) = 0$, so that finally

$$(43)\quad V_P = -\frac{1}{4\pi}\int\int\int \frac{\Delta V}{r} d\tau,$$

the integral being taken over all space. But this is the required theorem, the converse of (38).

Solutions of Laplace's equation can be found for the case of uniplanar flow, where the velocity is parallel to a given plane, and independent of the coordinate perpendicular thereto A plane diagram then represents the flow. If the given plane is that of X, Y, Laplace's equation becomes

$$(44)\quad \frac{\partial^2\phi}{\partial x^2} + \frac{\partial^2\phi}{\partial y^2} = 0.$$

An infinite number of solutions are furnished us by the method of functions of a complex variable $x + iy$, where i is the imaginary defined by $i^2 = -1$.

If now we take any function $w = f(z)$ of the combination $z = x + iy$, on arranging it in powers of x, iy, all even powers of i will be real, all odd ones real multiples of i; accordingly w will be of the form $\phi + i\psi$, where ϕ, ψ are real functions of the two real variables x, y. Differentiating partially,

$$\frac{\partial w}{\partial x} = f'(z)\frac{\partial z}{\partial x} = f'(z), \quad \frac{\partial w}{\partial y} = f'(z)\frac{\partial z}{\partial y} = if'z = i\frac{\partial w}{\partial x},$$

$$\frac{\partial w}{\partial y} = \frac{\partial \phi}{\partial y} + i\frac{\partial \psi}{\partial y} = i\frac{\partial w}{\partial x} = i\frac{\partial \phi}{\partial x} - \frac{\partial \psi}{\partial x},$$

and equating real and imaginary parts,

$$(45)\quad \frac{\partial \phi}{\partial x} = \frac{\partial \psi}{\partial y}, \quad \frac{\partial \phi}{\partial y} = -\frac{\partial \psi}{\partial x}.$$

Differentiating the first equation by x, the second by y, and adding, we have

$$\frac{\partial^2\phi}{\partial x^2} + \frac{\partial^2\phi}{\partial y^2} = 0,$$

and similarly

$$\frac{\partial^2\psi}{\partial x^2} + \frac{\partial^2\psi}{\partial y^2} = 0.$$

Thus either function ϕ or ψ derived from any function of a complex variable gives us a case of uniplanar flow of an incompressible fluid. From the equations (45) we obtain by cross-multiplication

$$(46)\quad \frac{\partial \phi}{\partial x}\frac{\partial \psi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{\partial \psi}{\partial y} = 0,$$

which is the condition that the normals to the family of curves $\phi = \text{const.}$ and those of the family $\psi = \text{const.}$ intersect each other at right angles. Such families are called orthogonal. For instance, the function

$$(47)\quad w = \frac{1}{z} = \frac{1}{x + iy} = \frac{x - iy}{x^2 + y^2}$$

gives

$$(48)\quad \phi = \frac{x}{x^2 + y^2}, \quad \psi = \frac{-y}{x^2 + y^2},$$

and the curves

$$\frac{x}{x^2 + y^2} = \text{const.}, \quad \frac{y}{x^2 + y^2} = \text{const.}$$

are a set of circles tangent to the Y-axis and the X-axis respectively, the two sets intersecting each other at right angles.

The flux across any cylindrical surface whose generator has the length unity parallel to the Z-axis, and which intersects the XY-plane in a curve from A to B, is, if $\rho = 1$,

$$(49)\quad \Phi_{AB}=\int_A^B q_n ds=\int_A^B \frac{\partial\phi}{\partial n}ds$$
$$=\int_A^B\left\{\frac{\partial\phi}{\partial x}\cos(nx)+\frac{\partial\phi}{\partial y}\cos(ny)\right\}ds.$$

But if the normal lies on the right as we go along the curve, Fig. 14,

$$\cos(nx)ds=dy,\quad \cos(ny)ds=-dx.$$

Using these values and equations (45), we have for the flux

$$(50)\quad \Phi_{AB}=\int_A^B\frac{\partial\psi}{\partial x}dx+\frac{\partial\psi}{\partial y}dy=\psi_B-\psi_A,$$

so that the quantity of liquid crossing the surface does not depend on the curve joining

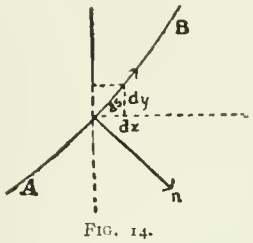

Fig. 14.

AB, but is the same for one as for another, as must be the case if the liquid is incompressible. The function ψ is called the *flux-function*, and since if $\psi_B=\psi_A$, no liquid crosses, it is evident that the curves $\psi=$const. are stream-lines. It is evident from equations (45) that either of the two functions ϕ, ψ may be taken for the velocity-potential, the other being taken for the flux-function. Functions satisfying equations (45) are called *conjugate functions*, and the two states of flow just described are called conjugate. In the case just investigated, the two conjugate flows happened to be identical; this is not generally the case.

For instance, consider the function $w=\log z$, and introducing polar coordinates r, θ,

$$(51)\quad w=\log z=\log(x+iy)$$
$$=\log\{r(\cos\theta+i\sin\theta)\}=\log\{re^{i\theta}\}=\log r+i\theta.$$

Thus we may put

$$(52)\quad \phi=\log r,\quad \psi=\theta,$$

obtaining a radial flow, or uniplanar squirt, with circular equipotentials, or

$$(53)\quad \phi=\theta,\quad \psi=\log r,$$

obtaining a circular flow with radial equipotentials.

Vortical Motion.—Let us now free ourselves from the restriction that the curl of the velocity vanishes. There will then be no velocity-potential in regions where there is curl. Lines whose tangent has everywhere the direction of the vector ω, the vorticity, are called *vortex-lines*, and tubes generated by such lines vortex-tubes, tubes of infinitesimal cross-section being termed vortex-filaments. The fluid within such a tube is called a vortex. Since the curl of any vector is solenoidal, as is seen by differentiating the equations (28) to find the divergence, the vorticity is a solenoidal vector and its tubes have the solenoidal property that the vorticity in any filament is inversely proportional to the area of the cross-section of the filament. The product $S\omega$, which is constant for the filament, is called the strength of the filament. Consequently the vorticity cannot vanish at any point on a tube, nor can the cross-section. The vortex-tubes must accordingly be closed, or end at a free surface of the liquid, as do those vortices formed by an oar at the surface of water.

The properties of vortex-motion were first investigated in an important paper by Helmholtz in 1858. Following him we shall now show that any continuous flow vanishing at infinity may be represented as the sum of a lamellar and a solenoidal part, and that the solenoidal part may be represented as the curl of another vector. Suppose that ϕ be the potential of the lamellar part, Q the vector with components U, V, W, whose curl represents the solenoidal part. Then we assume

$$(54)\quad \begin{aligned} u&=\frac{\partial\phi}{\partial x}+\frac{\partial W}{\partial y}-\frac{\partial V}{\partial z},\\ v&=\frac{\partial\phi}{\partial y}+\frac{\partial U}{\partial z}-\frac{\partial W}{\partial x},\\ w&=\frac{\partial\phi}{\partial z}+\frac{\partial V}{\partial x}-\frac{\partial U}{\partial y}.\end{aligned}$$

Finding the divergence of q we have

$$(55)\quad \operatorname{div} q=\frac{\partial u}{\partial x}+\frac{\partial v}{\partial y}+\frac{\partial w}{\partial z}=\Delta\phi,$$

since the divergence of the curl vanishes. But by (43) we have

$$\phi=-\frac{1}{4\pi}\int\int\int\frac{\Delta\phi}{r}d\tau=-\frac{1}{4\pi}\int\int\int\frac{\operatorname{div} q}{r}d\tau.$$

Since q represents a continuous flow, div q is finite. Accordingly we find that the lamellar part of the flow is completely determined by the distribution of its divergence.

Secondly, find the curl of q,

$$(56)\quad 2\xi=\frac{\partial w}{\partial y}-\frac{\partial v}{\partial z}=\frac{\partial}{\partial y}\left\{\frac{\partial\phi}{\partial z}+\frac{\partial V}{\partial x}-\frac{\partial U}{\partial y}\right\}$$
$$-\frac{\partial}{\partial z}\left\{\frac{\partial\phi}{\partial y}+\frac{\partial U}{\partial z}-\frac{\partial W}{\partial x}\right\}$$
$$=-\Delta U+\frac{\partial}{\partial x}\left\{\frac{\partial U}{\partial x}+\frac{\partial V}{\partial y}+\frac{\partial W}{\partial z}\right\}.$$

Since the vector Q is as yet undetermined except as to its curl, let us assume it to be solenoidal, which will make the divergence in (56) vanish, giving

$$(57)\quad 2\xi=-\Delta U,\quad 2\eta=-\Delta V,\quad 2\zeta=-\Delta W.$$

As before, we find the integrals of these equations to be

$$(58)\quad U=\frac{1}{2\pi}\int\int\int\frac{\xi}{r}d\tau,\quad V=\frac{1}{2\pi}\int\int\int\frac{\eta}{r}d\tau,$$
$$W=\frac{1}{2\pi}\int\int\int\frac{\zeta}{r}d\tau.$$

The integrals are to be taken over all space, but as any part of space where the vorticity vanishes will contribute nothing to the integrals, we may suppose them restricted to the vortices. Thus we see that the solenoidal part of the flow q, which is due to the vortices, is completely determined by the distribution of curl q. Thus the statement is justified that

a continuous vector - function is completely determined by its divergence and curl. Kinematically we may say that any flow is the resultant of squirts and vortices. The vector Q, whose components are formed in the manner of potentials from the components of 2ω, is called the *vector-potential* of 2ω.

Thus the velocity due to a vortex is the curl of the vector-potential of twice the vorticity. We may find this velocity by differentiation. Let us distinguish the point of integration from the point for which the potentials are calculated, and by which we differentiate, by attaching an accent to the coordinates of the former. We have

$$(59)\quad u=\frac{\partial 1V}{\partial y}-\frac{\partial V}{\partial z}$$
$$=\frac{1}{2\pi}\left[\frac{\partial}{\partial y}\int\int\int\frac{\zeta'}{r}d\tau'-\frac{\partial}{\partial z}\int\int\int\frac{\eta'}{r}d\tau'\right]$$
$$=\frac{1}{2\pi}\int\int\int\left\{\zeta'\frac{\partial}{\partial y}\left(\frac{1}{r}\right)-\eta'\frac{\partial}{\partial z}\left(\frac{1}{r}\right)\right\}d\tau'.$$

Thus the portions of velocity contributed by the element of the vortex $d\tau'$ are

$$du=\frac{1}{2\pi r^3}\{\zeta'(y'-y)-\eta'(z'-z)\}d\tau',$$
$$(60)\quad dv=\frac{1}{2\pi r^3}\{\xi'(z'-z)-\zeta'(x'-x)\}d\tau',$$
$$dw=\frac{1}{2\pi r^3}\{\eta'(x'-x)-\xi'(y'-y)\}d\tau'.$$

These are immediately seen to be, aside from the factor $1/2\pi r^3$, the projections of the parallelogram whose sides are the vectors ω', and r the vector from x', y', z' to x, y, z. If dq be the magnitude of the resultant, we accordingly obtain

$$(61)\quad dq=\frac{\omega'\sin(\omega' r)}{2\pi r^2}d\tau',$$

the direction of dq being perpendicular to both ω' and r, as shown by (60).

Let us take for the element of volume $d\tau'$ a length ds of a vortex-filament of cross-section S. Then $d\tau'=Sds$, and since $S\omega'=\kappa$, the strength of the filament

$$(62)\quad dq=\frac{\kappa ds\cdot\sin(\omega r)}{2\pi r^2}.$$

The velocity is connected with the vorticity in the same way that the magnetic field due to an electric current is connected with the current-density, equation (62) giving us the magnetic field produced by a current of strength $\kappa/2\pi$.

Hydrodynamics.—We now arrive at the subject of Hydrodynamics proper, in which we take account of the forces that are capable of producing the states of flow that have been previously described. Suppose that the coordinates of a particle are x, y, z, then $u=\frac{dx}{dt}$, $v=\frac{dy}{dt}$, $w=\frac{dz}{dt}$. The principles of dynamics tell us that the product of the mass by the acceleration of any particle is equal to the resultant of all the forces applied to it. Taking the mass contained in the element of volume $d\tau$, and the resultant of the bodily forces and pressures, as found under the treatment of hydrostatics,

$$(63)\quad \rho d\tau\frac{d^2x}{dt^2}=\rho d\tau\frac{du}{dt}=\left(\rho X-\frac{\partial p}{\partial x}\right)d\tau,$$

from which we obtain the equation with two similar ones,

$$\frac{du}{dt}=X-\frac{1}{\rho}\frac{\partial p}{\partial x},\quad \frac{dv}{dt}=Y-\frac{1}{\rho}\frac{\partial p}{\partial y},$$
$$(64)\quad \frac{dw}{dt}=Z-\frac{1}{\rho}\frac{\partial p}{\partial z}.$$

By the derivative $\frac{du}{dt}$ is meant the rate of change of velocity of a particular particle as it moves about. If we have any function F of the position of a particular particle, we may write its derivative

$$(65)\quad \frac{dF}{dt}=\frac{\partial F}{\partial t}+\frac{\partial F}{\partial x}\frac{dx}{dt}+\frac{\partial F}{\partial y}\frac{dy}{dt}+\frac{\partial F}{\partial z}\frac{dz}{dt},$$

where $\partial F/\partial t$ would be the rate of change of the function if the particle were at rest. The derivatives $\frac{dx}{dt}$, $\frac{dy}{dt}$, $\frac{dz}{dt}$ are the velocity-components u, v, w. Accordingly we have

$$(66)\quad \frac{dF}{dt}=\frac{\partial F}{\partial t}+u\frac{\partial F}{\partial x}+v\frac{\partial F}{\partial y}+w\frac{\partial F}{\partial z}.$$

We call this mode of differentiation *particle differentiation*.

Introducing this terminology, our equations of motion become

$$\frac{\partial u}{\partial t}+u\frac{\partial u}{\partial x}+v\frac{\partial u}{\partial y}+w\frac{\partial u}{\partial z}=X-\frac{1}{\rho}\frac{\partial p}{\partial x},$$
$$(67)\quad \frac{\partial v}{\partial t}+u\frac{\partial v}{\partial x}+v\frac{\partial v}{\partial y}+w\frac{\partial v}{\partial z}=Y-\frac{1}{\rho}\frac{\partial p}{\partial y},$$
$$\frac{\partial w}{\partial t}+u\frac{\partial w}{\partial x}+v\frac{\partial w}{\partial y}+w\frac{\partial w}{\partial z}=Z-\frac{1}{\rho}\frac{\partial p}{\partial z}.$$

These equations are due to Euler. These three equations, with the equation of continuity, (24), and the physical relation between ρ and p furnish five equations for the determination of the five variables u, v, w, ρ, p as functions of x, y, z, t.

Subtracting from both sides of the first of equations (67) the quantity

$$\frac{\partial}{\partial x}\left(\frac{q^2}{2}\right)=\frac{1}{2}\frac{\partial}{\partial x}\{u^2+v^2+w^2\}=u\frac{\partial u}{\partial x}+v\frac{\partial v}{\partial x}+w\frac{\partial w}{\partial x},$$

we obtain

$$(68)\quad \frac{\partial u}{\partial t}+w\left(\frac{\partial u}{\partial z}-\frac{\partial w}{\partial x}\right)-v\left(\frac{\partial v}{\partial x}-\frac{\partial u}{\partial y}\right)$$
$$=X-\frac{\partial P}{\partial x}-\frac{\partial\left(\frac{q^2}{2}\right)}{\partial x}.$$

If the bodily forces are conservative and derived from a potential V, the right-hand member is the derivative of the quantity $-(V+P+q^2/2)=U$, and inserting the values of ξ, η, ζ,

$$\frac{\partial u}{\partial t}+2(w\eta-v\zeta)=\frac{\partial U}{\partial x},$$
$$(69)\quad \frac{\partial v}{\partial t}+2(u\zeta-w\xi)=\frac{\partial U}{\partial y},$$
$$\frac{\partial w}{\partial t}+2(v\xi-u\eta)=\frac{\partial U}{\partial z}.$$

If the motion is *steady*, that is, independent of t, the time-derivatives vanish. Then multiplying the equations (69) by dx, dy, dz re-

spectively, adding and integrating along any curve, we obtain on the right the difference between the terminal values of $V+P+q^2/2$. If the curve is either a stream- or vortex-line, that is, if dx, dy, dz are proportional either to u, v, w, or to ξ, η, ζ, the sum on the left will also vanish, so that along a stream-line or a vortex-line we have $V+P+q^2/2=\text{const.}$ If the motion is non-vortical, the left-hand side of (69) vanishes, so that the above sum is constant throughout the fluid. In this case

$$V+P+\tfrac{1}{2}q^2=\text{const.}, \tag{70}$$

this result being called Daniel Bernoulli's theorem.

If the fluid is incompressible, $P=p/\rho$, and if there are no bodily forces $V=0$, so that (70) becomes

$$\frac{p}{\rho}+\frac{1}{2}q^2=\text{const.} \tag{71}$$

Accordingly where the velocity is small the pressure is large and vice versa. By constricting the tube the velocity is made large and the pressure small. This is the principle of jet exhaust-pumps, like that of Bunsen, the air being sucked in at the narrow part of the jet. The same principle is used in the Venturi water-meter. The horizontal main being reduced in diameter in a certain portion and the difference of pressure at a point in that portion and in the main observed, the velocity is computed. If the pressure at the two cross-sections S_1 and S_2 is p_1, p_2, we have

$$p_1-p_2=\frac{\rho}{2}(q_2^2-q_1^2). \tag{72}$$

But since the flow is solenoidal, $S_1q_1=S_2q_2$. Combining with (72),

$$p_1-p_2=\tfrac{1}{2}\rho q_1^2\left\{\left(\frac{S_1}{S_2}\right)^2-1\right\}, \tag{73}$$

which determines q_1 in terms of the pressure-difference. The efflux in unit time is $\rho q_1 S_1$.

For the adiabatic expansion of a gas,

$$P=\frac{b\kappa\rho^{\kappa-1}}{\kappa-1}=\frac{b\kappa}{\kappa-1}\left(\frac{p}{b}\right)^{\frac{\kappa-1}{\kappa}}. \tag{74}$$

We may use Bernoulli's theorem to calculate the efflux of gas from a reservoir. If we consider a point in the reservoir where the pressure is p, so far from the orifice that the air may be considered at rest and if the velocity at the orifice is q and the atmospheric pressure p_0, we have

$$q^2=2b^{\frac{1}{\kappa}}\frac{\kappa}{\kappa-1}\left\{p^{\frac{\kappa-1}{\kappa}}-p_0^{\frac{\kappa-1}{\kappa}}\right\}, \tag{75}$$

which is the usual formula for the efflux of gases.

If the external force be gravity, $V=gz$, and we have for an incompressible fluid,

$$\frac{p}{\rho}+gz+\tfrac{1}{2}q^2=\text{const.} \tag{76}$$

If we again consider efflux from a reservoir whose upper free surface $z=z_1$ is so large that q is negligible, the pressure being that of the atmosphere, the same above and at the orifice where $z=z_2$, the velocity of efflux is given by

$$\begin{aligned}&\frac{p_0}{\rho}+gz_1=\frac{p_0}{\rho}+gz_2+\tfrac{1}{2}q^2,\\ &q^2=2g(z_1-z_2),\end{aligned} \tag{77}$$

or the velocity of efflux is that acquired by a body falling freely from a height equal to that of the free surface above the orifice. This is the theorem of Torricelli, one of the oldest on hydrodynamics.

Wave-motion.—The case of uniplanar waves may be dealt with by the method of the complex variable. We shall find that the waves travel with constant velocity a and that it will simplify the problem if we impose upon the whole fluid a horizontal velocity equal and opposite to that of the waves. The waves then stand still, and the motion is *steady*, as in the case of waves about an obstruction in a running river.

Let us consider waves in deep water. At a great depth the vertical motion will disappear, so that

$$u=-a, \quad v=0, \quad \phi=-ax.$$

The function

$$w=-az+Ae^{-ikz}=-a(x+iy)+Ae^{-ik(x+iy)}$$

gives

$$\phi+i\psi=-a(x+iy)+Ae^{ky}(\cos kx-i\sin kx).$$

$$\begin{aligned}\phi&=-ax+Ae^{ky}\cos kx,\\ \psi&=-ay-Ae^{ky}\sin kx.\end{aligned} \tag{78}$$

When $y=-\infty$ this makes $\phi=-ax$, as required. The free surface of the water being composed of stream-lines is represented by one of the lines $\psi=\text{const.}$, and if we take the origin in the surface its equation is

$$ay+Ae^{ky}\sin kx=0, \tag{79}$$

which shows that y is a periodic function of x with the wave-length $\lambda=2\pi/k$. The longer the wave-length, that is the smaller k, the more nearly does the exponential reduce to unity and the profile to a curve of sines. The velocity is given by

$$\begin{aligned}u&=\frac{\partial\phi}{\partial x}=\frac{\partial\psi}{\partial y}=-a-Ake^{ky}\sin kx,\\ v&=\frac{\partial\phi}{\partial y}=-\frac{\partial\psi}{\partial x}=Ake^{ky}\cos kx,\end{aligned} \tag{80}$$

$$q^2=u^2+v^2=a^2+A^2k^2e^{2ky}+2Ake^{ky}\sin kx. \tag{81}$$

So far we have merely kinematics. The dynamical relation required is that for steady motion,

$$\frac{p}{\rho}+gy+\tfrac{1}{2}q^2=C. \tag{82}$$

At the surface putting $p=0$ and making use of (79),

$$gy+\tfrac{1}{2}\{a^2+A^2k^2e^{2ky}-2a^2ky\}=C.$$

Since the surface passes through the origin, putting $y=0$,

$$C=\tfrac{1}{2}(a^2+A^2k^2).$$

$$(g-a^2k)y+\tfrac{1}{2}A^2k^2(e^{2ky}-1)=0. \tag{83}$$

This equation can be only approximately fulfilled, but if the height of the waves is so small in comparison with the wave-length that the square of $2ky$ may be neglected, developing the exponential gives

$$(g-a^2k+A^2k^3)y=0,$$

giving the relation between the velocity and the wave-length.

$$g-a^2k+A^2k^3=0. \tag{84}$$

If ky is small, the equation of the profile (79) is approximately

$$y=-\frac{A}{a}\sin kx, \tag{85}$$

so that the height of the waves above the origin is $B=\lambda/a$, inserting which in (84) gives

$$(86)\qquad a^2\left\{\frac{2\pi}{\lambda}\left(1-\frac{4\pi^2B^2}{\lambda^2}\right)\right\}=g.$$

For long waves we accordingly have $a^2=g\lambda/2\pi$, or the velocity of long waves in deep water is equal to the velocity acquired by a body in falling freely from a height equal to one half the radius of a circle whose circumference is the wave-length.

In order to study the motions of the individual particles of water let us now impress upon the motion given by (80) a uniform velocity a in the X-direction. Equations (80) now give the motion with respect to axes traveling with the waves, so that in order to obtain the motion with respect to fixed axes we have to add a to the u of (80) and replace x by $x-at$, obtaining

$$(87)\qquad \begin{aligned} u&=-Ake^{ky}\sin k(x-at),\\ v&=\ Ake^{ky}\cos k(x-at).\end{aligned}$$

If the displacement of a particle which when at rest was at x, y is ξ, η, the above values are $\frac{d\xi}{dt}$, $\frac{d\eta}{dt}$, and if we neglect the small change of velocity from x, y to $x+\xi$, $y+\eta$, we may integrate with respect to the time,

$$(88)\qquad \begin{aligned} \xi&=-Be^{ky}\cos k(x-at),\\ \eta&=-Be^{ky}\sin k(x-at).\end{aligned}$$

Thus each particle performs a uniform revolution in a vertical circle of radius Be^{ky} in the time $T=\frac{2\pi}{ka}=\frac{\lambda}{a}$. The rapidity of decrease of the motion as we go below the surface is seen by the fact that at a depth $y=-\lambda$ the amplitude has diminished in the ratio $e^{-2\pi}=.001867$. The form of the wave-profile is shown in Fig. 15, the crests being farther above the

Fig. 15.

level than the troughs are below it. As the height increases the waves become sharper at the crest.

Vortex-motion.—Let us consider the change in circulation along a line that always contains the same particles. We have

$$(89)\qquad \begin{aligned}\frac{d\phi_{AB}}{dt}&=\frac{d}{dt}\int_A^B(udx+vdy+wdz)\\ &=\int_A^B\left\{\frac{du}{dt}dx+u\frac{d}{dt}(dx)+\frac{dv}{dt}dy+v\frac{d}{dt}(dy)\right.\\ &\qquad\left.+\frac{dw}{dt}dz+w\frac{d}{dt}(dz)\right\}.\end{aligned}$$

Now consider an element ds which at a time later by dt has moved to a position ds', Fig. 16. Since one end has moved in the X-direction a distance udt and the other a distance

$$\left\{u+\frac{\partial u}{\partial x}dx+\frac{\partial u}{\partial y}dy+\frac{\partial u}{\partial z}dz\right\}dt$$

the new value of its X-projection is

$$dx'=x+dx+\left\{u+\frac{\partial u}{\partial x}dx+\frac{\partial u}{\partial y}dy+\frac{\partial u}{\partial z}dz\right\}dt-(x+udt),$$

from which we obtain the derivatives

$$(90)\qquad \begin{aligned}\frac{d}{dt}(dx)&=\frac{dx'-dx}{dt}=\frac{\partial u}{\partial x}dx+\frac{\partial u}{\partial y}dy+\frac{\partial u}{\partial z}dz,\\ \frac{d}{dt}(dy)&=\frac{dy'-dy}{dt}=\frac{\partial v}{\partial x}dx+\frac{\partial v}{\partial y}dy+\frac{\partial v}{\partial z}dz,\\ \frac{d}{dt}(dz)&=\frac{dz'-dz}{dt}=\frac{\partial w}{\partial x}dx+\frac{\partial w}{\partial y}dy+\frac{\partial w}{\partial z}dz.\end{aligned}$$

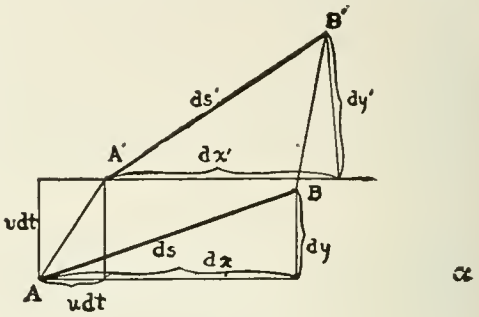

Fig. 16.

But the equations of motion (67) are, in abbreviated form,

$$(91)\qquad \begin{aligned}\frac{du}{dt}&=\frac{\partial(U+q^2/2)}{\partial x},\quad \frac{\partial v}{dt}=\frac{\partial(U+q^2/2)}{\partial y},\\ \frac{\partial w}{dt}&=\frac{\partial(U+q^2/2)}{\partial z},\end{aligned}$$

where $U=-(V+P+q^2/2)$. Accordingly,

$$(92)\qquad \begin{aligned}\frac{d\phi_{AB}}{dt}&=\int_A^B\left\{\frac{\partial(U+q^2/z)}{\partial x}dx+\frac{\partial(U+q^2/z)}{\partial y}dy\right.\\ &+\frac{\partial(U+q^2/z)}{\partial z}dz+\left(u\frac{\partial u}{\partial x}+v\frac{\partial v}{\partial x}+w\frac{\partial w}{\partial x}\right)dx\\ &\left.+\left(u\frac{\partial u}{\partial y}+v\frac{\partial v}{\partial y}+w\frac{\partial w}{\partial y}\right)dy+\left(u\frac{\partial u}{\partial z}+v\frac{\partial v}{\partial z}+w\frac{\partial w}{\partial z}\right)dz\right\}\\ &=\int_A^B\frac{\partial(U+q^2)}{\partial x}dx+\frac{\partial(U+q^2)}{\partial y}dy+\frac{\partial(U+q^2)}{\partial z}dz\\ &=(U+q^2)\Big]_A^B,\end{aligned}$$

which vanishes for a closed curve. Therefore if the bodily forces are conservative, the circulation around any closed curve moving with the fluid is independent of the time. If the circulation around a closed path is zero at one time, it remains zero, so that if the velocity-potential once exists, it always exists. This theorem is due to Lagrange.

From the equations (69), whose right-hand members are derivatives of the same quantity V, this quantity may be eliminated by differentiation. Differentiating the last equation by y, the second by z, and subtracting,

$$\begin{aligned}\frac{1}{2}\frac{\partial}{\partial t}\left(\frac{\partial w}{\partial y}-\frac{\partial v}{\partial z}\right)&+\xi\frac{\partial v}{\partial y}+v\frac{\partial\xi}{\partial y}-\eta\frac{\partial u}{\partial y}-u\frac{\partial\eta}{\partial y}-\zeta\frac{\partial u}{\partial z}\\ &-u\frac{\partial\zeta}{\partial z}+\xi\frac{\partial w}{\partial z}+w\frac{\partial\xi}{\partial z}=0,\end{aligned}$$

or otherwise,

$$(93)\qquad \begin{aligned}\frac{\partial\xi}{\partial t}+u\frac{\partial\xi}{\partial x}+v\frac{\partial\xi}{\partial y}+w\frac{\partial\xi}{\partial z}&=u\left\{\frac{\partial\xi}{\partial x}+\frac{\partial\eta}{\partial y}+\frac{\partial\zeta}{\partial z}\right\}\\ &-\xi\left\{\frac{\partial u}{\partial x}+\frac{\partial v}{\partial y}+\frac{\partial w}{\partial z}\right\}+\xi\frac{\partial u}{\partial x}+\eta\frac{\partial u}{\partial y}+\zeta\frac{\partial u}{\partial z}.\end{aligned}$$

On the right the coefficient of u, being the divergence of the vorticity, is zero, while that of ξ is by the equation of continuity equal to $\frac{1}{\rho}\frac{d\rho}{dt}$, so that equation (93) becomes

$$\frac{d\xi}{dt}=\frac{\xi}{\rho}\frac{d\rho}{dt}+\xi\frac{\partial u}{\partial x}+\eta\frac{\partial u}{\partial y}+\zeta\frac{\partial u}{\partial z},$$

which may be written, with its two companions,

$$(94)\qquad \begin{aligned}\frac{d}{dt}\left(\frac{\xi}{\rho}\right)&=\frac{\xi}{\rho}\frac{\partial u}{\partial x}+\frac{\eta}{\rho}\frac{\partial u}{\partial y}+\frac{\zeta}{\rho}\frac{\partial u}{\partial z},\\ \frac{d}{dt}\left(\frac{\eta}{\rho}\right)&=\frac{\xi}{\rho}\frac{\partial v}{\partial x}+\frac{\eta}{\rho}\frac{\partial v}{\partial y}+\frac{\zeta}{\rho}\frac{\partial v}{\partial z},\\ \frac{d}{dt}\left(\frac{\zeta}{\rho}\right)&=\frac{\xi}{\rho}\frac{\partial w}{\partial x}+\frac{\eta}{\rho}\frac{\partial w}{\partial y}+\frac{\zeta}{\rho}\frac{\partial w}{\partial z}.\end{aligned}$$

Thus the time-derivatives of $\frac{\xi}{\rho}$, $\frac{\eta}{\rho}$, $\frac{\zeta}{\rho}$ for a given particle are homogeneous linear functions of those quantities. By continued differentiation with respect to t and the substitution of the derivatives from these equations, we see that *all* the time-derivatives are homogeneous linear functions of the quantities themselves. Thus if at any time these quantities are zero, all their derivatives are zero, and developing by Taylor's theorem, we find that the function remains zero for all times. Thus if a particle is once not vortically revolving, it never can acquire such rotation under conservative forces.

Let us now consider two points A and B lying on the same vortex-line at a distance apart $ds=\varepsilon\frac{\omega}{\rho}$, where ε is a small constant. Since the particles lie on the vortex-line we have

$$(95)\qquad \frac{dx}{\xi}=\frac{dy}{\eta}=\frac{dz}{\zeta}=\frac{ds}{\omega}=\frac{\varepsilon}{\rho}.$$

For the difference of velocity at A and B we have

$$(96)\qquad \begin{aligned}u_B-u_A&=\frac{\partial u}{\partial x}dx+\frac{\partial u}{\partial y}dy+\frac{\partial u}{\partial z}dz\\ &=\varepsilon\left\{\frac{\xi}{\rho}\frac{\partial u}{\partial x}+\frac{\eta}{\rho}\frac{\partial u}{\partial y}+\frac{\zeta}{\rho}\frac{\partial u}{\partial z}\right\},\end{aligned}$$

or, by equations (94),

$$(97)\qquad u_B-u_A=\varepsilon\frac{d}{dt}\left(\frac{\xi}{\rho}\right).$$

Now at an instant later by dt, when the particles are at A' and B',

$$(98)\qquad \begin{aligned}dx'&=dx+(u_B-u_A)dt=\varepsilon\left[\frac{\xi}{\rho}+\frac{d}{dt}\left(\frac{\xi}{\rho}\right)dt\right],\\ dy'&=dy+(v_B-v_A)dt=\varepsilon\left[\frac{\eta}{\rho}+\frac{d}{dt}\left(\frac{\eta}{\rho}\right)dt\right],\\ dz'&=dz+(w_B-w_A)dt=\varepsilon\left[\frac{\zeta}{\rho}+\frac{d}{dt}\left(\frac{\zeta}{\rho}\right)dt\right].\end{aligned}$$

Therefore the projections of the arc ds' in the new position are proportional to the new values of the components of ω/ρ, as they originally were, so that the particles still lie on a vortex-line. Accordingly a vortex-line is always composed of the same particles of fluid. Also, since the components of ds have changed so as to be always proportional to the components of ω/ρ, if the liquid is incompressible the rotation is proportional to the distance between the particles. And whether ρ vary or not, if S is the cross-section of a vortex-filament, since the mass ρSds of a length ds remains constant, so does $S\omega$, the strength of the filament. Accordingly the strength of a vortex-filament is constant, not only at all points in the filament, but at all times, consequently a vortex existing in a perfect fluid is indestructible, however it may move. It is from this remarkable property of vortices discovered by Helmholtz that Lord Kelvin was led to imagine atoms as consisting of vortices in a perfect fluid.

From the kinematical properties of flow due to vortex-motion (62), we see that the velocity at every point of a circular vortex-ring, Fig. 17, due to all the elements of the vortex,

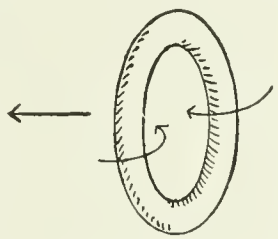

Fig. 17.

is in the same direction perpendicular to the plane of the ring, and in the direction in which the inside of the ring is turning; the ring therefore advances with a constant velocity, as if it were rolling in a tube which it just fits. We may verify this by an experiment due to Professor Tait, where smoke is suddenly forced out through a circular hole in a box provided with an elastic back. The smoky air rolling on the edge of the hole is endowed (by the friction, a *non-conservative* force) with a vortical rotation, and issues as a vortex-ring, which advances with approximately constant velocity for a considerable distance. That it consists always of the same air is seen by the smoke which it carries with it. Such a ring, on striking an edge or obstacle, is not destroyed or cut. Similar experiments can be performed with the rings formed by letting drops of ink fall into water. The loss of velocity finally obtaining in all these cases is due to the viscosity, that is, to non-conservative forces. The treatment of viscosity is beyond the scope of this article.

Hy'drogen (Greek, «producing water,» in reference to the fact that in burning in air or oxygen, hydrogen forms water-vapor), a gaseous element, discovered by Cavendish in 1766. It was at first called «inflammable air,» the present name being due to Lavoisier. Hydrogen is

the lightest known substance, and it also has the smallest known atomic weight. The atomic weight of hydrogen is often taken as unity in stating the relative atomic weights of the different elements (see ATOMIC THEORY), but it is now more usual to assume the atomic weight of oxygen to be precisely 16, which amounts to making the atomic weight of hydrogen 1.0076. According to Regnault's experiments, hydrogen has a density equal to 0.06926 of that of an equal volume of air, at the same temperature and pressure. In absolute measure, the mass of a cubic centimetre of hydrogen, at the freezing point of water and under a pressure of 76 centimetres of mercury at Paris, is 0.00008957 gram, or 0.08957 milligram. Hydrogen has the chemical symbol H, and is one of the most abundant elements known. It occurs in the free state in volcanic gases, and in the sun and in many of the fixed stars. Free hydrogen is also present in the earth's atmosphere in exceedingly small amount. Water (or hydrogen monoxid) is its commonest and most abundant compound, and it is an essential constituent of nearly all organic tissues. Hydrogen may be prepared very easily by many methods. One of the most convenient of these consists in acting upon metallic zinc with dilute sulphuric acid, the reaction in this case being: $Zn + H_2SO_4 = ZnSO_4 + 2H$. Hydrogen is chemically inert towards most of the elements, at ordinary temperatures, but it combines with chlorine when exposed to light,—quietly in diffused daylight, and explosively under the direct action of sunlight. At elevated temperatures it combines with other elements also, and it burns in air (or oxygen) with the development of an intense heat, but with very little light; water being produced as the result of the combustion. Hydrogen has been both liquefied and solidified. Its critical temperature is estimated, by Dewar, to be about 402° F. below zero, and the same authority gives 15 atmospheres as the critical pressure. (See CRITICAL POINT, and GASES, LIQUEFACTION OF.)

Hydrogen combines with oxygen in two proportions. The monoxid, or common water, H_2O, is formed, as already noted, when hydrogen is burned in air or in oxygen. It is also formed in many of the double decompositions that occur in chemistry, as when metallic oxids or hydrates are dissolved in acids. Sodium hydrate, for example, combines with sulphuric acid according to the equation $2NaOH + H_2SO_4 = Na_2SO_4 + 2H_2O$, sodium sulphate and water being formed.

Hydrogen peroxid (or dioxid), H_2O_2, may be prepared by acting upon barium dioxid, BaO_2, with dilute sulphuric acid; the reaction being: $BaO_2 + H_2SO_4 = BaSO_4 + H_2O_2$. The barium sulphate that is formed at the same time is a heavy, insoluble substance, which is easily removed from the solution by filtration, or by settling and subsequent decantation. The aqueous solution of the peroxid may then be concentrated by evaporation over strong sulphuric acid, under the receiver of an air pump. When the water has all evaporated, the pure peroxid remaining behind has a specific gravity of 1.452, and is a colorless, oily liquid, devoid of odor, but having a disagreeable, metallic taste. The peroxid does not freeze, even when cooled to 0° F. At 70° F. it slowly gives off half its oxygen, passing into water. At 212° F. this change takes place very rapidly. Owing to the facility with which hydrogen peroxid gives off oxygen, it is used quite largely as a bleaching agent, and also, in surgery, as a disinfectant in the treatment of wounds.

When hydrogen is passed through boiling sulphur, combination takes place, with the formation of hydrogen sulphid, or sulphuretted hydrogen, H_2S. This compound is more conveniently prepared, however, by treating sulphid of iron, FeS, with dilute sulphuric acid, ferrous sulphate ($FeSo_4$) being formed at the same time. The reaction is: $FeS + H_2SO_4 = FeSO_4 + H_2S$. Sulphuretted hydrogen is a gas, devoid of color, but possessing an overpowering odor, suggestive of rotten eggs. It burns with a bluish flame, and is poisonous when inhaled in any considerable quantity, even though largely diluted with air. Under ordinary atmospheric pressure, sulphuretted hydrogen gas condenses, at 80° F. below zero, to a colorless liquid, which freezes to an ice-like solid upon being further cooled to 121° F. below zero. Liquefaction may also be induced at the ordinary temperature of the air by the application of a pressure of from 17 to 20 atmospheres. Sulphuretted hydrogen is an invaluable reagent in the chemical laboratory, where it is greatly used for separating the metals into groups, in inorganic analysis. (See CHEMICAL ANALYSIS.)

With carbon, hydrogen forms a large number of compounds which are collectively known as hydrocarbons (q.v.). With carbon and oxygen, and with carbon, oxygen and nitrogen, hydrogen forms compounds past enumeration. For further information concerning these, consult any treatise on organic chemistry, and also, in this encyclopedia, the articles FATTY COMPOUNDS and AROMATIC COMPOUNDS.

Hydrogen Peroxid, Hydrogen Sulphid, etc. See HYDROGEN.

Hydrograph'ic Surveying. See SURVEYING.

Hydrography, hī-drŏg'ra-fī (Greek *hydōr* or *hudor,* water, *grapho,* to describe), meaning literally a "description of water," is the name applied to that branch of physical geography which describes the water on the surface of the globe, whether occurring on land, as in springs, rivers, and lakes, or in seas and great oceans. It is sometimes used in a more restricted sense, and confined to a description of the bearings of coasts, of currents, soundings, islands, shoals, etc., with a more immediate view to navigation, and the construction of charts and nautical tables. Henry the Navigator was the first who constructed a tolerably reliable sea-chart, and laid the foundation of hydrography as a science. This was in the 15th century. In France and other countries, institutions specially formed for teaching navigation are called hydrographical schools. The hydrographic office is now an important department of the naval administration, its officers consolidating into available maps the results of the observations sent to them from time to time by those engaged in exploring expeditions, and by navigators from all parts of the world. See SURVEYING.

Hy'drolite. See GMELINITE.

Hydrom'eter, an instrument for determining the specific gravity of fluids. When a solid body floats in a liquid, and displaces a quantity of the liquid, it is supported by the same upward

pressure that formerly supported the liquid which it displaces. The weight of the solid body is thus equal to the weight of the liquid that it displaces. Hence, the depth to which

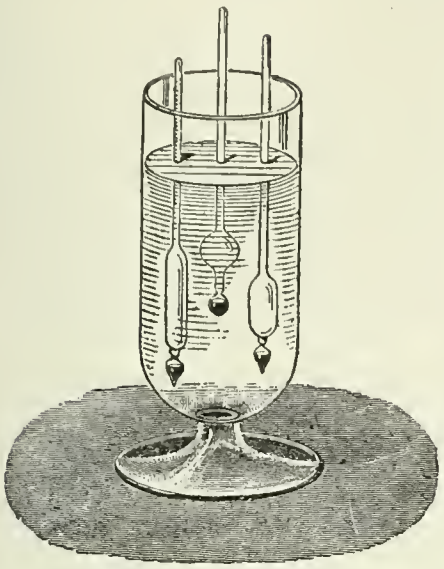

Fig. 1.— Forms of Hydrometer.

the same solid body is immersed in a liquid is greater as the density of the liquid is less, and less as the density of the liquid is greater. And, likewise, the weights required to immerse a given body equally deep in various liquids are inversely proportional to the densities of the liquids. On each of these principles a form of hydrometer is founded. One is called the constant weight hydrometer, the other the constant volume hydrometer. The first, usually made of glass, is shown in Fig. 1. It has a large hollow bulb, and below that a smaller bulb, weighted with mercury, to make the instrument float upright and it is surmounted by a cylindrical glass stem which is graduated, the divisions being usually marked on a piece of paper enclosed within the stem. The depth to which the hydrometer sinks in the liquid gives the density.

Of constant volume hydrometers, Nicholson's hydrometer, the best known, possibly, is adapted for determining the specific gravities not only of fluids, but of solids also. It is shown in Fig. 2. It consists of a hollow cylinder of metal, surmounted with a very fine metallic stem, to the top of which there is attached a plate or pan for weights. From the bottom of the metallic cylinder hangs a kind of cup or basket. The whole instrument is weighted so as to float upright. On the fine metallic stem there is a marked point: and by putting weights on the upper pan the hydrometer is always made to sink precisely to the point. If the weight of the instrument itself is known, and also the standard weight, or weight required to sink it to the marked point in distilled water, the calculation of the specific gravity of any liquid from an observation with the instrument is very easy. To determine the specific gravity of solids, the instrument is placed in distilled water and the solid body is put on the upper pan. Weights are then added till the hydrometer sinks to the marked point. But the standard weight of the instrument being known, it is plain that the difference between it and the weights that must be added on the upper pan to the weight of the body whose specific gravity is to be determined must be the weight in air of that body. The body is now transferred to the basket below the instrument, and the weight of the solid in water is similarly determined. From these data the specific gravity of the solid is calculated in the ordinary way. (See Specific Gravity.)

Hydrop'athy, a name for the treatment of diseases by the use of water. This name is now largely superseded by the term hydrotherapy (q.v.).

Hydrophobia (from Greek words meaning "fear of water"), an acute or subacute infectious disease, particularly of canine animals. It is usually communicated by a bite of the afflicted animal, and the contagion, the exact nature of which is unknown, is resident for the most part

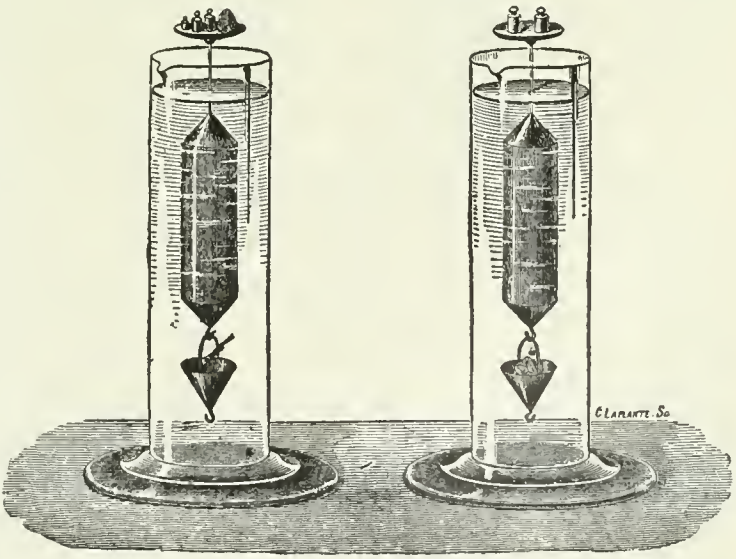

Fig. 2.— Nicholson's Hydrometer.

in the saliva, although it has been found in the peripheral nerves, the pancreas, and the suprarenal gland. It is frequently communicated to man, although the dog, wolf, fox, deer, cat, cow, and skunk are the animals most frequently affected; it has been known to occur also in the

horse, pig, birds, and other animals. Nine tenths of all the cases are contracted through the bites of rabid dogs. Hydrophobia may be produced, however, by wounds occurring during the dissection of rabid animals; it is said to have been caused by eating the flesh of animals that have died of the disease; and the milk of sucklings, animal and human, is thought to contain the virus. This poison has been found to be active in a dog 44 days buried, and in a rabbit buried 21 days.

In dogs the disease is comparatively common. In 1900 D. E. Salmon, chief of the United States Bureau of Animal Industry, determined that the disease was prevalent throughout the United States, and largely on the increase. The chief symptoms in dogs may be divided into two classes. Dogs suffer from furious rabies, and from dumb rabies. In the former Pasteur thought that the brain was involved; in the latter, the spinal cord. The furious form of the disease shows (1) a period of melancholy or depression; (2) a period of irritation; (3) a period of paralysis. The first varies from a few hours to two days. During this period the anxious and restless dog may also be cross. He hides from his master, obeys sullenly, and changes his position frequently. His appetite may not be at first affected, but it soon fails; he may lick everything in sight, or bite everything within reach, swallowing all sorts of foreign bodies. The period of irritation usually persists three or four days, during which the dog is spasmodically mad; restlessness increases, and the animal has an irresistible impulse to run away. During the running spells dogs may bite at everything in sight; at such times they usually seem fearless, and rarely avoid other dogs or people. If caged, they tear and chew on the bars, even breaking their teeth or fracturing their jaws. The bark is modified into a peculiar howl. During the third or paralytic period the dog is subdued and more sullen; the lower jaw becomes paralyzed and hangs down, saliva dripping from the mouth; the gait is staggering; from the fourth to the eighth day after the onset he dies of paralysis or exhaustion.

In dumb rabies the characteristic second stage may be entirely absent. The most persistent feature of dumb rabies is the dropped lower jaw, the paralysis of the jaw in the later stages preventing the dog from biting. Veterinarians see many cases of dumb rabies in dogs brought to them by owners who think that the trouble is caused by a bone in the throat. Beware of a dog that becomes listless and dull and hides away, is always on the go, prowling about and restless; one that is sullen and walks with his head down like a bear. A dog that scrapes incessantly and tears things up, and one that suddenly becomes excessively fond of its master, desiring to lick his hands and face, should be watched and guarded. A dog that has trouble in swallowing, that seems to have a bone in his throat, or, having wandered away from home, returns covered with dirt, exhausted and miserable, should be put under lock and key.

So far as the water-test is concerned, it is nonsense. The mad dog is often very fond of water; he is thirsty and rushes into water, thrusts his head into it; but he may have great difficulty in swallowing it, the act of swallowing usually bringing about severe convulsions.

In man the disease may go through somewhat similar stages, but the course is greatly modified; males are more likely to be affected than females, the difference in dress and exposure accounting for this; and two fifths of the subjects are below the age of 15. Bites on the face, neck, and hands are thought to be the most liable to develop the disease, and punctured wounds are more dangerous than lacerated wounds because of the difficulty in cleansing them. In man the period of incubation varies widely, from 20 to 60 days is the usual range, but six months may represent an extreme limit. In exceptional instances the period of incubation seems to have been greatly prolonged. The pathological changes recently discovered are found to be extremely characteristic, so that it is now even possible to diagnose rabies in a dog within a reasonable time after his death.

In all cases of suspected hydrophobia it is best not to kill the dog; but if, by accident or design, the death is accomplished the body should at once be sent to the health board authorities for a confirmation of the diagnosis. The characteristic changes, as described by Nèlis in 1900, consist in minute alterations in the spinal ganglion cells, especially in a proliferation of the endothelial cells of the ganglionic cell-capsule. These changes are considered characteristic of this disease, and are not known to occur in any other affection. The general treatment is both prophylactic and remedial. All stray dogs should be destroyed; or, if they have bitten anyone, they should be imprisoned and watched. It is best to have dogs muzzled or held in leash. In Germany muzzling has entirely eradicated hydrophobia. London in 1889 had 176 cases of hydrophobia. Muzzling was made compulsory, and in 1890 the number of cases of rabies had fallen to 44; in 1891 to 28; and in 1892 to 3. The muzzling was then allowed to lapse, owing partly to the sentimental agitation of many so-called lovers of dumb animals, and the cases of rabies increased, 25 persons dying of the disease in five years, while 174 patients were sent for treatment to the Pasteur Institute.

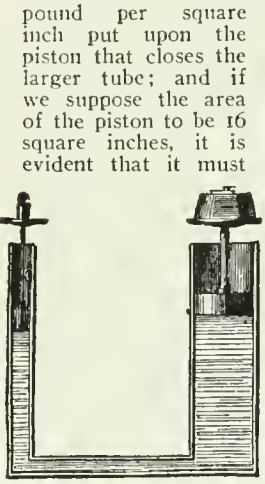
The direct treatment of the wound causing rabies is important. The poison seems to diffuse slowly, so that, if a ligature is promptly placed about the limb on the body side of the wound, a suction-cup or direct sucking may extract all of the virus. In the non-abraded mouth the virus is not very poisonous. If the wound is deep it is sometimes wise to make immediately a free incision, permitting the flow of blood to wash away the virus, and also allowing a more open surface for the actual cautery. One of the best cauterizing agents to use is strong nitric acid. The after-treatment will depend very largely on the promptness and thoroughness of the first treatment. If there is reason to believe that the early cauterization was ineffectual, the Pasteur method of treatment (see PASTEUR, LOUIS) is advisable. This is a complicated method which was elaborated by Pasteur about 1880. He found that the virus was present in the spinal cord of a rabid animal; that its virulence slowly diminished after the death of the animal; that the virus could be artificially weakened by passing it through a series of monkeys until it was powerless; and that, conversely, this virulence could be restored by inoculating the attenuated virus in a series of rabbits. Thus Pasteur made a weak virus and a strong one at will, and he later produced immunity to the virus by the use of

his attenuated material. The final plan that was adopted was to kill a rabbit by means of his strong virus, remove its spinal cord, cut this up into short sections, and dry it for varying periods of time. In this manner he secured a graded series of cord-sections of gradually decreasing virulence. These were emulsified in salt-solution and used to inject into animals or man, the weaker virus being first used and the stronger later. Two methods are now (1903) in vogue — the simpler method, for the less severe bites, in which 19 injections are given in 14 days; and the intensive method, for the severe bites about the neck and face and the large nerve-trunks, in which 28 injections are administered in 21 days. The serum-treatment of the disease is also rapidly becoming a possibility. Two Italian investigators, Tizzoni and Centanni, have made an anti-rabic serum that promises something for the future. For the present, however, the Pasteur method is the most reliable. It is certainly harmless, and is worthy of trial. The results are assuring, and the statistics, to most minds, convincing. It should not be forgotten that there is a false hydrophobia which is of purely hysterical origin, during an attack of which some patients have died. Consult: Bradford, 'Two Lectures on Rabies' ('Lancet,' 3 March 1900); 'Hydrophobia in Germany' ('Hygienische Rundschau,' 7 Nov. 1899); 'Report of Select Committee of the House of Lords on Rabies in Dogs' (Blue Book, 1887); Medical News' (15 Aug. 1903); Sixteenth Annual Report Bureau of Animal Industry (1899). See HYSTERIA.

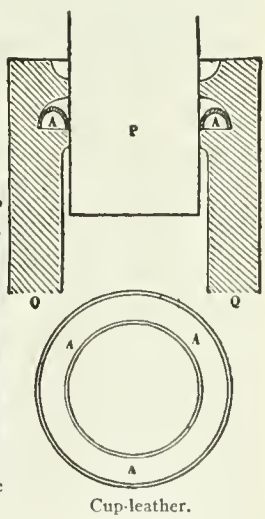
SMITH ELY JELLIFFE, M.D.,
Managing Editor Journal of Nervous and Mental Disease.

Hydrophytes, plants which grow in water or mud. They may be wholly submerged, completely without roots, and derive their sustenance wholly from the water; or may live amphibiously, rooted in soil and lifting some or all of their leaves into the air, and so differ only in a greater or less degree from land plants. Adaptations of water plants are especially to meet the difficulty of obtaining oxygen and of effecting pollination under water. In plants which grow wholly in or under water, roots, when present, are comparatively small and free from hairs, stems are slender and abound in air-spaces, and leaves are, as a rule, either long and narrow, or else greatly subdivided, so as to expose the greatest possible amount of surface. The cuticle of the leaf, also, is very thin, and lacks several of the structures, such as palisade cells and stomata, always present in aerial leaves. Water therefore enters easily into the tissues of the plant and carries with it a large amount, not only of oxygen, but of dissolved nutriment, so that in any oceanic plants, and plants of ponds and rivers, no roots whatever are developed, and these live practically independent of any connection with the land. The fertilization of submerged cryptogams is effected by the passing of generative elements through the water, but only a few submerged phanerogams make such use of the agency of the water. The pollen of the eel-grass (*Zostera*) has been modified for under-water efficiency. It does not form round grains, but elongated thread-like filaments which have the same specific weight as the water, and hence neither float nor sink, but move about at the level of eel-grass growth until they come in contact with the stigma of some neighboring flower. In the duckweeds and some other submerged plants, the male flowers break loose, rise to the surface and float away like little boats carrying pollen to the female blossoms, which at that time have risen to the surface but sink again as soon as fertilized. The hydrophytes show many examples of exceedingly wide distribution, as might be expected of oceanic plants, but is not so easily explained of those of fresh waters, many genera and species of which, nevertheless, are cosmopolitan.

Hydrostat'ic Press, a machine, sometimes called Bramah's press, from Joseph Bramah, its presumed inventor, which by the force obtained from water under pressure performs work, especially packing, as of cotton. Two tubes of unequal area are connected, and the whole vessel filled with water. Let the area of the smaller tube be one square inch, and let the piston that closes it be loaded with one pound. A pressure of one pound per square inch will be exerted on every part of the boundary of the fluid. There will thus be a pressure of one pound per square inch put upon the piston that closes the larger tube; and if we suppose the area of the piston to be 16 square inches, it is evident that it must be loaded with 16 pounds in order that the pressure to which it is exposed may be equilibrated. Thus a load of one pound on the smaller piston supports 16 pounds on the larger.



Principle of the Hydraulic Press.



Cup-leather.

The principle of the hydrostatic press was pointed out by Stevinus; but it was Bramah who, in 1796, by an ingenious contrivance, gave the principle practical application. A Bramah's press, as ordinarily constructed and used to provide immense pressure, is a simple enough contrivance. By means of a small pump water is pumped from a cistern through a small horizontal tube into the space that receives a large piston. The goods to which pressure is to be applied are placed between the plate attached to the large piston and an upper plate that is kept in position by powerful iron rods. The water-tight stuffing of the piston is the great difficulty in the construction of the machine, and it was the invention of a water-tight collar by Bramah that made the use of the press practicable. The diagram shows a section AA of the collar surrounding the piston P. The collar consists of a

circle of solid leather, which is stamped by means of a die into the half-ring, of which a section is seen. When pressure is applied the water fills the channel formed by the half-ring, and squeezes the inner side of the ring against the piston, and this takes place with greater force the greater the pressure to which the water is subjected.

Hydrostatics, the part of hydrodynamics that treats of the application of forces to fluids at rest. It is generally divided into two parts, one, hydrostatics proper, which deals with incompressible fluids, or liquids, and the other, which deals with compressible fluids, that is, with gases. The latter part of the subject is commonly called pneumatics.

The property of fluids which distinguishes them from solids, is want of rigidity. A fluid offers no permanent resistance to forces tending to change its shape. The particles of a fluid are mobile; and while in the case of liquids very considerable forces of cohesion are exhibited, yet the particles show great freedom to alter their relative positions, and to pass from place to place within the general mass. A very important property that follows from the nature of fluids is that of the equable transmission of pressure. Suppose a weightless liquid inclosed in a vessel A, which is fitted with a piston P. If pressure is applied to P it will be transmitted in all directions through the liquid. If other openings are made, and if they are fitted with pistons, it is evident that to keep each of these pistons in its place, pressure inward must be applied. The pressure that must be applied to any piston equal in area to the area of P is equal to the pressure on P; and if the area of one of the other pistons is greater or less than the area of P, the pressure required to keep it in its place is proportionately greater than or less than the pressure that is applied to P. This principle, which is the most important in hydrostatics, finds a practical application in the hydrostatic press (q.v.).

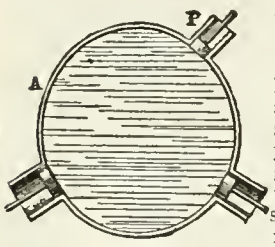


FIG. 1.

In measuring fluid pressure the area exposed to the pressure of the fluid is to be considered. If it were required to calculate the force that must be applied to the rod of one of the pistons in the figure in order to keep the piston in its place, it would be necessary to know the area of the piston and the pressure on it in grams per square centimetre. When the pressure over a given area is not uniform we must then know the law of variation, or at least the average pressure over the whole area, in order to calculate the whole pressure on it; and it will be readily understood that when, in such a case as this, the pressure per unit area at a point is spoken of, it is understood to mean the pressure which would be exerted on unit area were there found a unit of area pressed with a uniform pressure, the same as that at the point in question. Not only is pressure transmitted out to the surface or envelope of the liquid, as is shown in the figure, but within the fluid itself the particles are all pressed together. The pressure is transmitted to every point within the liquid and may be observed to be acting there. When a solid is immersed in the liquid it is pressed at every point of its surface in the direction perpendicular to the surface at that point, and, in the case of the hypothetical weightless liquid, with a pressure equal in amount per unit of the area to that applied from without to the liquid. The pressure about any point in a fluid is equal in all directions, and when any surface is exposed to the pressure, the direction of it is normal to the surface at every point.

In actual fluids, which have weight, it is evident, in the first place, that the lower layers of the fluid sustain more pressure than the upper layers. For whatever pressure the upper layers are exposed to is transmitted to the lower layers; and besides the lower layers have to support the weight of the superincumbent liquid. The most important case to consider is that of liquids having a free surface, that is, a surface exposed to the air. Here the surface itself is level. Otherwise there would be a tangential force which would make it flow down till the level state is reached. In every horizontal layer throughout the liquid the pressure per unit area is the same; and this is the case independently of the shape of any vessel in which the liquid may be contained. The pressure per unit area in any horizontal layer depends only on the height of the free surface of the liquid above the layer considered, and the specific gravity of the liquid; and it is equal to the weight of a column of the liquid of unit sectional area whose height is the height of the free surface. This principle gives rise to remarkable results. Take, for instance, an apparatus consisting of a pair of circular boards connected by a belt of pliable leather (like a pair of bellows), and having a small tube inserted into an opening near the bottom, and from it a tall tube rising perpendicularly. Heavy weights may be put on the upper circular board, and if water be then poured into the upright tube they will be raised up by the pressure from below of the water. For the pressure to which the under side of the circular board is exposed is equal to the weight of a column of water whose section is that of the circular board, and whose height is the difference of the heights of the under surface of the circular

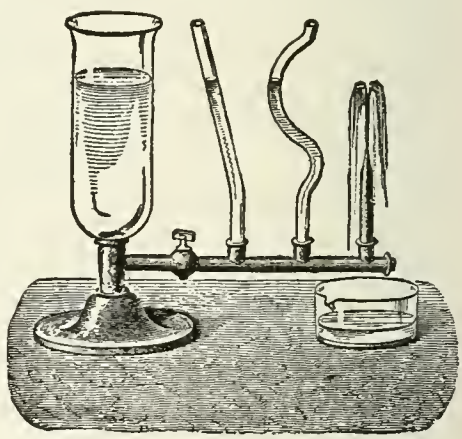

FIG. 2.

board and of the free surface of the water in the small upright tube. When shown in this form the principle here employed is often called the hydrostatic paradox, on account of the very great pressure that a very small quantity of water may be made to give rise to.

It is a well-known principle that liquids tend to find their own level. Thus, in the accompanying figure, showing a series of connected vessels, the liquid is seen to stand at the same height in the principal vessel and in the variously shaped tubes communicating with it, while from the short, narrow mouthed tube it spouts up to nearly the level of the water in the principal vessel.

When a solid is immersed either partially or wholly in a liquid a portion of the liquid is displaced. The solid is at the same time pressed at every point by the liquid, the pressure being always normal to the surface. The upward pressure on the solid is greater than the downward by an amount equivalent to the weight of the liquid displaced by the solid; for if, instead of the solid, the quantity of liquid displaced by it were present, its weight would be upborne by the pressure on every side. These pressures now act on the solid and whether or not the solid floats under their influence, as much of the weight of the solid as corresponds to this pressure is supported by the surrounding fluid. These considerations applied to the phenomenon of floating bodies illustrate the principle just explained; and the experiments that are made for the purpose of determining the specific gravity of bodies heavier than water also depend on that principle. See SPECIFIC GRAVITY.

If a body be immersed in water or other fluid, the resultant of the fluid pressures meets the surface at a point called the centre of pressure, which will coincide with the centre of gravity of the body if the body be horizontal, but will pass below it if the plane of the body is inclined to the fluid's surface.

The conditions of floatage and of stability of a body floating in a liquid are of great importance. A floating body displaces a certain quantity of the liquid, and the weight of the

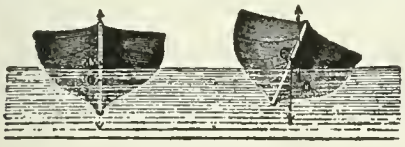

FIG. 3.

solid body is equal to the weight of the liquid that is displaced by it. To calculate how much of the body is submerged, and how much floats above the liquid, it is only necessary to consider what volume of the liquid would be equal in weight to the weight of the floating body. For example, the specific gravity of ice is about nine tenths of that of ordinary sea-water. Hence 9 cubic feet of sea water weigh as much as 10 cubic feet of ice. Thus in an iceberg nine tenths of the ice is under water, and one tenth is above the surface. In ships and other floating bodies the stability depends on the form of the body. A sphere of wood floating in water is indifferent as to position. The slightest force is sufficient to overturn it from any given position or to set it rotating in the water. With a ship or other body that must float with one side upward, the stability is quite as important as the floating power. The accompanying figure illustrates the conditions of stability. When a solid body is slightly displaced from its ordinary position of equilibrium, the forces that act upon it are seen to be twofold. First, there is the force of gravity on the solid acting vertically downward, which, if G be the centre of gravity, may be considered to act downward through that point; and secondly, there is the resultant of the upward pressures of the various portions of the liquid, which, if O be the centre of these upward parallel forces, may be considered as equivalent to a single force acting vertically upward through that point. In the figure these two equal parallel forces are seen to form a mechanical couple whose tendency is to right the boat, and bring it back into its ordinary floating position. But if the upward vertical line through O were on the other side of the downward vertical line through G, it is plain that the effect of the couple would be to carry the boat away from the position in which it ought to float; and the boat would thus be unstable.

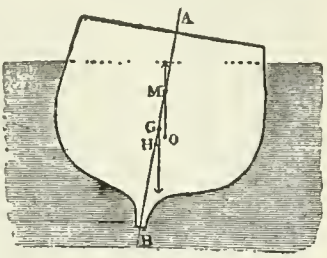

FIG. 4.

The metacentre is a point in a floating body of great importance, as its position determines whether the equilibrium is stable or unstable. Let A B in the figure be a line drawn through the points G and H, the centre of gravity of the floating body, and the centre of the figure of liquid displaced when the body is floating with A B vertical. Let the body be then slightly displaced, and let O be the new position of the centre of the figure of the displaced liquid, and let M be the point in which A B is cut by a vertical line through O: M is the metacentre when the displacement from the original position is infinitesimal. If the metacentre is above G then the equilibrium is stable; if it is below G the equilibrium is unstable, and the body being slightly displaced, it tends to fall farther and farther from its position of equilibrium.

Among the instruments and machines founded on the hydrostatic principles here laid down are the barometer, the siphon, the hydrostatic press, and the hydrometer (qq.v.).

Hydrotherapy (Greek, *ὑδωρ*, water, and, *θεραπεία*, cure), a method of treating diseases by the application of hot and cold water, which has come extensively into practice of late years, and is recognized by the medical profession as a very efficient therapeutic agent. The efficacy of water as a hygienic medicine has been recognized from the earliest times. Hippocrates, Celsus, and Galen regarded water as of especial value in the treatment of acute diseases; and during the Middle Ages the same view was advocated by many famous physicians. During the 18th century there was a growing belief in

its virtue as a curative agent, though rather in acute than in chronic diseases. Some physicians used water for internal treatment, others for external treatment, but hydrotherapy, as now understood, combines both methods. It was originated by Vincent Priessnitz, a Silesian peasant. When a boy of 13, having sprained his wrist, he applied it to the pump, and afterward bound a wet bandage upon it. As this became dry he rewetted it, and thereby reduced the inflammation, but produced a rash on the surface of the skin. Shortly afterward he crushed his thumb, and applied the wet bandage as before, and again an eruption showed itself. He concluded that the rash was an indication of impurity of blood; and having instituted a series of observations in regard to various wounds and ulcers on the persons of his neighbors, he was led to form a pathological theory, according to which disease is caused by an accumulation of morbific matter, which must be eliminated from the system by cold water applications and the observance of a strict regimen. His views were confirmed by an accident to himself, in which, through a cart running over him, he received some broken ribs and severe contusions, and was given up by the physicians; but on learning their opinion he tore off their bandages, and applied others wet with cold water. He also replaced his ribs by inflating his lungs while pressing his abdomen against the window-sill. Either through or in spite of this treatment Priessnitz recovered and the carrying out of this cold-water theory became the object of his life. In rapid succession he invented the sponge-bath, the wet-sheet packing, the sitz, foot, and arm baths, the douche, the steam-bath, the dripping sheet, the plunge, the dry-blanket packing, and other appliances of the hydropathic system. In 1829 he established, at his native village of Gräfenberg, a range of baths, which speedily grew in reputation, and attracted visitors from all parts of Europe. The Austrian government lent him its patronage, and all the opposition of the medical faculty was unable to stem the popularity of the new system. The original establishment at Gräfenberg soon expanded into an extensive suite of buildings, stretching along the slope of one of the Sudetic Mountains, and resorted to by troops of invalids, who sought to regain health by bathing, exercise, simple diet, and agreeable society. Similar institutions soon sprung up in other parts of Germany, and were at length introduced into England, a hydropathic society having been formed in London in 1842. At the present time hydropathic institutes exist in great number throughout the world, and so universal have hydrotherapeutic procedures become that a large body of quacks thrive on the prestige given to hydrotherapy by regular physicians. The theories of Preissnitz are now known to be fallacious.

The work of Winternitz and his disciples has put the general principles of hydrotherapy on a rational footing; there is little doubt, however, that hydrotherapy, like any other therapeutic agent, may be greatly abused. It is by no means a universal panacea. There are a large number of ways of applying hot and cold water to the body. One enthusiastic advocate has described over 300 separate kinds of application. In general, however, the water may be applied in the shape of tub-baths, ablutions, packs, rain-baths, and douches. These may be divided and subdivided as indicated. *Tub-baths* may be full, half, or local baths, as to the pelvis, the feet, the hands, etc. The full tub-bath is usually given at a temperature of 55° F., unless special indications are to be met. If the patient's reaction is not of the best, the temperature should be about 60° F., and vigorous friction of the skin should be maintained. The time spent should be short, 10 to 20 seconds. The full tub-bath is a strong tonic. In severe illness the tub-bath should be given only by a trained nurse under the physician's orders. Half-baths are taken at a temperature of 60°–75° F. After wetting the face and chest the patient sits in a tub about one third to one half filled with water, sufficient at least to cover the legs and the pelvis. The attendant splashes the cold water over the patient's body, maintaining at the same time a vigorous friction by means of a flesh-brush. The time is from one to five minutes, but the bath should not be continued if the teeth begin to chatter or if there is any evidence of defective reaction, as blueness of the lips, or thin pulse. Local cold baths, such as sitz-baths and foot-baths are very important hydriatric measures. The cold foot-bath, plunging the feet for from one to three minutes in cold running water, is of service in sluggish circulation of the feet, neurasthenia and hysteria. Warm full baths at a temperature of 90°–98° F., for a period of from 5 to 20 minutes are very useful as sedatives to the nervous system, particularly so in insomnia and nervousness from overwork, especially when taken at night. The best effect is obtained if they are taken at the time of retiring and are followed by a brief application of cold water, either in the shape of a half-bath, or a douche. After the bath the patient should wrap up in a linen sheet and a blanket to keep up the dilatation of the blood-vessels of the skin. Perspiration is to be avoided, save in particular instances.

Ablution.— This is one of the simplest of hydriatric measures. It is a valuable skin and nerve tonic, and is particularly adapted for children and women. It consists in the application of water to the body at a temperature of 50°–60° F., from the hollow of the hand, or by means of a bath-glove or wash-cloth. The entire body is gone over, one part after another being systematically treated. One to two minutes' application followed by vigorous rubbing with a coarse towel or flesh brush, is sufficient. Ablution is particularly valuable for reducing temperature, often bringing about quiet, restful sleep in tossing and fretful children.

Affusion.— In this treatment a volume of water from a pitcher or a pail is poured over the entire body, or upon certain parts, the patient sitting or standing erect in a tub or bath. The temperature should be 50°–60° F., and the whole procedure should not consume over 10 or 15 seconds. The reaction is obtained by rubbing. In certain muscular tremors, in neurasthenia, etc., this procedure is of service.

Packs or Compresses.—These may be dry or wet, general or local. The dry and wet packs are applied in the same manner. The patient is placed on a narrow bed or couch with a rubber sheet, a blanket, and a linen sheet beneath him, the blanket and sheet falling on each side of the couch. The sheet is then brought up and, with the arms to the side, wrapped thoroughly about him, the face alone being exposed. The blanket

is then wrapped about the patient in a similar manner. Cloths wrung out in cold water may be applied to the head. In a wet pack the sheet is first wrung out in cold water; in the dry pack it is frequently warmed. The object of the application is to bring about free perspiration, and this is the usual result. Hot drinks may be administered freely. The time given to the application will depend largely on the conditions to be met. If reduction of temperature alone is desired, the patient may remain in the pack until the perspiration is free, and he may then be wrapped up in a dry blanket. In certain uræmic states, and in infantile convulsions, a longer period may be necessary. The wet pack is an excellent procedure in the treatment of alcoholic excesses. The initial effect of a cold pack is constriction of the blood-vessels; this is soon followed by a dilatation which continues throughout the application and is the main cause of the free perspiration. The pulse-rate is reduced and the arterial tension falls. The stress of elimination is taken from the kidneys, the amount of blood within the brain diminishes, and sleep is encouraged. In the hot general pack a blanket only is used. This is wrung out in water at 140°–150° F., the temperature at the time of application not being over 105°–108° F. Local packs or compresses are of inestimable service in a variety of conditions. These are usually made of pieces of heavy muslin, canton flannel, or linen, varying in shape according to the site of application. They are wrung out in cold or hot water and applied to the head in headache, to the neck in sore throat, tonsillitis, diphtheria, earache; to the chest in pleurisy, pneumonia, neuralgias; to the heart in rapid overacting heart-action; to the stomach in indigestion; to the joints in sprains, rheumatism and gout; to the abdomen in gastroduodenal catarrh, irritable bladder, catarrhal appendicitis, colitis, peritonitis. Hot applications are particularly serviceable in painful menstruation. Hot water-bags have largely taken the place of hot compresses since they have been made so handy in shape and size and so reasonable in price.

The Douche.— This application is one of the best tonics, but requires special rooms for its use. These are found in the best appointed hydropathic institutes. The douche consists in the application of hot and cold water delivered through a hose. It combines the elements of the water, heat, cold, and force. The regulation of the pressure and temperature is an important feature in the scientific use of the douche.

Smith Ely Jelliffe, M. D.,
Instructor in Pharmacology and Therapeutics, Columbia University.

Hydrozo'a, a class of *Cœlenterata* (q.v.) embracing the polyps, all of which bear a general resemblance to *Hydra* (q.v.). There are two alternating generations, that is, (1) the sessile asexual polyp, which (2) gives rise to a jelly fish or medusa. The hydroid polyp is like hydra, a two-layered vase-like sac, with a circle of tentacles around the mouth. This gives off by a budding process a bell-shaped medusa, which is much more highly organized than the polyp, having a well developed digestive and nervous system, and sense-organs (eyes and ears, or otocysts). The *Hydrozoa* are at present divided into seven orders, the most important of which are, besides *Hydraria* represented by hydra; the *Hydrocorallinæ* of which *Millepora* (q.v.) is the type; the *Tubulariæ* comprising *Hydractinia, Tubularia,* etc.; the *Campanulari* of which *Campanularia, Clytia,* and *Obelia* are examples. Near this group belongs the extinct order of *Graptolites,* which were floating forms living in the Paleozoic seas. The last order (*Siphonophora*) comprises the Portuguese man-of-war (q.v.) and other forms, which are beautiful transparent pelagic animals, very brightly colored and highly specialized.

Hyena, hī-ē'nä, one of a family (*Hyænidæ*) of carnivorous mammals, having relations in structure to the bears, the cats and the civets, familiar in Africa and southern Asia. They are of moderate size, have large, rather short heads, powerful forequarters, feeble and drooping hindquarters and short tails. The eyes are large, and have longitudinal pupils; the ears are long, erect, very open, and directed forwards. The teeth are numerous, massive, tuberculated, and well adapted to aid the muscular jaws crunch the strongest bones, as hyenas are able to do. Hyenas are nocturnal animals which pass the day in solitude in caves or other hiding places, which they quit at night in order to seek their prey in bands. Carrion is a favorite food, and the stench attracts the hyena by night as it does the vulture by day. In some cases they dig up dead bodies and devour them. They also prey on living animals, and flocks of sheep and goats suffer severely from their ravages in some localities. The common or striped hyena (*Hyæna striata*) is a native of Northern Africa and parts of Asia, even eastward to Burma. It is about the size of a large dog, brownish-gray and marked with transverse bands of dark brown on the body, which become oblique on the flanks and legs. The hair upon the line of the back is much thicker and stronger than on any other part, forming a sort of mane, extending from the nape of the neck to the origin of the tail. This species was well known to the ancients, who entertained many absurd notions respecting it, believing that its neck consisted of but one bone; that it changed its sex every year; that it could imitate the human voice, etc. It was formerly supposed that the hyena was untamable, but that it can be completely tamed there is not the shadow of a doubt. The spotted hyena (*H. crocuta*) has a considerable resemblance to the former species, but is larger, and is marked with numerous round blackish-brown spots instead of stripes, nor is the mane so large. This species inhabits many parts of Africa, and used to be peculiarly numerous around the Cape of Good Hope. There is another species, the brown hyena (*H. brunnea*), which differs from the preceding by having stripes on the legs, the rest of the body being of a dark grayish-brown. It also inhabits the south of Africa. An extinct species, the cave hyena, was abundant in England, France, and Germany anterior to the glacial epoch, and has left its remains in many caves of these countries. Though named *H. Spelæa,* it seems practically identical with the existing *H. crocuta.*

The fossil ancestry goes back into the tertiary whence it seems to have sprung from the same stock that gave rise to the viveroids. Consult writers upon nature and sport in Africa and India.

Hyena-dog, an African canine animal (*Lycaon pictus*), which takes its name from its hyena-like appearance in shape and color, and is also called Cape hunting-dog because it hunts in packs. It differs from the typical dogs in having only four toes on both the fore and hind limbs, and in its dental fauna, and it seems to be a comparatively recent immigrant into South Africa, since its bones are found in British caves. It preys upon antelopes, cattle, etc., and was a scourge to the early settlements, when it was more numerous and bold than now.

Hy'giene, broadly, the science and art of preserving health; as currently restricted, not by curing disease but by its prevention, through the removal of its generating causes. As we cannot remove them until they are known or truly inferred, the science advances *pari passu* with that of medicine, and had no general basis till the past century, during which unprecedented progress was made in all branches of medicine, than which none is more important than that of preventive medicine (q.v.). Still, good sense had been applied to it for ages, especially in regions where ignorance was speedy death. The Mosaic laws recognize the three great principles of cleanliness, isolation, and wholesome diet, with a thoroughness that leaves little to be desired. Hence, the Jews were almost immune for many centuries from the plagues which swept away their Christian neighbors; this was one reason why they were often suspected of starting or spreading the plagues. As in most ancient religions, these sanitary principles were part of their religious observances. In the 18th century some elementary ideas of hygiene had become known: the prevention of scurvy by lemon-juice and vegetable diet, of jail-fever by less crowding and more cleanliness, and of smallpox by inoculation, were among the foremost advances. Our new scientific acquaintance with ultimate causes for the first time enables us to make hygiene a true science on a basis of exact knowledge.

The subject naturally divides itself into two main branches, those of environment and of the person: though there are some items which belong to neither, and the two cannot always be separated.

Environment.— This includes (1) climate; (2) private: the site, construction, elevation, warming, water-supply, and purification of dwellings; (3) public: the cleaning of streets, disposal of the dead, prevention of befoulment either by excreta or sputa, and other methods of public sanitation. The third will be dealt with under another title by an expert authority on public health. See SANITARY SCIENCE.

Climatic conditions cannot to any extent be modified: they must be neutralized, when unsanitary, by other conditions pertaining to hygiene. All nations have more or less adapted their habits to their climate, unless acclimated so that they become part of its working: the hours of work or travel, the character of dwellings, the sites selected, the diet found wholesome by experiment, all form part of a hygienic system built up by social experience and tradition. Those unacclimated may have personal advice from predecessors; too often nothing but personal experience can be of any avail, and frequently that is only acquired by fatal results.

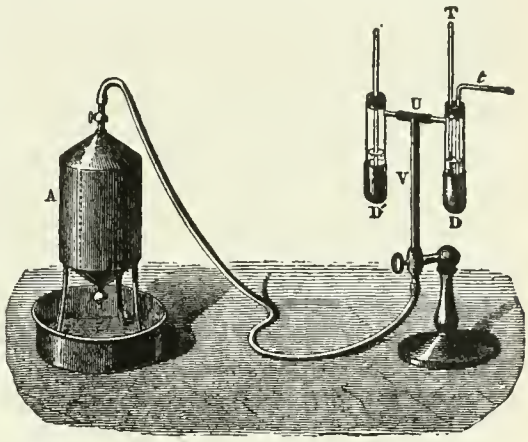
The subject of *dwellings* includes a number of considerations. The site, if possible, should not be one where the ground-water is near the surface, or freshets or tides set back the drainage of closets, or where there are great fluctuations in the level of the ground-water, which it is better to have nearer the surface and steady than lower and more unstable. "Made" land in cities is often unhealthy, but tenants cannot in practice exercise much choice; the city authorities should prevent bad results by thorough sewerage with a good fall. The construction most important to have right is the plumbing; including the drains at the bottom: it is a commonplace which need not be dwelt on, that leaking sewer-pipes and clogged drainage mean the infection of a house with disease-laden air. Paint is better than paper for walls, as it can be washed; and old paper should be scraped off before new is laid on. When possible, rooms should be large enough not to need incessant change of air; when not possible, as is usual in cities, plenty of windows and the fullest possibilities of draft should make up; if this, too, is not available, the best systems of artificial ventilation. Unhappily, science is very backward in this class of invention, and small, close, unventilated rooms shorten millions of lives and prematurely break down working power in even the civilized cities of the world. The normal supply should be at least 3,000 cubic feet of air per head each hour, and this largely increased in work or sickness. The volume of consumption and other scrofulous diseases, bronchitis, pneumonia, etc., is directly dependent on foul air, which also increases the virulence of all zymotic diseases. The ventilation of public buildings rests on the same principles, and has the same results. The warming of houses is of great importance, and is generally ill done, with disregard of ventilation. The vast majority of houses in America are grossly overheated even when the air-supply is enough, giving a sensitive skin which "catches cold" as soon as it touches fresh air. Little children especially are literally killed by thousands from overheating and overdressing. The water-supply is a matter of public concern: where there is a flat price, people do not stint themselves. Where there are meters, they often do; but closets should be kept fully flushed at any cost. In country houses, where city water and sewerage are not available, it is not necessary to insist on the frequent cleaning and disinfection of receptacles for excreta. Advice on this point is obtainable gratis from physicians, apothecaries, and others. If the dry methods are carefully used, they have many advantages in healthfulness over the elaborate city systems.

Personal Hygiene.— This has very many divisions: the most obvious are considerations of food, and drink, nerve stimuli, clothing, cleanliness, natural necessities, work and rest, and moral self-control. In the matter of diet, there can be no one rule: "at forty," says the proverb, "one is either a fool or a physician"; and each must use his own experience as a guide to whether meat is a necessity or vegetarianism an advantage, what foods agree with him, whether

dry meals give him heartburn or drinking with them impedes digestion, and whether he is eating so much as to make him heavy, impairing his capacity for work and enjoyment, or making his body gross. In general, probably professional and sedentary workers as a class overeat, and would find their minds more alert and their bodies freer from disorders with less gratification of appetite. Nerve stimuli, ranging from tea, coffee, and cocoa, to tobacco, alcoholic drinks, and opium, are hard to frame a general rule upon: they, too, have infinitely varied effects. Cocoa is most of a food; coffee with most is an agreeable stimulant, with many an active nerve-poison, producing heavy headaches and incipient stupor; tea is a real nerve-food on occasion and in small quantity, while taken steadily and largely it is a poison and a very mischievous one; tobacco sparingly used by grown men probably does little harm, and sometimes saves worse things, but should not be used by those under age, nor by those with weak nerves, and is highly injurious in heart disease, Bright's disease, and venereal diseases; alcoholic drinks suggest too many questions for discussion here; narcotics like opium, hashish, etc., as well as chloral and its like, should be used only on a physician's prescription. Clothing, if there is time and means, can be accommodated to changes of weather and occasion so as greatly to advance health; with most, there must be a rough average. Personal cleanliness within limits is a *sine qua non* of reasonable immunity from disease, and with delicate persons, of reasonably good ordinary health; but even this good thing can be irrationally overused and make mischievous. Too frequent hot baths in a northern climate are a great aggravator of lung-diseases, and one great city (Pittsburg) had a marked decrease of pulmonary complaints one winter when the water-supply broke down, and people resorted greatly to dry rubbing. Especially it is possible to use too much soap, and keep the natural oil of the skin washed away. Natural necessities should be attended to more constantly than they are: workmen especially often grudge the time, but the waiting till there is severe pressure often creates dangerous bladder and intestinal complaints. Work, for most, is not under their own control; but to some extent resting is, and the average American perhaps owes more to compulsory public holidays than he is aware. There is more temptation to overwork than to idle, for the average man. Exercise should be taken by the sedentary, even a homespun house-method being preferable to nothing. Grotius preserved his health in prison by whipping a top two hours a day. This should be one of the most rigidly imposed forms of self-control, which in all forms is all-important. Excessive sexuality, either of act or imagination, is simply destructive of will-power as well as bodily fibre; giving way to fits of anger or despondency is almost a recipe for entire nervous wreck. As to laziness, of mind or body, it is one of the worst and most incurable forms of this evil.

The management of children is really personal hygiene, only controlled by another than the subject, the care of the dead belongs to public hygiene; the prevention of disease belongs either to medicine, by the use of drugs like quinine or inoculations, or to house-hygiene as disinfection. The hygiene of the sick-room should be under the direction of the physician.

Hygrom'eter (Gr. "moisture-measure"), a meteorological instrument used to ascertain the quantity of moisture in the air. The first hygrometers, or rather hygroscopes (for they did not determine the quantity of humidity, but merely showed the difference between a dry day and a damp day), were constructed of catgut, hair, or other fibrous material, having the property of lengthening when wet, and contracting when dry. The first hygrometer properly so called was made by Professor Daniell. It consists of a glass tube, bent at right angles into arms of unequal length. Each arm terminates in a bulb, one bulb being two thirds filled with sulphuric ether, and the other bulb being, at the commencement of an experiment, empty. In process of construction the tube is exhausted of



Regnault's Hygrometer.

air, and is thus filled with vapor of ether through its entire length. A thermometer with a bulb immersed in the ether of the lower arm is inserted in the tube to register variation of temperature, and a second thermometer is attached to the stand of the instrument to show the temperature of the outer air. For use one bulb containing the sulphuric ether has a zone of polished gold, and the other bulb a muslin cover. If sulphuric ether be dropped on the latter, as it evaporates the bulb is cooled, and the vapor of ether is condensed within it from the other bulb; the temperature of which rapidly falls owing to evaporation from it. The operation is carried on, ether being dropped on the second bulb as is required, till the temperature of the first is so far reduced that dew from the surrounding air just begins to condense upon it. By means of the thermometer contained in the first bulb the temperature is read off at the instant at which vapor begins to condense, and the dew-point is thus obtained. The hygrometric condition, that is, the ratio between the quantity of moisture that the air actually contains and the quantity which it is capable of containing at the existing temperature is then easily deduced.

Regnault's hygrometer, shown in the above figure, is an important modification of Daniell's instrument. D and D' are two precisely similar cups or thimbles of polished silver; each is surmounted with a similar glass tube into which,

by means of a cork, two thermometers are fitted, and the bulbs of the thermometers are covered with ether. Through the cork in one of the tubes a small glass tube *t* passes, and is carried down below the surface of the ether; while a side tube establishes communication with the vertical tube U V which is connected with an aspirator A (or vessel into which air is sucked at the top to supply the place of water which escapes at the bottom). There are no corresponding side tubes connecting the left-hand tube of the hygrometer D′. By means of the aspirator a current of air is drawn through *t*, it therefore bubbles through the ether, causing evaporation and cooling the ether till the dew-point is reached. This is observed with great nicety by means of the silver cap; for the instant the dew commences to deposit, the brilliant polish of the silver is dulled. The temperature of the air is at the same time read off by means of the other thermometer in D′. Regnault's hygrometer, both from its construction and from the use of the aspirator, avoids the too great proximity of the observer, which, from the nature of the experiments, is objectionable.

Mason's dry and wet bulb hygrometer consists of two thermometers arranged side by side as in the figure. The dry bulb gives the temperature of the air at the time of observation; and the other bulb, which is covered with muslin, and kept moist by filaments of cotton carried from it into a small cistern of rain or distilled water, reduces the height of the mercury in its tube in proportion to the capacity of the air for drying, or taking up additional vapor. This instrument does not give the dew-point directly. The difference between the readings of the two thermometers is multiplied by a special factor for every temperature of the dry bulb.

Hyksos, hĭk′sōz, according to the Egyptian annals, a conquering nomadic race from the East, who, under Salatis, their first king, took Memphis, and rendered the whole of Egypt tributary. Their name probably means "foreign kings," the explanation "shepherd kings" being of later origin. The date of their invasion and conquest was about 1700 B.C., of their expulsion about 1600 B.C. The seat of their rule was the strongly garrisoned fortress of Avaris, on the northeastern border of the Delta. They followed Egyptian customs, and their six monarchs took Egyptian names. It seems likely also that a great part of Syria was subject to them. The only detailed account of them in any ancient writer is an unreliable passage of a lost work of Manetho, cited by Josephus in his rejoinder to Apion.

Hymans, Louis, loo-ē ē-măn, Belgian historian, journalist, novelist, and poet: b. Rotterdam 1829; d. Brussels 22 May 1884. He removed to Belgium in boyhood and rose rapidly to distinction as a Liberal journalist. He edited the Belgian 'Star' and the Parliamentary 'Echo' for some years, and was elected to Parliament in 1859. He wrote: 'History of the Marquisate of Anvers' (1848); 'Popular History of Belgium' (1860); 'Political and Parliamentary History of Belgium' (1869–70); two popular novels, 'André Bailly' (1861), and 'The Buvard Family' (1858); and some pleasing poems.

Hy'men, the god of marriage in Grecian mythology. The common legend is that he is the son of Apollo. No marriage took place without his being invoked to sanction it. He is described as having around his brows the flower of marjoram, in his left hand the flame-colored nuptial veil, and in his right the nuptial torch.

Hymenoptera, an order of Hexopoda or insects, considered by many entomologists to be the highest and most perfect expression of the insect type. The metamorphosis is complete and extensive. The larvæ are short, thick grubs, footless except in the saw-flies (*Tenthredinidæ*) and in most cases are carefully nurtured and fed in nests. The pupæ have nearly the form of the perfect insects. The imagos are of compact, highly complex construction, with the three regions well marked except that the first segment of the abdomen is united with the thorax. A considerable part of the large head is occupied by the conspicuous compound eyes besides which there are three ocelli. The jaws or mandibles are conspicuous biting organs, and the remaining mouth-parts usually form more or less of a proboscis with a large ligula or tongue. Although the wings are small they move with great rapidity and sustain the body in rapid and extended flight; there are two pairs (sometimes absent), membranous, veined and transparent. The genital appendages of the females are modified to form a sting or, more rarely, an ovipositor. Marked sexual dimorphism is very frequent especially among the social forms, in which a third class of individual, the worker or neuter, in reality imperfect females, also occurs. Many of the ant communities are still farther polymorphic. The order is one of great extent and exceptional interest, as it includes the ants, bees and wasps, the ichneumon-flies, gall-flies and saw-flies, divided into numerous families. Among the ants and bees are exhibited most remarkable and complex social states, which are described in the articles on these groups. The habits of the numerous species of wasps, and especially the varied architecture of their nests, are of nearly equal interest. A remarkable series of adaptations to special conditions are presented by the parasitic ichneumon flies and their allies, which lay their eggs within the bodies of the larvæ or even in the eggs of other insects, on the substance of which their own larvæ feed. Confining their parasitism to plants, the gall-flies produce by the irritation caused by their eggs or secretions deposited with them in the tissues of leaves, twigs or fruits, the familiar excrescences whose shapes are almost as numerous as the species which produce them. (See GALLS.) Finally, the saw-flies are least typical of the order but stand nearest to the main hexapod stem. Their larvæ have both thoracic and abdominal legs and closely resemble caterpillars; they are vegetarians and many of them are very destructive to plants.

Consult standard works of Entomology (see INSECTS), and the bibliographical list given by L. O. Howard in the appendix to his 'Insect Book' (New York 1902).

Hyndman, hĭnd′măn, **Henry Mayers,** English socialist and author: b. London 7 March 1842. He was educated at Trinity College, Cambridge; and entered journalism. He was special correspondent for the *Pall Mall Gazette* in the war of 1866 between France and Italy, and wrote leading articles in favor of free education in the Melbourne 'Argus' in 1869. In

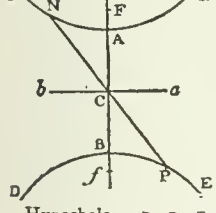
1881 he was one of the founders of the Social Democratic Federation, and has since been active in the Socialist movement, being the acknowledged leader of the Marxian Socialists in England. In 1884 he founded the paper 'Justice,' of which he is editor. His works include 'Historical Basis of Socialism in England' (1883); 'Socialism and Slavery,' a reply to Herbert Spencer; 'The Commercial Crises of the Nineteenth Century' (Social Science Series, 1892); and 'Economics of Socialism' (1896).

Hyne, Charles John Cutliffe, English novelist: b. Bibwry, Gloucestershire, 11 May 1866. He was graduated from Clare College, Cambridge, traveled widely both overland and by sea, and has published several rigorous stories, including: 'The Stronger Hand' (1896); 'The Adventures of Captain Kettle' (1898); 'Through Arctic Lapland' (1898); 'Further Adventures of Captain Kettle' (1899); 'The Filibusters' (1900); and 'Thompson's Progress' (1902).

Hypatia, hī-pā'shĭ-ạ, Greek philosopher of the eclectic school, daughter of Theon, a celebrated astronomer and mathematician, who was at the head of the Neo-Platonic school in Alexandria early in the 5th century. Such was her reputation that she became a preceptress in the school of Plotinus at Alexandria, and expounded the principles of his system to a numerous auditory of students from all parts of the East. Her house became the resort of all the persons of learning and distinction in Alexandria, and, among others, of Orestes the Prefect, between whom and Cyril, patriarch of Alexandria, a conflict respecting authority existed. A fanatical mob believing that Hypatia encouraged Orestes in his opposition to the patriarch, set upon and murdered her (March 415). Hypatia appears as the central figure of Kingsley's novel of the name (q.v.) (1853).

Hypatia, a work of historical fiction, by Charles Kingsley (q.v.), named from the principal character, the philosopher Hypatia (q.v.). The book presents a brilliant and stirring though not historically trustworthy picture of the 5th century of the Christian era, against the background of the learned city of Alexandria in Egypt.

Hyper'bola, in geometry, a curve formed by the intersection of a plane with two cones united at their apexes. The intersecting plane has such an inclination to the axis of the upper cone that it produces a similar section of the lower cone; the two branches thus formed are called opposite or conjugate hyperbolas. The two points where the branches approach nearest to each other are called the vertices, the straight line which joins them is called the major or transverse axis, and its middle point the centre of the hyperbola. A line of a certain definite length drawn through the centre and continued both ways at right angles to the major or transverse axis, is called the minor or conjugate axis. When the major axis is produced beyond the vertices two points called foci occur at equal distances from the centre, and the difference of their distances from any one point of the hyperbola is always equal to the major axis. Every line drawn from any part of the hyperbola to one of the foci is called a radius vector. If at one of the vertices a perpendicular to the major axis be erected, so as to be bisected by this axis and made equal in length to the minor axis, and if through the extremities of this perpendicular and the centre of the hyperbola two indefinite straight lines be drawn, these form what are called the asymptotes, which though they lie entirely outside the hyperbola, are always drawing nearer and nearer to it, but never actually reach it. The equation of the hyperbola referred to its centre and axis is $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$



Hyperbola — D B E, G A H, are opposite hyperbolas; F *f*, foci; C, centre; A B, major or transverse axis; *a b*, minor or conjugate axis; N C P, a diameter.

Hyperion, hī-pē'rĭ-ŏn, in Greek mythology, a Titan; son of Uranus and Ge, and father of Helios, Selene, and Eos. Homer and later poets apply the name as a patronymic for Helios himself. The attribute of beauty has therefore been connected with the name, as in Shakespeare's comparison of "Hyperion to a satyr."

Hyperion, in astronomy, the name assigned to the 7th satellite of Saturn, discovered in 1848, at the Harvard Observatory by G. P. Bond. It is outside the satellite Titan, whose mass causes perturbations in the orbit of Hyperion, which have proved to be a difficult problem in celestial mechanics, and a unique case in the solar system. They apparently give large eccentricity to Hyperion's orbit, and cause the apparent line of apsides to follow the conjunction points of Titan and Hyperion, in a direction contrary to the usual motion of this line.

Hyperion, a romance, by H. W. Longfellow, published in 1839. It is the tale of a young man in deepest sorrow, wandering from land to land in search of occupation for his mind, and forgetfulness of grief. This motive forms the thread of a story which connects a series of philosophical discourses, and romantic legends and poems. Many of these last are Longfellow's translations of German poems, and have found a place in his collected poems.

Hyperpyrexia, hī-pĕr-pĭ-rĕk'sĭ-ạ. See FEVER.

Hyperspaces. *Dimensionality.*—In order to make quite intelligible the concept variously denoted by such terms as hyperspace, space of higher dimensions or dimensionality, multidimensional space, *n*-space, *n*-fold or *n*-dimensional space, it is in the first place necessary to explain the meaning of dimensionality and to indicate the way in which the dimensionality, or number of dimensions, of a given space in a given element is determined or ascertained. Because, in order to determine the position of a *point* in a curve or straight line, it is necessary and sufficient to know *one* fact about the point, as, for example, its distance (with algebraic sign) from a fixed point or origin, a line is said to be a *one*-dimensional space of *points*. But instead of the point, we may choose for element of the space (line) a *pair* or a *triplet*, . . . or an *n-set* of points. In such cases, in order to deter-

mine the element, *i.e.*, to pick it out or distinguish it from among all others of its kind, it is necessary and sufficient to know *two* or *three*, . . . or *n independent* facts about it. Hence a line is a *two-* or *three-*, . . . or *n*-dimensional space of *pairs* or *triplets*, . . . or *n-sets*, of points. In like manner a flat pencil (totality of lines of a plane that have a common point) is a *one*-dimensional space of *lines*, while its dimensionality is 2 in line *pairs*, 3 in *triplets*, and so on. For like reasons a plane is a *two*-dimensional space of *points* or of *lines*. In *circles* its dimensionality is 3, in *conics* 5, in *curves of third order* 9, and so on. It is at once seen that the dimensionality of a given space depends on the entity chosen for primary element, the element, *i.e.*, in terms of which we elect to study and express the properties of the given space. Illustrations abound. A curved surface, as, say, a sphere, regarded as the envelope of (its tangent) planes, is a *two*-dimensional space of *planes*, while, conceived as the assemblage of (its tangent) lines, it is a *three*-dimensional space. The reader will observe that the term space is employed generically to denote any unbounded continuum of geometric entities. The generalization is, however, a natural one, for, for geometric purposes, ordinary space is viewed primarily as an assemblage of elements of one kind or another. To determine the position of a point in ordinary space, three independent data (as the distances of the point from three mutually perpendicular planes of reference) are necessary and sufficient. Ordinary space is, therefore, *three*-dimensional in *points*, and that is what is meant, consciously or unconsciously, when, without specifying the element (point), it is simply said that space is three-dimensional. But tri-dimensionality is in no strict sense a *definitive* property of ordinary space. For some little understood, probably economical, certainly extra-logical, reason, the point recommended itself to primitive man as the element par excellence with which to geometrize, and so it has become traditional and proverbial that our space is essentially, uniquely, characteristically, intrinsically, exclusively three-dimensional. Such, however, it is not. It is indeed *three*-fold in *planes* as in points, but in *lines* it is *four*-dimensional. So, too, it is *four*-fold in *spheres*, but in *circles* its dimensionality is *six*. In general, it is possible by proper choice of element to endow any given space with any prescribed dimensionality however high. Accordingly, if by hyperspace is meant a space of dimensionality greater than 3, the notion is simple and near at hand, we need not go beyond ordinary space to realize it, we detect it in the line, in the plane, in ordinary space, here, there, and yonder. Well, such *is* one of the recognized significations of the term. But it has 'another,' namely, hyperspace usually means a space whose *point* dimensionality is four or more. Now this latter meaning is *logically* and *conceptually* quite consistent with the other, it is indeed a special case of it; but a hyperspace of *points* is difficult or impossible to *picture*, to realize in *visual imagination*, and it is this non-logical circumstance that renders the term hyperspace at once so tantalizing, mysterious, baffling, and fascinating to the non-mathematician. To the mathematician, however, whose activities, so far from being confined within the limits of the visual imagination, lie for the most part quite beyond them, the conception in question offers as such no difficulty whatever, and it has long since established itself among the most approved of orthodox scientific notions.

Definition of Hyperspace of Points.—What, then, is a *hyperspace* of *points?* How is the notion arrived at? And what is its utility? The values of a single continuous variable x are familiarly representable by the points of a right line; the ordered *pairs* of values of two independent variables x_1 and x_2, by the points of a plane; and the ordered triplets of values of three independents x_1, x_2, x_3, by the points of ordinary space. To the analyst with geometric bias or predilection, the suggestion immediately and forcibly presents itself that there *ought* to be a space whose points would serve to represent, as in the preceding cases, all ordered sets of values of n independent variables x_1, x_2, . . . , x_n; and, not finding such a space present to *intuition*, *vision*, or *visual imagination*, he *posits*, or, if you prefer, he *creates*, one in *thought*. This done, it becomes immediately practicable to appropriate the terse, sensuous, stimulating language of geometry to the uses of analysis. Moreover, the hyperspaces serve as boundless playgrounds for the human spirit. They are immeasurable and immeasurably interesting fields for geometric research and exploration. In them light is found for the illumination of many otherwise dark or undiscovered properties of the lower, ordinary, spaces of intuition. By their study, the geometrician discovers how such higher and higher worlds would appear to a vision capable of beholding them.

Another Mode of Generating the Concept.—Another way, and, by virtue of its appeal to the intuition, possibly the best way, of arriving at the notion of hyperspaces of points, is the following: Posit two *points* (spaces of *zero* dimensionality in *points*). These determine a line, a space of dimensionality *one* in points. Next posit a point *outside* the line. The locus of all the points of all the lines determined by the posited point and the points of the given line is a plane, a space of *two* dimensions in *points*. Posit a point *outside* of the plane. The locus of all the points of all the lines (planes) determined by the posited point and the points (lines) of the given plane is a space (like our ordinary space) of *three* dimensions in *points*. Let the process continue. If intuition fail, reflect that in any case it is only a non-essential, extra-logical auxiliary, and hence proceed by positing *conceptually*, in *thought*, a point *outside* of the threefold space S_3, before obtained. The locus of all the points of all the lines (planes, 3-fold spaces) determined by the posited point and the points (lines, planes) of the given S_3 is a space of *four* dimensions in *points*. Obviously the principle of genesis here exemplified admits of endless application and leads directly to the concept of an n-fold space of points.

But we need not suffer ourselves to be dominated by the conception of point. Among possible elements, the point has no *logical* claim to preference or primacy, and the foregoing process is equally available for the generation of the concept of a space n-dimensional

in any other element, *e.g.*, the line. Posit two intersecting lines (spaces of *zero* dimensionality in *lines*). These determine a flat pencil, a *one*-fold space, of *lines*. Posit a line *outside* the pencil, *i.e.*, not belonging to it but going through its vertex. The assemblage of all the lines of all the pencils determined by the posited line and the lines of the given pencil is a hyperpencil (sheaf of lines), a *two*-dimensional space of *lines*. Next posit a line outside the sheaf (but cutting all of its lines). So is determined a 3-fold space of lines, the assemblage of lines of which each with the posited line determines a pencil. The next step leads to a 4-fold line space; the next, to a 5-fold line space; and so *in infinitum*.

It is clear that the lower spaces are contained in the higher, as points in lines, lines in planes, etc., or as lines in pencils, pencils in sheaves, etc., etc. It should be noticed, too, that any space S is *zero*-dimensional in such spaces S taken as *elements*. The complete understanding of the geometry of a space of k dimensions demands a study of the like variety of space of $k+1$ dimensions, and so on. In particular the point geometry of ordinary 3-fold point space is quite as much illuminated by that of 4-fold point space as is the point geometry of the plane by that of 3-space.

Coordinates, etc.—In point space of n dimensions the simplest coordinates of the point are the distances $x_1, x_2, \ldots, x_n$ of the point from n mutually perpendicular point spaces of $n-1$ dimensions. These coordinate spaces, taken $n-1$ at a time, determine n coordinate axes. A linear equation $\xi_1 x_1 + \xi_2 x_2 + \ldots + \xi_n x_n + 1 = 0$ defines or represents an $\overline{n-1}$-dimensional space of order *one*, the analogue of the plane in ordinary space. The ξ's are the negative reciprocals of the axal intercepts of the $\overline{n-1}$-space. Holding the x's fixed and letting the ξ's vary, the foregoing equation will represent a point as envelope of its generating $\overline{n-1}$-spaces. Two such equations together define an $\overline{n-2}$-space as their intersection or a straight line as their envelope. Similarly, three such equations serve to represent an $\overline{n-3}$-space as locus of points or a plane as envelope of $\overline{n-1}$-spaces, and so on. A space that is n-fold in points is also n-fold in spaces of $\overline{n-1}$-dimensions. Its dimensionality is $2(n-1)$ alike in lines and in spaces of $n-2$ dimensions. In general, its dimensionality is $p(n-p+1)$ if the point space either of $p-1$ or of $n-p$ dimensions be taken as generating element. Not only, however, do the two last mentioned elements furnish the same dimensionality, but they are indeed reciprocal elements of n-fold point space, for the same system of equations which on proper interpretation defines one of the elements admits of a second (dual) interpretation defining the other. It thus appears that by taking as elements the various simple spaces of less than n dimensions for generating elements of n-fold point space, there arise n geometries of this space; or, if we regard two reciprocal theories as but two aspects of one geometry, the elements in question yield $n:2$ or $1+(n-1):2$ geometries according as n is even or odd, the element having $(n-1):2$ dimensions being, in case of n odd, its own reciprocal, or *self-reciprocal*, like the line in ordinary space (see Line Geometry and Allied Theories).

Remarks on Four-space.—Thus point space of 4 dimensions is also 4-dimensional in ordinary spaces (say *lineoids*), the point and the lineoid being reciprocal elements. It is 6-dimensional in *lines* and also in *planes*, which are also reciprocal elements of this space. It appears that this space, unlike ordinary space, does not admit of self-reciprocal construction. An equation of degree n in point (lineoid) coordinates x_1, x_2, x_3, x_4 ($\xi_1, \xi_2, \xi_3, \xi_4$) represents a locus (envelope) of *order* (*class*) n. If $n=1$, the locus (envelope) is a lineoid (point). Two linear equations define a plane as locus or a line as envelope; three, if independent, represent a line as locus or a plane as envelope; and four give a point or a lineoid. In general, two planes have, not a line, but only a point in common; reciprocally, two planes are not in general in a same lineoid. A lineoid being determined by four independent points, it appears that two arbitrary lines determine a lineoid. In 4-space a point can pass from the inside to the outside of a (two-dimensional) closed surface, such as an ordinary sphere, without going *through* the surface, just as in ordinary space a point can pass from the inside to the outside of a circle without *crossing* the circumference. Accordingly, in 4-space a 3-fold solid like the human body could be literally seen through, and no ordinary prison-house could confine.

Do hyperspaces exist? Undoubtedly they have *logical* existence, the *concept* of hyperspace being interiorly consistent and available for thought. More mathematics does not demand. The hypothesis of their 'physical' existence, 'natural' science may yet be compelled to employ. Indeed it has been conjectured that certain chemical phenomena (as of the carbon compounds) may be due to greater freedom of motion than ordinary space affords.

Bibliography.—The literature of the geometry (both pure and analytical) of hyperspaces is very extensive. It is, however, chiefly contained in the mathematical journals. All scientific nations have contributed to the subject, the Italians probably more than any other. The best work for the beginner is P. H. Schoute's 'Mehrdimensionale Geometrie' (1902). An excellent explanation, addressed to the non-mathematician, of the concept of 4-space is found in Hermann Schubert's 'Mathematical Essays and Recreations.'

Cassius J. Keyser,
Adrain Professor of Mathematics, Columbia University.

Hyphomyceteæ, hī-fō-mī-sē'tē-ē. See Fungi.

Hypnotics are agents that induce sleep. They may be mental, physical, or medicinal. Thus certain kinds of music, the human voice, and suggestion may have power to induce sleep, which may also follow from eating, or from a warm bath before retiring. All such simple measures should be used before drugs are resorted to in the treatment of insomnia (q.v.). Hypnotics *per se* may be divided into two broad groups—those that induce sleep by alleviating pain and those that have no pain-relieving character. The latter are pure hypnotics. Combinations of the two are frequently employed in medicine. The pain-relieving drugs all come under the head of analgesics (q.v.). The pure hypnotics may be divided into a number of groups based on their chemical relationship, for in this class of drugs the relation between chem-

ical composition and physiological action is peculiarly close. Alcohol is one of the most prominent of the hypnotics, but while it is extensively used to induce sleep, the practice of taking a "nightcap" cannot be regarded as a safe one. Substituted alcohols, however, yield some of the most widely employed of all hypnotics. Chloral, paraldehyde, amylene hydrate belong to this series, while from chloral as a basis a number of allied hypnotics have been made. These are chloralamide, chloralose, chloretone, urethane, etc. The fundamental action of these is to cause a peaceful sleep without leaving ill after-effects. They all dilate blood-vessels, relieve spasm, and induce sleep. In large doses they depress the heart-action. Another group of hypnotics includes substituted sulphur compounds. The most important of these are sulphonal, trional, and tetronal. They are all closely allied in chemical structure. Sulphonal is the weakest, tetronal the strongest, trional occupies a middle position. In poisonous doses, and even in small doses if long continued, hypnotics of this group cause a form of chronic poisoning in which the red blood-cells are disintegrated. This is shown by the appearance of a cherry-red, or purple-red discoloration in the urine. A third group of hypnotics depends on some form of bromine, as bromides. Sodium bromide, potassium bromide, bromal, bromoform, etc., are representatives. They depress the activity of the brain, and are useful hypnotics. If used very long the bromine compounds cause skin-eruptions, foul breath, and heart-depression. See ALCOHOL; CHLORAL; INSANITY; INSOMNIA; MELANCHOLIA; NEURASTHENIA; SULPHONAL.

Hypnotism, hĭp'nō-tĭsm (Greek *hypnos,* "sleep"), an artificial sleep. The nervous phenomena exhibited in hypnotism resemble those induced by animal magnetism, though they arise solely from the condition of the patient, and not from any influence proceeding from others. Mr. Braid, of Manchester, England, brought this subject prominently before the public in the 17th volume of 'The Monthly Journal of Medical Science' (1853), but it has been long known in India. The actual foundation of modern hypnotic suggestion was discovered by Liébault, of Nancy, France, the famous "father of the therapeutic application of suggestion." After several years of practical experience, in 1866 he wrote his first book on the subject. It was shelved and he was pronounced erratic. Hypnotism remained a curiosity and Liébault's book was not reproduced till six years after Charcot, in 1878, began his studies in hypnotism. In 1884 Bernheim wrote his charming book on suggestion, and this created a demand for Liébault's book which then gave him lasting reputation. He was Bernheim's teacher. Formerly a profound skeptic, Bernheim became unavoidably converted by seeing the results of Liébault's application of suggestion to invalids. Bernheim was a clever clinical professor in the great hospital of Nancy and in his wards he convinced himself of the great value of hypnotic suggestion.

The word hypnotism is generally and largely misunderstood and misused. For example, if a person seems to be wholly influenced by another, it is commonly said that he has been hypnotized. This is a great error. The word hypnotism means putting a person to sleep and means nothing else. If an individual seems to be subjected to another in the waking state it should be said that he is unduly influenced. He is not hypnotized. That would mean that he was asleep. The means by which hypnotism is used is "suggestion." A person may be influenced by suggestion in the waking state, for suggestion is a great force in daily life. As connected with hypnotism, however, suggestion is the expression of an idea or combination of ideas which becomes impressed upon the mind of the somnolent subject to whom it is addressed. Conscious or unconscious results are sure to follow. This explanation sums up the meaning, use, and results of suggestion as applied to hypnotism and the hypnotic state. If a subject be awake he can, according to the strength of his will and desire, control to a greater or lesser degree the effect of a suggestion which he has received.

In the hypnotic state this self-control is decreased in a degree corresponding to that of the increase of the degree of sleep. Nevertheless, if merely the first degree of hypnosis has been attained, the subject, conscious of all he hears, may be influenced by the suggestion of the operator. In this way a vast amount of relief has been given to individuals who may claim that they have not been affected at all. In the hypnotic state there are nine sharply marked degrees of somnolence. In the first six degrees, notwithstanding he has been perfectly quiet and apparently asleep, the patient remembers all that has been said. In the last three degrees the patient, on waking, remembers nothing. Strange as it may seem, however, a person may be more influenced by suggestion in the lighter degrees of sleep than in the more profound degrees, and *vice versâ.* This is due to the patient's suggestibility. For example, the writer treated by hypnotic suggestion a very severe and prolonged case of intemperance. The patient claimed that not for an instant had he been sleepy, but he so responded to suggestion that from that day to this, a period of eleven years, he has not once touched alcohol. He had been intemperate from boyhood. On the other hand, a person may fall into profound sleep and yet not respond markedly to suggestion. Generally, however, if the subject be made to reach any degree of somnolency he can be relieved by suggestion. In the majority of cases the relief endures. In the popular mind exists the belief that this form of treatment is attended by danger, that the patient once hypnotized is thereafter under control of the operator, even at a distance, that the will is weakened, etc. This is all a mistake. No person can be hypnotized unless he be willing. No person can be hypnotized at a distance, unless by telephone, or if he be a good and willing subject, by letter; and the patient must first have been hypnotized by the operator at some previous time. Otherwise the operator cannot influence him at a distance in the slightest degree. The will is not only not weakened, but there is no other existing treatment which can so strengthen the will as can hypnotic suggestion. If any physician object to the treatment we know that this physician, however intelligent he may be in other professional matters, is ignorant of this method of relief. This treatment is not peculiarly useful in hysteria, as is commonly supposed, but has accomplished greatest benefit

in all cases attended by bodily distress, neuralgia, dyspepsia, headache, disturbance of menstruation, pains of rheumatism, mental unrest, sleeplessness in particular, intemperance, opium habit, and all drug habits, vicious propensities, lack of mental vigor, fear, illusions, stammering, and wherever calmness has disappeared. In short, it will give relief in many cases which it cannot cure. It can relieve, but cannot create. It can assuage pain, for instance, in heart ailments, while it cannot dispose of damages which the heart may have received.

It is an absolutely safe and beneficent form of aid. It may not always bring relief, but never in the hands of a competent operator has it done harm. The patient will always choose the operator as he would choose a surgeon. The object of all reliable operators in the use of hypnotic suggestion is the relief of the patient, and to the operator the treatment is a sacred thing.

The method of the operators of the school of Nancy is wholly verbal. The patient is talked to sleep, and on waking he is delighted by the changes in himself which are apparent, and he has become convinced of the agreeable effects of the treatment.

Formerly a bright object was held between and above the patient's eyes, and he was directed to fix his eyes upon it. This created sleep. But it was found that nervous distress was apt to follow this method, and it has been abandoned by followers of the school of Nancy. The rationale of the treatment is that a person whose mind is in a sleepy or sleeping condition offers no resistance to the suggestions of the operator and, just as in thirst, in the waking state, "the mouth waters," just as a woman blushes, because of a personal remark, or turns pale if a pistol be pointed at her, so the suggestions of the operator made to a sleeping person will follow a nerve path which is in accordance with the quality or nature of the mental impression created by the suggestion. In other words, the suggestion is followed by changes in sensation, act, or idea on the part of the patient, which correspond with the nature of the suggestion. Thus, if a sleeping person be assured by the operator that he will lose his craving for alcohol, or opium, or cocaine, or, that his pain will cease, that he will sleep at night, that his nervous unrest will disappear, that his power of will or a mental concentration will increase, and so forth, in nine out of ten cases the desired result will follow. Lack of space forbids further mention of this phase of the subject.

Brief reference should be made to an influence, wholly unappreciated by the popular mind, which is exerted by what is nothing but suggestion. For example: The sick people who were aided by the "magnetized" tree of Marquis Puysegur thoroughly believed in the therapeutic power of the tree, and therefore were cured or relieved. This was suggestion. The benefit of the electro-magnetic belts and rings formerly so largely in vogue was derived from suggestion. The influence of the waters of Lourdes is due to suggestion. The benefits which occur from many, if not the majority, of the medicines given by regular physicians are due to suggestion and temporary unusual care of the health. Therefore, in the absence of better means they are wisely given.

The people who resort to these things thoroughly believe in their efficacy, and this belief, acting through the mind, so influences the nerve and blood supply of the part or organ for which relief is sought, that the ailment passes away.

There are indeed scores of popular forms of relief which act wholly through the patient's mind and in themselves literally have no value. The effect of the mind cure and Christian Science is due to a weak form of suggestion, behind which an intelligent knowledge of anatomy, physiology, and disease is wholly lacking. The results are owing to influences produced upon the minds of those who seek these forms of relief, which thus have accomplished a degree of benefit but are dangerous aids where serious disease exists. These forms of suggestion, exactly speaking, are auto- or self-suggestion, that is, a belief which creates a mental power over bodily ailments, and which, in a certain percentage of people, is capable of large development.

The wise choice of a source of needed suggestion would be to seek it at the hands of a cultivated physician who is familiar with the application of suggestion to a somnolent patient.

With reference to causation of crime by means of hypnotic suggestion: few or no scientific men believe it possible. Habit is as strong as death. If a man's habit of mind be honest, no suggestion, sleeping or waking, can cause him to commit crime of any sort. If he be dishonest, naturally or by inclination, the suggestion would be unnecessary. In so far as physicians are concerned they are not interested in this phase of the subject because they use the treatment wholly as a means of relief, and, as a class, physicians are reliable men who would not even attempt to misuse hypnotism any more than they would use ether for evil purposes. The so-called "laboratory crimes," that is, imitation of crime in the presence of the operator who suggests it, would not occur unless he were present. The subject simply feels safe under the direction of the operator and, as has been proved many times, would not attempt suggested wrongs if he were alone.

The hypnotic sleep is a natural sleep. Those who claim that it is not natural are not intelligent in the matter, and their opinions are based upon pure and uninformed theory.

As has been shown by scores of thousands of cases, treated by brilliant and educated physicians, the treatment is absolutely innocuous. It either relieves or produces a neutral effect, and is useful in a multitude of ailments which baffle ordinary means of relief.

But the operator must be educated in the use of this valuable method of treatment. Hypnotism should be used only by physicians, and amateurs should by no means experiment with it as a means of amusement.

HAMILTON OSGOOD, M.D.,
Boston, Mass.

Hypochlorites. See HYPOCHLOROUS ACID.

Hypochlo'rous Acid, an acid having the chemical formula HClO, which is formed when chlorine monoxid, Cl_2O, is dissolved in water.

The most convenient method of preparing it, however, is by distilling a mixture of dilute nitric acid and a salt of hypochlorous acid. The sodium salt of hypochlorous acid, known as sodium hypochlorite, NaClO, may be prepared by passing a stream of chlorine gas through a cold dilute solution of caustic soda, NaOH; the reaction being $2NaOH + 2Cl = NaClO + NaCl + H_2O$. Potassium hypochlorite may be prepared in a similar manner. Crude calcium hypochlorite, $Ca(ClO)_2$, known in the trade as "bleaching powder" (q.v.), is prepared by acting upon slaked lime with chlorine gas. Hypochlorous acid and the hypochlorites possess powerful bleaching properties, owing to the readiness with which they part with a portion of their chlorine or of their oxygen. (See BLEACHING.) Hypochlorous acid is only known in its aqueous solution, which is a colorless liquid, with a peculiar smell. It decomposes readily with the liberation of chlorine, and the formation of chloric acid, $HClO_3$, the decomposition proceeding rapidly in the sunlight. Hydrochloric and sulphuric acids also decompose it with liberation of chlorine, the reaction in the case of hydrochloric acid being $HClO + HCl = H_2O + 2Cl$. Heat decomposes the hypochlorites, with formation of the corresponding chlorates and chlorides.

Hypochondriasis, hī″pō- or hĭp″-ō-kŏn-drī′a-sĭs, a morbid condition of the mind in which an individual fears himself afflicted with various diseases. The name comes from the ancient belief that the symptoms of this disorder came from perversions of the vital force in the liver and pylorus of the stomach. The tendency to this condition is frequently inherited; it is more common in males, and is sometimes brought on by excesses. Patients afflicted with hypochondriasis are apt to watch for any expression of abnormality in their bodies, to connect various symptoms, and to reach the conclusion that they are sufferers from some disease. In conditions of perfect health any individual may have slight, temporary twinges of pain, or may show passing changes in the functions of the organs; but by the hypochondriac these abnormalities are seriously regarded, and efforts to disabuse him are usually futile. Such constant fear and worry divert the nervous energy from its proper course, and may cause actual disturbance of the bodily functions that are serious. The condition known as neurasthenia may follow; also, more rarely, true melancholia. The milder cases continue in actual good health, but become an unhappy burden to themselves and others. In the treatment it is to be remembered that mental occupation outside of the thoughts of self is essential to a cure.

Hypoder'mic Injection (Greek, *hypo,* under; *derma,* skin), a method of introducing medicines through the skin into the subcutaneous cellular tissue, sometimes deep into the fibres of a muscle by an instrument specially made for the purpose. This instrument is the hypodermic syringe, which is made of glass, with a graduated scale engraved on it, and fitted with a long, hollow needle-shaped point of steel. It must be filled before using, to prevent the possibility of introducing air into the veins. Hypodermic injection should never be resorted to excepting under the specific directions of a physician, and no patient should ever employ this method upon himself.

Hypodermic Medication, as opposed to endermic medication, means the administration of medicine by piercing the skin so as to throw the drug directly into the circulation, and bring it immediately in contact with the seat of pain, if pain is to be treated. There are some drugs which act on the system in a manner which differs in accordance with the method of their administration; thus podophyllin is a powerful cholagogue when administered through the mouth; when administered hypodermically it promotes the secretion of the kidneys. There are, however, distinct advantages of a general character in this method of administering drugs. The action of the drug is more rapid, sometimes instantaneous; the effect is concentrated and intensified; it takes a smaller dose to produce the desired effect; it is sometimes easier and pleasanter than administration by the mouth, and often obviates unpleasant or even dangerous complications. The process of hypodermic injection (q.v.) was invented and brought into vogue by Dr. Alexander Wood (q.v.) of Edinburgh.

Hypophosphites, salts of hypophosphorous acid (q.v.).

Hypophosphorous Acid, an oxyacid of phosphorus, having the formula H_3PO_2. The free acid is of no importance in the arts, but its salts, which are called "hypophosphites," are used in medicine. The acid is monobasic, only one of its hydrogen atoms being replaceable by a metallic atom. Sodium hypophosphite, $NaH_2PO_2 + H_2O$, may be prepared by acting upon caustic soda with phosphorus, phosphoretted hydrogen being given off, while sodium hypophosphite remains in solution. It crystallizes in small, rectangular tablets, which are easily soluble in water and in absolute alcohol. The evaporation of solutions of this substance is often attended by explosions. Barium hypophosphite, $Ba(H_2PO_2)_2 + H_2O$, may be prepared by heating baryta, BaO, with phosphorus and water until the elimination of phosphoretted hydrogen has ceased, the excess of BaO being then removed by a current of carbon dioxid, after which the solution is filtered and crystallized. Barium hypophosphite crystallizes in monoclinic needles, which are soluble in water, but insoluble in alcohol. Calcium hypophosphite may be prepared in the same manner as the barium salt. It has the formula $Ca(H_2PO_2)_2$, and crystallizes in thin, monoclinic tablets, which are soluble in six parts of water, but insoluble in strong alcohol. Free hypophosphorous acid may be prepared by decomposing the barium salt with sulphuric acid, and evaporating the solution at a temperature not exceeding 230° F. It crystallizes in large white tablets, which melt at 63° F., and are decomposed by heat, with the formation of phosphoretted hydrogen and ordinary tribasic phosphoric acid.

Hy'poscope (from Greek words meaning "to see under"), is the name given to an instrument adapted to be secured to the stock of a rifle near the breech, and intended to enable a marksman to fire with accurate aim without exposing his head to the fire of the enemy. The successful American contestants for the Palma trophy at Brisley, England, in 1903, brought

back with them this device, which seems likely to play an important part in the warfare of the future. It was invented by William Youlton of Brighton, England, who conceived the idea of it after the battle of Colenso in the Boer war, during which it is stated that not a single Boer was to be seen. Later in the war it was employed with good results, its use at Mafeking receiving particular mention.

The hyposcope consists of a series of mirrors mounted in a tube of inverted L shape; the shorter arm lies across the barrel of the rifle, while the longer arm hangs down at one side. The first mirror reflects the light coming in along the barrel of the rifle to a second mirror at the elbow of the instrument, which directs the rays downward to a mirror at the lower end of the tube, and thence it passes out at right angles to the eye. Thus on looking in at the eyepiece one can see the sights of his rifle, and take accurate aim while holding the gun above his head. The vertical arm of the instrument comprises two telescoping sections so that, by means of a thumbscrew at the side, this arm may be extended to elevate the device for long-range shooting. The amount of elevation may be accurately determined by means of a fine scale on the upper section. In order to allow for windage, a thumbscrew at the end of the horizontal arm may be rotated to move the mirror contained therein slightly to one side or the other. A scale on this arm shows just how far the mirror must be moved for different velocities and directions of the wind. The entire instrument is very compact and light, weighing about a pound. It is provided with a holster, in which it may be encased to prevent it from sustaining any injury when not in use.

The advantages of this instrument in actual warfare will be apparent to all. Only the muzzles of the rifles are exposed to the enemy, and the soldiers are entirely concealed in the trenches. But aside from its advantages as a means of protection, the device will be found greatly to increase the effectiveness of the firing. The fear of being shot while taking aim makes the soldier fire hurriedly and at random; with the hyposcope attached to his rifle no fears will be entertained, and the soldier may fire deliberately and with perfect aim. By applying it to the end of a field-glass, an observer can watch the movements of the enemy without danger of discovery. It has also been designed for use on Maxim guns.

Hypostatic Union, the union of the divine and human nature in the one person of Jesus Christ.

Hypoth'esis, in mathematics the term denotes what is assumed in order that the conclusion may follow from it as a consequence. It has sometimes been applied in a disparaging sense to suppositions that have been made for the purpose of drawing foregone conclusions, and not with the view, as has been generally the case in physics, to supply probable antecedents to conclusions which have already been experimentally established. In some cases the hypothesis may only acquire a certain degree of probability; in others it may account for all the known circumstances, and it then acquires the name of a theory; and if subsequent observation reveals no exceptions to its application, it gradually amounts to certainty. The conjecture of Newton that the force of gravity, as exemplified on the earth, might extend to the moon was at first a hypothesis; but when it was found that it accounted for all the facts it became a theory. There has an attempt been made to institute a distinction between a hypothetical cause and a true cause, but it is practically of no value.

Hypsom'etry (Greek, "height-measurement"), the art of determining differences of elevation on the earth's surface. Three distinct modes of procedure may be adopted for measuring a given difference in level. The first and most accurate of these consists in running a "line of levels" between the two stations whose difference in height is to be determined. This operation is conducted as follows: Let A, B, and C be any three points on the earth's surface, such that the difference in level between any two of them is not more than a few feet; and let us suppose that B lies between A and C, and that it is not more than a few hundred feet distant from either of them. A precise spirit level is set up at B, so that its telescope is higher than either A or C. A graduated staff is then held in a vertical position upon the point A, and the observer at the level determines, by looking through the telescope, which division of the staff is of precisely the same height as the cross-hairs of his instrument. If the height of A is known, we have merely to add to it the known length of the graduated staff, from the ground up to the division that has been observed, in order to ascertain the exact height of the cross-hairs of the level. The staff is next carried forward to the point C, and a second observation of the same kind is made upon it at this point. The height above the ground of the division that is here found to be on a level with the instrument is then subtracted from the known height of the cross-hairs in the telescope, and the result is the height of the point C. The instrument is then carried forward to a point, D, situated beyond C, and the altitude of a still more remote point, E, is determined in the same manner, by observing the graduated staff at C and at E, and then calculating the height of E from the known height of C, as determined by the preceding operation. A chain of observations of this sort is called a "line of levels," and it is obvious that the difference of elevation of any two points whatever may be determined with great precision by running such a line from one of them to the other.

The labor and expense of joining two distant points by a line of precise levels are often prohibitively great; and hence when a high order of accuracy is not essential, trigonometric or barometric methods are used instead. In determining the height of a mountain (for example) by the trigonometric method, a conveniently situated station is selected, from which the summit of the mountain can be well seen, and the horizontal distance from this station to the vertical line passing through the summit of the mountain is first determined by any of the methods used by surveyors for determining the distance of an inaccessible object. The apparent angular elevation of the mountain is next observed; that is, the angle included between the horizontal plane through the station and the line joining the station to the top of the mountain is measured.

If the earth were flat and devoid of any atmosphere, these data would enable us to compute the height of the mountain with considerable precision. For the vertical height of the mountain above the station, and its horizontal distance from the station, and the line joining the station to its summit, would constitute the three sides of a right-angled triangle; and the base of this triangle being known, as well as one of the adjacent angles, its vertical height (that is, the height of the mountain above the observing station,) could be easily calculated by the ordinary rules of trigonometry. In the actual case, however, the problem is complicated by the curvature of the earth's surface, and by the refraction effects due to the presence of the atmosphere. Corrections can be easily applied for the curvature, since that is constant in any given spot, and its value is well known. The refraction effects, however, are variable from time to time, according to atmospheric conditions; and it is impossible to determine them, at any given moment, with a precision sufficient to enable the trigonometric method to compete, in accuracy, with the method of leveling already described.

The third general method of determining elevations on the earth's surface depends upon the fact that the atmosphere possesses weight, so that its pressure diminishes as we pass upward. The difference in depth of two given points below the surface of the sea can be determined with a good deal of precision by noting the hydrostatic pressures at the two points. If these pressures are expressed in pounds per square foot, and their difference is divided by the weight, in pounds, of a cubic foot of the water, the quotient will be the difference in depth of the two points, expressed in feet. The same general principle applies to the determination of the differences of elevation in the atmosphere, only in this case the problem is far less simple in its actual application, because the air, instead of having a practically constant density as water has, is very elastic and compressible, and very sensitive to changes of temperature. The observations, therefore, have to be combined by means of a formula which will take these facts into account, so far as possible. In determining differences of height by this method (which is called "barometric hypsometry"), the difference in atmospheric pressure at the two points that are to be compared is usually determined by means of barometric readings, though the boiling-point method, to which reference will presently be made, is also used. The mercurial barometer gives the most accurate results, but the aneroid form is so much more convenient to manipulate and transport that it is commonly preferred for ordinary work. (See BAROMETER.) When the difference of elevation between two given stations is to be determined, it is preferable to make the barometric observations at both places simultaneously, simultaneous observations of the atmospheric temperature being also taken. This implies the co-operation of two observers, and the possession of two sets of instruments; and hence it is not always feasible. When the work is carried out by a single observer, or with a single set of instruments, the observations should be made first at Station A, then at Station B, and finally at Station A again; the average readings at Station A, both of barometric pressure and of temperature, being adopted as the definite observations at that station. In this way the effects of variations of temperature and pressure are eliminated as far as possible. If h is the average reading of the barometer at the lower station, in inches, and H is the reading of the barometer at the upper station, also in inches, and if t and t^1 are the temperatures observed at the two stations, on the Fahrenheit scale, then the difference in height between the two stations, as expressed in feet, is approximately

$$(\log h - \log H) \times 60384 \times (1 + \frac{t + t' - 64^\circ}{900}).$$

In place of the barometer, an instrument called a "hypsometer" is sometimes used for determining the difference in barometric pressure between the two stations. The hypsometer is essentially an instrument for determining the boiling point of water with a considerable degree of precision. Water, which at the normal atmospheric pressure boils at 212° F., boils at a lower temperature on the tops of mountains, where the atmospheric pressure is less. The change in the boiling point is approximately 1° F. for every 555 feet of ascent; though this relation is not exact. In the practical application of the method, the boiling point is observed, on the mountain top, by an accurate thermometer which should be graduated as fine as fiftieths of a degree on the Fahrenheit scale. The difference between the temperature so obtained and 212° F. is then multiplied by the constant factor 555, and the product is the desired estimate of the height of the mountain above the sea. This procedure, it will be seen, assumes that at the time the observation is made, the atmospheric pressure at the sea-level has its normal (or average) value, so that water would boil there at 212° F. precisely. This condition will seldom be more than approximately fulfilled, and hence the method by boiling points, as usually carried out, is more uncertain than the barometric method as described above. The thermometric method is very convenient, however, and for this reason it is in strong favor among travelers and explorers, who usually are content with a more or less rough approximation to the height to be measured. The method is capable of being refined further than has here been indicated; but when more accurate results are desired than are obtainable by the process as described above, it is better to make use of simultaneous readings of the barometer and thermometer, at the two stations to be compared.

Hyrax, hī'raks, the type-genus of a group of small rabbit-like animals forming the group *Hyracoidea*. There are two species, not very sharply defined, the daman (*H. Syriacus*), which spreads from the African shores of the Red Sea to Syria, and the Klipdas, or dassy (*H. Capensis*), which ranges from Abyssinia to the Cape of Good Hope. The former is the animal meant by the Scripture reference to "conies," as a "feeble folk." They are gregarious, plant-feeding, and make their homes among loose rocks, where they are little seen during the day. Hence English settlers call them rock-rabbits. The zoological position of these animals is astonishing in view of their size, appearance and rodent-like habits, for they are most nearly related to the elephant and rhinoceros. In west-central Africa live two

or three small arboreal species (*Dendrohyrax*). The latest monographer of these singular animals is O. Thomas (Proc. Zool. Soc. of London 1882), who says that the rules of priority require that the family and genus should be called *Procaviidæ* and *Procavia*. They are believed to be little modified descendants of the *Condylarthra*.

Hyrcanus (hẽr-kā'nŭs) **I.,** JOHN HYRCANUS, a Jewish high-priest and prince of the Asmonean family, who ruled in 135-105 B.C. He was the son and successor of Simon Maccabæus. At first dependent on the Syrians, he succeeded in throwing off their yoke, and also in subjugating the Samaritans. He next overcame the Idumæans, and obliged them to submit to Judaism. He afterward confirmed his power by an alliance with the Romans and made Judæa more powerful than it had been since Solomon's time. He was originally a Pharisee, but ultimately favored the Sadducees.

Hyrcanus II., high-priest of the Jews and prince of the Asmonean family, who ruled intermittently from 69 B.C. to 38 B.C. He was the grandson of Hyrcanus I. His younger brother, Aristobulus, seized the government, and finally Pompey removed Hyrcanus from the kingship, and made Antipater of Idumæa governor of the colony. In 47 B.C. Cæsar proclaimed Hyrcanus tetrarch and high-priest. Antigonus, son of Aristobulus, deposed Hyrcanus and removed him to Seleucia whence later, at the request of Herod, he returned to Jerusalem, where he was finally put to death (30 B.C.).

Hyslop, hĭs'lŏp, **James Hervey,** American scholar and educator: b. Xenia, Ohio, 18 Aug. 1854. He was graduated from Wooster University (Ohio), studied also at Leipsic and the Johns Hopkins University, taught successively in Lake Forest University, Smith College, and Bucknell University, and was appointed professor of logic and ethics in Columbia University. He became well known for his connection with the investigations of the Society for Psychical Research, and contributed extensively to its proceedings. His further work includes articles in prominent periodicals; an edition of Hume's 'Ethics' (1893) with introduction; a text-book on 'The Elements of Logic' (1892); one on 'The Elements of Ethics' (1895); 'Democracy: A Study of Government' (1899); 'Logic and Argument' (1899); and 'A Syllabus of Psychology' (1899).

Hyssop, hĭs'ŭp (*Hyssopus*), a genus of plants of the natural order *Labiatæ*, with four straight diverging stamens, and a 15-ribbed calyx. The common hyssop (*H. officinalis*) is a perennial shrubby plant about two feet in height. The leaves stand in pairs without footstalks. The flowers are blue, growing chiefly on one side, in short verticillated spikes. It is a native of the south of Europe and the East, and is naturalized in the United States. The leaves have an agreeable aromatic color, and an extract from them is produced by water and spirits. The hyssop of Scripture (that is, the plant whose Hebrew name *ezob* has been translated "hyssop") has not been ascertained. As it "grew out of the wall," it must have been a diminutive plant, and may have been one of the mosses. The most probable and most widely accepted view is that it was the caper-plant (*Capparis spinosa*), but it is not unlikely that the name was applied to several plants of somewhat similar properties. The name of hedge-hyssop is applied to species of plants of the genus *Gratiola*, belonging to the natural order *Scrophulariaceæ*.

Hysteria, a morbid state of the nervous system in which the clinical manifestations present a wonderful variety of symptoms closely simulating some forms of organic disase. There is often increased physical irritability; the condition is frequently manifested by neuralgic pains, hyperæsthesias, hallucinations, and convulsive and paralytic phenomena. It may be regarded as a brain affection — a mild insanity.

Among the causes of hysteria heredity plays a most important part. There may be direct transmission of the hysterical temperament from parent to child, or other nervous manifestations in the family and its branches, such as epilepsy, chorea, neuralgia, insanity, etc. It occurs more frequently in women, but it is much more common in men than is ordinarily believed; it occurs in boys and girls at a tender age or about the time of puberty. Briquet found that one eighth of his cases were in children under ten years of age. Anything which lowers the general tone of the nervous system may give rise to it in predisposed persons. Hæmorrhages, severe illness, poor food, anæmia, overwork in uncongenial occupations, anxiety, fright, jealousy, disappointments make a profound impression; so does an education which fosters and stimulates inherited instability. The enforced social restrictions of women, which they often inflict upon their young children, with lack of proper exercise for physical development and an artificial and premature education and habits heighten this predisposition. Accidents are a frequent cause of the first appearance of hysteria, as has been clearly pointed out by Charcot. The disease may, at times, occur in young girls who have witnessed attacks in others.

To understand the symptoms of hysteria, it must be borne in mind that there are two classes of phenomena. These have been termed the *mental stigmata* and the *mental accidents*. The stigmata are anæsthesias (loss of sensation), amnesias (forgetfulness), abulias (loss of will power), motor disturbances, and modifications of character. These are the cardinal symptom-groups that characterize the mental state of the hysteric. Any or all of the mental accidents may likewise be noted — suggestibility and sub-conscious acting, fixed ideas, ecstasy, automatism, convulsive movements, sleep-walking, deliriums, etc. The occurrence of these constitutes important corroborative evidences of hysteria and while not found in all hysterics, they may be very common symptoms.

Hysterical persons often complain of some of the symptoms found in neurasthenia — neuralgic pains in various parts and hyperæsthetic areas about the abdomen, chest, or back, frequently in the neighborhood of the ovary, mammary gland, etc. There may be anæsthetic patches in various parts of the body, or there may be complete loss of sensation on one side associated with anæsthesia of the mucous membranes. The special senses on that side are involved — sight, taste, and hearing.

There may be irritations of the bladder and

urethra; pain in the joints, which may be mistaken for joint disease.

In some cases the senses are exceedingly acute. Persons notice odors imperceptible to others; are often made sick by odors which do not affect normal individuals; may have a liking for odors and substances disagreeable to others. Perverted sense is shown in an abnormal taste, in eating soap, slate-pencils, etc. Hysterical manifestations in some are simply emotional exaggerations; they laugh and cry without cause. In serious attacks there are likely to be various hysterical manifestations. Occasionally tactile sensibility is disturbed, and the muscular sense may be abolished. The anæsthesia may affect the mucous membranes of mouth, pharynx and nose, abolishing the reflexes of the parts. The secretions may be diminished or arrested.

Spasmodic convulsions and paralytic phenomena may occur. The spasmodic attack may be rhythmic; may simulate the trembling of organic disease; may be confined to one member or involve the entire half of the body; may be coarse, as in disseminated sclerosis, or a fine tremor, as in paralysis agitans, or the tremor may simulate the trembling of organic brain disease. It may occur in any muscle or group of muscles; may manifest itself as contracture, which may be intermittent or may last continuously for months or years. Contracture may be confined to the strong muscle of the jaw and other muscles in their neighborhood, causing trismus. Spasms of the glottis may take place, giving rise to severe difficulty in breathing; or of the pharynx, causing difficulty in swallowing. Globus hystericus is a constant symptom, but is not as frequent as it is often thought to be. Persistent and severe vomiting often occurs, but the nutrition rarely suffers materially from these attacks. Retention of urine is frequent, owing to spasm of the sphincter, and the catheter may have to be used for months.

Paralysis occurs in these cases; it is variable in distribution, and may come on suddenly after a convulsive attack or without it; it may be flaccid or associated with contracture; it may come on slowly; it may be confined to one limb or be hemiplegic in type.

Hysterics are easily affected by pleasurable or painful impressions, and there is often a morbid craving for sympathy and attention. They may show moral perversion; may lie, steal, quarrel with and intrigue against their own family; may form and change attachments and dislikes without obvious reason; may manifest aversions, as to frogs, spiders, mice, cats, etc.; may deceive for deception's sake or to excite wonder. Some are painfully depressed; they have forebodings, or are compelled to do certain acts. Here the hysterical insanities are approached on the one hand, and the imperative conceptions and neurasthenias, on the other.

Hystero-epileptic attacks in their greatest severity are often preceded by general discomfort, or by hallucinations of vision and hearing. Usually sudden, they may be preceded by an "aura," globus hystericus, singing in the ear, etc. Breathing is spasmodic; consciousness is obscured; the convulsion may be similar to those of mild epilepsy. In some cases the body is thrown into all sorts of contortions. An extreme opisthotonos may be present, the body being bent backward, resting on the head and heels. Gestures and noises are made. Sometimes religious ideas have an influence over the attitudes assumed; at other times, ideas of demoniacal possession.

From milder forms, recovery is the rule. In graver cases, and when there is a strong neuropathic tendency, the persons will probably pass from one hysterical manifestation to another.

Treatment.— In cases where there is deterioration of the physical health, tonics and nutritious diet should be given. Hydrotherapy improves nutrition and also the mental state. Many drugs have been recommended, but they are all uncertain in their action, at one time giving a result, and failing at another. Convulsive attacks may at times be stopped by the cold douche to the spine. Isolation from the family circle is of the utmost importance in the treatment of these cases. Every effort should be made to discover the psychic shock which has produced the attack. Only the patient may have knowledge of this, and he will not often reveal it. There is no disease the treatment of which it is more difficult to describe. Suggestion-therapy gives by far the best results, but the great difficulty is that good results are rarely permanent.

Hyvernat, hē'vĕr-nat, **Eugene Xavier Louis Henry,** American scholar: b. St. Julien-en-Jarrêt, Loire, France, 30 June 1858. He was graduated from the University of France at Lyons in 1876, studied divinity at the St. Sulpice Seminary, Issy, in 1877–9, at Paris in 1879–82, was Oriental interpreter to the Propaganda at Rome in 1885–9, and taught in the Roman Seminary in 1885–8. In 1889 he was appointed professor of Oriental languages and archæology in the Catholic University of America at Washington, D. C. His writings include: 'Les Actes des Martyrs de l'Egypte' (Vol. I. 1886); 'Album de Paléographie Copte' (1888); and 'Du Caucase au Golfe Persique' (with Muller-Simonis 1892).

