ä	far, father
ā	fate, hate
a or ă	at, fat
ã	air, care
ạ	ado, sofa
â	all, fall
ch	choose, church
ē	eel, we
e or ĕ	bed, end
ė	her, over: also Fr. *e*, as in *de; eu*, as in *neuf;* and *oeu*, as in *boeuf, coeur;* Ger. *ö* (or *oe*), as in *ökonomie.*
ẹ	befall, elope
ë	agent, trident
ff	off, trough
g	gas, get
gw	anguish, guava
h	hat, hot
h or H	Ger. *ch*, as in *nicht, wacht*
hw	what
ī	file, ice
i or ĭ	him, it
i	between e and i, mostly in Oriental final syllables, as, Ferid-ud-din
j	gem, genius
kw	quaint, quite
ṅ	Fr. nasal *m* or *n*, as in *embonpoint, Jean, temps*
ñ	Span. *ñ*, as in *cañon* (căn'yŏn), *piñon* (pēn'yŏn)
ng	mingle, singing
nk	bank, ink
ō	no, open
o or ŏ	not, on
ȯ	corn, nor
ȯ	atom, symbol
o͝o	book, look
oi	oil, soil; also Ger. *eu*, as in *beutel*
ö or oo	fool, rule
ou or ow	allow, bowsprit
s	satisfy, sauce
sh	show, sure
th	thick, thin
t͟h	father, thither
ū	mute, use
u or ŭ	but, us
u͝	pull, put
ü	between u and e, as in Fr. *sur*, Ger. *Müller*
v	of, very
y	(consonantal) yes, young
z	pleasant, rose
zh	azure, pleasure

' (prime), " (secondary) accents, to indicate syllabic stress

THE ENCYCLOPEDIA AMERICANA

Hamilton Stage, the upper division of the Hamilton series of rocks, consists chiefly of shaly sandstone and fine shales with a few thin seams of limestone. In Ulster, Albany, and Green counties, N. Y., the thick-bedded shales are known as North River flagstone, and are quarried on the Hudson River near Kingston, Saugerties, and Coxsackie. Some of the thicker layers of these flagstones are known as bluestone, and are used not only for flags and curbing but for architectural purposes.

Hamirpur, or **Humeerpoor,** a former district of the Northwestern Provinces, British India, now a part of the United Provinces of Agra and Oudh, and the name of its former capital; south of the Jumna and east of the Betwa and Dhasan rivers, and part of the great plain of Bundelkhand. From the 9th to the 14th century its chief city, Mahoba, was one of the most important in India.

Hamites, hăm'īts (decendants of Ham), the name given to several races in North Africa, who are regarded as of kindred origin and speak allied tongues. They include the ancient Egyptians and their modern descendants, the Copts, the Berbers, Tauregs, Kabyles, the Gallas, Falashas, Somali, Dankali, etc.

Hamlet, the hero of Shakespeare's most famous tragedy, a personage who appears in history, yet is half mythological, but has been transformed by the genius of the English poet into one of the most dominating figures of literature. It is allowed that Shakespeare's Hamlet was suggested by the Hamleth, or Amleth, of Saxo Grammaticus. The latter's 'History of Denmark' had been published in Paris (1514). François de Belleforest included the tale of Hamlet in his 'Tragic Histories' (1570), an English translation of which appeared in 1608. Shakespeare's drama was written earlier than this last date and must have derived its plot either from de Belleforest's work, or a translation executed before the end of the 16th century, unless the poet, who, we know, was a great reader of histories, took the incident direct from Saxo Grammaticus. According to the Danish historian Hamleth was Prince of Jutland; his father, the King of Jutland, had been murdered by his own brother Fengo, who took the throne and queen of the dead man. Hamleth feigned madness to save his own life. He stabbed one of Fengo's courtiers sent to spy upon him, and had for this purpose concealed himself under a truss of straw. He reproached his mother with her shameful second marriage to such effect that she promised to help him in avenging his father by putting Fengo to death; a promise which she kept. These are the very incidents Shakespeare has selected for his play, sometimes emphasizing the points of the narrative, sometimes softening them or changing them in harmony with his own vivid conception of dramatic requirements. Shakespeare's 'Hamlet' was first played in 1600 or 1601, and first printed in 1603. The second quarto is dated 1604; the third, which is merely a reprint of the second, appeared in 1605, and the fourth in 1611. There is a fifth quarto, undated, which was also printed in the poet's lifetime.

Hamlet Case, the designation of the first recorded action in 1850 under the Fugitive Slave Law (q.v.) of that year. It is named after Hamlet, a free negro with a family, who was surrendered after a cursory examination, as a fugitive slave of Mary Brown of Baltimore. He had been arrested by a deputy United States marshal in New York, and the whole circumstances of the case so aroused public opinion that Hamlet was finally redeemed.

Ham'ley, Sir **Edward Bruce,** English general: b. Bodmin, Cornwall, 27 April 1824; d. London 12 Aug. 1893. Entering the army in 1843, he served through the Crimean war; was professor of military history at Sandhurst 1858–64, and commandant there 1870–77; and division commander in the Egyptian war of 1882. His 'Operations of War' (1866) is a recognized text-book for military examinations. Among his other publications are: 'The Story of the Campaign' (1855), a narrative of the Crimean War; 'Wellington's Career' (1860); 'Voltaire' (1877); 'The War in the Crimea' (1890). He was also the author of a popular novel, 'Lady Lee's Widowhood,' and the admirable sketch entitled 'Shakespeare's Funeral.'

Ham'lin, Alfred Dwight Foster, American architect: b. Constantinople, Turkey, 5 Sept. 1855. He is a son of Cyrus Hamlin (q.v.). He was graduated from Amherst in 1875, studied architecture in the Massachusetts Institute of Technology in 1876–7 and at the Beaux Arts of Paris in 1878–81, and in 1883 became special assistant in Columbia University. In 1889 he became assistant professor of architecture at Columbia, and in 1891 adjunct professor. His published works include: 'A History of Architecture' (1896); and a 'Handbook of the History of Ornament.'

Hamlin, Augustus Choate, American surgeon: b. Columbia, Maine, 28 Aug. 1829: d. Bangor, Me., 19 Nov. 1905. He was graduated from Bowdoin in 1851, from the Harvard Medical School in 1855, was appointed assistant surgeon to the 2d Maine infantry in 1861, and from 1863 until mustered out in 1865, lieutenant-colonel and medical inspector, United States army. Subsequent to the War he practised in Bangor, of which he was twice mayor, and in 1882–6 was surgeon-general of Maine. Among his works are: 'Martyria' (1866); 'The Tourmaline' (1873); 'Leisure Hours among the Gems' (1884); and treatises on 'Transfusion' (1868); 'Tetanus' (1868); and 'The Transmission of Disease' (1870).

Hamlin, Cyrus, American missionary: b. Waterford, Maine, 5 Jan. 1811; d. 8 Aug. 1900. He was graduated from Bowdoin College in 1834 and from Bangor Theological Seminary in 1837; and was missionary of the American Board of Missions in Turkey 1837–59. From 1860 to 1876 he was president of Robert College, established after long controversy with the Turkish government. In this position he did much in molding the character of modern Bulgarian leaders, and producing autonomy for Bulgaria. Returning to the United States in 1877 he became a professor in the Theological Seminary in Bangor; and was president of Middlebury College, Vermont, 1880–5. Some of his works are in the Armenian language; those in English include 'Among the Turks' (1877); and 'My Life and Times' (1893).

Hamlin, Hannibal, American statesman: b. Paris Hill, Oxford County, Maine, 27 Aug. 1809; d. Bangor, Maine, 4 July 1891. Though prepared for college, he did not enter, but became the editor of 'The Jeffersonian,' a weekly of Paris, Maine; studied law, was admitted to the bar in 1833, and began practice at Hampden, Maine. He was active in Democratic politics, was elected to the lower branch of the State legislature in 1835, served by re-election until 1840, and was speaker in 1837, 1839, and 1840. Nominated for Congress in 1840, he was defeated by the Whig candidate, but in 1842 was elected, and in 1844 re-elected. Chosen to the Senate in 1848 to fill a vacancy, he was again elected in 1851, but in 1856 resigned his seat to accept the governorship of Maine, to which he had been elected as a Republican. In less than a month, however, he re-entered the Senate for a full term. In 1860 he was elected vice-president on the ticket with Lincoln, and in 1861–5 was president of the Senate. He was thereafter successively collector of the port of Boston (1865–6), United States senator (1869–81), and minister to Spain (1881–3). Hamlin's separation from his party was due to his strong anti-slavery convictions. During the absence from the House of David Wilmot, he introduced the bill now known as the "Wilmot proviso," and obtained its passage in the House by 115 to 106. As vice-president he was a highly valued counsellor of Lincoln. Consult: C. E. Hamlin, 'Life and Times of Hannibal Hamlin' (1899).

Ham'line, Leonidas Lent, American Methodist bishop: b. Burlington, Conn., 10 May 1797; d. Mount Pleasant, Iowa, 23 March 1865. He was educated for the ministry, but afterward studied law, was admitted to the bar at Lancaster, Ohio, was licensed to preach by the Methodist Church, and was a traveling minister in the Ohio conference. When in 1844 the Methodist Church divided on the slavery question, he was one of the members of the general conference, and drafted the plan for the separation of the northern and southern branches. He was a bishop from 1844 to 1852, when he was retired at his own request. His 'Works' were edited by F. G. Hibbard (1869). Hamline University of Minnesota (q.v.) was named in his honor.

Hamline University, a coeducational institution at Hamline, Minn., between Minneapolis and Saint Paul. The school was established, under the auspices of the Methodist Episcopal Church, at Redwig, Minn., but it was closed in 1869. In 1880 it was reopened at Hamline. In 1903 there were connected with the school 21 professors and instructors in the college of liberal arts and 50 in the medical department. In the preparatory school there were about 125 students, in the college of liberal arts about 210, and in the medical department 161 students. There were 6,500 volumes in the library, and the endowment was $200,000.

Hammer, a tool for driving nails or wedges and for beating malleable materials. (See MALLET.) There are hand hammers, steam hammers and electric hammers. The ordinary hammer of to-day is essentially an American product. Exactly when the hammer came into use is not told in history, but it is certain that some rude form of the instrument must have been used in the earliest days of handicraft. Of the hammers made in America to-day there is no end. There is the little tack hammer which weighs only a few ounces, and is indispensable in house, store or factory. Then there is the twenty and thirty ton hammer, driven by steam and used for making immense forgings. The numberless effects which are due to its remarkable force of impact have made the hammer a necessity in all trades. Immense manufactories, employing thousands of men, are grinding year in and year out making hammers, while ten times as many wholesale houses are busy putting the product on the market. The industry has advanced to such a stage that many general hardware firms in the United States have thrown out the hammer, leaving it to the houses that deal in tools exclusively.

Hammers are made in a variety of shapes, the most in demand being the claw hammer. This and the shoemaker's hammer have retained their shapes for hundreds of years. One gold beating firm relies on them entirely. The sheets or leaves of gold are hammered to such exceeding thinness that two hundred and fifty thousand are required to make up the thickness of an inch.

Another odd product of the hammer factory is the butcher's hammer, used for killing cattle. It is capable when properly wielded of carrying a very heavy blow. Then there are the stone-cutter's hammer, the carpet layer's hammer, the wood carver's mallet and the plumber's odd implement. All of these have a good sale in the markets of the world, because they possess a "something" which users cannot find duplicated in the output of other countries.

The modern hammer is made to fit every requirement of a driving tool. One individual of the family, the magnet hammer, has a loadstone in its head, and every little tack jumps at it. The magnet hammer is very useful where canvas is being tacked on the walls. It saves the user the trouble of holding the tack and taking chances at smashing his fingers. The magnet hammer is much in use in tacking tin signs on trees. It is necessary to secure the advertisement at a height beyond the reach of the small boy and the magnet hammer answers the requirement. A clip on the side holds the card or sheet of tin while the tack is retained in position by the magnetized head. One firm blow drives the tack through the tin into the fence or tree trunk and secures the sign. A great variety of power hammers are used. These, for the most part, are masses of iron raised by steam or electricity, and then allowed to fall by their own gravity on the work. The "helve" or "shingling" hammer, used for compressing the mass of iron drawn from the puddling-furnace, and the "tilt" hammer, used in the manufacture of shear-steel, are important examples of such hammers. The first is a heavy bar of cast iron about 10 feet long, weighing 3 or 4 tons or more, to which is attached a head of wrought iron faced with steel, weighing nearly half a ton additional. It works on an axis at the end of the bar farthest from the head, and is raised by cams attached to a heavy wheel set in motion by steam or water power. These cams strike or "lick" a projection extending beyond the head, and thus raise it about 18 or 20 inches at the rate of 70 to 100 times per minute. The tilt hammer is similar, but much lighter, and is adapted for striking more than 300 blows per minute.

Hammer-head Sharks, sharks of the genus *Zygæna*, in which the head is produced on either side into a broad lobe, so that the whole has somewhat the appearance of a double-headed hammer; the eyes on the outer ends of the lobes. Five species are known, two of which (*Z. tiburo and Z. malleus*) occur in the warm American seas, and the latter reaches a length of 15 feet or more.

Hammer-toe, a deformity most frequently affecting the second toe, in which the first bone is sharply extended or pulled back and the other two are flexed at a right angle with the first. It is usually due to the long continued pressure of short shoes, particularly in early life. Amputation of the toe may be necessary in severe cases, as the discomfort becomes unbearable.

Hammer-Purgstall, Joseph, yō'zĕf häm'mĕr-poorg'stäl, Freiherr von, Austrian Orientalist: b. Gratz, Styria, 9 June 1774; d. Vienna 24 Nov. 1856. In 1799 he accompanied as interpreter to Constantinople the internuncio Freiherr von Herbert, who afterward entrusted him with a mission to Egypt, where he collected various antiquities and manuscripts for the Imperial Library. In 1810, on the occasion of the marriage of Napoleon with Maria Louisa of Austria, he accompanied the latter to Paris, where he became intimate with Sylvestre de Sacy and other Orientalists. In 1817 he was appointed imperial councillor at the court of Austria, where he also held the post of interpreter. In 1835 he received the title of Freiherr. Among his numerous literary works may be mentioned: 'Constitution and Administration of the Ottoman Empire' (1815–16); 'Constantinople and the Bosporus' (1821); 'History of the Ottoman Empire' (1835–6); 'History of the Assassins'; 'History of the Golden Horde in the Kiptshak'; 'History of the Ilkhans'; 'History of Persian Eloquence'; 'History of Turkish Poetry' (1836–8); 'History of Arabic Literature' (1850–7); besides numerous translations from Oriental authors, and contributions to various periodicals.

Hammock, from the Spanish, *hamaca*, originally used in Peru to denote a couch or bed of canvas or grass-netting, suspended from the branches of a tree. A sailor's hammock, common on ship-board, is generally made of hempen cloth or cotton canvas, six feet long and about three feet in width. It is gathered together at each end by means of a cord and a clew, and fastened to hooks in the ceiling of the cabin or deck. On a ship-of-war hammocks are hung about three feet apart and in the morning are taken down and stowed away in the hammock netting. The man-of-warsmen use the hammocks for their clothing and bedding during the day time. In former times when a warship entered battle the hammocks were taken on deck to form a barricade against musket balls. In recent times the hammock has become very popular for domestic use, especially in the United States, being hung on verandas and balconies and under the trees on the lawns of private estates during the summer months. These hammocks for home use are made of various materials, but usually of cotton card or manila hemp. They are dyed in bright colors and are made very attractive and picturesque.

Ham'mond, Edward Payson, American evangelist: b. Ellington, Conn., 1 Sept. 1831. He was graduated at Williams College in 1858; studied theology at Union Seminary, New York, and afterward at the Free Church Seminary, Scotland. He was ordained to the Presbyterian ministry in 1862, and was long prominent as an evangelist in Great Britain and the United States. He wrote: 'Children and Jesus'; 'Jesus the Way'; 'Golden Gleanings'; 'Early Conversion'; etc.

Hammond, Henry, English prelate: b. Chertsey, Surrey, England, 18 Aug. 1605; d. Westwood, Worcestershire, 25 April 1660. He was educated at Eton and Oxford, took orders in 1629, and in 1633 was rector of Penshurst in Kent, in 1643 archdeacon of Chichester. He was an adherent of Charles I., and took part in the unsuccessful rising of Tonbridge. He served as chaplain to the king 1645–7, and was in 1648 made sub-dean of Christ Church. In 1649 he removed to Westwood. Among his works are: 'A Practical Catechism' (1644); 'Paraphrase and Annotations upon the New

Testament' (1653). His 'Miscellaneous Theological Works' were published at Oxford, together with the 'Life' by Fell (1847–50, 3 vols.).

Hammond, James Henry, American politician: b. Newberry, S. C., 15 Nov. 1807; d. Beach Island, S. C., 13 Nov. 1864. He studied law, was admitted to the bar in 1828, and in 1830 became the editor of a political journal in Columbia, which maintained the doctrine of state rights and advocated nullification in respect to the tariff act of Congress. He entered zealously into the nullification contest which then divided the State, and took an active part in organizing the military force which South Carolina raised in 1833 to resist the Federal government. He was elected to Congress, and took his seat in 1835, but declined a re-election on account of ill health. In 1841 he was elected general of brigade, and in 1842 governor of South Carolina. While governor he published in 1844 a letter to the Free Church of Glasgow on slavery in the United States, and in 1845 two others in reply to an anti-slavery circular issued by Thomas Clarkson, the English abolitionist. These, in connection with other essays on the same subject, were published in 1853, in a volume entitled 'The Pro-Slavery Argument.' In November 1857 he was elected to the United States Senate, remaining there till 1860.

Hammond, John Hays, American mining engineer: b. San Francisco, 31 March 1855. He was graduated from the Sheffield Scientific School of Yale in 1876, studied at the Royal School of Mines, Freiburg, Saxony, and became an expert on the United States Geological Survey and mineral census, with the duty of examining gold mines in California. In 1882 he was appointed superintendent of silver mines in Sonora, Mexico, but later was again in California as consulting engineer at mines in Grass Valley, and as consulting engineer to the Union Iron Works at San Francisco, and to the Southern and Central Pacific railway companies. In the capacity of consulting engineer he visited many portions of North and South America and Mexico. In 1893 he went to South Africa as consulting engineer to the mining companies operated there by Barnato Bros. of London. He was associated with Cecil Rhodes in the latter's numerous mining interests, and consulting engineer to the Randsfontein Estates Gold Mining Co., the British South African Co. (chartered), and the Consolidated Gold Fields Co. He was one of the four leaders in the reform movement in the Transvaal and for his connection with the well-known Jameson raid, with which, however, he did not sympathize, was sentenced to death by the Boers. This sentence was later commuted to 15 years' imprisonment, and then to the payment of a fine of $125,000. He resides in New York, with offices there and in London, and is general manager and consulting engineer of the Guggenheim Exploration Co., one of the largest mining companies in the world. His reputation as a mining expert is world wide.

Hammond, Samuel, American soldier: b. Richmond County, Va., 21 Sept. 1757; d. Horse Creek, near Augusta, Ga., 11 Sept. 1842. His impulses led him, while a mere boy, to volunteer in the wars of the Virginia frontier with the Indians, where he is said to have greatly distinguished himself, and to have acquired that skill in stratagem which marked his subsequent military performances. In 1775 he raised a company, and took part in the battle of Longbridge; and in 1779 he was at the battle of Stono Ferry, S. C. After the fall of Charleston he kept the field with a small cavalry force, pursuing the active partisan warfare which alone maintained the revolutionary cause in South Carolina. He subsequently settled in Georgia; in 1802 was elected to Congress from Georgia; in 1805 was appointed by Jefferson to the civil and military command of upper Louisiana; and in 1824 removed to South Carolina, where he became surveyor-general of the State in 1827, and secretary of state in 1831.

Hammond, William Alexander, American surgeon: b. Annapolis, Md., 28 Aug. 1828; d. Washington, D. C., 5 Jan. 1900. He was graduated from the University of the City of New York in 1848; and entering the United States army in 1849 as assistant surgeon, became surgeon-general in April 1862. After the Civil War he practised his profession in New York for some years and in his later life took to writing fiction. Among his publications are included: 'Military Hygiene' (1863); 'Sleep and Its Nervous Derangements' (1869); 'Diseases of the Nervous System' (1871); 'Neurological Contributions'; etc., and the novels, 'Robert Severne'; 'A Strong-Minded Woman'; 'A Son of Perdition'; 'Doctor Grattan' (1884); 'Mr. Oldmixon'; etc.

Hammond, Ind., city in Lake County; on the Grand Calumet River, on the Baltimore & O., the Erie and the Michigan Central, and other R.R.'s; about 19 miles southeast of Chicago. It was settled in 1869 and incorporated in 1883. It is situated in an agricultural region, and its railroad facilities make it of considerable commercial importance. It has a number of manufactories, the principal of which are chemical works, steel-spring, starch, glue, carriage, nail, and flour-mills. It has a large distillery, a slaughtering and meat-packing plant, brick-yards, tanneries, and foundries. The city owns and operates the waterworks. The government is under the charter of 1883. The officers are a mayor, who holds office for four years, a city council, and administrative officials elected by the city council. The industrial growth of Hammond has been rapid, and the population has more than doubled in the last decade. Pop. (1890) 5,428; (1900) 12,376.

Ham'mondsport, N. Y., town in Steuben County, on the Erie, and the New York, O. & W. R.R.'s; about 55 miles southeast of Rochester and 50 miles southwest of Auburn. The town is in a fertile agricultural section, noted especially for the large number of vineyards. The chief manufactures are wine, fruit-boxes, flour, cigars, barrels, wire hoods, and baskets. Hammondsport has a large trade in wine, and in grapes and other fruits. It contains a high school, and several other good public buildings. Pop. 1,230.

Ham'monton, N. J., town in Atlantic County; on the Philadelphia & R. and the Camden & A. R.R.'s; about 27 miles southeast of Camden and 28 miles northwest of Atlantic City. It is situated in a region noted for its rich farms and abundance of fruit. The chief manufactures

are shoes and cigars; but it is the trade centre for the northeastern part of the county, and from Hammonton a large amount of small fruits are shipped to New York and other cities. Pop. (1900) 3,481.

Hammurabi, hăm-moo-rä'bē, The Code of, a recently discovered code, instituted by Hammurabi, king of Babylon, about 2200 B.C. The code is a thousand years older than the Mosaic age; older than the laws of either Manu, or Moses. It is engraved on a pillar of black diorite, eight feet high, which was finally unearthed, January 1902, in the acropolis mound at Susa. The obverse of the column is surmounted by a bas-relief which represents the god Bel, the lawgiver, before whom the king stands to receive the law. The inscription which covers this stately monolith is the longest Babylonian record ever discovered. It contained originally about three thousand lines of writing, divided into forty-nine columns; but five columns on the front have been erased by some Elamite king, probably Sutruk Naknunti, who served the stele of Naram-Sin in a similar manner. The writing is a very beautiful type of the best archaic script, a kind of black-letter cuneiform, long used by kings for royal inscriptions. The code is divided into about 280 clauses, and opens with the words, "Law and justice I established in the land, I made happy the human race in those days."

Character of the Code.— The code shows a most careful and systematic order, beginning with witchcraft, which connects it with a religious code; it passes through all grades of social and domestic life, ending with a scale of official wages for all classes of workmen, even the lowest in the scale. Hammurabi's laws of witchcraft preserve the "ordeal of water."

"If a man has placed an enchantment upon a man, and has not justified himself, he upon whom the enchantment is placed to the Holy River (Euphrates) shall go; into the Holy River he shall plunge. If the Holy River holds (drowns) him he who enchanted him shall take his house. If on the contrary, the man is safe and thus is innocent, the wizard loses his life and his house."

The same ordeal was applied to a wife for unfaithfulness or extravagance, or to a wine-seller who sold drink too cheap.

The three essential features of the code may be clearly defined. First it is based on personal responsibility and the *jus talionis.* Thus: "If any one destroys another's eye, his own eye shall be destroyed. If any one breaks another's bone, his own bone shall be broken. If any one knocks out the tooth of his equal, his own tooth shall be knocked out." Next the belief in the sanctity of the oath before God, as in the Hebrew code, and also the absolute necessity of written evidence in all legal matters, as became a nation of scribes. Judgments in the law courts required a "sealed" document; an agent must take and give receipts for all money or goods entrusted to him; bonded goods required a deposit note. One of the most interesting series of clauses relates to officers or constables employed on active service; the estate of such a person could be entrusted to management, must not be sold or mortgaged, but he must depute a representative, or three years' absence and neglect forfeited fief. Substituted service was not allowed. As might be expected in a land so rich in cultivation, the agricultural laws are most explicit. Land must be cultivated, and if neglected the owner had to pay the same as neighboring land. Damage to crop by storm excused the payment of interest on loan. There are very stringent laws as to the tending of the irrigation canals and ditches, and any damage to adjacent land by neglect had to be made good. The commercial laws are extremely important, as showing a highly developed system. Noticeable are the clauses relating to agents or peddlers, commercial travelers of the period.

"If on the road on his business, the enemy have caused him to lose the property he bore, the agent by the name of God shall swear and he shall be quit. If a merchant gives goods to an agent to trade with, the agent shall write down the money, and to the merchant he shall render; the agent a sealed (receipt) for the money he gave to the merchant shall take."

Monetary Transactions.— Money for which no receipt was taken was not to be included in the accounts. In case of dispute all witnesses and documents must be produced. Among the commercial laws are some of much interest at the present time relating to licensed premises. It is curious to note that all wine merchants were females.

"If riotous persons assemble in the house of a wine merchant and those riotous persons she seizes not and drives to the palace that wine merchant shall be put to death."

Curious, too, is the following, which seems to reflect the Hebrew Nazarite law: "No votary or woman residing in the cloister may open a wine shop or enter one for drink on pain of being burned."

In the code's domestic legislation, the most striking feature is the high position and legal protection extended to women. If a man causes a votary or the wife of a man "to have the finger (of scorn) pointed at her and has not justified himself" he is to be branded on the forehead.

To justify herself from scandal a woman could claim the ordeal of plunging in the sacred river. The mere formula of marriage "taking to wife" was not sufficient, for "if a man married a woman and executed not her deeds that woman is no wife." Divorce law is most fully given — a childless woman could be divorced. If divorced without cause the husband must allow alimony and custody of her children, and a portion of the estate equal to a son, and the woman was free to marry. The woman could get a divorce, but must justify her right to do so. Thus we read:

"If the wife of a man who dwells in the house of that man has set her face to go forth, and has acted the fool, and wasted his house, and impoverished his house, they shall call her to account. If the husband shall say, I put her away, he shall put her away. She shall go her way; for her divorce he shall give her nothing."

If the husband insisted, such a wife could be drowned. There is, however, a kindlier tone in the law as to a sick wife. "If a man has married a wife, and sickness has seized her, he may take a second wife, but the sick wife he shall not put away; in the home she shall dwell; as long as she lives he shall sustain her."

Laws of Property.— The laws of property

are most full and based on a most equitable system, one clause relates to the remarriage of a widow with young children, and might be present-day law:

«If a widow whose children are young has set her face to enter into the house of another, without the consent of the judge she shall not enter. When she enters into the house of another, the judge shall inquire regarding the house of her former husband. The house of her former husband to that woman and her future husband he shall entrust and cause them to deposit a deed. They shall keep the house and rear the little ones, but furniture for money they shall not sell. A purchaser that has bought any furniture from the children of the widow shall forfeit his money and return the property to its owner.»

Here we have all the essential features of the modern ward in chancery. In the conclusion of this code Hammurabi repeatedly calls himself «King of Righteousness,» as did his contemporary Melchisedek of Jerusalem, and enjoins upon all of his successors upon the throne to observe this code and its laws.

Hamon, Jean Louis, zhŏñ loo-ē ä-môñ, French genre artist: b. Plouha, Cotes-du-Nord, France, 8 May 1821; d. St. Raphael, Var, France, 29 May 1874. His work though not strong exhibits grace in drawing and has been popular. His most important work in the United States is 'Among the Flowers,' to be seen in the New York Metropolitan Museum.

Hamp'den, John, English statesman: b. London 1594; d. Thame, Oxfordshire, 24 June 1643. He was educated at Oxford and possessing an ample estate, led for several years the usual career of country gentlemen. He was cousin-german, by the mother's side, to Oliver Cromwell. He entered Parliament in the beginning of Charles I.'s reign as member for Grampound, and continued to sit in the House of Commons three times in succession as member for Wendover, and finally for Bucks. In 1636 his resistance to Charles' demand for ship-money made him the argument of all tongues, especially as it was after the decision of the judges in favor of the king's right to levy ship-money, that Hampden refused to pay it. Being prosecuted in the Court of Exchequer, he himself, aided by counsel, argued the case against the crown lawyers for twelve days before the twelve judges; and although it was decided against him by seven of them to five, the victory, as far as regarded public opinion, was his. From this time he received the title of the "patriot Hampden." In the following year (1637) he was one of those who meditated emigration to America, which they were prevented from carrying out by an order in council detaining them. Henceforward he took a prominent part in the great contest between the crown and the Parliament, and was one of the five members whom the king, in 1642, attempted, in person, to seize in the House of Commons. When civil war broke out Hampden acted with his usual decision, took command of a regiment in the parliamentary army, under the Earl of Essex. Prince Rupert having appeared near Thame, in Oxfordshire, Hampden joined a few cavalry that were rallied in haste, and in the skirmish that followed on Chalgrove Field, received a wound which proved fatal six days after its infliction. His death was a great subject of rejoicing to the royal party, and of grief to his own. His character and conduct, from first to last, evince his conscientiousness, and he has taken his rank by acclamation on the one side, and tacitly on the other, high in the list of English patriots. Consult: Nugent, 'Memorials of John Hampden' (1831); Forster, 'Life of Hampden' (1837); Gardiner, 'History of the Great Civil War,' Vol. I. (1880).

Hampden, Renn Dickson, English Anglican bishop: b. Barbadoes, W. I., 29 March 1793; d. London, England, 23 April 1868. Although a man of moderate abilities both as philosopher and theologian, it was his fortune to precipitate one of the most notable controversies in the English Church. As Bampton lecturer for 1832 he lectured on 'The Scholastic Philosophy Considered in its Relation to Christian Theology,' which brought upon him the charge of Arianism, and when he became regius professor of divinity at Oxford, in 1836, opposition to the appointment was very bitter and widespread. He was accused of heresy and all the leading men in the Anglican Church took sides in this theological war of words. In 1847 he was nominated by Lord John Russell for the see of Hereford and the strife of ten years previous was renewed in organized fashion, many bishops uniting in remonstrance and the dean of Hereford openly resisting. He was nevertheless consecrated in March 1848, and his episcopate of 20 years was quiet and uneventful, the echoes of the great controversy having ceased long before his death.

Hampden, Maine, town in Penobscot County; on the Penobscot River; about five miles southwest of Bangor. The chief manufactures are flour and lumber. There is an extensive river trade, chiefly in lumber and food products. The town is one of the oldest in the State, but recently it has grown steadily in industries and population. Pop. 2,484.

Hampden-Sidney College, in Hampden Sidney, a village near Farmville, in Prince Edward County, Va. The school was founded by the Presbyterian Church of Hanover, in 1776, and in 1783 was incorporated by the legislature of Virginia. The land was donated by Peter Johnston, but the acreage has been increased by gifts and purchases, and the college now owns 250 acres. Among the incorporators were Patrick Henry, James Madison, Nathaniel Venable, Paul Carrington, William Cabell, Sr., and many other famous Virginians. Rev. John Blair Smith, the first president of Union College, New York, had previously been president of Hampden-Sidney, also Rev. Archibald Alexander, a founder of Princeton Theological Seminary. It grants the degrees of bachelor of arts, bachelor of science, and bachelor of literature. In 1902 there were in attendance 107 students. The library contained 15,000 volumes.

Hampton, Wade, American general: b. South Carolina 1754; d. Columbia, S. C., 4 Feb. 1835. During the Revolutionary War he served under Sumter and Marion. He was a Democratic representative in Congress from South Carolina 1795–97, and again from 1803 to 1805. In 1809, he was promoted to be brigadier-general, subsequently was stationed in command at New Orleans, was superseded; in 1813 he was raised to the rank of major-general and ap-

pointed to command the force stationed at Norfolk, whence he was shortly afterward ordered to the northern frontier and placed in command of the army on Lake Champlain, with directions to threaten Montreal. The attack on Montreal, for which 12,000 men had been concentrated near Lake Champlain, was frustrated by Hampton's unwillingness to co-operate with his colleague General Wilkinson, with whom he had been long at enmity. Hampton resigned his commission 6 April 1814, and passed the rest of his life in agricultural pursuits. He was considered the wealthiest planter in the United States, and was reputed to be the owner of 3,000 slaves.

Hampton, Wade, American soldier: b. Columbia, S. C., 28 March 1818; d. there 11 April 1902. He was graduated from the University of South Carolina, studied law but never practised, managed extensive plantations in South Carolina and Mississippi, served in both houses of the State legislature, but, as a Union Democrat, was not popular among South Carolinians. At the beginning of the Civil War, he formed and equipped at his own expense the command of cavalry, infantry, and artillery known as 'Hampton's legion.' With this he won distinction at the first Bull Run and at Seven Pines, where half his troops were killed and himself severely wounded. Having been made brigadier-general of cavalry and assigned to J. E. B. Stuart's command, he took part in Lee's advance northward (1863), was prominent at Gettysburg, and later brilliantly opposed Sheridan's progress in the Shenandoah valley. He attained the rank of lieutenant-general in 1864, and was placed in command of Lee's entire cavalry forces. In 1865 he commanded J. E. Johnston's cavalry, and endeavored to prevent Sherman's northward advance from Savannah. After the war he was an active reconstructionist; in 1876 was nominated as the Democratic candidate for governor, and, after a contest regarding the election with D. H. Chamberlain, the Republican nominee, served until 1878, when he entered the United States Senate. He was in the Senate until 1891, and in 1893–7 was United States commissioner of railroads.

Hampton, Iowa, city, county-seat of Franklin County; on the Chicago G. W., and the Iowa C. R.R.'s; about 29 miles by rail south of Mason City and 60 miles north by west of Marshalltown. It is situated in an agricultural and stock-raising region. The chief industrial establishments are cigar factories and aluminum works; and its principal trade, in addition to the manufactured articles, is in grain, tobacco, live stock, and horses. Pop. (1900) 2,727.

Hampton (formerly HAMPTON COURT-HOUSE), S. C., village, county-seat of Hampton County; on a branch of the Atlantic C. L., and the Hampton & Branchville R.R.'s; about 67 miles southeast of Augusta. The village is in the yellow pine section, but cotton, sweet potatoes, and Indian corn are the staple products of the surrounding farm lands. Its chief manufactured article is lumber. Pop. 320.

Hampton, Va., town, county-seat of Elizabeth City County; on the north shore of Hampton Roads, on the Chesapeake & O. R.R.; about two and a half miles from Fortress Monroe and 15 miles north by west from Norfolk. In the last of the 16th and first of the 17th centuries the Indian village Kiquotan occupied the site of the present town of Hampton. John Smith and Lord Delaware mention (1608–10) the peaceful friendly Indians of Kiquotan, the hunters and fishermen; but before 1610 there were whites living along the shore and in this Indian village which retained its Indian name for some time after it became a white settlement. In the first session of the Virginia House of Burgesses or Colonial Legislature (1619), the borough of Hampton was represented. In the war of 1812 the town was attacked by the British and a large part was burned. In 1861 it was again burned by the Confederates. The Church of Saint John, Protestant Episcopal, built 1660, is still in good repair. Hampton contains a National Soldiers' Home, which has 2,000 resident veterans; a National Cemetery which contains 3,323 graves of soldiers, 600 of them of unknown dead. It is the seat of Hampton Normal and Agricultural Institute (q.v.). It has some manufactures; brick, fish-oil, and canned crabs. It has considerable trade in fish, especially oysters, and in fruits and vegetables. It has excellent bathing facilities and is a popular resort. Pop. (1890) 2,513; (1900) 3,521.

Hampton Court, England, a royal palace situated near Hampton, a village of Middlesex, 15 miles southwest of London. The palace is about one mile from the village. The original edifice consisted of five quadrangles, of which two remain; it was built by Cardinal Wolsey in 1525, and presented in 1526 to Henry VIII., by whom it was subsequently enlarged, and who formed around it a royal park or chase, which he enclosed and stocked with deer. A third quadrangle was added by Sir C. Wren for William III., who laid out the gardens and park in Dutch style. Hampton Court contains many valuable pictures by Holbein, Lely, Kneller, West, etc. The gardens comprise about 44 acres, and contain a famous "maze" and "wilderness." Hampton Court was inhabited by successive monarchs and their families until the reign of George II. Suites of apartments in Hampton Court palace are now set apart for persons of rank in reduced circumstances. The state apartments, picture gallery, gardens, and home park are open to the public. In 1886 the palace suffered considerable damage by fire.

Hampton Court Conference, a meeting at Hampton Court (q.v.), on the 14th, 15th, and 16th of January 1604, which was convened on the petition of the Puritan ministers to King James I. for moderation and tolerance on religious questions. By the composition of the conference,—on the episcopal side being the Archbishop of Canterbury, eight bishops, five deans, and two doctors, and on the Puritan side only four representatives,—the king sufficiently indicated his attitude toward the aims of the Puritans, and the proceedings consisted chiefly of adulation of James on the part of the episcopal party, and lecturing of the Puritan members by King James. A few alterations were made in the Prayer Book, and a new version of the Bible was agreed upon, the result being the authorized version of 1611.

Hampton Normal and Agricultural Institute, a school for negroes and Indians,

opened in 1868, in Hampton, Va., under the auspices of the American Missionary Association. It was chartered by the State in 1870. The school is owned and controlled by a private corporation, administered by 17 trustees. The charter gives the trustees power to choose their own successors, and to hold property without taxation to the amount of $800,000. In 1875 the General Assembly of Virginia passed an act giving the Institute one third of the agricultural college land-grant of Virginia (see COLLEGES, LAND-GRANT) amounting to 100,000 acres, which was sold for $95,000 and which pays regular annual interest. The school was first opened in an old barracks (used during the Civil War), with two teachers and 15 pupils. It now (1903) owns 185 acres on Hampton River, upon which have been erected dormitories, a library, class-room buildings, a church, gymnasium, saw and planing-mill, shops, hospital, domestic-science school, trade school,— in all numbering 55 buildings. The Institute owns also a stock farm of 600 acres, about five miles from the school. The farm land, and the workshops where trades are taught, furnish occupation for the boys and young men. The girls are instructed and employed in sewing and cooking classes, in all the domestic work of the school, and wherever possible learning trades side by side with the boys. In 1896 the Armstrong and Slater Memorial Trade School was opened. (See NEGRO, EDUCATION OF THE.) In this school is taught the theory and practice of blacksmithing, carpentry, house painting, tailoring, and general repairing. The pupils are taught also, mechanical, civil, electrical, and mining engineering. On the farms they are taught how to care for stock, how to raise different crops, and the theory and practice of farming in general. The students are charged $10 a month for board, which is largely paid in labor. They are expected to provide their own books and clothing, and for the tuitions, buildings, furniture, and the implements used on the farms and in the shops, the school is dependent on the charity of the country. In 1878, 15 Indians, who had been prisoners of war at Saint Augustine, Fla., and in charge of Capt. R. H. Pratt, were admitted as students. Since then the Indian department has increased steadily, the pupils being chiefly from the Sioux tribe, of whom two thirds make a fair or good record. The young men of the school are organized into six military companies, all forming one battalion. This places the young men under military discipline. The 'Southern Workmen,' a monthly school periodical, is edited, printed, and managed by the pupils with only a general supervision by one of the teachers. The vacation is from June to October for all except the pupils in the industrial departments, which continue work all the year. During the regular long vacation a large number of the colored teachers of the South assemble here for a summer school. For the past ten years the average attendance at these summer schools has been nearly 500. The graduates number about 1,000, more than half of whom are teaching in the colored schools of the South. In 1902 the number of pupils in the Hampton Institute was 1,161, about 90 per cent of whom were in the industrial and preparatory departments, the remainder in the college department. The same year there were 82 instructors in the school. The library contains about 12,000 volumes. Many of the graduates are engaged in farming or working at trades; some are teaching. Booker T. Washington (q.v.), of the class of 1875, is the most noted graduate. Hampton's endowments amount to about $1,100,000. The annual income is about $170,000, and comes from the Government Indian Funds, the Slater and Peabody Funds, the State land-grant and agricultural funds, and from private donations.

Hampton Roads, Va., a broad deep channel which connects the estuary of the James River with Chesapeake Bay; really a part of the estuary which is at the mouths of the James, Elizabeth, and Nansemond rivers. Some of the good harbors along the shore are Norfolk and Portsmouth on the south; Hampton, on the Hampton Creek, an arm of the Hampton Roads, on the north. At the entrance are Forts Monroe and Wool. On the north side of the entrance is Thimble Shoal light, at lat. 37° 42′ N. and lon. 76° 14′ 5″ W. A large number of railroads have terminals on Hampton Roads, especially at Norfolk. This estuary, or channel, is considered of great military importance. During the Civil War its advantages as a military station were demonstrated. On Hampton Roads occurred the battle of Hampton Roads (q.v.), the first engagement between ironclads.

Hampton Roads, Battle of. Hampton Roads was the rendezvous of several important naval and military expeditions during the war, and the scene of two memorable encounters. On 8 March 1862 the Confederate ram Merrimac (or Virginia) left her anchorage at Norfolk, 12 miles from Fort Monroe, steamed down Elizabeth River and, with her consorts, five in number, attacked the Union fleet of five vessels in the roads, destroying the Congress and Cumberland, which lost over 250 men, and then retired to the mouth of Elizabeth River. Next morning the Merrimac returned to the roads to complete the destruction of the Union fleet, but was met by the Monitor, which had arrived the night before from New York, and a novel naval battle ensued, resulting in the return of the Merrimac to Norfolk and the saving of the remainder of the Union fleet. See MONITOR AND MERRIMAC.

E. A. CARMAN.

Hampton Roads Conference, an informal conference held 3 Feb. 1865, between President Lincoln and Secretary of State Seward, representing the United States government, and Vice-President Alexander H. Stephens, Senator Robert M. T. Hunter, and Assistant Secretary of War John A. Campbell, representing the Confederate States. The meeting took place on board the River Queen, near Fort Monroe, and its object was the arrangement of a peace between the North and South. The originator of this conference was Francis P. Blair (q.v.) who thought a combination of North and South against Maximilian in Mexico, in enforcement of the Monroe doctrine, would bring in peace by a diversion. President Lincoln refused to join the conference excepting with a view to the restoration of union, and on the understanding that the Emancipation Proclamation was to

stand without qualification. He disapproved of a joint action against the French in Mexico. The conference lasted for four hours, but broke up without reaching any definite conclusion.

Hamstring. See ANATOMY; MUSCLES.

Han-yang, hän-yäng'. See HANKOW.

Han'aford, Phebe Ann Coffin, American Universalist minister: b. Nantucket, Mass., 6 May 1829. In 1849 she was married to J. H. Hanaford, a teacher. She was the first woman ordained to the ministry in New England and since her ordination in 1868 has held pastorates in Hingham and Waltham, Mass., New Haven, Conn., and Jersey City. She has been industrious as a writer, among her many published works being 'Life of Abraham Lincoln'; 'Life of George Peabody'; 'Lucretia the Quakeress'; 'Leonette, or Truth Sought and Found'; 'The Best of Books and its History'; 'Frank Nelson, the Runaway Boy'; 'The Soldier's Daughter'; 'Field, Gunboat, and Hospital'; 'Women of the Century'; 'From Shore to Shore, and Other Poems'; etc.

Han'cock, John, American statesman: b. Braintree, Mass., 23 Jan. 1737; d. Quincy, Mass., 8 Oct. 1793. He was graduated at Harvard College in 1754, but shortly after entered the counting house of an uncle, on whose death in 1764 he received a fortune of £80,000. After 1766 he was several times elected to the Massachusetts General Court. It was the seizure of his sloop, the Liberty, that occasioned the riot in 1768, when the royal commissioners of customs narrowly escaped with their lives. After the so-called "Boston massacre," in 1770, he was a member of the committee to demand of the royal governor the removal of the troops from the city, and at the funeral of the slain delivered an address which greatly offended the governor, who now endeavored to seize the persons of Hancock and Samuel Adams. Both were members of the Provincial Congress at Concord and later of that at Cambridge, and Hancock was president of each. This arrest is said to have been one of the objects of the expedition to Concord which led to the first battle of the revolution after which Gage offered pardon to all the rebels except these two, "whose offences," he added "are of too flagitious a nature to admit of any other consideration but that of condign punishment." In 1775 Hancock was chosen president of the Continental Congress, and in 1776 signed the Declaration of Independence. He resigned from the presidency in 1777, but was a member of the Congress until 1780, and again in 1785–6. With rank of major-general, he commanded the Massachusetts forces in the Rhode Island expedition, in 1780 was a member of the Massachusetts constitutional convention, and under that constitution was in 1780 chosen first governor. To this office, with an interval of two years (1785–7) he was annually re-elected till his death. Hancock was a man of strong common sense and great decision of character, of polished manners, easy address, affable, liberal, and charitable. His personal vanity, and his jealousy were at times conspicuous, but he was a sincere patriot, and of much ability. John Adams said of him: "He was by no means a contemptible scholar or orator. Compared with Washington, General Lincoln, or Knox, he was learned." See A. E. Brown, 'John Hancock: his Book' (1898).

Hancock, Winfield Scott, American soldier: b. Montgomery Square, Pa., 14 Feb. 1824; d. Governor's Island, New York harbor, 9 Feb. 1886. He was graduated from the United States military academy in 1844, and after frontier service in the Sixth infantry fought with credit in the Mexican war, was successively regimental adjutant and quartermaster in 1848–55, and briefly assistant adjutant-general to the Department of the West. Appointed assistant-quartermaster with rank of captain in 1855, he was stationed at Fort Myers, Fla., during the Seminole disturbances, and in 1857–8 was in Kansas, whence, after service, in the border troubles, he was ordered successively to Utah and California. In 1859–61 he was chief quartermaster of the southern district of California, with headquarters at Los Angeles. At the beginning of the Civil War, he was commissioned brigadier-general of volunteers, and assigned to the command of a brigade in Smith's division, Fourth corps, Army of the Potomac. He distinguished himself at Williamsburg and during the second day's fight at Antietam (17 Sept. 1862) was placed in command of the 1st division, Second army corps. Promoted major-general, U. S. V. (November 1862), he commanded his division at Fredericksburg in the attack on Marye's Heights, on which occasion he lost 2,013 from a total of 5,006 troops. He largely saved the day at Chancellorsville (2–4 May 1863), and shortly afterward was assigned to the command of the Second corps. In July 1863, he was ordered by Meade to proceed to the field of Gettysburg, take command, and report whether battle should be given at that point. He reported Gettysburg as the suitable place for the ensuing battle, reorganized the Federal lines, on 2 July commanded the left wing, and on the next day the left centre, against which was directed a Confederate charge in the course of which the Second corps lost about 4,000 killed and wounded out of less than 10,000 troops and Hancock was shot from his horse. In 1866 he was appointed major-general, U. S. A., in 1866–8 commanded successively the departments of Missouri, and of Texas and Louisiana, in 1868–9 the military division of the Atlantic, in 1869–72 the department of Dakota. He was again assigned to the division of the Atlantic in 1872. In 1880 he was Democratic candidate for the presidency, but was defeated by Garfield by a vote of 4,454,416 to 4,444,952. He was a brilliant leader, known as "Hancock the Superb," — "the most conspicuous figure," says Grant, "of all the general officers who did not exercise a separate command." Consult the 'Life' by Walker (1894).

Hancock, Mich., village in Houghton County; on Lake Portage, and on the Duluth, S. S. & A. railroad; opposite Houghton (q.v.). Although the northern part of Michigan and this region had been explored by missionaries in the 17th century, the first permanent settlement was made in Hancock in 1859, and the village was incorporated in 1863. It is situated in a section rich in minerals, the Lake Superior copper belt. The Calumet and the Hecla copper mines are nearby, and the village has foundries, machine-shops, smelters, stamp-mills, lumber and brick yards. A ship-canal to Lake Superior brings a large portion of the lake traffic to and

from Duluth and Superior through the "short cut," by way of Hancock. It is the seat of a Finnish college. The government is vested in a president, whose term of office is one year, and a village council who are elected by the people. The village owns and operates the waterworks. Pop. (1890) 1,772; (1900) 4,050.

Hancock, N. Y., village in Delaware County: at the junction of the two branches of the Delaware River, on the Erie and the New Y., O. & W. R.R.'s. Nearby are bluestone quarries, which add to the industrial wealth of the village. Hancock has flour-mills, tanneries, a wood alcohol factory, and large lumber-yards. It is a trade centre for an extensive agricultural region. Pop. (1900) 1,283.

Hancock, Mount, a peak of the Big Game Range, in the southern part of the Yellowstone National Park, on the boundary between the Park and Wyoming. It is on the western border of Two Ocean Plateau, a portion of the continental divide. The Snake River (q.v.) has its rise on the east side of Mount Hancock, flows north by west, then south by west around and almost circling the mountain. Mount Hancock is 10,235 feet in height.

Hand, Edward, American revolutionary soldier: b. Clyduff, King's County, Ireland, 31 Dec. 1744; d. Rockford, Lancaster County, Pa., 3 Sept. 1802. In 1774 he came to America as surgeon's mate in the 18th Royal Irish regiment, but he later resigned and entered medical practice in Pennsylvania. At the outbreak of the Revolutionary War, he became a lieutenant-colonel in Gen. William Thompson's brigade, participated in the siege of Boston, and in 1777 was appointed brigadier-general. In 1778 he succeeded General Stark in the command at Albany, and later took part in General Sullivan's expedition against the Iroquois. He sat in Congress in 1784–5, and signed the Pennsylvania constitution in 1790.

Hand. The human hand is composed of 27 bones, namely eight bones of the carpus or wrist arranged in two rows of four each, the row next the fore-arm containing the scaphoid, the semilunar, the cuneiform, and the pisiform, and that next the metacarpus, the trapezium, the trapezoid, the os magnum, and the unciform. The metacarpus consists of the five bones which form the palm, the first being that of the thumb, the others that of the fingers in succession. Lastly, the fingers proper contain 14 bones called phalanges, of which the thumb has but two, all the other digits having three each. These bones are jointed so as to admit of a variety of movements, the more characteristic being those by which the hand is flexed backward, forward, and sideways, and by which the thumb and fingers are moved in different ways.

The chief muscles which determine these movements are the "flexors," which pass down the fore-arm, are attached by tendons to the phalanges of the fingers, and serve to flex or bend the fingers; and the "extensors" for extending the fingers. There are two muscles which flex all the fingers except the thumb. The thumb has a separate long and short flexor. There is a common extensor for the fingers which passes down the back of the fore-arm and divides at the wrist into four tendons, one for each finger, each being attached to all three phalanges. The fore-finger and little finger have, in addition, each an extensor of its own, and the thumb has both a short and a long extensor. The tendons of the muscles of the hand are interlaced and bound together by bands and aponeurotic fibres, and from this results a more or less complete unity of action. It is sometimes difficult to make a movement with a single finger without the others taking part in it, as in executing instrumental music, for instance; but practice gives to these movements perfect independence.

Of all the movements of the hand the opposition of the thumb to the other fingers, alone or united, especially characterizes the human hand. This action of the thumb results from its length, from the first metacarpal bone not being placed on the same plane as the other four, as is the case in the monkey, and from the action of a muscle — the long flexor of the thumb — peculiar to the human hand. This muscle completes the action of the other motor of the thumb and permits man to hold a pen, a graver, or a needle; it gives to his hand the dexterity necessary in the execution of the most delicate work. Properly speaking then, the hand, with its highly specialized muscles, belongs to man alone. It cannot be considered, as in the ape, as a normal organ of locomotion. It is essentially the organ of touch and prehension. It molds itself to a body to ascertain its form; it comes to the aid of the eye in completing or rectifying its impressions. The functions of touch devolve principally on its anterior or palmar face, the nervous papillæ abounding specially at the ends of the fingers. A layer of adipose tissue very close in texture protects, without lessening its power or its delicacy, the network of muscles, vessels, and nerves with which this remarkable organ is equipped.

Hand'ball, a popular game of ball, the bare hand only being used. The game is indigenous to Ireland, but has been transplanted to America, where are the most expert players. Two or four men can play, one or two on a side. As far as is known the game of handball came to the United States about 1840, and has since become one of the sports under the regulations of the Amateur Athletic Union. The game consists of scoring the ball against a single back wall, with a lined-out space of 60 feet in front. The ball coming from the wall must fall between these two lines to be in play. The game is simply to strike the ball on the rebound with the hand.

Han'del, George Frederick, (properly Georg Friedrich Haendel), English composer: b. Halle, Saxony, 23 Feb. 1685; d. London 20 April 1759. His father, intending him for the law, discouraged the strong passion which he evinced early in life for the science of music. But although forbidden the use of musical instruments, the young musician contrived to hide a small clavichord in a garret, where he amused himself during great part of the night after the rest of the family had retired, and made such progress that, when at seven he accompanied his father to the court of Saxe-Weissenfels, he played on the church organ with such power and effect that the duke, who accidentally witnessed his performance, used his influence successfully with his father to permit him to follow his inclination. He was accordingly placed under

Zachau, organist of the cathedral, and was soon so far advanced in the practical part of the science as to officiate occasionally as deputy to his instructor. At 14 (1698) he went to Berlin, where at that time the opera under the direction of Buononcini and Attilio was in a very flourishing condition. Attilio became his teacher and friend. In 1703 he went to Hamburg, and procured an engagement in the orchestra at the opera there. On 30 Dec. 1704, he brought out his first opera, 'Almira,' in the February following succeeded by his 'Nero,' and subsequently by 'Florindo' and 'Daphne.' He then went to Italy, where he composed the operas 'Rodrigo' and 'Agrippina,' and the first form of the serenade 'Acis and Galatea.' On his return to Germany in 1710 he entered the service of the Elector of Hanover, afterward George I. of England, as chapel-master; but having received invitations to visit London, he set out for England, where he arrived in the latter end of 1710. On the occasion of his first visit to England he composed the opera 'Rinaldo.' He soon returned to Hanover, but at the end of two years again received permission to visit England. At the time of his arrival in London the negotiations for the Peace of Utrecht were just about to be concluded, and Handel was invited by Queen Anne to compose a 'Te Deum' and 'Jubilate' in celebration of the peace. But this act was so distasteful to the Elector of Hanover that Handel did not venture to return, but remained in England on an income of £200 a year allowed him by the queen. He was, in consequence, on the accession of his royal patron to the throne of Great Britain in 1714, in much disgrace, till Baron Kielmannseck restored him to favor. From 1715–18 Handel resided with the Earl of Burlington, and then quitted that nobleman for the service of the Duke of Chandos, who entertained him as chapelmaster to the splendid choir established at his seat at Cannons. For the service of this magnificent chapel Handel produced those anthems and organ fugues which alone would have been sufficient to immortalize him. When the Royal Academy of Music was instituted by some of the leading noblemen of England, Handel, whose fame had now reached its height, was placed at its head; and this, for a short period, may be considered as the most splendid era of music in England. The warmth of his own temper, however, excited by the arrogance and caprice of some of his principal Italian singers, caused many violent quarrels; and public opinion becoming enlisted in favor of his opponents, and especially of his rival, the musician Buononcini, his popularity waned somewhat and the Academy was dissolved (1728). Handel then started a new operatic company. But a rival company to his was afterward started, and the result was that much money was lost by both. The operas which he had composed up to this date (1735), from the institution of the Academy of Music, were 'Radamisto'; 'Ottone'; 'Giulio Cesare'; 'Floridante'; 'Flavio'; 'Tamerlano'; 'Rodelindo'; 'Alessandro'; 'Scipione'; 'Ricardo I.'; 'Tolomeo'; 'Siroe'; 'Lotario'; 'Parthenope'; 'Poro'; 'Orlando'; 'Sosarme'; 'Ariadne'; 'Ezio'; 'Ariodante'; and 'Alcina.' Among other works should be mentioned his first English oratorio, 'Esther', and his delightful pastoral 'Acis and Galatea.' In 1736 his famous setting of Dryden's ode, 'Alexander's Feast,' was performed with brilliant success. His last opera was performed in 1741. Handel had by this time begun to devote himself chiefly to music of a serious nature, especially the oratorio. The approval which his first works of this kind 'Esther,' 'Deborah' (1723), 'Athalia' (1733); had met with encouraged him to new efforts; and he produced in succession 'Saul,' 'Israel in Egypt,' and 'The Messiah.' The last-mentioned, his chief work, was brought out at Dublin in 1742. This sublime composition had been composed the previous year, in the incredibly short period of twenty-three days. When Handel returned to London his oratorios were received at Covent Garden Theatre with the greatest approbation by overflowing audiences — 'The Messiah' in particular increased yearly in reputation. Before it was given, however, a new oratorio, 'Samson,' was produced (1743), and there next followed 'Joseph and his Brethren' (1744), 'Belshazzar' (1745), 'Judas Maccabæus' (1747), 'Joshua' (1748), 'Solomon' (1749), and 'Jephthah' (1752). Some time before his death he was afflicted by nearly total blindness; but he continued not only to perform in public but even to compose. His own air, however, 'Total Eclipse,' from the oratorio of 'Samson,' is said always to have affected and agitated him extremely after the loss of his sight.

Handel's habits of life were regular; his appetites were coarse, his person large and ungainly, his manners rough, and his temper even violent; but his heart was humane, and his disposition liberal. His musical powers can hardly be estimated too highly. In boldness and strength of style, and in the combination of vigor, spirit, and invention in his instrumental compositions he has never been surpassed. His choruses have a grandeur and sublimity which have never been equaled. Yet a singular fact in regard to him as a musician is that in some of his works he shows himself as an unscrupulous plagiarist — a fact of which various explanations and palliations have been attempted. He was buried in Westminster Abbey, where a monument by Roubillac was erected to his memory. See 'Lives by Chrysander' (1858–67); and Rockstro (1883); Whittingham, 'Life and Works of Handel' (1882); the articles in the 'Dictionary of National Biography' and Grove's 'Dictionary of Music.'

Han'dicap, Brooklyn. See HORSE-RACING.

Handicapping, a term used in racing: The allowance of time, distance, or weight made to the inferior competitors in a race with the object of bringing all as nearly as possible to an equality; the extra weight imposed on a superior horse in order to reduce his chance of winning to an equality with that of an inferior animal. The handicap is framed in accordance with the known previous performances of the competitors, and in horse-racing also with regard to the sex and age of the animals engaged. The principle is the same in other contests, as in billiards a superior player is handicapped by having to allow his inferior competitor a start of a certain number of points.

Handies (hăn'dĭz) **Peak,** in the southeastern part of Colorado, in the San Juan Range; about 12 miles northeast of Silverton. Rich

deposits of silver ore are found in all the mountains of this vicinity; the range is known as the 'Silver San Juan.' The altitude of Handies Peak is about 14,000 feet.

Handwriting, Expert Analysis of. A mental image may be made either consciously and with attention to every detail, or with varying degrees of consciousness amounting in some cases to almost complete automatism, but it must in any case be largely influenced by the machine which produces it. No matter what care may be employed to make two objects alike, a sufficiently minute inspection will always discern differences between them. It is from this fact we are able to distinguish a particular tone of a bell, a particular face, etc. All things, and notably those which owe their existence to organic life, are resultants of very complex forces acting simultaneously or in sequence, and in comparing similar resultants it is ever found that quantitative or qualitative differences of the constituent forces employed in fashioning them have occasioned differences in the objects themselves. These differences may be indiscernible to the casual view, but will never fail to reveal themselves to an examination sufficiently searching.

The factors employed in making marks may be roughly divided into: A, the model in the mind which it is the intention to reproduce; and B, the mechanism by which the act is to be accomplished. Under the latter head there is to consider not only the permanent structure of the individual, which necessarily limits his performance, but also the manner of employing this structure, which becomes a habit, and the fluctuations, due to disease, drugs, variations of mood, increasing age, etc., in the motor impulses controlling it.

The basis of any sound judgment on the authorship of designs such as pictures or handwriting, depends upon the recognition of sorts of differences; which it is essential to distinguish from each other. In general, designs by different authors differ in kind, while those of the same author differ in degree. The methods for distinguishing these two sorts of differences will be more particularly treated hereafter.

The general subject of the study of those characteristics which distinguish each handwriting from every other has been called *Grammapheny;* the study of methods for detecting frauds relating to handwriting either in imitating, altering, or suppressing a record, is called *Plassopheny;* and the general study of the records of human thought including their forms, their purport, and the tools and materials by means of which they are produced is called *Bibliotics.*

Ever since the more or less permanent records of human thought have had a value they have been the objects of falsification. It is not known to how great an extent this may have been practised in the hieroglyphic and ideographic carvings on stone, but doubtless interpolations were frequent in recording the deeds of their kings, and the sculptors imitated each other's style with a view of bettering their own; or each other's peculiarities to convey false impressions as to the narrator.

But with the introduction of writing in pigments on parchment and papyrus the greater facility with which alterations and erasures could be made immediately attracted the attention of the unscrupulous. According to historians the Greeks, Romans, Egyptians, Assyrians, and others practised garbling and forgery by erasing, resurfacing, and bleaching manuscripts to change their purport, or give false impressions of their age and authorship. These depredations, then as now, were chiefly made upon manuscripts of persons absent or, more commonly, deceased; whole compositions which they never saw being ascribed to them. As an example may be cited the interpolation in the text of Josephus with which Eusebius has been charged. A host of epistles, papal decrees, productions of the Fathers, and dogmatical treatises were in early times altered, erased in part, and falsified from the original text, sometimes by learned and reverend scholars for the greater glory of the Church, and sometimes by obscure copyists from ignorance, or trifling incentives. Erasmus declared he knew not a single important old manuscript which was not tainted by this kind of fraud. The methods of effacing the writing of a parchment multiplied in proportion to the increase of manuscripts and the cost of parchment. The practice of using such effaced parchments for other writings was common in the time of Cicero, as a letter from him to Trebatius testifies. Such writings were called palimpsests; and the custom of producing them gave dangerous experience to perpetrators of fraud in the art of effacing written characters by mechanical and chemical means. Plutarch speaks of this practice as one well known. As the price of parchment rose it began to be the habit in the early libraries to efface the letters from parchments "of little value" in order to replace them by more valuable compositions. Dangerous as was such a rule at any time it became fatal to learning when the choice was in the hands of ignorant monks inflamed against their adversaries in controversy, and against all "pagans," in which class almost all the great authors of our classics were included, and willing to sacrifice the choicest thoughts of the Greeks and Romans in favor of the fanatical dissertations of those they were pleased to call the "faithful."

When the Caliph Omar put an end to the manufacture and sale of papyrus he caused a wholesale destruction of the writings in the libraries throughout the world. Michelet states that "the fatal patience of the monks" accomplished more ruin than the conflagrations of Omar, of the hundred Spanish libraries, and of the Inquisition. (Consult Gustave Itasse, 'Le Faux devant l'histoire,' etc., from which much of the preceding is taken.) According to Adolphe Bertillon ('Revue Scien.' 25; 4 Ser. Vol. VIII. 18 Dec. 1897) the first recorded student of bibliotics was François Demelle in 1609, and the first writer on the subject one Raveneau (1656). In his treatise the latter deplores the lack of science of his colleagues, which however did not prevent their landing him in jail for forgery.

The methods employed in judging the authorship of handwriting by these and almost all later writers on the subject are the same as those relied upon by connoisseurs of painting. They deal exclusively with the pictorial and apparent peculiarities, and the undefined effect these produce upon the mind. The most daring of these methods is the so-called

"Graphology," described in a pamphlet of the Abbé Michon in 1880, which has many conscientious supporters and partial government recognition in Germany and France. This curious study has for its object the revelation of the character and peculiarities of a writer by his handwriting. It would lead to too long a digression should the various claims of the advocates of graphology be reviewed. It must suffice here to say that some of these not content with finding in the manuscript of an unknown writer personal peculiarities which he already possesses, have imagined they could detect the lurking tendencies to virtuous or vicious deeds such as self-sacrifice, kleptomania, murder, etc., which he has never developed. These are deduced from the pen habits which they think they detect in the writing: such as deliberation, precipitancy, economy of paper, or of effect, etc., etc. M. Bertillon thinks "To the public no proof is so decisive as that of personal identification of individuality, yet how many mistakes are made?" He believes with the exception of the advance in photography the art of handwriting judgment is just where Raveneau left it in the reign of Louis XIV. He forgets the aid he himself has rendered to the art of differentiating and identifying handwriting by the application of his anthropometrical measures for the identification of criminals. The former art without such methods is in precisely the state in which Bertillon found the latter before his demonstration that exact measurements of different parts of the body and the relation to each other of the results of such measurements entirely removed the chance of error in identification, whereas there have been many instances of mistaken identity, or denial of identity by a wife or other near relative of the person in question. The history of this minute branch of research resembles that of other and larger branches. Subjective impressions such as those supplied by the feelings, indicating supposed relative amounts or intensities of emotions or sensibility, which were the only guides to the pioneers of inductive research, gave way to exact methods by employment of instruments of precision recording facts in intelligible units, in estimating, for example, degrees of acidity, pitch of sounds, height of temperatures, intensity of lights. One after the other the old subjects of research were furnished with these unequivocal means of recording phenomena, and all the new subjects were required to find such means or forfeit recognition. Thus through mathematics astronomy, already in the van of exact sciences, was enabled to make enormous enlargements of our view of the universe in the last two centuries, and even those objects of research which seemed to defy such treatment were provided with mathematical methods. Psychology became a science admitting experimentation of which the results can be expressed in units, and chemistry is becoming as loyal a subject of that science of relation — mathematics — as its sisters, physics and mechanics.

The purpose of the investigation of a handwriting will determine the kind of examination that is made. If the object be to ascertain whether a particular signature has been legitimately placed as an authentification of a writing, it is necessary to scrutinize the paper on which it is written for evidence of scratching, erasing, or other tampering; the ink for peculiarities of constitution which may be inconsistent with its use at that time and in that place. The question of superposition of lines may show that the writing it validates was made after the signature. In numerous criminal trials each of these and of many other unmentioned demonstrable facts have at once stamped documents as fraudulent and obviated the necessity of the more particular study of the character of the writing. (Thus a water-mark in a paper on which was written a statement bearing date 1868 represented the German Eagle which was not adopted till after 1870, and this of course showed the whole instrument to be a fraud. A similar conclusion is forced in the case of traced characters purporting to have been written before Hofmann's discovery of the aniline colors yet demonstrably produced by aniline ink.) The value of a signature as authenticating a contract is forfeited if it is clear that parts of the body of the document were written after the signature was written. These and other problems in the domain of plassopheny are too numerous to treat in this place and attention will be directed exclusively to the grounds for deciding two specimens of writing to be by the same or by different hands.

The first and most obvious method is to compare their respective features; large or fine writing; perfect or imperfect shaping of the letters; slant or angle of the stems and tails of letters with the line of writing; peculiarities (of which there are always a number) in the forms of individual letters or in the manner of connecting or grouping them; alterations in pressure producing shading in certain directions, and many other similar details. These peculiarities are pictorial. In all genuine writing they arise from the limitations of the writer, first in forming a mental picture of what he wants to produce, and secondly in producing it. Any one of these peculiarities can be easily imitated by another, and indeed all the visible details together can be drawn or traced by a skilful artist, yet in the latter case not without revealing to one using a magnifying glass that the lines have been slowly and carefully drawn and not dashed off with ease. Even if words are photographed or traced from an original and afterward inked, an ordinary magnifying glass will show a difference in the pen marks from the current facility of the original writer. The careful study of such details constituted the entire basis of judgment of the expert till within recent years, and usually they will suffice; for though the forger should know all the minute peculiarities which are disclosed to the patient study of a handwriting, yet he could not reproduce many of them without betraying in the result a painstaking, labored use of the pen which would excite suspicion. Where the same word or signature occurs twice or more in a document the forger must avoid exact repetition of all the minutiæ and at the same time not make such deviations as are inconsistent with the habits of the writer. The most important of these habits for purposes of identification are not pictorial nor immediately apparent to the eye.

Proportions.— Among the most important kinds of characteristics which insensibly influence the judgment in forming a conclusion as to identity of authorship of two specimens of

handwriting are the proportions between certain parts of a letter, or word, or group of these, which often occur together. Especially is this the case with a signature, which is written so frequently that the act becomes almost automatic and therefore one in which the peculiarities due to the hand and arm making it, and to the brain furnishing the pattern, are most prominent because without the interference of voluntary effort. The result in fact resembles typewriting where the defects in the levers and type-faces of a type-writing machine can be detected; but with this difference that in handwriting they are still recognizable even when from lack of space or other causes the signature is written smaller or larger than usual. In such cases there is found a greater conformity to the established relations of parts of the signature than any foreign hand could make without a pantograph or other artificial aid. These proportions of parts may be detected either individually by carefully noted measurements, or by composite photographs of genuine signatures. Each method has some advantages over the other. In employing composite photography one attains to an ideal signature because all the possible characteristics of relation in every signature have been introduced, but on the other hand by this means only a form has been evolved — a graphic average — which must then be made the standard for comparison.

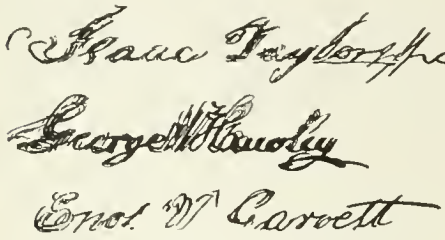

FIG. 1.— Composites of genuine signatures.

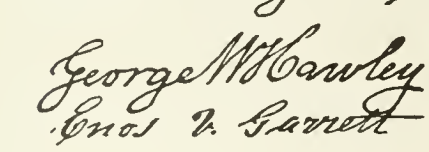

FIG. 2.— Forgeries of the above signatures.

In the case of the method by actual measurements although only a small fraction of the total number of relations is noted, yet these are in numerical form and can be averaged and the results compared directly.

The principle on which the method by investigation of proportions of parts rests is that the spaces between various distinctive points of a signature bear numerical relations to each other, and to the heights of certain letters, which are constant within comparatively narrow limits whether the signature be written small or large.

The following illustration (Fig. 3) represents a small part of a letter written with pen and ink and photographed at an enlargement of 30 diameters:

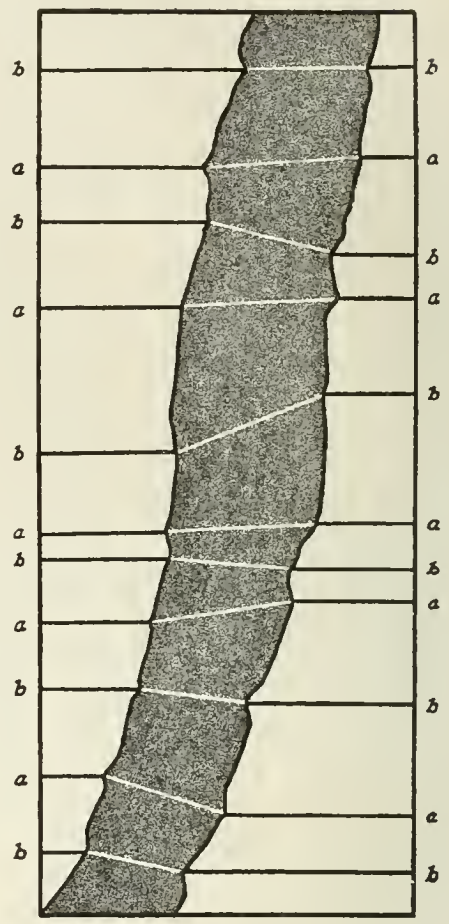

FIG. 3.— The points *a* show the widest and *b* the narrowest parts of the ink lines. It is to be noted that the maxima and minima of the two margins are not always opposite to each other, but show a tendency to oscillate about a horizontal line so that the *a*'s and *b*'s of one margin will be observed alternately above and below such line in following the ink mark downward, while those of the other margin will be found in opposite phase. This is made clearer by the white lines uniting the *a*'s and *b*'s of the opposite margins. This can be accounted for by the simultaneous operation of lateral and vertical movements which are not coincident in period.

Tremograms.— Another valuable individuality in writings executed by means of pen and ink are the irregularities observed in the margins of the lines when examined under a sufficiently high power of the microscope (about 120 diameters). How far this examination will enable one to identify an individual is not yet known, but it has been established that there are characters in the general disposition, number, arrangement, and position of these serrations, which remain comparatively constant in the writings of the same individual with different pens, ink, and paper, and under different mental and physical conditions, and which therefore cannot have other source than peculiar motions imparted to the writing instrument and writing fluid by the writer.

Fig. 1.

Photomicrograph of part of a hand-drawn ink line. Magnified 120 diameters.

Fig. 2.

Photomicrograph of a small part of a machine-drawn ink line made with an ordinary steel pen, the nibs pressing equally on the paper and being drawn downward. The paucity and minuteness of the serrations and the absence of curvature on the margins distinguish this from ink lines made by hand. Magnified 180 diameters.

Inks.—Tables for the determination of the characters of inks by qualitative chemical tests have been published by Robertson, Hofmann and others. To the same end special devices have been made to solve questions relating to the composition of inks without affecting the document or writing fluid: Doremus by means of the spectroscope, Frazer through absorption of light admitted to and reflected by the ink through colored prisms. Sharples has shown that an otherwise invisible record may be made visible through shorter or longer exposure to the sensitive plate of the photographic camera, etc.

FIG. 4.—A tracing by camera lucida of the margins of an ink line drawn by a pen fixed to a ruling machine. It is enlarged 60 diameters. There is an absence of the irregularities always found in the margins of ink lines made by the human hand.

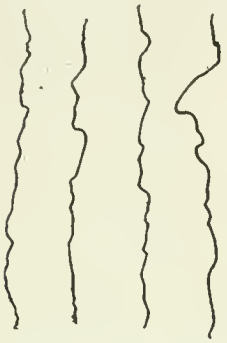

FIG. 5.—Camera lucida tracings of the margins of two ink lines by the same hand made at an interval of fifty-two days. The similarity of character of the serrations in both is noticeable.

Bibliography.— Chabot, 'The Handwriting of Junius Professionally Investigated,' with a preface and collateral evidence, by the Hon. Edward Twisleton (1871); Cross & Bevan, 'A Text-Book of Paper-Making' (1888); S. Weir Mitchell, M. D., 'Mary Reynolds: a Case of Double Consciousness' (with a letter on the handwritings peculiar to each of the two states by Persifor Frazer). Traduit par M. L. Vossion et Mme. H. Bouett' (1899); Minovici, 'Les faux en écriture et la photographie au service de la justice'; Ames, 'Forgery, its Detection and Illustration' (1900).

PERSIFOR FRAZER,
Docteur ès-Sciences Naturelles Univ. de France.

Handy Andy, a novel by Samuel Lover, published in 1842. It is a broadly humorous tale of life among the Irish gentry and peasantry in the first half of the 19th century, by an accomplished author who not only could illustrate his own narrative, but could write songs for it and furnish music for them as well.

Han'ford, Cal., city and county-seat of Kings County; on the Southern Pac. and Santa Fe R.R.'s, about 30 miles southeast of Fresno, and 250 miles south of San Francisco. It was first settled in 1871 and was made a city in 1891. Its chief industries are agriculture, fruits, raisins, and livestock. It has also flour and planing mills, milk condensing factory, butter and cheese factories, etc., and is a distributing centre for food products and clothing sent to mining sections in the vicinity. The city government is by a Board of Trustees, the board choosing its own chairman. The city has six banks, and a Carnegie Library. Pop. (1903) 3,000.

FRED A. DODGE,
Editor 'The Hanford Sentinel.'

Hanfstängl, Franz, fränts hänf'stengl, German lithographer: b. Rain, Germany, 1804; d. 1877. He studied art at the Munich Academy, and in 1826 went to Dresden where he began his series of lithographic copies of pictures in the Dresden Gallery, which he completed in 1852. During the latter part of his life he devoted himself to photography and kindred processes.

Hang-Chow, häng'chow, China, the capital of the province of Che-kiang, on a plain at the southern terminus of the Imperial Canal, and within two miles of the head of the estuary of the Tsien-tang River, about 40 or 50 miles from its mouth, nearly 100 miles southwest of Shanghai. It is a strongly fortified city of oblong form, surrounded with high well-built walls about eight miles in circuit, enclosing many large vacant spaces. The streets are well paved and clean, and there are numerous triumphal arches, monuments to great men, and gorgeous Buddhist temples. The stores and warehouses are noted for their size and the quantity and quality of the goods displayed. More than 100,000 persons are employed in silk manufactures, and among other industries are the weaving of cotton, manufacture of tapestries, carving in ivory, the making of lacquered ware, fans and screens, etc. The houses generally are one story high. A large portion of the inhabitants reside in the suburbs, and in boats on the waters around them. The governor-general of Che-kiang and Fe-kien resides in this city, and also the governor of the province. With their courts and troops, in addition to the great trade passing through, and its activity as a centre of literary and ecclesiastical life, Hang-Chow is one of the most important and richest cities in China. The river, opposite the city, is about four miles broad at high-water, and is crowded with vessels of all descriptions, being the channel by which vast quantities of merchandise are received from and exported to the southern provinces. The extensive Lake of Si-hou, "West Lake," close by the city, is celebrated for its natural and artificial beauties. Chapu, the seaport of Hang-Chow, is 20 miles down the river. Hang-Chow is the celebrated "Kinsai" of Marco Polo—the capital, in his time, of Southern China. It was captured by the Taiping rebels in 1861, and deserted by all its rich or respect-

able inhabitants. A disciplined force of Chinese, under the command of French officers, united with the Imperialist troops, recaptured the city on 31 March 1864. By the Treaty of Shimonoseki (1895) it was opened to foreign trade, and a district platted for a foreign settlement. Pop. estimated at 700,000.

Hanging, a form of capital punishment inflicted under the common law; also a mode of death sometimes lawlessly visited upon a person, or occurring from accident, or by suicide. In cases of hanging, death seldom results from pure asphyxia, but is usually in some degree owing to apoplexy and injury to the spinal cord. In attempted suicide, bleeding from the jugular vein and artificial respiration may be tried for resuscitation. In difficulty of inducing artificial respiration, laryngotomy and tracheotomy should be performed, and the lungs inflated through the opening in the neck. In judicial hanging, the noose ought to be so adjusted as to produce immediate dislocation of the spinal column, death in that case being instantaneous. In New York State electrocution as capital punishment is substituted for death by hanging, and it has to some extent been tried in other States. (See ELECTRICITY, CAUSE OF DEATH BY.) In several American States infliction of the death penalty is forbidden by law. Hanging, drawing, and quartering were once the punishment of treason in England. See CAPITAL PUNISHMENT.

Hanging Rock, Battle of, fought 6 Aug. 1780. It occurred on Hanging Rock Creek, S. C., between Col. Sumter's Americans, some 800 in number, and about as many Loyalists commanded by Maj. Carden. After driving back the Loyalists, the Americans, becoming disorganized while plundering the enemy's camp, were in turn put to flight. The American loss is unknown; that of the Loyalists, in killed, wounded, and missing, is recorded as 269. Consult Lossing, 'Field-Book of the American Revolution.'

Hankow, hän-kow' ("Mouth of the Han"), China, a town and river-port in the province of Hu-peh, at the junction of the Han with the Yang-tse-kiang, 688 miles above the mouth of the Yang-tse, which is navigable for large vessels up to the town. On the opposite bank of the Han is Hanyang, on the other side of the Yang-tse is Wuchang, the three together forming one immense city. In addition there is a large floating population, the Han being densely crowded with junks for about half a mile above its mouth. In 1857 the city was almost totally destroyed by the Taipings. The port was opened to foreign trade by the Treaty of Tientsin, ratified in 1860; and soon became the chief emporium for the tea trade of the central provinces. A concession of about 90 acres of land apart from Chinese jurisdiction is laid out like an English town. The residents of the British concession are formed into a municipality, with a council empowered to levy taxes. There are also German, French, and Russian settlements. The foreign trade of this port is one of the most important in China. The imports are brought almost exclusively from Chinese ports (about one half from Shanghai), and consist partly of foreign produce, such as cottons, woolens, and opium; partly of native produce, such as tea, silk, cotton, etc. Pop. about 850,000.

Han'na, Marcus Alonzo, American politician: b. New Lisbon, O., 24 Sept. 1837; d. 15 Feb. 1904. In 1852 his family moved to Cleveland, where he was educated in the public schools and he also took a year's course of study in Western Reserve University. He left college to enter the grocery trade with his father, and later had entire control of the business. In 1867 he became a partner with his father-in-law in the firm of Rhodes & Co., engaged in handling coal and iron; he soon mastered the details of the business, greatly extended the work of his firm, and was the first to build steel steamships for the lake trade. In 1877 he became the controlling partner of the firm, the name of which was changed to M. A. Hanna & Co., and acquired large interests in lake navigation. He also was for a time manager of a theatre, and president of the Union National Bank of Cleveland, and of the Cleveland City Railway Co. In 1880 he organized a business men's political club, and from that time was active in politics. In 1884 he was sent as a delegate to the Republican National Convention, and in the next convention (1888) was John Sherman's political manager. He first gained a national reputation, when he obtained the nomination of McKinley for President at the Convention of 1896, and as chairman of the Republican national committee, conducted the Presidential campaign, which resulted in a large plurality for McKinley. In this campaign he adopted the methods which had made him successful in business, studying the situation and its needs, and carefully attending to details. In 1897 he was appointed United States Senator to succeed Sherman, who resigned before the completion of his term of six years. In 1898 he was elected to a full term, and in 1904 re-elected, but died before taking his seat. In 1900 he again conducted the Presidential campaign. As a large employer of labor, Senator Hanna had a number of questions to settle with his own employees, and as a rule won their respect and confidence by his fairness and willingness to listen to their claims. He was a firm believer in arbitration between labor and capital, and was active in the organization, in 1901, of the National Civic Federation, a non-partisan organization formed to consider such topics as trusts, tariffs, taxation, etc., becoming its president, and a member of a permanent committee appointed to consider and settle labor disputes.

Han'nay, James, Canadian historian and journalist: b. Richibucto, N. B., 22 April 1842. After many years of editorial work upon influential Canadian journals, he was chief editorial writer on the Brooklyn, N. Y., *Daily Eagle* (1885–7), and editor of the St. John, N. B., *Daily Gazette* (1888–92), and St. John *Daily Telegraph* (1892–1900). Since 1902 he has been official reporter of the New Brunswick Provincial Parliament. Besides reports of the New Brunswick Supreme Court, he has published 'Nine Years a Captive' (1875); 'History of Acadia' (1879); 'The History of the Loyalists' (1893); 'The Story of the Queen's Rangers in the American Revolution' (1883); 'Life and Times of Sir Leonard Tilley' (q.v.) (1897); 'The History of the War of 1812'; 'New Brunswick: its Resources and Advantages' (1902).

Han'nibal, Carthaginian soldier: b. 247 B.C.; d. probably 183 B.C. He was the son of Hamilcar Barca (q.v.) and at the age of nine his father made him swear at the altar eternal hatred to the Romans. He was a witness of his father's achievements in Spain; but Hamilcar having fallen in battle in Lusitania, in 228 B.C., and his son-in-law Hasdrubal having been appointed to succeed him, Hannibal returned home. At 22 he returned to the army at the request of Hasdrubal. The soldiers perceived in him the spirit of Hamilcar, and in three campaigns his talents and his courage were so conspicuous that the army, on the murder of Hasdrubal in 221, conferred on him the chief command by acclamation. In 219 B.C. he laid siege to Saguntum, a town which had concluded an alliance with Rome. In eight months Saguntum fell. The Romans, alarmed by this, sent ambassadors to Carthage to demand that Hannibal should be delivered up. The demand being refused, they declared war. Hannibal raised a powerful force, and conceived the design of attacking the Romans in Italy. After providing for the security of Africa, and having left his brother Hasdrubal with an army in Spain, he began his march with 90,000 foot-soldiers, forty elephants, and 12,000 horsemen, traversed Gaul in the depth of winter with incredible rapidity, and reached the foot of the Alps. In nine days he crossed these mountains, probably by the pass leading over the Little St. Bernard. The conquest of the Taurinians and the capture of their chief city encouraged the people of Cisalpine Gaul to join him. These auxiliaries would have been still more numerous had not Publius Scipio approached at the head of a Roman army, which had landed at Pisa. On the banks of the Ticinus the armies engaged, and a charge of the Numidian horse left Hannibal master of the field (218 B.C.) Scipio avoided a second battle, and retreated beyond the Trebia, leaving the strong town of Clastidium in the enemy's hands. Meanwhile Sempronius arrived with a second army, but Hannibal soon provoked his impetuous adversary to an engagement, disposed an ambuscade near the Trebia, and surrounded and destroyed the Roman forces. The Romans lost their camp and 26,000 men. Hannibal now retired to winter quarters among his allies in Cisalpine Gaul; and at the opening of the next campaign (217) found two new armies awaiting his approach in the passes of the Apennines. He determined to engage them separately, and destroy Flaminius before the arrival of his colleague. He deceived him, therefore, by feigned marches, crossed the Apennines, and traversed the Clusian marsh. He then employed every means to compel Flaminius to a battle. He wasted the whole country; feigned a march to Rome; but suddenly formed an ambush in a narrow pass surrounded by almost inaccessible rocks. Flaminius, who followed him, was immediately attacked. A bloody engagement took place near the Lake Trasimenus. Assailed on every side, the Roman legions were cut in pieces. Hannibal now armed his soldiers in the Roman manner, and marched into Apulia, spreading terror wherever he approached. Rome, in consternation, entrusted her safety to Fabius Maximus, the dictator, who determined to exhaust by delay the strength of the Carthaginians. He attacked Hannibal with his own weapons, and hung upon him everywhere without attempting to overtake him, convinced that the Carthaginians could not long hold a desolated territory. Hannibal marched into the plains of Capua, with the design of separating the terrified cities from their alliance with the Romans, and drawing down Fabius from the mountains. But suddenly he found himself in the same toils in which Flaminius had perished. Shut up between the rocks of Formiæ, the sands of Liternum, and impassable marshes, he was indebted for his safety to a stratagem. Having collected a thousand oxen, and fastened burning torches to their horns, he drove the animals at midnight into the defiles guarded by the Romans. Panic-struck at the terrible sight, the Romans abandoned the heights, and Hannibal forced his way through their ranks. Minutius Felix, master of the horse, was then made colleague of Fabius in the dictatorship. Eager for combat, he fell into an ambush at Geronium, and would have perished but for the aid of Fabius. After this campaign the other Roman generals seemed unwilling to trust anything to chance, and imitated the delay of Fabius. Hannibal saw his army slowly wasting away, when the new consul Terentius Varro, an inexperienced and presumptuous man, took the command of the legions. Hannibal had occupied Cannæ, and reduced the Romans to the necessity of risking an engagement (216), Æmilius Paulus, the colleague of Varro, wished to put off the battle, but Varro chose the day of his command, and directed the attack. The Roman army was destroyed, and Hannibal now marched to Capua, which immediately opened its gates. In 215 Hannibal sustained, at the hands of Marcellus, a repulse before Nola — the first check which he had received in the open field — but in 212 B.C. made an important acquisition in the capture of Tarentum. Capua, however, was invested by two consular armies, and was on the point of surrendering. Hannibal marched to Rome, and encamped in sight of the capitol, 211 B.C.; but the Romans were not thus to be discouraged; Capua fell. This success gave the Romans a decided superiority, and nearly all the people of Italy declared in their favor. Held in check by the consul, Claudius Nero, Hannibal could not effect a union with his brother Hasdrubal, who had set out from Spain with reinforcements, but after having passed the Apennines was attacked and defeated by Nero on the Metaurus in 207. Hasdrubal himself fell, and his bloody head was thrown into the camp of Hannibal. The latter then retired to Bruttium, where, surrounded with difficulties, he yet maintained the contest with inferior forces against victorious armies. But Scipio now carried the war into Africa, and Hannibal was recalled to defend his country. He reluctantly embarked his troops, and in 203 left the country which for 16 years he had held in spite of all the efforts of Rome. He landed at Leptis, gained over a part of the Numidians, and encamped at Adrumetum. Scipio took several cities, and reduced the inhabitants to slavery. Pressed by his countrymen to come to a decisive engagement, Hannibal met Scipio at Zama, and was defeated with 20,000 loss. Peace was concluded in 201 B.C. Hannibal, accused by his enemies of stirring up Antiochus the Great to war against the Romans, went to Ephesus, to the court of Antiochus. In the ensuing struggle with Rome, Antiochus was signally defeated, and obliged to

conclude a peace, one of the terms of which was that Hannibal should be delivered up. Hannibal, again obliged to flee, went to the court of Prusias, king of Bithynia. Prusias, to whom the senate had sent ambassadors to demand the person of Hannibal, was on the point of complying with the requisition, when Hannibal prevented the disgrace by swallowing poison, which he always carried about in his ring.

Hannibal, Mo., city in Marion County, on the Mississippi River, and on the Missouri, K. & T., the Chicago, B. & Q., the Wabash, and the Saint Louis, K. & N. W. R.R.'s: about 90 miles northwest of St. Louis and 15 miles south of Quincy, Ill. Hannibal was settled in 1819 and incorporated in 1839. It is situated in an agricultural region. The chief manufactures are foundry and machine-shop products, flour, lumber, cigars, lime, cement, stoves, car-wheels, shoes, and furniture. It is an important trade centre, as it has the advantages of several railroads and steamboat connection with the cities and towns on the Mississippi. A steel bridge for railroad cars and wagons crosses the river from Hannibal to East Hannibal, Ill. The trade is principally in tobacco, lumber, flour, potatoes, ready-made clothing, dairy products, and the city manufactures. It has a free circulating library, public and parish high schools, the Douglas colored high school, and a number of fine public buildings. The city charter of 1845, revised in 1873, provides for the annual election, by the people, of a mayor and a certain number of the members of the school board. The officials of the administrative departments are under the control of the mayor. The electric-light plant is owned and controlled by the city. Pop. (1900) 12,780.

Hanno, hăn'ō, or **Anno**, German mediæval prelate: b. not earlier than 1000; d. Siegberg, near Bonn, 1075. The emperor, Henry III., made him his chancellor, and presented him to the archbishopric of Cologne, to which he was consecrated in 1056. After the death of Henry III., Hanno made himself master of the person of Henry III.'s young son Henry IV., and secured for himself the administration of the empire (1062). His energetic government and his holy life, his paternal care for his see, his zealous reformation of monasteries and foundation of churches, gained him the character of a saint. The hymn in his praise is by some thought to have been written soon after his death; by others about 1183. It is one of the most important monuments of the early German national literature. The best version of it is to be found in Müllenhoff and Scherer's 'Denkmäler deutscher Poesie und Prosa' (1864).

Hanotaux, Albert Auguste Gabriel, äl-bār ō-güst gä-brē-ĕl ä-nō-tō, French politician: b. Beaurevoir, Aisne, 18 Nov. 1853. He chose for himself the profession of the law, took a scientific course in the Ecole des Chartes, and afterward became a teacher in the Ecole des Hautes Etudes. In 1879 he received an appointment in the French foreign office; in 1881 became a member of the cabinet, and was sent to Constantinople as ambassador in 1885. From 1886 to 1889 he was republican deputy; and in May 1894 received a portfolio in the second Dupuy cabinet. He has published: 'Les Villes Retrouvées' (1880); 'Origines de l'Institution des Intendants des Provinces' (1884); 'Henri Martin, Sa Vie, Ses Œuvres, Son Temps' (1885); 'Etudes Historiques sur le XVIe. et le XVIIe. Siècle en France' (1886); 'Histoire du Cardinal de Richelieu' (1893).

Han'over, Germany, the northwesternmost province of Prussia, prior to 1866 an independent kingdom. It borders on the North Sea, and has an area of 14,870 square miles. In the south the Harz mountains attain an altitude of over 3,000 feet; the rest of the country is an alluvial plain with a gentle slope to the sea. The Elbe on the northeast boundary, the Ems, and the Weser, with its tributaries, the Leine and Aller, are the principal rivers. Coal and lignite, rock salt, iron, copper, zinc, silver, and gold, are found in the mountainous districts, and there are large peat beds in the north. Over one fourth of the area is arable land, producing large quantities of grain and flax. The keeping of bees is generally practised on the moors, and a breed of superior cattle is raised along the marshy coast land. Forests of hardwood and pine, extensively used in smelting, occupy one sixth of the surface. The manufactures are extensive, and include iron goods, machinery, woolens, linens, cottons, leather, paper, beet-root sugar, beer, spirits, and numerous domestic commodities. Hanover has over 1,500 miles of railroads, numerous canals, and an extensive traffic is carried on at its several ports, among which are Geestemünde, Emden, and Harburg, although practically its chief port is the free city and port of Bremen (q.v.). The capital is Hanover (q.v.). For administrative purposes, the province is divided into the six districts of Hanover, Hildesheim, Lüneburg, Stade, Osnabrück and Aurich. The highest court is in Celle. The province sends 36 members to the Prussian Chamber of Deputies, 10 to the Upper House, and 10 to the German Reichstag. Education is compulsory and free: chief of the higher institutions of learning is Göttingen University. The majority of the inhabitants are Lutheran Protestants. Roman Catholics inhabiting Hildesheim and Osnabrück constitute about one seventh of the population. Hanover was long connected with the Brunswick family, a scion of which, Ernest Augustus, in 1692, became the first Elector of Hanover. He married the daughter of the Elector Palatine, granddaughter of James I., and niece of Charles I. of England. He was succeeded in 1698 by his son George Louis, who in accordance with the Act of Settlement (q.v.), became George I., king of England, at the death of Queen Anne in 1714. The connection with England continued during four reigns, and in 1814 the Congress of Vienna raised Hanover to the rank of a kingdom, George IV. and William IV. thus being kings of Great Britain and of Hanover. On the accession of Queen Victoria, however, by the Salic law, the Hanoverian crown passed to the nearest male heir, Ernest Augustus, Duke of Cumberland, and at his death in 1851 to his son George V. In 1866 Hanover sided with Austria in the Austro-Prussian contest; the capital was occupied by Prussian troops; the king lost his throne, his estates were sequestrated, and Hanover was annexed to the Prussian dominions. Pop (1900) 2,590,336.

Hanover, Mass. (1) Village in the town of Hanover in Plymouth County; on a branch of the New York, N. H. & H. railroad; about

10 miles east by north from Brockton and 25 miles southeast of Boston. It is the seat of Hanover Academy. It is situated in an agricultural region, and the chief industries are connected with agricultural products. Its chief manufactures are tacks and nails. (2) The town of Hanover contains several villages, and the chief manufactures are shoes, nails, tacks, and dairy products. Pop. of the village is about 420; of the town 2,200.

Hanover, N. H., town in Grafton County; on the Connecticut River, and on the Boston & M. railroad, about 72 miles northwest of Concord. It is situated in an agricultural region and its industries are connected chiefly with farm products and lumbering. It is a summer resort, but is known principally as a college town, being the seat of Dartmouth College (q.v.). It contains also the Mary Hitchcock Memorial Hospital. Pop. (1900) 1,884.

Hanover, Pa., borough in York County; on the Western Maryland and the Pennsylvania R.R.'s; about 32 miles south of Harrisburg. It was settled about 1729 and incorporated in 1813. It is in a rich agricultural section of the State, and nearby are iron-ore mines. The chief manufactures are shoes, machine-shop products, cigars, carriages and wagons, gloves, and leather. Hanover is the commercial centre of a considerable part of York County; the trade is largely in agricultural and dairy products, the manufactures of the borough, and in live stock. The government is vested in a burgess and borough council. Pop. (1890) 3,746; (1900) 5,302.

Hanover, Prussia, the capital of a province, and formerly of the kingdom of Hanover, in an extensive plain northeast of and dominated by Mount Linden, at the confluence of the Ihme with the Leine, 44 miles by rail west by north of Brunswick. It consists of an old town, intersected by the Leine, and of various modern suburbs. The old town is unattractive, but the new quarters are regular and well built. The principal features are the Markt church, of antique appearance; the Kreuz church; Schloss church, a handsome structure, with an altar-piece by Cranach, and some curious relics collected by Henry the Lion; several handsome modern churches; the palace (1636–40, rebuilt since 1817), now a royal Prussian residence; the former palace of King Ernest Augustus (in government occupancy); the royal library; the museum of art and science; the restored townhouse (1439–55); the new town-house (formerly palace of George V.); the Kestner museum of antiquities; the provincial assembly house; the Franco-German war monument; the Waterloo monument; various schools, among which is the technical high-school, a remodeled building of great extent, formerly the Welfenschloss (palace of the Guelfs), and the Schloss-Herrenhausen, formerly a royal residence. Trade and industries are important, the latter including railway works, machinery, iron castings, cotton, linen, tobacco, lacquered wares, lamps, glass, chemicals, etc.; breweries and distilleries. The city has electric street railroads.

Hanover is first mentioned in 1163. It joined the Hanseatic League in 1481, and received the Reformation in 1533. It became the residence of the Dukes of Brunswick-Lüneburg, and the capital of the principality in 1636. In 1866 the kingdom was absorbed by Prussia, and since 1890 the city has held the position of a royal residence and capital. Sir William Herschel, the two Schlegels, and Iffland were born here. Pop. (1900) 235,649, with suburbs, 302,054.

Hanover, Pa., Cavalry Action at. During the Gettysburg campaign Gen. Stuart, commanding the Confederate cavalry, was ordered by Gen. Lee to observe the movements of the Army of the Potomac and harass its rear should it attempt to follow the Confederate army and pass into Maryland. Leaving two brigades south of the Potomac, to guard the passes of the Blue Ridge, Stuart, with the rest of his command, crossed the Potomac at Seneca Creek, 20 miles north of Washington, on the night of 27 June 1863 and, learning that Hooker had crossed the river, marched north by way of Rockville, captured a train of 125 wagons and 400 prisoners between Rockville and Washington, struck the Baltimore & Ohio Railroad at Sykesville and Hood's Mills, and, ascertaining that the Union army was marching from Frederick northward, endeavored to get ahead of it, reaching Westminster at 5 P.M. of the 29th, where he struck a squadron of the First Delaware cavalry, which offered a stubborn resistance, but was finally dispersed, and Stuart, continuing his march, bivouacked at Union Mills, about midway between Westminster and Littlestown. Hearing that Union cavalry was at Littlestown, and that Early was on the Susquehanna, he marched by crossroads for Hanover, on the morning of the 30th and, at 10 o'clock, his head of column reached that place, 16 miles east of Gettysburg, and attacked the rear and flank of Kilpatrick's cavalry division, as it was passing through the town from Frederick and Littlestown, in advance of Meade's central column. His first attack threw the rear of Farnsworth's brigade into confusion, but Farnsworth rallied his men, Custer's brigade was recalled and thrown into action and, after two hours' fighting in and around the town, Stuart was driven back on the Littlestown road, having lost nearly 100 men. Kilpatrick reports his own loss as 59 killed and wounded, and 123 missing.

Stuart was now in a perilous position; he had thrust himself unwittingly between Kilpatrick's cavalry and Meade's main body; Gregg's cavalry division was moving north on his right, but he extricated himself by marching all night over a circuitous route through Jefferson to join Early at York. The latter, however, was on his way to Gettysburg, and Stuart passed almost within sight of him, without knowing it. Finding that Early was not at York, Stuart continued his march to Carlisle, hoping to find Lee's main body there, but found the place occupied by Union troops, and heard that Lee was concentrating at Gettysburg, where by marching night and day, he joined him in the afternoon of 2 July. See GETTYSBURG, CAMPAIGN AND BATTLE OF.