I

I the ninth letter and third vowel of all the alphabets of western Europe, came into the Latin alphabet from the Greek. It is named in Greek iota, which is the yod of the Hebrew and the corresponding letter of the Phœnician alphabet from which the Greeks derived it. Iota and yod (whence jot) being the smallest letter in the Hebrew and Greek, gave occasion for the New Testament phrase "one jot or one tittle." In ancient Latin the i appears to have stood for a semi-vowel like y as well as for the vowel i: thus the Latins would write Ianus, Iulia, pronouncing them Yanus, Yulia. And till a comparatively recent date words beginning with I and J were in English dictionaries classed together.

The dot over the i appears first in MSS. of the 13th century. The sound value of i in all languages except English is constant and is equal to e in he and to i in him. What is called the long sound of English i as in hide is a diphthong made up of the two vowels a and i: this value of i in English is believed to have been given to the letter not earlier than the 16th century: till then the letter had the same sound in English as in other languages.

In the standard alphabet of philologists the values of the vowels are about as in the languages of continental Europe, in which i is sounded as English e.

It is the general rule in English pronunciation that i followed by two consonants in the same syllable is short; yet when the two consonants are ld or nd the i is nearly always long and diphthongal, for example, mild, rind; in wind (noun) it is short, but in wind (verb) it is long. Combined with o it forms a true diphthong oi as in oil; or mere digraphs representing sounds in which often the i has no part; examples: bail, rein, seize, pier, friend. Usually a final e indicates that the i in a word is to be pronounced as the diphthong; for example, fine, fin; yet genuine is genuin; or the i is pronounced as e long, — marine, quinine, Augustine.

In Pope's time and long after oblige was pronounced obleege and rhymed with besiege: the i in oblique is pronounced either e or i.

Ian Maclaren. See WATSON, JOHN.

Iba, ē'bä, Philippines, pueblo and capital of the province of Zambales, Luzon, situated on a river two miles from its mouth, 85 miles northwest of Manila. It has a good anchorage and is on the south coast road. It is a well built town, and has several fine public buildings. In 1901 a United States meteorological station was established there. Pop. 3,500.

Ibach, Lawrence J., American astronomer: b. Allentown, Pa., 17 Jan. 1816; d. Newmanstown, Pa., 9 Oct. 1888. He learned the blacksmith's trade and followed it throughout his life, chiefly at Sheridan, Lebanon County, Pa. He studied with the astronomer, Charles F. Engleman, who, on his death in 1860, bequeathed all his charts, books, and instruments to Ibach. His benefactor having promised to make several series of astronomical calculations for almanacs Ibach filled the first order (1863), and thereafter till his death made annual calculations for almanacs in the United States, Canada, South America, and Cuba. He was commonly known as the "blacksmith-astronomer."

Ibajay, ē-bä-hī', Philippines, pueblo of the province of Capiz, island of Panay, situated on the Ibajay River, 42 miles northwest of Capiz, the capital of the province. Pop. 11,350.

Iberia, ī-bē'rĭa. (1) The ancient name of a district of Asia, between the Euxine and Caspian seas. It now forms part of Russian Georgia, and consists of an extensive fertile plain, surrounded by mountains traversed by four passes. It probably belonged to Persia, until subjected by Pompey and Trajan to the Roman empire, under which it remained till after the time of Julian. (2) The ancient name of Spain, the Ebro, the principal river, being called Iberus. The Iberian language still lives in the Basque. See BASQUES and CELTIBERI.

Iberville, Pierre le Moyne, pē-ār lė mwän ē-bĕr-vēl, SIEUR D', French-Canadian naval and military commander: b. Montreal 16 July 1661; d. Havana, Cuba, 9 July 1706. He entered the French navy, in 1686 took part in the expedition for the capture of the English forts on James' Bay, in 1690 in that for the destruction of Schenectady, N. Y. He took Fort Nelson, on Hudson Bay; captured and demolished Fort Pemaquid, built for the protection of the New England settlements; laid waste all the British posts on the island of Newfoundland; and, having defeated three English vessels with his one, reduced Fort Bourbon, the last station of the Hudson's Bay Company. In 1699 he ascended the Mississippi for some distance, and built Fort Biloxi at the head of Biloxi Bay. This post he removed to Mobile in 1701. In 1706 he captured the island of Nevis. He was considered the ablest officer in the French naval service of his time, and is generally called the founder of Louisiana.

I'bex, any of several species of wild goat (q.v.), sometimes placed apart in a sub-genus *Ibex*, distinguished by the form of the horns of the ram, which are large (30 to 50 inches long),

backward curving, compressed, and marked on the front with bold cross-ridges or knot-like protuberances. The ibexes are larger than other goats, that of the Himalayas standing 40 inches high at the withers. Their coats are harsh, uniformly brown, becoming much grayer in winter, whitish on the under surface and buttocks, and with darker tints on the face and fore-legs. These animals inhabit the most precipitous and inaccessible heights of lofty mountains, where they assemble in flocks, sometimes consisting of 10 or 15 individuals. During the night they feed in the highest woods, but at sunrise they again ascend the mountains, till they have reached the most perilous heights. They are remarkably swift, and display amazing agility and dexterity in leaping. They are objects of the chase, and the hunter must have great skill and hardihood to succeed. Several species are distinguished by locality and minor differences. The typical ibex, bouquetin or steinbock (*capra ibex*), once numerous throughout the European Alps, now exists only as a semi-domesticated animal in certain valleys on the Italian border.

Three other species are recognized: The Arabian ibex (*C. sinaitica*) of Palestine, Arabian and northern Egypt (see BEDEN); the Abyssinian ibex or walie (*C. walie*); and the great Himalayan ibex (*C. sibirica*); which ranges over the high mountains and plateaus of all central Asia, keeping as near the snow-line as possible, and affording the best sport known to that region of game.

Ibicuhy, ē-bē-kwē', or **Ibicui, Brazil,** an affluent of the Uruguay River, which rises in the Serra de Santa Anna, province of Rio Grande do Sul, and after a westward course of about 400 miles joins the Uruguay at Yapeyu opposite St. Martin in Argentina.

Ibilao, ē-bē-lā'ō, a head hunting Philippine tribe inhabiting the border lands of the provinces of Nueva Ecija and Nueva Vizcaya in the central part of the island of Luzon. They are heathens, of the Malay race, with an infusion of Negrito blood. See PHILIPPINE ISLANDS.

I'bis, a family of wading-birds (*Ibididæ*) inhabiting warm regions. They are related to the storks on the one hand and to the spoonbills and flamingoes on the other. Their bills are long, weak, curved, and the nasal grooves are very long. The legs are long, the tibia partly naked, and the toes long with small webs. In size they are like herons, rather less than storks; and in color present a great and beautiful variety of tints, often with a metallic sheen; the sexes are similar. Ibises are shy birds, which inhabit not only watery and wooded country, but dry plains and rocky gorges. They perform a powerful and elevated flight, extending their neck and legs, and uttering a hoarse croak. They ordinarily wade for their food, poking in the mud with the long bill for aquatic insects, worms and small shellfish; they also catch fish, and on land eat insects, especially locusts, frogs, newts and crustaceans. Some species breed in communities, like herons, others apart, but the nest is always a rude cradle of sticks on a tree or ledge of rocks and occasionally on marshy ground, and the eggs are usually green, with or without markings. There are 12 or 15 genera and a large number of species scattered throughout the whole tropical zone. The typical genus, *Ibis,* contains the sacred ibis (*I. æthiopica*), called by the natives of upper Egypt *abu Hannes,* or "Father John," which arrives in Egypt about the time that the inundation of the Nile commences, its numbers increasing or diminishing with the increase or diminution of the waters; and it migrates southward about the end of June. This species is about the size of a fowl; the head and neck are bare; the body white; the wing tipped with shining, ashy black, among which the white forms oblique notches; the secondaries and scapulars, which in summer curve gracefully over the hinder parts, are bright black. This was one of the birds adored by the ancient Egyptians, and of which numerous mummies are found. The Greek and Roman writers give many fabulous stories relating to ibis, which Savigny has gathered in 'Histoire Naturelle et Mythologique de l'Ibis.' He concludes that the reverence for this ibis was not due to its alleged destruction of snakes, which, in fact, does not occur, but arose from the birds' return at the time the Nile began to rise, the commencement of the season of abundance. Modern writers on Egyptian customs and antiquities may be consulted further on this point. Many other interesting species occur in Africa, Asia and the Australian region; and many species reside in the American tropics,—two, the white ibis (*Eudocimus albus*) and the scarlet ibis (*E. ruber*), flocking in summer in the southern United States. Both are birds of extreme beauty of plumage, and both have been so ruthlessly persecuted by plume-hunters, seeking feathers of millinery purposes, that the scarlet ibises are nearly exterminated.

Wood-ibises and shell-ibises are names for birds of other groups, elsewhere described.

Ibn Sina, ĭb'n sē'nä. See AVICENNA.

Ibsen, Henrik, hĕn'rĭk ĭb'sĕn, Norwegian novelist and dramatist: b. Skien, Norway, 20 March 1828, of mixed Scottish and German descent. At 16 he became apprentice to an apothecary at Grimstad, a small village on the southeast coast of Norway, and here were composed his first works, 'Hösten,' a poem, and 'Catilina,' a play published in 1850 over the signature Brynjolf Bjanne. After a few months at the University of Christiania in 1850, where he wrote 'The Warrior's Mound,' played at the Christiania Theatre that year, he became manager of the new National Theatre at Bergen and turned his attention directly to dramatic composition. In 1856 his 'Banquet at Solhaug,' a Norwegian historical drama, was produced here, and from 1857 to 1862 he was manager of the Norwegian Theatre at Christiania. To this period belong his historical plays, 'Lady Inger of Östraat' (1857); and 'The Vikings at Helgeland' (1858); 'The Comedy of Love' (1852), and several poems. His greatest historical drama, 'The Pretenders,' appeared in 1864, and indignant at the political position of Norway at the time, Ibsen then left Norway to be absent (save for short visits) for, as it is proved, 27 years, living for a time in Germany and then in Trieste and Rome. His noble dramatic poem, 'Brand,' was first published in 1866, and the Storthing thereupon voted him the "poet's salary." In 1867 appeared the famous dramatic poem, 'Peer Gynt,' followed by a political com-

HENRIK IBSEN.

edy, 'The League of Youth' (1869); and the play, 'Emperor and Galilean,' his longest work (1873). In 1864 he returned to Norway for a short visit and was everywhere enthusiastically welcomed. His subsequent works include the social dramas which are the basis of his fame: 'The Pillars of Society' (1877); 'A Doll's House' (1879); 'Ghosts' (1881); 'An Enemy of the People' (1882); 'The Wild Duck' (1884); 'Rosmersholm' (1866); 'The Lady from the Sea' (1888); 'Hedda Gabler' (1890); 'Master Builder Solness' (1892); 'Little Eyolf' (1894); 'John Gabriel Borkman' (1896); 'When we Dead Awaken' (1900); 'Digte' (poems) appeared in 1871. By Ibsen's countrymen the poems 'Brand' and 'Peer Gynt' are considered his greatest works, both being intensely national, but nevertheless of universal application. Brand, the hero of the first, represents a protest against compromise, while 'Peer Gynt,' sometimes styled "the Scandinavian Faust," is an analysis of the human soul. The modern life dramas are the works by which Ibsen is best known to the world at large. The setting only is Norwegian, the lesson they convey is of world-wide extension. 'The Pillars of Society' is an attack upon hypocrisy as exemplified in the principal personages in a small town, while 'A Doll's House,' which has had a wide popularity in America, is concerned with the failure of marriage. 'Ghosts' is perhaps the most impressive and awesome of all of Ibsen's works, its theme being the consequences of hereditary vices. 'The Wild Duck' and 'Rosmersholm' are gloomy, despairing dramas; 'Hedda Gabler' presents in the character of Hedda a woman of the undomestic, selfish type, while the fearful price of success forms the motive of 'Master Builder Solness.' The theme of 'A Doll's House' is in effect that of 'Little Eyolf,' but in the latter Ibsen, who has hitherto seemed pessimistically to foretell the dissolution of modern society, now admits a hope of its regeneration. Over Ibsen's works a vast amount of controversy has arisen, and he has been fiercely assailed as cynical and even immoral, and as zealously defended. The truth of the matter appears to be that he is *par excellence* the poet of protest against social sophistry, and that he unerringly indicates the danger spots in modern life. There is nothing conventional in the construction or motive of his plays. More than once the climax of the play is represented as occurring prior to the opening of the drama which is concerned only with the consequences. Ibsen has made a deep impression upon the literature of his century and his fame is not likely to decrease. Consult: Brandes, 'Henrik Ibsen,' in 'Eminent Authors of the 19th Century' (1886); Jaeger, 'Henrik Ibsen: a Critical Biography' (1890); Wicksteed, 'Four Lectures on Henrik Ibsen' (1892); Shaw, 'The Quintessence of Ibsenism' (1893); Boyesen, 'A Commentary on the Writings of Henrik Ibsen' (1894).

Ica, ē-sä', Peru. (1) A littoral department bounded north by the department of Huancavelica, east by Ayacucho, south by Arequipa, and west by the Pacific Ocean. Area, 8,718 square miles; pop. (1896) 90,962. (2) A town, capital of the above department on a river of the same name, 46 miles southeast of Pisco on Pisco Bay, with which it is connected by rail. It was founded in 1563. It is in a grapevine and sugar-cane producing region and has manufactures of wine and brandy. Pop. 9,000.

Ice, water in the solid state. When sufficiently cooled, water loses its fluidity, and becomes filled with multitudes of needle-like crystals belonging to the hexagonal system (see CRYSTAL), which increase and interlace until the whole mass becomes solidified. In nature, this change begins at the surface of the water and spreads gradually downward, so that the exact course of the freezing is not so easy to trace as it is in the laboratory, where the water can be uniformly cooled throughout its entire mass. When the freezing process is complete, the crystalline nature of the solid that results from it is not at all obvious. It is clearly visible, however, in snow-flakes, where the hexagonal form is also evident. In a solid block of ice the crystalline structure can also be demonstrated by a method that was used with much success by Tyndall, as a beautiful and instructive lecture experiment. The image of a slab of pure ice is thrown upon a screen by means of a projection lantern provided with a powerful electric light. At first nothing is seen, but very shortly the heat-rays passing through the ice cause it to melt internally, and the melting takes place according to the internal crystalline structure, which is gradually brought out upon the screen in great beauty. Six-sided stars, suggestive of the snow-crystals, appear, and these enlarge and become serrated at the edges as the electric beam gradually destroys the molecular architecture, the process continuing until the ice has been again reduced to the liquid form.

Pure water normally freezes at a temperature which is denoted by 32° on the Fahrenheit scale, and by 0° on the centigrade and Réaumur scales. It is possible, however, to cool pure water to a temperature considerably lower than this, if proper precautions are taken. As long ago as 1836, for example, Gay-Lussac observed that water, when placed in a vessel and covered with a layer of oil, may be cooled to 10° F. without freezing. If the vessel be slightly shaken or jarred, however, solidification ensues at once.

Pressure has a slight effect upon the temperature at which water freezes. This effect was predicted, from theoretical considerations, by James Thomson, in 1849. Dewar has since measured its amount with much care, finding that the freezing temperature is lowered by 0.014° F. for each atmosphere of pressure. Small as this quantity is, it is of importance in some branches of physics. In 1858 Mousson, by the application of an enormous pressure, succeeded in reducing the freezing point to 4° below zero, Fahrenheit. The presence of dissolved substances in the water also depresses the freezing point. Sea-water, for example, freezes at about 27° F. (the ice that is formed being nearly free from salt), and strong brine is used in the circulating pipes and cooling coils of refrigerating plants, since it can be cooled much below this temperature without freezing.

The effect of pressure in lowering the freezing point is illustrated in the familiar process of making a snow-ball from damp snow, — that is, from snow whose temperature is precisely 32° F. Under the pressure of the hand, the freezing point of the snow mass is lowered slightly, with

the result that a partial melting of the crystals takes place. When the pressure is removed, the freezing point rises to its normal position, and the water that was formed by the pressure alone freezes again, and cements the mass together. (The superficial moisture, due to the warmth of the hand, is not here contemplated. The melting from this cause is a separate phenomenon.) The slight but real plasticity of large masses of ice, such as are met with in glaciers, is probably related to this phenomenon of the variation of the freezing point by pressure, but there is some difference of opinion among the authorities as to the precise way in which the slow downward flow of these ice masses is accomplished. The melting of ice by pressure, and its subsequent solidification upon the removal of the pressure, is known to physicists as "regelation".

Experiments that have been conducted in connection with precise thermometry, by Pernet and Marek, show that the temperature of melting ice is slightly different, according to the source of the ice, and the way in which it is treated; this variation being independent of the pressure, and existing even when the ice is sensibly pure. A variation in the melting point of as much as 0.164° F. has been observed; and in order to eliminate the effects of error from this cause, it is necessary, for the purposes of precise thermometry, to adopt a uniform mode of procedure in the treatment of the ice that is to be used for the establishment of the freezing point upon accurate thermometers. (Consult: Guillaume, 'Thermométrie de Précision,' ch.ii.).

When water that contains solid matter in solution or in suspension is frozen, the solid matter is mostly eliminated, so that the ice is much purer than the water from which it is produced. Some of the solids are almost invariably entangled among the interlacing crystals of the ice, however, so that numerous little particles of foreign matter often remain in the ice, imprisoned in tiny cavities. Bacteria and other germs that may have been present in the original water appear to be largely excluded from natural ice by the freezing process, though some of them are undoubtedly caught among the crystals and retained. In artificial ice, where a mass of water is frozen simultaneously on all sides, so that the solidification proceeds from the outside toward the centre of the cake in all directions, purification from this cause is hardly possible, and the middle part of the ice-cake is likely to be rich in whatever germs the original water may have contained. Fortunately the recent experiments of Sedgewick and others indicate that freezing and protracted storage of the ice is much more fatal to typhoid bacilli than was formerly supposed. Artificial ice, if prepared from distilled water, or from water that is certainly known to be free from disease germs, is undoubtedly safer than natural ice that is taken from streams or ponds of unknown purity; but in choosing between natural and artificial ice from the same identical water, the preference should be given to the natural product.

Water expands upon freezing, one volume of water at 32° F. becoming transformed, by freezing, into 1.0908 volumes of ice at the same temperature; which is equivalent to saying that water expands by one-eleventh of its own bulk upon freezing. The quantity of heat required to melt one pound of ice, from the state of ice at 32° F. to that of water at 32° F., is 142 times as great as the quantity of heat required to raise the temperature of a pound of water from 32° F. to 33° F. The specific heat of ice, near the temperature 32° F., is approximately 0.50.

Ice Age. See Glacial Period.

Ice, Artificial. See Ice Industry.

Ice Boat. See Ice Yachts and Ice Yachting.

Ice-breaker, a vessel, especially a strong, heavy steamer, with powerful engines, for opening up navigable channels in frozen waters. On the Great Lakes of the United States, where such vessels are extensively used, they are generally fitted for carrrying cargoes or transporting railroad cars. Such vessels are usually so built as to run their bows up on the ice and break it by means of their great weight. An ice-breaker called the Yermak, built in England in 1899, for use in Russian waters, is 305 feet long, with 71 feet beam and draft of 25 feet. She did good harbor work in polar ice in 1900, but proved unequal to the heavy pack of the sea. Admiral Marakoff of the Russian navy, who superintended her trials, believes that the best way to reach the north pole is by means of a powerful ice-breaker, using liquid fuel instead of coal.

Ice Industry. Though the use of natural and artificial ice as an article of commercial value practically began only in the first part of the 19th century, yet the artificial production of cold began long before it was generally supposed to have been thought of.

In Greece and Rome during the early ages snow was more commonly used, being placed in cone-shaped pits 45 feet in diameter, 50 feet deep and lined with straw and prunings of trees. The snow was packed down and covered with more straw and prunings, over all of which a thatched roof was placed; after the ice was formed it was cut and carried out through a door left in the side of the pit for the purpose. During the 16th century snow and ice was stored in cellars for the purpose of cooling drinks.. This custom spread from Greece and Italy to Western Europe and to France during the reign of Henry III. in the 16th century and by the end of the 17th century the sale of snow and ice had become a profitable trade. From that time until the beginning of the 19th century the ice trade was practically at a standstill, no material advance was made in the direction of improving the methods of harvesting the ice supplied by nature, nor was any attempt of any importance made to produce artificial ice. For purposes of description and comparison, ice may be divided into two classes, the natural and the artificial.

Natural Ice.— Probably the first ice cut and shipped as an article of commercial value was sent, in 1799, from New York to Charleston, S. C. This cargo was cut from a pond near Canal street. While this shipment was the first recorded it was of little importance; the real beginning of the industry came in the year 1805 when Frederic Tudor, of Boston, shipped a cargo of 130 tons to the West Indies. This resulted in a loss of $4,500, and Tudor's second shipment, two years later to Havana, likewise

was made at a loss enormous for those days. He stuck to the business, however, and finally, in 1812, was granted by Great Britain a monopoly of the trade with her colonies in the West Indies, and later, in 1815–16, Spain granted him the same concession to export to Havana. In 1817–18 the trade was extended to Charleston and Savannah; to New Orleans in 1820; to Calcutta in 1833; and to Rio Janeiro in 1834. Thus a large and lucrative trade with southern countries and southern cities of the United States was built up; competitors began to come into the field, the first of these to enter the export field being the firm of Gage, Hittinger & Co. of Boston who introduced American ice to the people of London. They were in turn followed by a Salem merchant named Lander, and others. The Treasury Department gives the following figures for the export trade from 1850 to 1900:

Year.	Tons.	Value.
1850	.....	$107,018
1855	41,117	190,793
1860	49,153	183,134
1865	59,927	225,825
1870	65,802	267,702
1875	53,724	208,249
1880	45,666	136,686
1885	38,901	89,420
1890	44,849	111,762
1895	17,295	41,915
1900	13,720	29,501

The harvest of natural ice is gathered on an enormous scale in the United States, the demand for the article being due in a large measure to the growth of other industries to which ice was a necessity. Before Croton water was introduced into New York and as far back as 1825, ice was cut on Sunfish pond, on the outskirts of the city, by some butchers who desired to preserve their stock of meat. In 1826 ice was cut on Rockland Lake, and at first all the ice cut was stored in the ground but later storehouses at Hubert street and Christopher street were built, and as the demand for ice gradually developed in all the larger eastern cities, large storehouses were erected nearby the places where the ice was cut. The capacity of these houses ranges from 10,000 to 90,000 tons and in size run from 100 to 150 feet in length by 30 to 50 feet in width. For gathering the ice there is an elaborate system of apparatus, but the usual methods employed are as follows: After the snow is cleared from the ice by means of scrapers or snow-plows, an ice-plow, either propelled by steam or drawn by horses — the latter means more commonly used — cuts deep grooves in the ice in one direction and then repeats the operation at right angles with the first, thus forming a perfect square, measuring a little more than 3 feet. As these grooves extend nearly through the ice it is a simple matter to saw through the remaining thickness, pry the cakes loose with crowbars, and float them to the icehouses through channels provided for the purpose. Upon reaching the icehouse the cakes are lifted on an elevator, run into the house, and packed in sawdust or other suitable material, to be held there in storage till needed.

The cost of harvesting a ton of natural ice varies greatly; it depending to a great extent upon the weather conditions, both during the process of the formation of the ice and during the process of cutting and housing. Under average conditions the cost of harvesting amounts to about 80 cents, though under very favorable conditions it has been known to have cost only from 25 to 30 cents per ton, but this has not been often. This, of course, does not include the cost of transportation, delivery, etc., and as the majority of the icehouses are a considerable distance from the centers of consumption, the cost of transportation is a large factor. The following figures, taken from 'The Ice Journal' give the quantities of ice harvested in Maine and on the Hudson River, the two most important fields of operation in the whole country:

Year.	Maine Tons.	Hudson River Tons.
1878	.....	2,225,000
1879	.....	2,371,000
1880	1,426,800	800,000
1881	994,800	2,558,000
1882	1,227,200	1,954,700
1883	1,364,500	3,017,600
1884	1,118,000	3,026,000
1885	1,499,400	3,019,500
1886	1,368,400	2,355,500
1887	1,311,100	3,266,000
1888	1,037,000	3,330,500
1889	1,529,600	2,742,000
1890	3,092,400	.....
1891	1,285,000	2,624,000

The moving of this enormous quantity of ice necessitates the maintainance of a large fleet of barges and other boats for the domestic trade, and of sailing vessels for the export trade, and to the cost of maintaining these vessels, when figuring the cost of harvesting, must be added the cost of towing, loading, discharging, dock and stable rent, repairs of boats, icehouses, and wagons, etc., all this before the ice is placed in the hands of the retailer.

The tools used in harvesting this crop are many and varied, and the manufacture of them has become a large and valuable source of income to several concerns in this country who have made this a specialty. Many of the ice tools now in use were invented by Nathaniel Wyeth and John Barker, of Boston. The ice plow was invented in 1839 and the patent clearing-tooth in 1872. Some of the most common tools now in use are: the snow-scraper or plane, the masher and the plow; augers and axes for tapping the ice in order to drain off surface waters; saws; forked bars for prying the cakes loose; trimming bars for squaring the cakes after loose; adzes, edging tongs, and chisels used in packing the ice when in the storehouse; saws and bars for prying loose previous to shipment; and tongs, scales, axes, etc., used on the retail delivery wagon.

Artificial Ice.— The manufacture of ice as an industry was begun as early as 1866, but only reached a degree of commercial importance

about 20 years ago. The beginning was naturally made in the Southern States, but as it became more generally used, factories sprang up over the entire country. The growth of the "infant industries" throughout the United States gave this industry an added stimulus, because the supply of natural ice was by far too small to meet the requirements of slaughtering and meat packing-houses, refrigerator cars, cold-storage warehouses, etc.

The growth of the industry from its inception may be seen in the following statistics:

	1900.	1870.
Number of establishments	787	4
Capital	$38,204,054	$434,000
Salaried clerks, officials, etc.	1,545	.....
Salaries	$1,234,803	.....
Wage-earners	6,933	97
Wages	$3,424,305	$40,600
Miscellaneous expenses	1,779,890	.....
Cost of materials used	3,339,724	82,165
Value of product	13,874,513	258,250

The first experiments for making artificial ice for mercantile uses started with the Italians in the 16th century. The first machine used for the actual manufacture was invented by Dr. William Cullen, this being based on the vacuum principle, the atmospheric pressure being reduced by means of an air pump. Later, in 1795, several experiments were made by a Mr. Walker of Oxford, England, in the line of freezing mixtures. Prof. Leslie, of England, produced a considerable degree of refrigeration by including in the exhausted receiver of an air-pump, sulphuric acid, a substance rapidly absorbing vapor. In 1834 Jacob Perkins, an American engineer residing in London, obtained a patent for a machine generally credited with being the forerunner of the modern compressor machine. The refrigerant used in this machine was ether and brine was circulated at a temperature of 5° Fahrenheit through pipes which encircled the evaporator containing the ether. After running through the pipes the brine flowed into a receptacle containing boxes filled with water and thus the water was frozen. Later experiments were made by French and German inventors, boxes were supplanted by cans and this developed into the manufacture of can ice. Many of the improvements made in the ice-making apparatus are due to the efforts of Prof. A. C. Twining, of New Haven, Conn. He patented an ice machine in England in 1850 and in the United States in 1853; in 1855 he invented a machine, and put into active operation in Cleveland, Ohio, which produced 1,600 pounds of ice in 24 hours; and later discovered that ice would be transparent, with the exception of a small porous core, if frozen at a temperature slightly below the freezing point. In 1857 Dr. John Gorrie of Appalachicola, Fla., patented his ice-making machine; this was later followed by the compressed-air machine of Dr. Alexander Kirk; in 1858–60 the machine, upon which the modern ammonia absorption system was founded, was brought forth by Ferdinand P. E. Carre; and later the plate-ice system was introduced by Capt. David Smith, of Chatham, Mass., who erected the first machine of this character in the United States at Oakland, Cal. There have been nearly 4,500 patents taken out in the United States alone for refrigeration processes.

Two systems of making ice are now used, the compressor, and the absorption systems, the former the more generally used. The first step is the compression of the anhydrous ammonia (that is, ammonia which contains no water) into the gaseous form by means of a steam pump, a pressure of from 125 to 175 pounds per square inch being exerted. The next step is to reduce the gas to a liquid state by passing the ammonia through pipes which are in contact with the cold water or some other cold substance. The gas as the beginning contained a certain degree of heat, but by the condensation process this heat is eliminated, and, after being reduced to a liquid state, the ammonia reaches the third and last process, that of expansion. As the ammonia in the liquid state reaches the pipes which are in contact with the water to be frozen, it becomes gaseous because of the expansion, its temperature is thus reduced below the freezing point of water and so draws from the water the heat which was taken away by the condensation process. This results in the freezing of the water.

In the absorption process aqua ammonia is first converted into gas by the application of heat which raises the pressure to from 120 to 160 pounds per square inch. The ammonia is then reduced to liquid form by being passed through pipes in contact with cold water. The ammonia is then changed from a liquid to a gaseous form by the expansion process, the methods being the same as in the compressor system. The expansion draws out any heat in the gas, which, as it passes through the pipes in contact with the water to be frozen, absorbs the heat from them till they are of a like temperature.

A large portion of the ice manufactured in the United States is produced by the can system or the plate system. In making ice by the can system the water is first boiled and allowed to settle, in order to free the ice from any foreign substances and to reduce it to the greatest possible degree of purity. The water is then distilled, boiled again, and run through three kinds of filters. A series of tanks, containing a strong solution of brine, is placed under the freezing room, and through this brine run the pipes containing the liquefied ammonia gas. Into the tanks containing the brine are submerged the cans holding the water to be frozen. As in the compressor system, the ammonia in the pipes is expanded into gas as it passes into the brine, and absorbs enough heat from the brine and water to form the water in the can into ice. The whole process requires from 20 to 66 hours, according to the size and weight of the blocks of ice and to the temperature of the brine. The can is then raised from the tanks by means of a hoist and dipped into a well of warm water to loosen the contents.

The production of ice by the plate system is much slower and more cumbersome. In this process the tank contains the water to be frozen and into it is placed a hollow iron plate holding the coils of pipe filled with the freezing medium. Thus the ice is formed on the outside of the iron plate, is taken out and removed, and is then ready for use.

The cost of producing a ton of ice averages throughout the country for all seasons of the year, between $1.10 and $1.50; the average price to the wholesaler ranges from $2 to $2.25; and the retail prices range from 15 to 40 cents per hundred weight according to the season. The changes and improvements in the methods of producing artificial ice have so reduced the cost of manufacture that it can now compete with the natural product. See REFRIGERATION AND REFRIGERATING MACHINERY.

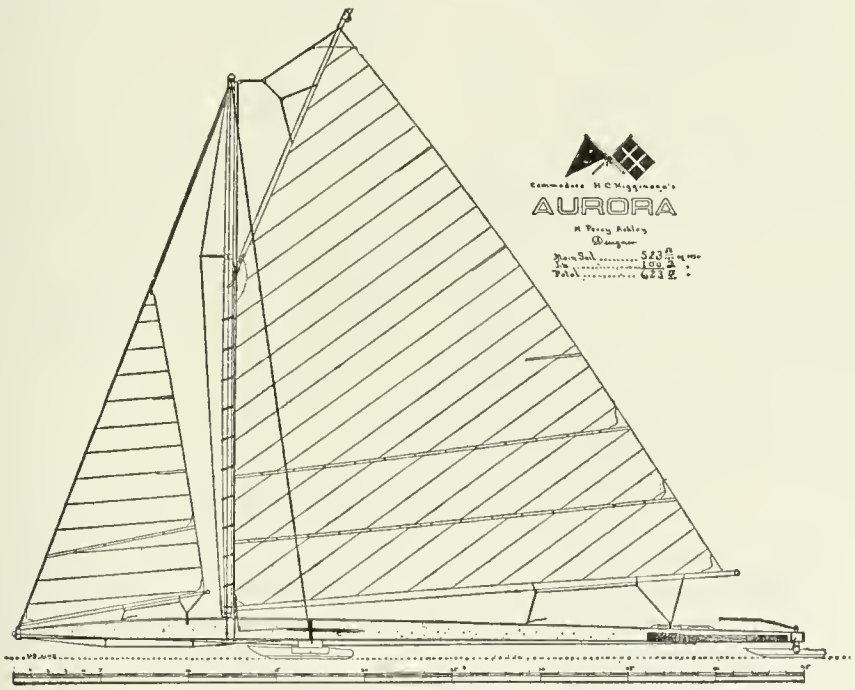
Ice Yachts and Ice Yachting. The amusement or sport of sailing yachts over the ice has reached its highest development in the United States. The sport abroad is confined to Russia, Sweden and Norway. Boats of the Russian River Club are sailed over a portion of the Gulf of Finland. In 1901 the Stockholm Ice Yacht Club of Sweden built a fleet of fast-racing ice yachts from American designs by Ashley.

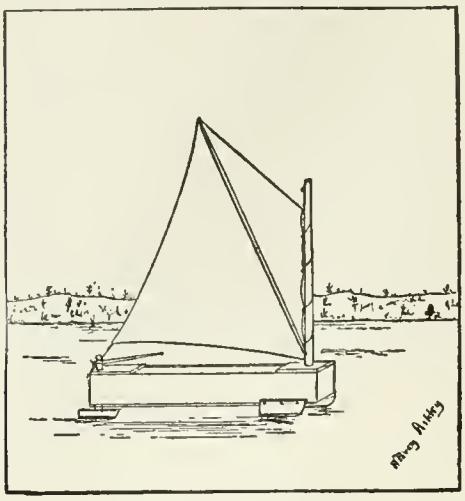
The first authentic ice boat in the United States was built by Oliver Booth, at Poughkeepsie, N. Y., in 1790. It was a square box mounted on three runners, shod with rough iron; with a rudder post and tiller of wood. In 1850 on the Shrewsbury River, in New Jersey, George D. Allaire, constructed an ice yacht of the box order, equipped with rough square iron bars for runners, sharpened with cutting edges. In 1855, on the same river, Nathan B. Clark built a three-cornered platform boat, having sharpened runners, and added a jib to the sprit sails previously carried. The type of side-rail boat came into use about 1871. Jacob Buckhout of Poughkeepsie was the pioneer designer of this type, and at the Centennial Exhibition (1876) exhibited the side-rail yacht Whiff, built for Commodore Irving Grinnell of the New Hamburgh, N. Y., Ice Yacht club. She carried 347 square feet of canvas and measured 40 feet from the top of the bowsprit to the end of the main-boom. The sloop-rigged Icicle built on these lines carried 1,070 square feet of sail, but this excess of canvas was found impracticable and the building of large boats was abandoned. The revolution in ice yachting began in 1879, when H. Relyea of Poughkeepsie built the Robert Scott, having a single backbone and an elliptical steering box. This boat carried 499 square feet of canvas and easily outsailed boats of twice her size. In 1883 the Jack Frost was built by Commodore Archibald Rogers of Hyde Park-on-the-Hudson and the famous racing yacht Haze was built the same year. The Jack Frost won the world's pennant in 1883 and the Haze in 1884. About this time the Shrewsbury Ice Yacht club of Red Bank, N. J., built a large lateen rigged boat, the Scud, carrying over 600 square feet of duck in a single sail. The Orange Lake, N. Y., club built at the same time the catboat Shadow, carrying 800 square feet of sail, and said to be the strongest ice yacht ever constructed. Both of these vessels proved unsuccessful as prize or pennant winners. In 1903 the "sloop" remained the fastest rig in the world, but in reality it is merely a catboat rig with a small jib. The 1903 model of the first class, carrying about 650 square feet of canvas, is capable of sailing a mile a minute, and costs to construct anywhere from $1,200 to $1,600.



The Most Modern and Expensive Ice Yacht (1902).

Racing Rules.— For class racing, ice yachts are divided into four classes: (1) Yachts carrying 600 square feet of sail area and over. (2)

Yachts carrying 450 square feet and under 600. (3) Yachts carrying 300 square feet and under 450. (4) Yachts carrying less than 300 square



Ice Boat of 1790.

feet. Handicap or time allowance for mixed classes is made as follows: One second per square foot for every foot of canvas carried over the smaller boat, providing the race is sailed in one hour. If the race is sailed in 30 minutes ½ second per square foot is allowed, and proportionately in accordance with the time of the race.

The course is usually a triangle sailed over as required to make the number of stated miles; or a straight course to windward and return or to leeward and return. The standard distances for ice-yacht races are 20 miles, 15 miles or 5 miles. The larger the yacht the longer the course. Time limit: 20 miles, 1 hour 15 minutes; 15 miles, 35 minutes; 5 miles, 20 minutes.

In the United States and Canada there are 45 ice-yacht clubs. The challenge pennant of America is open to any American or foreign built yacht. It was held in 1903 by Jack Frost the Second, owned by Commodore Archibald Rogers of the Hudson River Ice Yacht club.

The record of leading American ice yachts are given in the following table.

It will be noted that the fastest time recorded in this table was made by the Jack Frost, 9 Feb. 1893, for 20 miles; time 49 minutes 30 seconds. In 1902 these records were excelled by the Joker, owned by Commodore D. C. Olin of the Kalamazoo, Mich., club, which sailed 20 miles on Gull Lake in 36 minutes 59 seconds. Ice yachts have actually sailed short distances at the rate of 85 miles an hour.

Ice Yacht Construction.—In the modern ice yacht the centre timber or backbone may be made of two pieces, one solid stick or a hollow truss

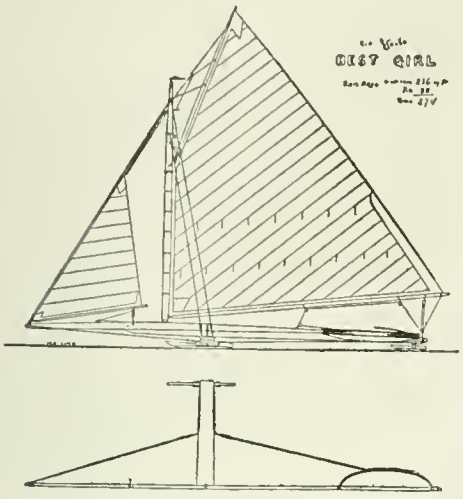
* Best two out of three races — all other races single races. All races sailed off Hyde Park, on the Hudson River, New York.

backbone. To this is joined at right angles the running plank, and a steering box or cockpit is attached at the aft extremity of the backbone. The best material is seasoned basswood, which



Side-guyed Ice Yacht, 1901.

is very light and stiff. The central objects in construction are lightness and strength and adaptability for perfect handling. The centre of sail balance should agree with the centre of balance of the hull.

	Lbs.
Hollow backbone (45 feet long)	489
Solid runner plank (26 feet long)	417
Hollow mast (32½ feet long)	118
Hollow boom	55
Hollow gaff	28
Runners and steel steering gear	225
Sails	71
Rigging	151
Total weight	1,554

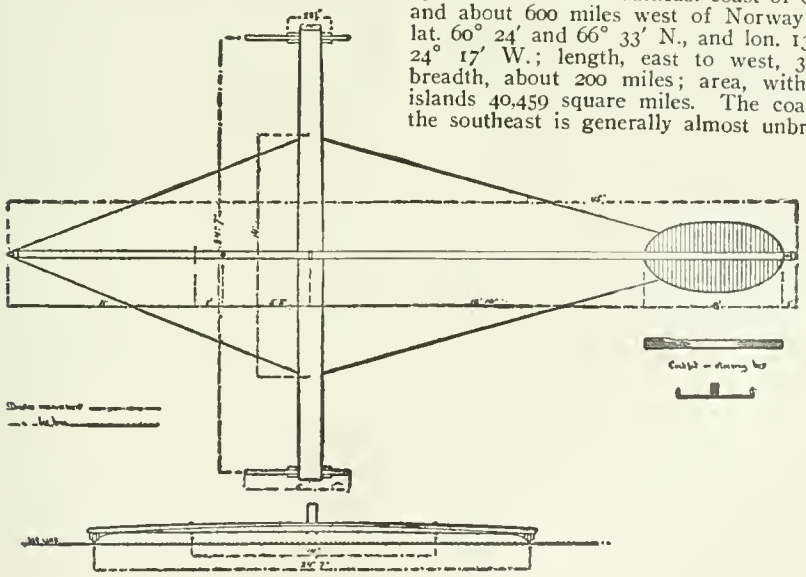
The cost to build an ice yacht of the first class, carrying about 650 square feet, is $1,200, and of the fourth class, carrying 300 square feet, about $350.

Sailing.— Racing on a lake is preferred to river racing, as there are neither tides nor ice cracks to interfere. In sailing a yacht the sheets are trimmed flat. The closest a boat will go to the wind is 30° or 2⅔ points. The best course, or the one that will take the yacht farthest to windward, is 60° or 5⅓ points from the wind, when the advance to windward should be at the rate of half the velocity of the wind, while the actual velocity is equal to that of the wind. The yacht encounters the greatest velocity of the wind when her course is 90°, or 8 points from the wind, when the apparent wind is twice the actual velocity. The greatest speed of the boat is attained at 120°, or 10⅔ points from the wind, when her speed is twice that of the wind. The most rapid progress to leeward is made at 150°, or 13⅓ points from the wind, when the apparent velocity of the wind will equal its true velocity.

H. Percy Ashley,
Ice Yacht Architect.

Icebergs. See Ice.

Iceland, an island dependency of Denmark, 250 miles from the southeast coast of Greenland, and about 600 miles west of Norway; between lat. 60° 24′ and 66° 33′ N., and lon. 13° 31′ and 24° 17′ W.; length, east to west, 301 miles; breadth, about 200 miles; area, with adjacent islands 40,459 square miles. The coast-line on the southeast is generally almost unbroken, but



Plan of The Aurora.

The fastest ice yachts are of the sloop pattern with about one-fifth of their sail area in the jib.

Commodore H. C. Higginson's ice yacht Aurora, of Orange Lake I. Y. C., carrying 623¾ square feet of sail, and equipped with hollow spars and backbone, weighs a total of 1,554 pounds, divided as follows:

on all other sides presents a succession of bays or fiords and promontories. The best harbors are those of Reykjavik and Eyrarbakki on the southwest, and of Eyja on the north. The interior of the island has for the most part a desolate appearance. Lofty mountains of volcanic origin rise crowned with snow and ice, which

stream into the intervening valleys and form immense glaciers. Glaciers cover a surface of upward of 4,000 square miles, and appear in all the mountains above 4,000 feet in elevation. These icy mountains, which take the common name of Jökul, have their culminating point near the southeast coast in Oræfa Jökul of 6,409 feet in height. Next to it in height are the Snæfell, near the east coast, 5,965 feet; and Eyjafjalls Jökul, in the south, 5,579 feet. The structure of these mountains is volcanic; in several of them the volcanic agency is still active, and eruptions have occurred within the last four centuries. Lava covers a large portion of the island. Of volcanic origin and agency are the numerous hot springs or geysers scattered throughout the island, but found more especially in the southwest, to the northeast of Reykjavik, where, from one of the principal geysers, jets of water are thrown to heights varying from 100 to 200 feet. (See GEYSERS.) The general effects of the volcanic agency and the geological formations exhibited on a magnificent scale in Mount Hecla, 5,095 feet high; lat. 63° 59′ N.; lon. 19° 44′ 15″ W. The hot springs are sometimes used for economical purposes; food is dressed over them, and in some places huts are built over small fountains, to form steam baths.

The immense reservoirs of snow and ice furnish supplies to numerous lakes and rivers. Of the former the most important are the Thingvalla Vatn, Hvitar Vatn, and Arnar Vatn in the southwest, and the My Vatn in the northeast.

The most valuable mineral product is sulphur, of which the supply appears to be inexhaustible, and surturbrand or lignite is also worked to some extent. The other minerals are chalcedonies, rock-crystals, and the double-refracting spar, for which the island is famous. On many parts of the coast, particularly the west, basaltic caves occur; that of Stappen is not unworthy to be compared with Fingal's Cave in Staffa.

The climate is mild for the latitude. At Reykjavik, on the southwest coast, the mean temperature of the year is 40°, that of summer 56°, and that of winter about 29° 30′. The air is damp and misty, the weather is extremely variable, and storms and hurricanes frequent. The prevailing winds are north and northeast. In the southern part of the island the longest day is 20 hours, and the shortest 4 hours, but in the northernmost extremity the sun at midsummer continues above the horizon a whole week, and of course during a corresponding period in winter never rises.

Vegetation is sparse and confined within narrow limits. Almost the only tree is the birch, which is stunted, hardly exceeding 10 feet in height. Heath and whortleberry cover the surface. Among flowering plants are saxifrages, sedums, etc. The want of fuel is sometimes supplied by sheep's dung or by drift-wood brought by the Gulf Stream and the polar currents; and the island furnishes a fine turf. Grain appears to have been at one time cultivated, but is not now grown; cole, potatoes, turnips, radishes thrive tolerably well. But the most valuable crop is grass, on which numbers of livestock are fed. Flocks and herds have been estimated at 750,000 sheep, 20,000 cattle, and 40,000 horses. The last, though small, are strong and active and numbers of them are exported. Some of the sheep are four-horned. Reindeer were introduced about 1770, but all that now remain are a few living in a wild state. Wild fowl, including the eider-duck, are abundant; the streams teem with salmon, and on the coast fisheries of cod, haddock, herrings, etc., are carried on.

Manufactures are entirely domestic, almost every family possessing within itself the means of supplying its wants, and occasionally furnishing a surplus, of coarse woolens, mittens, stockings, etc., to be disposed of at the markets. The exports are wool, oil, fish, horses, feathers, worsted stockings and mittens, sulphur, and Iceland-moss. The inhabitants are Scandinavians, and speak a Scandinavian dialect, the original Norse. They are of a tall manly form, open countenance, florid complexion, and flaxen hair. They are simple in manners and customs, having no distinctions of rank, pure in morals, and hospitable. Their houses are chiefly composed of drift-wood and lava; fresh meat and bread seldom appear at their tables, but fish, butter, milk, and preparations of milk constitute their staple food. Their intellectual capacity is superior, education is diffused, and it is rare to meet with an Icelander who cannot read and write.

In religious profession they are Lutherans, the whole island forming a single bishopric. The civil division is into three bailiwicks — Süderamt, Westeramt, and Norderamt with Osteramt — subdivided into 20 smaller districts called Sysler. The governor takes the name of Stiftsamtmann, and presides over the althing or parliament (from "thing," a public assembly), which meets twice a year at Reykjavik, the capital and only town in the island, and consists of 36 members, of whom 30 are chosen by popular suffrage, and 6 (2 spiritual and 4 temporal) are nominated by the king. In response to petitions and complaints Iceland was granted home rule in 1874, and now has the entire management of all matters concerning the island particularly. A minister for Iceland, nominated by the king, is at the head of the administration, but the highest local authority is vested in the governor.

Christianity was introduced in 981, and legalized in 1000; when schools and two bishoprics, those of Holar and Skalholt, were established. The Latin language and the literature and learning of the West, introduced by Christianity, were warmly received in Iceland where poetry and history had been cultivated more than elsewhere in the north. Previously to this the Icelanders had discovered Greenland (983) and part of America (about 1000), and they were now led to make voyages and travels to Europe and the East. The most flourishing period of Icelandic history as regards church and state, — the period too when its intercourse with the outside world abroad was most active — was from the middle of the 12th to the beginning of the 13th century.

Early History.— In 1264 Magnus VI. of Norway united Iceland with his own kingdom, with which it passed to Denmark in 1380, remaining with the latter in 1814, when Norway was joined to Sweden. Toward the end of the 14th century science and art, which had begun to decay with the introduction of the Norwegian rule, sank to the lowest ebb, but they gradually re-

covered their position during the following century. In the 17th century the island was ravaged by Algerian pirates, who in 1627 murdered or carried off a large number of the inhabitants. In the 18th century the island suffered from 43 years' failure of crops and 18 famines. In 1707 about 18,000 persons died of smallpox. Between 1783 and 1785 volcanic eruptions, failure of crops, and famine reduced the population from 48,668 to 38,142. Famine raged again in 1824–5, principally through violent volcanic outbreaks; and a deadly epidemic scourged the country in 1827. In the beginning of the last century the althing, which had existed for about 900 years, was abolished, but it was reorganized in 1843. As already mentioned, a new constitution was granted in 1874, and in August of the same year the 1000th aniversary of the colonization of the island was celebrated, the king of Denmark being present.

Language and Literature.— The Icelandic language is the most northerly of all cultivated tongues. It is rich in roots and grammatical forms, soft and sonorous to the ear, being free from gutturals and excess of hissing sounds. There are 28 letters, namely, all the English except *w*; also *æ*, *ö* (the German *ä* and *ö*), and a character for English *th*. Icelandic literature may be divided into an ancient period, extending to the fall of the republic, and a modern, extending from that date to the present time. Poetry was early cultivated, and among the most important works in Icelandic literature is the collection of ancient heathen songs called the elder or poetic Edda, compiled soon after the introduction of Christianity. (See Edda.) Many other poems, especially songs of victory, elegies, and epigrams, belong to the ancient period of the literature. Histories and romantic works, known by the name of Sagas, were also numerous. Among these we may mention the Völsunga Saga, the most important of all, the Vilkina Saga, the Saga of Hrolf Kraka and his companions, the Saga of King Ragnar Lodbrok, Frithiofs Saga, and the younger or prose Edda. Some of these are partly historical, but there is a larger and more valuable class that are altogether historical in their character, consisting of local and family histories and biographies. Among these we may mention the Islendingabók; the Landnamabók, an account of the settlement of the island; the Kristni Saga, an account of the introduction of Christianity; Njáls Saga (translated into English by G. W. Dasent); Viga Glums Saga; Egils Saga, the biography of a well-known poet and chief; Eyrbyggja Saga, an abstract of which was published by Sir Walter Scott; the Sturlunga Saga, a history of the important Icelandic race of the Sturlungar; the Orkneyinga Saga, a history of the jarls of Orkney (an English translation of which was published in 1873); the Færeyinga Saga, on the Faroe Islands; the Knytlinga Saga, a history of the Danish kings from Harold Blaatand to Canute VI.; and lastly, the famous Heimskringla or Chronicle of the Norwegian Kings, by Snorro Sturleson. Many of these works are masterpieces of style, and are still read with delight by the people of Iceland. The early portion of the second period was barren of anything worth mention in the way of literature, nor can the modern period boast at all of works possessing the interest of those belonging to the ancient. In the 17th century there was a considerable revival of literary activity, the principal names being those of Arngrimur Jonsson (1568–1648), Gudmundur Andræ (died 1654), Runolfur Jonsson (died 1054), Arni Magnusson (died 1730), and Thormodur Torfason or Torfæus. The first complete edition of the Icelandic Bible was issued under the direction of Gudbrandur Thorlaksson (died 1627). The true revival of letters may be said to date from the middle of the 18th century, since which time there is scarcely a department of literature in which Icelandic writers have not done something, not to mention works on various branches of science. Many of the most valuable works of Europe have been translated into Icelandic, even the poems of Milton. Pop. (1895), 73,449; (1903), 78,470.

Consult: Von Toil, 'Letters on Iceland' (1772); Poestion, 'Island, das Land und seine Bewohner' (1889); Burton, 'Ultima Thule, a Summer in Iceland' (1875). For language and literature, Vigfusson, 'Sturlunga Saga' (1878).

Iceland Moss, a lichen (*Cetraria islandica*), found in all the northern parts of the world. It is valued for its nutritious and medicinal properties, and as an article of commerce is collected in Iceland and Norway. In the extreme north it grows even near the sea-level; farther south, only on the mountains. In Iceland it often thickly covers great tracts, and the gathering of it is a summer industry. It grows about 1½ to 4 inches high, consists of an almost erect thallus, and is of a substance leathery and rather cartilaginous. It has a bitter principle which is reduced by steeping in water, and the moss is prepared as food either by pounding and making it into bread or by boiling, with water or milk, till it makes a jelly, in which form it is an agreeable and beneficial diet in some forms of disease, especially in pulmonary disorders. It is also utilized in dressing the warp in weaving, and for sizing paper, being mixed in the vat with pulp.

Icelandic Language and Literature. See Iceland.

Icer'ya, a genus of scale insects, containing the fluted scale. See Scale Insects.

Ichneumon-fly, ĭk-nū'mŏn, the name of a large family (*Ichneumonidæ*) of insects of the order *Hymenoptera*. As the species of this family are very numerous (more than 1,100 genera had been described before 1903) so their manners are extremely diversified; but, in the general outlines of their character, they all agree, particularly in their depredations among the insect tribes. In some the female has the ovipositor in the form of a boring instrument, with which she is capable of perforating the hardest substances. The larvæ of wasps are the devoted prey of these insects, who no sooner discover one of their nests than they perforate the material of which it is constructed, and deposit their eggs within it. Others glue their ova to the skin of a caterpillar, while others again penetrate through it, and lay their eggs in its body. In all these cases the young, as soon as they are hatched, prey on the caterpillar or larva, without, however, destroying it at once, as upon the life of its victim that of the spoiler appears to depend. The caterpillar, in fact, seems healthy until the larvæ of the ichneumon have spun their cocoons, and entered the chrysalis state.

These carnivorous insects are of various sizes; some are so small that the aphis, or plant-louse, serves as a cradle for their young; others again, from their size and strength, are formidable even to spiders, destroying them with their stings. They are, as a whole, highly beneficial to humanity, as a large part of their prey consists of insects which are injurious to crops and valuable vegetation.

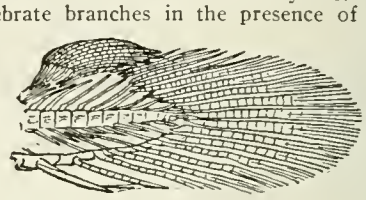
Ichneumons, small carnivorous animals of the civet family (*Viverridæ*) and sub-family *Herpestinæ,* which are distinguished from the true civets by the straight non-retractile claws, and various skeletal characters. While there are a number of genera the typical and most important is *Herpestes,* many species of which inhabit Africa, southern Asia, and the neighboring islands. The teeth are numerous, usually 40; the head is elongated, with short rounded ears; the limbs are short; and the body and stout tail are covered with long hairs. They vary in size from that of a squirrel to a cat. Their food consists of all kinds of small animals; rats and mice, birds and their eggs, snakes, lizards, etc., which they pursue chiefly on the ground but also in trees. The Egyptian ichneumon (*H. ichneumon*) or Pharoah's rat, is famous as one of the many animals venerated by the ancient people of that country, and because of its reputation as a destroyer of crocodile's eggs. While the eggs of this reptile may be occasionally devoured, the importance of the ichneumon in this respect is purely mythical. The Indian ichneumon or mungoose (*H. mungo*) is still better known. It lives in a semi-domesticated state, and performs an invaluable service as a destroyer of venomous serpents, whose fangs it generally manages to escape by its wonderful agility. This species has been introduced into Jamaica for the purpose of destroying rats, and has multiplied exceedingly and become a serious pest, though of late years it has been held in check by a great increase in the number of ticks.

Ichnology, ĭk-nol'ō-jĭ, that department of palæontology which treats of the foot-prints petrified in sedimentary rocks and made by extinct animals; the science of fossil foot-prints. Such foot-prints frequently occur in all formations, and have sometimes been the first and most instructive intimation of the existence of the animals that made them. This was particularly true of the foot-prints of dinosaurs (q.v.) so numerous and sharply marked in the brown sandstones of the Connecticut Valley; and they have greatly assisted in arriving at a true realization of those reptiles, which were at first regarded as birds. The tracks, trails, burrows, outlines of bodies, feathers and appendages of a vast variety of animals occur in the rocks and interest the ichnologist.

Ichthyol'ogy (Gr. *ἰχθύς,* fish; *λογός,* a discourse), is the science of fishes. It is that branch of human knowledge which treats of the aquatic gill-bearing vertebrates, popularly known as fishes to English-speaking people.

Classification of Fishes.— In different treatises on fishes there appear very great differences in the classification proposed or adopted. Often in two works of parallel scope scarcely a group will appear in both with the same boundaries or under the same name. For this condition there are several causes. First, the tendency in some minds toward the extreme of subdivision, and in others toward the extreme of aggregation; second, the various values assigned by different authors to different sorts of characters, the actual value of each only to be determined by the final judgment of palæontology; third, the tendency of many writers to give new names to old groups. On this account a single class order may have half a dozen virtually synonymous names. Thus the terms *Chondropterygii, Elasmobranchii, Plagiostomi, Selachii, Placodii, Antacea,* and other less known names have been applied to the group of sharks and skates. Again various authors, recognizing the validity of a given group, may find it necesssary at times to change its boundaries. In such case a new name may be proposed, or a new definition be given to an old one. Either arrangement may lead to confusion. Thus with some writers, the groups of sharks, under various names, may include the order of *Chimæroids,* or, under the same names, the *Chimæroids* may be excluded from it.

The Chordata.— The great branch of chordate animals finds its origin probably in worm-like forms. It differs essentially from the invertebrate branches in the presence of a more



A Diphy-cercal Tail.

or less developed notochord (which in the higher forms gives place to a backbone), and in the presence of gill-slits, connected with respiration. These gill-slits and accompanying gill-structures are persistent in fishes, while in the higher vertebrates they are mostly relegated to the embryonic stages.

The *Chordata* include several classes of marine animals leading up to the true fishes, as follows:

Enteropneusta.— Balanoglossus (q.v.).

Tunicata.— Ascidians (q.v.).

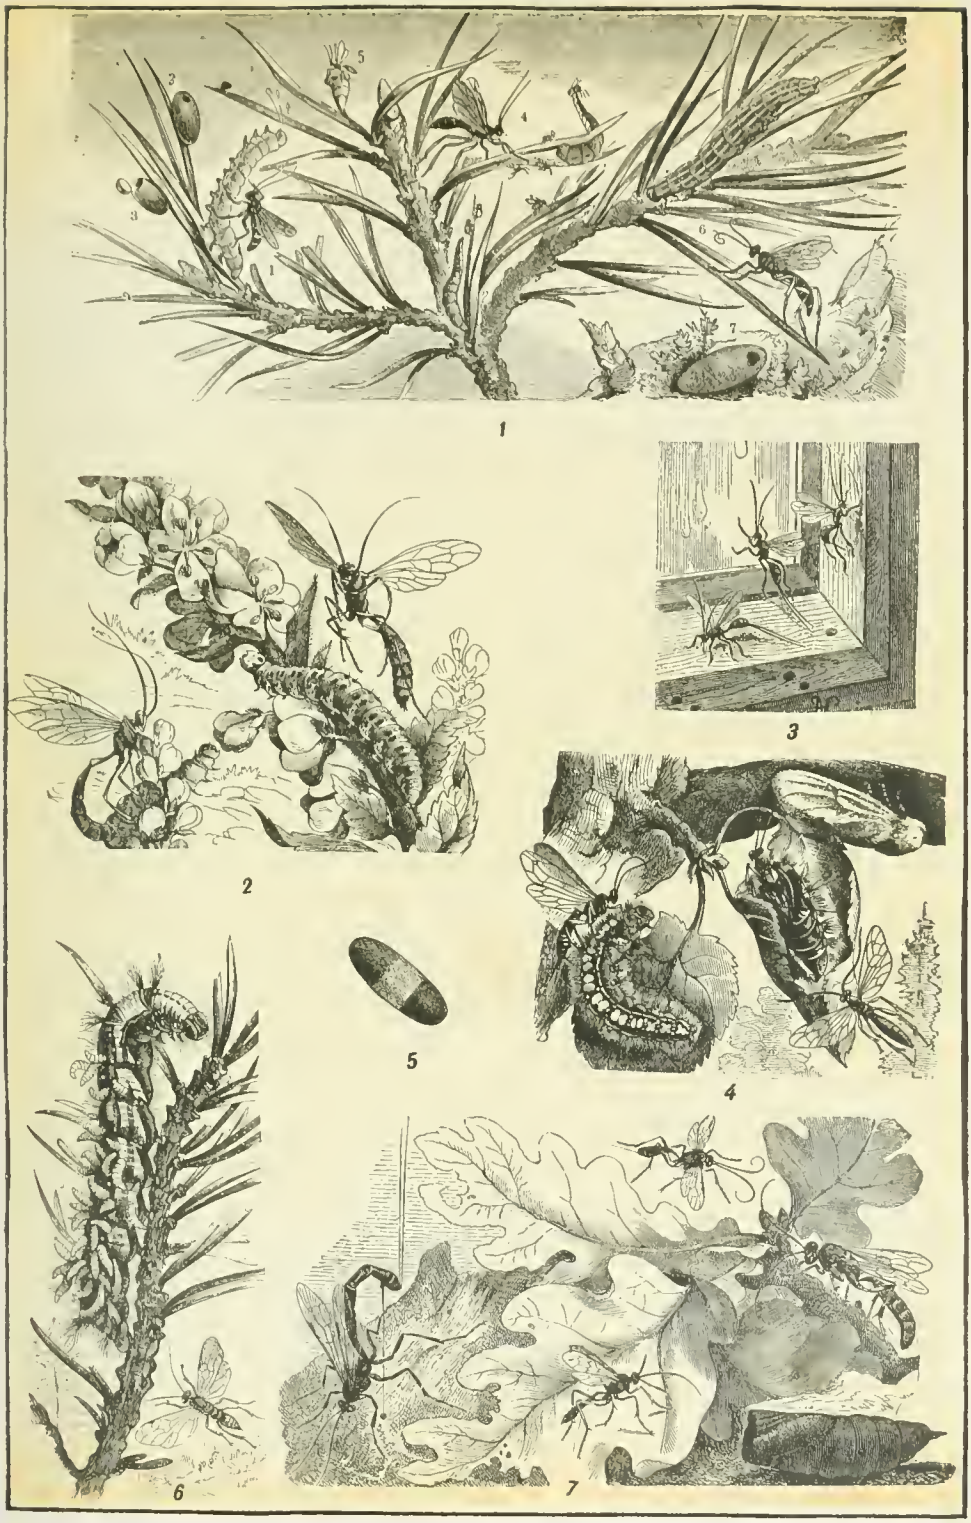
Leptocardii.—Lancelots (q.v).

Cyclostomi.—Hag-fishes and Lampreys (qq. v.).

Cyclic.— Extinct (palæozoic) fish-like forms.

Pisces.— Fishes, properly so called; the various primary divisions of which are usually called sub-classes.

But in view of the uncertainty attached to the mutual relations and origin of these groups, we may follow recent American custom in regarding the elasmobranchs, ostracophores, arthrodires, and teleostomes as distinct classes, the last named group containing the typical or true fishes. On anatomical grounds we must regard the *Elasmobranchii* (sharks) as the most primitive of these classes. As to this, palæontology gives no certain answer. There is no doubt that fishes existed and that some of the classes were well differentiated at a period long antecedent to the deposition of the oldest known remains. The earliest remains of fossil fishes now known occur in the Ordovician or Lower Silurian deposits at Cañon City, Colorado. Among the broken fragments are apparently parts of shields of ostracophores, scales of cros-



1. (1) Exenterus marginatorus attacking the larva of the pine-tree moth; (2) the cocoon of the latter as left by an ichneumon-fly; (3) as left by its rightful occupant; (4) Bassus albosignatus attacking the larva of the syrphus-fly; (5) male of the same; (6) Banchus falcator stealing upon a caterpillar; (7) larva of the ichneumon-fly.

2. Anomalon circumflexum attacking a caterpillar; and Ophion undulatus thrusting its ovipositor into the body of a caterpillar

3. Spathius clavatus, in a window

4. Pimpla instigator, preying upon a willow-moth.

5. Pupa-case of an Ophion.

6. Larva of Microgaster nemorum emerging from an infested caterpillar of the pine-tree moth.

7. Ichneumon pisorius, the left-hand figure being that of a female depositing eggs in a boring in the trunk of an oak.

sopterygians and vertebræ of a possible chimæroid. It is probable that primitive sharks existed still earlier than this, but no definable remains precede the Devonian.

The class or sub-class of *Elasmobranchii* (also called *Chondropterygii, Antacea,* etc.) agrees with the higher fishes in the presence of lower jaw, shoulder-girdle, pelvic girdle, paired fins, well developed skull, brain, and viscera. The gills are well developed, and the general structure and anatomy may be described as fish-like.

In distinction from the true fishes, the gills are differently formed, adnate by their outer margin, there are no membrane bones about the head, the ova are very large, the ventral fins are provided with claspers, there is no trace of air-bladder, the arterial bulb has three series of valves, there is a spiral valve in the rectum, the upper jaw is formed of palatal elements, the typical jawbones of the fish being undeveloped. The lower jaw is also different in structure from that of the true fishes.

The existing elasmobranchs are known as sharks, rays and chimæras. The vast majority of the known species are extinct. There are two strongly marked sub-classes among the elasmobranchs, the *Selachii* or sharks and rays, and the *Holocephali* or chimæras. In the *Selachii* there are five to seven gill-openings, the jaws are distinct from the skull, and the teeth are distinct. In the *Holocephali* there is but one external gill-opening, the jaws are coalescent with the skull, and the teeth are united to form bony plates or lamellæ. Both groups are very old in geologic times, having been separated at least since the Devonian. For this and other reasons some writers prefer to regard the sharks and chimæras as separate and coordinate groups.

We may without serious violence divide the sharks and rays into six orders; namely, *Pleuropterygii, Acanthodii, Ichthyotomi, Notidani, Asterospondyli,* and *Tectospondyli,* the first three of these being confined to Palæozoic time. We may regard the *Pleuropterygii* or the allies of *Cladoselache* as the most primitive, and therefore as standing first in an ascending series.

In this group the pectoral and ventral fins are broad and fold-like, the notochord is apparently not segmented, the tail is short and keeled, well specialized, its tip abruptly turned upward. There are no spines, the teeth are small, with many cusps. There is probably but one family, the *Cladoselachidæ* (extinct), *Cladoselache fyleri,* a large elongate shark from the Devonian of Ohio, is the best known species.

The *Acanthodii* are small sharks with a spine at the front of each fin except the caudal. The teeth are minute or wanting, and the skin is covered with small checker-like plates. There are three families, *Acanthœssidæ* (extinct), with one dorsal fin, *Diplacanthidæ* (extinct), with two, and the *Ischnacanthidæ* (extinct), small sharks found from the Devonian to the Permian.

The *Ichthyotomi* have the pectoral fin developed as an archipterygium or jointed limb with a fringe of rays on one or both sides. The dorsal fin extends along the back, and on the head is a first dorsal preceded by a long spine. There are two well-marked families, *Pleuracanthidii* and *Cladodontidæ,* abundant in the Carboniferous and Permian, but now extinct.

The *Notidani* or *Diplospondyli* have the notochord imperfectly segmented by vertical partitions, and the gill-clefts are six or seven in number instead of five, as in other sharks. Most of the species are extinct, the teeth being found in the rocks from the Jurassic to the present time. Two families are represented, the *Hexanchidæ* and the *Chlamydoselachidæ,* the latter eel-shaped sharks of the open sea, chiefly about Japan.

In the large order of *Asterospondyli* the vertebræ are strengthened by secondary plates of calcified tissue, which radiate outward from the small primitive cylinder. In these typical sharks there are five gill-slits, two dorsal fins, and one anal fin.

In the most primitive group, the sub-order *Cestraciontes,* the dorsal fins are each armed with a spine, the numerous teeth are small and mostly blunt, differing in form in different parts of the jaw, and the vertebræ are imperfectly formed. A curious fact in geological distribution is that a multitude of early types of shark disappear in the Permian or toward the end of Palæozoic time. Only cestraciont sharks are known to have any representatives in the Trias-

A Lancelet (*Amphioxus*).

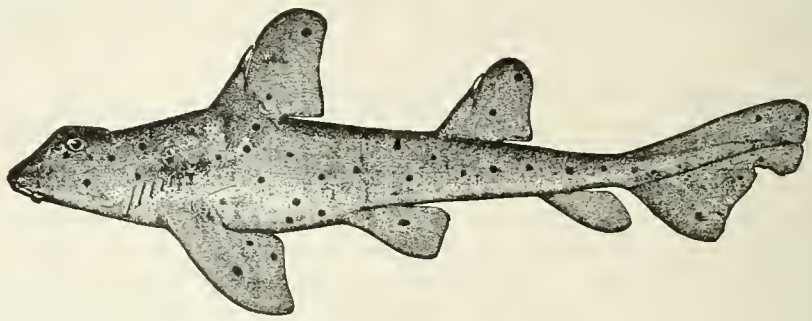
sic, and this group may be ancestral to all modern sharks.

Of the *Cestraciontes* the Palæozic families of *Cochliodontidæ* (extinct) and *Orodontidæ* (extinct), known mainly by the teeth, occur in the Lower Carboniferous. In some and probably all of these forms the dorsal fins were each armed with a spine. The *Edestidæ* (extinct), known only from coiled whorls of fused teeth, are doubtless closely related to these forms. These are found in the coal measures. The principal family of *Cestraciontes,* the *Heterodontidæ,* begins in the Permian, and is represented by five living species all in the Pacific Ocean, the longest known being the Port Jackson shark of Australia (*Heterodontus philippi*). We may here mention two families of sharks of uncertain relationship, the species confined to the Carboniferous Age. These are the *Petalodontidæ* (extinct), with blunt teeth, and some of them with broad fins like rays, and the *Psammodontidæ* (extinct), known from the blunt teeth only. Still more uncertain is the group of *Tamiobatidæ* (extinct) from the Devonian of Kentucky, resembling a ray, but probably a primitive offshoot from the sharks.

The remaining asterospondylous sharks from a sub-order, *Galei,* without dorsal spines, and with the vertebræ more perfectly calcified. The principal family is the *Carchariidæ.* Others are the *Sphyrnidæ* or hammer-heads, *Scyliorhinidæ* or cat-sharks, *Ginglymostomidæ, Hemiscylliidæ, Orectolobidæ, Lamnidæ* or man-eater sharks,

Odontaspididæ, or sand-sharks, *Alopiidæ,* or thresher-sharks, *Mitsukurinidæ* or spoon-bill sharks, *Cetorhinidæ* or basking-sharks, *Pseudotriakidæ* and *Rhincodontidæ*. Of the *Lamnidæ* and related families fossil teeth are very numerous from the Jurassic to modern times.

The *Tectospondyli* have the vertebræ each provided with secondary plates of calcified tissue concentrically arranged in one or more series. In these sharks there is no anal fin. To these belong the *Squalidæ* or dog-fishes, *Dalatiidæ, Oxynotidæ,* and *Echinorhinidæ* or bramble-sharks, these families forming together the sub-order *Cyclospondyli,* having the vertebral centrum a simple constricted cylinder pierced by the notochord. To the *Tectospondyli* proper we may refer a few families of sharks, the *Squatinidæ* or monk-fishes, and *Pristiophoridæ* or saw-sharks. A third sub-order, *Batoidei,* includes all the skates or rays. These agree with the true *Tectospondyli* in having a number of series of concentric plates within the vertebræ. The body is, however, more or less depressed, the broad pectoral fins outlining a body disk, and the gill-openings lie underneath instead of being lateral, as in all the sharks. The rays are first certainly known from the Jurassic, although several of the Carboniferous sharks have ray-like teeth, and have been referred to the group of rays.



Bullhead Shark of California (*Gyropleurodus francisci*).

The recognized families of rays are the *Pristididæ* or saw-fishes, the *Rhinobatidæ* or guitar-fishes, the *Narcobatidæ* or torpedos, the *Rajidæ* or skates, the *Dasyatidæ* or sting-rays, the *Myliobatidæ* or eagle-rays, the *Mobulidæ* or devil-fishes, and the *Ptychodontidæ* (extinct) of the Cretaceous. The earliest of these groups, the *Rhinobatidæ,* date from the Jurassic.

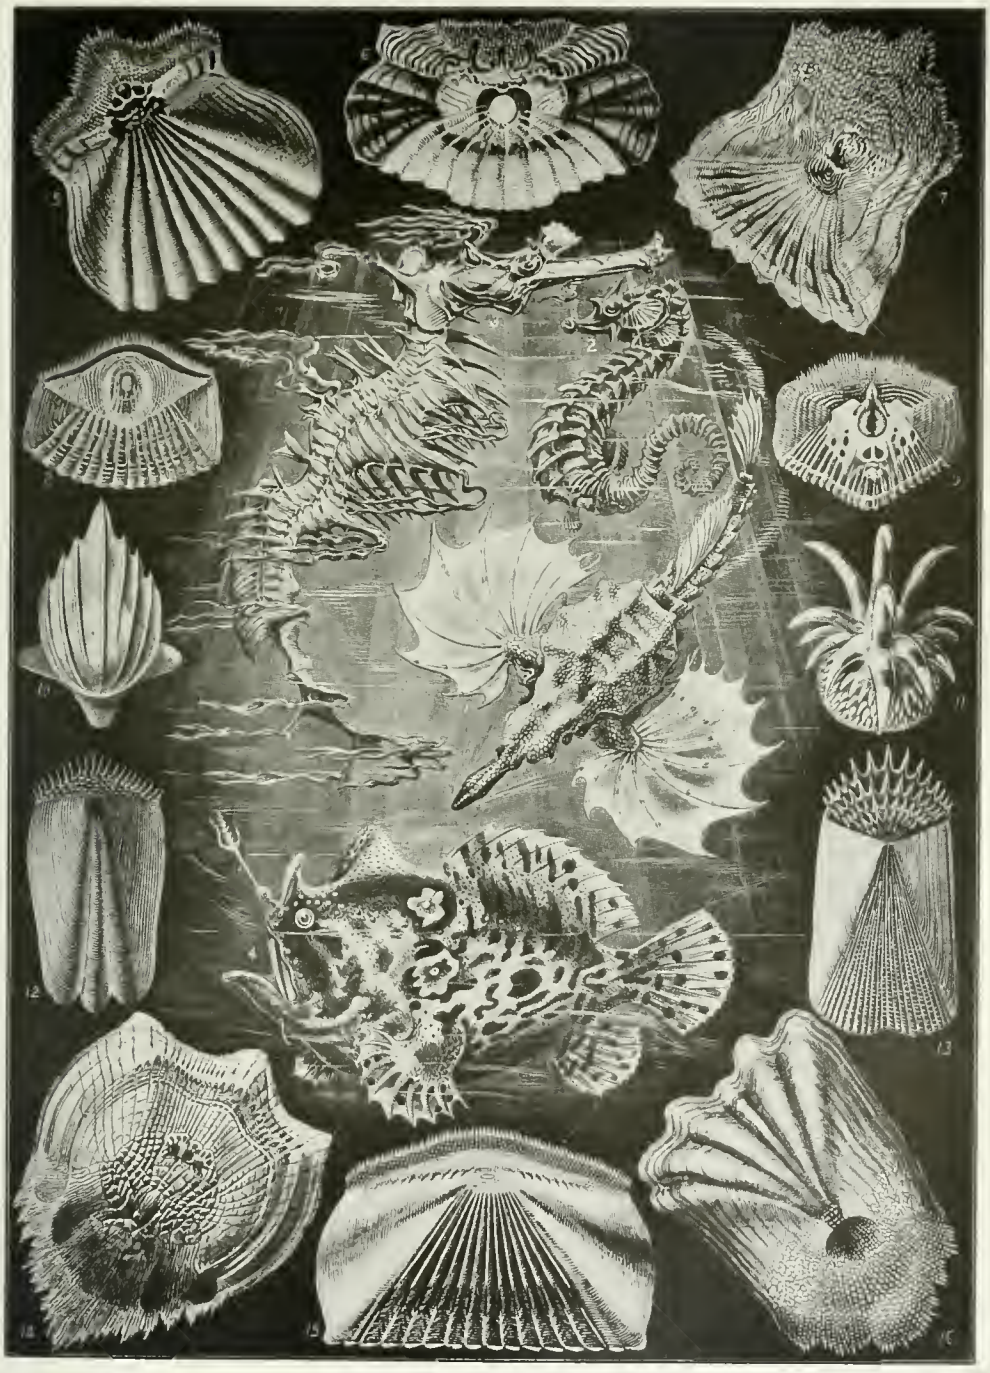
In the sub-class of *Holocephali* or *Chimæroids* the upper jaw or pterygoquadrate arcade is immovably joined to the skull. The teeth are coalesced into broad plates, and a fold of skin covers the gill-clefts so that there is but one external opening. The vertebral axis is imperfectly segmented, and the notochord is surrounded by partially calcified rings. In all recent genera, and in most others, there is a strong spine in the first dorsal, and in the male the forehead has a singular cartilaginous hook with a brush of spines at the end.

There are fragments referred to the skeleton of a chimæroid found in the Lower Silurian at Cañon City, Col. Numerous forms appear in the Devonian. Four genera, representing three families, are now extant, the *Rhinochimæridæ* (*Rhinochimæra* and *Harriotta*) in the deep seas, *Chimæridæ* or elephant-fishes (*Chimæra*) in the north and south temperate seas, and *Callorhynchidæ* (*Callorhynchus*) in the seas of the southern hemisphere only. Extinct families are the *Ptychodontidæ* (extinct), the *Squaloriidæ* (extinct), and the *Myriacanthidæ* (extinct). Numerous extinct genera are referred to the *Chimæridæ*. Fossil fin-spines of many species of sharks and chimæroids, fishes otherwise unknown, occur in the rocks. These are called ichthyodoroulites, and their proper classification is often a matter of much uncertainty. The earliest of these are known as *Onchus,* occurring in the Upper Silurian.

Class Ostracophori.— The earliest vertebrates actually recognized as fossils are known as ostracophores (ὄστρακον, a box; φορέω, to bear). These are most extraordinary creatures, which may be described as jawless, limbless, enveloped in a coat of mail. While they have been called mailed lampreys, the likeness to lampreys is almost wholly negative, resting in the total absence of jaws, limbs, and limb-girdles. What the mouth was like can only be guessed, but no trace of jaws has yet been found in connection with it. The most remarkable distinctive character is found in the presence of a hard shell, made of bony plates covering the anterior part of the body, while the backbone is developed as a persistent notochord, imperfectly segmented. The entire absence of jaw structures, as well as the character of the armature, at once separates them widely from the mailed arthrodires of a later period.

This group was originally called *Ostracodermi,* a name preoccupied for the group of bony trunk-fishes (*Ostraciidæ*). The names *Protocephali* and *Aspidoganoidei* have also been used for them. The still earlier name *Placodermi* included the *Arthrodires* as well.

The ostracophores are found in the Ordovician, Silurian, and Devonian rocks, after which they disappear. The species are very numerous and varied. Their real affinities have been much disputed. Traquair regards them as much modified allies of ancient sharks, which view of the case is supported by features in the structure of the most shark-like of the orders, *Anaspida.* The absence of jaws and limbs separates them widely from true fishes, and there is no clear evidence in the structure of the fins and fin-supports that these structures are homologous with the fins and fin-supports of true fishes, or even of sharks. In this group are four well-marked orders, *Heterostraci, Anaspida, Aspidocephali,* and *Antiarcha.*



SCALES AND ARMOR OF TELEOST FISHES.

1. Flying Gurnard (Pegasus chiropterus). 2 Seahorse (Hippocampus antiquorum). 3. Seaweed fish (Phyllopteryx eques). 4. Tentacle fish (Antennarius tridens). 5–16. Characteristic forms of scales among teleost fishes: 5, 6, 7, Sparidæ (sea-breams); 8–9, Percidæ (perches); 10, Centriscidæ (snipefish); 11, Siluridæ (catfish); 12, Fistularidæ (flutemouths); 13, Pleuronectidæ (soles); 14, Labridæ (wrasses); 15, Pristipomidæ (fossil); 16, Sparidæ (Cantharus).

The *Heterostraci* (ἕτερος, different; ὄστρακον, box) have no bone-corpuscles in the coat of mail. This order includes the *Pteraspidæ* (extinct), *Thelodontidæ* (extinct), *Drepanaspidæ* (extinct), and *Psammosteidæ* (extinct).

The *Anaspida* are more fish-like in appearance, having the armature of the head not plate-like, but formed of tubercles. There are two families, all of recent discovery, *Birkeniidæ* (extinct) and *Euphaneropidæ* (extinct).

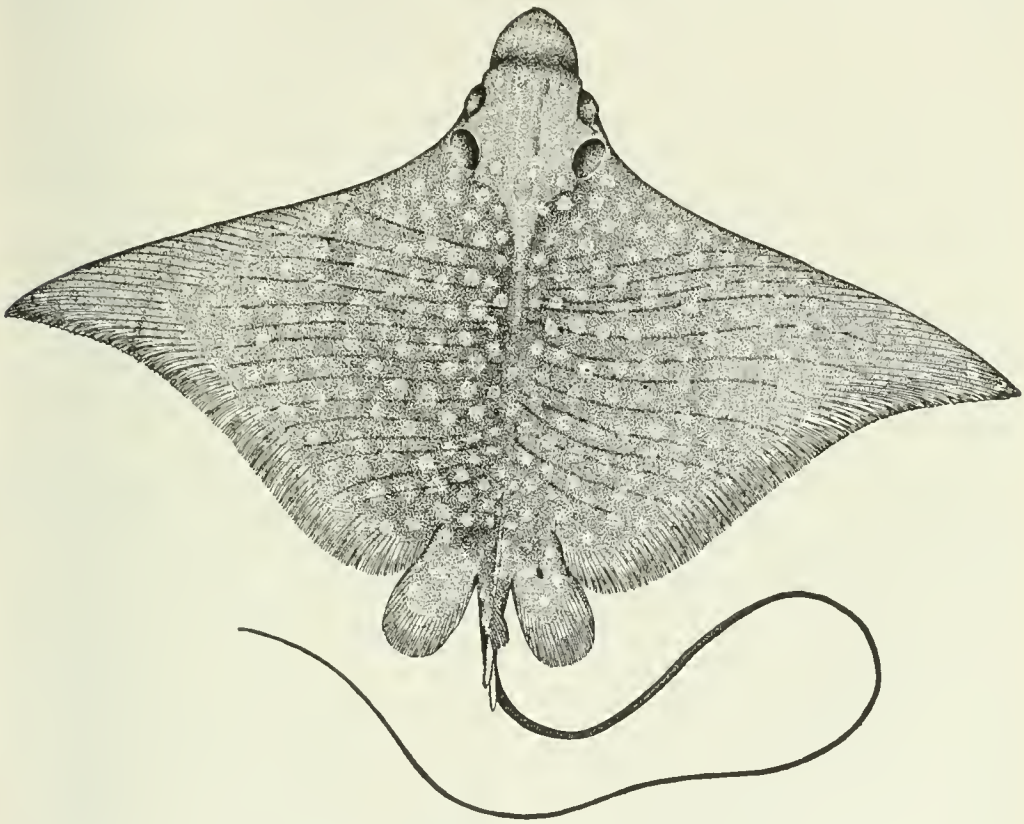
The *Aspidocephali* (also called Osteostraci) have bone-corpuscles in the shields, and the shield of the back is of one piece, without lateral line-channels or sense-organs. The order includes four families, *Ateleaspidæ* (extinct), *Cephalaspidæ* (extinct), *Thyestidæ* (extinct), and *Odontodontidæ* (*Tremataspidæ*) (extinct), with many genera and species.

The *Antiorcha* have also bone-corpuscles in the plates, which are also enameled. The sense-organs occupy open grooves, and the dorsal and ventral shields are of many pieces. The head is jointed on the trunk, and jointed to the head are paddle-like appendages covered with bony plates and resembling limbs. There is no evidence that these erectile plates are real limbs. They seem to be rather jointed appendages of the head-plate, erectile on a hinge like a pectoral spine.

There is but one family, *Asterolepidæ* (extinct). *Pterichthyodes milleri*, named by Agassiz for Hugh Miller, from the Lower Devonian, is the best-known species.

Class Arthrodires.— Another group of extinct mailed fishes is known as *Arthrodira* (ἄρθρον, joint; δειρή, neck). In this group jaws are developed, but of peculiar character, the mandibles being regarded as mere dermal elements, not forming part of the skeleton. The head in all the species is covered with a great bony helmet. Behind this on the nape is another large shield, and between the two is typically a hinge-joint, which has been compared to the hinge of a spring-beetle (elater). Some of these plates are traversed by sensory grooves. Nothing whatever is known of the internal structure, and as the skeleton is soft, the backbone notochordal, there is no trace of shoulder-girdle, nor any certain evidence of limbs, although peculiar structures have been interpreted as such. The presence of a peculiar type of jaws separates the group from the mailed ostracophores, from which the arthrodires differ also widely in the character of the armature.

Dr. Woodward and several other recent writers have regarded the arthrodires as armored, widely modified offshoots of the primitive *Dipneusto*. But the evidence does not seem to justify the union of the arthrodires with the latter group, and it would seem as reasonable to regard them as derived directly from the sharks or the ostracophores. The arthrodiran fishes occur in abundance from the Silurian times to the Mesozoic. In the Devonian their gigantic size and thick armor gave them the leading position among the hosts of the sea, ranging in



Spotted Sting-ray (*Aetobatus narinari*).

size "from that of the perch to that of the basking-shark."

The class, called by Dr. Dean *Arthrognathi,* is divided by him into two sub-classes, *Arthrodira,* with a hinge at the neck, and *Anarthrodira,* without hinge. In the first of typical sub-class are two orders, *Temnothoracici,* with the single family *Chelonichthyidæ* (extinct), *Arthrothoroci,* with the families *Coccosteidæ, Dinichthyidæ* (extinct), *Titanichthyidæ* (extinct), *Mylostomidæ,* and *Selenosteidæ* (extinct). To the *Chelonichthyidæ* belongs the noted species *Homosteus milleri,* celebrated by Hugh Miller under the name of "the Asterolepis of Stromness," in his 'Footprints of the Creator.'

The arthrodires without joint at the neck constitute the order *Stegothalami,* with the families of *Macropetalichthydiæ* (extinct), and *Asterosteidæ* (extinct).

The best known of the many genera of arthrodires is *Coccosteus,* found in the Scottish Devonian.

Class Teleostomi.— We may unite the remaining groups of fishes under a single class for which the name *Teleostomi* (τέλεος, true; στόμα, mouth), proposed by Bonaparte in 1838, may be retained. The fishes of this class are characterized by the presence of a suspensorium to the mandible, by the existence of membrane-bones (opercles, suborbital, etc.) on the head, by a single gill-opening, leading to gill-arches bearing bilamellate gills, and by the absence of claspers on the ventral fins. The skeleton is more or less ossified in all the *Teleostomi.* More important as a primary character distinguishing these fishes from the sharks is the presence typically and primitively of the air-bladder. This arises at first as a diverticulum from the ventral side of the œsophagus, and develops as a lung, but in later forms it becomes degraded to a swim-bladder, springing from the dorsal side of the alimentary canal, and in very many forms it is altogether lost with age. The group comprises the vast majority of recent fishes, as well as a large percentage of those known only as fossils. In these, the condition of the lung can be only guessed.

The *Teleostomi* are doubtless derived from sharks, their relationship being perhaps nearest to the *Ichthyotomi* or to the primitive chimæras. The lowest *Teleostomi* retain the shark-like condition of the upper jaw, made of palatal elements which, as in the *Chimæra,* may be fused with the cranium. In the lower forms also the primitive diphycercal or protocercal form of tail is retained, as also the archipterygium or jointed axis of the paired fins, fringed with rays on one or both sides.

We may divide the teleostomes or true fishes into three sub-classes, the *Crossopterygii* or fringe-fins, the *Dipneusti* or lung-fishes, and the *Actinopterygii* or ray-fins. Of these, recent writers are disposed to consider the *Crossopterygii* as most primitive, and to derive from this, by separate lines, each of the remaining sub-classes, as well as the higher vertebrates.

Sub-class Crossopterygii.—The earliest teleostomes constitute the class called after Huxley, *Crossopterygii* (κροσσός, fringe; πτερόν, fin). Its essential character is the retention of the jointed pectoral fin or archipterygium, its axis fringed by series of soft rays. This character it shares with the *Ichthyotomi* among sharks, and with the *Dipneusti.* From the latter it differs in the hyostylic cranium, the lower jaw being suspended from the hyomandibular — and by the presence of distinct premaxillary and maxillary elements in the upper jaw. In these characters it agrees with the ordinary fishes. The skeleton is more or less perfectly ossified. Outside the cartilaginous skull is a bony coat of mail. The skin is covered with firm scales or bony plates. The tail is diphycercal, straight, and ending in a point. The shoulder-girdle, attached to the cranium, is cartilaginous, but overlaid with long, bony plates, and the branchiostegals are represented by a pair of gular plates.

In the single family represented among living fishes the heart has a muscular arterial bulb with many series of valves on its inner edge, and the large air-bladder is divided into two lobes, having the functions of a lung, though not cellular as in the lung-fishes.

The fossil types are very closely allied to the lung-fishes, and the two groups have no doubt a common origin in Silurian times. It is now usually considered that the crossopterygian is more primitive than the lung-fish, though at the same time more nearly related to the ganoids, and through them to the ordinary fishes.

From the primitive *Crossopterygii* the step to the ancestral amphibia, which are likewise mailed and semi-aquatic, seems a very short one. It is true that most writers until recently have regarded such dipneustans as the *Ceratodontidæ,* as representing the parents of the amphibians. But the weight of recent authority, Gill, Boulenger, Dollo, and others, seems to place the point of separation of the higher vertebrates with the crossopterygians.

Cope and Woodward divide the *Crossopterygii* into four orders or sub-orders, *Haplistia, Rhipidistia, Actinistia,* and *Cladistia.* To the last belong the existing species (*Polypteridæ*) alone. In all these the pectorals are narrow with a single basal bone, and the nostrils, as in the dipneustans, are below the snout.

In the *Haplistia* the notochord is persistent, and the basal bones of dorsal and anal fins are in regular series, much fewer in number than the fin-rays. The single family *Tarrassiidæ,* regarded as lowest of the crossopterygians, are small fishes of Carboniferous Age.

In the *Rhipidistia* the basal bones of the median fins are found in a single piece, not separate as in the *Haplistia.* Four families are recognized, *Holoptychiidæ* (extinct), *Rhizodontidæ* (extinct), *Osteolepidæ* (extinct), *Onychodontidæ* (extinct), the first of these being considered as the nearest approach of the crossopterygians to the dipnoans.

In the *Actinistia* there is a single fin-ray to each basal bone, the axonosts of each ray fused in a single piece. The notochord is persistent, causing the backbone in fossils to appear hollow, the cartilaginous material leaving no trace in the rocks. The genera and species are numerous, ranging from the Subcarboniferous to the Upper Cretaceous, and belonging to the single family *Cœlocanthidæ* (extinct).

In the *Cladistia* the axis of the pectoral limb is fan-shaped, made of two diversified bones joined by cartilage. The notochord is restricted and replaced by ossified vertebræ. The axonosts of the dorsal and anal are in regular series, each bearing a fin-ray. The order contains the single family *Polypteridæ,* represented

by numerous species in the Nile, Senegal, and Kongo rivers. In this group the pectoral fin is formed differently from that of the other crossopterygians, being broad, its base of two diverging bones with cartilage between. This structure, more specialized than in any other of the crossopterygians or dipneustans, has been regarded by Gill and others, as above stated, as the origin of the fingered hand (chiropterygium) of the frogs and higher vertebrates. The base of the diverging bones has been identified as the antecedent of the humerus, the bones themselves as radius and ulna, while the intervening, non-ossified cartilage breaks up into carpal bones, from which metacarpals and digits ultimately diverge. This hypothesis is at least a reasonable one. The nostrils, as in true fishes, are superior. The body in these fishes is covered with rhombic enameled scales, as in the garpike, the head is similarly mailed, but in distinction from the garpike, the anterior rays of the dorsal are developed as isolated spines.

The young have a bushy external gill, with a broad scaly base. The air-bladder is double, not cellular, with a large air-duct joining the ventral surface of the œsophagus. The intestine has a spiral valve.

The cranium is remarkable for its generalized form, this forming a trait of union between the ganoids and the primitive *Amphibia* or *Stegocephali*. Without considering *Polypterus*, it is not possible to interpret the homologies of the cranium of the amphibians and the sharks.

Sub-class Dipneusti or Lung-Fishes.— The *Dipneusti* (δίς, twice; πνέω, to breathe) are a group characterized by the presence of paired fins consisting of a jointed axis with or without rays. The skull is autostylic, the upper jaw being made, as in the *Chimæra*, of palatal elements fused with the cranium and without premaxillary or maxillary. Dentary bones little developed. Air-bladder cellular, used as a lung, in all living species. Heart with many valves in the muscular arterial bulb. Intestine with a spiral valve. Teeth usually of large plates of dentine covered with enamel on the pterygopalatine and splenial bones. Nostrils concealed, when the mouth is closed, under a fold of the upper lip. Scales cycloid, mostly not enameled.

This group has been usually known as *Dipnoi*. But this term was first taken by Leuckart, in 1821, as a name for amphibians, before any of the living *Dipneusti* were known

The *Dipneusti* agree with the crossopterygians by the presence of lungs, a character which separates them from all the earlier orders of fishes. In its origin the lung or air-bladder arises as a diverticulum from the alimentary canal used by the earliest fishes as a breathing-sac, the respiratory functions lost in the progress of further divergence. Nothing of the nature of lung or air-bladder is found in lancelet, lamprey, or shark. In none of the remaining groups of fishes is it wholly wanting at all stages of development.

In the Dipneusti or dipnoans, as in the crossopterygians and higher vertabrates, the trachea or air-duct arises from the ventral side of the œsophagus. In the more specialized fishes, yet to be considered, it is transferred to the dorsal side, thus avoiding a turn in passing around the œsophagus itself. From the sharks these forms are further distinguished by the presence of membrane-bones about the head. From the *Actinopteri* (ganoids and teleosts) dipneustans and crossopterygians are again distinguished by the retention of the fringe-fin or archipterygium as the form of the paired limbs. From the crossopterygians the dipnoans are most readily distinguished by the absence of maxillary and premaxillary, the characteristic structures of the jaw of the true fish. The upper jaw in the dipnoan is formed of palatal elements attached directly to the skull, and the lower jaw contains no true dentary bones. The skull in the dipnoans is in the *Chimæra* is autostylic, the mandible articulating directly with the palatal apparatus, the front of which forms the upper jaw, and of which the pterygoid hyomandibular and quadrate elements form an immovable part. The shoulder-girdle, as in the shark, is a single cartilage, but it supports a pair of superficial membrane-bones.

In all the dipnoans the trunk is covered with imbricated cycloid scales and no bony plates, although sometimes the scales are firm and enameled. The head has a roof of well-developed bony plates made of ossified skin and not corresponding with the membrane-bones of higher fishes. The fish-like membrane-bones, opercles, branchiostegals, etc., are not yet differentiated. The teeth have the form of grinding-plates on the pterygoid areas of the palate, distinctly shark-like in structure. The paired fins are developed as archipterygia, often without rays, and the pelvic arch consists of a single cartilage, the two sides symmetrical and connected in front. There is but one external gill-opening, leading to the gill-arches, which, as in ordinary fishes, are fringe-like, attached at one end. In the young, as with the embryo shark, there is a bushy external gill, which looks not unlike the archipterygium pectoral fin itself, although its rays are of different texture. In early forms, as in the ganoids, these scales were long and enameled, but in some recent forms, deep sunken in the skin. The claspers have disappeared, the nostrils, as in the frog, open into the pharynx, the heart is three-chambered, the arterial bulb with many valves, and the cellular structure of the skin and of other tissues is essentially as in the *Amphibia*.

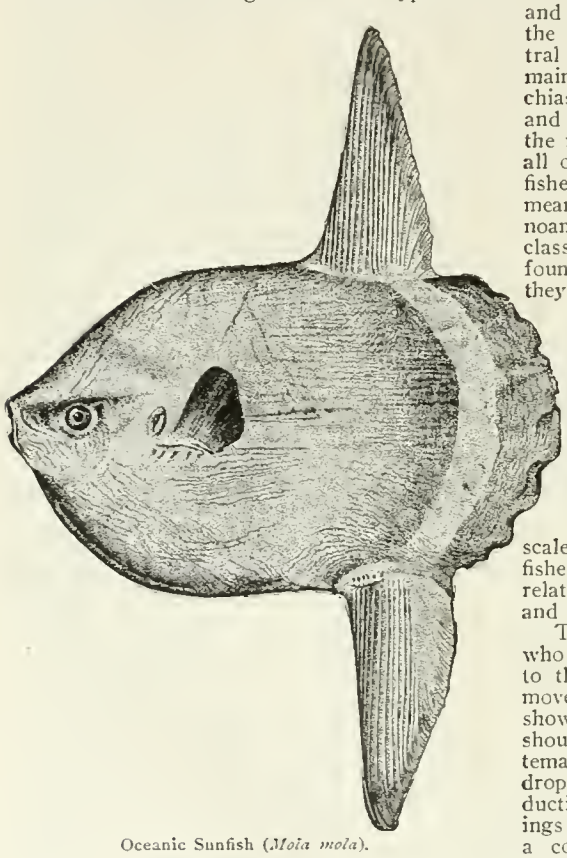
The developed lung, fitted for breathing air, which seems the most important of all these characters, can, of course, be traced only in the recent forms, although its existence in all others can be safely predicated. Besides the development of the lung we may notice the gradual forward movement of the shoulder-girdle, which, in the dipneustans, as in the crossopterygians, is attached to the head. In the fishes generally there is no distinct neck, as the post-temporal, the highest bone of the shoulder-girdle, is articulated directly with the skull.

We may divide the dipnoans into two orders, *Ctenodipterini*, with the families *Uronemidæ* (extinct), *Dipteridæ* (extinct), and *Ctenodontidæ* (extinct). These families occur from the Devonian to the Mesozoic. The more specialized order of *Sirenoidei* includes the families of *Ceratodontidæ* and *Lepidosirenidæ*, each of these represented by living forms. Most of the *Ceratodontidæ* are extinct, occurring in the Mesozoic; but two species, *Neoceratodus forsteri* and *N. miolepis*, live in rivers of Australia. No fossil *Lepidosirenidæ* are known. *Lepidosiren paradoxus* lives in the swamps of southern Brazil and *Protopterus annectens*, *P.*

dolloi, and *P. æthopicus,* in those of the Nile region.

Sub-class Actinopteri.—After setting off from the great group of fishes primitive or archaic types, one after another, we are left at last with only those having fish-jaws, fish-fins, and in general the structure of the typical fish. For all these in all their variety, as a class or subclass, we adopt the name of *Actinopteri,* suggested by Prof. Cope. The name (ἀκτίς, ray; πτερόν, fin) refers to the structure of the paired fins. In all these, the bones supporting the fin-rays are highly specialized, and at the same time concealed by the general integument of the body.

In general, two bones connect the pectoral fin with the shoulder-girdle. The hyperacoracoid is a flat square bone, usually perforated by a foramen lying above, and parallel with it the irregularly formed hypocoracoid. Attached to these is a row of bones, the actinosts or pterygials, short, often hourglass-shaped, which actually support the fin-rays. In the higher forms the actinosts are few (four to six) in number, but in the lower types they may remain numerous, a reminiscence of the condition seen in the crossopterygians and especially in *Polypterus.* Other variations may occur; the two coracoids are sometimes imperfect or specially modified, and the actinosts may be distorted in form or position. Among the lower *Actinopteri* many archaic traits still persist, and by its earlier representatives the group is joined very closely to the *Crossopterygii.* The great class may be divided into two series or sub-classes, the *Ganoidei,* which retain the ancient traits, and the *Teleostei* or bony fishes, in which most of these have disappeared.



Oceanic Sunfish (*Mola mola*).

Even among the *Ganoidei,* as the term is here restricted, there remains a great variety of form and structure. The group constitutes several distinct orders, and as a whole does not admit of perfect definition. All of the species known have the tail strongly heterocercal. Most of them have the skeleton still cartilaginous, and in some it remains in a very primitive condition. Most of them have an armature of bony plates, diamond-shaped with an enamel like the surface of teeth. All of them have the air-bladder highly developed, usually cellular and functional as a lung, but connecting with the dorsal side of the gullet, not with the ventral side, as in the dipnoans. In all these remain more or less perfectly developed the optic chiasma, the many valves of the arterial bulb, and the spiral valve of the intestines found in the more archaic types. But traces of some or all of these structures are found in some bony fishes, and their presence in the ganoids by no means justifies their separation with sharks, dipnoans, and crossopterygians as a great primary class, *Palæichthyes.* All forms of body may be found among the ganoids. In the earlier seas they were scarcely less varied and perhaps scarcely less abundant that the teleosts in the seas of to-day. So far as fossils show, the characteristic actinopterous fin, with its reduced and altered basal bones, appeared at once without intervening gradations.

The name *Ganoidei* (γάνος, brightness; εἶδος, resemblance), alluding to the enameled plates, was first given by Agassiz to those forms, mostly extinct, allied to the garpike, and covered with bony scales or hard plates. As originally defined, catfishes, sea-horses, *Agonidæ,* and other wholly unrelated types were included with the garpikes and sturgeons as ganoids.

These were eliminated by Johannes Müller, who recognized the archaic characters common to the existing forms. Still later Huxley removed the crossopterygians, and others have shown that the *Ostracophori* and *Arthrodira* should be placed far from the garpike in systematic classification. Cope and Woodward have dropped the name ganoid altogether as productive of confusion through the many meanings attached to it. Others have retained it as a convenient group name for the orders of archaic *Actinopteri.* For these varied and more or less divergent groups it seems convenient to retain it.

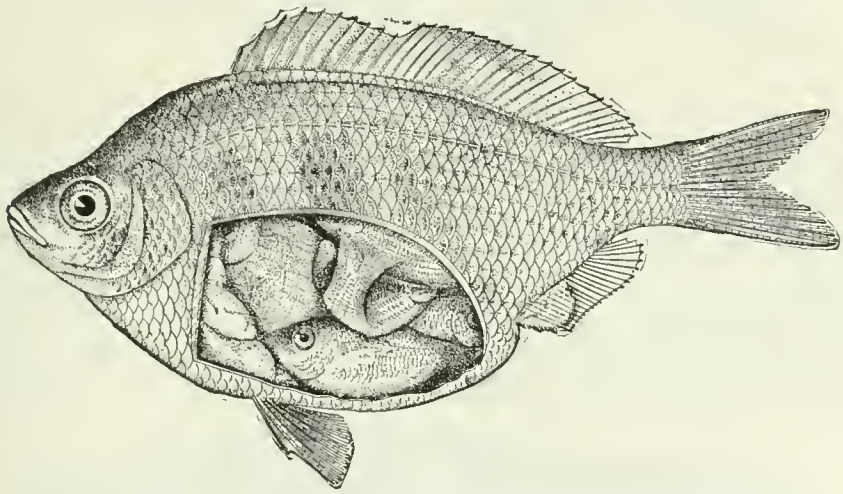
The order *Lysopteri* (λύσις, a loosing; πτερόν, fin) comprises the earliest ganoids, beginning in the Devonian, covered with enameled scales. The families are *Palæoniscidæ, Platysomidæ, Dictyopygidæ,* and *Dorypteridæ.* The order *Chondrostei* (χόνδρος, cartilage; ὀστέον, bone) includes a great variety of forms, characterized by the less cartilaginous skeleton, the distinctly heterocercal tail, and the presence of bony plates, rather than scales, on most parts of the body. These represent a degenerate offshoot from the *Lysopteri,* the form being less like that of the typical fishes. The earliest members of this group appear in the Tertiary.

the most primitive family being the *Chondrosteidæ* (extinct). Another family is that of *Belonorhynchidæ* (extinct). The *Acipenseridæ* (sturgeons) are well represented among living fishes. The order *Selachostomi* (σέλαχος, shark; στόμα, mouth) includes the paddle-fishes (*Polyodontidæ*), two living species, and one extinct, in the Eocene. The order *Pycnodonti* including the family of *Pycnodontidæ* (extinct), consists of a deep-bodied, compressed fishes with small mouths and a peculiar physiognomy. The order *Lepidostei* (λεπίς, scale; ὀστέον, bone) includes numerous families with rhombic enameled scales. The families are *Semionotidæ, Lepidotidæ, Isopholidæ, Macrosemiidæ, Pholidophoridæ, Aspidorhynchidæ,* and *Lepisosteidæ,* all extinct save the *Lepisosteidæ,* represented by four species known as garpike in the rivers of North America. The earliest fossil garpikes occur in the Eocene. The *Halecomorphi* (*halec,* herring; μορφή, form) comprise the *Pachycormidæ, Protosphyrænidæ, Liodesmidæ, Oligopleuridæ,* and *Amiidæ.* All these have perished, except the *Amiidæ,* which group is represented by a single species, the Bowfin, *Amia calva,* in the waters of the eastern United States. In these forms there is a gradual transition from diamond-shaped scales, covered with enamel, to the cycloid scales of the ordinary soft-rayed fishes. The line separating the *Lepidostei* and *Halecomorphi* from each other and from the *Isospondyli* is a very narrow one.

Sub-class Teleostei or Bony Fishes. — The fishes which still remain for discussion constitute the great sub-class or series of *Teleostei* or bony fishes. They lack wholly or partly the ganoid traits, or show them only in the embryo. The tail is slightly if at all heterocercal, the fulcra disappear, the actinosts of the pectoral fins are few and large, rarely if ever over five in number, the air-bladder is no longer cellular in most species, nor does it assist in respiration. The optic nerves are separate, one running to each eye without chiasma. The skeleton is almost entirely bony, the notochord usually disappearing entirely with age. The valves in the arterial bulb are reduced in number, and the spiral valve of the intestines disappears. Traces of each of the ganoid traits may persist somewhere in some group, but as a whole we see a distinct specialization and a distinct movement toward the fish type with the loss of characters distinctive of sharks, dipnoi, and ganoids. In a general way the skeleton of all teleosts corresponds with that of the striped bass, and the visceral anatomy is in all cases sufficiently like that of the sunfish.

The mesocoracoid or præcoracoid arch, found in all ganoids, persists in the less specialized types of bony fishes, although no trace of it is found in the perch-like forms. With all this, there is found among the bony fishes, an infinite variety in details of structure. For this reason the *Teleostei* must be broken into many orders, and these orders are very different in value and in degrees of distinctness, the various groups being joined by numerous and puzzling intergradations.

Order Isospondyli.— Of the various subordinate groups of bony fishes there can be no question as to which is most primitive in structure or as to which stands nearest the orders of ganoids. Earliest of the bony fishes in geological time is the order of *Isospondyli* (ἴσος, equal; σπόνδυλος, vertebra), containing the allies recent and fossil of the herring and the trout. This order contains those soft-rayed fishes which have the ventral fins abdominal, the mesocoracoid or præcoracoid arch developed (sometimes lost in degeneration), and the anterior vertebræ unmodified, essentially similar to the others.



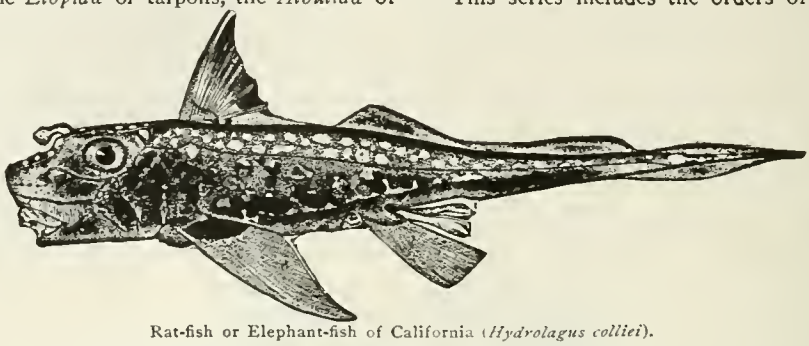
Sparada, or Viviparous Perch of California (*Cymatogaster aggregatus*).

The ganoids pass by degrees into the *Isospondyli,* and the soft-rayed fishes pass again by imperceptible gradations into those more specialized forms having spines in the fins, structures which are again lost in the most modified members of the same group.

Ganoid traits are present in certain families of *Isospondyli.* Among these are the gular plate (found in *Amia* and the *Elopidæ*), presumably derived from the similar plate in the earliest ganoids, additional valves in the arterial bulb in *Albulidæ,* the cellular air-bladder of *Notopterus* and *Osteoglossum,* the spiral intestinal valve in *Chirocentridæ,* and the ganoid

scales of the extinct *Leptolepidæ*. From these characters it is inferred that the soft-rayed fishes are descended from the *Lepidostei* or *Halecomorphi*. The more primitive *Isospondyli* approach more nearly to these ganoid forms than to their later descendants, the catfishes, the eels, or the pikes.

Most ancient of the *Isospondyli* is the extinct family of *Leptolepidæ* of the Triassic. Families mostly still extant, but nearly all of them more or less represented in fossils from the Jurassic on, are the *Elopidæ* or tarpons, the *Albulidæ* or



Rat-fish or Elephant-fish of California (*Hydrolagus colliei*).

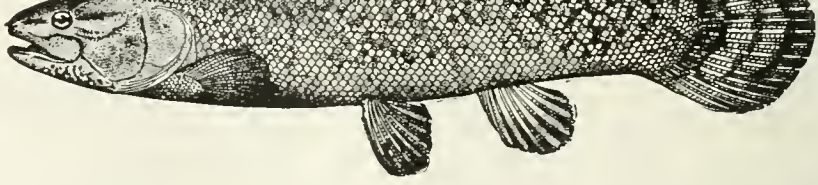
lady-fishes, the *Chanidæ* or milk-fishes, the *Hiodontidæ* or moon-eyes, the *Spaniodontidæ* (extinct), the *Pachyrhizodontidæ* (extinct), the *Thryptodontidæ* (extinct), the *Pterothrissidæ*, the *Chirocentridæ*, the *Notopteridæ*, the *Enchodontidæ* (extinct), the *Ichthyodectidæ* (extinct), the *Osteoglossidæ*, the *Phareodontidæ* (extinct), the *Clupeidæ* or herrings, the *Dussumieriidæ* or round herrings, the *Dorosomidæ* or gizzard-shad, the *Engraulididæ* or anchovies, the *Alepocephalidæ*, the *Pantodontidæ*, the *Salmonidæ* or salmon and trout, the *Thymallidæ* or graylings, the *Argentinidæ* or smelt, the *Microstomidæ*, the *Salangidæ* or ice-fish, the *Galaxiidæ* or New Zealand trout, the *Haplochitonidæ*, the *Gonorhynchidæ*, the *Notopteridæ*, and a host of other forms, mostly from the deep seas, constituting (sub-order *Inomiæ*) the families of *Aulopidæ*, *Ctenothrissidæ* (extinct), *Synodontidæ* or lizard-fishes, *Benthosauridæ*, *Bathypteroidæ*, *Ipnopidæ*, *Rondeletiidæ*, *Cetomimidæ*, *Myctophidæ* or lantern-fishes, *Rhinellidæ* (extinct), *Dercetidæ* (extinct), *Chirothicidæ* (extinct), *Exocoetoididæ* (extinct), *Mauroliciдæ*, *Chauliodontidæ* or viper fishes, *Gonostamidæ*, *Astronesthidæ*, *Stomiatidæ*, *Malacosteidæ*, *Plagyodontidæ* or lancet-fishes, *Evermannellidæ*, *Paralepididæ*, *Sternoptychidæ*, and *Idacanthidæ*.

The order of *Lyopomi* (λύω, loose, πόμα, opercle), contains a few deep-sea fishes, without mesocoracoid and with the opercular bones distorted. One family, the *Halosauridæ*, with fossil allies.

A series of soft-rayed fishes descended from the *Isospondyli* are grouped together to form the super-order or series called *Ostariophysæ*. These differ from the *Isospondyli* in having the four anterior vertebræ much modified, the air-bladder being connected, by a series of ossicles called the Weberian apparatus, with the auditory organ.

This series includes the orders of *Eventognathi*, *Heterognathi*, *Nematognathi*, and *Gymnonoti*, immense groups comprising the vast majority of the fresh-water fishes of the world.

The *Eventognathi* and *Heterognathi* have the mouth-parts normal, the maxillary not rudimentary, and the body usually covered with ordinary scales. In the order *Heterognathi* (ἕτερος, differing; γνάθος, jaw) the lower pharyngeals are not especially modified, and the jaws usually with teeth. This group comprises most of the river-fishes of South America and Africa. It includes the families of *Characidæ* and *Erythrinidæ*, the former with and the latter without the adipose fin characteristic of catfishes and salmon.

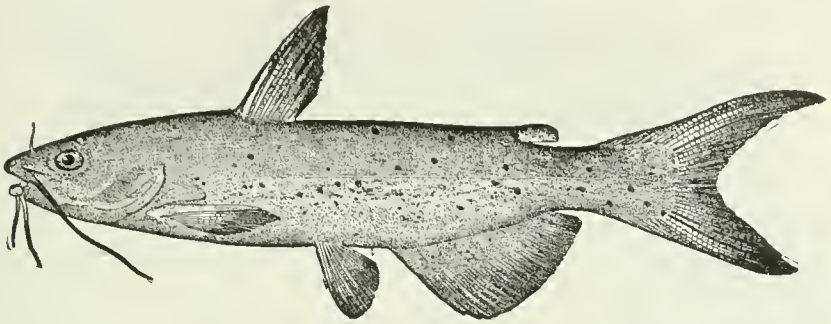


The Bowfin (*Amia calva*).

The order *Eventognathi* (εὖ, well; ἐν, within; γνάθος, jaw) is characterized by the absence of teeth in the jaws, and by the high degree of specialization of the lower pharyngeals, which are scythe-shaped, and in typical forms are armed with a relatively small number of highly specialized teeth of peculiar forms and arranged in one, two, or three rows. In all the species the gill-openings are restricted to the sides, there is no adipose fin, and the broad flat branchiostegals are but three in number. In all the species the scales, if present, are cycloid, and the ventral fins, of course, abdominal. The modification of the four anterior vertebræ and their connection with the air-bladder are

essentially as seen in the catfishes. The families of *Eventognathi* are the *Kneriidæ, Homalopteridæ, Cobitidæ* or loaches, *Catostomidæ* or suckers, and *Cyprinidæ* or carp, dace and minnows. The last is the largest family recognized in ichthyology, comprising over 2,000 species, almost all confined to the north temperate zone.

The order of *Nematognathi* or catfishes is characterized among the *Ostariophysæ* by the fact that the maxillary bone is rudimental, forming the base of a long barbel. There are no true scales, the body being naked or mailed, and about the mouth are always fleshy feelers. The multitude of species inhabit chiefly the rivers of



Channel Cat-fish (*Ictalurus punctatus*).

the tropics, only the typical catfishes of the principal family of *Siluridæ* occurring in waters of the United States and Europe. The families are *Diplomystidæ, Siluridæ, Bunocephalidæ, Plotosidæ, Chacidæ, Chlariidæ, Hypophthalmidæ, Argidæ, Sisoridæ, Pygidiidæ, Loricariidæ,* and *Calliichthyidæ,* the members of the last three groups armed with a bony coat of mail.

The order *Gymnonoti* contains elongate eel-like fishes without dorsal fin and with the tail excessively long. The vertebræ are modified, as in the preceding orders, but there is no mesocoracoid arch. The families are *Electrophoridæ* and *Gymnotidæ*, all river-fish of South America.

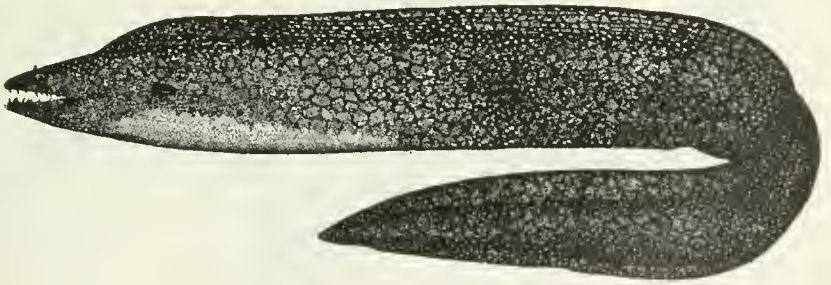
The order *Scyphophori* contains river-fishes of Africa in which the small mouth is at the end of a long snout. There are no pharyngeal teeth, and the opercular bones are considerably modified. In all there is a deep cavity on each side of the cranium, covered by a thin bony plate, the supertemporal bone. The families are *Mormyridæ* and *Gymnarchidæ.*

Next we may place a long series of more or less related families, known collectively as eels. In all these the upper jaw is more or less degenerate, the ventral fins are wanting, and the shoulder-girdle has typically lost its connection with the skull. The earliest fossil eels have traces of scales, the caudal fin separate, and, according to Dr. O. P. Hay, abdominal ventral fins. These characters are lost in all or most of the living forms.

The eels may be distributed among different orders. The *Symbranchia* (δύν, together; βράνχος, gill) — *Ichthyocephali,* and *Holostomi* — have normal fish-like jaws, and the shoulder-girdle is sometimes joined to the skull. The families are *Monopteridæ* or rice-field eels, *Symbranchidæ, Amphibnoidæ,* and *Chilobranchidæ.*

The true eels or apodes have the shoulder-girdle free from the skull, the premaxillaries more or less coalesced with the vomer, and the body elongate and of many vertebræ. The families are *Anguillavidæ* (extinct), with distinct caudal and sometimes with ventral fins, *Anguillidæ,* or true eels, *Leptocephalidæ* or conger-eels, *Simenchelidæ, Muræsocidæ, Nettostomidæ, Nemichthyidæ, Ophichthyidæ, Hyophidæ, Heterocongridæ, Dysommidæ, Eucheliidæ* (extinct), *Murænidæ* or morays, *Myrocongridæ,* and *Moringuidæ.*

The small order of *Carencheli* contains one family, *Dcrichthyidæ,* characterized by the



Muræna.

snake-like neck and the structure of the jaws.

The order *Lyomeri* includes deep-sea eels of enormous gape, with the parts of the head very loosely joined, and with the fifth gill-arch not modified to form a pharyngeal. There are two families, *Saccopharyngidæ* and *Eurypharyngidæ.*

Still more aberrant is the small order of *Heteromi* (ἕτερος, differing; ὦμος, shoulder), the spiny eels, elongate fishes, having the shoulder-girdle detached from the head and the coracoids united in an imperforate plate. This group includes eel-like fishes of the deep

sea, with spines in the dorsal fin — the families, *Protonotocanthidæ* (extinct), *Notacanthidæ*, and *Lipogenyidæ*.

Another order of uncertain relationship is that of *Opisthomi*, with normal coracoids, spines in the dorsal fin, and the shoulder-girdle remote from the skull. It contains one family, the *Mastacembelidæ*, small fishes from the streams of tropical Asia and Africa.

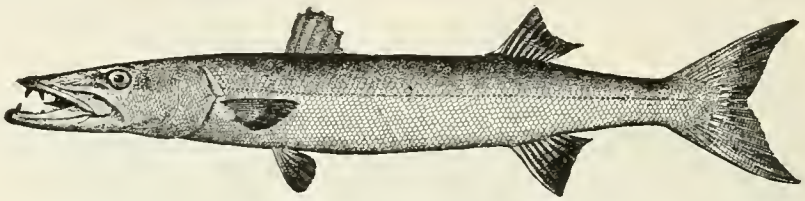
Another small order, the *Xenomi* (ξένος, strange; ὦμος, shoulder), has the coracoids rudimentary and cartilaginous, with no basal bones or actinosts to the pectoral fin. One family, *Dalliidæ*, characterized by the black-fish of the marshes of Alaska and Siberia.

In the order *Haplomi*, the mesocoracoid arch is wholly undeveloped, as is the case in all of the other groups remaining to be enumerated.

In common with the soft-rayed fishes in general, the air-bladder has a persistent air-duct, the fins are without spines, the ventral fins are abdominal, and the scales are cycloid.

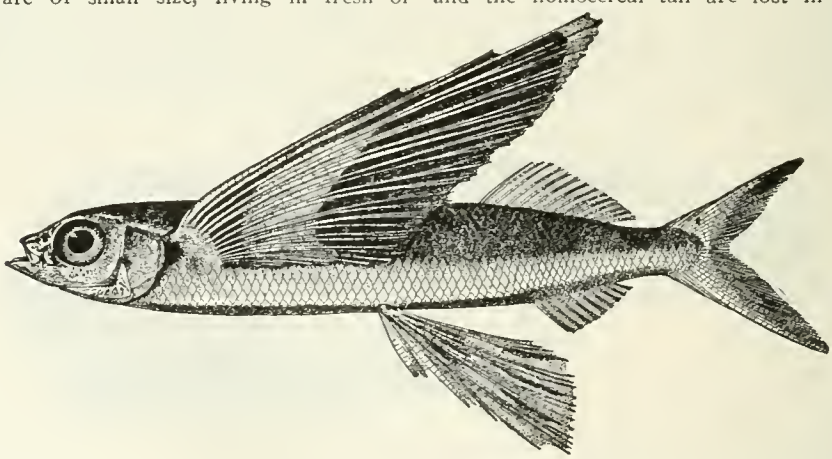
There is no adipose dorsal in the *Haplomi*, the dorsal is inserted far back, and the head is generally scaly. Most, but not all, of the species are of small size, living in fresh or brackish waters, and they are found in almost all warm regions, though scantily represented in California, Japan, and Polynesia. The families are *Esocidæ* or pikes, *Umbridæ* or mud-minnows, *Poeciliidæ* or killifishes, and *Amblyopsidæ* or blind-fishes of the caves. The *Gonorhynchidæ* and the extinct families of *Crossognathidæ* and *Cobitopsidæ* may be doubtfully added to this group.

Order Acanthopterygii.— The most of the remaining bony fishes constitute a natural group for which the name *Acanthopterygii* (ἄκανθα, spine; πτερόν, fin or wing), may be used. This name is often written *Acanthopteri*, a form equally correct and more euphonious and convenient. These are characterized, with numerous exceptions, by the presence of spines in the fins, by the connection of the ventral fins to the shoulder-girdle, by the presence, in general, of more than one spine in the anterior part of dorsal and anal fins, and as a rule of one spine and five rays in the ventral fins, and by the absence in the adult of a duct to the air-bladder. Minor characters are these: The pectoral fins are inserted high on the shoulder-girdle, the scales are often ctenoid, and the edge of the upper jaw is formed by the premaxillary alone, the maxillary being always toothless.



Barracuda (*Sphyræna barracuda*).

But it is impossible to define or limit the group by any single character or group of characters. It is connected with the *Isospondyli* through the *Haplomi*, on the one hand, by transitional groups of genera which may lack any one of their characters. On the other hand, in the extreme forms, each of these distinctive characters may be lost through degeneration. Thus fin-spines, ctenoid scales, and the homocercal tail are lost in the cod-fishes, the connection of ventrals with shoulder-girdle fails in certain peculiar forms, and the development of the air-duct is subject to all sorts of variations. In one family even the adipose fin reappears.



A Flying-fish (*Exocætus volitans*).

The *Acanthopterygii* or preferably *Acanthopteri*, the *Physoclysti* of Müller, the *Thoracices* of older authors, and the *Ctenoidei* of Agassiz, include substantially the same series of forms.

Among the many subordinate groups, suborders or super-families, a few stand out as susceptible of definition. Among these is the

group of *Salmopercæ*, composed of perch-like fishes, with spines in the fins and with ctenoid scales, yet retaining at the same time the abdominal ventrals and the adipose fin of the salmon. This constitutes the family of *Percopsidæ*, trout-perches or sand-rollers. The extinct *Erismatopteridæ* and *Asineopidæ* probably belong here.

The sub-order *Symentognathi* agree externally with the *Haplomi*, but have the lower pharyngeals solidly united, and the air-duct lost in the course of development. The families are *Belonidæ*, the gars, *Scombresocidæ*, the sauries, *Hemiramphidæ* or half-beaks, and *Exocætidæ* or flying-fishes. This order and the *Haplomi* are joined by Hay under the name of *Mesichthyes*, the groups forming a perfect transition from soft-rayed to spiny-rayed fishes.

The group of *Percesoces* has the general traits of the spiny-rayed fish, with the ventral fins abdominal. Here belong the *Sphyrænidæ* or barracudas, the *Atherinidæ* or silversides, and the *Mugilidæ* or mullets. Another sub-order, *Rhegnopteri*, includes the *Polynemidæ* or thread-fins. Other transitional forms, with the ventrals abdominal, and spines usually present in the fins, constitute the sub-orders of *Hemibranchii, Lophobronchii* and *Hypostomides*. In all of these the bones of the gill-arches are reduced in number, and the gill-structures are distinctly degenerate. For this reason Dr. Hay has proposed to unite them as a distinct order, *Phthinobranchii* (*φθίνων*, waning). The *Hemibranchii* include the families *Gasterosteidæ* (sticklebacks), *Protosyngnathidæ* (extinct), *Aulorhynchidæ*, *Fistulariidæ* (cornet-fishes), *Aulostomidæ* (trumpet-fishes), *Urosphenidæ* (extinct), *Rhamphosidæ* (extinct), *Marcorhamphosidæ* (snipe-fishes), and *Centriscidæ* (shrimp-fishes). The more degenerate sub-order of *Lophorbranchii* includes the *Solenostomidæ*, the *Syngnathidæ* (pipe-fishes), and the *Hippocampidæ* or sea-horses. The singular order of *Hypostomides* includes the *Pegasidæ* (sea-moths or sea-dragons).

In another sub-order we may place the *Berycoidei*, fishes perch-like in general structure and usually well armed, with the ventral fins thoracic, but their number of rays never I, 5, the typical number in all perch-like forms. The berycoids are especially characterized by the presence of the orbitosphenoid bone, a structure wanting in all perch-like families; are the earliest in time of the fishes of this pattern, appearing in the Cretaceous or earlier. The families are *Berycidæ, Trachichthyidæ, Holocentridæ* or soldier-fishes, *Polymixiidæ*, and *Monocentridæ* or pine-cone fish.

Another group or sub-order *Zeoidei*, agrees well with the beryces in the presence of more than five soft rays in the ventral fins and in the armature of the fins. It differs, however, in the character of the skeleton, the post-temporal, especially being adnate to the skull, as in the butterfly-fishes or *Chætodontidæ*.

One family, *Zeidæ*, the John-dories, belongs here. In the same group we may place provisionally an extinct family, *Amphistiidæ*. Dr. Boulenger has suggested that to fishes allied to the *Amphistiidæ* we may trace the origin of the John-dories, and of the great group of flounders as well. This is an interesting suggestion, but the actual line of descent is as yet not proved.

The sub-order *Selenichtyes* includes the family of *Lamprididæ* or opahs. In this group is a single species, a huge fish almost as deep as long, with the hypercoracoids greatly developed and the ventral fin with many soft rays, an archaic character unknown in other spiny-rayed fishes.

In this neighborhood belongs the sub-order of *Heterosomata*, or flounders, characterized by the twisting of the cranium, an arrangement which permits the fish to lie flat on one side on the sand, while both eyes are turned to the upper or colored side. In this group there are no fin-spines. The young flounder when first

A Sea-horse (*Hippocampus*).

hatched has the skull and eyes symmetrical, and the modification of the head proceeds by degrees.

There are two families, *Pleuronectidæ* or flounders, and *Solcidæ* or soles.

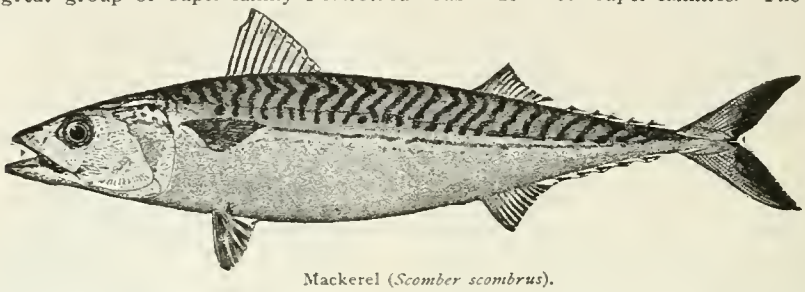
To the group or super-family *Scombroidea* belong a great variety of fishes, usually swift in motion and with thin soft scales, the ventral fins, if present, having a spine and five soft rays.

The families are *Rachicentridæ*, the sergeant-fishes, *Pomatomidæ* or bluefishes, *Carangidæ* or Cavallas, *Nematistiidæ* or papagallos, *Scombridæ* or mackerels, *Palæorhynchidæ* (extinct), *Lepidopidæ* or scabbard-fishes, *Trichiuridæ* or cutlass-fishes, *Istiophoridæ* or sail-fishes,

Xiphiidæ or sword-fishes, *Coryphænidæ* or dolphins, *Bramidæ* or pomfrets, *Pteraclididæ*, *Stromateidæ* or harvest-fishes, *Icosteidæ* or rag-fishes, *Acrotidæ*, *Zaproridæ*, *Luvaridæ* or Lowars, *Menidæ*, *Leiognathidæ*, *Steinegeriidæ*, and *Tetragonuridæ* or square-tails. The *Grammicolepidæ* perhaps belong in this neighborhood.

The imperfectly known families, *Bathyclupeidæ*, *Stephanoberycidæ*, and *Pempheridæ* have some resemblance to berycoids, but the ventral rays are I, 5.

The great group or super-family *Percoidea* agrees with the mackerel-like fishes in general structure, but the scales are usually coarser and rougher, and the structure less adapted to swift movement. Many members of this group are confined to the fresh waters. The families are *Centrarchidæ*, the sunfishes, *Kuhliidæ*, the silver-bass, *Elassomidæ*, the pigmy-perch, *Aphredoderidæ*, the pirate-perch, *Percidæ*, the river-perch and darters, *Apogonidæ*, the beardless mullets, *Scombropidæ*, *Acropomidæ*, *Serranidæ*, the bass, *Lobotidæ*, the flashers, *Rypticidæ*, the soap-fishes, *Kyphosidæ*, the chopas, *Scorpididæ*, *Theraponidæ*, the slave-fishes, *Hæmulidæ*, the grunts, *Lutianidæ*, the snappers, *Sparidæ*, the porgies, *Cæsionidæ*, *Gerridæ*, the majorras, *Mænidæ*, the picarels, *Sciænidæ*, the drums, *Centropomidæ* (or *Oxylabracidæ*), the robalos, *Polycentridæ*, *Nandidæ*, *Oplegnathidæ* or stone-wall perch, *Sillaginidæ*, *Pentacerotidæ*, *Priacanthidæ*, the catalufas, *Mullidæ*, the surmullets. Remotely allied to the percoid fishes are the *Pseudochromididæ*, the *Opisthognathidæ* or jaw-fishes, the *Malacanthidæ*, the *Latilidæ* or tile-fishes, and possibly the *Cepolidæ* or band-fishes.



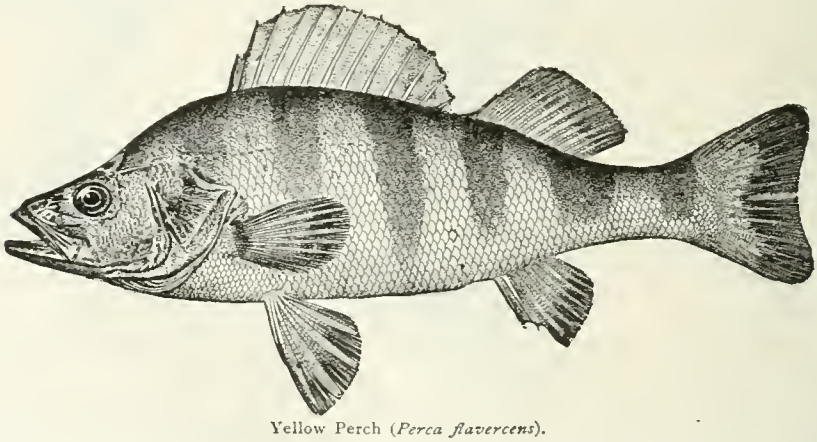
Mackerel (*Scomber scombrus*).

The group or sub-order of *Labyrinthici* comprises fresh-water fishes of the Indian region, with a peculiar apparatus for storing water connected with the gills. The families are *Osphromenidæ* or gouramies, *Anabantidæ* or climbing perch, *Helostomidæ*, *Luciophalidæ*, and *Ophiocephalidæ* or snakehead-fishes.

Another group, called *Pharyngognathi* by Müller, is characterized by the complete union of the lower pharyngeals, a character developed independently in the *Synentognathi* and in some *Sciænidæ*. It contains three sub-orders or super-families. The *Chromides* have a single nasal opening on either side. Of these there are two families, the *Pomacentridæ* or damsel-fishes, chiefly beautiful inhabitants of the coral reefs, and the *Cichlidæ*, river-fishes of the tropics of both continents.

The *Holconoti* comprise the viviparous perch or surf-fishes of California and Japan; one family, *Embiotocidæ*.

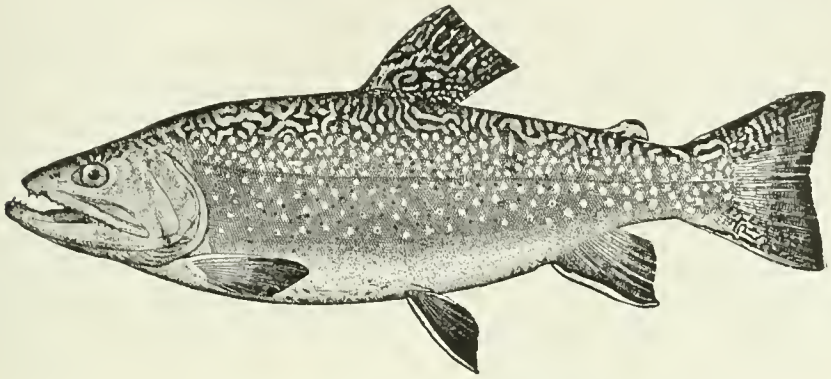
The *Pharyngognathi* proper, having two nostrils on either side, smooth scales and the gills three and one half, constitute four families, *Labridæ*, wrasse-fishes or doncellas, *Odacidæ* *Siphonognathidæ*, and *Scaridæ* or parrot-fishes, in which the teeth are united to form a bird-like beak.



Yellow Perch (*Perca flavescens*).

A large group of more or less related forms, perhaps derived from ancestors of the *Zeoidea* is known as *Squamipinnes* or *Chætodontoidea*. These are characterized in general by the union of the post-temporal or uppermost bone of the shoulder-girdle with the skull. The ventral fins in these fishes have one spine and five (rarely fewer) rays. The scales are small and often rough. The presence in the more primitive forms of 24 vertebræ and five soft rays in the

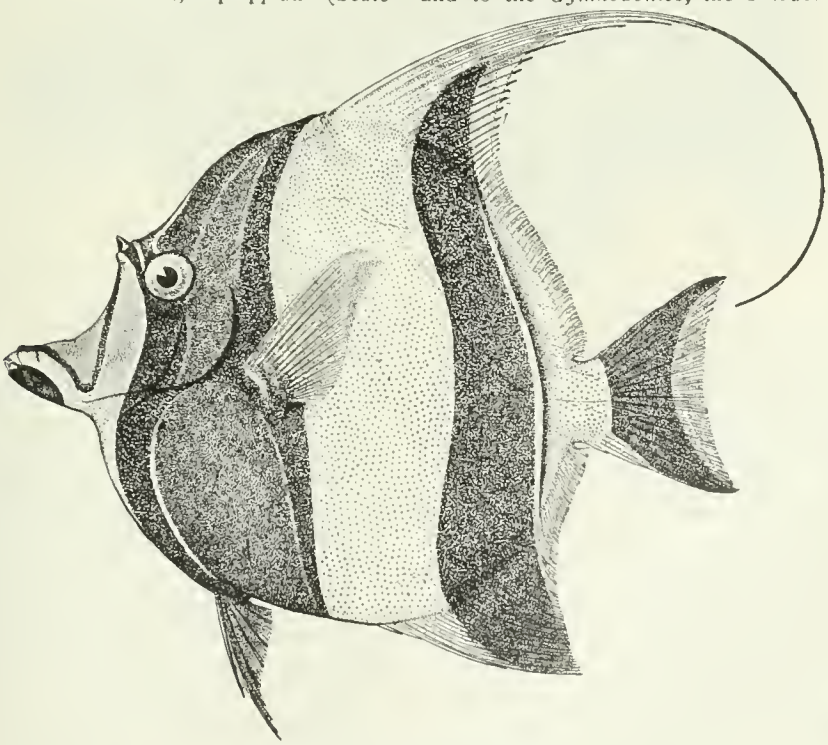
ventrals indicates the common origin of these fishes with the members of the scombroid, percoid, and labroid groups. While the more primitive of the chætodontoid series much resemble primitive members of the other series, the extremes of the former represent a wide divergence, specialization, and degeneration.



Brook or Speckled Trout (*Salvelinus fontinalis*).

The typical families are the *Ilarchidæ* or spade-fishes, the *Chætodontidæ* or butterfly fishes, characteristic of coral reefs and the *Zanclidæ* or Moorish idols. Aberrant types are the *Toxotidæ* or archers, *Ephippidæ* (*Scatophagidæ*), *Antigoniidæ* or boar-fishes, and *Drepanidæ*. Still more aberrant are the *Acanthuridæ*, tangs or surgeon-fishes, the *Siganidæ*, with the last ventral ray spinous like the first. From the tangs are descended the degenerate types known collectively as *Plectognathi*, the bones of the jaws being more or less consolidated. Three sub-orders exist among these forms, *Sclerodermi*, with separate rough scales and separate teeth, the *Ostracodermi*, with the body enclosed in a bony box, and the *Gymnodontes*, with the teeth coalescent into one or two plates in each jaw.

To the *Sclerodermi* belong the three families, *Triacanthidæ*, *Balistidæ* or trigger-fishes, and *Monacanthidæ* or file-fishes. To the *Ostracodermi* belong the *Ostraciidæ* or trunk-fishes, and to the *Gymnodontes*, the *Triodontidæ*, the *Tetraodontidæ* or globefishes, the *Tropidichthyidæ*, the *Chonerhinidæ*, the *Diodontidæ* or porcupine fishes, the *Heptadiodontidæ* (extinct), and the *Molidæ* or head-fishes.



Moorish Idol (*Zanclus cornutus*).

A small group known as the super-family

Cirrhitoidea is characterized by the thickened and unbranched character of the lower pectoral rays, the third suborbital being at the same time not enlarged. Here belong the *Cirrhitidæ*, the *Aplodactylidæ*, the *Latrididæ*, and possibly the *Trichodontidæ*. This group seems to mark a direct transition from the perch-like fishes to those with mailed cheeks.

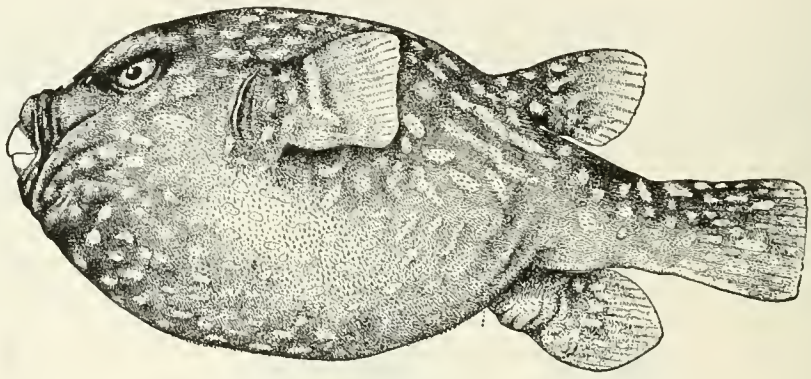
The sub-order of mailed-cheek fishes, *Parcioplitæ*, is characterized by the presence of the suborbital stay, a process extending backward from the third suborbital to or toward the upward limb of the preopercle. This stay is subject to great exaggeration in some forms, while in others it is much reduced. It is, however, always present in these fishes and in no others. In the more primitive types, the ventrals have one spine and five rays. There are 24 vertebræ, and the scales are normally developed. In the extremes there are remarkable cases of specialization on the one hand and of degeneration on the other.

The families of mailed-cheek fishes are the *Caracanthidæ*, the *Hexagrammidæ*, or greenfishes, the *Anoplopomidæ*, or skil-fishes, the superfamily *Trachinoidea* for the most part retain the normal number of ventral rays, the spine, and five soft rays. To this group belong the *Trachinidæ* or weavers, the *Uranoscopidæ* or stargazers, the *Percophidæ*, *Notothæniidæ*, *Pteropsaridæ*, *Harpagiferidæ*, *Chænichthyidæ*, *Champsodontidæ*, *Bovichthyidæ*, the *Draconettidæ*, *Callionymidæ* or dragonets, the *Platypteridæ*, and perhaps the *Chiasmodontidæ* and *Hemerocætidæ*.

Other divergent or aberrant families in this neighborhood are the *Comephoridæ*, or Baikal-fishes, the *Bathymasteridæ* or ronquils, and the *Gadopsidæ*. The *Batrachoididæ* or toad-fishes represent the group *Haplodoci*.

The group *Xenopterygii*, without spinous dorsal and with a large sucking disk between the ventral fins, contains the *Gobiesocidæ* or cling-fishes.

The super-family *Blennioidea* contains the blennies and their relatives, with the ventrals jugular and always few-rayed. Here belong the *Blenniidæ*, *Pholididæ*, *Stichæidæ*, *Xiphasiidæ*, *Cryptacanthodidæ* or wry-mouths, *Anarrhichadidæ* or wolf-fishes, *Ptilichthyidæ*, *Cer-*



A Californian Globefish (*Ovoides setosus*).

Scorpænidæ or rose-fishes and sea-scorpions, the *Platycephalidæ*, the *Bembridæ*, the *Hoplichthyidæ*, the *Cottidæ* or sculpins, the *Cyclopteridæ* or lump-fishes, the *Liparididæ* or sea-snails, the *Rhamphocottidæ*, the *Agonidæ*, sea-poachers or alligator-fishes, the *Triglidæ* or sea-robins, the *Peristediidæ*, and the *Cephalacanthidæ* or flying gurnards. The last three families differ considerably in osteology, and are segregated by Dr. Gill as the sub-order *Craniomi*.

In the sub-order *Discocephali* the spinous dorsal fin is modified to form a sucking disk. This is placed on the head, and is made of two series of flat plates. There is one family, the *Echineidæ* or remoras.

The large family of *Gobiidæ* forms a super-family called *Gobioidea*. The gobies are distinguished by numerous minor traits, the restricted gill-openings, the short spinous dorsal and usual connection of the ventral fins among others. With the gobies may be associated the small family of *Oxudercidæ*.

To the sub-order *Jugulares* we may refer many families which agree in having the ventral fins inserted before the pectorals. The *dalidæ*, *Pataecidæ*, *Gnathanacanthidæ*, and the extinct family of *Blochiidæ*.

Very closely allied to the blennoid series, and also belonging to the *Jugulares*, is the superfamily *Ophidioidea*, differing in the absence of fin-spines. Here belong the *Zoarcidæ* or eelpouts, the *Ammodytidæ* or sand-launces, the *Bleekeriidæ*, the *Brotulidæ*, the *Brotulophidæ*, the *Ophidiidæ* or cusks, the *Fierasferidæ* or pearl-fishes, the *Xenocephalidæ*, *Scytalinidæ*, *Congrogadidæ*, and *Bregmacerotidæ*.