E. A. CARMAN.

Hanover College, at Hanover, Ind.; founded in 1828, under the auspices of the Presbyterian Church, as Hanover Academy. It was chartered as a college in 1833. Women have been admitted since 1880. The regular departments are letters, arts, science, law, philosophy, and divinity; also a course for teachers. No charges are made for tuition. In 1903 the college

reported 14 instructors, 160 students, and about 17,000 volumes in the library. The endowment fund is over $200,000, and the annual income is about $15,000.

Hanover Court House, Engagement Near. On 21 May 1862 Gen. McClellan had marched the Army of the Potomac up the York peninsula to the banks of the Chickahominy, 7 to 12 miles distant from Richmond. On the 26th he heard that R. H. Anderson's Confederate brigade and Stuart's cavalry were near Fredericksburg, and that another body, Branch's brigade, was in the vicinity of Hanover Court House, 17 miles north of Richmond, to his right and rear. These bodies threatened his communications, and were in position to reinforce Jackson, in the Shenandoah valley, or to oppose McDowell, whose advance was then eight miles south of Fredericksburg. Gen. Fitz-John Porter was ordered to clear the enemy from these positions and destroy the bridges over the South Anna and Pamunkey rivers. Warren's small brigade had been already detailed to destroy the bridges, had destroyed all means of communication over the Pamunkey as far as Hanover Court House, and was then posted at Old Church. On the morning of the 27th Warren moved toward the court house, on a road running parallel to the Pamunkey. Porter left New Bridge at 7 A.M. with Morell's division and Emory's cavalry brigade and, marching by way of Mechanicsville northward toward the court-house, about noon his cavalry and the Twenty-fifth New York infantry, encountered a portion of Branch's brigade, supporting two pieces of artillery, attempting to hold the road leading to the court-house. A Union battery was brought up and Butterfield's brigade deployed, which charged and drove the Confederates from the field, capturing one gun. A part of the Twenty-fifth New York was captured by the Confederates. Supposing that the Confederates had all retreated in the direction of Hanover Court House, Porter pursued, the cavalry, under Emory, and the Seventeenth New York, overtaking and capturing a large number of the Twenty-eighth North Carolina. Upon nearing the junction of the Ashland and the Court House roads, a part of Martindale's brigade was sent toward Ashland to guard that flank against an approach from Richmond and to destroy the railroad running to that city. Near Peake's station Martindale ran into Branch's brigade, was immediately attacked, and was driven back some distance. When Porter, whose advance had reached Hanover Court House, heard that Martindale had been attacked, he faced about his entire column, reached Martindale, struck Branch on his left and rear, and routed him. Branch retreated to Ashland and formed a junction with Anderson's brigade, which had fallen back from McDowell's front. After destroying the railroad in several places and opening the way for McDowell's advance from Fredericksburg, Porter returned to his old camps on the night of the 29th. The Union loss in the engagement of the 27th, was 62 killed, 223 wounded, and 70 missing. The Confederate loss was 73 killed, 192 wounded, and 730 prisoners, of whom about 150 were also wounded. E. A. CARMAN.

Hanover, Treaty of, an alliance between England, France, and Prussia, made in September 1725, for the purpose of mutual assistance, in opposition to that between Austria and Spain.

Hansa, or **Hanse.** See HANSEATIC LEAGUE.

Hanseatic (hăn-sē-at'ĭk) **League, Hansa,** or **Hanse,** a confederacy of certain cities of northern Germany for mutual protection, especially in matters of commerce; for the extension of trade, and of rights and immunities received from sovereigns, and which had suffered curtailment. The union was formed in the 13th century, at a time when sea and land swarmed with pirates and robbers, and German trade, no longer guarded by the privileges of armed attendants, was exposed to many dangers, while government had degenerated into a power for extorting taxes without giving protection.

The first alliances known to have been concluded are those between Hamburg and Lübeck (1241 and 1255) to keep open the road across Holstein connecting the North Sea with the Baltic, and between Lübeck, Rostock, and Weimar in 1259 for defending themselves against the pirates. About the same time a similar league was concluded between the Westphalian towns, Münster, Dortmund, Soest, and Lippstadt. When a wider union came to be formed for like purposes, the name of *Hansa,* signifying a league, which was at first applied to any such confederacy, survived exclusively as the name of that influential league. During its most flourishing period it embraced 90 towns, scattered over the whole length and breadth of Germany, including Holland. Its organization was very loose, the towns of which it was made up being at first divided into three and, after the 16th century, into four provinces, each with a chief town. These divisions had, however, little more than a geographical significance. The town of Lübeck, which already held an important rank, from the fact that it was the highest court of appeal for all those towns which were governed by the Lübeck law, was recognized as the chief town of the league. Here assembled the deputies of the other Hanse towns to deliberate on the affairs of the confederacy; the decrees of the diet had no effect unless they received the sanction of the separate towns.

In the 14th century the league everywhere attained a high political importance, and gave rise to the development of that commercial policy which has since become intimately connected with all political relations, but of which the sovereigns of that time had little idea. Kings and princes were, in reality, more dependent on the league than it was on them. The extensive carrying trade of the Hanseatic League was a great source of wealth and at length there was no mart in Europe which was not gradually drawn within the circle of its influence. England, Denmark, and Flanders concluded treaties with the league for the extension of their commerce. It undertook to provide for the security of commerce on the Baltic and North seas. In the country under its immediate influence it constructed canals, and introduced a uniform system of weights and measures.

But the prosperity of the Hanse towns was naturally dependent on the continuance of the circumstances which gave rise to it, and when circumstances changed, the league was destined to decline. When the routes by land and sea were no longer insecure; when princes learned the advantages of trade to their own states, and turned their attention to the formation of a naval force of their own, and the encouragement of navigation; when the inland members of the confederation perceived that the great seaport towns had a separate interest of their own, and used them principally to promote their own ends; then the dissolution of the Hanseatic League was evidently approaching. There remained at last as active members of it only Hamburg, Lüneburg, Lübeck, and the towns in the neighborhood (Wismar, Rostock, Greifswald, Stralsund, whose interests were identified with those of Lübeck. The league existed no longer as a political power, but merely as a loose association of towns for commercial purposes.

In England, during the reign of Queen Elizabeth, the league lost its privileges by its refusal to grant complete reciprocity. About 1614 there remained only 14 towns which contributed to the support of the league, and had a voice in the management of its affairs. These were: Lübeck, Wismar, Rostock, Stralsund, Greifswald, Stettin, Danzig, Magdeburg, Brunswick, Hildesheim, Lüneburg, Hamburg, Bremen, and Cologne. The Thirty Years' war, which destroyed the prosperity of the German towns generally, gave the death-blow to the league. At the diet of 1629 it was entrusted to the cities of Lübeck, Bremen, and Hamburg to consult for its general interests, and in 1630 these towns concluded among themselves a closer union, which was renewed in 1641. After the Peace of Westphalia (1648) repeated but vain attempts were made to bring the league together again, and a last diet was held in 1669. Hamburg, Lübeck, and Bremen still retain their independence, and now form separate constituents of the German empire.

Hansen, hän'sĕn, **Gerhard Henrik Armauer,** Norwegian physician: b. Bergen, Norway, 1841. He was educated during boyhood in the cathedral schools of his native city, afterward entered upon the study of medicine, and was eventually appointed resident physician in the Rigs Hospital of Christiania. He was afterward government medical officer for the Lofoten fisheries, but did not reach the field of his fame until he was appointed in 1868 to the post of assistant physician at the Bergen Leper Hospital. From this time forth he devoted himself to the study of leprosy, and following the lines laid down by Virchow, traveled from one to another university of Europe, continuing his investigations. On his return to Norway the Medical Society of Christiania voted a sum of money to pay the expenses of his further researches. He at last was enabled to demonstrate the fact that leprosy was contagious. Continuing his investigations he discovered at last the leprosy bacillus in unstained preparations. Later it was stained and became known as Hansen's bacillus (1873). He was not successful in employing the bacillus for purposes of inoculation with a preventive object; but on the basis of his contagion theory, legislation has been enabled to check to a considerable extent the spread of the disease.

Hansom, or Hansom Cab. See CARRIAGE.

Han'son, Alexander Coutee, American journalist and politician: b. Maryland 1786; d. 1819. After being graduated at St. John's College, Annapolis, he adopted journalism as a profession, and in 1812 his office was wrecked by a mob on account of an article attacking the Madison Administration which appeared in the 'Federal Republican,' of which he was editor. He was elected to the lower house of Congress in 1813, and from 1817 until his death had a seat in the Senate.

Hanus, Paul Henry, American educator: b. Hermsdorf-unter-dem-Kynast, Prussia, 14 March 1855. He came to the United States in childhood, was educated at the University of Michigan and has been professor of the history and art of teaching at Harvard from 1891. He has published 'Elements of •Determinants' (1886); 'Geometry in the Public School' (1893); 'Contemporary Educational Problems' (1899).

Hap'good, Isabella Florence, American author and translator: b. Boston, Mass., 21 Nov. 1851. She has written 'The Epic Songs of Russia'; 'Russian Rambles,' etc., and is widely known by her translations from the Russian of Tolstoy, Gogol, etc., and she has also made important translations from the French and Spanish.

Hapgood, Norman, American journalist: b. Chicago 28 March 1868. He was graduated from Harvard in 1890, and the Harvard Law School in 1893, and has since become well known as a keen, discriminating essayist and dramatic critic. He has published 'Literary Statesmen and Others' (1897); 'Daniel Webster' (1899); 'Abraham Lincoln' (1899); 'The Stage in America' (1901).

Hapsburg, hăps'bĕrg (Ger. häps'boorg) (properly HABSBURG), the imperial house of Austria-Hungary, so named from the ancestral castle, in the canton of Aargau, Switzerland, on the right bank of the Aar. The castle was built in the 11th century by Bishop Werner, a descendant of Ethico I., a count of Alemannia, in the 7th century. It stands on the Wüpelsberg, a steep rocky situation, whence the name *Habichtsburg* (Hawk's Castle). The proprietors of Hapsburg became at a later period counts of Hapsburg and gradually extended their territories. Werner II., who died in 1096, is said to have been the first to assume the title. After the death, about 1232, of Rudolph II., the fourth in succession from Werner II., the family divided into two branches, the founder of one of which was Albert IV., and that of the other Rudolph III. The latter is known as the Hapsburg-Lauffenburg line, which became extinct in the direct male line in 1408. A younger son of Rudolph, called Eberhard, founded the Kyburg branch of the Hapsburg-Lauffenburg line, which did not become extinct till 1415, and Godfrey, a grandson of Rudolph, who settled in England in the 13th century, there became the founder of the Fielding family, to which the Earls of Denbigh belong, and of which the novelist Fielding was a member. The line descended from Albert IV. is that to which the historical celeb-

rity of the house is almost entirely due. In 1273 Rudolph, the son of Albert IV., was chosen emperor of Germany or Holy Roman Emperor. He is the founder of the reigning house of Austria, which is of the line of Hapsburg-Lorraine. From Rudolph to Charles VI. the Austrian monarchs were of the Hapsburg male line. Maria Theresa, who succeeded Charles VI., married Francis Stephen of Lorraine, who in 1745 was chosen Emperor of Germany. Francis II., the third emperor of Germany of the line of Hapsburg-Lorraine, was the last who bore that title till the establishment of the new empire, the last of the so-called "Holy Roman Emperors." He changed it in 1806 for that of Emperor of Austria, and the present imperial house of Austria continues to represent that line. From the Emperor Rudolph was also descended a Spanish dynasty which began with the Emperor Charles V. (Charles I. of Spain), and terminated with Charles II. in 1700.

Haraforas, or **Alfures,** names applied in Celebes, the Moluccas, Mindinao, and the adjacent islands to certain native tribes, particularly of the interior, which differ from the Malays, and have been thought to be perhaps pre-Malayan aborigines.

Hara-kiri, hăr'a-kĭr'ē, or **Seppuku,** a mode of inflicting death upon themselves allowed in Japan to criminals of the Samurai or two-sworded class as more honorable than public execution. It consists in cutting open the body so as to disembowel it, by means of a wound made with one sword perpendicularly down the front and another with the other sword horizontally. Till recent times Japanese of the two-sworded class who had been guilty of any crime frequently resorted to this mode of killing themselves before their guilt had been proved, and it was regarded as honorable in them to do so, indicating a strong sense of shame. Sometimes they were commanded to put themselves to death in this manner. Consult: Mitford, 'Tales of Old Japan' (3d ed. 1876); and Chamberlain, 'Things Japanese' (1891).

Harald. See HAROLD.

Haran (Assyrian *Kharranu,* road), the name of a district of northern Mesopotamia and of a town situated therein, on the stream called Jullab, southeast of Edessa. The name is probably derived from the fact that at this town the trade-routes from Media, Assyria, and Babylonia met to proceed along the same highway to the coast of Cilicia. Haran is mentioned in the Old Testament in Gen. xi. 31–32, and Ezekiel xxvii. 23. To the Assyrians it was a strategic post of great importance. In the inscriptions references to it appear as early as the reign of Tiglath-pileser I. (about 1100 B.C.). An extensive commerce centred here. To the Greeks and Romans it was known as Carræ (Gk. κάρραι or Χάρα). Crassus, the Roman commander, was here defeated and slain by the Parthians during his eastern expedition (53 B.C.), and Caracalla assassinated by the soldiery of Macrinus (217 A.D.). It was of importance even in the time of Arab supremacy, but the geographer and historian Abulfeda (d. 1331) speaks of it as in ruins in his day. It was the seat of an episcopal see in the 4th century. Consult Metz, 'Geschichte der Stadt Harran' (1892).

Harar, or **Adari,** a Semitic dialect spoken in the Abyssinian province of Harar (q.v.). It includes some Hamitic words. For an account of it, consult an article by Prätorius in the 'Zeitschrift der Deutschen Morgenländischen Gesellschaft,' Vol. XXIII. (1869).

Harar, Harrar, or **Adari,** capital of the province of Harrar in eastern Abyssinia, south of the Gulf of Aden, about 180 miles from the coast. It is situated at an elevation of 5,500 feet above the level of the sea. The surrounding district is very fertile and produces chiefly coffee. Cotton is also a large crop, and excellent in quality. There is a brisk trade in gums, ivory, and fruits. Harar was formerly the capital of a small, independent country, ruled by an emir. In 1876 it became a dependency of Egypt, and later was under Italian protectorate. After the Italian defeat at Adowa in 1896, it passed with the province to Abyssinia. Its first European visitor was Sir Richard F. Burton, who obtained admission there as an Arab in 1855, and described it in his 'First Footsteps in East Africa, or An Exploration of Harar' (1856). Pop. (1900) 40,000. Consult further the 'Bulletin de l'Etat Major-Général de l'Armeé Egyptienne' (1876), and Paulitschke, 'Harar, Forschungsreise nach den Somal- und Gallaländern' (1888).

Harar, Harrari, or **Harrur,** the most easterly of the Abyssinian provinces; bounded on the east and north by British and French Somaliland, and on the south and southeast by British East Africa and Italian Somaliland. The country is a table-land, with a maximum elevation of nearly 11,000 feet. Previous to the insurrection of the Mad Mullah (q.v.) it was a part of the Egyptian Sudan. It was captured by Italy in 1891, but after the severe defeat of the Italian forces by the Abyssinians at Adowa 1 March 1896 it passed to Abyssinia. The foreign trade of Abyssinia is conducted largely through Harar.

Haraucourt, Edmond, French poet and novelist: b. Bourmont (Haute-Marne) 1857. His first work appeared in 1883 and was entitled 'La légende des sexes, poèms hysteriques.' A collection of his verses was published in 1891. He also published 'Amis' (1887); 'Shylock' (1889); 'Don Juan' (1894); 'Elizabeth' (1894). He was awarded the Academy prize for his poem 'Les Vikings' (1890).

Harbaugh, Henry, American clergyman of the German Reformed Church in America: b. near Waynesborough, Pa., 24 Oct. 1817; d. Mercersburg, Pa., 28 Dec. 1867. He studied at Franklin and Marshall College (Mercersburg) and at the Mercersburg Seminary, was ordained in 1843, and in 1843–64 held pastorates successively at Lewisburg, Lancaster, and Lebanon, Pa. In 1864 he was appointed professor of theology in the Mercersburg Seminary. He was one of the leading exponents of the "Mercersburg theology" (q.v.), and belonged to the high-church school of his denomination. From 1850 to 1866 he was editor of the 'Guardian,' and in 1866–7 of the Mercersburg 'Review.' Besides a collection of poems in the "Pennsylvania Dutch" dialect, he published: 'Heaven' (1843–53); a 'Life of Michael Schlatter' (1857); 'Christological Theology' (1864), and other works.

Harben, William Nathaniel, American novelist: b. Dalton, Ga., 5 July 1858. He has contributed many short stories to magazines, and his published novels include: 'White Marie' (1891); 'Almost Persuaded' (1890); 'A Mute Confessor' (1891); 'The Land of the Changing Sun' (1894); 'From Clue to Climax' (1896); 'The Caruthers Affair' (1898); 'The North Walk Mystery' (1899); 'The Woman Who Trusted' (1901); 'Westerfelt' (1901); 'Abner Daniel' (1902); 'The Substitute' (1903). He is also the author of 'Northern Georgia Sketches' (1900).

Harbin, Manchuria, a city on the Sungari River at the point where the Manchurian branch of the Trans-Siberian railway crosses that stream. The Chinese eastern branch of the railway, running to Dalny (Talienwan) (q.v.) and Port Arthur (q.v.) begins here. Prior to the Russian occupation in 1900 (see MANCHURIA), Harbin was a small Chinese village. On account of its geographical and strategical position it was chosen as a military centre, and very quickly it became also headquarters for railway and governmental affairs. Commerce and manufacture have also greatly developed, although not originally considered in the promotion of Harbin; and here more than elsewhere Russia gradually asserted its intention of becoming an active industrial force in the Orient. Every system of protection that could be devised has been employed by the government to advance its commercial prestige. Harbin consists of the old town, three miles distant from the central dépôt; Prestin, the river town, the present commercial portion; and the administration town, about the railway. Only Russians and Chinese are allowed to hold land, construct buildings, or enter any permanent enterprise. The territory for many miles surrounding has been secured so as to make it impossible for any foreign interest or influence to obtain a foothold or profit near to the city. The principal railway engineer is the chief administrative official. A census of 1903 showed a population of 60,000 exclusive of soldiery; of these all but 700 were Russians.

Harbor, a recess or inlet of the sea, a lake, or other large body of water, either landlocked or protected from winds and waves by artificial means, so as to be a secure haven for vessels in all weathers. In selecting or constructing a harbor regard is also had to convenience in loading and unloading vessels. The two chief classes are harbors of refuge and commercial harbors. Often the latter are merely tidal, only to be entered by vessels as the tide serves, and where with the tide they rise and fall. Harbors of refuge or shelter are accessible in all conditions of tide. Sometimes there is a combination of the harbor or haven with a capacious protected roadstead outside of it, as at Cherbourg, France, and other places.

Construction.—In the construction of harbors the great desiderata are sufficient depth of water and perfect security for the vessels likely to frequent them, together with the greatest possible facilities for ingress during any weather, while the chief obstacles to be surmounted are the action of the waves upon the protecting piers and breakwaters, and the formation of sand-banks and bars, which diminish the depth of water at the entrance and also within. All good harbors should possess the following characteristics: A deep, broad entrance-channel, which can be kept by ships of all kinds in all sorts of weather; an ample anchorage, free from rocks and shoals, with good holding-ground, and protected from winds and waves. Commercial harbors should also be supplied with adequate constructions and appliances for loading and discharging vessels.

Ground-plan.—In designing the ground-plan of harbors, some rules should be kept in view: (1) the entrance should always be kept seawards of the works of masonry, care being taken that the direction of the piers does not throw the sea across the entrance; (2) there should be a good "loose," or point of departure free of rocks or a lee shore; (3) spending-beaches inside should be provided to allow the waves that pass in to break and spend themselves (a harbor-basin surrounded with vertical quay-walls becomes a "boiling pot"), but this is a point frequently overlooked by engineers; (4) the relation of the width of entrance to the area of a harbor should be a matter of careful study, as upon this depends the tranquillity of the interior.

Anchorage.— The anchorage of a harbor should be large enough to afford shelter to the maximum number of vessels seeking it. The space required by a vessel at anchor is, roughly, a circle whose radius is six times the depth of water plus the vessel's length. First-class harbors should have a depth of at least 40 feet, to admit and give secure anchorage to the largest ships now existing. An available depth of 25 feet is sufficient for ordinary transatlantic freight and passenger steamers. Coasting vessels rarely have a draft of more than 20 feet.

Natural Harbors.—Some of the best known natural harbors are those of Queenstown, Ireland; Rio de Janeiro, Brazil; Portland, Me.; Boston, Mass.; Narragansett Bay, R. I.; New York, N. Y.; Old Point Comfort (Norfolk), Va.; Port Royal, S. C.; Havana, Cuba; San Francisco, Cal.; Puget Sound, Wash.; King George's Sound, and Princess Royal Harbor, in southwestern Australia.

Artificial Harbors.—These are as old as naval warfare, and may almost be said to date from the birth of commerce. The Phœnicians protected their little strip of the Levant coast. Tyre and Sidon were well provided with harbors, having effectual breakwaters, mainly built of loose rubble. Carthage, Greece, and Rome, each in its own way, utilized their harbors for commercial and warlike purposes. That of Carthage was artificial, those of Greece but slightly so, nature having provided so many navigable inlets that little remained to be done by man. The great harbors of Rome, constructed in the solid and workmanlike manner of her practical race, may still be studied with profit, for the coasts of Italy yet show how well the Romans understood both the principles and the practice of this branch of marine engineering. One of their finest and most complete constructions of this nature was the port of Ostia, at the mouth of the Tiber, now more than two miles inland. The Romans were distinguished in harbor-making by the open or

arched mole or enclosing work, which gave full play to the currents, preventing the deposit of sand or mud. "The foundations of Nero's port," says Addison, "are still to be seen. It was altogether artificial, and composed of huge moles running round it, in a kind of circular figure, except where the ships were to enter." Harbor-making came to an end with the decay of commerce and civilization consequent upon the fall of the empire, to be revived by the Italian republics of the Middle Ages. The rich traffic of Venice and Genoa soon led to the construction of suitable ports at those places, and the moles of the latter city and the works in the lagoons of Venice remain to this day. France was next in the field, embanking, protecting, and deepening the mouths of the rivers along her northwestern shores, as at Havre, Dieppe, Dunkirk, etc. In 1627, during the siege of Rochelle, Metezeau constructed jetties of loose rubblestone, to prevent access to the city.

British Harbors.— Great Britain, whose ocean commerce is of comparatively recent date, lagged far behind her Continental rivals. With few exceptions her ports were absolutely unprotected, or rather uncreated; and this state of things continued until late in the 18th century. Two of the few exceptions were Hartlepool, where a harbor was formed about 1250, and Arbroath in 1394; in the 17th century at Whitby and Scarborough rough piers were thrown out, protecting the mouth of the port; at Yarmouth a north jetty, and subsequently a south one, were formed; an ancient mole existed at Lyme Regis; but the chief efforts of the early English engineers were directed against the shoals and waves of Dover. When, however, John Smeaton (q.v.) rose to vindicate the engineering talent of England, things took a different turn, and now few countries surpass Great Britain in the number of artificially improved commercial harbors. In Great Britain the construction and regulation of harbors is primarily under authority of the crown, but Parliament now usually names commissioners and boards with powers of ownership or management specially conferred by that body. All individual owners are required to manage harbors subject to the rights of public use, while final government control of them is practically absolute.

Harbors in the United States.— In this country all harbor-making in a public sense has been done since the beginning of the 19th century. The date of its first undertaking is 1802, when the project of building public piers in Philadelphia received government aid by an appropriation of $30,000. Twenty years later, for a harbor of refuge in Delaware Bay, $22,700 was appropriated; and in 1826 appropriations aggregating about $150,000 were made for river and harbor improvements at many places. From this time river and harbor bills have steadily increased the Congressional appropriations, which now amount in the aggregate to hundreds of millions.

Federal control over the ports of the United States, including all the important harbors, is exercised under the constitutional power of the government to regulate commerce; but in most of the details of harbor management — such as ownership and use of wharves, docks, warehouses, and the provision and disposal of facilities generally — management is left to the States. Pilot laws, the appointment of harbor-commissioners, harbor-masters, etc., and all other harbor regulations are made and enforced by the States, subject in certain things — as, for example, quarantine rules — to the jurisdiction of the Federal government. Consult: Rennie, 'Harbors'; Stevenson, 'Design and Construction of Harbors'; Moore, 'History of the Foreshore and the Law Relating Thereto'; Harcourt, 'Harbors and Docks'; Birdseye, 'Laws of the State of New York' (Navigation Law and New York Harbor); United States Revised Statutes, Secs. 5,244–5,255. See BREAKWATER; DOCKS AND DOCK YARDS; JETTIES; LIGHTHOUSES.

Harbor Grace, Newfoundland, a port of entry on Conception Bay, 27 miles west by north of St. John's, 84 miles by rail. It has a large but exposed harbor, with an inner secure port, a patent slip, and a lighthouse with a revolving light. It is the see of a Roman Catholic diocese with a handsome cathedral and convent. Its commerce is second to that of St. John's. Pop. (1901) 5,184.

Harbor Seal, or **Hair-seal,** the common small seal (*Phoca vitulina*), once common on both sides of the North Atlantic, down to Virginia in the United States, but now only occasionally seen south of Cape Cod. See SEAL.

Harbor Springs, Mich., village, county-seat of Emmet County; on Little Traverse Bay, an arm of Lake Michigan, and on the Grand Rapids & I. R.R. The landlocked harbor is much used by lumber vessels. The village is in a part of the State where the large forests make lumbering the chief industry. The chief manufactures are flour and lumber. The cool climate in summer makes Harbor Springs a favorite resort during July and August. Pop. (1900) 1,643.

Harby, Isaac, American dramatist and journalist: b. Charleston, S. C., 1788; d. New York 14 Nov. 1828. In 1822 he conducted the Charleston *City Gazette* and later the *Mercury*. His plays were 'The Gordian Knot'; 'Alexander Severus'; and 'Alberti.' He was vice-president of the Hebrew Orphan Asylum of Charleston and leader of the reformed movement among the Jews of that city — the first of its kind in the United States. In 1828 he removed to New York and engaged in journalism, until his death the same year.

Harby, Levi Charles, American naval officer; b. Georgetown, S. C., 21 Sept. 1793; d. Galveston, Tex., 3 Dec. 1870. While a midshipman in the United States navy in 1812, he was taken prisoner and confined in Dartmoor Prison, England, until the end of the war. He served under Gen. Jackson in the Creek war, and participated in the Texas struggle for independence and the conflict with Mexico. Subsequently he fought in South America under Bolivar. On the secession of South Carolina, he resigned his commission in the United States service and joined the Confederate forces as commander of the fleet at Sabine Pass.

Harcourt, här'koort, SIR **William George Granville Venables Vernon,** English statesman: b. 14 Oct. 1827; d. Malwood, Hampshire, 1 Oct. 1904. He began his education in a private school at Salisbury, and then studied at Trinity College, Cambridge, whence he was

graduated with high honors in 1851, receiving the degree of M.A. He then studied law, being called to the bar in 1854, and in 1866 he became queen's counsel. In 1858 he made an attempt to enter Parliament as an Independent Liberal, but was defeated. During these years he wrote largely for the 'Saturday Review' and other journals, and in 1860 attracted considerable attention by a series of letters on international law and kindred subjects contributed to *The Times* over the signature of "Historicus," and which he continued throughout the American Civil War. In 1868 he entered Parliament as Liberal member for Oxford, serving his constituents at that post till 1880, when he was defeated for re-election. He was, however, selected to represent Derby and continued in that position until 1895, when, having been defeated at the general election, he found a seat in West Monmouthshire. In 1869 he was elected Whewell professor of international law at Cambridge; at the same time he was appointed a member of the royal commissions for amending neutrality laws and for amending the naturalization laws. He was appointed solicitor-general in 1873, but held the office only three months, and in the same year was knighted by the queen. Although he had not supported Mr. Gladstone during his retirement from power, yet upon that statesman's return to the office of prime minister in 1880, he was appointed secretary of state for the home department, continuing in that capacity until the Liberal party went out of power in 1885. At that time his name became famous through his connection with the 'Ground Game Act' (1880), the 'Arms (Ireland) Act' (1881), and the 'Explosives Act' (1883), the last one being pushed through all its stages in the shortest time on record. In 1884, his bill for unifying the municipal administration of London was introduced. Upon the return of the Liberals to power in 1886, he was made chancellor of the exchequer, holding that position only a short time, as the fortunes of politics again took him from office. During the years 1880 to 1892 he was Gladstone's lieutenant in political life, and his services were of immense value, especially on account of his brilliant oratorical powers. Again in 1892 he was made chancellor of the exchequer, acting as such until 1895. It was during this term, in 1894, that he introduced and carried his famous tax budget, in which the income tax became more graduated and the "death duties" on real and personal property were equalized, thereby giving the government much aid in solving their financial problems. Upon Gladstone's retirement in 1894, Harcourt was looked upon as his successor, but his title was ignored and Lord Rosebery appointed in his stead. Sir William then became leader of the Liberals in the House of Commons, and it became evident that he and the new prime minister did not agree as to party policy, and, though their differences were from time to time patched up, it was clear in his defeat at Derby in 1895 that the party was divided on many issues, and the effect was then seen of Sir William's Local Veto Bill, not only in the utter rout of the Liberals, but in the setback given to temperance legislation. From 1895 to 1900 he represented West Monmouthshire in the House of Commons, but the task of leadership of the Liberal party became particularly onerous because of the tendency of the various sections to break away from control. In the session of 1896, against the overwhelming Unionist majority, he scored several successes, but was severely criticised by his own party for concurring in the majority report of the special committee, of which he was a member, appointed in 1897 to investigate the Jamieson Raid and the British South Africa Company. The internal dissensions in the Cabinet became more marked as time went on, and the divided counsels manifest among the leaders of the Liberals led to his decision to retire from the leadership of the party on the floor of the House of Commons, and in 1898 with John Morley he retired from active work and thereafter sat as a private member. As a private member, he no longer restrained his attacks on the government, paying not the least deference to Liberal imperialism. He actively opposed the government's policy with regard to the sinking fund, their attitude in the negotiations with the Transvaal, and the financing of the South African war, and throughout the war he lost no opportunity in criticising the South African developments. In 1898–1900 he became prominent, both on the platform and in his letters to *The Times*, in advocating active measures against ritualistic practices in the Established Church. The general election of 1900 found him full of fight, favoring the official Liberal programme as distinct from that of the imperialistic section which favored the return of Lord Rosebery to the leadership, and when the new Parliament met his attitude signified that his former claims would not be dropped. Sir William had refused twice to enter the peerage, and in a speech delivered at the National Liberal Club on 28 July, after announcing his determination to retire at the close of the session, said: "It is not because I am weary of the fight or am lukewarm in the cause that I intend to retire. It is because I do not think it for the public advantage that persons should attempt to fulfil duties that they are unable to perform." And yet after this announcement he vigorously attacked Joseph Chamberlain, whose weightiest political antagonist he was, for his fiscal proposals, in a lengthy speech, delivered in his familiar Homeric style. It has been written of him: "Sir William Vernon-Harcourt is one of the few public men whose addresses out of Parliament are printed in full by the London journals. His reputation has steadily improved while his party has been in the minority, and his caustic wit, polished satire, and brilliant epigrams have stung and irritated the conservative peers time and again. He has Lord Beaconsfield's trick of giving phrases the stamp of his own originality, so that there is no one on the Liberal side whose speeches are quoted more frequently. It has been aptly said that Sir William's distinguishing characteristic is his cleverness. His platform speeches are not only rattling and rollicking, but are generally brimful of witty and happy phrases. He has a great gift of lucid exposition and on rare occasions, when he condescends to be serious, commands a flexible and sinuous prose." Sir William Harcourt was married in 1859 to Lady Thérèse Lewis, widow of Sir George Cornwall Lewis, and daughter of T. H. Lister, and again in 1876 to Mrs. Elizabeth Ives, widow of J. P. Ives, and daughter of John Lothrop Mot-

ley, the historian, and at one time United States minister in London.

Hard Labor, in law, compulsory work, mechanical or other, sometimes judicially imposed upon criminals in addition to imprisonment or other punishment. It is a provision of statute law both in this country and Great Britain. Its first English adoption was secured through the demand for some adequate penalty in cases where penal servitude and transportation were for any reason inexpedient. In the United States the punishment of hard labor (which, however, is generally looked upon by humanitarians and sanitarians as being rather a healthful and merciful privilege) can only be imposed by a court on the authority of statute, the mode of applying the punishment being in some cases prescribed by State or Federal laws, and in others left to prison regulation.

Hardecanute, härˈdē-ka-nūtʹ, **Harthacnut,** or **Hardacnut,** king of England and Denmark; son of Canute: b. about 1019; d. 8 June 1042. At the time of his father's death in 1035 he was in Denmark, where he was immediately recognized as king. His half-brother, Harold, however, who happened to be in England at the time, laid claim to the throne of that part of their father's dominions. For a time the mother of Hardecanute succeeded in holding Wessex in his name, while Mercia and Northumbria were held by Harold, such an allotment having been made by a witenagemote held at Oxford. Hardecanute was about to make an armed descent upon England, when Harold died (1040), and his brother peacefully succeeded him. He reigned till 1042, but his reign was not marked by any important event. He left the government almost entirely in the hands of his mother and the powerful Earl Godwin (q.v.), while he gave himself up to feasts and carousals.

Harʹdee, William Joseph, military officer: b. Savannah, Ga., 10 Oct. 1815; d. Wytheville, Va., 6 Nov. 1873. He was graduated at West Point in 1838; served with distinction in the Mexican War; and in the Civil War entered the Confederate army with the rank of colonel. He commanded a corps at Shiloh; and was promoted lieutenant-general in 1862. At Perryville he commanded the left wing of the Confederate army and in December 1864 defended Savannah against General Sherman.

Harden, William, American historian: b. Savannah, Ga., 11 Nov. 1844. He left his studies in the schools of Savannah to join the Confederate army, serving throughout the Civil War in the 54th Georgia infantry and in the signal corps. After the war he studied law and was admitted to the bar in the early 70's. He was assistant librarian of the Georgia Historical Society from 1866 to 1869, when on 5 August he was appointed librarian, a position he still occupies. He has been a member of the board of managers of Telfair Academy of Arts and Sciences since 1882, and custodian since 1894; organizer and secretary of the Georgia Society of the Sons of the Revolution since 1891; and was a Democratic member of the Georgia House of Representatives from 1900–4. Has written much on historical subjects in magazines and journals.

Hardenberg, Georg Friedrich Philipp von, gā-ōrg frēdʹriH fēʹlēp fōn härʹdĕn-bĕrg, "Novalis," German poet: b. Wiedenstadt, Prussia, 2 May 1772; d. Wessenfels, Prussia, 25 March 1801. He made himself well acquainted with law, natural philosophy, mathematics and philosophy, but was most eminent for his poetical talents. In the works of "Novalis" there is a singular mixture of imagination, sensibility, religion and mysticism. He was the gentlest and most amiable of enthusiasts. His novel, 'Heinrich von Ofterdingen', was left unfinished. His 'Hymns to Night' and the 'Geistliche Lieder' are greatly admired. With the Schlegels and Tieck he assisted in founding the romantic school in Germany. Consult: Schubart, 'Novalis Leben' (1887); Bing, 'Friedrich von Hardenberg' (1893).

Hardʹhack, or **Steeple-bush,** an erect species of American *Spiræa* (*S. tomentosa*), common in pastures and low grounds, and celebrated for its astringent properties, which cause it to be used medicinally. It is distinguishable by the dense woolly tomentum, which covers its stem and the underside of its leaves; and bears in late summer "a compact, steeple-shaped panicle of peach-blow pink."

Harʹdie, James Allen, American soldier: b. New York 5 May 1823; d. Washington, D. C., 14 Dec. 1876. He was graduated from the United States Military Academy in 1843, entered the artillery, during the Civil War served on the staffs successively of Generals McClellan and Burnside, was judge-advocate-general of the Army of the Potomac on Hooker's staff, became brigadier-general of volunteers in 1862, and inspector-general with rank of colonel in 1864. He was brevetted major-general, United States army, in 1865. His writings are largely confined to military reports.

Hardie, James Keir, English labor leader: b. Lanarkshire 15 Aug. 1856. He worked in the coal mines until 1879, when he was blacklisted on account of his activity in organizing the miners; he was then appointed paid secretary of the miners' union. In 1886 he organized the Ayrshire miners, and in 1887 attended his first Trade Union Congress. He was one of the founders of the Independent Labor Party, and was elected member of Parliament in 1888, 1892, and 1900. He is proprietor and editor of a weekly paper, the 'Labour Leader.'

Hardie, Robert Gordon, American portrait painter: b. Brattleboro, Vt., 29 March 1854; d. Brattleboro, Vt., 9 Jan. 1904. He studied drawing at the Cooper Union Institute, the Academy of Design, and the Art Students' League, N. Y., and at Paris became a pupil of Gérôme. He exhibited at the Salon in 1880 and following years, and in 1882 studied under Cabanel. A picture of his appeared at the Exhibition of the National Academy of Design in 1888, and he exhibited a portrait of his wife at the World's Columbian Exposition in 1893.

Harding, Chester, American portrait painter: b. Conway, Mass., 1 Sept. 1792; d. Boston 1 April 1866. As an artist he was self-taught, his trade being that of a turner. He fought as a soldier in the War of 1812, and found employment on his discharge as a sign-painter in Pittsburg, Pa. Crossing the ocean he became a favorite portrait painter in London and found

patronage among the royal family. His 'Portrait of Daniel Webster' is owned by the New York Bar Association, while his 'Portrait of John Randolph' is in the Corcoran Gallery, Washington.

Harding, Karl Ludwig, German astronomer: b. Lauenburg 29 Sept. 1765; d. Göttingen 31 Aug. 1834. Called to be a tutor to the son of the illustrious Schröter, he became inspector and observer in Schröter's observatory. In 1805 he was appointed professor of astronomy in the University of Göttingen, and remained in this position till his death. He discovered the asteroid Juno, the third of the planetoids, in 1804, and independently, the second comet of 1813 credited to Pons. His 'Atlas Novus Cœlestis' (1808–23; new ed. 1856) was for years the best of its sort.

Hardness, the quality of bodies which enables them to resist abrasion of their surfaces. It depends on the cohesive forces with which the minute particles of the body are joined together. The hardness of bodies is compared by observing which of two scratches the other when they are rubbed together; sometimes a scale is used in which a set of standard bodies is arranged and numbered, and other bodies are referred to this scale with respect to hardness.

Hardness, Scale of. In mineralogy, the hardness of a mineral is estimated by observing which of certain standard minerals will scratch a smooth surface of the given mineral, and which will not. On Mohs' scale (which is usually adopted), ten such standard minerals are selected for the establishment of the scale, their hardnesses being arbitrarily defined as 1, 2, 3, etc., up to 10. The minerals that are commonly used for this purpose are as follows:

1. Talc.
2. Gypsum.
3. Calcite.
4. Fluorite.
5. Apatite.
6. Feldspar.
7. Quartz.
8. Topaz.
9. Sapphire.
10. Diamond.

A mineral which will neither scratch apatite nor be scratched by it, for example, has a hardness of precisely 5; and the same may be said of one which will both scratch apatite and be scratched by it. A mineral which feldspar will scratch but apatite will not, has a hardness intermediate between 5 and 6. The decimal expressing the precise degree of hardness in such a case must be assigned by guess; but there is little use in attempting to determine a hardness more closely than to the nearest half-degree on the scale given above.

Hards, the designation of a faction of the Democratic party in the political history of New York from 1852 to 1860. They were distinguished from the "softs" in their favoring alliance with the pro-slavery Democracy throughout the States. They were also called "hardshells" and were identical with the "hunkers" or conservative Democrats of 1845.

Hard'tack, a cracker or biscuit, large, hard, and coarse, much used by soldiers and sailors. About 20 of these crackers are served daily to each man. When the United States soldiers were about to be shipped from Tampa to Cuba, during the Spanish-American War, two factories in Atlanta furnished the government in two days with 80,000 pounds (1,120,000) of hardtack.

Hardware Trade in America. Hardware is essentially a business that belongs to a new section of country, and it can readily be seen that the larger distributing centres for the hardware business would naturally be in the central West, where growth began about 1850, and new communities required new household furnishings. At the present time it is safe to say that there are larger distributers of hardware in Chicago and St. Louis than anywhere else in the world. A distinctly American branch, there is no other line upon which Yankee ingenuity so distinctly impresses itself, which is so entirely free from imitation of the ideas of the Old World; and which has so quickly turned the universal import trade into a great and constantly increasing export business. All this has been done within the brief period of the last half century, during which this industry had to struggle against the flood of cheap and ill-constructed foreign goods.

Hardware is very comprehensive. Indeed it embraces almost everything that is not, strictly speaking, assignable to any other specific line of trade. It used to mean chiefly mechanics' tools and builders' hardware, whereas at this time it includes so vast a variety of goods as to make it difficult to enumerate them correctly. Comprising, as it does, almost all the small articles made of metal that are patented and used in the construction of houses or for household purposes, as well as tools for all classes of mechanics or professional men, it covers house furnishing-goods for kitchen and dining-room service, the product of the tin-shop and of stamped-ware manufactories, tin-plate, sheet-iron, barbed wire, and such sporting goods as guns, rifles, pistols, ammunition, baseball supplies, and bicycles. An idea of its vast range is conveyed by the fact that one hardware house in this country alone has in its catalogue about 45,000 kinds and sizes of articles, all of which it carries regularly in stock.

Before the first commercial treaty with England, in 1795, all of our supplies in this line, substantially speaking, came from England and Germany. Immigrants could frequently be seen bringing with them their hoes, rakes, and forks, upon which were strung their bundles of clothing. Afterward German goods made great gain over the English. These goods were, as a rule, very crude, poorly made, and not at all to be compared even with the articles that were first manufactured in this country. The genesis of hardware in the United States was undoubtedly in Connecticut, where the village blacksmith was the manufacturer of such implements and tools as were wanted. Very little progress was made in this line of manufacture until 1850, when the manufacture of hardware, speaking generally, was commenced in the United States. Until that time perhaps four fifths of all hardware used in this country was imported. In general both English and German goods as imported into the United States were shipped in awkward and unprepossessing packages, files, saws, and horseshoe nails being so poorly wrapped that they usually broke through their covers. So, too, small goods, such as padlocks, door-locks, screw-drivers, scissors, rules, etc., were all put up in rough but strong English paper, which, while substantial, was very clumsy and inconvenient. Such goods have long since

ceased to be imported, and the manufacturers of this country particularly excel in their method of packing; for example, files are put in wooden boxes, with dovetailed corners and slide-lids, hand-saws in compact pasteboard boxes, and horse-nails in wooden boxes, and all small goods, even screws and tacks, in boxes of most convenient form and shape for the small dealer. Particularly striking is the convenient and neat boxing of tacks, a product, by the way, now manufactured more largely in the central West than in New England, although there are still several important factories in Massachusetts.

All this time the introduction of labor-saving machinery was continued, so that the foreign article could compete with ours neither in price nor in quality. It has come to pass that our imports of hardware have almost entirely ceased, although there is yet some cutlery imported, and each year our export business in hardware shows a considerable and substantial gain. As will be noted in the detailed items which follow, we send our hardware all over the world; and in London, and even Sheffield itself, the birthplace of mechanical ingenuity, our American edge-tools are advertised as special attractions.

The experience of the last few years has thoroughly demonstrated the fact that the hardware business and its kindred lines is the pulse of the country's prosperity or depression; for so closely is it allied with iron-producing and railway interests, that it shows more quickly than any other branch the first approach of depression, and recovers sooner from the effects of it.

It is a fact worthy of attention that of all the goods that are sold by the hardware jobbers of the United States to-day fully 35 per cent have been invented or originated within the past 20 years. In door-locks, latches, padlocks, and small builders' hardware, Americans have been particularly successful. In point of fact, their goods possess so many advantages over those made abroad as to defy comparison. England, France, and Germany still use a large, weighty wrought-iron door-lock, with its heavy brass key 8 or 10 inches long, clumsy and awkward, a great contrast to the compact and convenient American lock and key. Door-lock manufacture was first begun in Connecticut, in New Haven and New Britain, about 1834. The first goods manufactured were the cheaper grades, chiefly plate and wood stock locks. Then English patterns in wrought iron were copied, and very soon thereafter, and not later than 1840, door-locks were made successfully from cast iron, and these immediately supplanted the old and clumsy wrought-iron locks. Owing to European conservatism, the use of cast iron has never become common in Europe, where a prejudice in favor of wrought metal still exists. These conditions long stood in the way of the introduction of American hardware into Europe, but this prejudice is gradually growing less.

American builders' hardware has in recent years advanced from the stage where each new article was originated by the pattern-maker or the lock-maker, working with sheet-metal and file, so that now the work of designing is done by skilled draftsmen working at the drawing-board. There is no reasonable doubt that there will be a very large export trade in door-locks and builders' hardware in the near future, because of increasing appreciation of the merit of the American goods abroad.

There is probably nothing in the hardware line in which the American dealer takes more pride than saws, and especially hand-saws and such other small saws as are used by the carpenter and cabinet-maker. It is believed that the first saws of any kind manufactured in the United States were made by William Rowland in the year 1806, in Philadelphia. In 1823 a small plant was started by Aaron Nichols in the same place. In 1828 or 1829, in New York, the firm of R. Hoe & Co. began to make circular saws from English steel, which were about the first manufactured in this country. In 1835 Noah Worrall started in New York the manufacture of small circular saws. The following year William & Charles Johnson commenced the manufacture of saws in Philadelphia; and it was with this firm that Henry Disston, who afterward achieved a world-wide reputation for his wonderful success, learned his trade. In 1840 the firm of William & Charles Johnson failed, and Henry Disston accepted from them some tools, steel, and such material as he could get in the saw line, on account of wages that were due him, and with these he began to manufacture saws in his own name. After this there were several small industries started — by Jonathan Paul 1840, J. Bringhaust 1842, James Turner 1843, and Walter Cresson 1845. These four were each in turn bought out by Henry Disston. Prior to 1863 all of the steel used in this country in the manufacture of saws was brought from England, but in that year Henry Disston built and operated the first crucible-steel melting plant for saw-steel in the United States, and from that time on used nothing but steel of his own production. Practically all improvements in quality, style, methods of manufacture, etc., have been made since 1865, and to Disston is due the credit of placing American saws in their present position. There are about 3,215 persons employed in this industry, with an annual product of about $6,443,000, and there is nothing made in this country that advertises the United States better, more substantially, more practically, or more permanently than American hand-saws, so excellent is their quality, and so beautiful are their design and finish. The capital invested in the manufacture of saws in the United States is $8,508,487.

The item of small farming-tools is one of the exceedingly interesting manufactures in the hardware line, because they were brought here a century ago by the immigrants. Immediately thereafter the village blacksmith began to make them, forging the goods by hand. The goods were very clumsy, unshapely, awkward to use, and heavy. But in the decade of 1820–30 the introduction of the trip-hammer revolutionized the entire business. At the present time there are more than 25 manufacturing works in the United States engaged on "hand agricultural tools," employing perhaps 1,500 people, with a capital of $1,500,000, and an annual product of over $2,000,000. The steel consumed in these productions is more than 4,000 tons annually. Of this product of $2,000,000 at least $250,000, and perhaps twice as much, is exported to foreign countries, leaving about $1,500,000 for home consumption. In this one class of goods foreigners have improved in their quality by reason of our competition.

The cutlery business of the United States has an interesting history. While the American

manufacturer of table cutlery has to a large extent driven out the foreign goods, by reason of the excellence of quality and the economy of manufacture, the pocket-cutlery makers have not been so successful, for the cost of making pocket-knives is 85 per cent labor and 15 per cent material. So that it can be seen how difficult it is for the manufacturer of pocket-knives in this country to compete with the cheap labor of England and Germany. The origin of pocket-knives in this country is traced back to Connecticut, as is so much in the hardware line, beginning in the year 1842. The first factory was quickly followed by the establishment of five others in the same State. The result was that many of the best English operatives from Sheffield came here, because they could find steady employment and higher wages. After a while some of these operatives formed a new co-operative company in Walden, N. Y., which is to-day the largest concern of the kind in the United States. The pocket-knife industry of this country is unquestionably in New York and Connecticut. Of 55 ventures since 1844 more than 32 have experienced failure, owing chiefly to their short-sighted policy of making goods for price rather than for merit, and attempting to compete with the cheap labor of the old country in price rather than in the excellence of quality and finish. A large majority of these pocket-knife manufactories have been founded on the co-operative plan, locating in small villages where cheap water-power was abundant. During prosperous times the consumption of pocket cutlery in the United States is in the neighborhood of 1,200,000 dozen per annum, representing perhaps $3,000,000. The larger part of this is imported from Germany and England, in the proportion of two to one in favor of Germany. Prior to 1850 the American market was supplied almost entirely from England, but the cheaper German grades are gradually driving out the higher-priced English goods. The home-made product has steadily improved in quality, and while it is not always as absolutely uniform as the English product, yet the best American knives are not surpassed by anything produced in Sheffield, and are far superior to the German in quality, temper, and finish. The genius of American manufacturers is much handicapped by the impossibility of employing any labor-saving machinery worth mentioning, since the quality of the knife depends entirely upon the skill of the mechanic in manipulation and tempering. Although there is no export business in pocket cutlery, the manufacturers, at times, have given evidence of what they can do in the line of cheapness. Recently a single-blade knife with a wood handle, handsomely finished, and of a quality of steel which would take a razor edge, was produced by the manufacturers so cheaply that after the jobber and retailer had each had his profit it passed into the hands of the consumer for 10 cents. The complexity of the business may be gathered from the statement that it is necessary to import mother-of-pearl from the Philippine Islands, tortoise-shell from the Indies, stag-horn from Germany and India, ebony from Ceylon and Madagascar, cocoa-wood from Cuba, and rosewood from South America. American manufacturers of pocket cutlery now employ about 3,000 men and produce about $2,000,000 of goods annually. Table cutlery was first manufactured in this country in 1832, before which period everything in this line came from England. By 1865 the business was pretty much in the hands of the home manufacturers, and in 1893 the entire amount of foreign table cutlery imported into the United States was only $195,000. Attempts have been made by foreigners to copy American patterns of table cutlery, but in no instance were they successful in producing so good an article, and the effort was finally abandoned. The State of Maine was probably the birthplace of the manufacture of table cutlery, the first effort being made at Saccarappa. In the "market of the world" there is no such great middle class as there is in the United States, and there is a demand for medium-grade, well-finished goods in this country which does not exist in others. The amount of table cutlery exported is a mere trifle — probably not more than five per cent of the product of the country. The estimated value of the production of the various table-cutlery manufactories of this country is $3,000,000.