A sub-order of uncertain relations, characterized by the absence of foramen in the hypercoracoid, by the peculiar form of the tail, by the jugular insertion of the ventrals and the absence of spines, is the *Anacanthini*. Here belong the *Gadidæ* or codfishes, the *Merlucciidæ* or hakes, the *Macrouridæ* or grenadiers, the *Ateleopodidæ* and *Bathyonidæ*.

Still more uncertain are the relationships of the sub-order *Tæniosomi*, ribbon-shaped fishes of the deep sea, soft in body and often reaching an immense size. The families are *Trachypteridæ* or deal-fishes, *Regalecidæ* or oar-fishes. The *Lophotidæ* or crest-fishes show some resemblance to these.

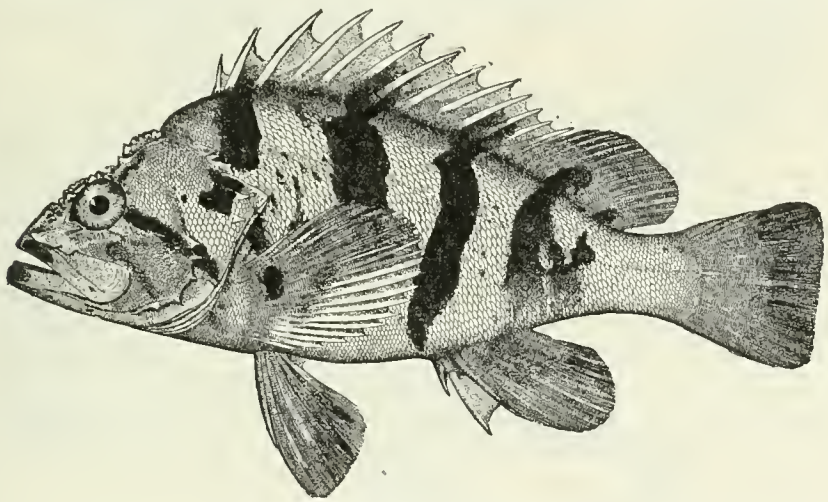
Finally we may close the long series with the order of *Pediculati*. These are jugular fishes, degenerate in structure, the small gill-opening *behind* the pectoral fins. The families are *Lophiidæ*, the anglers, *Antennariidæ* or walking-fishes, *Ceratiidæ* or sea-devils, and *Ogcocephalidæ* or sea-bats.

History of Systematic Ichthyology.— The title of "Father of Ichthyology" is justly given to Petrus Artedi, a Swede, associate and intimate friend of Linnæus. Artedi was the first to recognize the meaning of genus and species in ichthyology, and to supply the outlines of a classification. After Artedi's untimely death (by drowning in a canal in Holland), Linnæus edited his manuscripts, publishing them in 1738, in five parts, as follows: (1) Ichthyological biography; (2) Ichthyological philosophy; (3) Genera of fishes, involving a complete classification of the forms he knew, his genera corresponding to the groups now called families; (4) Synonymy of all species recorded by authors, and (5) Description of all the species actually examined by Artedi. Of true fishes (exclusive of whales) 228 species are recorded by Artedi — a small portion of the 12,000 species now actually known (1903).

But the work of Artedi is masterly in its method and shows a stronger touch than that of any of his successors in ichthyology until the time of Cuvier. In the 'Systema Naturæ' Linnæus did little more for fishes than to substitute binomial names for the descriptive phrases of Artedi.

With the 'Règne Animal' (1817–28) of Cuvier, a new era in zoology began. In this epoch-making work the "Animal kingdom," as the title indicates, was "arranged according to its organization." Comparative structure founds its reflection in the schemes of classification. The application of the principles of morphology was carried out in detail with the fishes in the great 'Histoire Naturelle des Poissons' (1828–49) of Georges Dagobert Cuvier and Achille Valenciennes, long the most valuable general work on fishes. The only general work on fishes since Cuvier and Valenciennes is the monumental 'Catalogue of the Fishes of the British Museum' (1859–70) by Dr. Albert C. L. G. Günther. In this work 6,843 species are described and 1,682 doubtful species are mentioned in foot-notes, the number of species known in 1870 being estimated at 9,000. Since that date about 3,000 have been described, the number of living species at present, according to an enumeration made by Dr. Boulenger, being about 12,000. The number of fossil species known may be estimated at 3,000 to 4,000.

The systematic arrangement of Cuvier was extended and modified by Louis Agassiz to include the multitude of fossil forms made known in his 'Poissons Fossiles.' Still more important corrections and changes in the general scheme of classification were suggested by Johannes Müller, the greatest comparative anatomist of the 19th century. Other valuable contributions to taxonomy have been made by Dr. Günther, Dr. Edward Drinker Cope, and especially by Dr. Theodore Gill, a critical writer who ranks with the first of taxonomists of the age, and whose views have been accepted in substance if not in name as representing our best present knowledge of the origin and relationship of forms among the vertebrate animals.



Black-banded Rock-fish (*Sebastodes nigricinctus*).

The contributions of Geoffroy Saint-Hilaire, Pieter van Bleeker, Carl Gegenbaur, Ramsay H. Traquair, George Albert Boulenger, Louis Dollo, Bashford Dean, Karl Zittel, Arthur Smith Woodward to the systematic arrangement of the higher groups of fishes have also been of great value.

In modern times the students of systematic ichthyology have been very numerous. The local faunal work in various nations has been very extensive. In Great Britain we may note Parnell's 'Natural History of the Fishes of the Firth of Forth' (1838); William Yarrell's 'History of British Fishes' (1859); the earlier histories of British Fishes by Edward Donovan and by William Turton, and the works of Jonathan Couch (1862), and Dr. Francis Day (1888), possessing similar titles. H. G. Seelye has also a useful 'Synopsis of the Fresh-water Fishes of Europe.' William Swainson studied the fishes of Sicily, W. Thompson those of Ireland, and Rev. Richard T. Lowe and J. Y. Johnson have done excellent work on the fishes of Madeira.

In Germany and Austria the chief local works have been those of Heckel and Kner on the fresh-water fishes of Austria (1858), and C. Th. von Siebold on the fresh-water fishes of Central Europe (1863). The two memoirs of Eduard Rüppell on the fishes of the Red Sea and neighboring parts of Africa, 'Atlas zu der Reise im nördlichen Afrika' (1828), and 'Neue Wirbelthiere' (1837), rank with the very best of descriptive work.

In Italy, Charles Lucien Bonaparte, Prince of Canino, has published an elaborate 'Fauna Italica' (1838), and numerous minor papers. O. G. Costa published (about 1850) a Fauna of Naples.

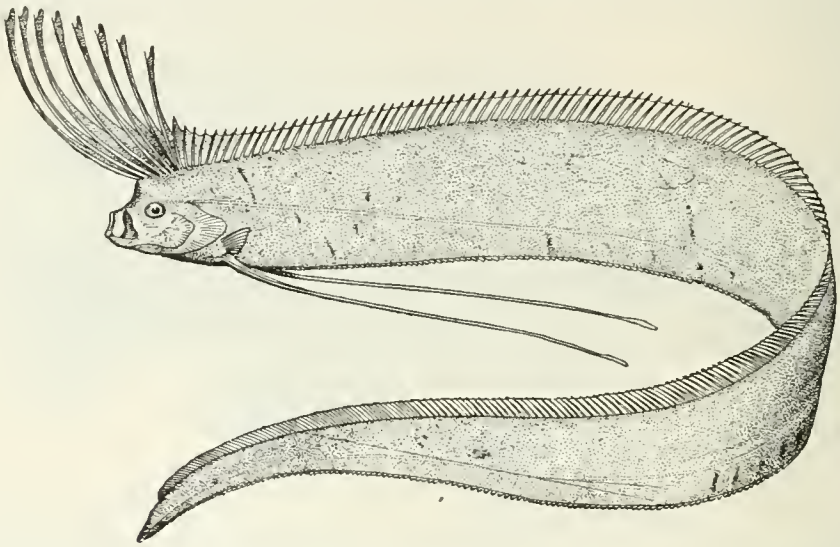
In France, the fresh-water fishes are the subject of works by Emile Blanchard (1866), and Emile Moreau. Léon Vaillant has written on various groups of fishes. The 'Mission Scientifique au Mexique,' by Vaillant and F. Bocourt, is a most valuable contribution to our knowledge of the fishes of Mexico.

In Holland the chief great works have been those of Schlegel and Pieter van Bleeker. Professor Schlegel, of the University of Leyden, described in 'The Fauna of Japonica' the fishes collected about Nagasaki in Japan by Ph. Fr. de Siebold and Bürger.

Pieter van Bleeker (1819–78), a surgeon in the Dutch East Indies, is the most voluminous writer in ichthyology. His chief work is the 'Atlas Ichthyologique des Indes Orientales Néerlandaises,' illustrated by colored plates. The writings of Dr. Bleeker constitute the chief source of our knowledge of the fauna of the East Indies. Dr. Van Lidth de Jeude, of the University of Leyden, is the author of a few descriptive papers on fishes.

The fish fauna of Cuba has been the lifelong study of Dr. Felipe Poey y Aloy (1799-1891), a pupil of Cuvier, for a half century or more the honored professor of zoology in the University of Havana. Of his many useful papers, the most extensive are his 'Memorias sobre la Historia Natural de la Isla de Cuba,' followed by a 'Repertorio' and an 'Enumeratio' on the same subject. Before Poey, Guichenot of Paris had written on the fishes collected in Cuba by Ramon de la Sagra. Philip H. Gosse (1810–88) wrote on the fishes of Jamaica. Much earlier, Robert Herrmann Schomburgk (1804–65) wrote on the fishes of British Guiana. Other papers on the Caribbean fishes were contributed by Johannes Müller and F. H. Troschel, and by Richard Hill and J. Hancock.

Besides the work in South America of Marcgrave, Agassiz, Reinhardt, Lütken, Steindachner, Jenyns, Boulenger, and others already named, we may note the local studies of Dr. Carlos Berg in Argentina, Dr. R. A. Philippi in Chile, and special records of Humboldt, Garman, J. F. Abbott, and others in recent times. Carl H. Eigenmann and also Jordan and Eigenmann have studied the great collections made in Brazil by Agassiz. Steindachner has described the collection of Johann Natterer and Gilbert those made by Dr. John C. Branner. The most recent extensive studies of the myriads of Brazilian river-fishes are those of Dr. Eigenmann.



A Ribbon-fish or Oarfish (*Regalecus*).

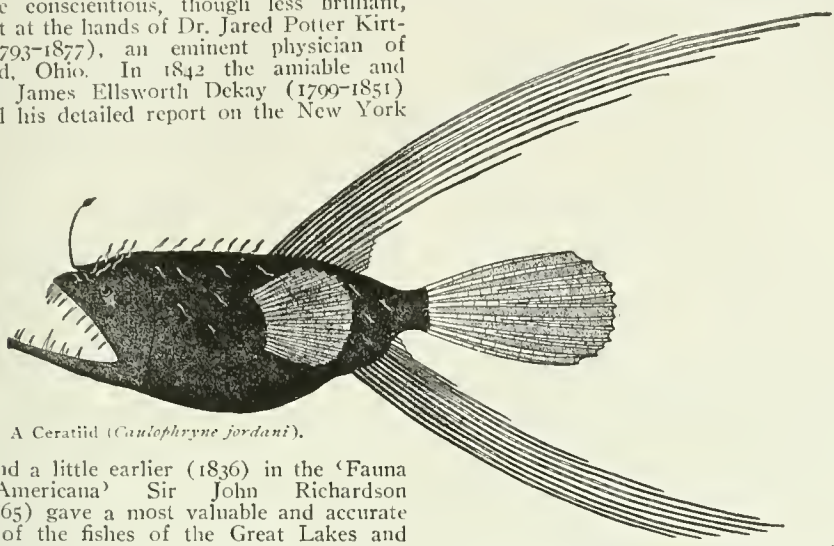
In New Zealand, F. W. Hutton and J. Hector have published a valuable work on the fishes of New Zealand. Later writers have given us a good knowledge of the fishes of Australia. Notable among them are W. Macleay, James Douglas Ogilby, and Edgar R. Waite. Clarke has also written on 'Fishes of New Zealand.'

The most valuable work on the fishes of Hindustan is the elaborate treatise on the 'Fishes of India,' by Francis Day.

The most recent as well as the most extensive studies of the fishes of Japan were made in 1900 by the present writer and his associate, John Otterbein Snyder.

The scanty pre-Cuvieran work on the fishes of North America has already been noticed. Contemporary with the early work of Cuvier is the worthy attempt of Professor Samuel Latham Mitchell (1764–1831) to record in systematic fashion the fishes of New York. Soon after followed the admirable work of Charles Alexandre Le Sueur (1780–1840), artist and nat-

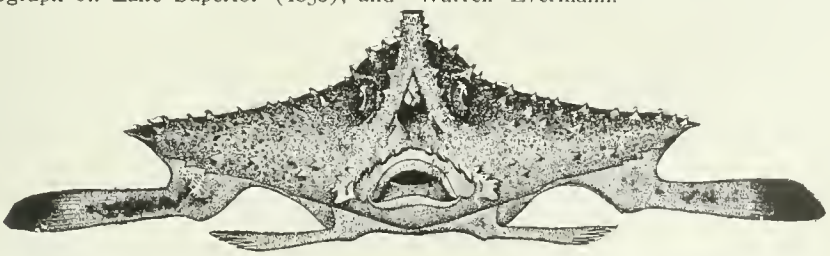
uralist, who was the first to study the fishes of the Great Lakes and the basin of Ohio. Constantine Samuel Rafinesque (1784–1842), the third of this remarkable but very dissimilar trio, published numerous papers descriptive of the species he had seen or heard of in his various botanical rambles. This culminated in his elaborate but untrustworthy 'Ichthyologia Ohiensis.' The fishes of Ohio received later a far more conscientious, though less brilliant, treatment at the hands of Dr. Jared Potter Kirtland (1793–1877), an eminent physician of Cleveland, Ohio. In 1842 the amiable and scholarly James Ellsworth Dekay (1799–1851) published his detailed report on the New York



A Ceratiid (*Caulophryne jordani*).

fauna, and a little earlier (1836) in the 'Fauna Boreali-Americana' Sir John Richardson (1787–1865) gave a most valuable and accurate account of the fishes of the Great Lakes and Canada. Almost simultaneously, Rev. Zadock Thompson (1796–1856) gave a catalogue of the fishes of Vermont, and David Humphreys Storer (1804–91) began his work on the fishes of Massachusetts, finally expanded into a 'Synopsis of the Fishes of North America' (1846) and a 'History of the Fishes of Massachusetts' (1867). Dr. John Edwards Holbrook (1794–1871), of Charleston, published (1860) his invaluable record of the fishes of South Carolina. The monograph on Lake Superior (1850), and was barely finished at the time of his death. The work of Theodore Nicholas Gill and Edward Drinker Cope has been already noticed.

The present writer began a systematic 'Catalogue of the Fishes of North America' in 1875, in association with his gifted friend, Herbert Edson Copeland (1849–76), whose sudden death, after a few excellent pieces of work, cut short the undertaking. Later, Charles Henry Gilbert (1860—), a student of Professor Copeland, took up the work, and in 1883 a 'Synopsis of the Fishes of North America' was completed by Jordan and Gilbert. Dr. Gilbert has since been engaged in studies of the fishes of Panama, Alaska, and other regions, and the second and enlarged edition of the 'Synopsis' was completed in 1898, as the 'Fishes of North and Middle America,' in collaboration with another of the writer's students, Dr. Barton Warren Evermann.



Atlantic Bat-fish (*Malthe vespertilio*).

other publications of Louis Agassiz (1807–73) are well known. One of the first of Agassiz's students was Charles Girard (1822–95), who came with him from Switzerland, and in association with Spencer Fullerton Baird (1823–87) described the fishes from the United States Pacific Railway Surveys (1858) and the United States and Mexican Boundary Surveys (1859).

Most eminent among the students and assistants of Professor Baird was his successor, George Brown Goode (1851–99), whose greatest work, 'Oceanic Ichthyology,' published in collaboration with Dr. Tarleton Hoffman Bean,

As students of the extinct fishes, following the epoch-making 'Poissons Fossiles' of Louis Agassiz, some of the notable names are those of Pander, Asmuss, Heckel, Hugh Miller, and Ramsay H. Traquair. An indispensable 'Handbuch der Palæontologie' is that of Karl A. Zittel, translated by Charles R. Eastman. The most valuable general work is the 'Catalogue of the Fossil Fishes in the British Museum' in four volumes, by Dr. Arthur Smith Woodward, a worthy companion of Günther's Catalogue of the living fishes.

In America Dr. John Strong Newberry, and Professor Edward W. Claypole have studied the

fossil fishes of Ohio. . Edward Drinker Cope and Dr. Joseph Leidy have written on the Eocene and Cretaceous fishes of the Rocky Mountains. Numerous recent papers of importance have been published by Dr. Bashford Dean, of Columbia University, Dr. Charles R. Eastman, of Harvard, and Dr. Oliver Perry Hay of New York. Other important records are due to Orestes St. John, A. H. Worthen, Charles D. Walcott, J. F. Whiteaves, S. W. Williston, and the Redfields, father and son.

Besides all this there has risen, especially in the United States, Great Britain, Norway, Canada, and Australia, a vast literature of commercial fisheries, fish culture, and angling, the chief workers in which fields we may not here enumerate even by name.

See FISHES, GEOGRAPHICAL DISTRIBUTION OF.

DAVID STARR JORDAN,
President Leland Stanford Jr. University.

Ichthyopsida, ik-thĭ-ŏp'sĭ-dạ. See HERPETOLOGY.

Ichthyopterygia. See ICHTHYOSAURIA.

Ichthyornis, ik-thĭ-ôr'nĭs, a genus of fossil carinate birds constituting an order *Ichthyornithes* and family *Ichthyornithidæ*. They were about the size of, and presumably had much the habits and appearance of, rather large gulls, but they had extremely large heads, and both mandibles of the long pointed beak were studded with sharp, backward pointing, snake-like teeth, each set in a distinct socket. These sea-birds fished in the great inland sea which during the Cretaceous Age covered so much of the present western half of the United States, and the remains of two species and of some allied forms, as *Aptornis,* are found in western Kansas, but they became extinct at the end of the period.

Ichthyosauria, Ichthyopterygia, or **Fish-lizards,** an order of reptiles, embracing primitive marine forms with a fish-like body, long head and tail, and no distinct neck, whose remains are found exclusively in the Mesozoic, and most plentifully in the Lias. They varied in length from 3 to about 30 feet, and, as shown by their numerous coprolites (q.v.), fed upon fishes and cephalopods (squids). "The members of this order," remarks Zittel, "differ conspicuously from all living reptiles and are distinguished chiefly by their fish-like form of body, paddle-shaped limbs with numerous oval or polygonal phalanges, large head with elongated rostrum, short amphicœlous vertebræ, and naked integument." They had no dermal armament like crocodiles, but the snout was prolonged, narrow like that of a gavial or a dolphin, the teeth were acutely conical, crocodile-like, and thickly set in a groove without separate sockets; as many as 400 have been counted in a single mouth. The eyes were surrounded by a circle of wedge-shaped sclerotic plates. That they breathed air is plain from the absence of branchial arches, the shape of the hyoid bones, and other evidences of pulmonary respiration; and their viviparous habit is demonstrated by several well-preserved skeletons embracing embryonic remains in the abdominal cavity,—as many as seven young in one case. As regards external form and adaptation to a marine existence, the ichthyosaurus "depart as widely from other reptiles as whales do from land mammals, and occupy as isolated a position." Their composite character is most puzzling to the phylogenist, and nothing is certainly known as to their origin or descent, except that they certainly were modified from terrestrial ancestors. The only family is *Ichthyosauridæ,* which existed from the Lias to the Cretaceous periods, and contains the small-sized and primitive genus *Mixosaurus,* the typical and exclusively Old World genus *Ichthyosaurus, Baptanodon* (q.v.), and *Shastasaurus,* the last two being American in their distribution. Consult: Zittel-Eastmann, 'Text-book of Palæontology,' Vol. II. (New York 1902); Gadow, 'Amphibia and Reptiles' (London 1901).

Ichthyosis, ĭk-thĭ-ō'sĭs, a congenital, chronic disease of the skin characterized by dryness, harshness, and a scaly appearance suggestive of the skin of fish. Nothing is known of its causation; it is not dangerous to life; its cure is impossible.

Iconoclasts, ī-kŏn'ō-klăsts (image-breakers), that Christian party in the Church of the 8th and 9th centuries who would not tolerate images in the churches or places of worship. The Byzantine emperor, Leo the Isaurian, issued an edict in 726 ordering the people to abstain entirely from paying religious reverence to sacred images and a second edict soon after ordered the destruction of the images. This order occasioned commotions, first in the islands of the Archipelago; and as the Popes Gregory II. and III., as well as Germanus, the patriarch of Constantinople, declared the veneration of sacred images to be in consonance with the Church's doctrine and constant practice, and the Emperor Leo refused to recall his edict on their command, they excommunicated him, and his subjects in Italy threw off their allegiance. Thence arose two parties, the Iconolatræ (image worshippers) and the Iconoclasts. Leo's son and successor, Constantine Copronymus, held the same views as his father. He convened a council at Constantinople (754), in which the use as well as the worship of images was condemned. Constantine's son, Leo IV., who ascended the throne 775, followed the same course, but proceeded with more clemency and moderation. On the death of Leo IV., in 780, he was succeeded by his son Constantine, under the guardianship of Irene, mother of the latter, and widow of Leo. Irene favored the orthodox party, and on attaining this position of authority openly avowed her sentiments, and summoned a council to be held in 787, under her protection at Nicæa (Nice) in Bithynia, to pass upon the question at issue. This council condemned the Iconoclasts. Among the Greeks the controversy concerning images broke out anew after the banishment of Irene (802), and lasted about half a century. Her successor, Nicephorus, did not, indeed, remove the images from the churches, but he forbade the adherents of the images from persecuting their adversaries. Finally the Empress Theodora, by a council held at Constantinople (842), restored the worship of images among the Greeks, which was confirmed by a second council, held 869–70, in the same place.

Icteridæ, ĭk-tĕr'ĭ-dē, a family of birds, the American orioles, or hangnests, and blackbirds (qq.v.).

Icy Cape, Alaska, a promontory so named on account of the immense masses of ice by which it is usually surrounded on the north coast, and projecting into the Arctic Ocean west of the Otukah River, about midway between Capes Lisburne and Barrow. It was discovered by Cook in 1778, and was the farthest point that he reached north of Bering Strait.

Ida, (1) the classical name of Kaz-Dagh, a mountain range of Asia Minor, 30 miles southeast of the plain of Troy, with its highest peak, Gargaron (4,650 feet), near the head of the Gulf of Adramyti. In mythology it is famous as the range where Ganymede was stolen; where Paris pronounced judgment on the beauty of the rival goddesses and where the celestials stationed themselves to witness the battles for Troy on the nether plain. (2) The classical name also of a mountain (now Psilotri) in Crete (q.v.), the loftiest (7,500 feet) of the range which traverses the island. The most celebrated legends connected with it are those relating to the infancy of Zeus.

Ida Grove, Iowa, a town, the capital of Ida County, 28 miles north of Denison, on the Maple River, and on the Chicago & N. W. railroad. Farming and stock-raising are carried on largely in the vicinity, and the town has flour mills, grain elevators, and manufactures of machinery, harness, brooms and bricks. Among the municipalized installations is a heating-plant. Pop. (1900) 1,967.

Idaho (Indian, "mountain gem"), a Rocky Mountain State of the United States, next east of Oregon and Washington; its slender northern prong abutting on British Columbia; Montana and Wyoming lie on the east, Nevada and Utah on the south. Capital, Boisé. Length, 485 miles; breadth, 50 to 300; area, 84,800 square miles, 510 water. Pop. (1903) est. 177,000.

Topography.— Idaho is part of the high plateau known as the Great Basin, the main Rockies bounding it on the east and the Cascade Range on the west; it has a mean elevation of some 4,700 feet, but the Bitter Root range in the northeast, extended north by the Cœur d'Alêne and Cabinet, and the Salmon range in the centre, have snow-capped peaks rising in the latter to 12,000 feet, of rugged grandeur. These send out spurs extending west entirely across the State. The Saw Tooth range in the west centre, and the Goose Creek and Bear River ranges in the south, are the other chief ranges, the last two stretching across the State. The river system belongs almost entirely to Columbia, with a basin of some 60,000 square miles within the State; the Snake or Lewis Fork winding across its whole southern breadth and up much of the west boundary for some 850 miles, navigable from Salmon Falls, in the centre, to the entrance of the Powder River from Oregon. The chief Idaho affluents are the Salmon and Clearwater; others are the Boisé and Payette. In the north are the Spokane, Pend d'Oreille, Kootenai, and others, all flowing into the Columbia. A large area in the southern part is drained by streams which sink into the earth not far from the mountains (the "lost river" drainage system), and some reach the Snake River by subterranean channels. A small part of the south drains into Salt Lake by the Bear River. The chief lakes are Cœur d'Alêne, Pend d'Oreille, and Kaniksu, all in the extreme north, and Bear Lake, in the extreme south, half in Utah. The State has many beautiful waterfalls; four of them are on the Snake,— the 210-foot Shoshone Falls, the Twin, Salmon, and American.

Geology.— The most conspicuous physical and geological feature is the vast barren lava plain, some 400 miles by 40 to 60, and about 20,000 square miles in extent, stretching along the Snake River. This is a relatively recent (Tertiary) overflow, which in enormous volume flooded the Pacific Slope to the ocean. The but recent quiescence of the volcanic activity is shown by the geysers, steam and soda springs, and hot pools, still plentiful in this region. It is rich in fossils, including those of the elephant and mastodon, tapir, simiads, and saurians.

Forests.— The timber region occupies about 11,000 square miles, mostly in the northern part, but somewhat in the upper Boisé, Payette, and Weiser valleys; a dense growth mostly of conifers,— white and yellow pine, red cedar, spruce, hemlock, etc. Of the Bitter Root Timber Reservation, 5,400 square miles are in Idaho; the loftier regions, the Alpine Fir district, produce a poor quality. The forest products were over $1,000,000 in 1892.

Climate, Soil, and Agriculture.— The upper levels have the severe winters of the northern latitudes, and heavy snowfalls from the abundant moisture; the lower ones and the sheltered valleys have a very agreeable and equable climate. The rainfall is light and the soil consequently arid in the southern parts, as in the Great Basin generally, the mountains cutting off the vapors from either side; but in the mountainous districts rain is abundant, and agriculture can be carried on without irrigation. Here, however, the sandy and clayey soil makes it less profitable than ranching. In the mountain valleys and along the rivers, where irrigation can be brought into play, and the soil from lava decomposition is exceedingly rich, production is abundant. The chief districts irrigated are those near swift streams with shallow channels, as the headwaters of the Snake in the east and the district around the Boisé and Payette in the west. Over 600,000 acres were irrigated in 1900. In 1902 a great effort was made to increase this by nearly one half, irrigating 276,000 acres in the Snake Valley by two great canals, with power developed at Shoshone Falls. The chief crop is hay, which in 1902 amounted to 955,676 tons, valued at $5,256,218. Next to this was wheat, 6,021,946 bushels, valued at $4,215,362; other cereals, as oats and barley, produced several million bushels, but wheat made about three fourths of the total. The State raised some $4,000 worth of flaxseed. The raising of vegetables to supply the mining towns is assuming importance, and the fruits for which the Pacific Slope is becoming noted are shared by Idaho, chiefly apples and prunes, grown mainly in the Boisé basin,—

the fruit product being about $400,000 a year. The stock-raising interest is very important, nearly half the surface of the State being pasture; but the long severe winters and deep snows make it precarious and costly in precisely the sections best adapted to it, and the northern packers and cattlemen generally winter their stock and draft animals in the Snake and adjoining valleys, where they can live and forage in the winter. The most important item is sheep, which are increasing with great rapidity; from 1,956,467 in 1899–1900, they numbered 4,541,815 in 1902, fourth in the United States. Idaho ranks third in the wool clip, which was 21,639,387 pounds in 1902. The sales of wool and mutton together in 1902 were $4,775,000. There are some 60,000 dairy cows in the State, and nearly half a million meat cattle.

Mining.— Idaho ranks high as a mining State, having rich deposits not only of gold, silver, copper, and lead, but of iron, coal (several new mines opened in 1903), salt of excellent quality, and other minerals. Its lead is the purest in the country, the Cœur d'Alêne district producing about one third of all in the United States. The gold is distributed all through the State; not only in the quartz, but in the gravels of the rivers, especially the Boisé (the most noted), the Salmon, and the Snake. Dredging from the Snake River bed is carried on; but the great event of the last year (1902) was the discovery of immense new quartz ledges in the Thunder Mountain district, which are expected to raise production to the old level of the days before the partial exhaustion of the placers. The yield of metals in 1902 was 92,750 ounces of fine gold, valued at $1,917,150; 5,591,734 ounces of silver, valued at $2,577,789, and 68,953 long tons of lead, besides about 300,000 pounds of copper. The production is restricted by the American Smelting and Refining Company, in order not to glut the market.

Manufactures.— The production of lumber is the chief industry, and flour milling next. Railroad cars, harness and saddlery (always needful in a ranching country), foundry and machine-shop products, furniture, and cigars are also of some importance. There are about 1,600 persons employed in the various manufactures, earning about $1,000,000 yearly in wages; the annual output is about $4,800,000 in value.

Railroads.— The mountainous character of the State, and its slight development, have retarded the construction of means of transportation; the Oregon Short Line through the Snake Valley in the south, and the Great Northern and Northern Pacific through its extreme northern tip, furnish what it has, except a Northern Pacific branch along the Clearwater and a short distance north. There are about 1,400 miles of main track in the State.

Banks.— In 1901 there were 13 national banks in Idaho, with $650,000 of capital stock, $223,354 in outstanding circulation, and $231,650 in United States bonds. There were also ten State banks, three private banks, and a loan and trust company.

Education, Charities, Religion, etc.— The State has over 750 school buildings, and 1,100 teachers, and spends over half-million dollars annually on the schools. Besides ten public high schools, and as many private academies, there are two State normal schools, at Albion and Lewiston, the University of Idaho at Moscow, State Academy at Pocatello, and an agricultural and technological school at Idaho Falls; with two industrial schools at De Smet for the Cœur d'Alêne Indians, academies at Lewiston, Boisé, Genesee, and Pocatello. The State has an insane asylum at Blackfoot, and a State prison at Boisé. In religion, it is predominantly Mormon, with the Catholics next; Methodists, Baptists, and Presbyterians follow in that order.

Indians.— There were 4,226 Indians in the State in 1900, at four reservations, Cœur d'Alêne, Fort Hall, Lemhi, and Nez Percé. But in 1902 the Fort Hall reservation was thrown open to settlement, and about 3,000 settlers took up claims. The Indians at Cœur d'Alêne and Nez Percé are self-supporting.

Government and Finances.— The governor and legislature are elected biennially; sessions are limited to 60 days, except at the members' expense. There are 21 members in the Senate and 46 in the House. The State has one Representative in Congress. After admission as a State a Republican governor was elected until 1897, when the Democrats and Populists united. Until 1902 the Fusion candidates for governor were elected, but in 1902 a Republican governor was elected, and the State is now Republican. The assessed valuation of property (1902) is about $52,000,000, and the bonded debt $443,500.

Population.— 1870, 13,999; 1880, 32,610; 1890, 84,385; 1900, 161,772. There were about 25,000 more males than females, as natural in a mining and ranching State. Only 24,604 were foreign born. The chief place was Boisé, with 5,957 inhabitants; next Pocatello, 4,046. The only others over 2,000 were Moscow, 2,484, and Lewiston, 2,425. There were 21 counties, as follows, with their capitals: Ada, Boisé; Bannock, Pocatello; Bear Lake, Paris; Bingham, Blackfoot; Blaine, Hailey; Boisé, Idaho City; Canyon, Caldwell; Cassia, Albion; Custer, Challis; Elmore, Mountainhome; Fremont, St. Anthony; Idaho, Mt. Idaho; Kootenai, Rathdrum; Latah, Moscow; Lemhi, Salmon; Lincoln, Shoshone; Nez Percé, Lewiston; Oneida, Malad City; Owyhee, Silver City; Shoshone, Wallace; Washington, Weiser.

History.— Idaho was first explored by Lewis and Clark in 1805 (See LEWIS AND CLARK'S EXPEDITION), and was part first of Oregon Territory, then of Utah, Washington, and Nebraska successively. The Jesuit, Father De Smet established a mission at Cœur d'Alêne in 1842, but till the discovery of gold in 1882 it was visited only by hunters and trappers. On 3 March 1883 it was organized as a Territory, but included the present Montana and most of Wyoming. In 1864 Montana was set off, and in 1868 Wyoming with other territory. When gold was discovered at Cœur d'Alêne, in 1882, a great migration set in, and in 1889 a convention framed a constitution and petitioned for admission to the Union. In 1883 all Mormons were disfranchised, a law held constitutional by the United States Supreme Court; but in 1893, on the Mormon Church disclaiming polygamy, the

law was repealed. Miners' strikes in 1892 and 1899 caused great disturbances; in the latter year the United States soldiery were compelled to intervene and imprison a great body of miners.

While Idaho was a territory there were 13 governors, two of whom resigned without acting. Since it has been admitted as a State, five governors have been elected (1903). Equal suffrage has resulted in the passage of several laws intended to safeguard the morality of the people, also laws in favor of liberal education.

LAWRENCE H. GIPSON,
University of Idaho.

Idaho Springs, Colo., town in Clear Creek County; on the Colorado & S. railroad; about 30 miles west of Denver. It is situated in the plateau region of the Rocky Mountains at an elevation of about 7,600 feet. Its cool temperature in summer, the magnificence of the scenery, and the hot and cold soda springs, all tend to make it a famous resort for health and pleasure seekers. In 1859 gold was discovered at Jackson's Bar, now a part of the town of Idaho Springs. This district has been most productive in its yield of gold. Some of the chief industrial establishments of the town are concentrating mills, lumber-yards, machine-shops, and wholesale stores in which are kept supplies for the miners. Pop. (1900) 2,502.

Idaho, University of, the State university situated at Moscow. Work was begun in 1892; it is open to both men and women, and there is no tuition for residents of the State; a small fee is charged to non-residents. The government is by a board of regents; the courses offered include the classical course, general science, civil and mining engineering, and agriculture. The university is also active in organizing farmers' institutes. The annual income, derived mostly from State appropriations is about $60,000; in 1902 the number of students was 347; the number of professors and instructors 30.

Iddesleigh, ĭdz'lĭ, EARL OF. See NORTHCOTE, STAFFORD HENRY.

Ide, Fannie Ogden, «RUTH OGDEN,» American author: b. Long Island 1853. She was married to C. W. Ide, and has written various juvenile stories, among them 'A Loyal Little Red-Coat' (1889); 'A Little Queen of Hearts' (1892); 'Little Homespun' (1896); 'His Little Royal Highness' (1897); 'Tattine' (1900); and 'Loyal Hearts and True' (1900).

Ide, Henry Clay, American jurist: b. Barnet, Vt., 18 Sept. 1844. He was graduated at Dartmouth in 1866. He was a member of the Vermont State Senate in 1882–5, a delegate to the National Republican Convention of 1888, and became a director of several manufacturing and banking establishments. In 1891 he was appointed United States commissioner in Samoa, and later (1893–7) was chief justice of Samoa under the joint appointment of the United States, Germany, and England. He became in 1900 a member of the Taft commission and in 1906 governor-general of the Philippine Islands.

Ide'alism, a metaphysical term, which has been used in various senses as expressing a theory of human perception and therefore of human knowledge. The idealism of Plato is associated with his theory of innate knowledge, supplemented as this is by reminiscence. He taught that there exist eternal forms or ideas in some supramundane sphere; that these forms are archetypes of all that the senses perceive on earth, as a cloud, a tree, a bird. These archetypes are perfect and eternal. Every human soul saw these archetypes in a prenatal state of existence, and recognizes the objects seen on earth by their likeness to the supramundane forms or ideas. Plato has allegorized this theory in his 'Shadows in the Cave.' Mankind are like people so confined in a cave that they can only see straight before them over a low wall which runs across the cave, and separates them from the fire that flings a glare upon the further wall. Between this lighted wall and the fire real things are passing, which the prisoners of the cave cannot see, though they perceive the shadows they cast moving across the lighted surface. Those shadows represent the objects of sense which are phenomena, appearances and not the things, the ideal and eternal things themselves. This was considered to be the theory of Idealism both to the Greeks, and after them, to the mediæval schoolmen. When philosophy became once more a living thing in the 17th century, Descartes arose as the founder of what has been called cosmothetic idealism. The things perceived by the senses, he taught, are not mere shadows, and subjective phenomena recognizable by reminiscence, they have a certain problematical existence, analogous to that which Plato attributes to his perfect and eternal ideas or forms. Kant was a cosmothetic idealist, and he was followed with some modifications by Malebranche. Berkeley came forward with a somewhat rough and ready correction of this hazy and indefinite theory. He cut the knot with the knife of theological dogma. All that we call material, he says, all that strikes our senses as objective, has no real existence whatever. The impressions and conceptions of the human mind are so many subjective creations called up by the direct interposition and an influence of the Supreme Being. Locke in his theory in which common sense and sensualism are combined has survived in modern intellectualism as the philosophic guide of scientific men. Without speculating on the truthfulness of sense, impressions, or the reality of the object, his idealism confines itself to what our senses and perceptions record as fact. An idea to him is nothing more than «whatever is the object of the understanding when a man thinks.» See LOCKE, JOHN; COMMON SENSE.

Ides, īdz, with the Romans, one of the threefold divisions of the month, the other two being the calends and the nones. The name ides, from a verb meaning «to divide,» was given to certain days (see CALENDAR) because they divided the month nearly in halves.

Idiocy, that state of permanent mental deficiency which arises from an affection of the brain either before or at birth or at an early period of life. In other words, it is a state of arrested development of the brain. It is thus distinguished from insanity, which is a condition of mental derangement occurring in the de-

veloped brain. Idiocy is a term of very wide applicability owing to the fact that very many grades of arrested development occur. In a general sense it is applied chiefly to the worst of these forms, while the term Imbecility is used to denote the milder forms. The distinction between idiocy and imbecility is thus a somewhat arbitrary one, for the two conditions shade into each other by almost imperceptible degrees.

Causes.— The causes of idiocy and imbecility are often very obscure. A large proportion of cases are congenital; that is, they arise from causes acting *in utero*. The child is born with a brain already hopelessly impaired. Heredity is thus a very evident cause; defects in the ancestral stock and vices in the parents and near progenitors are doubtless very active. Alcoholism, syphilis, and other toxæmias are certainly among these causes; as well as consanguinity and various diseases in the parents. Injuries to the mother while pregnant may be responsible. The subject of ante-natal disease is still a very obscure one, but evidence is not lacking to show that the fœtus may suffer from disease; and in the critical stage of development of the brain before birth this organ may suffer irreparable damage. The same may be said of the infant and very young child. Injury and disease may act most disastrously upon the undeveloped brain. Thus blows upon and injuries to the head may cause idiocy; also injuries at the time of birth, due to difficulties in the labor, may act. The various infectious diseases of childhood are responsible for some cases; thus scarlet fever, measles, whooping cough, and cerebro-spinal fever have been noted as causes of permanent arrest of development. No doubt in many cases it is difficult or even impossible to detect the active cause.

The following are the most universally recognized varieties of idiocy:

Microcephalus.— In this form the brain and its enveloping skull-case remain abnormally small. In extreme grades the deformity is very striking. These are among the lowest and worst forms of idiocy, and in some cases there is scarcely a spark of intelligence. The patient cannot be said to do more than vegetate. The original cause probably acts in these cases at a very early period in the ante-natal life, and determines an almost complete arrest of brain development.

Hydrocephalus.— In this form the natural cavities or ventricles of the brain become enormously distended and the skull is correspondingly enlarged. The mental impairment varies within wide limits. In some cases the idiocy is almost if not quite as great as in microcephalus, but in other cases a fair degree of intelligence is preserved. There may be also various forms of paralysis, speech defect, epileptoid seizures, and impairment of the special senses. Hydrocephalus probably depends upon closure of one or other of the outlets for the cerebro-spinal fluid between the ventricles of the brain.

Porencephalus.— Occlusion or stoppage of one of the main arteries of the brain at an early period of development, not necessarily ante-natal, may cause such an arrest of development of a portion of the brain-mass that a cavity results, and this is called porencephalus. Such a stoppage of an artery may be caused presumably by injury or by one of the infectious diseases. The symptoms are usually arrest of development of the mental faculties in various degrees, speech defects, paralysis, such as hemiplegia, athetoid movements, and epilepsy.

Mongolian Idiocy.— In some cases the patient bears a real or fancied resemblance to certain racial types, as the Negroid, Mongolian, etc. The latter of these is the best marked, and is now included (after Langdon Down) in most descriptions. The patient's head is deficient in the posterior region; he is of short stature, has oblique and widely separated eyes, and a flattened nose. The attempt is made by some writers to construct special mental features for the Mongolian idiot, but with not very great success. He is simply an idiot, with varying degrees of mental power, and his resemblance to a Calmuck is only accidental.

Paralytic Idiocy.— In the fœtus and in the infant and very young child certain accidents or diseases may cause cerebral hemorrhages, which, just as in the adult, cause in turn various kinds of paralysis. The most common are hemiplegia or paralysis of the arm and leg on one side; diplegia, or paralysis of both arms and legs; and monoplegia, or paralysis of one limb. Such an accident in early life is apt to cause more or less idiocy or imbecility in addition to the paralysis. Some of these patients are also epileptic.

Epileptic Idiocy.— A rather large proportion of feeble-minded children are epileptic. This symptom may be associated with paralysis of various kinds, as already said, or it may not be complicated in any way with marked physical defects. It is only too likely, however, to induce a progressive mental deterioration; or, to speak more accurately for some cases, to prevent a normal brain development. The epileptic child is usually feeble-minded — some more, some less.

Sensorial Idiocy.— In some cases the organs of sight or hearing, or both, may be defective, or undeveloped, and the child's brain does not develop normally merely because it is deprived of these important avenues of sensation. Such children may have more brain capacity than at first appears, and they can be educated. In some cases, however, as in some deaf-mutes, the mental faculties remain more or less undeveloped.

Genetous Idiocy.— Ireland, a well known authority, proposes this term for a certain class of congenital idiots, but it is not very distinctive. It includes feeble-minded children, usually of a rather low grade, who are born with undeveloping brains. The term really applies to many members of the other groups already referred to.

High and Low Grade Idiots. — These terms and intermediate ones are often applied merely to designate feeble-minded children according to the approximate degree of their lack of development. While lacking in scientific precision, such terms denote conveniently various grades of idiocy. There are many idiots who are not microcephalic, nor hydrocephalic, nor Mongolian, nor paralytic, nor epileptic, nor in fact to be included in any usually accepted class, and yet they are unmistakably idiots, and often of low grade. The truth is, that all classifications must remain unsatisfactory until we know more about the causation and pathology of the various forms.

Cretinism.— A highly specialized form of idiocy is cretinism. This is always associated with defect in the thyroid gland; sometimes this

gland is entirely absent, at others it is immensely hypertrophied, and thus practically destroyed. Cretinism is endemic in some countries, as in and about the Alps and Pyrenees. The cretin is both physically and mentally stunted. He is of low stature, of peculiar and characteristic physiognomy, of pale and unhealthy skin, usually beardless, sometimes sexually undeveloped, and with many defects in the skeleton and muscular system. Mentally he is usually an imbecile at least, and in some cases even quite idiotic. Cases vary widely, however, in the degree of feeble-mindedness. In the United States cretinism is only sporadic.

Pathology.— As already indicated, idiocy is due to a wide variety of causes, and therefore its pathology also varies extensively. Among the processes found in the brains of idiots are sclerosis, atrophy, porencephalic defects, old inflammations, occluded and destroyed blood vessels, distended ventricles, and thickened membranes.

Treatment.— In recent years the effort has been made to train and educate the feeble-minded child, and to develop in it as far as possible the defective mental faculties. Training schools for these patients now exist in this country and in Europe, and the most humane and enlightened efforts are being put forth to ameliorate the condititon of these unfortunates, and to render the more hopeful of them useful members of society. It is needless to say, however, that not much can be accomplished with feeble-minded children of low grade, and with the very lowest nothing whatever can be done. With the imbecile and demi-imbecile, however, the results obtained sometimes justify the pains and expense. For the vast majority of feeble-minded children asylum treatment is desirable, even indispensable. These unfortunate patients cannot associate with healthy children, and they require a special environment. The prospect for cure in most cases is quite hopeless. See also Insanity.

Bibliography.— Brush, 'Idiocy and Imbecility' in Keating's 'Cyclopedia of the Diseases of Children,' Vol. IV. (1890); Ireland, 'Idiocy and Imbecility' (1887); Seguin, 'Idiocy, and its Treatment by the Physiological Method' (1866); Tuke, 'A Dictionary of Psychological Medicine' (1892).

James Hendrie Lloyd,
Formerly Neurologist Philadelphia Hospital.

Idol, in a sense now obsolete, or nearly so, an image (Greek εἴδωλον) or likeness of anything; in later and chiefly present signification, any image or likeness of a deity used or designed as an object of worship. By extension the term has also come to be applied to anything which is an object of adoration or of supreme affection or regard. (See next article.)

Idol'atry, the worship of idols in any sense; in the restricted usage ordinarily observed, it is the worship of the Deity or of a deity under a visible form; and from the point of view of the Christian, or any other religion which rejects the worship of images, consists in worshipping as God what is not god. With regard to the origin and character of idolatry, there is a wide divergence of opinion. The Christian religion conceives idolatry as a declension from the one true God, sees in the various forms of heathen worship only more or less complete degradations of an original revelation, and ascribes to it the same origin as to sin. Some philosophical and historical writers, on the other hand, see in idolatry an innate searching after God, and accordingly the first stage of human development, the necessary beginning of a knowledge of God. Idolatry may assume various forms. One nation seeks its god in the powers of nature, worships the heavenly bodies and the elements, and creates for itself a nature-worship; another develops a hero-worship, and a third has merely an animal and image worship, the lowest form of which is fetishism (q.v.). To this last and rudest form of idolatry, that consisting in animal and image worship, the name of idolatry is sometimes confined. See Image Worship.

Idrisi, ĭd'rē-sē, or **Edrisi, Abu-Abdallah Mohammed,** Arabian geographer: b. about 1100; d. about 1180. He studied at the Moorish University of Cordova, traveled through various countries bordering on the Mediterranean, visited France and England, and was then invited to the court of Roger II. of Sicily, where he resided under the patronage of Roger and his successors till his death. He constructed at the request of Roger a terrestrial globe of silver, on which the figure of the earth was shown with as much accuracy as the state of geographical knowledge then permitted. He accompanied this with a descriptive treatise bearing the title 'Nuzhat Almushtâk,' completed about 1150. An old manuscript of this work was discovered at Paris in 1829, and published in a French translation by Jaubert.

I'dyl, or Idyll (from a Greek diminutive meaning a "little form or image"), the name originally and still most usually applied to a short and highly finished descriptive poem, especially if it treats of pastoral subjects. This last circumstance is not, however, an essential character of the idyl. All that is necessary to constitute a poem of this class is that it presents to view a complete picture in small compass, and accordingly the idyl may refer to a great variety of subjects, and the fact that the subjects of idyls are usually pastoral is due to this, that pastoral life, at once simple and picturesque, affords the best material for such short descriptive poems. The term idyl is sometimes used even more extensively but in a manner so capricious as to be incapable of definition.

Iglesias, José Maria, hō-sā' mä-rē'ä ē-glā'-sē-äs, Mexican historian and publicist: b. City of Mexico, 5 Jan. 1823. He studied law in the University of Mexico, was appointed professor of jurisprudence there, became secretary of justice in 1857, and, after service as head of the treasury department, again held the post in 1853–67. In 1868 he was elected to Congress, in the same year was appointed secretary of the interior, in 1873 chosen president of the supreme court. After the fall of Lerdo de Tejada, he established a government which soon yielded to the superior power of Diaz. His publications include: 'Apuntes para la Historia de la guerra entre Méjico y los Estados Unidos' (1852); and 'Revistas históricas sobre la Intervenciòn Francesca' (1870).

Igloo'lik, Canada, a small island in the Arctic Ocean, near the east end of Fury and

Hecla Strait in lat. 69° 21′ N. and lon. 81° 53′ W. It is noted as the place where Parry wintered in 1822–3.

Ignacio (ēg-nä′sē-oo) **Islands,** Mexico, a chain of islands in the Gulf of California, off the Bay of Topolobampo, in the State of Sinaloa. The chief are Macapule and Altamura.

Ignatius, ĭg-nā′shĭ-ŭs, **Father.** See LYNE, JOSEPH LEYCESTER.

Ignatius, Saint, bishop of Antioch, said to have been a disciple of the Apostle John, and on that account reckoned among the number of the apostolic fathers. According to the most trustworthy tradition he was appointed bishop of Antioch 69 A.D., and thrown to wild beasts in the circus of Antioch by the command of Trajan, about the time of that emperor's expedition against the Armenians and Parthians. Another account places his execution at Rome. The year of his death is variously stated; by some 107 A.D. is given as the date, by others placed so late as 116 A.D. By the Greek Church his festival is celebrated on 20 December, by the Latin on 1 February. In the literature of the early Christian church Ignatius holds an important place as the reputed author of a number of epistles. These have come down to us in three forms. In the longest text they are 13 in number, but since the discovery of a shorter text containing only seven (addressed respectively to the Ephesians, Magnesians, Philadelphians, Trallians, Smyrniots, Romans, and to Polycarp), the first has been universally recognized as in great part spurious, some of the letters entirely so, and others containing interpolations. But even in this shorter form the genuineness of the Ignatian epistles has been disputed by numerous scholars. Both of these texts are in Greek, but a still shorter text in the Syriac language, containing only three letters (to the Romans and the Ephesians, and to Polycarp), and even these in a shorter form, was published in 1845 by Cureton. There has been much discussion as to the genuineness of these shorter collections. At present the prevalent belief is that the seven are genuine, and the Syriac an abridgment of them. An edition of the Greek text of the seven epistles was published at Amsterdam by Voss in 1646. An English translation by Archbishop Wake was published in 1693. Lightfoot's edition of the Greek text in his 'Apostolic Fathers, Part II.' (St. Ignatius and St. Polycarp, 1889), supersedes all others, and presents a complete discussion of the subject.

Ignatius of Loyola. See LOYOLA, IGNATIUS OF.

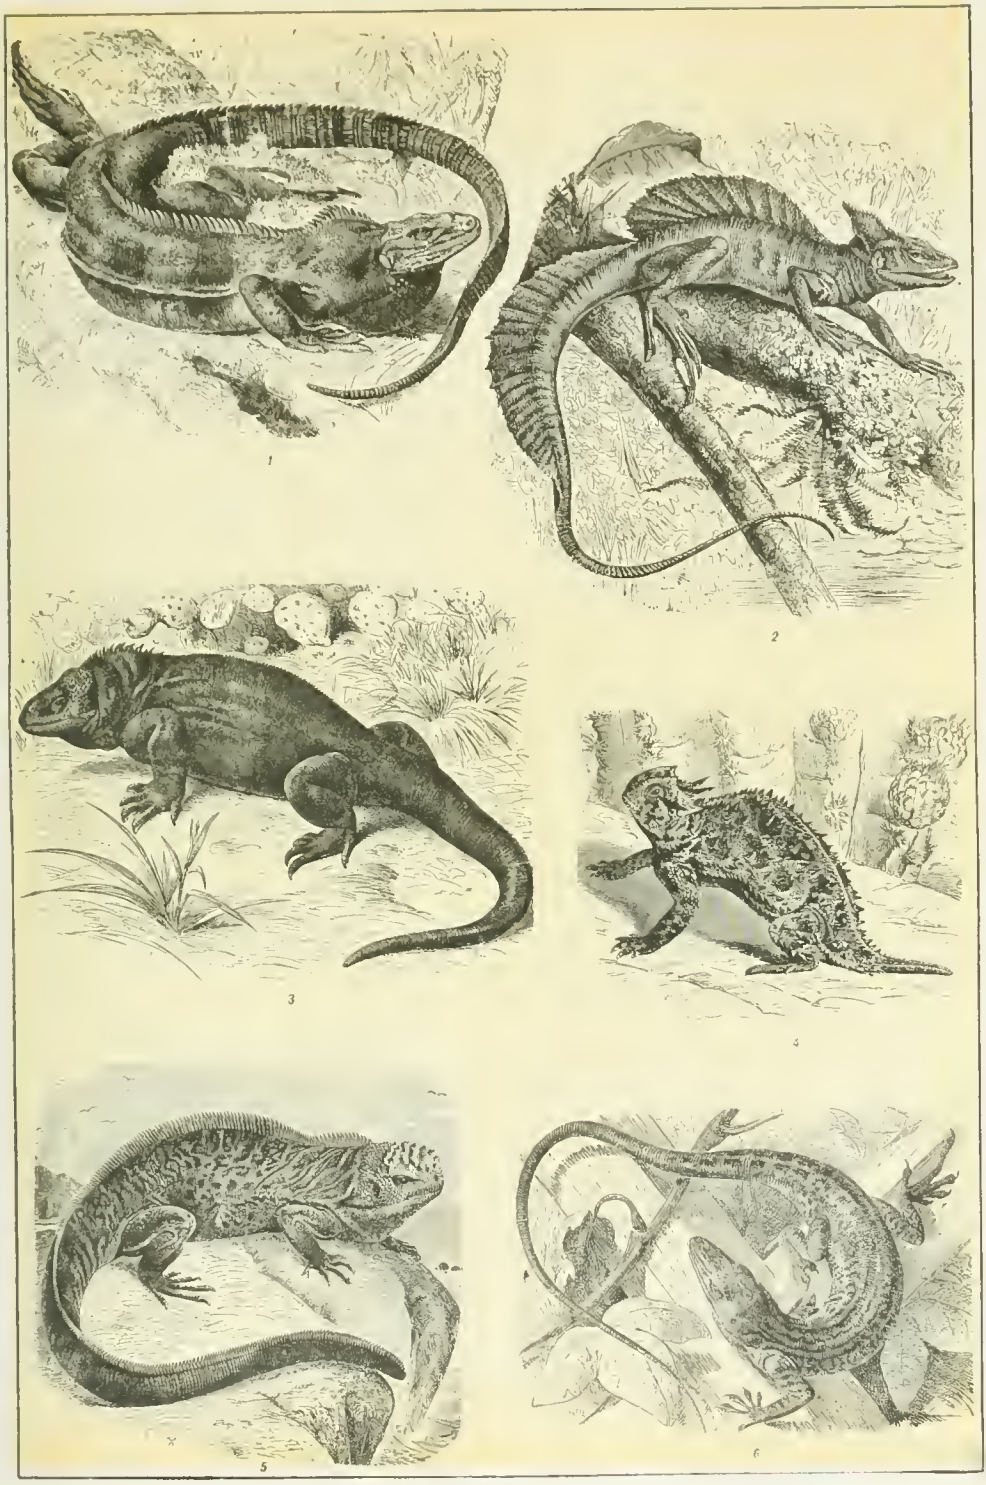
Igneous (ĭg′nē-ŭs) **Rocks,** the term applied in geology to those rocks the special structure of which is due to their having been once in a molten state, from which they were solidified into their present character. They include lava, basalt, granite (qq.v.), etc. Such rocks are not stratified, and may occur in connection with sedimentary rocks of any age, as the igneous rocks have usually been erupted from the heated interior of the earth and forced up toward, sometimes to, the surface. In petrological classification igneous rocks may be grouped under two heads — crystalline and fragmental — although petrography has not yet provided any method of classifying them which can be called complete or systematic. Many of the rocks considered as crystalline are rather to be classed as vitreous or glassy, while some others are partly of non-crystalline materials. Among the crystalline rocks, some of those called orthoclase contain much free silica (see QUARTZ). Most of the crystalline rocks called plagioclase contain less silica than the last-mentioned and a basalt to which close resemblance is found in nepheline and leucite rocks. Of the other crystalline rocks, the olivine and serpentine are generally rather basic, the former often showing much alteration into the latter. The fragmental igneous rocks consist of loose material which has been ejected from volcanic orifices. These rocks are frequently consolidated and, when fine-grained, it is sometimes difficult without the help of the microscope to distinguish them from compact crystalline igneous rocks.

Ignis Fatuus, ĭg′nĭs făt′ū-ŭs (Latin *ignis,* fire, *fatuus,* foolish), an atmospheric light or a luminous appearance sometimes seen in swamplands, in churchyards, and over stagnant waters. The light usually appears shortly after sunset; it is common in the north of Germany, in Italy, in the south and northwest of England, and the west of Scotland, and has been noticed in many other countries in undrained marshy districts.

The appearance generally resembles a flame; seen closely, the color appears as bluish, reddish, greenish, or yellowish, merging into purple, but never a clear white. Sometimes the flame seems fixed in position, shining steadily close to the ground or a few feet above it; again, it appears in rapid motion, sometimes rising high in the air, at others separating into smaller flames, which are seen advancing, retiring, recombining, etc.

Some supposed appearances of the ignis fatuus are probably due to luminous insects, or to the phosphorescence of decaying vegetable matter. By setting all such possible cases aside, both fixed and moving ignes fatui have been proved to exist, although the spectrum of the light seems not to have been fully observed. The common hypothesis that ignis fatuus is the flame of burning marsh-gas, CH_4, is untenable, for although this gas is produced abundantly in many marshy places, it cannot ignite spontaneously. The more plausible suggestion that phosphoretted hydrogen, PH_3, which is spontaneously inflammable, might be produced in churchyards or marshes where there is decaying animal matter does not account for some of the effects observed. The early supposition of a phosphorescent vapor is more reasonable, although excepting that of free phosphorus, which could not occur in nature, no such vapor is known to exist. The phenomenon was undoubtedly more common a century ago than it is now, and its disappearance in many localities may be directly traced to the draining of fens and marshes.

Popular names for the ignis fatuus — Will-o'-the-Wisp, Jack-a-Lantern, Spunkie, etc.— abound in folklore, and the superstitions regarding it are connected with many stories of travelers mistaking the marsh-lights for those of cottage windows, and with tales of evil spirits decoying men into dangerous places, often to their doom.



REPRESENTATIVE IGUANID LIZARDS.

1. Ring-tailed Iguana (Cyclura carinata)
2. Helmeted Basilisk (Basiliscus americanus).
3. Galapagos Land-lizard (Conolophus subcristatus).
4. Horned-toad Lizard (Phrynosoma cornutum)
5. Galapagos Sea-lizard (Amblyrhynchus cristatus)
6. Red-throated Anolis (Anolis carolinensis).

Ignorance of the Law. Every person is presumed to know the laws of his own country, and what is termed ignorance of the law is a lack of understanding of those laws. Such want of understanding furnishes no excuse for their violation, and cannot be pleaded even in extenuation of their infraction. But this presumption does not extend to the municipal laws of countries or States other than that in which a person resides. Such laws are regarded as foreign and a knowledge of them on the part of one who disregards them must be established by proof in the same manner as any other facts are proved. This applies only to a non-resident of such foreign state, and as soon as a person becomes even a temporary resident thereof he is presumed to know its laws and to yield obedience to them. He cannot plead his want of opportunity to become acquainted with them.

Igorrote, ē-gôr-rō'tā, a name given to various wild tribes of Luzon, especially to a people of mixed blood and language living mainly in Venguet province. The name is also more loosely applied to other wild Filipinos.

Igor's (ē'gŏrz) March, Song of, an antique battle song, associated with the name of Igor, Prince of Novgorod, son of Prince Swajatoslaw II. of Tchernigof. Igor, in his fifty-first year is recorded to have engaged in an unsuccessful war with his neighbors (1202), and from that time has been looked upon as the national poet of old Russia, on account of a lyrical epic poem, or ballad, called in Russian, 'Slavo o Polku Igoreve' ('The Song of Igor's March'). It has come down to modern times, somewhat like the songs of Ossian. The poem was probably produced by one of the followers of Igor, and in 1795 was found by Count Alexis Mussin-Putchkin in a cell of a monastery in Jaroslav. It was discovered among some 14th century MSS., and was first published by the Count at Moscow in 1800. The original was lost in the fire of the Napoleonic campaign (1812), which destroyed the Count's fine library. Another copy with many variants was found in 1864 among the papers of Katharine II. and published at St. Petersburg the same year. It has been translated into several European languages. Consult: Wolfsohn, 'Schönwissenschaftliche Litteratur der Russen' (1843); Wjasemski, 'Bemerkungen zum Igorlied' (1875).

Iguana, ĭ-gwä'nä, a large lizard of the typical genus of the family *Iguanidæ*. This family is distinguished by having pleurodont teeth, a thick, villous, nearly immobile tongue, a round pupil, and by various skeletal characters. The 350 species belong to about 50 genera and, with the exception of a few in the Fiji Islands and Madagascar, are confined to America, in the warm parts of which they fairly swarm. Only one species (*Sceloporus undulatus*) reaches as far north as the Middle States. They vary greatly in appearance and habits; most are arboreal, many terrestrial, and one, the Galapagos *Amblyrhynchus*, is even marine; the majority eat insects, but some are herbivorous. The true iguanas, of which *I. tuberculata* is the best known, are rather widely distributed through the West Indies, Central and South America. Owing to the high crest or fringe which extends along the back and tail, the deep, fringed, gular pouch, and the loose-fitting skin, these animals present a remarkable appearance. The trunk and tail are covered with small granule-like scales, and the head with larger plate-like ones; the feet are large and powerful; the tail very long, slender, and compressed; and the teeth high and finely serrated. A length of five feet or more and a weight of 25 pounds is commonly attained. The iguanas are arboreal, their mottled green color serving admirably to conceal them among the foliage; but when alarmed they have the habit, remarkable in a lizard, of retreating into the water of the streams along which they live. The 20 or 30 large eggs are deposited in a burrow usually dug in the bank of a stream or sometimes in a hollow tree. Notwithstanding its formidable size and aspect, the iguana is a timid, harmless creature, and the stories sometimes told of its ferocity are pure fabrications; moreover it is purely vegetarian in its diet. The flesh is a favorite article of food with the natives, and many travelers have pronounced it to be white, tender, and sweet, and is regularly brought to the markets. Consult Wallace, Müller, Bates, Belt, Gosse, and other authorities on South and Central America. See Lizard.

Iguan'odon, a dinosaur (q.v.).

Iguvium. See Eugubine Tables.

Ik Marvel. See Mitchell, D. G.

Ilagan, ē-lä'gän, Philippines, pueblo and capital of the province of Isabela, Luzon, situated on the Grande de Cagayuan River, 84 miles from its mouth at its junction with the Pinacanauan, 275 miles northeast of Manila. It has road and water connections with Bayombong and Manila; it is the trade centre for a large agricultural region, and also the industrial centre of the province. Pop. 13,800.

Iles, George, American author: b. Gibraltar 20 June 1852. He received a secondary education in Montreal, and from 1887 was employed in literary work in New York. His original works include: 'A Class in Geometry-Lessons in Observation and Experiment' (1894), and 'Flame, Electricity, and the Camera' (1900). He also edited: 'The Reader's Guide on Economic, Social and Political Science' (1891; with R. R. Bowker); 'A List of Books for Girls and Women and their Clubs' (1895; with A. H. Leypoldt); and 'A Bibliography of Fine Art' (1897), and gave $10,000 to the American Library Association to defray the cost of 'The Literature of American History' (1902), a bibliographical guide which appeared under the direction of the publishing board of the association.

I'lex, a tree often mentioned in the Latin classics, the evergreen oak or holm-oak (*Quercus ilex*). It is a native of the Mediterranean region, and often attains large dimensions. In general it grows singly or in small groups, and especially near the sea. Its leaves vary much in size, and from being very spiny at the edge to perfect evenness. Where it is indigenous, its astringent bark is used for tanning hides. Its wood is hard, heavy, and durable, and is useful for axles, pulleys, screws, etc. In modern botany Ilex is the generic name of the holly. See Aquifoliaceæ.

Ilfracombe, ĭl'fra-kōm, England, a seaport and fashionable health-resort in North Devon,

on the Bristol Channel, 41 miles by rail northwest of Exeter. It has a fine harbor and promenade, and the town built in terraces on a hill, is noted for its picturesque situation and the beauty of the surrounding scenery. Pop. (1901) 8,557.

Ili, il'ē, a river of Central Asia, flowing partly in China and partly in Russia. It is formed in Chinese Kuldja by two streams, the Tekes and Kunges, rising in the Thian-shan Mountains, and flows west, falling into Lake Balkash by several mouths after a course of 800 or 900 miles, half of which is navigable.

Iliad, in Greek literature, a celebrated epic poem, consisting of 24 books. Its composition is generally ascribed to Homer, of whose parentage, birth, and life nothing is known for certain. It is, however, a matter of dispute as to whether the poem is a homogeneous whole, or a series of ballads or rhapsodies on different episodes in the Trojan war, united into a continuous poem. It is further doubtful whether, in the latter case, the union was made by Homer himself, or by some person after his time. It is said that Pisistratus, tyrant of Athens, first collected and arranged the 'Iliad' and 'Odyssey' in the form in which we now have them. The chief subject of the poem is the wrath of Achilles, and the consequent troubles thence arising, whence we have the phrase *Ilias malorum* = an Iliad of woes or troubles, a world of disasters. The reader of the poem is assumed to know that the beautiful Helen has been carried off by Paris from her husband Menelaus. The action of the poem is confined to the 10th and last year of the siege of Troy. See HOMER.

Il'ion, N. Y., village, Herkimer County; on the Mohawk River, the Erie Canal, and on the West Shore and the New York C. & H. R. R.R.'s; about three miles west of Herkimer and 12 miles southeast of Utica. Ilion is in the vicinity of the locations of some of the old "castles" of the Indian tribes who inhabited the Mohawk valley. White people lived here in the early part of the 19th century, but no permanent settlement was made until 1828. It is situated in an agricultural county, but the village is noted for its manufacturing industries. The chief manufactures are typewriters, firearms, sewing-machines, filing-cases, bicycles, knit goods, flour, and some dairy products. Its export trade consists chiefly of the manufactured articles and farm products. It has a public library containing about 11,500 volumes, and a number of fine public buildings. Pop. (1890) 4,057; (1900) 5,138.

Ilini'za, or **Ilinisa**, a mountain of Ecuador, 20 miles south-southwest of Quito. It is capped by two peaks, the southernmost, as determined trigonometrically by Reiss and Stübel, being 17,406 feet high. Iliniza is presumably an extinct volcano, but there is no record of an eruption. The upper portion is covered with perpetual snow, and usually cloud-capped.

Ilissus, il-is'us, a small river in Greece, flowing through Athens, famous in the classical age, but now unimportant and often wholly dry.

Ilithyia, il-ith-ī'ya, in Greek mythology, the goddess who assisted women in childbirth. In after times she was almost identified with Artemis.

Ilium, or **Ilion**, a name of Troy, in Greece, which was founded by Ilus.

Iliyats, il'ē-yats, a nomadic Mohammedan race of Persia, Khiva, and Turkestan. The name Iliyat is the plural of *iel* (eel), a tribe equivalent to the Arabic *kabilah*. The Iliyats are mostly of Turkish, Arabic, and Kurdish descent, and form an important portion of the population of Persia and adjacent countries; their actual numbers are not known, but it is said that the Iliyat tribes tributary to Khiva number 195,000. They live in tents and have no settled habitations. They are of the Sunni sect, but are not very strict. The women are said to be chaste, and many of the best families in Persia are of Iliyat origin.

Illampu, or **Sorata**, a mountain of Bolivia, in the eastern Cordillera, overlooking Lake Titicaca; 50 miles north-northwest of La Paz. It is 21,484 feet in height, and is believed to be the highest mountain of the Bolivian Andes, though this distinction is also claimed for Illimani (q.v.); it is probably exceeded by the Cerro de Huascan in Peru and by Aconcagua in Chili. Illampu is a magnificent mass, with three principal peaks. Seen from Titicaca it is the grandest mountain in America. It has never been scaled.

Ille-et-Vilaine, ē-lā-vē-lān', France, a maritime department, formed out of the northeast portion of the old province of Brittany; area, 2,596 square miles; pop. 622,039, mostly of Celtic race. It is watered chiefly by the Vilaine and its tributary, the Ille, which unite near Rennes, the capital of the department. Ille-et-Vilaine consists of a granite plateau traversed by ranges of low hills. It is agricultural, cultivation having been greatly improved during recent years. The cider of this district is the best in France; the butter of Rennes is celebrated; the horses of the department are noted for their endurance, and are in great request for the army; and bee keeping is prosecuted. Iron is mined; slates are quarried; and salt is extracted. Saint Malo is the principal seaport.

Illegit'imacy, the legal status of children born out of wedlock, is a subject discussed under three points of view, moral, legal, and economic. As to what constitutes illegitimacy, is variously defined in different countries where great variety exists both in theory and practice. As to the legal status of illegitimate children from the moral point of view, see BASTARD.

Only in a few European countries are statistics available to show the extent of illegitimacy, and there are no statistics in Canada. In the United States there seems no efficient national system of registration of marriages and births. Some of the individual States record the illegitimate births, but the figures are misleading, because incomplete. Thus, the State of Indiana a few years ago, returned 38,370 legiti-

mate and 560 illegitimate births — the illegitimate being only about 1.40 of the whole.

In the following table is shown the comparative prevalence of illegitimacy in the principal European cities:

ILLEGITIMATE BIRTHS TO EVERY 1,000 BORN.

Vienna 449	Leipzic 211	Ghent 144
Prague 439	Dresden 208	Hamburg ..138
Munich 439	Milan 204	Frankfort ..132
Stockholm ..396	Rome 194	Turin 132
Moscow 300	Venice 189	Antwerp ...129
Budapest ...299	Breslau 186	Cologne ...124
Copenhagen 279	Bucharest ..175	Palermo ...101
Paris 268	Liége 174	The Hague. 99
St. Petersh'g 236	Christiania ..162	Naples 86
Trieste 211	Berlin 154	Rotterdam . 70

None of the above figures are presented as absolutely accurate. They can only be approximate in the best case, for in every country there must always be a large number of bastards who either are not registered at all, or who are registered as legitimate. But as far as they go the figures are instructive. They do not, however, enable one to form any conclusion as to the causes of illegitimacy in respect either of religion, of education, of industrial occupation, or of distribution of population. Neither can any theory be well evolved from a racial basis.

From the only available statistics the following table has been prepared showing illegitimacy in various countries, from 1881 to 1900:

	Per cent of illegitimates to total births.		Per cent of illegitimates to total births.
England and Wales.	4.6	Portugal	14.00
Scotland	8.34	Roumania	5.00
Ireland	2.9	Russia	3.00
Austria (average)...	14.89	Spain	5.40
Lower Austria	26.00	Sweden	14.88
Upper Austria	20.00	Norway	7.90
Dalmatia	3.50	Switzerland	4.80
Hungary	8.00	Brazil	25.00
Belgium	9.30	Canada	....
Denmark	10.00	Costa Rica	24.00
France	8.20	Guatemala—Whites..	50.00
Germany (average)..	9.47	Indians..	25.00
Upper Bavaria....	15.67	New South Wales...	4.65
Prussia	8.24	Victoria	4.78
Alsace-Lorraine ..	8.10	Queensland	3.97
Greece	1.60	West Australia	3.95
Holland	3.22	Tasmania	3.40
Italy	7.45	New Zealand	3.12

In Scotland, where education is general, and thrift national, the rate of illegitimacy is notoriously high. And, as regards morals, it should be remembered that a high percentage of illegitimacy may mean that there is little or no prostitution. In Europe, generally, although not universally, there seems a tendency to decrease in the rate of illegitimacy; but how far that appearance may be due to moral causes it is impossible to say.

Illimani, ēl-yē-mä'nē, Bolivia, a volcanic mountain mass of the East Andean Cordillera, about 20 miles south of La Paz. It is a serrated ridge with four principal peaks, the loftiest of which, Condor Blanco, is 21,149 feet above sea-level. Illimani signifies "snow-mountain"; the line of perpetual snow commences at 15,000 feet, and there are glaciers on the north side at an elevation of 16,350 feet. At an altitude of 15,950 feet there is a considerable lake also bearing the name of Illimani. Among the first Europeans to make the ascent of the highest peaks are Wiener, Grumbhow, and Ocampo in 1877 and Sir Martin Conway in 1898.

Illinois, ĭl-lĭ-noi' or -noiz', the name given to a confederacy composed of five distinct Indian tribes, who at one time occupied what is now the State of Illinois and parts of Wisconsin, Missouri, and Iowa. The tribes were the Michegamia, Peoria, Cahokia, Kaskaskia, and Tamaroa. The confederacy was most powerful and many attempts were made to secure by war the lands of the Iroquois. In 1675 Marquette visited the Illinois tribes and established missions among them. In 1769 a member of the Kaskaskia tribe murdered Pontiac, the Indian chief, for which offense the Lake tribes destroyed the Kaskaskia and killed many of the members of the other tribes of the confederacy. In 1840 the remnant of the Illinois tribes was removed, by the government, west of the Mississippi. The few now in existence are in the Indian Territory.

Illinois, the eighth State admitted into the Federal union, and since 1890, the third in population. It is bounded upon the north by Wisconsin, upon the east by Indiana, upon the south by Kentucky, and upon the west by Iowa and Missouri. It is separated from the two last named States by the Mississippi River; by the Wabash and the Ohio from Indiana; and by the Ohio from Kentucky. Its water courses flow generally from the north and northeast, to the southwest and south. Its soil consists of a rich black loam, or mold, underlaid by drift deposits in many places of great depth.

Topography.— By the enabling Act of Congress by virtue of which the State was organized, its boundaries were fixed as follows: "Beginning at the mouth of the Wabash River, thence up the same, and with the line of Indiana, to the northwestern corner of said State; thence east with the line of the same State to the middle of Lake Michigan; thence north along the middle of the lake to north latitude 42° and 30'; thence west to the middle of the Mississippi River, and thence down along the middle of that river to its confluence with the Ohio River, and thence up this latter river along its northwestern shore to the beginning." The total land area of the State is 56,000 square miles — 35,840,000 acres; its extreme length 385 miles, and extreme breadth 218 miles. With the exception of Georgia its area is greater than that of any one of the original States of the Union. It comprises a territory larger than England; larger than Belgium, Switzerland and Holland united. Illinois is no longer in the class of States denoted "western" upon the old maps, but is now chief of the great interior States of the Union. With two exceptions — Louisiana and Delaware — it is the most level of the States. Its greatest elevation is 1,150 feet above the sea, and its mean elevation 550 feet. The greater part of Illinois consists of level or slightly undulating prairies; a portion of the extreme northwestern part of the State is hilly, and there are occasional bluffs upon the Illinois and Mississippi rivers. The counties lying between East St. Louis and the Wabash River are the great apple growing region, and thence southward to its border other fruits are grown in large quantities. Of its total population in the year 1900, 2,459,638,

or 51 per cent reside in its seventy principal cities and towns.

Population.— In 1810, one year after its organization as a territory, the population of Illinois was 12,282; in 1820, two years after its admission its population was 55,211, and in rank it was the 24th State in the Union; in 1830, population 157,445 and its rank the 20th; in 1840 population 476,183, and rank the 14th; in 1850 population 851,470, and rank the 11th; in 1860, population 1,711,951, and rank the fourth; in 1870 population 2,539,891, and rank the fourth; in 1880 population 3,077,871, and rank the fourth; in 1890 population 3,826,351, and rank the third; in 1900 population 4,821,550, and its rank still remains the third. Of the aggregate population given for the year 1900, 85,078 are negroes, 1,538 Mongolian, and 16 Indian; 3,854,803 of the population of the State are natives, and 966,747, foreign born. The excess of the male over the female population of the State as shown by the last census is 124,014. The population above the age of 10 years is, 3,727,745; of this number 1,804,040 are engaged in gainful occupations; 462,781 in agricultural pursuits; 96,321 in rendering professional service; 366,342 in domestic or personal service; 397,046 in trade or transportation; and 481,550 in manufacturing or mechanical pursuits. The total number of dwellings in the State is 845,836, and of families 1,036,158.

Cities.— The following cities of the State have each a population exceeding 10,000, viz.: Chicago, 1,698,575 (as shown by census of 1900, now exceeding 2,000,000 as appearing by local census reports of later date); East St. Louis, 29,655; Joliet, 29,353; Peoria, 56,100; Quincy, 36,252; Rockford, 31,051; Springfield, 34,159; Alton, 14,210; Aurora, 24,147; Belleville, 17,489; Bloomington, 23,286; Cairo, 12,566; Danville, 16,354; Decatur, 20,754; Elgin, 22,433; Evanston, 19,259; Freeport, 13,258; Galesburg, 18,607; Jacksonville, 15,078; Kankakee, 13,595; La Salle, 10,446; Moline, 17,248; Ottawa, 10,588; Rock Island, 19,493; Streator, 14,079. Fifty-seven other cities in the State have a population each, exceeding 3,000. The land surface in square miles of the largest county in the State, McLean, is 1,166; while that of the smallest, Putnam, is 176.

Manufactures.— The development of manufacturing in the State is unprecedented. This is due in large measure to its transportation facilities. There were 10,997 miles of railroad in the State in the year 1900, a mileage greater than that of any other State. Illinois now ranks third in the value of its manufactured products —the gross value thereof for the last mentioned year being $1,259,730,168. The greatest number of wage earners employed in manufacturing establishments at any one time in the year 1900, was 528,099, or 11 per cent of the total population of the State. As tersely stated in the last census report: "The communication with the East afforded by Lake Michigan and its connecting waters early made Chicago the great distributing centre for eastern products to all points in the West and Southwest, while the Mississippi River bordering the western portion of the State afforded communication with the entire Mississippi Valley. Superior railroad facilities were a direct result of the trade routes established by these operations for water transportation; for when railroad building began Chicago was the natural focusing point, and to reach that city all sections of the State were traversed and opened up to settlement." It holds the first place in the States of the Union in the manufacture of agricultural implements; its proportion of the entire capital invested in this industry in the United States being 39 per cent. It leads in the production of alcoholic liquors; the output in 1900 was 32,508,435 gallons. This industry is concentrated in a few large establishments located principally in the city of Peoria. An important factor to be considered in this connection, is the abundant supply of bituminous coal in many parts of the State. In 1900, the 24 leading industries of the State embraced 8,209 establishments; capital used $477,485,672; wage earners employed, 219,415; value of their products for the year mentioned was $810,636,482.

Agriculture.— Illinois takes high rank as an agricultural State; 32,794,728 acres — or something over 91 per cent of its total land area — are included in farms. The total number of farms in the State as shown by the last official report is, 264,151; the estimated value being $1,765,581,550; of this amount 14 per cent represents the value of buildings, and 8.6 per cent the value of the land, and other improvements; the value of farm implements and machinery in June 1900 was $44,977,310, and of live stock $193,758,037. The total value of farm products for 1899 exceeds that of the year '89 by $160,890,598. The average size of farms for the State is 124 acres. The larger farms are generally in the north and the smaller in the extreme southern portion of the State. The value of all live stock on farms in June 1900 was $193,758,037; of this amount 36 per cent represents the value of horses; 24 per cent that of neat cattle other than dairy cows; 17 per cent that of dairy cows, and 12 per cent that of swine. Twenty-eight counties each reported more than $1,000,000 received from the sale of live animals for the year last named. Of the total area of cereals in the year 1899, 61 per cent was devoted to corn, 27 to oats, 10 to wheat, and the residue principally to rye, barley and buckwheat. Some idea of the enormous yield of what is known as "the corn belt" can be gleaned from the following: for the year 1899 the corn product of the county of Iroquois exceeded 12,000,000 bushels; that of the counties of La Salle and Livingston, each exceeded 13,000,000, while the counties of Champaign and McLean each produced over 15,000,000 bushels. Twenty-seven other counties produced from 5,000,000 to 10,000,000 bushels of corn each. In the decade 1890 to 1900 the apple trees in the State increased 100 per cent in number, and of some other varieties of fruit the increase was even greater. Of the total number of fruit bearing trees in the State in 1900, 74 per cent were apple, 13 per cent peach, and 5 per cent pear trees. Apples were grown generally throughout the State, but the four counties of Clay, Jefferson, Marion, and Wayne produced one fifth of the entire amount. The entire vegetable product for the year 1899 exceeded $10,000,000 in value; of this amount 45 per cent represents the value of potatoes. The small

fruits were grown upon 56,763 farms. Of late years there has been a steady decrease in tobacco production; in the year 1899 the total in tobacco being 2,242 acres; the total value of the production being $85,411; Saline County in the extreme southern part of the State taking the lead and producing near one third of the entire amount. During the last decade the broom corn product of the State has increased almost four fold; the total value of this product for the year 1899 was $2,357,066; five sixths of the amount produced was in the east central part of the State in the five counties of Coles, Douglas, Moultrie, Edgar, and Cumberland. Sugar beets were grown in 15 counties in the year 1899, 1,370 acres being devoted to this production, and the value of the total product being $36,223. The value of nursery stock sold in the last named year was $578,306; area in cultivation 7,760 acres, its valuation $1,442,220. The area devoted to the cultivation of ornamental plants and flowers for the year 1899 was 679 acres; the value of the product $1,894,960. The total expenditure for labor on farms in Illinois for the year 1899 was $22,182,550; this included the value of board furnished and averaged $84 per farm. The gross value of the agricultural products of the State for 1900 was $345,649,611 — placing it second in rank.

Rivers.— The Illinois, the principal river of the State is formed by the junction in Grundy County, 40 miles southwest of Chicago, of the Kankakee and Des Plaines. The last named river takes its rise in Wisconsin and flows in a southerly direction, while the head waters of the Kankakee are in northern Indiana. The Illinois empties into the Mississippi after a somewhat tortuous flow of near 500 miles, at a point 40 miles above the city of St. Louis. The Illinois is navigable for 245 miles, and is connected by the Illinois and Michigan canal with Lake Michigan. Other rivers in the State are the Kaskaskia, which flowing in a southwesterly direction empties into the Mississippi near the ancient village of Kaskaskia, the first capital of the State; Rock River, which flowing in a southwesterly direction from Wisconsin empties into the Mississippi not far from the city of Rock Island; of other smaller streams, are the Little Wabash and the Embarras, which flow into the Wabash in the southeastern part of the State, and the Vermilion and the Fox, tributaries of the Illinois.

Education.— Illinois has an excellent public school system. The number of persons in the State between the ages of 6 and 21 years 30 June 1902, was 1,601,175; of these, 811,724 were males, and 789,451 females. The number of persons enrolled in the schools during the year ending as above was 971,841; of these, 489,109 were males, and 482,732 females. The average daily attendance was 765,057. The number of school houses 12,865. The estimated value of the school properties is $52,764,922; this includes buildings, grounds, libraries and apparatus. The number of male teachers employed in the common schools in 1902 was 6,800; of female teachers 20,386; total 27,186. The amount expended for the years 1901–2 for the salaries of teachers and superintendents was $12,132,075. The Normal Universities of the State, five in number, are located as follows: the State Normal University at Normal; the Southern Illinois State University at Carbondale; the Northern Illinois Normal School at De Kalb; the Eastern Illinois Normal School at Charleston, and the Western Illinois Normal School at Macomb. These universities are appropriately located for the convenience of their patrons, and the attendance is large. The first to be organized was the State University at Normal, and the total number of students in attendance there for the years 1901–2 was 1,529. In addition to the above is the Chicago Normal School, which has since 1896 been maintained by appropriations made by the Chicago Board of Education. In large measure the teachers in the public schools of the State have received their training in some one of these Normal Schools. The purpose of the Normal Schools of the State will appear from the following clause in the organic act of one of the last to be organized: "The object of the said Northern Illinois State Normal School shall be to qualify teachers for the common schools of this State by imparting instruction in the art of teaching in all branches of study which pertain to a common school education, in the elements of the natural and of the physical sciences, in the fundamental laws of the United States and of the State of Illinois, in regard to the rights and duties of citizens." The University of Illinois (q.v.) is located at Urbana, and has in its various departments a total of near 3,000 students.

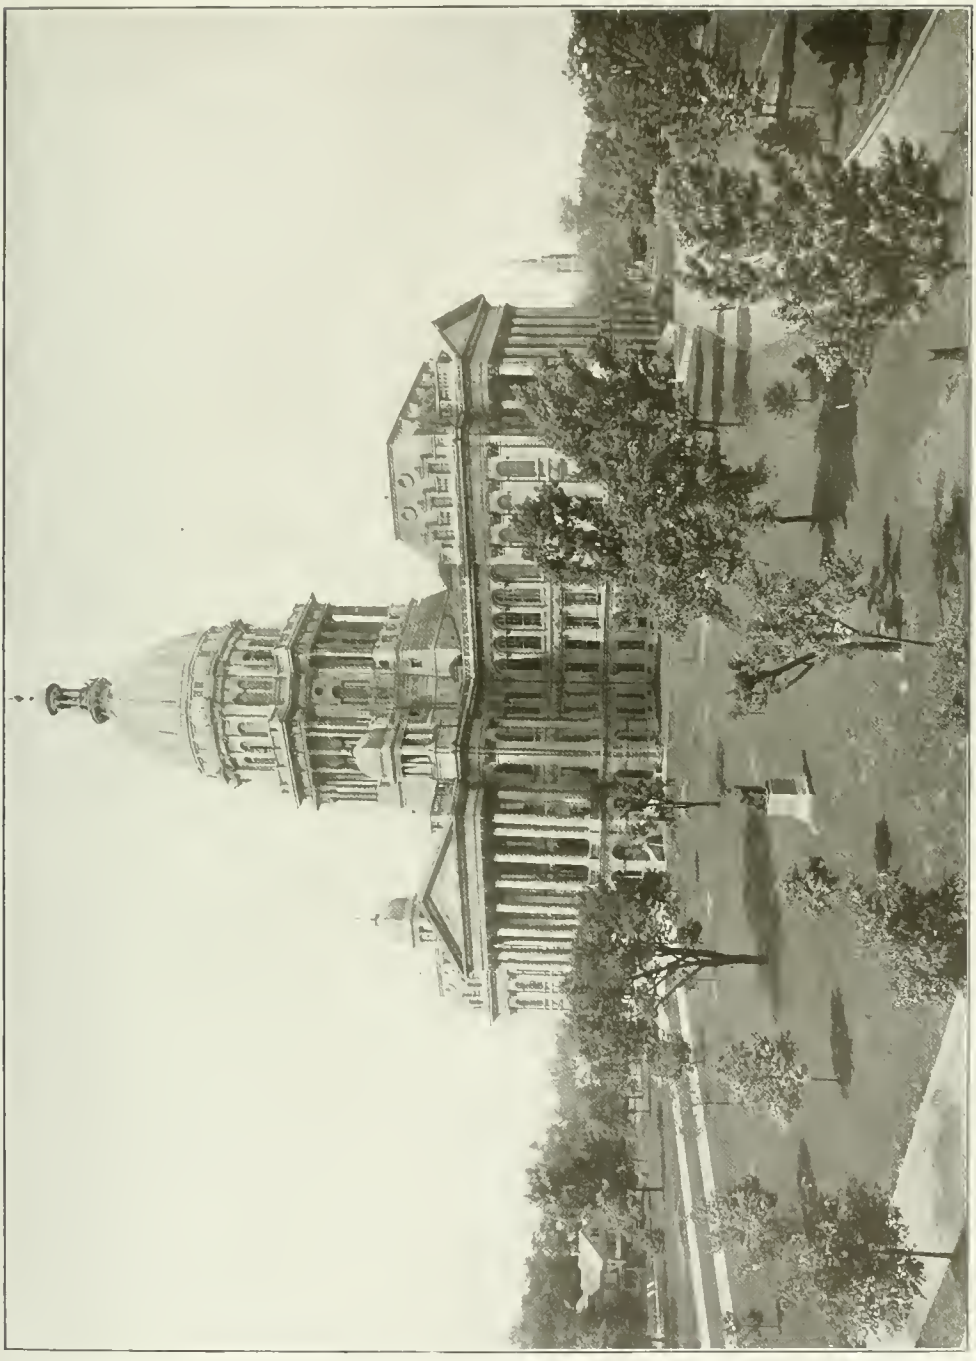
Charities.— The State charitable institutions, 16 in number, are as follows: Northern Hospital for the Insane at Elgin; Eastern Insane at Kankakee; Central Insane at Jacksonville; Southern Insane at Anna; Western Insane at Watertown; Incurable Insane at Bartonville; Criminal Insane at Chester; Deaf and Dumb at Jacksonville; Blind at Jacksonville; Feeble Minded at Lincoln; Soldiers and Sailors at Quincy; Soldiers Orphans' Home at Normal; Soldiers Widows at Wilmington; Eye and Ear at Chicago; Girls Training School at Geneva; Boys Home at St. Charles. The sums appropriated by the General Assembly for the two years ending 30 June 1903 for these institutions aggregated $4,438,024.92.

Penal Institutions.— The Illinois State Reformatory is located at Pontiac, has excellent buildings and appointments for the care of its inmates. The total number of inmates confined in this institution during the 21 months ending 30 June 1902 was 2,352, of whom one fifth had reached the age of 19 years. Under the law no one could be admitted who had reached the age of 21 at the time of the commission of the offense for which he was sentenced. Trade schools, and a farm are provided for in the act creating this institution, and every effort practicable made to reform its inmates. The total amount appropriated by the General Assembly for the support of this institution for the two years beginning 1 July 1901 was $400,000. The State penitentiaries, two in number, are located as follows: The Illinois State penitentiary at Joliet and the Southern Illinois penitentiary at Chester. The number of inmates in the former is about 1,300; and in the latter about 900.

History.— The name of the State is derived from "Illini," an Indian word signifying "men." The euphonic termination added by the early French explorers gives the name "Illinois." The veritable history of Illinois begins with the coming of the French explorers Marquette and Joliet.

Their names are inseparably interwoven with the early history of the great Mississippi Valley. In June 1673 they landed upon the east bank of the Mississippi upon the soil of what is now Illinois. Their first visit was to one of the villages of the "Illini," the ancient and once powerful tribe from which the State takes its name. It is said that upon the first appearance of Marquette and Joliet at the door of the principal wigwam of the village they were greeted by an aged chieftain with the words: "The sun is beautiful Frenchmen when thou cometh to visit us; thou shall enter in peace into all our cabins."

Upon this historic expedition Marquette and Joliet bore the commission of the French Commandant at Quebec — the seat of authority of France in the New World. The narrative of the adventures and discoveries of Marquette and Joliet savors rather of the romantic than of the real. But it was theirs to add the vast domain under the name "New France" to the empire of the Grand Monarch. After descending the Mississippi to a point possibly within 400 miles of the Gulf, these bold voyagers reluctantly turned their faces to the northward. After his separation from Joliet, Marquette visited the Indian villages near the Mississippi and established a mission of his church at the ancient village of the Kaskaskias. He died upon the banks of a small stream within the present limits of the State of Michigan and was buried at Saint Ignace in that State. The city of Joliet in northern Illinois, was named in honor of his daring fellow-voyager, while his own statue has been given place in the great historic hall in the Capitol at Washington. The names of Hennepin and La Salle likewise are associated with these events and times. The first was the scholarly historian and priest, the latter the knightly adventurer. Much, indeed, that is romantic surrounds the entire career of La Salle (q.v). Severing his connection with a theological school in France, his fortunes were early cast in the New World. From Quebec, the ancient French capital of this continent, he projected an expedition which was to add empire to his own country and to cast a glamor about his own name. It has been said, that his dream was of a western waterway to the Pacific Ocean. In 1669 with an outfit that had cost him his entire fortune, with a small party, he ascended in canoes, the Saint Lawrence, and a few weeks later was upon the broad Ontario. Out of the mists that envelop much of his subsequent career, it is impossible, at all times, to gather that which is authentic. It is enough, that with Hennepin as one of his fellow-voyagers, he reached the Ohio and in due time navigated the Illinois, meantime visiting many of the ancient villages. But his great achievement — and that with which abides his imperishable fame — was his perilous descent of the Mississippi from the falls of St. Anthony to the Gulf of Mexico. On 9 April 1682 upon the east bank of the lower Mississippi, with due form and ceremony, and amid the solemn chanting of the Te deum and the plaudits of his comrades, La Salle took formal possession of "the Louisiana country," in the name of his royal master, Louis XIV. of France. For the period of 92 years, beginning with the coming of Marquette and Joliet, Illinois was a part of the French possessions. Sovereignty over the vast domain of which it was a part, was exercised by the French king, by his commandant and his subordinate officers. First, the dependency of Canada, "the Illinois country," by decree of the Royal Council in 1717 passed under the government established for Louisiana. Subsequently in 1721 it became, by virtue of the same authority, one of the separate provinces into which the Louisiana country was then partitioned. A commandant and judge were duly appointed, and the seat of authority transferred to Fort Chartres. Population meanwhile gradually increased in the great American bottom, then embracing the French settlements in Illinois. Cahokia and the other villages were, in a measure, prosperous. In the words of one of our own historians: "The early history of the French settlements reads in these days of a higher civilization and broader culture, like a romance of Arcadia. The wants of the people were few and simple. In each hamlet was a rude chapel, with its attendant priest, who was not only in matters of religion, but in all the affairs of everyday life, 'the guide, philosopher, and friend, of his rude parishioners.'" The same writer referring to this period of foreign domination, truly said: "The French sought and claimed more than they had the ability to hold or possess. Their line of domain extended from the Saint Lawrence around the Great Lakes and through the valley of the Mississippi to the Gulf of Mexico, a distance of over 3,000 miles." Truly a magnificent domain, but one destined soon to pass forever from the possession of the French monarch and his line. Upon the North American continent, the ancient struggle for supremacy between France and her traditional enemy was to find bloody arbitrament. Great Britain claimed as a part of her colonial possessions in the New World, the territory bordering upon the Great Lakes and the rich lands of the Ohio and the Mississippi Valley. As to the merits of the French and English contention as to superior right by discovery, or conquest, it were idle now to argue. Our concern is with the marvelous results of the long continued struggle which for all time determined the question of race supremacy upon this continent. Passing rapidly the minor incidents of the varying fortunes of the stupendous struggle which had been transferred for the time from the Old World to the New, we reach the hour which was to mark an epoch in history. The time, 13 Sept. 1759 — the place, the Heights of Abraham at Quebec. Here and then, was fought out one of the pivotal battles of the ages. It was the closing act in a great drama. The question to be determined: whether the English speaking race, or their hereditary foe, was to be master of the continent. It was literally a struggle for empire — the magnificent domain stretching from the Saint Lawrence to the Gulf of Mexico. The incidents of the battle need not be told. Never were English or French soldiery led by more knightly captains. The passing years have not dispelled the romance or dimmed the glory that gathered about the names of Wolfe and of Montcalm. Dying at the self-same moment — one amid the victors, the other amid the vanquished — their names live together in history. By the treaty of Paris which followed, France surrendered to her successful rival, all claim to the domain east of the Mississippi River. In accordance with the terms of the treaty, Gage, the commander of the British forces in America,



STATE CAPITOL AT SPRINGFIELD.

took formal possession of the recently conquered territory. Proclamation of this fact was made to the inhabitants of the Illinois country in 1764 and a garrison soon thereafter established at Kaskaskia. Here the rule of the British was, for the time, undisputed. British domination in the Mississippi Valley was, however, to be of short duration. Soon the events were hastening, the forces gathering, which were in turn to wrest from the English crown no small part of the splendid domain won by Wolfe's brilliant victory at Quebec. An event of transcendent interest and one of great consequence is now reached. While our Revolutionary War was in progress, General George Rogers Clark planned an expedition whose successful termination has given his name to the list of great conquerors. Partly to mete out punishment to the savage bands whose depredations upon the sparse white settlements in Kentucky were unrestrained by the British commander at Kaskaskia, and partly for the purpose of reducing to possession territory claimed by an ancient charter of the colony of Virginia — the famous expedition was undertaken. Bearing the commission of Patrick Henry, governor of Virginia, with 200 followers equally brave as himself, the heroic Clark crossed the Ohio River and began his perilous march. After enduring great hardships, the undaunted leader and his little band reached Kaskaskia. The British commander and his garrison were surprised and quickly captured. This was on 4 July 1778, 15 years after the Treaty of Paris. The British flag was lowered — and the Illinois country taken possession of in the name of the commonwealth whose governor had authorized the expedition. Thus on the anniversary of our historic day, the symbol of British authority disappeared forever from the Illinois country. In the month of October following the capture of Kaskaskia, the House of Delegates of Virginia extended civil jurisdiction over what had previously been known as the Illinois Country. A law was enacted creating "the county of Illinois," and a commandant was appointed by Patrick Henry, who has, by one of our historians been called "Ex-officio the first Governor of Illinois." Courts were established at Cahokia and Kaskaskia and an election held for civil officers. This was the first election held in Illinois. The history of the next few years is enveloped in much obscurity. Evidently there was but little progress until the close of the Revolutionary War and the ratification of the treaty of peace between the colonies and Great Britain in 1783. The event now to be mentioned, was one of deep consequence and has been called the genesis of Illinois history — the cession by Virginia of the vast territory of which Illinois was a part, to the general government. The claim of Virginia to the vast area mentioned was controverted by some of the other colonies. In fact, this claim was for a time an obstacle to the ratification of the Articles of Confederation. Pending the ratification, the Continental Congress resolved: "That it be earnestly recommended to those States who have claims to the Western country, to pass such laws as may remove the only obstacle to the final ratification of the Articles of Confederation." This important resolution was, a few days later, supplemented by one declaring, "that the lands ceded to the United States pursuant to the above recommendation, shall be disposed of for the common benefit of the United States, and shall be formed into distinct republican States, which shall become members of the Federal Union, and have the same rights of sovereignty, freedom, and independence, as the other States." In response to the above, the House of Delegates of Virginia in January 1781, proposed to cede to the general government the lands mentioned upon the conditions named. After much discussion and delay the proposition of Virginia was accepted by the Congress and in time a deed of cession was duly executed. To this famous instrument — by virtue of which Illinois became a part of the United States — are attached as commissioners upon the part of Virginia, the historic names of Thomas Jefferson, Arthur Lee, and James Monroe. In the manner indicated, the territory out of which Illinois has since been carved became part and parcel of the Federal Union. The daring and successful expedition of George Rogers Clark and the subsequent act of Virginia, form a bright page in our history. As has been truly said "The timely campaign of Colonel Clark was the outgrowth of Virginia foresight, enterprise, and valor. But for this conquest, the Northwest, at the close of the Revolution, would have been in possession of the British and would have doubtless so remained as did Canada; and the western line of the United States would have been the ridge of the Alleghanies and the Ohio River, instead of the channel of the Mississippi.

Another milestone is now reached on the pathway of "the Illinois country," to the dignity and sovereignty of statehood; reference is had to what is well-known in our political history as the Ordinance of 1787. Not inaptly has it been called "the second Magna Charta." On the historic day, 1 March 1784 that Virginia ceded to the United States the domain stretching from the Mississippi to the Ohio, Mr. Jefferson proposed to the Continental Congress a plan for its government. His far-seeing statesmanship is unmistakably evidenced by two provisions in the plan he formulated. One, that slavery should not exist in the territory after the year 1800; the other, that the States to be carved from the territory were to remain forever members of the American Union. This plan failed to receive the sanction of that Congress — and in later days and by other hands, the great ordinance was destined to come into being. Antedating the Federal Constitution, the ordinance for the government for the Northwestern Territory was enacted 13 July 1787. As this was indeed the genesis of Illinois history under the Federal government, it may be well to note briefly some of the provisions of the great ordinance. By its terms, a government was established for the territory and a governor, secretary and judges duly appointed, with power to adopt such laws of the original States as were most convenient; a Legislature was authorized when the territory should have five thousand free male inhabitants; religious freedom and civil rights — not to depend upon religious belief — were guaranteed; likewise the writ of habeas corpus and trial by jury, and judicial procedure according to the common law; private property to be taken for public use only after just compensation; and provision to be made for the encouragement of education. Two of the provisions of the famous ordinance possessed a value that cannot be measured by words. One, the States to be

formed from said territory, were to remain forever a part of the United States of America; the other, that neither slavery nor involuntary servitude should exist in the territory, otherwise than for crime whereof the party should have been duly convicted. The value of the great ordinance to that generation and to the millions who have since found homes within the limits of the vast area embraced within its provisions, cannot be overstated. In pursuance of the recommendation of Mr. Hamilton, Secretary of the Treasury, a General Land Office was established for the new territory and a surveyor-general, registers, and receivers duly appointed, and provision made for the sale of the public lands to actual settlers, in small holdings, and at nominal prices. The commission of General Arthur Saint Clair, the first governor of the Northwest Territory, bears date 1 Feb. 1788, and soon thereafter judges and other officers were appointed, and the new government duly organized. The first visit of Governor Saint Clair to Kaskaskia was in 1790, the county bearing his name meanwhile having been established. Five years later out of its territory, the county of Randolph was created and Kaskaskia established as its county-seat; Cahokia being that of the county of Saint Clair. Thus was the beginning of the historic counties — out of which so many have since been carved — and whose history is, in so large a degree, that of the two first decades of Illinois. Pursuant to the provision of the ordinance of 1787, the Northwest Territory having attained the requisite population, a General Assembly was convened in Cincinnati in February 1799. Illinois was now, for the first time, represented in a legislative chamber. In May 1800 the Congress of the United States provided by law for the division of the Northwest Territory, and the creation of a political division to be known as the "Indiana Territory." The new territory embraced the present States of Indiana and Illinois, and the seat of government was established at Vincennes. The first governor was General William Henry Harrison, at a later day the President of the United States. Of his wise and efficient administration of the affairs of the territory, too much cannot be said. By judicious treaties with the Indian tribes, peace was maintained and cession obtained of valuable grants which in time became the homes of the white emigrants. It is an interesting fact, that the fierce hatred of the great Shawnee chief, Tecumseh, to the whites, was at a later day, in a measure, the result of the grants already mentioned. His own tribe allied with the Pottawatomies and the Kickapoos failed to exterminate — as was the intention of Tecumseh — the white settlers, and ended in his own disastrous defeat at Tippecanoe in 1811, by which the power of these tribes was forever broken. Events were now leading up to the separation of Illinois from Indiana and its own organization as a territory. From the time of the presentation of the first petition to that end in 1806, the legislative chamber at Vincennes and the entire territory in fact, was the theatre of exciting controversy. Its culmination, however, was in February 1809, when by Act of Congress, "the territory of Illinois" was duly organized. The seat of government was established at Kaskaskia — and henceforth Illinois has a history, separate and apart. A wave of emigration from the older States had now reached the new territory, and additional counties were organized by the Territorial Assembly. The people were, in a measure, prosperous, and the question of statehood soon became the theme of earnest discussion. By the year 1818 the population of the Territory was near 40,000 and the General Assembly in January of that year forwarded a petition to Congress, praying the necessary legislation preparatory to its admission to the Union. The people were, indeed, fortunate in having as their Territorial delegate, Nathaniel Pope, eminent at a later day, as a United States judge. The bill providing for the legislation indicated, was introduced into Congress in April 1818. The valuable service rendered by Judge Pope to the future State, will now appear. The bill as reported back to the House of Representatives, by the committee to which it had been referred, fixed the northern boundary of the new State on the north parallel of 41°, 39′. Pending the consideration of the bill, Judge Pope offered an amendment to that part fixing the boundary, containing the significant words: Thence north along the middle of Lake Michigan to north latitude 42° and 30′. This amendment was adopted and became part of the bill. Thus amended, the bill became a law, under it a convention was held at Kaskaskia, a constitution framed, and in December 1818, Illinois was duly admitted as a State of the Federal Union.

During the first decade which followed the organization of the State, the habits of the people, in the main, were simple and their wants few. Barter in a large measure supplied the place of a medium of exchange. Commerce, in so far as it had an existence with the outer world, was by wagons across the Alleghenies, and by flat boats down the Ohio, and the Mississippi. The log cabin furnished protection to the pioneer from the winter's storm. With rude implements of his own construction, he cultivated his fields, and with his rifle defended his loved ones from the incursions of the savage. At the time of its admission, there were but 23 post-offices within the limits of the entire State. At the period indicated and for years afterwards, the frontiersman regarded himself as especially favored if located within a dozen miles of a post-office. The mails reached the settlements weekly or monthly upon horseback or by stage-coach. The log cabin with its puncheon floor supplied the double purpose of temple of learning, and place for public worship. Articles of apparel, were, with rare exception, of home manufacture. Railroads, colleges and universities were unknown. Less than 10,000 persons within the entire State were engaged in agricultural pursuits. Chicago had hardly a place upon the map. The rapid emigration which immediately followed its admission soon rendered the selection of a capital nearer the centre of population a necessity. The commissioners designated by the legislature, for this purpose, having in view the possible flow of emigration northward, chose a site for the new location, 140 miles north of the Ohio River, to which was given the name Vandalia — then a wilderness, but now a beautiful and prosperous city. During the two decades which followed the location of the capital at Vandalia, the population of the State increased to 476,000. The drift of emigration was to the Wabash, to the Sangamon, to the Vermillion, to "the Military Tract," to the

rich lands drained by the Kankakee and the Fox, and to the grand prairies stretching northward and westward to Wisconsin and to the Mississippi. In 1836 Springfield became the seat of government. Then a village of but a few hundred inhabitants, it is now a splendid city and an honor to the commonwealth. Its nearness to the geographical centre of the State; its accessibility and the erection of a superb State House, renders the present location, for our time at least, permanent.

Constitution.— Three constitutions have been in force in Illinois since its admission as a State. The first was formulated by a convention of 32 delegates — representing the fifteen counties of the territory — which assembled in Kaskaskia in August 1818. This constitution — under which the State was admitted — remained the organic law of Illinois for 30 years, and until the adoption of the constitution of 1848. Meanwhile the State had gradually increased in wealth and in population. Many new counties had been organized and the northern boundary of actual settlement extended from the county of Madison to the Wisconsin line. Chicago and other cities unknown to the framers of the first constitution, had sprung into being. An attempt to procure the calling of a convention to frame a constitution to supplant the first, was made in 1823. By Article 7 of the latter, the legislature was empowered, by a two thirds vote thereof, to submit to the electors of the State, the question of calling a convention to alter or amend the existing constitution. By the legislature of 1823 there was such submission under the above provision. The purpose of the originators of this movement unquestionably was to secure by constitutional provision, the introduction of slavery into the State. For more than a year this was the all-absorbing topic of debate. Political leaders and newspapers were divided and fierce personal antagonisms engendered. The discussions at the fireside, in the public press and upon the hustings, touched all phases of the question from the standpoint of material advantage, as well as from the high plane of right. The verdict of the people was rendered 2 Aug. 1824 against the proposed convention and the introduction of slavery into Illinois. The question of calling a convention was again submitted by the legislature in 1846; the returns showed a large majority favorable, and delegates were chosen in April 1847. This convention consisting of 162 members assembled in Springfield in June of that year and its deliberations were concluded 31 August. Unlike the first constitution, this was submitted to the people. It met popular approval and by its terms went into operation on the first Monday of April 1848. This remained in force until the adoption of the present constitution. The latter was formulated by a convention consisting of 85 members which assembled in Springfield 13 Dec. 1869. The constitution it framed was submitted to popular vote and approved, and has since August 1870 been the fundamental law of the State. The existing constitution is in large degree an improvement upon both of those which preceded it. Some of its most important provisions are: the division of the powers of the government of the State into three departments — the legislative, the executive, and the judicial; vesting the legislative power in a General Assembly to consist of a Senate and House of Representatives, both to be elected by the people; senators required to be 25, and representatives 21 years of age; also to be citizens of the United States, and five years resident of this State; no person convicted of infamous crime or a public defaulter to be eligible as senator or representative or to any office of profit or trust in the State; in addition to the ordinary official oath each senator and representative is required to swear in substance that his election has in no manner been secured by bribery; the number of senators was fixed at 51, and of representatives at 153; minority representation was provided for in the election of members of the House; senators to be elected for four years and members of the House for two years; a majority of the members elected to each House shall constitute a quorum; bills may originate in either House subject to amendment in the other; upon the final passage the yeas and nays shall be taken upon each bill separately; every bill to be read at large upon three different days in each House; no act to embrace more than one subject and that to be embraced in its title; no money to be drawn from the treasury except in pursuance of an appropriation made by law; the General Assembly permitted to make appropriations for expenditures incurred in suppressing insurrection, or repelling invasion; compensation of senators and members fixed at $5.00 per day during the session; the General Assembly prohibited from releasing the indebtedness, liability or obligation of any corporation or individual to the State, or to any municipal corporation therein; to have no power to authorize lotteries or gift enterprises for any purpose. Two important mandatory provisions upon the General Assembly were incorporated in the constitution: one requiring legislation protecting coal miners, and the other the passage of liberal homestead and exemption laws. Under the former constitution, the State and people had suffered from special legislation. To the end that such legislation be discontinued and general laws when necessary enacted, the General Assembly was prohibited from passing local or special laws in any of the following cases, viz.: for granting divorces; changing the names of persons or places; laying out, opening, altering and working roads or highways; vacating roads, town plats, streets, alleys and public grounds; locating or changing county seats; regulating county and township affairs; regulating the practice in courts of justice; regulating the jurisdiction and duties of justices of the peace, police magistrates and constables; providing for changes of venue in civil and criminal cases; incorporating cities, towns or villages or changing or amending the charter of any town, city or village; providing for the election of a board of supervisors; summoning and impaneling grand or petit juries; providing for the management of common schools; regulating the rate of interest on money; the opening and conducting of any election or designating the place of voting; the sale or mortgage of real estate belonging to minors or others under disability; the protection of game or fish; chartering or licensing ferries or toll bridges; remitting fines, penalties, or forfeitures; creating, increasing or decreasing fees, percentage or allowance of public officers during the term for which said officers are elected or appointed; changing the law of descent; granting to any corporation, association

or individual the right to lay down railroad tracks or amending existing charters for such purpose; granting to any corporation, association or individual, any special or exclusive privilege, immunity or franchise whatever.

Government.— The supreme executive power of the State is vested in a governor, "who shall take care that the laws be faithfully executed"; his term of office fixed at four years; he is required to be 30 years of age and for five years next preceding his election, a citizen of the United States, and of this State; he is required at the commencement of each session to give to the General Assembly, information by message of the condition of the State, and recommend such measures as he shall deem expedient; he can, by proclamation, convene the General Assembly upon extraordinary occasions; may remove officers of his appointment for incompetency, neglect of duty or malfeasance in office; may grant reprieves, commutations, or pardons after conviction for all offenses; shall be Commander-in-Chief of the Military and Naval forces of the State — except when they are called into the service of the United States; is vested with a qualified negative upon all bills passed by the General Assembly, but bills can be passed over his veto by a two-thirds vote of each House; in case of his death, resignation, or conviction upon impeachment, the duties of his office devolve upon the lieutenant-governor; the last named officer is president of the senate, and is, with the secretary of state, auditor of public accounts, treasurer, superintendent of public instruction, and attorney-general, elected in the same manner, and except the treasurer, for the same length of time as the governor; two years is the term of the treasurer. The judicial powers of the State are vested in a supreme court, circuit courts, county courts, justices of the peace, police magistrates, and in such courts as may be created by law for cities and incorporated towns; the supreme court consists of seven judges, and their term of office is nine years; the terms of the circuit judges fixed at six years, inferior appellate courts of uniform organization and jurisdiction to be composed of circuit judges, to be created.

Suffrage.— One year's residence in the State necessary to its exercise; voting to be by ballot; persons convicted of infamous crimes to be excluded from the right of suffrage.

Revenue.— The General Assembly to provide for needed revenue by levying a tax, by valuation, so that every person and corporation shall pay a tax in proportion to the value of his, her, or its property; certain property, religious, charitable, etc., may by general law be exempt from taxation.

Corporations.— No corporation to be created by special laws, except those for charitable, educational, penal, or reformatory purposes, and these to be under State patronage and control; the General Assembly to provide by general laws for the organization of all corporations hereafter to be created; no State Bank hereafter to be created, nor shall the State own any stock in any corporation for banking purposes; every stockholder in a banking corporation to be individually liable to its creditors for double the amount of his stock; the rolling stock and all other movable property of all railroads in the State, to be considered personal property, and subject to execution for the debts of such company; railroad corporations prohibited from consolidating with parallel or competing lines; all railroads in the State declared to be public highways, and free to all persons for the transportation of their persons and property thereon, under such regulations as may be prescribed by law — the General Assembly to establish reasonable maximum rates of charges for the transportation of passengers and freight; the right of eminent domain by the State against such corporations never to be abridged; the General Assembly by appropriate legislation to prevent unjust discrimination and extortion in the rates of passenger and freight tariffs on all railroads in the State; appropriate legislation authorized for the protection of producers, shippers and receivers of grain and produce. By a two thirds vote in each House the General Assembly may submit to the electors, the question of calling a convention to alter or amend the Constitution, to be voted upon at the next general election; by the same vote in the General Assembly proposed amendments to the constitution (without the intervention of a convention) may be submitted to the electors for adoption or rejection. The General Assembly prohibited from releasing the Illinois Central Railroad Company from its charter obligation to pay the State the agreed percentage of the gross earnings of said company; no county, city, town or township permitted to become a subscriber to the capital stock of any railroad, or private corporation, or to make donations to, or loan its credit in aid of any such corporation.

Politics.— Under the recent apportionment by virtue of the 12th census of the United States, Illinois has 25 representatives in Congress. The electoral vote of the State at successive Presidential elections, since its admission has been cast as follows, viz.: In 1820, for Monroe; in 1824 one vote for Adams and two for Jackson; in 1828 and 1832 for Jackson; in 1836 and 1840 for Van Buren; in 1844 for Polk; in 1848 for Cass; in 1852 for Pierce; in 1856 for Buchanan; in 1860 and 1864 for Lincoln; in 1868 and 1872 for Grant; in 1876 for Hayes; in 1880 for Garfield; in 1884 for Blaine; in 1888 for Harrison; in 1892 for Cleveland; in 1896 and 1900 for McKinley. The vote of Illinois in the electoral college during the 85 years of its existence as a State, has increased from 3 to 27. The Black Hawk war of 1831–2 and the Mormon war of 1844 are chief among the interesting historical events of the State. As the result of the first, Indian depredations ceased, and the remnants of once powerful tribes disappeared forever from the State. What is known in local history as "the Mormon War" occurred in Hancock County on the Mississippi River. Nauvoo in the last named county was the Mormon city, the home of Joseph Smith, "the prophet" and head of the church; it was the seat of Mormon authority, and the site of a splendid temple. The assassination of Joseph Smith by an anti-Mormon mob in 1844 was soon thereafter followed by the complete exodus of his followers from the State.

Bibliography.— Ford, 'History of Illinois'; and a 'History of Illinois' by Davidson and Stuve; Moses, 'History of Illinois'; the twelfth census of the United States; the several official reports of State officers published by authority of the General Assembly.

ADLAI E. STEVENSON,

Illinois Central Railroad. The history of the Illinois Central Railroad embraces many interesting episodes, some of which bore directly in their effect on the building up of the nation, of the State of Illinois and of the city of Chicago. Prior to the incorporation of this line, the State of Illinois had vainly endeavored to establish an effective and profitable central railroad. In doing this, a large State debt accumulated and the outlook for wiping out that debt was not at all promising when the act to incorporate the Illinois Central Railroad Company was approved by Governor French, on 10 Feb. 1851. As events have proved, this act produced results more momentous in the history of the State and of the United States than any act approved by an Illinois Executive before or since.

The inception of this important enterprise dates back to 1835, when two of the State's most famous men, Hon. Sidney Breese and Hon. Stephen A. Douglas, first discussed publicly the advisability of penetrating the centre of the State by means of a railroad and thus opening up a vast territory which at that time was an uninhabited and partially unexplored wilderness. On 16 Jan. 1836, the State Legislature passed an act incorporating "The Illinois Central Railroad Company." Two years later an attempt was made to start this road, which was intended to run 457 miles. The sum of $3,500,000 was appropriated for the route, but within a few months the difficulties surrounding the situation in the matter of actual track-laying became so great that, after an expenditure of $506,000, principally on surveys and preliminary work, the plan was abandoned.

In 1843, a private corporation entitled "The Great Western Railroad" secured a charter and began work, but soon became discouraged and surrendered their charter. In 1849 this charter was renewed, only to be again surrendered to make room for the road now operating and known as The Illinois Central Railroad. At the time the road was commenced by the present corporation, it was estimated that the aggregate cost would be about $15,000,000. The actual cost for construction, including all extension up to the present time, has been nearly $50,000,000.

Original Charter Directors.— The twelve directors selected in 1851, under the charter and known as the "Charter Directors" included nine prominent New York men and three well-known citizens of Boston. The directors from New York were Robert Schuyler, George Griswold, Governeur Morris, Jonathan Sturges, Thomas W. Ludlow, John F. A. Sanford, Henry Grinnell, Joseph W. Alsop and Leroy M. Wiley. Those from Boston were Franklin Haven, Robert Rantoul, Jr., and David A. Neal.

Population.— In 1850, shortly before the chartering of the railroad, Illinois stood 11th in population and 17th in wealth among the States. The marked difference during the following 10 years is worthy of note as showing the direct effect of improved and extended railroad accommodation. In 1860, Illinois stood fourth in population among the States, also fourth in wealth.

Railroad Conditions in 1851.— In 1851, when the charter of the present road was granted, the population of Chicago was 30,000. That city had no railroad connection with the east nor in any other direction. In the same year the Hudson River Railroad, 140 miles, from New York to East Albany, was opened. Other events of importance during 1851 were the extension of the Baltimore and Ohio Railroad to Cumberland and the opening of an Erie Railroad line from Pierpont on the Hudson to Dunkirk on Lake Erie. Wisconsin had 20 miles of railroad at that time. The railroad mileage of Indiana was 228 miles, and of Kentucky, 78 miles. Just prior to the chartering of the Illinois Central there were 111 miles of railroad track in the State. When the 50th anniversary of the road was held at Chicago in 1901, it was announced that the company was then operating railroads in 13 States.

Development.— The first section of the road, covering 705.50 miles, and running from Chicago to Cairo and from Centralia to Dubuque, was opened on 27 Sept. 1856, being about five and one half years after the issuing of the charter. Since the opening of this main line other lines have been purchased, including part of the Saint Louis, Peoria and Northern railroads from Springfield to East Saint Louis, Illinois, in 1900. This purchase was followed by a number of other purchases and absorptions.

Roads Acquired by Purchase, etc.— From Springfield to East Saint Louis, Ill. (part of the Saint Louis, Peoria and Northern); Indiana Division of the former Peoria, Decatur and Evansville, extending from the Illinois State line to Evansville, Ind., with a branch to New Harmony, Ind.; Evansville and Mattoon, from the State line to Mattoon, Ill. This was formerly a division of the Peoria, Decatur and Evansville; Chicago, Madison and Northern; Kankakee and Southwestern; Chicago and Springfield; Saint Louis, Alton and Terre Haute; Chicago, Havana and Western; Mound City; Chicago and Texas; Riverside and Harlem; the parts of the Rantoul and Illinois and Indiana railroads lying in the State of Indiana, extending from West Lebanon to State line and from Switz City to State line.

Leased Lines.— The leased lines of the Illinois Central Railroad are Chicago and Eastern; South Chicago; Blue Island; Peoria, Decatur and Mattoon; Peoria and Pekin Union; Dubuque and Sioux City; Chicago, Saint Louis and New Orleans, and the Canton, Aberdeen and Nashville railroads.

Mileage.— The corporation now controls one of the most important groupings of railroad lines in the United States. The total mileage operated, according to the latest official report available, is 4,374.04, exclusive of the Yazoo and Mississippi Valley Railroad (1,209.91 miles). The length of the main line, from Chicago to Cairo, Illinois, is given as 364.73 miles; Omaha Division, from Chicago to Council Bluffs, Iowa, 513.96 miles; New Orleans Division, from Cairo to New Orleans, Louisiana, 547.79; Louisville Division, from Memphis, Tennessee, to Louisville, Kentucky, 398.12 miles; other lines owned or leased operated in the system, 2,549.12.

Additional Tracks.— The length of line having two tracks is 654.33 miles; third and other additional main tracks, 72.56 miles; sidings, etc., 1,514.04. The gauge of this system is 4 feet 8½ inches. The average weight of steel rails is 72.78 lbs

Charter Tax.— The charter of the company, reserved to the State of Illinois, calls for payment, in lieu of taxes, of 7 per cent of the gross receipts of the 705.50 miles of road originally built under that charter. The total amount paid to the State of Illinois under the provisions of this charter, from the opening of the road in 1855 to 30 June 1904, was $22,359,316.21.

Dividends.— Between the beginning of operations in 1851 and 30 June 1904, the stockholders received $118,403,661.59 as dividends out of the earnings of the company.

Rolling Stock.— The rolling stock of the company, 30 June 1904, included 1,086 locomotives, 444 passenger and chair cars, 14 café dining cars, 148 baggage, mail and express cars, 42 postal cars (3 of these partly owned), and 52,957 freight cars, making a total, with minor items under this head, of 55,809 cars.

Earnings.— The earnings of the road, for the year ending 30 June 1904, amounted to $46,831,136, or $10,789.72 per mile. These earnings were divided as follows: Passenger traffic, $9,554,743; freight traffic, $31,692,575; mail and express service, $1,694,280; miscellaneous earnings, $3,889,538. For 1905, the total earnings were $49,508,649.

Net Earnings, Receipts and Dividends.— The net earnings of the road for the year ending 30 June 1904, were $14,037,885, or 29.48 per cent; for 1905, $14,396,943; net receipts from land sales, $41,053; investments and miscellaneous profits, $2,675,495.72; surplus dividend fund (30 June 1903), $1,178,186.92; surplus dividend fund, 30 June 1904, $1,225,766.92.

Expenses.— The total expenses of the road for the year ending 30 June 1904, amounted to $32,793,251.31, or $7,555.44 per mile; for 1905, $35,111,706. The amount paid for taxes, rents, interest and sinking fund during the same period was $7,888,506; in dividends at 6 per cent, $5,702,400.

Bonded Debt.— The bonded debt of the road, including 25 investments, aggregates $137,599,525. Of this total the first issue yet to mature is $88,000, issued in 1880 and maturing in 1910. An issue of $2,800,000, placed in 1869, matures in 1917. The next, following in order, is an issue of $968,000 made in 1881 and maturing in 1921; an issue of $470,000 made in 1883 and maturing in 1923; an issue of $538,000, made in 1886 and maturing in 1931; an issue of $241,000, made in 1887 and due in 1932.

Opening up of the State.— The beginning of active operations in establishing the line marked the beginning of State development throughout a vast area which, up to that time, had been inaccessible to traffic of any kind except by means of the most rural contrivances, utterly inadequate for any but the most restricted local demands. The new move toward opening up commercial possibilities immediately doubled the price of public lands. These tracts were readily bought up as conditions improved and steadily increased in value year by year.

At a critical juncture in the nation's history, when it became necessary to move regiments, brigades and divisions of western troops to the scene of active civil war operations, the Illinois Central Railroad provided the only available means of adequate rapid transportation. At the same time, the existence of that railroad and its excellent management made the prompt supply of rations and forage possible.

Payment of State Debt.— As mentioned in a previous paragraph, the attempt of the State to operate successfully a central railroad ended in utter failure. In 1851 the people of Illinois were under a burden of some $60,000,000 as the outcome of the experiment. The establishment and active operation, with ever continuing development of the road, enabled the whole of that debt to be paid off in due course with proper interest.

Other Benefits to State and City.— The persistency of the railroad authorities in extending their own lines and giving added vitality to smaller railroads made possible the cultivation of the Grand Prairie, previously waste, thereby raising the prestige of the State as a productive national factor of extraordinary importance. It is on record that over $3,000,000 has been expended since about 1836 by the railroad company upon the construction of dikes, piers and breakwaters to protect the city against lake encroachments. Very great benefits, too, have been derived by Chicago from being brought into close commercial touch with prairie lands and the agricultural area of the Lower Mississippi Valley. Chicago has also gained an outlet by rail to the Gulf of Mexico. It is said, to the credit of the Illinois Central Company, that the extent and vigorous administration of its affairs during the period extending from the inception of the World's Fair in 1893 until its close made the success of that enterprise possible by furnishing ample transportation within its jurisdiction for the immense passenger and freight traffic which impended there from start to finish.

Statistical.— The States in which the Illinois Central Railroad is now operating are Illinois, Indiana, Wisconsin, Iowa, Minnesota, South Dakota, Kentucky, Tennessee, Mississippi, Louisiana, Missouri and Alabama. The present total mileage of the road, including leased lines and the Yazoo and Mississippi Valley Railroad, is nearly one-half the railway mileage of the State. The total number of stockholders in the company, according to the latest report of the Interstate Commerce Commission, is 9,123. The value of stock outstanding, according to the latest quotations, 1905, is $95,040,000. The highest rate at which stock was quoted in 1904 was 159; lowest 125¾. The highest rate quoted for 1905 was 183; lowest 152¾.

Other lines operating in Illinois are the Santa Fe; Baltimore and Ohio; Chicago and Alton; Chicago and Northwestern; Chicago, Burlington and Quincy; Chicago Great Western; Chicago, Indianapolis and Louisville; Chicago, Milwaukee and St. Paul; Chicago, Rock Island and Pacific; Cleveland, Cincinnati, Chicago and St. Louis; Erie; "Frisco System"; Grand Trunk; Great Central Route; Iowa Central; Lake Erie and Western; Lake Shore and Michigan Southern; Louisville and Nashville; Michigan Central; Missouri Pacific; Mobile and Ohio; New York, Chicago and St. Louis; Pennsylvania; Southern; Toledo, St. Louis and Western; Vandalia; Wabash, and Wisconsin Central.

Illinois College, an institution located in Jacksonville, Ill., the oldest college in the State, founded in 1829, largely through the efforts of the "Yale Band of Seven," an Eastern organization of college men. The courses of study are arranged according to the group system, which permits a fair amount of choice. In 1902 the attendance was 125 students with 17 instructors. In 1903 the college was affiliated with the University of Chicago. The same year the endowment fund was increased from $155,000, in 1902, to nearly $500,000. The college library contains 12,000 volumes, and the literary societies 1,000, available for reference.

Illinois River, an affluent to the Mississippi, formed by the confluence of the Kankakee, Des Plaines, and Du Page rivers, in Grundy County, about 44 miles southwest of Chicago. Its entire course of over 350 miles is within the State, through a fertile, undulating country, rich in bituminous coal deposits. It flows first westward to Ottawa and Lasalle, at Depue bending southwestward past Lacon, Chillicothe, Peoria, Pekin, Havana, and Beardstown, and near Naples turning due south and joining the Mississippi about 18 miles above Alton, at the mouth of the Missouri. The river is 1,200 feet wide at its mouth and is navigable throughout to Lasalle where a ship canal about 120 miles long connects it with Lake Michigan at Chicago, thus ensuring a clear waterway from the Great Lakes to the Mississippi and the Missouri. The Illinois has numerous tributaries of which the Fox and Sangamon rivers are the chief.

Illinois State Normal University, located at Normal, a suburb of Bloomington, Ill., was founded in 1857. It is the oldest State normal school in the Mississippi Valley, and has furnished principals or instructors for nearly all of the younger normal schools in the central and western States. Up till 1904 it had given instruction to 15,652 normal students, nearly all of whom have become teachers. Its graduates number 1,549. The school occupies three buildings upon a beautiful campus of 57 acres. It is well equipped with library, laboratories, gymnasium, and apparatus for instruction in all the various branches of study. Its revenue, about $60,000 per year, appropriated from the State treasury, includes the interest derived from the College and Seminary Funds granted by the Federal government in 1818. It is governed by the Board of Education of the State of Illinois, a body of 15 appointed by the governor. The State superintendent of public instruction is *ex-officio* secretary of the board. Its sole purpose is to prepare teachers for the schools of the State, accordingly students are required to sign a pledge declaring their intention to teach. Tuition is free. The programmes of study leading to graduation vary from two to four years, according to the preparation of the student. The required work includes courses in pedagogy, psychology, and general method, history and philosophy of education, school management and the Illinois school system and one year of practical teaching in the training department. Along with these are provided courses in special method in the various branches of elementary and high school course. Special courses are provided in manual training, art, vocal music, kindergarten and elementary agricultural science. The attendance in 1902–3 was 1,014, besides 502 in the training department. The faculty of instruction numbers 31. The presidents of the institution have been: Gen. Charles E. Hovey (1857–61); Richard Edwards (1862–76); Edwin C. Hewett (1876–90); John W. Cook (1890–99); Arnold Tompkins (1899–1900); David Felmley (1900——).

David Felmley, *President.*

Illinois, University of, the State university situated at Urbana. It was founded in acceptance of the national land grant of 1862 (see Colleges, Land Grant), and was incorporated in 1867 as the Illinois Industrial University. In 1870 women were admitted; in 1877 the State legislature granted power to confer degrees; and in 1885 the name was changed to the University of Illinois. It was the first American university to give shop instruction, a mechanical shop being equipped in 1870. It is governed by a board of trustees, consisting of three *ex-officio* members, including the governor, and nine elective members. The undergraduate department includes the college of literature and arts, of engineering, of science, and of agriculture; corresponding graduate courses are given: other departments of the university are the academy, State library school, the school of music, the college of law, the college of medicine, the school of dentistry, and the school of pharmacy, the three latter being situated in Chicago. The university has a number of valuable scientific collections; the agricultural experiment station organized under the Federal law of 1887 is controlled by the university trustees, but is separately supported by the national appropriation; the general university library numbers 71,039 volumes besides pamphlets; other libraries under university control are the library of State Laboratory of Natural History (15,000 volumes), the library of the college of law, and the special collection of the department of education (1,500 books and 3,000 pamphlets). The annual income amounts to $900,000; the number of students in all departments was 3,725 in 1904–5, the number of professors and instructors, 392.

W. L. Pillsbury,
Registrar University of Illinois.

Illinois Wesleyan University, founded in 1850 under the auspices of the Methodist Episcopal Church, at Bloomington, Ill. The college courses provide for the degrees of B.A., B.S., Ph.B., LL.B., M.A., Ph.D., and two honorary degrees. It has, also, a preparatory school. In 1902 the number of students was over 1,400, of which 478 were non-residents; professors and instructors, 38; volumes in the library about 11,000.

Illit'erates, those unable to read or to write, or to do either. The percentage of illiterates indicates the average intelligence, or at least of education, in the people of a country. The United States, Hungary, Italy, and Portugal, and the Australian colonies of Victoria and Tasmania, have attempted to take an exact census of illiterates; all children below six years of age were excluded, except in the United States, where all children below 10 years of age were excluded. The following gives the result:

	Per cent
United States (1880)	22.15
Italy (1881)	54.30
Hungary (1880)	57.14
Portugal (1878)	79.07

But the most exact results are gained by estimating the number of men and women who

are unable to sign their names in the marriage registers. From this estimate the following are the results for 1886:

	Men	Women	Mean
England and Wales..	9.60	11.50	10.55
Scotland	4.65	8.28	6.46
Ireland	23.40	25.30	24.35
Victoria	2.00	1.98	1.99
New South Wales...	3.76	4.20	3.98
Queensland	4.52	6.71	5.62
South Australia	3.04	3.49	3.26
New Zealand	1.92	2.89	2.40
Prussia (1884)	3.31	5.11	4.21
France (1882)	14.39	22.62	18.50
Italy (1887)	42.36	62.80	52.58

The subjoined table gives the number of conscripts of the countries named who were illiterate in the fullest sense of the term:

	Per cent		Per cent
Baden (1884)	0.02	Holland (1887)	8.5
Würtemberg (1884)..	0.02	France (1886)	10.30
Bavaria (1884)	0.08	Belgium (1887)	13.87
Saxony (1884)	0.15	Austria (1888)	25.00
Sweden (1883)	0.27	Hungary (1888) ...	38.60
Denmark (1881) ...	0.36	Italy (1888)	42.98
Germany (1884) ...	1.27	Russia (1882)	78.79
Switzerland (1888)..	1.3	Servia (1881)	79.31
Prussia (1884)	1.97		

At the last general election in Great Britain and Ireland there voted in England and Wales 38,587 illiterate persons, in Scotland 4,836, in Ireland 36,722, giving a percentage of 2.69 out of a total of 2,969,381 voters. Illiteracy among voters, both white and black, increased greatly in the South between 1870 and 1880. In Texas in 1870 there were 17,500 illiterate voters; in 1880 there were 33,085. But between 1880 and 1890 the illiteracy in the States was reduced to 13.4 per cent of the total population.

Illuminati, ĭ-lū-mĭ-nā'tī ("the illuminated"), the name given to themselves by an association of people who professed to have attained to a higher knowledge of God, and heavenly things, and a deeper insight into the spiritual world than the rest of mankind. They were represented by the *Alombrados* in Spain and the *Guérients* in France. In the last half of the 18th century a sect of mystics rose in Belgium which from its foundation 1 May 1776 at Ingolstadt, spread over a large portion of Catholic Germany. At first they called themselves "Perfectibilists." Their founder was Adam Weishaupt (q.v.), a professor of canon law at Ingolstadt.

Illuminating of Manuscripts. See Books; Manuscripts, Illuminating of.

Illusion. In mental pathology it is necessary to distinguish the term "illusion" from the terms "delusion" and "hallucination." In common parlance these terms are often confused, and many persons in using them have not very clear ideas of what they wish to express by them. But this is not so among writers in psychiatry, for in this science these three terms are very clearly and very strictly demarcated. And it is highly necessary that these distinctions should be observed, because these terms stand for very different phenomena in mental disease — phenomena of different value and importance, and each with its own special significance as to the patient's welfare.

By an illusion is meant a misinterpretation of a sensory impression. Ordinarily, when the mind is acting in a perfectly normal way and there is nothing to confuse its impressions or to obstruct its proper perceptive powers, a sensation, whether of the eye, ear, taste, or skin, is conveyed to the consciousness and is recognized correctly. Thus a sound, as the note of a bird or the voice of a friend; or the sight of some object, as of an animal moving in the distance, is properly conveyed to the intelligence and is properly recognized. But this process may be interfered with in various ways. The senses, notoriously, are not always to be relied upon. Even the normal mind may make mistakes in the interpretation of sensations, and still more so may the mind that is impaired. It thus happens that all illusions are not necessarily evidences of a diseased mind; this faulty action of the senses, or of the perception, may and often does happen in the cases of persons of sound mind. For instance, a person walking along a path in the dusk may mistake a bush for an animal; he simply misinterprets an object, and this object is not imaginary but has a real existence. So, too, the mirage which sometimes appears at sea, might lead a perfectly ignorant person to maintain that he saw a ship inverted sailing in the sky. These are instances of illusions in which the normal mind may be temporarily deceived. But the normal mind tends to correct its illusions, and this it does sooner or later according to its opportunity and its degree of knowledge. In this respect the insane mind differs from it; the illusions of the insane are usually firmly believed in; there is no spontaneous tendency on the part of the insane mind to correct its illusions. On the contrary, they are firmly embraced, and are often made the starting point of a train of associated morbid ideas, whereby the mental disorder is all the more confirmed.

An hallucination differs from an illusion in the fact that it is entirely subjective. In a strict sense it is a disorder of perception in which the external sense organs do not participate, and it leads to a belief on the part of the patient that he perceives some external object, whereas in fact there is no such object corresponding to the perception. In other words, it is a disorder of perception giving rise to a false belief in a sensation. For instance, a person believes that he hears the voice of an acquaintance speaking to him, when there is no voice either of the acquaintance or of any one else; or, again, a person thinks he has a vision of a deceased friend or of some other spiritual being, whereas there is no external object or person whatever giving rise to this or any other sensation. The whole process, therefore, is subjective, or within the patient's own mind; it is without any objective equivalent. It is thus readily seen that an hallucination is much more deeply seated than an illusion, and is a much more direct evidence of a disorder of the mind. Some authorities doubt indeed whether a true hallucination ever occurs in a normal person; what appears to be so in any given case would probably be found on strict inquiry to be an illusion. Although this may be an extreme position, the fact remains that hallucinations are very rare in the sane and very common in some forms of insanity; and that, as in the case of illusions,

the sane tend to correct them, while the insane adhere to them with unswerving belief. The most common hallucinations of the insane are the visual and the auditory, and they are sometimes very grave symptoms. Auditory hallucinations are especially dangerous, for they may lead the patient to commit acts of violence in response to their suggestions.

A delusion differs from both an illusion and an hallucination in the fact that it is not a sensory disorder — but a derangement entirely within the intellectual sphere. It is an erroneous belief, but one which is due entirely to mental disorder. The latter part of this definition is essential, because a delusion is essentially something more than a mere error of belief or judgment. It is an erroneous belief that is due to insanity, or to a disordered mind. Mere errors of belief may and do occur in persons who are sane: no person, in fact, is exempt. Such errors may be due to ignorance, prejudice or faults of education, but they are not evidence of insanity; otherwise the whole world would be insane. In the case, however, of an insane pauper who believes that he is a multi-millionaire, or that he is emperor of the United States, there is obviously something more than a mere erroneous belief in the sense of an error of judgment or opinion. Such a patient has developed an idea which no sane man in similar circumstances could have developed; in other words, he has a delusion, and he is not insane because he has the delusion, but he has the delusion because he is insane. The insanity or mental unsoundness is the fundamental fact, and is shown usually by other symptoms besides the tendency to form delusions. As in the cases of illusions and hallucinations, the insane cling to their delusions with great tenacity; no argument, no logic moves them. The delusions of the insane are usually distinguished as systematized and unsystematized. In the former the delusion has a certain consistence, coherence and endurance; in the latter the ideas are more or less incoherent and changing. Delusions again may be expansive or depressive, according to the emotional tinge. See also IMAGINATION; INSANITY.

JAMES HENDRIE LLOYD,
Formerly Neurologist Philadelphia Hospital.

Illustra'tion of Books, the art of making and reproducing pictures to supplement or adorn the text. In England book illustration may be said to have reached its culminating point as regards engraved and etched plates, in the first half of the 19th century, in the series of annuals, keepsakes, and the higher class books illustrated by such masters as Stothard, Turner, etc. The revival of wood engraving by Bewick and his pupils gradually led to the restoration of that art as an illustrating medium. In this it was greatly aided by the facility with which wood-engravings can be printed along with the text, together with the advance made in typographic printing. The series of Christmas books illustrated by John (afterward Sir John) Gilbert and Birket Foster had no small share in that advancement. Among the artists who have helped to raise the art to its present high position may be mentioned Cruikshank, H. K. Browne ("Phiz"), Doyle, Leech, Tenniel, Millais, F. Walker, W. J. Linton, Herkomer, etc. The development of what has been called the American school of wood-engraving has still further increased the influence of that branch of art for illustrative purposes.

Relief-Block Processes for Book Illustrations.— Many processes have been invented to produce relief blocks with a view to supersede wood-engraving in book illustration. The object aimed at is to reproduce drawings in line or wash, in fac-simile, on a relief block capable of being printed from the surface on the type-press. That is, the lines or parts which impress the paper are to be left in relief, while the white parts are cut out so as to leave the paper unprinted. "Process" relief blocks may be divided into two kinds, those reproduced from black-and-white, or line drawings in pen and ink; and those from half-tone photographs, or wash drawings. When pen-and-ink drawings, engravings, or any other drawing in line are to be produced the subject is photographed to the required size. This process allows the drawing to be made of any convenient size, while a drawing on transfer paper must be of the exact size required. There are also several gelatine processes, all of which are based on practically the same principle. The production of relief blocks from ordinary photographs or drawings made by washes of black and white baffled all efforts till the invention of Meisenbach's process. In relief block every part which touches the paper prints black, and every part which does not touch the paper leaves it white. Some method had to be devised of turning the smoothly graded tones of a photograph into pure black and white. The method sought after was to break up the photo-tones into a grain, stipple, or line, which should be closest in the darkest parts, and become more open as the lights were approached. That patented by Meisenbach of Munich in 1882 as the one on which nearly all the most successful subsequent processes are based, may be briefly explained. A glass plate is prepared with fine parallel lines. This is exposed between the lens and the sensitive plate in the camera, at a very short distance from the plate, and when the exposure is half completed the cap is put on the lens, the lined plate is taken out and put in with the lines in the reverse direction, and the exposure is completed. The resultant negative is thus broken into minute regular dots. In a successful process invented by Mr. Ives, of Philadelphia, and patented in 1884, a swelled gelatine relief is taken of the subject, and on a plaster cast of this a stipple is impressed by means of an elastic stamp, which gives the operator greater control over the effect. He is then able to ink the plaster cast and transfer an impression of it to a sheet of india-rubber, and from that to a plate of zinc. A "grained" photograph being finally obtained by means of any of the thousand and one processes, it is transferred to zinc and etched. Besides these photo-chemical processes there are various mechanical methods of producing relief blocks. Some of them are very technical. Dawson's typo-etching process, an improvement on Palmer's glyphographic process (patented in 1848) is very extensively used for the production of maps, plans, diagrams, etc. This process is carried to great perfection in the United States, where most beautiful maps are produced by it.

These processes, though simple enough in theory, give great scope for skill in manipulation, and much of their success depends on the

ability of the operator. The rapidity with which they can be produced has rendered the daily illustrated paper a possible and accomplished fact. As to cost, blocks can be produced for from 8 to 30 cents a square inch of surface, according to the nature of the drawings — the stipple process being the more expensive. In France, Germany, and the United States the processes have been much more employed as a means of book illustration than in Great Britain, though even there every year shows rapid advance in their use. As to the comparative merits of wood-engraving and the processes, opinions differ greatly. Generally, it may be said that the processes are more suited for subjects on a large than on a small scale, unless they are very slight, in which case they can never pretend to be more than sketches. In wood-engraving the photograph can be transferred direct to the wood and engraved without further expense for drawing, and the result, both artistically and from a printing point of view, is much more satisfactory. Though within its limits the process makes good work and the future is before it, the fact remains that as yet for finished picture work, good wood-engraving has not been superseded. See Books: Engraving; Lithography; Manuscripts, Illumination of; Photo-Engraving; Photogravure

Halsey C. Ives,
Director School of Fine Arts, St. Louis.

Illyria, ĭ-lĭr'ĭ-ạ, or **Illyricum,** a name anciently applied to a considerable region on the east side of the Adriatic Sea, the inhabitants of which were the ancestors of the modern Albanians. In 228 B.C. it became a Roman province. After various vicissitudes under different rulers it formed part of the Franco-Napoleonic empire as the Illyrian provinces. In 1815 it reverted to Austria and became the kingdom of Illyria, a title it retained until 1849, when it was divided into the provinces of Carinthia, Carniola, and the Coast-lands.

Il'menite, or **Menaccanite,** also known as titaniferous iron ore, is a black, heavy, mineral crystallizing in the hexagonal system. It is widely distributed, occurring in diorites and many other igneous rocks. It is an oxide of iron and titanium containing when pure 36.8 per cent iron and 31.6 per cent titanium, and is frequently associated with magnetite. Iron ores containing ilmenite occur in vast masses in the Adirondack region of New York, in Quebec, Canada, and in northern Minnesota, and ilmenite is a common constituent of the black sands found on some ocean beaches. The presence of titanium decreases the fusibility of an iron ore, hence the failure of many attempts to work black sands in the blast furnace. It is likely, however, that the titaniferous iron ores will become important sources of iron by the development of special methods for their treatment. See Titaniferous Iron Ores.