American shear-makers have set the pace for the world in that line of goods. They were the first to solve the problem of welding a high-grade steel blade to an iron backing or soft casting made to fit the hand. This was the invention of Seth Boyden in 1826. The manufacture of shears in this country was started in a crude way the year before, at Elizabethport, N. J. Welding by hand was carried on from that date until early in the sixties, when a drop-hammer was constructed by H. Wendt, the ram of which was raised by the friction of a rope pulled by hand around a revolving wheel or pulley. This rope later gave way to a flat leather strap, which was succeeded by power drop-hammers operated by friction-rolls upon a flat board, under perfect control by the foot of the operator, the hands being free for the proper manipulation of the work. American shears are exported in great quantities, especially to England, South America, and Australia. None of the foreign countries has adopted our method of manufacturing shears, and for that reason their goods do not compare with the American product. There are eight manufacturers engaged in this business in this country with a total capital of about $750,000, employing about 1,000 people, and with a product of about $1,500,000.

In the manufacture of fine mechanics' tools, such as are used by the higher class of machinists, the United States is the peer of any country. To-day one of the foremost concerns in this line, located in Providence, R. I., sends its tools to England, France, and Germany, where they are in great demand because of their great accuracy and almost infallible uniformity of manufacture. An illustration of the esteem in which they are held is shown in the fact that these American tools are used in the manufacture of the new French rifle which is attracting so much attention. Some idea of the exactness of such work may be gathered from the statement that in the production of fine firearms it is necessary that thousands of parts should be interchangeable, and should not vary by 1/1000 of an inch. Some of the micrometer calipers from these works will measure the two-hundred-and-fifty-thousandth part of an inch with accuracy; and this same firm have in their office a tool whereby the difference in

diameter between two steel bars of the ten-thousandth part of an inch is made perceptible to both the eye and the touch.

The manufacture of axes in America has been a particularly successful branch. Exports go to all quarters of the globe, notably to Tasmania, where the American axe is regularly used in the famous tournaments of the Axemen's associations. The annual output is 350,000 dozen, of which more than 20 per cent are exported.

The manufacture of wire cloth, or netting, has become a large industry in this country. It was first introduced from Germany in the year 1870, and it cost at that time to import it from 10 to 12 cents per square foot. In 1873 an improved hand-loom was operated in Cortlandt, N. Y., made by Wickwire; and in 1874 he invented a shuttle motion known as the positive motion, the shuttle being carried through the cloth instead of being thrown, as was the case in former manufacture. With this principle to work upon he succeeded in making a power-loom in 1876, which was the first to make a hard-drawn wire cloth. This principle is now used by all manufacturers of wire cloth. The present price is less than 1½ cents per square foot. In 1876 the consumption in this country was about 10,000,000 square feet. At the present time it is more than 125,000,000. There is a total capital of about $3,500,000 invested in the manufacture of wire cloth in this country, consuming about 7,000 tons of steel. The export trade in wire cloth is chiefly with Canada, Nova Scotia, South America, Mexico, and the West Indies, and although light at present, being about seven per cent of the entire output, is growing steadily. The American product far excels that of foreign manufactories in quality. There is no country that uses screen-cloth in windows and doors so generally as does the United States.

The manufacture of files in this country was begun half a century ago in Providence, R. I. The product at first was entirely hand-cut, with the old-fashioned hammer and chisel; for although machines were invented at an early date, they were not used until about 1858. These first machines, however, were not successful, and it was not until 1865 that machine-made files can be said to have been fairly under way. The first year's output was only about 90,000 dozen, whereas now it is something like 4,000,000 dozen. At present about 15 per cent of the product is exported. Up to 1870 the importation of files from England and from Switzerland was very large; but in that year imports began to fall off rapidly, and have now practically ceased, with the exception of a few fine Swiss files which are still brought over for special purposes. On the other hand, the exports are steadily growing. American files now being used in China, Japan, India, Africa, in many of the European centres, and in Great Britain itself. The merits of the American files are so pronounced, both as to wearing qualities, handsome appearance, and cheapness of price, that the preference is given them over files made in other countries. The manufacture is extremely intricate and involves the most careful inspection. It is a well-recognized fact in this country that machine-made files are more evenly cut than hand-made files can possibly be; and as nearly all the foreign files are still made by hand, the American product has a great advantage. In addition to this, Americans put up their files in better, more convenient, and more attractive packages than any manufactured in foreign countries. This particularly appeals to the trade of Australia, South America, and the West Indies. A very large percentage of the files manufactured in the United States is made by the Nicholson File Company of Providence, R. I., and Henry Disston & Sons of Philadelphia, in the various factories which they own or control. The American file manufacturers employ 3,160 hands. The estimated capital invested is $3,857,647, and the total value of the annual product about $3,400,000.

There seems to be good evidence, as in the case of many other apparently modern inventions, that the gimlet-pointed screw was made as far back as 1755. The first application of machinery on record for making screws was in France in 1569. The first English patent was obtained in 1760. From 1846 to 1849 came the inventions of Thomas J. Sloan, and these, in connection with the inventions of Harvey, form the basis of the screw-machinery of to-day. Screw-machinery was in operation in this country in 1810 in threading wood-screws, and was known as French machinery, having originated in eastern France. Some of it was in use as far back as 1798 in New York State. In 1835 came the invention of machines for heading, nicking, and shaving screws, and in 1842 the very important invention of the automatic feed for supplying blanks to screw-threading and shaving machines. One of the earliest manufactories in this country was established in 1838, with a capital of only $20,000. About 1841 the first American gimlet-pointed screws were placed on the market. Since that time screw-machinery of this character has been largely exported, and at present there are 20 screw-manufacturing concerns in this country. The machinery itself is among the most perfect ever invented, working with almost human intelligence and precision. Few screws are exported, owing to the severe competition of the great screw-manufactories of Birmingham, but the American article is generally regarded as more perfect than any made abroad. At present $7,931,000 capital is invested and 3,527 operatives employed in screw-manufacture in the United States.

Shovels and spades were manufactured in this country, in Massachusetts, as far back as 1776, in a small way; but since that time the methods of manufacture have improved so rapidly and intelligently that the American product now far outstrips that of the rest of the world. The Ames factory at North Easton, Mass., has a world-wide reputation, and exports its goods in great quantities to almost all parts of the civilized world. There are many other large factories in this country, producing an enormous quantity of these goods annually. The American goods are greatly preferred to the foreign article, being vastly superior in quality and attractiveness, and much lighter. There are about 14 shovel-manufactories in this country, with the total product of about 400,000 dozen shovels and spades.

The progress of horse-nail making in this country was very slow, and it was not until 1872 that much had been done in this line. After that the progress was rapid, and soon thereafter the foreign goods were entirely driven out of the market. Nails in this country are made

by what is called the hot-forging process, and are hammer-pointed. None are made in this manner abroad, and for that reason the American horse-nail is far superior to those made in other countries. There are 12 horseshoe-nail manufacturers in the United States, employing about 1,000 workmen, with a capital of about $2,000,000, having a total product of 1,500,000 kegs, of which 15 per cent are exported.

Wire nails, which have so rapidly superseded the cut nails, were not made in this country until 1886. The total production that year was 600,000 kegs. In 1887 this output was doubled, and continued increase has been shown each year since. The present annual product is about 10,000,000 kegs. In 1901 there were 19 wire-nail mills in operation in the United States, controlled by 10 different companies, with a capital invested of about $8,000,000; the value of the product was $15,000,000, and these mills gave work to 5,000 employees.

Barbed wire was first manufactured in the United States in 1874, at De Kalb, Ill. In that year there were not over 500 to 600 tons produced, and the price was 20 cents for painted wire. The next year the product increased to 3,000 tons, and five years later (1880) it had made such a great gain that the record was 100,000 tons; while for the year ending 1 March 1895, the total product was 190,000 tons, at which time the average price, which was originally 20 cents, was reduced to about 1½ cents per pound. Of all the barbed wire manufactured in the world fully 90 per cent is produced in the United States, and there are annually exported from 20,000 to 30,000 tons. The barbed-wire mills in operation have a capital of $8,350,000, and a total product of more than $15,000,000. In recent years the product of this industry has been greatly displaced by woven wire for use in fences. This latter industry has an annual product of 50,000 tons.

Tin-plate making is among our youngest manufactures, considered in reference to the amount of its product. No industry in the United States has shown such phenomenal growth as has that of the production of tin-plate. It is safe to say that there was substantially none of it prior to 1891. Since that time the American production has grown steadily until it has reached the annual figures of 8,000,000 boxes. Importation has fallen off and now consists of only a few cheap grades of bright plates. An allied industry is the manufacture of sheet steel, the annual product being 650,000 tons of black sheets and 100,000 tons of galvanized sheets. The exports increased nearly 1,000 per cent between 1897 and 1900. The native product is superior to the foreign both as to the quality of steel used for tinning, and again in that advantage which Yankee ingenuity almost invariably brings — labor-saving machinery of every kind. The Welsh tin-plate makers have progressed very little since they began the industry, and the prospects are that a hundred years from this date will find them just where they are now; while the American manufacturers have already made radical changes and introduced a number of marked and valuable improvements.

The great advance in the American hardware trade during the last half dozen years has been due to the steady concentration of business, the aggregation of capital in the steel and iron manufactures being perhaps the most notable of the last few years of trust-building.

EDWARD C. SIMMONS,
Pres't Simmons Hardware Co., St. Louis.

Hard'wick, Mass., village in Worcester County, about 22 miles northwest of the city of Worcester and four miles north of Gilbertville, the nearest railroad station. Hardwick is in a fertile agricultural section, and its chief industries are connected with the products of the surrounding farms. Its beautiful scenery and distance from a railroad make it the summer resort of a large number of health and pleasure seekers. Pop. (1900) 2,655.

Har'dy, Arthur Sherburne, American novelist: b. Andover, Mass., 13 Aug. 1847. After a single year at Amherst College he entered the West Point Military Academy, graduating in 1869. He became a second lieutenant in the 3d Artillery regiment, saw some service during 1869 and 1870, and then resigned to become a professor of civil engineering at Iowa College for a brief time. In 1874 he went to Paris to take a course in scientific bridge-building and road-constructing, returning to take a professorship in that line of instruction at the Chandler Scientific School, connected with Dartmouth College. He assumed a similar professorship in Dartmouth College in 1878. This position (in connection with which he published 'Elements of Quaternions' (1881), followed by his translation of 'Argand's Imaginary Quantities,' by his own 'Analytical Geometry'; and 'Elements of the Calculus'; 'Imaginary Quantities'; and 'Methods in Topographical Surveying') he held until 1893, when he became editor of 'The Cosmopolitan Magazine.' He was United States minister to Persia, 1897–9, and envoy extraordinary and minister plenipotentiary to Greece, Rumania and Servia, 1899–1901. He is, however, best known as a novelist, his works in this field including: 'But Yet a Woman' (1883); 'The Wind of Destiny' (1886); 'Passe Rose' (1889); 'His Daughter First' (1903).

Hardy, Edward John, English author and clergyman: b. Armagh, Ireland, 7 May 1849. He took orders in the English church, became an army chaplain and in 1903 was stationed at Hong Kong. He is known the world over as the author of 'How to be Happy though Married' (1884), which has been translated into many languages. Other works by him, several of which have been extremely popular, as well in the United States as in England, are: 'Manners Makyth Man' (1885); 'Faint yet Pursuing' (1886); 'Uncle John's Talks with his Nephews' (1886); 'The Five Talents of Women' (1888); 'The Love Affairs of Some Famous Men' (1897); 'Mr. Thomas Atkins' (1900); 'Concerning Marriage' (1901); 'Love, Courtship and Marriage' (1902); 'Pen Portraits of our Soldiers' (1902).

Hardy, Iza Duffus, English novelist, daughter of Sir Thomas Hardy, the English historian. Among her numerous novels are: 'Glencairn' (1877); 'Only a Love Story' (1877); 'A Broken Faith' (1878); 'The Love that He Passed By' (1884), an American novel; 'A Woman's Loyalty' (1893); and two volumes of transatlantic reminiscences, 'Between Two Oceans' (1884), and 'Oranges and Alligators: Sketches of South Florida Life' (1886).

Hardy, Thomas, English novelist: b. Dorsetshire, England, 2 June 1840. He was educated as an architect and practised his profession 1862–73. He then turned to literature and is now recognized as the first of living English novelists. His published works include 'Desperate Remedies' (1871); 'Under the Greenwood Tree' (1872); 'A Pair of Blue Eyes' (1873); 'Far from the Madding Crowd,' which first established his fame (1874); 'The Hand of Ethelberta' (1876); 'The Return of the Native' (1878); 'The Trumpet-major' (1880); 'A Laodicean' (1881); 'Two on a Tower' (1882); 'The Mayor of Casterbridge' (1886); 'The Woodlanders' (1887); 'Wessex Tales' (1888); 'A Group of Noble Dames' (1891); 'Tess of the D'Urbervilles' (1891); 'The Three Wayfarers' (1893); 'Life's Little Ironies' (1894); 'Jude the Obscure' (1895); 'Wessex Poems' (1898); 'Poems of the Past and Present' (1901). Consult: Johnson, 'The Art of Thomas Hardy' (1894); Macdonnell, 'Thomas Hardy' (1894); Windle, 'The Wessex of Thomas Hardy' (1901); Sherren, 'The Wessex of Romance' (1902).

Hare, Augustus John Cuthbert, English descriptive writer: b. Rome, Italy, 13 March 1834; d. St. Leonards, Sussex, 22 Jan. 1903. He was a nephew of J. C. Hare (q.v.). His life was spent mainly in travel, on descriptions of which his fame chiefly rests. Among his many works may be cited 'A Winter at Mentone' (1861); 'Walks in Rome' (1870); 'Wanderings in Spain' (1872); 'Memorials of a Quiet Life' (1872); 'Days near Rome' (1874); 'Walks in London' (1877); 'Days near Paris' (1887); 'Sussex'; 'The Story of My Life' (1895); 'Shropshire.'

Hare, John, English actor: b. London 16 May 1844. He made his first appearance in Liverpool, then going to London played at the Prince of Wales theatre, and later was manager of the Court theatre, the Garrick theatre, and the Globe theatre. He became distinguished as a comedian, and visited the United States, playing in the chief cities. The plays he has brought out include 'A Scrap of Paper'; 'Still Waters Run Deep'; 'A Bachelor's Romance'; and 'Gay Lord Quex.'

Hare, John Innes Clarke, American jurist: b. Philadelphia 17 Oct. 1817. Graduated from the University of Pennsylvania in 1834, he was admitted to the bar in 1841, was successively associate and presiding judge of the Philadelphia district court (1851–75), and in 1875–95 presiding judge of the court of common pleas. He was also for a time professor of the institutes of law in the University of Pennsylvania, and published: 'American Leading Cases' (1847; with Wallis), 'The Law of Contracts' (1887), 'American Constitutional Law' (1889), eleven volumes of chancery reports, and other works.

Hare, Julius Charles, English Anglican clergyman and author: b. Valdagno, Italy, 13 Sept. 1795; d. Hurstmonceaux, Sussex, 23 Jan. 1855. He was vicar of Hurstmonceaux from 1832 and published 'Vindication of Luther' and other works, but is much more widely known as co-author with his brother A. W. Hare, of 'Guesses at Truth' (1827), a work which still enjoys popularity.

Hare, Robert, American scientist: b. Philadelphia 17 Jan. 1781; d. there 15 May 1858. He was professor of chemistry in the University of Pennsylvania 1818–47. He will be longest remembered for his discovery of the oxyhydrogen blowpipe to which he gave the name "hydrostatic blowpipe," but he also invented the valve-cock, the calorimeter and a process for denarcolizing laudanum. He wrote 'Brief View of the Resources of the United States' (1810); 'Chemical Apparatus and Manipulations' (1836); 'Memoir on the Explosiveness of Nitre'; etc.

Hare, William Hobart, American Protestant Episcopal bishop: b. Princeton, N. J., 17 May 1838. He studied at the University of Pennsylvania, was ordained priest in 1862, was minister of St. Luke's, St. Paul's (Chestnut Hill) and other churches of Philadelphia, and in 1873 was consecrated missionary bishop of Niobrara. In 1883 his diocese, having been enlarged so that its limits were identical with those of the territory of South Dakota, was renamed that of South Dakota. He became known as an authority on the Indian question, and wrote pamphlets on mission work in the western United States.

Harebell, or **Bluebell,** a familiar species of bell-wort (*Campanula rotundifolia*), common throughout the northerly parts of the whole northern hemisphere (see BLUEBELL; CAMPANULA), growing in dry and hilly pastures, on waysides, and open lands generally. It is, however, rare in America south of Canada, although other species are to be found here. It is perennial, with a slender stem 6 to 14 inches high, bearing a loose raceme of a few drooping flowers, on very slender stalks; the flowers, generally bright blue, but sometimes white, bell-shaped, and about half an inch long, appear in summer and autumn. The juice of the flowers yields a fine blue color, and may be used as ink.

Harel, Paul, pōl ä-rĕl, French innkeeper-poet: b. Echauffour (Orne) 1854. He became landlord of the "Croix Saint-André," an inn at Echauffour, and within a modest range of subject wrote picturesque verses in an excellent lyric style. He was elected to the Caen Academy, and on the recommendation of Sully-Prudhomme received a prize from the Académie Française. Among his works are: 'Sous les Pommiers' (1879); 'Rimes de Broche et d'Epée' (1883); 'Aux Champs' (1886); and 'L'Herbager,' a three-act poetic drama (1891).

Harelip. A fish. See CUTLIPS.

Ha'rem, or **Hareem'** (Ar. "the prohibited"), is used by Mussulmans to signify the women's apartments in a household establishment, forbidden to every man except the husband and near relations. The women of the harem may consist simply of a wife and her attendants, or there may be several wives and an indefinite number of concubines or female slaves, with black eunuchs, etc. The greatest harem is that of the sultan of Turkey. The women of the imperial harem are all slaves, generally Circassians or Georgians. Their life is spent in bathing, dressing, walking in the gardens, witnessing the voluptuous dances performed by their slaves, etc. The women of other Turks enjoy the society of their friends at the baths or in each other's houses, and appear in public accompanied by slaves and eunuchs; but the women of the sultan's harem have none of these privileges.

It is of course only the richer Moslems who can maintain harems; the poorer classes have generally but one wife.

Hares. In the United States the names hare and rabbit are used indiscriminately for various species of rodents of the family *Leporidæ*. Hare is the generic term, while rabbit is applied properly to a single short-legged species of essentially burrowing habits whose naked, blind, and helpless young are nurtured in underground nests (see RABBIT). None of the native American species have these characteristics. The second pair of upper incisors are small, non-functional and placed directly behind the large gnawing teeth, a peculiarity which distinguishes the hares and a few allied forms from all other rodents. The ears are always large, the tail short, bushy, and upturned, the forelimbs short and five-toed, the hind ones long and four-toed, and the soles of the feet densely hairy. Hares are exclusively vegetarian. They are extremely timid, alert and have keen senses. They move with peculiar erratic leaps and with great speed for short distances, and walk with a peculiar shuffling gait by placing the entire sole of the hind foot on the ground. A favorite attitude is that of resting on the haunches with the head erect; but the forelimbs lack altogether the prehensile powers of the squirrels. None of them are arboreal or aquatic. The older catalogues enumerate from 20 to 30 species from all parts of the world except Australasia, but chiefly belonging to the northern hemisphere. With a very few exceptions all the hares are included in the single genus *Lepus*.

The gray rabbit, wood rabbit or cottontail (*L. floridanus* or *L. sylvaticus*) is very plentiful throughout eastern North America north to Ontario. It frequents thickets and brier patches on the borders of woods, multiplying excessively in the more thickly settled regions and replacing the more retiring varying hare. All kinds of succulent herbage, bark, berries, and buds, the latter especially in winter, form the rabbit's food, which it seeks to a large extent along regularly established runways, not infrequently leading to the farmer's truck-patch. Although it does not itself burrow, the cottontail frequently escapes its pursuers by retreating into the holes of woodchucks, skunks, etc., in this respect and some others resembling the true European rabbit more closely than any other American species. Several broods of four to six young are raised each year. At birth they are blind and helpless, and are protected in a nest built in a depression in the ground of dried grass or weeds lined with the rabbit's own fur.

The varying hare or white rabbit (*L. americanus*) is a larger species with longer hind legs, taking its name from the alternating brown and white color of summer and winter respectively, a change which is less complete southward. Much difference of opinion has prevailed regarding the manner in which this change occurs, the latest competent view being that the white coat is due to the growth of new white-tipped hairs among the soft short fur, the brown tint of which again appears with the loss of the white ends of the hairs in the spring. In one or other of its varieties it ranges from Virginia northward to Hudson Bay, and is common in the hemlock forests northward. This is a typical hare, which depends for its safety from foxes, lynxes, weasels, hawks, owls and numerous other enemies solely upon its quick senses and great speed. It never enters burrows, but lives by day and night with no other shelter than that afforded by thickets. Feeding chiefly by night it travels along regular runways used in common by several individuals, a fact which is sometimes taken advantage of by foxes and other enemies to compass their destruction. A favorite winter food is the bark and buds of the birch tree. Scarcely any nest is formed for the young, which are fully active a short time after birth. A somewhat similar species is the polar hare (*L. arcticus*), a pure white species of high northern latitudes.

The jack-rabbit or prairie hare (*L. campestris*) is representative of a group of large, long-legged, big-eared hares which inhabit the western plains, and whose lives are spent mostly "on the jump." For short distances they are perhaps the swiftest quadrupeds known. Their lives are spent among the bushes, upon the twigs of which they feed, and where their young are dropped and within a short time required to shift for themselves. In cultivated districts the jack-rabbits increase enormously and become great pests. As a consequence they are much hunted, not only with dog and gun and snare, as are the eastern species, but by the organization of extensive "drives" which result in the destruction of thousands, the bodies of which are shipped to the markets. Coursing them with greyhounds after the English fashion (see COURSING) is an exciting and favorite sport.

The marsh hare (*L. palustris*) and water hare (*L. aquaticus*), of the Southern Atlantic seaboard and the Mississippi valley respectively, are rather short-legged species, which differ from the others in the readiness with which they will enter water.

In Europe the common hare (*L. timidus*), the mountain hare (*L. variabilis*) and the rabbit (*L. cuniculus*), from which the domestic races have been derived, are the principal species. Consult: Coues and Allen, 'Monographs of the Rodentia' (1877); Thompson, 'Wild Animals I have Known' (1898); Stone and Cram, 'American Animals' (1902).

Hargraves, här'gravz, **Edmund Hammond,** English discoverer of the gold-fields of Australia: b. Gosport, England, 1815; d. Sidney, N. S. W., October 1891. When 18 he settled in Australia, but attracted to California in 1849, he there tried his luck as gold-digger, and detecting a similarity in the geological formation of California and Australia, inferred that gold would be found in the latter, also on his return established the correctness of his surmise by finding gold on the west slopes of the Blue Hills in New South Wales in 1851. He was appointed commissioner of crownlands, and received from the government of New South Wales a reward of $50,000. In 1855 he published 'Australia and Its Gold-fields.'

Hargreaves, här'grēvz, **James,** English inventor: b. Stanhill, near Blackburn, Lancashire; d. Nottingham, England, April 1778. In 1760 he invented a machine consisting of a revolving cylinder with cards or combs set round it as a substitute for the hand-cards formerly in use in combing out cotton. Some years after this he invented the spinning-jenny, by which he was able to spin with several spindles at once. With his new machines he succeeded in turning out a

much greater amount of yarn than his neighbors, which excited their jealousy, and they accordingly broke into his dwelling, and destroyed his machine. In consequence of repeated persecution of this kind Hargreaves removed in 1768 to Nottingham, and in 1770 obtained a patent for his invention. Here, however, he reaped scarcely any more benefit from it than before. After refusing £3,000 offered him by a private company for his patent, this was declared invalid on the ground that he had sold several of the machines before taking out the patent. For the rest of his life he carried on business as a cotton manufacturer in partnership with Mr. James. The only public recognition this invention ever obtained was in the form of a bounty of £250 granted by Sir Robert Peel, nearly 70 years after Hargreaves' death, to his last surviving daughter.

Häring, Wilhelm, vĭl'hĕlm hā'rĭng, "ALEXIS WILIBALD," German historical novelist: b. Breslau 29 June 1798; d. Arnstadt 16 Dec. 1871. His work was suggested by the 'Waverley Novels' and in fact, his first two important works, 'Walladmor' and 'Avalon Castle,' purported to be translations from Scott. His works are historical tales of Prussia, with Frederick the Great for hero: among these may be cited 'Cabanis'; 'The False Waldemar'; 'Peace is the First Civic Duty.' He was very fertile in plot and incident, but his style is mannered; the tales are still popular, however, from their patriotic fervor.

Harivaṅśa, hă-rĭ-văn'sha, a Sanskrit epic poem, later than the Mahâbhârata, to which it forms a sort of sequel or epilogue. It has been translated into French by Langlois (1834).

Hark, Joseph Maximilian, Moravian clergyman: b. Philadelphia 4 June 1849. Graduated from the Moravian College and Theological Seminary in Bethlehem, Pa., he entered the Moravian ministry and was successively pastor of Moravian churches in Lebanon, Philadelphia and Lancaster, Pa. Since 1893 he has been principal of the Moravian Seminary at Bethlehem, Pa., the oldest girls' boarding school in America. He has been a frequent contributor to 'The Outlook' and other periodicals, and has published 'The Unity of the Truth in Christianity and Evolution.'

Hark'ness, Albert, American Latinist: b. Mendon, Mass., 6 Oct. 1822. He was graduated from Brown University in 1842, and in 1855 was appointed professor of Greek in that institution. He was a founder of the American Philological Association, and its president in 1875–6. In 1884 he was elected director of the American School of Classical Studies at Athens, Greece. His best-known work has been in connection with a series of Latin text-books widely used and of much influence; including a first book, readers, a manual of prose composition, editions of Cæsar, Cicero, and Sallust, and an excellent 'Latin Grammar' (1881), revised and enlarged as 'A Complete Latin Grammar' (1898).

Harkness, William, American astronomer: b. Ecclefechan, Scotland, 17 Dec. 1837; d. 1903. He was graduated from Rochester University in 1858, studied medicine, was a surgeon in the Federal army for a time, in 1862–5 was an aid in the United States naval observatory, and during the total eclipse of 7 Aug. 1869 discovered the line K. 1474 of the solar corona. He is best known for his theory of the focal curve of achromatic telescopes, and for his invention of the spherometer caliper, the most nearly accurate device for the measurement of the inequalities of pivots in astronomical instruments. In 1894–9 he was astronomical director of the Naval Observatory, and in 1899 was retired with relative rank of rear-admiral. He published 'The Solar Parallax' (1891).

Harlan, James, American legislator: b. Clarke County, Ill., 25 Aug. 1820; d. Mount Pleasant, Iowa, 5 Oct. 1899. He was graduated from Indiana Asbury (now De Pauw) University in 1845, in 1853 was elected president of Iowa Wesleyan University, in 1855–65 served as United States senator, in 1865–6 was secretary of the interior, and then served a third term (1866–72) in the Senate. Subsequently he was editor of the Washington *Chronicle*, and in 1882–5 presiding judge of the court of commissioners of Alabama claims.

Harlan, John Marshall, American jurist: b. Boyle County, Ky., 1 June 1833. He was graduated from Centre College, Kentucky, studied law at Transylvania University, and entering upon the practice of his profession at Frankfort, became county judge in 1858, and was Whig candidate for Congress in 1859, but was not elected. In the Civil War he served in the Union army as colonel of a Kentucky regiment, and in 1863–6 was attorney general of his State. He was Republican nominee for governor in 1871 and 1875, but was defeated on both occasions. In the Republican National Convention of 1872 his name was presented by the Kentucky delegation for the nomination for vice-president of the United States. In 1877 he was appointed a member of the commission to investigate the troubles in Louisiana; and in November of that same year he was appointed associate justice of the United States Supreme Court, of which he is considered one of the most able and independent members. He supported the constitutionality of the income tax clause of the Wilson Tariff Bill.

Harlan, Iowa, city, county-seat of Shelby County; on the West Nishnabotna River, the Chicago, R. I. & P., the Chicago & N. R.R.'s; about 90 miles west of Des Moines. The chief manufactures are foundry products, agricultural implements, flour, bricks, gasoline engines, and furniture. Its shipping trade is in agricultural products and the manufactures of the city. Pop. (1900) 2,422.

Harland, här'land, **Henry,** pseudonym 'SIDNEY LUSKA,' Anglo-American novelist: b. St. Petersburg, Russia, 1 March 1861; d. San Remo, Italy, 21 Dec. 1905. He was educated at Harvard and after being in the surrogate's office in New York 1883–6 removed to London, where he edited the 'Yellow Book.' He published 'As It Was Written' (1885), a musician's story; 'Mrs. Peixada' (1886); 'The Land of Love' (1887); 'My Uncle Florimond' (1888); 'The Yoke of the Thorah' (1887); 'Mr. Sonnenschein's Inheritance' (1888); 'A Latin-Quarter Courtship'; 'Comedies and Errors' (1898); 'Cardinal's Snuff-box' (1900); etc., books which have been extensively circulated in both America and England.

Harland, Marion. See TERHUNE, MARY VIRGINIA.

Harlech, här'lĕh, Wales, an ancient town, the former capital of Merionethshire, situated on the coast, 10 miles north of Barmouth. On a steep hill overlooking the sea is the castle, which held out for the Lancastrians in the wars of the Roses, and later for Charles I. The 'March of the Men of Harlech' commemorates its capture by the Yorkists in 1468.

Harlem, a part of New York city above 106th street, between the East and Harlem Rivers and Eighth Avenue. See NEW YORK CITY.

Harlem, Ill., village in Cook County; on the Illinois C. and the Chicago & N. W. R.R.'s; about seven miles from Chicago and near Oak Park. The first permanent settlement was made in 1854, and the village of Harlem was incorporated in 1883. It is a residential suburb of Chicago, and is noted for its race track (see HORSE-RACING). Waldheim and Forest Home cemeteries are in Harlem. A monument to the men executed as anarchists who were connected with the Chicago riots of 1886 is in the Waldheim cemetery. The government is vested in a president and board of trustees elected annually. Pop. (1900) 4,085.

Harlem Plains, Battle of, in the Revolutionary War, a conflict on 16 Sept. 1776, which followed Howe's occupation of New York and Manhattan Island. On the Harlem Plains or Flats an advance guard of British troops came into contact with a body of Virginian and Connecticut troops commanded respectively by Majors Leitch and Knowlton. In attempting to flank the enemy Knowlton was killed, and by Washington's orders the Americans retreated, with a loss of 60 killed and wounded.

Harlem River, the name given to the tidal channel north of the island of Manhattan, which separates the boroughs of Manhattan and the Bronx, in New York. The Harlem is connected with the Hudson River by Spuyten Duyvil Creek, and extends south by east about seven miles to East River. Randall's Island is at its entrance to East River. In 1895 a ship-canal was opened which connects the Hudson and the Harlem south of the Spuyten Duyvil channel. A number of bridges span the Harlem, the finest being High Bridge, an aqueduct bridge, and Washington Bridge which crosses the river a little north of a point opposite Fort Washington on the Hudson. Along the western shore is the excellent roadway called the Speedway, and on the same side of the river are the polo and ball grounds, the High Bridge park and a number of fine public and private buildings.

Harlequin, här'lĕ-kĭn or -kwĭn (French, *arlequin*, Italian *arlecchino*), a word of doubtful origin, but probably from old French *Hellequin*, *Herlequin*, the name of a demon figuring in mediæval legends; this again is supposed to be of German origin, its elements corresponding to English "hell" and "kin." Riccoboni conjectures ('History of the Italian Theatre') that the dress of the harlequins is no other than the *centunculus* of the old Roman *mimi* or mimes, who were players in ridiculous pieces or farces of a loose character. The character of the ancient harlequin was a mixture of extravagant buffoonery with great bodily agility. But in the middle of the 16th century his character was essentially changed. He became a simple, ignorant servant, who tries very hard to be witty, even at the expense of being malicious. He is a chameleon, who assumes all colors, and can be made, in the hands of a skilful actor, the principal character on the stage. He must excel in extempore sallies. This account applies more particularly to the Italian harlequin. The gallant, obsequious French harlequin is an entirely national mask. In the vaudeville theatre he is silent, with a black half-mask, and reminds one throughout the representation of the grace and agility of the cat. In Great Britain, in the Christmas pantomimes, he becomes a lover and a magician; and in exchange for the gift of language, of which he has been deprived, he has been invested with a wonder-working wand. With this wand he protects his mistress, the columbine, against the clown and pantaloon, who pursue and endeavor to capture her, until the pursuit is brought to a termination by a good fairy. The harlequin wears a tight dress of bright colors, and glittering with spangles.

Harlequin Cabbage-bug. See CABBAGE-INSECTS.

Harlequin Duck. See DUCK.

Harlequin Snake. See CORAL SNAKE.

Har'ley, Robert, 1st EARL OF OXFORD, English statesman: b. London 5 Dec. 1661; d. 21 May 1724. After the accession of Anne he and his colleague St. John, afterward Lord Bolingbroke, became leaders of the Tories. The former was chosen speaker of the House of Commons in 1702, and was chief secretary of state 1704–8. After the fall of Marlborough Harley became chancellor of the exchequer in 1710, and next year was created Earl of Oxford. He and Bolingbroke secured the Treaty of Utrecht (1713), but afterward quarrelled. Early in the reign of George I. he was impeached of high treason on the ground of his alleged Jacobite intrigues, and was kept in the Tower for two years, but owing to the inability of the Peers and the Commons to agree about the mode of procedure, was acquitted. His patronage was extended to Swift, Pope, and other literary men, and he made a valuable collection of books and MSS., which latter are preserved in the British Museum, where they form the 'Bibliotheca Harleiana.' Those which have been printed constitute the 'Harleian Miscellany.'

Harlow, här'lō, **George Henry,** English painter: b. London 10 June 1787; d. there 4 Feb. 1819. After studying under other masters, he entered the studio of Sir Thomas Lawrence, who used to employ him to dead color. In 1818 he visited Rome, where he astonished the artists there by completing an effective copy of the 'Transfiguration' of Raphael in 18 days. This gained him the friendship of Canova, who procured his election as a member of the Academy of St. Luke. His best original works are two designs from Shakespeare, 'Hubert and Prince Arthur,' and the 'Trial of Queen Catharine.' The principal characters in the latter are portraits of members of the Kemble family; and the figure of Queen Catharine is a likeness of Mrs. Siddons (q.v.). He was eminent as a portrait painter, and his portrait of Fuseli is regarded as a work of great merit.

Harlowe, Clarissa, a novel published by Samuel Richardson in 1748. The story is told by means of letters, and while somewhat prolix

for modern taste, is an accurate record of many of the manners and ideals of the 18th century.

Har'maline and **Harmine,** two alkaloids which occur, probably in the form of phosphates, in the seed-coatings of the harmel or Syrian rue (*Peganum harmala*), a plant growing in the Mediterranean region and in southern Asia. The seeds are extracted with dilute acetic or sulphuric acid, and the hydrochlorids of the two alkaloids are precipitated by the addition of common salt. The precipitate is washed with salt solution, and afterward with water, in which the hydrochlorids dissolve. The filtrate is clarified by animal charcoal and heated to 140° F., after which ammonia is added. Harmine is precipitated first, and by the continued addition of ammonia the harmaline is thrown down subsequently. Harmine has the formula $C_{13}H_{12}N_2O$. It is practically insoluble in ether, and is but slightly soluble in water. It dissolves in alcohol, from which it crystallizes in colorless monoclinic prisms, melting at 495° F. Harmaline is the hydrid of harmine, and has the formula $C_{13}H_{14}N_2O$. It is somewhat soluble in water, ether, and cold alcohol, and dissolves freely in hot alcohol. It crystallizes from solution in alcohol in the form of octahedra belonging to the trimetric system, and melts at 460° F. The salts of harmine are mostly colorless, while those of harmaline are yellow; and the salts of both of these bases exhibit marked fluorescence. The name «harmaline» is also applied to the coloring matter now more commonly known as fuchsine.

Har'mar, Josiah, American soldier: b. Philadelphia 1753; d. there 20 Aug. 1813. He entered the patriot army as captain, became colonel in 1777, served with Washington (1778–80) and with Greene in the South. In 1784 he brought to France the ratification of the final treaty. In 1789 he was made brigadier-general in the United States army, and was general-in-chief of the army from 1789 to 1792. He conducted an expedition against the Miami Indians, which suffered a severe defeat, and shortly afterward resigned his commission. From 1793–9 he was adjutant-general of Pennsylvania.

Harmattan, här-măt'an, a land-wind, very dry and hot, blowing upon the coast of Africa between Cape Verde, in lat. 14° 43′ N., and Cape Lopez, lat. 0° 36′ S., during December, January, and February. It is generally attended by fog, through which the sun shines red. It hurts vegetation and injuriously affects man, drying up the eyes, the mouth, etc., even peeling off the skin. On the other hand, it tends to terminate fever and dysentery, and to mitigate cutaneous diseases. It corresponds to the sirocco of Italy and, to a certain extent, to the Indian and Australian hot wind.

Harmodius (här-mō'dī-ŭs) and **Aristogiton,** ă-rĭs-tō-jī't'n, two Athenian youths who in 514 B.C. killed Hipparchus, the younger brother of the tyrant Hippias, partly because of an insult offered to the sister of Harmodius, and partly with a view to the overthrow of the Pisistratidæ. Harmodius was slain by the soldiers of Hipparchus, while Aristogiton fled, but was afterward taken and executed. Subsequently they came to be regarded as patriotic martyrs, and received divine honors from the Athenians, and had statues raised to their memory. They were strongly attached to each other, and are sculptured in a group in the Museo Nazionale, Naples, copied from the bronze originals which once adorned the Acropolis at Athens.

Har'mon, Judson, American jurist: b. Hamilton County, Ohio, 3 Feb. 1846. He was graduated at Denison University, 1866, and at Cincinnati Law School, 1869. He was judge of the common pleas court (1876–8); judge of the superior court of Cincinnati, 1878–87; and attorney-general of the United States, 1896–7. He is president of the Ohio Bar Association, and a member of the faculty in the law department of the University of Cincinnati.

Harmonic Analysis, The. «The Harmonic Analysis» is the name first given by Thomson and Tait in their 'Natural Philosophy' to a method extensively and fruitfully employed in investigations in many branches of Mathematical Physics, and first used by Daniel Bernouilli and Euler in the middle of the eighteenth century in studying the musical vibrations of a stretched elastic string.

From the physical side it is described by J. Clerk Maxwell as «a method by which the solution of an actual problem may be obtained as the sum or resultant of a number of terms, each of which is a solution of a particular case of the problem.» The method is applicable to physical problems where the actual complicated state under investigation can be regarded as due to the superposition of a number of simpler states that can coexist without interfering with one another.

For example, in dealing with the small oscillations of a musical string it is known that the string is capable of sounding a variety of so-called pure notes, known as the fundamental note, the first harmonic or octave of the fundamental note, and the higher harmonics of the fundamental note, and that the forms of vibration giving these various notes may coexist, so that the string may be sounding at once its fundamental note and its various harmonics and thus be giving a note quite distinguishable from its pure fundamental note though of the same pitch. If we are dealing with the problem of the motion of a string sounding such a complicated note, the harmonic analysis enables us to obtain and to express its solution as a sum of the terms expressing the motions which separately would give the separate pure notes actually present.

From the mathematical side the problems to which the harmonic analysis is applicable are those in which it is necessary to find a solution of a homogeneous linear differential equation which shall satisfy a set of given initial or boundary conditions sufficiently numerous to make the problem determinate. It is well known that if a solution of such a differential equation has been obtained, it may be multiplied by any constant and will still be a solution; and that if several solutions have been obtained, their sum will be a solution. In using the harmonic analysis we attempt by a skilful use of these two principles to so combine simple particular solutions of the differential equation involved in the problem as to form a solution of the equation which satisfies all the given conditions. This usually makes it necessary to analyze some one of the given conditions into a sum or series of simpler so-called harmonic terms, or in other words to develop some function of one of the

independent variables, or of a set of the independent variables into a series whose terms are of specified form.

For instance, suppose a harp-string of length l initially distorted into a curve whose equation referred to the position of equilibrium of the string as the X-axis and to one end of the string as origin is $y=f(x)$, and then released, and that it is required to solve the problem of the subsequent motion of the string, the initial displacement being small.

Here we have to solve the differential equation

$$\frac{\partial^2 y}{\partial t^2}=a^2\frac{\partial^2 y}{\partial x^2}, \qquad (I)$$

subject to the conditions $y=0$ when $x=0$; $y=0$ when $x=l$; $\frac{\partial y}{\partial t}=0$ when $t=0$; $y=f(x)$ when $t=0$. It is known and is easily verified that $y=\sin\beta x\cos a\beta t$ is a particular solution of (I) if β is any constant. If we take $\beta=\frac{m\pi}{l}$, where m is any whole number, $y=\sin\frac{m\pi x}{l}\cos\frac{m\pi at}{l}$ is a solution of (I) which satisfies our first three conditions; and so is

$$y=a_1\sin\frac{\pi x}{l}\cos\frac{\pi at}{l}+a_2\sin\frac{2\pi x}{l}\cos\frac{2\pi at}{l}+a_3\sin\frac{3\pi x}{l}\cos\frac{3\pi at}{l}+\ldots, \qquad (1)$$

where a_1, a_2, a_3, ... are any constants. When $t=0$ (1) reduces to

$$y=a_1\sin\frac{\pi x}{l}+a_2\sin\frac{2\pi x}{l}+a_3\sin\frac{3\pi x}{l}+\ldots, \qquad (2)$$

and if we can choose a_1, a_2, etc., so that the series in (2) is equal to $f(x)$ for all values of x between 0 and l, (1) becomes our required solution. This calls for the development of $f(x)$ into a Trigonometric Series of somewhat peculiar form known as a Fourier's Series, and when that is accomplished our solution is complete.

Fourier's Series.—It was first shown by Fourier in his researches into the Conduction of Heat in 1812 that

$$f(x)=\tfrac{1}{2}b_0+b_1\cos\frac{\pi x}{c}+b_2\cos\frac{2\pi x}{c}+b_3\cos\frac{3\pi x}{c}+\ldots$$
$$+a_1\sin\frac{\pi x}{c}+a_2\sin\frac{2\pi x}{c}+a_3\sin\frac{3\pi x}{c}+\ldots, \qquad (3)$$

where $$a_m=\frac{1}{c}\int_{-c}^{c}f(x)\sin\frac{m\pi x}{c}dx,$$

and $$b_m=\frac{1}{c}\int_{-c}^{c}f(x)\cos\frac{m\pi x}{c}dx,$$

for all values of x between $-c$ and c.

If $f(-x)=-f(x)$, that is, if $f(x)$ is an odd function, (3) reduces to

$$f(x)=a_1\sin\frac{\pi x}{c}+a_2\sin\frac{2\pi x}{c}+a_3\sin\frac{3\pi x}{c}+\ldots, \qquad (4)$$

where $$a_m=\frac{2}{c}\int_0^c f(x)\sin\frac{m\pi x}{c}dx.$$

If $f(-x)=f(x)$, that is, if $f(x)$ is an even function, (3) reduces to

$$f(x)=\tfrac{1}{2}b_0+b_1\cos\frac{\pi x}{c}+b_2\cos\frac{2\pi x}{c}+b_3\cos\frac{3\pi x}{c}+\ldots, \qquad (5)$$

where $$b_m=\frac{2}{c}\int_0^c f(x)\cos\frac{m\pi x}{c}dx.$$

If the development need hold good merely for values of x between 0 and c, any one of the forms given above may be employed.

Harmonic Functions.—Laplace's Equation,

$$\frac{\partial^2 V}{\partial x^2}+\frac{\partial^2 V}{\partial y^2}+\frac{\partial^2 V}{\partial z^2}=0, \qquad (II)$$

in the numerous forms it assumes in different systems of coördinates plays a larger part in the various branches of mathematical physics than any other differential equation, and the harmonic analysis is required in a large proportion of the physical problems that obey the law it expresses.

A function which together with its first space derivatives is continuous within a specified region and which satisfies Laplace's equation at every point within the region is said to be *harmonic* in the region in question.

The form to which a harmonic function reduces on one of the level surfaces of the appropriate coördinate system is called a *Surface Harmonic.*

Zonal Harmonics.—The coefficient of z^m in the development of $(1-2\mu z+z^2)^{-\frac{1}{2}}$ in ascending powers of z, where $\mu=\cos\theta$, is represented by $P_m(\mu)$ and is called a *Surface Zonal Harmonic* of the mth degree, or a *Legendre's Coefficient* or *Legendrian.*

It can be shown that $V=r^mP_m(\cos\theta)$ and $V=\frac{1}{r^{m+1}}P_m(\cos\theta)$ are particular solutions of Laplace's equation in spherical coördinates,

$$\frac{r\partial^2(rV)}{\partial r^2}+\frac{1}{\sin\theta}\frac{\partial\left(\sin\theta\frac{\partial V}{\partial\theta}\right)}{\partial\theta}+\frac{1}{\sin^2\theta}\frac{\partial^2 V}{\partial\phi^2}=0. \qquad (III)$$

They are called *Solid Zonal Harmonics.* The first form is harmonic within the sphere whose centre is at the origin of coördinates and whose radius is unity, and the second form is harmonic in all space outside of that sphere. They are appropriate functions to use in solving problems where a solution of (III) is required, if it is evident from considerations of symmetry that the solution is independent of the coördinate ϕ.

$$P_m(\mu)=\frac{1\cdot3\cdot5\cdot\ldots\cdot(2m-1)}{1\cdot2\cdot3\cdot\ldots\cdot m}\left[\mu^m-\frac{m(m-1)}{2(2m-1)}\mu^{m-2}+\frac{m(m-1)(m-2)(m-3)}{2\cdot4\cdot(2m-1)(2m-3)}\mu^{m-4}\cdots\right],$$

whence

$$P_0(\mu)=1, \qquad P_2(\mu)=\tfrac{1}{2}(3\mu^2-1),$$
$$P_1(\mu)=\mu, \qquad P_3(\mu)=\tfrac{1}{2}(5\mu^3-3\mu),$$
$$P_4(\mu)=\tfrac{1}{8}(35\mu^4-30\mu^2+3),$$
$$P_5(\mu)=\tfrac{1}{8}(63\mu^5-70\mu^3+15\mu).$$
$$\ldots\ldots\ldots\ldots\ldots$$

A very important property of the Surface Zonal Harmonic $P_m(\mu)$ which follows readily from its definition is $P_m(1)=1$. That is, the function

reduces to unity at all points on the polar axis.

If, in a problem where V must satisfy Laplace's Equation and there is symmetry about the polar axis, the value of V on the axis is represented by a convergent series $a_0+a_1z+a_2z^2+\ldots$, z being the distance of the point from the origin, then the series formed by writing $r^mP_m(\cos\theta)$ instead of z^m in the given series gives the value of V at any point in space at which the new series is convergent. If the value of V on the axis is represented by a convergent series $\frac{a_1}{z}+\frac{a_2}{z^2}+\frac{a_3}{z^3}+\ldots$, then the series formed from the given series by replacing $\frac{1}{z^{m+1}}$ by $\frac{1}{r^{m+1}}P_m(\cos\theta)$ gives the value of V at any point in space at which the new series is convergent.

For instance, if a charge M of statical electricity be placed on a conductor in the form of a thin circular disc of radius a, it is known that the charge will so distribute itself that the surface density σ at any point of the disc at the distance s from its center will be $\sigma=\frac{M}{4a\pi\sqrt{a^2-s^2}}$.

If the axis of the disc is taken as the polar axis, the value of the Potential Function V due to the charge, at a point of the axis at the distance x from the centre is $V=\frac{M}{2a}\cos^{-1}\left(\frac{x^2-a^2}{x^2+a^2}\right)$. This can be developed into the series

$$\frac{M}{a}\left[\frac{\pi}{2}-\frac{x}{a}+\frac{x^3}{3a^3}-\frac{x^5}{5a^5}+\ldots\right] \quad \text{if} \quad x<a,$$

or $$\frac{M}{a}\left[\frac{a}{x}-\frac{a^3}{3x^3}+\frac{a^5}{5x^5}-\frac{x^7}{7a^7}+\ldots\right] \quad \text{if} \quad x>a.$$

Hence

$$V=\frac{M}{a}\left[\frac{\pi}{2}-\frac{r}{a}P_1(\cos\theta)+\frac{1}{3!}\frac{r^3}{a^3}P_3(\cos\theta)-\frac{1}{5}\frac{r^5}{a^5}P_5(\cos\theta)+\ldots\right] \text{ if } r<a, \text{ and } \theta<\frac{\pi}{2};$$

and

$$V=\frac{M}{a}\left[\frac{a}{r}-\frac{1}{3}\frac{a^3}{r^3}P_2(\cos\theta)+\frac{1}{5}\frac{a^5}{r^5}P_4(\cos\theta)-\ldots\right] \quad \text{if} \quad r>a.$$

If, in a problem where V must satisfy Laplace's Equation and there is symmetry about an axis, the value of V on the surface of the sphere $r=a$ is given and can be expressed as a sum or as a series of Surface Zonal Harmonics, the value of V at a point not on the sphere will be obtained by replacing the Surface Zonal Harmonics by the appropriate Solid Zonal Harmonics.

To take a very simple example: If a charge of electricity is placed on a spherical conductor of radius a, it is known that it will so distribute itself that all points on the surface will be at the same potential $\frac{M}{a}$.

Now $\frac{M}{a}=\frac{M}{a}P_0(\cos\theta)$ and is a Surface Zonal Harmonic. Hence any point at the distance r from the centre of the conductor is at potential $\frac{M}{a}\frac{r^0}{a^0}P_0(\cos\theta)$ or $\frac{M}{a}$ if $r<a$, and at potential $\frac{M}{a}\frac{a}{r}P_0(\cos\theta)$ or $\frac{M}{r}$ if $r>a$.

If the value of V on the surface of the sphere had been less simple, say $V=F(\theta)\equiv f(\cos\theta)\equiv f(\mu)$, then $f(\mu)$ would have had to be expressed in the form $a_0P_0(\mu)+a_1P_1(\mu)+a_2P_2(\mu)+\ldots$ before we could have used the simple method illustrated above. This can be done by the aid of the formula

$$f(\mu)=a_0P_0(\mu)+a_1P_1(\mu)+a_2P_2(\mu)+a_3P_3(\mu)+\ldots,$$

where $a_m=\frac{2m+1}{2}\int_{-1}^{1}f(x)P_m(x)dx$, the development in question holding good when $-1<\mu<1$.

For instance, let one half of the surface of a homogeneous sphere be kept at the temperature zero and the other half at the temperature 1; to find the stationary temperature u of any internal point. Here $f(\mu)=1$, $0<\mu<1$, and $f(\mu)=0$, $-1<\mu<0$. Consequently

$$a_m=\frac{2m+1}{2}\left[\int_{-1}^{0}0\cdot P_m(x)dx+\int_{0}^{1}P_m(x)dx\right]$$

$$=\frac{2m+1}{2}\int_{0}^{1}P_m(x)dx.$$

Letting $m=0, 1, 2, \ldots$, successively, and using the corresponding values $1, x, \frac{1}{2}(3x^2-1)$, etc., of $P_m(x)$, we get $a_0=\frac{1}{2}$, $a_1=\frac{3}{4}$, $a_2=0$, $a_3=-\frac{7}{8}\cdot\frac{1}{2}$, $a_4=0$, $a_5=\frac{11}{12}\cdot\frac{1}{2}\cdot\frac{3}{4}$, ... and $f(\mu)=\frac{1}{2}P_0(\mu)+\frac{3}{4}P_1(\mu)-\frac{7}{8}\cdot\frac{1}{2}P_3(\mu)+\frac{11}{12}\cdot\frac{1}{2}\cdot\frac{3}{4}P_5(\mu)-\ldots$.

If a is the radius of the sphere, the required temperature

$$u=\frac{1}{2}+\frac{3}{4}\frac{r}{a}P_1(\cos\theta)-\frac{7}{8}\cdot\frac{1}{2}\frac{r^3}{a^3}P_3(\cos\theta)+\frac{11}{12}\cdot\frac{1}{2}\cdot\frac{3}{4}\frac{r^5}{a^5}P_5(\cos\theta)\ldots.$$

Tables giving the numerical values of the Surface Zonal Harmonics have been computed and are accessible, and by their aid numerical results can be obtained in such problems as those we have been considering as readily as if we were using simple trigonometric functions. The following is such a table carried only to three places.

TABLE 1.—SURFACE ZONAL HARMONICS.

θ	$P_1(\cos\theta)$	$P_2(\cos\theta)$	$P_3(\cos\theta)$	$P_4(\cos\theta)$	$P_5(\cos\theta)$
0°	1.000	1.000	1.000	1.000	1.000
10	.985	.955	.911	.853	.784
20	.940	.824	.665	.475	.272
30	.866	.625	.325	.023	−.223

50	.643	.120	−.300	−.428	−.254
60	.500	−.125	−.438	−.289	.090
70	.342	−.324	−.413	−.004	.328
80	.174	−.455	−.247	.266	.281
90	.000	−.500	.000	.375	.000

Legendrians were first used by Legendre in a paper published in 1785 on the attraction of solids of revolution.

Laplace's Coefficients. — $P_m(\cos\gamma)$, where $\gamma\equiv\cos\theta\cos\theta_1+\sin\theta\sin\theta_1\cos(\phi-\phi_1)$, and is the angle made by the radius vector with a fixed

line through the origin whose direction is given by the angles θ_1 and ϕ_1, is called a Laplace's Coefficient or Laplacian, the fixed line being called the Axis and its intersection with the unit sphere the Pole of the Laplacian. A Surface Zonal Harmonic $P_m(\cos\theta)$ is merely a Laplacian whose axis coincides with the axis of coördinates. $r^m P_m(\cos\gamma)$ and $\frac{1}{r^{m+1}} P_m(\cos\gamma)$ are solutions of Laplace's Equation (III). The first is harmonic within and the second without the unit sphere.

Laplacians may be used in problems symmetrical about an axis if the axis does not coincide with the axis of coördinates just as Zonal Harmonics are used when the problem is symmetrical about the polar axis.

Laplacians were first used by Laplace, in one of the most remarkable memoirs ever written, in determining the attraction of a Spheroid. The paper in question was published in 1782.

Spherical Harmonics.—A Surface Spherical Harmonic of the mth degree Y_m may be most simply defined as the function obtained by dividing a rational, integral, homogeneous, algebraic polynomial of the mth degree in x, y, z which satisfies Laplace's Equation (I), by r^m, that is, by $(x^2+y^2+z^2)^{\frac{m}{2}}$. For example, $\frac{1}{r}(x+y+z)$, $\frac{1}{r^2}(x^2+xy+y^2)$, $\frac{1}{r^3}(2x^3-3xy^2-3xz^2)$ are Surface Spherical Harmonics of the first degree, of the second degree, and of the third degree, respectively.

It is clear that $r^m Y_m$ satisfies Laplace's Equation. The same thing can be shown of $\frac{1}{r^{m+1}} Y_m$. The first is harmonic within, the second without, the unit sphere. They are known as Solid Spherical Harmonics.

It is clear that if the value of V on the surface of a sphere whose centre is the origin can be expressed as a sum of terms each of which is a surface Spherical Harmonic, its value at any point not on the surface is the sum of the appropriate corresponding Solid Spherical Harmonics.

It can be shown by transforming from spherical to rectangular coördinates that the Surface Zonal Harmonic $P_m(\mu)$ or $P_m(\cos\theta)$ and the Laplacian $P_m(\cos\gamma)$ are Surface Spherical Harmonics, and by the reverse transformation that the general Surface Spherical Harmonic Y_m can be formulated as

$$Y_m = A_0 P_m(\mu) + \sum_{n=1}^{n=m}\left[(A_n\cos n\phi + B_n \sin n\phi)\sin^n\theta \frac{d^n P_m(\mu)}{d\mu^n}\right].$$

A function given arbitrarily on the surface of the unit sphere, i.e., a function of θ and ϕ, if expressed as a function of $\cos\theta$ and ϕ can be developed into a series of Surface Spherical Harmonics by the formulas

$$f(\mu,\phi) = \sum_{m=0}^{m=\infty}\left\{A_{0,m}P_m(\mu) + \sum_{n=1}^{n=m}\left[(A_{n,m}\cos n\phi + B_{n,m}\sin n\phi)\sin^n\theta\frac{d^n P_m(\mu)}{d\mu^n}\right]\right\},$$

$$A_{0,m} = \frac{2m+1}{4\pi}\int_0^{2\pi} d\phi \int_{-1}^{1} f(\mu,\phi)P_m(\mu)d\mu,$$

$$\frac{2\pi}{2m+1}\frac{(m+n)!}{(m-n)!}A_{n,m} = \int_0^{2\pi}\int_{-1}^{1} f(\mu,\phi)\cos n\phi \sin^n\theta \frac{d^n P_m(\mu)}{d\mu^n}d\mu,$$

$$\frac{2\pi}{2m+1}\frac{(m+n)!}{(m-n)!}B_{n,m} = \int_0^{2\pi} d\phi\int_{-1}^{1} f(\mu,\phi)\sin n\phi \sin^n\theta \frac{d^n P_m(\mu)}{d\mu^n}d\mu.$$

The following theorems concerning the integration of Spherical Harmonics are important. We give them without proof.

The integral of the product of two Surface Spherical Harmonics $Y_m Y_n$ of different degrees taken over the surface of the unit sphere is equal to zero.

The integral over the surface of the unit sphere, of the product of a Surface Spherical Harmonic by a Laplacian of the same degree, is $\frac{4\pi}{2m+1}$ multiplied by the value the Spherical Harmonic assumes at the Pole of the Laplacian.

These theorems enable us to solve many problems in the theory of Gravitation and the theory of Electrostatics by direct integration.

Bessel's Functions.—A Bessel's Function or Surface Cylindrical Harmonic of the nth order $J_n(x)$ may be defined as the coefficient of z^n in the development of $e^{\frac{x}{2}\left(z+\frac{1}{z}\right)}$ into an ascending Power Series in z. It can be shown that

$$V = \cosh(\mu z)(A\cos n\phi + B\sin n\phi)J_n(\mu r)$$

and

$$V = \sinh(\mu z)(A\cos n\phi + B\sin n\phi)J_n(\mu r),$$

where μ is any constant, are solutions of Laplace's Equation in Cylindrical Coördinates

$$\frac{\partial^2 V}{\partial r^2} + \frac{1}{r}\frac{\partial V}{\partial r} + \frac{1}{r^2}\frac{\partial^2 V}{\partial\phi^2} + \frac{\partial^2 V}{\partial z^2} = 0. \qquad \text{(IV)}$$

The Bessel's Functions most used are $J_0(x)$ and $J_1(x)$, which are appropriate when the problem has axial symmetry about the Axis of Z.

$$J_0(x) = 1 - \frac{x^2}{2^2} + \frac{x^4}{2^2\cdot 4^2} - \frac{x^6}{2^2\cdot 4^2\cdot 6^2} + \cdots,$$

and is convergent for all values of x.

$$J_1(x) = -\frac{dJ_0(x)}{dx}.$$

Important properties are given by the formulas

$$\int_0^x x J_0(x)dx = xJ_1(x)$$

and

$$\int_0^x x\{J_0(x)\}^2 dx = \tfrac{1}{2}x^2[\{J_0(x)\}^2 + \{J_1(x)\}^2],$$

and the following formulas for development in Cylindrical Harmonic Series, the development holding good for values of r between 0 and a.

$$f(r) = \Sigma A_\kappa J_0(\mu_\kappa r),$$

where μ_κ is a root of the transcendental equation in μ, $J_0(\mu a) = 0$, or of $J_1(\mu a) = 0$, or of

$$\mu a J_1(\mu a) - \lambda J_0(\mu a) = 0,$$

and

$$A_\kappa = \frac{2}{a^2[\{J_0(\mu_\kappa a)\}^2 + \{J_1(\mu_\kappa a)\}^2]} \int_0^a r f(r) J_0(\mu_\kappa r)\, dr.$$

For the important case where $f(r) = 1$,

$$A_\kappa = \frac{2}{\mu_\kappa a[\{J_0(\mu_\kappa a)\}^2 + \{J_1(\mu_\kappa a)\}^2]} J_1(\mu_\kappa a).$$

As an example in the use of Bessel's Functions let us find the stationary temperature of any point (r, z) in a homogeneous cylinder of radius a and altitude b if the convex surface and one base are kept at the temperature zero and the other base at the temperature 1.

Here we seek a solution V of equation (IV) which reduces to zero when $z = 0$, and when $r = a$, and to 1 when $r = b$. By the aid of the formulas above this is easily formed and is

$$V = \frac{2}{\mu_1 a J_1(\mu_1 a)} \frac{\sinh(\mu_1 z)}{\sinh(\mu_1 b)} J_0(\mu_1 r) + \frac{2}{\mu_2 a J_1(\mu_2 a)} \frac{\sinh(\mu_2 z)}{\sinh(\mu_2 b)} J_0(\mu_2 r) + \frac{2}{\mu_3 a J_1(\mu_3 a)} \frac{\sinh(\mu_3 z)}{\sinh(\mu_3 b)} J_0(\mu_3 r) + \ldots$$

If numerical results are desired, tables for $J_0(x)$ and $J_1(x)$ are needed. Such tables have been computed and are accessible. We give here a small three-place one.

TABLE II.—BESSEL'S FUNCTIONS.

Bessel's Functions of the zeroth order were first used successfully in the Harmonic Analysis by Fourier in 1812, in dealing with the flow of heat in a right circular cylinder.

Other more complicated Harmonic Functions are Lamé's Functions or Ellipsoidal Harmonics, Conal Harmonics, Toroidal Harmonics, etc. Each set is adapted to dealing with Laplace's Equation expressed in a suitable system of Curvilinear Coördinates.

Bibliography.—For general treatises on the Harmonic Analysis and on the Harmonic Functions the reader is referred to Heine, 'Handbuch der Kugelfunktionen' (second edition, 1878); Todhunter, 'The Functions of Laplace, Lamé, and Bessel' (1875); Thomson and Tait, 'Natural Philosophy' (Appendix B, 1879); Ferrers, 'Spherical Harmonics' (1881); Byerly, 'Fourier's Series, and Spherical Harmonics' (1895); Gray and Matthews, 'Bessel's Functions' (1895). An excellent account of the history of the subject with detailed references to the early papers, memoirs, and other publications, prepared by Professor M. Bôcher, will be found at the end of Byerly's above-mentioned treatise. For the contemporary literature see the recent volumes of the 'Jahrbuch über die Fortschritte der Mathematik' under the heading Kugelfunktionen und verwandte Funktionen.

WILLIAM E. BYERLY,
Professor of Mathematics, Harvard University.

Harmon'ica, a musical instrument invented by Benjamin Franklin in 1762. It is formed of a number of glasses of water, and is played by touching them with the dampened finger. The less the quantity of water, the lower the tone of the scale. The name is also applied to a small wind instrument, or mouth-organ, which has a series of holes to conduct the breath to free reeds, like those of an accordion.

Harmon'icon, a chemical apparatus consisting of an open glass tube, the air in which may be made to give a sound resembling a musical note, when held over burning hydrogen. The note depends upon the size of the flame and the length of the tube.

Harmon'ics, the accessory or collateral sounds accompanying the primary, fundamental, or predominant tone of any string, pipe, or other sonorous body, and constituting in varying degrees what in English is known as "quality," in French as "timbre," and in German as "Klangfarbe." No purely simple sound—one whose vibrations are all in the same period—is producible. When a sound is produced by the vibration of an open string, the whole string vibrates as a unity, giving rise to a tone called the fundamental. The string, however, further divides into various sections, which vibrate separately and more rapidly, and produce sounds—the harmonics—differing from the fundamental, but bearing certain fixed proportions to it. By whatever vibrating body a musical sound is evoked harmonics also are produced; and although some of the harmonics are suppressed by modifying circumstances, some are always present. There is a regular succession of intervals in which the harmonics naturally accompany a fundamental sound, which is represented in the following scale of vibrations: 1 2 3 4 5 6 7, etc. These also are the intervals which produce the successive chords in harmony, although the natural harmonics when produced further go beyond the range of harmony which human ears can recognize or musical instruments produce at the will of the performer. (See illustration.) 1 is the interval of the octave; 2 is the fifth; 3 is the fourth; 4 is the major third; 5 the minor third; from 6 to 7 is already beyond the range of production on a keyed instrument, but is recognized by musicians as the complement of a four-part simple chord, and is represented approximately on the pianoforte, by E flat, for example, for the key of F.

A musical tone, then, is always complex, but the harmony which attends it is not always the

same. The different structure of different instruments suppresses now some, now others, of the succession of harmonics, and a different body of tone is thus produced, distinguishing a note in one instument from the same note in another. Hence the distinctive construction of the pianoforte in which dissonant harmonics are suppressed, and on the other hand, the use in the organ of mutation and mixture stops—the thirteenths and fifteenths — whereby the consonant harmonies of a given tone are much emphasized. Again, many of the higher harmonics are strongly dissonant both with the fundamental tone and with each other, whence arises the discordant quality of such instruments for instance as the cymbals. Harmonics are also called "overtones," and all the primary and secondary tones constituting an actual tone are frequently termed "partials" or "partial tones," the fundamental tone being the first partial, and the harmonics, the upper partials. See HARMONY.

Harmonics, Spherical. See HARMONIC ANALYSIS.

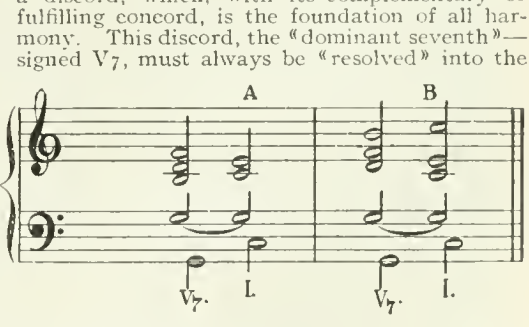
Har'monists, also called RAPPISTS and ECONOMITES, a religious-socialistic community founded in 1787 by George Rapp (1757–1847), a German of Würtemberg. The peaceable and spiritual tenets of the organization aroused antagonism and persecution, and in 1803 they emigrated to America, settling in the Connoquenessing Valley, where the Harmony Society was established on a working basis. By 1805, houses, churches, mills, and manufactories had been built, and the settlement had a population of 750 persons. In 1815 they removed to Posey County, Ind., where they founded New Harmony (q.v.); 10 years later, however, they returned to Pennsylvania, and built the township of Economy, in Beaver County, on the Ohio, 20 miles north of Pittsburg. In 1832, a German adventurer, Bernhard Müller, settling among them, caused dissensions and a split in the society; a separation and apportionment of the property was agreed upon, and 250 members retired. They held all property in common, believed in the second coming of Christ, the near advent of the millennium, and practised celibacy. As a result of the latter condition, the membership in 1902 was reduced to eight, and the valuable estate will pass finally into the hands of the last survivor. Consult Hinds, 'American Communities' (1902); Nordhoff, 'The Communistic Societies of the United States' (1874).

Harmon'ium, a modern musical instrument which produces sounds resembling those of the organ. The invention is ascribed to Alexandre Debain of Paris; but he has at the most merely the credit of perfecting an instrument previously known, called the *orgue expressif*, a kind of organ furnished with an apparatus of free vibrating reeds, intended to increase or diminish the intensity and volume of the sound, by regulating the pressure of the wind, by the aid of which the sounds were produced. The instrument has a keyboard like that of a piano, and when one of the keys is pressed down a valve is opened, which allows the wind from the bellows to rush through one of the wind-boxes and act on the vibrator. There are also several stops, like organ stops, by means of which the performer can direct the stream of wind into the wind-boxes, which produce a flute, clarinet, or any other sound, according to the number of stops which the instrument possesses. Such is the harmonium which was patented by Debain in 1840, but since that time various other improvements of more or less value have been made. The chief of these are the addition of a knee action, which either serves as an expression stop, or brings all the stops of the instrument into play at once, and what is called the percussion action, the invention of Kaufmann of Dresden, which consists in the application of a small hammer, which strikes the vibrator as soon as the key is pressed down, and thus aids the action of the wind.

Harmony, (from the Greek *ἁρμόζειν*, to join or fit together), in music is the science which controls the relationship of chords, and decides that of the dissonant elements in a discord to the fundamental concord; the fundamental law being that discord is an unfinished design which requires concord for its completion.

A chord, or combination of tones, in any scale or key may be a concord or discord. The one concord in a major key consists of the keynote or tonic with its major third and fifth. This means of course the tonic triad; but in every major key there are two other major triads, absolutely equal in consonance with the tonic triad—those founded on the dominant and subdominant. In a minor key the triad on the keynote consists of the tonic with a minor third and perfect fifth. The major third and fifth are the notes which produce, naturally, a perfect sound in combination; they are called "consonances," and any foreign element is a "dissonance." They can be inverted, that is, any tone of a chord can be in the bass or lowest part. (See FUNDAMENTAL NOTE, TONE, OR BASS.) This, the "common chord" or "major triad," makes a starting point and a point of finality, from which the harmonies proceed, diverge and converge, and into which they resolve themselves finally.

The seventh harmonic of nature (see HARMONICS), which is one semitone less than the seventh consecutive note in an ascending major scale, constitutes a minor seventh, and produces a discord, which, with its complementary or fulfilling concord, is the foundation of all harmony. This discord, the "dominant seventh"—signed V_7, must always be "resolved" into the



chord of the tonic (1) of the key to which it belongs. (See illustration.)

A is an example of "close," B of "open" or "extended" harmony. The discord on G instinctively demanding the chord of C as its resolution, the note G, or the similar fifth degree in any scale, is called the "dominant"—signed V, of that key, and the chords and discords built on it constitute the dominant harmonies. Position B is the most satisfactory to the ear, be-

cause of the effect of finality induced by the resolution to the first position of the triad. The two chords together form the dominant or authentic cadence — the most important of those terminal phrases which serve the same purpose in music as the marks of punctuation in literary composition. "My country, 'tis of thee" exhibits examples of two other important cadences, showing at the same time how these mark the completion of more or less final musical periods.

The first period is closed at A by a "half" or "imperfect" cadence — that is, the order V.—I. is reversed; the second at B by a "false" or "deceptive" cadence — that is, the dominant chord, instead of proceeding to the tonic, "deceives" the ear by proceeding to another chord; the third period is brought to a close by the authentic cadence at C.

The dominant chord can also bear the more elaborate dissonances of the 9th, 11th, and 13th, as well as the 7th, but it is impossible here to enter into the varieties of discord — "suspensions," "double-root chords," etc., into the analogous discords which may be built on the tonic as a ground-note, or the chords belonging to the minor scale. Suffice it to say the effects which can be evolved from the almost innumerable inversions and involutions of single chords and combinations of chords are subject to stringent natural laws, and the possibilities of variety are infinite.

An important branch of harmony, however, must be mentioned, that is "modulation" or change from one key (or "mode") to another. Modern scales have had the relation of their intervals so modified (see TEMPERAMENT) as to be approximately alike. By the addition of a single sharp or flat any melody can proceed from the key of C to G (with F♯), F (with B♭), or A minor (with G♯). These — the dominant, subdominant (next below the dominant), and the minor of the sixth degree — are the keys of the first relation, as out of the seven notes which constitute each scale six are present in the scale of C, thus providing as it were six more or less convenient bridges by which to pass from one key to the other. The conventionality of these modulations makes them inadequate to convey the more passionate coloring of modern music, and more striking changes to remoter keys are necessary. A favorite device with modern composers is to take advantage of the "tempered" system, and by using one note in two significations (for example, F×E♯) to secure means of startling and also of very tender effects in modulation.

Harmony comparatively is of modern growth. In counterpoint (q.v.), the science which preceded harmony, attention was given altogether to the correct progression of the individual voices or parts, while the combinations made by the voices at any moment were regarded as merely accidental. But unconsciously the ear of musicians was being cultivated, and in the richness of Palestrina's simpler writings was shown the possibility of obtaining undreamt-of effects from chords as integral units in a march of harmonies, rather than accidental combinations of independent melodies. One of the fundamental rules of counterpoint was that a dissonance must either be "prepared" — that is, it must appear as a consonance in the previous chord — or else it must be approached very gradually. This rule of the old science was disregarded by Monteverde (1608), who used unprepared discords, and at one blow released the new feeling for chords from its bondage to counterpoint.

Only those who understand counterpoint and harmony can appreciate the full importance of the new departure. It meant that discords were no longer mere variations of concords, but individual creations with an individual's rights and duties. The discord most easily used was the dominant seventh, the first discord produced by nature's harmonics; and so the relation of dominant to tonic — the central idea of all harmony — developed from an increasingly general tendency into a recognized rule. During the 17th century many experiments were made by Monteverde's followers, until at the end of the century Rameau's famous treatise called attention to the fact that all chords are derived from some note which is the generator or root, and the relationships of these roots govern the progressions of the harmonies. The less known, but hardly less important, researches of Tartini formed a good supplement to Rameau's theory; and the basis of scientific harmony established by these two works was not seriously disturbed even by the thorough investigation and the astonishing discoveries of Helmholtz, who extended the foundation and built a complete superstructure thereon. In the meantime, notwithstanding that theorists fought each other with great fierceness, the science made extraordinary progress under such practical harmonists as Bach, Mozart, and Beethoven, while Wagner, who handled any number of parts as easily as did Bach himself, so enlarged the possibilities of harmony that it is difficult to conceive of any further advance. Consult the manuals by Bannister, Bowman-Weitzmann, Jadassohn, Macfarren, Ouseley, Richter, and Riemann.

Harmony of the Spheres, a hypothesis of Pythagoras and his school, according to which the motions of the heavenly bodies pro-

duced a music imperceptible by the ears of mortals. He supposed these motions to conform to certain fixed laws, which could be expressed in numbers, corresponding to the numbers which give the harmony of sounds.

Harmotome, här'mō-tōm, a mineral of the zeolite family; a hydrous silicate of aluminum and barium, invariably occurring in twin crystals of various colors from white to red-brown.

Harms'worth, Alfred Charles, English newspaper proprietor: b. Chapelizod, County Dublin, Ireland, 15 July 1865. He is the principal proprietor of the London *Daily Mail,* and *Evening News,* as well as some 30 other English journals, and equipped the arctic expedition under F. G. Jackson in 1894.

Harnack, här'näk, **Adolf,** German theologian: b. Dorpat 7 May 1851. He began his studies in his native town in 1869 and in 1874 took up his residence at Leipsic, for the purpose of pursuing a course in church history, and was made extraordinary professor there in 1876, and ordinary professor of theology, first at Giessen in 1879, and eventually at Berlin 1889. In 1890 he was made a member of the Berlin Academy. He has been a prolific writer, both in theology and church history, and some of his books have given rise to much controversy; among his works are: 'Lehrbuch der Dogmengeschichte' (1894); 'Die Ueberlieferung und der Bestand der altchristlichen Litteratur' (1893); etc.

Har'ned, Virginia, American actress: b. Boston 1868. She became a member of a traveling company about 1884, in 1895 appeared as Trilby in P. M. Potter's dramatization of Du Maurier's story, and subsequently took various roles, including Alice Rousillon in 'Alice of Old Vincennes,' and the title-part in A. W. Pinero's 'Iris.' She was married to E. H. Sothern (q.v.) in 1896.

Harness and Saddlery Trade, The. It is extremely difficult to trace the history of the harness and saddlery industry in America as far back as the days of the colonies, for in that period of our existence as a nation oxen were so generally used for purposes of plowing and carting that harnesses were in small demand. Those were the days in which roads were so poor that driving could scarcely be regarded as a pleasure, and the equipments required in saddle riding were chiefly imported from England.

The first attempt to make saddlery hardware, one of the most important accessories to the saddlery trade, was inaugurated by Seth J. and Alvin North, at New Britain, Conn. Originally engaged in the blacksmithing business, they began to extend the facilities of their shop until they were finally making bridle-bits, and other harness equipments, including shoe-buckles, and rings to be used for a variety of purposes. All these articles were originally produced from wire drawn out by hand. Later, horse-power was introduced for this purpose, but it was many years before all the finishing work on these products, the polishing, the welding, etc., ceased to be a matter of manual labor. The discovery of a more rapid method of polishing was made by a blacksmith at Middletown, Conn., to whom Alvin North paid $25 to learn the process, which simply consisted in taking an old woolen stocking, which, after all the holes had been darned, was filled with the articles to be polished. A number of small pieces of soap were added, after which the stocking was dipped in a pail of warm water and was rubbed briskly between the hands. This method of polishing was finally improved by the substitution of canvas bags for the stockings, but, with this exception, no better process was found until the tumbling-barrels were introduced.

The advent of better roads, and the corresponding increase in the popularity of driving and riding, was the means of creating a greater demand for both saddlery and harness. To meet these requirements of the trade, factories were established at Newark, N. J., Hartford, Conn., St. Louis, Mo., Wheeling, W. Va., Louisville, Ky., and Cincinnati, O., but the greater part of the harness made in those days was suitable only for the heavy stages and wagons, which were then so generally utilized both for the transportation of passengers and in business traffic. At that period in our history the movement for the betterment of roads had been confined almost exclusively to the more populous sections of the East, and as the black soil of the western prairies made the use of wagons practically impossible during certain seasons of the year there was an insistent call for heavy riding saddles. Those that were made in foreign countries had proved to be utterly unsuited, either for the rough frontier life of the West, or for the hard usage which they received in the South, and, as the result of these conditions the manufacturers of saddlery, with the characteristic inventive genius of the Yankee, devised the tree made of wood, and covered with rawhide, with long skirts and fenders to act as a protection, both from the elements and the many deep quagmires which the rider was quite certain to encounter.

It was in 1828 that the Franklin Institute presented a medal to Seth Boyden for his achievement in inventing the first buckles and bits made of annealed cast iron. The discovery had been made by putting a few pounds of cast iron into an ordinary cooking stove, in which, in the process of baking, it became annealed, a process which was largely responsible for the early success of the manufacture of saddlery hardware in this country. About the same time, Peter Hayden, then 22 years of age, began to manufacture hames and saddlery at Auburn, N. Y. His shop was a small one, and as there was little demand for such goods in his neighborhood, he extended his trade by loading his sleigh or wagon with his stock and peddling it through Central New York and Canada. By these methods his business became so well established that, in 1835, he entered into a contract with the State of Ohio, by which he agreed to furnish employment for its convict labor in the making of hames, saddle-trees, saddlery hardware, and chains. At times he employed upward of 300 convicts, to say nothing of a large force of free labor, and he was soon able to open connections for the sale of his product with the largest mercantile houses in Chicago, St. Louis, Cincinnati, Detroit, Galveston, San Francisco, and New York. Thus, from a small beginning, for Hayden's business netted but a few thousand dollars during the first years of its existence, he increased his trade until it reached millions, while it was largely due to

his control of the domestic market that the importations of foreign saddlery almost entirely ceased.

The first horse-collars regularly manufactured in this country were made by Timothy Deming, in East Hartford, Conn., in 1828. Prior to this time the making of horse-collars had been the work of itinerant laborers, who traveled from place to place, hiring themselves to make collars for individuals who were in need of several, or to any local harnessmaker whose stock might need replenishing. When Deming invented and patented his short-straw collar and the block upon which it was made, the event marked the first stage in the development of collar-making in America.

Although the wax-thread, chain-stitch sewing-machine was invented by a New England concern, as early as 1853, it was three years later before it had attained such practicability that it could be used in the sewing of boots and shoes, and fully 10 years before it was applied to the making of harness. Even then the prejudice against machine-stitching was so great that such products were not easily disposed of, and it was only the enormous reduction in cost that ultimately brought it into favor. Another important improvement came in 1858, when W. K. Thornton, of Niles, Mich., perfected the invention of the creasing-machine, but so slow was the trade of those days in the matter of adopting any process which necessitated a radical departure from the old-time and traditional methods that the inventor found that the only way in which he could introduce his machines was to leave them on three months' trial at such shops as would accord him this privilege. A few years later, he entered into partnership in Cincinnati, under the firm name of Thornton & Perkins. In 1865 the business was sold to Randall & Company, the concern which is now engaged in the manufacture of similar, but vastly improved machinery. In fact, the sewing-machine and the creasing-machine were such important inventions that they may be said to have practically revolutionized the industry of harness-making. Other inventions have been patented, but few of them have been of lasting benefit to the trade. The most important, perhaps, was the iron gigtree which was patented by Samuel E. Thompkins, of Newark, N. J., in 1872, the radical change which this invention heralded being indicated by the fact that all buggy saddles up to this time had been made on wooden trees imported from England, but only a few years elapsed after the introduction of the iron gigtree before the wooden tree was entirely discarded.

It was about this time that the harness industry began to enjoy a period of almost phenomenal progress. The invention of labor-saving devices enabled manufacturers to produce goods at a cost which naturally tended to increase the demand for such articles.

Among the inventions which were patented at about this time one must mention the Bosworth lock-stitching, wax-thread sewing-machine, which first appeared in 1872, as well as the Campbell lock-stitching machine, patented first in 1880. With the introduction of these inventions, hand-sewed harness largely disappeared, for these stitches, which were interlocked, made the sewing alike on both sides, which gave the appearance of hand work, a great improvement upon the product of the old harness-sewing machines which produced a sometimes unsatisfactory chain-stitch. The other kinds of harness machinery which have proved themselves such great labor-saving inventions that they are now regarded as indispensable in all well-equipped factories are the tubular riveting-machines, which entirely dispensed with the old processes of hand riveting; the box-loop sewing-machines, which now sew up all the long loops formerly sewed by hand; the quilting-machines, by means of which pads, gig and riding saddles are quilted; the power trace-trimmers, and trace-polishers; the power splitters, and the dieing-out machines. The first factory for the making of harness thread in this country was established at Paterson, N. J., by Barbour Brothers, in 1863, prior to which time such thread had been imported from Ireland, while the hard-rubber-covered harness trimmings were invented by Andrew Albright, of Newark, N. J., in 1867.

The great development in the making of horse-collars dates only from 1883, for it was in that year that William Fogelsong, of Dayton, O., invented a machine for the stuffing of collars. Some 10 years later R. Brownson, of St. Paul, Minn., perfected a metal-staple machine for sewing collars, and, with these two practically recent innovations, one set of machinery will now do the work which formerly required the labor of some 20 men. It was by means of such machinery, practically all of which is due to American push and enterprise, that the trade of saddlery and harness-making has been advanced from a position of inferiority to a commanding place among the great industries of the United States. To comprehend the extent to which this business has progressed it is only necessary to glance at the following table in which the figures prepared by the census bureau are recapitulated:

SADDLERY AND HARNESS, 1880–1900.

	1880	1890	1900
Establishments	7,999	7,931	12,934
Capital	$16,508,019	$35,346,620	$43,354,136
Wage earners	21,446	23,672	24,123
Wages	$ 7,997,752	$10,908,918	$10,725,647
Cost of materials	$19,968,716	$24,674,225	$31,127,926
Value of products	$38,081,643	$52,970,801	$62,630,902

The fever for the organization of combinations, "trusts," and other associations had its natural effect upon some of the saddlery manufacturers, and, in 1890, the first move was made toward the establishment of an organization for conference and mutual improvement. This initiative was taken by the Western manufacturers who called a meeting of the trade to be held at St. Louis, Mo., and it was at this time that the organization known as "The National Wholesale Saddlery Association of the United States," was formed. According to the terms of the constitution adopted at this first gathering, the objects of the association were to correct abuses, adopt uniform terms, and encourage a more fraternal feeling among competitors, but, although its annual meetings and elections have been held, and men prominent in the trade have been elected as officials, its effect upon the growth of the industry is entirely problematic.

See CARRIAGE AND WAGON INDUSTRY.

Harnessed Antelopes. See BUSHBUCK.

Har'nett, Cornelius, American statesman: b. England 20 April 1723; d. North Carolina 1781. He came in early life to America, and was one of the earliest to denounce the stamp act and kindred measures. In 1770–1 he was representative of Wilmington, N. C., in the Provincial Assembly, and chairman of the most important committees of that body. In 1772 he was appointed with Robert Howe and Maurice Moore, to prepare a remonstrance against the appointment, by the royal governor Martin, of commissioners to fix the southern boundary of the province. Josiah Quincy, who visited him in 1773, called him "the Samuel Adams of North Carolina"; and, as the Revolution approached, he was its master spirit throughout the Cape Fear region. He was elected to the Provincial Congress in 1775, and drew up the instructions to the North Carolina delegates in the Continental Congress. When in 1776 Sir Henry Clinton appeared with a British fleet off Cape Fear, Harnett and Howe were excepted, as arch-rebels, from the terms of a general pardon. As member of the Continental Congress he signed the articles of confederation. When in 1780–1 the British held possession of the country around Cape Fear, Harnett was made prisoner, and died while a captive.

Har'ney, John Hopkins, American journalist: b. Bourbon County, Ky., 1806; d. 1867. He was educated at Oxford University, Ohio; became professor of mathematics at the University of Indiana and at Hanover College, and was president of a college at Louisville, Ky. He was for a number of years editor of the Louisville *Democrat*, a paper which took a radical attitude during the Civil War.

Harney, William Selby, American soldier: b. Haysboro, Tenn., 27 Aug. 1800; d. 9 May 1889. He entered the army in 1818; served as colonel in the Mexican War and was brevetted brigadier-general for gallantry at Cerro Gordo, and promoted to that rank in 1858. While commanding the department of Oregon, in 1859 he took possession of the island of San Juan, which was claimed by the English government. He was in consequence recalled. He retired in 1863 and was brevetted major-general in 1865.

Harney's Peak, the highest point of the Black Hills, South Dakota, named in honor of Gen. W. S. Harney; height 7,215 feet.

Haro Islands. See SAN JUAN ISLANDS.

Harold I., surnamed HAREFOOT, king of England: d. Oxford 17 March 1040. He succeeded his father Canute in 1035, notwithstanding a previous agreement that the sovereignty of England should descend to the issue of Canute by his second wife, the Norman princess Emma. Hardecanute, who was about to invade England at the time of Harold's death, dug up his body and beheaded it. See Freeman, 'The Norman Conquest,' Vol. I.

Harold II., king of England, second son of Godwin, earl of Kent: b. about 1022; d. Senlac, near Hastings, Sussex, 14 Oct. 1066. On his father's death in 1053 he succeeded him in the earldom of Wessex and other great offices, and upon the death of Edward the Confessor, 5 Jan. 1066, who had named him his successor, he was chosen king by the nobles, notwithstanding the claim of Edgar Atheling, or the asserted bequest of Edward in favor of William, duke of Normandy. The latter called upon him to resign the crown, and upon his refusal prepared for invasion. He also instigated Harold's brother, Tostig, to invade the northern coasts of England in conjunction with the king of Norway. The united fleet of these chiefs sailed up the Humber and landed a numerous body of men, who defeated the opposing forces of the Earls of Northumberland and Mercia; but at Stamford Bridge, on the river Derwent, in Yorkshire, were totally routed by Harold, whose brother Tostig fell in the battle. A day or two later he heard of the landing of the duke of Normandy at Pevensey, in Sussex. Hastening southward with all the troops he could muster, a general engagement ensued at Senlac, near Hastings, in which Harold was slain with an arrow, and the crown of England was passed to William. See SENLAC. Consult: Freeman, 'The Norman Conquest,' Vols. II. and III.; Tennyson, 'Harold' (1876).

Harold, or **Harald I.,** surnamed HAARFAGER (Fair-haired), king of Norway, son of Halfdan the Black: d. Trondjhem 933. He succeeded to the throne in 860. While he reduced the lesser kings he left them with the title jarl, the administration of their territories, and the third part of their income; but many of them emigrated, and founded Norwegian colonies. Hrolf or Rollo emigrated to Neustria (France). Others, with their followers, established themselves in Iceland, the Shetland Isles, the Faroes, and the Orkneys, then uninhabited. When Harold found that the emigrants often extended their incursions into his dominions he embarked with a naval force to subdue them, conquered the Orkneys, etc., and returned.

Harold, or **Harald III.,** surnamed HAARDRADA, king of Norway: d. Stamford Bridge, England, 25 Sept. 1066. The date of his birth is unknown. During a great part of his youth and prime he served in the imperial bodyguard at Byzantium, returning to Norway about 1045. He persuaded his nephew Magnus to divide the supreme power with him, in return for a share of his treasures, and two years later (1047) his nephew died, when he himself became sole king of Norway. In 1066 he joined Tostig, the brother of Harold II. (q.v.) of England, in an invasion of that country, having been promised half of it in case of success; but he was slain at the battle of Stamford Bridge.

Haroun-al-Rashid. See HARUN-AL-RASHID.

Harp, the oldest of stringed instruments. The Bible mentions Jubal as the inventor. It has been used by all nations in one form or another. The modern instrument is nearly triangular and the strings are extended from the upper part to one of the sides. It stands erect, and is played with both hands, the strings being struck or pulled with both fingers and thumbs. The improvements which have rendered the modern harp an efficient musical instrument are due to Sebastian Erard, who in 1794 took out a patent for a harp with seven pedals, and again in 1808 for a double-action harp with the same number of pedals, each of which effects two changes in the pitch of the strings. The harp thus constructed contains 43 strings tuned according to the diatonic scale, every eighth string being a replicate in another

octave of the one counted from. Various improvements over Erard's harp were made during the 19th century.

Harp, or Saddleback, Seal. See SEALS.

Harp-shell, a genus (*Harpa*) of gasteropodous mollusks of the whelk family (*Buccinidæ*), having the last whorl of the shell large, and covered with numerous sharp smooth ribs, resembling the strings of a harp. The foot is large, and there is no operculum. These shells are elegantly marked, and much prized for their beauty. Nine species are known, all of them tropical, and living in deep water, on soft, sandy, or muddy bottoms.

Har'per, Charles G., English artist and author: b. 1863. He is one of the best-known of English book illustrators, and his own books, mainly lively, entertaining descriptions of pedestrian and bicycle tours in England illustrated by himself, have been popular in the United States as well as in his own country. Among them are: 'Some English Sketching Grounds'; 'From Paddington to Penzance'; 'The Brighton Road'; 'The Great North Road'; 'The Norwich Road'; 'Cycle Rides Around London.'

Harper, Ida Husted, American journalist and author: b. Fairfield, Ind. She attended the University of Indiana for two years; entered journalism when about 18, conducted a woman's department in the Terre Haute 'Saturday Evening Mail' and in the 'Firemen's Magazine,' and was a contributor to many papers, including the Cleveland *Leader,* San Francisco *Chronicle,* and Washington *Post.* She was managing editor of the Terre Haute *Daily News,* for a year, has written for the McClure syndicate, and since January 1899 has been on the editorial staff of the New York *Sun.* She was a member of the International Congress of Women in London in 1899, and was appointed chairman of the international press committee for a five years' term. She prepared the Indiana State monograph for the World's Fair at Chicago under the title 'Organized Work of Indiana Women,' and has written 'Life and Work of Susan B. Anthony' (1898) and 'History of Woman Suffrage to the Close of the Nineteenth Century' (1901).

Harper, John Murdock, Canadian educator: b. Johnstone, Renfrewshire, Scotland, 10 Feb. 1845. He was graduated from Queen's University (Kingston, Ont.), later was appointed superintendent of education for Prince Edward Island, but declined the appointment, and became successively rector of Quebec High School, and inspector of superior schools for the province of Quebec. Among his publications are textbooks and various pamphlets.

Harper, Robert Goodloe, American lawyer and statesman: b. near Fredericksburg, Va., 1765; d. Baltimore, Md., 15 Jan. 1825. In his 15th year young Harper joined a troop of horse, and under Gen. Greene served during the latter part of the southern revolutionary campaign. He was graduated from Princeton College in 1785, while there acting for a time as tutor to lower classes. Sailing from Philadelphia for Charleston, with the intention of studying law, he arrived at his destination nearly penniless, but was assisted by the father of a former pupil, who obtained a position for him in a lawyer's office. In one year he was qualified to practise, and soon established a reputation, and became well known by a series of newspaper articles on the proposed change in the State constitution of South Carolina. He was soon after elected to the State legislature, and in 1794 to the national Congress. In this position he showed marked ability, supported the administrations of Washington and John Adams, and was regarded as one of the leaders of the Federal party. On the election of Thomas Jefferson as President in 1801 he retired from Congress, and resumed the practice of his profession in Baltimore. At the Maryland bar he attained great eminence, at the period too of its highest renown. He was associated with Joseph Hopkinson as counsel for Judge Chase of the United States Supreme Court, when under impeachment. In 1815 he was elected United States senator from Maryland.

Harper, William Rainey, American college president and Hebrew scholar: b. New Concord, Ohio, 26 July 1856; d. Chicago, Ill., 10 Jan. 1906. He was graduated at Muskingum College in 1870; was professor of Hebrew at the Baptist Union Theological Seminary, Chicago, in 1879–86; and of Semitic languages in the graduate faculty of Yale. From 1889 he was also professor of biblical literature. He was principal of the Chautauqua College of Liberal Arts in 1885–91, and in 1891 was appointed director of the Chautauqua system. In 1891 he was chosen first president of the new University of Chicago, where he was also head of the department of Semitic languages and literature. He was a founder and editor of 'Hebraica' and the 'Hebrew Student,' was an editor of three of the publications of the University of Chicago — the 'Biblical World,' the 'American Journal of Theology,' and the 'American Journal of Semitic Languages and Literature.' His administration was noted for its rapid development of the facilities of the university. Among his works are: 'Elements of Hebrew' (2d ed. 1890), 'Hebrew Method and Manual' (1885), and 'Elements of Hebrew Syntax' (1888), 'The Trend in Higher Education' (1905); 'The Priestly Element in the Old Testament' (1905).

Harper, William Saint John, American artist: b. Rhinebeck, N. Y., 8 Sept. 1851. He studied painting at the National Academy of Design, New York, and afterward became pupil of Munkacsy and Bonnat at Paris. He has done much successful work both as a painter and book illustrator.

Harper and Brothers, the designation of a noted firm of New York publishers. It consisted originally of James (1795–1869), John (1797–1875), Joseph Wesley (1801–70), and Fletcher (1806–77). The first two commenced to publish in 1818, as J. & J. Harper. The firm of Harper and Brothers, established in 1833, is now managed by descendants of the founders. It not only publishes books but 'Harper's Magazine' (monthly, since 1850), 'Harper's Weekly' (since 1857), 'Harper's Bazar' (fashions, social life, etc.; since 1867), and 'Harper's Round Table' (started in 1881 as 'Harper's Young People' and recently consolidated with 'St. Nicholas').

Harper's Ferry, W. Va., is situated in Jefferson County, 55 miles northwest of Washington, on the Baltimore & O. railroad. It is at the confluence of the Potomac and Shenandoah

VIEW OF HARPERS FERRY, VA.

rivers, where the former breaks through the Blue Ridge, presenting one of the most picturesque scenes in America. Attracted by its fine water-power, Washington, in 1790, chose it as a site for a United States arsenal and armory, and up to 1860 $1,800,000 had been expended for land and improvements. Here 10,000 muskets were made annually, and over 75,000 small arms were usually in store. It is the seat of Storer College and of a normal school for colored pupils. Pop. (1900) 896.

Harper's Ferry came into great prominence in 1859 through the acts of John Brown (q.v.), and was the scene of noteworthy military events during the Civil War. When Virginia seceded, Harper's Ferry was held by Lieut. Roger Jones, with 45 men. On the night of 18 April 1861 a large body of Virginia militia, hastily assembled from the surrounding country, appeared before the place. Jones set fire to the arsenal, destroyed as much public property as possible, and retreated across the Potomac to Hagerstown, Md., and thence to Carlisle, Pa. The Virginia militia occupied the place, and troops were hastened to it from other States of the Confederacy. The Confederate government attached much importance to the place as a strategical point, but it was abandoned by Gen. J. E. Johnston, 15 June 1861, when he heard that Gen. Patterson, marching from Chambersburg, Pa., was threatening to cross the Potomac at Williamsport. The place was then occupied by the National forces. When Gen. Lee invaded Maryland early in September 1862, Harper's Ferry was held by Col. Dixon S. Miles with a large garrison, and there were strong outposts at Winchester and Martinsburg. Lee supposed that his presence at Frederick, Md., would cause the evacuation of Harper's Ferry and its outposts, and thus open his communications by way of Shenandoah Valley, but as it was still held by the National forces it became a necessity to dislodge them. On the morning of 10 September he set three columns in motion from Frederick to surround the place and capture its entire garrison. Gen. Jackson, with 14 brigades, marched rapidly over the South Mountain, crossed the Potomac at Williamsport on the 11th, drove the garrison from Martinsburg into Harper's Ferry, and appeared before Bolivar Heights on the 13th, thus investing the place from the west. Gen. McLaws, with 10 brigades, marched through Brownsville Gap, and, after a severe engagement with Col. Thomas H. Ford on the 12th and 13th, drove him from Maryland Heights and into Harper's Ferry. Gen. Walker, with his division, crossed the Potomac at Point of Rocks, 12 miles below Harper's Ferry, and on the 13th seized Loudoun Heights beyond the Shenandoah. Miles was now completely surrounded, the Confederates occupying high ground, commanding his position. Artillery fire was opened from all these points on the 14th, and late in the afternoon Jackson moved upon Bolivar Heights, drove in Miles' skirmish lines, and gained an advantageous position on the left of the Union line. During the night 1,500 Union cavalry crossed from Harper's Ferry to the Maryland side and escaped. During the same night Jackson crossed 10 guns to the right bank of the Shenandoah and established them on a plateau at the foot of Loudoun Heights, enfilading Miles' entire position on Bolivar Heights. Early on the 15th the Confederate guns on Maryland Heights, Loudoun Heights, and in front of Bolivar Heights opened fire, which was responded to for more than an hour, but the direct and plunging flank-fire from the Confederate batteries partially silenced the Union guns and created some disorder in the Union ranks. Jackson had advanced his lines to within 150 yards of the Union works on Bolivar Heights, and was about to assault, when Miles ordered a white flag displayed on his works and directed Gen. Julius White to arrange terms of capitulation, soon after which Miles was mortally wounded by a shell from a battery that had not seen the white flag. The Union loss during the siege was 44 killed and 173 wounded, and the number of prisoners surrendered and paroled 12,520. The Confederates captured 70 guns, 13,000 small arms, 200 wagons, and a large amount of quartermaster and commissary stores. The Confederate loss was 41 killed and 247 wounded, the greater part of whom were lost in the engagement on Maryland Heights. The Confederates abandoned Harper's Ferry on the 20th, and it was again occupied by the Union forces on the 22d. Consult: 'Official Records,' Vols. II. and XIX.; Allan, 'Army of Northern Virginia in 1862'; The Century Company's 'Battles and Leaders of the Civil War,' Vols. I. and II.