Ilocos Norte, ē-lō'kōs nōr'tā, Philippines, a province of Luzon, occupying the northwestern part of the island; greatest length, 79 miles; area, 1,265 square miles (including the dependent islands). Two mountain chains inland extend parallel with the coast; the surface otherwise is much broken by foothills, but it is fertile and well watered. Among the natural wonders of the province is a grotto 39 acres in extent and of great beauty, situated in Lice Mountain. The products include rice, cotton, chocolate, corn, sugar, and a fair grade of tobacco; there are deposits of iron and copper in the mountains, the latter having been worked by the natives. The chief industries are agriculture, horse and cattle raising, fishing, and the weaving done by the women. Civil government was established in September 1901; the people of the province are among the most progressive and industrious of the native races, and the new government was received with general satisfaction. Pop. 164,000, mostly Ilocanos.

Ilocos Sur, soor, Philippines, a province of Luzon, on the west coast, bounded on the north by Ilocos Norte and on the south by Unión; length 70 miles; area 492 square miles (including dependent islands). The eastern boundary consists of a chain of mountains which slope toward the coast in terraces; the rivers are small. The coast road runs through the province from north to south, connecting the important towns and villages. The soil is fertile, the principal products are rice, corn, sugar, indigo, chocolate, peanuts, and vegetables; the chief industries, other than agriculture, are the weaving of cotton cloth, the manufacture of baskets, hats, card cases, and pipes, and cattle raising. There is also considerable trade, carried on mainly through the native markets in the different towns, and some export. Civil government was established 1 Sept. 1901. Pop. 180,000, mostly Ilocanos.

Iloilo, ē-lō-ē'lō, Philippines, province of Panay, including the eastern and southeastern coast of the island; greatest length, 111 miles; area 2,102 miles (with dependent islands). A range of mountains follows the northern and western boundary lines; the rest of the surface is undulating, sloping to the sea. There are several large rivers, the most important being the Jalaur and the Jaro. This province has some of the best roads in the archipelago; the principal towns are connected with the capital, Iloilo, and some of the rivers are navigable for native boats to the foot of the mountains. The products include sugar-cane, corn, rice, coffee, chocolate, tobacco, and hemp; there are also in the province deposits of gold and iron, stone quarries, and extensive forests. The chief industries are live-stock raising, the weaving of fabrics of pineapple fibre (piña) and cotton, and the manufacture of sugar. In 1899 the United States troops occupied the province, immediately began operations against the insurgents who were located there with headquarters at Santa Barbara, and succeeded in dispersing their forces. In April 1901 civil government was established. The inhabitants are mostly of the Visayan race and are generally Catholics, though some of the mountain tribes are still heathen. Pop. 423,500.

Iloilo, Philippines, capital of the province of Iloilo, Panay, situated on the Iloilo Strait at the mouth of the river of the same name. It is irregularly built, but the public buildings and the houses are of good construction. It has an excellent harbor, and is the second town of the Philippines in commercial importance; it is the centre of the trade of the province and has also a large foreign trade, exporting tobacco, rice, coffee, hides, and hemp, and im-

porting Australian coal and general merchandise. There are also several industries, chief among them being the manufacture of piña, jusi, and sinay. In February 1899 the insurgents who were in possession of Iloilo fired upon the United States gunboats Petrel and Baltimore; the town was then bombarded and taken by the Americans. Pop. 10,500.

Ilopango, ē-lō-pän'gō, **Illabasco,** or **Cojutepeque,** San Salvador, Central America, a lake of volcanic origin, 6 miles southeast of the city of San Salvador, about 14 miles long by 6 miles broad. It is surrounded by high, precipitous hills, composed of scoriæ and volcanic stones, and has several islets, one of conical shape about 400 feet high, formed during a volcanic eruption in 1879–80. Fish abound, although the waters exhale a disagreeable sulphurous odor, and are unpotable. The surface of the lake is 1,200 feet below the level of the surrounding country; when ruffled by a breeze the waters have a singularly brilliant parrot-green color.

Image, in optics, the picture or impression produced by the luminous rays from an object reflected or refracted in mirrors or lenses when they enter the eye of an observer as if they had proceeded from a representation of the object. More correctly, the image is the locus of the foci (or circles of least confusion. See Focus) of rays from consecutive points of the object. When the light rays actually pass through the points of the image the image is real and may be thrown upon a white screen. If no screen is interposed the image can be seen by an eye placed in the pencil of rays which pass through it. When the light rays do not actually pass through the points of the image, but diverge from one another on leaving the mirror or lens, the image is said to be virtual, and cannot be thrown upon a screen; it becomes visible to an eye placed in the pencils of rays which appear to have passed through it. See Mirror; Lens.

Images, Veneration of, the practice of venerating and honoring in public or private graven or painted representations of sacred things or persons. Because of the general prevalence of idolatrous worship of images, the Jews in the Old Law were forbidden the making of images, although evidence of the lawfulness of the practice is afforded in the positive command to "make two cherubim of beaten gold on the two sides of the oracle," to "make a brazen serpent and put it up for a sign." The walls of the catacombs, which were the refuge of the first Christians in times of persecution, show many sacred pictures, and after the period of the persecutions the use of sacred images or paintings became open and undespised. Consult Damascene, 'Treatise on Holy Images,' translated by M. H. Allies (1898).

Imaginary Quantity, the result of an algebraic calculation, when the application of the rules for resolving equations leads to an operation that cannot be performed. The operation referred to is the extraction of the square root of a negative quantity. Thus in the equation

$$x^2 = -a^2,$$

to find the value of x we should require to take the square root of $-a^2$; and this is impossible. To indicate this impossibility the roots of the equation above are written thus: $x = +\sqrt{-a^2}$, $x = -\sqrt{-a^2}$, or more frequently and more neatly $x = +a\sqrt{-1}$, $x = -a\sqrt{-1}$. The name imaginary quantity is given to the $\sqrt{-1}$, and any algebraic expression containing $\sqrt{-1}$ is called an imaginary expression: thus $a + b\sqrt{-1}$ is an imaginary expression.

These imaginary roots have proved of great importance in algebraic geometry. In fact, the employment of imaginary quantities systematically is the foundation of some of the greatest modern discoveries and improvements in geometry. Even in algebra, although it is impossible to obtain a value for the expression, or to explain the meaning of it, yet it may prove of use in indicating how to alter the statement of a problem so as to obtain a real solution.

Imagination, that mental power which, according to McCosh, puts in new forms and dispositions what had been previously in the mind. It is therefore not a productive but a reproductive power, for it cannot create anything *de novo,* but can only reproduce in new forms those ideas or images of which it has derived the elements from previous experience. This is in accord with Locke, who says that man's power is much the same in the material and intellectual worlds, the elements in both being such as he hath no power either to make or to destroy.

The imagination differs from the memory, which is also one of the reproductive powers of the mind, in the following way. The memory reproduces what had formerly been before the mind in the form in which it first appeared, but the imagination separates and combines the mental contents in various ways. An act of memory is also accompanied with a belief in the past reality of what the mental picture represents, but an act of imagination (at least in the normal mind) is not accompanied with such a belief. As McCosh has expressed it, the memory may be compared with the mirror which reflects exactly what is before it; whereas the imagination may be likened to the kaleidoscope which reflects objects in an infinite variety of shapes and colors.

When an attempt is made to analyze the workings of the imagination, it is found that this faculty, like all the other mental functions, is governed by certain laws. First in importance among these are the laws of association of ideas. According to these laws the ideas which are summoned up and utilized by the imagination arise according to the principles of contiguity and correlation. By the association of ideas is meant the tendency of ideas to recur in the order or groups in which they naturally stand, either by virtue of some resemblances or some identities of time and place. Thus by correlation is meant the association of ideas in the mind because of some mutual resemblances of parts or qualities; and by contiguity is meant such association because of the proximity in time and place, and not because of any mutual resemblances. In analyzing any act of the imagination it will be found that it follows one or other of these laws of association, although they can be variously grouped and subdivided.

The uses of the imagination and its moral and hygienic relations open up vast questions which can scarcely be more than named

here. It is almost enough to recall the activity of this faculty in the realms of poetry, of fiction and of art, but its offices are not confined to these fields, for in science also its activity is very great and of first importance. Imagination goes before theory, and theory points the way to new discoveries in science. Of such widespread activity is this faculty that practically it is almost impossible to dissociate it from the other mental functions. It is always manifesting itself in some way in even the most prosaic affairs of daily life. The conduct or control of the imagination is a subject that suggests many moot points in psychology, in psychiatry and in ethics. That the imagination is subject to control within certain limits may be granted, although these limits are not fixed, and outside of them the imagination may often run riot without the possibility of control. Its action, in fact, like that of most mental faculties, is largely automatic, and its control by the will, the intelligence and the conscience, is often a matter of the mental training and mental health of the individual. In ethics the control of the imagination, or at least its guidance, so that it shall not minister to sensuous or immoral pleasures, even though these be purely imaginary, is a self-evident rule of conduct, but one which is doubtless often broken with some degree of impunity. In mental discipline its control is also essential, for its too great or mere idle indulgence is no doubt unwholesome and wasteful.

In psychiatry, the imagination, like most or all of the other faculties, is found to be subject to derangement, and this in various degrees, according to the patient and the form of disease. That it is active in the formation of delusions, and is much disturbed in both depressed and exalted states of the mind, is quite evident. In all insane states, except the advanced dements, the kaleidoscopic function of the imagination is apparent. The mental pictures are broken reflections of past mental contents, arranged often at seeming haphazard, and often of only the most sombre and melancholy tints.

Imam, ĭ-mäm, or -mâm', a Mohammedan chief or leader; a title given to the four successors of Mohammed, and to the twelve great leaders of the shütes. In Turkey, applied to the functionaries who call the people to prayer from the minarets, perform circumcision, etc. They are chosen by the people, and confirmed by the secular authority, under whose jurisdiction they also are in criminal and civil affairs.

Imbriani, Vittorio, Italian poet: b. Naples 24 Oct. 1840; d. 1 Jan. 1886. He pursued historical and philosophical studies at Naples, Zürich, and Berlin, but later became a soldier, serving in the wars of 1859 and 1866. The best known of his works are 'Canti populari delle provincie meridionali' (1871–2); 'Dodici canti pomiglianesi' (1876); and 'La novellaja fiorentina' (1877).

Im'bricated Snout-beetle. See Snout-beetle.

Imbros, an island in European Turkey, west from the entrance to the Dardanelles. It is 18 miles long, east to west, 8 miles broad, and terminates west in Point Auflaka, and east in that of Basse. It is mountainous, rising in its loftiest peak to the height of 1,959 feet; well wooded, and intersected with richly-fertile valleys, producing wine, honey, oil, cotton, and lead. It has only two towns — Flio and Castro. Pop. 10,000, mostly Greeks.

Imide, ĭmīd, or -mīd, a chemical substance derived from ammonia, NH_3, by replacing two of the hydrogen atoms by a divalent radical. If all three of the hydrogen atoms of the ammonia are replaced by one trivalent radical, the compound is called a nitrile. When one or more of the hydrogen atoms of the ammonia are replaced by a corresponding number of monovalent radicals the compound thus formed is called an amide or an amine, according to the nature of the radical by which the hydrogen is replaced. See Amide; Amine.

Imitation. Imitation is the process of reproducing by one's own act the observed actions of others. Its beginnings lie therefore in perception. It is the result of a desire to change from the role of spectator to that of actor. Imitation may be of two kinds (1), a primitive and (2) a developed form. The primitive form is an unconscious copying of some object of perception; and is simply a reaction in response to the outer stimulus which excites it. The best example of this kind of imitation is to be found in the sounds which a baby is wont to repeat when it has once heard them. It is a peculiar characteristic of the primitive imitation that the sound, for instance, when once imitated becomes in turn a new stimulus to start the process over again, the result being that the imitated sound is repeated rapidly again and again until the organs are wearied, or the attention is diverted. The exercise is evidently found to be pleasurable, and is therefore continued indefinitely. Mr. Baldwin has given the name "circular reaction" to this kind of imitation, the phrase indicating a sort of self-perpetuating process. The name also of "suggestive imitation" has been given to this class of acts which appear imitative to an observer, but are not consciously felt to be so by the imitator.

The second form of imitation is more complex, and marks a more developed stage of consciousness. The imitation has now become a conscious act. The object perceived has aroused some degree of interest, and there is consequently a conscious effort to reproduce it with the original set before one as a model. In imitation which is of this form, we find the process intimately connected with the attention. In attention there is always a conscious striving for a more accurate knowledge of the object of perception, and imitation serves to gratify this desire, inasmuch as one comes to closer quarters as it were with any act when one tries to reproduce it. Knowledge of it comes then from the inside. This means a concentration of attention, and a consequent result of more definite and satisfying knowledge. Moreover, attention will vary as the interest, for that which one attempts to do himself is always far more interesting than merely that which is observed.

In the development of consciousness imitation as a social factor plays a most conspicuous part. Through it a child acquires all of its social tendencies, and becomes a part of the social organism in which it is to live and move and have its being. Its education starts with the first rudimentary efforts at imitation; and is carried on from this initial stage to the very highest and most advanced forms in constant dependence upon the imitative tendencies. Through imitation the knowledge of one generation is acquired by the succeeding, and a continuity in development is assured which makes for the progress of the race.

In this connection, it is to be noted, however, that with the imitative impulse there are two other tendencies which have free play and a wide scope. These tendencies must be reckoned with also. They are the tendency to social opposition, and the tendency to inventiveness. The tendency to social opposition is a desire for self-assertion, an impulse primarily to do something different from that which others are doing merely from a feeling of native opposition. This impulse is seen in very young children, and remains throughout life. It is often recognized as unreasonable, but nevertheless irresistible. It is a fertile source of the differences of opinion which so early develop in childhood. It prevents a slavish imitation and the loss of initiative in action. However in order to act in a manner which differs radically from one's social environment, there is implied a preliminary training of an imitative sort; for there must be a basis of common activity in order that a departure from the accepted mode may have any significance, and there must be also a body of common beliefs, in order that there may be any such thing as a real difference of opinion. The other tendency is a more pronounced and a more definite form of opposition to imitation; it is the tendency to inventiveness, not for the sake of opposition, nor as the result of an inevitable clash of opinion in one's social setting, but for the sake of producing that which is suggested from within, and not from without. It is the working out of one's own individuality without waiting for a copy or model. It is a shifting of the centre of interest from some object which is perceived, to some object of the inner sense, a fancy born within the brain, an idea which has its origin in the depths of one's own consciousness. This tendency is seen even in early acts of imitation, a tendency to depart from the copy, to introduce variations of design, to improve upon the model.

Here again in order that there may be increased power of independent production, there must be a previous schooling in the art of exact imitation. The original artist is not one who has never copied from a model nor studied the works of the masters. It is the interplay of the imitative impulse with the tendencies to social opposition, and to inventiveness which make progress possible. Progress is not repetition nor is it on the other hand activity which swings clear of any past. Where there is progress there is imitation, but the kind of imitation which allows full range for inventive play, and independent opinion.

There is a special form of imitation which appears on a large scale in the so-called mob impulse, where individuality seems merged in the tendencies of the mass, and imitation is in the nature of a reaction. The individual is swept along with the crowd, not because he wills it necessarily, but because the action of the crowd carries him away as with a flood. This kind of imitation has been given the name of "plastic imitation." Much study has been devoted of recent years to the relation of imitative impulses in animals to congenital tendencies. The instinctive furnishes a strong predisposition to imitation, and in many of the early activities of animals it is most difficult to draw a line of distinction between instinct and imitation.

JOHN GRIER HIBBEN,
Professor of Philosophy, Princeton University.

Immaculate Conception of the Blessed Virgin Mary, a doctrine of the Roman Catholic Church whereby it is declared that "The Blessed Virgin Mary, at the first instant of her conception, was, by a singular privilege and grace of Almighty God, in virtue of the merits of Jesus Christ, Savior of mankind, preserved immaculate from all stain of original sin." In these words is the doctrine proposed for the acceptance of the faithful in the Apostolic Letter of Pope Pius IX., dated 8 Dec. 1854. Previously, for at least 600 years, the doctrine of the Immaculate Conception had been canvassed in the theological schools, and had from an early period in the Church's history been entertained with more or less definiteness by eminent Fathers of the Church and other ecclesiastical writers. The most notable passage from the writings of any of the Fathers relating to this subject is, doubtless, that quoted from St. Augustin's treatise on 'Nature and Grace' (c. 25) in which he makes an exception of Mary when he declares that all mankind are in sin because of Adam, "except the Holy Virgin Mary," he writes, "concerning whom, for the honor of the Lord, I would have no question at all raised in treating of sin — *nullam prorsus, cum de peccatis agitur, haberi volo quæstionem.*"

In the 12th century the great St. Bernard protested vigorously against the usage of certain churches of France in commemorating by an annual festival the Conception of the Blessed Virgin; but the ground of St. Bernard's complaint was, not that the belief in the Immaculate Conception was erroneous, but that the See of Rome had not signified its approval. At the same time St. Bernard refers the whole matter of his dispute with his opponents, the canons of Lyons, to the judgment of the Holy See. The authenticity of his letter has been disputed, but on grounds, as Benedict XIV. implies, absolutely insufficient. Throughout the 13th and following centuries the doctrine of the Immaculate Conception was a subject of keen disputation in the theological schools, its chief advocates being theologians of the order of the Franciscans, its opponents the children of St. Dominic. But the doctrine won ground steadily. In 1439 the Council of Basel declared it to be "A pious doctrine consonant with Catholic faith"; the Council of Trent abstained from formally approving it as an article of Catholic belief; but in their definition of original sin, the Tridentine Fathers took care, with St. Augustin, to except the Blessed Virgin out of the number of those bearing the stain of original sin.

At last, in 1849, Pope Pius IX. judging that the time had arrived for expressing the mind of the Church upon this question, addressed letters to all the bishops of Catholic christendom inviting them to report the opinion and feeling of their respective churches regarding the expediency of declaring the doctrine to be an article of Catholic belief. Five years were allowed to elapse before the next step was taken — that of pronouncing with the unanimous consent of the chief pastors throughout the world and of the churches, the dogmatic definition that "the doctrine was revealed by God, and therefore should firmly and constantly be believed by all the faithful." To catholic-minded men, says Cardinal Newman (Apologia p. 279). "there is no burden at all in believing that the Blessed Virgin was conceived without original sin: indeed it is simple fact to say, that Catholics have not come to believe it because it is defined, but it was defined because they believed it."

JOSEPH FITZGERALD.

Immigration to the United States. The subject divides itself broadly into seven heads: (1) the general history of the foreign influx, its numbers, fluctuations, and causes; (2) its relation to the previously existent population; (3) its sources, and the changes in them; (4) its distribution, the changes in it, and the constituents of the population due to it; (5) its industrial character; (6) its social effects, in occupations and wages of the native population, politics, crime, insanity, pauperism, and illiteracy; (7) the legislation with regard to it, and the public feeling which produced the legislation.

1. The same causes which were bringing a small but steady stream of European emigrants to this country before the Revolution continued to operate after it. From 1783 onward, it was estimated at 4,000 a year till 1794, when the French-English war raised it to 10,000. It dropped again to about 6,000 a year till 1806, when the British and French Continental blockades and the American Embargo practically annihilated it for a decade. (See EMBARGO.) In 1816 the passenger arrivals (including returned Americans) numbered toward 8,000, in 1817 22,240. The numbers and hardships from overcrowding drew out legislation noted later; and from 1 Oct. 1819 account has been kept at all customs ports of the number, sources, and conditions of arriving aliens. The following table gives the number in each year since.

IMMIGRATION TO UNITED STATES BY YEARS.

Year ending 30 Sept.		Year ending 30 Sept.	
1820	8,385	1843	52,496
1821	9,127	1844	78,615
1822	6,911	1845	114,371
1823	6,354	1846	154,416
1824	7,912	1847	234,968
1825	10,199	1848	226,527
1826	10,837	1849	297,024
1827	18,875	1850	310,004
1828	27,382	1850 (1 Oct. to 1 Dec.)	59,976
1829	22,520	1851 (Jan. to Dec.)	379,466
1830	23,322	1852	371,603
1831	22,633	1853	368,645

1881	669,431	1902	648,743
1882	788,992	1903	857,046
1883	603,322		

Totals since 1820, 20,952,467. But it must be remembered, first, that up to 1856 the record is of all "alien passengers arrived," without discriminating passengers from immigrants, so that much should be abated from this total; second, that the immigration overland from Canada and Mexico is not counted in — and in 1900 Canada was put down as the birthplace of 1,183,255 persons, and Mexico 103,445 — so that a great amount should be added to the total. On the whole, it seems probable that these accessions have far more than balanced the above duplications, though not the other duplications of the same emigrants coming and going.

IMMIGRATION BY DECADES.

1821-1830	143,439	1861-1870	2,318,824
1831-1840	599,125	1871-1880	2,812,191
1841-1850	1,713,251	1881-1890	5,246,616
1851-1860	2,598,214	1891-1900	3,844,420

Since 1900, 1,993,707, or half as much in the past three years as in the whole previous decade. The number of arrivals reported in 1903 exceeds the largest number for one year (1882) by 68,054.

The barest glance at the first table shows that it has eight well-marked periods, though with notable fluctuations within them. The first is from the beginning to 1826 inclusive, with a slow increase to about 10,000 in 1794. Thence to the end of 1831 it rather more than doubles; probably from reports of the fertile lands just reaching a wider stratum of peoples, and the miserable European industrial conditions of the time of the Holy Alliance. Then with a sudden bound it almost trebles, and with a sharp drop after the panic of 1837, rises to seven-fold in 1846; the first leap perhaps due to the opening up of the West by steamer navigation, the steady increase due to the same and to railroads making the central lands easy of access. The Irish famine then begins to swell it to a torrent, shortly increased by the California gold discoveries, which do not exhaust their effect till 1854. The sudden drop then, and its continuance later, may be laid to several causes. The anti-foreign agitation in this country, owing to the flood of foreigners demoralizing politics and industry, probably had much effect; then the business depression of 1857 and the following years, merging into the War, kept it down in spite of the efforts of the steamship agents, now penetrating every country for business. Later in the War, the scarcity of labor here, owing to the drain of the able-bodied, drew in a larger immigration of laborers; but the new period fairly begins only after the War. From 1866 to 1873, the great

inflation time, when countless new enterprises were started and new railroads built by thousands of miles, was naturally a palmy time of immigration. Then the great panic and the ensuing hard times struck it down and kept it down till 1879. The revival in 1880 brought it back instantly to the mark of eight years before, and two years later it reached a climax not again attained till 1903; and it has never gone down to near its old mark except for two years, 1897 and 1898, the drop 1894–8 being due to the panic and hard times. Of course each increase tends to widen the next, arrivals encouraging others to come.

2. The following table shows the number and proportion of the foreign-born for the past half-century, and also the native-born of foreign parentage, single or mixed, for 30 years, indicating the foreign strain in American blood.

Census years	Total Pop.	Foreign-born		One or both parents foreign	
		Number	Per cent	Number	Per cent
1850	23,191,876	2,244,602	9.7	.....	.....
1860	31,443,321	4,138,697	13.2	.....	.....
1870	38,558,371	5,567,229	14.4	10,892,015	28.2
1880	50,155,783	6,679,943	13.3	14,922,744	29.8
1890	62,622,250	9,249,547	14.8	20,676,046	33.
1900	76,303,387	10,460,085	13 7	26,198,939	34.3

Comparison of this table with the first two shows some striking facts. In 1850, of the 2,500,000 (about) who had come into the country since 1815, only one tenth were dead or had re-emigrated in the 35 years. It is true that nearly one half the whole had come in within five years; but even so, this is a suspicious showing, and suggests a large overland emigration from Canada (especially during the gold fever 1849–50) which does not figure on the records. Every succeeding census has shown a large and increasing discrepancy between the arrivals and the remaining foreign population, the falling-off being sometimes difficult to explain except by duplications, re-emigrations, and a heavy death-rate. As the grandchildren of the arrivals of two generations ago are now "Americans," the percentage of foreign-born is not rising, and even that of the whole foreign-parentage class is but little greater than that of old, under the enormous flood of immigrants.

3. Most of the early arrivals came from Great Britain; about 110,000, or 76.5 per cent, from 1820 to 1830, while Germany sent about 10,000. In 1850 the foreign-born of Anglo-Saxon blood, English, Scotch, and Canadian, must have been over 750,000, while that from Celtic Ireland was probably 650,000 — about 60 per cent from all Great Britain; the Germans furnished 584,000, or 36 per cent. The Teutonic blood was overwhelmingly dominant still, and the Anglo-Saxon largely so. In 1860 the elements were still much the same: Great Britain claimed nearly 2,500,000, or 60 per cent, Germany 1,276,000 or over 30 per cent. None others were of much account. In 1870 the totals were much larger for the older elements, but the British percentage was dropping, and other elements coming forward: Great Britain and Canada showed 3,120,000, or about 55 per cent; Germany 1,690,000, about 30 per cent as before; but there were nearly 250,000 Scandinavians against some 60,000 the decade before, and 40,000 Bohemians. Of the Canadians, probably 150,000 were French. In 1880 the still increasing British and English-Canadian contingent showed about 47.5 per cent; the German holding its own well, some 30 per cent; making over 2,000,000 in all. But there were 85,000 Bohemians, 48,000 Poles, 440,000 Scandinavians, 44,000 Italians, and 35,000 Russians. In 1890 the change was marked, though the Teutonic strain was still farther to the fore: the Germans and German Swiss and Austrians footed up nearly 3,000,000, or about 33 per cent, Great Britain and English Canada furnished about 2,700,000, now only about 29 per cent. But Poland, Russia, and Bohemia now showed nearly 450,000; Italy, 182,500; Hungary, 62,435; Austria, 123,271, much of it Slav; Scandinavia, 933,000. In 1900, the tendency had become so striking as to necessitate a further grouping for clear perception of its meaning: Poland, Russia, Bohemia, and Hungary — in a word the Slav countries — were the birthplaces of over 1,000,000 Americans, nearly 10 per cent of all our foreigners; Italy of nearly 500,000; Mexico of over 100,000; Scandinavia of over 1,000,000; France and French Canada of about 500,000: the whole representing nearly as great a share as Great Britain. If the showing is by immigration and not by the masses still living from the old immigrations, the account is far more impressive: the percentage of Great Britain had sunk in half a century from over half the total to 19.4 per cent; of Germany, from 38 per cent to 14; while the Scandinavian had risen from a neglectible quantity to about 10 per cent of the whole, and the East European, from practically nothing, had risen in the decade to 1,186,000, or nearly 31 per cent. The following table for half a century by decades, and for 1901–3 separately, tells its own story:

	England and Scotland	Ireland	Germany	Norway and Sweden	Italy	Russia including Poland	Austria-Hungary
1851-1860.....	423,974	914,119	951,667	20,931	9,231	1,621	.....
1861-1870.....	606,896	435,778	787,468	109,298	11,728	4,536	7,800
1871-1880.....	548,043	436,871	718,182	211,245	55,759	52,254	72,969
1881-1890.....	817,357	655,482	1,452,970	568,362	307,309	265,088	353,719
1891-1900.....	342,357	403,496	543,922	325,943	665,668	588,866	597,047
1901-1903.....	64,065	94,542	90,041	144,547	544,993	328,697	491,380

A still further condensation will present the essential elements even more clearly:

	Teutonic and Anglo-Celtic	South and East European
1871-1880	1,914,341	179,982
1881-1890	2,494,171	926,116
1891-1900	1,615,718	1,841,581
1901-1903	393,195	1,365,070

Nearly as many have come from southern and eastern Europe in the past three years as

in the entire preceding decade; while the Teutonic strain, even when reinforced by the great Scandinavian flood, has dropped to less than a fourth of that, and less than a sixth of what it was 20 years before.

4. The distribution of this mass of immigrants in the United States may be considered in various aspects — of foreigners as a whole, and of special races; of foreign-born as bearing on politics and industry, and of all with immediate foreign blood as bearing on heredity and sociology. Here we shall consider both; the latter to some extent, but the second first. In the last census, of 25,928,462 persons of foreign parentage, about seven eighths were in the North Atlantic and North Central divisions, where are the great manufacturing cities and abundance of fertile land. The first division had slightly the more. Only 1,659,069 were in the South Atlantic and South Central divisions together. Of cities, too many to mention have a majority of this population of foreign parentage; of cities with 25,000 and over, by the census of 1900, 93 had over 50 per cent, and 18 over 75; while 6 — Fall River, Holyoke, and Lawrence, Mass., Hoboken, N. J., Woonsocket, R. I., and Milwaukee, Wis. — had over 80 per cent. The highest percentage was in Fall River, 86.1. Of Massachusetts' 20 cities of this size, only 1, Haverhill, had less than half of foreign parentage, and that had 48.9.

Of course these figures, which seem very large, have no bearing on the question of Americanism in feeling or action. The children of foreign parents are not less intensely American than those of natives; it is their own country. The figures of actual foreign birth are very different. North Dakota still leads, but with only 35.2 per cent; Rhode Island 31.1, Massachusetts 29.9, Connecticut 26.1, New York 25.9, Minnesota 28.8, Wisconsin 24.8. Of cities, none have a majority of foreign-born, and but one over 40 per cent. But this concentration of the foreign-born in the cities is precisely one of the gravest elements in the problem. In 161 principal cities in 1900 was nearly half — 49.2 per cent — of the total foreign-born, making 26.1 of their population, against 9.4 per cent of the total in the rest of the country.

Of the nationalities which have formed "colonies" in the different places, those with the less understood tongues are of course the most prominent. Religion is occasionally potent, as well as proximity: thus the French Canadians keep together as Roman Catholics, and mostly in New England as nearest home. The Italians, city more than farming folk, are most numerous in New York, Boston, Chicago, New Orleans, and San Francisco; the Norwegians, mostly agriculturists, in Wisconsin, Minnesota, and the Dakotas; the Poles, city men, chiefly in New York, Boston, Philadelphia, Chicago, Milwaukee, Detroit, Minneapolis, and St. Paul; the Bohemians in New York, Chicago, and Cleveland; the Swedes in New York, Boston, the Connecticut cities, Philadelphia, Illinois, and Minnesota; the Welsh, not as Celts but as miners, mostly in the Pennsylvania mines. In 29 cities of which the census gives a special report, the Germans predominate over all other foreigners in 17: the greatest actual number being in New York, which had 322,343; though the greatest percentage, 65.9 of the whole foreign population, is in Cincinnati, Milwaukee having 60.5, Louisville 57.8, and St. Louis 52.8. The Irish nave a majority in 9, the chief lead being in Cambridge, Mass., 36.9. The French Canadians predominate in Fall River and Lowell, Mass., cotton-mill cities, with 40.3 and 35.8 per cent. The Swedes have the greatest number in Minneapolis, 32.8 per cent.

5. The question of occupations of the foreign-born is of the first importance, as bearing on that of wages, which they are supposed to lower. We have to discriminate between several facts in this: (1) their distribution between occupations; (2) the total number of working age; (3) their concentration in cities where most of the manufacturing is carried on. The last has already been shown. For the others, the government volume dealing with the census of 1900 is not yet issued; but that of 1890 in this regard probably differs little. The report of the occupations assigned by intending immigrants year by year gives little help, as they drift into various occupations; but it may be said that in 1902, of 495,500 male adults, only 80,000 were skilled laborers, and less than 3,000 professional men. This is natural, the best men being fairly placed at home, as a rule. In 1890, while the foreign-born over 15 formed 22 per cent of the whole population of that age, they formed 36 per cent of the domestics and menials, and 34 per cent of the hands in the manufactories. In special employments, they showed far more striking totals. They formed 71.12 per cent of all tailors, 59.52 per cent of bakers, 53.13 per cent of hucksters and peddlers, 49.66 per cent of restaurant and saloon keepers, 47.62 per cent of leather-workers, over 46 per cent each of stone-cutters, textile-mill hands, and cabinet-makers, and 44.5 per cent of gardeners, florists, and that class.

6. As to social effects, where the foreign-born are of moderate numbers, and do not increase faster than the general development of industries, they can hardly depress wages much; and two of the complaints made against them — that they lower wages by willingness to accept a poor standard of living, and demoralize industry by readiness to strike — cancel each other. They cannot at once be satisfied with poor pay and unsatisfied with fair pay. But when concentrated into special occupations in the cities, as the enormous tailoring contingent in the sweat-shops, where for a time they are willing to work for starvation wages to get on their feet, they can and do for a considerable time ruin all decent workers' prospects, depress wages below an endurable point, and drive natives or better-grade foreigners out of the trade, after extreme distress.

Politically, facts do not warrant the belief that the foreign element exercises the corrupting influence, either by ignorance or venality, that is often attributed to it. There are no worse governed or more corrupt cities in the Union than some where the foreign element is relatively small; nor is there any evidence that as a whole they are more easily swayed by appeals to selfishness. They are, however, the chief ingredient of political and industrial mobs.

Regarding crime, the usual statistics are misleading both for and against the immigrants. On the one hand, they restrict the records to the serious crimes, in which the native-born

"tough," from his rearing and training into thorough knowledge of his surroundings, and superior chances of escape, naturally takes the lead; while the foreigner, from his great predominance among those with short sentences, seems to swell heavily the volume of petty crime. It is believed also, probably with truth, that the native-born of foreign parents are worse than their fathers and vastly worse than the native white. On the other hand, the statistics of crime are for the whole population, not for the adult males of youth and middle age, who mainly commit it; on the same basis, the foreign portion makes no worse showing than the native. Still again, it is believed that the fact of the foreign population being mostly of the lower orders in wealth and social position has much to do with it, and that class for class, there is little difference.

In pauperism, there can be no question that the foreigners, mostly coming with nothing and having no friends to care for them, should swell the pauper population immensely. In 1890 there were over 3¾ times as many foreign-born as native-born paupers.

As to insanity, there is a considerably larger tendency to it in the foreigner than the native; most likely from greater average debility of constitution, which shows in the brain as well as in other organs. Between the ages of 25 and 55, the period which furnishes most of the patients, there was in 1890 a percentage of insane foreigners more than half as large again as that of natives.

With regard to illiteracy, while the foreign-born white is naturally much less educated than the native, his children average fully as well.

7. The first legislation in the United States on the subject of immigration was of 2 March 1819, and merely provided that a record should be kept of the number of passengers arriving in each customs district, with their sex, age, occupation, and country of birth. For many years there was no thought of anything but exultation in the number of arrivals, as increasing the wealth of the country, and providing an asylum for the poor and oppressed. Even the Know-Nothing agitation of the fifties, prompted by political reasons (see AMERICAN PARTY), led to no restrictive legislation. In 1864 the first immigration act was passed by Congress, and was to promote and not restrain it; this was repealed 1868. Several States established immigration bureaus to encourage it and draw it their way. On 3 Aug. 1882 the first restrictive act was passed, but only to bar out criminals, insane, paupers, etc. Head taxes were imposed as a fund for relieving the distressed, etc. Foreign convicts (non-political), lunatics, idiots, and those liable to be a public charge, were to be returned at the expense of the owners of vessels on which they came. The secretary of the treasury was empowered to carry it out and make suitable regulations, and to make contracts with the State officials. On 26 Feb. 1885 a more drastic one was passed, which was well meant, but from its sweeping character has been, as enforced by fanatical or interested persons, the source of much useless hardship, and has tended to make the country ridiculous. This was to prohibit any laborer coming over under contract to work; it did not except professional men or skilled laborers, and while it was aimed at strike-breakers and cheap gangs, was enforced against artists, musicians, architects, etc., and even clergymen, to the discredit of the country's good sense. It has since been somewhat modified. In 1891 the act of 1882 was extended to other classes, and to all "assisted" immigrants not affirmatively shown to be without the terms of the act. This act took the entire matter into the hands of the general government. The act of 3 March 1903 still further amended it by requiring a preliminary inspection at point of departure, and giving the government the right to deport the immigrant landed in defiance of the act within two years after arrival; it also extended to all persons advocating the overthrow of all governments and the assassination of public officials. The number of persons deported under the act of 1882, mainly for pauperism, had been 28,184 from 1891 to 1900, out of 3,844,420 immigrants.

For statistics, see 'Monthly Summary of Commerce and Finance,' by the government; and U. S. Census, 1890 and 1900. See also 'Reports of the United States Industrial Commission on Immigration,' and the article 'Restriction of Immigration,' by Francis A. Walker, in the 'Atlantic Monthly,' LXXVII., 23.

FORREST MORGAN.

Immortality, the survival of the individual, with complete self-consciousness, after death. The belief in immortality can be traced with more or less clearness in the general races of mankind, excepting the most primitive and barbarous.

Barbarous Races.— Sir John Lubbock, in his 'Origin of Civilization, and the Primitive Condition of Man,' denies that the African negroes have any idea of a future life. He quotes Captain Burton as saying that "they believe in a ghost but not a spirit, in a present immaterial, but not in a future; counting on nothing but a present life there is for them no hope beyond the grave." Other negroes, however, think that after death they become white men, a belief which is found in Tasmania, in Tanna, New Guinea, and New Caledonia. In the Tonga islands the chiefs are regarded as immortal; Tooas or common people are mortal. Although the Fijians believe that almost everything has a spirit, few spirits are immortal; the road to Mbulu, the abode of the happy dead, is long and well-nigh impassable, so that few attain to immortality; and a similar view is held by Eskimos and Kaffirs. "The hill tribes of Bengal," says Colonel Dalton in his 'Ethnology of Bengal,' "utterly reject all notions of a future state." The Haitians, however, believed that there was a paradise of the dead situated in the beautiful western valleys of their island. In Tonga the souls of the dead are thought to be transported to a large island stocked with the richest fruits and the fairest flowers. In Dahomey the king constantly sends messages to his deceased father, by messengers who are put to death for that purpose. But there is much contradiction in the reports given by travelers and ethnologists; thus Daniel G. Brinton, in his 'Religions of Primitive Peoples', says: "So filled was the mind of primitive man with the vision of universal and immortal life, that to him there was no such thing as death. The fact, indeed, remained. The tree was shriveled by the lightning, the brute fell by the arrow, man himself gasped his last breath, and lay an inert mass. The

loved child, the warrior hero, passed out of sight to the unseen beyond. But not forever. No! They hovered around the familiar spot, they visited the living in dreams, their voices are heard in the rustling leaves and the falling waters." According to Tylor and Brinton the Indians of both North and South America believe in a future state of existence. The Scandinavians had their Valhalla; the Celts of Britain and Gaul would lend money, taking a note for its repayment in the next world, as the Japanese of to-day are said to do.

Among civilized peoples the idea of immortality has been one of the clearest and most potent elements in their religious systems. Man is a religious animal, and generally his belief in his own survival beyond the grave has been the centre of his creed.

Assyrians.—According to Maspéro, the Assyrians did not, like the Egyptians, believe that the tomb was a house for eternity. The eternal dwelling-place for the soul was far from the tomb, either in the bowels of the earth, or at the Oriental or southern extremities of the universe. There they are judged by the gloomy goddess Allat, who assigns them their places. But the great and good are welcomed into a fertile island, cheered by the sun and having in the midst of it the tree and the river of life. At last heroic souls are received by the gods into their own kingdom on the serene summit of the mountain of the world.

Egyptians.— The Egyptians had dogmatized their views of immortality into a clear and consistent system. After embalming and burial, the soul takes the form of a double, and leaves the tomb occasionally in search of food; but it is also believed that after a longer or shorter sojourn with the dead body the soul migrates to another land. This land consists of three kingdoms of the dead, over each of which reigns a separate divinity. Those Egyptians who have been especially devout toward the sovereign divinity are welcomed here. The most populated is the kingdom of Osiris, consisting of many islands, which may be seen from the earth at the southern extremity of the Milky Way. The voyage to these islands is long and perilous. At last they are reached and the souls are ushered into the court of Osiris, with his 42 assessors. The hearts of the dead are weighed in the scales of Thoth, and they are eventually declared worthy of entering the Field of Beans, a place of teeming fertility, where their life is spent in cultivating and harvesting the crop, and in feasting, singing, playing during their hours of leisure.

Hindus.— The followers of Brahma and Buddha believe in the eternity of the human soul under some form or other, Nirvana or metempsychosis; the Chinese, by their ancestor-worship, acknowledge the immortality of mankind; while the Parsees, like their forefathers, the Zoroastrians of Persia, have always believed in the undying nature of the soul.

Greece.— Before the dawn of Ionian philosophy in Greece there was a vague and poetic anticipation of a future life among the Hellenic races. In Homer we see the under-world revealed to Ulysses, where the wrong-doers are punished. Heroes, like Hercules, are given a place among the gods of Olympus, where they are classed as demigods. More or less conventional as was the idea of a future state, it was yet permanent in Greek religious thought. Both as suggested in the mysteries and in poetry, which was the theology of the age, the notion of a prolonged existence beyond the tomb was never extinguished. The death of Œdipus was hinted at by Sophocles as a sort of translation to a happier life. When Greek philosophy reached its highest culmination in Plato the doctrine of the soul's immortality became an integral part in accepted doctrine, and Socrates drank the hemlock with the immortal declaration, "Those who have lived well and piously, pass from these scenes of earth, like prisoners set free, to a home on high, where they shall dwell in unclouded peace."

Romans.— In the palmy days of their literature the Romans absorbed the ideas of the Greeks with regard to a future life. Cicero had a philosophical belief in immortality, but he does not allude to it in the time of his bereavement. Virgil and Horace each reflect the mythologic imagery of the Greek poets. Horace sees "Augustus with gleaming face sipping nectar" with the Olympian divinities; Virgil copies Homer in his description of the Elysian Fields and the torments of the under-world. None of the Greeks or Romans, excepting Epicurus and Lucretius, his Latin expounder, ever maintained that death is the end of all things.

The Hebrew View.— It has sometimes been considered that the Jews had no definite ideas or beliefs about a future life. It would not be safe to assert this. There can be no doubt that the patriarchs' creed of the future, "of the last days," was one of hope. In the 8th century B.C. all the prophets looked forward to what they styled "The Day of the Lord," that is, the day of final and universal judgment. That day was terrible to the wicked; by the just it was looked forward to with unmixed joy, for with it was the coming of the perfect kingdom of God, which, according to Ezekiel, would result in a restoration of Israel even from the dry bones of the Valley of Death.

The Christian View.— The Christian view of immortality is well known. It is stated by Christ and Saint Paul in the most distinct and literal terms. It is connected with "the Day of the Lord" of the Jews, the coming of Christ to judgment, the opening of the graves, the resurrection of the body, the punishment of the wicked, the eternal life of the faithful in Jesus and through Jesus.

The Philosophical View of Immortality.— The belief in immortality among savages has been largely a matter of instinct. Among the non-Christians of the civilized world it has been a portion of a hieratic tradition enforced by custom. Among the Hebrews and Christians it has been considered matter of revelation and subject of faith. There have nevertheless been many attempts made to base this doctrine on reason. The first attempt was made in Plato's 'Phædo,' which no one nowadays can seriously consider. Kant, Locke, and many other modern metaphysicians have excluded the immortality of the soul from the province of natural theology. Other philosophers maintain the immortality of the soul on the ground that the soul has capacity for knowledge and goodness not attainable in this life; that the law of contraries obtains in nature, and if life ends

in death, death itself must be succeeded by life. They argue for immortality from the reminiscences of a previous existence which the soul seems to bring with it into this life; from the invulnerability and vitality of the soul, which survives the loss of sight, hearing, taste, dismemberment, or power of locomotion, and does not suffer with the body, and must therefore outlive it.

The belief in immortality has been a great motive power in human regeneration since the collapse of the Roman empire. It was certainly the keystone of the arch in the splendid civilizations of Egypt and of Assyria. It has been claimed for this doctrine that it raised the conquered barbarians of the broken Roman rule to a refined reign of humanity and order, that it abolished slavery in Europe and taught the equality of man; that it opened a new era of justice in government, of pity to the weak and poor. It is certain that without this doctrine there would have been no Saint Paul, no Saint Francis, no Dante, none of the great works of Christian piety, the great Christian institutions which have preserved and disseminated letters, fostered the arts of medicine, raised the fairest monuments of architecture, and not only discovered new islands and continents, but opened up the great missionary highways which have carried light and civilization to the ends of the earth.

Immortelle. See EVERLASTING FLOWERS.

Immunity. It has been a common observation that certain individuals are prone to the infectious diseases, and others not. Some children in a family always "take things hard," while others are not susceptible. This resistance to the poisons of the infectious diseases, or to the bacteria that cause the poisoning, is termed immunity. It is a relative quality of living matter, and is not confined to man alone, for lower animals, and even plants, show marked variations in their reactions to chemical and organic poisons. Thus certain plants are capable of growing in soils impregnated with metallic poisons of sufficient strength to destroy animal life; many animals are immune to poisons that would kill man; thus birds are comparatively immune to strychnine; young children can take comparatively larger doses of belladonna than adults; the diseases of plants are almost unknown among animals, and *vice versâ;* certain diseases affect the lower animals and are rare or unknown in humans, and the reverse condition also holds true; thus swine-plague is comparatively unknown in other animals than pigs, and such human diseases as typhoid fever and cholera are not common in lower animals; thus plants, lower animals, and man, individually and collectively, enjoy certain relative immunity from destruction when exposed, under ordinary circumstances, to disease-producing agencies.

Natural immunity may be so modified as to be lost entirely, certain forms of disease predisposing the sufferer to ready secondary infection, as, for instance, is seen when tuberculosis follows measles; or a partial immunity be made more effective, or a new immunity conferred. This has been termed acquired immunity. The evolutionary doctrine would tend to interpret natural immunity as an inherited acquired immunity. In the case of man immunity sums up those powers of resistance which the body naturally possesses, or which it acquires in the struggle with infectious diseases, both in endeavoring to destroy the bacteria — bacteriolytic power—and to counteract the toxins—antitoxic power. Modern pathology has shown that the battle-field is a large one, and that the opposing forces are numerous and their powers largely unknown; and it must be remembered that the struggle has been going on perhaps for millions of years.

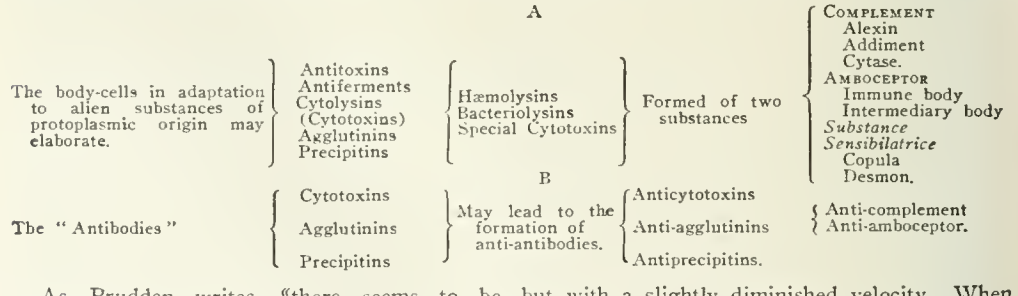
The observation that certain diseases—as measles, scarlet fever, smallpox—once acquired, confer a marked immunity, led up to vaccination, this inoculation against smallpox being the first conquest of disease by such means. It is certain that others will follow. Certain diseases—notably pneumonia, influenza, erysipelas—confer an immunity, but it is not lasting; thus demonstrating the principles of variability in the "immune bodies" as a class, and of an active and a passive immunity which may be conferred by various means, an active immunity being acquired by the animal for itself by direct adaptation, a passive immunity being conferred by a body made in the blood-serum of another animal.

Former theories for explaining the varied picture in this rapidly widening study have been numerous. They may be classed under the *exhaustion theory* of Pasteur, which assumed that the bacteria used up the available food-supply and died; or, as the laity often express it, "the disease wore itself out." This theory has been thoroughly disproved. The *retention theory*—that the bacteria are killed by their own products—is also untenable. The *mechanical, humoral,* and *phagocytosis* theories, which teach that the bacteria are destroyed by the humors or cells of the body, are partly true, but do not convey the whole truth, which in fact may never be known. The most popular theories of the present time are chemical, and that known as Ehrlich's *side-chain theory* is uppermost in discussion. This theory is extremely elaborate, but its fundamental principle is that the blood-serum of man and other animals may be so modified, in whole or in part—experimentally played upon, as it were — that it can be made to overcome the effects of infections, of poisons, or of both. The development of the diphtheria antitoxin in the blood-serum of the horse, to counteract the effects of the toxin of the diphtheria bacillus in man, was the first important practical deduction of this great principle. It was the first illustration of the production of a successful passive immunity in human

pathology. In the discovery of the diphtheria antitoxin it was hoped that all the infectious diseases were conquered, but this hope was premature, as it was learned that other diseases involved other factors of a more elusive character than the simple toxin. The destruction not only of the bacteria within the body, but the neutralization of the poison as well, was found necessary, and hence the terms bacteriolytic immunity and antitoxic immunity. Ehrlich's side-chain theory tries to explain antitoxic immunity in chemical terms. He assumes that the cell-body has a number of side-chains upon it — receptors, as they are termed. These are capable of combining with food-products for the metabolism of the cell. There are certain receptors that can combine with toxic products as well, with damage to the cell. Antitoxins, according to Ehrlich, consist of surplus receptors made by the cell and cast off in the blood-serum. These unite with the toxin in the serum, and thus save the receptors of the cell for their normal food-taking properties. Any surplus of receptors over and above those combined with the toxin molecules floating in the blood are available as free antitoxins in the treatment of toxin-caused disease.

The other phase of the subject of immunity is concerned with the ability of bodies themselves to destroy bacteria — bacteriolytic immunity. It is known that if the blood-serum of certain animals is injected into an animal of a different species, the red blood-cells of the injected animal are destroyed. This process has been termed hæmolysis, and is observed under other conditions, as in poisoning by drugs, such as acetanilid, sulphonal, etc. A similar action of blood-serum on certain bacteria can be brought about by artificial means, thus manufacturing a *bacteriolytic* serum for use in destroying given bacteria in the human body. The various terms that are used in elaborating this hypothesis may best be expressed in the form of a chart, since in medical literature so many synonyms have been in vogue.

Table showing various forms of adaptation products with their relationships and synonyms. (From Prudden.)



As Prudden writes, "there seems to be abundant ground for the belief that the protective agencies which are evoked in both natural and artificial immunization are simply those which the body makes use of in its normal metabolism, exaggerated and diverted to different ends, it is true, in the face of emergencies, but giving evidence of the birth of no new physiological capacities." "The new methods of research and the far-reaching conceptions which they have stimulated and fostered seem likely to mark a new era in physiological chemistry, and to link more closely than any other extension of knowledge in our time some of the most subtle and urgent problems of medicine to the wider outlooks of general biology."

Smith Ely Jelliffe, M.D.,
Professor of Bacteriology, College of Pharmocy, City of New York.

Im'pact, the action which results on the coming together of two bodies, one or both of them in motion. If an ivory ball fall on a marble table which has a thin coating of oil, after impact the ball is found to have on its surface a patch of oil, which shows by its size that the ball must have been compressed at the moment of impact. When two bodies come into collision they compress each other at the points that touch until they have each the same velocity; during this time of compression each body acts upon the other with exactly the same impulse, the momentum lost by the one being gained by the other; if now the bodies are perfectly inelastic no further mutual rebound will take place; if the bodies are elastic they will regain their old shape, and the mutual impulsive forces of restitution will cause separation. The impulsive forces of restitution are found to be less than those of compression; that is (see Impulse), the momentum lost or gained by either of the bodies during the second or restitution part of the impact is less than the momentum lost or gained in the first or compression part of the impact in a certain ratio which is called the elasticity of the bodies. In a perfectly elastic body this ratio would be equal to 1, in a perfectly inelastic body it is 0.

Thus, when one ivory ball comes into direct collision with another of equal size at rest, the first comes to rest and the second moves in the direction of motion of the first before impact, but with a slightly diminished velocity. When two equal ivory balls come together with equal and opposite velocities each returns on its old path with a velocity slightly lessened. When one perfectly inelastic body overtakes or meets another directly the common velocity after impact is equal to the sum or difference of momenta of the bodies before impact divided by the sum of the masses.

In a collision of two balls not perfectly elastic it may be shown that the total energy of

motion (see ENERGY) of the two balls after collision is less than it was before, some of it having been converted into heat.

Impeach'ment, the accusation and prosecution of judicial and executive officers for misdemeanors involving an abuse of their official functions, or immediately connected with those functions. In Great Britain the tribunal before which impeachments are tried is the House of Lords, and the impeachment is made by the House of Commons. The person impeached may be either a peer or a commoner; but while a peer may be impeached for any crime whatever, a commoner cannot be impeached for a capital crime. The method of procedure is this. A member of the House of Commons charges the accused with high crimes and misdemeanors, and moves that he be impeached. If the motion is carried the member is ordered to go to the bar of the House of Lords, and lay the impeachment before that tribunal. The lord high-steward presides at the trial. After the charges have been laid, and the answers of the accused heard, the lord high-steward puts the question whether the accused be guilty or not guilty of the crimes charged in the first article of impeachment to each of the peers in succession, beginning with the junior baron, and each of the peers answers "guilty" or "not guilty," as the case may be, "upon my honor." The lord high-steward gives his own opinion after all the other peers. The same question is then put with regard to all the other articles of impeachment successively, and the result is declared by the lord high-steward. The question of guilty or not guilty is decided by a majority of votes.

By the Constitution of the United States the House of Representatives is given the sole power of impeachment; and the Senate has the sole power to try all impeachments, and provides that at the trial of a President the chief justice of the Supreme Court shall preside. Section 4 of Article II. provides that the President and Vice-President and all civil officers of the United States shall be removed from office on impeachment for and conviction of treason, bribery, or other high crimes or misdemeanors, and the trial of officers by impeachment has been attempted seven times in the history of the United States. First came the Blount case. William Blount, United States Senator from Tennessee, was in 1797 impeached for conspiring with British officers to steal part of Louisiana from Spain for England's benefit. The Senate expelled him, after putting him under bonds for trial, but his defense being that a Senator was not a civil officer liable to impeachment, on the question of jurisdiction he was acquitted. John Pickering, judge of the Federal district court for New Hampshire, being impeached in 1803, for drunkenness and profanity on the bench, was convicted and removed from his office. Samuel Chase of Maryland, a justice of the Supreme Court of the United States, in 1804 was charged with having indulged in "highly indecent and extra-judicial reflections upon the United States government," in the course of a charge to a Maryland grand jury, and with other improper conduct on the bench. The impeachment proceedings, instigated and managed by John Randolph of Virginia, were political in their origin and animus. Judge Chase was acquitted. The prosecution failed to obtain a two thirds vote against him on any one of the eight articles of impeachment and, resuming his seat on the bench, he held it as long as he lived. Judge West H. Humphreys of the Federal district court of Tennessee, joined the Confederacy at the opening of the Civil War, and accepted office under it, without previously sending his resignation to Washington. He was impeached, mainly in order to vacate the office, and convicted on 26 June 1862. Andrew Johnson was impeached on 4 March 1868. He was charged in 11 articles with violating of the Tenure of Office act, with violating of the Constitution, conspiring to prevent the execution of the Tenure of Office act, and with utterances tending "to bring the high office of President into contempt, ridicule, and disgrace." This memorable trial lasted for nearly three months, and the fiercest of political passions were excited by it. Thirty-six votes were needed to convict. No vote was ever taken except on the three strongest articles, the 2d, 3d, and 11th, and on each of these the Senate stood 35 for conviction to 19 for acquittal, impeachment failing by a single vote. The seventh impeachment recorded was that of William W. Belknap, secretary of war under President Grant. He was accused in 1876 of corruption in office, and the House voted unanimously to impeach him. He resigned before the passage of the resolution, but, although his resignation was accepted by the President, the trial proceeded. The impeachment proceedings failed by the lack of a two thirds majority in the Senate for conviction.

Imperative Mandate. See REFERENDUM.

Impe'rialism, the national policy which tends toward the expansion of national domination and national ideas over a geographical area wider than that of national boundaries. Thus ancient Rome extended her dominion and system of government, attended with her laws and language first over the whole of Italy, then over Sicily, Northern Africa, Spain, Gaul, Greece, and parts of Asia. Charlemagne's idea was to hold France, Germany and Spain under one imperial head. Napoleon wished his empire to comprise all Europe. English nationalism has been partly a wide scheme of colonization, and partly as in India a plan for subjugating and Anglicizing a cluster of Oriental races. In the United States the term imperialism has been used in a more or less factitious sense. The avowed object of the government at Washington in the Spanish War was the liberation of Cuba from the Spanish yoke. The term "imperialism" was employed as a political catchword in the presidential campaign of 1900, especially with regard to the purchase of the Philippines. Yet the United States cannot scientifically be styled an empire, or likely to develop into an empire. The Supreme Court on 2 Dec. 1901 has, however, decided on the constitutionality of expansion. The principles settled by the decision are thus to be stated: (1) The Constitution does not follow the flag till it is planted on new territory by special act of Congress. (2) The extension of the sovereignty of the United States to new territory guarantees the enjoyment of liberty, the right to property and the protection of the United States to the people thus affected in securing justice and public

order and promoting peaceful progress. (3) The islands acquired from Spain by the treaty of Paris are "property of the United States," and Congress can dispose of these islands in any way conducive to the interests of the people of the United States and of these islands.

A corollary of these propositions finds expression in the statement that the territory of the United States may be described under three heads: (1) The States. (2) Incorporated territories. (3) Unincorporated territory, belonging to the United States.

This gives to the nation three different classes of people dependent upon it: (1) Citizens vested with full political power, or the residents of the States. (2) Citizens of the incorporated territories, who are not vested with full political power as long as they are residents of the incorporated territories. (3) The people of the "territory belonging to the United States," as such, who cannot become citizens of the United States till Congress extends to such territory they occupy the privileges of the Constitution.

Impetigo, ĭm-pĕ-tī'gō, popularly known as Pustular Tetter, Honey Scab, and Honey Sickness, a skin disease found mostly in children, consisting in an eruption of itching pustules, appearing in clusters, and terminating in a yellow, thin, scaly crust. They appear chiefly on the head and face, and sometimes on the hands. Feverishness and sensations of chilliness accompany the disease. The treatment is both external and internal, the former consisting in the application of ointments, etc., and the latter in the administering of various medicines calculated to improve and maintain the health of the patient.

Impeyan (ĭm'pĭ an) **Pheasant,** a pheasant of the genus *Lophophorus* generally; specifically the species (*L. impeyanus*) of southern Kashmir, first brought to notice by Lord and Lady Impey. These are among the most splendidly clothed of birds, rivaling the humming-birds in the brilliance of their metallic hues. There are four or five species, each restricted to a particular region in southeastern Asia. The Himalayan species or Monal (*L. refulgens*) is the best known and is often exhibited in zoological gardens. The male is perhaps the most gorgeous of the *Phasianidæ*, presenting a wonderful combination of sparkling metallic purples, blues, browns and greens, with golden and coppery reflections and contrasting patches of snowy white and deep black; on the head is a crest composed of long racquet-shaped feathers. The female is plainly colored. High up in the mountains near the snow line the monal lives during the summer, breeding up to an elevation of 12,000 feet, but in the autumn, as the weather becomes cold, it gathers into flocks and descends to the deep woods or, in very severe weather, even to the cultivated lowlands. It both runs and flies swiftly, but is chiefly terrestrial, and feeds largely on roots and grubs dug from the ground. The impeyan pheasant has the black and white areas replaced by golden green.

Implements, Agricultural. See Agricultural Machinery and Implements.

Im'post, in architecture, the point at which an arch rests on the column, pier, or wall. It is often marked by horizontal moldings, though these may be absent. Imposts have received various names, according to their character. Thus, a continuous impost is one in which the moldings are carried perpendicularly down the pier, as in the later decorated Gothic; a discontinuous impost, one where the moldings abut, and are stopped on the pier; shafted imposts are those in which the arch moldings spring from a capital and differ from those of the pier.

Im'potency, a diseased condition of the male; in common law failure to consummate the marriage relation within three years is presumptive evidence, and constitutes a sufficient ground for divorce, or annulment of marriage.

Impress'ionism, the style of painting adopted by the Impressionists, a group of modern French painters, who held their first exhibition in Paris in 1877. This coterie included Claude Monet, Alfred Sisley, C. Pissarro, Auguste Pierre Renoir, and Berthe Morisot. These artists professed to have cut themselves free from all traditions of color, line or technique, and to paint things, not from what they had learned about things from other painters, but from what they saw in things. Their one immediate impression of a landscape, or a group of figures, they would transfer to the canvas without modifying one jot or tittle. "The Impressionist," says Theodore Duret, one of their earliest critical interpreters, "sits down on the bank of a river, and the water takes its tones, in accordance with the condition of the sky, the angle of vision, the hour of the day, the stillness or agitation of the air. Without hesitation he sets upon his canvas exactly all the tints and tones which he sees in the water. The sky is overcast, the weather showery, he paints the water steely gray, dull, opaque. The sky is clear, the sun brilliant, he paints the water sparkling, silvery, azure blue. The wind blows, he paints the myriad hues of the rippling surface. The sun sets and darts his last rays into the water. The Impressionist smears yellow and crimson on his canvas. The winter comes. The Impressionist paints the snow, and as he sees that shadows cast upon the snow are blue he unhesitatingly paints blue shadows. Certain clayey soils seem to clothe the plains in lilac. The Impressionist therefore paints lilac landscapes. In the summer sunlight under the dim-lit arcades of green foliage, skin and clothes take a violet tint. The Impressionist paints them violet." The French Impressionists claim Corot, Courbet and Manet for their fathers in art. It is certain that they owe much to Japanese masters. "Before our acquaintance with Japanese art," says the critic already quoted, "painting kept on its course of falsehood, and Impressionism was impossible."

Nevertheless, Impressionism is dying out, if it is not already dead in Paris, as Quilter some years ago stated. It has not taken any root in England, where the Pre-Raphaelite movement, with its idealism, linked to its freshness and originality of style, was the most recent dominating innovation. Among American artists it did, however, obtain some foothold, and Whistler, a great Anglo-American painter, began his

IMPEYAN PHEASANT (*Lophophorus impeyanus*).

career as an Impressionist, and though he did not continue on the extreme left of this radical school, he always was their friend and was willing to learn all they could teach him. In New York there are some survivors of the school, and Twachtner and Childe Hassam were for some years its exponents, and the death of the latter so early in life removed a really sincere and quickening influence in American art. It is certain that Twachtner never went to the extremes of the French Impressionists. He was one who felt their influence rather than a blind and literal follower of their theory. He was delicate and refined, as well as bold in color, and he cultivated to perfection what the French Impressionists sometimes seemed to neglect,—the sense of form as defined by the invisible line that divide the tones in a picture and in life, and which great painting defines with a magic and unerring accuracy that cannot be secured by daubing on the canvas a mass of tints in which color and value are everything and line nothing. Impressionism is chiefly notable as being a revolt from academic stiffness and conventionality, from slavery to certain pigments and methods of technique, long in use. It is a movement which has added fresh life to art by teaching the painter to use his eyes, and to trust them. Compare Sabrin, 'Science and Philosophy in Art' (1886); Duret, 'Les Peintres Impressionistes' (1878); 'French Impressionism' (in 'The International Monthly,' Vol. V. 1902); Duranty, 'La Nouvelle Peinture.'

Impress'ment, The right of changing one's natural allegiance (see CITIZEN; EMBARGO) was not acknowledged as a legal right in the 18th and early 19th century by any nation but the United States, which lacked power to enforce it against the world. Great Britain denied it, and Chancellor Kent early in the 19th century admitted that the denial was common law. During the Napoleonic wars, that country in its struggle for life especially on the seas, demanded the help of all its citizens; and not only refused to recognize any ceremonies of naturalization, but seized its alleged subjects wherever it found them, searching neutral vessels on the high seas and impressing into its service whoever were claimed as such. The naval officers were the reverse of particular whether they made mistakes and kidnaped born Americans, and many hundreds of the latter were impressed in this way. Not only this, but the right of search in itself, were rasping grievances which worked up the national temper to the pitch of explosion, resulting in the War of 1812; the right of search resulted in the bloody outrage of the Leopard on the Chesapeake (q.v.), which was one of the chief agencies in bringing about the Embargo.

Impris'onment is one of the three classes of punishment for crime, death and penal servitude being the other two. It has always been a power inherent in courts of justice to imprison for contempt of their authority, and under certain conditions for non-payment of debt. In criminal proceedings a person may, by a warrant of a justice of peace or magistrate, be imprisoned before trial, provided the justice considers it is not a proper case for allowing bail; and though in minor offenses an accused person may insist on being discharged on tendering sufficient bail, yet in more serious crimes it is in the discretion of the justice to accept or refuse the bail tendered, and on his refusal application may be made to judges of the common law courts to accept bail. Imprisonment may be with or without hard labor, or it may be solitary. Penal servitude may be inflicted for life, or any shorter term, but in the case both of imprisonment and penal servitude the convict can at any time apply for commutation or remission. In police and other petty offenses tried summarily at common law and under a variety of statutes, imprisonment is usually awarded with the option of a fine. The unlawful detention of the person by any one, or "false imprisonment," constitutes a personal injury, and may be treated as a criminal or as a civil offense. See DEBT.

Imprisonment for Debt is the restraint of the liberty of a debtor in a civil action. An arrest for debt is usually made by some mandate of a court having jurisdiction, after the nature and amount of the debt has been established by due process of law. But sometimes a debtor is restrained of his liberty on a preliminary proceeding, by order of a court, for the purpose of holding him to bail. In the United States, imprisonment for debt is made only by virtue of statutory regulations, several States having constitutional provisions prohibiting it under certain circumstances, and seven of them having absolutely prohibited restraint in any form of personal liberty on account of debt, by such provisions; namely, Alabama, Georgia, Maryland, Mississippi, Missouri, Tennessee, and Texas. Several of the States provide in their constitutions that there shall be no imprisonment for debt except in cases of fraud on the part of the debtor. In some of the States acts have been passed providing for imprisonment founded on contracts deliberately entered into, while others have provided that only absconding debtors shall be subject to imprisonment. The tendency of modern legislation is adverse to imprisonment for debt. Many of the States have provided in case of imprisonment that the restraint shall be made as free from indignity as is consistent with the safe-keeping of the debtor, and that his restraint shall be considered more in the nature of misfortune than as punishment for an offense.

Improved Order of Red Men, an American civic society, with benevolent and social characteristics, organized 14 Oct. 1833. Founded upon the manners, traditions and customs of the aborigines of the Western World, the Order adopted their unique figures of speech, which it transmits with historical accuracy. Knowing that some time the Indian race will become extinct it intends to occupy an original place in public interest as the repository of Indian customs, Indian traditions, and Indian nomenclature. The Order's motto is "Freedom, Friendship, and Charity." Its interpretation, as promulgated by official authority, may be concisely stated in these words: Freedom, in honor of that race to whom the forests, the plains, the hills, and the valleys of this land were as free as the air to the eagle, and in memory of the early struggles to wrest these United States from dependency to foreign rule. Friendship, to commemorate the unswerving loyalty with which an Indian maintained a noble and unselfish affection for him to whom it was plighted,

and which makes sweet and lasting the relations that one member bears to another. Charity, the love expressed to a brother by those who meet around the brightly burning council fire; the sympathy which is pleased at his success, and the fraternal affection that grieves over his sorrows and disappointments.

Government.— The Order is organized along the familiar lines of civic societies. Its supreme power is the Great Council of the United States, and from this body emanates all authority for the establishment of local branches in towns and cities; also Great Councils in States and Territories and in the Dominion of Canada. State and Provincial Great Councils, under restricted delegated authority, exercise governmental oversight,— within their respective jurisdiction,— similar to that of the Great Council of the United States. Local branches of the order are: Tribes, Degree Councils, and Councils of the Degree of Pocahontas. The Great Council of the United States has for its chiefs, or officers, the presiding and executive official, who is called the Great Incohonee; the Great Senior Sagamore, second in authority; Great Junior Sagamore, third officer; Great Prophet, who is often a Past Great Incohonee; the Great Chief of Records, or Grand Secretary; the Great Keeper of Wampum, or Grand Treasurer; Great Tocakon, the messenger of the presiding officer, or Grand Marshal; the Great Minewa, an officer in charge of the inner wicket; and the Great Guard of the Forest, guardian of the outer door. State Great Councils have chiefs whose duties correspond to the officers of the supreme body, as follows: Great Sachem, presiding chief; Great Senior Sagamore, Great Junior Sagamore, Great Prophet, Great Chief of Records, Great Keeper of Wampum, Great Sannap, Great Mishinewa, Great Guard of Wigwam, Great Guard of Forest. The chiefs of a tribe are: The Sachem, who presides; Senior Sagamore, Junior Sagamore, Prophet, Chief of Records, Keeper of Wampum, Collector of Wampum, First and Second Sannap, four Warriors, four Braves, the Guard of the Wigwam, and Guard of the Forest. In Degree Councils the chiefs governing them are similar to those of a tribe. The Councils of Pocahontas admit white women to membership, and those of the order who have attained to the Chief's Degree. The chiefs of the council,— whose duties are defined in an ornate ritual,— are: Pocahontas, presiding officer; Wenonah, Powhatan, Keeper of Records, Collector of Wampum, Keeper of Wampum, First and Second Scout, First and Second Runner, two Counselors, four Warriors, Guard of Wigwam, and Guard of the Forest. Provision has also been made for the establishment of State Great Councils of the Degree of Pocahontas, similar in authority to those of the Tribal Branch, the officers of which run parallel with local councils. The names of the chiefs have the prefix of "great," and these Great Councils are given jurisdiction over this degree, all under the sovereignty of the Great Council of the United States. After various attempts to organize a branch for the "display element," legislation created, in 1899, the Red Men's League, with a uniform resembling the "Continental," and a perfect military code. Into this organization were merged prior uniformed bodies and beneficial councils. The adoption of consistent laws at once secured a continued increase in this branch of the Improved Order of Red Men.

Ritual.— The ceremonies of the Order are purely American. The ritual stands, and must ever stand, unique, and distinct, growing more valuable as the only realistic demonstration of those mystic ceremonies of the aborigines, which otherwise might fade into oblivion. Founded, as has been stated, on the manners, traditions, and customs of the American Indian, it portrays an existence more fascinating the longer it is studied, and gives the keynote to those bursts of eloquence which were at once the wonder and the admiration of the early missionaries, and of which the renowned "Black Hawk" is a shining example. The work of the Order is divided into three sections or degrees— the Adoption, the Warrior's, and Chief's,— each of which illustrates a phase of the characteristics mentioned. The degrees of the auxiliary branches of the Order are written in harmony with the general theme of the original ritual.

Nomenclature.— The attention arrested by the recital of this Order's official life is greatly enhanced when its terminology is considered. The expressions used not only differentiate the Improved Order of Red Men from other civic societies, but these form links connecting it with prior organizations of Red Men. This is further outlined in the "history" following. Time is not computed as in the common era, but according to a phraseology that has a hidden meaning and significance to the "initiated." Up to 1865, the Jewish style, namely, the year of the world, was used in dating documents. This was superseded by a revised system and "G. S. D.," or Great Sun of Discovery, was adopted, the year 1492 being considered G. S. D. 1. For convenience the year begins with that of the common era, and the enumeration follows: A year, *Great Sun;* a month, *Moon;* January, *Cold Moon;* February, *Snow Moon;* March, *Worm Moon;* April, *Plant Moon;* May, *Flower Moon;* June, *Hot Moon;* July, *Buck Moon;* August, *Sturgeon Moon;* September, *Corn Moon;* October, *Traveling Moon;* November, *Beaver Moon;* December, *Hunting Moon;* a week, *seven suns;* a day is a *sun,* and a night is a *sleep.* Morning is called the *rising of the sun;* evening, *setting of the sun;* noon, *high sun;* midnight, *low sun;* an hour is a *run,* and a minute a *breath.* Examples: 30 July 1903 A.D. would be expressed as "30th Sun, Buck Moon, G. S. D. 412," 1903—1491 = 412. "Tribes . . . shall, within two seven suns after the last council sleep in Hot and Hunting moons, transmit," etc. Wampum Belt signifies treasury, and wampum or money is computed as follows: *Fathom,* one dollar; *foot,* a dime, and an *inch* is one cent. To illustrate: "In case the wampum shall at any time be reduced to a less amount than five feet for each member, or to less than 50 fathoms, the tribe," etc. Non-members are called *pale faces;* tribal jurisdictions are *hunting grounds;* Great Councils govern *reservations;* opening and closing meetings consist of *kindling* and *quenching council fires;* minutes are called *records;* addresses or reports, *talks* or *long talks;* attending to business is *following the hunt,* and wronging another, *crossing the path. Wigwam* and *tepee* signify the halls of meeting, and *council chamber,* a room therein. Voting is called *twigging.*

History.— An attempt has been made to establish a succession from the patriotic societies

of the American Revolution to the Improved Order of Red Men, but without much historical basis. That such organizations existed, there is no doubt. Moreover, the War of 1812, with England, served to foster the assembling and banding together of men fired with patriotic ardor. It is quite likely these associations may have led to the formation of the societies of Red Men,— possessing the terminology hereinbefore mentioned,— known to have flourished between the years 1813 and 1830, of which fragmentary records have been preserved. The impulse also may have come from the Tammany societies of the national period prior to 1812. A society of Red Men existed in Philadelphia, Pa., in 1824, and there were branches in other cities and States at earlier and later dates; but the movement, which began in Baltimore, Md., in 1833–4, really seems to be the authentic date of foundation. The Improved Order of Red Men was anti-convivial in its character, and was first brought into public prominence by the observance of Saint Tammany's Day (still on the calendar), 12 May 1837. The Order spread, and, on 20 May 1835, the Great Council of Maryland was instituted, and soon became an incorporated body. On 30 Jan. 1847 the Great Council of the United States was formed as the supreme government, and this, in turn, became a corporation, by special charter from the legislature of Pennsylvania, approved 30 March 1866. The policy of the Order has been to possess a legal standing in the State; and a brotherly hand extended early secured the adherence of the scattered bands of Red Men to the "improved" institution, so that unity of effort soon promised much for the future. The fortunes of the "Improved Order," however, were fluctuating at first, and, until 1881, when it began to assume its present proud proportions of 350,000 members, embracing the entire republic, and reservations in Canada.

Impulse. This is a term used in mechanics to designate the "time integral" of a force. If the force is constant, the impulse it produces in a given time is the product of the force and the time in question. If the force is variable, its time of action may be divided into an infinite number of equal intervals. Then the impulse will be the sum of the products of each variable value of the force by the common infinitesimal time interval just defined. Impulse is a quantity of the same kind as momentum; that is, it is the product of mass and linear velocity.

It should be observed that in the cases of impulses in nature the forces are never infinite and their times of action never infinitesimal, though it is sometimes convenient to adopt these fictions in analysis. For the theory of impulses see especially Thomson and Tait's 'Natural Philosophy,' part I.

Imputa'tion, as a term in Protestant theology, is used to signify three things, first the imputation of the sin of Adam to all of his posterity, second the reckoning of the sins of man to Christ, third the reckoning of the righteousness of Christ to believers. Thus, on the theory of imputation the sin of Adam is so attributed to each individual of the human race as to be considered in the Divine counsels as the act of that individual, who is thus rendered guilty of it. When sin is spoken of as imputed to Christ it is meant that the condition or state which was actually man's becomes by imputation judicially his, and thus in law Christ became fitted to be a sacrifice and sin-offering for man. Had he not been man's substitute by the imputation of sin he could not have become his substitute in the endurance of the penalty of sin. The two are inseparably connected. In the very same sense in which Christ was made sin men are made the righteousness of God in him. According to this view he was made sin, not actually and personally, but by imputation; and men are made righteousness, not actually and personally, but by imputation.

Imus, ē'moos, Philippines, pueblo of the province of Cavite, Luzon, eight miles southeast of Cavite, the provincial capital; it is an important road centre. In 1896 it was the stronghold of the insurrection, Aguinaldo and other chiefs having their headquarters in its principal building. Pop. 14,700.

In-breeding, Evils of. See Breeding.

In Cœna Domini, ĭn sē'nä dom'ĭ nĭ, a papal bull, so called from its first words, it being annually read "at the Lord's Supper" on Holy Thursday. Its earliest form was that promulgated in 1363 by Urban V. against all heretics and favorers of heretics. The bull was annually promulgated at Rome till the year 1770, when a much modified document took its place, this in its turn being withdrawn by Pius IX. in 1869.

In Personam, spoken of legal rights, means such as are maintainable only against a specific person, and not against the whole world (see *in rem*). Rights *in personam* arise out of a specific engagement between individuals, or out of domestic or fiduciary relations. But the majority of rights *in personam* spring from the violation of rights either *in rem*, or *in personam*. A right once violated, a right of action against the violator immediately arises. An action brought against the violator is also called an action *in personam*.

In Rem, spoken of legal rights, means such rights as are not only maintainable against a specific person (see *in personam*) but can be maintained against the whole world. Nor are rights *in rem* limited to property rights, but include all rights, such as freedom from personal assault, from causeless imprisonment, from trespass. The term includes the right not only of suing for damages but of seizing and detaining certain articles. In admiralty practice this is a common resort, though in ordinary processes for the recovery of land or goods, it is rarely made use of nowadays.

Inagua, ē-nä'gwä, Great and Little, two of the Bahama Islands in the West Indies, at the southern extremity of the group. Great Inagua has an area of 660 square miles, and Little Inagua 36 square miles. The latter has few inhabitants. There is a considerable town on Great Inagua called Matthew Town, pop. (1900) 1,500.

Inar'ching, a form of graftage (q.v.).

Inaugura'tion Day, the day set aside for the inauguration of the President of the United States every four years on 4 March. It is said that Benjamin Franklin selected this date because in the next two centuries it would fall less often on Sunday than any other day in the year. President Washington took the oath the first time on 30 April, and Taylor and Hayes were inaugurated on Monday, 5 March. The same is true of Monroe's second inauguration, but his first was on the regular day. The second Adams, Pierce and Garfield were inaugurated on Friday. Five inaugurations have been on Monday and five on Wednesday.

On 2 July 1788 the President of the Confederation Congress then in session at New York, notified that body that New Hampshire had ratified the Constitution on 21 June preceding, and as it was the ninth State to do so that instrument was now by its own terms to become the supreme law. After prolonged debate Congress on 13 Sept. 1788 passed the following:

> Resolved, That the first Wednesday of January next (1789) be the day for appointing electors in the several States which before the said day shall have ratified the said constitution; that the first Wednesday in February next be the day for the electors to assemble in their respective States and vote for president, and that the first Wednesday in March next be the time and the present seat of congress the place for commencing proceedings under the said constitution.

Incandes'cence. See ELECTRIC LIGHTING.

Incandescent Gas-light. See ILLUMINATING GAS.

Incarna'tion (from the Latin *in,* in, and *caro, carnis,* flesh), a word used to express the appearance on earth of the Deity, or his manifestation in the flesh under the human form; thus we speak of the incarnation of Christ. (See JESUS CHRIST; CHRISTIANITY.) The Hindus believe in innumerable incarnations of their deities. See AVATAR.

Inca or **Ynca,** the name of a tribe of Peruvian Indians — not exclusively that of a royal family or caste, as has been commonly asserted. The members of this tribe sometimes called their war-chief "Cuzco," meaning chief or lord of Cuzco (compare the 'True Account of the Province of Cuzco,' by Francisco Xeres, secretary to Francisco Pizarro, and himself one of the conquerors), but probably more often "the royal Inca," or simply "*the* Inca" (compare 'Royal Commentaries of the Yncas,' by Garcilasso de la Vega: Lisbon, 1609: Part I, chapters viii and xv). The latter usage was in the end adopted by Spanish chroniclers; and Garcilasso, half Spaniard, half Indian, in the 15th chapter of his commentaries, which were written, he tells us, 71 years after the conquest, uses both the longer and the abbreviated forms — "Yncas Kings" and "Yncas" — though feeling that he must explain that he means by the latter the "native kings of Peru." Throughout the tribe mother-right prevailed, and marriages were contracted between members of different clans: therefore offices could not descend from father to son; and especially the office of war-chief, or Inca *par eminence,* must usually have been filled by selection. The tribal dialect was called Quichua. See also PERU and SOUTH AMERICA.

MARRION WILCOX.

Inca Semi-Civilization, the state of advancement in arts and learning reached by the most progressive tribe of South American Indians, occupying a portion of the Andean Sierra, and exercising control, in the regions now known as Peru, Ecuador, and northwestern Bolivia, over many other tribes of the highlands and lowlands before the Spanish conquest.

In the articles INCA, CUZCO, and PERU, reference has been made to certain popular misconceptions touching Inca government, chronology, and the tribal name. It is necessary to add that the evidence at present available is entirely insufficient to warrant such assertions as the following, which occurs in one of the leading works of reference: "The Inca was the absolute but, in most cases, *kindly* ruler. . . . In many respects the Inca government will compare favorably with any which at that time existed in Europe"; or this, from a popular account published in December 1903: "The far-famed Inca race had developed in pre-Columbian times an astonishing and marvellous civilization." Far from lending itself to such conclusions, the evidence furnished by Spanish writers of the 16th and 17th centuries, when their works are tested and corrected by a comparison with the results of modern archæological research, points to social conditions which cannot be ranked above semi-civilization. Moreover the objects collected by archæologists to illustrate or represent industrial and artistic activity in ancient Peru (especially the important Bandelier collection which was put in order at the American Museum of Natural History in 1904) in point of fact illustrate and represent the activities of a race very slightly elevated above semi-barbarism. One may look in vain among thousands of rude, unpleasing, or at best rather coarsely grotesque designs by Inca artisans and artists, if his hope is to find out, by searching, even slight indications of potential, germinating refinement and enlightenment; certainly that striving after perfection which among races capable of genuine civilization has expressed itself in beautiful, symbolic and ideal forms is unrepresented here, the occasional achievements of a better sort appearing to be accidental, rather than truly characteristic or normal. In the customary treatment of their dead the same lack of higher symbolism made itself felt oppressively: the crouched position of the body, bound in a tawdry pack, and the commonplace offerings buried with it suggested nothing better than the petty comforts, or ig noble miseries, of a life forever limited to alter nating phases of servile toil, crouching rest, sensual indulgence, and childish diversions. The North American redskin had a freer and wider outlook in his "savage" state. The various tribes of the Sierra, from Quito to Lake Titicaca, were bound together by roads which ran from one highland village to another; the lowland Indians were held in subjection through fear alone, the Inca supremacy signifying to them simply a prolonged reign of terror. From time to time marauding bands of highlanders swept down upon the coast zone, despoiling the lowlanders, murdering or carrying them off into captivity, and threatening to divert from the natural courses streams which, rising in the Sierra, flowed westward to the Pacific, fertilizing narrow valleys in the arid littoral.

Some of the war-chiefs may have been "kindly rulers": we shall, in all probability, never know whether they were or not. Cristoval de Molina, who described the "Fables and Rites of the Yncas," and who, in order to gain the knowledge of those rites which he imparts, "assembled" as he says, "a number of aged persons who had seen and participated in them in the days of Huayna Ccapac," believed that some definite, if scanty, records existed. He says: "It is so that these people had no knowledge of writing. But in a house of the sun called Poquen Cancha, which is near Cuzco, they had the life of each one of the Yncas, with the lands they conquered, *painted with figures* on certain boards." Another chronicler, Juan de Santa Cruz, who wrote about 1620, says: "I affirm that I have heard, from a child, the most ancient traditions and histories, the fables and barbarism of the heathen times, which are as follows." Such as these are the sources of our knowledge of the story of the Inca rulers. Some of the events in the lives of the war-chiefs were depicted, as valuable records or as parts of an ornamental design, in a "house of the sun"; otherwise all rests upon the prattle of Indian dotards and of Indian nurses. Accounts written by the conquerors themselves (for example, Xeres) leave almost everything to the imagination. We may be certain, at least, that tradition retained most accurately the traits of the last two or three native chiefs, whom the "aged persons had seen"; and though we may not condemn the unknown by reason of the credibly reported misconduct of the known, we shall be obliged to suspend judgment, instead of accepting the easy platitudes now current with respect to the succession of war-chiefs from Manco down to Huayna. The shameless private life of Huayna Ccapac is set forth in the 'Antiquities of Peru' by Juan de Santa Cruz. As for that great war-chief's still more famous son, we read in Garcilasso de la Vega's 'Royal Commentaries of the Yncas' (Book 9, chapters 35–37) that Atahualpa summoned all Incas of the blood royal to assemble at Cuzco, and put them to death. "The cruelty of Atahuallpa," says this historian, himself half Inca, "was greater than that of the Turks, for, not content with the blood of his own 200 brothers, the sons of the great Huayna Ccapac, he passed on to drink that of his nephews, uncles, and other relations . . . so that none of the blood royal might escape, whether legitimate or bastard. They were all murdered in different ways." The same fate was meted out to all the loyal captains of his rival Huascar; furthermore "he ordered all the women and children [of royal blood] to be assembled, of whatever age and condition, reserving only those who were dedicated to the sun in the convent of Cuzco. He ordered that they should be killed outside the city, by little and little, and by various cruel tortures, so that they might be long in dying." The varieties of ingenious tortures mentioned by Garcilasso are similar to those inflicted by North American aborigines upon captive women and children; and "though the work could have been done in a shorter time, they prolonged it in order to enjoy their cruelties more fully."

It appears to be altogether improbable that the Inca semi-civilization, if it had not been interrupted by the coming of the Spaniards, would have reached the height of 16th or 17th century European civilization, or by native merit have kept abreast of the advancing nations of the Old World. That the tribe had neglected to provide itself with a written language, and failed to develop high ideals in art, we have already noticed. A third essential for progress was equally wanting: the Incas had no money, or any medium of exchange corresponding to the wampum of the Indians who lived near the North Atlantic coast. But it is impossible for any people deprived of trustworthy records of human experience to construct a convincing system of morality; and without some convenient medium of exchange an extensive and pacific commerce is equally impossible. Both deductive and inductive methods of reasoning must, therefore, lead an unbiased student of old Peruvian institutions to the conclusions that, at home, inveterate and fully sanctioned practices made for degeneration; while steady blackmail, varied by occasional slave-raids, took the place of mutually beneficial dealings with neighboring, subject or independent tribes.

Limitations of the race's genius or experience may be exemplified in the department of music. The Inca musicians used drums which "were made by stretching a skin over a hoop of wood or over one end of a short section of the trunk of a tree which had been hollowed out to a thin cylinder" (compare 'The Musical Instruments of the Incas,' by Charles W. Mead, assistant, Department of Archæology, American Museum of Natural History). Other musical instruments of percussion in common use were copper bells, in form resembling sleigh-bells; rattles, made of small shells, gourds, and nuts, often strung together and attached to the wrists, ankles, or other parts of the body, in dancing; also cymbals of rudimentary form. Wind instruments were the syrinx or pan-pipe, consisting of reeds of graduated lengths, held in position by a crosspiece of split cane lashed to the reeds with a cord made of llama wool — the reeds being sometimes closed at the lower end, sometimes open, and occasionally arranged in double rows, yielding octaves; flutes, made of cane or bone, "simply tubes, open throughout their length, and all belonging to the class known as 'end-blown'," not scientifically constructed and not attuned one to another; resonator whistles, emitting several different notes; trumpets, made either of terra cotta or of conch shells,— primitive instruments, producing only four or five distinct tones (as shown by actual test of specimens taken from the ancient tombs); a double musical water bottle, consisting of two pottery vessels connected near the bottom in such a way that water passes freely from one to the other, and in its passage (when the vessels are swung backward and forward) forces air through an opening near the top, producing a series of whistling sounds; and finally the "cornets" mentioned by Garcilasso ('Royal Commentaries') and Herrera — instruments formed like the oboe, rather than the cornet in the modern sense. With this enumeration the list is exhausted. Such evidence as we have at the present time disproves the existence in Peru of any form of stringed instrument before the coming of the Spaniards. In other words, the unaided genius of the Inca Indians, exerting itself in the field of music, stopped short of the

more complex instruments: ancient Peruvians were satisfied, as their Quichu and Aymara descendants are to-day, with the wild discords evoked from pan-pipes, flutes (or fifes), drums or clashing shells, all of rude construction.

And, as in music a great volume of sound — not harmony — was the desideratum, so in architecture they neglected beauty and strove to attain resistant mass, with walls as solid and homogeneous as possible — the prime essentials in a country shaken by destructive earthquakes; and their solicitude in this respect, which was less justified in Cuzco valley, suggests that the tribe, before the migration to which old legends refer, may have dwelt in the volcanic western part of the Sierra (see PERU). Hence the so-called "cyclopean" walls of the temples and palaces, structures built to endure, for which the builders utilized enormous stones of irregular shapes, fitted together so skilfully that mortar was not required.

It is safe to say that nearly all features of the ancient industrial life of the tribes inhabiting the Andean Sierra and Peruvian coast strip are either intimated or plainly shown by specimens in the Bandelier collection. With the utmost care products which are not properly to be classified as Incan have been separated from those showing the activities of the dominant race; and such care is obviously indispensable, for the Incan objects, though they may be discriminated by a trained archæologist, do not stand out from the rest quite unmistakably. One finds practically nothing to support the theory that there was ever a nearly unrelated, or a wholly distinct and marvellously superior, Inca civilization. Especially instructive are the examples of the potter's art which have been secured in great numbers — representing such different social classes as the warrior, musician, and water-carrier. Costumes, weapons, occupations, etc., are depicted faithfully, though without artistic charm. Fabrics of cotton, or woven from the wool of the llama, vicuña, and alpaca; looms, spindles, and colored threads, bear witness to the wide extension of the industry of weaving so often mentioned by early writers. Offerings made to the dead in the graves which have been explored (and, in the sacred cause of science, discreetly rifled) recall the fact that agriculture shared with warfare the distinction of being the chief occupation of able-bodied men. Inca women are shown to have been, like their Quichua descendants at the present time, eminently domestic in their tastes and employments, ruling supreme in the house, taking no part in public affairs, and perhaps never developing the characteristics of the Amazons who dwelt beyond the montaña in the region of tropical forests. Gold and silver appear to have been not less abundant — perhaps they were even more abundant — in the lowlands than in the highlands: at any rate vessels formed from the precious metals are found more commonly in the burial places near the coast. It is not to be supposed that the natives failed to appreciate the beauty and utility of silver, gold, and copper. An ingrained preference for the clumsy methods of barter — which the Quichuas have not even yet forsaken — prevented them from adopting any medium of exchange or setting apart one or more of the metals to be used as "money."

MARRION WILCOX.

In'cense, aromatic substances burned in religious rites on account of the sweet odor they emit. The custom of burning incense is ancient and widely spread. Among the Jews the practice was enjoined as part of the worship of the sanctuary (Ex. xxx. 27), the ingredients of the incense also being laid down, and it was to be burned on a special altar called the altar of incense. This altar was made of acacia (shittim) wood, and was overlaid with gold, hence it was called the golden altar, as distinguished from the altar of burnt-offering, which was made of brass. The incense was burned daily — morning and evening. Both the Greek and the Latin churches use incense in worship. Among Catholics it is used at every high mass, at consecration of churches, in processions, funerals, etc.

Inch, a lineal measure, the 12th part of a lineal foot, anciently said to consist of three barley corns. A statute of Edward II. (1324) makes "three barley corns round and dry" the definition of an inch. It is subdivided into halves for mechanical work, and for a scientific purpose decimally into thousandths, as in gunnery, and into ten thousandths by the makers of gauges. The English inch is equal to 2.54 centimetres. The old Scotch inch was slightly larger than the English.

Inch-worm. See MEASURING-WORMS.

Inch'bald, Elizabeth Simpson, English actress, dramatist, and novelist: b. Stanningfield, Suffolk, 15 Oct. 1753; d. London 1 Aug. 1821. In 1772 she was married to an actor named Inchbald, and the same year went upon the stage. She retired from this profession in 1789 and devoted herself to literature. Some of her plays, which belong to the class of high comedy, still keep the stage, but her greatest success was the novel 'A Simple Story' (1791), which was translated into several languages. She also wrote 'Nature and Art,' and among her plays may be cited: 'Such Things Are'; 'The Married Man'; 'The Wedding Day'; 'The Midnight Hour'; 'Every One Has His Fault'; and 'Lovers' Vows.'

Inclina'tion, Magnetic, or Magnetic Dip. See DIPPING NEEDLE.

Inclined Plane, one of the mechanical powers. When a body lies on an inclined plane part of its weight is supported; so that if a cord be fastened to it and pulled, a force less than the weight of the body, acting in a direction parallel to the plane, will prevent it from sliding, or will move it up the plane. Thus a heavy wagon is raised on an inclined road by a horse which would be quite unable to exert a pull equal to a quarter of the weight of the wagon. A body lifted by means of an inclined plane is moved through a greater distance than if it had been raised vertically, so that although the force employed may be smaller, it is exerted through a greater space. When the plane is smooth, so that friction may be neglected, the force parallel to the plane necessary to raise the body is equal to the weight of the body, multiplied by the vertical height through which it is lifted, divided by the distance it is moved along the plane. For instance, when a train moves up an incline which rises 3 feet for every 100 feet of rail, the engine exerts a pull equal to 3/100 of the weight (neglecting friction). Inclined plane

railroads are common in the United States, the best known being located in Pittsburg and Cincinnati.

Income Tax, a tax levied directly from income of every description, whether derived from land, capital, or industry; first imposed in Great Britain in January 1799, during the ministry of Pitt, after the failure of an attempt to raise a revenue adequate to the exigencies of the period by trebling the amount of the assessed taxes. In the Pitt act incomes under $200 were exempted; the tax rose by a series of gradations till it reached 10 per cent, at which rate it was charged on all higher incomes. This tax was repealed in 1802, but was again imposed in the following year, though with a change of name to property tax, and a difference of rate.

But one income tax has been imposed by the United States government, arising from the necessities incident to the Rebellion. In 1861 Congress authorized a tax of 3 per cent on all incomes over $800 per annum. In July 1862 an act was passed taxing all incomes under $5,000 5 per cent, with an exemption of $600 and house-rent actually paid. Incomes in excess of $5,000 and under $10,000 were taxed 2½ per cent additional, and incomes over $10,000 5 per cent additional with no exemptions. Further taxes of 5 per cent on incomes of Americans living abroad and of 1½ per cent on incomes from United States securities were laid, these expiring in 1865. In 1864 a special tax of 5 per cent was imposed on incomes above $600. A readjustment the same year imposed a 5 per cent tax on incomes between $600 and $5,000; 10 per cent on incomes above $5,000. During Cleveland's second administration a bill was passed imposing a tax upon all incomes above $4,000. The constitutionality of the law was tested before the Supreme Court, which after a protracted hearing decided adversely by a majority of one.

Inconnu, ĭn-kŏ-nū′, Fr. ăṅ-kŏ-nü′, the French-Canadian name of a fish of the rivers that enter the Arctic Ocean (*Stenodus mackenzii*), intermediate between a salmon and a whitefish in its characteristics, and of great value as food for the people of that region.

Inco-ordina'tion, a lack of control over muscular movements. In inco-ordination there may be (1) some interruption in the paths of the motor impulses as sent from the motor areas in the brain to the muscle-centres in the spinal cord; or inco-ordination may result from (2) deficiency in the incoming sensory paths, thus causing an interference with the sense of muscular localization. One of the most familiar illustrations of inco-ordination is seen in acute alcoholism. In this condition the lack of motor control is largely due to interference in the conduction-paths of motor impulses. The intoxicated person is unable to control the movements of his hands to make them perform in their wonted fashion ordinary acts. In locomotor ataxia, a disease in which inco-ordination of the movements is very striking, the inco-ordination seems to result from a loss of muscle and joint sense, whereby the patient's mind is rendered unable accurately to realize just where his limbs are. Inco-ordination is a symptom of a number of different forms of poisoning, and is extremely characteristic in diseases such as locomotor ataxia, multiple sclerosis, chorea, and paralysis agitans. It is also found in a number of infantile diseases.

Incubator, a machine employed for the artificial hatching of chickens from eggs. Such devices were known to mankind from early ages. Pliny says that the Egyptians thus hatched 100,000,000 chickens a year. While artificial incubation was introduced into France and England during the 18th century, the incubator was brought to greatest perfection in the United States in the 19th century. The first patented invention of the modern incubator was in 1847, but any practical success in such machines cannot be met with before 1877, when Rouillier and Arnoult exhibited their hydro-incubators at the Paris Exposition.

There are two general classes of incubators, those in which hot air is used for the maintenance of heat and the application of it to the eggs, the other in which hot water serves this purpose. An automatic incubator of first class make is equally efficient whichever of these two heating mediums is employed, but there are many different types of machine offered for sale, and the struggle between cheapness and efficiency sometimes leads to the sacrifice of the latter. There are certain essentials to an incubator which must be attained at any cost, and the machine that is deficient in anyone of these is a failure, which means that it cannot guarantee to yield of living chicks at least 80 per cent. The following may be enumerated as absolute requisites in a good incubator: (1) An egg chamber heated at a uniform temperature. It is best that the heat should come from above, when it is likely to be reverberated from the floor of the chamber, and to more evenly affect the eggs, and may at once strike the germinal vesicle which from its lightness always rises to the upper surface of the yolk. (2) A source of heat which is self-regulative. The thermo-regulator in general use is actuated by an arm thrust within the egg chamber, and must be sensitive to an atmosphere ½° or at most 1° above that which is desired. (3) Good ventilation within the egg chamber, with some provision by which a certain degree of moisture may be maintained in the air. (4) Added to this, is a good turning apparatus. There are very many devices for effecting this purpose; perhaps the best is that of a tray fitting exactly over the tray in which the eggs are laid, and by the turning of which the eggs may be replaced in a reversed position in the applied tray.

Of course the aim of a true incubator is to reproduce as accurately as possible by artificial means the conditions of natural hatching under a sitting hen. Thus the supply of heat and air must be conformable to a fixed standard. The temperature is to be kept unchanged at 100° F., or a little above that, by placing the incubator in a room not exposed to draughts. To make accident in this respect impossible, a cellar, or specially built chamber, should be used, where no access of colder air may cause a fall in temperature, and a sensitive thermo-regulator furnish automatic means of preventing excessive heat from destroying the vitality of the eggs. Moisture must be preserved in the air of the egg chamber that the eggs may not be shriveled by excessive evaporation. There must also be adequate ventilation, that no harmful gases

sicken or kill the hatching chick. The turning of the eggs is considered necessary, because the sitting fowl has the habit of so doing, but the eggs should not be disturbed after the 18th day, nor the incubator be opened after that date, until the hatch is completed. With regard to the moisture of the air, it has been considered proper, after studying the progress of evaporation, as reckoned from the loss of weight in a fertile egg during the process of hatching, that a humidity of 45 per cent is the safest degree of saturation.

Various ways have been resorted to of taking care of the chickens after they leave the incubator. They must at first be kept in an atmosphere of from 90° to 100°, at least for the first week, and heated places of shelter, known as brooders, must be prepared for them. There are many patterns and kinds of brooders, which are manufactured by the same firms as those which make incubators. The requisites for brooders are: (1) The temperature of the first week, as given above should be gradually lowered. (2) The greatest diligence should be applied to secure and maintain cleanliness, dryness, and good ventilation. (3) Their construction should be such that newly-hatched chickens may always be in view. As the chicks grow toward fledging, facilities should be afforded them to leave the brooder for exercise. See also Poultry. Consult: Watson, 'Farm Poultry' (1901); Stoddard, 'The New Egg Farm' (1900).

In'cubus (Lat. "one who lies upon"), a spirit to whom was ascribed the oppression known by the common name of nightmare, in Greek *ephialtes* (from *epi,* and *hallomai,* I leap upon). These demons play an important part in the superstitions of the Middle Ages, having been perhaps not unfrequently employed, like the older gods of Greece, to cloak the advances of earthly lovers. See Nightmare.

Incunab'ula, is a term applied by bibliographers to editions of books printed during the early period of the art, and is generally limited to works which appeared previous to 1500. The incunabula are divided into xylographic and typographic, the former those printed from engraved blocks, the latter from movable types. Among the most highly esteemed of the incunabula are those which are first editions of the ancient classics. See Bibliography.

In'daja Palm. See Attalea.

Indemnity Contract, a form of contract which, while not of recent origin, is becoming much more common than formerly. Such a contract is any form of written agreement between two parties whereby one party agrees to indemnify or save harmless the other party for loss or damage arising out of a particular transaction, or against some specified claim of a third party. It is an original contract and must be in writing in order to come within the statute of frauds. Such contracts are frequently made in the form of a mortgage. But the substance and not the form is important, and the courts have usually given them a liberal construction with the intent of furnishing the party to be indemnified with all of the protection that was manifestly in the minds of the contracting parties when the contract was signed. Indemnity contracts are not adverse to public policy; but they are not binding when they undertake to protect persons against the consequences of illegal acts. Like other contracts, they must be founded on a sufficient consideration, and furnish indemnity only to the party named as indemnitee, and do not extend to a person having only a contingent or collateral interest in the subject matter of the contract.

Indepen'dence, Iowa, city and county-seat of Buchanan County, on the Wapsipinicon River, 70 miles southwest of Dubuque, and on the Rock Island and the Illinois Central R.R.'s. It is the centre of an extensive horse-breeding, farming and dairying region. There is located here the well known Rush Park, with its kite-shaped race track, the State insane asylum for northern Iowa, public library and other buildings. The electric-light plant and waterworks are owned by the municipality. Pop. (1890) 3,163; (1900) 3,656.

Independence, Kan., city and county-seat of Montgomery County; on the Verdigris River, 85 miles southwest of Fort Scott, and on the Atchison, T. & S. Fe and the Missouri P. R.R.'s. It is the centre and distributing point for a large agricultural section, and has cotton-mills, paper-mills, window-glass factories, flour-mills, cracker factories, brick works, planing-mills, and creameries. It has a public library, court house and other large buildings. Natural gas and oil wells are numerous near the city. Pop. (1890) 3,127; (1900) 4,851.

Independence, Mo., city and county-seat of Jackson County, five miles from Kansas City, on the Kansas C. & I., Missouri P. and the Chicago & A. R.R.'s. The city is considered a residential suburb of Kansas City. The town was settled in 1827, and in 1838 the Mormons' rendezvous was located here, and from hence the Latter-day Saints pursued their journey to Utah. Under the charter of 1889 the city is governed by a mayor and city council elected every two years. The electric-light plant is owned by the municipality. Pop. (1890) 6,380; (1900) 6,974.

Independence, Declaration of. See Declaration of Independence.

Independence Hall, Philadelphia, a low plain brick building on Chestnut Street, begun in 1732 and completed in 1741, as a state-house for the colony of Pennsylvania, as closely connected with great national events as Faneuil Hall or the Old South in Boston. The architect was J. Kearsley, the builder E. Wooley. It was occupied as a state-house while unfinished, in 1735; the tower was added in 1750. Here the Continental Congress held its sessions; here Washington was appointed commander-in-chief of the Continental armies, on John Adams' motion; here the Declaration of Independence was adopted, and was read from its steps to the assembled crowds in front. The Convention of 1787 (q.v.), which framed the Constitution, was also held here. It is now kept as a museum of historical relics, especially of the Revolution.

Independent Catholic Church of the United States, a Polish religious body organized in Chicago, among disaffected Roman Catholics. Its founder, Rev. Anthony Kozlowski, attended one of the conferences of the Old Catholic Church in Europe and was there consecrated

a bishop. The church has acquired considerable property in Chicago and has established a hospital, dispensary, orphanage, home for the aged, primary, grammar, high, and industrial schools. The society had in 1902 over 45,000 members, and 33 ministers and 43 churches.

Independent Telephony. In 1901-2, the expiration of numerous fundamental telephone patents enabled individual and independent companies to extend the telephone service to small communities, rural districts and farms in the West and Northwest. Many co-operative telephone lines were established in 1902 by farmers in the Middle West, and in 1903 it was estimated that 500,000 farms were in close communication by telephone with neighboring cities and commercial centres. The farmer finds that with the telephone he can keep in touch with the market, selling his produce or live stock when quotations are the most favorable. It is a common practice for the country doctor to give directions by telephone for caring for the patient, both diagnosing and prescribing. In Illinois the speeches of a political convention in 1903 were listened to by the farmers on a rural system as they sat in their homes from 15 to 36 miles away. Being in speaking distance of his neighbor, not only does the farmer feel a new sense of personal security, but he knows that his belongings are safer from molestation than they ever were before. The telephone has been instrumental in causing the arrest of many horsethieves and outlaws, and in some districts the farmers have almost broken up chicken stealing and petty larceny by telephoning the police and commission merchants of their losses, and thus enabling prompt arrests to be made.

An innovation in the use of the telephone which promises to be the vogue is already very popular. The local grocer or butcher, realizing that time is money, pays for the monthly rent of the telephone of any of his customers who spend $25 at his store during the month, or makes a corresponding discount for a smaller expenditure. He finds that in the increased amount of business coming through the greater ease of transmitting orders, and the reduction in his staff of order men, he can well afford to throw in the telephone service, which furthermore becomes a splendid advertisement for his store.

In the early days of the rural telephone the farmers were content to utilize their fence wires for intercommunication, and in many districts, particularly in the Western States, this method so reduced the cost of installation as to enable many communities to have a tolerably effective service, which otherwise would have had to go without any. But the farmers becoming more fastidious, demanded a better service. The systems employed range from a single line, with from three or four to a dozen instruments connected, to comprehensive systems covering entire counties and having hundreds of patrons. For instance, in Geauga County, Ohio, near Cleveland, where there is a population of about 14,000, there are over 1,000 patrons, the number in each township ranging from 50 to nearly 400. Great attention is paid to toll service, and the best construction and apparatus are insisted upon, as being in the long run the most economical. An example of the village and rural exchange is New Augusta, Ind., with 75 subscribers, 50 of whom are farmers, the most distant being about seven miles. When a single neighborhood line with a few instruments attached is desired, a switchboard is not necessary. The subscribers signal each other direct by giving different combinations of rings.

So easy has the organization of rural telephone systems become that it is safe to predict that within a decade the majority of the 4,000,000 farmers said to be yet unprovided with telephone service will have followed the example of their more enterprising brethren and brought themselves within touch of civilization. If any community wishes to install a system, no matter how limited, it has only to communicate with a reputable installation firm to receive the fullest and the clearest instructions as to how to go about it. A favorite method of organizing is for the farmers to form partnerships or co-operative (mutual) companies for the furnishing of service only to the locality in which the subscribers live. Sometimes the service is furnished by nearby telephone exchanges running lines into the rural districts.

In some places service cannot be given by city companies. In such case, the farmers can form themselves into a company, subscribe for the stock on pro rata or other basis, and install the system, running a direct line from their switchboard to that of the nearest town or city exchange. This is called the community system, the heart of which is the small switchboard, from which radiate in different directions the lines to which the various telephones are attached. See also, Telephone System, Independent.

Independents. See Congregationalism.

In'dex Libro'rum Prohibito'rum ("list of prohibited books"), in the Roman Catholic Church, a title used to designate the catalogue or list of books prohibited by ecclesiastical authority, on account of heretical or immoral opinions supposed to be contained in them, or maintained by the authors or editors of them; when the list or catalogue is of books allowed to be read after correction or alteration, agreeably to the orders of the Papal authorities, it is termed *Index Expurgatorius.* Such prohibitory catalogues have been in use from a very early period in the history of the Church, commencing with a list of prohibited books drawn up by a council held at Rome in 494, or even earlier, with the proscription of the writings of Arius. These prohibitions, in fact, were often issued by other than the Papal authorities. In 1408 a synod at London prohibited the reading of the books of Wickliffe. In 1544 the Faculty of Theology in Paris published a catalogue of books censured by them, and in 1546 the University of Louvain published an index of books regarded as dangerous. The indexes of the Church were a subject of consideration at the Council of Trent, which referred the business of drawing up a complete index to a select committee under the Pope. Their Index was published in 1564, and besides the catalogue of prohibited books contains general rules relative to such books. In 1586 a special ecclesiastical board, the Congre-

gation of the Index, was formed, consisting of a cardinal-prefect, with other cardinals and examiners of books, with authority to judge of new works, to indicate those of which the reading is entirely prohibited, and those which are permitted after correction, and also to grant to learned and pious men the right of reading prohibited works. The most important editions are those of Alexander VII. in 1664, and of Benedict XIV. in 1744. An edition appeared in 1881, with a supplement in 1884. In 1607 the first volume of an 'Index Expurgatorius' was published at Rome, edited by the Dominican Brasichelli. In Spain the Inquisition maintained its right to issue its own index, the last edition of which, dated 1790, was reprinted, with a supplement in 1805. The Spanish indexes, which are mostly both prohibitorial and expurgatorial, contain most of the books found in the Roman index and many others besides. Pope Leo XIII. had a revision made of the Roman Index and the names of about 3,000 books were taken from the prohibited list.

Index of Refraction. See LIGHT.

India, also called **Hindustan** or **Indostan,** derived from the Persian form of the Sanskrit *sindhu,* a river, and signifying "the land beyond the Indus," is a name used both in ancient and modern times with great latitude of signification, and applied more or less comprehensively to the great central peninsula of southern Asia. British conquests having extended to and beyond the utmost limits of the central peninsula, India, in its widest sense, may now be taken to include all the territories in this region that are directly or indirectly under British rule, or at least under British control, and, as the Empire of India, are supervised under the government of which the viceroy of India is head. India, thus defined, excludes the island of Ceylon, which ranks as a separate colony, but includes a considerable portion (namely, Burma) of the eastern peninsula and some adjacent islands. Small portions of territory still owned by France and Portugal are also comprised in it. The mainland of India proper is bounded north by the main range of the Himalaya Mountains: east by mountain ranges which divide it from Burma; southeast by the Bay of Bengal; south by the Gulf of Manaar, which separates it from Ceylon; west by the mountain chains enclosing the valley of the Indus, which separates it from Afghanistan and Baluchistan, and by the Indian Ocean. Its length north to south is nearly 2,000 miles; its greatest breadth east to west about 1,800 miles. It extends between lat. 8° 5′ and 35° 15′ N., and lon. 65° 45′ and 97° E.

Political Divisions.— India as a whole is partly under direct British rule and partly under native rule subject to control by British political agents. The total area of British India is 1,560,160 square miles, of which 964,993 square miles are under direct British rule. Ajmir Merwara, Berar, and Kurg are under the immediate control of the governor-general or viceroy of India; Madras and Bombay (with Sind, Aden, and Perim), former presidencies, are each ruled by a governor; Bengal, the United Provinces of Agra and Oudh, Panjab, and Burma are each under a lieutenant-governor; and there are chief commissioners over Assam and the Central Provinces. In 1901 the Northwest Frontier Province was formed, consisting of the trans-Indus Panjab districts of Peshawar, Kohat, Bannu, and Dera Ismail Khan, with the tribal country beyond their limits and the existing agencies of Dir, Swat, Chitral, the Khaibar, etc. The following table gives the area of the British provinces and their populations in 1891 and 1901:

PROVINCES	Area sq. miles	Population 1891	Population 1901
Under Gov.-General —			
Ajmir-Merwara	2,711	542,358	476,330
Berar	17,718	2,897,491	2,752,418
Kurg	1,583	173,055	180,461
Under Governors —			
Bombay { with Sind / Aden, Perim	125,144	18,901,123	18,584,496

Other Parts —	.....	27,270	810,811
Baluchistan			
Andamans	.....	15,609	24,499
Total	964,993	221,172,952	231,085,132

In the case of Burma, Assam, Sind, Panjab, and Baluchistan the 1901 figures include certain areas not previously enumerated.

Seven of the eight large provinces have a number of native states attached to them. Attached to Bengal, with an area of 35,834 square miles, and a population in 1901 of 3,735,715, are the individual states of Orissa, Chota Nagpur, Kuch Behar, and Hill Tipperah; to the United Provinces of Agra and Oudh, with an area of 5,109 square miles, pop. 799,675, are Rampur and Garhwal; to the Panjab, with an area of 38,299 square miles, pop. 4,438,816 — the chief states are Patiala, Bahawalpur, Kapurthala, Jind, and Nabha; to Madras, area 9,609 square miles, pop. 4,190,322 — the chief states are Travancore and Cochin; to Bombay, area 69,045 square miles, pop. 6,891,691 — the chief states are the Kathiawar group, Kolhapur, Rewa Kantha, Palanpur, Mahi Kantha, Cutch, and Khairpur (Sind); to Central Provinces, 29,435 square miles, pop. 1,983,496 — the chief states are Patna, Kalchandi, Bastai, Bamra, and Raigarh.

The other native states and agencies are: the Rajputana Agency, including among others the states Jaipur, Jodhpur, Udaipur, Bikanir, Alwar, Bhartpur, and Jaisalmir, with a total area of 130,268 square miles and a pop. (1901) of 9,841,032; Central India Agency, including among others the states Gwalior, Rewa, Indore, and Bhopal, with a total area of 77,808 square miles and a pop. of 8,501,883; Baroda, area 8,226 square miles, pop. 1,950,927; Hyderabad, area 82,698 square miles, pop. 11,174,897; Mysore, area 27,936 square miles, pop. 5,538,482; and Kashmir, area 80,900 square miles, pop. 2,906,173. The total area of native states and agencies is thus 595,167 square miles, and their total population in 1891 66,050,479, in 1901 63,181,569.

Physical Features.— The natural boundaries of the peninsula of India, which forms a triangle washed on two sides by the sea, and having

its base in the great mountain chain which separates it from Tibet on the north, are completed by its three great rivers, the Indus, the Ganges, and the Brahmaputra. These all rise in the Tibetan Mountains beyond the Himalayas, and the first flowing west, the two latter east, descend in a southern direction toward the sea; the Indus discharging itself into the Indian Ocean; the Ganges and the Brahmaputra, after watering in their separate course a large part of Northern India, uniting to pour their waters together by numerous mouths into the Bay of Bengal. The mountains enclosing the basins of these rivers form the east and west boundaries of the northern part of the peninsula. The Himalayas, the loftiest mountain range in the world, with heights of upward of five miles above the level of the sea, descend by successive slopes to the elevated plain of Northern India. (See INDUS, GANGES, BRAHMAPUTRA, HIMALAYA.) The entire peninsula is sometimes distinguished by three natural divisions. The Vindhya Mountains, a range of about 3,000 feet in height, which extends irregularly across the peninsula, from Gujarat to the basin of the Ganges, forms an anciently-recognized division into two parts under the names of Hindustan and the Deccan (Southern Land). The name Hindustan, given in this restricted sense to the northern part of the peninsula, is frequently applied to the whole. The ancient division of the Deccan is again subdivided into two, the name Deccan being restricted to the northern part, the southern from the river Krishna or Kistnah, which flows from west to east almost across the whole peninsula, being called Southern India or India south of the Krishna. The portion of India watered by the Ganges and its tributaries is by far the most fertile and populous of the whole. At no great distance from the opposite extremities of the Vindhya Mountains two great ranges proceed southward along the line of the coast. The Western Ghâts, which attain a height of 5,000 to 6,000 feet, though at some parts much lower, proceed along the west coast to Cape Comorin, the southernmost point of India. They do not generally recede more than 40 miles from the sea, and rarely more than 70. On the sea side their descent is generally precipitous, forming a regular sea-wall. On the land side they descend gradually, and sometimes almost imperceptibly, to the elevated plains of the interior. The Eastern Ghâts recede farther from the east coast, are less elevated and precipitous. Before reaching as far in their southern course as Madras, they trend inward, and unite with the transverse range of the Nilgiri Hills, which connects them with the Western Ghâts. This mountain-formed triangle encloses an elevated table-land with a gradual slope eastward from the Western Ghâts, and which is continued beyond the Eastern Ghâts to the sea. The elevation of the plain of Southern India also increases toward the south. In the Deccan it is about 3,000 feet above the level of the sea. In the neighborhood of the Nilgiri Hills, which rise 3,000 feet above it, it reaches 7,000 feet.

Hydrography.— The chief rivers of India besides the Indus, Ganges, and Brahmaputra, already named, are the Jamna, Ramganga, Gumti, Gogra, Gandak, Kusi, etc., tributaries of the Ganges; the five rivers of the Panjab, Satlej, Bias, Ravi, Chenab, and Jhilam, tributaries of the Indus; the Nerbudda, enclosed on its northern bank by the Vindhya Mountains, and the Tapti, which flow west into the Gulf of Cambay, the Mahánadi, the Godávari, the Kistna, North and South Pennar, Vellar, Kaveri, etc., all flowing eastward into the Bay of Bengal. The uniform direction of the great rivers south of the Tapti is explained by the inclination of the land already described. The coasts of India have very few indentations, and consequently very few good natural harbors. The western coast is known by the name of the Malabar, the eastern by that of the Coromandel coast. There are no lakes of any extent in India — Chilka and Kolair near the east coast being the largest.

Geology.— All the great mountain ranges are chiefly composed of granite and of granitic rocks, which form also the base of the plateau of the Deccan. Both in the peninsula and in the Himalayas gneiss predominates, associated with mica-schist, hornblende-schist, chlorite slate, and primitive limestone. Syenite prevails in the southeast of the peninsula. In the southern portion of the Western Ghâts the granitic rocks are overlaid by an iron clay, which is continuous to the end of the peninsula, and reappears in the island of Ceylon. In the upper portion of the Western Ghâts and adjoining ramifications of the Vindhya range, basaltic trap in various forms overlies the granite to an extent unparalleled elsewhere in the world. It entirely covers a large portion of the table-land of the Deccan. In this district trap and granite frequently pierce the surface in isolated masses, forming flat-topped hills nearly perpendicular, and which can only be ascended by steps, or winding, dangerous paths. These have been converted into strongholds from a remote antiquity. They are frequently crowned with forts, and form a peculiar feature of the landscape. On the lower sides of the Himalayas regular strata of the Secondary and Tertiary periods are largely developed. Many of the sandstones and shales of the Secondary period belong to the coal-measures. The Indian Tertiary formations attain their greatest breadth toward Sind and the Panjab, where fossil remains, including many of singular forms and gigantic dimensions, are abundant.

Mineral Resources.— The principal coal fields in India are found in the region bounded north by the Ganges, south by the Godávari, and stretching east and west from the neighborhood of Calcutta to the middle of the valley of the Narbada. Indian coal is distinguished by its excessive lamination. The annual production in India was 6,635,727 tons in 1901, from 427 collieries worked throughout Bengal, Hyderabad, Assam, Rewah, the Central Provinces, Panjab, Baluchistan, and Burma. The most important mines are those of the East Indian Railway Company near Giridhi (Bengal) and the Singareni mine in Hyderabad. Of the coal used on the railways 95 per cent is Indian coal. Iron ore is abundant in many parts of India, but the amount produced is still small. The only large iron-work in India is at Barrakur in Bengal, but iron is manufactured locally on a small scale in other parts of Bengal and in the central provinces. The chief obstacle to the successful development of the iron industry of India is the difficulty of finding the ore, fuel, and flux sufficiently near to one another to

make it profitable, but it is believed that iron-works near Calcutta, using Madras ore and Bengal coal, would succeed. Gold is worked to some extent, more especially in Mysore, the total production in 1900 being 513,266 ounces. Copper, lead, antimony, and other metals are fairly abundant. Burma yields a large amount of petroleum annually, and smaller quantities are obtained from Assam and the Panjab. The total output for 1900 was over 37,500,000 gallons, but much is still imported. There are valuable ruby mines in Upper Burma, and a few diamonds are still obtained in Central India. Salt is an important manufacture and source of revenue: its production is treated under the head of *Finance*.

Soils.— The alluvial deposits along the mountain valleys and in the plains, and the soil composed of disintegrated rock masses on the plateaus, are especially rich and of great productivity. Their fertility is greatly enhanced and maintained by an elaborate system of irrigation. See paragraph in this article on *Canals and Irrigation*.

Climate.— India extends 15½° within north tropical latitudes, and 12½° within the temperate zone. Owing to modifying circumstances, the climates contained within this range are not only extremely various, but distributed with great irregularity. One of the chief modifying circumstances is the distribution of moisture, the great regulators of which are the monsoons. The northeast monsoon blows from October to March, the southwest from April to September. The latter surcharged with vapor from the Indian Ocean condenses in torrents on the heights of the western Ghâts, and forms the rivers which flow to the east. Before it reaches the Coromandel coast, it becomes a dry wind which scorches up vegetation. In Hindustan, on the contrary, this wind passes over the low plains in the lower valley of the Indus, is arrested by the Himalayas, and fills the tributaries of the Ganges. The northeast monsoon runs a similar course in the opposite direction, but deriving less moisture from the Bay of Bengal, which is of less extent than the Indian Ocean, it has less influence on the climate, and its season is in general the dry one. The great plain of Southern India being exposed to greater heat than that of Hindustan, and not being watered by the snow-fed streams of the Himalayas, is naturally much less fertile. The seasons in India are divided into rainy, cool, and hot. The periods of these different seasons vary according to latitude and modifying circumstances. On the Malabar coast the rain begins earliest to the south. At Calcutta rain falls from June to October; the cool season begins about November, the hot season in February, the heat increasing gradually till May. In Calcutta where the mean annual temperature is about 79°, the range is from 50° to 85° F. In Bombay the mean annual temperature is about 82°, the range about 10°; in Madras mean about 84°, range 7° to 8°. The annual rainfall in India is much greater than that of England; but it is distributed with great irregularity. The basin of the Indus, including all Sind and the half of the Panjab, is an arid region with an annual rainfall under 15 inches. The high plateau in the interior of South India has an annual rainfall generally under 30 inches. On the whole Malabar coast the rainfall is over 75 inches; at Kananor it reaches 128 inches. On the Coromandel coast it is very much lower, being 45 inches at Vizagapatam, 50 inches at Madras, while farther south it falls below 30 inches. Between the arid region of the Indus and the Ganges runs a dry zone of 100 to 200 miles wide, including Lahore, Delhi, and Agra, with a rainfall between 15 and 30 inches. The valleys of the Tapti, the Nerbudda, the lower part of the Jamna, the Ganges, and the Brahmaputra, are generally over 30. Along the slopes of the Himalayas from Cashmere east to the boundaries of India, and southeast to the mouths of the Mahánadi runs a belt of country with a rainfall over 60 inches, within which is included the lower course of the Ganges. Within this is another belt, including a lower slope of the Himalayas, and the lower course of the Brahmaputra before its junction with the Ganges, in which the rainfall rises above 75 inches.

Forests.— The three most valuable timber trees of India are the teak (*Tectona grandis*), the sál or saul (*Shorea robusta*), and the deodar (*Cedrus Deodara*). The teak grows most luxuriantly along the Bombay coast, in Travancore and Cochin, and in Burma, but it is also abundant throughout much of Central India and elsewhere. The sál is the chief forest tree of the Himalayan slopes, from the Satlej eastward to Assam, and it grows also in the forests of Central India and the Eastern Ghâts. The home of the deodar is the northwestern Himalayas. Among the most valuable trees of the densely forested Western Ghâts from Kanara to Travancore and Mysore are teak, blackwood, bamboos, sandal-wood, a kind of ebony, and *Calophyllum inophyllum*, whose wood is prized for the spars of ships. In the United Provinces and neighboring districts the leading species are sál and several varieties of pines, and in the extensive jungles of the Ganges delta the most useful wood is that of the sundari (*Heretiera littoralis*). The forests of Assam yield sál. *Pinus Kasya*, caoutchouc (*Ficus elastica*), and other useful species, and plantations of teak, tun or toon (*Cedrela toona*), and sissoo (*Dalbergia sissoo*) have been laid out. Beside teak the Burmese forests contain ironwood and the cutch-tree (catechu). Before the formation of the Indian Forest Department the forests were recklessly destroyed by timber-cutters, nomadic cultivators, and others, but large forest areas in all the provinces have now been marked off as reserved forests under the immediate care of the forest officers, and other forest areas have been brought under partial conservancy. Timber-cutting and grazing have been either prohibited or restricted; and plantations of the more useful trees have been formed in many parts of the country. In every province a few of the most valuable timber trees are declared to be reserved trees, and can only be felled under special license. Forest revenue is raised by royalties on, or by the sale of, timber or other produce, and by the issue at specified fees of permits to graze cattle, or to extract for sale timber, firewood, charcoal, bamboos, canes, and other minor forest produce. The reserved forests now cover an area of more than 80,000 square miles, and the protected or partially conserved forests occupy other 30,000 square miles. Some of the native states, such

as Mysore, Travancore, Baroda, and Kashmir, have followed the example of the British government.

Flora.— Where moisture is plentiful, as in the valley of the Ganges, vegetation is superabundant. The delta of the Ganges, in particular, called the Sunderbunds, is covered with dense jungle full of the largest wild animals, and the excessive vegetation renders most of the mouths unnavigable. There are many other similar tracts of extensive forest and jungle. On the Coromandel coast, on the other hand, the heat, which reaches 100° or 120° F., destroys vegetation, and the delta of the Indus from the southeast of the Panjab to the Ran, or great salt marsh of Kach (Cutch), forms a great sandy desert, continuous across the river with the desert of Baluchistan, and with a wide band stretching across the whole continent of Asia to Central Africa. In the various altitudes of the Himalayas forms of vegetable and animal life belonging to all the various climates from tropical to polar are to be found. These as well as the Western Ghâts are magnificently wooded. Orchids, rhododendrons, and other valuable flowers are common. Among the staple natural products of India are rice, maize, wheat, barley, cotton, flax, hemp, jute, rhea, indigo, tea, coffee, sugarcane, opium, tobacco, ginger, pepper, cardamoms, palms bearing nuts which are extensively consumed, anise, dye-woods, etc. European fruits abound, and among indigenous fruits may be mentioned the mango, plantain, pomegranate, citron, date, almond, grape, pineapple, and tamarind. Palms, including the date, cocoanut, palmyra, betel-nut, and other species, the banyan, and bamboo, are common features of the vegetation.

Fauna.— The elephant, the rhinoceros, the camel, the tiger, a few lions in the northwest, the leopard, bears, hyena, jackal, wolf, and numerous smaller carnivora, the boar, antelopes, deer, wild ox, ass, sheep, and goat, monkeys in great variety, and the greater number of European quadrupeds are found. There are several large species of ox, such as the gaur or "bison" and the arnee or wild buffalo. Crocodiles, snakes (including the dreaded cobra), and reptiles in all varieties are very numerous; of birds, the eagle, vulture, falcons, peacock, parrots, kingfishers, mina-bird, partridge, quail, heron, stork, are characteristic species, and other varieties, both indigenous and common to other regions, are numerous. Fish are plentiful and in great variety both on the coasts and in the rivers.

Land Tenure and Revenue.— In India the state, or the monarch, has always enjoyed a share in the rent or profits from the land. Before the advent of the Mohammedans and the establishment of the Mogul Empire the almost universal unit for the purposes of revenue collection was the village community. In a village community land was held, not by private owners, but by cultivators occupying it under the village corporation, and the land revenue was collected from the head-man as representing the community. With the Mohammedan conquest new methods of revenue collection were introduced. The state claimed one third of the gross produce of the soil as its share, and entrusted its collection to persons who each agreed to pay a definite amount from the district assigned to him. These revenue farmers, known as *zamindars*, were often local magnates under the old Hindu system. Under British rule the aim has been to substitute private property in the soil, wherever practicable, for the older communal systems, and in consequence the zamindars, who were in no sense proprietors, have become so in several parts of British India, while in others the cultivating *rayots* (or *ryots*) have been raised to the status of peasant proprietors. The village community, however, in some form still exists both in British and in native territory.

The term "settlement" is applied in Indian revenue affairs to the process of assessing the land revenue demand. Occasionally, in newly acquired or specially backward tracts, the land revenue is assessed for a short term of years on a general review of the circumstances and capabilities of the land and people concerned; such a process is called a summary settlement. But a regular settlement is a more complicated affair, and consists of many stages. In the first place, every separate estate or holding is demarkated by permanent marks on the ground; and disputes between neighboring right-holders are investigated and decided. Every estate or holding is then surveyed and mapped, all boundary-marks, wells, and buildings being shown on the field or cadastral maps. After the field maps are prepared, the next process is to classify or record each field according to its productive value, as evidenced by its soil, the amount of its produce, or by the rent it pays. A record is at the same time drawn up of all rents paid, and of all rights, whether landlord rights, or tenant rights, or rights of user, over all the ground, buildings, wells, and trees shown in the map. Then the assessing officer (or settlement officer, as he is often called) compiles the information obtained for all the lands in a circle of villages; and on a review of all these data, of the past fiscal history of the tract, of the range of prices, of the accessibility of markets, and of other general considerations, he proposes rent rates or revenue rates for the several classes of lands in the circle. The rent rates or revenue rates proposed by the settlement officer, and the grounds on which they were based, are then investigated by a superior officer, and are not adopted until they have been accepted or modified by the latter.

In provinces where the zamindari tenure prevails, that is, where single proprietors or proprietary brotherhoods possess large estates of several hundreds or thousands of acres, the state revenue is assessed at an aliquot part (usually about one-half) of the ascertained or assumed rental. The revenue, though it is fixed with reference to acreage rates on the land actually cultivated, is assessed on, and is payable by, each estate as a whole; the assessment remains unchanged for the 30 years, or other period of the settlement; the proprietor can bring as much as he likes of his waste and fallow land under the plough; and it is only on re-assessment at the end of the term of the settlement that the state obtains any increase of revenue on account of the extensions of cultivation during the settlement period. In provinces where the rayatwari tenure prevails, that is, where each petty proprietor holds directly from the state, generally cultivates his own land, and has no landlord between himself and the government, the revenue is separately assessed at an acreage rate on each petty holding, and land revenue becomes payable at once, or

after a short term of grace in the case of uncleared lands, on all extensions of cultivation. The rayatwari proprietor is at liberty to throw up his holding, or any portion of it, at the beginning of any year, after reasonable notice; the zamindar, or large proprietor, engages to pay the revenue assessed upon him for the term of the settlement.

The land revenue assessment was fixed permanently more than 100 years ago on the greater part of Bengal, about a third of Madras, and certain southern tracts of the Northwest now the United Provinces, paying in all about $14,250,000 a year. In the temporarily settled tracts, comprising the rest of India, it is fixed periodically for terms of 12 to 30 years. In the nine chief provinces (Bengal, Bombay and Sind, Madras, the United Provinces of Agra and Oudh, Central Provinces, Panjab, Burma, Assam, Berar) the number of rayatwari holders is about 273,000, of whom none belong to Bengal, Panjab, and the United Provinces and Oudh. The total number of zamindars and village communities is about 318,500, of which only Sind and Berar have none. The total number of holdings is thus about 591,500. In the greater part of Bengal land is held by zamindars under a permanent settlement, but the tenants are protected by recent legislation. The rayatwari system is the prevalent one in Madras, and in Bombay a similar system has been established. In the latter province the cultivators are now protected by law against the extortions of the money-lenders. The village community is still common in the United Provinces and the Panjab. In Oudh much of the land is held by talukdars, who have been granted certain privileges which are denied to the zamindars.

Agriculture.— The total area accounted for in the agricultural returns for 1901 is 546,000,000 acres, of which 66½ millions are under forest, 135½ million not available for cultivation, and 147½ million culturable waste and current fallows. The net crop-yielding area is thus 198½ million acres, or, taking account of land cropped several times in a year, 223½ million acres. The three chief food-grains of India are rice, millet, and wheat. Rice is the staple food of about a third of the population, and is grown on 75 million acres, but it is nevertheless essentially a local crop, which can be cultivated with profit only under exceptional circumstances. Of the total rice area 40 million acres belong to Bengal, where it is the staple crop, and about 7 million each to Madras and Burma. Over 90 per cent of the cultivated area of Lower Burma is under rice, and it is grown on nearly three quarters of the area of Assam, about one third of that of the Central Provinces, a quarter of that of Oudh, while it is of importance also in the United Provinces and Sind. It is grown to a less extent in the Panjab and Bombay. Rice is also cultivated by hill tribes in all parts of India. In Bengal there are two chief rice harvests in the year, the *áus* or early crop, chiefly for local consumption, and the *áman* or winter crop, chiefly for export; but in Lower Burma, whence most of the exported Indian rice comes, there is but one harvest, corresponding to the Bengal winter crop. The total area under wheat is 24 million acres, mainly in the Panjab (7½ million), where it is the leading crop, the United Provinces of Agra and Oudh, the Central Provinces, Bombay, Central India, and Bengal. Taking India as a whole, it may be broadly affirmed that the staple food-grain is neither rice nor wheat, but millet. The area under the various kinds of millet and maize is 43 million acres, chiefly in Bombay (13½ million), where these are the chief food crops; Madras, where also, though to a less extent, millets are the chief food-grains; Panjab, United Provinces, Berar, in which millets are by far the most important food crops; Central Provinces, Sind, Oudh, Bengal, and Upper Burma. The chief varieties of millet grown in India are *joár*, or *jawárí*, or *cholam*, great millet (*Sorghum vulgare*); *bájra*, or *kambu*, spiked millet (*Pennisetum typhoideum*); and *ragí*, or *náchani* (*Eleusine corocona*), grown chiefly in Southern India. About 8 million acres are sown with barley, chiefly in the upper Ganges valley, the Himalayan valleys, and the Panjab. Gram crops or pulses, especially chick-pea, green-gram, horse-gram, lentil, and pigeon-pea, occupy 10 million acres, mainly in the United Provinces of Agra and Oudh, the Panjab, and Bengal. The large native demand for oil has been reinforced in recent times by a rapidly-increasing foreign demand, and in consequence the cultivation of oil-seeds has greatly developed. They are grown in many parts as a second crop on ground from which rice or some other food crop has already been taken. The chief varieties cultivated are linseed, rape-seed, sesamum (*til* or gingelly), and castor-oil, and the total area occupied by them is 22 million acres, chiefly in Bengal, Bombay, and Sind, Madras, Central Provinces, and Panjab. The area under ground-nuts in Bombay and Madras is about 170,000 acres. The cultivation of vegetables for household use is general, and near some of the towns it is carried on more extensively. Potatoes thrive best in the more elevated tracts. Among cultivated fruits are the mango, guava, orange, melon, citron, lime, fig, plantain, pineapple, pomegranate, tamarind, shaddock, jack, papaw, and custard-apple. The area under sugar-cane is about 2,800,000 acres in Bengal (especially Orissa), United Provinces, Panjab, Oudh, Madras, and Bombay. Jaggery sugar is made from the bastard date-palm, which is grown for this purpose in the neighborhood of Calcutta and in northeastern Madras. The tea crop is one of great and increasing importance, and occupies about half a million acres, of which 330,000 are in Assam, the rest being in Bengal, Panjab, United Provinces, Madras, Burma, and native states. With the exception of a few hundred acres in Burma, Assam, etc., the whole of the coffee-growing area, amounting to about 280,000 acres, is in Southern India, in Mysore, Kurg, Madras, Travancore, and Cochin. The chief cinchona plantations are the government ones at Darjiling and in the Nilgiris. The tree was introduced by the Indian government.

Cotton is one of the most valuable vegetable productions of India. The total area under the cotton-plant is 14,000,000 acres, distributed thus: Bombay and Sind (3,900,000), Berar (2,500,000), Hyderabad (1,700,000), Madras (1,400,000), United Provinces of Agra and Oudh (1,250,000), Panjab (1,200,000), Central Provinces (1,000,000), and smaller areas in Central India, Rajputana, Burma, and Bengal. Next in importance to cotton among Indian fibres comes jute, which is cultivated in eastern Bengal along the valleys of the Ganges and the Brah-

YOUNG BRAHMIN AND WIFE.

maputra, occupying fully two million acres. The cultivation of the mulberry, for the rearing of the silk-worm, is chiefly carried on in eastern and northern Bengal, with Murshidabad as a centre. The indigo industry is one of the oldest in India, but it is at present in a languishing condition. The area under the plant is about 964,000 acres, chiefly in Bengal (360,000), United Provinces of Agra and Oudh, Madras, and Panjab. The opium poppy is cultivated in certain parts of western Bengal and the United Provinces of Agra and Oudh, in the Panjab, and in the native states of Rajputana and Central India, occupying in all about 600,000 acres. (See below under *Finance*.) Tobacco is grown in every district for local consumption. Among the numerous minor cultivated vegetable products of India are turmeric, chillies, ginger, coriander, aniseed, black cummin, fenugreek, pepper, cardamoms, betel-pepper, areca or betel-nut palm, cocoanut palm, palmyra palm, and date-palm. Experimental cultivation of rhea, rubber, sisal-hemp, and other valuable economic plants has been carried out on the experimental farms maintained by government in various parts of the country.

Stockraising.— Horned cattle are used in agricultural operations throughout all India, except Sind and the Panjab, where camels generally take their place. The total number of cattle in India is over 100 millions, of sheep and goats 40 millions, of horses, ponies, mules, and donkeys, 2½ millions, and of camels about a quarter of a million. There are large numbers of buffaloes in all parts of the country. A public veterinary department has been organized to attend to the improvement of the breeds of horses, ponies, mules, and cattle, the prevention of disease among domestic animals, and the provision of veterinary instruction. Its operations are mainly confined to Northern India, where the conditions are most favorable for the breeding of horses for military purposes.

Commerce.— From a very early period down till comparatively recent times Western traders visited India in order to obtain the gold and silver, jewels, spices, and other costly products for which India was then celebrated, but the present foreign trade of India has developed under British rule and rests on an entirely different basis. In the year 1700 the total value of the exports from India was under $5,000,000, in 1834 the value had risen to $50,000,000, and now goods and treasure to the value of about $400,000,000 are exported every year. In 1899–1900 the total value of private imports by sea (excluding treasure) was $235,706,200, of government imports of stores, $15,308,725; total of all imports other than treasure, $251,014,925. The total value of private exports of Indian merchandise was $352,379,510, of foreign merchandise re-exported $10,975,525, of government exports of stores $357,115; total of all exports other than treasure, $363,712,150. Treasure was imported to the value of $69,912,285 and exported to the value of $26,521,295. Thus, including treasure, the total exports by sea amounted to $390,233,445, and the total imports to $320,927,210, the total sea-borne trade being $711,160,655. The exports by land in the same year were valued at $18,800,925, and the imports by land at $23,529,025. Thus, the total trade of India by land and sea amounted in 1899–1900 to $753,490,605. The chief articles of import were: cotton woven goods, metals and hardware, oils, chiefly petroleum, sugar, railway material, machinery and mill-work, cotton yarns, chemicals, medicines, dyes, woolen goods, silk, raw and manufactured, provisions, liquors, and apparel. The chief exports were: jute, raw and woven, husked rice, hides and skins, oil-seeds, raw cotton, tea, opium, cotton yarns, wheat, indigo, coffee, raw wool, and cotton woven goods. The proportion of trade directly with European countries is about 63½ per cent, omitting the trade with Egypt, much of which really goes to Europe. The trade with the United Kingdom is over 70 per cent of the trade with Europe and nearly 45 per cent of the total trade. Next to the United Kingdom, the chief countries trading with India are China, Germany, United States, Straits Settlements, France, Japan, Belgium, Ceylon, Austria-Hungary, Italy, and Russia. The figures for 1900–1 show that, while Indian imports of American goods were valued at only some $49,000, Indian exports to America amounted to $241,640. The chief articles of export appear to be gunny bags and cloth, of which latter America takes more than all other countries. The trade of India with America, however, is only of short standing, but, wisely organized, is capable of being greatly expanded. At present Germany supplies many things this country should furnish, particularly in the electrical and chemical lines, in which it at present holds the market. Other important articles of Indian export are tea, jute and jute manufactures, wheat, oil-seeds, rice, leather, wool, indigo, coffee, teak-wood, cotton, and lac. The share of the five chief seaports of India in the total foreign trade (excluding treasure and government stores) in 1899–1900 was as follows: Calcutta, $264,130,000; Bombay, $188,230,000; Rangoon, $40,590,000; Karáchi, $35,170,000; Madras, $32,180,000. India has many other seaports of minor importance. The value of merchandise and treasure carried in coasting vessels during 1899–1900 was $135,470,000. The trade across the land frontiers is steadily increasing, the chief item among imports being food grains, and among exports cotton goods. Much greater than her trade with foreign countries is the internal trade of India, but no returns of its amount are available. It is mostly in the hands of natives, and to a large extent in those of particular groups or castes. It is still carried on, as it has long been, at village markets, town bazaars, religious fairs, and similar gatherings, but the development of railway and canal communication and the transformation in the system of agriculture have greatly altered its character in many ways.

Manufactures.— The domestic industries of India, such as weaving and spinning, pottery, brass-work, iron-work, and art work of many kinds, continue to be practised after ancient methods all over the continent of India. But Indian fabrics and products, made on a small scale by workers at their homes, have for years past been giving way before the cheaper, less artistic, and often less durable cotton yarn and fabrics, and the iron or steel products of British factories. Meanwhile an important manufacturing industry has been growing up, and steam-power factories are at work, among which those for spinning and weaving cotton, for spinning and weaving jute, for making paper, for husking and cleaning rice, for sawing tim-

ber, and for brewing beer, are the most important. Steam power is also largely employed in factories, on tea gardens, and indigo estates. In 1900 the number of cotton-mills in British India and native states was 186, containing 38,420 looms and 4,728,000 spindles, and giving employment to 163,000 persons. Of these mills 136 were in Bombay Province (80 in Bombay City), the rest being in Madras, Bengal, Central Provinces, United Provinces, Burma, Panjab, and Berar, besides some of the native states. The number of jute-mills was 33 in 1899–1900, containing 14,021 looms and 293,218 spindles, and employing over 100,000 persons. All the jute-mills are in Bengal, except one in Cawnpore, which is the chief manufacturing centre of the United Provinces. Four woolen mills produce blankets, serges, and cloths worn by the army and the police. The largest brewery is at Murree, in the Panjab Himalayas. Among other industrial works of importance are silk-mills, soap-factories, tanneries, iron and brass foundries, sugar-factories, coffee-works, cotton-presses and ginning-factories, jute-presses, rope-factories, oil-mills, cutch and lac factories, flour-mills, ice-factories, pottery and tile factories, bone-crushing works, tobacco and cigar factories, silk filatures, glass-factories, dye-works, indigo-factories (over 5,000), printing-presses, and dairy farms. The total number of persons employed in all these manufacturing industries is about 700,000. The present Indian Factory Act came into force at the beginning of 1892. The daily wages of a man employed in a factory vary, according to locality, from 2 to 4 annas (4 to 8 cents).

Shipping and Navigation.— In 1897–8, 9,759 vessels of 7,784,630 tons burden entered and cleared the ports in British India, as against 8,613 vessels of 9,625,317 tons in 1901–2. Of these in the latter period 3,988 were of British nationality, 2,003 native, 1,289 British Indian, and 1,333 foreign; included in these numbers were 1,644 steam vessels of 4,299,948 tons entering and clearing via the Suez Canal. In 1901–2 115 vessels of 4,833 tonnage, were built in Indian ports, 81 in Bombay, 13 in Madras, and 10 in Sind.

Railways and Roads.—The first Indian railway, from Bombay to Thana, was opened in 1853. The main trunk lines constructed from that time till about 1875 were built and managed by private companies on whose capital the Indian government guaranteed a fixed rate of interest, generally 5 per cent. The government in return for this assistance, exercised a general control over the companies, and reserved the right of buying the undertakings at specified dates on stated terms. In 1870 Lord Mayo initiated the policy of railway construction by direct state agency, but in more recent times several lines have been constructed by "assisted companies." Several of these latter lines have been taken over by government. There are also native state railways constructed from capital raised in native states, but generally worked by a staff employed by the government of India or by the trunk railway companies to whose lines they serve as feeders.