E. A. Carman.

Har'pies (Greek, *Harpuiai*, swift robbers), the goddesses of storms. Their ages, appearance, names and number are so differently given by the poets that it is difficult to say anything definite concerning them. In the Homeric poems they are represented as personified storm-winds. The later poets and artists vied with each other in depicting them under the most hideous forms. One has given them the head of a fowl, with wings and a body covered with feathers, human arms with claws, a white breast, and human legs which terminate in the feet of a fowl. Others have given them the face of a young woman with the ears of a bear. See Furies.

Harpignies, Henri Joseph, ŏñ-rē zhō-zĕf är-pēn-yē, French landscapist: b. Valenciennes 28 July 1819. He studied at Paris with Achard, first exhibited at the salon of 1853, and in 1861 attracted attention by his 'Edge of a Wood beside the Allier.' His landscapes, done with equal success in oils or water-colors, evince a skilfulness of drawing and a coloristic truthfulness marred only occasionally by a harshness in matters of technique. His works number: 'View of Capri,' 'Le Saut du Loup,' 'Banks of the Rhone' (Metropolitan Museum, N. Y.), and 'Garden of the Villa Medici.'

Harp'sichord, a stringed instrument formerly in use, in appearance and construction similar to a grand pianoforte. In the front the keys were disposed, the long ones being the naturals, and the short ones the sharps and flats. This instrument, called by the Italians *clavicembalo*, by the French *clavecin*, was an improvement upon the clavichord, which was borrowed from the harp. Both are now superseded by the pianoforte. See Pianoforte.

Harps'well, Maine, a township including the post village of Harpswell Centre, and comprising a peninsula and some islands in Casco Bay, 14 miles east of Portland. It has agricul-

tural interests and grist-mills, but is chiefly noted as a summer resort. Pop. (1900) 1,750.

Harpy-eagle. See EAGLE.

Har'raden, Beatrice, English novelist: b. Hampstead, London, 24 Jan. 1864. She took her degree at London University at 21, and subsequently traveled extensively in the United States and on the Continent. Her first novel, 'Ships that Pass in the Night' (1893), was instantly successful and was widely circulated. It has been followed by 'In Varying Moods' (1894); 'Hilda Strafford,' a Californian story (1897); 'The Fowler' (1899).

Harrier, a small mottled hound used in Europe in ancient times, and up to the end of the 18th century for chasing hares, the sportsmen following on foot. The old breed has disappeared except a few bred for show purposes by fanciers; its place being taken in sport by a small kind of foxhound followed on horseback.

Harrier. See MARSH-HAWK.

Har'rigan, Edward, American actor and playwright: b. New York 1845. He entered upon the stage as a variety performer and was a partner of Tony Hart (1871–85), when they opened in New York their first Theatre Comique (1876). Among his dramas, which are strong in character drawing, but of little value in a literary sense, are: 'Squatter Sovereignty'; 'Cordelia's Aspirations'; 'Old Lavender'; and 'Reilly and the Four Hundred.'

Harrild, Robert, English inventor: b. London 1780; d. 1853. He was the inventor and manufacturer of composition rollers for inking type, the introduction of which alone rendered cylinder presses practicable. He began the manufacture of printers' materials in London in 1809 and the printing-press with which Franklin worked in London was owned by him before it was brought to the United States in 1841 and put into the Patent Office at Washington, where it now stands.

Har'riman, Tenn., city in Roane County; on the Emory River, the Southern, the Tennessee C., and the Queen & C. R.R.'s; about 78 miles northeast of Chattanooga, and 37 miles west of Knoxville. It was founded in 1890 and received its city charter in 1891. The charter was revised in 1899. It is situated in an agricultural region which contains rich deposits of coal and of iron ore, and some timber land. Its chief manufactures are foundry and machine shop products, leather, farm implements, iron, flour, lumber, cotton goods, and furniture. It is the seat of an industrial school for colored children, and of the American University, established in 1893. Its trade in agricultural and mining products and in its own manufactured articles is rapidly increasing. The waterworks and electric-light plant are owned and operated by the city. Pop. (1900) 3,442.

Harriman Alaska Expedition, an American scientific and artistic expedition which visited the southern coast of Alaska during the summer of 1899. The party was organized by Edward H. Harriman, and consisted of the members of his own family, a few friends, and 50 gentlemen interested in science, art and literature. Among them were Messrs. Henry Gannett, W. H. Dall, C. H. Merriam, R. Ridgway, G. K. Gilbert and F. V. Calville of Washington; D. G. Elliot of Chicago; William Trelease of St. Louis; John Muir and W. E. Ritter of California, and several professors from Eastern institutions of learning. Messrs. John Burroughs, Swain Gifford and F. S. Dellenbaugh represented the literary and artistic contingent. These gentlemen made good use of their opportunities in investigating the geography, geology, glacial phenomena, and fauna and flora of the region visited.

The results so far as announced (1904) are over 300 species and sub-species of animals and plants, records of observations of 22 "living" glaciers, those which discharge icebergs directly into the sea, and of 100 "dead" glaciers, those whose fronts do not reach the sea. A new chart was made of the part of the coast explored. (See HARRIMAN FIORD.) Some of the new animal species found are two of foxes, five species and sub-species of shrews, five of hares, one crab, a shrimp, and 25 sea-worms. One of the sea-worms is about six feet long and of a deep vermilion color; another about the same size is blood-red with a white head. In no other part of the world have been found sea-worms of such varied and striking forms and colors. Among the plants found were a large number of new species and sub-species. Each department of science was represented by one or more experts who made critical observations and accurate reports. Consult: 'Reports of the Harriman Alaska Expedition'; 'The World's Work' (1900); 'Discoveries in our Arctic Region.'

Harriman Fiord, on the southern coast of Alaska, at about lat. 61° N. and lon. 145° W., is an arm of Prince William Sound, 15 miles in length. This fiord was discovered by the Harriman Alaska Expedition (q.v.), in 1899. The finding of this fiord is described by John Burroughs, a member of the Expedition, as follows: "Later in the afternoon we ascended an arm of Port Wells more to the westward and entered upon a voyage of discovery. We steamed up to a glacier of prodigious size that reared its front across the head of the inlet and barred further progress in that direction — the Barry Glacier. According to the United States Coast Survey map we were at the end of navigation in these waters; but we went on under a good head of steam down this new inlet where no ship had ever before passed. Glaciers hung on the steep mountain sides all about us. One of these was self-named the Serpentine by reason of its winding course down from its hidden sources in the mountains — a great white serpent with its jaws set with glittering fangs at the sea. Another was self-named the Stairway, as it came down in regular terraces or benches. As we neared the front of this glacier the mountains to the left again parted and opened another new arm of the sea, with more glaciers tumbling in mute sublimity from the heights, or rearing colossal palisades across our front. Another ten-mile course brought us to the head of this inlet, which was indeed the end of navigation in this direction. Subsequently this inlet was fitly named the Harriman Fiord, and the glacier at the head of it, Harriman Glacier."

Har'rington, Mark Walrod, American astronomer: b. in Sycamore, Ill., 18 Aug. 1848. He was educated at the University of Michigan, and in 1870–1 assisted in the United States Coast and Geodetic Survey of Alaska. He was

professor of astronomy and director of the observatory at the University of Michigan, 1870–91. In 1884 he established the 'American Meteorological Journal' and was its managing editor until 1892. In 1891 he became chief of the Weather Bureau at Washington, D. C., which post he held till 1895, and was president of the Washington State University 1895–7.

Harriot, Thomas, English mathematician: b. Oxford 1560; d. London 2 July 1621. He entered Saint Mary's Hall, Oxford, and was graduated in 1580. In 1585 he was sent by Sir Walter Raleigh as surveyor on the Grenville expedition to Virginia, and on his return he published an account of Virginia, later printed in Hakluyt's 'Voyages.' He gained the favor of the Earl of Northumberland, who gave him an annual pension, and thereafter devoted himself entirely to mathematical and scientific research. His chief work, 'Artis Analyticæ Praxis ad Equationes Algebraicas Resolvendas,' published in 1631, embodied the most important results of his mathematical work. He practically gave to algebra its modern form, improving the notation, being the first to equate all the terms of an equation to zero, and announcing the principle that every equation has as many roots as its dimension. He also did important work in astronomy. See ALGEBRA, HISTORY OF THE ELEMENT OF.

Harris, Amanda Bartlett, American writer b. Warner, N. H., 15 Aug. 1824. She is a popular writer for young people and has published: 'How We Went Bird-Nesting' (1880); 'Wild Flowers, and Where They Grow' (1882); 'American Authors for Young Folks' (1887); 'The Luck of Edenhall' (1888); etc.

Harris, George, American college president: b. East Machias, Maine, 1844. He was graduated at Amherst, 1883; and at Andover Theological Seminary 1860. After taking several pastoral charges he became professor of Christian theology at Andover 1883, from which position he passed in 1899 to the presidency of Amherst, which he now holds. He was one of the editors of the 'Andover Review,' 1884–93. Among his works are 'Moral Evolution' (1806); 'Inequality and Progress' (1897).

Harris, James Rendel, English scholar. He was graduated at Cambridge University, where he was fellow and librarian of Clare College. He was professor at Johns Hopkins University and at Haverford College, and is now university lecturer in palæography at Cambridge, England. He has written many volumes on philology, palæography and kindred subjects, his latest work being 'Annotators of the Codex Bezæ' (1901).

Harris, Joel Chandler, American journalist and author: b. Eatonton, Ga., 8 Dec. 1848. He began his career as a printer's apprentice on the Forsyth (Ga.) 'Countryman' and was on the staff of the Savannah *Daily News,* 1871–6. He has been connected with the Atlanta *Constitution* from 1876 and became its editor in 1890. The series of "Uncle Remus" sketches and songs which have given him an international reputation were first printed in the *Constitution.* His published books include: 'The Folk-Lore of the Old Plantation' (1880); 'Nights With Uncle Remus' (1883); 'Mingo and Other Sketches' (1883); 'Daddy Jake, the Runaway' (1889); 'Free Joe and Other Stories' (1887); 'Balaam and his Master' (1890); 'Mr. Rabbit at Home' (1895); 'The Story of Aaron' (1896); 'Stories of Georgia History' (1897); 'Sister Jane,' a novel (1897); 'Minervy Ann' (1899); 'On the Wing of Occasion' (1900); etc.

Harris, Joseph, American agricultural writer: b. Shrewsbury, England, 1828; d. 1892. He began his scientific study of agriculture with Lawes and Gilbert at Rothamsted and in 1864 emigrated to the United States, and began to contribute to the agricultural press. His 'Walks and Talks on the Farm' was a series of articles which appeared partly in the 'Genesee Farmer,' and partly in the 'American Agriculturalist,' in which the former had become merged. Among his other writings are: 'Harris on the Pig' (1888); 'Talks on Manures' (1883); and 'Gardening for Young and Old' (1882).

Harris, Miriam Coles, American novelist: b. Dosoris, L. I., 7 July 1834. She was married to Sidney S. Harris in 1864 and has since lived in New York. She wrote: 'Rutledge' (1860); 'The Sutherlands' (1862), both widely read, and among many later and almost equally popular works of hers are: 'A Perfect Adonis' (1875); 'Missy' (1800); and 'An Utter Failure' (1891).

Harris, Samuel, American theologian: b. East Machias, Maine, 14 June 1814; d. Litchfield, Conn., 25 June 1899. He was graduated from Bowdoin College and from Andover Theological Seminary. He was a teacher for a time and held Congregationalist pastorates in Conway, Mass., 1841–51. In 1855 he was appointed professor of systematic theology in Bangor Seminary; was president of Bowdoin 1867–71; and then became professor of systematic theology in the Yale Divinity School. His writings include: 'Zaccheus or the Scriptural Plan of Benevolence'; 'Kingdom of Christ on Earth' (1874); 'Philosophical Basis of Theism' (1883); 'Self-Revelation of God' (1887); 'God, Creator and Lord of All' (1897).

Harris, Thaddeus William, American naturalist: b. Dorchester, Mass., 12 Nov. 1795; d. Cambridge, Mass., 16 Jan. 1856. He was graduated at Harvard College in 1815, studied medicine and practised his profession in Milton, Mass., until appointed librarian of Harvard in 1831. This position he occupied until his death. Early in life he exhibited a fondness for natural history, and though plodding alone, attained to a scientific eminence which secured for him the fellowship of all the principal learned societies of America, and of many abroad. For several years he gave instruction in botany and general natural history in the college, and originated the Harvard natural history society for the students. He was chiefly distinguished, however, as an entomologist, and has been surpassed as such by no one in the United States. He was one of the founders of the Massachusetts Horticultural Society. In 1837 he was appointed one of the commissioners for a zoological and botanical survey of Massachusetts, the result of which was his 'Systematic Catalogue of the Insects of Massachusetts' (1832), in which 2,350 species are enumerated. He also published: 'A Treatise on some of the Insects of New England which are Injurious to Vegetation' (1842), a work of permanent value.

Harris, Thomas Lake, American socialistic and religious reformer: b. Fenny Stratford, England, 15 May 1823. He accompanied his father to the United States in childhood, was for a time a Universalist pastor, and founded an 'Independent Christian Society' in 1850; but became a lecturer upon spiritualism. He lectured abroad in 1858, and on his return to the United States organized the society of the "Brotherhood of the New Life." This was established at Wassaic, Dutchess County, N. Y., 1861–7, but removed to Brocton, Chautauqua County, N. Y., in the last named year. Its nature was co-operative rather than communistic, and farming and industrial occupations were engaged in by his followers, numbering at one time about 2,000 in the United States and Great Britain, among them Lady Oliphant and her son, the well-known writer, Laurence Oliphant (q.v.). Harris removed to California in 1887, and retired to private life in 1895, residing in New York city. He published many works in prose and poetry, among which are 'Wisdom of Angels' (1856); 'Arcana of Christianity' (1857); 'Modern Spiritualism' (1860); 'God's Breath in Man' (1891).

Harris, Townsend, American merchant and diplomatist, of Welsh descent and of Revolutionary stock, the youngest of five children: b. Sandy Hill, N. Y., 4 Oct. 1804; d. New York city 25 Feb. 1878. He received his education at the village school and academy. From 1817 to 1848 he was in business in New York city, continuing his self-culture by continuous and critical reading of the best literature, learning also the French, Spanish, and Italian languages; was member of the Board of Education and in 1846–7 its president. He was the practical founder of the New York Free Academy, now the College of the City of New York, and in many ways was a typically useful citizen. He never married. In 1848 he went to California and during the following six years made trading voyages to China and the Dutch and English Indies, becoming thoroughly acquainted with the manifold Oriental varieties of human nature. He acted for a time as American vice-consul at Ningpo. He was appointed Consul General to Japan and on the U. S. S. S. San Jacinto arrived at Shimoda, his future dwelling place (and now noted for its stone quarries), where the flag of the United States was hoisted 4 Sept. 1856. From the first Mr. Harris spoke the truth as against the constant deceit and prevarication of the corrupt officials of the Yedo Shogunate, demanding the courtesies due to an accredited envoy of a civilized power and refusing to deliver the President's letter to any one but the Shogun in Yedo and to him personally. Unbacked by a single ship or man, and with his secretary only, after prolonged negotiations lasting 18 months, he made a triumphal progress to Yedo, and standing erect received personal audience of the Shogun in the palace. Then began four months' instruction of these political hermits in the methods of modern international law and procedure. He concluded the treaty and received the promise of signature by the premier, without regard to anything happening in China. Nevertheless the arrival of Commodore Tatnall with two American men-of-war, bringing news of the humiliation of the Chinese emperor and court, undoubtedly had its influence on the Japanese. Mr. Harris urged the importance of having the treaty signed without a moment's delay, and the premier Ii despatched commissioners to affix their signatures and soon after an embassy to the United States, for which reason chiefly, Ii was assassinated in Yedo, 23 March 1860. The Harris treaty secured the right of trade, residence, and of missionary operations and teachings. He was buried in Greenwood cemetery, Brooklyn, N. Y. Mr. Harris has always been very highly thought of by the Japanese, and is still the subject of much praise and appreciative writing by Japanese writers. His journals with comment and biography were published in 1896.

William Elliot Griffis,
Author of 'Townsend Harris, First American Envoy in Japan.'

Harris, William Torrey, American educator and metaphysician: b. North Killingly, Conn., 10 Sept. 1835. He studied at Yale in the class of 1858 but was not graduated, and after teaching in the St. Louis public schools, 1857–67, was superintendent of the schools of that city 1867–80. While in St. Louis he founded in 1867 the 'Journal of Speculative Philosophy,' which he still edits. He removed to Concord, Mass., in 1880 and aided in founding the Concord School of Philosophy at which he lectured on metaphysical themes. Since September 1889, he has been United States Commissioner of Education. He has edited Appleton's School Reader and Appleton's Educational Series and is the author of 'Hegel's Logic: a Critical Exposition' (1890); 'The Spiritual Sense of Dante's Divina Commedia' (1891); 'Introduction to the Study of Philosophy'; 'Psychologic Foundations of Education.'

Harrisburg, Pa., city, State capital; county-seat of Dauphin County, on the Susquehanna River, the Pennsylvania canal, and on the Northern Cent.; Pennsylvania; Cumberland Valley, and Philadelphia & R. R.R.'s., and is situated 105 miles northwest of Philadelphia. This is an important railroad, agricultural, industrial and commercial centre, and is the home of a system of municipal reform known as "the Harrisburg Plan" which has attracted widespread attention throughout the United States. The Susquehanna River is nearly a mile in width at this point, and is crossed by numerous bridges.

History.—The site of the future city was selected by John Harris in 1785, and the settlement was incorporated as a borough in 1791. Harris was an adventurous English trader who built the first house here in 1726, and secured a grant of 800 acres. His son established a ferry here in 1753, and the place was known for many years as Harris Ferry. The town became the capital of the State in 1812, and was chartered as a city in 1860. The Harrisburg convention (q.v.), famous in American political history, was held here in 1828, and Harrison and Tyler were nominated here in 1839.

Topography.—The city has a most picturesque location on the left bank of the Susquehanna, which is spanned here by five bridges, three of

them modern steel structures. The old historic "Camel-back Bridge," a part of which was burned during the middle of the 19th century, has been removed (1904). There is an extensive and beautiful park of 16 acres, well-made streets, an abundance of shade, and a fine sewage system with natural drainage.

Commerce and Industry.— The iron, steel, lumber and railroad interests of Harrisburg are of great importance. The roundhouses and repair shops of the Pennsylvania Railroad are located here and give employment to thousands of workmen. There are extensive manufactories of machinery, malt liquors, boilers, castings, brooms, cars, coaches, tanned leather, lumber, cotton goods, beds, mattresses, coffins, silk goods and a large number of rolling-mills, tin-mills, blast furnaces, nail-works, typewriter works and boot and shoe factories. The city has two morning and two evening newspapers and many weekly and monthly publications.

Public Buildings.— Prominent among the public buildings is the new State capitol, erected at a cost exceeding $4,000,000. It is built of brick and steel, with facings of marble and granite. At the main entrance is a fountain 78 feet wide, from which the water leaps down an incline in many cascades. On each side of the fountain rises a granite stairway 48 feet wide, broadening at the top into an esplanade and widening at the corners of the building to the proportions of a reviewing ground for troops. The lesser approaches to the grounds are ornamented with statues of the animals native to Pennsylvania. The State Library here, founded in 1790, contains over 100,000 volumes. In State Street stands the Dauphin County soldiers' monument, 110 feet high, in memory of the soldiers who died in the Civil War. There is also a statue here of Gen. John F. Hartranft, and a monument erected to the memory of the soldiers who fell in the Mexican War adorns the Capitol Park. Among other points of interest are the State Arsenal, the court-house, lunatic asylum, executive building, post-office, Harris Park, and Harrisburg Cemetery. The educational institutions include the high school, Harrisburg academy, St. Genevieve's academy, and the Young Ladies' Seminary. Harrisburg is the seat of a Roman Catholic bishop, and its charitable organizations include several hospitals, the Home of the Friendless, and the Children's Industrial Home.

Transportation.— Harrisburg has in operation one of the most extensive and perfect electric street railway systems in the United States. Every part of the city, and suburbs, and the neighboring towns and city are reached by electric trolley lines. The suburban railway service of the Pennsylvania and other railroads is unusually advantageous in extending the outlying residential sections of the city.

Municipal Administration.— The city government is vested in a mayor, elected every three years, with no second term, and a bicameral and select council. The highway commissioner, police officials, building inspector, fire department and sanitary officers are selected by the select council. The city solicitor, board of tax revision and appeals, water commissioners, city engineer, city clerk, 3 members of the board of public works and 5 members of the board of park commissioners, are selected by the common council. The treasurer, controller, school directors, supervisors and assessors are elected by vote of the citizens.

Banks and Finance.— Harrisburg has four national banks and a dozen other banking institutions and building and loan associations. The assessed property valuation is $26,000,000, the tax rate of course constantly changing. The municipal income amounts to $600,000 and the expenditure to $530,000. The principal items of expense are: Fire department, $15,000; waterworks, $30,000; street lighting, $30,000; police, $35,000; schools, $185,000. Public improvements involving an expenditure of $1,000,000 were begun in 1902, for the development of a new sewer system, water filtration, park development and street paving.

Municipal Reform.— Harrisburg through the progressiveness and enterprise of her citizens in the municipal improvement of the city, has been called "the model city," and the plans of 1902, for an expenditure of $1,000,000 have created an improvement system now known as "the Harrisburg plan." In May 1901, a citizen wrote a letter to a daily paper offering $100 toward a fund of $5,000 to engage expert engineers to examine the city and to report a plan of improvement. The proposal met instant approval. In a few weeks the $5,000 was pledged by 60 citizens. An organization and an executive committee soon followed, and these included the mayor, civil engineer and other officials elected by a reform element in local politics. Three noted engineers were employed, and their reports published in October 1901, included plans and estimates for the immediate improvement of the city. The subject was presented to the people at the annual election, 18 Feb. 1902. "The Harrisburg League for Municipal Improvements" carried on an aggressive campaign, proposing a million dollar expenditure. Objections were raised and to overcome these a board of public works was formed (under the laws of the State), composed of citizens who would serve without pay, and to have entire control of the improvements. An ordinance authorizing this board and providing for its appointment before the election was passed by councils immediately after an ordinance had been passed submitting to the voters the question of increasing the city's debt for the following purposes:

"The sum of $310,000 for the extension, improvement and filtration of the water supply; $365,000 for the extension and improvement of the sewerage system; $65,000 for the construction of a dam in the Susquehanna River to form part of the improved sewerage system; $250,000 for acquiring land and property for parks and for making park improvements; and $100,000 for the creation of a fund out of which the city may defray the cost of paving the intersections of streets hereafter authorized to be paved."

Upon this board three leading citizens of high character were appointed, the campaign was opened, the newspapers supported the movement, and even the women formed a civic league and aided in the work. Pamphlets, maps and diagrams were issued and a booklet, 'The Plain Truth About the Proposed Improvements for Harrisburg,' was widely circulated. The result of the election was a casting aside of party lines, and out of a total of 11,048 ballots, the "improvement" party had a majority of 3,590 votes. It

was a mixed ticket selected for reform that won the election, the mayor being a Democrat (in a city naturally Republican), the treasurer, also a Democrat, while the controller was a Republican. Of the six candidates for the board of assessors, an important body, fixing the tax valuation of the city, the best three (two Republicans and one Democrat) were selected. Harrisburg in 1904 with her $1,000,000 improvements well advanced, is on the high road to remarkable prosperity. The State construction of a capitol building costing over $4,000,000, and the local railroads projecting improvements involving the expenditure of several millions, add additional strength to the movement toward municipal reform. Pop. (1900) 50,167; (1903) 52,951.

Harrisburg Convention, the assembly convened in 1828 at Harrisburg, Pa., by the protectionist faction of the New England and Middle States, consequent on the rejection of the high tariff "Woolen Bill" in the Senate, by the casting-vote of the Vice-President. The forcible presentation of the cause of protection, and the demands of the convention for an increased duty on several manufactured articles, resulted in the passage of the high tariff bill of 1828.

Harrison, Benjamin, American statesman: b. Berkeley, Va., about 1740; d. April 1791. While a very young man he was elected to the House of Burgesses of which he was twice Speaker, and in 1773 was chosen a member of the committee which united the colonies against Great Britain. He was a member of the Continental Congress, 1774–7, and on 4 July 1776, reported, as chairman of the committee of the whole House, the Declaration of Independence, of which he was one of the signers. He was opposed to the ratification of the Federal constitution, but after its adoption, supported the national government. His brother, Charles, was a noted general in the American army during the Revolution, and his son, William Henry, became ninth President of the United States.

Harrison, Benjamin, 23d President of the United States: b. North Bend, Ohio, 20 Aug. 1833; d. Indianapolis, Ind., 13 March 1901. He was a great-grandson of Benjamin Harrison, signer of the Declaration of Independence (q.v.), and grandson of William Henry Harrison, ninth President (q.v.) He was graduated from Miami University (Oxford, Ohio) in 1852, studied law in Cincinnati, was admitted to the bar in 1853, and in 1854 began in Indianapolis the practice of his profession. In 1860 he was elected reporter of the supreme court of the State. At the time of his election to the Presidency (1888) he was one of the foremost leaders of the State bar. At the outbreak of the Civil War he assisted in recruiting the 70th regiment of Indiana Volunteers, of which he became colonel (August 1862). He was an exceedingly efficient commander. For some time he was detailed to guard railways in the West; and in the campaign from Chattanooga to Atlanta the regiment was in the 20th Army Corps, the commander of which was Gen. Joseph Hooker. Harrison commanded a brigade at Peach Tree Creek, where he served with especial distinction, and also at Nashville. He was present at Johnston's surrender at Durham Station, N. C., in 1865 was brevetted brigadier-general for his services in command of the brigade, and in June of that year was mustered out. The supreme court of Indiana had declared that Harrison by his enlistment vacated his office of reporter, and a Democrat was elected by default to fill that office for the unexpired term. At the election of 1864 Harrison, while still in the field, was rechosen. In 1867 he refused a renomination, and recommenced his legal practice, in which he was largely retained in both the Federal and State courts. In 1876 he became, on the retirement of the original candidate, the Republican candidate for the governorship, and though he ran about 2,000 votes ahead of his ticket, he was defeated by a Democratic plurality of 3,000. He was appointed a member of the Mississippi River commission in 1879, and in 1880 was chairman of the Indiana delegation in the Republican national convention. At that convention, where he cast nearly the entire vote of the State for Garfield, he was himself mentioned in connection with the Presidency. From 1881 to 1887 he was in the United States Senate, in which he took rank as a prominent debater. He opposed Cleveland's vetoes of the pension bills, urged increase in the navy and civil-service reform, and as chairman of the committee on territories demanded the admission as States of North and South Dakota, Montana, Washington, and Idaho. In 1884 he was a delegate to the Republican national convention. At the convention of 1888 (Chicago, Ill.) he was presented by the solid Indiana delegation as a candidate for the nomination to the Presidency; and on the eighth ballot he received the nomination by a vote of 544. The campaign was a vigorous one, and Harrison made many excellent speeches. He was elected, receiving in the electoral college 233 ballots to 168 for Grover Cleveland. His administration was broadly characterized by a firm defence of American interests in foreign affairs and a general promotion of industry and governmental effectiveness. During this time the 55th Congress passed the tariff act known as the McKinley law; the reciprocity system was introduced; the new navy was extended; civil-service reform was promoted; and the Pan-American congress with representatives from all Central and South American countries was held at Washington in the winter of 1889–90. The Bering Sea arbitration respecting the seal fisheries was also organized between Great Britain and the United States. The Samoan difficulties were adjusted; and the Chile affair, concerned with an attack on American sailors either connived at or permitted by Chilean authorities, was promptly and satisfactorily settled by enforced reparation on the part of Chile. At the Minneapolis convention of 1892 Harrison was renominated without serious opposition. He was a second time opposed by Cleveland, and his defeat by 276 electoral votes to 145 was an occasion for some surprise. Upon his retirement from office, he returned to the practice of law, and in 1893–4 delivered a course of lectures on constitutional law at Stanford University. In 1899 he appeared as council for Venezuela in the Anglo-Venezuelan boundary arbitration commission. He was appointed a member for the United States of the Peace Conference held at The Hague in 1899, and became one of the International Board of Arbitration. He wrote 'This

BENJAMIN HARRISON,

TWENTY-THIRD PRESIDENT OF THE UNITED STATES.

Country of Ours' (1897). A complete collection of his public addresses from 1888 to 1892 was edited by Hedges (1892). A posthumous collection of articles, 'Views of an Ex-President,' was published in 1901. Consult the campaign life by Lew Wallace (1888), and Wilson (editor), 'The Presidents of the United States' (1894). GEORGE EDWIN RINES,
Editorial Staff, 'Encyclopedia Americana.'

Harrison, Burton Norville, American lawyer: b. New Orleans 1836; d. Washington, D. C., 29 March 1904. He was graduated from Yale in 1859, shortly afterward became professor of mathematics and astronomy in the University of Mississippi, and at the outbreak of the Civil War was appointed private secretary to Jefferson Davis, president of the Confederate States. Captured with Davis, he remained in imprisonment until January 1866, when his release was effected by the intervention of F. P. Blair and President Johnson. Subsequent to the war he followed the law in the north with much success.

Harrison, Mrs. Burton. See HARRISON, CONSTANCE CARY.

Harrison, Carter Henry, American politician: b. Elk Hill, Fayette County, Ky., 15 Feb. 1825; d. Chicago 28 Oct. 1893. He was graduated from Yale in 1845, from the Transylvania University law school (Lexington, Ky.), in 1855, and in the latter year was also admitted to the bar and removed to Chicago. There he invested in real estate, in 1869 was defeated as a candidate for State senator on the Democratic ticket, but in 1871 was elected county commissioner of Cook County, and in 1874 was sent to Congress from the 2d Illinois district, and in 1876 re-elected. In 1879 he was elected mayor of Chicago, and again in 1881, 1883, 1885, and 1893. He was also an unsuccessful independent candidate in 1891. In 1891 he purchased the Chicago *Times*, in the direction of which he was active until his election as mayor in 1893. In several instances his mayoralty contests assumed national interest, particularly so that of 1893 — the "World's Fair year" — when the success of the great exposition was thought to depend much upon the occupant of the mayor's chair. He was opposed by the united Citizens' and Republican forces and by nearly the entire press of Chicago, but after a vigorous campaign of public meetings was elected by more than 21,000 majority. He wrote: 'A Race with the Sun'; and 'A Summer Outing.'

Harrison, Carter Henry, American politician: b. Chicago 23 April 1860. He is son of the preceding. He graduated from St. Ignatius College, Chicago, in 1881, and from the Yale Law School in 1884. He practised law in Chicago, was later engaged in the real estate business, and in 1891 became editor of the Chicago *Times*, a position which he held for two years. He has been active in Chicago politics as a Democrat, and has been four times elected mayor of the city, in 1897, 1899, 1901, and 1903.

Harrison, Constance Cary, American novelist and miscellaneous writer: b. Vaucluse, Va., 25 April 1846. She was married in 1867 to Burton N. Harrison (q.v.) and has since lived in New York. She is one of the most popular of American authors and among her published books are: 'Woman's Handiwork in Modern Homes' (1881); 'Old-Fashioned Fairy-Book' (1884); 'Bar Harbor Days' (1887); 'The Anglomaniacs' (1887); 'Sweet Bells Out of Tune' (1893); 'An Errant Wooing' (1895); 'A Bachelor Maid' (1894); 'A Son of the Old Dominion' (1897); 'A Merry Maid of Arcady' (1897); 'Good Americans' (1898); 'A Princess of the Hills' (1901); a play, 'The Unwelcome Mrs. Hatch' (1901); etc.

Harrison, Frederic, English philosopher and historian: b. London 18 Oct. 1831. He was educated at Oxford; was called to the bar at Lincoln's Inn in 1858, and for a time practised as a conveyancing and equity lawyer. In 1877 he was appointed professor of jurisprudence and international law at the Inns of Court, a post which he held till 1889. He is the chief living representative in England of Positivism and the Religion of Humanity. He has been widely read in the United States, which he visited on a lecturing tour in 1901. He is a master of English style and his literary judgments command the fullest respect. Among his publications 'The Meaning of History' (1862); 'Science and Humanity' (1879); 'The Present and the Future' (1880); 'Byzantine History in the Early Middle Ages' (1900), his Rede Lecture. The volume entitled 'The Religious Systems of the World' (1893) includes an account by him of the Religion of Humanity.

Harrison, Gabriel, American author and artist: b. Philadelphia 25 March 1825; d. Brooklyn, N. Y., 15 Dec. 1902. He began life as a photographer and an actor and in 1845 supported Charles Keane at the Park Theatre, New York, and later taught elocution, and wrote dramatic and art criticism. Among his works are: 'Life of John Howard Payne' (1873); dramatization of 'The Scarlet Letter' (1878); etc.

Harrison, James Albert, American philologist: b. Pass Christian, Miss., 21 Aug. 1848. He was graduated at the University of Pennsylvania in 1868; and has since been professor of Latin and modern languages at Randolph-Macon College, Va., 1871–6; of English and modern languages at Washington and Lee University 1876–95, and of English and romance languages at the University of Virginia. He is a prominent member of the American Philological Association and the founder and editor of the 'Library of Anglo-Saxon Poetry.' Among his works are: 'Group of Poets and Their Haunts'; (1881); 'Story of Greece' (1885); 'Dictionary of Anglo-Saxon Poetry' with Baskerville (1886); etc.

Harrison, Joseph, American engineer: b. Philadelphia 20 Sept. 1810; d. there 27 March 1874. In 1834 he began the construction of locomotives, and in 1840 designed for the Reading railway an engine which was copied and introduced into Russia with such success that he was invited to Russia, and there with two other American engineers concluded a contract with the Russian government to build the rolling-stock and locomotives of the St. Petersburg and Moscow railway. He executed also other important contracts with that government, and in 1852 returned to the United States, where he subsequently patented a safety-boiler and received both the gold and silver Rumford medals from the American Academy of Arts and Sciences. In 1869 he published a folio containing his autobiography, incidents of his Russian ex-

perience, and his poem, 'The Ironworker and King Solomon.'

Harrison, Lowell Berge, American artist: b. Philadelphia 28 Oct. 1854. He studied with Alexander Cabanel in Paris, became known for his landscapes, especially snow-scenes, and obtained medals at the Paris Salon of 1887 and the Columbian Exposition (1893). His works include: 'Friends, or Foes?'; 'A Waif from the Sea'; 'Calling Home the Cows'; and 'November,' purchased by the French government for the Marseilles Museum.

Harrison, Mary Saint Leger ("Lucas Malet"), English novelist: b. Eversley, Hampshire. She is a daughter of Charles Kingsley (q.v.) and was married to Rev. William Harrison, rector of Clovelly, who died in 1897. She inherits the talent of the Kingsleys and her novels published under the pseudonym of "Lucas Malet" have been as widely popular in America as in England. They are marked by vigorous characterization and skilful construction, and include: 'Mrs. Lorimer' (1882); 'Colonel Enderby's Wife' (1885); 'Little Peter' (1887); 'A Counsel of Perfection' (1888); 'The Wages of Sin,' a notably strong tale (1891); 'The Carissima' (1896); 'The Gateless Barner' (1900); 'Sir Richard Calmady' (1901).

Harrison, Thomas, English regicide: b. Newcastle-under-Lyne 1606; d. London 13 Oct. 1660. He was a soldier of Parliament in the civil war and commanded the guard that carried King Charles from Hurst Castle to London, sat among his judges, and signed his death warrant. He fought at Worcester, but his uncompromising attitude in religion and politics was unacceptable to Cromwell and he was deprived of his commission, and later imprisoned for his share in some of the plots devised by the extremists. At the Restoration, he was seized, tried, and condemned to death.

Harrison, Thomas Alexander, American painter: b. Philadelphia 17 Jan. 1853. He studied painting under Gérôme in the Ecole des Beaux Arts at Paris, and first exhibited in the Salon of 1881. He was awarded the gold medal by the Pennsylvania Academy of Fine Arts in 1894 and elected an associate of the National Academy in 1898. His best known works are: 'Coast of Brittany'; 'Little Slave'; 'The Sea-Shore.'

Harrison, Susan Frances Riley, Canadian author: b. Toronto 24 Feb. 1860. She was at one period literary editor of the Toronto 'Week' and has been a frequent contributor to American and English periodicals. She has written 'Crowded Out and Other Sketches' (1889); 'Pine, Rose, and Fleur-de-Lis' (1891); 'Down the River and Other Poems' (1891); and edited an anthology, 'French and English Native Writers' (1889).

Harrison, William Henry, 9th President of the United States: b. Berkeley, Charles County, Va., 9 Feb. 1773; d. Washington, D. C., 4 April 1841. He studied at Hampden and Sidney College, later pursued a course in medicine, and was about to be graduated as a practitioner, when the sudden death of his father gave him the liberty to disengage himself from a profession for which he had no natural bent nor aptitude. He received from Washington a commission in the army, and was soon on his way to Cincinnati, making the journey from Philadelphia to Pittsburg on foot, to join the regiment to which he had been assigned. He arrived at Fort Washington just after the defeat of General St. Clair's army. His first military service was to command a company of twenty men as an escort for a train of pack-horses to Fort Hamilton, a military post on the west bank of the Big Miami River from which the seat of Butler County was named. In 1793 he joined the new legion under General Anthony Wayne who made him an aide-de-camp, and in December of that year he took part in the expedition which repossessed General St. Clair's field of battle, and erected thereon Fort Recovery. He participated in all the engagements with the Indians and their British allies during this campaign, and displayed conspicuous gallantry at the Battle of Fallen Timbers. Shortly after the close of this campaign Harrison was advanced to the rank of captain and placed in command of Fort Washington. The position was largely a confidential one. The conduct of the Spaniards on the Mississippi was exasperating. French citizens and agents were engaged in exciting the people of Kentucky into a war with the Spanish of Louisiana with the object of thus embroiling our government with Spain and of forcing it into a league with France. Captain Harrison was instructed to prevent the passage down the river of boats laden with military stores belonging to the French agents. The English posts on the northern frontier, which had been held so long in violation of good faith, were now evacuated by the English in obedience to the Jay Treaty of 1794; the new garrison and supplies were sent to Fort Washington and forwarded thence through the wilderness under the supervision of the commandant of that post. In the spring of 1798 Harrison resigned his commission in the army and settled on a tract of land at North Bend about 16 miles from Cincinnati, but was immediately appointed by President John Adams as secretary of the Northwest Territory under Gen. Arthur St. Clair as governor. A year later he resigned this position to take his seat in Congress as the first delegate from the Territory. Up to this time the public lands had been sold in such vast tracts that none but men of wealth could buy them. Harrison secured the division of the land into small tracts and made it possible for the poor man to obtain a homestead. During that session of Congress a part of the Northwest Territory was formed into the Territory of Indiana. It included the present States of Indiana, Illinois, Michigan, Wisconsin, and a part of Minnesota, and contained a civilized population of nearly five thousand souls. Harrison was appointed its first governor by President Adams, and so satisfactory was his administration, he was successively reappointed by President Jefferson and President Madison. He was also made superintendent of Indian affairs. Governor Harrison organized the new government at Vincennes. Many difficult questions demanded his attention, but the most difficult and delicate was the restless and finally hostile attitude of the savages under the leadership of Tecumseh, and the preaching of Tecumseh's brother, "the Prophet." The beginning of open warfare by the Indians was averted many times by his calmness and courage. He made in all thirteen treaties with the Indians, and secured the cession from several tribes of more than three million acres of land on the Wabash and White Rivers. Tecumseh condemned these treaties on

WILLIAM HENRY HARRISON,

NINTH PRESIDENT OF THE UNITED STATES.

the ground that the land belonged to all of the Indians, and that a single tribe could not give a legal title without the consent of every other tribe. Harrison invited Tecumseh to Vincennes for a conference, and directed that he should bring with him not more than thirty warriors; but he came with four hundred completely armed. There were many evidences that treachery was intended, and but for the conciliatory methods of the governor, the council would have terminated in bloodshed. Nothing was accomplished by this interview, nor by a second in the following summer. Meanwhile, frequent depredations by the Indians made it evident that conciliatory measures could no longer be employed, and on 26 Sept. 1811 Harrison set out with 900 men to punish them. On 6 November, when the army was within a short distance of Tippecanoe, it was met by messengers demanding a parley. A council was agreed upon for the next day, but at 4 o'clock on the following morning, the treacherous savages fiercely attacked the camp of Harrison in an endeavor to take it by surprise. The fighting continued till daylight when the Indians were routed with great loss. In the war of 1812 Harrison was appointed to the chief command of the Northwest, and given a major-general's commission. He urged upon the government the importance of creating a navy on the Lakes. That advice was heeded, and the splendid achievement of Commodore Perry on 10 Sept. 1813, was made possible by the military sagacity of this accomplished soldier. Six days after Perry's victory General Harrison embarked his artillery and supplies for a descent on Canada. The British general, Proctor, burned the fort and navy-yard at Malden and retreated, closely pursued by Harrison who overtook him and his Indian allies led by Tecumseh near the river Thames. Within five minutes almost the whole British force was captured, and shortly afterward the Indians were completely routed, and their leader Tecumseh was slain. The battle of the Thames and Perry's victory ended the war in Upper Canada, and gave the United States undisputed possession of the Great Lakes excepting Lake Ontario.

The years between the War of 1812 and the presidential campaign of 1840 Harrison devoted in part to the service of his country, and in part to the life of a country gentleman. He was in turn a member of Congress, state senator in the general Assembly of Ohio, presidential elector, United States senator from Ohio, and minister to the United States of Colombia. In 1829 he retired to his farm at North Bend. In December 1839, he was nominated by the National Whig convention for the Presidency of the United States, with John Tyler of Virginia for vice-president. The campaign which followed was one of the most exciting in the history of the country. Political mass meetings and processions were introduced for the first time, and party watchwords and emblems were employed with telling effect. That canvass has commonly been called the "log-cabin and hard cider campaign." The eastern end of General Harrison's house at North Bend consisted of a log cabin covered with clapboards, and his table was reputed to be well supplied with good cider, instead of wines. Log cabins and hard cider thus became party emblems typifying republican simplicity. "Tippecanoe and Tyler too" was shouted and sung and emblazoned from one end of the country to the other. Nothing could stem the tide of wonderful popular enthusiasm for the hero of Tippecanoe and the Thames. Van Buren, the Democratic candidate, received only sixty electoral votes out of two hundred and ninety-four. The death of the President occurred only thirty-one days after his inauguration. Consult Bostwick in Wilson's 'Presidents of the United States' (1894).

Harrison, Ark., town, county-seat of Boone County; on the St. Louis & N. A. railroad; about 120 miles northwest of Little Rock. It is in the lead and zinc section, and its industries are chiefly connected with mining. Considerable fruit is grown in the vicinity, and it has flour-milling and dairy interests. It is the seat of a collegiate and normal institute for women. The United States government building cost about $80,000. Pop. 1,603.

Harrison, N. J., city in Hudson County; on the Passaic River, the Pennsylvania and the Erie R.R.'s. It is a suburb of Newark, and a sub-station of the Newark post-office, but has an independent municipal government. It was settled in 1668 and incorporated in 1873. The charter of 1873 is still in force, and by it the government is vested in a common council elected by wards. The chief manufactures are wire-cloth, marine-engines, steel, machinery, tubes, refrigerators, ink, beer, and leather. The water-plant is owned and operated by the city. Pop. (1900) 10,596.

Harrison, Ohio, village in the township of Harrison, Hamilton County, on the boundary between Ohio and Indiana, and on the Cleveland, C., C. & St. L. railroad, 23 miles by rail west-northwest of Cincinnati. The village situated on the north bank of the Whitewater River, a tributary of the Great Miami, in a fertile farming section, has manufactures of furniture, sashes, blinds, brushes, bricks, shoes, a corn-drill factory, a cannery, and lumber, flour, and roller mills. Its public buildings include a high school and six churches. Pop. (1900) 1,456.

Har'risonburg, Va., town, county-seat of Rockingham County; on the Chesapeake & W., the Southern, and the Baltimore & O. R.R.'s; about 100 miles northwest of Richmond. It is in the Shenandoah Valley, and is surrounded by a rich agricultural country. Its chief manufactures are flour, staves, saw and planing mill products, foundry and machine shop products, and pottery. It is the trade centre for the greater part of the county. The town owns and operates the water-works. Pop. (1900) 3,521.

Harrisonburg, Engagement Near. Harrisonburg, Va., on the Great Valley Turnpike, 22 miles north of Staunton, and 122 miles northwest of Richmond, was the scene of many stirring events in the Civil War. The place was occupied by Gen. Banks late in April 1862, and abandoned when Jackson forced Banks down the valley in May. When Jackson, in turn, was forced up the valley by the combined armies of McDowell and Frémont, he abandoned the main valley, moving from Harrisonburg to Cross Keys and Port Republic, his rear-guard, two regiments of Virginia cavalry, under Gen. Turner Ashby, halting about two miles southeast of Harrisonburg. On 6 June 1862 Col. Wyndham, with the First New Jersey cavalry and a battalion of the Fourth New York, moving from Harrisonburg, attacked Ashby and

was defeated and followed to within one mile of the town, with the loss of several men killed and wounded, and about 60 taken prisoners, including Wyndham himself. Gen. Bayard then pushed forward with cavalry and infantry and Ashby fell back and called for infantry support. Jackson sent him Stuart's brigade — First Maryland, Forty-fourth, Fifty-second, and Fifty-eighth Virginia. A few miles beyond Harrisonburg Bayard attacked with the Pennsylvania «Bucktails» under command of Lieut.-Col. T. L. Kane, and in the engagement Ashby was killed, and Kane was wounded and captured. While this was happening on the right, the Sixtieth Ohio infantry and First Pennsylvania cavalry, on the left, drove in the Confederate skirmish-line, without loss on either side. As soon as the wounded could be removed the Confederates fell back in the direction of Port Republic, and the Union forces retired to Harrisonburg. The Union loss in the engagement was 65 killed, wounded, and missing. The Confederate loss including Ashby, was 18 killed, 50 wounded, and 3 missing. Consult: 'Official Records,' Vol. XII.

E. A. Carman.

Har'risonville, Mo., city, county-seat of Cass County; on the Missouri, K. & T., and the Missouri P. R.R.'s; about 30 miles southeast of Kansas City. It is situated in an agricultural and stock-raising region and the trade and manufactures are connected chiefly with the products of the surrounding farms. The shipping consists mostly of grain, live stock, lumber, and dairy products. Pop. (1900) 1,844.

Harrisse, hăr-ēs', **Henri,** American critic, bibliographer, and historian: b. Paris 1830, of Russian-Hebrew parentage. He became a citizen of the United States, and for several years practised law in New York. He has published 'Bibliotheca Americana Vetustissima' (1866); 'Christopher Columbus' (1884–5); 'John and Sebastian Cabot' (1883); 'The Discovery of North America'; etc.

Har'rodsburg, Ky., city, county-seat of Mercer County; on a branch of the Southern railroad; about 45 miles southwest of Lexington and 58 miles southeast of Louisville. It is the oldest permanent settlement in the State, and was founded by James Harrod in 1774. Two years later Kentucky was incorporated as one of the counties of Virginia and Harrodsburg was made the county-seat. Stock-raising and farming are the principal occupations in the surrounding country. It has flour and planing mills, a distillery, brick-yard, and ice factory. The climate, scenery, and the Greenville Springs nearby make it a pleasure and health resort. It is the seat of Beaumont College, an institution for women, opened in 1894. Pop. (1900) 2,876.

Harrow School, England, an academic institution situated at Harrow-on-the-Hill, a town of Middlesex, 12 miles northwest of London. It is one of the famous public schools of England and was founded by John Lyon in 1571. The original red brick school house, now the Fourth Form School, was built 1608–15. New buildings were added in 1819 and since, the chief of these being the Vaughan Memorial Library (1863), and the semi-circular speech-room (1877). The school was primarily intended to afford free education to 30 poor boys of the parish; but provision was also made for the admission of 'so many foreigners as the place can conveniently contain.' The age of admission is 12 to 14; and there are six entrance scholarships of from $150 to $400 per annum, offered every Easter. The most valuable learning scholarships are Baring's three of $500 a year for five years to Hertford College, Oxford. Among the distinguished alumni of Harrow are Dr. Parr, Theodore Hook, Sheridan, Byron, Palmerston, Anthony Trollope, and Cardinal Manning. Under the Public Schools Act of 1868 the governing body comprises six members, elected respectively by the Lord Chancellor, the universities of Oxford, Cambridge and London, the Royal Society and the undermasters.

Hart, Albert Bushnell, American historian: b. Clarksville, Pa., 1 July 1854. He was graduated from Harvard in 1880, subsequently becoming professor of history there. He has written: 'Coercive Powers of the United States Government' (1885); 'Formation of the Union'; 'Introduction to the Study of Federal Government' (1890); 'Studies in American Education' (1895); 'Life of Salmon P. Chase' (1899); 'Practical Essays on American Government' (1893); etc. He has also edited 'American History Told by Contemporaries' (1898–1901); 'American Citizen Series' (1899); and since 1895, the 'American Historical Review.'

Hart, James McDougal, American painter: b. Kilmarnock, Ayrshire, Scotland, 10 May 1828. He came to the United States in 1831, and studied art under his brother William (q.v.), and at Düsseldorf in the studio of Schirmer (1851). He was elected a member of the National Academy in 1859, and devoted himself principally to American forest scenery with a preference for autumnal effects. His 'Landscape with Cattle' is in the New York Metropolitan Museum, and his best known pictures are 'On the Croton'; 'Morning in the Adirondacks'; and 'Oaks in Autumn.'

Hart, James Morgan, American scholar: b. Princeton, N. J., 1839. He was the son of John S. Hart (q.v.). He was graduated from Princeton in 1860, studied in Göttingen, and took the degree of A. M. from Princeton in 1863. He was professor of modern languages at Cornell (1868–72); professor of modern languages and English literature in the University of Cincinnati (1876–90); returning to Cornell as professor of rhetoric and English philology in 1890. He has written: 'German Universities' (1874); 'Syllabus of Anglo-Saxon Literature' (1887); 'Hand-book of English Composition' (1895); has revised and edited his father's 'Manual of Composition and Rhetoric' (1897); and has translated 'German Classics' and 'Goethe Prose Selections.'

Hart, Joel T., American sculptor: b. Clarke County, Ky., about 1810; d. Florence, Italy, 2 March 1877. He was of humble parentage, and in 1830 entered a stone-cutter's establishment in Lexington. He was induced to attempt modeling busts in clay, and among others, Gen. Jackson and Cassius M. Clay (q.v.) sat to him, the latter giving him his first commission for a bust in marble. This when completed proved so satisfactory that Hart was commissioned to execute a marble statue of Henry Clay. He began this, but various delays prevented its completion, and it was not set up in Richmond, Va., till 1859. Other important

works by Hart are 'Woman Triumphant' in the court-house, Louisville, Ky., and 'Il Penseroso.' He was particularly well known for his portrait busts.

Hart, John, American patriot: b. Hopewell, N. J.; d. there, at an advanced age, 1780. Frequently elected to the colonial assembly he was prominent especially in the legislation for local improvements. In 1774 he was chosen to the general Congress at Philadelphia, where he was noted for his sound judgment and inflexible determination; was re-elected in the two following years, and was one of the signers of the Declaration of Independence. New Jersey was soon invaded by the British army, his estate devastated, and special exertions were made to take him prisoner. The capture of the Hessians by Washington permitted his return home.

Hart, John Seeley, American educator: b. Stockbridge, Mass., 28 Jan. 1810; d. Philadelphia 26 March 1877. He was for many years principal of the New Jersey State Normal School, at Trenton, and subsequently professor of English literature at Princeton College. His textbooks on English and American literature had a wide circulation, and in the long course of his career as educator he did much to stimulate a taste for good literature among students.

Hart, Sir **Robert,** English diplomatist, director of the Chinese imperial maritime customs: b. Portadown, County Armagh, Ireland, 1835. He was educated at the Taunton Wesleyan School, and was graduated at Queen's College, Belfast. He entered the British consular service in China in 1854, was appointed inspector-general of customs in 1863 and accepted his present position in 1885. During the Boxer outbreak in 1900, he underwent the siege in the British legation, at Peking, and since then has published his views on the position of things in China in a very remarkable work, 'These From the Land of Sinim' (1901). He attributes the disturbances in China to the arrogance of foreigners and the unyielding pride of the Chinese. He discusses China's army, law, transportation, communication, currency, education, administration, and religion in a highly optimistic vein, and shows that the Chinese government does a great deal better than it gets credit for. He is a firm believer in the Chinese plans for reform. He is certainly deeply trusted by the Chinese authorities and is one of the best oriental administrators that England has ever been blest with in China.

Hart, Samuel, American Episcopal clergyman: b. Saybrook, Conn., 4 June 1845. He was graduated from Trinity College in 1866, and was ordained priest of the Episcopal Church in 1870. He was at Trinity College as assistant professor of mathematics (1870–3), professor of mathematics (1873–83), and professor of Latin (1883–99). In 1899 he became vice-dean and professor of doctrinal theology at Berkeley Divinity School. In 1886 he was appointed custodian of the Standard Prayer Book of the Episcopal Church of the United States, in 1892, secretary of the House of Bishops, and in 1896, historiographer of the church. He is a member of several learned societies, including the American Historical Society, the American Oriental Society, and the Society of Biblical Literature and Exegesis. He is editor of 'Satires of Juvenal,' 'Satires of Persius,' and Bishop Seabury's 'Communion Office.'

Hart, Thomas Norton, American merchant and politician: b. North Reading, Mass., 20 Jan. 1829. He entered business in Boston as partner in a mercantile firm, later founding a firm under the name of Hart, Taylor & Co. When he withdrew from this business, he became president of the Mount Vernon National Bank, and was connected with many eleemosynary institutions. He has also been active in politics, was a member of the common council, and of the board of aldermen; was nominated for mayor of Boston in 1887 and 1888, but defeated at the election; was, however, elected in 1889, 1890, 1900 and 1901.

Hart, William, American painter: b. Paisley, Scotland, 31 March 1823; d. Mount Vernon, N. Y., 17 June 1894. Emigrating with his parents to the United States in 1831, he settled in Albany, and was at first apprenticed to a firm of coachmakers, in Troy, by whom he was employed to paint the panels of coaches. He subsequently painted landscapes, portraits, and even window shades. In 1848 he became a regular exhibitor at the National Academy of Design, of which in 1858 he was elected as academician. He was president of the American Water Color Society 1870–3. He was a brother of James McDougal Hart (q.v.).

Hart, a hunting term, applied to the male, or stag, of the red deer after it has completed its full antlers at the age of six or seven years.

Hartbeest, härt'bēst, one of the large African antelopes of the genus *Bubalus,* specifically the caama (*B. cama*), formerly excessively numerous on the South African plains. They have long narrowing heads, doubly-curved, ringed horns, cow-like tails, and usually are of a grayish or reddish color, with decided markings on the face, especially in the bontebok (*B. pygargus*), blesbok (*B. albifrons*) and sassaby (*B. lunata*). All were noted for swiftness. Other very distinctive species are the konzi, tora, korigum and hunter's antelope. Most of these have become greatly diminished in numbers since about 1870.

Harte, Francis Bret, American novelist and poet: b. Albany, N. Y., 25 Aug. 1839; d. Aldershot, England, 6 May 1902. In 1854 he went to California, attracted there by the gold excitement. He was first a teacher at Sonora, then tried mining, in which he was unsuccessful. He next entered a printing-office, and in 1857 was compositor on the San Francisco 'Golden Era.' At that time he began to write short sketches, which appeared in the 'Golden Era,' and soon attracted attention; he was invited to join the staff of the 'Californian,' to which he contributed a series of clever parodies on famous contemporary writers of fiction, later published as 'Condensed Novels.' In 1864 he was appointed secretary to the United States branch mint; in 1868 became editor of the 'Overland Monthly,' for which he wrote 'The Luck of Roaring Camp' and others of his most successful stories of frontier life. In 1871 he went to New York and became a regular contributor to the 'Atlantic Monthly.' In 1878 he was appointed United States consul in Crefeld, Germany, and in 1880 received the consulship at Glasgow, Scotland. In 1885 his tenure of office as consul came to an end, and he settled in London, devoting his whole time to literary

work. He was a prolific writer, and continued for the most part to deal with California themes. Among his shorter stories the following may be mentioned: 'Miggles'; 'The Outcasts of Poker Flat'; 'M'Liss' (1872); 'The Twins of Table Mountain' (1879); 'An Heiress of Red Dog' (1879); 'Flip' (1882); 'On the Frontier' (1884); 'By Shore and Sedge' (1885); 'Devil's Ford' (1887); 'A Phyllis of the Sierras,' and 'A Drift from Redwood Camp' (1888); 'The Heritage of Dedlow Marsh' (1889); 'A Sappho of Green Springs' (1891); 'The Bell-Ringer of Angel's' (1894); 'A Protégé of Jack Hamlin's' (1894); 'Barker's Luck' (1896); 'Tales of Trail and Town' (1898); 'Stories in Light and Shadow' (1898); 'Mr. Jack Hamlin's Mediation' (1899); and 'From Sand Hill to Pine' (1900), a collection of short stories. His longer stories and novels include: 'Gabriel Conroy' (1876); 'Thankful Blossom: A Romance of the Jerseys' (1877); 'In the Carquinez Woods' (1883); 'Maruja' (1885); 'Snowbound at Eagle's' (1886); 'The Crusade of the Excelsior' (1887); 'Cressy' (1889); 'A Waif of the Plains' (1890); 'A Ward of the Golden Gate' (1890); 'A First Family of Tasajara' (1892); 'Colonel Starbottle's Client, and Some Other People' (1892); 'Clarence' (1895), dealing with incidents in the American Civil War; 'In a Hollow of the Hills' (1895); and 'Three Partners' (1897). He has also written much verse comprised in volumes entitled 'Poems' (1871); 'East and West Poems' (1871); 'Echoes of the Foot-Hills' (1874); and 'Some Later Verses' (1898).

In estimating Harte's work it must be remembered that it was his rare good fortune to break new ground, and to become the first literary interpreter of a life which with its primitive breadth and freedom, its striking contrasts of circumstance and character, offered singular opportunities to the novelist. That he ever did anything quite so good as his first group of stories and poems cannot be said, for his later volumes are marked, as a whole, by the repetition of well-worn motives and by declining spontaneity and power. Still, the average quality of his output remained high; and when the circumstances of its production are borne in mind, it may perhaps seem remarkable that it should have preserved so many traces of the writer's youthful freshness and vigor. Among qualities of his work those which perhaps most constantly impress the critical reader are his dramatic instinct, his keen insight into character, his broad sympathy, and his subtle and pervasive humor. Dealing for the most part with large, strongly marked, elemental types, as these develop and express themselves under conditions which give free play to instinct and passion, he does not indulge in lengthy analyses or detailed descriptions. His men and women are sketched with a few strokes, and left to work out their own personalities in speech and deed; and yet, such is the skill with which this is accomplished that they stand out before us as creatures of real flesh and blood. He did not purposely soften the shadows in his pictures; the sin and wretchedness of frontier life are frankly portrayed; none the less, there can be little doubt that consciously or unconsciously he contrived to throw an idealizing glamor over the mine and the camp, and that many of his most lifelike and successful characters are wrought in the imagination, though out of the stuff of fact. But it is here that we touch upon what is perhaps one of the finest qualities of his work,—a quality not to be separated from his tendency toward idealization. Though he dwelt habitually upon life's unexplained and inexplicable tragic complexities, he nevertheless suffused his stories with an atmosphere of charity, clear, sweet, and wholesome. The weakness of his writing is closely connected with some of its main elements of strength. A master of condensed and rapid narration, he produced many stories which are too sketchy in method to be completely satisfactory; while in his desire to achieve terseness he occasionally sacrificed clearness of plot. This is particularly the case with his more ambitious efforts, especially with his long novel 'Gabriel Conroy,' an elaborate study of the culture conditions of early California civilization, which, though it abounds in memorable descriptions and vivid character sketches, lacks wholeness and proportion. As a writer of verse, he is unequal; some of his poetry shows the originality and power of his earlier prose, while much is of too temporary a character to find a lasting place in literature. Consult: Pemberton, 'Life of Bret Harte.'

Hartford, Conn., State capital, seat of Hartford County, port of entry, and head of navigation on the Connecticut River, 60 miles from Long Island Sound. By the main line of the New York, N. H. & H. railroad it is 110 miles from New York and 124 from Boston (a midway position which has enhanced its business development), 36 from New Haven, and 26 from Springfield, Mass.; the Highland Division (old N. Y. & N. E.) connects it with Fishkill on the Hudson (110 miles) and Providence, R. I. (90 miles); the Valley Division extends down the river to its mouth, the Connecticut Central to Springfield east of the river. The Central New England runs to Poughkeepsie and beyond. Pop. (1903) about 86,000.

Hartford lies on the west bank of the river, on rolling ground; Prospect Avenue in the west and Fairfield Avenue in the south afford a superb view across the entire Connecticut Valley, some 20 miles wide. It extends about 5½ miles north and south to Windsor and Wethersfield lines, by 3½ west to West Hartford line, about 18 square miles in all; the town and city are conterminous. It is divided about equally by the little Park River, which joins the Connecticut just south of the centre and is crossed by many bridges, and through whose bed runs the great main sewer into the Connecticut. The chief business street is Main, following the river line along the first high ground back from its shore, the latter frequently overflowed in the spring freshets; next Asylum, west past the railroad station, and State east to the steamer landing with the chief wholesale warehouses; Pratt and Pearl parallel to Asylum, and Central Row opposite Pearl across Main. It is a place of great beauty; and from its age, early and continuous business importance, and consequent accumulated wealth and generations of inherited incomes, is of noted social and intellectual cultivation,—more like the old European provincial capitals in a mingling of metropolitan advantages with those of moderate numbers and coun-

BRET HARTE,
Died May 6th, 1902.

try roominess than any other American city. There are several costly residence districts: the most notable are Washington Street with its magnificent arch of old elms, Asylum Avenue, and a portion of Farmington, and Woodland Street, with some handsome places on Wethersfield Avenue. One of the finest streets, Prospect Avenue, is the West Hartford boundary, and built up only on that side; and fine places extend well into West Hartford. The street-railway system is very extensive and well managed: it runs in all directions for many miles. The Connecticut is spanned by a wooden bridge to East Hartford; but work has begun on a splendid stone bridge, to be completed by the end of 1904, at a cost with handsome street approaches of nearly $2,000,000.

The park system contains some 1,200 acres: within the past few years the munificence of several citizens has endowed the city with a ring of beautiful parks, which with the city's help will ultimately encircle it entire. The oldest is Bushnell Park, in the heart of the city, 48½ acres, crowned by the State capitol and containing monuments to Israel Putnam and Horace Wells. The largest is Keney Park in the extreme north, extending into Windsor, 663.4 acres; next Goodwin Park in the extreme south, some 200 acres. Elizabeth Park in the extreme west, largely in West Hartford, 90 acres, is the nursery for the other parks; Pope Park southwest of the centre has 73 acres, ultimately to be 92 with city additions; and Riverside Park is a reclamation and beautifying of the formerly squalid river front north of the East Hartford bridge. There are also smaller squares and spaces.

The city has a remarkable number of handsome and architecturally notable buildings. Foremost is the State capitol, of white marble, towering over Bushnell Park; the handsomest in the country except the one at Albany, and architecturally surpassing that in many ways. It was completed in January 1880, at a cost of $2,534,024.46; land and other expenses made the total $3,342,550.73. The general plan was of 13th-century Gothic, but modern needs forced very much change in this. Each side is an individual and separately beautiful design; and the interior is as notable as the exterior. Its extreme length is 295 feet 8 inches; depth of centre part, 189 feet 4 inches; depth of wings, 111 feet 8 inches; height from ground line to top of crowning figure, 256 feet 6 inches. It is fireproof, the only known fireproof capitol. The red-sandstone Cheney Building was designed by H. H. Richardson. Trinity College (q.v.) has fine buildings on high ground in the south part, ultimately to form a quadrangle. The homes of the Connecticut Mutual Life, the Ætna Life, the Phœnix Mutual Life, and the National Fire, are the finest insurance buildings; the Phœnix Bank and the First National, of the bank buildings. The white granite government building (post-office and custom-house) may be noted; and the Wadsworth Atheneum is pleasing and dignified. Of several handsome church structures, St. Joseph's Cathedral (R. C.) is most notable. Of interest historically is the city hall, formerly the state house, completed May 1796: the famous Hartford Convention (q.v.) was held here in 1814. Of the city monuments, the two most notable are the Soldiers' Memorial Arch, forming a gateway into Bushnell Park across the Park River; and the superb Corning fountain in that park, a bronze with symbolical figures.

The educational institutions are widely famed. At their head stands Trinity College noted above. The Hartford high school is the most completely equipped in the country; it has cost in buildings, land, and equipment, $598,500. The pupils from surrounding towns are admitted on payment of a fee. A manual-training department was added in a new wing in 1897. The city schools are operated on the district system; several attempts to consolidate them have been heavily defeated. There are nine districts, with 18 buildings altogether. The school expenses are about $400,000 a year. The school tax is assessed with the city taxes, but each district by itself. Hartford has also a theological seminary managed by the Pastoral Union (Congregational) of Connecticut. There are 71 church societies, of which the Congregational (13), Roman Catholic (10), Baptist (9), Episcopal (8), and Methodist (7), are the chief denominations. Hartford is the seat of a Roman Catholic bishop. Its charitable institutions are renowned; it was the earliest seat of attempts to instruct the deaf and dumb in the United States, through Gallaudet and Clerc; and the School for the Deaf, formerly Deaf and Dumb Asylum (whence Asylum Street, where it is located), carries on the work. The Retreat for the Insane, the Hartford Hospital, the Hartford Orphan Asylum, the Y. M. C. A., the City Mission and Open Hearth, and the Union for Home Work, are only part of its overflowing charities. The Connecticut Humane Society also has its head office here.

The library facilities of the city are very large for its size, and far more varied in contents than if they had been collected by a single institution. In the Wadsworth Atheneum are housed the Hartford Free Public Library with 79,000 volumes, the Watkinson Library (reference only) with 59,000, and the Connecticut Historical Society with about 25,000, besides as many pamphlets, and toward 50,000 MSS. The libraries of the Theological Seminary (81,000, and about 40,000 pamphlets) and Trinity College (43,000) contain many valuable specialties; and the State Library in the capitol (40,000, and some 50,000 MSS.), with its great collection of statutes, law reports, public documents, Hansard, etc., is of extreme value.

Hartford, as the head of navigation and therefore distributing point for the Connecticut Valley, early gained an importance as a centre of wholesale trade which it has never lost; to accommodate this, the Hartford Bank, the fifth in the United States, was organized in 1792. But its largest importance is now as one of the leading insurance centres in the world, and third in the United States. This business developed from the marine insurance on its West India cargoes, added fire insurance as a branch, and in 1846 life insurance. The loans of its insurance companies with their vast assets, not restricted by law as are those of New York, have been one of the greatest agencies in developing the West, amounting to several hundred millions of dollars. There are now six life companies, two of which also have accident branches — the latter being the original and chief department in one; five fire companies besides a county mutual, and the United States branches of three foreign companies; and a

steam-boiler insurance company. There are 7 national and 5 other banks of discount, 4 savings-banks, and 4 trust companies. The manufacturing interests are heavy and varied. Firearms, including Gatling guns, at the famous Colt Works; electric machinery and vehicles; bicycles, of which it is the centre in the United States; cyclometers; woven-wire mattresses; horse nails; screws; steam-engines and boilers; typewriters; leather belting; and special machinery of all kinds, besides knit goods, furniture, carriages, harness, and many other things are manufactured here. It has also one of the largest printing houses in New England, which has manufactured many famous works; four daily papers, one of them the oldest newspaper in the United States (The *Courant,* 1764), and a number of wecklies, monthlies and quarterlies.

The mayor holds office for two years, and the representative body is two-chambered. The assessed valuation of property is about $81,000,000, making it *per capita* one of the richest cities in the United States. The tax rate is under 2 cents on the dollar.

The first white settlement of Hartford was by the Dutch in 1633, at the junction of the Park and Connecticut, still called Dutch Point (though the original point is now out in the Connecticut). They built there a fort called the "House of Hope." (For the settlement by the Newtown men in 1635–6, and the adoption of the first written constitution of modern times, whence Hartford is called the "birthplace of American democracy," see CONNECTICUT.) Hartford was first named Newtown, changed to the present name from Samuel Stone's English birthplace. From here in 1637 sailed the first organized military expedition in the English colonies, John Mason's against the Pequots. The Dutch were ejected from their fort in 1654; they had never really made a settlement. (For the attempt of Andros to seize the charter, in 1687, see CHARTER OAK.) In 1701 Hartford became joint capital with New Haven. In the Revolution, Hartford, as the head of the one rich store of food which the British could not seize, became of prime importance; the second commissary-general of the United States army, Jeremiah Wadsworth, was a Hartford merchant. Gov. Trumbull was also a strong reliance of Washington, who came to Connecticut to consult him; and in 1780 Washington and Rochambeau planned the Yorktown campaign here. The Hartford Convention (q.v.) of 1814 sat here. In 1873 Hartford became the sole capital of the State.

Its native and adopted citizens have made the city one of the literary glories of New England. It was the birthplace of Noah Webster, Frederick Law Olmsted, and John Fiske, with others of note; had the services of George D. Prentice, John G. Whittier, Joel Barlow, and others; and was the long or permanent residence of Harriet Beecher Stowe, Mark Twain, Charles Dudley Warner, and Horace Bushnell, besides John Trumbull and Lydia H. Sigourney. In the business world, both Edwin D. Morgan and Junius S. Morgan began their career as Hartford merchants.

Population.— 1800, 5,347; 1810, 3,955; 1820, 4,726; 1830, 7,074; 1840, 9,468; 1850, 17,966; 1860, 29,152; 1870, 37,180; 1880, 42,015; 1890, 53,230; 1900, 79,850. Of these 23,758 were of foreign birth: 8,076 in Ireland, 3,364 in Germany, and Austria, 2,260 in Russia, 1,952 in Italy, 1,714 in Sweden, 2,073 in England and Canada (English).

FORREST MORGAN,
Of Connecticut Historical Society.

Hartford, Mich., village of Hartford Township, Van Buren County, 15 miles west of Paw Paw on the Paw Paw River, and 17 miles northeast of Benton Harbor, on the Chicago & M. L. S. R.R. It has a graded school and five churches. It carries on a considerable traffic in agricultural produce and stock, has grain elevators, flour, saw-, and planing-mills, canneries, electric light plant, and manufactures staves, cigars, cheese, vinegar, etc. Pop. (1900) 1,077.

Hartford, Vt., town of Windsor County, on the White River, about one mile above its junction with the Connecticut River, and 60 miles south of Montpelier, on the Central Vt. and on the Woodstock R.R.'s. It has woolen, saw, and grist mills, and manufactures of agricultural implements and furniture. Pop. (1900) 3,817.

Hartford City, Ind., city, county-seat of Blackford County; on the Pittsburg, C. C. & St. L. and the Lake E. & W. R.R.'s; about 45 miles southwest of Fort Wayne, and 60 miles northeast of Indianapolis. The natural resources which contribute to the industrial and commercial interests are the products from the surrounding agricultural country, the natural gas supply, and the oil fields. The chief manufactures are iron, glass, flour, pulp, and paper, strawboard, and wagons. The city owns and operates the waterworks. Pop. (1900) 5,912.

Hartford Convention, of 1814: a gathering of New England Federalists to discuss measures for securing New England interests against the South and West; especially in relation to the War of 1812. The convention opposed the war on several grounds,— the vital objection being that it was destroying all American commerce in order to punish Great Britain for crippling a part of it. It was believed by the delegates that the agricultural States were sacrificing New England, whose life-blood was commerce, from ignorance mingled with sectional malice (see EMBARGO). All through the war, the New England Federalists, impoverished and excluded from the national councils, harassed and hampered the government in conducting it; the government retorted by leaving the whole section to its fate; the British inflamed the discord by exempting the New England coast from blockade, and the government countered by laying a new embargo which did the same work. All the New England States and New York were swept by the Federalists on this issue. In November 1813 the governor of Vermont recalled a brigade of militia from garrison duty; the government threatened prosecution, the Massachusetts legislature threatened to use the State power to support him. In the autumn of 1814 the destruction of New England industries had become intolerable; the coast was undefended, the British were occupying that of eastern Maine, and Congress was proposing a conscription so severe as to enlist minors without the consent of their parents; whereupon the Connecticut legislature ordered the governor to call a special session to protect its citizens

THE STATE CAPITOL AND SOLDIERS AND SAILORS' MEMORIAL BRIDGE AND ARCH,
IN BUSHNELL PARK.

if the measure were adopted. On 18 October the Massachusetts legislature proposed a convention of the New England States, to take action "not repugnant to their obligations as members of the Union," and "lay the foundation of a radical reform in the national compact" through a future national convention. Connecticut and Rhode Island accepted the proposal with similar qualification; New Hampshire was divided politically and Vermont was excited over Macdonough's victory at Plattsburg, but certain counties sent delegates. The war was a growing and alarming failure. England was demanding the renunciation of the whole Northwest as the price of peace, national bonds were at 25 per cent discount. The government sent a regular army officer to oversee the convention, and use force if it attempted disunion; deputed secret agents to see if it was true that there was a plot to make New England an English grand-duchy under a prince of the blood; and appointed the succeeding 12th of January a national fast-day. The convention met at Hartford, Conn., 15 Dec. 1814, with 12 delegates from Massachusetts, 7 from Connecticut, 4 from Rhode Island, 2 from New Hampshire, and 1 from Vermont,—26 in all. George Cabot of Massachusetts was chosen president, Theodore Dwight of Connecticut, secretary. A secret session of three weeks was held, a report to the New England legislatures prepared, and 5 Jan. 1815, the convention adjourned. The report stated the before-mentioned grievances, and charged the government with making naturalizations too easy and with destroying the balance of sections by forming new States at will out of the western territory; but denied any present intention to dissolve the Union. It was proposed that Congress should confide the defense of each State to the State itself, and return a share of its taxes for the purpose; and recommended seven changes in the Constitution, namely: abolition of the three fifths slave representation, the requirement of a two thirds vote for the admission of new States, the limitation of embargoes to 60 days, the requirement of a two thirds vote to sanction the prohibition of commercial intercourse, or to declare war or hostilities except in case of invasion; the exclusion of naturalized foreigners from civil offices or a seat in Congress, and prohibition of a President's re-election. They proposed also that two Presidents in succession should never be elected from the same State. They also recommended that another convention should be held at Boston the following June if affairs did not mend or the amendments were rejected. The Massachusetts and Connecticut legislatures adopted the report and sent commissioners to Washington; but before they arrived a satisfactory peace was made, all disasters forgotten in the blaze of the battle of New Orleans, and the promoters of the convention detested as traitors preparing to secede. They were in fact killed for public life. But in 1819 Cabot deposited the journal of the convention with the Massachusetts secretary of state as a permanent testimony that nothing treasonable was attempted; in 1833 Dwight wrote its history.

Hartford Fern. See *Filicales* (2), under FERNS AND FERN ALLIES.

Hartford Theological Seminary, an institution founded in 1834 for the education of Congregational preachers, at East Windsor Hill, Conn. It was formerly called the Theological Institute of Connecticut, and took its present name on its removal to Hartford in 1805. Its control is vested in a board of trustees elected by the Pastoral Union, an association of 200 ministers who have subscribed to the creed of the Union. The aim of the institution is to train ministers for pastoral work on the broadest lines of intellectual and spiritual life. The seminary has always been a leader in theological pedagogy. In 1903 its faculty comprised 12 professors and 12 lecturers, and the number of students was between 80 and 90. It has a library of 81,000 volumes, and nearly 45,000 pamphlets. Hosmer Hall, the main building, was erected 1880 by James B. Hosmer, and as it is estimated, at a cost of $150,000. In 1902 the Case Memorial Library was built by Newton Case at a cost of $100,000. Since 1890 the faculty have issued their valuable theological quarterly, 'The Hartford Seminary Record.'

Harting, James Edmund, English naturalist: b. London 29 April 1841. He was a solicitor until 1878, since when he has devoted himself to zoological research. Among his numerous publications are: 'The Ornithology of Shakespeare' (1871); 'Handbook of British Birds' (1871); 'Rambles in Search of Shells' (1875); 'British Animals Extinct within Historic Times' (1880); 'Essays on Sport and Natural History' (1883).

Har'tington, Spencer Compton Cavendish, MARQUIS OF. See DEVONSHIRE, SPENCER COMPTON, DUKE OF.

Hartington, Neb., city, county-seat of Cedar County; on Bow Creek, and on the Chicago, St. P. & O. R.R.; about 42 miles west by north of Sioux City, Ia., and 18 miles south by east of Yankton, S. D. It is in a fertile agricultural region and is the commercial centre of a large part of Cedar County. Large shipments of wheat and live stock are made annually. Pop. (1900) 971.

Hart'ley, SIR Charles Augustus, English civil engineer: b. Heworth, County of Durham, England, 1825. After being employed on several important engineering works he served in the Crimean war as captain of Turkish engineers, was knighted in 1862, and in 1867 was awarded, against 20 competitors, the prize for plans for extending the harbor of Odessa. He was appointed by President Grant a member of a board of engineers to report on the improvement of the lower Mississippi and recommended the improvement of the South Pass of its delta. He has been consulting engineer on many other notable engineering projects and has received many medals and decorations from home and foreign societies. He has published 'The Delta of the Danube'; 'Public Works of the United States and Canada'; 'Inland Navigation in Europe'; 'History of the Engineering Works of the Suez Canal.'

Hartley, David, English philosopher and physician: b. Armley, Yorkshire, 30 Aug. 1705; d. Bath, Somerset, 25 Aug. 1757. He practised medicine at Newark, Bury St. Edmund's, and London, and is remembered for his 'Observations on Man' (1749) in which is stated his hypothesis of nervous vibration and of the association of ideas.

Hartley, Jonathan Scott, American sculptor: b. Albany, N. Y., 23 Sept. 1845. He early developed a taste for working in marble and after spending several years in studying art in England, Rome, and Paris, he established himself in New York where he was professor of anatomy in the schools of the Art Students' League, 1878–84, and president of the league, 1879–80. Among important works by him are: 'King René's Daughter'; 'The Whirlwind'; bas-reliefs on the battle monument at Saratoga; and the Miles Morgan statue at Springfield, Mass.

Hart'man, Sadikichi, American author and artist: b. Nagasaki, Japan, 1867, of German and Japanese parentage. He was educated in Germany, came to New York in 1890 and has since devoted himself to painting and literary work. He has published 'Schopenhauer in the Air' (1899); 'Shakespeare in Art' (1901); 'Modern American Sculpture' (1901); etc.

Hartmann, härt'män, **Karl Robert Eduard von,** German philosopher: b. Berlin 23 Feb. 1842. He was educated in the School of Artillery, resigning in 1861. A year later he was attacked by an incurable disease which has confined him to his bed for the greater part of the time, but which has not prevented his engaging in the most profound philosophical studies. His great work, 'The Philosophy of the Unconscious' (1868), was followed by 'The Ethical Consciousness,' at first entitled 'Phenomenology of the Ethical Consciousness' (1879); 'The Philosophy of Religion' (2d ed. 1888); and 'Æsthetics' (1886–7). These constitute his exposition of a system of philosophy. Among other works of his are: 'Critical Grounds of Transcendental Realism'; 'The Crisis of Christianity in Modern Theology' (1880); 'Judaism in the Present and the Future' (1885); 'Lotze's Philosophy' (1888); 'The Ghost Theory in Spiritism' (1891); 'The Fundamental Social Questions' (1894); and many other works on society, religion, etc.

Hartranft, härt'tränft, **Chester David,** American educator: b. Frederick Township, Montgomery County, Pa., 15 Oct. 1839. He was graduated at the University of Pennsylvania in 1861 and at the New Brunswick Theological Seminary in 1864; was pastor of the Dutch Reformed church at South Bushwick, N. Y., in 1864–6, and of that in New Brunswick, N. J., in 1866–78. In 1879 he was appointed professor of ecclesiastical history at the Hartford Theological Seminary; in 1888 was elected its president, and held the chair of Biblical theology 1892–7 and of ecclesiastical dogmatics from 1897. He is a writer on theological subjects, and was at one time president of the Conservatory of Music at New Brunswick, N. J.

Hartranft, John Frederick, American soldier: b. New Hanover, Pa., 16 Dec. 1830; d. Norristown, Pa., 17 Oct. 1889. He was graduated at Union College in 1853, and in 1859 was admitted to the bar. At the outbreak of the Civil War he organized the 51st Pennsylvania regiment, was made its colonel, and with it participated in Burnside's expedition to North Carolina (1862). He also commanded the regiment in a charge at Antietam, and at Fredericksburg. In March 1865, he commanded a division of the Ninth corps in their assault on Fort Steadman, and was brevetted major-general. He received the nomination of the Republican convention in 1865 for auditor-general of Pennsylvania, was elected at the succeeding election, and was re-elected to the office in 1868. From 1872 to 1878 he was governor of Pennsylvania, and during his administration thoroughly reorganized the Pennsylvania militia, which from 1879 he commanded, with rank of major-general.

Hart's-horn, the horn of the common stag and its decomposition products. The substances derived from the horns were the volatile liquor, salt, and oil, and the ash which remains when the horns are calcined in the air. The fluid portions are got by destructive distillation in a convenient still, and are separated, the salt mechanically, and the others, after washing with water, by repeated rectification either alone or with quicklime, by which the more volatile portions are got free from the tarry matter and heavier oils. The salt which is formed in this operation is ammonic carbonate, which in part condenses in the neck of the retort, in part is washed over by the aqueous vapor into the receiver; and when the ammonia is got pure from the distillate and is condensed in water it constitutes the spirit of hart's-horn. The volatile alkali or spirit of hart's-horn is now no longer obtained from that source, except in special circumstances; the ammonia of commerce is now obtained from gas-liquor, from blast-furnaces, or from other sources.

Hart'suff, George Lucas, American soldier: b. Tyre, Seneca County, N. Y., 28 May 1830; d. New York 16 May 1874. He was graduated from West Point in 1852, entered the artillery, was on duty on the frontier and in Florida, in the Civil War became assistant adjutant-general, with rank of captain, in 1861, and major in 1862. Later appointed major-general of volunteers, he was one of the board for revision of the rules and articles of war and the preparation of a code for the government of the armies in the field. He was mustered out of the volunteer service in 1865, and in 1871 was retired from the regular army for disability from wounds received in battle, with rank of lieutenant-colonel and brevet major-general, United States army.

Hartsville, Engagements at. Hartsville, Tenn., on the north bank of the Cumberland River, about 35 miles northeast of Nashville, is an important crossing and connected by good roads with Lebanon on the south and Gallatin on the northwest. In August 1862 Gen. John H. Morgan, with his Confederate command, was operating north of the river and Gen. R. W. Johnson, with a cavalry command, was sent to drive him back. Johnson, approaching on the Gallatin road, attacked Morgan 21 August, near Hartsville, and was defeated with a loss of 80 killed and wounded, and 75 prisoners.

On 6 Dec. 1862 Hartsville was held by Col. A. B. Moore, with a Union force of three regiments of infantry, a regiment and a company of cavalry, and a section of artillery, in all about 2,100 men. Morgan had been instructed by Gen. Bragg to operate on Gen. Rosecrans' lines of communication in rear of Nashville and, learning that Moore was isolated, with no supports near, resolved to capture him. While two infantry brigades of Cheatham's division

and Wheeler's cavalry demonstrated on Nashville, Morgan, with four regiments and a battalion of cavalry, two regiments of infantry, and a battery, set out from Baird's Mills, 25 miles south of Hartsville, on the morning of 6 Dec. 1862, marched through Lebanon, crossed the Cumberland below Hartsville, during the night, disposed his forces so as to cut off Moore's retreat on the roads leading to Gallatin and Castalian, posts occupied by other Union commands, and early in the morning of 7 December, closed in on the Union camp, surprised it, attacked the troops, who were being hastily drawn up to receive him and, after a stubborn fight of an hour and a half, defeated and captured the entire command. Col. John M. Harlan, in command of a small Union brigade at Castalian Springs, nine miles away, hearing the noise of battle, marched to Hartsville and attacked Morgan's rear-guard as it was recrossing the river, recapturing some of the wagons taken. The Union loss was 58 killed, 204 wounded, and 1,834 captured and missing. The Confederate loss was 21 killed, 104 wounded, and 10 missing. Consult: 'Official Records,' Vol. XX.

E. A. Carman.

Hartt, Charles Frederick, American geologist: b. Fredericton, N. B., 23 Aug. 1840; d. Rio de Janeiro, Brazil, 18 March 1878. He was a pupil of Agassiz in the Museum of comparative anatomy at Harvard, and accompanied the great naturalist as geologist of a Brazilian expedition (1865). During this expedition he explored the coast from Bahia to Rio, made extensive zoological collections, and by his researches made himself a leading authority on the natural history of South America. In 1875 he was appointed chief of the geological surveys of the empire of Brazil. He was also from 1876 director of the National Museum at Rio, where are deposited his collections, the most complete of South American geology in existence. He published: 'Geology and Physical Geography of Brazil' (1870), and 'Contributions to the Geology and Physical Geography of the Lower Amazon' (1874).

Hart'well, Ga., town and county-seat of Hart County, the terminal of a branch of the Southern railway, 50 miles northeast of Athens. Its educational institutions include a high school. There are cotton, flouring, and sawmills, and a fruit cannery. Pop. (1900) 1,672.

Hartwell, Ohio, village of Hamilton County, 11 miles north of Cincinnati, on the Cincinnati, H. & D. and on the Cleveland, C. & C. R.R.'s. It has manufactures of wagons and carriages and a general retail and agricultural trade. Pop. (1900) 1,833.

Harty, Jeremiah J., American Catholic prelate: b. St. Louis 1853. He was graduated from the St. Louis University in 1872, and took a theological course at St. Vincent's College, Cape Girardeau, Mo. He was ordained priest in 1878, and appointed assistant pastor of St. Bridget's parish in St. Louis, holding this position until 1888, when he was commissioned to build the church and organize the parish of St. Leo in the same city. His organizing work has been most successful, and in 1902 he built a school accommodating over 700 children. In 1903 he was appointed archbishop of Manila, the most important see in the Philippines.

Hartz'ell, Joseph Crane, American Methodist bishop and missionary: b. Illinois 1 June 1842. He was graduated from Wesleyan University and Garrett Biblical Institute (Evanston, Ill.), and in 1896 was elected missionary bishop to Africa where he has since been actively engaged in organizing missions. In June of 1903 he sailed from New York on his seventh missionary tour of inspection in Africa.

Harugari, hä-roo-gä'rē, a social and benevolent order established in the United States in 1847. It had in 1903 over 300 lodges with a total membership of 30,000. Its purpose is largely the preservation of German language, customs, and traditions.

Harun-al-Rashid, hä-roon'äl-räsh'ĭd, or **Haroun-al-Rashid,** caliph of Bagdad: b. Rhey about 765 A.D.; d. Thous 2 April 809. (See Caliph.) The popular fame of this caliph is by the 'Arabian Nights' Entertainments,' in which Harun, his wife Zobeide, his vizier Giaffar, and his chief eunuch Mesrur, are frequent and conspicuous characters. He was the fifth caliph of the dynasty of the Abbassides, and the most powerful monarch of his race. In 786 he succeeded his elder brother Hadi, who had vainly attempted to exclude him from the throne, and by his conquests and vigorous internal administration raised the caliphate of Bagdad to its greatest splendor, and made his reign esteemed the golden era of the Mohammedan nations. His favorite ministers were Yahia and his son Giaffar, of the ancient Persian family of the Barmecides, whose ancestors had for many generations been hereditary priests at the fire temple of Balkh, and who now rapidly exalted the family to the highest dignities under the caliphate.

Harus'pices. See Aruspices.

Har'vard, John, American clergyman, founder of Harvard University: b. England, probably in Middlesex; d. Charlestown, Mass., 24 Sept. 1638. He was entered as a pensioner at the university of Cambridge in 1628, was graduated B.A. in 1631–2, and M.A. in 1635, and having emigrated to America was made a freeman of the colony of Massachusetts, Nov. 2, 1637. The following year, as appears from the town records, a portion of land was set off for him in Charlestown, where he exercised the ministry. In April 1638, he was appointed one of a committee "to consider of some things tending toward a body of laws." These are the only particulars known of his life. His property at his death was worth about £1,600, one-half of which he gave for the erection of the institution which bears his name; but part of this bequest, it is said, was diverted from its original purpose. He also left to the college a library of more than 300 volumes, indicating in their selection the taste and skill of a scholar. A monument to his memory was erected in the burial ground of Charlestown by the alumni of the university, and inaugurated with an address by Edward Everett, 26 Sept. 1828. See Harvard University.

Harvard, Ill., a city and important railway junction in Chemung Township, McHenry County, at the intersection of three divisions of the Chicago & N. railroad, 63 miles northwest of Chicago. It has railroad repair shops, a malt house and brewery, manufactures

of agricultural implements, wagons, and carriages, and grist and woolen mills. Pop. (1900) 2,602.

Harvard University, the oldest institution of learning in the United States, was founded in Cambridge, Mass., in 1636. At a meeting of the general court of the Colony of Massachusetts Bay, convened on 8 September, 6 years after its first settlement, it was voted to give £400 toward a "schoale or colledge," for the purpose of educating the "English and Indian youth in knowledge and Godliness." The ensuing year 12 of the eminent men of the colony, including John Winthrop and John Cotton, were authorized "to take order for a college at New Towne." The name Cambridge was adopted soon afterward in recognition of the English University where many of the colonists had been educated. In 1638 John Harvard, a young nonconformist minister, died in Charlestown, leaving to the college £750 and his entire library of 300 volumes. The institution was opened soon after and was named Harvard in honor of its first benefactor.

In 1637 the first building was erected. The first president was Rev. Henry Dunster, who was elected in 1640. The first graduating class was in 1642, and consisted of nine members. This same year a change was made in the government of the college; a board of trustees was created, the members of which were the governor, the deputy governor, the teaching elders of the "5 next adjoining towns"— Boston, Cambridge, Charlestown, Dorchester, and Roxbury — the magistrates, and the president of the college. The college was established as a corporation in 1650, with power of control over the educational and financial concerns of the institution. The members of the corporation were the president, the treasurer, and 5 fellows. In 1657 the corporation charter was changed so that the overseers had practically no control over the internal management of the college, although a final appeal might be made to them if necessary. Now there were two governing bodies; the overseers and the corporation, at times working in harmony and again antagonistic to each other. In 1780 the board of overseers consisted of the governor, lieutenant-governor, senate, and council of the commonwealth, the president of the college, and the ministers of the Congregationalist churches of the "6 adjoining towns" already mentioned. In 1810 a further change was made in the board of overseers, and instead of the senate and the ministers of certain churches, there were substituted 15 Congregationalist ministers, 15 laymen, the president of the senate, and the speaker of the house, all to be inhabitants of the State. The members constituting the senate were restored as overseers in 1814. A still further broadening of the spirit of the board was shown by the act of 1834, but not ratified until 1843, when clergymen of all denominations were made eligible for membership to the board, and in 1851 an act was passed in which no mention was made of clergymen, but the clause that made only inhabitants of the State eligible was retained. It was not until 1880 that Harvard was freed from all sectional lines, and non-residents of the State of Massachusetts became eligible for membership to the board of overseers.

During the 17th century Harvard had to contend with serious obstacles, many of which had their origin in religious differences or shades of differences; but the desire to give the youth of Massachusetts an opportunity to learn the things taught to their fathers in the schools of Europe never faltered. It required heroic courage then to persevere in such a work, which at present seems a comparatively easy task. The religious controversies continued even after donations and endowments had come to the aid of the institution and had made its success seem almost certain. Under the presidency of Rev. Increase Mather, the college was placed under the control of the Calvinists (1692), but in 1707 the liberals gained the ascendency. An English merchant, Thomas Hollis, in 1721, founded a chair of divinity, and directed that no religious test should be given to the candidate for the professorship. The gift was refused by the overseers, but the corporation urged its acceptance, and the latter finally prevailed. However, the first candidate for a professorship was really subjected to a religious test, for a confession of faith on various disputed points was exacted of him. The religious controversies were carried so far that at one time there was a strong effort made by the orthodox friends of learning to found another college in the colony; but Governor Bernard refused them a charter.

In 1764 the college met with a serious loss by fire; the first Harvard Hall, containing the library and apparatus, was entirely destroyed, but the loss was repaired to some extent by the generous aid of the Colonies. Harvard was loyal to the American cause during the Revolutionary period; even going so far in the readjustment of its financial affairs as to suffer considerable loss. The alumni and students have ever been patriotic, ready to contribute their best to the needs of their country. The fine building, Memorial Hall, was erected by the alumni in memory of their dead who fell in the Civil War. Harvard has always followed a conservative course when parties were agitating questions of government.

Between 1636 and 1782 Harvard College conferred only the degrees of bachelor and master of arts, but in 1780 the term university was applied to it in the Constitution of the State of Massachusetts. The class of 1768 evidently gave some attention to dress, as they voted to wear homespun at their graduating exercises, although their action on the matter is often quoted to prove their democratic simplicity. In 1782 and 1783 three professorships of medicine were established, and the first degree of bachelor of medicine was conferred in 1788. In 1810 the lectures in medicine were transferred to Boston, and there the first medical college was built. The law school was established in 1817, and it has the distinction of being the earliest school of law in the country connected with a university and authorized to confer degrees in law. The divinity school was a gradual outgrowth of the college; the Hollis professorship of divinity, which has been mentioned, was established in 1721, but the divinity faculty was not formally organized until 1819. It is now undenominational, no assent to the special doctrines of any sect or denomination of Christianity being required of any instructor or student. The schools of medicine, law and divinity are the three oldest additions to the college proper, and it was de-

THE GREAT ELECTOR,

THE STATUE PRESENTED BY EMPEROR WILLIAM II, TO HARVARD UNIVERSITY.

cided that such an institution, having 4 schools and several departments, justified the title, university.

In about 1822, a number of the friends of education and of the institution thought the time had come when further changes should be made in the work required of the students. George Ticknor (q.v.), professor in the department of modern languages, urged that some division of studies should be made whereby students might be permitted to pursue special courses or specialize on certain subjects. A committee, with Joseph Story as chairman, was appointed to investigate the wisdom of such a change, and how best to meet the needs of the students. The committee reported (1824) the advisability of instituting two lines of study — the one a course necessary for a degree, the other a scientific and mechanical course for those not intending to take degrees, but who desired to fit themselves for certain departments of work. The departure from old customs as recommended by the committee was opposed by many, but in 1825 changes were made and the special students were admitted. Prof. Ticknor and later his successor, Henry W. Longfellow, introduced to some extent elective courses in the department of modern languages, but not until a number of years later did they become popular in other departments.

Charles William Eliot (q.v.) was elected president in 1869. At this time the departments were almost independent schools, to which no entrance examinations were required; but the students were largely from classical preparatory schools, the majority of which were located in New England. The college required certain courses, and all demanded good work and a high degree of scholarship before graduation. In four years, so rigorous and thorough had been the work of President Eliot, that practically a reorganization had been made, the departments had been correlated, and individual work had been given recognition.

To Harvard much credit is due for the conservative manner in which it has dealt with the question of higher education of women. The Society for the Collegiate Instruction of Women was the name of an organization which began the work (1869) of providing ways and means for giving young women an opportunity to obtain a collegiate education. The name of the organization was changed, in 1894, by the general court of Massachusetts to that of Radcliffe College (q.v.). Systematic collegiate instruction is now given in this college, under the professors and teachers of Harvard University. The requirements are the same as for admission to the university. The schools and departments of Harvard University now comprise: (1) Harvard College, the Lawrence Scientific School, and the Graduate School, established in 1872 for students making original research. The Scientific School was established in 1847 as an advanced school in science and literature; later the name was changed to Lawrence Scientific School, in honor of Abbott Lawrence who presented it with $50,000. Those three schools, which include 14 departments offering elective courses, were placed, in 1890, under the charge of the faculty of arts and sciences. In 1904–5 there were in attendance 2,905 students under the faculty of arts and science. Of this number 366 were in the graduate school and were engaged in original research. For the students of this school who are engaged in original investigations there is available a number of fellowships, at present 58, which are from $200 to $1,000. The Edward Austin Fellowship and the Austin Teaching Fellowship are given only to resident graduate students. Some of the fellowships may be given to persons pursuing their studies in other parts of the country or abroad: but non-resident appointments are given only to persons who have been resident students in some department of the university. (2) The law school has been mentioned. The attendance in 1904–5 was 758. (3) The divinity school, already noticed, has an attendance of 43. (4) The medical school, founded in 1782, and the dental school, established in 1867, were united in 1899 and are in charge of the faculty of medicine. The school is located in Boston. The attendance in 1904–5 was, in the medical school, 307; in the dental school, 106. The new buildings for the medical school (1903), in process of erection, promise to be second to none other in the world. There will be seven separate buildings, the central structure and two of the side pavilions are provided for by the gift of $1,000,000 from J. Pierpont Morgan, and $1,000,000 from other friends. The site comprises 26 acres, in Brookline, about three miles from the main buildings of the university in Cambridge (5) The Bussey Institute, a school of agriculture and horticulture, was established in 1870 in accordance with the will of Benjamin Bussey. It is at Jamaica Plain, in the southwestern part of Boston. (6) The Arnold Arboretum, established in 1872, is devoted to scientific research in forestry, dendrology, and arboriculture. It was founded under the will of James Arnold. It is practically a large park containing about 220 acres, and is located in West Roxbury. (7) The astronomical observatory was established in 1843 by means of a public subscription. The Sears Tier was built in 1846, and two years later Edward Bromfield Phillips bequeathed to the university the sum of $100,000 for the observatory; this early bequest has since been supplemented by many others, so that the observatory now has an endowment of about $900,000. It has a director and four other professors and 40 assistants. A branch station is established on a mountain 8,000 feet high, near Arequipa, Peru. The annals of the observatory fill about 50 volumes. Among the more important instruments are the 15-inch and 6-inch equatorial telescopes, the 8-inch transit-circle, the 11-inch Draper photographic telescope, the 8-inch photographic telescope, and the meridian photometer. A grant has recently (1903) been made by the Carnegie Institution, for the study of the collection of photographs at the Harvard Observatory. The amount of material, including photographs and photographic charts of the sky that has been collected in this department, requires a special building for its accommodation. (8) The university library, including the libraries of the schools and departments, contains about 673,394 volumes and 393,892 pamphlets. (9) The Gray Herbarium, so named because it contains the Herbarium of Asa Gray (q.v.), presented to the university in 1864. (10) The university museum is made up of the following collections:

the Peabody Museum of American Archæology and Ethnology; the Museum of Comparative Zoology, established in 1859 by private subscription, State aid, and the collection of Louis Agassiz, and valuable gifts from his son; the Mineralogical Museum, established in 1890–1; the Semitic Museum, completed in 1902; the William Hayes Fogg Art Museum, completed in 1895; and the Germanic Museum, established in 1902. (11) The botanical garden, established in 1809, covers about seven acres and contains thousands of plants for scientific study.