The importance of railroads in India is largely increased, in a governmental sense, by reason of their forming strategical links between the various military cantonments through which the vast Indian population is held in check by a comparatively small army of British soldiers. This, more than any other incentive, has hastened the development of railways in India.

The main lines are two in number, and are known as the Bombay-Calcutta and the Bombay-Madras lines. The former crosses the great northern plain, the latter the great southern plain of India, and are both connected by means of branch lines with all the large cities of the empire — the capitals of the rajahs, maharajahs and nabobs. These two great trunk lines have also been extended to the farthest limits of India, and even into adjoining territories, as where the line which crosses the Indus at Sukkur enters Afghanistan, the terminus being not more than 60 miles from Kandahar. There is also the Burman line, which passes up the valley of the Irawaddy in the direction of the Chinese frontier. These three main lines, with their several offshoots, may be roughly sketched as follows: In the north, a direct line from Bombay on the west coast to Calcutta on the east coast; a line to Benares from Bombay; a direct line from Calcutta to Peshawar, on the Afghanistan border, by way of Benares, Delhi and Lahore; a line from Lahore to Karachi, with the branch line between these two cities to Kandahar. In the south, the main line between Bombay and Madras through Hyderabad; the line from Bombay to Goa, and from Goa to Madras, with lines connecting with Calicut and with the line from Madras to Tuticorin in the south. In Indo-China, the main line from Rangoon to the Chinese frontier, by way of Mandalay, and with an extension to Bhamo and another to Meaday. (It is proposed to extend the Bhamo line to Bishi and the main line to Yun-nan in China with offshoots to Tching-tou and Hai-pong.)

The total mileage of railways in India on 31 December was distributed as follows: State lines worked by the state, 5,884; state lines worked by companies, 11,654; total state lines, 17,538. Lines owned by native states and worked by state railway agency or by the states themselves, 1,314; native state lines worked by companies, 1,560; total native state lines, 2,874. Total of lines owned by government and native state, 20,412. Lines worked by guaranteed companies, 2,663; lines worked by assisted companies, 1,518; total private lines, 4,181. The total capital outlay of these railways till the end of 1900 was slightly over $1,000,000,000; the total number of passengers carried in 1900 was 117,613,218; and the total weight of goods carried slightly over 43,000,000 tons. The chief highways are well metalled with a kind of limestone called *kankar*, but in Lower Bengal and similar districts, where there is no available stone, roughly-made bricks are used for road-metal. Many of the roads are planted with avenues of trees. The total length of roads in India maintained by public authorities is over 152,000 miles, of which over 36,000 miles are metalled.

Posts, Telegraphs, and Telephones.— The number of post-offices in India in 1899–1900 was 10,823, and the length of postal lines 91,534 miles. The total number of letters and post-cards carried was 448,868,998; of packets of every kind, 509,006,476. Adding the district post lines and the political and military lines administered by the Imperial post-office, the total length of the lines over which mails were carried was 127,934 miles. The Indian telegraph system now consists (1900) of 52,909 miles of line, 170,766 miles

FEASTING THE IDOLS.

of wire, and 283 miles of cable. The number of telegraph offices is about 5,000, and the annual number of messages over 6,000,000. There are telephone companies at important towns, such as Bombay, Calcutta, Karáchi, Madras, Madmain, Rangoon, and Ahmadabad. India is now in direct telegraphic communication with the Straits Settlements and the Australian colonies, with Europe via Suez, via Teheran, and via Turkey, with the East Coast of Africa, and with China via Bhamo.

Canals and Irrigation.— In some parts of India, such as Sind, cultivation is impossible without irrigation, while in others, such as much of Lower Bengal, irrigation may be regarded as quite unnecessary; but in the greater part of all the provinces the rainfall is either insufficient for the proper cultivation of the soil, or so uncertain as to expose the agriculturists to the constant risk of scarcity and even of actual famine. Hitherto irrigation has had only a secondary place in the governmental development of India, the attention of the administration having run more to railways. The profit on the railways is, on an average, 5 per cent, while on the expenditure on irrigation works on which only $125,000,000 have been spent, the profit has averaged 7⅓ per cent; on the Eastern Jumna canals the profits rise to 25 per cent. The annual irrigation expenditure under the present Indian budget comes to only $7,500,000 for major and minor works together.

In 1903 it was proposed by a special commission that the sum of $150,000,000 be devoted to irrigation works, the expenditure to be spread over 25 years. This period is regarded by some as too long, and they think it should be curtailed by one-half, as the question is urgent from both the political and economic point of view. While not considering the expenditure on railways excessive, seeing their military importance, it is felt that they have more than sufficient capacity for draining away all the produce of the country, to which it is time to cry a halt, and to devote more money and attention to works that will extend and stimulate production. The larger irrigation works have been found unprofitable in four districts only, and in those the loss has been very small.

Many of the irrigation works now administered by the Public Works Department are simply old native works restored, and in some cases extended or improved. The total irrigated area of India is about 37 million acres. Tank irrigation is common in some districts, especially in Southern India, and the tanks are mostly of native origin. Many old tanks, however, have been repaired or improved by the British government, and new ones have been constructed in Madras (where there are now 60,000 tanks), the Bombay Deccan, and Ajmir Merwara: In parts of Baluchistan, where the rainfall is scanty and capricious, water for irrigation purposes is drawn from underground springs by means of tunnels driven into the hill-sides. The most common method of irrigation in India, however, is that by wells, which prevails over large areas in all the provinces. Canal irrigation was practised to some extent by the native rulers, but all the important canals have been constructed since the British occupation. Irrigation canals are of two kinds, inundation and perennial. The latter are furnished with permanent headworks and weirs, and are capable of irrigating large areas throughout the year, independently of the local rainfall; while the latter, which are peculiar to Sind and the Panjab, are simply earthen channels supplied with water by the annual rise in May of the Indus and its affluents. Many of the perennial canals are, either in whole or in part, used for navigation, and there are, besides, a few canals used for navigation alone. The total length of irrigation canals in operation was 42,352 miles, of which 12,497 miles were main canals and the rest distributaries. The total mileage of navigable canals in Bengal, Panjab, United Provinces of Agra and Oudh, and Madras is fully 4,000 miles, of which about 1,600 miles are for navigation only.

The total area irrigated by canals in Bengal exceeds 720,000 acres, and the length of irrigation canals is 3,381 miles, of which 747 miles are main canals. Of these canals 495 miles are open to navigation, and there are besides 1,339 miles of canals used for navigation only, thus giving a total length of 1,834 miles of navigable canals. The area in the United Provinces of Agra and Oudh irrigated by canals exceeds 2,800,000 acres, over 1½ million acres being irrigated by the Upper and Lower Ganges Canals (q.v.), and the total length of irrigation canals is 12,534 miles, 1,554 miles being main canals. Of these canals 537 miles are open to navigation. Over 5,000,000 acres in the Panjab are irrigated by canals, the total length of these being 12,069 miles, of which 3,478 are main canals, 432 miles of the latter being utilized for navigation also. Three million acres are irrigated by canals in Madras, and rather more by tanks and in other ways. The total length of irrigation canals in the province is 10,522 miles, of which 3,474 are main canals. The total length of canals used for navigation is 1,252 miles, of which 262 miles are for navigation only. In Bombay proper the canals are generally small, and they are usually associated with storage reservoirs. Taking Bombay and Sind together, the total irrigated area is 1,700,000 acres; the length of irrigation canals 3,801 miles, of which 3,240 miles are main canals. There are no large irrigation works in Lower Burma, but a considerable amount has been expended on river embankment and drainage works, and on making navigable channels. The chief work in Upper Burma is the Mandalay Canal.

Money, Weights, and Measures.— By an act passed in 1835 a uniform monetary system was established throughout India, with the Madras silver rupee of 180 grains, $\frac{11}{12}$ fine, as the monetary unit. The rupee was subdivided into 16 annas, and each anna into 12 pies (or four pice). Silver was made the universal standard of value, and the silver rupee and half-rupee were declared to be legal tender to any amount. The other smaller coins were made legal tender up to the value of one rupee; 100,000 rupees are called a lakh or lac, and 100 lakhs a crore. Under this system large sums are punctuated differently from the usual European method. For instance, the Indian Post-Office Savings banks' statistics show that in 1900–1 816,651 depositors had to their credit 100,432,569 rupees, or, according to the Indian method, crores 10, lakhs 04, rupees 32,569.

The coins under this system are: Silver — Rupee, half-rupee, quarter-rupee; Bronze or Copper — Three pies (or a pice), six pies, one pie. There are also gold coins called mohurs,

but they are not a legal tender, and there is no fixed ratio between them and the silver coins. Small payments in the bazaars are made in cowries, of which from 2,500 to 5,000 are equivalent to one rupee. The rupee was formerly valued at 48 cents, but it has fluctuated greatly, mainly downwards. In January 1895 it was nearly as low as 24 cents; at present it is about 32 cents. In view of the steady depreciation of silver, and the consequent financial embarrassments and burdens to which the government of India was subjected in its dealings with gold-standard countries, an act was passed by the Governor-general's Legislative Council in 1893 under which the Indian mints were closed to the free coinage of silver. On 15 Sept. 1899 a further act was passed, by which gold coins issued from the Royal Mint in England, or any branch of the Royal Mint, were made legal tender at the rate of 15 rupees to the sovereign. Arrangements are being made for the coinage of gold in India. By an act of 1861 and some subsequent acts, promissory notes for amounts varying from 5 to 10,000 rupees have been emitted under the authority of a public issue department. Currency circles have been established from time to time, and these notes are legal tender only within the circle of issue. They are payable at the place of issue and also at the capital city of the presidency in which the place of issue is situated.

By the Measures of Length Act of 1889 the British imperial yard of 3 feet or 36 inches was made the standard of length for the whole of British India. The most important of the old native measures of length was the *guz* of Bengal, which was practically equal to a yard. An act was passed in 1871 to prepare the way for the adoption of a uniform system of weights and measures of capacity throughout British India. The unit and standard of weight established by the act is the *ser*, which is equal to a kilogram or 2 1-5 lbs. The unit of capacity was declared to be a measure containing one ser of water, at its maximum density, weighed in a vacuum, and is thus equal to a litre or 1¾ pint. Among native weights the most important are the tola (Bengal) of 180 grains, and the imperial or Indian maund of 40 seers, equal to 82 2-7 lbs.

Government.— The government of the Indian empire is regulated by an act passed in 1858, by which all the territories formerly possessed by the East India Company are transferred to the crown, and all the powers of the said Company exercised in name of the sovereign, all taxes being received and disposed of for the purposes of the government of India alone. His majesty's secretary of state for India is invested with the powers formerly exercised by the Company or the board of control, and he must countersign all orders and warrants under his majesty's sign-manual. He is assisted by a council of from 10 to 15 members, the greater number of whom must be persons who have resided 10 years in India, and have not left it more than 10 years previous to their appointment. The secretary for India fills up vacancies in the council. The members receive a salary of $6,000 a year payable out of the revenues of India, and they hold their office for 10 years. All orders sent to India must be signed by the secretary, and all dispatches from the Indian government must be addressed to him. The executive authority in India is vested in the governor-general or viceroy appointed by the crown, and acting under the direction of the secretary of state for India. He has a salary of 250,000 rupees, or about $83,500. The governor-general in council has power to make laws for all persons, whether British or native, within the dominions subject to the British crown, and for all British subjects residing in allied native states. His council consists of five ordinary members and one extraordinary member, namely, the commander-in-chief. The ordinary members preside over the departments of home affairs, foreign affairs, finances, revenue and agriculture, military administration, legislation, and public works, and together with a certain number (not less than 10 nor more than 16, by the act of 1892) of "additional members for making laws and regulations," appointed by the viceroy, form a legislative council. The meetings of the legislative council are open to the public, and the governor of the province in which a meeting is held is a member for the time being. The members may discuss the annual financial statement, and ask questions about it, but they are not allowed to propose resolutions or to divide the council. The whole of India is now divided into a number of separate provinces, each with a separate administration of its own, but all subordinate to the supreme government at Calcutta, the capital. These are not all on exactly the same footing nor ruled by officials having the same title. Two of them, Bombay and Madras, are each under the rule of a governor, appointed by the crown, and assisted by a separate executive council. Bengal, the United Provinces of Agra and Oudh, the Panjab, and Burma are each under a lieutenant-governor, appointed by the governor-general with the approval of the crown, and the lieutenant-governor of the United Provinces is also chief commissioner of Oudh. The head of the government in Assam and the Central Provinces is a chief commissioner, appointed by the governor-general in council. The two governors and the four lieutenant-governors are each assisted by a legislative council similar to that of the governor-general. Ajmir Merwara, Berar, and Kurg are under the more immediate control of the central government.

Finance.— The gross revenue of India in 1899–1900 was $343,185,820, and the gross expenditure charged against revenue $329,312,705. In addition, there is a capital outlay on railways and irrigation not charged against revenue, amounting in 1899–1900 to over $20,000,000. The total public debt of India on 31 March 1900, was $995,637,675, of which $374,915,670 represented the debt in India, and the rest the debt in England. The largest item in the revenue is that derived from land, which amounted in the year under review to $89,376,150. (See paragraph on *Land Tenure and Revenue.*) The revenue from forests was $6,177,125, and the total amount of tribute received from native states was $2,933,015. The revenue from opium amounted to $22,009,610, but the net revenue is less than that amount by about $8,500,000. The opium revenue is raised partly by a monopoly in Bengal, and partly by the levy of a duty on all opium exported from native states. The cultivation of the opium poppy is absolutely prohibited in British territory, except in certain parts of Bengal and the United Provinces of Agra and Oudh, but a few thousand acres in the Panjab grow it for local consumption. The opium

HALL IN TEMPLE, MADURA.

grower in the monopoly districts receives advances from government to enable him to prepare the land for the crop, and he is required to deliver the whole of his produce to government agents at the fixed price of 6 rupees per seer. The manufacture for the foreign market is carried on only in the government factories at Patna and Ghazipur, and the chests of manufactured opium are sold by auction at monthly sales in Calcutta. Outside of British territory opium (known as Malwa opium) is cultivated in the native states of Rajputana and Central India, and some of these states have agreed to control the manufacture and sale of opium in much the same way as the Indian government does in British territory. They levy heavy duties on opium exported from their territories for the China market, and the Indian treasury imposes on all such opium a duty now fixed at $166.66 per chest. The revenue from taxation is $201,000,000, the chief item in it being the salt revenue, $29,252,315. The salt revenue is raised by a duty on all salt imported into, or manufactured in India, the duty being now 2½ rupees (80 cents) per maund, except in Burma, where it is 1 rupee (32 cents) per maund. The native sources of salt supply are the coast, especially the Rann of Cutch (Baragra salt) and Mauripur (Sind), the salt lakes and pits (especially Sambhar Lake) of Rajputana, and the salt mines (especially the Mayo mine) of the Panjab. Bengal and most of Burma import their salt by sea, much of it coming from England. Several native chiefs have entrusted the management of their salt sources to the British authorities in return for certain payments. The excise accounts for $19,299,710 of the revenue from taxation. The only excisable articles are intoxicating liquors (including toddy, palm-wines, and rice-beer), and certain drugs (opium, ganja, bhang, charas), and the aim of the government in taxing these has been as much to reduce consumption as to raise revenue. The government treats the right to manufacture and the right to sell spirits at state monopolies, which are granted to individuals on special terms. Throughout Bombay and the Panjab, the most populous tracts of Madras, the United Provinces, Oudh, and Burma, and in some parts of Bengal and the Central Provinces, the central distillery system in some form prevails, and a still-head duty is levied on all spirits manufactured at the recognized distilleries. Except in Madras and some other parts, these central distilleries are government establishments at which private persons distil spirits. In other districts the spirit revenue is raised by farming out the spirit monopoly to the highest bidder, or by licensing the establishment of private stills, the latter method being called the out-still system. The Indian government is replacing the farming and out-still systems as far as possible by the central distillery system. The customs revenue amounted in 1899–1900 to $15,353,140. Import duties were abolished in India in 1882, but in 1894 they were reimposed, and now all goods, with the exception of railway material and industrial machinery, food grains, coal, jute, wool, and other raw materials, gold and unset precious stones, and some other commodities, are subject to import duty. The amount of the duty is generally 5 per cent, but petroleum is charged at the rate of 1 anna per gallon, and iron and steel are subject to a duty of only 1 per cent. Since 1896 all cotton yarns imported into or manufactured in India have been duty-free, while all woven cotton goods imported from abroad, or manufactured at power-mills in India, pay an *ad valorem* duty of 3½ per cent. There is an export duty on rice and rice-flour of 3 annas per maund of unhusked rice. A countervailing duty on bounty-fed sugar came into force in March 1899. The revenue from stamps was $16,327,385. The provincial rates, amounting to $12,493,925, are levied mostly on the land to meet local charges for roads, schools, etc., and are generally collected with the land revenue. The income tax, which yielded $6,501,425 in 1899–1900, is levied at the rate of four or five pie per rupee, certain incomes being exempted. Other important heads of revenue are: Post-office, telegraphs, and mint, $11,680,890; civil departments, $5,876,500; railways, $82,939,225; irrigation, $13,087,880; buildings and roads, $2,209,000. The chief elements in the expenditure are: Railways, $82,535,430; army, $74,250,000; civil salaries, etc., $47,987,720; charges of collection, $22,244,195; buildings and roads, civil and military, $20,673,260; miscellaneous civil charges (furlough and superannuation allowances, pensions paid in England, etc.), $17,565,690; irrigation, $12,208,825; famine relief and insurance, $10,494,240; post-office, telegraphs, and mint, $8,427,935; interest on public debt, etc., $6,711,415; refundings, compensations, drawbacks, etc., $7,295,000.

Army and Navy.— The army in India is under a commander-in-chief, who is under the control of the Indian government, and has directly under him four lieutenant-generals commanding respectively the forces in Bengal, the Panjab, Madras, and Bombay. The Indian army numbers usually from 215,000 to 220,000 in all, the native soldiers being twice as many as the Europeans. The native troops are officered by Englishmen. Wherever European troops are stationed there is always a larger native force, and in many of the smaller and less important posts there is a native force only. Much money has been spent in recent years on defensive works and military establishments, strategic roads, etc. India has also a certain number of vessels for coast defense.

Ethnology— India is inhabited by numerous peoples belonging to several distinct groups or families. Previous to the Mohammedan ascendency the dominant race were the Hindus, who, however, were not the aboriginal inhabitants nor even the first invaders. From the northwest of India, through Kashmir and down the valley of the Indus, and from Tibet through the passes of the Himalayas, the inhabitants of Northern Asia from a very early period migrated southward to the milder and more fertile plains of India. Two great successions of these invasions are recognized as having taken place before the period of authentic history. The first immigrants, of dubious ethnological connections, but commonly known as the Tamil races, appear to have overspread the entire peninsula. Following them the Sanskrit-speaking peoples, called the Hindus, of Aryan speech, dispossessed the Tamil races, and superseded their language in the whole of India north of the Nerbudda. The Hindus subsequently descended into the peninsula and penetrated as far as Cape Comorin; but though their influence on the languages of Southern India was considerable in the way of introducing

new terms, the grammar and construction of the Tamil languages maintained their place in the districts south of the Nerbudda. The native tribes were not exterminated by these invasions, but are still to be found under various names, as Bhils, Catties, Coolies, Gonds, etc., inhabiting the fastnesses of the mountain-ranges in Bengal, the Vindhya and Satpura Mountains, the Ghâts, etc. The hill tribes and other aborigines in all India are estimated at 70,000,000.

Population.— The first census of all India was taken in 1871–2, but it was not till that of 1891 was taken that a really reliable and comprehensive statistical account of the people of India was available. In 1871–2 the total population of India was returned at 240,931,521, in 1881 at 253,793,514, in 1891 at 287,223,431, in 1901 at 294,266,701, of which, as shown under *Political Divisions,* 231,085,132 were under immediate British authority. The total number of Europeans was only 168,000.

France still possesses in India Pondicherry, Karikal, and Yanaon, on the east coast of Madras; Mahé, on the west coast of Madras, and Chandarnagar on the Hugli, north of Calcutta. To Portugal belong Goa, Damão, and the small island of Diu, on the coast of Bombay. These French and Portuguese possessions have a total area of 1,754 square miles and a population of 852,752.

Education.— A system of education for India was inaugurated in 1854 in conformity with the instructions of the home government, and the despatch of Sir Charles Wood (afterward Lord Halifax) of 19 July 1854 is the basis on which the educational system still rests. The fundamental principle of the despatch was that the native languages should be made the medium of communicating European knowledge. Examining universities with affiliated colleges were to be founded, and English and vernacular elementary schools were to be established. The despatch enumerated five government colleges in Bengal; the Sanskrit College and Mohammedan Madrasa at Calcutta; five colleges in the United Provinces; the Elphinstone Institution, Puna College, and Grant Medical College in Bombay; the High School at Madras, and several missionary schools, as proper to be at once affiliated to the universities. In 1857 the three universities of Calcutta, Madras, and Bombay were formally incorporated by law as examining bodies based on the model of the University of London as then constituted. A somewhat different university, with teaching powers, was established in 1882 at Lahore in the Panjab, and in 1887 a fifth university was founded at Allahabad for the Northwest Provinces. The Education Commission of 1882–3 extended the system of Wood's despatch by placing education on a more popular basis and giving greater recognition to indigenous schools, and the first proposals for extending education to Indian women were made by this commission. Educational institutions in India are officially divided into two classes: (1) Public Schools, in which the course of study conforms to the standards prescribed by the Department of Public Instruction or by the University, and which either undergo inspection by the Department, or else regularly present pupils at the public examinations held by the Department or by the University. These institutions may be under either public or private management, and among them are many schools receiving grants-in-aid. (2) Private Schools, comprising all which do not fulfil the above conditions. The three main grades of institutions through which the system of education operates are: (1) Primary schools, which aim at the teaching of reading, writing, and such elementary knowledge as will enable a peasant to look after his own interests; (2) Secondary Schools, either English or vernacular; and (3) Colleges, the students in which, having passed the matriculation examination of a university, are reading for the further examinations required for a degree. There are also many other colleges teaching special branches of knowledge, such as medicine, law, and engineering, and special colleges for sons of native chiefs and noblemen. In Burma primary education is still very largely in the hands of Buddhist monks. Outside of a few exceptional districts female education is exceedingly backward in India, but slow progress is being made. There are schools of art in Madras, Calcutta, and Bombay, and many of the chief towns have good museums. Many normal schools have been established for the training of teachers.

The total number of colleges in India in 1899 was 169, of which only 5 were for females. The number of pupils in these colleges was 21,006. Secondary schools numbered 5,396, with 569,271 pupils, 43,403 of the latter being females. The number of primary schools was 100,858, with 2,824,257 male and 313,289 female pupils, or 3,137,546 in all. The total number of training and other special schools was 720, with 28,158 pupils, 2,371 of them being females. Beside all these, there were 42,805 private institutions, with 558,914 male and 42,926 female scholars, in all, 601,840. The total number of educational institutions of all kinds was thus 149,948, of which 7,454 were for females, and the total number of persons under instruction, 4,357,821, of whom 402,153 were females. Of these institutions 22,804 are under public management, 61,494 are state-aided, and 65,650 are unaided private schools. It has been estimated that 22.2 per cent of the boys of school-going age attend school, but for girls the percentage is only 2.3. In nearly all branches of education in India the missionaries have been the pioneers, and their work is still important.

Languages, Literature, and the Press.— All the Hindu languages are cognate dialects founded upon the Sanskrit, a language of the Aryan or Indo-European family, which has been extinct as a spoken language for more than 2,000 years, and bears a similar relation to the spoken languages of India with that of Latin to the modern European tongues. See SANSKRIT LANGUAGE AND LITERATURE, and VEDAS. In the time of Alexander the Great, Sanskrit had already been superseded by a vulgar tongue, the Prakrit, founded on it. In ancient Hindu dramas persons of rank are represented as speaking Sanskrit, common people Prakrit. Pali, a dialect of Prakrit, became the sacred language of the Buddhists, their scriptures being compiled in it. It was spread by them into Ceylon and India-beyond-the-Ganges. It is still used for works, chiefly religious, for which a wider circulation is desired. Hindi, the prevailing literary language of the non-Mohammedan population, is a modernized form of an older dialect, Hindui, which flourished during the middle ages, having grown out of the Prakrit dialects

GREAT HALL IN TEMPLE OF RAMISSERAM, ISLAND OF PAUMBEN.

about the 10th century. Both Hindui and Hindi are rich in poetical chronicles. Hindustani or Urdu, a kind of Hindi mixed with Persian and Arabic, is the language of the Mohammedan conquerors, and grew up after the conquest of Delhi at the close of the 12th century. It is also rich in literature, particularly in translations from the Persian, Arabic, and Sanskrit. It is the language which has been favored by the British government for purposes of administration and diplomacy. The Dakhni, a mixture of similar elements, grew up from the same cause in the Deccan. Among the numerous other descendants of the Sanskrit the most important are the Bengâli, the Orissa, Uriya, or Utkala, the Marâthi, the Gujarâti, the Sindhi, and the Panjabi. The languages of Southern India form a distinct group called the Dravidian, differing in structure from those of the north. The most important of them are Tamil, or Malabarese, spoken on the Coromandel and Malabar coasts, Telugu or Telinga, in the middle of the Deccan, Kanarese in the Carnatic and neighborhood of Mysore, Malayâlam on the Malabar coast from Mount Dilli to Cape Comorin. From all these Burmese stands apart.

The chief vernacular languages in which books are published are: Urdu (Bengal, N. W. Provinces, Panjab, Bombay), Bengali (Bengal), Hindi (Bengal, N. W. Provinces, Panjab, Bombay, and Central Provinces), Panjabi (Panjab), Marathi (Bombay and Central Provinces), Gujarathi (Bombay), Tamil and Telugu (Madras), and Burmese (Burma), and the bilingual works are mostly either in English and another language, or in a classical and a vernacular language. Many works are also published in English alone, or in one of the three classical languages, Arabic, Sanskrit, and Persian. The greater number of these publications belong to the departments of poetry, religion, philosophy, and philology, but Urdu and Hindi fiction has developed greatly in recent years. Till about 1850 newspapers were prevailingly religious, but since then the native press has become more and more a medium for the discussion of social and political questions.

Religions.—The religions of India like the races are numerous. The most important is the Hindu or Brahmanical, which is very ancient. The earliest period of the Hindu religion is called the Vedic, from the Vedas (q.v.) or sacred books in which its records are preserved. These exhibit several marked phases of transition. The earliest date of the Vedic literature cannot be satisfactorily determined, either from philological or internal evidence. Its latest writings are not more recent than the 2d century B.C. Each Veda consists of two parts, the Sanhitâ, a collection of mantras or hymns, and the Brâhmana, which contains the doctrinal and ceremonial development of the religion. The worship represented in the greater number of the hymns is that of natural objects: Indra, the cloudless firmament; the Maruts, the winds; Ushas, the dawn; Vishnu, Surya, Agni, and other deities, to whom various attributes of the sun were attributed. These deities were invoked for assistance in the common affairs of life, and were reminded by the suppliants of their former glorious deeds. In the earlier Vedas no attempt is made to classify the gods and assign them particular ranks. In the Upanishads, a species of commentary on the Vedas, a systematic attempt is made to solve the problems of creation, of the nature of the supreme being, and of his relations with the human soul. Some of the Upanishads are legendary in form, others doctrinal or exegetical. These commentaries, though not in form philosophical, being professedly founded on the Vedas, contain the germs of the great systems of Hindu philosophy which were afterwards developed.

A new era in the history of Hinduism begins about the time of the Christian era with the composition of the two great epics, the Râmâyana and the Mahâbhârata, the latter of which was the product of successive ages. The vulgar creed had by this time experienced the influence of the theological and metaphysical speculations of the Upanishads, and had assumed a mystical unity. Brahmâ, Vishnu, and Siva, the three emanations of the great soul Brahma, representing respectively the creative, preserving, and destroying principles, had become the leading objects of worship.

The third or Purânic period of Hinduism corresponds with the period of the Middle Ages in Europe. The Purânas are discussions upon religion and philosophy, in the form of dialogues conducted by sages. They are designed for popular instruction, and mark a rapid and extensive corruption of the Hindu religion. The epic legends are amplified and distorted. The Vedânta philosophy, which had become the basis of the educated creed, still exercises a favorable influence on the popular worship. The creed of the Purânas is that of the masses in India.

Buddhism arose in India in the 6th century B.C. It prevailed there extensively, and spread itself through the adjoining regions of Asia. It became extinct in India before the 12th century, but still flourishes in China, Japan, and in the southeastern regions of Asia, as well as in Nepal and Ceylon. (See BUDDHA.) The Jainas or Jains, whose religion is a mixture of the Buddhist and the Brahmanical creeds, are still numerous in Hindustan, and particularly in Gujerat. There are two sects of this creed, called Digambaras and Swetâmbaras. Sikhism is another heretical form of Brahamanism prevalent in the Panjab. There are numerous other minor sects of Hinduism and worshippers of particular gods in the Hindu mythology. The Brahmo-Somaj (q.v.) is a modern Hindu theistic sect. The Hindu Fakirs are devotees, who give themselves up to penance, filth, and self-torture. The Parsees or fire-worshippers are descendants of the Persian followers of that religion, who took refuge from Mohammedan persecution on the western coast of India. Their principal emigration was to Surat, and is supposed to have taken place about the end of the 8th century. They were well received in Gujarat. They are now to be found mostly in the mercantile towns in India, and are most numerous in Bombay. The Mohammedans of India are chiefly descendants of its Asiatic conquerors from Afghanistan, Persia, Baluchistan, and Arabia. They are said to be more liberal-minded than the Mohammedans of Western Asia. There is among them a sect of Fakirs like those of the Hindus. There are also numerous Jews in India. On Christianity in India see below under *Christian Missions.* Hinduism recognizes four castes — the Brahmans, or sacerdotal class; the Kshatriyas, or military class;

the Vaisyas, or mercantile and agricultural class; and the Sûdras, or servile class. These casts are hereditary (see CASTE). Closely connected with the Hindu religion is the collection of laws commonly known as the Institutes of Manu. (See MANU.) In the Indian census table of religions (1901) 8,584,349 people are returned as heathens or aboriginals, that is, devotees of some form of animism. Practically, for the purposes of the Indian census, all are classed as animistic who are not locally acknowledged to be Hindu, Mohammedan, Christian, Buddhist, Jew, Parsee, etc., but every stratum of Indian society is in reality more or less saturated with animistic conceptions. Of the total population of British and Native India in 1901, 207,146,422 were registered as Hindus, the greater number of these being in Bengal, the United Provinces of Agra and Oudh, Madras, Bombay, Hyderabad and Rajputana. There were 62,458,061 Mohammedans chiefly in Bengal and the Panjab, 9,476,750 Buddhists almost all in Burma; 2,923,241 Christians of whom two thirds are in Madras and in the Madras States; 2,195,268 Sikhs, chiefly in the Panjab; 1,334,148 Jains, chiefly in Rajputana and in Bombay; 94,190 Parsees, and 18,228 Jews mostly in Bombay.

Christianity and Christian Missions in India. — The introduction of Christianity into India is variously ascribed by tradition to St. Thomas the Apostle, Thomas the Manichæan of the 3d century, and Thomas, an Armenian merchant of the 8th century. The earliest Christian church in India of which we have any definite knowledge was Nestorian, but after the Portuguese occupation these Nestorians came into the Roman obedience. In 1663, after the arrival of the Dutch, some of these renounced their allegiance to Rome. In 1665 these latter received from the Patriarch of Antioch a Jacobite bishop known as Mar Gregory, and to this day they have remained faithful to his Jacobite tenets. Thus, the ancient Nestorian Church of southwest India is represented now by two bodies, namely: (1) Catholics of the Syrian Rite, owning the supremacy of the pope, but retaining the Syrian language and ritual in their services; and (2) the Jacobite Catholics, rejecting the errors of Arius and Nestorius, and following the Nicene creed, though not acknowledging papal supremacy. The spread of the Roman Catholic faith in India was mainly the work of Jesuits from the 16th century onwards, the first of these being the celebrated St. Francis Xavier, who reached India in 1542. The Jesuits were suppressed in the 18th century, but since the re-establishment of the order in 1814 they have made great progress. The Roman Catholics of India are at present organized in seven archbishoprics (Goa, Agra, Bombay, Calcutta, Madras, Pondicherry, and Verapoly), and 16 bishoprics (Daman, Cochin, Mailapur, Allahabad, Lahore, Poona, Dacca, Krishnagar, Hyderbad, Nagpur, Vizagapatam, Coimbatore, Mangalore, Mysore, Trichinopoly, and Quilon), and there are also several vicars and prefectures apostolic. The earliest Protestant missionaries in India were the Lutherans Ziegenbalg and Plutschau, who arrived in the country in 1705 and began work at the Danish settlement of Tranquebar. The Lutheran missions were supported from the first by the Society for Promoting Christian Knowledge, and from 1719 till 1844 they were entirely maintained by that body. The celebrated Christian Friedrich Schwarz worked under the auspices of this society from 1750 till his death in 1798. Kiernander, a Dane, was the pioneer of Protestant missionary enterprise in Bengal. He was allowed by the East India Company to settle at Calcutta in 1758, but soon afterwards the Company changed its policy, and began to prevent missionaries from landing in the country controlled by it. When William Carey, the great Baptist missionary, arrived in 1793, he had to settle on Danish territory at Serampore, 15 miles from Calcutta, and it was not till 20 years later that the Company's opposition to missions was withdrawn. Carey was followed at Serampore by Marshman and Ward, whose names will always be associated with his and with the wonderful literary activity begun by him. Other celebrated Indian Protestant missionaries are Henry Martyn and Bishop Heber of the Anglican Church, and Dr. Alexander Duff, at first of the Church of Scotland, afterwards of the Free Church of Scotland. The head of the Anglican Church in India is the bishop of Calcutta, and under him are the seven bishops of Madras, Bombay, Lahore, Rangoon, Lucknow, Chutia Nagpur, and Travancore. Many American missionaries also work in India.

Judiciary.— The law administered by the courts of India is chiefly based on the enactments of the Indian legislative councils, the statutes of the British parliament relating to India, the Hindu and Mohammedan laws of inheritance and their domestic law in cases affecting Hindus and Mohammedans, and the customary law affecting particular castes and races. Bengal, Bombay, Madras, and the United Provinces have each a High Court supreme in civil and criminal cases (but with an ultimate appeal to the Privy Council in England), and somewhat similar tribunals exist in the other proinces. There are numerous courts of different grades throughout the country, and many of the judges are natives of India. Various enactments have been passed for the establishment of local government, and there are now upwards of 760 cities and towns with municipal government in the different provinces under these acts, and local taxation for police and local improvements has been enforced.

Local Government.— All the provinces, except Madras, are divided into divisions, each under an official called a commissioner, and all, including Madras, are divided into sections distinctively designated districts, the district forming the unit of administration. At the head of each district is an officer called a collector-magistrate or deputy commissioner, the former name implying the twofold nature of his duties, since he is not only a fiscal officer charged with the collection of the revenue from the land and other sources, but is also a revenue and criminal judge, both of first instance and of appeal. Police, jails, education, municipalities, roads, sanitation, etc., all come under his supervision; and he is expected to be familiar with the social life of the natives in all its phases. The districts are sub-divided into lesser tracts, known in Bengal as sub-divisions, in Madras and Bombay as *taluks*, in northern India generally as *tahsils*. The unit of police administration is the *thana* or police circle. An important portion of the

administrative staff consists of persons who have received appointments in the Indian civil service, after being successful in competitive examinations held in England: these form what is called the *covenanted* civil service. A certain section of the civil service, known as "the statutory civil service," consists of natives specially selected. The native states are generally governed by hereditary princes, who exercise sovereign power within their own dominions. They are more or less controlled, however, by British influence, a British resident, agent, or commissioner being stationed at their courts. They have no power to make war or peace, to send ambassadors to each other or to non-Indian states; they can only keep up a certain specified military force, and they may be dethroned for misgovernment.

History.— Little is known of the political history of India previous to the expedition of Alexander to the Indus, 326 B.C. The 20th satrapy of the Persians comprehended, as Herodotus states, part of the northwest of India. Alexander did not penetrate beyond the tributaries of the Indus, and between his invasion and the Mohammedan conquest there is no authentic political history of India, although the territory was divided among a number of rulers of whom Asoka (q.v.), the founder of Buddhism, was one of the chief. At the time of the Mohammedan invasion a Hindu monarchy was the dominant power in India. The conquest of Persia (632–651) brought the successors of Mohammed to the Indus, and they subsequently acquired a temporary hold of some parts of India, as Sind, which they conquered in 710 and lost in 750. The foundation of a more durable Mohammedan empire in India was laid some centuries later. The Kingdom of Ghazna, in Afghanistan, founded, according to Ferishta, by Alpetegin, an ex-governor of Khorassan, in 962, was declared independent by Mahmud in 999. This monarch, of whom as many as 12 expeditions into India are recorded, penetrated in one direction beyond the Jamna; in another he occupied Gujarat and captured Somnauth. He annexed the territory of Lahore to his kingdom, and nominally extended his dominion to the Ganges on the west, and to Gujarat on the south. His last expedition was to Gujarat in 1024. About the middle of the 12th century the Kingdom of Ghazna was divided, and Lahore became the capital of the Indian portion. The Ghaznavid Kingdom of India was overthrown in 1186 by Mohammed Ghori. On his assassination in 1206 Kutb-u-din, his governor in India, established the Afghan or Pathan dynasty at Delhi, and conquered Behar and Bengal. His successor Altamsh conquered Sind (1225), and completed the subjugation of Hindustan. About this time Genghis Khan overthrew the western empire of Ghazna, and founded a great Mongolian empire, which began to extend eastward, and came into collision with the monarchs of Delhi while these were still pushing their conquests to the south and east of India. The Delhi kingdom was, moreover, exposed to frequent commotions, both from the revolts of its own rajahs and from the predatory excursions of the hill tribes. A revolt of the rajahs was suppressed in 1250, and in 1265, after an extensive slaughter of the predatory tribes, a line of forts was constructed to check their incursions. But though frequently defeated the Mongols continued their incursions into all parts of India. In 1240 they reached Lahore, in 1244 they invaded Bengal; Gujarat, the Deccan, and the Carnatic were assailed in turn; the Panjab was subject to frequent invasions; in 1298 they were defeated at Delhi. A new dynasty, the Khilgi dynasty, arose under the usurper Jelal-u-din in 1288, which was succeeded by a fresh dynasty in 1321, the house of Toghlak. The invasions of the Mongols still continued with greater or less success. During the reign of the last Toghlak king the celebrated Tamerlane invaded India at the head of a great host, took and sacked Delhi in 1398, leaving behind him his deputy Khizr Khan, who now assumed the government. A period of anarchy ensued, which terminated in the conquest of India by the Mogul emperors. Ibrahim, the last of the dynasty of Lodi, the third in order from that of Toghlak, was defeated in 1526 by Baber, who established the Mogul dynasty in Hindustan. His grandson Akbar succeeded his father at the age of 14 (1556), and during a long reign of about 50 years, terminating in 1605, subdued nearly the whole of India, which, by introducing religious toleration, he succeeded in consolidating into an empire. At the death of Akbar his empire was divided into 15 subahs or vice-royalties, which indicate its extent, namely, Allahabad, Agra, Oudh, Ajmir, Gujarat, Behar, Bengal, Delhi, Cabul, Lahore, Multan, Malwa, Berar, Khandesh, Ahmadnagar. His son Selim succeeded him under the title of Jehanghir. The Portuguese, as will be seen in another section, had already established their territorial dominion in India. In 1615 an English ambassador appeared for the first time at the court of the Mogul emperor in Hindustan. He died in 1623, and was succeeded by his son Shah Jehan, who had disturbed his father's reign by rebellions, and during his own reign the country was filled with civil wars. He quarreled with the Portuguese, and expelled them from their settlement at Hugli. During his reign the Mahrattas or Marathas, under their chief Sivaji, began to be an important power in the Deccan. He was deposed in 1658 by his youngest son Aurengzebe, who also murdered his brothers. His reign was passed amid continual contests, both for extending his dominion, and subduing the revolts of the numerous peoples under his sway, both within the limits of India and beyond the Indus. He made war successfully with the Afghans, the Rajputana tribes, and the rising power of the Mahrattas. The Sikhs, a Hindu sect which had been persecuted by the Mohammedans, formed a religious and military commonwealth in the Panjab in 1675. Aurengzebe died at Ahmadnagar, in the Deccan, in 1707. On his death the Mogul empire began to decline. The succession was disputed by his four sons. Bahadur Shah, who succeeded, died in 1712, and was succeeded by his son Jehundar Shah, who, in the following year, was put to death by Farokshir, a great-grandson of Aurengzebe, who usurped the crown. He was deposed and put to death in 1718 by Hosen Ali. Mohammed Shah, grandson of Bahadur, was raised to the throne in 1718. His reign was disturbed by the insubordinate spirit of his viceroys, and through the defection of one of them the Mahrattas succeeded in subduing the Deccan. In revenge for an insult Nadir Shah of Persia invaded Hindustan in 1738, took possession of

Delhi, and gave it up to be sacked and plundered by his soldiers. The country west of the Indus was ceded to Nadir Shah in 1739. Mohammed died in 1748, and was succeeded by his son Nadir Shah. The empire was now tending to dissolution. The new emperor called in the Mahrattas in 1751 to aid him against the Rohillas, who, in 1749, had defeated the last imperial army ever called into existence. The various states were seized by the former viceroys or by independent chiefs. The Mahrattas, now the most powerful people of India, possessed, besides the Deccan, part of Malwa, and the greater part of Gujarat, Berar, and Orissa. The whole empire was at this time in extreme agitation and disorder, every government fearing the attacks and intrigues of its neighbors. Ahmed Shah was deposed in 1754 by Ghazi-u-din, a former vizier of the empire, who set up Alamgir II. In 1757 Delhi was captured by the Afghans, against whom Ghazi-u-din called in the Mahrattas. In 1759 the vizier assassinated the emperor. His successor, Shah Alum, without the shadow of power, escaped from Delhi, and finally took refuge with the British. The rival powers of the Afghans and the Mahrattas, which had been brought into collision by the feebleness of the empire, now engaged in a fierce struggle for the mastery over its ruins. This terminated at the decisive battle of Paniput, fought 6 Jan. 1761, in the complete overthrow of the Mahrattas. The victor, Ahmed Shah, recognized the grandson of Alamgir as emperor by the title of Shah Alum II.; but the empire was now only a shadow, and the native states, which had divided its power, were destined soon to give way to the superior European commercial organizations which the pursuit of gain had brought to their shores. See Colonies and East India Companies. Henceforth the history of India follows the course of these European colonies, until it is merged in the Indian empire of Great Britain.

The doubling of the Cape of Good Hope opened up the way by sea to India, and led the Portuguese to the possession of a kingdom in Asia. A few years after Vasco da Gama had landed on the coast of India they were already the most favored merchants upon the whole coast, and in spite of the active jealousy of the Mohammedans, who had hitherto monopolized the lucrative commerce of India, they formed settlements, and made commercial treaties with some Indian princes, in which the latter acknowledged the King of Portugal for their lord. By 1542 the Portuguese ruled from the Arabian to the Persian Gulf; nearly all the ports and islands on the coasts of Persia and India fell into their power; they possessed the whole coast of Malabar to Cape Comorin, and had settlements on the coast of Coromandel and the Bay of Bengal; Ceylon was tributary to them; they had factories in China; and the ports of Japan, to which a tempest had shown them the way, were open to their merchant ships. For 60 years they carried on their lucrative commerce without any considerable rivals. Portugal owed this power to a few able men, among others Francis of Almeida, and Alfonso de Albuquerque (qq.v.). But the successors of the men were not endowed with the same talents, and a revolting abuse of power excited the resistance of the natives, who became united by the sight of their common danger. The union of Portugal with Spain, under Philip II., in 1580, decided the fall of their commercial power in India. The Portuguese, satisfied with bringing the commerce of India to Lisbon, had allowed the Dutch to become the carriers between that port and the markets of Europe. But Philip II. closed the harbor of the Portuguese capital to the Dutch ships on account of the revolt of the United Provinces, and thus obliged that enterprising people to go to the sources of this commerce. Cornelius Houtmann in 1595 was sent with four ships to India to explore the coasts and gain information concerning the inhabitants and the commercial relations in that region. He returned with favorable accounts, for in this very first voyage treaties of commerce were made with the princes of the island of Java. The hatred of the natives against the Portuguese, who had at times landed here, assisted in the accomplishment of the enterprise. After the Dutch East India Company had formed settlements at Java and upon other points, and had made commercial treaties with several princes of Bengal, there began the long struggle with the rival Portuguese. The stronger and better-served navy of the Dutch enabled them to take one place after another from the Portuguese. In 1607 the latter were stripped by their victorious rivals of the Moluccas; in 1641 of Malacca; in 1658 of Ceylon; in 1660 of Celebes, where the Portuguese had settled after the loss of the Moluccas, to retain by smuggling some part of the spice trade; and after 1663 the most important places on the coast of Malabar, where they had longest maintained themselves, fell into the power of the Dutch. The Dutch made Batavia the capital of their eastern dominions. Their power in India began to decline from the time of their wars with Louis XIV. The English began to form commercial settlements in India about the same time as the Dutch. A settlement was formed at Surat in 1613, which became the chief station of the Company on the west coast in 1615, and in 1657 the seat of a presidency. A grant of a small territory around Madras was received from the Rajah of Bijnagar in 1639, on which was erected the fort of St. George. Madras became a presidency in 1654, and till the rise of Calcutta commanded the Company's possessions in Bengal. Calcutta, the third presidency, and ultimately the seat of government in India, was settled in 1690, and became a presidency in 1707. The English had to defend themselves against the Mahrattas in Surat in 1664, and early came into collision with the Portuguese and Dutch in the Indian seas. It was, however, the struggle with the French, who followed them, and who had acquired considerable territorial possessions in India, and the alliances of both parties with the native princes, coinciding with the decay of the Mogul empire, which brought about that long succession of almost unbroken successes by which this great empire was established. The claims of rival candidates for the governments of the Deccan and the Carnatic brought the two parties into collision at various points, and after a succession of maneuvers Dupleix, the French commander, succeeded in compelling the English to take refuge in Trichinopoly. Here Clive, who had already distinguished himself in an unsuccessful attack upon Pondicherry, proposed to carry the war into the enemy's country. In 1751 he besieged and took Arcot, Tinnevelly, Conjeveram, and Arani. On his return

to Fort St. David he was despatched by Major Lawrence on another expedition, which he again conducted successfully. Lawrence at the same time gained other successes against the French and their allies. These successes led to the Treaty of Pondicherry in December, 1754, in which the French and English agreed to divide their territorial possessions on a footing of equality, and abstain from interference in native affairs. This treaty procured for the English the cession from the French of the Four Circars; nevertheless, they treated it as a dead letter, and immediately began to reduce Madura and Tinnevelly. The French, after vainly remonstrating, followed their example in disregarding the treaty. About this time important events took place in Bengal. Suraj-ud-Dowla, nabob of Bengal, in 1756 besieged Calcutta with a large army, when it was evacuated so suddenly by the English that a considerable part of the garrison was left behind. These had no alternative but to surrender (20 June 1756). To secure the prisoners taken in the capitulation, 146 of them were thrust, apparently more from mere recklessness than intentional cruelty, into the common prison of the garrison, a room 18 feet square, with two small windows barred with iron, since famous as the Black Hole of Calcutta. After a night of unparalleled suffering only 23 were found alive in the morning. Clive, who was sent from Madras with an armament to Bengal, recovered Calcutta on 2 Jan. 1757. War had again broken out between France and England, but the French refused the alliance of Suraj-ud-Dowla, and maintained their neutrality. Suraj again invested Calcutta, but Clive, though he failed in a night attack, inspired him with so much respect for his means of resistance that he restored the English factories and made peace. Regardless of the benefit he had received from the neutrality of the French, Clive, in spite of the opposition of the nabob, determined to attack their settlement at Chandernagor, which he succeeded in taking. The nabob supported the French till he was attacked by the Afghans, when he became desirous of peace with the English. Clive, however, had determined to dethrone him and replace him by Mir Jaffier, his aunt's husband. In the battle of Plassey, 23 June 1757, the nabob was overthrown, and afterward assassinated by the son of his rival. Mir Jaffier bound himself to pay for his elevation a sum of over £2,500,000 sterling. This plunder was partitioned among the Company and the Company's servants, with the exception of a small share assigned to the native allies.

While the English in the Carnatic were engaged as collectors for Mohammed Ali in reducing the districts of Madura and Tinnevelly, the French recommenced hostilities. An attack upon Trichinopoly failed (May 1757), but Bussy reduced Vizagapatam, and established the French superiority throughout the Deccan. Count Lally, who had arrived with a formidable armament in April 1757, besieged and took Fort St. David, 1 June 1758. He afterward besieged Tanjor and Arcot, the latter of which he took. The want of funds, which crippled his operations, compelled him to engage with inadequate forces in the siege of Madras, which, after lasting two months, entirely failed in February 1759. The English took Conjeveram, to which the French retired, by assault. In the following campaign the French, after some successes, were totally defeated by Col. Coote near Wandewash on 22 Jan. 1760. Their power was now completely broken, their fortresses one after another fell into the hands of the English, and the English fleet, which had the command of the seas, co-operated in the reduction of those on the coast. Pondicherry, their last stronghold, surrendered on 15 Jan. 1765. The English had now established themselves, as a formidable if not altogether a ruling power, both in West and South India; but in both they committed the mistake of greatly over-estimating the resources of the country, and their rapacity and extortion, though they ultimately led to the extension of their power, were the cause of serious and protracted troubles. Mir Jaffier was deposed in favor of his son-in-law, Mir Cossim, who rebelled against English extortions, but, notwithstanding his skilful and vigorous preparations for a war he had anticipated, was worsted in successive engagements, particularly at Gheriah, 2 Aug. 1763, and forced to flee. In revenge he massacred his English prisoners. Sujah Dowlah, the nabob of Oudh, who received him, was defeated and deprived of his dominions, with the exception of Corah and Allahabad, which were given to the Mogul Emperor, who formally invested the Company in the dewanee or collectorship of revenues and virtual sovereignty of Bengal, Bahar, and Orissa, by a firman dated 12 Aug. 1765. The English came to terms with Nizam Ali, subahdar of the Deccan, who opposed their occupation of them, by agreeing to pay him a rent for the territory, and assist him with their forces, but this agreement brought them in 1766 into collision with Hyder Ali, the powerful sovereign of Mysore. Nizam Ali afterward joined Hyder against the English, and both invaded the Carnatic, and, in spite of several defeats, laid waste the country to the gates of Madras. Finally, Nizam Ali deserted Hyder, and the latter concluded a treaty with the English, April 1769, by which their conquests were mutually to be restored.

Notwithstanding the protests and prohibitions of the directors, the administration of the Company's affairs left much to be desired even during Clive's governorship, and during the administration of Verelst, who succeeded Clive in 1767, the Company's affairs were in extreme embarrassment. Parliament took advantage of the discontent and clamor raised against the Company's servants, and in 1773 remodeled the constitution of the Company, and appointed Warren Hastings (q.v.) governor-general of India, with a salary of $125,000, and a council of four members, each of whom had $50,000.

His administration was marked by firmness and resourcefulness in upholding British interests, and also by his unscrupulous methods in raising money to carry out his projects. In 1778 war again broke out between France and England. The English captured Pondicherry and Mahé, the last port of the French on the Malabar coast. This place was considered by Hyder Ali as one of his dependencies. In revenge for its capture he seized the passes of the Eastern Ghâts, invaded the Carnatic with an army of 120,000 men and laid waste the country. Sir Eyre Coote was sent into the Carnatic to conduct the war against him. Hyder Ali died in 1782, but the war was continued with his son Tippoo Saib, till 11 March 1784, when it was

concluded by a treaty of mutual restitution. In 1784 Pitt's India Bill was passed. In 1786 Lord Cornwallis succeeded Hastings as governor-general. Cornwallis made various administrative reforms for the relief of the people from former exactions, but Tippoo Saib diverted his attention from these peaceful measures by attacking the Rajah of Travancor, now an ally of the British. Having made an alliance with the Mahrattas and the Nizam, Cornwallis invaded Mysore, besieged Tippoo in his capital, compelled him on 9 March 1792 to conclude a treaty, by which he ceded half his territory and undertook to pay the expenses of the war. On the death of Mohammed Ali in 1795, Lord Hobart, governor of Madras, determined to assume the government of the Carnatic, but the plan was opposed by the supreme government and was not carried out. In 1798 Lord Mornington arrived in India as governor-general, when Tippoo Saib was making arrangements to renew his enterprises against the British and soliciting the alliance of France and of Cabul. Early in 1799 Lord Mornington invaded Mysore. On 4 May he stormed Seringapatam. Tippoo was killed in defending his capital, and Mysore was divided among the British, the Mahrattas, and the Nizam. Some time before this (1775) Oudh had agreed to receive and subsidize auxiliary troops for the defense of their territory, and the fortress of Allahabad was ceded to the British, who undertook to defend Oudh against all enemies. Subsequently in 1801 the subsidy was commuted for the cession of Southern Doab, Allahabad, and other territories. During the war with Tippoo, Lord Mornington, whose policy was to induce the native powers to accept British protection and mediation in their disputes, endeavored to induce his allies the Mahrattas and Nizam Ali to come under similar arrangements. The Nizam in 1798 agreed to dismiss his French troops and receive British auxiliaries. The Peshwa, the nominal head of the Mahratta Confederacy, forced by the contentions of the chiefs Holkar and Scindia, accepted the policy of the governor-general. Under the Treaty of Bassein, signed 31 Dec. 1802, Sir Arthur Wellesley restored the Peshwa, driven from his capital by Holkar. Scindia and the Rajah of Berar now entered into an alliance against the British. After a campaign in 1803 distinguished by the successes of Generals Wellesley and Lake, the former defeating the allies at Assaye, 23 September, the latter at Laswaree, 1 November, Scindia was compelled to make peace. He ceded to the British Baroach, Ahmadnagar, and the forts in the Doab (29 December); the Rajah of Berar ceded Cuttack (17 December). Scindia, thus weakened, accepted the British alliance, and received an auxiliary force to defend him against Holkar, 27 Feb. 1804. A war with Holkar immediately followed, which the skill of that chief in predatory warfare enabled him to sustain with some dexterity, and in 1805 he was joined by Scindia, but the British arms finally prevailed and he was forced to flee. The Marquis of Cornwallis succeeded Wellesley on 30 July 1805. He disapproved of the ensnaring alliances into which the former statesmen had drawn the native powers, and although he died before being able to carry out his views (5 Oct. 1805), Sir George Barlow, who succeeded him, adopted his policy. New treaties were made with Scindia, 23 November, and Holkar, 24 December, restoring their territories and their independence. The new policy was even carried so far as to abandon the petty princes who had trusted to the British alliance. Lord Minto succeeded to the governor-generalship in 1807. During his administration the chief enterprises of the English were directed against the insular possessions of the French and Dutch in the Indian seas. The Moluccas, Java, and other islands were taken; many of which were restored at the peace. Some disturbances took place during this period at Travancore, and among the British troops at Madras and elsewhere, which threatened at one time serious consequences. Travancore and Cochin were placed under British management. The Earl of Moira (Marquis of Hastings) succeeded to the governor-generalship in 1813. In 1814 a war broke out with Nepal, which was at first attended with some serious repulses, but was brought to a successful close by Sir D. Ochterlony in 1815, and resulted in the cession of Kumaon. Hastings was also called upon to suppress the Pindaris predatory bands of the former troops of Holkar and Scindia; and the Peshwa of Indore rebelling against a treaty his capital was seized, he himself deposed, and the Mahratta Confederacy dissolved. His ally the Rajah of Nágpur, Scindia, who submitted, and Holkar, who was defeated, were compelled to accept alliances virtually placing them under British protection. This pacification was completed in 1818, and greatly improved the revenues of the districts effected by it. The Marquis of Hastings was succeeded in 1823 by Lord Amherst, under whom the first Burmese war was concluded in 1826 by a treaty ceding to the British the Aracan and Tenasserim provinces together with a large pecuniary indemnity. During the governor-generalship of Lord William Bentinck (1828–35) various administrative reforms were effected, but no great political events took place. Lord Auckland assumed the governor-generalship in 1836. The Afghan war broke out in 1838, in consequence of long and complicated intrigues arising from the advance of Russia in the East, and the mutual jealousy of that power and Great Britain. War was declared on 1 October, the object of the British was to dethrone Dost Mohammed and restore Shah Sujah, a former ruler. It was at first attended by great disasters, particularly the famous massacre of the Khoord Cabul Pass. It was terminated in 1842, under the governor-generalship of Lord Ellenborough, by the evacuation of Afghanistan by the British, after they had relieved their captives and vindicated the superiority of their arms by the capture of Cabul. Sind was annexed to British India after a war conducted by Sir Charles Napier in 1843. After a brief war, arising out of a disputed succession, the dominions of Scindia lay at the mercy of the British, and were disposed of by a treaty dictated by the governor-general at Gwalior in January 1844. While he was thus engaged Lord Ellenborough was recalled and superseded by Sir Henry Hardinge (May 1844), who was soon engaged in one of the most formidable wars the British had yet had to encounter in India. The Sikhs, a politico-religious sect already mentioned, had, under their leader, Runjeet Singh, conquered the Panjab about the beginning of the century. Runjeet Singh, who had always maintained friendly relations with the British, died in 1839, and the government fell into a

chaotic state; the army, being without a head, began to commit disorders and threaten encroachments on the British territory. In December 1845 the Sikh army crossed the Sutlej in great force, and in the short war which followed the Sikhs were defeated by Sir Hugh Gough and Sir Henry Hardinge at Moodkee, Ferozeshah, Aliwal, and Sobraon. Peace was made at Lahore, by the surrender of the Sikh territories on the left of the Sutlej, and between the Sutlej and the Bias (Jalindar Doab), and the payment of an indemnity. During the governor-generalship of the Marquis Dalhousie, 1848–56, a new war broke out with the Sikhs, and after their final defeat by Gen. Gough at Gujerat, 21 Feb. 1849, the Panjab was annexed to the British dominions. This was immediately followed by the second Burmese war, ending in the annexation of Pegu, 20 June 1853. Sattara, Jhansi, Nágpur, and Oudh were, on the failure of the native succession, also annexed to the British possessions, 1852–6. During Lord Dalhousie's administration the extensive scheme of Indian railways and telegraphs was planned and inaugurated, the Ganges Canal opened, and the Panjab Canal begun. His last important act as governor-general was the annexation of Oudh, 7 Feb. 1856. The administration of Viscount Canning was distinguished by a short war with Persia, by the great Sepoy rebellion (see INDIAN MUTINY) and by the British assumption of the direct sovereignty of India, and of the powers of government hitherto vested in the East India Company by the crown. After the mutiny had been suppressed Lord Canning pursued with energy those schemes for the development of the resources of the country, adverted to elsewhere, which had already been inaugurated by his predecessors, and which have chiefly occupied the attention of his successors. He returned to England early in 1862, and was succeeded by the Earl of Elgin, who died at Dhurumsalla, 20 Nov. 1863, while similarly engaged. Sir John (afterward Lord Lawrence) was governor-general from 1863 to 1868, when he was succeeded by the Earl of Mayo, who earned a high character for the ability of his administration. He was assassinated by a Mohammedan fanatic at Port Blair, in the Andaman Islands, 8 Feb. 1872.

Famines.— India has suffered severely from famine on many occasions, and not seldom the scourge of famine has been accompanied by that of plague. The chief famines which have occurred under British rule are the following: That of 1769–70 in the lower Ganges Valley, in which one third of the population of Bengal perished; that of 1780–3 in the Karnatik; the Madras famine of 1790–2; that in the Northwest Provinces in 1838; that of 1860–1 in the same district, when the first serious attempts at relief were made; the terrible Orissa famine of 1865–6, in which one fourth of the population perished; the great famine of Southern India in 1876–8; that of 1896–7; and that of 1899–1900, in Bombay, Berar, Central Provinces, Central India, Rajputana, Southeast Panjab, and other parts, at one period of which about 6½ million persons were in receipt of relief. The problem of famine is not really a problem of scarcity at all, taking India as a whole, but it is partly a financial problem, partly one of irrigation, and partly one of inland communication.

Recent Events.— The other chief events since 1870 are: The proclamation of Queen Victoria as Empress of India at Delhi and elsewhere, 1876; the Afghan war of 1878–80; the rendition of Mysore to its native dynasty, 1881; the annexation of Upper Burma after a short war, 1886; the passing of the Indian Councils Act of 1892; closing of the Mints, 1893; Chitral campaign, 1895; the war against the Afridis and other frontier tribes, chiefly remembered by the action at Dargai, 1897; the creation of a gold standard, 1899; and the accession and proclamation of King Edward VII., as Emperor, at the grand durbar at Delhi in 1902. The governors-general since Lord Mayo's assassination have been: Lord Northbrook (1872–6); Lord Lytton (1876–80); Marquis of Ripon (1880–4); Marquis of Dufferin and Ava (1884–8); Marquis of Lansdowne (1888–94); Earl of Elgin (1894–9); and Viscount Curzon of Kedleston, whose rule began in 1899.

India Rubber, the manufactured products of caoutchouc, or gum-elastic. Some of the properties of india rubber must have been known in America at a very early period, because balls made by the Haytians of the gum of a tree, bouncing better than the wind-balls of Castile, are mentioned by Herrera in his account of Columbus' second voyage. In a book published in 1615 Juan de Torquemada mentions the tree which yields it in Mexico, describes the mode of collecting the gum, and states that it is made into shoes; also that the Spaniards use it for waxing their canvas cloaks to make them resist water. More exact information was furnished by M. de la Condamine in 1735. India rubber

was at first known as Elastic Gum, and received its present name from the discovery (about 1770) of its use for rubbing out black-lead pencil marks, for which purpose it began to be imported into Britain in small quantities about the end of the 18th century. Its application to the manufacture of waterproof cloth first gave it commercial importance. About the same time a method was discovered of fabricating articles of various kinds by casting india rubber in molds. The india rubber of commerce is obtained most largely from South America, but considerable quantities are also procured from British India, the Indian Archipelago, the west coast of Africa, and the Mauritius.

Pure India rubber is now used only to a limited extent in the arts, but it is applied in the vulcanized state to a very large extent. In the process of vulcanizing, the rubber, as a preliminary step, is either torn into shreds or crushed into thin pieces by machinery, and afterward washed. There are two principal kinds of vulcanized rubber, one hard and horny in its texture, the other soft and elastic. In the case of the former the caoutchouc is mixed with about one third of its weight of sulphur, and heated for several hours, the temperature finally rising to fully 300° F. For the soft kind of vulcanized rubber, on the other hand, a much smaller proportion of sulphur is required — viz. from 2½ to 10 per cent, and the heat to which it is subjected in the vulcanizing chamber is considerably less. Usually, too, with this latter kind, the articles are made before the rubber is heated. The sulphur is commonly added in the ground state, but sometimes the rubber is treated with some solution containing this element, such as the bisulphide of carbon.

Hard vulcanized rubber, termed vulcanite, and sometimes ebonite, is made into a great many small articles, such as combs, chains, bracelets, boxes, penholders, paper-knives, knife-handles, buttons, etc., as a substitute for materials like horn, bone, ivory, and jet. Like these substances themselves, it is formed into various objects by molding, cutting, carving, polishing, and other processes. Vast numbers of these articles are now sold. The black color of vulcanite ornaments has still a tendency to turn gray, but the brittleness which was a fault of combs made of it a few years ago seems to be overcome.

More than 50,000,000 pounds of india rubber, valued at more than $30,000,000, was imported into the United States in 1902. In 1890 the quantity was only 33,000,000 pounds; in 1880, 16,000,000; in 1870, 9,000,000, and in 1862, the earliest date at which it was separately shown in the import statements, was only 2,125,561 pounds.

Over $100,000,000 worth of manufactures from india rubber are now turned out from the factories of the country every year, and about half of this total is in the form of boots and shoes. So great is the demand for india rubber for use in manufacturing that not only has the importation grown from 2,000,000 pounds in 1862 to over 50,000,000 annually at the present period, but in addition to this the forests of the East Indies are called upon for several million pounds annually of a new substitute for gutta-percha, known as "gutta-joolatong," while at the same time the highways and byways of Europe and other countries are ransacked for cast-off rubber manufactures from which the rubber is "reclaimed" and re-used in conjunction with the new rubber from the forests of Brazil, Africa, and the East Indies.

The industry of importing and "reclaiming" india rubber for re-use in manufacturing is a comparatively new one, and while it utilizes large quantities of worn-out rubber boots and shoes and other articles of this character from the scrap heaps of the United States, it has only extended to other parts of the world in recent years.

Gutta-joolatong is another comparatively new material which may be used as a substitute for or in conjunction with India rubber. It is a product of the East Indies, chiefly the island of Borneo, located not far from our Philippines.

The tables which follow show the quantity and value of crude India rubber imported into the United States from 1893 to 1903, also the scrap and old India rubber for use in remanufacturing, also for gutta-joolatong from 1899, the date at which it was first separately stated, to 1903:

IMPORTATION OF CRUDE INDIA RUBBER, 1893 TO 1903.

Year Ending June 30	Pounds	Value
1893	41,547,680	$17,809,239
1894	33,757,783	15,077,993
1895	39,741,607	18,353,121
1896	36,774,460	16,603,020
1897	35,574,449	17,457,976
1898	46,055,497	25,386,010
1899	51,063,066	31,707,680
1900	49,377,138	31,376,867
1901	55,275,529	28,455,383
1902	50,413,481	24,899,230
1903	55,010,571	30,436,710

IMPORTATION OF OLD AND SCRAP RUBBER, FIT ONLY FOR REMANUFACTURE, 1893 TO 1903.

Year Ending June 30	Pounds	Value
1893	910,543	$25,633
1894	1,774,008	55,803
1895	2,032,563	63,112
1896	3,874,677	123,068
1897	3,653,945	113,722
1898	9,488,327	339,374
1899	10,513,604	462,044
1900	19,093,547	1,249,231
1901	15,235,236	988,316
1902	22,894,900	1,437,960
1903	24,659,394	1,516,137

IMPORTATION OF GUTTA-JOOLATONG, 1899 TO 1903.

Year Ending June 30	Pounds	Value
1899	6,473,882	$166,419
1900	8,701,753	237,214
1901	9,371,087	248,838
1902	16,850,821	501,418
1903	13,984,817	345,431

IMPORTATION OF GUTTA-PERCHA, 1893 TO 1903.

Year Ending June 30	Pounds	Value
1893	582,378	$155,428
1894	498,763	84,340
1895	1,326,794	122,261
1896	3,843,854	178,513
1897	1,117,665	100,187
1898	636,477	159,381
1899	518,939	167,577
1900	427,678	178,616
1901	280,560	130,957
1902	525,767	252,329
1903	316,290	22,400

Indian, Catholic Education of the. Upon the discovery of America in 1492, the various religious orders of the Roman Catholic Church hastened to send missionaries to the new field. A small school for the education of the natives was an accompanying feature of each mission station, and after Cortes had conquered Mexico, Franciscans, Dominicans, and Jesuits, in course of time educated and converted the natives to Christianity, and founded missions and schools which exist there to-day, and in California, now an integral portion of the United States, but formerly part of Mexico. North and south the missions and schools were established and as germs of diocesan organizations bore fruit in the foundation of the see of Caracas in Venezuela in 1531; that of Lima, Peru, in 1539; of Chiquisaca, Bolivia, in 1551; and of Santiago, Chile, in 1561. Brazil was entered in 1500 by Franciscans who were followed half-a-century later by Jesuits. The first Brazilian see was founded at Bahai in 1561; in La Plata, now the Argentine Republic, the see of Cordova was founded in 1570, and there in course of time the Jesuits built up a magnificient college. In Central America, Franciscans began their work of education and conversion in Costa Rica in 1560, and during the last 30 years of the century friars labored successfully in Guatemala, teaching the arts of civilized life along with the doctrines of salvation. Early in the 17th century, Jesuit fathers entered Acadia (Nova Scotia), and Canada, and in 1659 the first episcopal diocese in the region was organized at Montreal. Torture and martyrdom did not deter these brave champions and pioneers of Christianity and civilization, and the development of the United States followed the pioneer growth of Catholic congregations and schools among the native Indians. In the first half of the 19th century, the Indian nations of the Rocky Mountains and Northwest Territories (American and Canadian) were pagan. The Jesuit father De Smet made the long and dangerous journey from St. Louis, Mo., to the headquarters of the Flathead nation in Montana, inaugurated the introduction of Christianity, and prepared the way for the advent of younger members of the order. See CATHOLIC INDIAN MISSIONS IN THE UNITED STATES.

Indian, Education of the. Indian education as at present conducted in the United States is in no way the outcome of any deliberate plan on the part of the Federal government, but is directly descended from the first attempts to teach the Indians of Virginia, and particularly from like beginnings in Massachusetts, where the remarkable results of John Eliot (q.v.) were achieved.

Eliot's Work.— Eliot was actuated by high motives, and his simple measures were chosen with consummate wisdom. Having familiarized himself with the language, disposition, and character of his Indians, he secured their confidence and respect. Those who would follow him he gathered in towns, where he taught them the liberties and responsibilities of township government and the devices and institutions of civilized life, among which the Church and the school naturally occupied places of honor. A number of "choice Indian youths" he induced to attend English schools that they might prepare themselves for missionary work among their own people. He was warmly supported by "the corporation for the propagation of the Gospel in foreign parts," by the General Court of Massachusetts, and particularly by Daniel Gookins, the official superintendent of the Indians in Massachusetts. Eliot began his work in 1646. In 1674 there were 14 towns of "praying Indians," whose schools and churches, in the majority of instances, were administered by educated natives, and an Indian college had been founded at Cambridge. Yet in due time this success was swept away by the fears and prejudices which developed under the baneful influences of the Indian wars. Similar successful work under the direction of John Cotton and Richard Bourne in Plymouth colony shared the same fate.

Other Endeavors.— Followers of Eliot in the 18th century were John Sergeant at Stockbridge, Mass., and Eleazer Wheelock in Connecticut and New Hampshire. The work of Sergeant, which involved the establishment of day schools, of a boarding-school, and an experimental "outing system," was almost ideal in conception, but ended with the deportation of his Indians to the West. Dr. Wheelock's labors led to the establishment of an effective training school and, indirectly, to the creation of Dartmouth College "for the education and instruction of youths of the Indian tribes in this land in reading, writing, and all parts of learning which shall appear necessary and expedient for civilizing and christianizing the children of pagans, as well as in all liberal arts and sciences, and also of English youths and any others." Only the last purpose was destined to achievement.

Surviving Influences.— But in spite of external failure, the spirit and much of the form of these early enterprises persisted. Their impress is observable to-day in almost every prominent feature of the Indian-school organization of the United States, notably in the establishment of day schools in or near Indian villages as a means of domestic and industrial uplifting of Indian family and village life; of industrial boarding-schools in territory occupied by Indians, to introduce among the young a taste for the refinements, duties, and responsibilities of civilization; of advanced training-schools in civilized English-speaking communities for the fuller equipment of "choice Indian youths" for full citizenship in such communities, or for missionary work in the ideals, institutions, and arts of civilization among their own people. It is seen in the universal stress in all schools upon instruction in husbandry, certain trades and domestic arts; in the "outing system," which places partially educated Indian girls and boys as paid helpers in suitable English-speaking families, and affords them instruction in the ordinary public schools; and in the importance attached to religious and ethical training.

Wrong Departures.— On the other hand, it is to be deplored that a number of valuable features of the early schools have been abandoned, and even supplanted by opposite tendencies — the unintelligent warfare against the Indian idiom; the introduction of certain brutalities of military discipline; an equally mistaken effort to wean Indian youth from Indian association by throwing contempt upon the Indian and by stimulating a feeling akin to hatred

of Indian family ties; and in general a policy of compulsion and repression, rather than a spirit of development and benevolent helpfulness. Serious harm came to government schools because patronage entered as a factor in the appointment of officers and employees. Thanks to the Indian Rights Association, the Mohonk Conference, and a number of other societies, in 1893 civil-service rules were applied to employees of the Indian schools.

History of Organization.— The successive steps in the organization of Indian schools have been as follows: After the Revolution little heed was paid to Indian education for 30 years. Only minor appropriations are recorded on the basis of treaties with a few tribes. But in the first quarter of the 19th century a religious revival directed attention to Indian education as a Christian and national duty. Congress responded in 1819 with an appropriation of $10,000 in addition to certain treaty obligations. In 1820 the President was authorized to apply this sum annually in aid of societies and individuals engaged in the education of Indians. In 1823 $80,000 was expended in 21 schools maintained by missionary bodies, $12,000 having been granted by the government. In 1825 the number of such schools had risen to 38, their entire expenditure to $202,000, of which the government, directly and indirectly, had contributed $25,000. In 1848 there were reported in operation 16 manual-training schools, 87 boarding-schools and other schools. These schools continued to increase in number and efficiency up to 1873, under the control of missionary bodies, with scanty aid from the government, which had established only a few small day schools directly under treaty provisions. After 1873, however, the government entered upon an era of great activity in the establishment of strictly government schools. In 1877 Congress appropriated for schools outside of treaty provisions, $20,000; in 1880, $75,000; in 1885, $992,800; in 1890, $1,364,568; in 1895, $2,060,695; in 1899, $2,638,390; in 1900, $2,936,080; 1901, $3,083,403.65; 1902, $3,251,254; 1903, $3,531,220. The expenditures have doubled within the decade, and trebled within 15 years. During the quarter century the average attendance rose in more than like ratio. Increased appropriations naturally stimulated a desire on the part of the government to control expenditures. Moreover, the Constitution, by implication, at least, forbids the appropriation of public funds for denominational purposes. Conclusions unfavorable to government support of missionary schools were further strengthened by the fact that the Roman Catholic Church had gradually outstripped the Protestant missionary bodies and was absorbing the lion's share of government support. In 1893 the Methodist Episcopal Church withdrew from participation in government aid, but without abandoning its schools. In 1895 this example was followed by the Presbyterians and Congregationalists; in 1896 by the Friends; and in 1897 by the remaining Protestant denominations. This left only the Catholics in the field with an appropriation, and in 1901 it was withdrawn from them also. In 1894 Congress had declared its policy of abandoning all support of denominational schools, and this policy has gradually been followed out.

The Schools of To-day.— The present Indian schools under government control are day schools, reservation boarding-schools, non-reservation boarding-schools, and industrial and normal training-schools. These in 1902 numbered 249, with an enrollment of 24,434 pupils; 323 other pupils were maintained by contract at Hampton and in white public schools.

Day Schools.—Day schools in Indian villages, or near Indian camps or settlements, are, as a rule in charge of a male teacher and his wife, or, as in the pueblos of New Mexico and in the Indian villages of southern California, of a white woman teacher and an Indian housekeeper. These teachers are employed for 10 months in the year; the male teacher's wife acts as housekeeper. The children spend 5 to 8 hours during the 5 days of the week under the care of these employees, and return to their homes in the evening. The instruction is of the simplest character. The children are taught to speak, read, and write English within narrow limits, to cipher, to draw, and to sing. They get some rudimentary notions of geography, of natural history, and of United States history. The methods are borrowed largely from the kindergarten and from object-teaching, and much stress is laid upon habits of cleanliness and order, mutual kindliness, and prompt obedience. The boys receive some instruction in the use of tools, in gardening, and in some instances in the care of cows. The girls are taught sewing, cooking, and other arts of housekeeping. In the poorer Indian communities a noon-day lunch of a few simple articles is furnished. While these day schools accomplish comparatively little in conventional school-room work, they serve as concrete illustrations of a civilized Christian home which the Indians learn to respect and, in an appreciable degree, to emulate. Moreover, they reconcile the Indian with the idea of sending his children to school, and render him more willing in due time to entrust them to the care of boarding-schools, as well as more ready to appreciate and to accept the lessons of civilization. The most successful of 134 such schools in 1902, were located in Wisconsin, North Dakota, and South Dakota; the least successful, probably, among the pueblos of New Mexico, where the Indians live in a state of half-civilization which they owe to their Mexican and Spanish antecedents, and which fully satisfies their ideals.

Reservation Boarding-Schools.—There were 90 of these in 1902, averaging 125 pupils. They are in charge of a superintendent, assisted by a matron and such teachers, industrial and domestice helpers as the capacity and character of the school may require. In addition to regular teachers, the school is provided with a cook, a seamstress, and a laundress, whose office it is not only to supervise their respective departments, but also to instruct the girls in these arts. For instruction of the boys there is a farmer, an industrial teacher, and, at larger schools, a tailor, a shoe and harness maker, a carpenter, and a blacksmith. An experiment to provide for more methodical instruction in the use of tools, by expert manual-training teachers, failed because the Indian office would not afford a salary for this position sufficient to attract competent men. In 1894 the experiment of connecting kindergartens with these schools was tried, and proved eminently successful. At the present time there are 40 kindergartens connected with boarding-schools, and the use of kindergarten

methods and material has entered the primary classes in practically all these schools with similar good results. In the kindergarten the children spend from 1½ to 2 hours each half-day. In most of the other schools children spend half a day in the school-room, and the other half-day in domestic or industrial work of a character suited to their age. Experience has proved that half-day instruction, at first forced upon the schools as an expedient, is commended by its good results.

The aim of the school-room work is to teach reading and writing within the usual limits of primary work; arithmetic for the needs of ordinary daily life; rudimentary geography and United States history; drawing and singing; the laws of hygienic living; garden and orchard work; and familiarity with the simpler requirements of agricultural and domestic industries suited to the locality. Moreover, in a few of the larger schools, the older boys have much opportunity to acquire skill in carpentry, blacksmithing, tailoring, and shoemaking. These institutions are to the children not only school, but home and community. The institution gives them shelter, food and clothing; it accustoms them to habits of cleanliness and decency; it cultivates their æsthetic tastes; it labors to secure right moral attitude, and in its Sunday-school seeks to stimulate the religious life of the children. The superintendent of the reservation boarding-school is subject in his work to the control of the Indian agent, who as representative of the government, administers the reservation's affairs. Inasmuch as these agents are selected on partisan grounds, usually at the suggestion of local politicians, this arrangement is fraught with danger to these schools.

In 1893, under civil-service regulations, there came some improvement. Still with reference to minor employees the superintendents, and even the Indian office, were powerless, and frequently good superintendents were forced out of service by combinations against them among the appointees of the agent, or through the aid and influence of unscrupulous partisan inspectors or supervisors. But in 1896 all employees of the school service were placed under civil-service protection, and since that time there has been marked improvement in the conditions and work of these schools. To a certain degree these evils still persisted, however, because of the power and political bias of the agents; but of late the government has adopted the policy of replacing the agents with bonded school superintendents, 22 agencies now being under such control. There has been decided gain in the equipment, in the sanitary condition, in the general character of employees, and in the conduct of the schools. For the Indian office, relieved of attention to office-seekers and their patrons, has been enabled to pay increased attention to the schools themselves. In the reservation boarding-schools instruction continues through 40 weeks; but often some children are kept at the school throughout the year.

Non-Reservation Boarding-Schools. — Of these there are 25. Seven of them are industrial training-schools, and three others are industrial and normal training-schools. The remaining 15, in their original scope of work, differed little from the reservation boarding-schools. But the superintendents of these schools are bonded and directly responsible to the Indian office. There is no intervening Indian agency, and the consequent sense of responsibility and self-respect in the head of the school finds its reflection in the attitude of his subordinates, as well as in that of the pupils. These schools are, as a rule, located at a distance from the Indian country, and in the vicinity of American towns which afford contact with the amenities of civilized life. Members of many different tribes are also brought together, and tribal antagonisms are broken down. The pupils are older than those at reservation schools, and some have had previous training in day schools or reservation boarding-schools. Because far away from their Indian homes, and near to English-speaking communities, they gain a better control of English; class-room work reaches far into the advanced grammar-school courses of study, with special stress upon language practice, arithmetic, geometry, geography, history, nature study, drawing, and civil government. Instruction in domestic and industrial arts is made effective by frequent opportunities directly to observe their practical applicability and value. The superintendents are paid from $1,200 to $1,500 per annum. Other employees are paid on the same scale as in reservation schools. The most noted and successful of these schools are located at Flandreau, S. D.; Pipestone, Minn.; Mount Pleasant, Mich.; Fort Mojave, Ariz.; Carson, Nev.; Perris, Cal.; Tomah, Wis.; Wittenberg, Wis.; Fort Lewis, Colo.; and Pierre, S. D.

Industrial Training-Schools. — There are schools of this class at Carlisle, Pa.; Chemawa, near Salem, Ore.; Chilocco, Okla.; Genoa, Neb.; Albuquerque, N. M.; Lawrence, Kan.; (the Haskell Institute), Grand Junction, Colo.; Sante Fe, N. M.; Phœnix, Ariz.; Fort Shaw, Mont. The most strenuous effort is now carried on at Chilocco; organized 1884; a large plant with a capacity of over 500 pupils, and a fine farm of about 9,000 acres. In organization these schools are similar to the schools just described, but in the scope of their work and in equipment they excel in a high degree. The government in 1894 added normal departments at Carlisle, at the Haskell Institute, and at Santa Fé. The experiment proved fairly successful with Carlisle and the Haskell Institute, at Santa Fé slightly so for a time, but of late it has shown better results there.

Contract Schools. — In addition to maintaining these strictly government schools, the Indian office up to 1901, as before said, paid by contract for the education of many hundreds of Indian pupils distributed in Catholic mission boarding-schools, in Catholic day schools; at Lincoln Institute, Philadelphia, and at Hampton Institute, Hampton, Va. In the appropriation for that year, the aid was withdrawn from all but the last-named, where 120 pupils were contracted for. Besides these, the government since 1891 has endeavored to place Indians in white public schools where there are many whites and few Indians, as the most rapid means of civilization. The antagonism of local or State authorities to this coeducation has made this plan a failure in some places; in others there has been some success. Rising from 8 to 45 between 1891 and 1896, the number of such schools has gradually sunk to 16 in 1902, with 110 pupils contracted for out of 189 enrolled, and average attendance of 98.

Supervision.— Direction of the Indian schools rests with the Indian office, which is under the supervision of the secretary of the interior. In the Indian office the details of the work are entrusted to the education division, to which all reports are made, and by which all directions and orders are drafted and issued. The education division is aided in its work by the superintendent of Indian schools and by 5 supervisors, assigned in their work to 5 districts respectively. These officials constitute a branch of the Indian-school service which occupies a very uncertain position. They have duties, but no rights. A similarly anomalous relation exists between the commissioner and the secretary of the interior with regard to all matters which the latter may wish to control directly. For this purpose the secretary has established under his direct control an Indian division, independent of the Indian office, to which all orders and directions the secretary may designate must be referred by the Indian office for approval. The power of this Indian division is further reinforced by a corps of inspectors in the field, appointed on partisan grounds, and responsible to him alone. Technically the superintendent of Indian schools may appeal from the commissioner to the secretary of the interior, and the commissioner from the decision of the secretary to the President. In view, however, of the hopelessly autocratic relation that runs through the chain, that is practically out of the question. Under these conditions, the fact that Indian education has prospered reflects credit upon all concerned.

Schools of Indian Territory.— The schools of the so-called "five civilized tribes" of Indian Territory are not included in the above sketch. The 5 tribes in 1900 included 25,639 Cherokees, 10,321 Choctaws, 7,963 Creeks, 5,872 Chickasaws, and 1,662 Seminoles. In addition there were in the Territory 36,853 freedmen and 302,680 whites. Missionary zeal availed itself promptly of this field for its efforts. Substantial boarding-schools were erected, more particularly by the Presbyterians, Methodists, and Baptists. In due time, however, the Indian authorities began to make appropriations for these schools. Ultimately they took entire charge of them. Unfortunately, administrative affairs were largely in the hands of whites, who, by intermarriage or bribery, had been adopted into the tribes, and there came over the schools, as well as over all other public interests, the blight of extreme partisanship and nepotism, which rapidly degraded them in character and efficiency. In 1898 the government at Washington assumed supervisory control over the affairs of all these tribes except the Seminoles. The conduct of the schools and orphan asylums in the 4 tribes involved was placed under the direction of a superintendent of schools in Indian Territory, appointed by the secretary of the interior. Under him there is for each of the tribes or nations a supervisor of schools, whose duty it is to inspect the educational institutions in his district, and to assist in their organization and conduct. The superintendent reports to the commissioner of Indian affairs at Washington through the United States inspector for the Indian Territory, who is his immediate superior. The initial report of this superintendent showed in the 4 tribes 24 boarding-schools, with an enrollment of 1,758 pupils, and an average attendance of 1,480, taught and cared for by 234 employees at an annual expense of $236,824. This does not include 363 neighborhood schools, in which more than 10,000 children are taught at an annual expense of $113,380, which, in character and equipment, show great inferiority.

WILLIAM N. HAILMANN,
Ex-Supt. Indian Schools.

Indian Affairs. The prevalent idea that the national government has always striven to dispossess the Indians from the lands they occupied, or has sympathized with such efforts, is the exact reverse of the truth. From its foundation until now, its history presents an unbroken record of quarrels between Indians and bordering or interdwelling white settlers, in which the government has been slowly and reluctantly pushed on to interfere; sympathizing with and justifying the Indians against its own citizens, its commissioners usually reporting in their favor, and even its generals in later days blaming the whites for the troubles; its courts deciding in their favor; attempting pacification amid local outcries against them, rebuffing appeals for aid, and only using its armies to reduce the Indians and its administrative power to remove them when it was no longer politically possible to leave them in possession. Even then, it has meant to deal righteously by them; but the complexity of the problem — one may say its insolubility till the country was very strong and the Indians very weak — along with the universal curse of "spoils" in the administration — has hindered success. While until 1887 there was no consistently formulated plan, there has been a sequence of government panaceas in a steadily descending line. First, there was to be one vast Indian reservation, large enough to give them all the hunting-room they needed, and so far from the United States that our growth would never reach to them and create more troubles; then three great reservations, to prevent so formidable an Indian district and internecine Indian wars; then a number of small ones, to segregate hopelessly hostile tribes, enable better training into civilized existence, and protect them from depredations; lastly, no reservations, but severalty ownership and individual citizenship. These changes of policy have been due not to fickleness or visionary causes, but to broadening experience and varying conditions.

The policy of removing the Indians west of the Mississippi was first formulated by Jefferson, who in a proposed constitutional amendment (1803) set off the Louisiana Purchase north of the Arkansas as a pure Indian country, in which no land was to be sold to whites. This was carried out, on a much reduced scale, in the formation of Indian Territory (q.v.) by act of 30 June 1834; by another act of same date a superintendent of Indian affairs was appointed, no one to trade or settle in the Indian country without permission from him or his agents. Previous to this the Indian matters had been under the War Department; in 1849 they were transferred to the new Department of the Interior, of which they still form a bureau. Under the commissioner of Indian affairs are eight inspectors and a large variety of subordinate officials and employees. The Indian agents, though under his control, are appointed by the President, for four years, with bonds; on their

action depends often peace or war to great white populations, but in too many cases they have been the football of politics, and sometimes scandalously unfit for their places.

The legal theory, until a recent date, was that each tribe was a nation, but not a foreign nor independent one; a "domestic dependent nation," but with which, nevertheless, all intercourse was to be conducted through special commissioners appointed by the President. In 1871 Congress abolished this method of procedure, and substituted immediate Congressional control, but the fiction of Indian nations remained; nor, indeed, could any other system well be applied so long as the Indians were recognized as national wards, and could not be made a part of the regular republican system or thrown into the current of unrestricted competition. It was the general plan to let the larger and better advanced ones, as the five "nations" of the Indian Territory, govern themselves and thus develop political life, including a full judiciary system. But the smaller ones could not be thus left, even in leading-strings; and in all, the government has recognized its duty to watch over their ignorance, improvidence, and savage instability of will and emotion from either violence or cunning on the part of the whites. Traders with them must have certificates of good character and be licensed by the Indian commissioner, and the goods they sell are subject to regulation; no one can hunt, cut timber, or pasture cattle on Indian lands without the agent's permission; intoxicating liquors may not be sold to them. Still more important and beneficial is the educational work, which has not only been carried on by churches, missionary societies, and private individuals from early times, but has been actively forwarded by the government. The five civilized nations of Indian Territory had their own school system, of considerable extent; but for others, and even for those where needed, the President was empowered in 1865 to appoint instructors of Indian children in reading, writing, arithmetic, and agriculture, and in 1882 to appoint an inspector of Indian schools. (See INDIAN, EDUCATION OF THE.)

From 1877, when a $20,000 appropriation was made for Indian schooling, to 1900, when over $3,000,000 was appropriated, over $35,000,000 had been thus expended by the government. It has spent since its foundation nearly $400,000,000 on the Indians, outside of the cost of wars against them; and the present expenditure is about $10,000,000 a year. In 1900 it was maintaining over 45,000 wholly by rations, and 12,500 partly, at a cost of about $1,250,000 per annum; and paying annuitants (partly from trust funds derived from sales of their lands) over $1,500,000.

On 8 Feb. 1887, however, an act was passed, amended in 1890, to sweep away as soon as feasible all this system of tutelage and pauperization, in the belief that abolition was best for Indians and whites alike. All reservations were to be surveyed; all Indians who wished to take up lands in severalty to a certain amount might do so — and by the act become citizens, as well as all who had previously done so under treaties and Congressional enactments, over 10,000 in number. Up to 30 Oct. 1900 6,736,514 acres had been so allotted, to 56,996 Indians; about 2,000 a year comply with the permission; and a few years will see an end of Indian tribes except as historical reminiscences. Many of these new citizens are made voters by their States: there are over 20,000 such in the United States at present. See CHEROKEE; CHEROKEE NATION V. GEORGIA.

Indian Art. In none of the fine arts except architecture have the Hindus attained much eminence. Their paintings are of very little merit, though the walls of temples, of palaces, and of the better class of private dwellings are often ornamented at great cost with pictures illustrating the characters and events of their mythology. More attention has been paid to sculpture than to painting, and in the temples cut from the living rock great numbers of statues are contained, some single figures and others large groups. Many of these are bold and spirited in design, though the human form is not exhibited in good proportion nor with its parts well developed.

Indian Architecture, however, comprehends a great variety of styles, among which we may distinguish, as the most important, the Buddhist, the Jaina, the Dravidian or Southern Indian, the Chalukyan, and the Modern Hindu or Indian-Saracenic styles. The history of Indian architecture commences in the 3d century B.C. with the religious buildings and monuments of the Buddhists. Among the principal forms of Buddhist architecture are first, the *topes, stupas,* or towers built to mark some sacred spot, and the *dagobas,* constructions of a similar nature, containing relics of Buddha or Buddhist saints. These buildings generally consist of a circular stone basement, varying from 10 or 12 to 40 feet in height, and from 40 to 120 feet in diameter, on which rose a rounded domical structure, generally of brick or small stones laid in mud, the whole edifice rising sometimes 50, sometimes 100 feet high. Second, the rock-cut *chaitya* halls or churches, and the *viharas* or monasteries. Most of these are found in Bombay; some also in Bengal and Behar. In rock-cut buildings architectural skill is confined to the façade and the interior. Among the most notable for beauty of design are those at Ajanta, and, finest and largest of all, the great Chaitya cave at Karli, near Bombay, the date of which is probably about 80 B.C. Another interesting example is at Ellora. The Jaina style is a development or corruption of the pure Buddhist. It is characterized by the square or polygonal court, the twelve-pillared dome, the slenderness and elegance of the columns, the horizontal arch, the *sikras* or towers surmounting the cells containing the images, and, lastly, by the peculiar grouping of many temples together on hill-tops. Prominent examples of Jaina architecture are found at Girnar in Gujerat, and at Mount Abu. The most flourishing epoch of the Dravidian style comprises the 16th, 17th, and even 18th centuries of our era. To this late period belong the great temples at Tanjore, Tiruvalur, etc. The distinctive parts of a Dravidian temple are the *vimana* or temple proper, with storied pyramidal roof; the *mantapas* or porches, covering the door which leads to the cell; the *gopuras* or gate-pyramids, in the quadrangular enclosures surrounding the vimanas; and the *choultries* or pillared halls, used for various purposes. The

general characteristics of a Dravidian temple of the first class are the storied pyramidal towers, the hall of 1,000 columns, the bold cornice with double flexure, the detached shafts, the richly carved stylobate, and the large tanks with flights of stone steps. The Chalukyan style, so named from a dynasty which rose in the 6th century in what is now Mysore and the Nizam's Territory, reached its perfection in Mysore from the 11th to the 14th century. The characteristic features are the open porch, the straight-lined, conical-shaped tower, the star-shaped temple, and the basement terrace of stone.

The Indian-Saracenic style is a general name for a number of somewhat varying styles, the result of the mixture of Saracenic principles of architecture, brought with them by the Mohammedan conquerors of India, and the distinctive architectural features of the different localities where they settled. Under the Mogul emperors in the 16th century were erected some most magnificent buildings, such as the tomb of Humayun Shah at Old Delhi; that of Akbar at Secundra; the palaces of Shah Jehan at Agra and Delhi; and the Taj Mahal, built by the same monarch at Agra. (See AGRA.) The Moslem architecture of India contrasts with the native Indian styles in its use of the radiating arch, in the superior simplicity and grandeur of its style — its flat ornamentation not interfering with the lines of true architectural construction. A characteristic feature also is its fine conventionalism of vegetable forms for decoration and tracery. See *Moslem Architecture* under ARCHITECTURE.

Indian Bean, a catalpa (q.v.); specifically the large southern tree (*Catalpa catalpa*), now planted as a shade or ornamental tree all over the country on account of the beauty of its masses of spring flowers and the quaint appearance in autumn of its long, bean-pod-like fruit.

Indian Bible, the first Indian translation of the Bible in the New England colonies. This translation was made in 1663 by John Eliot, "The Apostle to the North American Indians." It was in the dialect of the Naticks, a Massachusetts tribe of the Algonquins. A second revised and corrected edition was printed in 1685, only 12 copies of which are known to exist. An edition with notes by P. S. Du Ponean, and an introduction by J. Pickering, was published in Boston in 1822. When the original edition was issued, 20 copies were ordered to be sent to England. A copy of the edition of 1663, with the Epistle Dedicatory, was sold in 1882 for $2,900.

Indian Bread-root, a plant of the genus *Psoralea;* the "large" was *P. esculenta;* the "small" *P. hypogæa.* See BREAD-ROOT.

Indian Corn. See CORN, INDIAN.

Indian Fig. See PRICKLY PEAR.

Indian Head, (1) the highest point of the Palisades, 550 feet; so called because it resembles somewhat the head of an Indian. It is in the northeastern part of New Jersey, on the Hudson and opposite Hastings. (2) The name of a village in Fayette County, Pa. (3) A small town in Maryland, on the Potomac River, below Washington, the seat of a naval station.

Indian Hemp. Sometimes called Canada hemp. See APOCYANACEÆ.

Indian Hippo, an American plant. See BOWMAN'S ROOT.

Indian Humped Cattle, a species of East Indian oxen (*Bos indicus*), now known only in the domesticated state, distinguished by a high fatty hump on the withers, by the prevalent ashy gray color, large drooping ears, enormous dewlap and several structural peculiarities. They vary in size from those as large as a European ox to the smallness of a half-grown calf. They form the working cattle and draft animals all over India and eastward more or less locally to China. They are venerated by the more pious sects of Hindus, especially in the persons of certain privileged bulls, called Brahma or Brahminy bulls, which wander about the bazaars of cities unharmed and unchecked in their depredations upon market produce.

Humped cattle are known in Madagascar, and in Abyssinia, and it has been suggested that the species was originally African. The Abyssinian form is a large animal with huge horns called "galla ox" or sunga. These animals seem to thrive only in hot countries, and have never been found profitable outside of their present range.

Indian Language and Literature. See INDIA.

Indian Mutiny. The British occupation of India had been largely aided by native troops called Sepoys, who were enrolled under British officers in the service of the East India Company. At the close of Lord Dalhousie's sway in 1856, when the whole of India seemed to have been either reduced directly under British rule, or if retaining its native princes to have placed itself under British protection, the Sepoy mutiny, a contingency for which the government ought not to have been altogether unprepared, occurred. Previous symptoms of disaffection had not been wanting. Mutiny had on several occasions broken out in the native army, in a way to indicate how easily through causes which Europeans, from their defective sympathy with native thought and feeling, could not anticipate, these troops might be alienated; but, on the other hand, the general fidelity of the Sepoys merited confidence, and this feeling prevailed over any grounds of suspicion which might have been formed from isolated occurrences. The Sepoys in Bengal were mostly either Mohammedans, or Hindus of the Brahmanical or military castes. The recent annexations had alarmed the native chiefs, while the fanatical Hindus had been deeply offended by reforms, including the successive abolition of various rites of their worship. Two European regiments had been drafted off for the Crimean war, and had not been replaced. Others had been sent to Burma, and in the beginning of 1857 fresh regiments were despatched to Persia, so that only eighteen regiments were left in all Northern India, of which nine were in the Panjab. In Oudh, where, from its recent annexation, disaffection was rife, there was only one British regiment, and Delhi and Allahabad, the two chief arsenals, were guarded by native troops. To add to these favorable cir-

cumstances a Hindu devotee had prophesied the termination of British rule at 100 years after the battle of Plassey. A slight incident sufficed to give point and direction to a spirit of disaffection which so many circumstances tended to favor. At this time the Enfield rifle was introduced into the Bengal army. This rifle was loaded with a greased cartridge, the end of which required to be bitten off at the time of loading. By a natural inadvertence the authorities had neglected to consider how this seemingly trifling requirement might affect the easily excited sensitiveness of the Hindus in regard to caste, and this insignificant circumstance removed the last security against a united movement of disloyalty among the native troops, by establishing a bond of sympathy between the Mohammedans and Hindus. A report got abroad that the cartridges were to be soaked in cow and pork fat. The prejudices of Hindus and Mohammedans were thus equally involved, and as this rumor rapidly spread, the excited imagination of the Sepoys conceived a conspiracy on the part of the government to convert them forcibly to Christianity, by compelling them to violate the laws of their own religion. When this grievance was explained it was at once removed, the manufacture of greased cartridges at Dumdum was stopped, and the men were instructed to grease them themselves with materials procured at the bazaars. Suspicion once aroused, however, was not to be allayed, and easily found a new object of contention. The paper of the new cartridges was glazed, and it was again alleged that grease was used in its manufacture. The spirit of disaffection became too deep-rooted for any measures of conciliation. Conferences among the disaffected gave rise to ambitious schemes, and the original grievances became a pretext in the hands of unscrupulous leaders, whose excesses debarred them even from the plea of patriotism, to extirpate the British power in India. On 26 February the first overt act of mutiny took place at Berhampur, when a regiment refused to receive their cartridges. Another dangerous outbreak took place at Barrackpur on 29 March. The arrival of a British regiment from Burma and the disbandment of the disaffected regiments was thought to have ended the trouble, but it soon became evident that disaffection, which had only wanted an occasion, was spreading rapidly not only among the Sepoys, but among the Hindus generally. Another outbreak took place on 2 May, near Lucknow, when a regiment of cavalry were, by some oversight of the government's instructions, ordered to bite their cartridges. Sir Henry Lawrence succeeded by a show of force in disarming it. A more formidable outbreak occurred about the same time at Meerut, 35 miles northeast of Delhi, when the mutineers, with the assistance of the native inhabitants, indiscriminately massacred the Europeans and escaped to Delhi. The advance-guard of the mutineers reached Delhi on 11 May, and at once entered the city, where they were assisted by the king's servants in massacring the Europeans. The native troops cantoned outside the city in the meantime joined the main body of the mutineers, and assisted in massacring their European officers. About 50 Europeans sought refuge in the palace, and placed themselves under the protection of the king, who had placed himself on the throne of the Moguls. These after some days were coolly murdered in an open court in presence of a general concourse of spectators, conspicuous among whom was Mirza Mogul, the king's eldest son, who had assumed the title of commander-in-chief. The magazine at Delhi had been blown up by its defenders; but the explosion was only partial, and most of its contents fell into the hands of the mutineers. European troops were now summoned from all quarters. Several regiments were detached from an expedition which was proceeding under Lord Elgin to China, and the Persian war having been concluded, the troops engaged there were immediately recalled. When intelligence of these events reached the Panjab the mutinous spirit which prevailed among the large body of Hindustani troops there was promptly subdued by disarmament. The Sikhs, though the Panjab had been so recently annexed, continued faithful. But the revolt had spread rapidly elsewhere, and British authority was almost extinct throughout the Bengal Presidency. Everywhere the mutiny was attended with savage excesses — women were outraged, and Europeans, without distinction of age or sex, barbarously murdered. Sir Hugh Wheeler, at Cawnpore, was betrayed by Nana Sahib, maharajah of Bithur, who, after offering aid, took the mutineers into his pay, and raising the Mahratta standard, besieged Cawnpore. The siege, or rather bombardment, lasted from 7–24 June, when a capitulation was agreed to, on a sworn promise of Nana Sahib to allow the garrison to retire to Allahabad. But as the embarkation was proceeding the boats were attacked by the Nana's troops, and the men indiscriminately massacred. The women and children were for the meantime made prisoners. Sir Henry Lawrence was besieged in Lucknow, where he died on 4 July from a wound received in a sortie.

Meanwhile mutineers had been converging on Delhi, and British reinforcements were hastening to the besieging camp on the ridge above the city. After protracted operations and repeated reinforcements on both sides Delhi was taken by assault, 14–20 September. Sir Henry Havelock, who had been engaged in the Persian campaign, had arrived in Calcutta, and immediately set out for Allahabad, to commence operations for the relief of Lucknow and Cawnpore. While his force was victoriously advancing on Cawnpore Nana Sahib, on 15 July barbarously massacred his prisoners, consisting of 210 women and children. Havelock was succeeded in the command at Lucknow by Sir James Outram, who held it till relieved by Sir Colin Campbell, on 17 November. At first it was feared that the mutiny might extend to the Bombay and Madras presidencies, and from this cause and the occupation of the troops in Bengal the mutineers had been left unchecked in Central India. At length columns organized in these presidencies entered Central India, and were united under Sir Hugh Rose. By the operations of these commanders the brave Rani of Jhansi, who died fighting at the head of her troops, was defeated, and Tantia Topi whose military capacity had prolonged Nana Sahib's resistance, was captured and the mutiny was

finally suppressed. The war was substantially closed by June 1858, although the complete pacification of Oudh was not effected till the end of the year. See INDIA, EAST INDIA COMPANIES. Consult: Malleson, 'History of the Indian Mutiny' (1897).

Indian Ocean, that body of water which has Asia on the north, the East Indian Islands, Nicobar and the Andaman Islands, Australia and Tasmania on the east, Africa on the west, and the Antarctic continent on the south. The Cape of Good Hope, and the southern extremity of Tasmania may be considered its extreme limits from east to west. Its length from north to south somewhat exceeds 6,500 miles, its breadth varies from 6,000 to 4,000 miles. Its gulfs are the Red Sea, the Gulf of Aden, the Persian Gulf, the Gulf of Oman, the Arabian Sea, the Bay of Bengal, and the Great Australian Bight. Its islands are Ceylon, Madagascar, the Laccadives, Maldives, Socotra, Andamans, Nicobar, Mauritius, Bourbon, Kerguelen's Land, etc. Rocks and coral reefs render navigation dangerous. The Ganges, Brahmaputra, Irrawaddy, Indus, Euphrates, Gadavari, empty into the Indian Ocean. The southeast trade-wind blows between the 10th and 28th parallels of south latitude from April to October, after which date its limits are contracted; south of these are the northwest winds, which prevail almost in the same latitude, in the Atlantic and Pacific. The monsoons are mainly to be found in the north, from the continent of Asia to about lat. 8° S., and from the Mozambique Channel on the west to the western shores of Australia and the sea of China. They blow for six months, changing about the equinoxes. North of the equator the northeast monsoon prevails from October to April, the southwest from April to October; while south of that the northwest monsoon blows while the northeast is blowing on the north side, and the southeast prevails during the time of the southwest monsoon north of the equator. In the hot season, likewise, when the southeast trade-wind recedes south, the northwest monsoon flows between the equator and the 12th south parallel. The hurricanes of this ocean usually range between lat. 9° and 35° S., extending from Madagascar to the Island of Timor. They usually come from the northeast, and travel southwest and south, returning again east. Their season is from December to April.

According to the most recent soundings the mean depth of the Indian Ocean is 2,300 fathoms, or somewhat greater than that of the Atlantic. The greatest depths are in the eastern part to the south of the equator, where it is estimated that there are fully 50,000 square miles with a depth of over 3,000 fathoms. Over 13,000,000 square miles lie between the depths of 2,000 and 3,000 fathoms.

The area of land draining into the Indian Ocean is estimated at 6,813,600 square miles, and the rainfall on this land amounts to 4,379 cubic miles of water annually. The rivers flowing from the Asiatic continent are by far the most important, and they carry a vast amount of detritus into the Bay of Bengal and Arabian Sea, these forming immense deposits of blue mud. Along the African coasts, in depths from 100 to 1,000 fathoms, there are glauconitic sands and muds, and on these as well as other coasts, coral muds and sands, and blue and green muds in the shallower depths. In the deeper parts of the ocean, far from land, there are deposits of red clay, radiolarian-ooze, and globigerina-ooze. Toward the Antarctic continent the ocean bed is covered with a diatom-ooze.

The temperature of the surface waters varies much in different parts of the ocean, at different seasons, and under the influence of different winds. In tropical regions the temperature usually varies from 70° to 80° F., and the yearly range is 7° or 8° F. Off the Cape of Good Hope and Cape Guardafui, the annual range may be from 20° to 30° F. Sudden changes of temperature are often noticed off Cape Guardafui when the wind blows off shore. The cold and deep water is thus drawn up along the coast to take the place of the warm surface water which is driven east by the wind.

The temperature of the water at the bottom is very uniform and subject to little, if any, annual variation. In the Bay of Bengal and Arabian Sea temperatures of 33.7° F. and 34.2° F. have been recorded; these are only very slightly higher than those recorded by the Challenger in lat. 50° S. It is certain, therefore, that this deep cold water is slowly drawn into the Indian Ocean from the Antarctic to supply the place of the warm surface currents that are driven south by the winds.

The currents of the Indian Ocean are less constant than in the other oceans, being largely controlled by the monsoons. Some characteristic coral atolls and islands are found toward the central part, such as the great Maldive group, the Chagos, Diego Garcia, and the Cocos Islands. The tropical shores are generally skirted by fringing and barrier reefs. Christmas Island is coral formation, while St. Paul's, Mauritius, Rodriguez, and others are of volcanic origin, and Madagascar, Ceylon, and Socotra, continental islands.

The Indian Ocean was little known to the ancients. The first Europeans who explored it seem to have been the Phœnicians, who in the 7th century B.C., held the thalassocracy, or marine domination of the Mediterranean. Necho, an Egyptian monarch who flourished about 610 B.C., is reported by Herodotus to have sent some of his vessels, manned by Phœnicians, into the Indian Ocean, then known as the Erythræan Sea, to circumnavigate Africa. This they did, starting from the Arabian Gulf and regaining Europe by the Columns of Hercules. In the 6th century B.C. this sea was traversed by Hanno, a Phœnician admiral of Carthage. There is still extant his account of the voyage which is translated into Greek under the title 'Hanno's Voyage of Circumnavigation.' The Greek historian Arrian has given us an account of the coasting voyage of Nearchus, one of Alexander's generals, from the Indus to the mouth of the Tigris and Euphrates.

Hippalus, an Egyptian navigator who flourished about the beginning of the Christian era, was the first to observe the regular monsoons of the Indian Ocean, and to profit by them. In the 9th century the Arabs made frequent voyages across the Indian Ocean. In 1486 the Portuguese rounded the Cape of Good Hope,

and in 1498 Vasco da Gama reached the coasts of India by the same route. In 1521 a ship of Magellan's squadron crossed the Indian Ocean in completing the first circumnavigation of the world, and has since been habitually traversed in a direct line between Arabia and Hindustan.

Indian Paint, the name of two American plants: (1) the golden seal (q.v.) or orange-root, which furnishes a yellow color; and (2) the bloodroot. (See SANGUINARIA.)

Indian Physic, an American plant. See BOWMAN'S ROOT.

Indian Pipe, or **Corpse-plant**, a smooth, waxy-looking, fleshy herb (*Monotropa uniflora*), of the order *Ericaceæ*, widely distributed in dark, rich woods almost throughout North America. It is said to derive some of its food from the roots of other plants, but much is obtained from decaying vegetable matter. From a matted mass of fibrous rootlets the white scaly, but not leafy, stems rise to a height of perhaps eight inches, and bear solitary, nodding, white, inodorous flowers during summer, followed by erect many-seeded fruits.

Indian Races. The numerous peoples of India belong to several distinct groups or families, speaking numerous dialects founded on two or three distinct stocks which are much blended by the intercourse of the different peoples with each other. Previous to the Mohammedan ascendency the dominant race were the Hindus, whose language is spread in various dialects over a great part of India, but who were not the aboriginal inhabitants nor even the first invaders. From the northwest of India, through Kashmir and down the valley of the Indus, and from Tibet through the passes of the Himalayas, the inhabitants of northern Asia have from a very early period migrated southward to the milder and more fertile plains of India. Two great successions of these invasions are recognized as having taken place before the period of authentic history. The first immigrants, of dubious ethnological connections, but commonly known as the Tamil races, appear to have overspread the entire peninsula. Following them the Sanskrit-speaking peoples, called the Hindus, of Aryan speech, dispossessed the Tamil races, and superseded their language in the whole of India north of the Narbada. The Hindus subsequently descended into the peninsula and penetrated as far as Cape Comorin; but though their influence on the languages of Southern India was considerable in the way of introducing new terms, the grammar and construction of the Tamil languages maintained their place in the districts south of the Narbada. Two great groups of languages were thus spread over India, which were further modified by the Mohammedan invasion. The native tribes were not exterminated by these invasions, but are still to be found under various names, as Bhils, Catties, Coolies, Gonds, etc., inhabiting the fastnesses of the mountain ranges in Bengal, the Vindhya and Satpura Mountains, the Ghâts, etc. The hill tribes and other aborigines in all India are estimated at 70,000,000. The leading religion is Brahmanism, the professed creed of the majority of the Hindus and the religion most distinctive of India. It reckoned 207,000,000 adherents in 1901. Large numbers in the north and northwest are Mohammedans (about 62,500,000). Buddhists number about 9,500,000, Parsees or Fire-worshippers 95,000; Sikhs 2,200,000. Among the Hindus the caste system still prevails. European missionaries have long been active, but only a mere fraction of the people are as yet Christians (2,284,380). Education is now making good progress, schools and colleges of all kinds having been established throughout the country. The pupils, however, only number about 4,000,000 in all. There are universities at Calcutta, Bombay, and Madras, besides other two at Lahore and Allahabad.

Indian Red, an impure oxid of iron, used as a pigment by painters. It was originally imported from India, but is now chiefly prepared by roasting ferrous sulphate. The sulphuric acid is expelled by the heat, and the red oxid of iron remains behind. It is very permanent, and the color varies from purplish to a yellowish red.

Indian River, an important stream in the eastern part of Florida, in Brevard and Volusia counties. It connects with the Halifax River at Titusville and extends 100 miles southeast to the ocean at Indian Inlet. Its width varies from 300 feet to 3 miles and it is navigable for vessels drawing five feet. The Indian River is famous for the excellent oranges grown along its banks.

Indian Schools, in the United States, are schools specially established either by private or denominational means or by the national government, for the education of children and youth of the Indian population of this country. For particulars concerning these schools see INDIAN AFFAIRS; INDIAN, EDUCATION OF THE.

Indian Shot. See CANNA.

Indian Summer, the name given to a period of mild summer weather which generally occurs toward the end of autumn. The term first made its appearance in the last decade of the 18th century. During the next decade the phrase was "second summer." This indicates that the spell of weather known by this name was not generally noticed much before 1800. The term Indian summer became established about 20 years after its first appearance, which was in western Pennsylvania, and spread to New England by 1798, to New York by 1799, to Canada by 1821, and to England by 1830. The term is, then, not an Americanism; to write in praise of Indian summer is now a literary convention of three continents.

It is by no means easy to account for the origin of the term. The principal characteristics of the season which it describes are haziness, smokiness, and high temperature. Some explanations of the origin of the term are (1) that the Indians predicted such spells of weather; (2) that the smokiness was produced by Indian fires; (3) that this was the last season of Indian attacks on the settlements of the whites; (4) that the season partook of the Indian character of deceptiveness; (5) that the name was given because one of the seasons of East India was similar in character. Horace Walpole used the term in 1778, not in reference to America, but in relation to weather in the tropics. "Squaw winter" was a name for the spell of cold weather preceding the Indian summer, and perhaps the key to the nomenclature is to be sought in this latter term.

Indian Territory, an organized body of land in the southwest centre of the United States, occupied by Indian allotments and reservations; not a "Territory" in the official sense, as it has no common local government, head, or capital, and sends no delegates to Congress. It lies between Kansas north and Texas south, Arkansas and a corner of Missouri east, and Oklahoma (till recently its own western half) west. It is about 250 miles north to south, and from 75 to 200 east and west. Area, 31,400 square miles, of which 400 are water.

The topography of the district is not yet fully studied, as Indians do not make surveys, and till less than a decade ago the government had no motive but a scientific one for undertaking them. Hence the interior was nearly as little known as central Africa, and as much misunderstood. Even yet, nearly every reference book describes the entire surface as "flat" or "gently rolling," and mostly prairie. But the government survey authorized in 1894, when the reduction to civilized conditions was undertaken, found it to be one fourth mountainous plateau, and two thirds woodland well distributed, mainly through the east and southwest portions. The prairie section is a continuation of the Kansas plains, and occupies most of the Cherokee district north of the Arkansas, and the Creek triangle between the Arkansas and Canadian, with about a fourth of the western half below the Canadian, the rest being timber land. In the extreme northeast is a rugged plateau cut by streams with a southward trend, west of which is a rolling plain with some hills. South of this the Ozark mountain chain, entering from Arkansas, stretches from northeast to southwest across the Territory, with a gradual declension; from about 2,500 feet high near the Arkansas line, they sink to about 1,000 feet in the centre. Their more pronounced elevations are termed the Boston, Poteau, Kiamichi, Sans Bois (treeless), Shawnee, etc. In the Chickasaw territory at the southwest, a set of low elevations from Tishomingo northwest, rising in the sharp spur called the Arbuckle Mountains, and again farther on in the Wichita Mountains of Oklahoma, connect the Ozarks with the outliers of the Rockies. The highest elevation in the Territory is about 3,000 feet above sea-level, the lowest 350. The timber north of the Canadian is mainly confined to a belt in the west, save for cottonwoods, elms, pecans, and a few other sorts along the streams; south of it the timber occupies much the greater portion, even in the west. The eastern half of the Territory is nearly all well wooded, the mountainous parts most heavily so; the woods besides the above are oak, largely in a belt from the Arkansas to the Red called the Cross Timbers (used only for fuel and railroad ties, not for construction), with valuable yellow pine and red cedar on the elevated grounds, and walnut in the bottoms.

The drainage belongs entirely to the Arkansas and Red River systems. The former, flowing across and cutting off a northern cantle, is joined east of the centre at Webber's Falls by the long Canadian, its main affluent, which forms nearly the median line of the Territory and its northern boundary with Oklahoma; and is further fed from the north by the Neosho and the Verdigris joining close together, and by the Illinois near the Canadian. The latter has hardly any water-shed on the south. Nearly the whole southern half of the Territory is drained by the affluents of the Red, forming the entire boundary with Texas; the chief are the Washita in the southwest and the Kiamichi in the southeast.

Geology and Minerals.— Geologically, the Territory may be divided into four sections: (1) The Arbuckle-Wichita region, with an outlying granite field at Tishomingo. This contains coal measures on the north and asphalt on the south; the former is the chief mineral product of the Territory. For the year ending 30 June 1903, there were employed in coal mining 6,091 men and boys; there were in operation for the same year 280 coke ovens, producing 52,625 tons of coke; the coal tonnage for the same year was 3,243,692 tons. Large bituminous asphalt deposits occur in the Choctaw and Chickasaw Nations; these have been worked some, but owing to the want of railroad facilities, and the asphalt trust, the operators have not been encouraged with very great success. There are also sandstone and limestone as well as granite. (2) The Ozark system, Carboniferous and Silurian, containing zinc and lead. (3) The northern prairie, Carboniferous, with coal and large quantities of petroleum. (4) The southern plains cropping over from Texas, underlaid by the Cretaceous, with artesian strata, and sand and marl above. There are valuable gold and silver deposits from which Indians have long made all their trinkets, but they have kept the places secret, to prevent an influx of miners.

Fauna.— The characteristic species are the timber and prairie wolves, panthers and foxes, black bear, deer, prairie dogs, and some smaller game. The wild turkey is the most important bird.

Climate and Rainfall.—The Territory belongs to the southern division by temperature and to the middle one by precipitation. It has a mean winter temperature of 35° to 48°, and a summer one of 77° to 82°; while the rainfall, light in the north like western Kansas, is heavy in the southeast (52 inches), and steadily decreases to the west (about 35 inches at Fort Gibson and 30 in the southwest). But hardly anywhere is it too scant for favorable agricultural conditions.

Agriculture.— Scarcely any region of the United States has greater natural advantages in fertile soil and plentiful water supply. With the opening of the Territory to white settlement and ownership, a vast increase in production will be effected. Until within the present year (1904) the word "ownership," as applied to tenures in the Indian Territory, had a peculiar meaning. To protect Indian interests, white men (except licensed traders and those made citizens by marriage to Indian wives in accordance with the laws of the tribe, or adopted into the tribe by tribal legislature) could not hold land, except as tenants of Indian landlords. The fee to the land in all cases was in the Indian tribes, and even the Indian citizen had only in a sense an occupancy right, owning the improvements absolutely, and cultivating the land practically as a fee simple owner, but always subject to future allotment among all the members of the tribe.

Within the past few years, agreements have been made between the United States and each of the five civilized tribes by which the lands of such tribes are being allotted in severalty to

the citizens thereof, with the power of alienation in most of the nations, under certain restrictions, of all, except a certain amount reserved as a homestead, which, in some cases, is inalienable during the life of the allottee, and in others for 21 years, if the allottee lives so long.

In the Creek Nation, 120 acres of an allotment can at present be alienated with the consent of the secretary of the interior, which is being rapidly accomplished, under the rules and regulations prescribed by him, and the allotments are being bought by whites, who are either occupying them themselves or leasing them to other whites. The real Indian, as a rule, is not much of a farmer, and, as the amount granted to an Indian family is generally greater than the head can utilize or cares to utilize, the remainder is leased to some white farmer or cattleman. The whites farm a large proportion of the farms at present. In the year 1890, of the 35,451 farms cultivated by whites only 3,475 were owned by them.

These allotments to the Indians vary in the different tribes. A Choctaw and Chickasaw allotment is 320 acres of average allotable land, and of this the homestead consists of 160 acres of average allotable land, the latter inalienable during the lifetime of the allottee, not exceeding 21 years from the date of the certificate of allotment; the remainder of the land is alienable after issuance of patent, as follows: one fourth in acreage in one year, one fourth in acreage in three years, and the balance in five years; in each case from date of patent.

The Creek allotment is 160 acres, 120 of which is inalienable before the expiration of five years from the 8th day of August 1903, except with the approval of the secretary of the interior; the balance of 40 acres constitutes a homestead, which is inalienable for 21 years, unless the allottee sooner die, in which event the homestead remains for the use and benefit of children born too late to receive an allotment; but, if there be no such issue, then the allottee may dispose of his homestead by will free from restrictions, and, if this be not done, it descends to his heirs free from any limitations.

In all the above cases, as well as in the Seminole Nation, where the land was divided equally between all the members of the tribe, the allottee had the right to select his allotment so as to include any improvements owned by him at the time. At present the allottees can rent their allotments for one year for grazing purposes, and five years for agricultural purposes, and longer in some cases with the consent of the secretary of the interior. Mineral leases may also be made up to 15 years with the consent of the secretary of the interior.

The productions might easily be of the greatest variety in this warm moist region, but the conditions of tenure hitherto did not encourage tenants to diversify crops or improve the condition of farms to revert to Indian owners. The great crop at present is corn, of which in 1900, 30,709,470 bushels were raised; 1,486,820 of wheat, and 1,102,200 of oats were reported. The territory is well within the cotton belt, and 154,850 bales were shipped in 1900. The other products of note were about $1,000,000 of vegetables and fruits. Stock-raising is largely carried on; the value of domestic animals in 1900 exceeded $40,000,000, and included 110,687 dairy cows, 275,000 horses, mules and asses, 17,000 sheep, 10,500 goats and 650,000 swine. It has been known to many that there was a large quantity of oil and gas in this country, but owing to the lack of laws permitting leases and development in the Indian lands, nothing was done until within the last 18 months. The change in the laws, however, has permitted a great deal of development work in some of the towns as well as on outside allotments, and the production is proving very satisfactory to the lessees, as well as the lessors. The field thus far developed is in the northern portion of the Cherokee Nation and the border of the Creek Nation.

Manufacturing.— The manufactures till recently have been mostly confined to the Indian hand-made blankets, shawls, baskets, and trinkets. But within the decade a considerable genuine manufacture by whites has arisen. With only 20 establishments in 1890, there were 789 in 1900; the capital had grown from $204,329 to $2,624,265, the wage-earners from 167 to 1,714, the value of products from $248,932 to $3,892,181. The one great industry, nearly a third of the total products, was flour and grist milling; next greatest, toward half a million each, were cotton-seed oil and cake; and lumber, saddlery and harness, and car-shop work were also noted.

Railroads.— There are about 1,800 miles of railroad in the Territory: Several great lines cross it, giving the facilities for the vast business growth. The main lines are the Frisco System (St. L. and San F.), the St. Louis, Iron Mountain & Southern, the Missouri, Kansas & Texas, the Choctaw, Oklahoma & Gulf, the Atchison, Topeka & Santa Fe, and the Ft. Smith & Western.

Banks.— In 1902 there were 69 national banks, with capital of $2,779,000, deposits of $5,896,000, cash and other resources $548,000, and loans and discounts of $7,277,000. There were also 20 private banks, having capital of $203,975, deposits of $495,810, cash of $56,354 and loans and discounts of $602,676.

Population.— The total population in 1890 was 180,182; in 1900, 392,060, the increase being all white. The real Indian population had probably somewhat decreased, though it showed on the face a slight increase, from 51,279 to 52,500. But the word "Indian" is misleading: for legal purposes and tribal recognition, any one is an Indian who has even 1-64 or in fact any degree of Indian blood in him; and probably two thirds of the so-called Indians are mixtures of various complexities and elements. The negroes, numbering 36,853, are for the most part the former slaves of the Indians, to whom the United States after the war forced the tribes to grant citizenship and a share of the tribal lands and bounties, or their descendants. These two and the vast white population — married and adopted, leaseholders and tenant farmers, hired farm laborers, business men with permits, coal and railroad company employees, etc.— were distributed among the chief districts as follows (besides 27 Chinese):

Chickasaw Nation, 124,306 whites, 9,066 negroes, 5,872 "Indians." Cherokee Nation, 66,951 whites, 9,162 negroes, 25,639 Indians. Choctaw Nation, 79,332 whites, 10,123 negroes, 10,321 Indians. Seminole Nation, 1,143 whites, 981 negroes, 1,662 Indians. The other reservations — Modoc, Ottawa, Peoria, Quapaw, Seneca, Shawnee, Wyandotte — had 5,762 whites and

1,043 Indians. The concentration of whites in the Chickasaw district had made it the industrial leader of the territory.

The towns which grew there formerly had a peculiar status. They were "white" towns with white men occupying the buildings they had erected, and doing business insecurely, without legal title, but the ostensible owners of the ground were the Indians. The so-called Curtis Bill and the various agreements made with the tribes above referred to have changed this condition, and made it possible for the white man, or any other occupants of towns in the Indian Territory to purchase lots under the various provisions of these bills upon which they owned houses or other valuable improvements. The result is that all the larger towns have been platted, surveyed and sold to the occupants, so that the Indian titles have become almost entirely extinguished. Within a year or eighteen months every town within the limits of the Indian Territory will have been so platted and sold. The changes are so great and constant that statistics are nearly as useless as in a new mining district, but it may be said that the present chief towns are Ardmore, and Chickasha, in the Chickasaw Nation, South McAlister in Choctaw Nation, and Muskogee in the Creek Nation, is the handsomest town in the Territory, with good public schools, churches and four colleges of the four leading denominations — Baptist, Methodist, Presbyterian, and Roman Catholic. These towns now have a population approaching 10,000 each and there are over 20 others with over 1,000. The oldest white settlement is Vinita in Cherokee; the oldest in the southeast is Caddo; the best known has always been Tahlequah, for some generations the capital of the Cherokee Nation.

Internal Conditions and History.— The Territory was part of the Louisiana Purchase. Early in the 19th century many of the Southern Indians, their old hunting grounds invaded by the whites, removed to this virgin forest. In 1832 it was fixed on by the national government as a place for the tribes whom agreements with the Southern States had bound us to deport, and in 1834 special reservations were set apart. The Five Civilized Tribes, as they are called, established governments on the civilized model, with elected legislature, council and governor, courts and schools and responsible financial management, and even newspapers in the Cherokee tongue, with Sequoyah's famous alphabet. But the vast enclave of nearly 70,000 square miles in the heart of a swelling settlement could not be maintained, and the Indians from some constitutional blight do not grow to fill their districts. In 1866 some 5,500,000 acres were purchased of the Indians in the present Oklahoma; on 22 April 1889 over 3,000,000 acres were thrown open to settlement; on 2 May 1890 this and other territory was formed into Oklahoma. Meantime the old system in the eastern part was going to wreck, not so much from the white immigration, following the railroads which began to cross it, as from internal development which was making the primal object of the system a mockery. It was designed to protect the half-helpless Indian from white greed till he could stand on his own feet; in fact, the half-breeds and the intermarried whites were rapidly appropriating everything to themselves, while the full-blood was "crowded out upon the mountain and unproductive land, to take care of himself as best he could." (Dawes Commission.) The tribal governments were under control of these governments and were "recklessly leasing the community lands to cattlemen and coal companies" (Hinton), to railroads, oil and lumber companies, etc. The government, therefore, under the lead of ex-Senator Henry L. Dawes of Massachusetts, set about negotiations to break up the tribal governments, and turn the Territory into a set of ordinary civilized communities with ownership in severalty, protecting the Indian for a time by restraining his liberty of alienation. The Dawes Commission of 1893 began this work; in 1897 the United States extended its judicial power over the district; in 1898 the Curtis Act carried out the work, providing for the enrollment of citizens for allotment of lands, for laying out town sites and incorporating towns with power to elect officers and tax themselves for schools, etc., and giving the President a veto power over the tribal legislatures. The arrangements vary with the different tribes; the Seminoles continue their government after a fashion for the present, the Choctaws and Chickasaws with some modifications till 4 March 1906. The present government consists in reality of four federal judges or one court of appeals and four district courts, with 20 commissioners acting as petty courts and justices of the peace, and a resident Indian Inspector. The statutory code is in the main that of Arkansas.

The educational situation has been a part of the anomalous position of all social matters. The tribes maintained schools and admitted white children on payment of a fee; and the missionaries have operated others. But all were very insufficient, and the tribal schools, once the best of the vicinity, have not kept their quality. The Curtis Act of 1898 for the first time provided a public-school system, in cities and towns, and power of towns to levy taxes for them. In 1900 it was estimated that 50,000 white children were deprived of school advantages. Of academic schools, some claiming collegiate rank, there are good ones in each nation; these have sent many pupils to Eastern colleges. By act of 19 May 1902 municipalities of 2,000 or more inhabitants may issue bonds up to 10 per cent of their assessed valuation for school buildings, sewers, and waterworks on a two-thirds vote and with a 20-year sinking fund. Pop. (1900) 392,062; (1903) fully 500,000. Consult: 'Report of the Dawes Commission' (1903); Curtis Act in U. S. Statutes.

WILLIAM T. HUTCHINGS,
Muskogee, Indian Territory.

Indian or Wild Tobacco, one of the North American lobelias (*Lobelia inflata*), also called asthma-weed and gag-plant,— a tall plant with small light blue flowers quite overshadowed by numerous thin, oval, or obovate dentate leaves; the plant branches as a panicle, is fubescent and the pod is inflated. Its leaves have an acrid taste, and are, as Gray says, "poisonous and a quack medicine"; they were dried by the Indians as a substitute for smoking tobacco, or to mix with it, for the sake of their narcotic properties. The dried flowers still have a place in materia medica. It grows in dry fields and thickets through North America. Compare KINNIKINICK.

Indian Turnip. See JACK-IN-THE-PULPIT.

Indian Yellow, known in commerce as PURREE, a pigment of unknown origin which is exported from India, China and probably from Arabia. It comes in the shape of balls, which are outside of a brown tint, and inside of a brilliant yellow. It has the odor of urine, musk or castoreum, is soluble in water or alcohol, and an essential element in its composition is carbonate of euranthin. It is used in India for house decoration, and is valued by artists all over the world as a dazzling pigment.

Indiana ("The Hoosier State"), a north-central State of the United States (No. 19 in order of admission) bounded north by Michigan, south by Kentucky, east by Ohio, west by Illinois; extreme length 276 miles, extreme breadth 177 miles; area (No. 34 in U. S.) 36,350 square miles, 440 water; pop. 1900 (No. 8 in U. S.) 2,516,462, or 70.1 to the square mile. (No. 11 in density.) The State boundary in Lake Michigan is an east and west line 10 miles north of the extreme southern point of the Lake. The Ohio River runs along the southern boundary, but, by a provision of the Virginia cession of Northwest Territory, Indiana extends only to low-water mark on the north bank of the Ohio. In consequence all islands in the Ohio belong to Kentucky, the Supreme Court having recently held this as to Green River Island (Indiana *v.* Kentucky, 136 U. S.) which, although an island at the time of the cession, became connected with the Indiana shore by alluvial deposits, and had been governed and taxed as part of Indiana for many years.

Topography.— The surface of the State is comparatively level, the highest point, in Randolph County, in the centre of the eastern tier of counties, being estimated at 1,285 feet above sea-level, and the lowest, at the southwest corner of the State, being 313 feet above sea-level. The Ohio at the southeast corner of the State is 436 feet above sea-level, and Lake Michigan at the northwest corner is 585 feet above sea-level. From the table-land of the east central part of the State, and western Ohio, radiate low water-sheds separating the drainage basins of Indiana. The northern part of the State is quite flat, the central part slightly rolling, and the southern part rather hilly on account of the valleys cut out by water. There are no mountains, and no large lakes, but there are hundreds of small lakes, chiefly in the northern part of the State.

River Systems.— The southern parts of the State are drained to the Ohio River by the Whitewater and smaller tributaries. The central part of the State — about four fifths of its area — is drained by the Wabash and its tributaries, the most important of which are the White, Tippecanoe, Eel, Salamonie and Mississinewa rivers, and Wild Cat Creek. The northeastern corner of the State is drained by the St. Joseph's and St. Mary's rivers; these unite at Ft. Wayne to form the Maumee, which flows into Lake Erie. The extreme northern part of the State is drained by another St. Joseph's, the Calumet, and smaller streams, into Lake Michigan. A part of the northwestern section is drained by the Kankakee and its tributaries to the Illinois River. The Wabash is navigated to a limited extent, by small boats, as high as Terre Haute, and also the lower part of White River. The remaining streams are not navigable.

Climate.— The climate of Indiana is mild, ranging from an average of 31° F. in the winter months to an average of 76° in summer. The mean temperature is 53°. The average annual rainfall is 43 inches, that in the southern part of the State being slightly in excess of that in the northern part. Serious droughts and destructive storms are rare. In earlier years parts of the State were malarial, but with the clearing of the forests and the drainage of lands this condition has almost wholly disappeared.

Geology.— The earliest geological formation that outcrops in Indiana is the Hudson and Trenton limestone, of the Silurian Age, which appears in the southeastern corner of the State, throughout the Whitewater Valley and the adjacent region. West of this is a belt of Niagara limestone, which broadens at the north and extends entirely across the State, covering all of a dozen counties and large parts of as many more. On the west of this, and also extending to the State line on the north, are belts of Hamilton limestone and sandstone of the Devonian Age. The remainder of the State — the southwestern corner and a broad belt to the north reaching beyond the Wabash — is of the subcarboniferous and carboniferous formations. The northern and central parts of the State are covered by glacial drift, which in some regions is of a depth of 400 feet.

Soils, Agriculture and Forests.— The soil of the State varies in character, but for the most part is fertile. Originally the southern part of the State, and as far north as the Wabash, was covered with a very heavy growth of forest, mostly of hardwood trees. North of this were low prairies interspersed with sand ridges and dotted with hundreds of small lakes. This region is now found very productive of cucumbers, melons and small fruits in the sandy parts. The richest lands are the alluvial valleys of the streams and the drained prairies. The forests have so far disappeared that the State is now encouraging tree planting. Agriculture is the chief industry of the State, the value of farm products in 1899 being reported at $204,450,196. The chief agricultural products were corn, 178,967,070 bushels, wheat 34,986,280 bushels, oats 34,565,070 bushels, potatoes 6,209,080 bushels, hay 3,470,378 tons. The value of animal products was $81,947,922, of forest products $5,235,459, of orchard products $3,166,338, of dairy products $15,739,594. The value of the poultry raised in 1899 was $8,172,993, and of the eggs produced $7,441,944.

Minerals and Mining Industries.— About one fifth of the surface of Indiana is underlaid by coal, workable veins having been found in 19 counties. There are at least 7 distinct veins of workable thickness, varying from 3 to 11 feet. The coals of the State are of two classes — caking or bituminous, and non-caking or block coal. The latter can be burned in blast furnaces without coking. The production in 1901 was 7,019,203 tons, valued at $7,370,163, the State ranking sixth in the Union as to quantity and seventh as to value of the product. The number of people employed in coal mining was 12,968. The mineral product second in value was petroleum, the production of which is a

comparatively new industry. In 1901 the oil product of the State was 5,749,975 barrels, valued at $4,795,312. This was largely increased — over one third — in 1902. Next in value of the mineral products of the State is building-stone, of which the chief varieties are the oolitic limestone, the blue Devonian limestone, the gray Niagara limestone, and sandstone. The oolitic, so called because composed of minute fossil shells resembling a mass of fish eggs, has become celebrated throughout the United States on account of its superior qualities. In 1901 Indiana was first in rank in the Union in the production of limestone for building purposes, and fifth in rank as to building-stone of all kinds, the product being valued at $3,028,145. There is also a large production of cement and lime. Good clay is abundant throughout the State, and brick and tile making are extensive industries. Kaolin and glass sand are also found in quantity in several counties, and are profitably mined. Natural gas has been found, by sinking wells, throughout a large part of the State. The supply at one time reached a daily flow of 900,000,000 cubic feet. It served to draw many manufactories to the State, but the pressure is now decreasing. In many places its cessation has been followed by a flow of petroleum. Many other minerals have been found in Indiana, but not in quantities of commercial importance.

Manufactories.— The manufactures of Indiana are chiefly a development of the past 30 years. In the earlier period manufacturing was confined almost wholly to supplies for domestic consumption, and was chiefly conducted at the homes of the people. In 1900 there were reported 18,015 manufacturing establishments in the State, employing 155,956 wage-earners, and producing goods to the value of $378,120,140. The leading classes of manufactures, with the value of products in 1900 and in 1890, are as follows:

	1900	1890
Slaughtering and meat packing	$43,862,273	$27,913,840
Flour and grist mills	30,150,766	31,239,627
Distilleries	22,738,106	9,677,973
Lumber and wood manufactories	34,471,902	32,725,647
Iron and steel (including foundries)	36,566,527	14,285,259
Glass and glassware	14,757,883	2,995,409
Carriages and wagons, and materials	15,891,826	10,531,683
Railroad cars	19,248,999	14,362,711
Agricultural implements	6,415,081	5,756,131
Textiles and clothing	8,618,360	7,736,890
Clay products	4,222,529	3,142,454

It is probable that this rate of increase will not be continued in the next decade, partly because of the decrease of natural gas, partly because of abandonment of plants under trust control, and partly for other reasons. The production of lumber in the State was almost stationary in the past decade, and will probably decrease in this on account of decreasing forest supplies.

Commerce and Navigation.—About one tenth of the people of Indiana (in occupations) are engaged in commerce and transportation. The navigation of the State is limited, being confined to the Ohio River on the south, with the lower Wabash and a small part of the White River, and Lake Michigan on the northwest. The canals of the State are practically abandoned except for water-power. The railroads furnish the chief means of transportation. Commerce is chiefly domestic, but both exportation and importation are steadily increasing.

Fisheries.— Indiana has no fisheries of commercial importance, though it has waters that might be made valuable. Recently laws have been passed for the protection of fish, and some interest is being shown in their propagation.

Railroads and Street Railways.— The railroad mileage of Indiana, in 1902, was 6,651 miles, exclusive of second main and side tracks. In 1850 it was 228 miles; in 1880, 4,320. Railroad lines extend through all but 3 counties in the State. The chief railroad centre is Indianapolis, from which 14 lines radiate. These are connected outside of the city by a belt railway. The valuation of railroad property for taxation in 1902 was $162,797,978. There are street railways in all of the cities and larger towns, the total aggregating 168 miles. In 1899 there began an extraordinary development of electric interurban lines. By the close of 1902 about 400 miles of these were in operation, and 500 miles were under construction, while new lines aggregating over 1,000 miles were projected. These lines have made a material change in the transportation of both passengers and freight, and will apparently furnish large competition with the steam railroads. One of these lines, operating between Indianapolis and Columbus, Ohio, has added sleeping-cars to its equipment.

State Finances.— The assessed valuation of the State in 1901 was $1,397,981,497, from which deductions for mortgage exemption were made amounting to $35,169,250. Individuals are permitted to deduct *bona fide* mortgage indebtedness from their schedules to the amount of $700. The total number of polls was 436,522. The State tax levy for general State government was 9 cents on $100, and 50 cents poll; for the benevolent institutions 5 cents; for sinking fund 3 cents; for State tuition — which is distributed to the school districts for support of the common schools — 11 cents and 50 cents poll; for State institutions of higher education 1⅔ cents; making a total State levy of 29⅔ cents and $1 poll. The reduction of the State debt was begun in 1889, when it amounted to over $10,000,000. On 31 Oct. 1902, it had been reduced to $2,887,615.12, on which the annual interest charge was $101,565.

Banks.— In 1902 there were 137 national banks with $16,618,552 capital, $4,789,956 surplus, $71,533,942 deposits, and $7,210,780 outstanding circulation; 113 State banks with $4,884,490 capital, $915,413 surplus, and $24,240,334 deposits; 5 savings banks, with $7,812,157 of deposits; 37 trust companies transacting bank business, with $4,392,500 capital, $465,947 surplus, and $12,378,348 of deposits, and 203 private banks, which are not required to make returns by the State. Of these last named, however, 68 made returns to the comptroller of the currency, showing $9,671,733 deposits. The only clearing-house organization in the State is at Indianapolis, and the volume of clearings in 1902 was $270,409,456.

Education.— Indiana has always given much attention to education and especially since the

adoption of the present school law in 1852. At that time there was created a public school fund, the interest on which was to be distributed to the various school districts. The principal factor in this was the profits which the State had derived from the State Bank of Indiana, amounting to about $3,500,000, to which was added $573,000 of the surplus revenue distributed by Congress in 1836, and several smaller funds. To this additions have been made by fines and other public receipts, until in 1902 the common school fund amounted to $7,978,580.68, to which is to be added the Congressional township fund, derived from the sale of school lands donated by the national government, amounting to $2,465,304.64. This total fund of $10,443,885.32 is held by the several counties, and the interest on it is applied to the support of the public schools. Added to this is a State tax of 11 cents on each $100, and 50 cents on each poll, the proceeds of State liquor licenses and dog licenses, and local taxes assessed by local authorities. From all these sources the actual revenues raised for the public schools in 1902 amounted to $8,585,354.98. The enumeration of children of school age — 6 to 21 years — was 761,801 (of whom 15,002 were colored). A large number of these attended private schools, and the attendance in the public schools for the year was 423,078. The revenue was therefore in excess of $20 to each child in attendance. There were employed 16,039 teachers, and the average number of days of school was, in townships 126, in towns 153, in cities 179, in the State at large 146. The number of public schoolhouses is 5,080 brick, 4,807 frame, 97 stone, and 3 log. The value of schoolhouses and grounds is $22,904,607 and of school apparatus $1,277,455. In these figures are included 704 high schools, which are a part of the public school system. There are also a large number of private schools, notably those maintained by the Roman Catholics and Lutherans for children of all ages, and a number of academies, seminaries, institutes, boarding-schools, military institutions, colleges, normal schools, etc., for intermediate education.

There are three institutions of higher education that receive aid from the State, Indiana University at Bloomington, the State Normal School at Terre Haute, and Purdue University at Lafayette. Indiana University has an income of about $125,000 derived from a State tax levy and the interest on an endowment fund of $600,000 raised by State taxation. It had 1,285 students in 1902. The State Normal is also supported by a State levy, and the city of Terre Haute pays one half the expense of keeping the buildings in repair. It has 1,406 students. Purdue has an income of $150,000 derived from State tax levy and interest on endowments, and including $57,000 paid to it annually by the United States government as an agricultural school. It has 1,180 students.

Among the private institutions for higher education the more important are Wabash College (Presbyterian), University of Notre Dame and St. Meinrad's College (Roman Catholic), DePauw University (Methodist), Earlham College (Society of Friends), Franklin College (Baptist), Hanover College (Presbyterian), Northern Indiana Normal (non-sectarian), Winona Technical Institute (non-sectarian), and the University of Indianapolis. The last named was formed by the union of Butler College (Christian) with the Medical College of Indiana, the Indiana Dental College, and the Indiana Law School, all of which are located at Indianapolis.

An important branch of educational work in Indiana is the development of libraries. A feature of the school system adopted in 1852 was the establishment of a free public library in each township in the State. The State expended $273,000 for books, and the system was received with great public favor, but no provision was made for maintaining or increasing the libraries, and in the pressure of the war times they were allowed very generally to fall into ruin. To some extent these have been replaced as school adjuncts by the libraries of the Young People's Reading Circle, which are found at many of the schoolhouses of the State. These libraries in 1902 contained 436,151 volumes. There has also been a notable development of town and city libraries, 28 towns having accepted donations from Andrew Carnegie, aggregating $660,000, agreeing to maintain libraries in the buildings thus provided. There are 25 others that are maintaining libraries in buildings provided by themselves. The general supervision of library work is lodged in the Public Library Commission, which has charge of a system of traveling libraries furnished by the State. It also maintains a school for the training of librarians engaged in the work in Indiana.

Churches.— The principal religious denominations of Indiana in the order of their strength are the Methodists, Roman Catholics, Disciples or Christians, Baptists, Presbyterians, United Brethren, and Lutherans.

Charitable and Penal Institutions.— The State maintains 9 charitable and 4 penal institutions, at an annual cost of over $1,500,000. Of the former, 4 are hospitals for the insane located respectively at Indianapolis, Logansport, Richmond and Evansville. On 31 Oct. 1902, these had 4,039 inmates. The annual cost of maintenance was $649,834.54, or $173.79 per capita. The other charitable institutions are the Institution for the Blind, Indianapolis, inmates 127, per capita cost $276.40; Institution for the Deaf, Indianapolis, inmates 318, per capita cost $231.66; Soldiers and Sailors' Orphans' Home, Knightstown, inmates 603, per capita cost $174.52; Soldiers' Home, Lafayette, inmates 739, per capita cost $167.30; School for Feeble-Minded, Fort Wayne, inmates 318, per capita cost $127.05. The correctional institutions are the State Prison, Michigan City, inmates 796, per capita cost $133.32, earnings $53,395.86; Indiana Reformatory, Jeffersonville, inmates 923, per capita cost $130.68, earnings $62,350.67; Reform School for Boys, Plainfield, inmates 531, per capita cost $122.13, earnings $298.91; Industrial School for Girls and Women's Prison, Indianapolis, inmates 52 women and 175 girls, per capita cost $191.55, earnings $1,436.69. At the legislative session of 1903 a law was passed for the division of the last named institution and the establishment of a new Industrial School for Girls. The State has the convict-contract-labor system, but efforts have been made to abolish it, and the legislature of 1903 provided for a commission to investigate and report on the subject. The convict labor is all done within the prisons. The State has the indeterminate sentence system with commutation of time for

good behavior. In addition to the State institutions each county maintains a poor asylum. In these, and the Marion County asylum for the incurable insane, there were on 31 Aug. 1902, 3,046 inmates, of whom 1,975 were men and 1,071 women. Of these inmates 518 were classed as insane, and 889 as feeble-minded. There are in the State 46 orphans' homes, in which there were on 31 Oct. 1902, 1,565 inmates, of whom 1,025 were boys and 540 girls. At the same date the Board of State Charities reported 811 orphan children maintained in private homes, without public expense.

State Government.— The elective State offices are held for periods of 2 years, with eligibility restricted to 4 years in any period of 6 years, except as to the governor, lieutenant-governor, and geologist, whose terms are 4 years. No one is eligible to the office of governor or lieutenant-governor for more than 4 years in any period of 8 years. The governor's salary is $5,000, with an allowance of $1,800 for house rent. The governor's veto power extends to all laws passed by the legislature, but the veto may be overthrown by a majority vote in both Houses. The legislature meets once in 2 years, and may be called in special session by the governor; regular sessions are limited to 60 days and special sessions to 40 days. The Senate is composed of 50 members elected for 4 years each, and the House of 100 members elected for 2 years each. The members receive $6 a day while in session, and $5 for each 25 miles traveled in reaching the capital and returning home. The State is required to be redistricted for legislative purposes every 6 years. The present Constitution was adopted in 1851, and is very generally considered unsatisfactory, especially as to legislative representation and the location of the appointing power. It can be amended only by the majority vote of both Houses of two consecutive legislatures, followed by a majority vote of the electors of the State.

Congressional Representation.— The State has 13 representatives in Congress.

Population and Divisions.— The population of Indiana territory in 1800 was 5,641, but only about 2,500 of this was within the boundaries of the State. In 1810 the population of the territory, with practically the same boundaries as the State, was 24,520. A territorial census taken in 1815 showed 63,897 inhabitants. After the admission of the State the census returns were as follows: 1820, 147,178; 1830, 343,031; 1840, 685,866; 1850, 988,416; 1860, 1,350,428; 1870, 1,680,637; 1880, 1,978,301; 1890, 2,192,404; 1900, 2,516,462. Of the population in 1900, 142,121 were foreign born, and 57,505 were negroes. The tendency of the negroes is to gather in the cities, more than one fourth of the entire number being found at Indianapolis, and an eighth at Evansville.

The State has 92 counties, whose names and county-seats are as follows:

Adams, Decatur.
Allen, Ft. Wayne.
Bartholomew, Columbus.
Benton, Fowler.
Blackford, Hartford City.
Boone, Lebanon.
Brown, Nashville.
Carroll, Delphi.
Cass, Logansport.
Clark, Jeffersonville.
Clay, Brazil.
Clinton, Frankfort.
Crawford, English.
Daviess, Washington.
Dearborn, Lawrenceburg.
Decatur, Greensburg.
Dekalb, Auburn.
Delaware, Muncie.
Dubois, Jasper.
Elkhart, Goshen.
Fayette, Connersville.
Floyd, New Albany.
Fountain, Covington.
Franklin, Brookville.
Fulton, Rochester.
Gibson, Princeton.
Grant, Marion.
Greene, Bloomfield.
Hamilton, Noblesville.
Hancock, Greenfield.
Harrison, Corydon.
Hendricks, Danville.
Henry, Newcastle.
Howard, Kokomo.
Huntington, Huntington.
Jackson, Brownstown.
Jasper, Rensselaer.
Jay, Portland.
Jefferson, Madison.
Jennings, Vernon.
Johnson, Franklin.
Knox, Vincennes.
Kosciusko, Warsaw.
Lagrange, Lagrange.
Lake, Crown Point.
Laporte, Laporte.
Lawrence, Bedford.
Madison, Anderson.
Marion, Indianapolis.
Marshall, Plymouth.
Martin, Shoals.
Miami, Peru.
Monroe, Bloomington.
Montgomery, Crawfordsville.
Morgan, Martinsville.
Newton, Kentland.
Noble, Albion.
Ohio, Rising Sun.
Orange, Paoli.
Owen, Spencer.
Parke, Rockville.
Perry, Cannelton.
Pike, Petersburg.
Porter, Valparaiso.
Posey, Mt. Vernon.
Pulaski, Winamac.
Putnam, Greencastle.
Randolph, Winchester.
Ripley, Versailles.
Rush, Rushville.
Scott, Scottsburg.
Shelby, Shelbyville.
Spencer, Rockport.
Starke, Knox.
Steuben, Angola.
St. Joseph, South Bend.
Sullivan, Sullivan.
Switzerland, Vevay.
Tippecanoe, Lafayette.
Tipton, Tipton.
Union, Liberty.
Vanderburg, Evansville.
Vermilion, Newport.
Vigo, Terre Haute.
Wabash, Wabash.
Warren, Williamsport.
Warrick, Boonville.
Washington, Salem.
Wayne, Richmond.
Wells, Bluffton.
White, Monticello.
Whitley, Columbia City.

Chief Cities.— The largest city in Indiana is the capital, Indianapolis, with a population (1900) 169,164. Next in size are Evansville (59,007), Ft. Wayne (45,115), Terre Haute (36,673), and South Bend (35,999). Each of these cities has a charter specially made for it, though under guise of a general law. These charters are of recent creation — the oldest made in 1891 — and establish advanced forms of city government. Of cities of secondary importance may be named Muncie (20,942), New Albany (20,628), Anderson (20,178), Richmond (18,226), Lafayette (18,116), Marion (17,337), Logansport (16,204), and Elkhart (15,184). There were in all 80 cities and 330 incorporated towns in the State in 1901.

History.— The first-known visits of white men to Indiana were those of Sieur de la Salle, who followed the Ohio River along its southern boundary in 1669–70, and crossed its northwestern corner by way of the St. Josephs-Kankakee portage in 1671. There were no Indians living below the Wabash at that time, and probably not many in the northern part of the State, but those there were LaSalle induced to join his confederacy against the Iroquois, and they all removed to the Illinois River, leaving Indiana practically uninhabited. After some years they began moving to the East, reaching Detroit by 1712, and shortly afterward located at points along the Maumee and Wabash rivers. The Delawares, who afterward lived in the central part of the State, on White River, came there about 1750. It is probable that the French first placed representatives at the Indian villages near the site of Ft. Wayne, and next, about 1720, at Ouiatenon — on the north side of the Wabash just below Lafayette — and that there were stockade forts at these places, but there is nothing to indicate a permanent settlement at either place. The post at Vincennes was established in 1731, largely under the influence of Father De Beaubois, a Jesuit who had been stationed at Kaskaskia. Families located there soon afterward, and it remained a permanent settlement, though there is but one land grant recorded of

STATE CAPITOL AT INDIANAPOLIS.

date prior to 1736. The French posts were small and unimportant, and the history of the region under French and British rule presents no very striking features. In 1778 Vincennes was surrendered to representatives of Gen. George Rogers Clark, and the Wabash country was brought under American control. A recapture by the British was followed by a second taking by Clark in 1779. The region was ceded to the United States by the treaty of 1783, and was included in the Territory northwest of the Ohio River, by the ordinance of 1787. It was thus governed until 1800, when Indiana Territory was formed, including all of the Northwest Territory except Ohio. From Indiana Territory, Michigan Territory was cut off in 1805, and Illinois Territory in 1809, leaving it with practically the present State boundaries. By act of Congress of 19 April 1816, Indiana was authorized to form a State government, and the State was formally admitted by act of 11 Dec. 1816. In the meantime a State Constitution had been adopted on 29 June; State officials had been elected, and the State government had been actually inaugurated on 7 November.

There were almost continuous Indian troubles in the Ohio Valley from 1788 to 1795, when, after Gen. Wayne's successful expedition, peace was made at Ft. Greenville. After that date the American immigration began, and there was no material trouble with Indians until the formation of Tecumseh's confederacy in 1811. The Indians were overwhelmed at the battle of Tippecanoe (q.v.) on 7 November of that year, by the troops under Gen. Harrison, and sued for peace, but when the war with England came on there were Indian hostilities of minor importance continuing until the close of the war in 1815. After that year there was a gradual extinction of Indian titles, the Indians being concentrated in the northern part of the State and finally removed west of the Mississippi. The last removals occurred in 1836 and 1838.

The sobriquet "Hoosier," commonly used to designate the State and its people, was first applied to them about 1830. It was not coined for that purpose, as is commonly supposed, but was a slang word signifying an uncouth rustic, which was in common use in the South at that time, and is still commonly used there in that sense.

The history of the State after its admission was chiefly that of peaceful development — clearing lands, opening roads, building towns and cities, and establishing industries. The most notable feature was the disastrous internal improvement enterprise on which the State entered in 1836. It contemplated transportation routes on 7 main lines, involving the construction of 1,289 miles of railroads and canals. That the routes were fairly well chosen is shown by the fact that they are now practically all occupied by successful railroad lines. The chief defect was that the improvements were mostly high-line canals, and the breaks in these before completion caused such great damage that the estimated cost was enormously increased. The financial panic of 1837 added to the difficulties, and the effects of this were aggravated by the general entering of the States on such enterprises on borrowed capital. The total debts of the several States swelled from about $13,000,000 in 1830 to $207,894,613 in 1842. In 1839 Indiana was unable to realize on the sales of her bonds, and was forced to default interest on those already issued. The canals and roads being unfinished, did not furnish the revenues anticipated. Compromises were effected by which the work done was turned over to creditors, but the State was left with a debt of about $10,000,000 without any property to represent it. In all, Indiana built 453 miles of canals, at a cost of $7,725,262, all of which are now abandoned so far as transportation is concerned. But under private management, and more favorable conditions, the transportation lines developed rapidly, and in 1849 the one railroad originally contemplated was paying 8½ per cent dividends on its stock. In 1860 there were 2,126 miles of railroads in successful operation in the State.

In the war with Mexico, Indiana furnished troops to the number of 4,470. Of these there were killed and wounded 183, and died of other causes 218. When the Civil War began the State occupied an important position, and its resources were utilized to the uttermost by its war governor, Oliver P. Morton. The State furnished 196,363 men for the War, and 784 paid for exemption, or in other words supplied 74.3 per cent of her total population capable of bearing arms, by the census of 1860. Only one State in the Union surpassed or equaled this record, Delaware being credited with 74.8 per cent of her military population. But of the supply credited to Delaware nearly one tenth was in money commutation for exemption, and nearly one tenth of the men in actual service were colored. On the basis of white troops furnished for 3 years or more of service, Indiana supplied 57 per cent of her military population of 1860, and on this basis was surpassed only by Kansas, which is credited with 59.4 per cent. Of the troops sent by Indiana 7,243 were killed or mortally wounded in battle, and 19,429 died of other causes, making a total death loss of over 13 per cent of all troops furnished. One feature of the War period in Indiana, and some adjoining States, was the formation of secret treasonable societies known as Knights of the Golden Circle, and later Sons of Liberty. These attracted much attention at the time, and much comment later, but in reality they were neither extensive nor dangerous. They were organized with a system of "circles within circles," with mysterious rites and bloodcurdling oaths, but the masses of the members understood that they were merely for mutual protection, and the treasonable designs were affairs of the inner circles. Among their members there were a number of government detectives who kept the authorities informed as to every movement, and at the final exposure the chief witness for the government was Felix Stidgers, a detective who had become so prominent in the order that he was made "Grand Secretary for Kentucky," and knew all of the secrets of the order. As is aptly stated by Gov. Morton's biographer, "No one can read the history of the secret organizations in Indiana and not feel that, widespread as they were, there was not an instant in which they were not securely within the grasp of the war governor." After the War, Indiana became peculiarly a political battleground. In 1868 the Republicans elected Conrad Baker governor by less than 1,000 plurality, and in 1872 the Democrats elected Thomas A. Hendricks to that office by the narrow plurality of 1,148, although Gen. Grant received the vote of the State for President. After 1872 neither

party carried the State at two consecutive Presidential elections until after 1896, and neither carried it by a majority of all the votes cast, or by a plurality of as much as 20,000. One result of this close balance has been an improvement in State legislation, the Democrats leading in the legislature of 1889 which they held although they had lost the State offices and the Presidential vote of the State in the preceding year. Indiana in that year adopted the Australian ballot system, being the second State in the Union to do so, with some improvements that have been extensively copied. Other notable reform laws are a school-book law that has made a large reduction in the cost of books used in the common scools; a Board of State Charities law that has greatly improved the charitable and penal institutions of the State; a fee and salary law putting officials on salaries and requiring the payment of all fees into the public treasuries; a compulsory education law; laws for the encouragement of public libraries; laws for the incorporation of cities which provide the most modern modes of city government; laws for the reform of county and township government providing supervisory boards to which local legislation is entrusted and a tax law that has been largely effective in equalizing taxation and has been copied elsewhere. Another feature of Indiana's development that has attracted notice in later years is its production of native writers of poetry and fiction. Among the former may be named Joaquin Miller, John Hay, John James Piatt and James Whitcomb Riley; among the latter Gen. Lew Wallace, Maurice Thompson, Edward Eggleston, Charles Major, Meredith Nicholson, Booth Tarkington and Annie Fellows Johnston. These with lesser lights and some writers of note in other lines form a notable group for a commonwealth whose settlement and development have occurred in little more than a century.

JACOB PIATT DUNN,
Secretary Indiana Historical Society.

Indiana University, the State university located near Bloomington. In accordance with a provision of the State constitution, the legislature passed an act in 1820 providing for the establishment of a State seminary, which was opened in 1824 under the name of Indiana Seminary; in 1827, it was raised to the dignity of a college, and in 1838 the name was changed to Indiana University. In 1868 the university was opened to women, and has since been coeducational in all its departments. The university is the head of the public school system of Indiana, and no tuition fee is charged; the government is by a board of trustees which reports biennially to the governor. Courses are offered in languages, science, and history, all graduates receiving the degree of A.B. The degrees of Ph.D. and A.M. are given for graduate work; there is also a school of law connected with the university which confers the degree of B.L. There is a biological experiment station on Winona Lake, under university control, and a summer session is maintained. In 1904–5 the university reported: faculty, 78; students, 1,538; volumes in library, 53,000.

Indianapolis, Ind., capital of the State, county-seat of Marion County, the largest city in the State and the 21st in the United States; situated on the west fork of White River. It is the centre for 16 radiating railroads, which connect it with Chicago, 184 miles northwest, Cleveland, 283 miles northeast, St. Louis, 240 miles southwest, Louisville, 110 miles south, Cincinnati, 111 miles southeast, Columbus, 181 miles east, New York, 819 miles east, and other termini in Ohio, Michigan, Illinois, and Indiana. Its area is 29.35 square miles.

The site was selected in 1820 as the location of the capital by a legislative commission, and its name was adopted by the legislature in session at Corydon, 6 Jan. 1821. The first plat included a square mile, which was laid out with broad rectangular streets and avenues radiating from a central circle. The character of the plan was undoubtedly influenced by l'Enfant, the designer of the city of Washington, D. C., for one of the surveyors who made the town plat had aided in the work at the national capital. While the additions to the city have not been developed upon the same broad lines, most of them have been treated liberally and the city is noted for its wide streets, well paved and beautifully shaded. The city is very level, nearly all of its area being 700 to 800 feet above sea-level. There are 439.6 miles of platted streets, of which 92 miles are paved, 44 miles with asphalt, 27 miles with brick, 17 miles with wooden blocks, and 4 miles with macadam. The chief business streets are Washington Street, which is a section of the old National road projected and partly completed to run from Baltimore to St. Louis; Market, Maryland, and Georgia streets, all running east and west; Meridian, Pennsylvania, Delaware, and Illinois streets, running north and south, and Massachusetts, Indiana, Virginia, and Kentucky avenues, which are diagonals, radiating from the circular Monument Place. This central circle contains the State's monument to its soldiers and sailors, perhaps the most successful of the innumerable monuments erected by towns, cities, societies, and States in commemoration of the nation's defenders, and is generally regarded as one of the greatest in the world from an artistic point of view. The finest residence streets are Delaware, Meridian, and Pennsylvania. Several other residence districts are particularly well designed and cared for, such as Woodruff Place — a residence park, with esplanades, fountains, statues, etc.,— which has a town government of its own, though completely surrounded by the city; Morton Place, and Meridian Heights.

Public Service.— The first water supply and the first sewer system were constructed in 1870 to 1875, and but little else was done in the way of comprehensive public improvements until after the adoption of the present efficient charter in 1891. Prior to that year the city government had been by mayor and council. Public-spirited citizens who recognized the impossibility of comprehensive public improvements, through the Commercial Club and Board of Trade agitated the adoption of the new charter, which separated the legislative and administrative functions of the city government, making the mayor and his appointees fully responsible for the latter. The first Board of Public Works devised a broad system of improvement, including sewerage, paving and street cleaning, which was supplemented in 1895 by a Park Commission. Under these two boards the progress in the establishment of municipal public works adding to the beauty and convenience of the city has been rapid. As a step preliminary to the era of im-

SOLDIERS' MONUMENT.

provement which began in 1890 a paving exposition was held for the purpose of educating the people of the city regarding paving materials and methods. It was the first ever held in America and attracted attention throughout the country. Official delegations were sent to it from many cities. Prior to 1890 less than two miles of pavements had been laid. The amounts expended since the adoption of the new charter in 1891, including the year 1902, are as follows: for pavements of asphalt, $2,726,668.01; brick, $1,011,214.39; wooden block, $969,652.82; macadam, $154,522.91; gravel, $757,112.50; for alley improvements, $46,655.26; for cement walks, $879,010.21; for brick walks, $65,995.41; making a total for paving of $6,611,431.51. During the same period the expenditure for construction of 105 miles of sewers added to the 23 miles previously in use was $1,828,878.67, and for bridges $240,485.32. The grand total for the 12 years shows $8,680,795.50 expended in these departments of public improvements. The waterworks owned by the Indianapolis Water Company have developed with the city. The system of pumping by direct pressure is used, and a system of filter beds to purify the water taken from White River some miles above the city has been installed. The company has 226 miles of water mains and receives from the city about $85,000 a year for public water and fire protection service. Electric lights are in general use. The city pays about $115,000 a year for about 1,350 electric arcs for street lighting and about $7,000 for about 400 gas and vapor lights. The police department contains 175 men and costs $150,000 a year. The police court, city clerk, city dispensary, and central station are housed in a handsome building of recent construction. The fire department has 100 horses, 9 steam fire-engines, 20 hose wagons, 1 water tower, 1 aerial, and 4 service trucks, 4 chemical engines, and 175 men, and is housed in 22 stations. It costs the city $175,000 a year. There are 50 miles of underground conduits used by the telephone, telegraph and electric light and power companies, and 125 miles of electric street railway lines, owned by the Indianapolis Street Railway Company. The city is the most prominent centre of interurban railway traffic in the United States. Ten systems are in operation or in active construction, and others are early probabilities The city has recently made a contract with the Indianapolis Terminal and Traction Company, lessee of the city lines, under which a great terminal station and belt lines for the passenger and freight traffic of the interurban lines are under construction, the whole making a model system.

Parks and Cemeteries.—The public park system includes 9 parks of nearly 1,200 acres area. Riverside Park, purchased in 1898, contains 950 acres along White River, Garfield Park 108 acres, and Brookside Park 80 acres. Since the establishment of the park commission in 1895 $300,000 has been spent in purchasing new parks and $400,000 in improving them. There are several small parks scattered about the city, such as Military Park, 14 acres; University and St. Clair Squares, each 4 acres; Spades Place, 8 acres; Indianola Place, 2 acres; Highland Square, and combinations of park, boulevard, and residences as Elmwood, Fletcher, Morton, and other places, of which the largest is Woodruff Place, above noted. The city street railway company maintains two parks a short distance outside the city limits. The first cemetery of the city, Greenlawn, has not been used as such for many years and is kept in park form by the Board of Park Commissioners. Crown Hill cemetery, one of the notable cemeteries of the country, embraces over 540 acres. There are also Roman Catholic, Lutheran, and Jewish cemeteries.

Buildings.— The Indiana State House, costing $2,000,000, and built of Indian oolitic stone, is perhaps the most notable building. With its grounds it occupies two large blocks. The county building was completed in 1878 at a cost approximating $1,750,000. The new Federal building, containing the post-office, custom-house, and United States courts, is under construction at a cost of $2,400,000. Other municipal buildings of note are the police building, the public library, containing also the offices of the public schools, and some of the new public school buildings. Tomlinson Hall, a bequest by Dr. J. M. Tomlinson, is a public building, its lower story being used as a market. The Indianapolis Art Association is considering plans for an art museum and school. Among the prominent business buildings ornamenting the city, special mention may be made in the order of their construction of the Commercial Club, Majestic, Law, Stevenson and Newton Claypool buildings and Claypool Hotel. The Columbia Club building is an important feature of one quadrant of Monument Place, which surrounds the Indiana State Soldiers and Sailors' monument. This massive shaft is the central and most notable decorative feature of the city. It is 285 feet high, including the bronze statue, and its base is ornamented with symbolic groups of statuary and reliefs in stone and bronze. It was designed by Bruno Schmitz and cost over $500,000. Four epochs in the history of the State are commemorated by the statues of George Rogers Clark, William Henry Harrison, James Whitcomb, and Oliver P. Morton, which are grouped about its base. The width of Washington street, 120 feet, and of the streets of the original plat, 80 and 90 feet, give space for the best possible display of architectural features.

Transportation.— Indianapolis is the centre of trade for the State. With the completion of the Indianapolis Southern Railway every county in the State except three, which are on the Ohio River, can be reached by railroad in less than one day's travel. Consolidations have placed most of the railroads in two systems. One of these, the Pennsylvania lines west of Pittsburg, now operates the Madison and Jeffersonville lines, which reached the city in 1847, and the Vincennes line, completed in 1868; the Indiana Central to Columbus and the East, completed in 1853, and the Terre Haute and Richmond, later the Vandalia, completed in 1852, and now reaching St. Louis; also a line to Chicago, partly over the Lake Erie and Western. The other, the Big Four system, operates the Bellefontaine road to Cleveland, completed in 1852; the Indianapolis and Cincinnati, which reached the city in 1850; the Indianapolis and Lafayette, of 1852, now reaching Chicago; the Indianapolis, Bloomington and Western to Peoria, finished in 1870, its eastern extension to Springfield, O., completed about 15 years later; the Indianapolis and St. Louis, completed in 1876. Through trains are also run to Benton Harbor, Mich., and to Louisville, over branches of these lines. The

Cincinnati, Hamilton and Dayton Railroad Company operates the Cincinnati and Indianapolis Junction road, completed in 1868, and the Indianapolis, Decatur and Springfield road to Springfield, Ill. The Indianapolis, Cincinnati and Louisville operates a line to Chicago, which was completed about 1880. The Lake Erie and Western Railroad Company operates the old Peru and Indianapolis road, completed in 1854, and reaches Michigan City, Toledo and Peoria.

The construction of the system of interurban electric roads began about 1890 with the Broad Ripple line, now a suburban city line. The next to be constructed was the Indianapolis and Greenwood line in 1900, now reaching Columbus, Ind. It was quickly followed by the Indianapolis and Eastern, which now connects with lines to Columbus, Ohio, and other Eastern points. The Union Traction Company entered the city with a line from its centre in Anderson in 1901 and completed a new line north to Tipton and other points in 1903. The Indianapolis, Shelbyville and Southeastern is another line completed in 1901. Lines entering the city in 1903 are the Indianapolis and Martinsville, the Indianapolis and Plainfield, and the Indianapolis and Northwestern, reaching Crawfordsville and Lafayette. The Indianapolis and Cincinnati is under construction in 1903 to Rushville, and contracts have been let for the Indianapolis and Southern railroad. The steam railroads are served within the city by the Union Railway Company owning the Union passenger station and the belt railway for facilitating the transfer of freight. The interurban electric roads will in like manner be served by the Indianapolis Terminal and Traction Company owning a large terminal station and belt lines for passenger and freight business.

Manufactures.— During the brief natural gas era in Indiana, Indianapolis benefited largely by the cheap fuel. Since the failure of the gas supply the superior shipping facilities of the city and relatively cheap coal fuel have attracted many more manufactories, and more than 160 industries are carried on in about 2,000 establishments. According to the United States census of 1900 there was invested in 1910 establishments capital amounting to $36,828,114, employing 27,478 persons, including proprietors, and turning out products valued at $68,607,579. Among the most important industries are slaughtering and meat packing, whose product was $18,781,442 in the census year from 7 establishments; iron work of all sorts, $6,727,990; flouring and grist mill products, $3,820,373; carriages and wagons and material therefor, $2,812,498; furniture factory product, $1,685,827; saws, $1,587,827; malt liquors, $1,770,939; printing and publishing books and newspapers, $2,924,385; clothing, $2,190,050, half of it factory product; lumber and lumber-mill products, $1,588,797.

Finances and Banking.— The assessed valuation of the city in 1870 was $24,656,460. In 1891 at the beginning of the era of public improvements it was $93,595,930, and in 1902 it had increased to $132,927,210. The tax rate for State, county, township, city, and school purposes was $2.08 in 1902. The bonded debt is $2,421,000. The city's expenses are about $1,200,000 a year. The post-office receipts are $635,000. The custom-house receipts are $165,000, and the valuation of imports $350,000. There are 14 banks and trust companies, including seven national banks. The aggregate capital of the national banks is about $4,300,000, their surplus about $1,900,000, and deposits over $18,000,000. The six trust companies have a capital of $2,900,000 and individual deposits of about $7,500,000. The trust companies and private banks carry savings accounts. There are about 90 building, loan and savings associations in various stages of progress and liquidation.

Churches.— Indianapolis is the seat of a Roman Catholic bishop, with an auxiliary bishop and of an Episcopal bishop. Including missions there are 12 Roman Catholic churches in the city, 47 Methodist, 16 Presbyterian, 7 Episcopal, 34 Baptist, 10 Congregational, 7 Lutheran, 15 Christian, 3 German Evangelical, 3 Evangelical Association, 3 Friends, 2 United Presbyterian, 5 German Reformed, one each of 11 other denominations. There are 4 Hebrew congregations.

Charities.— In the city there are 15 hospitals, State, county, college, church, charitable, and private, 4 homes for the aged, 6 industrial schools and orphan asylums, 4 homes for women and girls, 16 organized charitable and relief societies, and several such institutions as the Y. M. C. A., Y. W. C. A., Friendly Inn, Bureau of Justice, Humane Society, Day Nursery. The township trustee is a source of official relief. The charities of the city are most efficiently administered, as a result of co-operation between organizations largely brought about through the efforts of Rev. Oscar C. McCullouch. In 1894 a plan of relief for the unemployed, whereby over 5,000 people were provided with the necessaries of life throughout winter without pauperizing influences resulting, became widely known as the "Indianapolis Plan of Relief." The plan was devised and carried out on behalf of the people of the city by a Commercial Club committee composed of Hugh H. Hanna, Col. Eli Lilly, and William Fortune.

Education.—There are 60 public school buildings, including 2 high schools, one giving manual training, in which about 700 teachers are employed, with a total enrolment of about 35,000 pupils; 22 Catholic schools, 2 Lutheran schools, 5 private schools and academies, besides the schools in connection with institutions. The University of Indianapolis is an organization formed in 1896 to unite several institutions of the city, including Butler College, first incorporated in 1850 as the Department of Liberal Arts; the Medical College of Indiana, organized in 1869; the Indiana Dental College, organized in 1878, and the Indiana Law School. There are in all five medical schools, prominent among them being the Central College of Physicians and Surgeons, founded in 1879, two dental colleges, a law school, and 21 business, music and other special schools. The United States Arsenal grounds in the city were purchased in 1902 for a technical institute. Free kindergartens are operated under the Free Kindergarten Association, and 23 kindergartens and a normal school are maintained largely from public funds, besides a number of private kindergartens. The Art Association of Indianapolis maintains the John Herron Art Institute, including art gallery, school, and museum. The Propylæum is a building erected by an association composed exclusively of women.

Libraries.—The most notable libraries are the public library with about 100,000 volumes, under

the control of the board of school commissioners, and the State library with about 35,000 volumes. The State law library with 40,000 volumes, and agricultural and horticultural libraries in the State House, and the county library and bar association's library in the court-house may be noted. There are seven branches of the public library, including the newly erected Bona Thompson library of Butler College and many small special libraries of schools and associations.

Newspapers and Literature.— In 1903 the city had 9 daily papers, 23 weeklies, 38 monthlies, and 5 with other periods of issue. The list of trade and class papers published in the city is particularly notable. Indianapolis is the home of many writers whose names are familiar to the public, and it has in recent years become an important western book-publishing centre.

Organizations.— The development of the city has been markedly influenced by organized work in various directions. There are a great number of literary, art, and musical societies, and largely as a result of this activity there is a high standard of cultivation in such matters. This has had a notable influence in establishing in the social life of the city a standard of merit rather than determining the standing of the individual on questions of lineage or wealth. There are many social clubs, among the most notable being the University, Country, Contemporary, and Woodruff Clubs, the Deutsche Haus, the Männerchor, and the Elks, while the Columbia, Marion, and Indiana Clubs are political organizations, established in comfortable homes. The Columbia Club building, located on the Circle, is one of the finest club-houses in the United States. The Commercial Club, with a membership of over 1,000, which owns as its home an eight-story office building, was a dominant force in the new era of progress and development which started in 1890, and devotes itself to the welfare of the city. The Board of Trade, an older organization with a membership of about 500, has also been active in this direction. Organizations of various kinds, commercial, trade, fraternal, social, literary, art, musical, and miscellaneous, number over 500.

Government.— The administrative department is in the hands of a mayor, elected biennially, and of boards appointed by him. The council consists of 15 members elected one from each ward, and 6 members elected at large, with a two-years' term of office. The city clerk and police judge are also elected biennially. The mayor's appointees are the city comptroller, attorney, civil engineer, boards of public works, 3 members of public health and charities, 3 members of public safety, and of commissioners of public parks 4 members. The school system is in charge of a board of 5 school commissioners elected at special elections held for that purpose only.

Population.— Beginning with two or three families in 1819 or 1820, Indianapolis has shown a steady and rapid growth, having a population of 1,085 in 1830; 2,698 in 1840; 8,091 in 1850; 18,611 in 1860; 48,244 in 1870; 75,056 in 1880; 105,436 in 1890; and 169,164 in 1900. Since the last census the increase in population has been still more rapid. The growth of the city has been almost exactly parallel with that of Buffalo, but 20 years behind, and the parallelism promises to continue. In 1890 Indianapolis was 26th in population, and in 1900 it was 21st in the United States.

History.— The first settler, George Pogue, arrived in March of 1819 or 1820. The legislature of Indiana, meeting at Corydon, by committee selected, in 1820, the site for a State capital, and named it Indianapolis, 6 Jan. 1821. Another committee laid out the plat. Lots were slowly sold for several years, and the government was actually removed to the new capital in 1824, the first session of the legislature being held there in 1825. The first State House, modeled after the Parthenon, was completed in 1835. A town government was instituted in 1832 under three trustees, a town council was established in 1838, and a city government under mayor and council in 1847. The present metropolitan form of government, with the mayor as the responsible administrative officer and the council as the legislative branch, was adopted in 1891. A volunteer fire department was formed in 1826, which had much help from the State when the capitol building was completed. The first fire chief was appointed in 1853, and the department was changed to a corps of paid men in 1859. The police department was first established in 1854. The new town began to support a newspaper in January 1822, and a church in 1823. The first railroad reached the city in 1847, and several others were completed in the next four years. Their effect upon the town is seen in the large increase in population. The State capital was the centre of great activity during the War, and there was great expansion in business and manufactures as well as increase in population, most of which was retained. The city did its full share in raising regiments for the War, and is said to have expended a million dollars in contributions, bounties, and war expenses. Camp Morton, on its outskirts, was first a camp for training soldiers, and later for prisoners of war. The free school system now cited as a model by educational experts, was begun in 1853 with the accumulations of several years of special taxation spent in buildings and grounds. The Citizens' Street Railway charter was granted 18 Jan. 1864. The slaughtering and packing business, now so large a factor in the city's trade, began its great expansion in the same year. Public improvements were but few in number until the adoption of the new charter in 1891.

Indianapolis has numbered among her prominent citizens Benjamin Harrison, Thomas A. Hendricks, and others high in the affairs of the national government.

WILLIAM FORTUNE,
Prest. Municipal Engineering Co., Indianapolis.

Indiano'la, Iowa, city and county-seat of Warren County, 18 miles south of Des Moines, on the Chicago, B. & Q. and the Chicago R. I. & P. R.R.'s. There is a large and increasing trade here in grain, butter, eggs, fruit, live stock and garden products. Here is the seat of the Simpson Methodist Episcopal College, founded in 1867. The electric light plant is owned by the city. Pop. (1890) 2,254; (1900) 3,261.

Indians, American. Columbus, when he discovered America, believed he had reached a part of Asia, or of India, and in a letter of February 1493 wrote of "the *Indians* (in Spanish, *Indios*) I have with me." Thus the aborigines of the New World came to be called "Indians" (French *Indiens,* German *Indianer,*

etc.), or, to avoid confusion with the natives of India, "American Indians," for which rather cumbrous term the word "Amerinds," susceptible of many modifications by means of prefix and suffix, and easily adaptable to the exigencies of modern European and other civilized languages, has been suggested by an eminent American lexicographer and is used more or less by a number of anthropologists and other writers. The word "American," originally applied to the Indians, is still somewhat in use, and Dr. D. G. Brinton styled his comprehensive sketch published in 1891, 'The American Race'; but its employment to designate the white population of the continent seems to bar its ethnological application to the aborigines without some qualifying term. By some writers the Indians are called the "Red Race," and, more popularly, "Redskins" (in French *Peaux-Rouges*, in German *Rothäute*), or "Redmen," terms of no exact somatic significance. A few American, and many European, ethnologists continue to separate the peoples who created the civilizations of Mexico, Central America, Peru, etc., from the Indians, while others exclude the Eskimo, and others, again, the "Mound-Builders." But somatic, cultural, and linguistic evidence justifies the conclusions of Powell and Brinton in using the term "American Indians" to include not only the aborigines now existing, or known to have existed since the discovery, but also all the pre-Columbian peoples of America concerning whom we have little data,—the most divergent are no more than sub-varieties of American man. This unity is the great ethnic phenomenon of American aboriginal history. The study of Indian languages, archæological remains, arts, and industries, games, social and religious institutions, mythology and folk-lore indicates a general psychic unity, while the somatic diversities do not transcend those observable in the other great races of mankind. Whether one investigates, as McGee has so admirably done, the Seri of the Gulf of California, who represent about the lowest type of savage culture on the North American continent, or the Mayas of Yucatan, whose approach to a phonetic system of writing touches the high-water mark of Amerindian achievement, one receives the same impression: that it is a question not of very recent civilized or semi-barbaric intruders from Asia or from Europe, but of a race (whatever their remoter origins may be) who have dwelt for ages in an American environment, which has shaped them into the peoples met with by the whites at the time of the Columbian discovery. The limited effect of the "discovery" of the Norsemen may be held to discount any "discoveries" by Europeans before them; while, on the other hand, the American-Asiatic contact revealed by the investigations of the Jesup North Pacific expedition is as much American as Asiatic, and the "Bering Sea" culture is a local phenomenon no more fundamentally indigenous to the Old World than to the New. The arguments in favor of a trans-Pacific Malayo-Polynesian influence upon primitive America are no stronger than those that can be adduced to support the contrary opinion. The culture of the "Mound-Builders" does not in any way transcend the possibilities of what the American Indian was and is yet capable of, nor is it necessary to assume the presence of foreign culture-elements to explain the civilizations of Mexico, Yucatan, Colombia, and Peru. Since very primitive times America has been essentially the "ethnic island" of Brinton, Keane, and other investigators. The impress of America has been upon the aborigines so long that physically, socially, linguistically they have been "Americanized" in so marked a fashion that their right to be considered one of the "races" of mankind is not to be dismissed without cause. To group them merely as a branch of the Mongolian, or, again, of the Malay "race," is to obscure many points of great importance in the prehistory of America or to ignore them altogether. The American Indian is in too many respects a modified (and anciently so) variety of mankind to be thought of as expressing in any serious degree the type of the Mongolian or the Malay.

Language and Culture.—The ethnic isolation of the American race has already been noticed. The apparent independence of the culture-centres of North and South America is another interesting fact. With the exception of a few possible traces of the presence of tribes of Arawak lineage in ancient Florida and the spread of art-*motifs* of the Caribbean type over a portion of the adjacent Gulf region, no direct evidence of the influence of South America upon North American culture is forthcoming. The independent origin of Mexican and Peruvian civilizations seems certain, and convincing proofs of the community of origin of Peruvian and Chibchan and even of Mexican and Mayan are lacking. The possibility of inter-cultural relations having once existed is, however, not to be denied. The Pacific coast, from the Gulf of California to the Argentine and Chile, has been a nursery of culture just as the Mediterranean area was for the Eurafrican peoples. There has been a Mexico and a "greater Mexico," a Peru and a "greater Peru," while the Mayas and the Chibchas have also had their extensive spheres of influence. To the Pueblo culture north of Mexico corresponds the Calchaqui culture south of Peru. On the northern borders of Mexico still lie the savage Seri and Yaqui, and the culture-areas of Colombia and Peru have also their primitive frontagers,—and this was so in the time of the ancient Montezumas and the Incas. This juxtaposition of civilization and savagery is one of the characteristic facts of American ethnology, as it was once likewise of the history of the Mediterranean area in the Old World. In both areas we meet with a large number of peoples who rose above savagery, but, for some reason or other, failed to develop high stages of culture. That the more material evidences of civilization should be so confined to the Pacific coast is, to some writers, a significant fact suggestive of Asiatic relations; but the intellectual power of such Atlantic peoples as the Iroquois and some of the Muskhogean tribes of North America, and the moderate but distinct progress made by a few of the Brazilian tribes of the Atlantic area relieve us from any such theory, environment, and historical incident in America quite sufficing to account for the phenomena involved. (See Ethnology.) Certain other resemblances and contrasts in the various aspects of aboriginal culture in America merit attention here. At the extreme north of the continent, one stock, the Eskimo, with closely related forms of speech, kindred mythology, and folk-

1. Labrador Eskimo Woman. 2. Mexican of the coast. 3. Mexican of the highlands. 4. Yucatan Indian Woman. 5. Ecuador Indian. 6. Peruvian Indian. 7. Brazilian Indian (Iputrina).
8. Dakota (Sioux) Indian. 9, 10. Apache. 11. Bellacoola (N. W. Coast). 12, 13. Pueblo Indians (New Mexico). 14, 15. Indians of Zapoteca, Mexico. 16. Bororo. 17. Caraiá.
18. Botocudo. 19. Umaua or Omagua (16-19 of Brazil). 20. Araucanian (Chile). 21, 22. Indians of Tierra del Fuego, with a child. 23. Patagonian.

lore, similar customs and social institutions, etc., extends in a narrow line from east to west, even overflowing into Asia, while at the extreme south (much less extensive) the Fuegians, numbering altogether less than 10,000, are divided into three distinct linguistic stocks (Yahgans, Onas, Alikulufs). Eastern and northern North America, and the corresponding regions in South America, are areas of wide distributions of single stocks. The Pacific coast of America, as compared with the Atlantic, is a place where, in diverse spots, languages seem to pullulate. This region (including the narrow limits of Mexico and Central America) contained probably more independent tongues than all the rest of the continent. Indeed, within the present bounds of the State of California alone 22 such tongues are found, with several others in Nevada, and in Prof. Cyrus Thomas' list of the stocks of Mexico and Central America, made in 1902, nearly 30 are recognized.

The multiplicity of languages in primitive America has called forth explanatory theories of various sorts, among them Horatio Hale's suggestion of the origin of linguistic diversity through the spontaneous language activity of the child. As Gatschet has noted, the very existence of such a multitude of tongues all over America is proof that neither in ancient nor in later times has this continent been the scene, on a vast scale, of the suppression and extermination of peoples one by the other, which have been characteristic features of Old World history. In spite of the common belief to the contrary, mutual destruction was probably never so rife as when the coming of the white man introduced new means of warfare, and, crowding the natives for subsistence, led them to attack each other more effectively. The recent studies of Dixon and Kroeber in California have strengthened the view of a certain parallelism of language and culture.

That some culture-elements, however, have spread from tribe to tribe is shown by the distribution of certain inventions discussed by Mason, the northward movement of such plants as maize, the use of tobacco, the transmission of many themes and incidents of myths and legends (as demonstrated by Boas), the modes of occurrence of certain art-forms, etc. Interminglings of culture of a more or less local, though often of an extensive, character, have taken place in the Bering Sea area, in the Columbia River region, in the habitat of the Pueblo Indians of New Mexico and Arizona, in the southeastern part of the United States, in the Isthmian region of Central America, in Ecuador, in the Pampean country of the Argentine, etc.,—larger and more significant intermixtures have, perhaps, taken place in earlier times in Mexico, the Mayan country, Colombia, and Peru. A number of the borrowed culture-elements may be explained as the result of trade and commerce, by means of which useful or artistic objects, food, plants, etc., were easily conveyed long distances under primitive conditions. The widespread custom of adoption would also account for not a few instances of alien culture-grafts. So, too, with the exogamic marriage, when the women are culture-bearers. Where language-mixture has taken place it is more or less easily detectable in most American Indian stocks and tongues. When families of the same stock possess, in the one case (Algonkian) dialects which differ as much as Micmac and Blackfoot, in the other (Iroquoian) as much as Cherokee and Mohawk, we are justified in looking for culture-differences as well in such widely separated peoples. Doubtless the results of careful somatological, sociological, and other investigations of the various tribes of American aborigines will furnish us ultimately with diverse ways of classifying them. At present, however, the most serviceable classification is a linguistic one, the result of the labors of Major J. W. Powell and the Bureau of American Ethnology, supplemented by the work of Dr. D. G. Brinton.

Linguistic Stocks.— The Bureau of American Ethnology has issued the Powell map showing the extent of the 58 linguistic stocks north of the Mexican boundary line; that is, of families or forms of speech, so independent of one another as to be catalogued as distinct stocks; apparently no more closely related than the Aryan and the Semitic families of the Old World. For South America no such authoritative map is extant. The exact number of such linguistic stocks in America has not yet been determined with certainty, but the following list probably represents the best view of the matter to-day:

1. Adaizan (Louisiana)
2. Algonkian (northeast North America)
3. Alikulufan (Tierra del Fuego)
4. Andaquian (Colombia)
5. Aruan (northwest Brazil)
6. Araucanian or Aucan (Chile)
7. Arawakan (Central and N. E. South America)
8. Atacameñan (S. Bolivia)
9. Athapascan (N. W. Canada, etc.)
10. Attacapan (Louisiana)
11. Aymaran (S. Peru, N. Bolivia)
12. Barbacoan (S. Colombia)
13. Beothukan (Newfoundland)
14. Betoyan (Colombia-Venezuela)
15. Caddoan (Texas)
16. Calchaquian or Catamarcñan (N. Bolivia)
17. Canichanan or Canisianan (N. Bolivia)
18. Carajan (S. Brazil)
19. Carihan (N. E. South America)

131. Zapotecan (S. E. Mexico)
132. Zoquean (S. E. Mexico)
133. Zuñian (New Mexico)

Of the stocks enumerated, 51 belong to South America and 56 to North America north of Mexico. The status of investigation is such that the number assigned to South America is approximate only, and may ultimately be considerably increased or reduced. Some stocks, like the Adaizan, Beothukan (exterminated by whites), Chetimachan, and a few of the minor stocks in South America, are extinct or nearly so. A goodly number — including, for example, many of the stocks on the northwest Pacific coast, the Texas-Louisiana country, parts of Central America and the Pacific region of South America — were or are of limited area; others, like the Eskimoan, Athapascan, Algonkian, Siouan, Shoshonean, Arawakan, Cariban, Tupian, etc., are noteworthy by reason of the extent of their domain. Some, like the Kootenay, consist of practically a single language, while others, like the Algonkian, Siouan, Athapascan, Salishan, Aztecan, Mayan, Arawakan, Tupian, Cariban, etc., have developed numerous dialects, sometimes only remotely resembling the mother-tongue. Doubtless, with the perfection of linguistic research, some changes will be made in the list of stocks, or perhaps a method of groups may be devised in which stocks showing certain resemblances other than those of a lexical nature may be classed together. The studies of Dixon and Kroeber indicate the possibility of this for the numerous Californian stocks, and a similar result may be predicted for certain other regions of the continent. As said, all the American Indian stocks are far from being of the same significance, many of them having hardly any historical importance. A few words about some of the most typical and most important must suffice here.

North American Stocks.— The Eskimoan stock is noteworthy by reason of being the first of all the aboriginal peoples of America to be visited by representatives of European culture,— the Norsemen in the 10th century, etc. It is also the only primitive people who, unaided by civilized races, occupy a portion of both hemispheres, for the Eskimo stretch from Labrador to a considerable distance within the borders of northeastern Asia. They illustrate the victory of man over a difficult environment, for they are a merry and sociable people in spite of the inclement and depressing character of their arctic surroundings. They have also a marked sense of humor, as the institution of the nith-song, or settlement of disputes by public judgment of the comparative merits of the two parties in competitive singing, would indicate,— the themes of the singing being the dispute and sarcasm at the expense of the opponent. The Eskimo are also very skilful carvers and engravers of ivory, their spirited drawings of animals, etc., resembling in marked fashion the similar art-products of prehistoric man of the French river-drift, a likeness which has induced some authorities (Dawkins, De Mortillet) to assume a racial connection between these two peoples. Mason has recently suggested that these drawings owe a good deal to the contact with Europeans (introduction of iron tools, etc.), but Boas considers that their close resemblance to the bark and rock piclographs of the Indians forbids the conclusion that these drawings are of other than native origin. The unity of language, and (to a considerable degree) of custom, mythology, etc., among the various Eskimo tribes is remarkable when one remembers the extent of their distribution. The use of the Eskimo dog with the sledge, the kayak, the harpoon, the snow-house (iglu), and the invention of many mechanical devices, show them to be gifted with native intelligence.

The Athapascan stock is notable for the contrasts in culture and diversities of culture-capacity presented by its members. Some of the Athapascan peoples of northwestern Canada and Alaska are among the lowest types of American man, and a few of them have hardly yet come to knowledge of the white man, the advent of the fur-trader being, according to J. M. Bell, a matter of the last two or three years in part of their domain. To this stock belong also the Apaches, once the terror of the civilization of the Southwest, whose depredations, in earlier times, disturbed the peace of the native civilization of Old Mexico. It is fair to say, however, of them that individual Apaches (Dr. Montezuma, for example) shows good capacity for adopting the chief elements of white American culture. Several small tribes of Athapascans are scattered through Washington, Oregon, and California, the most noteworthy being the Hupa, on Trinity River, the "Romans of California," as they have been called. The Navaho, who

THE SNAKE DANCE OF THE MOKI INDIANS.

have assimilated to a considerable extent the culture of the whites, were good agriculturists before the coming of the Spaniards, from whom they adopted the sheep, a fact which modified their environment and their response to it. The contrast between the rude tribes of the "Barren Grounds" of Canada and the Navaho of New Mexico and Arizona is, as Horatio Hale pointed out, one of the most remarkable instances of culture-change by process of environmental variation on record. The recent loan-word *Klondike* comes from an Athapascan dialect.

The Algonkian stock, members of which were found from Labrador to South Carolina, and from the confluence of the Ohio and Mississippi northwesterly to the foot of the Rocky Mountains and the borders of the domain of the Athapascans, are of interest for many reasons. The great area over which they are spread has brought members of this stock into contact with many other Indian peoples,— the Naskopi, Crees, and northern Ojibwa with the Eskimo; the Micmacs with the Eskimo and Beothuk; the Ojibwa and related tribes of New England, New York, and Pennsylvania, the Lenâpé of New Jersey, the Nanticokes, Powhatans, etc., of Maryland, Virginia, and the Carolinas with the Iroquois (who, both north and south, form an *enclave* in the Algonkian territory); the western Ojibwa, etc., with the Siouan tribes in the upper Mississippi region, and in the southern Mississippi country the Illinois and kindred peoples with the Caddoan and other stocks; the Blackfoot in the extreme northwest of the Algonkian area with the Athapascan Sarcees and the Kootenay. The aberrant Cheyennes and Arapaho (recently studied by Kroeber) belong to the Algonkian stock. Another evidence of the importance of this stock is the fact that many other stocks and tribes are known to us by names of Algonkian origin: *Eskimo, Athapascan, Siouan,* and possibly also *Iroquoian* and *Muskhogean; Chipwyan, Assiniboin, Mohawk,* etc. Of all the Indian stocks of North America none have made a greater impression upon the whites (French and English) than the Algonkian. This is seen when we remember that Powhatan and Pocahontas, King Philip, Pontiac, Tecumseh, Black Hawk, etc., the Indians who have appealed most to our historians, novelists, and dramatists, have all been of Algonkian lineage. This stock has also contributed to the vocabulary of spoken and written American-English some 140 words, of which many are hardly felt to be of Indian origin: *Carcajou, Caribou, Caucus, Chipmunk, Hickory, Hominy, Manito, Maskinonge, Menhaden, Moccasin, Moose, Mugwump, Opossum, Pappoose, Pemmican, Persimmon, Powwow, Pung, Raccoon, Sachem, Skunk, Squash, Squaw, Tammany, Terrapin, Toboggan, Tomahawk, Totem, Tump, Tuxedo,* etc. A people who have contributed to such a cosmopolitan tongue as English important words like *Caucus, Mugwump, Tammany,* and *Totem,* deserve more than passing mention. Our civilization owes to them also more material things than these,— tobogganning and lacrosse, canoeing (in large measure) and numerous devices of agricultural and domestic industry adopted by the early colonists from the aborigines. From the Algonkian Indians the whites also learned how to make maple sugar and maple syrup. (See AMERICANS.)

The Iroquoian stocks are famous through the confederacy of the "Five (afterward Six) Nations" and the great "League of the Iroquois" (so sympathetically studied by Morgan). Their physical characteristics at the time of the war of 1861–5 were such that they exceeded the recruits of all other races (white included) in points of excellences demanded by military requirements. The high position occupied by woman among the Iroquois lifts them above many of their Amerindian kindred. The story of the Iroquoian statesman of the 16th century, Hiawatha, and his founding of the League that was to end all war and unite all the nations in one lasting bond of peace is a historical fact, which Longfellow's confusion of the Iroquoian patriot with the Algonkian demi-god Manabozho cannot altogether obscure. In political and social organization the Iroquoian tribes attained a position that was largely *sui generis.* The tale of their long struggle to preserve their independence against the whites will be found in Morgan and Parkman, while the Jesuit Relations contain their reaction to the efforts of the missionaries to convert them to the Christian faith, as well as the account of the fratricidal strife resulting in the extermination of the Hurons. The fame of the Iroquoian tribes (for example, Mohawks) as fierce warriors has caused the general public to neglect them in other respects. Through the researches of Horatio Hale and others it has been shown that the Cherokee of the Carolinas (recently so well investigated by Mooney) belong to the Iroquoian stock, together with several minor tribes in the south Atlantic region. This stock has produced a number of eminent men: Hiawatha (q.v.), Red Jacket (q.v.), Joseph Brant, and Dr. Oronhyatekha (q.v.), the present head of the Independent Order of Foresters; J. N. B. Hewitt, of the Bureau of American Ethnology at Washington, is also of Iroquoian blood. Sequoia, the half-blood Cherokee, who invented the alphabet now in use by his people, deserves mention here likewise. As compared with the prominent part played by them in the French-English and colonial wars, and in the Revolutionary War, War of 1812, etc., the Iroquoian people left little impression upon the culture and the speech of the English in America,— the words from their language which have crept into our own have been originally place-names: *Chautauqua, Concstoga* (horse), *Saratoga* (trunk), etc. To the French of Canada they have given a few more words. In the place-names of the region about lakes Ontario and Erie (Ontario, Niagara, Erie, Cataraqui, Oswego, Cayuga, Seneca, Onondaga, Tuscarora, Oneida, Ticonderoga, Tonawanda, Genesee, Ohio, etc.) the Iroquoian peoples are generously remembered, while their Cherokee kinsmen in the south have likewise left their impress upon the topographical nomenclature of the country. In both New York and Ontario, where considerable numbers of Iroquois still live, with no immediate danger of dying out, but particularly in the latter province on the Grand River Reserve, the pagan and Christianized Iroquois have existed side by side in the same community for so long a time as to make this phenomenon, the details of which have been pointed out by David Boyle, of great value to sociologists. See CANADA, INDIANS OF.

The Muskhogean stock (Choctaws, Chickasaws, Creeks, Seminoles, etc.) as their subsequent career in the "Civilized Nations" of the Indian Territory with the Cherokee has shown, are among the most gifted intellectually of the aborigines of America. Gatschet notes as characteristic of this stock: Their color-symbolism for peace and war, their totemic system, the use of the "black drink," the doctrine of the "Master of Life," sun-worship, mound-building (some regard this stock as having been one of the so-called "Mound-Builders"), the ceremony of the *busk*, etc. This stock has had many intertribal wars, and the Creeks and particularly the Seminoles of Florida are famous for their contests with the whites.

The Siouan stock (Crows, Mandans, Assiniboins, Hidatsa, Sioux, Winnebagos, Omaha, Tutelos, Catawbas, Biloxi, etc.) are noteworthy by reason of their migration from the Atlantic slope in the region of the Carolinas to the trans-Mississippian and Missouri country, where their culture was conditioned by the presence of the buffalo and the adoption (from the whites) of the horse. Their wars with the surrounding tribes, particularly the Algonkian, and their subsequent numerous collisions with the whites (Minnesota massacre of 1862, the troubles in which Sitting Bull figured, etc.), are matter of history. The use of buffalo-skins made it possible for some of the Sioux tribes to develop pictography to a high degree. The researches of J. Owen Dorsey and Miss Alice Fletcher have shown the Omaha in particular to be gifted with a religio-social consciousness of a marked character, reflected in their name-giving and the ceremonies associated with the passage from childhood to manhood, in which individuality is much emphasized. That their capacity for producing men of ability is not confined to those of the primitive type (Sitting Bull) is indicated by the way in which individual members of this stock (Dr. Eastman, La Flesche, the collaborator of Dorsey, etc.) have responded to the stimuli of modern culture. The Dakotan federation is well remembered by the names of the twin States of the Northwest; Minnesota, Nebraska, etc., are terms of Siouan origin; while the minor place-nomenclature of the northwestern States contains a multitude of names from the same source.

The Shahaptian stock is noteworthy on account of the Nez Percés and the famous chief Joseph (still living), one of the most remarkable Indians of any age, whose "retreat" in 1877 has been compared to the celebrated march of the Ten Thousand of old.

The "Pueblos" Indians, as they are called from their village life, have risen in New Mexico and Arizona above the stage of savagery into a state of semi-civilization, representing the triumph of man over the adverse conditions of the desert and the inroads of fierce enemies of the lowest culture. Their relations to the so-called "Cliff-Dwellers" has been the subject of some ethnological speculation. (See PUEBLOS.) The diversity of culture among the Pueblos is not as great as that of speech. Besides the Moqui or Hopi, who belong to the Shoshonian stock, there are found in the Pueblos group three other distinct linguistic stocks,— Keresan, Tañoan and Zuñian. The Pueblos culture has apparently been developed independently in several local centres, and the studies of Bandelier, Hodge, Fewkes, Cushing, etc., have thrown much light on the origins and interrelations of stages of culture largely the reflex of environment.

The Shoshonean or Uto-Aztecan stock offers the most wonderful contrasts in its members of any Amerindian stock. Linguistic and other evidence appears to justify the conclusion that not only certain peoples of the Sonoran country (Cahitas, Coras, Tepehuanas, etc), some of whom achieved a sort of half-civilization in contact with their more cultured neighbors, but the Bannacks, Shoshones, and Utes (even the wretched "Root-diggers") are kith and kin with the ancient Aztecs upon whose civilization Cortes intruded, and the tribes of Nahuatl lineage who carried that culture more or less from central Mexico to beyond Lake Nicaragua. The change from the low type represented by the Utes to the high type of the old Mexicans may have been due in large measure to environment. Intermediate stages are represented by some of the Sonoran tribes. The Mexican or Aztec branch of this stock has furnished to English and other civilized languages a number of interesting and valuable words: *Axolotl, chocolate, coyote, cacao, tomato, ocelot, chilli, copal, chinampa, jalap*, etc. The Moqui group of the Pueblos Indians belong also to the Shoshonean stock.

The Mayan stock (Cakchiquels, Huastecs, Tzotzils, Kekchis, Quiché, Tzendals, Mayas, etc.), creators of the civilization destroyed by the Spaniards in Central America, left, besides graven monuments in large numbers, other evidences of their having invented a system of "writing," which is the nearest approach by any of the aboriginal peoples of America to a phonetic method of record,— the solution of the Mayan hieroglyphics is perhaps *the* question of American archæology. Their calendar-system, nagualism in religion, and the important role of woman in religious and social functions, deserve especial notice. The recent explorations of the Peabody Museum (Cambridge) have resulted in many new discoveries.

Central and South American Stocks.— The Chibchan stock, whose culture varied from that of the savage Aroacos of the mountains of Sta Marta to the civilization of the country about Bogota represent a rise from barbarism independent of that to the south in Peru, etc. There is some reason to believe that the "gold-culture" of the Chiriqui country and allied remains in the same region to the borders of Nicaragua may be due to the Chibchan stock,— the Talamanca, Guaymi, and a few other dialects of Costa Rica, etc., show affinities with Chibchan tongues. Their use and working of gold were of a high order, but neither in architecture nor in pictography could they compare with the Peruvians, the Mexicans, and the Mayas. They had a characteristic hero-legend of Bochica, and a tale of the great flood. The shrine of Lake Guatavita was a famous religious resort. Some of the famous "El Dorados" were in their territory. The Quechuan stock, which is best known through the civilization of the Incas, superimposed upon an older, widespread culture, represents but one phase of higher human activity in the Peruvian area. The extension of Quechuan language especially von Tschudi and Brinton agree in attributing not to the military achievements of this people, which antedated the

A GROUP OF UTE INDIANS.

coming of the Spaniards by only a few centuries, but to intellectual and culture influences millenniums old. The marks of their language can be traced from near the equator on the north to the Pampean tribes on the south. Common in the Peruvian area seem to have been a highly developed agriculture (stimulated, as in the southwestern United States, by the necessity for irrigation and artificial treatment of the soil),—maize, tobacco, potatoes, cotton, etc., the breeding of the llama and the paco, the making of pottery (useful and artistic), metal-working of a fine and ingenious sort, stone architecture more massive and imposing than artistically beautiful, or of the highest order as regards decorative art. The Inca form of government was never probably so far removed from the system common to most of the American stocks as some writers have believed. The Incasic conquest has caused the Peruvians to be styled the "Romans of America," but the analogy is misleading. Beyond the use of picture-writing and the employment of the quipu (knotted colored strings) for purposes of record, the Peruvians had not advanced, and the semi-phonetic system, like that of the Mayas, was not developed by them. Ancestor-worship and sun-worship (state religion) were professed by the Peruvians, but the most far-sighted of their thinkers touched almost upon monotheism. The hero-god of the Peruvians was the sea-born Viracocha, about whom centred a rich and imaginative mythology. The mixture of races in the production of ancient Peruvian culture is indicated by the diversity of cranial type among the skulls from the old burial grounds and mummy-caves. North of the Quechuas, on the coast about Trujillo, were the Yunca-Chimus, etc., whose civilization is represented by the ruins of Gran Chimu and other remains in the valley of Trujillo, which preceded the period of Inca domination. Southeast of the Quechuan culture was that of the Aymaras on the Andean table-lands. To them are usually assigned the ruins of Tiahuanaco, near Lake Titicaca, which in their completeness were probably the most imposing structures raised by the hand of aboriginal man in America,— in architecture they differ in several notable ways from the buildings of Inca origin. Dr. Uhle has very recently sought to show the "succession of cultures" at Pachacamac, Trujillo, and their relations to that of Tiahuanaco. The Peruvian tongues have furnished modern English, etc., many words: *guano, condor, alpaca, pampa, paco, llama, coca, quinine, jerked* (beef), *vicuña*, etc.

In the northern part of the Argentine Republic (Province of Jujuy, etc.) the architectural and archæological remains brought to light by recent investigators (Ambrosetti in particular) indicate the presence of a "civilization,"—village life in a desert environment, offering striking analogies with the culture of the Pueblos Indians of Arizona and New Mexico. This Calchaqui culture is evidently much more than the mere reflex of Quechuan-Aymaran conquest which it was formerly considered to be. Its origin and growth, however, remain to be clearly demonstrated.

The Araucanian stock, whose language has been studied by Lenz, are famous for their long resistance to the Spanish arms (the story of the "conquest" has been written in the last few years by Guevara), part of which gave rise to De Ercilla's epic of 'La Araucana.' To the Araucanian stock belong tribes on both sides of the Chilean Andes and a number of the nomadic peoples of the Pampas, where they seem to be intruders rather than aborigines. Chilean Spanish has borrowed many expressive terms from Araucanian.

The Patagonians, Tzonek, or Tehuelche, famous since the time of Pigafetta as "giants" (many of them exceed six feet and some are said to reach seven). To them belongs the "Setebos" of Shakespeare's 'Tempest.'

The Tapuyan stock of Brazil is looked upon by some authorities as the oldest people of the continent — some would affiliate with them the Fuegians, in this respect — representing a race once inhabiting a great part of South America. The man of the caves of Lagoa Santa and the man of the remarkable *sambaquis* or shell-heaps of the Brazilian coast are by many authorities considered to have related to the Tapuyans. Characteristic modern Tapuyans are the Botocudos, so called from the labret they wear in the lower lip. According to Ehrenreich, some of these ancient men of Brazil show affinities with prehistoric man of eastern Europe.

The Tupian stock (or Tupi-Guaranis, as they are also called), whose language was much used by the missionaries for general intercourse with the natives and is the basis of the *ligoa geral*, or "common language" of the region of the Amazons, were perhaps the highest in culture of the Brazilian tribes, having the elements of agriculture, village life, pottery (well developed and rather artistic), urn-burial, etc., but nothing beyond the Stone Age. Intermixture with both whites and negroes has taken place in the Tupi area, and the rich and imaginative tales of animals, etc., belonging to Tupi mythology have thus been given a wider extension, while negro and white influences have made themselves felt, both on the language and the literature of these people. According to Hartt, the Tupi language has influenced the Portuguese of Brazil quite as much as has the latter the former. Tupi-Guarani speech has furnished to the various European tongues a considerable number of words — to English, *ipecacuanha, jaguar, tapioca, tapir, toucan*, etc.

The Cariban stock were long famous for their cannibalism (the word *cannibal* is a corruption of one of their ethnic names), real and attributive, and their skill in making and using canoes. The shaman, or medicine-man, had great power among them, and they practised the curious and remarkable custom of the *couvade*. Rock-inscriptions and pile-dwellings are found in their territory. Some of them have been reduced to sad straits by the contact of the whites, but some of the Venezuelan tribes of this stock are still good, typical representatives of the American Indian.

The Arawakan stock, through its representatives (the Bahamian Lucayans, the natives of Haiti, Porto Rico, Cuba, etc.), was the first of the aboriginal peoples of the New World (exclusive of Greenland and Labrador) to come into contact with the white race, and likewise the first to come under its devastating influence. Many of the tribes of this stock were of a mild and gentle disposition, good agriculturalists, pottery-makers, workers in stone, wood and gold, and excellent canoe-men (the word canoe comes from an Arawak dialect). They were

users of cotton, and to them we owe the first Indian invention adopted by the whites (*hammock*, both name and thing are Arawak). From the Arawaks, too, the Spaniards first learned the use of tobacco. Like the Caribs they practised the *couvade*. The name of the stock is said to mean "flour-eaters," on account of their use of cassava, which has also passed over to the white. The Arawak and Carib stocks have furnished to English and to the other civilized languages of Europe a large number of important words, the exact ethnic distribution of which is not easy to determine with exactness: *Agouti, anotto* (and French *roucouyenne*), *barbecue, cacique, caiman, cannibal, canoe, cassava, colibri, hammock, hurricane, iguana, macaw, maize, manati, potato, tobacco,* etc. And with these names has gone the use of many of the things indicated and made known for the first time to Europeans. The debt of the Spanish and Portuguese settlers of South America and the West Indies is in these respects very great, for, naturally new fruits, plants, trees, etc., and many of their products came to be known by their aboriginal names or by corruptions of them. Thus a number of "balms" and "balsams" and other medicinal products retain in the pharmacopœia names of American Indian origin — *copaiba, tolu,* etc. Timber-trees, ornamental and dye-woods, have also largely kept their native appellations throughout Central and South America — the list would run into the hundreds. Large also is the catalogue of birds and other animals bearing Indian names.

Original Habitats.— The question of the original habitats of the important aboriginal stocks is one of the most interesting in American ethnology and archæology. The researches of Rink and Boas in particular seem to have demonstrated that the primitive home of the Eskimo was in the region west of Hudson Bay, whence they spread northward and westward to Alaska, etc., and eastward (north and south) to the Arctic islands, Greenland and Labrador. See Eskimos.

The earliest habitat of the Athapascans was in northwestern Canada, to the westward of the home of the Eskimo. From there they migrated over the lake country, across the Rockies to the southward, leaving colonies along the Pacific to northern California, and sending out, through Arizona and New Mexico to the borders of the Nahuatl territory, the important branches of the Apaches and Navaho — the raids of the Apaches often reaching far into Mexico.

The original habitat of the Algonkian stock was, as Brinton and Hale have assumed, "somewhere north of the St. Lawrence and east of Lake Ontario," while that of the Iroquoian lay "between the lower St. Lawrence and Hudson Bay." The final result of the migrations and wars of these two stocks was to leave the Iroquois of the Ontario-Erie country entirely surrounded by Algonkian tribes. From their primitive home the Algonkian sent out numerous branches west, south, southwest, etc., making the extent of territory covered by them very large, and bringing them into immediate contact with many other Indian tribes and with the white settlers over a vast area. The Iroquois (in the Cherokee and the kindred tribes of the south) had branches, which were so separated from their northern kin as to be long taken for non-Iroquoian peoples.

The Muskhogean stock, according to Gatschet, have been from time immemorial inhabitants of the country between the Appalachian Mountains, the Atlantic, the Gulf of Mexico, and the Mississippi. The scene of their earliest development was in the neighborhood of the Mississippi, or possibly even beyond it.

The chief migrations of the Caddoan (Pawnee) peoples have taken place in historical times northward and southward from the Platte River, from which region they expelled in part the Siouan tribes, etc. If their own traditions are reliable, their primitive home lay farther to the south, on the Red River of Louisiana.

The primitive home of the Siouan stock (characteristic Plains Indians since the introduction of the horse) was eastward in the region of the Carolinas. This fact has been revealed by the study of the Tutelo and Catawba languages belonging to this eastern area, and by inspection of the traditions of the various Siouan tribes. The main bodies of Siouan migrants followed the Ohio and the Missouri far to the north and west; the Mandans, Assiniboins, etc., reaching to within the borders of Canada. Other minor bodies traveled to the southwest, their representatives still existing in the Biloxi, etc., of southeastern Mississippi. The Siouan tribes seem to have followed the buffalo in its retreat westward, and their migration from the Carolinas is of considerable sociological interest. At one time their trans-Mississippian habitat included practically all the territory between the Arkansas and the Saskatchewan from the great river to mid-Montana, with the Winnebagoes jutting out on Lake Michigan. Their forays and trade-excursions led some of them from time to time across the Rocky Mountains — the present writer, in 1891, met a friendly party of them far within the Kootenay territory.

The original habitat of the Shoshonean or Uto-Aztecan stock, which embraces the Ute, the Sonoran, and the Aztecan (Nahuatl) peoples, and has representatives from the north of Idaho to the Isthmus of Panama, was probably somewhere in the northwestern section of the United States. The primitive home of the Shoshonean section was "somewhere between the Rocky Mountains and the Great Lakes," and the traditions of the other two branches bring them from the far north, as compared with their present southern abode.

The Mayan stock, creators of the civilization of Central America, according to their own traditions, came from somewhere to the north,— the position of the Huastecan branch of this stock north of Vera Cruz suggests that the Mayan emigrants from the home-land skirted along the Gulf of Mexico from some region considerably to the north.

The Arawakan stock (including the natives of the Bahamas and the Antilles, except the intrusive Caribs) had an extension in South America comparable only to that of the Algonkians and Athapascans in the northern half of the continent,— from the high Paraguay to the Goajiran peninsula in Venezuela, and in its greatest expansion from the Xingù to the Amazon and Orinoco. Its primitive habitat was in some part of the Brazilian interior, probably between the Xingù and the Paraguay, the general trend of their migrations having been northward. The Cariban stock, another very extensive people, who at the time of the Colombian

PICTURE WRITING OF THE OJIBWAY INDIANS.

discovery were to be found in the smaller West Indian islands, and the northern part of the continent from the Essiquibo in Guiana to about the Isthmus of Panama, came originally, as the presence of the Carib Bakairi on the Xingù indicates, from the high interior of Brazil, at the sources of the Xingù and Tapajos.

The Tupian stock were widely extended at the time of the discovery along the Atlantic coast region from the La Plata to the Amazon, with branches scattered along the Paraguay and the Madeira to the foot of the Andes. Their primitive home, Brinton, with reason, assumes to have been in the central highland country to the east of Bolivia. The general direction of the earliest migrations of this stock was therefore southward (down the Paraguay to the Atlantic), after which the Tupi branch followed the coast to the Amazon. The Tapuyan stock, who once occupied the region between the Xingù and the Atlantic coast (from the latter they have been driven by the Tupis), are probably the oldest human residents of part of this area, their tenure of the seacoast reaching far back into prehistoric times.

The Chibchan stock, to which was due the civilization of the Bogota region of Colombia, had their original habitat in the Andean highlands of central or southern Colombia, whence they wandered northwest into the Isthmus of Panama and northeastward up the Magdalena.

The Quechuan stock, authors of the most remarkable of South American civilizations, according to their own traditions spread from vtry small beginnings in the country about Lake Titicaca; but von Tschudi and Brinton, for linguistic reasons chiefly, find the primitive home of this people to have been in the extreme northwest of their characteristic area. The Aymara stock, which some authorities consider to have been a branch of, or perhaps an older member of the Quechuan, had its original habitat to the southeast of the latter. The relation of the Aymaran stock to that which produced the Calchaqui civilization of the northern Argentine is not clear.

Language and Writing.— Although the languages of the American aborigines constitute so many independent families of speech, the vocabularies of which are entirely divergent one from another, nearly all (if not all) of them posseŋs centain general grammatical characteristics which justify us in classing them together as one great group of human tongues. Brinton enumerates as points of resemblance: Development of pronominal forms, fondness for generic particles and for verbs over nouns, and incorporation,— the inclusion of subject or object (or both) in the verb, etc. Most American Indian tongues may be called "holophrastic," from the practice of compressing a whole "sentence" into a "word," the length of which is sometimes very remarkable. As an example may be cited the Micmac Algonkian) *yălcoolemăktâwepokwŏse*, "I am walking about carrying a beautiful black umbrella over my head." This word, according to Rand, is derived from *pokwŏsŏn*, "an umbrella"; *mâktāwāe*, "I am black"; *wolāe*, "I am beautiful"; *yăleā*, "I walk about." From the Kootenay language may be cited: *Nātltlāmkinē*, "he carries the head in his hand" (*n*, verbal particle; *ātl*, "to carry"; *tlām*, composition form of *āaktlām*, "head"; *kin*, "to do anything with the hand"; *inē*, verbal); *hinūpqanāpinē*, "thou seest me" (*hin*, "thou," (subject pronoun); *ūpqa*, "to see"; *āp*, "me" (object pronoun); *inē*, verbal). As typical incorporative languages the Iroquoian and Eskimo may serve. All the incorporative forms of speech in America do not, however, proceed upon identical lines; and some that do incorporate, like Kootenay and Eskimo, often have one or more cases. According to Dixon and Kroeber many Californian languages do not possess the feature of incorporation at all (such are, for example, Maidu, Pomo, Yuki, etc.). As types of incorporating languages less complete than Iroquoian we have Kootenay, Siouan, Aztecan. Some of the Central and South American tongues seem also to have little incorporation. Otomi and Maya appear to be evolving in somewhat the same direction as modern English, away from incorporation and grammatical plethora. Many of the Amerindian tongues are both prefix and suffix languages; others prefer prefixes, others, again, suffixes. Some possess, and some do not, a plural form for nouns; a dual; gender-distinction in pronouns; a high development of demonstratives; reduplication; syntactical cases, etc. A few possess grammatical gender and some exhibit differences in the words used by men and women. In the matter of phonetics the languages of the American aborigines are remarkably divergent, some being extremely harsh, guttural and consonantic, others equally smooth, soft, and vocalic. The absence of certain consonant sounds and the equivalence of certain vowels and consonants characterize some forms of American speech. Euphonic changes are of major or minor importance. Sentence-construction differs greatly in various tongues. The position of the adjective is not always the same. The Haida language has even a distinction like that between our *shall* and *will*. Careful investigation of the many Indian languages, as yet studied imperfectly, if at all, may reveal other interesting linguistic phenomena. How much has been written about and in some of the languages of primitive America may be seen from the bibliographies of Pilling! Our knowledge of them varits from a brief vocabulary of the Esselenian to the exhaustive dictionary of Yahgan compiled by Bridges. The native literature runs from the unrecorded tales of the northernmost Athapascans to the poetry of the ancient Mexicans and Peruvians, some of which has been handed down from pre-Columbian times. The only actually phonetic (syllabic) alphabet now in use among the Indians (except the syllabaries introduced by missionaries among the Athapascans, Crees, etc.) is post-Columbian, — the invention of a half-blood Cherokee. A sort of alphabet has, however, sprung up more recently among the Winnebagos. The development of picture-writing varied very much among the numerous tribes, as may be seen from Mallery's classic study of the subject. Sometimes, as is the case with the Kootenays, ability to draw does not seem to have been accompanied by exuberant pictography. The Walum Olum of the Delawares, the "calendars" of the Kiowa, Sioux, Pima, etc., are special developments of primitive records, the highest form of which is seen in the manuscripts ("books") of the Aztecs and Mayas of a religio-historical character. The pictographic records of the Ojibwa "medicine men" have been studied by

Hoffman, and the rite-literature of the Cherokee by James Mooney. The native literature of primitive America has been the subject of special monographs by Dr. D. G. Brinton. The Spanish-American countries have furnished several writers and investigators of Indian descent.

Religion.— The mythology and religion of the American Indians have received particular treatment at the hands of Müller, Brinton, Powell, etc. Perhaps the most general myth of importance is that of the divine hero, teacher, and civilizer, who after accomplishing his labors, leaves the earth, promising to return at some future time. This myth is found in Mexico (Quetzalcoatl), Yucatan (Kukulkan), Colombia (Bochica), northeast North America (Manabozho, Gluskap, etc.) Somewhat analogous is the myth of the twin reformers of the primitive world among the Pueblo Indians, Navahos, etc. The Iroquoian stock have the myth of the contest of the good and the bad mind. The Algonkians have a myth-cycle of the rabbit, the tribes of the northwest Pacific coast one of the raven and thunder-bird, the Rocky Mountain peoples one of the coyote, the Brazilian Indians one of the jaguar, etc. Some of the tribes are very rich in animal myths and, as Mr. Mooney asserts, the characteristic tales of "an 'Uncle Remus' nature" found among the Cherokee and other peoples have not, as many suppose, been borrowed from the negroes of the South. Even the famous "tar-baby" tales have their independent Amerindian analogues. Flood-legends are widespread in America and vary from the simple, locally colored stories of rude Athapascans to the elaborate conceptions of the civilized peoples of Mexico, Central America, etc. The cardinal points and the number four have developed with many tribes a rich symbolism, with which the chief colors are often connected.

The "medicine men" of the Ojibwa, the Cherokee, the Apache, have been investigated by Hoffman, Mooney, and Bourke, and a large amount of accurate and authentic information concerning shamanism among the Amerindian peoples has been accumulated. The power of the "medicine man" varies much from tribe to tribe,— with some he is a personage of little or no importance; with others he is the controlling influence in secular as well as in religious affairs. The acme of such influence is found among some of the tribes of Guiana and Brazil. These "medicine men" had often their secret societies and "lodges" into which chosen neophytes were admitted with appropriate ceremonies. They had also, with many tribes, the control of the rites to which the youth were subjected at the time of puberty, with others they performed such marriage ceremony as existed. Besides these shamans, there were "prophets" and religious reformers, especially since contact with the whites. The widespread "Ghost Dance," in its more recent outbreaks, has been studied in detail by Mooney. Worthy of note is also the "new religion" of the Iroquois, and the "Shaker" religion of the Indians of Puget Sound. The investigations among the Pawnee by Miss Fletcher and G. A. Dorsey have demonstrated the existence of a relatively high form of primitive religion in a rather unexpected quarter,— their worship of the morning star in connection with agriculture was, however, at one time accompanied by human sacrifice. The mortuary rites of the American Indians, corresponding to diverse ideas of the soul and its future in the other world, varied from simple neglect of the corpse to what is represented in material form by some of the mounds of the Mississippi Valley and the stone tombs of Peru. The mortuary customs of the aborigines of North America have been made the subject of a special monograph by Dr. Yarrow, and the doctrine of "animism" among the South American peoples has been treated at length by Koch. The contemplation of the *totem* (properly Ojibwa *ododema*),— tribal or family mark,— of certain Algonkian tribes has given rise to theories of "totemism," concerning which there is much dispute in the world of science. "Fetishism," as exemplified in the Zuñis, has been investigated with some detail by Cushing. Cannibalism (the word *cannibal* is the corrupted form of a South American tribal name) has been rarer in America than is generally believed. Outside of its occurrence through necessity in ways known to civilized peoples, it was chiefly partial and ceremonial. Epicurean cannibalism flourished along the coast of South America and on some of the Caribbean islands; ritual cannibalism among certain tribes of the northwest Pacific coast, in ancient Mexico, etc. The almost extinct Tonkaways of Texas have the reputation of being the "last of the cannibals," while the Attacapas owe their name to this practice attributed to them by their neighbors. In the legends of the Cree and Ojibwa tribes of the Algonkian stock, a cannibal giant (wendigo) figures, and a horror of human flesh eating is expressed at the present time, whatever may have been the case in the past. From the condition of human bones and other remains in the shell-heaps of various parts of the coast, some authorities have come to the conclusion that cannibalism did exist in prehistoric ages among some of the Indian tribes. Religious ideas approximating to monotheism are attributed by some chroniclers and investigators to some of the more enlightened aboriginal rulers of Mexico and Peru. In these regions of the continent, as also in Central America, architecture and the arts of commemoration and record were at the service of religion. See MYTHOLOGY.

Amusements.— The games of the American aborigines, some of which, like lacrosse, have passed over to their conquerors, are of sociological and religious significance in many instances. Stewart Culin has made a special study of the games of the North American Indians, and rejects the theory favored by Tylor and others, that many of them (for example, Mexican *patolli*), are imports from Asia. The games of the civilized Aztecs seem to be but "higher developments of those of the wilder tribes," and those of the Eskimo are modifications of games found among other aboriginal peoples of America. Among characteristic Amerindian games may be mentioned: The gambling game with sticks, the hoop-and-pole game, the ball-race of the southwestern United States, the ball-games of eastern North America, the woman's game of double ball, foot-races, the snow-snake, etc. Culin holds that back of every game lurks "a ceremony in which the game was once a significant part." The variations in games do not follow linguistic lines. One centre whence games have radiated and where some of their oldest forms are still to be found, is in the southwestern United States, from which their migrations can

be traced north, northeast, east, and south. Interesting modifications arise from conditions of environment.

Arts and Inventions.— The arts and inventions of the American Indians correspond to the extent and variety of their environment. The mass of the inhabitants of the continent at the time of its discovery were hunters and fishers, or agriculturalists of the Stone Age, most of whom had some knowledge of pottery-making. The house followed the lines of climate and culture, from the snow *iglu* of the Eskimo and the rude *wickiup* of the Utes to communal houses of the Mohegans, the Iroquian "long-house," phalansteries of the Pueblan and Central American areas, and the stone dwellings of a more or less pretentious sort of the civilized peoples of Mexico, Central America, and Peru. The cavate lodges and cliff-dwellings of Arizona and New Mexico, the wooden (sometimes underground) houses of the northwest Pacific coast, the skin-tents of the plains tribes and the wigwams of the Algonkians, the earth-lodges of the Mandans, etc., correspond to environmental stimuli. A like variation may be seen in the cradles of the American aborigines, studied by Mason, and in their means of transport on the water,— kayaks, "bull-boats," woodskins and balsas, dug-outs, canoes of pine and birch bark, large and small, and of all varieties of design and finish. In North America the Algonkians and Iroquois, and in South America the Indians of the great Brazilian water-ways, have made themselves celebrated for their skill in navigation. So too has the Eskimo with his kayak and the Peruvian with his balsa. The Algonkian Etchemins are literally "the canoe-men." The seagoing canoes of the fishing tribes of the coast of Alaska and British Columbia also deserve mention. On land some of the American Indian tribes have used the dog (Eskimo in particular) and the sled (the Algonkian toboggan, adopted by the whites for amusement purposes, is a special form), while in Peru the llama has been employed for ages for "packing," but not for draft purposes. The use of the horse and the modifications of primitive culture thereby induced in the Indians of the plains of the Missouri-Mississippi valley, the llanos of Venezuela, the pampas of the Argentine, etc., are, of course, post-Columbian. So, too, the influence of sheep culture upon the Navaho and their primitive industries, and of the cow among certain South American tribes. The only animals domesticated by the Indians whose use amounted to a considerable factor in their social and religious life were the dog and the llama, the latter in Peru and Bolivia only. The other half-domesticated animals and birds are of little importance as culture elements. The domesticated dogs of pre-Columbian America represent several diverse species of *Canidæ*. The absence of such domesticated animals as the cow, the horse, the sheep, etc., in pre-Columbian America accounts for certain limitations of its culture as compared with that of the Old World. Pets, however, bird and beast, were very common, especially in Brazil and Guiana. The disappearance of the wild buffalo and other animals of the chase, since the coming of the whites, has been fateful for some tribes,— the contact with the latter as represented by the various "fur companies," etc., has caused many changes in the life of the aborigines, seldom for the better.

As Mason has pointed out, the Amerindian traps and other devices for the capture of wild animals indicate intellectual skill and marvelous adaptation to the habits and actions of these creatures. The Eskimo harpoon and its appurtenances, the simple and composite bow, the arrow-poisons of some North American and many South American peoples, the manufactures of obsidian and jade in ancient Mexico, cotton weaving and dyeing in the more southern regions, maguey-paper making in Mexico and Central America, stone carving (from Mexico to the Argentine), feather-work (in the southern United States, Mexico, Central America, and parts of South America), gold working (in the Isthmian region, Colombia, etc.), the hammocks of the Venezuelan tribes, the fish-poisoning devices of many peoples of South America in particular, the fine pottery of many regions of the continent, the *quipus* or knotted record-strings of the ancient Peruvians, the primitive drum-telephone of certain Brazilian Indians, the blow-gun (southeast United States and South America), cassava preparation (northern South America), the bolas of the Pampean tribes, etc., represent the diversity of invention and manufacturing skill among the American aborigines. The lamp of the Eskimo and some of the Indian tribes of northwestern North America is *sui generis* (its importance has been emphasized by Hough). Methods of computing time, season, etc., vary from the slanting stick of the Algonkian Naskopi to the elaborate calendar systems of Mexico and Central America. Of musical instruments, the drum, the flute, the pan-pipe, and the "musical bow" were known to the American Indians. Songs and dances to the accompaniment of these were in vogue. Practically all stages of primitive culture were to be found in pre-Columbian America, if we may judge from the tribes now surviving, from the savage Seris to the ancient Mexicans, Mayas, and Peruvians. Moreover, within the bounds of the same linguistic stock, as noted above, there may be found tribes representing a high and a low stage of development; as for example, the Aztecs and the Utes of the Shoshonean stock, the Dogribs and the Navahos of the Athapascan, etc. Some tribes were pre-eminently fishers, others hunters. Many excelled in both, like the Eskimo and some of the peoples of the northwest Pacific coast. Some sort of agriculture was widespread in America — the cultivation of corn, beans, varieties of pumpkin and squash, etc., was known all over eastern North America, and the regions of the southwest, etc.; and typical tropical and semi-tropical and other plants and fruits (potato, tomato, maize, pine-apple, tobacco, varieties of cotton, manioc, sweet-potato, cacao, coca, etc.) were cultivated in the more southern regions of Mexico, Central and South America. The spread of tobacco and maize in North America and of certain other plants in Central and South America indicates agricultural receptiveness on the part of the many tribes concerned. The capacity of the American Indians generally for agriculture has been underrated probably, as both the desert-born cultivation of the Pueblos Indians and the tropically stimulated cultivation of the Indians of South America indicate. The arid regions of the Peruvian coast offer another example of considerably developed agriculture. In America the utilization of the gifts of earth varied from

the seed picking and root digging of the Utes to the market gardens and chinampas of ancient Mexico. How the necessities of agriculture can shape a religious system may be seen from the rites and ceremonies of the Pueblos Indians, the cult of "mother corn," etc. With some tribes tobacco was more or less of a sacred plant, also tht mescal.

Position of Woman.— The relation of women to agriculture gave them a higher standing with certain tribes than would otherwise have been the case. With the Iroquois the position of women was very high and to them was allotted a considerable share in the government, peace negotiations, etc., and female chiefs were by no means unknown,— women were the "mothers of the nation." Among the Mayan peoples of Central America woman's position was also high. Many of the priests were women, and they were also commonly the leaders of their tribes in rebellion against the Spaniards — the most famous was Maria Candelaria, "the American Joan of Arc," who led the insurgent Tzendals in the 18th century. In ancient Mexico and Peru the position of woman was perhaps not quite so high. Among some tribes the position of woman was very low, and her sexual peculiarities added to the disesteem in which she was held, as for example, among the Tacanan Araunas of Bolivia. The Athapascan tribes vary much in their treatment of woman,— with some she is little better than a slave or servant, while with at least one Alaskan people of this stock female chiefs existed at times. The "purification" of women at the period of their menses, and the segregation of girls at the time of puberty, were accompanied with many rites and ceremonies among various tribes from the rude Athapascans to the civilized Aztecs. The curious custom of the *couvade* (imitative child-bed on the part of the husband) prevailed among many Venezuelan, Guianian, and Brazilian peoples. The relations between environment and the share of the sexes in culture has been investigated by Mason; according to whom the zenith of virile Amerindian art is reached in Peru, while in Colombia we find woman as farmer, weaver, and potter. In the Oregon-California region one art, basket-making, reaches its acme of development in the hands of woman. A large female influence in religion is noticeable among the Pueblos Indians. Among some tribes, for example, the Hurons, the weregild for killing a woman was greater than that for a man. Some sort of matriarchal system, with maternal descent, prevailed very commonly in pre-Columbian America; among certain of the Koloschan Indians, for example, a man was considered to be in no sense related to his father, his sole parent being the mother. Besides this extreme form, numerous other varieties occur among the tribes now existing, the system in vogue among the Iroquois, etc., being more complicated and adapted to social needs. The systems of marriage known to the American Indians varied from the absence of any particular rite or ceremony to selection of the wife by the old women of the tribe, as among the Hurons, or the uniting of the couple by the "medicine men." Some of the tribes of the Brazilian forests, ranking very low in culture, are strictly monogamous; while peoples of higher civilization, like the Chibchans, Mexicans, Peruvians, etc., were polygamous or concubinative, or both. Marriage by purchase was found over a large area of America; but here as in other parts of the globe, the "money" received was often rather a compensation to the parents for the loss of their daughter than a real sale of her to a suitor. Divorce, in many forms, is known to the primitive Americans, both by mere word of the husband and according to set forms and rites. Consanguineous marriages were strictly avoided by many tribes; but among a few, such as some of the lowest Athapascans, incest was not condemned. In the matter of the sex-relations, as in many other fields, the American Indians exhibit almost all possible phases from the monogamic chastity of some of the lowest peoples to the unnatural indulgences of the Peruvians. Runaway matches and marriages for love, in spite of the contrary opinion entertained by some authorities, have been by no means uncommon throughout the continent. Suicide on account of unsuccessful wooing by both sexes is also not at all rare. Some peoples, too, have developed love-songs of a romantic order, for example, the *yaraveys* of the Quechuas.

Government.— The systems of government of the American Indians and their tribal organizations range from the simple democracy of the Kootenays and some of the Brazilian Indians to the elaborate state institutions of the ancient Mexicans and Peruvians, which in several respects resembled the corresponding institutions of mediæval Europe or the ancient classic world. The power of the chief, however, seems everywhere to have had limitations, and some tribes distinguished the permanent peace chief and the temporary war-chief. Chiefs were generally elected, either from the body of the tribe or from certain specified families. "Totemism" and secret societies are not found to any extent, if at all, among certain tribes (the Kootenay, for example); while with many of the peoples of the northwest Pacific coast they are perhaps the chief feature of aboriginal society, as Boas has recently shown. Property rights are represented in many stages, from the semi-anarchic Eskimo to the Aztecs of Old Mexico and other peoples of Central and South America. Slavery existed among many tribes, and on the northwest Pacific coast a sort of traffic in human chattels had arisen. See SLAVERY.

Trade and Commerce.— Within the spheres of the culture-centres of Mexico, Central America, Peru, etc., trade and commerce were well developed. The Columbia River region was the scene of a less developed trade; while the southeastern United States, the region of the Great Lakes and country west and south of them, had also their important distributing points. The region of Bering Strait was likewise an Asiatic-American commercial centre.

Education.— With the lower tribes generally, such education as was imparted to the children was given by the father to the boys and by the mother to the girls. Peoples like the Iroquois, the Siouan Omahas, etc., used the instruction of tales, legends, and proverbs. The ancient Aztecs and some of the other semi-civilized peoples of Mexico and Central America had schools for boys and others for girls, in which the duties proper to each sex were taught under the supervision of the priests.

Physical Characteristics.— The physical characteristics of the aborigines of America mingle uniformity with diversity. The skin color, popu-

larly styled "red" or "copper," is designated by Mantegazza, "burnt coffee," and by Brinton "brown of various shades, with an undertone of red." This but varies from rather dark to rather light. Among the lighter tribes have been reckoned the Koloschan Tlinkit, the Bolivian Yurucari, etc., and among the darker the Charmas of the Gran Chaco, the Bolivian Canisianas, and a few other tribes of South and Central America. The hair is generally termed "black," but, as Brinton notes, there is in it "a faint under-color of red," which shows up more in childhood and seems much more prominent with certain tribes than with others. Red hair is known among American Indians, but in some cases (certain South American tribes, for example), its occurrence may be due to infusion of white blood. The eyes of the Indians are, with rare exceptions, dark brown. The stature varies from rather low to rather high, represented on the one hand by some of the shorter Brazilian tribes and on the other by the Patagonian "giants." Among the peoples presenting many individuals of tall stature, may be mentioned the Yumas and Pimas, some of the Muskhogean tribes, some of the Crees, Ojibwa and eastern Algonkians, Pawnees, Iroquois, Siouans, Huaveans, Ramas, some of the Cariban tribes, Yurucari, Cayubabas, Guaycuruans, Patagonians, etc. So far as is known no dwarfish people comparable to the dwarf races of the Old World existed in America, although the skeletons from certain Peruvian tombs prove the existence of a dwarfish element in the general population; and the stature of many individuals among certain Brazilian tribes is so low as to induce some authorities, with Kollmann, to predicate the former existence of a dwarf race. In the relations of trunk and limbs and in the relation of one limb to another many variations occur among the Indians, due to occupation (canoeing, etc.,—and, since the advent of the whites, horse-riding). In primitive America all the chief forms of skull (often with artificial flattening, etc.) are found. Among the dolichocephalic (long-headed) peoples are the Eskimo and Iroquois generally, some of the Muskhogean tribes, Otomis, Aymaras (partly), Tapuyas, and Tupis (largely), etc. Of the brachycephalic (broad-headed) may be mentioned the Araucanians, Caribs, Arawaks, Patagonians, Mayas, many of the tribes of the Pacific coast region of North America, etc. The civilized peoples of Mexico, Central America, and Peru appear to have been of stature below the average and of varied skull form tending to brachycephalic, indicating mixtures of types. In the Columbia River region type-mingling is indicated also by both stature and skull-form. The Peruvian region is another centre of race-mixture, as evidenced by skull-form. The oldest skulls discovered in prehistoric burial-places or in geological *situ* are not distinct from the American types,—the latest found, the "Lansing skull," is quite Indian. The skull capacity of the Indian is below that of the white in general, but many exceptions occur. The brains of the less cultured Indian peoples (Fuegians, Eskimo), show no decided anatomical inferiority to those of civilized Europeans. Great varieties of build and set of body are found among the American Indians, from the half-starved Fuegians to the well-fed and corpulent Iroquois. Small feet and hands are very common. Among many tribes in various parts of the continent handsome men and women of considerable beauty are to be found. In the case of women an admixture of white blood often enhances their beauty.

Race-Fusion.—The intermingling of the American Indians with the intruding white race has been much greater than is generally believed. The extent of this fusion of races varies from certain parts of North America with their classic Pocahontas examples to Uruguay, in South America, where 90 per cent of the population are said to be of mixed blood. The Eskimo of Greenland have intermarried with the whites (Danish fathers, native mothers), so that except in the parts remote from settlements no pure-blood Eskimo exists; and the same is true of a good deal of Labrador, where the contact has been with fishermen of English descent. The Micmac, Abnaki, and related Algonkian tribes of Maine, New Brunswick, etc., have a large admixture of white blood (French fathers, native mothers), and all over Canada and the northwestern United States in the early days of colonization and exploration the French traders, trappers, *voyageurs,* and *coureurs des bois* mingled freely with the native women, particularly those of the various Algonkian peoples of the Great Lakes and the West. The Hudson's Bay Company, by introducing employees of English and Scotch descent into the Canadian Northwest, made possible other *métis,* of which those of Scotch descent on the father's side are said to be healthy and sturdy specimens of humanity, with more than ordinary capacities. As indicated by the present condition of the Iroquois on the reservations in Quebec, Ontario, and New York, some infusion of white blood has taken place from very early times. Here the combination of white mother (often an adopted captive) and native father is more common than is usual in race-mixture. The Cherokee had an admixture of white blood in ante-Revolutionary days, to which Mooney attributes much of their culture-achievement since that time. In Mexico, Central America, and South America generally, as Talcott Williams has very recently noted, the half-breed element is very large indeed, for the native population was never exterminated by the whites as some histories still teach. Of the 40,000,000 inhabitants of South America it has been estimated that less than 10,000,000 can lay any claim to pure white blood. There is reason to believe that the future of some of the South American countries will be as much in the hands of the Indians as in those of the whites. In Mexico, parts of Central America, Colombia, Peru, and Chile, the strain of Indian blood represents able and intellectual aboriginal peoples. In certain parts of South America, and, sporadically in northeastern North America, intermingling of Indians and negroes has occurred, giving rise to the so-called Cafusos, etc., of Brazil, and a few other small groups. The mixture of white-Indian-negro is also found here and there. In some of the Spanish-American countries there is a special vocabulary to designate the numerous degrees of *métissage.* In the Canadian Northwest the half-breeds have taken a prominent part in the development of the country (one noted *métis,* Norquay, was premier of the province of Manitoba), and they are likewise noteworthy in the annals of the northwestern United States. In Mexico and Central America, not alone the *métis* but

the Indians themselves have produced celebrated men. Juarez, the liberator of Mexico, a really great man, was a full-blood Zapotec, and President Barrios of Guatemala a Cakchiquel (Mayan stock).

Treatment by Whites.— The ill treatment of the American Indian by the whites has often been such as to stamp with eternal dishonor the conquering race. Massacres, broken treaties, land-robbing, commercial swindles, etc., mark the path of advancing "civilization," — English, Dutch, French, Portuguese, and Spanish have all been guilty at some time or other. The English in Newfoundland, the Americans in the West, the Castilians in northern Mexico and Yucatan, have exterminated or sought to exterminate whole tribes. We must, however, believe that the accounts of the early chroniclers concerning the "millions" of Indians slaughtered by the Spaniards, were the customary exaggerations of those who sing the victor's deeds. Peru and Mexico, for example, would not contain so many Indians to-day were those stories literally true. Against the centuries of dishonor in the treatment of the Indians by the whites, we may place the efforts of missionaries of all faiths, from the good Las Casas in New Spain to Duncan of Metlakahtla. The Jesuits among the Iroquois and Algonkians in North America, the Moravians among the Eskimo and some of the Algonkians and Iroquois, have all done good work, which only the incapacity or worse of governmental authorities has made null. The missions in California and the "reductions" in various parts of South America (Paraguay in particular) might have succeeded in keeping the Indians gentle and loyal sons of the Church had the good fathers been forever in charge, but the oncome of the more strenuous life of the whites doomed them to helplessness. The story of the Paraguayan experiment is one of the most interesting in the annals of mankind, but also one of the most disheartening. Against such failures a few bright spots may be set, — the Fuegian mission, for example; but even there all is not well. Signs of a better treatment of the Indians still within the borders of the United States are not wanting, and it is to be hoped that the present educational fads with which white children are being experimented upon will be kept far from the Indian schools.

Influence on Civilization.—The contributions of the aborigines of America to the world's stock of civilizing factors and influences are much more numerous and of greater importance than is generally thought. Besides the innumerable place-names in all parts of America of Indian origin, the Algonkian, Peruvian, Brazilian, West Indian, Guianian, Venezuelan, and Mexican words in English, French, Spanish, and Portuguese (whence many of them have spread into all the civilized languages of the world) are able remembrancers of the conquered race. The literature of the Spanish-American countries and of Brazil has been more or less affected by the stimuli of native theme and treatment. Many of the old dances and folk-customs still survive even where Christianity has been at least outwardly accepted and have sometimes been adopted by the descendants of the European colonists. The 'Hiawatha' of Longfellow, and the tales and dramas based upon the deeds, adventures and romantic episodes in the lives of King Philip, Pocahontas, Pontiac, Tecumseh, etc., to say nothing of the novels of Cooper and his successors, indicate that the Aryan mind of the Anglo-Saxon order has found treasure in the Amerindian soil. In Mexico and other parts of Spanish America the cathedrals and other religious edifices, by intention or by happy chance, often occupy sites sacred ages before the Columbian discovery to pagan deities, — so the new religion gathers strength from the old, and the dislocation of faith so common in Protestant countries is avoided to a very large extent. Of more material things, we owe largely to the Indian the paths over which our highways and our railroads run, while many of our cities and towns have only sprung up on the old camp-sites of our predecessors. The great importance of some of these "Indian ways" in the history of the United States has been pointed out by Hulbert. The Indians' knowledge of the great water-ways of the country, of portages and trails through forest and over mountain, has made possible colonization and settlement otherwise utterly out of the question. Indian hunters and fishers, scouts, guides, canoe-men, carriers and packers, in all sections of the American continent, have been indispensable to the progress of white civilization. Nor have Indian slaves and servants been few or without social significance in some quarters; while French, Spanish, and English have at times availed themselves of the services of Indian warriors, — the Iroquois enlisted for the North and some of the Cherokee for the South in the Civil War, and then the government has sometimes set one tribe off against another. In Canada and part of the northwest of the United States, where commingling of the races has taken place, the civilization of the land owes even more to the half-breed, *voyageur, coureur des bois,* etc., than to the Indian himself. (See CANADA.)

Throughout the continent — more especially, however, in parts of South America — devices for hunting and fishing and appliances in woodcraft, primitive agriculture, etc., were transferred to the European colonists during the period of settlement, and many of them are still in active use. Fish-poisoning by narcotics, the use of the blow-gun for killing birds and small animals without damaging the skin, methods of stalking beasts of the chase, certain traps and snares, etc., belong here. In connection with agriculture we have menhaden-manure, guano, etc., the planting of corn and beans or pumpkins together, the burning over of land before tillage, etc. But it is upon the food-supply of the world that the American Indian has exerted the greatest influence. Potatoes (common and sweet, both), maize, and the tomato, now in use by all the civilized world, were first cultivated by him and taken over by the whites after the discovery. Cacao, vanilla, jalap, the kidney bean, several varieties of squash and pumpkin, manioc, Jerusalem artichoke, coca, agave, quinoa, persimmon, and perhaps also the peanut, came to us from the Indians. Maple-sugar and maple-syrup, pemmican, jerked beef, etc., are from a like source. Tobacco, the great narcotic, was one of the first gifts of America to the Old World. Of drinks the American Indian has given us Paraguayan *maté,* "Labrador tea," and several other like concoctions, chocolate, Mexican *pulque,* and a considerable number of other intoxicating beverages from South America.

Many medicines and medicinal plants were made known to the whites by the Indians, and in the era of settlement and colonization the "Indian doctor" (male and female) was not unimportant, — New England, for example, had its "Joe Pye," after whom the "Joe Pye weed" (*Eupatorium purpureum*) is named. The Californian Indians have furnished perhaps the three most important contributions of recent years to the American pharmacopœia. South America, besides numerous locally known remedies, etc., has furnished the world-famous *quinine*, and *ipecacuanha*, while the drugs *cocäine* and *curari* must ultimately be credited to the aborigines of America. Many dye-stuffs and dye-woods were first given to the civilized world by the Indians, both for domestic use and for employment in the larger world of æsthetic manufacture. These dyes range from the poke of northeast North America for dyeing basketry to the famous roucou or anotto of Venezuela, used, among other purposes, for staining cheese. Pottery and other household utensils of Indian manufacture are used throughout Spanish America. The hammock of the Arawak Indians belongs now to all civilized peoples. All that india rubber means, civilization owes to the Indian. Both in small things and in great the American aborigines, through their gifts to the white race, will long be remembered, even if, as some authorities (upon imperfect evidence) believe, they are rapidly passing away. On this point one may cite the remark of Deniker that Humboldt in 1825 estimated the total population of America at 13,000,000 whites, 6,000,000 half-breeds, 6,000,000 negroes, and 9,000,000 Indians, while a computation made in 1895–7 reckoned 80,000,000 whites, 37,000,000 half-breeds, 10,000,000 negroes and 10,000,000 Indians.

There might be mentioned here also the "Chinook Jargon" of the Columbia River region, the "Ligoa Geral" of Brazil, and the minor jargons and trade languages of other sections of the continent, which prove how the Indian has compelled the white man, more or less, to use his language in some form or other for the purposes of friendly or commercial intercourse.

Antiquity of Man in America.— The question of the antiquity of the American Indian culture is difficult to settle satisfactorily. Time must be allowed for the divergence of the original stock into the numerous (more numerous in pre-Columbian eras) tribes and peoples inhabiting America at the time of its discovery, — time for the production of the Eskimo and the Iroquois, the Carib and the Patagonian. Time, again, must be allowed for the development of the Aztec from the primitive Shoshonean, the Mayan from the rude stock of that people, the Chibchan from the savage Bolivian, the Peruvian from the ancient barbarian of equatorial America. Then the civilizations of Mexico, Central America, and South America as such probably took ages to rise and flourish. Town and village life, with all its social and religious implications, the differing architectural monuments of the various centres of American civilization, etc., did not spring up in a day, any more than did the culture of mediæval Europe. The domestication of the dog, the llama, etc., the change of maize, tobacco, the squash, the tomato, the potato, the pineapple, etc., from wild to cultivated plants, require a long lapse of time. Moreover, it is now known that American Indian languages do not now change and have not in the past changed at the fast rate once assigned to them by philologists. So, while one may not believe that America was the original habitat of the human race, he may be certain that very many millenniums have elapsed since the "Red Man" began his career as the autochthone of the New World. There seems every reason to believe that at the close of the Glacial Age man had spread over a considerable portion of both North and South America, and was contemporary with European man of an early epoch. To calculate man's residence in the American environment by years is impossible on present evidence. Dr. Stoll assures us that the linguistic phenomena met with in the Mayan dialects alone require thousands of years for their evolution, and some of the results deduced from the Mayan hieroglyphs by certain investigators imply the existence of civilization of the Central American order for very many millenniums. Perhaps it is fair to say that man has been in America at least 25,000 years and not more than 200,000, and that the civilizations of Mexico, Central America, and South America were probably as long-lived as those of Rome, Greece, etc. They were also in many respects just as typical of human attempt and achievement, for the American Indian was a man as we are men.

Y.); Morgan, 'Houses and House Life of the American Aborigines' (1881, Vol. IV. of Centr. Amer. Ethn.), 'League of the Iroquois' (1902); Müller, 'Amerikanische Urreligionen' (1867); Papers of the Archæological Institute of America, American Series (1890—); Payne, 'History of the New World' (1900); Pilling, 'Proof Sheets of a Bibliography of the Languages of the North American Indians' (1885) — and subsequent special bibliographies — Algonquian, Athapascan, Chinookan, Eskimo,

Iroquoian, Muskhogean, Salishan, Siouan, Wakashan; 'Publications of the Field Museum'; Ratzel, 'History of Mankind' (1898); 'Relations des Pères Jésuites' (1902); 'Reports of Ontario Archæological Museum'; 'Reports of Committee of British Association on Northwestern Tribes of Canada'; 'Reports and Memoirs of Peabody Museum'; Von den Steinen, 'Durch Zentral-Brasilien' (1886); 'Unter den Naturvölkern Zentral-Brasiliens' (1894); Schmidt, 'Die Vorgeschichte Nord-Amerikas' (1894); Thomas, 'American Archæology' (1898); Tooker, 'Algonquian Series' (1901); Winsor, 'Aboriginal America' (1884–9).

The 'Publications of the Bureau of American Ethnology,' embracing original monographs by eminent specialists, are a lasting monument to the founder of the Bureau, the late Maj. J. W. Powell, to whom all students of the aborigines of the New World owe a debt of deepest gratitude. Among workers not connected with the Bureau, the death of D. G. Brinton in 1899 removed perhaps the most gifted and representative Americanist.

ALEXANDER F. CHAMBERLAIN,
Clark University, Worcester, Mass.

Indicator, in steam engineering an instrument invented by James Watt, to record, graphically and automatically, the pressure in an engine cylinder at every point of the stroke. By means of the diagram that the indicator

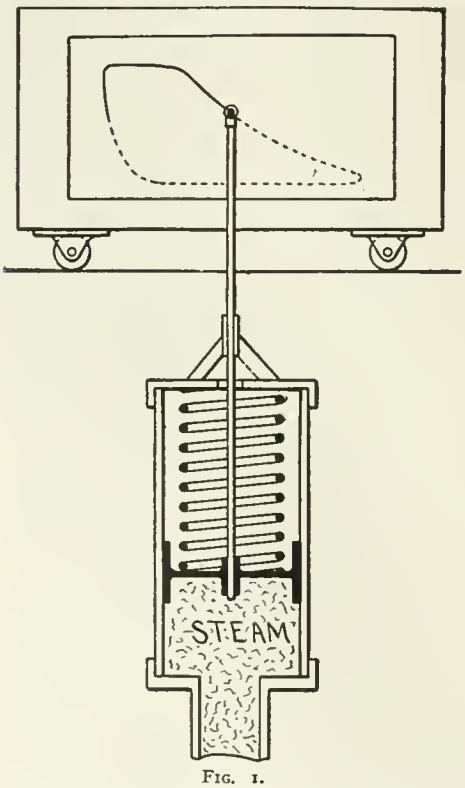

FIG. 1.

draws, it is possible to determine whether the valves of the engine are working correctly or not, and it is also possible to estimate the horsepower that the engine is developing, with considerable accuracy. Commercially, the steam-engine indicator may be had in many forms; but all are based on the same fundamental principle, which will be understood by reference to the diagram presented in Fig 1. The paper upon which the indicator diagram is to be drawn is here supposed to be secured, flat, to a carriage which travels back and forth upon a track; the motion of the carriage corresponding precisely

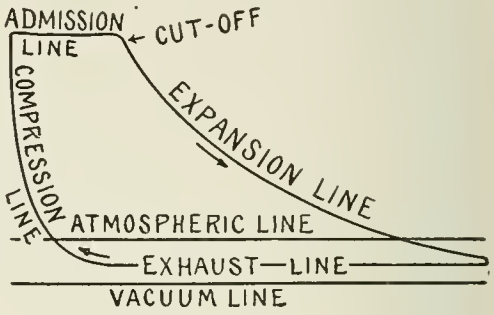

FIG. 2.

to the motion of the piston of the engine. In practice it would be inconvenient to have the carriage travel a distance equal to the whole stroke of the engine, and hence some form of reducing motion is used, so that the motion of the carriage may follow the motion of the engine piston accurately, but with materially reduced velocity. The indicator diagram is draw by means of a pencil-point carried on the piston rod of a small steam cylinder which is situated below the carriage, and which opens freely into the cylinder of the engine from which the diagram is to be taken. The piston of the indicator is pressed downward by means of a spring whose strength is accurately known, so that the increase of pressure corresponding to a rise of one inch in the position of the pencil-point is known. When the indicator is in operation, the pencil rises and falls proportionately to the pressure of the steam in the engine cylinder, and the carriage, with its attached paper, travels back and forth, horizontally, at the same time, keeping pace precisely with the motion of the piston of the engine. Under these circumstances the pencil-point traces a diagram somewhat like that shown in the illustration. In practice, the paper upon which the diagram is drawn is usually wrapped about a cylindrical drum, which rotates back and forth as the instrument works, following the motion of the engine piston just as the carriage here shown is supposed to do. In Fig. 2 an enlarged view of an indicator card (or diagram) is given, together with the technical names of some of its more important parts. The arrows show the direction in which the pencil travels as the diagram is drawn. The «admission line» is the part that is drawn while the engine is in full communication with the boiler, and drawing steam from it. The angle marked «cut-off» corresponds to the moment at which the steam supply is cut off, and the expansion of the steam begins. The «expansion line» is drawn during the expansion of the steam, and on the return stroke, after the exhaust valve has opened, the «exhaust line» is drawn. When the exhaust valve has closed again, the steam remaining in the engine cylin-

der is compressed until the end of the stroke, the indicator meanwhile drawing the "compression line." The "atmospheric line" is the straight, horizontal line drawn by the engine when the connection is broken between the engine cylinder and the indicator cylinder, and the latter is open freely to the air. The "vacuum line" is the line that would be drawn by the instrument under like circumstances, if a perfect vacuum could be maintained in the indicator cylinder. The "vacuum line," of course, must be drawn in by hand. It is parallel to the "atmospheric line," and at a distance below it corresponding to a pressure of about 14.7 pounds per square inch, on the scale to which the diagram is drawn. The diagram shown in Fig. 2 refers to a condensing engine. In a non-condensing engine, the exhaust line would not be lower than the atmospheric line, and would, in fact, be above it, if there were any sensible back-pressure in the engine during exhaust.

For detailed information concerning the indicator and its uses, consult: Pray, 'Twenty Years with the Indicator'; Peabody, 'The Steam Engine Indicator'; also, for less extended treatment, any good book on steam engineering.

Indictment, ĭn-dīt'mĕnt, a formal charge made before a legal tribunal against an accused person. The essential requisites of a valid indictment are,—first, that the indictment be presented to some court having jurisdiction of the offense stated therein; second, that it appear to have been found by the grand jury of the proper county or district; third, that the indictment be found a true bill, and signed by the foreman of the grand jury; fourth, that it be framed with sufficient certainty; for this purpose the charge must contain a certain description of the crime or misdemeanor of which the defendant is accused, and a statement of the facts by which it is constituted, so as to identify the accusation; fifth, the indictment must be in the English language, but if any document in a foreign language, as a libel, be necessarily introduced, it should be set out in the original tongue, and then translated showing its application, 6 Term. 162. The formal requisites of an indictment are, first, that the venue, which at common law should always be laid in the county where the offense has been committed, although the charge be in the nature transitory, as a battery. The venue is stated in the margin thus: "City and County of ——, to wit." Second, the presentment, which must be in the present tense, and is ordinarily expressed in the following formula: "the grand inquest of the State of ——, inquiring for the city and county aforesaid, upon their oaths and affirmations present." Third, the name and addition of the defendant; but in case an error has been made in this respect, it is cured by the plea of the defendant. Fourth, the names of third persons, when they must be necessarily mentioned in the indictment, should be stated with certainty to a common intent, so as sufficiently to inform the defendant who are his accusers. When, however, the names of third persons cannot be ascertained, it is sufficient in some cases, to state "a certain person or persons to the jurors aforesaid unknown." Fifth, the time when the offense was committed should, in general, be stated to be on a specific year and day. In some offenses, as in perjury, the day must be precisely stated, but although it is necessary that a day certain should be laid in the indictment, yet in general the prosecutor may give evidence of an offense committed on any other day previous to the finding of the indictment. Sixth, the offense shall be properly described. This is done by stating the substantial circumstances necessary to show the nature of the crime, and next the formal allegations and terms of art required. As to the substantial circumstances: the whole of the facts of the case necessary to make it appear judicially to the court that the indictors have gone upon sufficient premises, should be set forth; but there should be no unnecessary matter, nor anything which on its face makes the indictment repugnant, inconsistent, or absurd.

According to the rules of pleading in criminal actions at common law there are certain terms of art used, so appropriated by the law to express the precise idea which it entertains of the offense, that no other terms, however synonymous they may seem, are capable of filling the same office; such, for example, as traitorously in treason; feloniously in felony; burglariously in burglary; maim in mayhem, etc. In New York, and in nearly all of the States which have adopted the code system, the common law rules of pleading in criminal actions have either been greatly relaxed or entirely abolished. Many of the statutes of the subject are similar to the New York statute, Code Crim. Pro. § 273, which in substance provides that all common law rules of pleading are abolished, and the forms of pleading prescribed by the code shall be substituted, and § 275 of the same code provides that all an indictment must contain is, the title of the section, specifying the name of the court to which the indictment is presented, and the names of the parties, and a plain and concise statement of the act constituting the crime, without unnecessary repetition. It is also provided in § 283 of the New York Code Crim. Pro. that words used in a statute to define a crime need not be strictly pursued in the indictment; but other words conveying the same meaning may be used.

Indigestion. See Dyspepsia.

In'digo, the name of a genus of plants, and of the blue coloring matter obtained from them. The indigo plants are tall herbs of the pea family, forming the genus *Indigofera,* of which there are several color-yielding species in various warm parts of the world. The one yielding the indigo of commerce, and formerly extensively cultivated, is *I. tinctarium,* which is native to India, grows five feet high, and has bipinnate leaves. The coloring matter most abounds in the leaves, and especially as the time of flowering occurs, and that is the time when the crop is gathered by cutting down the plant, and making immediate use of the green stems or foliage, or by drying them for subsequent treatment. This coloring matter is a chemical substance called *indican,* the glucoside of indoxyl, which is converted by oxidation into indigo. Until the discovery of the sea-route to India the only blue vegetable dye available in Europe was that derived from the woad (q.v.), which was limited and costly; this dye-substance was therefore regarded as one

of the most valuable of new commodities and a large capital was soon embarked in its cultivation in India, Ceylon, China, and other regions, where a profitable industry continued until after the middle of the 19th century. The indigo was obtained by macerating the leaves and stems in vats for several hours. Fermentation arises and the water becomes clear yellow. It is then run off into a lower basin, where it is subjected to incessant agitation and gradually turns green, whereupon the indigo begins to form in flakes and settle. The residuum is then thoroughly boiled, filtered through linen, molded into small cakes and dried. The best quality comes from Bengal and eastern India. Indigo plantations were made with more or less success in Brazil, Central America, and Mexico; and one of the foremost inducements held out to settlers in the southern colonies, from Maryland to Louisiana, was the probability of its successful cultivation there. The experiments never yielded results of much importance, partly because crops of tobacco, cotton, and food-stuffs were more profitable. Since the discovery of cheap methods of forming blue dyes from coal-tar the cultivation of indigo has declined greatly, but still supplies a steady demand from cloth-dyers who wish an imperishable blue of certain tints.

The wild indigo of the United States is any of several species of a closely related genus *Baptisia,* which flourishes especially in the Southern States. The best known is the yellow-flowered false indigo (*B. tinctoria*), or indigo brown, from which country people obtain a blue dye, and a domestic medicine.

Indigo Dyeing.— Before it can be employed in dyeing, the indigo must be brought into solution; and as indigo itself is insoluble, it must be first transformed into a soluble substance, so that it can penetrate the pores of the cloth, where it is subsequently again restored to the form of indigo. To bring the indigo into solution, it is ground up to a soft paste with water, after which it is thrown into vats along with ferrous sulphate, slacked lime, and water. The ferrous sulphate reacts with the lime to form calcium sulphate and ferrous oxid, the latter being immediately oxidized at the expense of part of the oxygen of the indigo, which in its turn is reduced to a substance called indigo-white. This dissolves in the presence of excess of lime, and the fabric to be dyed is dipped into the vat after the liquid in it is clear. On removing the fabric the indigo-white which has penetrated its pores is reoxidized by the air to indigo blue; and by repeating this treatment a shade of blue of any desired depth may be obtained. The dyed fabric is finally passed through dilute acid to remove any adhering lime or ferric oxid. Indigo appears to exist in the plant in the form of a glucoside known as "indican," which has the formula $C_{52}H_{62}N_2O_{34}$, and to be developed from this glucoside in the course of the fermentation by the action of a special bacillus, which closely resembles the bacillus of pneumonia. Indigo is now made artificially, the total production of synthetic indigo being probably about one fourth of the world's consumption. Although artificial indigo-blue appears to have the same chemical formula ($C_{16}H_{10}N_2O_2$) as the natural product, and to be identical with it in every way, it is more expensive than the natural product at the present time. If it could be made more cheaply, it would work as great a revolution in dyeing as did the introduction of alizarin in the place of madder. (See Coal Tar Colors, and the references there given.)

Indigo-bird, a numerous and beautiful North American finch (*Passerina cyanea*), the male of which is dark greenish blue, while the female is grayish brown. They are migratory, but in summer spread over most of the United States, placing their neat nest and unspotted bluish eggs in garden bushes as well as in wild thickets. The male has one of the brightest and most persistent songs of any American bird; and he is easily habituated to captivity.

Indigo-snake. The gopher-snake (q.v.).

In'direct Damages, claims for damages not directly inflicted by the illegal act complained of, but by other causes themselves due to that act. The great historical case is that of the United States claim for many hundreds of millions of dollars' worth of loss, resulting from Great Britain's bad faith or carelessness in letting the Alabama (q.v., and Alabama Claims) escape from her ports to prey on our commerce. It was alleged that aside from the actual loss to our shipping and cargoes, we had been damaged to a far greater extent by the resultant effects, chiefly of three sorts: (1) The prolongation of the Civil War due to the encouragement given to the South and the straitening of the North. (2) The destruction of commercial lines and relations, which took long to recover after the War. (3) The raising of the rates of marine insurance. As these claims exceeded the cost of a war plus the indemnity we should have exacted if victorious, Great Britain refused to consider them; and the commission threw them out altogether as contrary to international law.

In'dium, the name given to a metal discovered by spectroscopic analysis in 1863. The zinc-blende of Freiburg was found by Reich and Richter, after a process of purification, to yield a substance the spectrum of which was different from all known spectra. They hence inferred the existence of a new element. This element has been isolated, but only in small quantities. It is of a silver white color, soft, and marks paper like lead; its specific gravity is 7.421 at 16.8°. The lead indium is related to cadmium and zinc, both of which occur associated with it in nature. The spectrum of indium exhibits two characteristic lines, one violet α and another blue line β; besides these two fainter blue lines are visible if the burner in which the metal is volatilized be fed with hydrogen instead of coal gas.

Individ'ualism is the name often applied to social systems founded on principles opposed to the essential principle of socialism, or to that theory of society which is opposed to state interference in industrial and economic and other relations. In its extreme form it is identical with one phase of anarchism. The word is also applied to social theories involving other and deeper views of individual rights than the mere non-interference referred to above.

Indo-China, the southeastern peninsula of Asia, formerly known as Farther India, including

Anam, Burma, Cambodia, Cochin-China, French Indo-China, Tongking (qq.v.), and other districts.

Indo-Europe'ans, the Aryan race (q.v.). For accounts of the Indo-European languages see ARYAN; INDO-GERMANIC LANGUAGES.

Indo-German'ic Languages, the languages which are ancient and modern varieties of one primeval form of speech, anciently spoken in Central Asia. These languages are sometimes called the Indo-Celtic languages, the Japhetic languages, or more commonly, the Aryan languages. There are three forms of human speech, the monosyllabic, or isolating languages, such as the Chinese, whose words are unchangeable roots, each of which stands separately and is modified by the juxtaposition of other monosyllabic roots; the agglutinating languages, such as the South African, the Japanese, and the American Indian, in which, instead of being isolated, the roots are placed in close association, so as to agglutinate or agglomerate into one word. Some Eskimo words are as long as the longest compound epithet of Aristophanes. The third group are the inflectional languages. The Indo-Germanic languages are inflectional. In these the roots of all words are not necessarily modified, but they may be modified, in order to express certain relations, and the roots are also added to by suffixes and prefixes. The Indo-Germanic languages do not extend over so wide an area as the monosyllabic languages, but are spoken by the most civilized and intellectual peoples of the world. The Indic branches are the ancient Hindu languages, the principal of which is Sanskrit, and the modern Hindu languages. The Iranic or Persian branch includes, Zend, Old Persian, Armenian, Parsee, modern Persian and the dialect spoken by the mountaineers to the northwest of India. The great Hellenic branch was spoken anciently by the inhabitants of Greece, of the west coast of Asia Minor, of the islands of the Ægean, as well as of the south and southwestern coasts of Italy. It is spoken in a modified form in Greece and the Greek islands of to-day. Parallel to the Hellenic is the Italic branch, which includes the primitive Italic languages, Oscan, Etruscan, Umbrian, and Latin, as well as the classic Latin of Virgil and Cicero, which settled into the Italian of Dante and, on being extended over western Europe, grew through many modifications into French, Provençal, Italian, Spanish, Portuguese and Roumanian. Distinct from this branch was the Celtic, which survives to-day in the Welsh and Gaelic dialects. The Teutonic tongues include the Gothic of Ulfilas (4th century A.D.) the Norse languages, the Low German and the High German group. The Sclavonic languages are spoken in Russia and Poland and include the Lithuanian and the Old Prussian. There are several other Indo-Germanic tongues and dialects which philologists have not been able to classify; such are the Etruscan in Europe and certain languages of Asia Minor. Compare: Schleicher, 'Compendium der vergleichenden Grammatik der Indo-Germanischen Sprachen' (1871); Corrsen, 'Ueber Aussprache, Vocalismus, und Betonung der lateinischen Sprache'; and most important Brugmann and Delbrück, 'Grundriss der vergleichenden Grammatik der Indo-Germanischen Sprachen' (1897 *et seq.*).

Induction. It is a familiar fact that an electrified (or magnetized) body causes electrical (or magnetic) disturbances in other bodies in its vicinity, when it is not in direct and visible connection with them, and the process by which these disturbances take place is called "induction." The ultimate mechanism of induction is still somewhat obscure, but something has been learned of its general nature. In the early days of physical science it was believed that bodies can act upon one another even across spaces that are absolutely void, and at the present time it is sometimes convenient to assume them to act in this manner, in forming mathematical equations for the treatment of physical problems. It is no longer believed, however, that this is what actually happens in nature; the phenomena of electric and magnetic induction being now attributed to motions or stresses in the ether which transmits light. (See ETHER.) Newton was of the opinion that induction is an ether-phenomenon, and in the first half of the 19th century Faraday may be said to have established the ether hypothesis upon a substantial experimental foundation. In later years Maxwell developed Faraday's conceptions mathematically, and added much more evidence that was partly theoretical and partly experimental; so that at the present time there are few or no physicists who doubt that induction is a manifestation of some form of activity in the light-bearing ether. Opinion is still divided, however, as to the precise nature of this activity. In fact, we cannot hope to gain any very precise information on this point until much more is known about the constitution of the ether itself.

The charging of a condenser is a phenomenon in electrostatic induction. If the condenser consists of two parallel plates (for example), of a given size and set at a constant distance from each other, and we charge it to a given potential, the quantity of electricity that must be put into it in order to charge it in this manner depends to a considerable extent upon the nature of the dielectric (or insulating material) which separates the plates. If the charge that is required when air is the dielectric is taken as unity, then with plate glass as a dielectric the charge will have to be 8.45 (according to Hopkinson), in order to bring the potential of the condenser up to the same value as before. If the space between the plates is filled with common turpentine, a charge 2.23 times as great as that required with air as the dielectric must be communicated to the condenser. It is evident, from these facts, and from others of the same nature, that electric induction depends, to a large extent at any rate, upon the nature of the medium which separates an electrified body from the other bodies upon which the inductive influence is felt. The constants that are given above are known as the "specific inductive capacities" of the dielectrics to which they refer.

Electrodynamic induction is the basis of practically all of the electrical machinery that has been found serviceable to man. The fundamental fact of electrodynamic induction may be stated as follows: If a closed electrical circuit, such as might be formed by joining the two ends of a copper wire, is placed in a magnetic field, then no current will be produced so long as the circuit is everywhere stationary, and the strength of the magnetic field remains every

where invariable. If the intensity of the magnetic field is increased, a current of electricity will flow around the circuit while the intensity of the magnetism is changing, the intensity of the current being proportional to the rapidity with which the intensity of the magnetism varies. As soon as the magnetism again becomes constant, the current in the circuit ceases. If the intensity of the magnetic field be diminished instead of increased, a current will also be produced in the closed circuit, but it will be opposite in direction to that produced by increasing the magnetic field. Currents produced in this manner are called "induced currents." Instead of varying the magnetic field while the circuit is fixed in position, we may move the circuit about in the magnetic field. If the magnetic field is everywhere uniform in all respects, and the circuit is moved so as to always remain parallel to itself, then no induced current will be produced; but if the circuit is moved from a region where the magnetism is strong to one where it is weak, or *vice versa,* a current will be induced in the circuit, just as if the circuit were kept stationary and the intensity of the magnetism varied. Induced currents are also produced when, instead of being translated from one region to another, the circuit is rotated in a magnetic field, in such a way that the number of lines of magnetic force passing through it is either increased or diminished. In the induction coil the intensity of the magnetic field is varied, while the circuit in which the induced current is to be produced is kept stationary. In dynamos, on the other hand, the magnetic field is maintained sensibly constant, while the circuit in which the induced current is to be produced is rotated or otherwise moved about.

A current moving in a closed circuit produces a magnetic field in the space above it, and this magnetic field, when it varies on account of the variation of the current that produces it, causes the production of induced currents in any closed circuit that may happen to be near. Let us conceive two closed circuits, A and B, to be situated near each other, and let there be a current produced by any means in the circuit A. So long as the current in A is constant, no current will be produced in B; but if the current in A is variable, an induced current will be observed in B, whose intensity depends upon the rate at which the current in A is varying, upon the resistance of the circuit B, and also upon a certain numerical factor, whose value depends upon the sizes and shapes of the two circuits, upon their positions with respect to each other, and upon the nature of the medium (air, oil, or whatever it may be) in which they are placed.

If a pair of circuits, A and B, are near each other, and A is carrying a constant current of intensity C_1, while B is carrying a constant current of intensity C_2, then the displacement of either circuit, relatively to the other, would cause induced currents to flow in both; and hence (in general) neither circuit can be moved without the energy of the system being affected. The difference between the energy of a pair of coils that are near together, and the energy of a similar pair of coils that are conveying identically the same currents but are infinitely remote from each other, is equal to MC_1C_2, where M is a numerical factor whose value depends upon the sizes and shapes of the two circuits, upon their relative positions, and upon the medium in which they are placed. The factor M is called the "coefficient of mutual induction" of the pair of circuits.

The various parts of a single circuit act upon one another inductively, just as separate circuits do; and a circuit that is wound upon a spool, or otherwise coiled so that its parts come near together, possesses greater energy than the same circuit would have, if it was not so coiled. This fact is expressed by saying that every circuit has a certain amount of "self-induction." The energy that a circuit possesses in virtue of its self-induction is proportional to the square of the current that it is carrying, and to a certain numerical constant called the "coefficient of self-induction," whose value depends upon the size and shape of the circuit, and upon the medium in which it is placed. Like the coefficient of mutual induction of a pair of circuits, the coefficient of self-induction of a single circuit can be computed, for certain simple cases, by methods given by Maxwell, in his 'Treatise on Electricity and Magnetism'; but in the general case the computation is exceedingly difficult, and altogether impracticable; so that the values of these coefficients for given circuits are usually determined experimentally, except when a very rough estimate will serve.

The general subject of induction is essentially mathematical in its character, and cannot be properly explained nor understood without the use of the calculus. Consult Nipher, 'Electricity and Magnetism'; Maxwell, 'Treatise on Electricity and Magnetism.' See also the articles ELECTRICITY and MAGNETISM, in this encyclopedia.

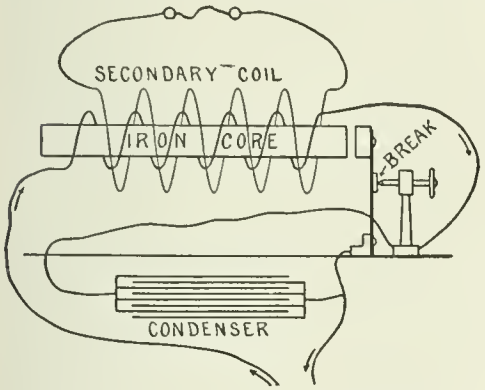
Induction Balance, in physics, an apparatus designed for detecting the presence of fragments of metal, or for studying the electrical conductivity of metals. It consists essentially of four coils of fine wire, an electric battery, a circuit breaker, and a telephone. Let the coils be designated, respectively, by the letters A, B, C and D; A being similar to B in all respects, and C being likewise similar to D. Coils A and B are placed in circuit with the battery, and coils C and D are placed in circuit with the telephone. The coils are disposed in pairs, A being placed near C, and B near D. If the current through A and B is rapidly interrupted, an induced current will, in general, flow through C and D, at each make and break; its presence being indicated by the sounds that it produces in the telephone that is in circuit with C and D. It is possible, however, to dispose the coils and their connections so that the current that A induces in C shall be sensibly equal and opposite to that which B induces in D. When the balance is perfect, no sound will be heard in the telephone. If a piece of metal be now brought near the coil A, the intermittent current in A will induce currents in the mass of the piece of metal, and these, in turn, will act upon the coil C, producing induced currents in this coil which are not compensated by similar currents in D. The loss of balance will be at once indicated by the recurrence of sounds in the telephone; and in this way the metal fragment will betray its presence. The induction balance has been used successfully for locating bullets in the human body. When applied for this purpose to President Garfield, however, it failed to give any useful indications,— owing, it is said, to difficulties of

manipulation due to the presence of metal in the mattress upon which he lay. The instrument is so sensitive that if it is balanced with a genuine coin near one of the coils, and the genuine coin is then replaced by a counterfeit imitation, the telephone at once betrays the substitution. The intensity of the sounds produced in the telephone depends not only upon the size and position of the disturbing piece of metal, but also upon its specific electrical resistance; and hence the balance may be used to compare the specific resistances of metals.

Consult Hopkins, 'Experimental Science'; Thomson, 'Recent Researches in Electricity and Magnetism'; Bell, 'The Induction Balance,' in the American Journal of Science for 1883.

Induction Coil, an electrical instrument used for the production of high potentials, and depending for its action upon the fact that induced currents are generated in a circuit, when the strength of the magnetic field to which the circuit is exposed is varied. (See INDUCTION.) The essential features of the instrument are represented, diagrammatically, in the accompanying cut. A soft iron core is surrounded by two



coils of wire, one outside of the other. The outer coil is the one in which the high tension induced currents are produced: it is called the "secondary coil," and is not in direct electrical connection with any other part of the instrument. The inner coil, which is called the primary coil, is wound close to the iron core, and is connected to a battery, so that when the current from the battery is flowing, the primary coil causes the iron core to become magnetised. As is explained in the article INDUCTION, no current is generated in the secondary coil, so long as the magnetism of the iron core remains constant; but whenever the magnetism of the core increases or diminishes, a current is produced in the secondary. A device called a "break" or "interrupter" is therefore provided, so that the magnetism of the iron core may be rapidly established and destroyed. The commonest form of interrupter is that indicated in the cut, which does not call for special explanation, since it is used in electric bells and other simple forms of electrical apparatus. The Wehnelt electrolytic interrupter is greatly in favor among physicists, however, and is now often used in connection with induction coils, especially when they are to be run with the commercial current used for incandescent lighting, where the potential difference that is used is something over 100 volts. In the Wehnelt interrupter the primary coil on the iron core is made of a few turns of relatively thick copper wire, its purpose being solely to effect the magnetisation of the core; but the secondary coil, in which the induced currents are generated, is made of fine wire, and in order to multiply the inductive effect as far as possible, the secondary is made of great length, often containing many miles of wire. In the celebrated Spottiswoode coil the secondary contained no less than 280 miles of wire. The primary coil, being wound directly upon a soft iron core, commonly has a very considerable amount of self-induction, so that when the circuit is broken by the interrupter the current does not suddenly cease, but continues to flow across the interval at the break for an appreciable fraction of a second, as is readily seen by the strong sparking that occurs at the moment of interruption. In order to reduce the sparking as far as possible, a condenser of suitable capacity is provided, so that when the break is made in the circuit, the "after-current" due to the self-induction of the primary can discharge into the condenser, instead of passing across the break in the circuit and causing a spark. The condenser causes the interruption of the current in the primary coil to be much more sudden, and it materially increases the potential that is developed in the secondary coil, since this is proportional to the rate of variation of the magnetism of the core, and is much greater when the magnetism falls off abruptly than when it persists for an appreciable fraction of a second after the break has been made.

The induction coil was brought into something like its present form by Ruhmkorff, and is frequently known, in consequence, by his name. Improvements in the winding of the secondary coil were introduced by Ritchie, of Boston, about 1857. Ritchie's most important improvement consisted in disposing the secondary wire in sections, which were so related to one another that the risk of internal disruptive discharge through the coil itself might be reduced to a minimum. Induction coils are very generally used in studying the discharge of electricity through gases, for exciting x-ray tubes, and for producing high potentials required in wireless telegraphy. Induction, Mathematical. Despite the age-long tyranny exercised by the Aristotelian logic — a tyranny having, at least in the domain of science, scarcely a match except in the case of Euclid's elements — the forms of thought, those diagrammatic representations of the orderliness of the reasoning processes, sustain to-day perhaps even greater interest than ever before (see SYMBOLIC LOGIC). The mathematician's interest in these forms is two-fold, attaching to them both as norms for testing the validity of arguments and as constituting exceedingly subtle matter for mathematical investigation.

Of all argument forms, there is one which, viewed as the figure of the way in which the mind gains certainty that a specified property belonging but not immediately by definition to each element of a denumerable (see ASSEM-

BLAGE THEORY) assemblage of elements does so belong, enjoys the distinction of being at once perhaps the most fascinating, and, in its mathematical bearings, doubtless the most important, single form in modern logic. This form is that variously known as reasoning by recurrence, induction by connection (De Morgan), mathematical induction, complete induction, and Fermatian induction — so called by C. S. Peirce, according to whom this mode of proof was first employed by Fermat. Whether or not such priority is thus properly ascribed, it is certain that the argument form in question is unknown to the Aristotelian system, for this system allows apodictic certainty in case of deduction only, while it is the distinguishing mark of mathematical induction that it yields such certainty by the reverse process, a movement from the particular to the general, from the *finite* to the *infinite* (see ASSEMBLAGE THEORY).

Of the various designations of this mode of argument, "mathematical induction" is undoubtedly the most appropriate, for, though one may not be able to agree with Poincaré (see *Bibliography* below) that the mode in question is *characteristic* of mathematics, it is peculiar to that science, being indeed, as he has called it, "mathematical reasoning par excellence."

The nature of mathematical induction as it is ordinarily understood may be made clear by an example. Perhaps the simplest application of the method is found in the proof of the theorem:

$$(\alpha) \quad 1+2+3+\ldots\ldots+n=\tfrac{1}{2}n(n+1)$$

where n denotes any positive integer whatever. Suppose it ascertained by observation or otherwise that

$$(1) \quad 1+2=\tfrac{1}{2}2(2+1),$$
$$(2) \quad 1+2+3=\tfrac{1}{2}3(3+1).$$

Facts (1) and (2) justify the *suspicion* that (α) may be a fact. The proof by mathematical induction that (α) is indeed true runs as follows: It is *assumed* that (α) is true for some definite but unspecified integer n. Then by adding $n+1$ to each member of the assumed equation, n having the same meaning as in the assumption, one finds that

$$(\beta) \quad 1+2+3+\ldots\ldots+n+n+1 = \tfrac{1}{2}(n+1)(n+2).$$

So it is seen that, if (α) *be* true for *some* integer n, it *is* true also for the *next* greater integer $n+1$. But by (2), (α) is true when n is 3; it is, therefore, true for $3+1$, or 4; therefore, for $4+1$, or 5. The argument is then usually closed by saying "and so on, hence (α) is true for any integer whatever," or by an equivalent speech. The reader will recall that the binomial theorem, the Newtonian expansion of $(a+b)^n$, where n is any positive integer, is justified in essentially the foregoing manner. Numerous other examples of propositions similarly established may be found in the better recent text-books of algebra.

The nature and the role of the foregoing *etcetera*, "and so on," demand consideration. Without it, the argument as stated seems obviously incomplete. But how is the *etcetera* to be logically justified? By reference to some axiom or principle of thought? If so, what? Or can the phrase be in some way dispensed with without damage to the argument?

Before attempting to answer them it may be well to show the inevitableness of the questions by a further analysis. Suppose it established, in regard to some property p (where, for example, p might signify the validity of the binomial theorem for some integral exponent): (1) that p belongs to the integer 1, that is, referring again to the mentioned example, the theorem is valid for the exponent 1; (2) that, *if* p belong to an integer n, it belongs to $n+1$. Propositions (1) and (2) furnish the means of generating, one after another, a sequence of syllogisms by which one proves first that p belongs to 2, then to 3, then to 4, and so on. Note that in order to ascertain by this analytic (syllogistic) method whether p belongs to a specified integer m, it is necessary to determine in advance the same question for each of the integers 2, 3, ..., $m-1$, in the order as written, a process requiring a number of syllogisms which is greater the greater the number m. Accordingly *this* method, of successive deductions, is not available for determining whether p belongs to each in the (infinite) *totality* of integers. Equally powerless to that end is experience (including observation), for this can take account of the individuals of a finite assemblage of objects at most. Either analysis or experience may avail if a sequence be finite, but if it be infinite both must fail. Not less vain is it to invoke finally the aid of induction as the term is understood and employed in the physical sciences, for this latter, resting upon a purely assumed order in the external universe, is confessedly *inductio imperfecta*, and, being such, can yield approximate certainty only.

Nevertheless, despite the inadequacy of the means mentioned, as soon as hypotheses (1) and (2) are admitted and the indicated sequence of deductions is *begun*, "the judgment imposes itself upon us with irresistible evidence" that p is a property of *all* the integers. Why? That is, how justify the "and so on"? It appears to be clear that the answer must be the adduction or invocation of an additional presupposition of formal thought, a presupposition whose formulation shall mark a conscious extension of the domain of logic by affirming as axiomatic that apodictic certainty can and does transcend every limited sequence of deductions or observations. Such presupposition, which may be called the axiom of infinity, is stated by Poincaré, in answer to the foregoing question, "why," as follows: "It is the affirmation of the power of the mind which knows it is capable of conceiving the indefinite repetition of a same act as soon as this act is found to be once possible." The act or operation, which can not indeed be indefinitely repeated, but which by the axiom can be conceived as so repeated, is, in the present case, the construction of the syllogisms of the sequence above mentioned.

The *etcetera* in question is capable of justification without appealing, apparently at least, to the axiom of infinity, namely, by use of the so-called indirect method of proof, the method known as *reductio ad absurdum*. Thus let it be *supposed* that the argument sought to be indefinitely extended by means of the phrase "and so on" does not admit of indefinite extension along the ordered sequence of integers. There will, then, be a first integer, say $m+1$, for which the property p fails. As, by hypothesis, $m+1$ is the first integer for which p fails, p belongs to the preceding integer m; but

since p belongs to m, it also belongs, by (2), to $m+1$. Hence the supposition that the argument does not admit of indefinite extension is false; and the conclusion is obvious. This procedure is convincing, but it is plainly less a natural completion than an "unindicated" fortification of the process it supplements. It is, besides, not entirely clear that the axiom of infinity is not surreptitiously subsumed by it.

By far the most penetrating investigation of the nature of mathematical induction was made originally by Richard Dedekind (see *Bibliography* below). His procedure and result are, in brief, as follows: Let S denote a system of elements (things of any kind) such that there is a scheme or law ϕ of depiction by which S may be depicted upon itself, that is, a scheme by which each element e of S may be thought as corresponding to one and but one element e' of S and so that no two elements of S shall be thought as corresponding to a same element of S. The correspondent e' of e is called the picture or image of e. Every part of S (including S itself as a special case) thus depicted upon itself is named *chain under* ϕ. Denote by A an arbitrary part of S and by A_0 the assemblage of all the elements common to all the chains (in S) that contain A. It is obvious that, S and ϕ being given, there is one and but one A_0 for a given part A of S. A_0, which is easily seen to be itself a chain, is described as the *chain of* A *under* ϕ. Now let Σ denote an assemblage of elements. Dedekind proves the following

THEOREM.—*In order to prove that* A_0 *is part of* Σ *it is sufficient to prove:* (1) *that* A *is part of* Σ; *and* (2) *that, if an element of* A_0 *belong to* Σ, *the image of that element belongs to* Σ.

Dedekind's proof, simplified, runs thus: Let $A_0 = A_1 + A_2$ where A_1 denotes the assemblage of all those elements of A_0 that belong to Σ. By (2), A_1 is a chain, and, by (1), contains A. Hence, by definition of A_0, A_2 has no element, whence $A_0 \equiv A_1$. Such is the beautiful and marvelously fundamental theorem which its author characterizes, perhaps a little extravagantly, as "the scientific basis" of mathematical induction. It is at any rate a basis, and by virtue of it, as shown below, proof by mathematical induction need have no recourse to an *etcetera* consisting of an endless sequence of syllogisms.

It will be instructive to apply Dedekind's theorem to the *completion* of the proof by mathematical induction of the binomial theorem

$$(\alpha) \quad (a+b)^n = a^n + na^{n-1}b + \cdots\cdots$$

for positive integral exponents. Let it be granted that

$$(\beta) \quad (a+b)^1 = a+b,$$

and supposed it established in the usual way that, (γ), if (α) be valid for some integer, as $n-1$, then it is so for the next, n. Denote by S the sequence of integers,

$$S \equiv 1, 2, 3, \ldots\ldots, n-1, n, \ldots\ldots,$$

by ϕ the scheme by which each number in S except 1 is the image of its predecessor, and let A be 1. Then A_0 is S identically. Let Σ denote the assemblage of positive integers for which (α) is valid. The reader will now observe that Dedekind's theorem enables one to prove by a *single* stroke, so to speak, that (α) is valid for all positive integers. For, by (β), (α) is valid for 1, that is, A is part of Σ and (1) is satisfied; and, as A_0, or 1_0, is S, it follows from (γ) that (2) is satisfied; hence S is part of Σ.

With the modern increasing interest in the philosophy of mathematics, mathematical induction has steadily gained in interest and acknowledged importance. Certain questions respecting its presuppositions and field await definitive answers. It is agreed that every argument by mathematical induction is a mathematical argument, no matter what the subject-matter, but there is difference of opinion as to whether every mathematical argument is mathematical induction either in terms or in disguise. Were this converse true, mathematics (see MATHEMATICS) would be definable in terms of this mode of ratiocination. This and kindred questions are considered in the works cited below.

Adrain Professor of Mathematics, Columbia University.

Indulgence. An indulgence is a partial or total remission by the Church, through an extra-sacramental channel, of the temporal punishment due for sin after its guilt and eternal penalty have been removed by the sacrament of penance. The theological basis upon which the doctrine rests is that all the acts of Christ, the God-Man, were of infinite value, that the acts of the Saints are his acts because vivified by divine grace, and from this treasury of divine, supereminent merit the Church is able, so to speak, to pay the debt of temporal punishment for the repentant sinner.

Certain cardinal principles of Catholic life are requisite to obtain a correct idea of the Catholic doctrine of indulgences. Growth and adaptation have characterized the Christian organism from the Apostolic Council of Jerusalem to the Œcumenical Council of the Vatican. The development of doctrine upon which such explicit emphasis was laid by the late Cardinal Newman, is of prime significance for the student who would institute a comparison between the teaching and practice of the Church in the matter of indulgences at the present day and during apostolic times. We may observe in passing that the principle of doctrinal development is in perfect harmony with the scientific spirit of the present age. Growth and adaptation are now believed to be distinguishing features of every living and progressive organism. We should not, therefore, expect to find the Catholic system of indulgences, in all its complex details, flourishing in the primitive Church. In harmony with the law of development, essential to every organization among men, we believe that the Church's "proud boast of *semper eadem*" is not defeated by calling attention to the richness, variety, and flexibility of the outer forms of its polity and liturgy, or to the varying emphasis given to special dogmas in the course of its history, in response to the needs of particular eras. Unity in diversity is the Church's

most appropriate motto. The doctrine and practice of indulgences, therefore, which obtain throughout the Catholic world at the present time must be sought for only in germ in Sacred Scripture and in the practice of the primitive Church, just as the bole, the branches, and the foliage of an oak tree, "the monarch of the forest," existed potentially in the acorn from which it sprung.

Indulgences being the remission of the temporal punishment due to sin, the interpretation of their true character should start from the Christian idea of the nature and purpose of punishment. It is therefore strange that writers of all schools of opinion concerning indulgences should fail to correlate the two concepts. At the present day the conviction prevails almost universally among non-Catholic students of penology that punishment is exclusively disciplinary and correctional. No theory could be more alien to the spirit of the entire Old Testament or to the mind of the early Christian Fathers. The inflexible and rigorous justice of God making death the wages of sin, appears in almost every page of the history of his covenant with Israel. The New Testament, founded on the atonement by Christ, only mitigates this view by impressing on the minds of men the possibility of vicarious satisfaction for their transgressions. But although Christ's atoning and vicarious sacrifice was all-sufficient in itself, or objectively considered, to satisfy the offended justice of his Heavenly Father, nevertheless the Christian economy of redemption demands each individual's co-operation at every stage in order to appropriate Christ's merits and make them subjective to himself. The opposite view (that is, the belief), that the creature has no active part in his sanctification and salvation, inclines toward Pantheism, robs good works and the Christian sacraments of genuine value, and differentiates the Lutheran from the Catholic position. According to Catholic teaching, the guilt of sin is cleansed from the soul by the application of the merits of the precious blood of Christ through the instrumentality of the Sacraments, whose efficacy, in the case of adults, depends on the subjective disposition of the recipient. The eternal punishment due to sin disappears with the guilt to which it is annexed. But, besides having these supernatural and eternal relations and consequences, sin viewed even within the circumscribed limits of man's natural life on earth, is an act of treason against God in his own kingdom involving forfeiture of all rights to life and all the good things with which God's providence has so bountifully enriched it. This temporal consequence of sin calls for a temporal reparation. The canonical penalties therefore imposed on the Church during the first centuries were intended to pay this temporal debt to the Divine justice, and were not merely disciplinary or correctional; and the sinner, in submitting to them, or in seeking mitigation from them through the intercession of the martyrs, recognized the necessity of his own personal act to satisfy the justice of God, either directly or vicariously by appropriating through the charity of the Church the superabundant merits of Christ and his Saints.

An indulgence granted to the living is an act of jurisdiction, or exercise by the Church of the power of the keys conferred on it in the well-known words of the Gospel of St. Matthew: "And I will give to thee the keys of the Kingdom of Heaven, and whatever thou shalt bind on earth, it shall be bound in Heaven, and whatever thou shalt loose on earth, it shall be loosed in Heaven." Every Church, in so far as it is a visible organization, claims in some degree a power of the keys, that is, the right to admit or exclude members — to determine fellowship. But the antithesis so emphatically expressed in the text between Heaven and Earth proves that the kingdom of Heaven there spoken of is more comprehensive than the visible Church of Christ. It is proclaimed that the power of binding and loosing on earth bestowed upon the apostles and their successors, is ratified in its every act by the supreme tribunal of God in the Church triumphant. In accordance with a well-known principle of Catholic exegesis, the best interpretation of a text of Sacred Scripture is furnished by the universal tradition of the Church from the age of the Apostles to the present time.

St. Paul, in his epistles to the Corinthians, describes how he imposed punishment on the incestuous Corinthian and how he subsequently remitted it. The penalty was not merely an ecclesiastical censure of excommunication inflicted primarily for the purpose of safeguarding the flock of Christ. The Apostle expressly states that the chief motive which actuated him was anxiety for the individual salvation of the transgressor. Nor could it have been (as has been already shown) a mere disciplinary measure to impress upon the sinner the gravity of his crime or to test the sincerity of his repentance. Having no organic relation to confession, whether public or private, and no expressed or implied connection with perfect contrition, it was not a part of any conceivable Christian ordinance for the remission of the guilt and eternal punishment of sin. According to Catholic reasoning, it was therefore an exercise of the power of the keys by the Apostle to remit a temporal debt due to God for the offense; and since, according to universal Jewish and Christian belief, the Divine Justice rigorously demanded either direct or vicarious satisfaction, the Apostle could only concede that "indulgence" by appropriating to the individual sinner the superabundant merits of Christ and the Saints out of the treasury of the Church.

It will be observed that the Apostle of the Gentiles granted the first recorded indulgence in the form of an absolution. Indulgences usually took this form in the primitive Church. The early Fathers frequently refer to their being thus conceded by bishops on the presentation of a "Libellus Supplex" given to the penitent by some Christian martyr on the eve of suffering an heroic death for Christ. It is interesting to note that the present practice of never granting those favors except to persons who are in full communion with the Church, and who have received the Sacrament of Penance, was substantially insisted upon by St. Cyprian. He demands that the martyrs should not grant "Libelli" except to persons who had abandoned their sinful career and given ample evidence of heartfelt contrition and sincere conversion. Indulgences in the first centuries of the Church

having implied a diminution of the period of canonical punishment (the name by which this act of leniency was then known was φλανθρωπια,) (vide Conc. Ancyra, can. 5; Cfr:Hefele, Conciliengeschichte), such expressions as an indulgence of seven years and seven quarantines came into use. An indulgence of seven years means the condonation of as much of the temporal debt due to God for sin as canonical punishment extending over seven years would atone for. Likewise an indulgence of seven quarantines connotes a canonical punishment extending over seven Lents.

We find in the writings of St. Augustine reference to the remission, in return for almsgiving, of temporal penalties imposed for minor ecclesiastical offenses. Thus there gradually grew up the custom of granting indulgences under the form of commutation. Under this form they were especially conspicuous during the period of the Crusades. Every person who confessed his sins in a sincere and contrite spirit, received Holy Communion and joined the Crusade for liberating the holy places from the infidels was declared to need no other penance. "*Iter illud pro omni Poenitentia reputetur*" was one of the decrees of the Council of Clermont, held under Urban II. in the year 1095. The system of commutation for almsgiving afforded opportunity for abuse, as was evident in the practice of "farming out" to laymen the collection of alms in return for indulgence. Thus, for example, in the case of the famous indulgence granted by Leo. X., in 1517, to the Catholic faithful on condition that they would contribute to the completion of St. Peter's basilica in Rome, the right of collecting the money was conferred, in the first instance, on Albert, bishop of Maintz, and then sold by him to an Augsburg banker. Circumstances like these gave occasion to the Protestant party to charge the Church with the "sale of indulgences." Cardinal Pallavicini, the celebrated Jesuit historian of the Council of Trent, does not hesitate to say that if Leo X. had been surrounded by able theologians and enlightened by their counsels he would have proceeded more cautiously in dispensing indulgences. However, it should in justice be recognized that the erection of St. Peter's in Rome, the ancient capital of the Christian world, was an enterprise of the deepest interest to every member of the faithful. Together with the incidental abuses connected with commutations, other circumstances combined to inspire disaffection for the Holy See in the minds of European rulers and their dependents; and, as in the case of every revolution fed by prolonged and deeply-rooted discontent in the minds of those who control public opinion, a spark sufficed to start the conflagration. The life of Luther recently published by the Rev. Heinrich Denifle, O.P., and the abundant controversial literature which it has called forth from the ablest Protestant historians and theologians of Germany, have proved that the first Apostle of the Protestant Reformation was an epoch-maker by reason of conditions, not because he possessed in any high degree the qualities of the *Uebermensch*. Yet the nailing of his ninety-five theses on the doors of the castle church of Wittenburg in protest against the indulgence granted by Leo X., and preached by Tetzel, sub-delegate of Albert, bishop of Maintz, set all Europe aflame and destroyed the dogmatic unity of Catholic christendom.

Opposition to the doctrine of indulgences arose at different times, not because of their alleged novelty or repugnance to the religious sense of the Christian people, but because they did not always approve of the object for which alms were obtained by the preaching of indulgences, or because of the personal defects of those entrusted with their promulgation. It should be distinctly noted that these purposes were not always strictly religious. They were frequently philanthropic, such as the construction of bridges, the erection of hospitals, etc., and in such cases received the unqualified approval of princes and people. In order to comprehend the outburst which Luther was able to evoke against the indulgence granted by Leo X. we must bear in mind, besides the questionable motives that are alleged to have partly inspired the action of that pontiff, also the bitter memories that tarried in the minds of European monarchs after their defeat on the question of investitures, and the death-blow dealt thereby to the feudal system. The entire antipathy aroused, for this and other reasons, against the Holy See in the time of Leo X. found vent in the attack initiated by Luther on indulgences.

An Indulgence may be acquired directly by the living and applied by them, with the consent of the Church, to the souls of the faithful departed. All Catholic theologians are unanimous in the opinion that an indulgence should not be granted without grave and substantial reasons, since the ordinary Christian economy demands that each individual should make personal reparation for the temporal debt due for his sins. Moreover, in order to participate fruitfully in an indulgence, certain conditions and dispositions are necessary on the part of the subject. He must be in the state of grace, have a genuine desire to gain the indulgence, and perform certain acts prescribed by the Holy See.

The application of indulgences to the dead is not a juridical act of the Church, whose jurisdiction is limited to the members of the militant or visible Church on earth. Remission of the temporal debt due to God for sin by the suffering members of Christ's mystical body in Purgatory is communicated to them by the Church by way of suffrage or supplication. In other words, she authorizes the living to join their petitions with hers that God may graciously accept the indulgences which they gain and in the measure in which they gain them, in behalf of the souls of the faithful departed. Indulgences are now dispensed partly by way of absolution and partly by way of commutation. The well-known distinction between partial and plenary indulgences should be understood in an objective sense. The degree in which any indulgence is actually gained or subjectively appropriated by the individual depends on his subjective disposition, according to the theological maxim: whatever is received is received according to the measure of the recipient. The most solemn of all plenary indulgences is that which is granted on the occasion of a jubilee such as that which was proclaimed for 1904 by His Holiness Pius X.

to mark the 50th anniversary of the definition of the Immaculate Conception by Pius IX.

THOS. E. JUDGE, S.T.P.,
Formerly Professor of Mental and Moral Philosophy, St. Patrick's College, Maynooth, Ireland; afterward Professor of Dogmatic Theology in The Saint Paul Seminary, Saint Paul, Minn. Editor of 'The Catholic Review of Reviews.'

Indulgence, Declaration of, the proclamation issued in 1687 by James II. of England by which he sought to relieve his subjects from observing laws opposed to their consciences. As the persons then suffering most from the laws were Roman Catholics, and as the laws would leave them free to worship according to their consciences, the proclamation was opposed by many king's subjects. Seven bishops of the Church of England refused to order their clergy to read the king's proclamation. Charles II. issued two similar indulgences in 1662 and 1672, both of which were unpopular with the people outside the Roman Catholic Church.

In'dus (Sanskrit, *Sindhu*), the chief stream of the northwest of India, and one of the great rivers of the world. It has a length of about 1,900 miles, and drains an area of more than 360,000 square miles. It rises in Tibet on the north of the Himalaya Mountains, nearly 100 miles northwest from the sources of the upper Brahmaputra (q.v.), on the north side of the mountain mass of Kailâs, 18,000 feet above sea-level. In the upper part of its course it takes a northwesterly direction along the northern foot of the main Himalayan range, enters the Kashmir territories, passes through Ladak, below the capital of which, Leh, it receives the Zanskar, farther on the Dras, after which it enters Baltistan. Here it receives, on the right, the Gilgit, from a glacier of the Karakoram, the largest tributary that joins it in the Himalayan regions, and takes the name of Indus or Sind. About 100 miles below this it takes a sudden bend toward the southwest, and after a course of about 180 miles more in this direction it leaves the loftier regions. At the British fortress of Attock in the Panjab — where it is crossed by a great railway bridge carrying the line to Peshawar — it is joined by the Kabul from Afghanistan, and here, 950 feet above the level of the sea, it is nearly 800 feet wide and from 30 to 60 feet deep according to the season. For the rest of its course (about 900 miles) it continues its southwesterly direction till it enters the Indian Ocean. At Kalabagh, 110 miles below Attock, it has a breadth of over 1,400 feet. Arriving in the low-lying country, its waters become charged with mud, and in the rainy season, and by the melting of the snow in the mountains, it overflows its banks. Near Mithankot it receives on the east the Panjnad, or united stream of the Five Rivers of the Panjab. Below the confluence it has a width of over 1,900 yards when the water is low. In Sind it gives off several extensive arms or canals, which are of great value for irrigation; and below Hyderabad it divides into a number of shifting mouths or estuaries, the most navigable of which is at present the Yatho mouth. The delta, formed by the enormous amount of alluvium brought down by the river, has a coast-line of about 130 miles, and the point or head of it at Tatta is 70 miles from the sea. The tide rises to this distance. The Indus loses much water from passing through dry and desert regions, and much is also drawn off for irrigation; accordingly it brings down much less water to the sea than the Ganges. Vessels drawing more than seven feet of water cannot generally enter any of its mouths; but steamers of light draft ascend from Hyderabad to Multan. A railway ascends the valley of the Indus from the important port of Karachi to Peshawar.

Industrial Commission, a non-partisan body authorized by Congress on 18 June 1898, to investigate the subjects of "immigration, labor, agriculture, manufactures, and business" in the United States, with the utmost fairness to both capital and labor, and report to Congress with suggested legislation, as a basis not only for national law and administration, but for uniformity of State laws. It was empowered to administer oaths in order to obtain sworn testimony, and send for persons and papers, as well as (by a supplementary act) to purchase relevant literature up to $1,500 a year. The members were to be five Senators appointed by its president, five Representatives appointed by the Speaker, and nine private gentlemen appointed by the President and Senate, fairly representing different industries and branches of national life. Originally appointed for two years, the term was extended to 15 Dec. 1901, and then to 15 Feb. 1902, the last report being dated the 10th. The actual work was done by the private members, who employed 27 experts on the various lines, and examined nearly 700 witnesses; making a report in 19 volumes, of the highest value from the unmatched thoroughness and authoritativeness of the view on every side of our industrial system brought out, and the competence of the witnesses, who represented all grades, from heads of trusts to presidents of colleges, and from lawyers to heads of trade unions, leaving no field untouched. The commission also digested a vast amount of facts from judicial decisions and official documents. The private commissioners were A. L. Harris, S. N. D. North (successor Albert H. Clarke), Ellison A. Smyth (successor D. A. Tompkins), J. M. Farquhar, E. D. Conger, T. W. Phillips, C. J. Harris, M. D. Ratchford (successor C. H. Litchman), J. L. Kennedy. The experts were on warehouse and grain inspection laws, immigration (two, statistics and labor questions), agriculture (four, distribution, labor, speculation, and taxation), labor organizations, prison labor (two), railroad labor, Asiatic labor, strikes, and arbitration, trusts, transportation (two), railroad legislation, taxation of corporations (two), domestic service, pure-food legislation, mining industries, mining labor legislation, tobacco industries, mechanical progress, besides advisory counsel and expert indexing.

Indus'trial Corporations in the United States, include the large number of trusts, or industrial combinations formed between 1800 and 1903. As the individual or private business firm gradually gave way to the limited partnership, so the limited partnership in turn practically yielded to the general corporate form of doing business, especially in respect to

manufacturing which followed the general tendency of business toward consolidation. This was a natural result of the rapid growth of capital, which consolidated for its own benefit. In this development some of the earlier and larger trusts undoubtedly played a very prominent part, creating a precedent, setting an example, as it were, notably the Standard Oil trust and the Sugar trust, both of which have been in corporate form for some years. They were the pioneers in consolidation of manufacturing interests, but compared with the more recent United States Steel Corporation, with its capital of more than a billion dollars, they are but pigmies. The great majority of these combinations have capitalizations in excess of $5,000,000 each, while only a very few are capitalized at less than $1,000,000. Many of these manufacturing combinations practically control a very large proportion of the entire business of the country in their particular lines and are even extending that control to other countries.

The most notable feature in the increase in the industrial growth of the United States from 1883 to 1903 is in the iron and steel industry, in which the production is nearly six times greater than it was at the beginning of that period. The total quantity of pig iron and steel produced in 1882 was 5,360,015 tons. In 1892 the quantity was 14,084,581 tons, and in 1902 it had increased to 31,255,595 tons. The increase in the production of pig iron in 1892 over 1882 was 98.99 per cent; and in 1902 over 1892 it was 49.18 per cent. The increase in the annual production of steel, however, was much greater in proportion. In 1892 it was 183.38 per cent greater than in 1882, and in 1902 it was 174.34 per cent greater than in 1892. Among the advantages of the corporate form over individual ownership which so largely tend to the advantage of consolidations of capital and the supplying of the demand for greater facilities for its employment in industrial fields is the fact that, while stockholders die, the corporation can go on forever. The ownership of these corporations is divided among hundred of thousands of individual stockholders, who are liable only for the amount of their stock, and which can be transferred without affecting the corporation or its liability and without any trouble. The number of stockholders of four of the largest corporations, for instance — namely, the United States Steel Corporation, the American Sugar Refining Company, the Amalgamated Copper Company and the Standard Oil Company — number about 100,000 persons.

The census of 1900 gave the statistics of industrial corporations (first table below):

In 1902 these figures had materially increased, there being 213 industrial combinations or trusts with a capital of $6,639,019,304, but even these figures are far from the estimates made in 1903 by Moody (Manual of Corporate Securities) who places the total capital at $9,000,000,000, and who states that the railroad consolidations would increase this to $15,000,000,000.

The United States Steel Corporation, the largest of the trusts, and its competition are marvelous examples of the "combination" plan of capital. The following are the figures for 1902 (see second table below):

Industrial Education. — The industrial growth of the country created a demand for higher instruction in commercial subjects which soon led to the establishment of separate institutions devoted exclusively to such instruction. For details see AGRICULTURAL EDUCATION; ARCHITECTURE, EDUCATION IN; COMMERCIAL EDUCATION; CORRESPONDENCE SCHOOLS; EDUCATION: ENGINEERING; INDUSTRIAL; PROFESSIONAL, IN AMERICA; SCIENTIFIC AND TECHNICAL; ENGINEERING, CIVIL; ENGINEERING, MECHANICAL; INDUSTRIAL TERMS; LAW, AMERICAN SCHOOLS OF; MANUAL TRAINING; MEDICAL EDUCATION; PAINTING, EDUCATION IN; SCULPTURE, EDUCATION IN; TECHNICAL EDUCATION; TECHNOLOGY, SCHOOLS OF; TRADE SCHOOLS; ETC.

No. of Co.'s.	Industries	No. of plants controlled	Capital issued	
			Stocks	Bonds
40	Iron and steel companies	489	$763,806,295	$20,614,000
21	Food and allied products	277	277,618,300	12,725,900
14	Chemical products	295	278,357,295	9,294,000
11	Metals other than iron	113	203,505,600	8,565,000
28	Liquors and beverages	258	193,301,158	55,529,142
6	Vehicles (land)	72	189,680,000	10,300,000
4	Tobacco	41	197,184,628	.....
8	Textiles	72	109,514,175	36,944,000
5	Leather	108	184,015,200	13,805,000
7	Paper and printing	119	130,006,500	42,461,217
15	Clay, glass and stone, etc.	203	63,896,858	5,567,500
8	Lumber, etc.	59	39,534,400	275,000
16	Miscellaneous industries	97	238,367,700	332,000
183	Total	2,203	$2,268,788,109	$216,412,759

Summary	Capital Authorized	Capital Outstanding
United States Steel Corporation proper	$1,404,000,000	$1,319,560,000
Underlying securities of 26 controlled properties	90,435,656	68,478,656
Securities of 3 companies controlled in the interest of the United States Steel Corporation	139,250,000	131,250,000
Securities of 4 companies operated in harmony with United States Steel Corporation	118,686,200	86,661,000
Grand total	$1,752,371,856	$1,605,949,856
Securities of 32 of larger competitors of United States Steel Corporation	452,164,600	385,740,100

Industrial Terms. The following list embraces many of the important terms that are used technically in the several commercial industries. Such terms as are usually regarded as self explanatory, as well as those that have no general application, have been omitted. Those that are of more than ordinary importance will be found defined more fully under their appropriate heading.

ABANDONMENT.— A term used in marine insurance to denote that all property saved has been relinquished to the underwriters in order that the insured may claim indemnification for a total loss.

ABB.— In wool-sorting the quality of the wool is denoted by the terms: "fine abb," and "coarse abb."

ABORDAGE.— A term used in marine insurance. If a collision between two vessels happens on the open sea and the damaged ship was insured the persons insuring her must pay the loss, although they are entitled to relief at civil law against the party causing the damage.

ACCEPTANCE.— A term usually used, in marine insurance, in cases of abandonment. It is this process which perfects the rights of the insured in the recovery of his loss.

ACTUARY.— An officer of an insurance company whose skill in the application of the doctrine of chance to financial affairs enables him to make the computations necessary to determine the valuation of contingent liabilities, as shown in the compilation of tables, the computation of risks, etc.

AGREEMENT.— In insurance the contract issued prior to the delivery of the official policy is known as the "agreement."

ANNEALING.— The process of treating substances by heat to remove their brittleness and yet make them tough and inclined to be elastic.

ANNUITY.— A fixed amount paid each year, whether in one sum, or periodically, in installments. When an annuity is continued for a specific number of years it is termed a "certain" annuity. If the period of its continuance is uncertain it is called a "contingent" annuity. When payment has already commenced it is an "annuity in possession," but when such payment does not begin until a specified period has elapsed, or a definite event has taken place it becomes known as a "reversionary" or "deferred" annuity.

AMOUNT OF LOSS.— An insurance term denoting the diminution or destruction of the values of, or of the charge upon, the insured by the direct consequence of the operation of the risk incurred, according to its value in the policy.

ASSESSMENT.— In insurance, an assessment is made (1) as an apportionment in general average upon the articles at risk for contribution for damage and sacrifices purposely made for escape from impending peril, and (2) also upon premium notes given by members of mutual companies as a substitute for the investment of the paid-up stock.

ATICHLOR.— A term used in bleaching to denote the method employed to remove or neutralize the injurious effects of the free chlorine left in some bleached materials.

ARCH.— When a portion of a lode is left standing, in mining, because it is too poor to work or is needed as a support, it is called an "arch."

ASTERISM.— A term in printing, denoting the 3 asterisks sometimes placed before a sentence to call attention to it.

ATTEMPERATION.— Regulating the temperature of the beer-worts in brewing.

ATTENUATION.— The decrease in density of the beer-worts in brewing is termed "attenuation."

AVIVAGE.— A process for clearing and brightening the colors in dyeing.

AVERAGE BOND.— A bond in marine insurance under which the consignees of cargo subject to general average, guarantee payment of their contribution as soon as ascertained in order that their goods may be delivered at once.

BACK.— (a) In metal-mining, the portion of the lode that lies between the level and the one next above it; (b) in coal-mining, the inner end of a heading where work is being conducted; (c) the thickest and best hides are termed "backs" in the leather trade.

BACK-CASING.— A wall of dry brick sunken through sand or gravel in mining.

BACKLASH.— A term denoting the backward suction after an explosion of fire-damp.

BACK-STAY.— In printing, the leather strap used to check the carriage of the press.

BALK.— When a bed of coal suddenly thins out it is termed a "balk."

BAND.— A layer of rock that is interstratified with coal.

BARNEY.— A small car used in mining to push the mine-car up a slope; the pit from which it runs is termed the "barney-pit."

BARRATRY.— In marine insurance, the commission of any fraudulent act in the management of a ship, or its cargo, by which the owners, consignors, or insurers are subject to injury.

BARREL-WORK.— Pieces of native copper too small to be handled as mass-copper, but large enough to be shipped in barrels.

BASTARD.— (a) An impure brown sugar made from the refuse of previous boilings; (b) the large mold into which the sugar is drained is also called a "bastard;" (c) in printing, any type whose face is out of proportion to the size of its body is termed "bastard" type.

BATING.— The process of steeping hides and skins to render them soft and fit for tanning.

BATTERY.— The timber structure that is used to prevent coal from sliding down a shute.

BAY.— In mining, an open space for waste in a long-wall working.

BEAMING.— (a) Winding the warp-yarn on a loom in the manufacture of cloth; (b) working hides with a slicker over a beam in the leather trade.

BEATER.— (a) A machine used in cotton manufacturing to open and clean the cotton before it passes to the carder; (b) a knife used for breaking flax or hemp; (c) the lathe or batten of the loom used in weaving.

BENCHING.— A term applied to the process used in getting the coal after it is holed.

BLACK-LIQUOR.— A crude acetate of iron used, in dyeing, as a mordant.

BLEED.— (a) In bookbinding, to trim the margin too closely; (b) in dyeing, extracting the coloring matter.

BLEU-DE-ROI.— The term used to denote the cobalt-blue color in European porcelain.

BLICK.— The iridescence appearing on gold and silver at the end of the refining process.

BLUE-CAP.— In mining, the bluish or brownish halo which, when it appears around the flame of the safety lamp, indicates a dangerous quantity of fire-damp, is termed the "blue-cap."

BOARDS.— The hard paper-stock inserted between the printed sheets in a press to remove an indentation of impression; often called "press-boards."

BONE.— The term used to define the slaty portions in a coal mine.

BONNET.— The shield used to protect a mine shaft from substance which might otherwise fall into it.

BORDER.— The rim fixed about the bed-plate used in milling to prevent the meal from falling off before it reaches the proper opening.

BRANNING.— A term that is applied both to the process of steeping cloth before or after it is dyed, and to the steeping of skins before tanning.

BROOD.— The term applied in mining to all heterogeneous mixtures found with copper or tin ore.

BRUSH.— An instrument constructed of several small trees, like the birch, and used by farmers instead of a harrow in covering grain, or small seed after sowing.

BUCK.— The breaking of ore into small pieces for jigging.

BUDDLE.— In mining, to wash ore free from earthy matter the water is run over an inclined hutch which is termed a "buddle."

BULLOCKS' HIDES.— The trade name given to the raw hides of cattle.

BULLY-HEAD.— The name by which the sledge-hammer used by miners is popularly known.

BULTOW.— In the fishing industry, the practice of stringing many hooks on one line, used in fishing for cod off the Banks.

BUNCHY.— Used in mining to denote that the ore is irregularly distributed through the lode in small masses, or "pockets."

BUNDLE.— (a) In paper-making, 2 reams of printing, or brown paper; (b) in spinning, 20 hanks, or 6,000 yards of linen yarn.

BUNTONS.— The timbers put across a mining shaft to divide it into compartments.

BUTT.— A hide of sole leather in which the belly and shoulders have been cut off.

CADE.— A term of measurement in the fishing trade, denoting either 500 herrings, or 1,000 sprats.

CAGE-SEAT.— The framework at the bottom of a shaft, so arranged as to reduce the jar when the cage drops upon it.

CALF.— A term applied to a bookbinding in calf-skin. This binding is of several grades: Divinity calf, a dark-brown binding, with blind stamping and no

gilding; half calf, in which the backs and corners only are of calf-skin; mottled calf, a calf binding of pale color in which the decorations have been made by the sprinkling of acid; smooth calf, or plain, undecorative leather; tree calf, a bright, brown calf binding stained by acid to imitate the trunk and branches of a tree.

CANCH.— A term used to denote that part of a floor or roof of a gangway that is removed to equalize the grade because of a fault, or break in the strata.

CANNEL.— A form of weaving that produces a corded or rep tissue.

CAP.— A term denoting certain sizes and shapes in paper: Double cap, 17x28 in.; exchange cap, a fine quality paper, used in printing bills of exchange; flat cap, or full cap, 14x17 in.; foolscap, usually 12x15 in.; legal, or pot cap, 13x16 in., etc.

CARDING.— The disentangling of wool, cotton, or other fibres preparatory to spinning.

CARROT.— In the fur trade, to dress a pelt to preserve it from insects.

CARROTS.— Rolls of tobacco after they have been so prepared that they require only to be ground and sifted to be made into snuff.

CASE.— (a) A shallow wooden tray, the partitions making the small boxes in which the various characters of type required by printers are kept in order for the use of compositors. (b) A book cover that has been made separately from the book for which it is intended.

CASSE-PAPER.— The wrinkled, broken, or otherwise imperfect paper rejected by the trade.

CASSETTE.— The utensil in which chinaware is baked; sometimes called the "coffin."

CAST.— (a) The water used in the preparation of beer. The quantity that is first placed in the mash-tub is termed the "first cast;" that which is subsequently added, the "second cast," "third cast," etc. (b) In bee culture, an after swarm led by a maiden queen.

CERTOSINA WORK.— A term used to denote the inlay of certain light materials — like ivory or satinwood — upon dark woods like walnut.

CHOP.— (a) In milling the product of the first crushing of the wheat; (b) also used to denote the brand and quality of tea imported from China, as "first chop," etc.

CLICKER.— The workman who cuts the uppers and soles for boots and shoes.

CLOG.— The short pieces of timber used in mines to prop the roof.

CLOSING-MACHINE.— (a) A machine that sews heavy cloth or leather with a lock-stitch, alike on both sides; (b) apparatus used in rope-making to twist the already made strands into rope.

COBBING.— In mining, a process of breaking the ore that the better parts may be sorted out.

COCKLE.— (a) A large stove used in the making of porcelain, to dry the biscuit-ware after its glazing preparatory to burning; (b) the kiln used for drying hops.

COLOR.— In gold mining, the particles of gold that are shown when auriferous sand is washed out.

CHASE.— In printing, a square, open framework of iron into which the type forms are fastened to facilitate moving and working on the press.

COMMERCIAL.— A term used to denote the shape and size of paper: Commercial letter, 11x17 in.; unfolded commercial letter, small, 10½x16½ in.; commercial note, 8x10 in., unfolded.

COMPANIONSHIP.— In printing, a number of compositors employed in setting up a quantity of copy under the direction of one leader.

COMPOST.— A mixture of various manuring substances used by agriculturists in fertilizing land.

CONCENTRATOR.— A machine used, chiefly in mining in the United States, to separate the ore from the rock with which it was associated in the lode.

CONSTRUCTIVE TOTAL LOSS.— A term used in marine insurance when the thing insured and damaged, while not entirely a total loss, is so nearly so that it is practically beyond recovery or repair. In such cases a notice of abandonment is served upon the insurers by the owners, after which the "constructive total loss" may be recovered.

CORD.— (a) In fancy weaving, the interval between two vertical lines of the design is termed a "cord;" (b) the same term is used in bookbinding when a book is tied firmly between two boards to assure its drying smoothly. The term "Maitland cord" is used in weaving to denote the cord which extends along the wooden shafts of leaves to which the heddles are secured.

CORDING.— The term denoting the arrangement of the treadles in a loom by which they are made to move in such clusters and time as the production of the pattern may necessitate.

CORE-PIECE.— The yarn running through the centre of a rope to assure its solidity.

CORNER.— The tool used in bookbinding to decorate the corners of a book.

COULH.— (a) The operation, in brewing, of spreading the steeped grain upon the floor to convert it into malt; (b) in paper-making, the act of removing the paper from the mold upon which it has been formed that it may be placed upon the felt.

COUNTER-LODE.— A term used in mining to denote a lode running in such a direction in relation to the main lodes that it crosses or intersects them.

COURSING.— The method of regulating the ventilation of a mine by conducting the air through various doors, stopings, etc.

CRAM.— In weaving, a warp that has more than two threads in each split of the reed.

CRAZING.— In the pottery industry, when the glaze separates from the body and forms blisters.

CREASER.— A tool used in bookbinding to define the width of the bands of a book, and to fix the position of the lines on the backs and sides.

CREEP.— If the pillars of a mine are not sufficiently large, or the roof is not fully supported the pressure of the superincumbent strata sometimes causes an apparent rising of the under-clay. Collieries have been entirely destroyed by these "creep."

CROP.— An untrimmed hide, struck for sole-leather, is termed a "crop," or "crop-hide" in the trade.

CRUTCH.— A term used in soap-making to denote the perforated instrument with which the various ingredients are stirred together.

CUT.— The block upon which a picture is engraved and from which it is impressed in printing.

CUTTER.— Usually applied, in mining, to a joint or crack which crosses a better defined system of cracks in the same rock. In coal-mining "cutting" is the work done in getting the coal into a condition where it may be broken down.

DABBER.— The use of the "dabber" by printers has largely ceased since the introduction of the ink-roller, but the same term is now applied to instruments used by etchers and stereotypers. The former is used to ink the surface of engraved blocks or plates; the latter to dab the back of the damp paper used in the papier-mache process of stereotyping, in order that it may be driven into the interstices of the type.

DARBING.— The term applied to the process in stone-working by which the surface of the stone is covered with small indentations, after having been made uniform.

DAM.— The term applied to the underground wall frequently constructed to hold back water, air, or gas.

DAMPING.— A process used in bleaching to add a certain amount of moisture to a fabric, after it has been starched, that it may be properly finished.

DANDY.— The running-out fire for the melting of pig-iron in tin-plate manufacturing.

DANDY-ROLLER.— The wire-gauze cylinder beneath which the web of water-pulp is passed in paper-making to drain it partially of water.

DASH-WHEEL.— The partially submerged wheel used in cotton manufacturing to wash and rinse calico in the piece.

DECK.— Used in mining to denote the loading or unloading of cars upon the cage.

DECKLE-STRAP.— The contrivance used in paper-making to define the width of the sheet by regulating the flow of pulp.

DECREMENT.— A term used in insurance, usually in the sense of the "equal decrement of life," or the doctrine of annuities upon which assurance companies base their existence. It is the theory that in a given number of lives there should be an equal number of deaths within a given period.

DELE.— A term used in proofreading to direct the compositor or printer to remove a letter, word; or phrase.

DEVIATION.— A term used in marine insurance to denote the voluntary departure of a vessel, without necessity or reasonable cause, from the usual course of the voyage for which she was insured. All unreasonable delays are also involved in the same law, which releases the underwriter from all risks.

DEVIL.— An errand-boy employed in a printing-office.

DIPPING.— A process in ceramics by which a coarse clay body is coated with fine enamel by being plunged into the liquid which constitutes the coating.

DISCHARGE.— The term used in dyeing to denote the process by which white patterns are produced on colored grounds.

DISCOVERY CLAIM.— In mining law, the portion of ground held by reason of the first discovery of its mineral deposits.

DISTRIBUTE.— A term used in printing for the process of returning dead matter (type no longer required)

to the cases; "throw-in" is another term used to define this process.

DOCTOR.— (a) A term in wine-making, used to indicate that the character of the wine has been changed by the addition of another liquor; (b) to alter any commodity for purpose of deception.

DOFF.— A term that has several distinctions in the textile manufacture: (a) The process of stripping the cotton or wool from the cards preparatory to spinning; (b) the act of mending broken threads; (c) the removal of full bobbins to give place to the empty ones.

DOSSIL.— The roll of cloth used to clean the ink from an engraved plate prior to printing.

DOUBLE.— A term used to denote the size and quality of paper: Double medium, a printing paper, 24x38 in.; double royal, a printing paper, 26x40 in.

DOUBLE-DYEING.— A method of dyeing mixed goods by which the wool and cotton are dyed separately with colors that have no affinity for each other.

DOUBLE INSURANCE.— A term used among insurance companies as a synonym for over-insurance. Thus, where divers insurances are made upon the same interests against the same risks in favor of the same assured, in proportions exceeding the value of the subject, the party insured may sue upon all the policies although he is entitled to but one satisfaction.

DOUBLE-MILLED.— A term applied to denote that cloth has been fulled twice to make it finer in quality.

DOUBLER.— (a) A machine for doubling and drawing silk; (b) a still made to intercept and redistill the vapors of distillation; (c) a felting placed between the fabric and the press before printing.

DOWNCAST.— A term used to denote the system of ventilation used in mining, the shaft down which the air passes into the mine being called the "downcast."

DRAFT.— Used in weaving to describe the cording of a loom or the arrangement of the heddles.

DRAG.— (a) A light iron-rod tool with a tapering spiral end, used by miners in cleaning out bore-holes before introducing the charge; (b) the device that guides wood to the saw in saw-milling; (c) also applied in printing to denote the thickened impression on one side of the letters produced by the scraping of the sheet on the type.

DRAWING-PAPER.— A term used commercially to describe a variety of stout papers manufactured expressly for use in drawing. The regular sizes are as follows: Cap, 13x16; in.; demy, 15½x18½ in.; medium, 18x22 in.; royal, 19x24 in.; superroyal, 19x27 in.; imperial, 21¼x29 in.; elephant, 22¼x27¾ in.; columbier, 23x33¾ in.; atlas, 26x33 in.; theorem, 28x34 in.; double elephant, 26x40 in.; antiquarian, 31x52 in.; emperor, 40x60 in.; Uncle Sam, 48x120 in.

DRAWING-ROLLS.— The rolls used in spinning machinery. As they are set in pairs, each of which turns more rapidly than any previous pair, the sliver passes through them in succession.

DRAW-BOY.— Formerly the weaver's assistant; now, a mechanical device used in drawing the heddles to form the pattern of the cloth to be woven. The machine upon which this figure-weaving is done is known as the "draw loom."

DRAWN.— A term denoting the method of freeing substances from all particles of iron and steel by use of a magnet.

DRESSER.— (a) The workman employed in type-foundries to remove all defects from the types in preparing them for sale; (b) the tool, or machine employed to cut and dress the furrows on a millstone; (c) a mallet used by plumbers in closing joints in sheet-lead; (d) one of the picks used in mining.

DRIFT.— A term used in mining to describe the nearly horizontal excavations that are frequently made in working a mine; sometimes called a "drive."

DRILL.— In agriculture, when a field is not sown broadcast, but in rows, it is said to be in "drills."

DRIP-JOINT.— When two sheets of metal used in roofing have been so united that the joint forms a water-conductor the arrangement is known, in plumbing, as a "drip-joint."

DROP-BAR.— A term applied to the bar or roller on a printing-press that regulates the passage of the paper sheets to impression.

DROP-DRILL.— The term denoting an agricultural instrument that is employed to drop the seed and fertilizer into the ground simultaneously.

DROP-FINGER.— In some cylinder printing-presses the rods that are employed to hold the sheets in place until they can be seized by the grippers are termed the "drop-fingers."

DROPPER.— A term used in mining to denote a branch or spur that connects with the main load but that does not materially enrich it.

DROPPING.— A term used to denote a defect in the product of the glassmaker. It is caused by the accidental dropping of the crude glass into the molten glass in the melting vessel.

DROP-ROLLER.— Used in printing to denote the roller that drops at specified intervals to supply the printing ink for distribution.

DROVING AND STRIPING.— A process in stone-cutting by which the shallow parallel grooves are made along the length of the rough-hewn stone.

DRYING-OFF.— A term denoting the process by which an amalgam of gold is evaporated.

DRYING-PLATES.— Used in brewing to denote the series of frames in the malt kiln. They are placed one over the other, and, being covered with woven wire, the hot air ascends through them in such manner as to dry the malt.

DUMP.— Used in printing to denote the act of removing types from the stick to place them on a galley.

DUNG-BATH.— In some processes of dyeing and calico-printing the cloth is subjected to a "dung-bath," composed of warm water, animal's dung, etc., for the purpose of removing the superfluous mordant.

EGG-SHELL.— A term used commercially to denote the thinnest and most translucent of china or porcelain.

ELBOW-PLATE.— A term used in paper-making when the cutter of the rag-cutting machine has been bent to something like an angle in the middle.

ELECTROPLATING.— The process of coating articles with silver or other metal by means of electrolysis.

ELECTROTYPING.— The process of making plate copies of any engraved or molded surface by means of electrical deposition.

ENDOWMENT.— A term used in life insurance to describe a policy in which the face value, with accrued earnings, is payable to the insured at, or after a stated period, or in which the face of the policy is paid to his representatives should he die prior to the expiration of that time.

ENSILAGE.— An agricultural term used to denote the process of preserving fodder, etc., in a green state by storing the materials in silos or pits dug in the ground.

FACE.— In coal-mining, the working, or portion of the seam that is being mined.

FASCET.— A rod, or basket of wire used in carrying the bottle from the mold to the leer in glass-manufacture.

FAT-WORK.— In printing, when copy is particularly profitable to the compositor owing to the fact that it has much open space that may be filled with leads, or that in other ways favors rapid execution, is termed fat-work. To beat, or ink "fat" in printing means that a form of type has been given an excess of ink.

FEEDING.— In printing, a term denoting the method of placing the sheets of paper in such position that they are ready to meet the requirements of the press.

FILATURE.— In silk-culture, a reel by which the silk is drawn from the cocoons.

FILLET.— (a) In weaving, a strip of card-clothing; (b) in dairying, a perforated curb used to confine the cheese-curds; (c) a wheel-shaped tool used in book-binding to impress a line, or decoration upon the covers of books; (d) in printing, a rule fixed with lines that may be used as a border.

FILLING.— The term by which the woof or weft thread of a woven fabric is known.

FILLING CAN.— Used in rope-making to denote the can in which the sliver is condensed and wound after coming from the doublers.

FINE-DRAWING.— The term applied to the finishing process in cloth manufacture. By exposing the cloth to a strong light all the minute holes due to breaks are discovered so that they may be repaired with a needle, by the introduction of sound yarns in the place of those that have proved defective.

FINING-ROLLER.— A cylindrical sieve of wire cloth used in paper-making to retain the coarse fibres and knots so that they cannot pass through with the finely ground stuff.

FIRE-GILDING.— A process of gilding by which the mercury is driven from the amalgam by the heat of a muffle, leaving a fine film of gold.

FIXING BATH.— In tanning, the catechu-bath is followed by another known as the "fixing" bath. It consists of water sufficient to cover the skins, acidified with nitric acid, modified with a little glycerin.

FLESHER.— The tool used in leather manufacture for the purpose of fleshing hides.

FLOAT.— A term used in weaving to denote the passage of the shuttle crosswise above or below the threads but without intersecting them.

FLONG.— The combination of moist tissue paper and paste used in stereotyping by the papier-mache process to form the mold or matrix from composed types or engraved surfaces.

FLOOR.—In brewing, each steeping is known as a "floor" or "piece."

FLOORING.—Used in brewing to denote the operation of spreading the grain on the malt-floor, that it may be kept at an even temperature, to check germination.

FLOW.—A term used in ceramics to denote the flux that is used to make the colors run and blend in firing.

FLURRY.—A term used in calico printing to denote the condition of frothiness which is sometimes developed by the colors during the process of printing.

FLY.—(a) One of the arms of a spinning-frame which revolves around the bobbin to twist the yarn as it is wound upon it; (b) in cotton-spinning, the term is applied to the waste cotton; (c) in weaving, a shuttle with wheels driven through the shed by a jerk; (d) in printing, the mechanism which receives and delivers the separate sheets as they are printed on the press; (e) in piano-making, the hinged board with which the keys are covered when not in use.

FOLIO.—While the word "folio" is used to denote the size of a book it is also applied as a descriptive term for several sizes of paper, each of which is designated by a specific name: Pot folio, 7½x12½ in.; foolscap folio, about 8x12½ in.; flat-cap folio, 8½x14 in.; crown, or post folio, 9½x15 in.; demy folio, 10½x16 in.; medium folio, 12x19 in.; royal folio, 12½x20 in.; superroyal folio, 14x22 in.; imperial folio, 16x22 in.; elephant folio, 14x23 in.; atlas folio, 16½x26 in.; columbier folio, 17¼x24 in.; double elephant folio, 20x27 in.; antiquarian folio, 26½x31 in.

FOOLSCAP.—A term applied to a writing paper varying in size from 12x15 to 12½x16 inches. The term was derived from the water-mark, a fool's cap, which formerly appeared upon all the papers that bore this name.

FOOTLINE.—A term used in printing to denote the last line of a page of type. It is usually left blank, although it sometimes contains the number of the page or the signature on the sheets.

FORWARDER.—A term used in bookbinding to designate the workman whose duty it is to receive the sewed book, put on its back, cover, etc., and prepare it for the finisher.

FULL-FACED.—A term used in printing to describe a type with the thick lines that make it print extremely black.

FURNITURE.—The term "furniture" in printing denotes the pieces of wood or metal that are placed around the pages of type, not only to keep them the necessary distance apart but to assist in fastening them securely in the chases. When the furniture has been systematically cut into various lengths and widths, so that they may be easily combined, the pieces are known as "labor-saving furniture."

FUSTIAN.—The term applied to a short twilled cotton fabric, usually a cloth having a short nap, like corduroy, velveteen, etc.

GAGING-THREAD.—In weaving, a thread introduced temporarily to stop the weft-thread at a specified point.

GALLEY.—An oblong, shallow tray, now usually made of brass, but sometimes of wood, used in printing by compositors as a place to deposit the type they have set. Galleys in which the type may be locked are known as proof-galleys. Standing galleys are inclined frames fitted with cleats on which the type galleys rest. A proof taken from types being held on galleys is termed a "galley-proof."

CASUALTY.—A term frequently used in insurance as a synonym for accident.

CO-INSURANCE.—A form of insurance in which the insured, in view of a reduced rate of premium agrees to maintain insurance upon a certain specified percentage of the total value of his property, failing which he becomes his own insurer for the difference, a fact which makes him jointly responsible with the assuring company in case of partial loss.

GATHERING.—Used in glass-making to describe the method of coiling the molten glass on the end of an iron tube preparatory to the work of blowing.

GIGGERING.—A process in bookbinding by which the burnished lines are rubbed upon the covers decorated in antique fashion.

GIGGING.—The process of finishing cloth by drawing the loose ends of wool in a fabric to the surface to form a nap. After the work of napping is completed the fabric is ready to be finished by shearing.

GILLING.—A term denoting a process for making all fibres level and even in the manufacture of woolen yarns or worsted.

GINGERBREAD-WORK.—A phrase used, somewhat as a term of contempt, in describing the fanciful shapes of the ornamental wood-work and carvings seen upon furniture, etc.

GLANCE.—A term used in mining to designate those ores in which a peculiar lustre and color indicates that they are of metalliferous combination.

GLOSSING.—A term denoting the operation of twisting the hanks of silk, in silk-manufacture, after they have been dyed and dried. This process is sometimes termed "stringing."

GOTHIC.—A term used by American printers to describe a style of square-cut printing-type very similar in appearance to the old Roman mural letter. In England this type is known as the "grotesque."

GRAVEL.—Used in brewing to denote the appearance of the beer when yeast-cells are floating about in it in the form of fine "gravel."

GRIZZLIES.—An arrangement in the mine sluice to receive and cast aside all the large stones brought down by the current during the process of washing the auriferous gravel.

GRAVEYARD INSURANCE.—A term used to designate a method of swindling insurance companies by the substitution of a person of robust health for the bad risk actually insured. Also used to describe other kinds of insurance swindling, or crimes committed in the collection of insurance moneys.

HACKLING.—In flax-manufacture "hackling" is the process of preparing the flax for spinning by the removal of all foreign substances and smoothing and equalizing all the lengths of fibre.

HALF-TONE.—A term used to designate a photographic process in which a screen made either of netting or ruled glass, is interposed between the lens and the sensitized plate, and from the image thus produced, a positive image is made upon the prepared metal plate. This is etched into relief by the use of acids.

HALL-MARK.—A term used industrially to designate any official stamp that has been placed upon an object of trade to denote genuineness.

HARD-CURED.—A term used in the fishing industry to designate that the fish specified has been cured by being thoroughly dried in the sun after salting, a process by which all the moisture has been evaporated.

HARDENING.—A process used in hat-manufacturing, by which the bodies of the hats are rubbed and pressed hard for the purpose of felting the material as well as to diminish the size and render them more dense. A hardening-kiln is a kiln in which the transfer printing process in pottery is completed: The pottery being relieved from all superfluous oils by exposure to a low heat.

HARNESS.—The term applied to the apparatus in a loom by the operation of which the warp-threads are shifted alternately to form the shed.

HARROWING.—A term used in agriculture to describe the process of dragging a many-metal-teethed instrument over plowed land, either to level it and break the clods, or to cover seed that has been sown. A "chain harrow" consists of a congeries of iron rings, instead of the metal teeth, and is employed to separate weeds from the earth and to cover grass seed. In a "revolving harrow" the teeth are arranged on radiating arms that have been pivoted to the draft-gear in such a manner that, by their horizontal rotation, they add greatly to the raking or tearing power of the teeth.

HESSIAN.—A coarse cloth made of a combination of hemp, and jute and used for bagging is known as "Hessian" by the trade.

HIGH-PROOF.—Commercially all highly rectified spirits are termed "high-proof."

HOLLAND.—A term which, while formerly applied only to linens imported from the Netherlands, is now used to designate the glazed and unglazed linen cloths that are made in many places. "Brown Holland" is a cloth that maintains much of the original color of the retted flax-fibre, it having been subjected to but little bleaching or boiling.

HONEYCOMBING.—In cloth-manufacture, a term applied to designate a thin fabric in which the stitches, running diagonally across the material, have been drawn up in such a manner that the spaces between them are puffed or in relief.

HOP-JACK.—A term applied to a vat with a false bottom used in brewing. It is so arranged that it retains the solid substances in the mash-tubs, but allows the wort to flow away after it has been boiled and the hops have been added.

HOPPER.—Used, in milling, to denote the inverted-cone-shaped trough through which the grain passes on its way to the shaking-shoe.

HORSE-POWER.—A term used as a unit of measurement in every industry in which power machinery is used. Although several values are assigned to this unit the prevailing value, both in America and England, is Watt's horse-power, which places it at 7,460 megaergs

per second, or about three-quarters of the actual power of a horse.

IMPOSITION.— The act of laying pages of type, etc., upon a smooth stone slab to secure them in the chases and prepare them for the press.

INDENTION.— A term used in printing to denote that a certain amount of blank space has been left before the line, or a specified number of lines of type. An indenting of every line after the first, with an increasing blank constantly shortening on both sides is termed "diamond" indention. An indenting of every line except the first, that being of full width and so overhanging the others, is termed "hanging" indention.

INFUSION.— A term used in brewing to denote the process of preparing the mash by treating the bruised malt with water at a temperature of from 70° to 75°.

INSURABLE INTEREST.— It is essential to the insurance contract that the insured should have a legal interest in the object for which the insurance was taken. In France the laws annul all policies that exceed the insurable interest of the assured at the time of the subscription.

INSURANCE.— A term used to describe a contract whereby for an agreed premium one party undertakes to compensate another party for loss in a specified subject by specified perils. There are several kinds of insurance companies in operation, but nearly all are either "stock" or "mutual" companies, while the risks covered include, life, accident, fire, health, marine, burglary, live-stock, plate-glass, etc.

JAPANNING.— The process of coating the surface of metal, wood, etc., with varnish which is immediately hardened by exposure to high temperature.

KERFING.— (a) The process of preparing wood for bending without breaking by making a series of small cuts in it with a sawing-machine; (b) in cloth-manufacture, the process of removing the wool by passing it through a shearing-machine.

KIPPERING.— In the fish trade, the process of curing fish by cleansing them, dressing them with pepper and salt, and curing them, either by drying them in the open air, or, artificially, by subjecting them to the smoke of some prepared substances.

LANDROLLING.— A term used in agriculture to denote the process of crushing clods, to make the earth friable, by means of a heavy roller.

LAYER.— The vat in which hides are left to lie in a strong solution of tannin towards the end of the tanning process.

LAYING.— The term is applied to two distinct stages in rope-making: (1) the twisting of three or more yarns to form a strand; (2) the twisting of three strands to form a rope. The machine that performs this operation is termed a "laying machine," the wooden cone placed between the strands to prevent a slack twist is termed a "laying-top."

MANIFOLDING.— A term used in business circles to denote the process of making several impressions of a single letter or document by one operation, as by means of a manifolding-machine, or by the use of carbon paper.

MASH.— Used in brewing and distilling to describe the mixture of ground grain that has been infused in warm water.

MILLING.— (a) The process of manufacturing cereals into flour or meal. There are two methods of milling: (1) low milling in which the grain is ground but once before being bolted, and (2) high milling, in which it is ground repeatedly; (b) in pottery, the operation of grinding and mixing the slip; (c) the process resorted to in tanning to open and soften the pores of hides; (d) in cloth manufacture, the process of felting cloth to thicken it, etc.

PIECE-GOODS.— The trade name for fabrics that have been woven in lengths suitable for retail sale by linear measure.

POINT.— The unit of measurement in types, each point being about one seventy-second of an inch. The various types in use in the United States and their relative sizes in "points" are as follows: Excelsior, 3 points; brilliant, 3½; semi-brevier, 4; diamond, 4½; pearl, 5; agate, 5½; nonpareil, 6; minion, 7; brevier, 8; bourgeois, 9; long primer, 10; small pica, 11; pica, 12; English, 14; two-line brevier, 16; great primer, 18; paragon, 20; two-line small pica, 22; two-line pica, 24; two-line English, 28; four-line brevier, 32; three-line pica, 36; double paragon, 40; four-line small pica, 44, and four-line pica, 48 points.

OPEN POLICY.— In insurance, a policy in which the value of the subject insured has not been fixed, but has been left to be determined in case of loss, or because it has been left open to permit of the addition of other things whenever occasion demands.

QUARTER-PLATE.— A term used in photography to denote the size of a plate. Thus, a quarter-plate measures 3¼x4¼ in.; a half-plate, 4¼x5½ in.; a whole plate, 6½x8½ in.

RECTIFY.— The term applied to the process of removing impurities from alcoholic distillations and to raise its strength to the required proof.

SALT A MINE, TO.— A swindling operation by which a mine is made to seem more valuable than it really is by the surreptitious introduction of ores obtained elsewhere.

SHELLS.— Those parts of the lay in weaving in the grooves of which the reed fits. They are of two classes and are termed "upper" and "under" shells.

SURRENDER.— A term in insurance to denote that the party insured has abandoned all right in his policy in consideration of having received a portion of the premiums already paid to the company. The percentage of premiums returned is known as the "surrender value" of the policy.

TOUTER.— Industrially, a person who makes it his business to solicit trade for a shop.

TONTINE POLICY.— In insurance, a policy in which the insured agrees that no money shall be received by him from the insuring party, either in the form of dividends, return-premiums, or surrender-value, for a specified term of years, but that, instead, the entire surplus shall be permitted to accumulate until the end of that period when it may be divided between those who have kept their policy in force.

TOTAL LOSS.— In marine insurance, total loss may mean that the subject insured has been absolutely destroyed by the peril against which it was protected, or it may mean that the loss by damage, seizure, or other causes has been so great as to be practically absolute. In the latter case it is often termed a "constructive total loss."

VALUED POLICY.— A term used in insurance to show that a policy is one in which the value has already been set upon the subject insured, the insertion of which fact in the policy, with the amount agreed upon, makes proof of damages in case of loss unnecessary.

WAGER-POLICY.— In insurance, a policy in which the insured has no insurable interest, and, being generally regarded as a form of gambling, such policies are not valid except in places where the validity of a wager may be recognized.

WALKING DELEGATE.— A person selected by a trade union or other labor organization to visit similar bodies of workingmen, to interest them in the order, voice their demands upon their employers, direct them in their strikes, etc.

WALL.— Used in mining to denote the surfaces of the rock between which the ore is inclosed. If the vein is inclined at such an angle that the ore is over the miner's head it is termed a "hanging" wall; if it is beneath him it is called a "foot" wall.

WARP.— (a) In agriculture, the operation of fertilizing a poor piece of land by artificial inundation from waters which have large quantities of earthy matter; (b) in weaving, the threads that extend lengthwise in a loom. The roller upon which the threads are wound is termed the "warp-beam;" the machine which treats them with size before they are wound is the "warp-dresser," while the machine which draws the warp threads through the dye beck is termed the "warp-dyer."

WASH.— Used in mining to denote the process of separating the ore from earthy and other matter by the employment of water. The fermented wort from which the spirit is extracted in distilling is also termed the "wash."

WINNING.— The work of developing a mine preparatory to the work of mining is termed "winning" in the United States.

WOOF.— In weaving, the thread that is woven into the warp is also termed the "weft."

Inebri'ety. See ALCOHOLISM.

Iner'tia, a term introduced by Kepler to signify that property of matter in virtue of which it is "inert," so that when a body is at rest, or in a state of uniform motion in a straight line, it preserves its state of rest or of uniform rectilinear motion, unless some agency external to the body acts upon it in such a way as to modify that state. We gain our first conception of inertia by the attempts that we make to move bodies that are at rest, or to stop those that are in motion. Even if they are suspended freely, so that fractional forces are negligible, we find that their state of rest or motion cannot be

modified without the exercise of a certain amount of muscular force; and by abstracting our own personality in the case, we gradually come to the conception of inertia as a physical property inherent in all bodies. Inertia has been popularly described as a "passive resistance" to change of motion; but this expression is objectionable because it is entirely inaccurate. Freely suspended bodies (that is, bodies that are free from frictional forces,) cannot be said to "resist" forces that are applied to them. On the contrary, they yield instantly to the smallest force; but a small force, when exerted upon a given body, for a given length of time, does not produce as great a change of motion as would be produced by a large force acting upon the same body for the same length of time. The conception of inertia shades insensibly into that of "mass"; the mass of a given body being proportional (by definition) to the velocity that is communicated to the body by a force of standard intensity, acting upon it for a standard length of time. (See Mass; Matter; Molecular Theory.)

Infallibil'ity, exemption from the possibility of error. The word is used as applied to arguments, statements, reasoning, or the formation of judgments, and does not include impeccability, or exemption from the error of sin. The infallibility of the Church as believed by Roman Catholics means that "the Church can neither deceive nor be deceived in matters of faith and morals"; and she is limited to the definition of truths already contained in Scripture and tradition. The seat of infallibility rests in the Pope as successor of Saint Peter (Matt. xv. 18), and in the bishops in communion with the See of Rome, whether dispersed or united in a General Council (q.v.). In the acts of the Vatican Council, held in Rome in 1870, the following is the text defining the nature of the infallibility of the Pope: "The Roman Pontiff, when he speaks *ex cathedra*, that is to say, when in the exercise of his office of pastor and teacher of all Christians; he, in virtue of his supreme apostolic authority defines that a doctrine on faith and morals is to be held by the whole Church, by the assistance of God promised to him in the person of blessed Peter, has that infallibility with which it was the will of our Divine Redeemer that His Church should be furnished in defining a doctrine on faith or morals, and that therefore these definitions of the Roman Pontiff, of themselves and not through the consent of the Church, are irreformable." The Greek Church, the Church of England, and the Protestant Episcopal Church which is its representative and in communion with it in the United States, believe that infallibility resides in the universal Church in accordance with Christ's promise of the Spirit that should guide His followers unto all truth. Consult: Allies, 'See of Saint Peter'; Ballerine, 'De Primatu'; 'De Potestate Summ. Pontif.'

In'famy and Infamous Crimes, in common law the first means disqualification from giving legal evidence as a result of having committed the second, the theory being that a person capable of such crimes is incapable of speaking the truth. Both in Great Britain and generally in the United States this disqualification has been abolished by statute, and previous convictions for crime have been considered to affect a person's credibility without impairing his legal capacity to give evidence. Infamous crimes are strictly those which entailed infamous punishments. The fifth amendment to the Federal Constitution speaks of "capital or otherwise infamous crime" and we read in 2 Dane, Abridgement, 560, 570: "Punishments clearly infamous are death, gallows, pillory, branding, whipping, confinement to hard labor and cropping." Infamous punishments include imprisonment in State prison, or penitentiary with or without hard labor, and crimes which entail such punishments are undoubtedly to be considered infamous crimes, in the sense implied in the fifth amendment to the Constitution.

Infancy. The term infancy is used variously by different writers to include a shorter or longer period of the earliest stage of human existence. By most writers it is limited to the first 12 or 14 months, extending to the time when the baby begins to walk and to talk, and so is synonymous with a "babe in arms"; many medical authors would make it include the whole period of the first dentition, or up to about two and a half years. The characteristics of the period are utter helplessness, rapid growth of body, gradual development of muscular functions and great impressibility of the nervous system. In mankind this helplessness is more marked and the period of dependence is longer than in any other of the higher animals. It has been pointed out by John Fiske that the present elevation of man above other animals is due largely if not entirely to this lengthened period of plasticity,—to his prolonged immaturity. Man is born with only a few of the lowest vegetative capacities fully developed, such as digestion, respiration, and circulation; the muscular and nervous functions are latent and only gradually develop; while the higher functions of the mind go on evolving until the fifth decade of life. A long infancy or period of immaturity means a great capacity for development.

Birth and Heredity.— The infant comes into the world with a fixed sum total of vital force, along with certain hereditary tendencies in development toward health and, perhaps, toward disease. These hereditary tendencies are all modified by the physical, social, intellectual and moral status of the child's family and surroundings: in a word, they are vastly influenced by the child's environment. Heredity was formerly regarded as the most important factor in the child's life; but heredity is really only one of three great factors,—the others being the nutrition of the child, and his physical, intellectual and moral environment. During the plastic years of infancy, childhood and adolescence, a bad heredity can frequently be overcome by proper management: on the other hand, the capital of a good heredity can be squandered. Nature always tends toward the normal or healthy, so that there is always the possibility for a bad heredity to be obliterated if only the natural tendency is assisted. More then depends on the nutrition and environment of the infant than upon its heredity.

Nutrition: Breast-Feeding.—The best method of nourishing the infant is nature's way—to have it nursed by the mother. But for various

reasons this is often impossible. Modern life — and especially city life — has in some way rendered a large proportion of women incapable of producing breast milk for their offspring. And the number of these mothers who desire to nurse their infants but cannot is increasing each year. Again, in not a few instances, the infant does not thrive upon the breast-milk, even though it may be abundant. In both these classes of cases some form of artificial or substitute feeding is a necessity. Good wet nurses are so difficult to procure in the United States that artificial feeding is generally preferable unless the baby is premature or feeble and failing: then the services of a wet nurse may be needed to save the infant's life.

Artificial or Substitute Feeding.— The best available substitute for human milk is an adaptation of fresh, clean unadulterated cow's milk. The milk should be diluted and otherwise modified to suit the infant's feeble digestive powers, and it should be given preferably, without being scalded or sterilized. In summer, or when there is any doubt as to the freshness of the milk, the cleanliness of the dairy or the careful handling of the milk, "Pasteurization," or heating the food to a temperature of 155° F. is advisable. Details as to milk modification and Pasteurization can be found in any book on "Infant Feeding." Ready-made infant foods,— the canned or bottled proprietary foods — do not contain the right ingredients for properly nourishing the infant, and their prolonged exclusive use is nearly always followed by some form of malnutrition — especially scurvy and rickets. These proprietary foods contain large proportions of sugar or starch, and so make fat babies, but such infants are generally pale, have feeble powers of resistance, and are prone to succumb to disease of the lungs or of the digestive tract. When the prepared infant foods are used as additions to milk they are less objectionable, and may at times be of advantage.

Weight and Development.— The infant that has been properly nourished before birth and is born at full term weighs on the average about 7½ pounds — boys being somewhat heavier than girls.

During the first few days, while the nourishment from the mother is insufficient, the baby regularly loses from six to eight ounces; but it soon begins to gain, and if the nutrition is normal and the infant remains well, there will be a steady increase in weight throughout the first two years. The gain during the first year is more regular, however, as well as more rapid than that during the second year. During the first three months the increase in weight each week is about half a pound: from the third to the sixth month the weekly gain is somewhat less, from four to six ounces: from the sixth to the ninth month about four ounces, and after the ninth month a little more, usually a weekly increase in weight of from four to six or even eight ounces. By the end of the fifth month the baby that has been perfectly well and is being properly nourished should have doubled its birth-weight and weigh about 15 pounds: at the end of the 15th month it should weigh three times its weight at birth. In many instances the baby will treble its original weight by the end of the first year; but 21 pounds may be considered the average weight for the end of the 12th month. Infants that were very large at birth do not increase so rapidly; while small or premature babies are apt to make a gain that is greater in proportion to their original weight. "Hand-fed" or "bottle" babies should weigh on the average about the same as breast-fed babies,— provided that they have had no disturbance of their digestion; the food must, however, have been perfectly adapted to the infant, and this is often a very difficult problem.

Height and Other Measurements.— At birth the length of the average baby is about 20 inches; during the first six months there is an increase of four to six inches, and during the second six months from three to four inches more; by the end of the second year the height is 32½ inches, a growth of over a foot since birth. By the end of the third year the stature is one half of the adult height. The head grows very rapidly during infancy and early childhood. The circumference of the head at birth is from 13 to 14½ inches; by the end of the sixth month it is 16½ or 17 inches; at the end of the first year 18 inches, and at the end of the second year it is 19 inches. By seven or eight years the circumference of the head almost equals the adult size of 21 inches. This is visible evidence that during the first months and years of life the brain is increasing in volume more rapidly than any other organ in the body,— the head or brain-box expanding to conform to the enlarging brain. The soft spot or "fontanel" usually closes between the 15th and the 20th months. The chest is smaller than the head at birth (13 inches), but its circumference increases rapidly, so that at 18 months that of the chest and the head are equal. After this the chest grows steadily but gradually until puberty, when there is a very rapid increase for four or five years. Aside from the regular increase in weight and measurement, the healthy infant shows other signs of well-being. The baby's flesh is firm, and the skin is satiny and elastic: the color is pink, and the body and extremities are well rounded. Very fat babies are not necessarily stronger or healthier than those that weigh less: as has already been noted they are apt to be pale, flabby and of weak resistance to disease. The healthy baby is happy and playful when awake, and sleeps from 16 to 20 hours out of the 24,— longer the younger the baby. It is desirable that the growing child have a nap during the day up to the time when kindergarten work is begun; with nervous or poorly nourished children the practice should be continued until the seventh or eighth year.

Muscular and Mental Development.— These begin with the entrance of the infant into the world, but are slow in unfolding. At first the grosser movements performed by the muscles working over the larger joints, next more complex movements, and during later childhood and early adolescence the finer movements requiring nice adjustment and delicate co-ordination. Hence it is that occupations or accomplishments requiring great manual dexterity, such as violin or piano-playing, should be taken up early,— "before the hand gets stiff," as the phrase is. The first movements are those of the legs, arms,

and neck: they are not purposeful but merely reflex. By the sixth week the infant can hold up its head, when the back is supported, but very unsteadily until about three months old. At some time in the third or fourth month the infant makes its first voluntary movement, grasping at some object in the range of vision. Within a month or two later the baby can co-ordinate the muscles of the eyes, arm and hand sufficiently to take firm hold. Sitting alone is an accomplishment of the seventh or eighth month, and creeping also begins at about this time, if the baby is ever to creep at all. During the eighth or ninth month the baby begins to stand, having made the attempt for many weeks before; at ten or eleven months the infant can stand alone, and shortly after the twelfth month the first tottering steps are taken. It is some months before the baby is secure upon the feet, the maintenance of the equilibrium requiring nice control of many groups of muscles. Healthy infants differ greatly as to the time when they can walk alone, some walking at as early as ten months, while others may not walk until eighteen months. Very fat babies walk late but, in some instances, an excess of caution seems to be a factor. If a child is far behind in performing any of these muscular functions, a physician should be consulted so that careful examination may be made for signs of rickets or of disease of the brain or of the spinal cord.

Development of Special Senses.— For the first few days the newly-born infant avoids the light, and for many weeks cannot endure a direct bright light. Perception of light soon develops, the color first attracting attention being red. Clear perception of objects comes during the fifth month. Hearing is in abeyance for several days, a baby at birth being practically deaf; but after a week or ten days this function begins, and later hearing becomes very acute, the infant being able to recognize the mother's voice or a footstep at about three months. Loud sounds cause the baby actual pain, so severe are their impressions on the delicate auditory apparatus. The sense of touch (contact) is early developed, especially in the tongue and lips; but sensitiveness to pain is very dull during infancy. Heat and cold are recognized from an early period, the variation of a few degrees in the temperature of the food causing the baby to refuse it. Taste and smell also are present at birth, taste being very discriminating.

Development of Speech.— Speech is very closely related to the higher functions of the brain, and is therefore the last of the simple functions to develop. Usually a baby begins to say "Mamma" and "Papa," with clear knowledge of the meaning, toward the end of the first year. Next names of objects and persons are learned and soon two words are put together. Then verbs are used, and about the end of the second year little sentences are made. Pronouns are regularly the last of all the parts of speech to be used. During the third year speech develops very rapidly, the baby bringing out some new term or expression almost daily. There are great variations in the time when children begin to talk; and for this there are many reasons. Girls generally talk earlier than boys by two or three months: babies that associate in the nursery with other children talk earlier than only children. If, however, a young child reaches the age of two years without attempting to talk, mental backwardness or organic brain disease is apt to be the cause. Tongue-tie is seldom the cause of backwardness in talking, although it does produce imperfect articulation.

Dentition — Teething.— The first teeth appear about the sixth or seventh month, but a perfectly healthy baby may have no teeth until 10 or 11 months old, or on the other hand may cut the first tooth at four months. The regular order is as follows: lower central incisors, upper central incisors, upper lateral incisors, lower lateral incisors — each pair coming at intervals of three to six weeks: at about the fourteenth month the front double teeth (anterior molars) appear in the two jaws, and four or five months later the canines, known popularly as the "eye and stomach teeth." Finally, the last four molars appear sometime between the twenty-fourth and the thirtieth month, and these complete the twenty teeth of the first dentition. Teething babies are apt to be fretful, they have a reduced resistance against disease, and they are prone to slight disturbances of digestion. To attribute most of the ills of infancy to the process of teething is a great mistake; usually some other and better cause for the disturbance can be found if the baby is carefully examined. During the time when the successive pairs of teeth are coming through the gums, the usual food should be largely diluted, so as to prevent any serious indigestion.

Fever.— Sudden high temperature is readily produced in young children by slight causes, inasmuch as the heat-regulating centre in the brain is but poorly developed. Again, the temperature in disease is erratic, and is apt to be higher than in adults suffering from the same ailment. Only persistent high temperature need cause anxiety.

Convulsions.— A characteristic of infancy is the easy excitability of the motor side of the nervous system. Hence convulsions or spasms are much more frequent and less serious than in adults. The immediate cause of the motor explosion may be an overloaded stomach, fright or mental excitement, or the fever of an oncoming disease. Severe earache, intestinal worms or a paroxysm of whooping cough may also serve as an exciting cause. Underlying or predisposing causes are a nervous heredity, malnutrition, or rickets; or there may be organic disease of the brain or the kidneys. The spasm usually begins with a turning of the eyes to one side and twitchings or grimaces of the face: there may be frothing at the mouth; then the arms and legs are rapidly contracted and relaxed; later the body stiffens out, the breathing becomes noisy and labored, the face, — especially the lips — becomes livid. Shortly afterward the body relaxes, the breathing becomes easy, and spasm ceases for the time being — having lasted anywhere from five to thirty minutes. Until the physician arrives certain simple measures are of value. The infant should be undressed, wholly or partially, and put into a warm bath (not warmer than 105° F.) to which a handful of mustard flour

has been added, and the baby should be rubbed all over while in the tub for about five minutes. Then remove from the bath and lay between blankets, putting a warm bottle at the feet and an ice cap or cold compress on the head. If the baby can swallow, a full dose of castor oil should be given. Most convulsions are due to the presence of decomposing food-remains in the alimentary tract, and the spasms usually cease when the stomach and bowels have been thoroughly evacuated.

Linnæus Edford LaFétra, M.D.,
Instructor in Diseases of Children, Vanderbilt Clinic, Columbia University.

In'fant, in law. By the common law persons come to majority at the age of 21 years, until which time they are called in law *infants,* but by common usage in the United States the word minor prevails. Infants cannot, in general, bind themselves by contracts, as they are supposed not to have sufficient discretion and ability for this purpose. But this is their privilege, and their contracts are accordingly held in general not to be void, but only voidable at their election; and they may elect to avoid their contracts during their minority, except such as they may have entered into for necessaries suited to their condition in life, but they cannot confirm them so as to be bound by them until their majority. Infants may possess property, but it must be under the management and control of a guardian. They have not the right of citizens as to voting, and discharging other political functions. But in regard to crimes and punishments, and trespasses and private wrongs, their conduct is regulated by the same laws as that of the other members of the community, in case of their being of sufficient age and discretion to understand their duties and obligations. And for this purpose no general limit can be assigned, as some children are much more intelligent than others of the same age; and it will again depend, in some degree, upon the nature of the offense committed, or the wrong done, whether a child of any given age can be considered legally guilty of it, since some offenses and wrongs can be more easily understood to be such than others. The law, in general, has a tender regard to youth, and does not permit them to be convicted and punished for offenses and trespasses unless it appears clearly that they have sufficient knowledge and discretion to distinguish them to be such. There are exceptions to the incapacities of minors as to contracting, and these exceptions are made for their benefit. Thus an infant not sufficiently furnished with necessary clothes, food, or instruction, by his parent or guardian, and not being under the immediate superintendence of the parent or guardian, may make a valid contract, in respect to those subjects, and such contract may be enforced against him. Infants require the consent of parents or guardians to marry. The jurisdiction in respect to infants is generally vested in either probate or orphans' courts. These courts appoint guardians to take charge of the property of infants, and, in case of the decease of the father, to take charge of their persons; but during the life of the father he has the guardianship and control of the persons of his children until they are 21 years of age.

Blackstone thus defines infant: "Infants have various privileges, and various disabilities; but their very disabilities are privileges, in order to secure them from hurting themselves by their own improvident acts. An infant cannot be sued but under the protection, and joining the name of his guardian, for he is to defend him against all attacks as well by law as otherwise; but he may sue either by his guardian, or by his prochein amy, or alone for wages in the county courts. In criminal cases an infant of the age of 14 years may be capitally punished, but under the age of 7 he cannot. The period between 7 and 14 is subject to much uncertainty; for the infant shall, generally speaking, be judged *prima facie* innocent; yet if he was *doli capax,* and could discern between good and evil at the time of the offense committed, he may be convicted, and undergo judgment and execution of death, though he has not attained to years of puberty or discretion."

Infant Jesus, Daughters of the Congregation of the, is an order in the Roman Catholic Church. It owes its origin to Anna Maroni, a native of Lucca, who having come to Rome entirely destitute, succeeded by her industry in securing a competency. In more advanced years, her charitable feelings prompted her to establish an institution where poor girls should be instructed in such work as would enable them to earn a livelihood. The clergy approved of her plan, and afforded her much assistance, and it was finally established as a regular institution, and in 1673 Pope Clement X. acknowledged the existence of the society, gave it by-laws, and endowed it with sundry privileges, under the appellation of "Daughters of the Infant Jesus." The number of the "Daughters" allotted to each convent was fixed at 33, in commemoration of the number of years Jesus lived upon earth. The novitiate lasts three years; the sisters make vows of poverty, chastity and obedience. Such as may wish to leave the convent are allowed to do so before taking the vows, but, in that case, they are to leave to the convent all they brought to it at their admission. Prayers and fasts are strictly enforced. The regular habit of the order consists of a wide, dark brown dress, and a white hood.

Infanta, ēn-fän'tä, Philippines, a former Spanish commandancia of the island of Luzon, consisting of a narrow strip of territory on the Pacific coast with Nueva Ecija on the north and Tayabas on the south. In 1902 it was made a sub-province of Tayabas, "the inhabitants to enjoy the same rights and privileges as if the said territory had been originally incorporated in the province of Tayabas." The surface is very rough and mountainous and the construction of roads impossible except at heavy cost; several trails lead over the mountains to the central provinces. The forests are valuable, among the trees most important to commerce is the balate, which produces the balate gum. The agricultural methods are most primitive; the chief crops are rice, cocoanut, chocolate and coffee; the most important industry is the manufacture of nipa wine; there was formerly a large manufacture of cocoanut oil in Infanta, but this industry was paralyzed by the hurricane of 1882. Pop. 10,800.

Infanticide, the murder of a child born alive, is a crime of frequent occurrence. The main cause of the crime is shame, induced by a dread of the social disgrace attaching to mothers of illegitimate children; though in many instances infanticide has been the result of violence produced by puerperal insanity. The morbid disposition to kill the newly born has also been observed in certain of the lower animals. The sanctity of human life, from its beginning to its close, is a maxim of modern civilization, and the law treats as a murderer whoever wilfully terminates it at any stage. According to the law of England every woman who employs means to procure criminal abortion is guilty of felony, and liable to penal servitude for life, or not less than three years; and severe penalties are inflicted on those who aid women to procure miscarriage. The concealment of birth is a misdemeanor, and may be punished with imprisonment for two years. In the United States, when a child's death is occasioned by an illegal act, such act is considered either murder or manslaughter according to the circumstances. The crime, however, is rarely punished, and in large cities many cases occur each year which are never reported to the authorities.

Infanticide was prevalent in Greece and Rome. In modern times many barbarous peoples are guilty of wholesale child-murder. Among some of the Pacific Islanders and aboriginal Australians there is a great destruction of infant life. The Hindus used to destroy female children without compunction. In China infanticide is said to be very common.

Infantry ("the juveniles," probably at first the knights' pages), foot soldiery, as distinguished at once from cavalry and artillery. In all ages this has naturally formed the numerical bulk of armies, but its tactical importance has varied greatly with circumstances. The name cannot be given to the mere unorganized fighters of barbarian *mêlées;* it implies some organization, and at least the rudiments of tactics. The first large armies were the Egyptian and Assyrian, continued by the Persian: the social system was aristocratic, and the large plains ideal for the utility of cavalry; hence the infantry was rather an auxiliary, to complete a rout after the mounted lords and the chariots had broken the ranks, than the main fighting body. The first development of infantry as the chief reliance was naturally in the small Greek states, whose independence rested on their citizen soldiery, and whose rough territory made cavalry evolutions difficult. Cavalry was therefore used mainly to guard flanks and to skirmish; the Spartans for a long time would not use it at all. The infantry was divided into classes according to armor; hoplites (with heavy defensive armor, long spear and dagger), psiloi and peltasts (very little armor, light barbed javelins to throw), and gymnetes (sharpshooters, light-armored and with slings or bows). The battle formation was the famous phalanx, whose one basic principle was the value of mass and momentum, and which was irresistible either for attack or defense against barbarians who lacked firmness in the ranks. It was commonly a rectangular block eight ranks deep, so that only the first two or three could use their spears at the same time, the rear ranks serving only for instant reinforcement and for impact; the men were from 18 inches to 6 feet apart, according to conditions of defense or attack; the phalanx had usually 2,000 to 4,000 men, but sometimes as high as 10,000 or more. Sometimes the formation was the triangular wedge. The first great improvement was by Epaminondas, who made the ranks 50 deep, and by the enormous impact crushed the Spartan phalanx at Leuctra. This was the Napoleonic principle of concentration at the critical point, most of the Spartan army being allies with no heart in the fighting, and kept at bay by a few skirmishers. Nevertheless, the step was backward except for immediate necessities, as it increased the main vice of the phalanx — its immobility, which made it break up dangerously on bad ground, and gave little power to change front or execute flanking movements. In later tactics the larger ones were subdivided into companies of 120 with a distance equal to the front, forming an approach to the legion; and the latter was copied also in the formation by lines, increasing rapidity of movement and flexibility on difficult ground, as well as power of extension and so of flanking. The Macedonian *sarissa* or long pike doubled the number of ranks which could thrust at once over each other's shoulders. But the whole system went down before the Roman legion, which essentially maintained its position till the Empire too went down. It consisted normally of 1,200 each of hastati (spearmen), principes (veterans), and velites (light troops), 600 pilani (veteran reserves), and 300 equites or cavalry. It was divided into three lines and 30 maniples or companies, and combined solidity with ease of maneuvering.

In the Middle Ages, till the general use of gunpowder, the feudal system insured the degradation of the infantry, as it depended on the fighting power of the knight, and consequently lavished all the care and expense on perfecting his armament. But even without this, the same result would have come, for without good field artillery, and with only bows and arrows at their best, the heavily armed man was invulnerable, as the Spanish conquests in the New World amply prove. Hence the logical result was the extension of defensive armor till some new missile force came in. But the cost of this was so great — a full suit of steel armor cost about $2,000 — that only the richer even of the knights could afford them, no king could raise money to equip a standing army, and the aristocracy would combine to refuse him money for such a purpose; and the rank and file were scattered and slaughtered in face of a charge of a small number of mailed knights. The defeat of the French knights by the English bowmen was that of a disorderly and insubordinate mob, by a splendid archery which slew their horses and pierced the cheaper armor. But gunpowder at once changed the whole situation. A serf with a $10 hackbut could stand out of reach and kill a knight with his costly armor; and a sovereign could collect and arm a great force of these and use them to put down his unruly vassals. Hence armored knights and horses began to decrease, and standing bodies of foot soldiery with firearms to increase. The change in battle array was correspondent: theretofore, even the ablest commanders had maintained the great depth of 10 ranks, traditional from classic times. Gustavus

Adolphus reduced this to six, deploying to three under fire; while Tilly and Wallenstein and the other imperial commanders kept to the old phalanx formation. Breitenfeld (1631) and Lützen (1632) were won by this and Gustavus' light artillery. The introduction of the bayonet about 1650 led to a reduction to four ranks. But the greatest single improvement was due to Leopold of Dessau early in the 18th century: he instituted the chief reforms usually credited to Frederick the Great, and formed the armies with which Frederick won his victories. He reduced the ranks to three, making it possible for all to fire, trained them to maneuver with great precision, and wrote the drill-book which is still the basis of all European and American manuals. Frederick's infantry organization, in regiments of two or three battalions, each 500 to 600 strong, was copied by all the other nations; and the general principle of open order, made necessary from the destructiveness of artillery on close masses of men, and possible by the confidence in each other bred by civilization, is still retained. Broadly, the difference between ancient and modern infantry is that between mass and mobility.

For obvious reasons — cheapness of maintenance, universal availability of men untrained in horsemanship, ability to march and maneuver on all sorts of ground, less liability to be crippled by loss of the animals, etc. — all modern armies consist mainly of infantry; and the nominal horse troops are most often dragoons, or soldiers mounted merely for quickness of movement, but who fight on foot. The quantities of other arms, as cavalry, artillery, engineer corps, etc., are based on the infantry numbers. The proportions vary in different armies and in different functions of the same army, according to nature of service: more or less cavalry and artillery being used according to need of concentration, or action in dispersed bodies. Forces like the United States Western troops a generation ago, for instance, in small squads on detached duty, would have different proportions from a great Continental army in the midst of a campaign. While there is no one system of infantry tactics which can be universally applied, the same cause which has made the change just spoken of has thus far continued to act with steadily increasing force. Artillery continues to grow in power and in range; the danger-line grows ever farther from the enemy; it is nearly impossible, and would be murderously losing, to charge in close column across the 2,000 yards which is now the average range. The system adopted is called "extended order," which means a considerable space between the men, and small bodies acting separately in a charge; each making a rush for some cover not so far off that they will be blown in reaching it, or will be decimated in the attempt. A certain relation between companies and regiments is kept up, to avoid destruction in detail and enable combined action, but precise parade alignment is not attempted. This involves not only the mutual confidence of civilized men, but some of the independent judgment of those who have not had initiative crushed out of them by red tape: the greatest of modern tacticians and commanders have expressed a preference for intellectual quality over mere numbers, even in the rank and file. In the United States, the extended order was first introduced in the Revolution.

For the organization of the line in this country, see ARMY OF THE UNITED STATES. In addition to this, a few facts may be given: The general orders of 19 May 1877 fixed the strength of the infantry at 9,575 men, in 25 regiments. The pay ranges from $3,500 a year for the colonel to $13 a month for the private. The appointments are made from the United States Military Academy, from the ranks after two years' service and severe examinations, or from civil life if there are no eligibles in the others. The arms are the Krag-Jorgensen and the new Springfield magazine rifle, with knife-bayonet. The equipment is knapsack, haversack with implements for meals, canteen, blanket wrapped in piece of shelter tent, and waist-belt with cartridges.

Infec'tion, the introduction of disease-producing micro-organisms in the body. Infection may result in a number of different ways. Micro-organisms may be introduced by means of direct injury. When a person falls and cuts the hand, the bacteria of pus-production or of tetanus may be so introduced, and blood-poisoning or tetanus may develop. Many infections come by means of the intestinal tract. Thus typhoid is commonly obtained from milk or drinking-water. The intestinal worms, tapeworm, roundworm, are contracted in this manner, and a number of other parasites, particularly the trichina, may come from infected food taken into the alimentary canal. Infection may also occur by means of the air-passages. The bacillus of tuberculosis is most often taken into the body in this way, and finding suitable soil, it causes the development of the dread disease. The bubonic plague is frequently contracted through the disease-germ entering the air-passages. At the present time it is deemed not unlikely that a number of infectious diseases, notably influenza, diphtheria, scarlet fever, measles, whooping-cough, are contracted through the respiratory tract by infection with the exciting cause. Occasionally direct contact seems necessary for infection, as in gonorrhœa and syphilis. In malaria, and probably in yellow fever, the active agent that causes the disease is introduced into the body by the bite of an insect, the mosquito. In malaria one particular genus (*Anopheles*) serves as an intermediate host in the developmental history of the parasite, in a manner analogous to the history of the development of a number of the intestinal worms. It is not unlikely that a large number of diseases may be disseminated by the bites of insects of one kind or another. In all the infectious diseases the element of a real, live, and active contagion should never be overlooked. Infectious diseases do not spring out of nothing. There must be some sort of contact in order that a person become infected. A most important part of the treatment of all infectious diseases is the protection of other people by proper care of all one's own excretions during sickness. The doctrine so frequently taught by some that sickness is ignorance is an important half-truth. But for the ignorance of people concerning the proper care of those afflicted with infectious diseases with reference to the protection of others, measles, diphtheria, scarlet

fever, whooping-cough, typhoid fever, consumption, and a number of other maladies would be entirely eradicated from civilized communities.

In'fidel, in modern parlance, one who deliberately rejects the Christian faith after obtaining knowledge of it. In former times a man might be an infidel who had never heard of Christianity. *Infidelis* in ecclesiastical language means "unbelieving," and is applied to unevangelized heathen as well as doubters and apostates. Thus in the Roman Catholic Church a bishop *in partibus infidelium* merely means a bishop whose diocese is set in heathen countries.

In'finite, a term in metaphysics, which means a reality which has no limit or boundary, in time or space. The idea of the infinite is as old as the Ionian philosophy, when Anaximander (610 B.C.) declared that the one in the many, the basis of being in Nature, was *το ἄπειρον*, the infinite. The reality of infinitude has been the source of much controversy, and the tendency of many modern philosophers is to deny it. "An infinite number," says Bosanquet, "would be a number which is no particular number, for every particular number is finite. It follows from this that infinite number is unreal." On the other hand F. H. Bradley states the contrary, in the clearest terms, "We may be asked whether Nature is finite, or infinite. . . . if Nature is infinite, we have the absurdity of a something which exists; and still does not exist. For actual existence is, obviously, all finite. But, on the other hand, if Nature is finite, then Nature must have an end, and this again is impossible. For a limit of extension must be relative to an extension beyond. And to fall back on empty space will not help us at all. For this (itself a mere absurdity) repeats the dilemma in an aggravated form. But we cannot escape the conclusion that Nature is infinite. And this will be true not of our physical system alone, but of every other extended world that can possibly exist. . . . Every physical world is, essentially and necessarily, infinite."

It seems as if Aristotle had a clearer and more logical view of infinity, *το ἄπειρον* than many modern Positivists, such as Bosanquet. He says, *λειπεται οὖν δυνάμει εἶναι το ἄπειρον.* He means of course, that, with regard to finite human intelligence, the infinite remains unrealized, although logically it could be realized, and of course, when we speak of infinite time, or infinite creative change in nature, we speak of something which potentially exists, but is only gradually becoming actual.

Infinity is also applied to the divisibility of matter. This is termed "infinite fission." If an atom is divided into two parts, and each of these is again divided into two parts, the mind cannot conceive of any individual fragment resulting from this division as incapable of being divided.

Professor Royce of Harvard has undertaken the task of vindicating the concept of the actual Infinite against the charge of self-contradiction. He is controverting Mr. F. H. Bradley of Oxford, who while he admits "we cannot escape the conclusion that Nature is infinite," expresses also his belief that such an assertion is a contradiction in terms. Professor Royce accomplishes this vindication by proving the following theses:

1. The true Infinite, both in multitude and in organization, although in one sense endless, and so incapable in that sense of being completely grasped, is in another, and precise sense, something perfectly determinate. Nor is it a mere monotonous repetition of the same, over and over. Each of its determinations has individuality, uniqueness, and novelty about its own nature.

2. This determinateness is a character which, indeed, includes and involves the endlessness of an infinite series; but the mere endlessness of the series is not its primary character, but simply a negatively stated result of the self-representative character of the whole system.

3. The endlessness of the series means that by no merely successive process of counting, in God or in man, is its wholeness ever exhausted.

4. In consequence, the whole endless series, in so far as it is a reality, must be present, as a determinate order, but also all at once, to the absolute experience. It is the process of successive counting, as such, that remains, to the end, incomplete, so as to imply that its own possibilities are not yet realized. Hence, the recurrent processes of thought reveal eternal truth about the infinite constitution of real Being,—their everlastingly pursued Other; but themselves,—as mere processes in time—they are not that Other. The true Other is, therefore, that self-representative system of which they are at once portions, imitations and expressions.

5. The Reality is such a self-represented and infinite system. And herein lies the basis of its very union, within itself of the one and the many. For the one purpose of self-representation demands an infinite multiplicity to express it; while no multiplicity is reducible to unity except through processes involving self-representation.

6. Nevertheless, the Real is exclusive as well as inclusive. On the side of its thought the Absolute does conceive a barely possible infinity, other than the real infinity, a possible world, whose characters, as universal characters, are present to the Absolute, and are known by virtue of the fact the Absolute thinks.

This brings metaphysics face to face with the notion of a Supreme Being, who is infinite or absolute. With the mystics God is infinite love, joy and wisdom to his human children. The Hindus taught that God was the infinite universe, the Other, the reality. "That (that is, the Universe) art thou," was their dictum. Christianity teaches that "God is of infinite power, wisdom and goodness," of which qualities the best of men have but a finite endowment.

The term "infinite" was introduced into geometry by Kepler in his 'Nova Stereometria Doliorum; accessit Stereometriæ Archimedeæ Supplementum.' Thus he considered a circle as formed by an "infinite" number of triangles, having their vertices at the centre, and their bases at the circumference. A cone likewise, he taught, was composed of an "infinite" number of pyramids, having their vertices at the vertex, and standing on an "infinite" number of triangular bases, bounded by the circular base of the cone. In this sense infinite means incommensurable, not to be expressed by a finite mathematical formula. Consult: Bradley, 'Appearance and

Reality'; Royce, 'The World and the Individual'; Bosanquet, 'Logic'; Couturat, 'L'Infini mathematique.'

Infin'itive, the indefinite mode in which the verb is represented without a subject. As the verb expresses an action, or a state, it generally belongs to a subject whose action or state is expressed; but if we wish to express the mere idea of this action or state we use the infinitive, which, therefore, in many languages is employed without further chance as a substantive — for instance, in Greek and German — only preceded by the neuter article; but as the verb expresses an action or state under certain conditions of time, the infinitive can also express the action or state in the present, past, or future, though these conditions are not expressed in all languages by peculiar forms. Some languages express it by some grammatical contrivance, as is the case in English, where it is denoted by *to* prefixed to the general uninflected form of the verb, as *to love* = Latin *amare; to have loved* = Latin *amavisse.* The infinitive may be regarded as the point of transition from a verb to a substantive, and is often used as the subject of a proposition.

Infinitesimal Calculus. See CALCULUS, INFINITESIMAL.

Infin'ity, and the Infinitesimal. See INFINITE.

Inflammation, a term long used to indicate the phenomena that follow mechanical, chemical, or physical injuries to living tissues. These changes have been described for centuries as rubor (redness), calor (heat), dolor (pain), and tumor (swelling), which are the phenomena particularly seen on surface inflammations. At the present time the idea is becoming fixed that inflammation is a conservative process, the phenomena attending nature's effort to rid the tissue of harmful substances. In the normal process of repair of an injury there are changes which closely resemble the milder types of inflammation; but when to a mechanical, chemical, or physical injury there is added a growth of micro-organisms, the reply on the part of the body-cells differs from the ordinary repair of injury. The changes witnessed depend upon the strength and kind of invading micro-organism and the particular tissue invaded. The first change is *hyperæmia,* a suffusion of the part with blood from capillary dilatation; following this the liquid part of the blood, the serum, is poured out into the tissues and offers its resisting powers to the poisonous substance. If these measures be insufficient, the white blood-cells called phagocytes congregate in the tissues, destroying the invading organisms, by actually consuming them and neutralizing their toxic products. During this struggle there is more or less death of the cells, called "degeneration"; large masses "slough"; the remnants of the cells and the phagocytes killed form the thick fluid called pus. When an inflammation goes on to the formation of pus, it is spoken of as *purulent* or *suppurative.* Certain poisons cause a peculiar reaction on the part of the tissues, characterized by the formation of new tissue that is unable to carry on the function of the part. This tissue is the same as the connective tissues, and the process is called *productive inflammation.* The poisons that continue to act for a long time are particularly apt to cause this reaction, and the inflammation is called *chronic* because of its permanency. Catarrhal inflammations are these same processes when they occur in mucous membranes; the appearance of these catarrhs, however, is different, owing to the peculiar structure of mucous membrane and to the fact of the epithelial covering offering excellent resistance to invasion. When death of cells occurs they can readily be cast off. Croupous inflammation is the term used to describe those in which there is considerable destruction of the superficial layers of the mucous membrane, which, with the fibrin of the blood, forms a coating or "false membrane" on the surface. Granulation tissue (q.v.) is the name applied to the tissue formed during the repair of an injury. Names are given to certain types of inflammation having a characteristic appearance to the naked eye, but microscopically there is nothing absolutely distinctive in these except their arrangement. Particular examples of these are tubercular and syphilitic inflammations.

The majority of the diseases of the body that we recognize as entities are due to inflammation in some tissue or organ, but the picture depends on the various changes in the functions of different parts of the body. The kind and virulence of the generated poison, together with the reaction on the part of the body-tissues, makes the complete picture that we seek to recognize. The treatment of inflammation is, in large part, the practice of medicine and surgery. Efforts to help the tissues combat against invasion are made with more success as knowledge is gathered of the peculiar invading forces and the natural modes of defense. It is not that we wish to combat the inflammation *per se,* but rather to make it unnecessary by helping it to a successful issue. The actual destruction of the bacteria by drugs introduced into the body is of little use, for they would be apt to cause as much destruction of the body-cells as of the invading cells; but their toxines, which cause the actual damage, we are learning to neutralize by the administration of artificially prepared antitoxins, and by placing the body and its special tissues under the most favorable conditions for developing its natural forces of resistance.

In exposed parts of the body, where antiseptics may be applied, the toxic germs may be killed, and various measures that change the blood-supply may be advantageous. Where death of tissue takes place, nature may require help in its removal. It has long been the rule to evacuate pus wherever it is formed, unless its escape from the tissues is easy.

The treatment of chronic inflammation is entirely different, as this is a process where actual structure is changed beyond repair in many instances. The all-important question is whether the tissue can carry on its proper functions; for if it can, the body need not suffer. The inflammatory process is arrested in its progress by the removal of the irritating cause, by improving the blood-supply of the part and the vitality of the body generally. These constitute the measures in general applied for the cure of chronic inflammations, it being understood that the endeavor is to place the tissues in such a condition that they may carry on their functions for the good of the whole organism; and the failure of these measures shows either that they are at

fault or that the tissue-change has gone too far. Inflammation of any part is indicated by adding the suffix "itis" to the name of the organ or tissue. See Bronchitis, Colitis, Laryngitis, Meningitis; etc.

Dudley D. Roberts, M.D.,
Brooklyn, N. Y.

Inflexion (Latin, *inflexio,* a bending), that process in grammar which modifies words when placed in relation to other words in a sentence. Pronominal and predicative roots are combined to form one word in the Semitic and Aryan tongues, which are therefore called inflexional, a process impossible in monosyllabic languages like the Chinese or in languages of the agglutinate order like those of the Turanian family. In grammar, cases, numbers, persons, tenses, etc., are known as inflexions, and in many instances the original affixes can be readily recognized. The Semitic and Aryan families of languages, which admit of phonetic corruption both in the root and the terminations, are called organic or amalgamating languages. The pronominal termination varies according to the person or number. Thus the Sanskrit *mi, si, ti,* the endings of the three persons singular of the present of the verb, are perhaps from the personal pronouns *ma, sva, ta,* and the persons of the plural indicate the plural number by the form of the pronominal affixes. The plural of masculine and feminine Greek and Latin nouns of the third declension is probably a contraction of the duplication of *sa,* the pronoun of the third person. The verbs *i,* to go, *as* and *fu,* to be, supply the inflexions of certain tenses of the verb, there being also a pronominal termination varying according to the person. In English the common auxiliary verbs am, do, have, shall, will, may, can, asserting respectively existence, action, possession, obligation, volition, liberty, power, assume the function of inflexions, and are themselves inflected to denote past time. In French the same inflexional law exists, the connection between the auxiliary and the root being closer than in English. *Aimer-ai,* I have to love, that is, I shall love, is compounded of the infinitive *aimer,* to love, and *ai,* I have, the first person present indicative of *avoir.* The same is the case in Italian and Spanish.

Inflores'cence, Infructescence, botanical terms referring respectively to methods of flowering and fruit-bearing. The flowering shoot, says Strasburger, frequently bears only a single flower, which may then be either axillary or terminal. In many cases, however, the metamorphosis of the generative region, which results in the production of flowers, has led to the formation of a special system of fertile shoots termed an inflorescence or, after the fruit is formed, an infructescence. (See Flowers; Fruit.) Such inflorescences are wanting or ill developed among the Gymnosperms, while in the Angiosperms they are often well differentiated, constituting unities of a higher order. The modifications exhibited by the fertile shoots of such an inflorescence are due, partly to a difference in their mode of branching, partly to the reduction or the metamorphosis of their leaves. These changes are the result of an adaption to pollination, in the endeavor to aggregate the flowers and at the same time render them more conspicuous by the reduction of the foliage-leaves. Sometimes the whole system of fertile shoots is converted into an attractive apparatus, as in the *Araceæ,* where the axis and the subtending leaf of the inflorescence have assumed the function, usually exercised by the perianth, of enticing insects. Viewed from a purely morphological standpoint, two types of inflorescences may be distinguished, the Botryose (racemose, monopodial) and the Cymose (sympodial).

Influenza, la grippe; an epidemic catarrhal fever, now believed to be due to a very minute bacillus that can be found in the various secretions. Epidemics of this disease have been traced back as far as the beginning of the 16th century, and since 1741 many such epidemics spreading over portions of Europe have been described. There are so many different types of the disease, and so many parts of the body may be distinctly attacked by it that it somewhat baffles close definition. The epidemics vary much in severity as well as in type. During the last decade it has become almost constantly present over portions of the United States, in some years being much worse than in others.

So great is the variation of its symptomatology that no standard description can be given, and the types are classified according to prominent features. After one to four days of incubation, the disease usually sets in abruptly with chilliness or true rigor; this is followed by a fever (which may be constantly low or may run very high), headache and general aching, and a degree of prostration out of proportion to any discoverable cause. The respiratory form is characterized by inflammation of the nasal, the pharyngeal, the laryngeal, the tracheal, and the bronchial membranes. Starting in the nasal mucous membrane, the inflammation is apt to involve the other membranes in the order given. It is quite common for the lungs to show small spots of bronchopneumonia. There is frequently nothing to distinguish such an influenza from similar acute catarrhs of the respiratory passages except the known presence of an epidemic and the disproportionate prostration. The gastro-intestinal form is characterized by nausea, vomiting, abdominal pain and profuse watery discharge, with prostration sometimes amounting to collapse. The typhoid form is characterized by the sudden development of rather high fever (with or without severe aches and pains), general apathy, or even a low muttering delirium. The fever runs from a few days to two weeks, and may very closely resemble typhoid. The nervous form is characterized by severe pains throughout the entire body, prostration, moderate fever, but no definite affection of any part or organ. The meningeal form is characterized by headache, fear of light, pain and stiffness of the muscles of the back of the neck.

Complications and extension of the inflammation to other parts are common. Pneumonia complicating influenza is rather apt to be very severe, and in some epidemics the mortality rises very high. Pleurisy is quite common. Great disturbance of the heart's action is seen in some cases, and the poison may actually attack the lining membrane of its chambers. Less commonly there is inflammation of the eye, ear, brain, liver, intestine, or kidneys. The skin is sometimes affected, showing a general blushing rash, herpes (small painful itchy blisters), or bloody patches. A very common sequel is great

nervous depression, either an inability to make bodily or mental exertion or "low spirits," even amounting to true melancholia. Unless influenza is epidemic, differential diagnosis may be very difficult, but hasty refuge in a diagnosis of "grippe" is far too common; in doubtful cases search should be made for the specific bacillus and considerable reliance placed on the presence or absence of the characteristic symptom, extreme weakness.

For the disease there is no specific treatment; the infecting organism must continue to grow until the natural defenses of the body overcome it; as yet no means has been discovered of killing the bacillus in the body or overcoming its poisons by an antitoxin. Careful isolation of the affected individual will prevent the spread of the disease to other members of the family, and much can be done for the patient's relief. Useful measures consist in securing thorough action of the bowels, keeping up the nutrition by simple, easily digested foods, and the administration of drugs such as phenacetin, acetanilid, caffeine, and bromides to relieve the distressing pains or nervous tension. The nervous exhaustion which is apt to follow is best treated by a period of mental rest, nourishing diet, and little or no bodily exertion.

DUDLEY D. ROBERTS, M.D.,
Brooklyn, N. Y.

Infor'mer, a person who sues for a penalty against those who have infringed any law or penal statute. To encourage the apprehending of certain felons, guilty of offenses not so much criminal as bordering on criminality, many English statutes, from 1692 downward, granted rewards to such as should prosecute to conviction. The penalty in whole or in part inflicted in the case of a successful conviction, and immunity from certain troublesome parish offices, were the inducements held out to informers. In many cases this practice has been resorted to in modern statutes. In the United States one who informs the government of the whereabouts of smuggled goods, counterfeit money, etc., is rewarded by a fee of ten per cent of the net value of the confiscated goods. In criminal law an informer is said to turn state's evidence (q.v.).

Infu'sion, in pharmacy, an aqueous solution of a medicinal substance obtained by treating with water, usually without the aid of boiling. The water may be either hot or cold, varying with the object to be obtained. According to the directions of the United States Pharmacopœia, infusions are generally prepared by pouring boiling water upon the drug and macerating in a tightly closed vessel until the liquid cools. The active principles are in this manner extracted more rapidly and, as a rule, in much larger portions than if the solution is colder. Heat is not advisable if the active principles are volatile. If an infusion is desired of a greater degree of concentration than that obtained by the process of maceration, it is frequently prepared by percolation, in which operation the drug is sliced or broken up into small fragments, packed in a percolator, and the water, either hot or cold, is passed through. Infusions are sometimes made with the aid of other liquids than water, but this is the exception rather than the rule. Infusions do not keep well, and therefore they should be made extemporaneously and in small quantities. In household medicine, infusions are very widely employed. These may be made at home or made by the pharmacist. It is essential to remember that if they are made in hot weather in large quantities they must be sterilized.

Infusion of saline solution into the blood-vessels is a very important procedure in medicine. It is employed largely in the treatment of shock, and in severe hemorrhage, especially following operations or childbirth. The solution that is used is known as a normal salt-solution, and consists of about one teaspoonful of common salt to a pint of water. This solution should be boiled carefully for one half to three quarters of an hour, the amount of evaporating water being made up as the boiling proceeds, and after being made it should be kept in large bottles provided with cotton plugs for stoppers. In severe cases of hemorrhage, infusion has often saved life, as it provides a body of fluid on which the heart and blood-vessels can act. The salt-solution is usually introduced into one of the large veins of the arm at a temperature of one to two degrees above that of the body-temperature. See BLOOD; TRANSFUSION.

Infuso'ria, Protozoa of the classes *Flagellata* and *Ciliata,* originally so-called from abounding in organic infusions. While the term is now restricted to the ciliate protozoans, it often includes the flagellate protozoans as well. The latter are represented by the monads. These are exceedingly minute round or pear-shaped animals, which move by one or two lash-like processes called flagella. They contain a nucleus and contractile vesicles. Some of them are fixed by a stalk, and are provided with a collar, as in *Codosiga,* out of which the flagellum projects. One of the simplest monads (*Heteromita*) is obtained by placing a cod's head in water at a temperature of about 70° F. In a few days the water will swarm with these monads. The young germs will live in boiling water, but perish at a temperature of from 212° to 268° F., while the adults are destroyed at 142° F.

In the ciliate infusoria the body is more or less flattened and covered with cilia (*Paramecium,* etc.). They have on the under side of the body a slightly defined mouth (or cytostome), which is permanently open, and the food is swept into it by the action of the cilia around it. The mouth leads into a funnel-shaped throat or cytopharynx, which ends in the protoplasm of the body. The food-particles swept into this throat and pressed into the protoplasm form a small enlargement which finally sinks farther in forming the "food vacuole," which, by the flow of the protoplasm, is carried about the body, while the digestible portions are absorbed and the waste matter is cast out at a fixed point,—a sort of vent (cytopyge). The fresh-water forms have contractile vesicles, and in certain species the animal possesses so-called stinging rods (trichocysts), which are very minute and are placed vertically to the surface of the cortex; by some students they are supposed to be tactile rather than stinging structures. What correspond to the muscular fibres of the higher animals, cause the quick convulsive movements observed in these creatures. Two important organs are present in all ciliate in-

fusoria, that is the nuclei. The larger nucleus (macronucleus) is an oval, rod-like or spiral body, which appears to control the processes of feeding and motion. The other nucleus (micronucleus) is much smaller and is concerned with reproduction. Reproduction occurs usually by self-division, and more rarely the infusorians contract into a ball and divide into spores, which grow to become adults. The periods of fission are at times interrupted by the process of conjugation, which only differs from sexual reproduction in the fact that two individual infusorians meet and fuse together and then separate, the result being a process of fertilization which leads to a complete new formation of the nucleus, and thus to a new organization of the animal. (For a more detailed account see Hertwig-Kingsley's 'Zoology' 1903.)

The more specialized infusoria are *Stentor* and *Vorticella*. The former is large enough to be seen without a lens. It is purplish, and under the microscope shows itself to be a beautiful creature. It is trumpet-shaped, with a spiral tract of thicker cilia around the mouth-end. The most highly organized infusoria are the bell-animalcules (*carchesium*, etc.), which are compound bell-shaped forms, forming colonies with forked branched stalks. The nucleus is sausage-shaped, and near it is the micronucleus. They form a white mass like mold on the stems and leaves of aquatic plants. Some of the infusoria are parasitic in the digestive and circulatory organs of the higher animals. Consult: Stein, 'Organismus der Infusions-Thiere' (1859–83); Saville Kent, 'Manual of the Infusoria' (1880–2); M. Hartog, 'Protozoa' (Vol. I., Cambridge Natural History, 1903); Ray Lankester, 'Treatise on Zoology' (1902); Hertwig-Kingsley 'Zoology' (1903).

In'galls, John James, American lawyer: b. Middleton, Mass., 29 Dec. 1833; d. Las Vegas, New Mexico 16 Aug. 1900. He was graduated from Williams College in 1855, and was admitted to the bar in 1857. In 1858 he moved to Kansas and established a law practice there. He was secretary of the territorial council in 1860, and of the State senate in 1861, and in 1862 was elected a member of the senate. In 1873 he became a member of the United States Senate, and was re-elected in 1879 and 1885. He was president pro tem. of the Senate from 1887–91. In 1891 he was again a candidate for senator, but was defeated by the Farmers' Alliance. From that time till his death he devoted himself chiefly to lecturing and writing.

Ingalls, Rufus, American soldier: b. Denmark, Maine, 23 Aug. 1820; d. 15 Jan. 1893. He was graduated from West Point in 1843, fought in the Mexican War and in 1854–5 was a member of Steptoe's expedition to the Northwest. At the outbreak of the Civil War he defended Fort Pickens, then became quartermaster of the Army of the Potomac, and was present at many of the important engagements, and at the close of the war had attained the rank of major-general. In 1867 he became quartermaster of the military division of the Atlantic, quartermaster-general of the United States army in 1882 and was retired in 1883.

Ingelow, ĭn'jĕ-lō, Jean, English poet and novelist: b. Boston, Lincolnshire, 1820; d. Kensington, London, 20 July 1897. Her first published work appeared anonymously in 1850 under the title 'Rhyming Chronicle of Incidents and Feelings.' It was followed by 'Allerton and Dreux: or the War of Opinion' (1851), a story, and 'Tales of Orris' (1860); but not till the publication of 'Poems,' in 1863, did Miss Ingelow become famous. This volume won the enthusiastic praise of critics and the instant approval of the public, and passed through 23 editions. The most widely appreciated poems in it are 'The High Tide on the Coast of Lincolnshire'; 'Songs of Seven'; 'Divided'; and 'Supper at the Mill.' Later volumes were: 'Studies for Stories' (1864); 'Stories told to a Child' (1865); 'A Story of Doom, and Other Poems' (1867); 'Mopsa the Fairy' (1869); 'Off the Skelligs' (1872), her first long story; 'The Little Wonder Horn' (1872), a new series of stories told to a child; 'Fated to be Free' (1875); 'Sarah de Berenger' (1880); 'Don John' (1881); and 'John Jerome' (1886). A third volume of verse, 'Monitions of the Unseen' was published in 1885. Her works have been even more popular in America than in her native country.

Ingeman, Bernhard Severin, Danish poet and novelist: b. Torkildstrup, on the island of Falster, 28 May 1789; d. Sorö 24 Feb. 1862. He was educated at the University of Copenhagen, and it was while a student there that he published his first 'Poems' (1811–12), of a dreamy, melancholy nature, showing the influence of German romanticism, and displaying the unhealthy state of his body and mind. In 1814 he published a long allegorical poem, 'The Black Knights,' which showed a marked advance. The next six works which he produced were plays, the tragedy 'Blanca,' brought out in 1815, being the most popular and successful, though 'The Miraculous Child Reinald' (1816) was undoubtedly the best. 'The Subterranean Ones, a Story of Bornholm,' his first prose work, was written in 1817, and the following year he started on a tour of the Continent, returning in 1819. On his return he wrote his 'Stories and Miraculous Tales,' which was published in 1820, followed in 1821 by a comedy, 'Magnetism in a Barber's Shop,' which, however, was unsuccessful, and thereafter he confined himself to prose work. In 1822 he accepted the chair of Danish language and literature at the Academy of Sorö, and then began his voluminous writings on historical subjects, his novels probably being inspired and copied from the Waverley novels, by Scott. The subjects and characters were taken from Danish history, and, while they were to a great extent inaccurate, were possessed of such strong nationality that they became of great interest. Among these historical romances were 'Valdemar the Victorious' (1826); 'Erik Menved's Childhood' (1828); 'King Erik and the Outlaws' (1833); 'Prince Otto of Denmark and his Time' (1835). From 1837–9 he wrote a collection of 'Evening and Morning Songs,' which became very popular on account of their great beauty of religious expression. From this time until his death his writings were mainly religious, and the last of his works, 'The Apple of Gold,' was published in 1856. His collected works in 41 volumes were published in Copenhagen (1843–65).

Ingenhousz, Jan, Dutch physician and scientist: b. Breda, Holland, 1730; d. Bowood, the

seat of the Marquis of Lansdowne, England, 7 Sept. 1779. He studied medicine, and after practising in his own country for several years removed to London in 1767. In 1769 he was appointed aulic councilor and body physician to the Austrian Empress, Maria Theresa, and to Joseph II. After serving for 10 years in that capacity he returned to London, where he began his scientific researches, later becoming a fellow of the Royal Society, and publishing in their 'Transactions' several treatises and essays. Among these were 'Experiments on Vegetables, Discovering Their Great Power of Purifying the Common Air in Sunshine, but Injuring it in the Shade, or at Night' (1779); 'Anfangsgründe der Electricität' (1781); 'Essay on the Food of Plants and the Renovation of Soils' (1796). Dr. Ingenhousz is credited with being the discoverer of the use of carbonic acid for medicinal purposes, and he also invented the plate electrical machine.

Ingersoll, ing'gėr-sŏl, **Charles Jared,** American statesman, lawyer, and author; son of Jared Ingersoll (q.v.): b. Philadelphia 3 Oct. 1782; d. there 14 May 1862. After finishing his collegiate course he studied law, was admitted to practice, traveled in Europe, and became attached to the American embassy to France. In 1812 he was elected to Congress, taking his seat in May 1813. In 1815 he was appointed United States district attorney for Pennsylvania, an office which he held until 1829. Shortly after he was elected to the legislature of Pennsylvania. He was a member of Congress 1841–7 as representative of one of the districts of which the county of Philadelphia was then composed. He was the author of the poems 'Chiomara' (1800), and 'Julian' (1831); and of 'Inchiquin — the Jesuit's Letters on American Literature and Politics' (1810); 'Historical Sketch of the Second War between the United States and Great Britain' (1845–52); etc. Consult Meigs, 'Charles Jared Ingersoll' (1896).

Ingersoll, Ernest, American naturalist: b. Monroe, Mich., 13 March 1852. He studied at Oberlin College and in the Lawrence Scientific School and Museum of Comparative Zoology of Harvard University, where he was a pupil of Agassiz, and in 1874 and 1877 was connected as naturalist with the Hayden survey. He was also an expert on the United States fish commission, and later became known as a popular writer and lecturer on scientific subjects. In 1901 he was lecturer in zoology at the University of Chicago. Among his works are: 'Nests and Eggs of North American Birds' (1880–1); 'Oyster Industries of the United States' (1881); 'Knocking 'Round the Rockies' (1883); 'Country Cousins' (1884); 'The Crest of the Continent' (1884); 'Down East Latch-Strings' (1887); 'Wild Neighbors' (1897); 'The Book of the Ocean' (1898); 'Nature's Calendar' (1900); 'Wild Life of Orchard and Field' (1902); and also 'The Ice Queen,' and several other popular juvenile tales.

Ingersoll, Jared, American politician: b. Milford, Conn., 1722; d. 1781. Upon the passage of the Stamp Act he was appointed, in 1765, a stamp agent in Connecticut, and accepted the post by the advice of Franklin. This subjected him to the personal abuse and insults from which all colonial stamp agents suffered, and finally he was forced to resign; later, in 1770, becoming an admiralty judge. He wrote and published a pamphlet called 'The Stamp Act' (1776).

Ingersoll, Jared, American lawyer: b. Connecticut 1749; d. Philadelphia 21 Oct. 1822. Having been graduated at Yale College in 1766, he went to London, was entered of the Middle Temple, and passed five years in the study of law. The American Revolution breaking out while he was still in London, he espoused the cause of the colonies, although the son of a loyalist. He went from London to Paris, where he remained for 18 months, making the acquaintance of Franklin. Returning home, he took up his residence in Philadelphia, where he won almost immediately a prominent position as a lawyer. In 1787 he was chosen one of the representatives of Pennsylvania in the convention which framed the United States Constitution. Twice attorney-general of the State, he was United States district attorney for Pennsylvania, and was in 1812 the federal candidate for Vice-President of the United States.

Ingersoll, Joseph Reed, American lawyer and politician: b. Philadelphia, Pa., 14 June 1786; d. there 20 Feb. 1868. After graduating from Princeton in 1804, he took up the practice of law in Philadelphia. He was a Whig member of Congress from 1835–7, and again from 1842–9. In 1852 President Fillmore appointed him minister to England, a post which he held for only a year. He wrote 'Secession a Folly and a Crime,' which appeared just previous to the outbreak of the Civil War; also a 'Memoir of Samuel Breck' (1863).

Ingersoll, Robert Green, American lawyer, lecturer and author: b. Dresden, N. Y., 11 Aug. 1833; d. Dobb's Ferry, N. Y., 21 July 1899. He received a common school education and was admitted to the bar in 1854. He soon became prominent in the courts and in Democratic politics. In the Civil War he recruited the 11th Illinois cavalry and entered the army as its colonel. On 29 Nov. 1862, while trying with a force of 600 men to intercept a Confederate raiding party, he was captured by a force of 10,000 men, but was soon paroled and given command of a camp in Saint Louis. He soon afterward resigned. After the war he became a Republican, and was made attorney-general of Illinois in 1866. He was a delegate to the Republican National Convention in 1876 and placed in nomination for President James G. Blaine, whom he termed "the plumed knight." His nominating speech gave him national reputation as an orator, and he afterward lectured frequently. He was an agnostic, and in his lectures attacked the Bible and the beliefs of the Christian religion. He was prominent in politics for several years, and had he not given such frequent expressions to his agnostic views he would doubtless have been honored with high offices. He took up his permanent residence in New York city in 1882 and practised law there till his death. His most famous lectures include 'Some Mistakes of Moses'; 'The Family'; 'The Liberty of Man, Woman, and Child'; 'The Gods'; and 'Ghosts.' His publications include 'Lectures Complete' (1886); 'Prose, Poems and Selections' (1888); and 'Great Speeches' (1887). A complete collection of his works was published in 1900.

Ingersoll, Canada, town in Oxford County, Ontario, on the Thames River and the Grand Trunk railway, 10 miles northeast of London. It is the marketing centre for a rich grain and fruit-producing section, and has an important trade in lumber, grain, cheese, and general country produce. It has manufactures of iron products, machinery, agricultural implements, woolen goods, woodenware, lumber, and creamery products; banks, and weekly newspapers. Pop. (1901) 4,573.

Ingham, Benjamin, English evangelistic leader: b. Ossett, Yorkshire, 11 June 1712; d. Aberford 1772. He received his education at Batley School and at Queen's College, Oxford, whence he graduated B.A. in 1733. In 1735 he was ordained, and, becoming associated with John Wesley, went with him to Georgia, remaining two years. In 1737 he went with the Wesleys on a visit to the Moravians in Germany, and became so strongly attached to their doctrines that he broke with the Wesleys and founded in Yorkshire several congregations of what were known as "Moravian Methodists," but more commonly as "Inghamites." He endeavored to unite in this organization the chief doctrines of the Moravians and Methodists, and so successful was he as bishop or general overseer that in a few years there were 84 of these congregations in England. He moved to Aberford about the time of his marriage with a sister of the Earl of Huntingdon in 1741, and succeeded in converting the whole surrounding neighborhood to his faith. In 1759, however, the greater part of his followers deserted him and went over to Sandeman, and in 1760 Ingham himself joined the Sandemanians and the Inghamites disappeared.

Ingham, Charles Cromwell, American painter: b. Dublin, Ireland, 1797; d. New York 10 Dec. 1863. He was a pupil of William Cunning at the Dublin Academy, came to New York in 1817, was there a founder of the National Academy of Design (1826), and its vice-president in 1845–50. De Witt Clinton and Lafayette were among his subjects. His works include: 'Day Dreams'; 'The White Plume'; 'The Death of Cleopatra.'

Ingham, Samuel Delucenna, American politician: b. Bucks County, Pa., 16 Sept. 1779; d. Trenton, N. J., 5 June 1860. He was for some time in the Pennsylvania legislature, and was then sent to Congress, 1813–18, and again 1822–9. In the interim he was appointed prothonotary of the courts of Bucks County, but resigned in 1819 to become secretary to Gov. Finley. On 6 March 1829 President Jackson appointed him secretary of the treasury, a position he continued to hold till 1 Aug. 1831.

Ingleby, Clement Mansfield, English author and Shakespearean critic: b. Edgbaston, near Birmingham, 29 Oct. 1823; d. Ilford, Essex, 26 Sept. 1886. After graduating from Trinity College, Cambridge (B.A. 1847; M.A. 1850) he entered into partnership with his father, but in 1859 gave up his law practice and moved to Ilford, where he began writing for the magazines on scientific and metaphysical subjects. His best known works are his Shakespearean studies, among which are 'The Shakespere Fabrications' (1859); 'Shakespere Controversy' (1861); 'Shakespeare's Centurie of Prayse, etc.' (1874); 'The Still Lion' (1874; new edition 1875, entitled 'Shakespere's Hermeneutics'); 'Shakespere: the Man and the Book' (1877–8). He also wrote 'Outlines of Theoretical Logic' (1856); 'An Introduction to Metaphysics' (1864–9); etc.

Inglis, ĭng'lĭz, **Charles,** American Anglican bishop: b. New York 1734; d. Halifax, Nova Scotia, 1816. He was ordained priest in England, and in 1765 became assistant minister at Trinity Church, New York. A stout loyalist, he refused to omit from the service the prayer for the king and royal family, and upon the occupation of New York by Washington retired for a time to Long Island. In 1777 he was chosen to the rectorship of Trinity, and in 1783, at the evacuation of New York by the British, went to Halifax in the emigration of the United Empire loyalists. He was consecrated in 1787 bishop of Nova Scotia (with jurisdiction over the other North American provinces), and was the first missionary bishop of the Church of England. He published sermons and pamphlets.

In'got, a small bar of metal formed by casting it in molds. The term is chiefly applied to the bars of gold and silver intended for coining.

Ingraham, ĭng'grȧ-ȧm, **Duncan Nathaniel,** American naval officer: b. Charleston, S. C., 6 Dec. 1802; d. there 16 Oct. 1891. He entered the navy as midshipman in 1812, and became a captain in 1855. While in command of the sloop-of-war St. Louis he arrived at Smyrna 22 June 1853, and was informed that Martin Koszta, Hungarian by birth, but entitled to the protection of the United States, was a prisoner on board the Austrian brig of war Hussar, then lying near the St. Louis. Ingraham went on board the Hussar, had an interview with Koszta, and learned that he had resided a year and 11 months in New York, where he took the usual oath of allegiance to the United States in July 1852, and was in possession of a legalized copy of a declaration of his intention to become an American citizen; that he had come to Smyrna from New York on business; that on the afternoon of 21 June he was seized by a party of armed Greeks, employed by the Austrian consul-general, carried on board the Hussar, where he was held in close confinement. Ingraham accordingly, on 2 July, at 8 A.M., demanded of the Austrian commander the release of Koszta by 4 P.M., declaring that he would otherwise take him by force. At 11 o'clock the Austrian consul-general proposed to deliver Koszta into the hands of the French consul, to be held by him subject to the disposition of the consuls of the United States and Austria, and not to be delivered without their joint order. As this proposition gave sufficient assurance of the personal safety of Koszta Ingraham accepted it, and the Hungarian was set at liberty. The conduct of Ingraham was fully approved by the government, and Congress by joint resolution, 4 Aug. 1854, requested the President to present a medal to him for his conduct on this occasion. In 1860 he resigned from the United States navy, entered the Confederate service and became a commodore.

Ingraham, Joseph Holt, American novelist: b. Portland, Maine, 1809; d. Holly Springs, Miss., December 1866. After a brief experience

of mercantile life he became teacher in Washington College, Natchez, Miss., and in 1836 published his first book, 'The South-West, by a Yankee.' Thenceforth he produced in rapid succession 'Lafitte'; 'Burton, or the Sieges'; 'Captain Kyd'; 'The Dancing Feather'; and other romances of small literary merit, some of which attained a large circulation. He subsequently entered the Episcopal ministry and was rector of a parish and of St. Thomas's Hall, an academy for boys, in Holly Springs, Miss. He still continued to write, publishing 'Prince of the House of David' (1855) and the 'Pillar of Fire' (1859); 'The Throne of David,' which were widely popular, but nearly worthless from a literary point of view.

Ingraham, Prentiss, American soldier and author: b. Adams County, Miss., 22 Dec. 1843. He was educated at Jefferson College (Miss.), also studied medicine at the Mobile Medical College, entered the army of the Confederate States in 1861, fought later with Juarez in Mexico, with the Austrian army in the war with Prussia, and in the ten-years' war for independence in Cuba. Subsequently he entered a literary career, and published a great quantity of fiction, including: 'Without Heart' (1878); 'Zuleikah' (1887); 'Red Rovers on Blue Waters' (1890); 'The Vagabond' (1891); and 'The Wandering Jew of the Sea' (1891).

In'gram, John Kells, English educator and author: b. County Donegal, Ireland, 7 July 1823. He was educated at Trinity College, Dublin, and was appointed professor of oratory and English literature there in 1852, Regius professor of Greek in 1866, and librarian in 1879. At one time he was vice-provost of the college, and also held the presidency of the Royal Irish Academy. His 'History of Political Economy,' originally printed in the 9th edition of the 'Encyclopædia Britannica,' was separately published in 1888 and widely translated. He further wrote: 'A History of Slavery and Serfdom' (1895); 'Sonnets and other Poems' (1900); 'Human Nature and Morals according to Auguste Comte' (1901), and other works.

Ingres, Jean Dominique Auguste, zhŏñ dō-mē-nēk ō-güst ăñg-r, French historical painter: b. Montauban 15 Sept. 1781; d. Paris 14 Jan. 1814. Placed in the school of David he made such rapid progress that at 20 he had gained in two successive years the first and second prizes of the Academy of Fine Arts, In 1806 he departed for Italy, where he passed nearly 20 years, abandoning, under the influence of a close study of Raphael and the old masters, the dry, classic style acquired from David. His works are numerous, and comprise generally serious historical and classical subjects; in the great exhibition of 1855 at Paris an entire salon was appropriated to them. Many are in the Louvre, on the ceiling of one of the apartments of which is painted his 'Apotheosis of Homer.' He painted the portraits of many distinguished personages, from Napoleon I. downward. The art of Ingres is adjudged to hold a middle place between the classic and the romantic schools.

Inhala'tion, in medicine, a mode of applying remedies directly to the respiratory tract. Either steam alone, steam charged with drug-vapors, or drugs finely subdivided in sprays, are breathed into the air-passages as deeply as possible. This method of medication is useful only in relieving inflammations of the upper air-passages and possibly the trachea and larger bronchi. The air in the smaller bronchi is not changed by breathing, but by the diffusion of gases, so that substances in aërial suspension are deposited on the surface before reaching the smaller divisions of the bronchial tubes. Steam does not penetrate far, but is cooled, and deposits moisture as far as the trachea. The old-fashioned croup-kettle and many devices for carrying out the same idea are used for the first stages of laryngitis. Many substances, such as tincture of benzoin, etc., are added to the boiling water, but render it no more efficacious. Instead of conducting the steam directly to the mouth and nose by a funnel or tube, it may be well to place the patient in a simply enclosed tent, formed of bedclothes, and to allow the steam to charge the confined air. This method is particularly advisable for infants and older children.

Inher'itance, in law, a perpetual or continuing right to an estate invested in a person and his heirs. There are nine "canons of inheritance"; three may be quoted: (1) That inheritance shall, in the first place, descend to the issue of the last purchaser in *infinitum;* (2) That the male issue shall be admitted before the female; (3) That where two or more of the male sex are in equal degree of consanguinity to the purchaser, the eldest only shall inherit, but the females all together.

Inheritance Tax, an assessment laid upon those made heirs of property, either by distribution or descent. Sometimes this assessment is confined to collateral heirs, when it is called collateral inheritance tax. The raising of public funds in this way has been sanctioned by legislation from the beginning of Roman law, and in England and other countries is a large and steady source of revenue, although such taxes have been stigmatized by certain economists as "death duties." During the Civil War taxes of this kind were made part of the internal revenue system of the United States, but abolished soon after the struggle ended. The rate and method of assessment vary in different countries, and in different States of the Union. The English inheritance tax ranges from a 1 to a 10 per cent assessment, in accordance with the amount of the inheritance and the degree of relationship of heirs. In the United States lineal, collateral and succession inheritance taxes have been instituted in several States, as a source of domestic revenue. In Connecticut the assessment on inherited property is 5 per cent on all sums and values above $1,000. In Delaware the assessment ranges from 1 to 5 per cent, according to the amount of property left, and the degree of relationship. In Illinois, 1 per cent on values over $20,000 to lineal descendants; 2 per cent to 5 per cent on all amounts to collateral relations. In Maryland, 2½ per cent on all legacies and successions. In New York, 1 per cent on all property over the amount of $10,000 to lineal heirs, 5 per cent on all amounts over $500 to collateral relatives. In Ohio, 5 per cent on all values over $500. In

Virginia, 5 per cent in every case. Several States leave untaxed the property descending or distributed to the lineal descendants, and place assessments of varying percentage on the amount or value of the legacy which falls to collateral heirs. These are California, Maine, Massachusetts, Minnesota, New Jersey, Tennessee, West Virginia. Inheritance laws have in the United States occasioned much discussion and litigation, but their justice and utility have been testified to by experience and the decision of the law courts. The economists of the present and other periods have seen the scientific propriety of such legal provisions, and have noted the uniformity with which they deal with all classes of the financial community.

In'ia, a genus of toothed cetaceans similar to dolphins, but placed on structural grounds in the allied family *Platanistidæ*, with the freshwater dolphins of the Ganges and the La Plata. The single species (*I. geoffrensis*) is called bouto and tucuxi, and is found in some of the upper tributaries of the Amazon, and in the lakes near the Cordilleras. It measures about eight feet in length, has a long cylindrical snout with stiff hairs, and a very slight dorsal fin. It feeds chiefly on fish, and is hunted for the sake of its oil.

Initiative. See REFERENDUM.

Injunc'tion, a writ issued by a court of equity, bidding, or forbidding, a person or persons to do a certain thing. The injunction originated in Roman law, and was anciently known as an interdict, a name it still bears in Scottish practice. It was introduced as a remedy for some of the abuses of common law, and as a preventive, when evasion of common law provisions seemed possible. It is to-day one of the most potent of the legal remedies of an equitable character which stand on the statute books.

There are three main divisions in the purposes for which a writ of injunction is issued. A writ may be prohibitive, protective, or restorative. In the first place it may forbid the commission of certain acts of a civil nature which are charged with injustice. Second, it may be so framed as to protect such civil rights of an individual or a corporation as seem to be threatened. Third, it may order the restitution or restoration of such rights as have unlawfully been taken away from an individual or a corporation. These characters of the writ have been clearly expounded by Blackstone, as follows:

"This writ may be had to stay proceedings at law, whatever stage they may have reached; to restrain alienations of property *pendente lite*, and tenants for life and others having limited interest from committing waste. It may be granted to restrain the negotiation of bills of exchange, the sailing of a ship, the transfer of stock, or the alienation of a specific chattel, to prohibit assignees from making a dividend, to prevent parties from removing out of the jurisdiction, or from marrying, or having any intercourse, which the court disapproves of, with a ward. The infringement of a copyright or a patent frequently calls for the exercise of this beneficial process; which may also be had to restrain the fraudulent use of trade marks, or of the names, labels, or other indiciæ of the makers or vendors of goods and merchandise, and in a large class of cases, far too numerous to be mentioned here."

The first two kinds of injunction are most commonly used, and a familiar example of the prohibitory writ is that which orders the abatement of a nuisance. A railroad which lays tracks without first gaining the right of way may be compelled by injunction to remove them. By such a writ patent rights, copyrights and trade marks are secured from infringement, or proceedings in a court of law are stayed. Sometimes a court of equity issues an injunction prohibiting litigants within its own jurisdiction from prosecuting a suit in another jurisdiction; for example, a United States court may restrain creditors for suing in State courts for the enforcement of their claims against a bankrupt, and reserve the disposition of his estate to its own jurisdiction. A court of equity only issues a writ of injunction when a remedy of law appears inadequate to give the wronged party the complete relief to which he is entitled. Thus in recent cases the courts have issued writs forbidding labor agitators and others from inducing or coercing workingmen, in such a way as to bring on a strike to the injury and damage of employers, who might thus be induced to sacrifice their rights in order to escape ruin or irreparable loss.

An injunction in the United States may be preliminary or perpetual. A preliminary writ is sometimes styled interlocutory, as it is issued *pendente lite*. The preliminary writ may be made perpetual, if, after arguments made and heard, the court decides that the grounds advanced for the continuance are valid, and have been so proved by evidence. Failure to obey an injunction is punishable as a contempt of court (q.v.) Consult Beach, 'Treatise on the Law of Injunctions' (1895).

Injunction, Government by. See GOVERNMENT BY INJUNCTION.

Injunction, Theatrical, a term applied to a mandate issued by a court of equity, to compel or prevent the performance of some act for which money damages would not properly compensate the injured party. Relief by injunction in matters pertaining to theatricals is probably more frequently sought than in any other business or profession, and precedents in law established in this class of cases has become of considerable importance. At first, courts of this country and England refused to grant injunctions against actors for the purpose of compelling them to perform their contracts, a learned justice saying: "The Court could not regard as law the old adage that 'a bird that can sing and will not sing must be made to sing.' " But latterly, when the service of an actor became recognized and it was made to clearly appear that an actor or singer, by intelligence, education and other artistic accomplishments and talents, was of extreme importance to one who had invested money in the production of a play or opera, it was held that a court of equity would by injunction enforce a covenant in a contract. But this has simply gone to the extent of compelling a fulfilment of the contract, or forcing the artist to remain idle during its term. The services of every actor will not be enjoined. He must actually possess some exceptional merit, so that his services may be

termed special, unique and extraordinary, and it must be shown they cannot be fulfilled by any other person without injury to the employer. In the case of Lumley *v.* Wagner, the courts of England enjoined Johanna Wagner, a prominent prima donna of the early 50's from appearing at Covent Garden Opera House, London, in violation of her contract with Lumley; and then for the first time the British courts asserted their authority over contracts of actors, and granted an injunction forbidding her rendering professional services for any but her original employer.

In the United States, the Federal courts recognized the right of a manager to have the exclusive services of his employee, and in McCall *v.* Braham an injunction was granted which prevented Lillian Russell from violating her contract. In the State courts, the case of Augustin Daly *v.* Fanny Morant Smith (49 How. Pr. 150), Superior Court Justice Freedman also appreciated the fact that the ancient rule had been abrogated and the modern one compelling actors to live up to their agreements, as other individuals, was there enforced. The contract must unquestionably be fair. The rights of both parties to it must be equal. In other words, if the contract gives the manager the right to terminate it by giving notice before the expiration of the contract, a like right of termination must also be given the actor; and as stated before, the actor's services must be special, unique and extraordinary. In this latter connection, it seems uncertain where to draw the line. In the case of Carter *v.* Ferguson the court refused to grant an injunction to Mrs. Leslie Carter against William J. Ferguson, an actor, saying that his services were not so special and unique as to warrant a court of equity's interference. In Charles Hoyt *v.* Loie Fuller, the court granted an injunction against the dancer, holding that a serpentine dance in the performance of which she became famous, warranted the court's interference by injunction. In George Edwardes, the London manager, *v.* Cissie Fitzgerald, the New York Supreme Court granted an injunction against Miss Fitzgerald, on the theory that a certain wink of her eye used in a play was of special merit, and a drawing card. In Harris *v.* Sparks, an injunction was granted against John Sparks, the Irish comedian, the ground being that his portrayal of an Irish character was special, unique and extraordinary. While in the still later case of Shubert Brothers *v.* Aimee Angeles, imitations given by the performer were considered so special, unique and extraordinary as to warrant the granting of an injunction. Each case, however, must be determined by its own peculiar circumstances. In the most recent case — Harrison Grey Fiske *v.* Tyrone Power — the court refused to grant an injunction against Tyrone Power, although his ability as an actor was exploited in the newspapers; on the ground that his services were not so special, unique and extraordinary, as to justify an injunction. But in guarding the rights of an actor, the courts will see that no advantage has been taken of him by the manager, and that the manager for whom he is to perform is of such financial responsibility as to insure the salary of the actor. In the case of Rice *v.* D'Arville, Edward E. Rice, the theatrical manager, sought to restrain Camille D'Arville from performing for others; but on the defense that Rice was insolvent and indebted to her on a previous contract, Justice Oliver Wendell Holmes, then of the Massachusetts Supreme Court, would not compel her to perform for Rice.

Injunctions in the theatrical profession are not confined to actors and actresses, but are often invoked to prevent the piracy of a play or the use of a name. Where a play, or a scene from a play, has been copyrighted, the Federal courts alone have jurisdiction of the matter, and will by injunction prevent anybody from performing or producing it as their own. When there has been no copyright the common law protects the work, so well as its title; and the use of a similar name, or a name which is apt to deceive the public into the belief that it is the one already used by an author, will likewise be enjoined. A recent instance is the case of Charles Frohman *v.* Arthur Fraser, where the use of the title "Sherlock Holmes" was enjoined, this name having been adapted by William Gillette as the title of a play, notwithstanding the name had been used by A. Conan Doyle as the title of his novel. In that case the court held that Mr. Gillette having first used the name in connection with a theatrical production was entitled to all emoluments arising from it. Notwithstanding the numerous attempts to avoid the principles of law applicable to this class of cases, it matters not whether it is the actor who is involved or the theatrical manager, the American courts are humane, equitable, just and careful, and invariably zealously guard the interests of those engaged in the theatrical profession, so well as those engaged in any commercial business. See INJUNCTION; GOVERNMENT BY INJUNCTION; COURT; EQUITY; CHANCERY; CONTEMPT; LAW; etc.

Ink, a colored liquid used for writing and printing. They are of various classes, as writing and copying, black or colored, India, printing and lithographing inks.

For long ages past the best black writing-ink has been made by mixing together solutions of nutgalls and of ferrous sulphate of iron, known as green vitriol, and holding in colloidal suspension, by aid of a gum, the colored substance produced. The gallo-tannic acid present in a freshly prepared solution of galls, upon exposure to the air, changes gradually largely into gallic acid, and the protoxide of iron changes into peroxide. The color of this changed product is much deeper than that of the original mixture. It has been found that the permanency of the writing is greater if the ink is used before this conversion is fully completed. The change is held in check by having present in the ink a slight amount of some free volatile acid such as hydrochloric. The trace of acid also serves to hold the iron color in the state of colloidal suspension or solution. The moulding to which such an ink is liable is checked by adding to it a trace of some antiseptic, such as carbolic acid. All known commercial substitutes hitherto used for nutgalls in black writing-ink produce a fluid somewhat inferior to that from nutgalls.

An exhaustive scientific investigation of the chemistry of ink to determine the best ingre-

dients and the proportions to be used of the same for the producing of the most permanent black writing-ink has been made in Germany by Osw. Schluttig and Dr. G. S. Neumann, and published in their work on 'Die Eisengallustinten,' issued by Zahn & Jaensch of Dresden in 1890. Their conclusions were followed in preparing the specifications for the official "Standard Record Ink" required under the laws of Massachusetts to be used on all the public records in that state. The same specifications have since been adopted by the U. S. Treasury for the ink used in that department. This ink has also been adopted by the Danish government for its official records. The specifications, which were prepared by Dr. Bennett F. Davenport of Boston, as ink expert for the State of Massachusetts, it is to be noted are for the required quality of the ink, and not for the compounding of it. The specifications are as follows:

It must be a gallo-tannate of iron ink, not inferior in any essential quality to a typical standard for comparison which has been properly prepared after the following formula, in which all the ingredients are of the quality prescribed by the United States Pharmacopœia, and the per cent of true acid present in the sample of tannic acid used has been determined by the Loewenthal and Schroeder method.

Take of pure, dry Tannic Acid, 23.4 parts by weight; crystal Gallic Acid, 7.7 parts; Ferrous Sulphate, 30.0 parts; Gum Arabic, 10.0 parts; diluted Hydrochloric Acid, 25.0 parts; Carbolic Acid, 1.0 part; Water, sufficient to make up the mixture at the temperature of 60° F. to the volume of 1000. parts by weight of water.

Inks submitted will be subjected to the following tests, as compared with the typical normal standard ink described above: (1) A fluid ounce allowed to stand at rest in a white glass vessel, freely exposed in diffused daylight for two weeks to the light and air, at a temperature of 50° to 60° F., protected against the entrance of dust, must remain as free from deposit upon the surface of the ink or on the bottom or sides of the vessel. (2) It must contain no less iron, and must have a specific gravity of 1.035 to 1.040 at 60° F. (3) It must develop its color as quickly. (4) After a week's exposure to diffused daylight the color must be as intense a black when used upon the standard record paper, and it must equally resist changes from exposure to light, air, water, or alcohol. (5) It must be as fluid, flow as well, strike no more through the paper, nor remain more sticky immediately after drying.

To such an ink a slight amount of some one of the water soluble coal-tar colors is usually added to give the desired initial color to the ink when used in writing.

Cheaper grades of black writing-ink are produced by substituting for the nutgalls other tannin containing substances, or by using logwood. In these other iron salts, or salts of other metals are sometimes used, as of copper, aluminum or chromium. For special purposes some of these have certain advantages. For copying, for instance, the ink made from logwood with alum cake and chromate has the highest efficiency known. This ink, however, fades out after a few years' exposure to the open air and daylight.

Within modern times colored liquid solutions have come much into general use as inks, made up with aniline and other dyestuff colors. They are easily and cheaply made, flow nicely from the pen, and allow of a great variety as to choice in coloring, but none of them have the permanency of the ancient nutgall iron ink on exposure to light and air.

The usual basis of commercial marking inks, for use on textile fabrics, is some salt of silver. The permanent color of this ink is developed through the action of light, heat or some chemical, after the ink has been applied. The usual basis of India ink is an exceedingly finely divided solid carbon, mixed with a size to hold it in suspension when the ink is prepared for use by being ground up with water. The usual base used for printers' ink is a linseed-oil varnish. To this the desirable color is imparted by the use of lampblack, or some other coloring substance.

Manual' (1904); Fehling, 'Handwörterbuch Chemie' (1903) vol. VII.; Haldane, 'Workshop Receipts,' series 2 and 5.

BENNETT F. DAVENPORT, M.D.,
Expert on Written Documents, the Writing, Ink and Paper.

Ink'berry, or Winterberry, a shrub (*Ilex glabra*) of the holly family which grows upon the Atlantic coast of the United States. It is a fine evergreen, two to four feet high. Its stems are slender and flexible, and its leaves, about an inch in length, are lanceolate in form, of leathery texture, and present a shining upper surface. It bears small, very black berries. Formerly its bark and leaves were used medicinally, especially in fevers. For bouquets and decorative purposes it is much valued, and finds a ready market in large Eastern cities.

Inkerman, ĭnk-ĕr-măn', Russia, a village on the site of a ruined town in the Crimea, at the head of the harbor of Sebastopol, 35 miles by rail southwest of Simferopol. It gives its name to the sanguinary battle fought on the heights overlooking the town, on 5 Nov. 1854, when the Russians unexpectedly attacking the British camp were repulsed with great slaughter, losing in killed 3,000 and in wounded 6,000, the loss of British and French allies being 850 killed and 3,500 wounded.

Inlay'ing is the art of ornamenting flat surfaces of one substance by inserting into them pieces of some other substance. Various kinds of metal or wood, or pearl, ivory, etc., are employed in this process, which is now applied chiefly to the production of ornamental articles of furniture. When wood of one color is inlaid with others of different colors, as in ornamental devices in flooring, it is generally called marquetry, the various pieces of wood being usually disposed in regular geometrical figures. The art of inlaying iron or steel with other metals, as gold or silver, is called damascening. Buhl and reisner work, once highly prized, have lost much of their celebrity. The former took its name from Buhl, an Italian resident in Paris in the reign of Louis XIV., and the latter was designated after Reisner, a German who not long after settled in the same city. Buhl for the most part inlaid brass on tortoise-shell, Reisner a dark wood on a tulip-wood ground. The usual instrument for cutting out veneers for inlaying is a fine saw, mounted in a bow or arched handle, and worked in short quick movements. Three or four veneers are sometimes cut simultaneously in this way. Inlaying with stone, in which the Florentines have long excelled, is called *pietra dura,* and differs from mosaic in having the holes not cut through the ground, which is commonly of black marble, but only to a regulated depth.

The best work of this kind is now produced at St. Petersburg, the art being stimulated by encouragement from the Russian government. An Indian variety of inlaying, in which the inlaid metal occupies more of the surface than that which forms the ground, is called *Kuftgari;* and in another variety, *Tutenague* or *Bederywork,* small pieces of silver are hammered into spaces previously cut in the ground, which consist of one part of copper to four of pewter, and is thus both hard and easily cut. See Mosaic.

In'man, Henry, American artist: b. Utica, N. Y., 20 Oct. 1801; d. New York 17 Jan. 1846. From early boyhood he manifested a taste for art, and in 1814 Jarvis, the portrait painter, offered to receive him as a pupil, and he was bound an apprentice for seven years. Upon the conclusion of his apprenticeship he devoted himself to portrait painting. Among his most characteristic portraits are those of Chief Justice Marshall and Bishop White. He painted also landscape, genre, and history. In 1844 he visited England, where he was the guest of Wordsworth, whose portrait he painted, and at whose suggestion he executed his 'Rydal Water,' near the poet's residence. During his residence in England he also painted portraits of Dr. Chalmers, Lord Chancellor Cottenham, and Macaulay.

Inn, a river of Europe which issues from a lake at the foot of the Rhætian Alps, flows northeast through the deep and narrow valley of the Engadine, in the Swiss canton of the Grisons, enters the Tyrol at Martinsbruck, passes Innsbruck, Hall, and Kuffstein, and shortly after enters Bavaria. At Mühldorf it turns east till it receives the Salza, where it begins to form the boundary between Austria and Bavaria, and joins the right bank of the Danube at Passau, after a course of over 300 miles.

Inn and Innkeeper. In Great Britain inns are houses where travelers are furnished, for the profit of the provider, with everything they have occasion for while on their journey, and may be set up without license by any person, provided he refrains from selling excisable liquors, which of course require a license. Hotels, public-houses, taverns, victualing-houses, and coffee-houses are all inns when the keepers of them make it their business to furnish travelers with food and lodging; otherwise they are not. In the United States there are no inns, but hotels in cities and taverns in rural districts. See Hotels in America; Taverns.

Innate Ideas, certain notions or conceptions declared by many philosophers to be given to the mind of man when he first receives conscious being. Their existence has been much disputed by philosophers. The term innate, as applied to ideas, was first used by Descartes. As his definition failed in precision, the doctrine of Descartes was assailed by Hobbes and Locke. As afterward more strictly stated by himself, his views were as follows: An innate idea is not one that presents itself always to our thought, for there could be no such idea; but we have within ourselves the faculty of producing it. He has nowhere given an enumeration of the ideas that he considers innate, though he attaches particular importance to that of infinity, which he makes the foundation of his proofs for the existence of God. What the followers of Descartes designate innate ideas, those of Cousin term universal, necessary and absolute. Some of the greatest names in European philosophy are associated with the discussion of this theory, or of cognate theories, as Clarke, Newton, Malebranche, Kant, etc.

Innes, ĭn'ĕs, Alexander Taylor, Scottish jurist: b. Tain, Ross and Cromarty, Scotland, 18 Dec. 1833. He was educated at Edinburgh University, was admitted to the Scottish bar in 1870, appointed advocate-depute in Scotland in 1881, and served under later Liberal governments. Among his works are: 'The Law of Creeds in Scotland' (1867); 'Church and State: A Historical Handbook' (1890); 'Studies in Scottish History' (1892); a life of Knox in the 'Famous Scots' series (1896); 'The Trial of Jesus Christ' (1899); and 'The Law of Creeds' (1902).

Inness, George, American painter: b. Newburg, N. Y., 1 May 1825; d. Bridge of Allan, Scotland, 3 Aug. 1894. His art education began in boyhood and when 16 years of age he learned map engraving. He first attempted nature sketching in 1843, when he showed such promise that he was admitted into the studio of Regis Gignoux, New York; but soon opened a studio for himself and through the liberality of a patron was enabled to visit Europe. After spending 15 months in Italy and one year (1850) in France he finally made his home at Eagleswood, near Perth Amboy, N. J. He is looked upon as the first among American landscape painters, and was not only a clever and imaginative interpreter of the scenery among which he lived, but a man of intellect, a thoughtful yet bold theorist on art subjects and an incisive critic. He had a keen appreciation of American scenery, and the sky and atmosphere of the eastern States were sympathetically portrayed with an earnestness that recalls the sentiment of the Fontainebleau-Barbizon school. His early paintings are distinguished by conscientious care for detail, vivid perception of color, and the panoramic breadth of a bold and unconventional originality. After 1878 his style had ripened, and his technique grew simpler and less highly elaborated. He was willing to sacrifice all cleverness of touch in handling detail for the sake of portraying the emotion, or transitory effect of light and cloud in a landscape, the perturbation of storm or wind, the pageant of sunset, or the magic calm of a moonlight scene. In such productions his command of color was very remarkable. His pictures are much prized by connoisseurs, and when offered for sale command high prices. Five of them are in the Metropolitan Museum of Art, New York. Among the finest are: 'Under the Greenwood'; 'Close of a Stormy Day'; 'Pine Groves of Barberini Villa'; 'An Autumn Morning'; 'Autumn Gold'; 'The Edge of the Forest'; 'Passing Storm'; 'Moonrise'; 'Winter Morning, Montclair, New Jersey.'

Inness, George, Jr., American painter: b. Paris, France, 5 Jan. 1854. He is the son of George Inness (q.v.), the landscape painter. He was a pupil of the elder Inness at Rome in 1870–4, of Bonnat at Paris in 1875, began to exhibit at the National Academy in 1877, and became a member of the National Academy of

Design in 1899. In 1899 he obtained a gold medal at the Paris Salon. His manner is forcible, and skilful in color. His work includes landscapes and animal subjects, among them: 'The Pride of the Dairy' (1878); 'Pasture at Chemung'; 'A Mild Day' (1887); and 'Morning on the River' (1902).

In'nocence. A wildflower. See HOUSTONIA.

In'nocent, the name of thirteen popes, as follows:

Innocent I., Saint: b. Albano; d. 12 March 417. He succeeded Anastasius I. as Bishop of Rome in 402. He supported Saint Chrysostom (q.v.) when the latter was driven from his see of Constantinople through the machinations of the Empress Eudoxia. Rome was pillaged by Alaric in 410, during his pontificate. He is commemorated by the Roman Catholic Church on 28 July.

Innocent II. (GREGORIO DE' PAPI, or PAPARESCHI, grā-gō-rē'ō dā pä-pē pä-pä-rĕs'kē): b. Rome; d. 23 Sept. 1143. He was elected pope in 1130 by a part of the cardinals, while the others elected Peter of Leon, who took the name of Anacletus. Innocent fled to France, where he was acknowledged by the Council of Etampes, by Louis VI., and soon after by Henry II. of England; also by the Emperor Lothaire, who conducted him in 1133 to Rome, where he occupied the Lateran, while Anacletus occupied the Castle of Crescentius, the Church of St. Peter, and a large part of the city and maintained himself against Innocent until his death in 1138. He held the second Ecumenical Council in the Lateran, which condemned Arnold of Brescia and his heresy, declared all the decrees of Anacletus null, and excommunicated Roger of Sicily, who had supported the latter. Roger, however, obliged Innocent to acknowledge him as king, absolve him from excommunication, and invest him and his heirs with Apulia, Calabria, and Capua.

Innocent III. (GIOVANNI LOTHARIO CONTI, jō-vän'nē lō thä'rē ō kōn'tē): b. Anagni, Italy, 1161; d. Perugia, Italy, 16 July 1216. On the death of Celestine III. (1198) he was unanimously elected at the age of 37. Innocent, in the vigor of manhood, endowed by nature with all the talents of a ruler, possessed of an erudition uncommon at that time, and favored by circumstances, was better qualified than any of his predecessors to elevate the Papal power. By his clemency and prudence he gained over the inhabitants of Rome, obliged the imperial prefect to take the oath of allegiance to him, and directed his attention to every quarter where he believed that a Papal claim of property or of feudal rights existed. He concluded treaties with many cities of Tuscany for the mutual protection of their liberties and those of the Church, and soon obtained possession of the ecclesiastical states in their widest extent. He excommunicated Philip Augustus, king of France; laid the kingdom under an interdict in 1200 because Philip had repudiated his wife Ingeburga, and obliged the king to submit. He was still more decided in his treatment of John, king of England, who refused to confirm the election of Stephen Langton as Archbishop of Canterbury. Innocent laid the kingdom under an interdict, and in 1212 formally deposed him. John was finally obliged to submit, resigned his territories to Rome, and received them as a Papal fief from Innocent. All Christendom acknowledged the Pope's spiritual sovereignty; two Crusades were undertaken at his order, and his influence extended even to Constantinople. Innocent was one of the greatest Popes and rulers. It has been said of his rule, as of that of Gregory VII., whom he most resembles, that in those times the power of the Pope was salutary as a bond of union for Europe, in which the still firmer bond of a common civilization and knowledge did not, as at present, exist. In 1215 he held a council, the fourth Lateran and twelfth general which passed the decree making confession and communion obligatory at Paschal time. Frederick II. was acknowledged as German emperor, and the Franciscan and Dominican orders were confirmed.

Innocent IV. (SENIBALDI DI FIESCHI, sā-nē-bäl'dē dē fē ĕs kē): d. Naples 7 Dec. 1254. He became Pope in 1243 and was perpetually at feud with the German emperor Frederick and his successors.

Innocent V. (PIETRO DI TARENTASIA, pē-ā'trō dē tä-rĕn-tä'sē-ä): b. 1225; d. Rome 22 June 1276. His pontificate lasted only from 20 January to 22 June of the year 1276.

Innocent VI. (ETIENNE D'ALBERT, ā-tē-ĕn dăl bār): b. Brissac, France; d. 12 Sept. 1362. His pontificate extended from 1352 to 1362, and during this period the Papal residence was at Avignon.

Innocent VII. (COSMO DE' MIGLIORATI, kōs'mō dā mē-glō-rē-ä'tē): b. Sulmona, Abruzzi, Italy, 1366; d. Rome 6 Nov. 1406. He was Pope from 1404 till his death, but was opposed by the antipope, Benedict XIII., who held his court at Avignon.

Innocent VIII. (GIOVANNI BATTISTA CIBO, jō-vän'nē bät-tēs'tä chē'bō): b. Genoa 1432; d. 25 July 1492. He became Pope in 1484 and was for some time at war with Ferdinand of Naples and held the sultan Bajazet's brother Zelim a prisoner.

Innocent IX. (GIOVANNI ANTONIO FACCHINETTI, jō-vän'nē än-tō-nē'ō fä-chē-nĕt'tē): b. Bologna, Italy, 1519; d. 30 Dec. 1591. He occupied the papal chair only from the 29th of October preceding his death.

Innocent X. (GIOVANNI BATTISTA PAMFILI, jō-vän'nē bät-tēs'tä päm-fē'lē): b. Rome 7 May 1574; d. 6 Jan. 1655. In 1629 he was elevated to the cardinalate and became Pope in 1644. Under him the temporal and spiritual power of the papacy was greatly increased. In 1651 he condemned the Treaty of Westphalia and he formally condemned Jansenism in 1653.

Innocent XI. (BENEDETTO ODESCALCHI, bā-nā-dĕt'tō ā-dĕs-käl'kē): b. Como, Italy, 1611; d. 12 Aug. 1689. He served in his youth as a soldier in Germany and Poland, took orders later and rose through many important posts, until he was elected Pope in 1676, on the death of Clement X. He was eminent for his probity and austerity; zealously opposed nepotism and simony, and restrained luxury and excess. He condemned the New Testament of Mons and several other Jansenistic works. He also anathematized sixty-five propositions drawn from the works of modern Casuists and condemned

Molinos and the Quietists. He determined to abolish the right of asylum exercised in Rome by foreign ambassadors; but Louis XIV. would not yield to so just a claim, occupied Avignon, and imprisoned the papal nuncio in France; in consequence of which the authority of the Pope received a severe blow by the IV. Propositiones Cleri Gallicani in 1682. These disputes were highly favorable to the English Revolution, as it induced the Pope in 1689 to unite with the allies against James II., in order to lower the influence of Louis XIV.

Innocent XII. (Antonio Pignatelli, ăn-tō-nē'ō pēn-yä-tĕl'lē): b. Naples 13 March 1615; d. 27 Sept. 1700. He became archbishop of Naples, a cardinal in 1681 and Pope in 1692. During his pontificate Louis XIV. and the French bishops revoked the Declaration of the French clergy, and submitted to the judgment of the Holy See in the matters in dispute during the pontificate of Innocent XI.

Innocent XIII. (Michelangelo Conti, mē-kĕl-ăn'jē-lō kōn'tē): b. Rome 15 May 1655; d. 7 March 1724. In 1695 he was made archbishop of Tarsus, and became a cardinal in 1707. He was also made bishop of Viterbo in 1712 and succeeded Clement XI. in the papal chair in 1721.

Innocents, Feast of Holy, variously styled Innocent's Day and Childermas, a festival generally observed on the 28th, but in the Eastern Church on 29 December, in commemoration of the massacre of the children at Bethlehem, "from two years old and under," by the order of Herod, with the purpose of destroying among them the infant Saviour. The Church of England at the Reformation retained it in its ritual among its anniversary festivals. St. Cyprian refers to these children as martyrs, as does St. Augustine with still greater explicitness. It is to them that the hymn of Prudentius, 'Salvete Flores Martyrum,' is addressed.

Innocents Abroad, The, a famous book of travels by Samuel L. Clemens ("Mark Twain"). In a vein of highly original humor this widely-read book records a pleasure excursion to Europe, the Holy Land, and Egypt, in the sixties. Descriptions of real events and the peoples and lands visited are enlivened by more or less fictitious dialogue and adventures.

In'novators, a name applied in Great Britain to educational reformers who, in the 19th century, succeeded in having corporal punishment abolished in public and private schools. The novels of Charles Dickens, particularly 'Nicholas Nickleby,' and 'Oliver Twist,' had much to do with the origin of the reform movement.

Inns of Court are certain societies in Great Britain exclusively invested with the right to call to the bar. The colleges of the English professors and students of common law are called inns, the old English word for the houses of noblemen, bishops, and others of extraordinary note, being of the same signification as the French *hôtel*. The opinion is, that societies of lawyers, which before the Conquest held their chief abodes for study in ecclesiastical houses, began to be collected into permanent residences, soon after the court of common pleas was directed to be held in a fixed place,—a stipulation which occurs in the great charters both of King John and Henry III. In these houses exercises were performed, lectures read, and degrees conferred. The inns of court are governed by masters, benchers, stewards, and other officers, and have public halls for dining, readings, etc. In London the four inns of court are: the Inner Temple and Middle Temple (formerly the dwelling of the Knights Templars, and purchased by some professors of law more than three centuries since): Lincoln's Inn and Gray's Inn (anciently belonging to the Earls of Lincoln and Gray). Each inn is self-governing, and all have equal privileges.

Innsbruck, ĭns'brook, or **Innspruck** (ancient Œnipontum; locally called Schpruck), Austrian town and capital of the Tyrol, beautifully situated 59 miles north of Munich, on the banks of the Inn, near the confluence of the Sill, and almost in the centre of the valley of the Inn (Innthal), the sides of which are enclosed by mountains several miles distant, but so lofty (7,000 to 8,500 feet) as apparently almost to overhang the town. In consists of the town proper, situated on the right bank of the river, and of five suburbs. It is for the most part well built. The houses are generally of a limestone breccia, and from four to five stories high, and built in the Italian style. The buildings most deserving of notice are the Hofkirche, containing the tomb of the Emperor Maximilian I., one of the most splendid monuments of the kind in Europe, though he himself is not interred in it; and the tomb of Hofer; the Church of St. James, with a painting by Lucas Cranach; the Jesuits' church, considered the handsomest in the town; the Capuchin church, with good paintings; the new palace, built by Maria Theresa, a very extensive edifice, with gardens which stretch along the side of the Inn, and form an excellent promenade; the old palace, in which the Archdukes of Tyrol and several of the German emperors used to reside; the university, founded in 1677, and re-established in 1826, well endowed, provided with a library, botanical garden, and cabinet of natural history, and attended by about 1,000 students; a gymnasium, and several other important educational establishments; and the museum, called Ferdinandeum, rich in all the productions both of art and nature within the limits of the Tyrol. The manufactures include woolen, silk, and cotton tissues, gloves, glass, etc. As the capital of the Tyrol, Innsbruck is the place of assemblage for its states, and the seat of superior appeal, civil, and criminal courts, and of many important public offices. Many of the spots in the immediate vicinity have become memorable for the noble exploits which the Tyrolese peasantry performed in the war of Independence. Pop. (1890) 23,325.

Innuits, ĭn'ū-ĭts. See Eskimos.

I'no, daughter of Cadmus and Harmonia, second wife of Athamas, king of Thebes, drew upon herself the anger of Hera by nursing Dionysus, the son by Zeus of her sister Semele. In order to favor her own children she projected the murder of her stepchildren, Phryxus and Helle, who saved themselves by flight. Hera, still more highly incensed, made Athamas, the husband of Ino, mad, and he dashed his eldest son by Ino, against a rock. Ino fled with

her youngest son, Melicertes, and threw herself with him into the sea. Ino and Melicertes were made sea deities at the prayer of Dionysus. Ino was worshipped under the name of Leucothea.

Inocarpus, ĭ-nō-kär'pŭs, a genus of leguminous plants, having unifoliate leaves and yellow flowers in axillary spikes. *I. edulis* is the South Sea chestnut, native of Tahiti. It is a large tree, with luxuriant foliage, the delicate evergreen leaves being six inches or more in length. It furnishes seeds or nuts much valued in the South Sea Islands, the inhabitants gathering them while green, and mashing them for food.

Inocula'tion. See INFECTION; VACCINATION.

In'osit ($C_6H_{12}O_6$), (from Greek *is, inos,* a nerve, a muscle), a saccharine substance found in the muscular tissues of the heart, as well as liver, brain, kidneys, etc. It appears both in health and, to an abnormal amount, in disease. It exists also in a number of plants, such as foxglove, potato, kidney-bean, acacia, asparagus, cabbage. See GLUCOSE.

Inouye Kaoru, kä-ō'roo ē-nō-oo'yā, **Count,** Japanese statesman: b. in Choshiu 1839, pupil of Yoshida Shoin. With Ito (q.v.), in 1862, he went secretly to Europe, and returning in 1864 became an unswerving exponent in Japan of the ideas lying at the root of Western civilization. Surviving the wounds made by reactionary assassins, he has, since 1868, served his country in various high positions, as the mikado's minister at home and as envoy abroad, especially in Korea. As minister of the interior he began the rebuilding of Tokyo from wood to brick. His famous memorial of 1873 called for moral improvement. For seven years, as head of the foreign office, he was active in treaty revision. He was created a peer in 1885, and again called to the office as minister of the interior in 1892, and retains the emperor's confidence as one of the surviving "elder statesmen," whose word in Japan is law. See KATSURA.

Inquiline, ĭn'kwĭ-lĭn, a term applied in zoology to animals which live as tenants within the nests or homes of other animals. The use of the term is almost entirely confined to entomology and then often restricted to the cases in which the rightful and the intruding tenants are closely related. Similar cases among other animals are commonly designated as commensalism (q.v.), but these and similar terms are used rather loosely. Examples of the inquiline relation occur among the termites, ants, and bees, but are known especially among the gall-flies (*Cynipidæ*); indeed, one entire division, comprising more than 500 species, is named *Inquilinæ,* because of the predominance of this mode of life. These insects differ but little in structure from the true gall-flies, but they lack the power to produce galls and consequently deposit their eggs within those of other species. They infest certain species of galls, as those of the blackberry and some oak-galls, in large numbers and sometimes more than one kind occur in a single gall. Perhaps the most remarkable feature of these inquilines is their frequent close resemblance to the insect which produces the gall which they infest.

Inquisi'tion, a tribunal or system of tribunals instituted by the Roman Catholic Church for the discovery, examination, and conviction of heretics and their punishment by the secular arm. Under the successors of Constantine in the Roman Empire the repression of heresy, or rather the enforcement of the decrees of church councils and synods, was a function of the imperial government, which inflicted temporal penalties upon the propagators of religious beliefs that contradicted the creeds approved by the State. When the reigning emperor was a favorer of Arianism or any other of the heterodox creeds, the orthodox bishops and their flocks were persecuted: when he was of the orthodox party the heterodox sects were put under the ban. In executing the decrees of the councils the imperial officials, called in the laws of Theodosius and Justinian "inquisitors" (*inquisitores*), were assisted by the bishops; but the tribunals were the ordinary secular courts, and judgment was rendered in the name of the State, not the Church. But in the 12th century, when the supremacy of the ecclesiastical power was universally recognized in western Europe, the initiative in the work of repressing heresy was taken by the Church as of course, and the discovery, trial and conviction of the offenders were functions of the ecclesiastical power solely: the secular power simply executed the judgments of the church tribunals. Boniface VIII.'s definition of the respective powers and the mutual relations of church and state was not proclaimed till the close of the 13th century; but had a similar definition been promulgated in the 12th century it would have expressed the universal sentiment of princes and peoples at the time. The celebrated bull, *Unam Sanctam,* defines that "Both swords, the spiritual and the temporal, are in the power of the Church; yet the one is to be wielded for the Church's behoof, but the other by the Church herself: the one by the hand of the priest, the other by that of the king and the soldier, though at the will and sufferance of the priest *ad nutum et patientiam sacerdotis.* And sword must be subordinate to sword — *oportet gladium esse sub gladio,* and the temporal authority subject to the spiritual power — *temporalem auctoritatem spirituali subjici potestati.*"

The first step toward the establishment of courts of inquisition would seem to have been taken in 1179 when the third council of the Lateran issued a decree of excommunication against the adherents of the heretical sects of southern France, who are charged not only with holding abominable heretical tenets but also with practising "unheard-of cruelties against the Catholics," demolishing the churches and massacring widows and orphans. The council grants "an indulgence of two years to those who shall make war on them." This decree was re-enforced by the Council of Verona (1184) over which Pope Lucius III. presided, and at which the Emperor Frederic I. assisted: the Council directs the bishops to bring to trial persons accused of heresy and to inflict fit punishment on the guilty. The fourth Council of the Lateran (1215), held in the reign of Innocent III., imposed on the bishops the duty of making a visitation of their dioceses twice or at least once a year either personally or by delegates to see that the Church's laws be enforced. Bishops are authorized to bind the

inhabitants of a district by oath to search out heretics and bring them to trial. By the Council of Toulouse (1229) in the pontificate of Gregory IX. the search for heretics (*inquisitio hæreticæ pravitatis*) was systematized. The bishops are to name for each parish two or three respectable laymen who shall take oath zealously to search out heretics and to deliver them up to the *baillis*. Whosoever knowingly conceals a heretic loses all his goods. If heretics are discovered on the estate of a land-owner, he incurs the penalties: the house of the heretic shall be torn down. Heretics who recant have to seek a new abode, and must wear on their clothing two crosses of different colors until the Pope or his legate permits them to assume the ordinary garb. Whoever abstains from use of the sacraments is held suspect of heresy. A person convicted or suspect of heresy is debarred from the practice of medicine. Lest the ordinary church authorities should be remiss in carrying out this system Gregory IX. named (1232) as "pontifical inquisitors" monks or friars from outside, chiefly Dominicans; shortly after the pontifical inquisitors were chosen from the order of the Dominicans exclusively. Thus the duty of inquisition was taken out of the hands of the bishops and was discharged by officials responsible only to the Pope; from the judgments of the inquisitorial tribunals there was no appeal but only to the Holy See: in 1263 Urban IV. appointed an inquisitor-general for Provence, as a means of lowering the flood of appeals to Rome. The institution passed from southern France into the other provinces of that kingdom and into Italy, Germany and Poland. The Inquisition in England was directed by the metropolitans and their suffragans without being responsible to any inquisitor-general: but as long as Lollardism disturbed the peace of the Church the search for heretics was prosecuted rigorously: bishops and archdeacons were required twice a year to make inquisition of suspects: any man might be compelled under penalties to inform against persons suspected of heresy; the statute *de haeretico comburendo* was enacted by the Parliament in 1396.

In Spain the Inquisition, as set up in 1481 by Ferdinand and Isabella, was as much (or more) a political as an ecclesiastical institution: the officials from highest to lowest were appointed by the sovereigns and its action was directed by them without responsibility to the Holy See: Ranke calls the Spanish Inquisition "a royal tribunal furnished with spiritual weapons"; Llorente admits as much. The number of persons put to death under sentence of the Inquisition in Spain is put by Llorente at 31,000 from first to last, that is during 330 years. But Llorente made it impossible to check his statements by burning the original documents. Ranke impeaches his honesty; Prescott says that his estimates are "most improbable." Catholic historians call attention to the fact that not only heresy, but many other offenses against the laws were judged by the courts of inquisition in Spain, viz: polygamy, seduction, unnatural crimes, smuggling, witchcraft, sorcery, false personation, etc. At the time when the Inquisition flourished, persecution for heresy was a universal practice amongst all Christian peoples, and the methods of punishment inflicted were general throughout Europe. Protestant England persecuted as harshly and vigorously as Catholic Spain, and in both countries denial of the state religion was equivalent to treason.

Insane Asylums, Cottage System, or Village Plan. A form of construction for insane asylums and charitable institutions, much in vogue at the present time, in which large and imposing buildings are replaced by detached cottages. The cottages vary in size from those which will accommodate six to a dozen patients to larger ones which will accommodate 20 or more. They are usually constructed either in groups or along streets and avenues as a village. In the former, the several groups are given up to a particular industry as a farm group, where the patients are employed at farming, and others, as the garden, the brick yard, shop industries, etc., all of these being a part of one institution on a single large estate. In the village plan the institution is laid off in streets and avenues, and has the appearance of an ordinary village, each cottage having a flower garden in front, shade trees, etc. In either plan, there is conveniently located near the centre of the plant an administration building, a hospital for the sick and those requiring special care, a bakery, a laundry, and other utility buildings. The cottages may be constructed of wood or other material, and the cost of construction is small as compared with the old plan of asylum construction. It is, besides, more homelike, more convenient for administration and permits of indefinite expansion. Some of the best known institutions constructed on this plan are Alt-Scherbitz near Leipsic; Gabersee near Munich, Germany; the Saint Lawrence State Hospital at Ogdensburg, N. Y., and the Craig Colony for Epileptics at Sonyea, N. Y.

Insanity, a disease of the brain characterized by disorder or derangement of the mental faculties. This is its strictly pathological or scientific definition. Therefore, according to this definition, any disease of, or accident to, the brain whatsoever, provided such disease or accident caused any derangement of the mental faculties, howsoever trifling or temporary, would furnish an example of insanity. Thus a blow on the head causing unconsciousness, or a fever giving rise to delirium, is an example of an affection of the brain characterized by disorder of the mental faculties. Practically, however, the term insanity is limited to a group of affections of the brain which is more distinctly fixed, and the members of which it will be the object of this brief sketch to define.

Causes.— The causes of insanity are many and various, and the chief of these are the following: Heredity, infection, poisoning, traumatism or injury, overwork or exhaustion, and mental and moral shock or strain. Of importance also are age, sex, race, and nationality.

Of all these causes the most important undoubtedly is heredity. As Krafft-Ebing, the German alienist, has well said, there is no ground, except in tuberculosis, upon which heredity shows itself more distinctly than in the case of mental disease. Statistics have been compiled by various authors to show as nearly as possible the exact prevalence of heredity in insanity, but the results have not been altogether in harmony. In fact, it is extremely difficult to determine this factor in many cases

in which it has been active, and this is so for two reasons: in the first place many patients and their friends conceal or deny a hereditary taint, and in the second place not a few patients and their friends, are really ignorant of their family histories beyond a generation or two. How many persons can tell accurately of what their grandparents died? The more this subject of heredity in insanity is investigated the more reason there is to believe that its importance has been underestimated rather than the reverse. And yet as a factor in causation it is much more common in some forms of insanity than in others — a fact which will be emphasized later in this article. Some authorities have limited heredity to the direct line of descent, ignoring collateral lines; but obviously this restriction cannot be maintained. And yet, if the attempt is made to trace a neurotic taint through collateral lines, the difficulty is greatly increased. the subject is vastly broadened, and, from the medico-legal standpoint, the inquiry becomes greatly involved. In mental heredity, moreover, it is not so much the particular disease that is passed on from parent to offspring, as it is the predisposition; and this predisposition, often called neurotic, is not the result entirely of insanity in the ancestry, but may be shown by a family history of other grave nervous disorders, such as epilepsy, hysteria, neurasthenia, and imbecility. This is a fact not sufficiently apprehended by the laity.

Infections of various kinds may act as causes of insanity. The most important of these is syphilis, and this acts especially to cause that form of insanity known as general paresis. The various infectious diseases, such as typhoid fever, septicæmia, smallpox, cerebro-spinal meningitis and, in minor degree, some others, may cause mental alienation. Post-febrile insanity may follow typhoid fever; and puerperal insanity may be due in part to a septic infection.

Poisons of various kinds may be very active causes of insanity. Chronic lead poisoning may give rise to a well-known form of delirium or mania; so in minor degree may mercury. But the most potent and most common of all poisons in the etiology of mental disease is undoubtedly alcohol. And this poison acts in two ways, for it may not only induce insanity in the individual, but it also is most active in causing that hereditary predisposition to insanity in the offspring to which reference has already been made. In fact, the subject of heredity is not a little involved with the subject of alcoholism in the progenitor.

Traumatism, or injury, may act as an exciting cause of insanity. This is true especially of injuries to the head. Trauma acts most readily in conjunction with other causes, such as alcoholism and syphilis. Injuries to other parts of the body, especially when associated with great shock, as in severe railroad accidents, may lead to various forms of mental alienation.

Overwork and exhaustion from any causes whatever may predispose to, or directly cause, a mental breakdown. This is true especially in cases in which the blood is depleted, the nutrition of the nervous system impaired, and the mind harassed with care and anxiety. These causes are most active in persons otherwise predisposed, as by alcoholism, syphilis or heredity.

Mental and moral shock and strain, such as sudden loss, grief, fright, mortification, intense religious and political excitement (as in the French Revolution), long continued anxiety, and the harassment of uncongenial surroundings, as in the home-life, may all act as causes of insanity.

The above are the chief categories of causes, but they do not exhaust the subject. It is in fact too extended for brief treatment. Finally, it must be borne in mind that in any individual case not one but a combination of several of the above causes has usually been active.

Classification.— Almost every alienist of repute has attempted a classification of the forms of insanity. The subject is one of peculiar difficulty, owing largely to the fact that our intimate knowledge of many of these various forms is far from complete. One of the most satisfactory schemes is the one by Krafft-Ebing, and is as follows, slightly abridged:

"A."

MENTAL DISEASES OF THE DEVELOPED BRAIN.

I. Diseases without Anatomical Lesions, or Functional Diseases.
  (1) Psychoneuroses, or diseases of a brain otherwise sound.
    1st. *Melancholia.*
      a. Simple Melancholia.
      b. Stuporous Melancholia.
    2d. *Mania.*
      a. Maniacal Exaltation.
      b. Frenzy.
    3d. Stupor, or Acute Dementia.
    4th. Hallucinatory Delirium.
    Note.— The above affections are primarily curable, but the worst of them may terminate in chronic incurable forms and in dementia.
  (2) Degenerative Insanities: Affections of a brain endowed with a morbid predisposition.
    1st. Constitutional Affective Insanity.
    2d. Paranoia.
      a. Congenital.
      b. Acquired. This form includes various subgroups according to the character of the delusions entertained by the patient.
    3d. Periodical Insanity.
    4th. Mental Affections arising from the constitutional neuroses.
      a. Neurasthenical.
      b. Epileptic.
      c. Hysterical.
      d. Hypochondriacal.
II. Organic Insanities or Mental Diseases with Recognizable Lesions in the Brain.
    1st. Acute Delirium.
    2d. General Paresis.
    3d. Cerebral Syphilis.
    4th. Senile Dementia.
    Note.— Chronic Alcoholic Insanity and Morphinism may yet have to be added to this group.

"B."

MENTAL AFFECTIONS OF THE UNDEVELOPED BRAIN.
Idiocy and Imbecility.

This scheme by Krafft-Ebing, while not without defects, is excellent for practical purposes and until someone can devise a better. Its great merit is that it is flexible: it readily admits new forms. Its defect is that it draws too sharp a distinction between the so-called functional and the organic insanities; and between the psychoneuroses and the constitutional forms. The truth is, all insanities are organic; and a constitutional taint may be present in the psychoneuroses.

Following this classification we note the following forms of insanity:

A. The whole group of insanities as distinct from idiocy is included under this head, and as a first great subdivision comes:

I. Mental Diseases without recognizable anatomical lesions: Functional Diseases. As

was inferred above, this whole group is only tentative in one sense, because as scientific knowledge advances it is found more and more that insanity in all its forms depends upon anatomical changes. For the present, however, this group may be allowed, with some reservation, to contain the following:

(1) The Psychoneuroses. In these forms the mental disease is such as can happen in a person with an otherwise perfectly normal brain. It is in a sense fortuitous, and not dependent necessarily upon a hereditary taint. Given the same causes, and it may be presumed that any person might develop a psychoneurosis, just as he might develop a fever. By this it is not implied, however, that heredity cannot act to predispose to these forms.

Melancholia is marked by depression. The affective or emotional, rather than the intellectual, faculties are involved. The patient has a sense of personal unworthiness; in other words, the depression centres about the patient's ego. He is not so much concerned about his misfortunes or his troubles, as about his unworthiness. Neither is he concerned about other persons: he is entirely self-centred. This may be said to be the keynote of melancholia. Delusions of a depressive character, as of having committed the unpardonable sin, may be present. The depression may become so profound and overwhelming that the patient passes into a stuporous or atonic state. (*Melancholia Attonita.*) In this state the physical functions, such as appetite, digestion, and nutrition, may be correspondingly depressed. Suicide may result. In some cases the patient is restless under the burden of his mental suffering (*Melancholia Agitata*).

Mania is marked by exaltation. The intellectual faculties are much more involved than in melancholia, and the patient is active, loquacious, sometimes destructive and combative, or else gay. He is somewhat incoherent, and his delusions are not well-defined, but fleeting and changeable in accord with his varying moods and disordered thoughts. The physical functions suffer as a result of exhaustion from over-activity. *Frenzy* is only a higher degree of mania, in which the mental functions are in entire disorder from over-excitation. Exhaustion is rapid.

Stupor, as its name indicates, is a psychosis in which the predominant tone is one of profound subversion of all the mental functions. *Acute Dementia* is another term for it. The patient may recover from a most unpromising state, especially in the case of young persons. *Dementia Præcox* is such a form, although the prognosis is not always good. *Primary* Dementia occurs without preceding acute stages.

Hallucinatory Delirium is a form of acute insanity marked by confusion and by the presence of hallucinations of sight and hearing. *Confusional* insanity is a term sometimes used, especially for the types which occur after acute infection, such as post-febrile insanity, and some forms following child-birth.

All these psychoneuroses may, in unfavorable cases, pass into chronic forms, and terminate in incurable dementia.

(2) The Degenerative Insanities.

In these forms mental deterioration is engrafted on a constitutional defect. Heredity plays a great part. The patients have been born with the neurotic predisposition. Their insanity is simply a logical evolution of a badly organized nervous system.

The great type of this form of insanity is *Paranoia.* The chief characteristic is the formation of systematized delusions. At first these may be of a persecutory tinge: the patient believes that he has enemies, who plot against his welfare or his life. He has hallucinations, especially of hearing. In a second stage, the delusions acquire a more expansive type: the patient believes that he is some great personage. As preliminary to all this, there is often a long career of moral and mental perversion: the patient has been noted as erratic, eccentric, visionary, and even immoral. He usually has displayed but little real brain power or steadiness, but often an intense egotism and a lack of common sense. Innumerable varieties and several stages occur. From this class are recruited in large part the criminal insane. These patients are the monomaniacs of the older writers, and they include also the moral lunatics, pyromaniacs and kleptomaniacs of more recent systematists. Among them are found also the victims of obsessions, morbid impulses and fixed ideas. The paranoiacs are the dangerous lunatics, and the prognosis is not favorable.

Periodical Insanity is a form of constitutional insanity in which, as the name indicates, there is a tendency to recurrence. This recurrence is sometimes in cycles (*Circular* Insanity), in which there is a period of maniacal exaltation, followed by one of melancholic depression, and then a somewhat prolonged period of apparent recovery, to be followed again by the morbid cycle. With every recurring cycle, however, the patient deteriorates somewhat, and may eventually degenerate into chronic insanity.

In the constitutional nervous diseases, such as Epilepsy, Hysteria, Hypochondria, and Neurasthenia, there are often mental changes of a morbid type, and these give rise to the forms of insanity named in accord with these respective neuroses. The symptoms vary widely in the several diseases.

II. In the organic insanities, so-called, the disease is marked by recognizable changes in the brain-structure.

Acute Delirium, or Bell's mania, is an acute infectious disease of the brain, of unknown origin, and of rapid progress, usually terminating fatally. It is marked by confusion and delirium, passing into coma and death. The changes in the brain are of an inflammatory kind.

General Paresis, or Dementia Paralytica, is caused by a progressive infectious or destructive process in the brain substance. Its dependence on syphilis is no doubt close, and it is further induced by alcoholism, dissipation and overwork. It is marked by change of character, erratic conduct and loss of mental and moral control, passing on into a stage of expansive delusions with progressive dementia. There are also characteristic speech defects, changes in the ocular muscles and in the gait, with increasing feebleness and paralysis. Various crises occur, such as maniacal, epileptoid and apoplectic, and in the last stage the patient is paralyzed and demented. Death is the inevitable result in the vast majority of cases.

In *Cerebral Syphilis* there is a characteristic inflammatory process beginning in the coats of the small blood-vessels. Mental symptoms oc-

cur in great variety, also many forms of paralysis.

Senile Dementia is a form of deterioration occurring in old age, and is dependent primarily on changes in the blood-vessels in the brain. Progressive failure of mental powers, with occasional delusions, is the chief feature. In some cases paralytic and epileptic crises occur.

B. Finally we have the great group in which the mental affections are the results of arrest of development of the brain. These are not included in insanity proper by systematic writers, but are regarded as a group apart. This group includes Imbecility and Idiocy, and is defined under the latter head.

No attempt has been made in the above classification to include various debatable forms. Among such forms are *Hebephrenia* (occurring in adolescence) and *Katatonia* (a psychoneurosis with both melancholic and confusional symptoms), and some others about which alienists are not yet agreed. The list must still remain open.

Pathology.— In the group of organic insanities it has been pointed out that these diseases rest upon a recognizable anatomical basis: thus in general paresis the structural changes in the blood-vessels and tissues of the brain are so marked and so well studied that this disease may be said to have as well known a morbid anatomy as pneumonia. But this is true of very few of the insanities, and the above classification is constructed largely on the distinction between forms of insanity with, and those without, well-defined anatomical changes. But while such changes cannot in many cases be detected even with the most powerful microscope, there is practically no doubt in the minds of most alienists that all insanities depend upon a physical or structural basis. In other words, they are but manifestations of morbid changes in the brain-cells. To detect these changes is still one of the great problems of psychiatry. The tendency of modern pathology is to seek for the anatomical changes of insanity mainly in two directions: first, in heredity; and, second, in infection or toxæmia. Heredity makes its impressions so invisibly upon the brain-cell that there may be wise doubts whether we shall ever be able to detect them; but its signs, or stigmata, on the body at large are not so difficult to distinguish. The main difficulty is to interpret them. By these stigmata are meant defects or peculiarities in the grosser parts of the body, as in the bones, especially of the head and face, the ears, eyes, teeth, etc. As to infection, and the marks of it as found in the brain-cells, the evidence accumulates more and more that in many forms of insanity, especially those called functional, the direct agent is often a poison circulating in the blood and interfering with the nutrition and functioning of the brain plasma. Syphilis and chronic alcoholic poisoning leave definite changes in the blood-vessels, tissues, and membranes of the brain.

Treatment.— The treatment of insanity resolves itself into the preventive and the curative. Modern practice is beginning to concern itself more and more with the former, while of course it does not in any way relax its attention to the latter. The prodromal, or initiative, symptoms of many forms of insanity, especially the psychoneuroses, are now so well understood, that it is often an easy matter to recognize the insidious changes that herald a mental breakdown, and to guard the patient from the dangers and misfortunes of a fully developed attack. Of first importance is to remove the patient from the exciting causes. Complete rest and isolation are therefore required and cannot be instituted too early. In order to secure these, hospital treatment is often essential. Very recently it has been proposed to treat these patients in general hospitals, in special wards, and not to hurry them into asylums under legal certification. In other words, they are to be regarded simply as other sick persons, and not to be immured merely as lunatics. The motive is thoroughly humane, and the practice is often successful in promising and selected cases. The indications are for rest, isolation and attention to the nutrition especially. There is no specific for insanity except in cases in which syphilis is active.

In very many cases, however, the nature and course of the disease render it imperative to commit the patient to special hospitals for the insane. This is not only for the good of the patient, but also for the welfare of society. These hospitals or asylums in all civilized countries are now among the very best of public institutions, and the prejudices once existing against them are no longer warranted. The indications for treatment vary according to the nature of the case. The weak and exhausted must be built up; the depressed must be encouraged and diverted; the violent and excited must be restrained; the chronic and demented must be cared for often as though they were children. The practice of to-day is in favor of all humane methods, such as by recreation, useful employment, amusements, and an appeal to the best remaining or active elements of the mental life. Physical restraint is reduced to a minimum, although in the most violent cases it cannot be entirely abolished. Punishment is practically abandoned. It is satisfactory to know that all our best regulated hospitals for the insane are enabled to report annually a good percentage of recoveries, and this is in accord with the teaching and practice of modern science, which regards insanity entirely from its physical aspect as a disease of the brain. With this definition this brief article may end as it began.

Formerly Neurologist Philadelphia Hospital.

Inscriptions. The term inscriptions comprises, in its widest sense, all words or word-signs engraved (or painted) on relatively durable materials such as natural cliffs, wrought stone, baked clay, metal, or even wood. For rea-

sons of practical convenience, however, certain sorts of inscriptions are grouped apart; for example, legends on coins and the lettering on painted vases. The etymological sense of inscription (Latin *inscriptio,* "in-scratching") is not to be taken so strictly as to exclude raised lettering. The role of inscriptions in modern times accords in general with the ancient use, but is much less extended. Then, copies of official and religious documents were frequently promulgated in the form of inscriptions, a usage that no longer survives, though commemorative and titular inscriptions are still plentifully employed. In general, inscriptions serve one of two purposes: (1) they constitute a record, and the material containing them is wrought for the express purpose of receiving the inscription (example, known from literature only, Moses' stone tables that held the decalogue); (2) the object on which the inscription is engraved fulfils a purpose of its own, while the lettering indicates the name, nature, purpose, maker, or owner of the material object (commemorative column, mirror, ring, etc.). To these may be added another class, (3) the incidental inscription, a notice or entry upon an object not prepared to receive it.

Inscriptions furnish materials of value to students in many fields. To the historian — and we must understand history to be the life-record of the nation and its citizens — they supply evidence of great value, all the more valuable because nearly always contemporaneous with the facts recorded. The incidental as well as the formal record may bear testimony. An example of this sort has been found on the leg of a colossal statue at Abusimbel in Nubia, whereon Greek mercenaries who had ascended the Nile under the leadership of Psammetichus — more probably the second (594–589 B.C.) than the first (654–617) of that name — traced a brief notice of their expedition. The incidental inscription is particularly apt to furnish details valuable for social history. To the archæologist inscriptions of the second class furnish testimony of value for topography (witness the fragments of the marble *Forma Urbis*, an ancient inscribed plan of the chief buildings of Rome) and for the precise identification of statues and other works of art. The discovery of inscriptions is among the express tasks of the excavating archæologist, who thus supplies the raw material, so to speak, for the historian or philologian. To the philologian inscriptions yield the key to the history of writting and, if his interests lie in the comparative and historical study of words, give him a fuller knowledge of their form. To the philologian of literary interests inscriptions yield a knowledge of historical fact or of vocabulary that may lead to a correct interpretation of a difficult literary passage. For example, the Greek historian, Thucydides, records (6.54) an altar inscription set up by Peisistratus (527–510 B.C.), which, he says, was still "in clear evidence," but "in dim letters." The identical inscription was found in 1877, with lettering perfectly distinct, and the literary interpretation of "dim" had to be revised and brought into accord with the facts. Meantime, the archæologists had learned that red or blue paint was employed to bring out more clearly the lettering of Greek inscriptions, and it was easy to infer that not the incision but the coloring of this inscription was dim in the time of Thucydides. Inscriptions previously known from literary works have for the philologian the added value of yielding testimony concerning the reliability of the manuscript tradition. Thus the best manuscript of Thucydides is of the 10th century A.D. and, as the last in a long chain of copies, must have been exposed to a great deal of corruption in transmission. The fact that a treaty recorded by the historian (5.47) corresponds almost exactly with the (fragmentary) inscription recording the alliance is reassuring for the MS. tradition. The *littérateur,* even, may be concerned with material furnished by inscriptions. One of the most considerable fragments of the poet Simonides, for example, has reached us in a copy on stone of an epitaph (epigram) in honor of the Megarians who fell in the Persian war. Some literatures have survived only as inscriptions.

It is safe to declare that inscriptions are as widely diffused as the art of writing. Even a primitive picture, if painted to convey a message, would constitute an inscription. Hieroglyphics (conventionalized picture writing) constitute the most primitive type of writing, and inscriptions of this sort, in the Maya language, are found in Yucatan. Though probably not earlier than the discovery of America, these represent, as regards writing, the same stage of culture as the hieroglyphics of Egypt (4700 B.C.). Chinese inscriptions — the Chinese being a highly conventionalized hieroglyphic script — of 1,200 B.C. are also extant. The Mayan (and Aztec) system is still very imperfectly understood. Egyptian hieroglyphics were likewise long undeciphered, but in 1822 the Rosetta Stone (q.v.), a trilingual in Greek, demotic Egyptian, and hieroglyphics, whereon the names Ptolemy and Cleopatra were of frequent occurrence, furnished a clue to the hieroglyphics which had been conventionalized, through a syllabary, to a pure phonetic system.— — This means, to invent an instance, that a picture (symbol) representing motion [=(to) go] comes to be used for the syllable *go* in a proper name like Goshen (this step was taken by Aztec hieroglyphics), or in a word like gopher: and that in the last stage the syllable sign *go* reduces to the letter *g*. — — The decipherment and interpretation of Egyptian inscriptions belongs to the science called Egyptology. See EGYPT.

The cuneiform script, invented by the Accadians of Chaldæa, found its way to the Semites of Babylonia and Assyria. This was a syllabary, developed from an earlier pictorial system, and such it remained in those countries, where not only small objects like seals and cylinders, but whole libraries of clay tablets (reaching back into the 4th millennium B.C.), have been found. These tablets contain genuine literary works as well as the documents and announcements commonly included under the term inscriptions. The University of Pennsylvania is in possession of some 35,000 cuneiform documents, a collection particularly rich in fourth and second millennium records, and outnumbered only by the British Museum and the Louvre collections. The Tell-el-Amarna Letters are historically among the most noteworthy cuneiform inscriptions. Found by an Egyptian peasant woman in 1887, the collec-

tion is now split up between the Berlin and British museums, though a part remains in Egypt. These tablets contain a correspondence between three kings of Egypt (15th century B.C.) and the rulers of Babylonia, Assyria, Armenia, the states of Asia Minor, Syria, and Palestine. Of transcendent importance for the early political history of Western Asia, this correspondence is also accounted to confirm the validity of the Hebrew Scriptures as an historical record. It is noteworthy for the history of culture that the petty chief of every town could command the services of a scribe able to write a letter in Assyrian — the common correspondence language, it would seem, of all those countries. The science of Semitic Cuneiform belongs to Assyriology (q.v.).

Fortunately the Assyrian syllabary, after being borrowed by the Medic Aryans, was converted into an alphabetic system. King Darius (521 B.C.) caused an Old Persian (Protomedic) inscription of 413 lines, averaging 6 feet each, with versions in Neo-babylonian and Neo-elamitic, to be inscribed on the Great Rock of Behistun, at a height of 400–500 feet. The same script had been observed on other short inscriptions found at Persepolis, which evidently contained proper names chiefly. As early as 1802 Grotefend allocated the names Darius, Xerxes and Hystaspes to certain script groups in these brief formulæ, and correctly isolated 9 of the 13 symbols concerned. In course of time the entire Protomedic cuneiform alphabet was identified and subsequently the more complex Semitic syllabaries were worked out, resulting in the decipherment of the older cuneiform. In the Behistun inscription Darius, following precedents of Assyrian kings, summed up the history of his accession and reign. Copied in 1844 by Mr. H. C. Rawlinson, it has been carefully inspected again (1903) by the American scholar, Mr. A. V. W. Jackson.

Farther west, the Phœnicians, also Semitic, developed, perhaps from Egyptian hieroglyphics, a true alphabet, out of which sprang, on the one hand, the scripts used by the Hebrews, Arabs, Persians and Hindus, and on the other the Greek (and Roman) type. The most notable early inscription in alphabetic Semitic is the Moabite Stone (q.v.) (9th century B.C.), which recounts the victory of Mesha, king of Moab, over Israel. The language used differs but slightly from that of the Hebrew Scriptures, of the historical validity of which the Moabite Stone, like the Tell-el-Amarna Letters, is held to be in general confirmatory. For facsimile, transcript and translation see Hastings' 'Dictionary of the Bible' iii., p. 405 seq. Phœnician-Greek bilingnals from Cyprus, belonging to the 4th century B.C., are extant; also Phœnician-Cypriote, which furnished the key to the Cypriote syllabary. Punic inscriptions proper are chiefly of the dedicatory sort, and relatively late, all after the Greek period. Aramaic dockets on Assyrian contract tablets (8th century B.C.) form another instance of early alphabetic Semitic.

India also has its inscriptions. The oldest (250 B.C.) and most interesting are the religious edicts of King Piyadassi, known as the Asoka Edicts, which are engraved on rocks and pillars. They inculcate the religion and morals adopted by this king after his conversion to Buddhism. These inscriptions, in two unknown alphabets (Karoṣṭhī and Brahmī), were deciphered chiefly by James Prinsep, who, in the winter of 1837–8, single-handed, unraveled the Brahmī script. He guessed that in certain brief Brahmī inscriptions, plainly of a votive character, a frequently recurring final group of letters must stand for the notion "gift" and be equivalent, if the language was Sanskritic, to *dānam*. He further surmised that the consonant preceding *dānam* must be the genitive (possessive) sign — *s*. He thus isolated the three consonants *s*, *d*, *n* and, with this start, soon identified the entire alphabet.

Greek and Roman inscriptions have been more studied and are accordingly more systematized for study than any others. The ancient Greeks were themselves conscious of the importance of inscriptions. Herodotus used them as sources, and Thucydides and Xenophon quoted them. Decrees are sparingly mentioned by Isocrates, but freely quoted by Demosthenes, who probably made use of the papyrus originals from the department of archives, not all decrees being promulgated on stone. Euripides alludes to the custom of inscribing formal compacts on tripods and dedicating them in temples. Greek antiquaries and scholars even made collections of inscriptions and Polemon (300 B.C.), who was neither the first nor the last of these collectors, owing to his zeal as an inscription hunter, got the nickname of *stèlokopas*, "tablet-picker." Roman writers also — Cicero, Livy, Pliny the Elder, Suetonius — occasionally mentioned inscriptions of historical interest. Varro, the antiquary, and the lexicographer, Verrius Flaccus, commented on the diction of inscriptions; while Polybius, the Greek historian of Rome, actually cited inscriptions, making a fuller use of them than Livy. But no interest in collecting inscriptions, comparable to the Greek interest, ever developed among the Romans. From the Revival of Learning on scholars were not lacking to show an interest in classical inscriptions, but the modern impulse may be said to have had its point of departure in the first quarter of the 19th century when the Prussian Academy, under the promptings of August Boeckh, inaugurated the great collection known as the 'Corpus Inscriptionum Graecarum' (4 vols, 1825–56), which contained nearly 10,000 numbers. But fresh inscriptions are ever coming to light — *dies diem docet* — and in 1891 the number was estimated at 50,000. There has been a steady increase ever since. Excavations are now pursued in Greece and Greekish countries with a diligence and at an outlay never before known. Almost all the great nations have established archæological institutes in Athens, and all of these issue some form of learned journal devoted in part to the publication of the new inscriptions discovered; for example, 'Papers of the American School of Classical Studies at Athens,' 'American Journal of Archæology,' 'Bulletin de Correspondance Hellénique,' 'Ephemeris Archaiologikè,' 'Journal of Hellenio Studies,' 'Mittheilungen des Deutschen Archæologischen Institut,' 'Archæologisch-Epigraphische Mittheilungen aus Oesterreich,' etc. Further great collections like Boeckh's have been issued, for example, the 'Corpus Inscriptionum Atticarum' and the 'Sammlung Dialekt-Inschriften' (in progress). A similar ac-

tivity has been exhibited at Rome also, with the same establishment of archæological institutes. In 1863 the first volume of the 'Corpus Inscriptionum Latinarum,' also supported by the Prussian Academy, was issued. Since then 15 volumes, with numerous supplements, have been published, new inscriptions being first provisionally printed in the 'Ephemeris Epigraphica.' In all, some 150,000 Latin inscriptions are now accessible in print.

Classical inscriptions require two classes of investigator, the field collector and the closet student. A knowledge of Greek and Latin acquired from printed books does not equip the student for field collecting. It is true that the decipherment of the known script of classical inscriptions does not present problems like those solved by the ingenuity of Grotefend and Prinsep but, for all that, training is needed for the accurate reading and copying of the inscription. Absolute accuracy in copying is difficult of attainment, but a "squeeze" made of (unsized) paper, wetted and packed into every crevice, or a copy made by covering the inscription with a sheet of dry paper and rubbing the same with powdered graphite secure excellent results. America has produced one collector of large and successful experience, Mr. J. R. Sitlington Sterrett, whose collections are to be found chiefly in the 'Papers of the American School.' After correct copies have been secured it remains intelligently to divine words and letters lost by mutilation and to expand the abbreviations, but the latter have been so thoroughly listed in works on epigraphy (= the science of inscriptions) as now to present little difficulty. The same works have so classified the script-forms as greatly to simplify the act of reading the inscription, and their topical arrangement of the subject matter of inscriptions is a great aid to interpretation.

Greek official inscriptions were chiefly recorded on marble, Roman on bronze. The latter material, being available for so many uses, proved the less enduring. But marble slabs were also converted into building material or foundation stones of ramparts, and at Rome many an inscribed stone was calcined into lime. So many were the hazards to which inscriptions were exposed that it is exceptional to find an important one in its original location. For purposes of study the modern habit of gathering inscriptions into museums is highly convenient. In Greece, besides public squares and buildings, temples were a favorite repository for inscriptions, such as state treaties, tribute and treasure lists; dress, armor, weapons and other offerings of gratitude — all with dedicatory inscriptions — made the temple a sort of museum; images of afflicted parts of the body that had been cured, with accounts of the case inscribed thereon, were offered to gods of healing, forming a sort of nucleus of an anatomical collection and a medical library. Commonest of all forms was the sepulchral inscription which began with simple announcements but grew into sounding eulogies. Among the Greek inscriptions none has been found so comprehensively important for history as the Great Rock of Behistun, but Mr. C. T. Newton, in his essays 'On Greek Inscriptions' ['Contemporary Review' (December 1876); 'Nineteenth Century' (June and August 1878, reprinted in 'Essays on Art and Archæology,' p. 95, seq.)], has set forth with great charm their collective value for history and the things pertaining to religion. At Rome, Augustus caused a succinct account of his deeds to be engraved in bronze and set up before his mausoleum. This inscription, widely diffused in the Augustus temples throughout the empire, was discovered at Ancyra (now Angora). The Monumentum Ancyranum constitutes an extensive historical document of the very first importance. The Edict of Diocletian (303 A.D.) has quite a modern ring, being a law to control mercantile "combinations in restraint of trade" by fixing a maximum price for provisions and other commodities. The Acta Fratrum Arvalium form an important memorial of a religious guild. A fragmentary black cippus unearthed in the Roman Forum (1899), supposedly near the grave of Romulus, aroused great enthusiasm. Its early date (550 B.C.) has been held to make for the credibility of the traditional account of Roman history as given by Livy rather than to give countenance to the skeptical method current since Niebuhr's time. Unfortunately, save for a few words of great interest for the comparative grammarian, the inscription admits of no more definite elucidation than the conviction that the words probably belonged to a religious prescript. The *graffiti* (wall-scratchings) of Pompeii form a large and interesting class of incidental inscriptions which comprises quotations, paraphrases, catchwords, proverbs; lovers' messages, complaints, tarryings, rendezvous; names and greetings. Among them the painted inscriptions (*dipinti*) contain election notices chiefly. The dialects of Latin are known almost entirely from inscriptions. The chief remains of the Umbrian language (dialect) are the Tabulæ Iguvinæ, seven bronze tablets found at Gubbio in 1444. They contain long ritual prescripts. Some 250 inscriptions, few of great importance save to the grammarian, represent the Oscan dialects. Etruscan inscriptions in considerable number have been found in Italy — one (supposedly) as far to the east as the island of Lemnos — but, pending the discovery of a long bilingual, these, though written in a well-known alphabet, still await definitive interpretation. The same is true of Iberian inscriptions (some 75 in number, several of between 50 and 150 letters). Runic inscriptions, in an alphabet derived from the Greek, have been found in Scandinavia and in England; the oldest (300 A.D.) being engraved on the utensils found at Thorsbjerg, others on stone monuments, rocks, weapons, ornaments and coins; the longest containing 16 words.

Iranischen Philologie' and 'Grundriss d. indo-arischen Philologie' (Strasburg, in progress); the Greek and Latin epigraphics in Mueller's 'Handbuch d. klassischen Altertumswissenschaft' (i.); Roberts, 'Greek Epigraphy' (Cambridge 1887–); Reinach, 'Traité d'epigraphie grecque' (Paris 1885); Solmsen, 'Inscriptiones Graecæ Selectæ' (Teubner); Roehl, 'Imagines (facsimiles) Inscriptionum Græcarum' (Berlin 1894); Hicks and Hill, 'Greek Historical Inscriptions' (Oxford 1901); Egbert, 'Latin Inscriptions' (New York 1896); Cagnat, 'Epigraphie Latine' (Paris 1898); Lindsay, 'Handbook of Latin Inscriptions.'

Edwin Whitfield Fay,
Professor of Latin, University of Texas.

Insecticide, any agent which destroys insects. This definition includes natural as well as artificial means of control, the latter being those operated by man. The most important of the former are adverse temperatures, excessive or insufficient moisture, fire, bacteria, fungi, mites, spiders, fish, reptiles, insects, and birds. The artificial controls may be grouped according to their mode of action. Two principal groups are recognized; those intended to reach the alimentary tract through which they act, and those that act through the respiratory apparatus. The former are effective only with such insects as bite off and swallow pieces of plant tissue; the latter more or less also with these, but most frequently used upon insects which suck the plant juices from beneath the punctured epidermis. Caterpillars, beetles and their larvæ, grasshoppers, etc., all chew their food and have been most effectively controlled by Paris green, hellebore, arsenate of lead, etc., applied to the infested foliage either as a spray or as a powder. Plant-lice, plant-bugs, and other sucking insects have been held in check best by kerosene emulsion, whale-oil soap, fir-tree oil, or other substances that choke the breathing-pores in the insects' bodies. Some of these insects are dreaded because of their great prolificacy, their small size and resistance to treatment. Gases are often used under favorable circumstances to reach insects troublesome in stored grain, among clothes, upon plants in greenhouses, and even upon plants in the open air — these last being covered with tents or boxes while being fumigated. Various chewing insects which tunnel through the tissues cannot be controlled by sprays, and are usually beyond the reach of gases. The leaf-miners, which burrow just beneath the epidermis of leaves and green stems, have never been effectively controlled. Some borers (currant-borer) can be kept in check by burning the twigs they infest, (peach-borer) by prodding them in their burrows, (squash-vine-borer), by cutting them out, the method being suggested by the nature of attack. Other chewing insects (plum curculio) are jarred into kerosene. Lastly there are various oils and greases which are used upon animals and man to destroy fleas, lice, etc. Tobacco water and carbolic acid are also similarly employed.

Formulæ and Methods of Application.— Paris green should be mixed with a little water to form a creamy fluid, and then added to water or Bordeaux mixture (see Fungicide) at the rate of one pound to 200 gallons or more. Arsenate of lead may be applied somewhat more liberally. Hellebore may be mixed with water (1 ounce to 3 gallons) and a little glue or flour paste to increase adhesiveness. Each of these may be applied as a powder sifted on the plant, through a salt sack or blown upon them through a powder-gun. A little flour aids the sticking quality. When powders are used, the plants should still be wet with dew or rain. Kerosene emulsion is made by intimately mixing a solution of hard soap (one pound to two gallons of hot water) with four gallons of kerosene, and diluting as needed for use with from 30 to 60 gallons of water. Pure kerosene and crude petroleum can be safely applied only to dormant plants, and then only upon bright breezy days, which will hasten evaporation. Kero-water pumps mix kerosene and water drawn from separate tanks, and apply the mixture direct to plants. They have hardly passed the experimental stage. Whale oil soap is mixed with water (1 pound to 1 or up to 10 gallons), and applied as a wash or spray. Carbon disulphide may be used where there is no danger of its inflammable fumes coming in contact with flame. An ounce is sufficient for from 50 to 75 cubic feet of air-tight space; and the exposure should be for 24 hours or longer. Hydrocyanic acid gas is prepared by adding cyanide of potassium (98–99 per cent pure) to water and sulphuric acid (cyanide, 1 ounce; water 2¼ ounces; acid, 1½ ounces for every 250 cubic feet of greenhouse; 100 cubic feet of nursery stock-room and 125 feet of dwelling house rooms, flour-mills, trees, etc.). Exposures may be from 30 to 60 minutes for trees, the former time being for plants in active growth, the latter for dormant ones; from 12 to 24 hours is usual for rooms, granaries, etc. Since these gases are considered violent poisons the greatest care should be exercised in their application. Oils and greases are merely rubbed on infested animals and man. Boiling water is effective in destroying both lice and eggs in clothing, but the clothing must be boiled for hours to destroy the eggs of the body-louse and the crab-louse. Dust, tobacco-dust, etc., are useful in poultry

yards for the birds to wallow in. Carbolic soap is the favorite remedy for insects on pet animals. But with all stock, poultry, pets and man, cleanliness is the great preventive.

Department of Agriculture, 1891; Marlatt, 'Important Insecticides,' Farmers' Bulletin No. 127, U. S. Department of Agriculture; Hinds, 'Carbon Disulphid as an Insecticide,' Farmers' Bulletin 145 (as above); Johnson, 'Fumigation Methods' (New York, 1902).

M. G. KAINS,
Horticulturist.

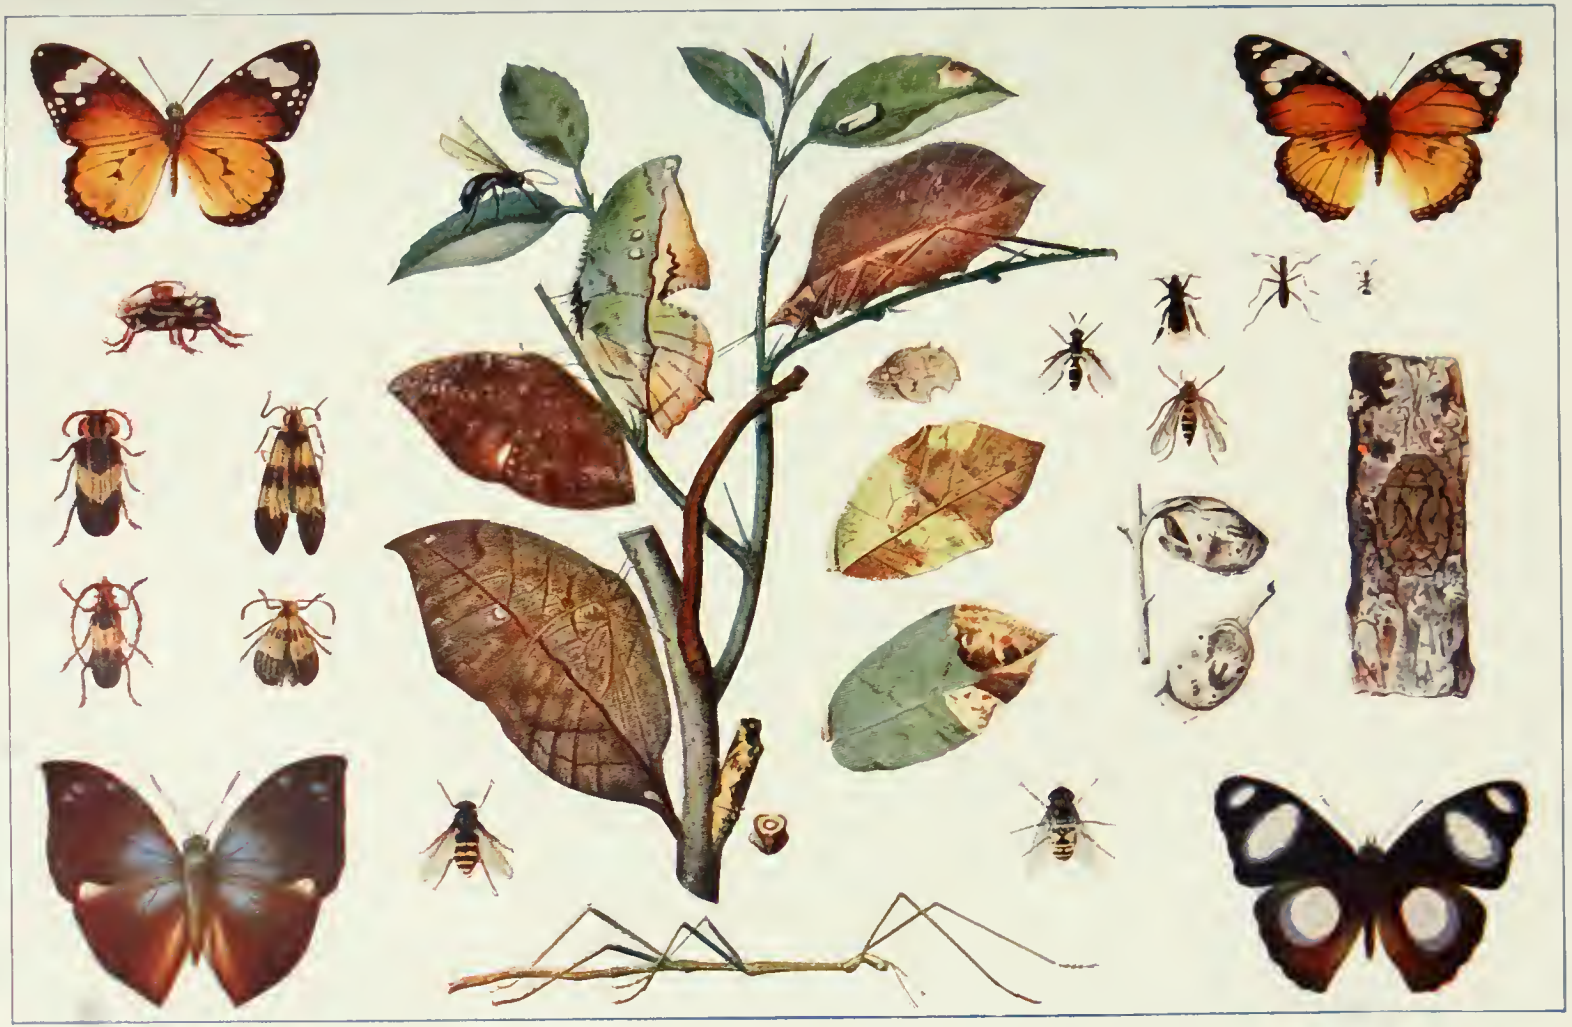
Insectiv'ora, an order of mammals, all of small size, usually five-toed, more or less plantigrade, and as a rule, possessing clavicles. "The snout is generally long, and is often prolonged into a small proboscis. There is a tendency for the teeth to be of a generalized type and their number is often the typical mammalian 44. Moreover, trituberculate teeth, which are certainly of an ancient form, are common." These teeth are adapted to feed on worms and insects alone. Many other evidences go to show that the type is a very old one, and Beddard thinks it may have survived because of the small size, imitative adaptiveness and nocturnal habits. Woodward speaks of the group as probably the little-altered survivors of some of the most primitive placental mammals, agreeing with the *Credonta* in their low type of brain. Most of the families may be traced back to the upper Eocene. The order falls into two divisions, (1) True Insectivores, including the hedgehogs (*Erinaceidæ*), squirrel-shrews (*Tupaiidæ*), tanrecs (*Centetidæ*) otter-shrews (*Potamagalidæ*), hutias (*Solenodontidæ*), golden moles (*Chrysochloridæ*), elephant-shrews (*Macroscelidæ*), aquatic moles (*Talpidæ*), shrews (*Soricidæ*); and (2) Dermaptera, embracing only the colugos (*Galeopithecidæ*). See HEDGEHOG; MOLE.

Insectiv'orous Plants. See CARNIVOROUS PLANTS.

Insects. (Lat. *insectum*), a class of *Arthropoda* characterized by the body being divided into three regions, that is, a head, thorax, and hind-body or abdomen, and by the presence, in all but the more primitive and certain degraded forms, of wings, and of three pairs of thoracic legs. The body of insects consists of 21 segments (somites) of which six are used together to form the head, while there are three thoracic, and from 10 to 12 abdominal segments. To the head are appended five pairs of jointed appendages, that is, the antennæ, mandibles, and two pairs of maxillæ, while in the embryo of certain insects and in the adult *Campodea*, there has been detected a pair of vestigial appendages. Besides these appendages, there are two compound eyes, one on each side, and usually three simple eyes (ocelli) situated in the middle of the head. While the antennæ are undivided the first maxillæ are subdivided into three branches, an inner (lacinia), a middle (galea), and outer (palpifer), bearing the palpus. The second maxillæ are fused together, forming the under lip or labium; each second maxilla is composed of a lacinia, the palpus, while vestiges of the galea occur in certain forms. In bees certain accessory appendages called paraglossæ are present. Besides the maxillæ, the so-called tongue or hypopharynx is present, being highly developed in bees; it lies on the under side of the mouth, just above the labium; in caterpillars it receives the end of the salivary duct, and is called the spinneret. Attention should also be called to the upper lip or labium, on the under side of which is the epipharynx, which bears minute taste-pits. The thorax consists of three segments, which can be easily distinguished in the primitive wingless forms (*Campodea*) and in the cockroach and locust, but in the more specialized forms as beetles, moths, bees and flies, the segments are more or less fused together and, owing to the movements of the wing muscles, are subdivided into many separate pieces. In the wasps and bees the basal abdominal segment becomes toward the pupa state transferred to the thorax. The legs as a rule end in five jointed tarsi, the last joint bearing a pair of claws with a cushion (pulvillus) between them. Insects are enabled to walk on glass, etc., by means of a sticky fluid exuded from the ends of hollow hairs fringing the cushion. They climb by means of their claws.

Insects differ from all other animals except birds and bats in possessing wings, and their presence, especially that of the muscles of flight, have greatly modified the shape and structure of the thorax. The front pair of wings is attached to the middle thoracic segment (mesothorax) and the hind wings to the metathorax. In the two-winged flies (*Diptera*) the second pair of wings are reduced and modified to form the balancers (halteres). The wings are flat sac-like outgrowths of the skin, and are strengthened by the "veins" which form hollow rods. These veins contain a trachea, so that there is a space between the air-tube and the outer wall. When the insect emerges from the nymph or the pupa, the vein is filled with blood. The spaces enclosed by the veins and their cross-branches are called cells, and their shape often affords valuable generic and specific characters. In the more primitive insects there are numerous cross-veins, and such wings as in locusts, etc., are said to be net-veined. In the *Lepidoptera* there are few cross-veins. In the *Diptera* and *Hymenoptera* the number of veins is limited, the cells also being few. The skin of insects is hard, dense and elastic, due to the deposition of chitin.

Internal Anatomy.— One of the distinctive characteristics of insects is their mode of respiration. This is effected by an intricate system of internal air-tubes (tracheæ), which are filled with air by openings (spiracles) in the sides of the body; of these spiracles there are from one to two pairs in the thorax, and eight pairs in the abdomen. The tracheæ are kept permanently open by a series of threads (tænidium) each of which makes from three to five turns around the thin tube; in this way the entire tracheal branch is provided with what at first was supposed to be a continuous spiral thread. The slit-like openings of the spiracles are guarded by a grate of stiff hairs to prevent the ingress of dust, etc. It should be borne in mind that no insect breathes through its mouth, but through the spiracles. Hence the efficacy of all oily or greasy substances in destroying every kind of insect in whatever stage of growth; wherever the oil touches the body a thin film spreads over it, covering the air-openings so that the insect soon dies by asphyxiation. Though



PROTECTIVE MIMICRY AMONG INSECTS

insects have a delicate pulsating tubular heart, they have no arteries and veins, since the air in the tracheæ seeks the blood in the remotest parts of the body. The blood is thin and colorless. The aquatic larvæ and a very few perfect insects breathe by external tracheal gills, the spiracles being in such cases often absent. The genital opening is always situated near the end of the body, in front of the vent on the under side. Besides a complicated digestive canal, insects have urinary tubes opening into the end of the intestine.

The nervous system consists, besides the brain, of a chain of ganglia the greatest number of which is 13, but which become more or less fused in the more specialized groups, especially in the flies. The brain is remarkably complex, in accordance with the varied and complicated movements of the segmented body and jointed appendages, all capable of different kinds of motions.

Sense of Sight.— The compound or facetted eyes (ommatea) are composed of numerous simple eyes called ommatidia, which vary in number from 12, in *Lepisma*, to 20,000 in the dragon-fly (*Æschna*), and even 25,000 in a beetle (*Mordella*). Yet notwithstanding the wonderful complexity of these compound eyes, most insects are near-sighted, and perceive rather the movements of other animals than their exact outlines; the dragonfly and butterfly can see for a considerable distance. The simple eye probably only enables the insect to distinguish daylight from darkness, or at most very near objects. Insects, like bees and butterflies, have the color-sense, and prefer certain colors to others.

Sense of Smell.— Insects are chiefly guided by the sense of smell. This resides in the antennæ, in which there are microscopic pits filled with fluid; to this pit goes a fine nerve whose fibres end in staff-like sense cells. The number of these olfactory organs is in some insects enormous; thus in the European cockchafer there are 39,000 in the leaves of the male antennæ, and about 35,000 in those of the female; in a single antenna of the hornet (*Vespa crabro*) are about 13,000 to 14,000. In the cockroach the abdominal cerci or feelers also possess such pits.

Sense of Hearing.— The auditory organs of the locust are drum-like ears situated one on each side of the base of the abdomen, directly behind the first abdominal spiracle; in the green grasshopper, katydids, etc., a little auditory sac is lodged in the fore-legs (*tibiæ*). It is supposed that most insects are destitute of the sense of hearing, at least auditory structures have not yet been detected; yet all sound-producing insects must have ears to hear.

Sense of Taste.— The taste organs are little pits or papillæ which resemble the olfactory organs, but which occur on the inside of the upper lips, on the epipharynx, or at the base of the proboscis and maxillæ in the bee.

The Egg and Growth of Insects.— The eggs and the fertilizing fluid of the male are produced in glands which open near the end of the body on the under side. The eggs are deposited by the female in the earth or in wood, leaves, etc., by means of the ovipositor, an apparatus composed of three pairs of hard appendages, and which in the wasps and bees form the sting. Most insects die on the approach of cold weather, when they lay their eggs, the species being represented in the winter by the eggs alone. The eggs hatch in spring, the embryo passing through remarkable changes.

Metamorphoses.— Most insects after hatching pass through a remarkable series of changes called a metamorphosis. The small flies, moths or beetles, are not the young of large ones, but adult insects, while the most primitive insects have no marked metamorphosis, the mature locust only differing from the young in having wings; the more specialized forms, as beetles, moths, wasps, bees, and flies, pass through two stages of growth, that is, the larva and pupa, before becoming winged and sexually mature.

Larva.— The name was first given by the ancients to the caterpillar because they thought it masked the form of the perfect insect. Swammerdam supposed that the larva contained within itself "the germ of the future butterfly, enclosed in what will be the case of the pupa, which is itself included in three or more skins, one over the other, that will successively cover the larva." But the discovery by Weismann (q.v.) of the germs of the imago (imaginal disks or buds) in the larva completely changed our notions of the nature of metamorphosis (q.v.), and revolutionized our knowledge of the fundamental processes concerned in the change from larva to pupa or chrysalis, and from pupa to imago. Not only are the larvæ of each order of insects characteristic in form, so that the grub or larva of beetles is readily distinguished from the larvæ of other groups, or the maggots of flies from the footless larva of ants, wasps and bees, but within the limits of the larger orders there is a great diversity of larval forms, showing that they are the result of adaptation to their surroundings and mode of life.

The larvæ of nearly if not all the metabolous animals are probably secondary in their origin. Fritz Müller (q.v.) pointed out that this is the case with the larvæ of the higher insects. The larva of a beetle is popularly called a grub; that of a fly a maggot. The young of the more primitive insects, such as the cockroach, locust, all bugs, etc., which undergo an incomplete metamorphosis, is called a *nymph*. See LARVA.

Pupa.— The word pupa is Latin, meaning baby. Linnæus gave it this name from its resemblance to a baby which has been swathed or bound up, as is still the custom in Southern Europe. The term pupa should be restricted to the resting, inactive stage of the holometabolous insects, that is, those with a complete metamorphosis. The typical pupa is that of a moth or a butterfly, popularly called a chrysalis. A lepidopterous pupa in which the appendages are more or less folded close to the body and soldered to the integument, was called by Linnæus a *pupa obtecta;* and when the limbs are free, as in Neuroptera, Mecoptera, Trichoptera, and the lepidopterous genus Micropteryx, it is called a *pupa libera.* When the pupa is enclosed in the old larval skin, which forms a pupal covering (puparium), the pupa was said by Linnæus to be *coarctate.* The pupa of certain Diptera, as that of the orthoraphous families, is nearly as much obtected as that of the tineoid families of moths, especially as regards the appendages of the head, the legs being more as in pupæ liberæ. The pupæ of Coleoptera and of Hymenoptera, though there is, apparently, no near relationship between these two orders, are much alike in shape, and,

as Chapman pertinently suggests, those of both orders are helpless from their quiescence, and hence have resorted for protection to some cocoon or shell. But it is quite otherwise with the pupæ of Lepidoptera and Diptera, which vary so much in adaptation to their surroundings, and hence afford important taxonomical and phylogenetic characters. This, as regards the Lepidoptera, was almost wholly overlooked until Chapman called attention to the subject, and showed that the pupæ had characters of their own, of the greatest service in working out the classification, and hence the phylogeny of the different lepidopterous groups. The pupæ of the Neuroptera, Coleoptera and Hymenoptera differ structurally from the imago, in the parts of the head and thorax being less differentiated. Thus in the head the limits or sutures between the epicranium and clypeus, and the occiput and gula, are obscurely marked, while the tergal and pleural sclerites of the imago are not well differentiated until the changes occurring just before the final ecdysis. It is easy, however, to homologize the appendages of the pupæ with those of the imago of all the holometabolous orders except in the case of the obtected pupa of the Lepidoptera (and probably of the obtected dipterous pupæ), where the cephalic appendages are soldered together.

Classification of Insects.— The number of known species of insects is from 200,000 to 300,000, but it is estimated that there are upward of a million species now living. In fact, the class of insects vastly outnumbers all other groups of animals. This is probably due to their being winged, and to their great fecundity. At present the class of insects is divided into two subclasses, that is, the (1) *Synaptera,* represented by the wingless orders Thysanura and Collembola; and (2) *Pterygota,* comprising 15 winged orders and which may be thus tabulated:

Series 1.— *Heterometabola,* with an incomplete or variable, though slight, degree of metamorphosis. No distinct larva or pupa state, the young being nymphs.
- Order 1. Dermaptera. (Earwig.)
- " 2. Orthoptera. (Cockroach, locust, grasshopper, stick insect.)
- " 3. Platyptera. (Bird lice, Perla, white ant.)
- " 4. Odonata. (Dragonfly.)
- " 5. Plectoptera. (Mayfly.)
- " 6. Thysanoptera, Thrips.
- " 7. Hemiptera. (Bugs.)

Series 2.— *Holometabola,* or with a complete metamorphosis.
- Order 8. Neuroptera. (Corydalus, lace-wing fly, ant-lion.
- " 9. Mecoptera. (Panorpa, Boreus.)
- " 10. Trichoptera. (Caddis flies.)
- " 11. Coleoptera. (Beetles.)
- " 12. Lepidoptera. (Moths and butterflies.)
- " 13. Siphonaptera. (Flea.)
- " 14. Diptera. (Mosquito, fly.)
- " 15. Hymenoptera. (Saw-fly, ant, wasp, bee.)

Fossil Insects.— About 3,000 species of fossil insects have been described, of these from 200 to 300 are Palæozoic, 500 Mesozoic, and the remainder are Tertiary. The oldest fossil insect-remains is the wing of a supposed bug (*Protocimex*) from the Ordovician of Sweden. The wing of a cockroach (*Palæoblattina*) has been detected in the middle Silurian of Calvados, France. From the Devonian shales of St. John, N. B., nine species of primitive net-veined insects have been collected. The coal measures are characterized by cockroaches, primitive dragonflies, May-flies, and grasshopper-like forms, phasmids, etc., also occurring. All of the Palæozoic insects known are very primitive. Modern forms, those having a complete metamorphosis, begin to appear in the Triassic and Jurassic, where remains of beetles, a saw-fly, and a moth occur. Ants, bees and butterflies date from the Oligocene and Miocene Tertiary.

Bibliography.— The latest general works on insects are Carpenter's 'Insects, their Structure and Life' (London, 1899), and Sharp's 'Insects' (Vols. V. and VI. of Cambridge Natural History, 1895–9); both contain sufficient references to other works. For American insects consult: Packard's 'Text-book of Entomology' (1898), and 'Guide to the Study of Insects' (1889); Comstock's 'Manual for the Study of Insects' (1895); 'Insects and Crustacea' (Vol. II., Standard Natural History, 1884); Howard's 'The Insect Book' (1901). The last named contains a copious bibliography, especially to the voluminous publications of the Entomological Division of the U. S. Department of Agriculture.

See FRESH-WATER INSECTS; MARINE INSECTS, and the names of groups and species, as FLIES, HYMENOPTERA, MOTHS, etc.

ALPHEUS S. PACKARD,
Late Professor of Zoology, Brown University.

Insects and Flowers. See FLOWERS AND INSECTS.

Insessores, ĭn-sĕ-sō′rēz, a discarded term in Ornithology designating a group styled "perchers," which included the majority of the smaller and more familiar birds. The term has been abandoned because the group denoted by it is a purely arbitrary one.

Insid'ious Flower-bug. See FLOWER-BUG.

Insolvency. In a popular sense the word insolvency applies only to persons without property or means sufficient to satisfy their creditors. The legal definition embraces all who are unable to pay their debts at maturity in the ordinary course of business, even though they may possess assets exceeding their liabilities. A failure to meet overdue obligations renders a person liable to proceedings against him in a court of insolvency, in which his assets may be taken into the possession of the officers, marshaled, and distributed to his creditors. Should there be an amount in excess of what is required to pay the creditors and the expenses of administration, the balance so remaining is the property of the debtor. From a very early period in the history of civil government, laws have existed providing for proceedings by creditors against insolvent debtors, by which the debtor's property could be taken from his possession, to be held by another as a trust fund to be applied to the payment of his just debts. In case of an insufficient amount to pay all debts in full, provisions are usually made for a *pro rata* distribution. These laws have generally provided for classes of preferred debts, payments of which were to be made in full, even though such payments exhausted the entire assets. Preferred claims commonly included all claims of the government or state, and often claims for labor to a limited

amount, and claims for the necessaries of life. Provisions are usually made for the exemption of certain articles to the use of the debtor, not to be included in the assets. The Constitution of the United States provides that Congress may establish uniform laws on the subject of bankruptcy throughout all the States, and the first act upon that subject was passed in 1800, since which time there has been some Federal bankruptcy law, with brief interregnums. A uniform national law upon the subject now exists. The first act of Congress upon this subject provided for proceedings by the creditors only, but in 1841 an amendment provided for voluntary proceedings by the debtor, by which he could surrender his property and obtain a discharge from all of his debts, provided he had been guilty of no fraud. In the absence of a national law on the subject of insolvency, the States all have authority to enact and enforce laws upon that subject. The Federal act now provides for voluntary proceedings by the debtor, as well as proceedings against him by the creditors, with provisions for his discharge. The various State acts have usually contained such provisions. The Federal act suspends all State insolvency laws during its continuance. See BANKRUPTCY LAWS.

Inspiration, in theology, the communication by the Holy Spirit, to writers and speakers, of a portion of the knowledge and feeling of God, in such fashion that they can be communicated to other men; especially used in relation to the Bible. On the fact of inspiration rests all attribution of divinity to the sacred writings above any others; but theories of its method and extent have necessarily changed with the advance of critical knowledge. They have never had an authoritative pronouncement even from the Church of Rome, which allows liberty of judgment on this; the Bible not holding the supreme place there as in Protestant bodies, and the latter being too divided for a credal statement on this point, by the very causes which call for one. All theories rest not only on the necessary implication of divine character in the Bible, but on two specific passages: 2 Tim. iii. 16: "All Scripture is given by the inspiration of God, and is profitable for doctrine" (Revised Version, "Every Scripture inspired of God is also profitable for teaching," which does not relinquish the claim of inspiration); and 2 Pet. i. 21, "Holy men of God spake as they were moved by the Holy Ghost" (Revised essentially the same). The Scriptures were the Old Testament.

The early Church did not generally dwell on theories of inspiration, regarding it as a passive "ecstasy" in which divine truth was communicated, but rarely going on to its effects on the inspired writings or the methods which produced them. Origen, however, the great builder of doctrinal framework, formulated an exact theory of "plenary" or entire inspiration, which preserved the writers from all faults of memory, and left no iota either incorrect or superfluous in Scripture. But others held that all believers were inspired in different degrees; as this made all believers infallible interpreters of the Scriptures, the perilous nature of such a doctrine led to the opposite one, that there was an inspired official depositary of interpretation as well as an inspired canon of writings. The mediæval schoolmen evolved the theory that there were two kinds of inspiration in the Scriptures: direct, found where moral and doctrinal truths are directly taught; and indirect, in historical passages, whence ethical truths can only be derived by allegorical interpretation.

Regarding inspiration not as a purpose but a method, there are three explanations within the limits of orthodox Christianity: the "plenary" or verbal, the dynamic, and what may be termed the "irradiant" theories. The remaining one, which makes the inspiration only that common to all human beings — who are part of the divine mind — and having no part in any special revelation, is really not a theory of inspiration at all, as it holds that there is none; that all things are parts of the world's evolution, and the sacred writers and the Bible were evolved like the rest, though the latter is the greatest moral product of the world, and to be reverenced in the moral rank as we reverence the greatest writers and thinkers in theirs.

In the early uncritical ages of the Protestant churches, the universal and obvious theory of inspiration was the plenary. The original text of the Bible was dictated word for word by the Holy Spirit, the writers being merely penmen, or media on whom were impressed certain phrases, which must not be varied on peril of distorting the divine revelation. The words of Scripture thus transmitted are God's words, to each reader as if spoken directly to him by the Deity, and no matter to what subject they relate, be it doctrine or history, the origin of man or the duty of man. That there are different styles, corresponding to different writers, means only that God has accommodated his expressions to their natures, for his own utilities. Hence the least particle in the Scriptures is surcharged with meaning, and if anything seems in conflict with science, history, or other portions of the Bible, it arises from corruption of text, bad translation, or other change from the actual revealed language. This is the only theory with perfect logical continuity; unhappily it can only be maintained, in face of the increasing body of knowledge of texts, facts, and natural ethics, by those willing to abnegate their own right of criticism wholly in favor of their own infallible interpretation. Indeed, the chief argument for the latter is that the divine purpose would be defeated, if its intention in giving the revelation were made null by the misunderstanding of fallible human faculties.

The dynamic theory is the first step outside this bulwark enforced by the impossibility of maintaining verbal inspiration, and relegates the divine agency to an indirect function. In place of its dictating the exact phraseology and the precise facts, the writers are so filled with divine force that for all purposes of conveying the essential divine purpose, that of showing the truths of sin and danger and the path of salvation, they are a portion of the divine and incapable of error. Under this theory the writers are left a free hand, according to their own limitations and those of their age, in dealing with narrative facts or their own guesses at them; but are guided explicitly in all matters of faith and morals. In order to be received, the revelation had to be accommodated to the mental conditions of different ages; and men of each received guidance from God to present it so that it was true in relation to them, and remained so for all ages under all conditions. The war-

rant of the Bible is its incomparable and superhuman system of ethics, and its proof of divine origin is that evident superiority to all human devices.

The "irradiant" theory is a recent one, and a step farther from the old claim of entire divinity. In this view the record as such has no divinity, nor infallibility of any kind. There is a divine revelation, but it acts by generating moral ideas in certain great selected men, and which, once generated, are left to fight their way and take their chance like the other useful ideas of the world, and undergo disbelief and mutilation, with the certainty that according to God's purpose, truth will prevail at last. The proof of divinity in Christianity lies in the fact that its moral truths are the greatest in the world, and were original with it.

Instinct. Instinctive acts are those physiological activities in which mind or consciousness is involved. Instincts may be regarded as intermediate between simple physiological or reflex actions and acts of reason exhibited by man. Animals of a grade higher than sponges, polyps, most mollusks and other forms of a corresponding grade, have organs of sense, of perception, and in the higher vertebrates a brain and nervous system and other organs of the same type as those of man, and such animals react to something more than mere physical stimuli. We know by observation that the social insects, birds and mammals, at least those which have become domesticated, have sufficient intelligence to meet the ordinary exigencies of life, and that at times the ant, bee, beaver, elephant, dog, and ape can meet extraordinary emergencies, that is, rise with the occasion; that they may to a very limited extent be free agents; that they are not mere automata. It has been observed that the more intelligent animals are not solely guided by the physical stimuli of light, odors, etc., but that they exercise the power of choice, selecting this or that kind of food, this or that mate. Animals are subject to what we call the passions: they show anger, even when not hungry or under the domination of the reproductive instincts; their sounds express dissatisfaction or contentment. They possess memory; with its aid ants and bees find their way back to their nests.

Definitions of Instinct.— Descartes believed that animals are automata. It is popularly supposed that animals are automata, physiological machines in which have been implanted by supernatural power what we call instincts. This view is still insisted on by two excellent observers of the habits of insects, Favre and Wasmann, who claim that instincts are special innate or natural propensities, "transcending the general intelligence or experience of the creature." But of late years the impression has arisen and gained force that instincts are "innate" and "natural" because they have arisen by a natural process and have been gradually acquired and transmitted from one generation to another.

Erasmus Darwin held that instincts were the result of imitation by young animals of the actions of their parents. This view is still held by Wallace, and, as Eimer claims, the power of rapid learning has played a part in the evolution of certain instincts. Thus the fox or rat learns from its parents, and becomes more cunning or sagacious with age and training. Lamarck practically regarded the lowest animals as automata, but in the higher animals, that is, those with a nervous system, we have instinct. "Hence, instinct in animals is an inclination which necessitates that from sensations provoked while giving rise to wants the animal is impelled to act without the participation of any thought or any act of the will." To satisfy these wants they contract different kinds of habits; these are transformed, he says, into so many propensities, from which "originate their habitual actions, and special propensities to which are given the name of instinct." He then adds that the same habits and the same instinct are perpetuated from generation to generation, "without offering any notable variation, so long as it does not suffer change in the circumstances essential to the mode of life." He thus intimates that instinct may vary, and he states that in birds and mammals instinct is variable.

Darwin does not give a formal definition of instinct, but after stating that several distinct mental actions are commonly embraced by this term, he adds that "a little dose, as Pierre Huber expresses it, of judgment or reason often comes into play, even in animals low in the scale of nature." He calls attention to the points of resemblance between instincts and habits, showing that habitual action may become inherited, whence it results that "the resemblance between what originally was a habit and an instinct becomes so close as not to be distinguished." He concludes that, by natural selection, slight modifications of instinct which are in any way useful accumulate, and thus animals have slowly and gradually acquired through successive generations, their power of acting instinctively, and that they were not suddenly or specially endowed with instincts. Herbert Spencer defines it as compound reflex action, and also as "a kind of organized memory," arguing that instinctive actions grow out of reflex, and in time pass into intelligent acts. Romanes defines instinct as "reflex action into which there is imported the element of consciousness." Lloyd Morgan also says: "It is a bit of animal automatism not necessarily involving more than the lower brain centres," but it is a bit of automatism accompanied by a consciousness in a broad sense. "The role of consciousness in a chick's pecking is to select the adequate responses, and to steady the muscular mechanism to its work." As the result of recent experiments Loeb regards instincts as inherited reflexes so purposeful and so complicated in character that nothing short of intelligence and experience could have produced them. Packard gives the following definition: "The sum of inherited reflex acts, becoming habitual and arising from blended reflex and subconscious though involuntary acts, performed at birth or through life blindly, without practice or previous experience, effort, training or thought."

Examples.— It should be understood at the outset that instincts in animals are fundamentally connected with the means of obtaining food, or with reproduction, the latter involving care for the young, as in egg-laying, the selection of a nesting place by insects and birds, the construction of the nest, and the defense of the young, and in the birds and mammals the training of the young to fly, or to hunt for prey.

Reflex acts are simply physiological responses

to external physical stimuli, as muscular irritability, the different tropisms, such as response to odors, and other chemical properties, to cold, heat, etc. Many of the movements of the lowest animals, as the protozoa, sponges, polyps, worms, etc., their modes of selecting and getting food, of escaping their enemies, are scarcely more than reflex. As examples of instinctive acts are those of very young chicks. Morgan regards as instinctive in these birds the act of "pecking, walking, scratching themselves, preening their down and feathers, stretching up and flapping their wings, squatting down and dusting themselves, scattering and crouching when alarmed, uttering the danger-warning *churr,* and other sounds." Young ducks afford examples in the way they "seize and mumble their food in the bill, their aptness in swimming directly on leaving their shell, piping, and smoothing the down of their breast with their bill."

It is when we observe the complicated nesting habits of the spiders, and of the social insects such as ants, wasps, bees, as well as those of birds and the muskrat and beaver, when such striking and inexplicable forms of intelligence arise that we become perplexed how to explain them. Thus take the mode in which the honey-bee builds its cells. Is it simply mechanical, the result of several bees working together, and due to the mechanical pressure of the insects against each other during the formation of the cell? While some contend that if left alone to build a single cell, this would probably be round, others show that a solitary wasp will build its cells in very regular hexagons. It is now conceded by Darwin, Romanes, and others, that the process is not a purely mechanical one, but is "constantly under the control of intelligent purpose." It is most probable that the hexagonal-cell building instinct is the result of habits which gradually arose, and which became fixed by heredity. In birds the modifications sometimes occurring in the shape and situation of their nests show that their instincts are, owing to change of conditions, plastic, reason teaching them to modify their nests so as to adapt them to new conditions. Experience and intelligence lead to such changes. The beaver manifests in his works intelligence and reasoning capacity, both in the construction of dams, canals, and in the mode of felling trees, and in the use in certain localities of "slides." In the monkeys and apes we apparently have the nearest approach to human intelligence, judging by the instances narrated by Romanes. Were it possible to breed apes for many successive generations more light would be thrown on their psychology. Meanwhile many acts performed by the domestic animals, the horse, dog, cat, elephant and even the pig, and their susceptibility to be trained, show that they may often act intelligently, and are prompted by a low degree of reason.

Instincts Variable and Sometimes at Fault.— Lemmings in their migrations, impelled by their instincts to go ahead, will swim out into the sea and be drowned. Ants will store up beads instead of seeds, and there are many instances where instinct is at fault. Certain instincts may also by change of the environment become directed into new channels. This is illustrated by numerous cases of insects, reptiles, and mammals which have become adapted to an aquatic life. An entire new crop of habits and instincts may thus arise. The instincts of young animals, particularly of larval forms, caterpillars, grubs and maggots, are of a different description from those of the pupa state, and more especially of the adult state. In fact, instincts are pliable, variable, and in certain cases may lapse altogether, to be replaced by a new set. Were this not the case we should have no progress in the evolution of life. The more generalized animals have vastly less intelligence than the highly specialized forms. Compare the instincts of so complex a being as the ant, or wasp, or bee, with that of the locust or bug, or the instinctive and intellectual acts of social insects, with their wonderful differentiation of the individual into workers of different castes and the normal and supplemental males and females. Such are what are called complex instincts, and they are all brought into action through the principle of the division of labor.

Do Animals Reason?— Lloyd Morgan observed that the chick rapidly profits by experience after a few practical trials; hence he concludes that intelligence is founded on experience. He allows that chicks have intelligence, this involving the association of impressions and ideas, and the power of making a choice. He then asks the question, "Do animals reason"? "Do they focus the therefore"? "Do they think the why"? Probably not. Reason is not (as animals "reason") adaptation; they do not profit by experience of actions to varying circumstances. Hence, he thinks that animals probably do not reason as man is capable of reasoning. Here might be quoted Herbert Spencer's definition: "Reason or intelligence is the faculty which is concerned in the intentional adaptation of means to an end." Finally, it is safe to assume that the higher animals, especially the domestic animals, which have been in contact with and more or less trained by man, exhibit the germs of reason, and while they cannot make inductions and deductions or predictions, their intellectual acts differ rather in degree than in kind from those of the lowest human races.

Alpheus S. Packard,
Late Professor of Zoology, Brown University.

In'stitute of France, a learned body organized after the first outbreak of the French Revolution, during which all the academies of learning and arts in France had been suppressed. It was formed by the decree of 25 Oct. 1795, to replace the Académie Française, the Académie des Sciences, and the Académie des Inscriptions et Belles-Lettres. Its object was the advancement of the arts and sciences by continual researches, by the publication of new discoveries, and by a correspondence with the most distinguished scholars of all countries, and especially by promoting such scientific and literary undertakings as would tend to the national welfare and glory. The Institute was composed of a number of members residing at Paris, and an equal number of associates in the different parts of the Republic. Each class could also choose eight learned foreigners as associates. It was at first divided into three classes, each of which was subdivided into several sections. The first class embraced the physical and mathematical sciences,

the second the moral and historical, and the third literature and the fine arts. The number of active members, exclusive of the associates, was limited to 144. The Institute received, however, its final organization by a decree of 23 Jan. 1803. It was then divided into four classes: (1) the class of the physical and mathematical sciences, consisting of 65 members; (2) the class of the French language and literature, consisting of 40 members; (3) the class of history and ancient literature, of 40 members; (4) the class of the fine arts, with 28 members. A royal ordinance of 21 March 1816, restored the former names of the classes, so that the name of Institute was applied only to the whole body collectively. The same ordinance assigned the first rank to the Académie Française, as being the oldest; the next rank to the Académie des Inscriptions et Belles-Lettres; the third to the Académie des Sciences; and the last to the Académie des Beaux-Arts. These united academies were under the personal direction of the king, and each had an independent organization. To each academy were attached 10 honorary members, who had merely the right of being present at the meetings. In 1832 the old class of Sciences Morales et Politiques was reconstituted as a separate academy, so that there are now five academies.

The Académie Française had for its chief object the cultivation of the French language, and was charged with the composition of a French dictionary, the merits of which have been often disputed and its plan condemned. The disposal of its vacant chairs has not always been regulated by the best taste and judgment, Descartes, Pascal, Molière, La Bruyère, J. J. Rousseau, Balzac, Dumas père, Daudet, and Zola having been rejected, while in former times many a shallow court favorite was accepted.

The Académie des Inscriptions et Belles-Lettres has 40 members, 10 free academicians, and 8 foreign associates. It has 40 correspondents at home and abroad, and devotes itself chiefly to subjects of a historical nature. The most distinguished scholars, both in and out of Europe, are, or have been, connected with it. Committees of this academy superintend the erection of public monuments and the preservation of those already in existence. Works brought out under its auspices are: 'Histoire littéraire de France,' 'Recueil des Historiens de France,' and 'Corpus Inscriptionum Semiticarum.'

The Académie des Sciences has for its province the various branches of knowledge connected with the physical and mathematical sciences, natural history, medicine, etc., there being in all 11 sections. It has 66 members, 10 free academicians, and 100 correspondents. The number of foreign associates is limited to eight.

The Académie des Beaux-Arts has 40 members, 10 free academicians, 10 foreign associates, and 61 correspondents. A committee of this academy was charged with the publication of a dictionary of the fine arts.

The Académie des Sciences Morales et Politiques, has 40 members, 10 free academicians, 6 foreign associates, and 48 correspondents.

Members of the Institute of France are elected for life by ballot, and have an annual salary of 1,500 francs.

Institute of Social Service, American. See SOCIAL SERVICE.

Institutional Church, a non-credal organization of Christians, to supplement the regular church methods and ministrations — preaching, prayer-meetings, Sunday school, and pastoral visitations — by helpful social work in the community. The moving spirit is the same as in the Y. M. C. A., University Settlement, Salvation Army, Rescue Missions, Christian Endeavor societies, etc.; but «with the emphasis on Church, not Institution.» The prime object is to reannex to the church the functions which other bodies have been compelled to fill by its neglect of its duty; and strengthen it by gathering potential Christian elements which under the old system do not come to it, as well as by combining in itself all the claims to public gratitude and interest now shared between the purely ecclesiastical and the purely social institutions, or the half-way houses like the Y. M. C. A. It differs from the latter in not merely furnishing a religious atmosphere which may lead to church membership, but enrolling members at once in a real church of Christian work by absorbing the secular features of the other; in a word, to do, without vows or uniforms, what the Catholic Church has always done with its charitable functions — make them an integral portion of the church organization. Hence, it is not by itself a church in the sense of the Roman Catholic or the Methodist Church, but in a broad sense a description of any church which adds educational or social work; in general use, a title of any which throws into this work its predominant vitality. Free pews are an essential accompaniment, as the social aristocracy fostered by rented pews contradicts the basal democratic principle of institutional work; hence it is sometimes called Free Church, but preferably Open Church. The present name originated with President Tucker of Dartmouth College, who applied it to Berkeley Temple, Boston.

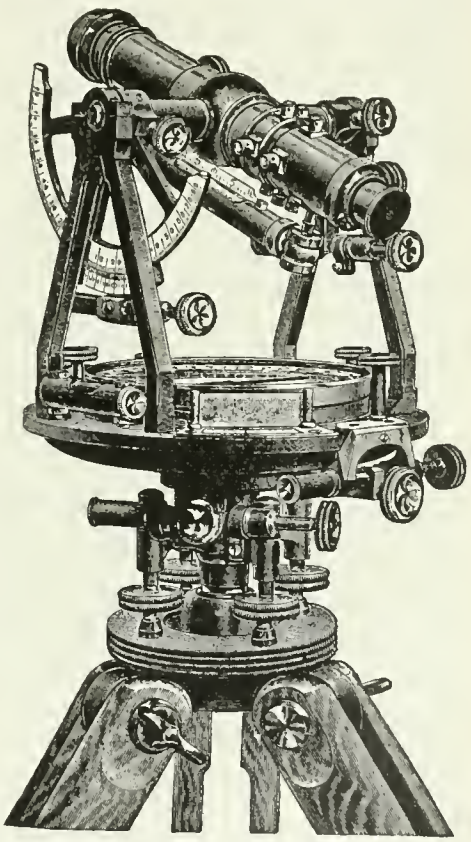
The movement started chiefly with the High Church element in England, modeled on the Catholic idea; it flourished for two generations in that country before reaching the United States, about 1880, and it has hardly been a vigorously spreading one here for above 15 years. Now, however, a large number of churches — Episcopal, Congregational, and Baptist in the forefront, but also Methodist, Presbyterian, Unitarian—have adopted the idea with increasing vigor, besides the work of this class always performed by the brotherhoods and sisterhoods of the Roman Catholic Church. One of the earliest of these was Plymouth Church of Indianapolis, inspired by the memory of Mr. Beecher. Notable among others are the St. Bartholomew, St. George, St. Paul, and Judson Memorial of New York, and the Tabernacle of Jersey City; Berkeley Temple, Parker Memorial, and Ruggles Street Baptist of Boston; Grace and Bethany of Philadelphia; Ninth Street of Cincinnati, Pilgrim of Cleveland; Plymouth Tabernacle of Detroit; People's of St. Paul; and the Denver Tabernacle. In 1894 the Open and Institutional Church League was organized in New York; it held several conventions in Eastern cities (1895–1901), and for three years published the 'Open Church' as its organ, but has practically lapsed, being merged in the 'National Federation of Churches and Christian Workers.' The total of its work, however, is not shown by its nominal member-

ship; the same spirit has infected outside churches, and their methods are being more and more adopted as a general basis of work.

The platform of the League stated that it aimed to save all men by "abolishing, so far as possible, the distinction between the religious and the secular"; by "open church doors for every day and all the day, free seats, a plurality of Christian workers, the personal activity of all church members, a ministry to all the community through educational, reformatory, and philanthropic channels, to the end that men may be won to Christ and his service, that the Church may be brought back to the simplicity and comprehensiveness of its primitive life." It is not correct to say, as is often done, that its methods are purely secular: its *additional* methods beyond the regular religious ones are so, for the very reason it exists. These involve a thorough organization for social and philanthropic work; but the religious features are sedulously conserved and carefully fitted to the work, the spirit of worship being cherished and made the centre of inspiration. The service generally ends in the communion; there is congregational singing of both hymns and chants, led by a highly trained choir, and often responsive readings; the whole with the sermon are intended to be brief, varied, and attractive. Sunday schools are carefully attended to; prayer meetings given new features; in summer there are open-air meetings; and other Christian associations, endeavor societies, brotherhoods, etc., are encouraged. The officers and workers of the church are given active special duties, such as pastoral visiting, reception and welcome of strangers, canvassing for the various activities of the church; and there are not only sub-pastors, but deaconesses, sisters, and nurses. The purely secular side embraces all departments of culture, physical, intellectual, and moral, as well as direct charities. Morally, the church work above should be sufficient. The charitable departments include not only direct aid to the poor, but wood-yards, employment bureaus, etc.; personal endeavor to provide employment for those willing to work; dispensaries, hospitals, and crèches; and encouragement to thrift by savings funds. Special buildings are often erected.

That the movement is liable to perversions is admitted; such is the case with every institution. Secularization is one; but unless it can be faced, the churches cannot influence or draw in those outside them, for the simple reason that the latter cannot be brought within hearing. Sensationalism, to draw in hearers to be benefited, is a graver one, and ill-judged; as one of its chief workers puts it, "a camp-stool congregation neither pays nor repents," and a lasting work must be content with slower processes.

Instruments, Engineering. To attempt a definition of an engineering instrument is hardly practicable, as the wide range of departments into which the profession is now divided demands so many special appliances for their requirements that no one description is possible, and an extended catalogue is inadmissible within the limits of this article. The earliest known engineering instrument was the Diopter of Hero of Alexandria, 130 B.C., although rude appliances must have been used long before that time by the ancient engineers in the construction of the public works of Chaldæa and Egypt, the ruins of which even now awaken our admiration and wonder. It was not, however, until the beginning of the 19th century that the great impulse to the construction and use of engineers' instruments was given by the advance of civilization and commerce incident to the application of steam as a motive power on sea and land. Since that time great advances have been made not only in the design and accuracy of engineering instruments but also in the invention of new instruments for the many purposes required by engineers in the construction of railroads, canals, bridges, harbors, etc.



The characteristics of engineers' instruments differ in the various nations as the requirements of engineering practice, and thus American engineers' instruments possess a distinct character of their own as compared with other nations, having as a rule few parts and lightness of construction combined with great strength and an adaptability of parts for the special service required. It is not the purpose of this article to attempt a description of the various instruments used by engineers — this may be found in the article SURVEYING, — but to give the reader a general idea of their construction. The metals used in the construction of engineers' instruments are principally the alloys of copper and tin with small quantities of silver, aluminum, and German silver. Great care must be constantly exercised that these substances be

free from iron or other material which would affect the magnetic needle. In the construction of an instrument such a distribution of the metals is aimed at that the greatest strength consistent with light weight may be obtained and that the metals coming into contact at the bearing surfaces may be of such varying composition as to cause the least friction.

Take, for the purpose of better illustration, an American transit, illustrated herewith, as typical, as far as the construction is concerned, of nearly all engineering instruments. The plate of the instrument on which the magnetic needle is mounted, or, as it is termed, the compass circle, is turned with great care so that the surface may be absolutely true, and is graduated usually into 720 spaces, each representing one half of a degree.

Compass circles are usually figured in quadrants of a circle, that is, from 0 at the point marked "N" or "North" to 90 and back again, while the figuring of the limb varies with the custom of the maker or the requirements of the engineer.

In engineers' instruments, however, the angular measurements are made usually without the use of the needle, by a telescope so mounted as to revolve in a vertical or a horizontal plane. The angular measurement of its movement being indicated on circles divided into fractional spaces of a degree and read for convenience to finer spaces by one or more verniers. Accuracy of graduation of the compass circle, and especially of the limb, is essential to the perfection of the instrument, and great pains are taken by manufacturers in perfecting and improving engines for graduating. The best machines are automatic in action and the spaces are so accurately laid off that there is no appreciable error in the finished work. The instrument rests on the socket or bearing surface to which the compass plate and limb are attached; the surfaces of the socket must be so accurately fitted together as to produce no error when the parts are moved on each other. The socket is mounted on a leveling head, which is actuated by three, or in the usual American practice, by four leveling screws, as shown, by means of which the instrument can be accurately leveled. Upon the compass plate are placed the standards which support the telescope, the preparation of the optical parts of which is next in importance to the fitting of the socket and the graduation.

The telescope consists of an eye piece and object glass mounted in a tube. The eye piece is simply a magnifier of the image produced at the focus of the object glass. Two kinds of eye pieces are used, one showing the image erect, and the other showing the image inverted. The object glass is composed of two plates of optical glass of such specific gravity and refractive index that it will magnify the image clearly without prismatic colors. To secure achromatism the two parts of the object lens are made the one of crown and the other of flint glass, the crown being a light glass of soda and silica and the flint being a heavier glass containing potash and lead. The surfaces of each are curved to such a degree that the rays of light entering the object glass may be properly refracted and concentrated at a point called the focus.

The making of the lenses is an operation requiring much skill in manufacture, as upon the accurate grinding of the curved surfaces depends the quality of the telescope.

At the focus of the object glass are placed the cross-wires, which are filaments of spider web or very fine platinum. In conjunction with these are often used two more wires commonly called stadia wires, so placed that they intercept on a rod a space proportional to its distance from the instrument, thus furnishing an efficient method of ascertaining distances directly by the observer. The metal parts of the instrument, having been prepared, are polished with some suitable material, a preparation of rouge being generally used for finishing the surface of the screws, and the larger surfaces being finished with fine emery paper. The larger parts are usually colored dark to avoid reflection of the sun, while the smaller ones, such as screws, etc., are left bright in order that there may be a pleasing contrast between the different parts of the instrument. The parts, prepared as above, are covered with a thin coat of lacquer, a preparation of shellac and alcohol, applied after heating. All the parts are assembled and fitted together, and the instrument is then ready for the final complete adjustment. This consists in fitting the sockets so that they will move freely on each other, placing the compass plate and limb in position on the sockets, making the limb truly concentric with the socket and placing the vernier in position. The telescope must be so adjusted that its parts may work freely, and having been supplied with optical parts, etc., it is then fitted to the standards or supports previously placed in position on the compass circle. The whole instrument is then tested for accuracy and if found correct is packed in its case and is ready for use.

The above description is only intended to give a general idea of the construction of a typical instrument, but in the same methods will practically apply in the construction of all engineering instruments, such as levels, plane-tables, the various kinds of compasses, etc.

W. F. Gurley,
of W. & L. E. Gurley, Troy, N. Y.

In'sulator, a body used to separate an electrified conductor from other bodies, and which offers great resistance to the passage of electricity. Glass, shellac, resins, sulphur, ebonite, gutta-percha, silk, and baked wood are notable insulating materials. Wires in which currents of electricity are passing are often arranged in coils. To prevent the lateral passage of electricity from one coil to another, the wires are usually covered with silk and shellac. Insulators on telegraph poles, to which the wires are attached, are usually made of porcelain, glass, or stoneware. Underground telegraph wires are usually of copper, insulated by means of a coating of gutta-percha or india-rubber, and protected by tape or iron wire, metal tubes, or wooden troughs filled with bitumen. The core of a submarine cable consists of a copper wire insulated by a covering of gutta-percha whose weight is greater than that of the wire. See Electricity (*Conductors and Insulators*).

Insur'ance, a contract by which one party, for a stipulated consideration, undertakes to indemnify or compensate another party against loss by certain specified risks. The

party undertaking to make the indemnity is usually called the insurer or underwriter, the other the insured or assured; the agreed consideration is termed the premium; the written contract, a policy; the events or causes of loss insured against, risks or perils; and the thing insured or the subject to be protected, the insurable interest. Marine insurance relates to property and risks at sea; insurance of property on shore against fire is called fire insurance; life insurance, in its widest sense, is a contract entered into by the insurer to pay a certain benefit contingent upon the duration of one or more lives. Besides these classes of insurance there are many others; the traveler may insure himself against loss entailed from damage by rail or sea; the farmer from the inroads of disease among his live stock; the employer from the fraud of a dishonest cashier, etc.

The practice of marine insurance seems to have long preceded insurances against fire and upon lives. It is impossible to state the precise period of its introduction, but it is probable that it dates from about the beginning of the 15th century; though it is contended, on the authority of certain ancient writers, that traces of this form of insurance are to be found among the Romans. Some Anglo-Saxon guilds insured their members against loss from fire, water, robbery, etc. Commercial insurance, however, seems to have originated in Flanders about 1300, although priority is claimed for both Italy and Spain. It is probable that insurance was introduced into England by the Lombards early in the 16th century, but few court cases pertaining to it are found till the middle of the 18th century.

In Great Britain fire insurance has been practised for over two centuries, but on the Continent its introduction dates considerably later. The history of life insurance, as well as that of various other forms now in practice, belongs to a still later time. For the history and development of the principal insurance systems in this country, see INSURANCE, MARINE; FIRE INSURANCE IN AMERICA; INSURANCE, LIFE, IN AMERICA; INSURANCE, FRATERNAL.

Insurance, Accident. See ACCIDENT INSURANCE.

Insurance, Casualty. The definition of the word casualty is, "chance, or what happens by chance; accident; contingency; an unfortunate chance or accident, especially one resulting in bodily injury or death," etc. The term Casualty Insurance is commonly held to include those forms of indemnity providing for payment in case of bodily injury or death, or for loss or damage to property (except from fire or the elements), resulting from accident or some other such unanticipated contingency. The four great headings into which this insurance is usually divided are Personal Accident, Liability, Steam Boiler, and Plate Glass.

Personal Accident Insurance.—The first of these to be introduced into this country was personal accident insurance which had flourished, in a limited way, for many years in Europe, but was not attempted here until 1863. The pioneer of accident insurance in America was James Goodwin Batterson of Hartford, Conn., who, while traveling in England in 1859, learned of accident tickets insuring against injuries or death resulting from railway accidents and purchased one of these tickets in going from Leamington to London. Being at once impressed with the possibilities of developing this idea to include all forms of accidents in place of travel accidents only, he consulted with many well-known English insurance experts on the subject, all of whom with the exception of the famous statistician, Walford, expressed grave doubts as to the feasibility of the scheme. However, Mr. Batterson came home determined to make the experiment and in 1863, the first American accident insurance company was organized at Hartford, Conn. There is reliable authority for the statement that the first contract made by this company was a verbal contract entered into by the president of the company with a citizen of Hartford, whereby in consideration of a premium of 2 cents, the company agreed to become liable in the sum of $5,000 in case of accident to the assured while journeying from the post-office to his home on Buckingham Street. The second contract was a more formal one and was issued in consideration of $2 to protect the assured against loss of life or personal injury while journeying from Hartford to Washington, D. C., and return.

An accident policy is a contract of insurance against loss of life, limbs, sight, or time through bodily injuries effected solely by external, violent, and accidental means. The full amount of the policy is payable in case of death, or for the loss of both hands or both feet, or both eyes, or one hand and one foot. Proportionate amounts are payable for the loss of one hand or one foot or one eye, and a fixed sum is payable per week during the term of temporary disability.

The first rates, based upon the statistics of the English companies proved inapplicable to American conditions and accident insurance had a hard struggle to obtain a legitimate foothold on American soil. However, a series of catastrophes by land and sea in the following two or three years emphasized the importance of this form of protection, and little by little the business became more firmly established. During this time about 70 companies started, but all either failed or were absorbed by the pioneer company, which held the field for many years alone.

Gradually, however, other companies were organized, each newcomer profiting by the experience of its predecessors until on 1 Jan. 1904 25 stock companies were writing accident and health insurance in the United States, with aggregate premiums amounting to the enormous sum of $13,337,000. The first accident policies were very primitive affairs compared with the elaborate and almost unlimited contracts of today. In the early times, policies covered merely loss of life, limbs, or total disability, conditions were numerous and technical, and policies for small amounts were the rule. Gradually, however, the competition of progressive and aggressive underwriters made itself felt in the broadening of the contract. One of the first important changes consisted in extending the period of weekly indemnity from 26 to 52 weeks. Some of the more conservative companies hesitated for a long time to follow this lead, but the pressure proved too great and they were finally forced to acquiesce. The policies of the leading companies have now reached the limit of liberality on this point by providing for the payment of weekly indemnity in a sum equal to the prin-

cipal sum insured. One of the important innovations was the introduction of the combination policy, covering not only all of the features of the regular policy, but giving double benefits for accidents happening in or on a moving conveyance using steam, electric or cable power and provided for the use of passengers. This clause was later extended to include accidents in elevators and burning buildings, as well as in any vehicle used as a carrier of passengers, such as carriages, coaches, omnibus lines, and the like.

During this period of evolution, other changes were taking place. Conditions and agreements, that for years had been considered indispensable, began to disappear one by one. The fundamental theory that accident insurance was indemnity for loss of income, resulting from total and absolute disablement, was qualified by the broader and more flexible rule of partial disability, whereby a varying percentage of the weekly indemnity called for by the policy became payable in case the assured was not totally disabled, but was partially prevented from attending to his business duties. This payment was fixed at 50 per cent by some companies, irrespective of the nature and extent of the partial disablement, whereas other companies adopted what may seem to be a more logical basis, providing for not less than 25 per cent, nor more than 75 per cent of the weekly indemnity, depending upon the special circumstances of each case. Other important concessions were made by the elimination of conditions that had been deemed a *sine qua non* to the safe and proper conduct of the business. One of the principal of these conditions was that "injuries, of which there is no visible mark on the body, the body itself in case of death not being deemed such a mark," were not covered by the policy. Others were the exclusion of accidents from "sunstroke or freezing; from injuries intentionally inflicted upon the insured by himself or by any other person, injuries from unprovoked assault excepted; from voluntary overexertion; violating law; violating rules of a corporation; voluntary exposure to unnecessary danger, expeditions into wild or uncivilized countries," etc. Many of these exceptions were reluctantly abandoned by the companies, oftentimes only after long and expensive litigation, the result of which was usually against the company.

The policies now issued by most of the companies are entirely free from all of the above-named conditions and are practically "conditionless," save as to the methods of reporting and adjusting claims. It was, however, not until 1899 that the most radical innovation yet to be introduced into the business of accident insurance was brought forward in the shape of health and disability insurance. It was perhaps but the logical sequence of events that after perfecting the accident policy to the point of the greatest liberality, the demand should make itself felt for insurance against "all the ills that human flesh is heir to" and underwriters in America again turned to their European neighbors, who had already taken the initiative. Sickness policies had become quite widely introduced into many Continental countries before that time and the system of compulsory insurance against accidents and sickness had been successfully instituted by many European governments. It is true that as early as 1847 sickness insurance was attempted in America, by the organization of companies in Massachusetts and Pennsylvania, but these companies, after brief and unprofitable careers, gave up the struggle, and nothing further was attempted in this way until about the year 1896. At this time a rider to accident policies, covering about eight diseases, was adopted by one or two companies. However, the statistics available on sickness insurance did not make the business appear very attractive, and hence, during the first year or two after its general introduction into the United States, few companies were prepared to assume the risk and then only from a limited number of diseases, about 15, comprising a few of the more prevalent forms, the balance being contagious and rare diseases. Soon, however, competitors entered this field and the number of diseases covered was increased to 30, and upwards, until finally all ordinary diseases were included under the policy. At first, a health policy was not issued alone, but was combined with the accident contract, the two constituting disability insurance. Many of the leading companies still adhere to this practice; others issue the so-called unlimited health policy alone, but do not write the limited health contract, which covers a specified list of about 30 diseases, except in connection with an accident policy, while a very few companies still issue either form of health contract separately.

The introduction of disability insurance was the signal for a still further broadening of the benefits and conditions under accident contracts. The most important of these benefits are the "Schedule of Operations," providing for a fixed sum, in addition to weekly indemnity, to cover the cost of a surgical operation for any of the injuries listed in the schedule; the "Schedule of Indemnities" providing for a specified sum to be payable in lieu of weekly indemnity for any of the injuries enumerated, and the "Accumulation Table" providing for a 10 per cent increase in the principal sum insured on each annual renewal until this accumulation amounts to 50 per cent of the original sum.

A startling innovation in the year 1903 consisted in the insurance of the beneficiary, without extra charge, in addition to the policy holder. This was limited, at first, to indemnity for loss of life from travel accidents, including accidents in elevators and burning buildings. However, this was extended in 1904 to cover loss of limbs as well, from accidents above described. It is difficult to predict what limit will be reached by the companies in the eager contest for business, unless a standard policy is adopted by agreement or through legislative enactment.

The figures for 10, 20 and 30 years of premiums written and losses paid, give some astonishing results. From 1873 to 1883, premiums amounted to $11,029,385 and losses to $4,221,616. From 1883 to 1893, premiums were $30,997,822 and losses $13,904,155, or an increase of 181 per cent in business and of 229 per cent in claims. From 1893 to 1903, premiums amounted to $64,832,874 and losses to $28,686,686, or an increase of 109 per cent in business and of 106 per cent in losses over the previous 10-year period, and an increase of 487 per cent in premiums and of 580 per cent in losses over the first 10-year period. These figures speak eloquently of the enormous strides already made by accident insurance in America, and are but a forerunner

of the growth and development that can reasonably be expected in the future.

Liability Insurance.— Liability insurance is of comparatively recent origin, and was unknown in America prior to 1887. As in the case of accident insurance, the business was first exploited in Europe, and its real development began after the passage of the English Employers' Liability Act of 1880. From time immemorial, the liability of employers for injuries caused by or suffered by their employees in the course of employment has been a part of the Common Law of all civilized nations. An eminent authority states that, as early as 1500 B.C. the Jewish law provided that "if a master were the means of causing the loss, either intentionally or unintentionally, of the eye or of the tooth of his slave, he was bound to let him go for his eye or his tooth's sake." And again, according to this same law, "if an employer allowed his ox to gore either his servant or a stranger, he was required to pay various compensations to the injured if he survived, or to his relatives in the event of the injury being followed by death."

Under the Roman law, a master was responsible not only for injuries suffered by his employees if due to his own negligence, but under the legal maxim, "Respondeat Superior," was liable for any personal injury sustained by a third person, due to the wrongful acts or omissions of his servants, acting as such and within the regular scope of their employment. The legal obligation to employees was expressed in the maxim, "*sic utere tuo, ut alienum non laedas*"; but the rule became subject to two important exceptions; firstly, that if the person injured and the one causing the injury were fellow-servants, the master was relieved from liability for the injury; secondly, under the doctrine of "*volenti non fit injuria*," if the person injured had actual knowledge or the means of knowing of and understanding the hazards incident to the employment and then voluntarily accepted the service, he was deemed to have assumed all the usual and ordinary dangers of the work and in case of injury, resulting therefrom, no recovery could be had against the master.

The passage of the Liability Act of 1880 by the English Parliament resulted in the organization of a number of companies for the protection of employers against the provisions of the act as well as against the expenses of litigation arising out of claims and suits instituted by employees for injuries sustained.

In 1887, the State of Massachusetts passed an Employers' Liability Act, fashioned to a great extent after the English statute, but with such changes and modifications as were necessary to suit the changed conditions.

One of the English companies then in successful operation abroad, deeming the time opportune to extend its field to America, determined to establish an American office and selected Boston, doubtless because of the existence of the act above referred to. It is stated that the local agency for the American branch was offered to various prominent insurance agents of Boston, but was declined by each in turn, as both the company and the class of business were unknown and there appeared to be no demand whatever for the kind of indemnity offered by the new-comer. It later became evident, however, that liability insurance had come to stay, and within the next few years a number of American companies were incorporated to carry on the business, and several foreign companies established American offices on somewhat the same lines as the first company had done.

During this early period, the business was entirely experimental and rates were constantly altered to suit the changing conditions, as they arose in the development of the various features of the insurance. At the outset, the indemnity was limited to employers' liability, under substantially the following form of contract: That the company, in so far as regards fatal or non-fatal injuries to any employee or employees of the insured at the place or places mentioned in the application, during the period covered by the premium paid or by any renewal premium, would pay to the insured or his legal representatives all such sums for which the insured might become liable in damages not exceeding the limits of liability stated in the policy, such payments to be made within one week after the receipt by the company of satisfactory proofs of claim. Soon, however, the insurance was extended to public or outside liability, whereby the insured was indemnified against loss in damages on account of common law or statutory liability for personal injuries suffered by any third person and due to the business operations of the insured or of his sub-contractors. This contract was limited for some time to contractors and builders, but gradually the demand arose for similar protection on the part of owners and lessees of buildings, which resulted in the further broadening of the insurance scheme to include general liability. This contract, briefly, provided indemnity to owners or occupants of hotels, apartment houses, office buildings and wholesale and retail stores "against claims for compensation for personal injuries to any person or persons whomsoever for which the assured may be legally liable, resulting from accident (fire excepted), happening to such person or persons on or about the premises of the assured, or caused by any of the horses or vehicles of the assured used in his or their business." It was further provided, that, subject to the limits of liability expressed in the policy in respect to any accident which should cause death or injury to any one person or to several persons, "the company will pay to the assured or his legal representatives, within one week after the receipt by the company of satisfactory proofs of claim, all sums for which the assured shall become liable for personal injuries caused and limited as aforesaid, during the period covered by the premium now paid or by any renewal premium, by virtue of the common law or any statute."

It was a comparatively short step from this contract to the issuance of separate policies, covering liability for injuries caused solely by horses and vehicles, known as teams insurance, and for injuries caused by elevators, known as elevator insurance. Meantime a few of the companies were engaging quite freely in the insurance of common carriers' liability, covering "any and every accident to or caused by the cars, horses, plants, ways, works, machinery or appliances" used in the business of steam or street railroads, steamships, steamboats and ferries. It is but proper to say that this feature of liability insurance was

looked on very unfavorably by the more conservative companies, and one of the companies engaging in the business notified its agency force after the disastrous results of this underwriting became first apparent in 1893 that, "we are not now seeking to push these specialties, as we find competitors (particularly companies whose managers have a commission interest), doing such business at rates which can only be productive of serious loss. Railways we take only when the lines are short, and street railways not at all in great cities." But the handwriting was already on the wall, and in November 1893 one of the largest and most important companies was forced into bankruptcy, largely through the losses sustained on common carriers' liability. This placed almost an embargo on that class of business, only two or three companies continuing to issue such policies. Two of these later discontinued the business entirely, and the other, after a somewhat meteoric career, collapsed in 1897 with heavy liabilities and few assets. In March 1896 the first significant action was taken with a view of placing liability insurance upon a sound scientific underwriting basis in the shape of a conference of the leading companies held in New York. After a series of meetings and discussions extending over a period of several weeks, an organization was effected known as the Conference of Liability Companies. A bureau of statistics was formed, with a well-known underwriter in charge, and the work of compiling the experience of the various companies was vigorously taken up. Frequent meetings of the Conference were called at which the managers and officers of the various companies discussed the different phases of the business and compared experiences. Policy forms were analyzed and conflicting conditions either eliminated or reconciled. As a result of these meetings, and of the work of the bureau, a manual of rules and rates was promulgated in the summer of 1896 and standard policy forms were adopted shortly afterwards. From time to time thereafter manuals and supplements have been issued by the Conference companies altering rates already established and publishing new rates, these changes and additions resulting from the statistical work carried on by the bureau.

Logical development of liability insurance in America dates from the formation of the liability Conference. Standard rates and policies having been adopted, competition was reduced to practically legitimate methods, and for three years the business went on smoothly and grew rapidly.

This highly satisfactory condition of affairs was rudely disturbed early in the year 1900 by the withdrawal of one of the largest companies from the agreement, and while the Conference continued in existence, its usefulness was considerably impaired. Shortly after this time three foreign companies established American offices and two additional companies were organized in this country, and as none of these newcomers became members of the Conference, the situation grew more critical than before and the companies comprising the Conference came to be the minority, while they had formerly constituted the majority. Early in 1903 one of the smaller companies in the agreement withdrew, being unable to withstand the competition of the outside companies. At the beginning of 1904, the Conference consisted of five companies, while twelve companies were operating independently.

This great discrepancy in numbers has forced the Conference to become almost solely a bureau of statistics and there is little attempt made to the adherence of standard rates in cases of competition, which are of course the rule rather than the exception. In spite, however, of what might be termed these unsatisfactory conditions, the business has grown and developed astonishingly. From the inconspicuous beginning in 1887 already noted, liability insurance has in the comparatively short space of 17 years taken its place as one of the most important branches of underwriting in this country involving more technical and difficult features than almost any other kind of insurance business.

The liability policies of the present day are substantially the same with all companies, and are known respectively as Employers' Liability, Public Liability, General Liability, Teams Liability, Elevator Liability, Owners' Contingent Liability, Theatre Liability, and Marine Vessel Liability. The premium is based, in most cases, on the estimated annual payroll of employees, and is subject to adjustment at expiration of the policy according as the actual payroll expended is greater or less than the amount estimated. To ascertain this, the assured is required to render a payroll statement to the company which is usually verified by an audit of the assured's books.

Under the various forms of policies issued, protection against legal liability for damages on account of accidental death or injuries to employees and the public is afforded to manufacturers, and contractors, owners, lessees, and tenants of buildings; to owners and users of horses and vehicles, including automobiles, elevators, vessels and boats; to theatres, agricultural exhibitions and shows, and to owners and general contractors of buildings in course of construction. While at first the limits of liability were rarely in excess of $5,000 for one person injured or killed and $10,000 for two or more persons injured or killed in any one accident it is now quite common to provide double these limits and in fact the indemnity is often fixed at limits of $10,000 for one person and $50,000 for a number of persons injured or killed in one accident. These increased limits are due not only to the inevitable tendency of the courts in the majority of States to sustain verdicts for large amounts, but more particularly to the enactment of laws increasing and extending the liability of employers and others in cases of negligence. For example, in New York State the statutory limit for damages in case of fatal injury from negligence was $5,000 for an individual until this limit was removed by the legislature a few years ago, leaving the amount recoverable in such cases unlimited. In Illinois, likewise, the sum of $5,000 was formerly the maximum amount payable, but an act of 1903 increased the individual limit to $10,000. While it was rare to read 10 years ago of a verdict for $5,000, such amounts are now deemed quite reasonable in serious or fatal cases, and it is not unusual to find that verdicts of ten, twenty, and even fifty thousand dollars are sustained by the courts of last resort. In fact, legislation is playing a most important part in the evolution of liability insurance in this coun-

try. The Employers Liability Act of 1887 of Massachusetts, while the most important statute yet to be enacted on this subject, in America, has never been quite satisfactory and just as changes and amendments have been constantly suggested for the English acts of 1880 and 1897, so the legislators of the Bay State have attempted from time to time to extend and alter the provisions of their act. The latest effort in this direction, proposed in 1904, is known as the Workingman's Compensation Act and is quite revolutionary in its character so far as this country is concerned, for nothing of the sort has ever been attempted here before. In the words of an eminent member of Congress from Massachusetts, while discussing this measure, "One of the principal reasons for it is because there have grown up in this country, lawyers and doctors who combine together to hunt up trouble and cheat the injured person out of his money. Another great trouble and reason for the proposed legislation is the employee's habit of bringing suit at once, without trying to bring about amicable relations with the employer. As things are to-day, while employers frequently have to pay out large sums of money, in many cases the injured employee is not benefited. Now, an employee has to show that he received his injuries as the result of the neglect or fault of the employer. This new law does away with all of this and favors the compensation of an employee for the loss of an arm or other serious injury, whether the employer is to blame or not." The passage of the so-called Slater Act of 1902 by New York State was another step in the direction of absolute compensation to workingmen and it is only a question of time and probably a short time, when most of the important States will have legislated on this subject. Not only so, but there is some talk of a national act to be put forward by the United States government affecting these vital questions of the relations between capital and labor.

It may not be entirely utopian to believe that the ameliorating influences of these State laws either with or without a national statute will result ultimately in the more friendly and unselfish attitude between employers and employees and in the discontinuance of strikes and labor disturbances generally.

The growth of liability insurance has kept pace with the industrial development of this country during the past 15 years as will be noted from the following exhibit: From 1889 to 1893 inclusive, premiums amounted to $9,319,591 and losses to $3,838,665. From 1894 to 1898 inclusive, premiums were $20,535,668 and losses $10,084,319, or an increase of 120 per cent in income and of 162 per cent in claims. From 1899 to 1903 inclusive, premiums were about $50,000,000 and losses about $25,000,000 or an increase of 250 per cent in premiums and of 250 per cent in losses over the previous five-year period, and an increase of 437 per cent in premiums and of 552 per cent in losses over the first five-year period.

Steam Boiler Insurance.—The first steam boiler insurance in America was written in 1866, dating almost as early as accident insurance, and like that other branch of indemnity, it owes its origin in this country to the thrifty, practical citizens of Connecticut. It was, however, not until 1869 that the business became well established. At the close of that year total premiums amounted to $55,819, and total losses to $2,188, a modest beginning considering that for the year 1903, premiums aggregated about $2,000,000, and losses about $200,000, while the amount of insurance in force had grown from $5,000,000 to over $600,000,000.

For many years the pioneer company had a monopoly of the field, as, for some unknown reason, capitalists seemed disposed to leave this business alone, due, perhaps, to the slow growth of the premium income, as well as to the mechanical technicalities of the insurance.

At the outset, the form of contract was limited to indemnity for loss or damage to the boiler or boilers and other property of the assured, and to property of others for which the assured could be held legally liable, due to the explosion, rupture or collapse of the boiler or boilers. As a guarantee of the value of this indemnity, as well as a protection to the company against the insurance of old and unsafe boilers, a periodical inspection is made of each boiler during the term of the policy by an inspector of the company, and a written report is forwarded to the policy holder showing the condition of the boiler, recommending such repairs or changes as appear necessary, and stipulating the pressure under which the boiler can safely be run. Steam users were at first slow to grasp the many advantages offered by this new scheme, and engineers of plants strongly resented the reflection on their skill and management implied by some of the features of the insurance. Conflicts of opinion between the inspector of the company and the engineer of the assured were of frequent occurrence and oftentimes much hard feeling was engendered. Nothing daunted by these obstacles, the company vigorously pushed forward the business and at the end of the first 20 years the premium income had grown to about $1,000,000.

In the year 1887 another company was organized which gave considerable impetus to the business and introduced a new feature, namely, indemnity against loss from legal liability for fatal or non-fatal injuries suffered by any person or persons due to the explosion, rupture, or collapse of the boiler or boilers. From this time forward the business increased rapidly.

On 1 Jan. 1904 nine companies were engaged in the business of the insurance of boilers, tanks, dryers, rotaries, digesters, and other objects operated under steam pressure. Nearly 150,000 boilers were regularly inspected in 1903 and a small army of inspectors are maintained by the various companies at an annual expenditure of several hundred thousand dollars. Policies are frequently issued for as much as $100,000 limit for any one loss, and a limit of $50,000 is quite common. Notwithstanding the great number of objects insured annually, and the large limits of liability as above mentioned, serious explosions have been comparatively rare, and the average loss ratio of the largest company for 35 years has not exceeded 10 per cent per year. This showing would seem to indicate that there is an exceptionally large profit to be made in this branch of casualty insurance, but such is not the case, for owing to the inspection system before mentioned, the management expenses range from 60 to 85 per cent of the premium income. Some of the companies maintain in connection with

the inspection department, a force of draughtsmen for the purpose of furnishing plans and specifications for new boilers, at the request of their policy holders or of prospective clients. This service is rendered without charge and adds somewhat to the already heavy expense of conducting the business. It is interesting to learn from the statistics of one of the companies, that from the beginning of their business to 1 Jan. 1903 the number of visits of inspection made was 1,815,465. The total number of boilers inspected was 3,568,838. The total number of defects discovered was 2,559,592, of which dangerous defects numbered 270,856, and 15,169 boilers were condemned as unfit for use. During the year 1902 the company made 142,000 visits of inspection, examined 264,708 boilers, condemned 1,004 boilers, found 145,489 defects, of which 13,000 were dangerous.

The total premiums of all companies during 35 years, to the close of 1903, amounted to nearly $25,000,000, and total losses to almost $2,500,000, and with the rapid increase in the number of new manufacturing plants throughout the country, and the general expansion of business, it is safe to predict that steam boiler insurance will develop much more rapidly in the next decade than in the past quarter century.

Plate Glass Insurance.— The first American plate glass insurance company was organized in New Jersey in 1868, but unlike the pioneers in the other casualty lines, this company does not rank among the leading companies in point of financial strength or amount of business written. In 1874, the first New York company was started, and from that year the business steadily increased in volume, total premiums for 1903 amounting to over $2,000,000, and total losses to over $800,000. There have been fewer changes in the plate glass policy than in any other of the casualty contracts, presumably because the business is less intricate and there has been no occasion to make many changes. Plate glass insurance provides indemnity on account of loss or damage caused by breakage of glass, provided that such breakage is the result of accident and due to causes beyond the control of the assured. No claim is paid, however, for breakage resulting directly or indirectly from fire, earthquake, inundation, insurrection, riot, or any military or usurped power, or from the blowing up of buildings or from alterations or repairs to the premises. While for years the insurance was limited almost entirely to what is known as plain plate glass, many different kinds of glass, such as bevelled, mitred, cathedral, leaded, chipped, bent, Florentine, jewelled, ribbed and wired glass are now insured freely by all companies.

In 1900 plate glass underwriters were confronted with an entirely new proposition in the shape of clamped or patented plate glass, resulting from riveting the sides and tops of plate glass together without the use of wooden frames that before that time had been indispensable. The rates formulated for patented glass were at first entirely inadequate and the companies lost a considerable sum while experimenting with the subject. Not only was there great trouble and delay in having broken glass replaced, but the patentees, having a monopoly, were disposed to secure the full benefit from the product of their ingenuity. As a result of these conditions, the companies placed an almost prohibitive rate on all patented glass in the hope that they could successfully taboo that kind of risk, but the public demand for it was too great and patented glass has come more and more into general use. However, near the close of the year 1903, the leading companies found that the experience with patented glass had been more favorable than had been anticipated, and, as a result, the rate was materially reduced.

Plate glass insurance is now almost as general as fire insurance, and while the average premium is small, the business has assumed very considerable proportions. During 30 years ending 31 Dec. 1903 total premiums amounted to over $20,000,000, and total losses to over $8,000,000. Fifteen stock companies were on that date engaged in the business, in addition to numerous local mutual companies located in various parts of the country. From time to time in the past 10 years, compacts have been formed between the largest companies for the purpose of regulating rates, and establishing sound underwriting practices. Unfortunately, however, these agreements have been of comparatively short duration and as oftentimes happens in similar cases, the demoralization following the termination of the compact has been even greater than before it was made.