Great credit is due Harvard for its leadership in the movement to better the teaching of the English language and literature in the schools of the country. Harvard mentioned the subject in its catalogue of 1865–6; an announcement was made, in the catalogue of 1869–70, that "Students would be examined, as early as possible after their admission, in English." In 1874, for the first time, every applicant for admission to Harvard was required to present English composition. The report of the committee who visited the preparatory schools to ascertain what they were doing with the subject of English, the discussions by educators on the "new demands of Harvard," the progress of the movement, the grand results, all now are parts of the "History of Education" of America.

The university summer school gives short courses of study under the charge of a committee of the faculty of arts and sciences, and is held in the college buildings during the summer vacation. The school is popular and has had a large attendance each year. In 1904 the students numbered about 1,007. Athletics are provided for — two fields of 24 acres each and the Hemmenidaу gymnasium furnish opportunities for physical training The stadium erected on Soldiers' Field has a seating capacity of about 30,000. It is shaped like the letter "U," with the open space toward the Charles River. It is of steel and concrete construction. The mezzanine floor under the seats, the promenade above the seats, the stairs, the perfect arrangement of all the parts make this stadium a model of construction. It was built under the auspices of the class of '79. A club house, called the Harvard Union, was donated by Henry Lee Higginson in 1901. The Phillips Brooks house is used for religious meetings. In 1903 Harvard received a valuable collection of plaster replicas of Germanic art; a number of them were given by Emperor William III. of Germany. Among them is a replica of the equestrian statue of the Great Elector, by Schülter, one of Frederick the Great, by Schadow, a cast of the golden gate of the Cathedral of Freiburg, the bronze door of Hildesheim Cathedral, on which the Biblical story of Creation, the wood screen of Naumburg Cathedral, and several other reproductions of great value.

The university has now about 60 buildings. In 1904–5 the number of members of the corporation was 6; of overseers, 30; of professors and instructors composing the faculty, 525; of students in all the schools and departments, 5,143. In 1904 the invested funds of the university amounted to $16,755,753.10; and the grounds, buildings, and apparatus were estimated to be worth about $21,000,000: the annual income was $1,572,539.50; and bequests and gifts amounted to $1,509,563.76. Harvard has had 22 presidents, including the present incumbent (1903), Charles William Eliot. There are 13 periodicals which represents the interests of the university as a whole, and of special schools and departments.

Harvest Bug or **Mite.** See MITES.

Harvest-fish. See BUTTERFISH.

Harvest-fly. A cicada (q.v.).

Harvest-moon, the full moon nearest to the autumnal equinox, when the earth's satellite, almost full, rises for several nights in succession about the same hour. This phenomenon is less plainly seen in the United States than in higher latitudes, and is not met with in the tropics. It is due to the fact that at the time of the autumnal equinox the full moon, being exactly opposite the sun, is in that part of her orbit which makes a small angle with the horizon at the point of moon-rise.

Harvest Mouse. See MOUSE.

Harvestman, or **Harvest Spider.** See DADDY-LONGLEGS.

Harvey, George Rossiter McClellan, American publisher and editor: b. Peacham, Vt., 16 Feb. 1864. After a secondary education, he became a reporter successively for the Springfield (Mass.) *Republican,* the Chicago *News,* and the New York *World,* was for a time managing editor of the *World,* and later a constructor and president of various electric railways. He purchased and became editor of the 'North American Review' in 1899, and in 1906 received the presidency of the reorganized firm of Harper and Brothers, publishers.

Harvey, Moses, Newfoundland historian: b. Armagh, Ireland, 25 March 1820; d. St. John's, Newfoundland, 3 Sept. 1901. He was graduated at Queen's College, Belfast, in 1840; later studied theology; and was ordained in the Presbyterian Church. He was pastor of the Free Presbyterian Church, St. John's, Newfoundland, 1852–78, when he retired from the ministry and devoted himself to literary and scientific studies, and became popular as a lecturer. He published 'Thoughts on the Poetry and Literature of the Bible' (1853); 'Lectures on the Harmony of Science and Revelation' (1856); 'Newfoundland, the Oldest British Colony' (1883); 'Text-Book of Newfoundland History'; etc. He also contributed articles to the Encyclopædia Britannica on Newfoundland, St. John's, Labrador, and the seal fisheries of the world.

Harvey, William, English physician: b. Folkestone, Kent, April 1578; d. Hempstead, Essex, 3 June 1657; he was graduated at the University of Cambridge in 1593, and later at Padua. He is famous as the discoverer of the circulation of the blood.

Harvey, William Hope, American author: b. Buffalo, Putnam County, W. Va., 16 Aug. 1851. He was educated at Marshall College

(W. Va.), and practised law in 1871–84. He appeared as an author under the pseudonym "Coin" in 'Coin's Financial School' (1894), in advocacy of bimetallism as a currency standard. Other works by him are: 'A Tale of Two Nations' (1894); 'Coin's Financial School Up to Date' (1895); 'Patriots of America' (1895); and 'Coin on Money, Trusts, and Imperialism' (1899).

Harvey, Ill., city in Cook County; on the Cleveland, C., C. & St. L. and the Illinois C. R.R.'s; south of Chicago, about seven miles from Blue Island. It was founded in 1891 and incorporated in 1892. Its proximity to Chicago gives it the advantages of a residential city and its railroad facilities are an aid in the development of its manufactories. Some of the chief industrial establishments are railroad supply shops, an automobile factory, gas-stove factories, machine-shops in which are manufactured ditching and mining machinery. The trade is principally in its manufactures and agricultural products. Pop. (1900) 5,395.

Harveyized Steel. See Steel.

Harwood, Andrew Allen, American naval officer: b. Settle, Pa., 1802; d. Marion, Mass., 28 Aug. 1884. He was a great-grandson of Benjamin Franklin (q.v.). In 1818 he entered the navy and served in the suppressing of the slave trade and piracy in the West Indies; in 1835–7 was with the Mediterranean squadron; in 1848 was given the command of the Cumberland, and in 1855 promoted to the rank of captain. In 1862 he was appointed chief of the bureau of ordnance and hydrography; in 1863 he was made commandant of the Washington navy yard and Potomac flotilla, having the rank of commodore, and retired in 1869 with the rank of rear-admiral. He published 'Law and Practice of United States Navy Courts-Martial' (1867), and 'Summary Courts-Martial.'

Harz (härts) **Mountain** (Ger. *Harzgebirge*), the northernmost mountain range of Germany, extending about 60 miles through Prussia, Brunswick, and Anhalt, between the rivers Weser and Elbe, and occupying an area of about 786 square miles. The range, composed chiefly of Devonian and Lower Carboniferous formations, broken through with granite, is divided into the Upper and Lower Harz, with average elevations of 2,100 and 1,000 feet, respectively, the maximum altitude, 3,745 feet, being reached in the Brocken (q.v.). Woods and fine pastures abound; silver, iron, lead, copper, and zinc are mined, and marble, alabaster, and granite quarried. Traversed by fine roads and accessible by railroads, the range is a favorite touring ground, its interest enhanced by the traditions and weird legends which had their birth in this romantic region.

Has'call, Milo Smith, American soldier: b. Le Roy, Genesee County, N. Y., 5 Aug. 1829; d. Oak Park, Ill., 30 Aug. 1904. He was graduated from West Point in 1852, resigned from the army, practised law in Indiana, entered the Federal army as a private at the outbreak of the Civil War, rose to the grade of brigadier-general of volunteers, distinguished himself at the battle of Stone River, where he saved the day; was present at the siege of Atlanta, and resigned his commission in 1864. Subsequently he was a banker at Goshen, Ind., and a real estate dealer in Chicago.

Hasdrubal, hăs'droo-bal, Carthaginian general. He was the son of Hamilcar Barca, and brother of Hannibal (q.v.), and, on the departure of the latter for Italy 218 B.C., was left in command of the army in Spain. Hanno, who had charge of the province north of the Iberus, was defeated and dispossessed by Cn. Scipio before Hasdrubal could come to his aid. Scipio, reinforced by his brother, now crossed the Iberus, and in 216 defeated Hasdrubal near that river. The Carthaginians then sent a force, intended for the assistance of Hannibal, to the relief of Hasdrubal under the command of his brother Mago. In 212 Cn. Scipio was defeated and killed by the Carthaginians. Publius Scipio was sent into Spain in 211, and after seizing New Carthage defeated Hasdrubal in his camp at Bæcula in 209. Hasdrubal withdrawing to the northern provinces, determined to proceed to Italy, leaving his colleagues, Hasdrubal, the son of Gisco, and Mago, to make head against Scipio. He crossed the Alps in 207, accompanied by Gallic allies, and descended into Italy, and sent messengers to concert a junction with Hannibal in Umbria, but his despatches fell into the hands of the consul, Claudius Nero, who joined his colleague, M. Livius, at Sena, and forced Hasdrubal to give battle on the right bank of the Metaurus. Being outnumbered, and ill-supported by his Gallic allies, he was defeated, after an obstinate engagement, in which both sides suffered severely. When he saw the battle irretrievably lost he rushed into the midst of the enemy, and perished fighting sword in hand. Nero hastened back to Apulia, and is said to have announced to Hannibal the defeat of his brother by causing Hasdrubal's head to be thrown into his camp, 207 B.C.

Haseltine, hā'zĕl-tīn, **William Stanley,** American artist: b. Philadelphia, 11 Jan. 1835. He was graduated from Harvard in 1854, studied art in Düsseldorf and Rome, and has been a member of the National Academy from 1861. Among paintings by him may be named 'Indian Rock, Nahant'; 'Castle Rock, Nahant'; 'Bay of Naples'; 'Ruins of a Roman Theatre.'

Hashish, hăsh'ēsh, an eastern narcotic preparation, made from the tops and tender parts of the cultivated hemp, the variety known as *Cannabis Indica* being chiefly employed. The resin picked from the hemp is kneaded together, or sometimes the drug is obtained by decoction or infusion of the leaves. The resin is taken in the form of pills or pellets, and the leaves are chewed, or smoked in conjunction with tobacco. It is called bhang in India, where it is mixed with sugar and eaten as confectionery. It is as powerful as opium and produces intoxication and hallucinations; sometimes transporting the hashish-eater into an ecstacy, or lulling him into somnolency or torpor. Its after-effects are not so depressing as those of opium, and it is often prescribed medicinally as a soporific or anti-spasmodic.

Haskell, Edwin Bradbury, American publisher and editor: b. Livermore, Maine, 24 Aug. 1837. He entered the office of the Portland (Maine) *Advertiser* in 1854, was a reporter for the *Journal* (1857–60) and *Herald* of Boston, bought an interest in the *Herald* in 1865, and

was editor of that paper 1862–87. He still holds an interest in the *Herald*, as well as in the Minneapolis *Journal*, the St. Joseph (Mo.) *News*, and the Los Angeles *Express*.

Haskell Institute. See INDIAN, EDUCATION OF.

Has'kins, Charles Homer, American historical scholar: b. Meadville, Pa., 21 Dec. 1870. He was graduated from the Johns Hopkins University in 1887, studied also at Paris and Berlin, was instructor in history at Johns Hopkins in 1889–90, and in the University of Wisconsin was successively instructor in history (1890–1), assistant-professor (1891–2), and professor of European history (1892–1902). In 1899–1900 he was a lecturer in history at Harvard, and in 1902 was appointed professor of history there.

Has'sall, Arthur, English historian: b. Bebington, Cheshire, England, 23 Sept. 1853. He was educated at Oxford, where he has been at various times since lecturer, tutor, and examiner. He is one of the recognized authorities upon European history, his published books including 'Life of Bolingbroke' (1889); 'Louis XIV.' (1895); 'Handbook of European History' (1897); 'The Balance of Power 1715–89' (1896); 'Class-book of English History' (1901); 'History of France' (1901); 'The French People' (1901).

Has'sam, Childe, American artist: b. Boston 1859. He studied art in Boston and Paris; he is a member of Ten American Painters, of New York, and of the Société National des Beaux Arts of Paris. He is one of the freshest in style and most original of the American impressionists, and has gained medals at Paris, Munich, Chicago, and Philadelphia.

Hassen Ben Sabbah, the founder of the sect of the Assassins (q.v.).

Hasselquist, häs'sĕl-kwĭst, **Frederick,** Swedish naturalist: b. Ostrogothia 1722; d. Smyrna 9 Feb. 1752. In 1741 he went to the University of Upsala, where his talents and industry drew the attention of Linnæus. In 1747 he published a dissertation 'De Viribus Plantarum.' Wishing to make researches on the spot into the natural history of Palestine he spent some time at Jerusalem, and afterward visited other parts of the country. Returning to Smyrna he brought with him a collection of plants, minerals, fishes, reptiles, insects, and other natural curiosities. The Swedish queen, Louisa Ulrica, purchased the whole of Hasselquist's acquisitions, which were deposited in the castle of Drottningholm. Linnæus, from the papers and specimens of natural history collected by his pupil, prepared for the press the 'Iter Palæstinum, or Travels in Palestine, with Remarks on its Natural History' (1757), which has been translated into English and other European languages.

Hassler, häs'lĕr, **Ferdinand Rudolph,** Swiss-American scientist: b. Switzerland, 6 Oct. 1770; d. Philadelphia, Pa., 20 Nov. 1843. After serving on the trigonometrical survey of Switzerland, he emigrated to the United States. He was appointed acting professor of mathematics at West Point in 1807, and held the post for three years. He was superintendent of the United States Coast Survey in 1815, and from 1832 worked on the same commission until his death.

Hassler Expedition, a scientific expedition of great importance despatched by the United States Government. In 1871 the steamship Hassler was fitted out for coast survey and marine exploration. The personnel of the expedition included Prof. Louis Agassiz, and Mrs. Agassiz; Dr. F. Steindacher, ichthyologist; Dr. Thomas Hill, botanist; Count L. F. de Pourtales, Mr. J. A. Allen, and others. The party left Boston 4 Dec. 1871 and reached San Francisco, August 1872. Deep-sea dredging was carried on at several points in the West Indies and South Atlantic. The glaciers in the neighborhood of the Straits of Magellan were explored. Collections were made at every point of the voyage; the results of the expedition have been published by Agassiz, Lyman, and Pourtales, and much valuable material, zoological, geological and botanical, deposited in the Museum of Comparative Zoology, Cambridge.

Hastings, hās'tĭngz, **Francis Rawdon,** 1ST MARQUIS OF HASTINGS and 2D EARL OF MOIRA, English soldier and statesman: b. 9 Dec. 1754; d. off Naples 26 Nov. 1826. He entered the army as an ensign, served in America during the Revolution, and on 25 April 1781 gained the battle of Hobkirk's Hill, which Lord Cornwallis described as the most splendid of the war. In 1781 he was elected a member of the Irish House of Commons, and two years later he was promoted to the English House of Lords with the title of baron. He was in command of a force which sought to aid the royalists of Brittany in 1793, and in the following year co-operated with the Duke of York in the Netherlands. In 1812 he was appointed governor-general of Bengal and commander-in-chief of the forces in India. His administration was distinguished by successful wars against the Ghurkhas of Nepaul and the Pindarees of Central India, but in 1821 he resigned because certain charges had been brought against him in connection with a banking firm in which he was interested. In 1824 he was appointed governor of Malta.

Hastings, Thomas, American musician: b. Washington, Conn., 1787; d. 1872. He early made sacred music the subject of his careful study; from 1823 to 1832 he edited a religious paper, 'The Recorder,' in Utica, but removed to New York, where he made his fame as a musical instructor and composer. His works include: 'Mother's Hymn Book' (1849); 'History of Forty Choirs' (1854); and 'Dissertation on Musical Taste' (1853).

Hastings, Warren, English soldier and administrator: b. Churchill, Oxfordshire, 6 Dec. 1732; d. Daylesford, Warwickshire, 22 Aug. 1818. An uncle in London sent him at 10 years of age to Westminster School. On the death of his uncle he obtained an appointment in the East India Company's service, and he arrived at Bengal in October 1750. He was appointed to the factory at Cossinbazar, and was taken prisoner by Surajah Dowlah (1756). On obtaining his freedom he joined Clive, under whom he served with distinction as a volunteer in his campaign of 1757. In 1758 he was appointed resident agent of the company at Moorshedabad, in which capacity he continued to act till 1761. It is recorded to his honor that he did not avail

himself of the opportunity of making his fortune in the mode then common among the servants of the company, by "presents" (forced) from the native princes. In 1764 he returned to England, but as a result of a bad investment of his fortune was compelled again to ask for employment from the company; and sailed for India in the spring of 1769. In 1771 the East India Company were contemplating extensive changes in the government of India. The government of Bengal was still carried on in the name of the nabob, although he had become a mere cipher, all his officers being appointed by the company, and they cast their eyes upon Warren Hastings as a fitting instrument to carry out their policy. Clive strenuously supported his appointment to the Calcutta council (1772), with succession as president of the council and governor of Bengal. He now received instructions from the directors to deprive of his offices Mohammed Reza Khan, who had exercised under the company the complete control of the revenues and administration of Bengal, and to bring him to trial for corruption. Mohammed bore a high character, and he was accused by Nuncomar, a man of notoriously bad reputation. Shitab Roy, dewan of Behar, was subjected to similar charges. After a protracted inquiry both Mohammed and Shitab were fully acquitted of all the charges against them. The object of these charges — the reorganization of the judicial and financial administration of the province under the direct control of the company's officers, had in the meantime been carried out by Hastings to the entire satisfaction of the directors. Another important step taken by him was to enter into a treaty with the Nabob of Oude (Treaty of Benares, 7 Sept. 1773), by which he ceded to him the districts of Corah and Allahabad for fifty lacs of rupees, and engaged to hire out the company's troops to him for the reduction of the Rohillas, whose territory the nabob coveted. By the subsequent act of 1773, Hastings was appointed first governor-general of India, and a supreme council was named, of whom three formed a majority unfavorable to Hastings. The natives were encouraged to bring charges against him, and Nuncomar, his old ally, came forward with various charges of bribery. A supreme court of justice had been appointed at the same time with the supreme council of Calcutta. The chief-justice, Sir Elijah Impey, its head, was a friend of Hastings. Nuncomar was brought before this court, charged with forgery, convicted, and executed. This stretch of jurisdiction, which Hastings could easily have prevented, alienated from him public sympathy in England. The directors of the company petitioned the crown on 8 May 1776 for his removal from the council. Hastings had deputed Colonel MacLean, who returned to England in 1776 to insist on certain conditions or tender his resignation. It was accepted, and a successor appointed to take his place in the council, 23 Oct. 1776. General Clavering assumed the title of governor-general, which Hastings still insisted on retaining, as the change had been made without the conditions he had appended to his resignation. The supreme court, which was appealed to, decided in favor of Hastings. To end a dispute between the council and the supreme court of Calcutta, and to bring the chief-justice under the influence of the council, Hastings now appointed Sir Elijah Impey superintendent of the native courts with a salary of £8,000 a year, an appointment regarded by some as equivalent to a bribe. He involved himself in disputes with the Madras government, made demands for a large war contribution upon the Rajah of Benares, and when the rajah resisted arrested and deposed him. He caused the "begums of Oude," mother and grandmother of the Nabob of Oude, to give up extensive estates in land and a large amount of treasure. The House of Commons had passed a resolution (30 May 1782) requiring the directors to pursue all legal and effectual means for his removal. In November 1784 he resigned his post, and in February 1785 elft India. In 1786 articles of impeachment were brought in by Burke against him. The preliminary forms were gone through from 13 to 14 February, and Burke opened the charges against him in a speech of three days' duration, begun on the 15th. He was supported by Fox, Sheridan, and Grey. Hastings began his defense on 2 June 1791, and on 17 April 1795 was acquitted by large majorities on all the charges. His acquittal met with general approval. The legal expenses of his trial amounted to £76,080. The company in 1796 settled on him an annuity of £4,000 a year for 28½ years, and lent him £50,000 for 18 years free of interest. He passed the remainder of his life in retirement. In 1813 he received the degree of LL.D. from the University of Oxford, and in 1814 was created a privy-councillor.

Hastings, Mich., city, county-seat of Barry County; on the Thornapple River, and on the Chicago, K. & S. and the Michigan C. R.R.'s; about 38 miles west by south of Lansing and 32 miles southeast of Grand Rapids. The city is in a fertile agricultural region. The chief manufactures are furniture, pumps, wagons and carriages, hose-reels, car-seats, flour, cigars, felt boots and lumber camp supplies. The principal buildings are the library, the city hall, jail and courthouse. The city owns and operates the waterworks. Pop. (1900) 3,172.

Hastings, Minn., city, county-seat of Dakota County; on the Mississippi River at the mouth of the Vermilion River, and on the Chicago, M. & S. P. railroad; about 15 miles southeast of Saint Paul. Its chief industrial establishments are breweries, a malt-house, flour-mills, grain-elevators, saw and planing-mills, sash, door, and blind factories, carriage and wagon factories, furniture factories, lumber and brick yards. In addition to the trade in manufactured articles, grain, lumber, and live stock are among the important shipments. Pop. (1900) 3,811.

Hastings, Neb., city in Adams County; on the Missouri P., the Burlington & M., the Fremont, E. & M. V., the Saint J. & G. I. R.R.'s; about 25 miles south of Grand Island and 95 miles west of Lincoln. Its first settlers were Eastern people who availed themselves of the benefits of the government "Homestead Act," but the city was not incorporated until 1874. It is in a fertile agricultural section. The chief manufactures are flour, wagons, and agricultural implements. The trade is principally in wheat, corn, and live stock. It is the seat of Hastings College, under the auspices of the Presbyterian Church, and opened in 1882, and of the State asylum for chronic insane. The government is vested in a mayor, who holds office two years,

and in a city council. The present charter is that of 1891. The city owns and operates the electric light plant and the waterworks. Pop. (1890) 13,584; (1900) 7,188.

Hastings-upon-Hudson, N. Y., village in the town of Greensburg, in Westchester County; on the Hudson River, and the New York Central & H. R. railroad; about three miles north of Yonkers and 20 miles from New York. It is largely a residential village; but in the vicinity are marble quarries which add to the industrial wealth of the place. It has some manufactures, chiefly chemicals and cigars; it has a large trade in coal and lumber. It is the seat of the Hastings Commercial and Collegiate Institute, and has several churches and good schools. Pop. (1900) 2,002.

Hastings, Battle of. See SENLAC.

Has'well, Charles Haynes, American engineer: b. New York 22 May 1809. His practical education as marine and mechanical engineer was learned in a steam-engine factory. In 1836 he was appointed chief engineer in the United States navy. He built the first practical steam-launch in 1837 and was the first to use zinc to protect the hulls of iron vessels and boilers from the galvanic action of salt water and copper. After 1898 he was the consulting engineer of the board of public improvements in New York city. His published works include 'The Mechanics' and Engineers' Pocket Book' (1901); 'Mechanics' Tables' (1854); 'Reminiscences of an Octogenarian' (1895).

Hatch, John Porter, American general: b. Oswego, N. Y., 29 Jan. 1822; d. 12 April 1901. He was graduated at West Point and rose through successive grades to lieutenant-colonel of cavalry in 1873. He served in the Mexican War from Palo Alto to the capture of the city of Mexico; and in the Civil War was appointed brigadier-general of volunteers in September 1861, and commanded a cavalry brigade in the Shenandoah Valley and Northern Virginia. He subsequently commanded various districts in the South; and was brevetted major-general.

Hatch, Rufus, American banker: b. Wells, York County, Maine, 1832; d. 1893. He began life as clerk in a grocery store, in Rockford, Ill., in 1854 entered the grain commission business in Chicago, and amassed a fortune. He managed the Chicago and Northwestern railroad combination in 1868 and made a financial failure in the Northern Pacific collapse of 1883.

Hatch, William Henry, American lawyer: b. Georgetown, Ky., 1833; d. 1896. He was admitted to the bar in 1854; served through the Civil War in the Confederate army, and was a member from Missouri in the United States House of Representatives from 1879 to 1895. The Hatch Act which distributed Federal aid to agricultural experiment stations in all the States and Territories was inspired by him.

Hatchee, or **Big Hatchee,** a river which has its rise in the northeastern part of the State of Mississippi, flows north by west into Tennessee, then northwest and west joining the Mississippi River about 30 miles in direct line above Memphis. It is navigable for small steamboats as far as Bolivar, about 100 miles from its mouth, or half its whole length. The area drained by the Hatchee, about 4,000 square miles, is excellent cotton land.

Hatcher's Run (BOYDTON ROAD), **Battle of.** On 27 Oct. 1864, Gen. Grant, with the intention to extend his lines to the South Side railroad, and under the belief that the Confederate works around Petersburg extended only to the Boydton road crossing of Hatcher's Run, and were but feebly manned, moved parts of the Ninth, Fifth, and Second corps, together with Gregg's cavalry division, in all about 38,000 men, in three columns to the left. Gen. Parke, commanding the Ninth corps, moving to surprise the right of the Confederate works, found them strongly held, and made no attack. The Fifth corps, on the left of the Ninth, crossed Hatcher's Run and endeavored to seize the bridge by which the Boydton road crossed that stream, and was repulsed. The Second corps and Gregg's cavalry succeeded in forcing a passage over Hatcher's Run by the Vaughan road, and reaching the Boydton road, moved down it to Burgess' Tavern, near the bridge over Hatcher's Run, some four miles above Armstrong's Mill, where the infantry was checked. Hancock's Second corps having effected the passage of Hatcher's Run, by the Vaughan road, Warren was ordered to cross Crawford's division of the Fifth corps at Armstrong's Mill and, sweeping up the right bank of the stream, endeavor to recross and assault the Confederate line in the rear, while Griffin's division assaulted in front. Hancock was advised of the orders given Warren and authorized to make the attempt to carry the bridge in his front and gain some high ground beyond. At 4.30 P.M., when Hancock was extending his right to connect with Crawford, and was about to assault the bridge, Gen. Heth, with his own division and a part of Mahone's, having crossed Hatcher's Run and penetrated the interval between Hancock and Crawford, vigorously attacked Hancock's right and rear, throwing it into some confusion and capturing many prisoners, but Heth was finally repulsed. At about the same time Hampton, with five cavalry brigades, attacked Hancock's left and rear and Gregg's cavalry, but was repulsed. Crawford, who had crossed at Armstrong's Mill, found great difficulty in moving up the bank of Hatcher's Run, and failed to make connection with Hancock. The object of the entire movement failed, with Hancock still six miles from the South Side railroad. The Union troops were withdrawn during the night and, next day, moved back to the line of entrenchments. The Union loss, the greater part of which fell upon the Second corps, was 1,194 killed and wounded, and 564 missing. The Confederate loss is unknown. Consult: 'Official Records,' Vol. XLII.; Humphreys, 'The Virginia Campaign of 1864–5'; Walker, 'History of the Second Army Corps'; The Century Company's 'Battles and Leaders of the Civil War,' Vol. IV.

E. A. CARMAN.

Hatcher's Run (DABNEY'S MILL and ARMSTRONG'S MILL), **Battle of.** It was on 5 Feb. 1865 that Gen. Grant put in motion an expedition to interrupt the Confederate line of communication by the Boydton road, running through Dinwiddie Court House to Petersburg. Gregg's cavalry division was directed to march early in the morning by way of Ream's Station to Dinwiddie Court House and strike the road; Warren's Fifth corps was to cross Hatcher's Run and support Gregg; Gen. Humphreys, command-

ing the Second corps, was ordered with two divisions to the crossing of the Vaughan road over the Run, and to Armstrong's Mill, to hold these two points and to keep up communication with Warren, four miles distant, on the one side, and with Miles' division in the Union entrenchments, three or four miles distant, on the other side. After severe skirmishing, Humphreys pushed Motts' division to the south side of Hatcher's Run, and established Smyth's division at Armstrong's Mill on the north side, about 1,000 yards from the Confederate works, where two brigades were brought to Smyth's support. At 5 P.M. parts of A. P. Hill's and Gordon's corps came out of their works and, under cover of the woods, attacked Smyth, but were repulsed. Smyth's line was now further strengthened by Hartranft's division of the Ninth corps and Wheaton's of the Sixth. Gregg captured some wagons and prisoners on the Boydton road, and in the evening fell back to Malone's Bridge on Rowanty Creek, from which he moved up to the Vaughan road crossing, where he arrived early in the morning of the 6th, with Warren, who had been ordered to support Humphreys. About 1 P.M. Warren, with two divisions, moved along the Vaughan and Dabney's Mill roads; Gregg, supported by one of Warren's divisions, going down the Vaughan road to Gravelly Run to observe the left. Gregg was attacked by a part of Pegram's division, but held his ground and, with the support given him by part of Griffin's division, drove Pegram's men back. Warren's leading division (Crawford's) moving on the Dabney's Mill road, also encountered part of Pegram's division, which was forced back to Dabney's Mill, where Evans' division came to Pegram's support, and Crawford in turn was driven back. Three Union brigades were now brought up to Crawford's support and, at the same time, Mahone's division arrived and took position between Evans and Pegram, and the whole Confederate line advanced, driving Warren back in great disorder, but some of his men rallied upon Wheaton's division, which had crossed from the north bank of the stream, and the Confederates were checked. On the morning of the 7th Warren made a reconnoissance, but did not find the enemy in force. The Union works were now extended to Hatcher's Run at the Vaughan road crossing. The Union loss was 1,352 killed and wounded, and 187 missing. The Confederate loss was about 1,500, among the killed being Gen. John Pegram. Consult: 'Official Records,' Vol. XLVI.; Humphreys, 'The Virginia Campaign of 1864–5'; Walker, 'History of the Second Army Corps'; Powell, 'History of the Fifth Army Corps.'

E. A. CARMAN.

Hatch'ettite, Adipocerite, or **Mineral Adipocere,** a native hydrocarbon, probably of the nature of a paraffin, occurring in certain parts of England and Scotland, mainly in connection with bogs and coal measures. It is wax-like, and melts at about 115° F. The specific gravity of the natural mineral is about 0.61, but after melting the specific gravity rises to 0.92 or even higher, owing to the elimination of air bubbles. Hatchettite is without odor, and when fresh it is commonly translucent and yellowish. Upon exposure, however, it blackens and becomes opaque.

Hatchie River, or **Davis' Bridge, Battle of.** After Gen. Van Dorn's defeat at Corinth, Miss., 4 Oct. 1862, he retreated and bivouacked for the night at Chewalla. Early on the morning of the 5th he continued his retreat on Pocahontas, but when his advance had crossed Hatchie River, at Davis' Bridge, he was met by Gen. Hurlbut's division, which had been sent by Gen. Grant from Bolivar, Tenn., to Pocahontas to intercept his retreat. Van Dorn's advance was driven back across the bridge, his main body came up, and Gen. Ord, who had arrived on the field from Jackson, took command of Hurlbut's division and attacked Van Dorn vigorously. A severe engagement ensued, in which Ord was severely wounded, and Hurlbut resumed command of the Union troops. Van Dorn, not closely followed from Corinth by Rosecrans, who was 12 miles away, held his position before Hurlbut the greater part of the day and, cut off from his route through Pocahontas, continued his retreat on the east bank of the Hatchie for six miles to Crum's Mill, where he crossed his army on a bridge during the night and continued his retreat to Ripley and thence to Holly Springs. Rosecrans followed as far as Ripley, when Grant ordered him to return to Corinth and Hurlbut to Bolivar. See CORINTH, ADVANCE ON AND BATTLE OF.

E. A. CARMAN.

Hatch'ment (a corruption of achievement, coat of arms) a funeral escutcheon, the arms of a deceased person within a black lozenge-shaped frame meant to be placed on the front of his home. If the deceased was unmarried or a widower or widow, the whole field of the escutcheon is black. In the hatchment of a married person the arms of husband and wife are impaled, and only that part is black which adjoins the side of it occupied by the arms of the deceased. Thus, in the hatchment of a husband the dexter side is black, the sinister white; in that of the wife the reverse. In a bishop's hatchment his arms being impaled with that of the see, those of the see have a white background. When the deceased is the last of his race a skull is set above the shield in place of a crest.

Hat'field, James Taft, American German scholar: b. Brooklyn, N. Y., 15 June 1862. He was graduated from the Northwestern University in 1883, from the Johns Hopkins University in 1890; was appointed professor of German language and literature at Northwestern in 1890, and became contributing editor of 'Americana Germanica.' During the Spanish-American War he served from seaman to chief yeoman on board the cruiser Yale. His publications include 'Materials for German Composition' (1896), editions of Freytag's 'Rittmeister von Alt-Rosen' and Goethe's 'Hermann und Dorothea,' and various articles and monographs on subjects of German literature.

Hath'amite, an explosive invented in 1902 by G. M. Hathaway, of Wellsboro, Pa., and remarkable not only for the enormous energy liberated by its explosion, but also for the safety with which the substance may be handled. Hathamite may be pulverized on an anvil with a sledge hammer without exploding, and rifle balls may be fired through it without effect. Lighted matches may also be thrown into it with impunity, and when poured upon a fire it burns

quietly, with the evolution of immense quantities of smoke. Apparently, explosion can be induced only through the agency of a dynamite percussion cap. Hathamite is a coarse powder, of a bluish-gray color, whose composition has not yet been divulged. It explodes with exceeding violence when fired with a suitable percussion cap. In one test a charge of an ounce and a half blew a two-inch hole through a piece of quarter-inch boiler plate, when merely laid upon the plate, and detonated in the open air. In another test a little over eight ounces of the explosive was actually melted and poured into a six-pound shell; and when the charge was afterward detonated, the shell was thoroughly fragmented. One marked advantage of hathamite is, that it will explode even when frozen.

Hath'away, Anne, the wife of Shakespeare. See SHAKESPEARE.

Hats and Hat-making. It is difficult to state just when hats were first worn, but it is a fact that fur-felt hats now form part of the attire of civilized man the world over. There is no record as to when or where the first hat was made. We find head covering in one form or another in vogue in the earliest times referred to in history. The first modern hat, as we now know this article of men's wear, was made in Paris about 1404 by a Swiss manufacturer, but it was not until 49 years afterwards that the French adopted any sort of a head covering. Charles XII., upon his entry in triumph into the city of Rouen in 1453, wore a huge hat made of fur, lined with red velvet, from which protruded a great feather. With royalty as its sponsor the hat at once became a necessary detail of man's wardrobe. The hat is distinguished from the cap or bonnet by its continuous brim. It has been traced back to the "petasus" of ancient Greece, just as the cap has been regarded as the descendant of the brimless "Pileus," also a form of Grecian head attire. These articles, as far as we know, were made almost exclusively of felt.

Felt hats became popular in England during the Norman occupation. In Queen Elizabeth's reign great beaver hats, usually black, were the favorite among the nobility, and they remained in vogue for more than 300 years. About the middle of the 17th century an effort was made to encourage this industry in America. In 1662 the assembly of Virginia, to stimulate activity among the colonists, offered, by special enactment, to give 10 pounds of tobacco for every good wool or fur hat produced in that colony from materials taken from animals native thereto. Hats were then made by hand, and no effort of any consequence was made to improve the primitive conditions until 1820, when the energy of the American inventor produced the first labor-saving machine. Improvement now followed improvement, each one, in its way, tending to economize the cost of making.

In 1810 the silk hat appeared. It was made by hand, and failed in its purpose to supplant the tiled beaver. It was not until 1830 that the silk plush hat was manufactured upon a paying basis.

In 1849 the soft felt hat made its bow in the United States. Its sponsor was the famous Hungarian patriot, Kossuth, who visited America in that year. He was given tremendous receptions everywhere, and won the heart of the great American republic. His great hat seemed to be typical of the vigorous character of the man, and it was not surprising that the "Kossuth" became a general favorite. From that time the soft hat has steadily gained friends, and to-day in many sections it is a predominant type.

While the industry in this country, prior to the Civil War, kept pace with progress in other lines, it was not able to hat the heads of thousands of Americans, and the foreign manufacturer found the States a very profitable territory. But to-day America has become a great exporter of hats. By far the largest share of this foreign trade is controlled by the city of Philadelphia, where the finest grades of hats in the world are made. The other well-known hat centres in America are Orange and Newark, N. J., Danbury, Bethel, and Norwalk, Conn., Brooklyn, N. Y., and Reading, Pa.

The kinds of hats now made are so numerous as to be almost beyond the possibility of listing. There are, however, three principal classifications: the felt hat, which includes the soft and the stiff or derby shape, the silk hat, and the straw hat. All other kinds are but variations in some way of these three. In this article the writer will deal exclusively with the felt hat, concerning which there is the greatest interest. But few people have any conception of the numerous perplexing details and methods which enter into the construction of the hat.

The furs most generally used in manufacturing felt hats are the beaver, which is found in the northwestern part of the United States and Canada; the coypou or nutria, known as the South American beaver; the Saxony and the Russian hare; the Scotch, English and French coney, and muskrats. The finest furs are taken from the nutria, beaver and otter, all water animals, that portion which is taken from the belly being regarded as the choicest. The others are land animals, the fur from the back being regarded as the best. In the more common grades of hats sheep's wool is used, while in the inferior grades wool is mixed with cotton and other vegetable fibres. These, however, cannot be properly termed felt hats, because the materials used are not felted together. They are cemented and are then stiffened by shellac.

Furs for the higher grade hats require the most exhaustive preparation. Upon their arrival at the factory the pelts are first washed with whale-oil soap to remove the superficial fatty matter which clings to the fur. A further purification is necessary, however, and for this purpose "carrotting" is employed. A solution of mercury and nitric acid is applied to the pelts. This chemical, deposited in the cellular tissues, absorbs and thoroughly destroys all animal fats and gives to the fur its felting properties.

After a thorough brushing the fur is next cut from the pelts and is then stored away to mellow and season, for the reason that, like good wine, it strengthens and improves with age. When these furs have become properly seasoned, and are in prime condition, they are subjected to an interesting process for the purpose of removing the hair; a machine, known as a "blower," containing powerful air blasts, accomplishes this work in a very thorough manner. The hair is blown from the fur without harming the latter. This is repeated over and over again, until all foreign matter has been removed. The by-products obtained through these preliminary opera-

tions are extensive. Many of them are used for other purposes than hatting; for instance, the shreds of the skins are used in the manufacture of the highest grades of glue.

The task of selecting the furs and of combining them in proper proportion to produce the best results in a high-grade hat demands the most careful attention of the experienced experts. Many years of experiment have been necessary, in order to learn just how these furs should be mixed, and just what would constitute the correct proportion. The strength and perfection, as well as the beauty of the completed hat, depend largely upon the efforts of those intrusted with this portion of the work.

The next stage in the life of the hat is the forming. Until recently this was a business in itself. Few hat-making firms engaged in it. To-day, however, many of the larger manufacturers are successfully doing their own forming. This work can be accomplished only by experts. It is one of the most interesting features of hat making. The exact quantity of properly mixed fur is carefully weighed and placed upon an endless apron at one end of a box-like machine. At the other end of the machine there is a large perforated cone of sheet copper, revolving rapidly over a funnel, under which there is a powerful suction fan at work. As the attendant carefully feeds the fur to the machine in the proper quantity it is carried by the apron toward the cone. The suction of air attracts this fur and causes it to adhere to the surface of the cone. This continues until the cone is covered with a sufficient quantity of fur to make the hat. The whole operation requires only two or three minutes. As soon as the cone has accumulated the necessary fur a wet cloth is thrown over it, and a second cone, larger in dimension, is placed over that. Both are immersed in a tank of hot water for a few moments. This is the first stage of the felting. It causes the perfect adhesion of the various fibres. The operator slips this conical body from the cone. It is now several times larger than its ultimate size. It has assumed the primary form.

Sizing, as the felting is termed, is the next process. The body, which has just been removed from the cone, is placed in a sizing kettle, where it is shrunk in hot water. Continuous rubbing and rolling reduces it in size almost one-quarter. It still retains its cone shape, but it is now firmly felted. Care as well as skill is required to insure the even shrinking and the uniform distribution of the stock. Failure in any detail will cause streaks and weak spots in the finished article. The hat is now ready for dyeing. It is immersed in a great color vat and dyed to meet the prevailing fashion. Great improvements have been made in this detail during the past few years. The old wood colorings have been discarded, and coal-tar products are now used because they have been found more serviceable and increase the durability of the hat. Up to this point the manufacturing of stiff and soft hats has been along similar lines, but from this time on different methods are used. After dyeing the next step is to stiffen slightly the brim of the soft hat by the application of "water stiff," a solution of shellac. The body is now beginning to assume a definite form. It is stretched, blocked and pulled, and, with the aid of hot water, steam and ingenious machinery, it is given stability of shape and form. The rough surface must now be cut off. This operation requires great care. If too much of the fur is removed all the previous skilled manipulation becomes valueless and the hat is ruined. This operation is known as "pouncing." It was formerly accomplished with a great deal of hand labor. It is now done by a machine and emery paper. This machine is a great time saver, and greatly facilitates the production of the plant. The crown is next given its shape, as demanded by the style. It is stretched over wooden blocks, ironed and re-ironed. It must then be carefully pounced by hand and steamed to tighten the felt. The brim must be treated exactly the same way, although it is not given shape at this time. Only men of skill and experience can engage in this portion of the work. There is a knack about pouncing by hand that can be acquired only by experience.

The hat is next flanged, or, rather, the brim is given its shape. The brim is placed upon a flange of metal or wood so as not to affect the crown. The entire hat resting on the flange is then placed under a huge receptacle containing heated sand and having on the under side a heavy cotton fabric, which comes in direct contact with the felt. After remaining in this position for several minutes the brim of the hat has its correct shape and trimming is in order. The turning up and edging each play an important part in the final process of shaping. In trimming artistic treatment is a necessity. Care must be taken in attaching the bands and bindings to preserve the neatness as well as the character of the design. The insertion of the sweat leather must be carefully done. All these and other details add greatly to the appearance and durability of the finished product.

The stiffening of the derby, better known as "the stiff hat," because of the character of the felting, is an interesting process. The hat body is impregnated with a solution of shellac and alcohol of given density. This substance is carefully worked into the heart of the body, and as a result the felting attains a condition of firmness. The hat is then placed on a wooden block, is immersed in hot water, and is given the proper proportion and shape before the final pressing. At the conclusion of this operation the superfluous gum is cleared away by a soda bath. When dry the hat is rigid throughout. It is then placed in an oven and kept there until it becomes pliable. A mould, to which tremendous pressure is given by mechanical or hydraulic means, completes the pressing after the derby has been pounced or finished. The pouncing of a derby is done upon a lathe. It is placed on a wooden block similar to the moulds used in pressing. Should the operator cut off too much of the surface fur, thus destroying the nap, the stiffening will be exposed and the work of the skilled men who preceded him loses its value. Curling or shaping of the brim is done with a variety of small tools, heat, steam, deftness of fingers and a good eye. The work of some of the experts who develop the stiff hat brims by the eye is little less than marvelous. The trimming, binding, etc., of stiff hats require even greater care in their selection and adjustment than in the case of soft hats.

Among American hat makers Charles Knox was one of the early specialists in beaver and

silk hats in New York. Robert Dunlop, of New York, has also an eminent name in the hat trade of America. The history of the John B. Stetson Company, of Philadelphia, is to a large degree the history of hat making in the United States for the last 39 years. From the small beginning of one room and two mechanics the Stetson factories have been developed to nine immense plants, having a floor space of over ten acres and a force of more than 2,500 employees. When John B. Stetson, in 1865, determined to manufacture hats he was known as the foremost expert in the mixing of furs and as one of the best hat finishers in the trade. He determined to avoid the cheap hat and to make only the highest grade of goods and to make them better than any other manufacturer. His output the first year did not exceed one hundred dozen hats. His capital was not more than $1,000. In 1903 the John B. Stetson Company, with its great force of employees, supplemented by improved machinery, most of the patents for which are owned by the company, produced 105,800 dozens of hats. This company has introduced new machinery, which cheapens the cost of production without a sacrifice in quality, and has carried the fame of the city of Philadelphia to every quarter of the globe. A process has also been perfected whereby pure nutria and beaver fur may be successfully utilized in superfine hat making.

Another important improvement in hat making is that known as the "Boss" raw-edge kettle finished hat. This was introduced in the early seventies. Prior to this time all soft hats were made with bands and bindings, the latter being used to hold the brim in shape. The "Boss" raw-edge hat, as its name indicates, has no binding around the edge. It is shaped in hot water by frequent immersions and by the skillful hand work of an expert. The brim curling is a feature that cannot be accomplished in any other factory. This hat is, beyond question, the most remarkable specimen of headwear the world has ever seen. The John B. Stetson Company has been awarded the grand prize or gold medal at nearly every world's fair since 1876, but it holds as of almost equal value an order which it received from the British government for 10,000 hats for the South African constabulary during the Boer war. Prior to this war a number of American miners and cattlemen drifted into South Africa wearing Stetson's hats. They came in contact with General Baden-Powell, who admired the hats they wore and made inquiries about them. They were made of nutria fur, were better in quality than those produced anywhere in Europe. General Powell requested his government to order 10,000 of these hats, and the Stetson factories made and delivered them within six weeks of the receipt of the order. In 1876 the Stetson Company was awarded a gold medal by the Philadelphia Centennial Exposition. In 1879 it won a medal at Paris. In 1889 and in 1900 it won the grand prix at Paris. The official report making the award at the Paris Exposition in 1900 said, concerning the Stetson exhibit: "The products displayed here are, from every point of view, absolutely remarkable, but very especially the manufacture of soft hats, which is incontestably the acme of perfection of this epoch."

WILLIAM F. FRAY,
First Vice-Pres. John B. Stetson Company.

Hat'teras, Cape. See CAPE HATTERAS.

Hatteras Inlet, Capture of. In the forenoon of 26 Aug. 1861, a Union fleet of 7 vessels carrying 143 guns, under command of Flag-officer Silas H. Stringham, and 3 transports, carrying 930 men and a light battery, under command of Gen. Butler, set sail from Hampton Roads. Next afternoon the fleet arrived off Hatteras Inlet, the entrance to Pamlico Sound, which was guarded by Forts Hatteras and Clark, built by North Carolina on the south end of Hatteras Island, and mounting respectively 25 and 5 heavy guns. The forts, which were garrisoned by over 700 men, were under command of Maj. Andrews. At 10 A.M. of the 28th Stringham began the bombardment of the forts, and a little later about 300 troops, with two howitzers, were landed on the island above the forts. Fort Clark was silenced before noon, the greater part of its garrison retreating to Fort Hatteras, some escaping from the island by boats. At night the fleet withdrew, but renewed the attack upon Fort Hatteras early in the morning of the 29th, drove the gunners from their guns to the shelter of the bomb-proofs, and before noon the fort surrendered, after a loss of 30 killed and wounded. The Union loss was one wounded. Stringham and Butler returned to Hampton Roads, leaving three vessels as a sea-force and detachments of the Ninth and Twentieth New York and the Union coast-guard, under Col. R. C. Hawkins, to garrison the captured forts. The immediate results of the expedition were the capture of the two strong forts with their garrisons of 715 men, 31 heavy guns, 1,000 stand of arms, and the possession of the best sea entrance to the inland waters of North Carolina. Consult: The Century Company's 'Battles and Leaders of the Civil War,' Vol. I.; Maclay, 'History of the Navy,' Vol. II.

E. A. CARMAN.

Hatti-Sheriff, the Turkish name of an edict signed by the sultan, who subscribes it usually with these words: "Let my order be executed according to its form and import." These words are usually edged with gold, or otherwise ornamented. An order given in this way is irrevocable. The firman of 18 Feb. 1856, called usually Hatti humayun, "exalted writing," is the constitutional charter of the Turkish empire. It is a long document, undivided into articles, and prescribing various reforms administrative and financial, etc., but its chief importance consists in its explicit recognition of the principle of religious liberty, already admitted by the hatti of Gulhana, 3 Nov. 1839.

Hattiesburg, Miss., city, county-seat of Perry County; on the Leaf River, and on the Gulf & S. I., the New Orleans & N., the Mobile, J. & K. C., and the Pearl & L. R. R.R.'s; about 65 miles north of Biloxi and 84 miles southeast of Jackson. The Gulf & Ship Island railroad is the shortest route to the Gulf of Mexico. Hattiesburg is the trade centre of a large fertile agricultural region in which an excellent quality of cotton is extensively cultivated. The industries are growing rapidly and its good railroad facilities mean good markets. The chief industrial establishments are saw-mills, planing-mills, cottonseed-oil mills, a cotton compress, a foundry, machine-shops, boiler works, brick-yards,

a naval store factory, railroad shops, an ice-plant, and the electric light and power plant. It has three banks, a number of fine public buildings. Pop. (1900) 4,175; (1903) 7,000.

Hatto, hät'tō, the name of two archbishops of Mainz, both somewhat conspicuous in the history of Germany. The first was chosen archbishop of Mainz in 891, d. 913. The second Hatto (d. 970) was a monk of the monastery of Fulda, and succeeded the celebrated Rabanus Maurus as abbot of the monastery of St. Boniface, about the year 942 and in 968 was raised to the see of Mainz, and continued one of the chief advisers of the emperor. Of his after-life and of his personal character most opposite accounts have been given. By some he is represented as an upright and successful administrator; by others as a selfish and hard-hearted oppressor of the poor; and the strange legend of his being devoured by rats, which Southey has perpetuated in his well-known ballad, is represented as an evidence of the estimate that was popularly formed regarding him. It is quite possible that this legend is of much later date, and that its real origin is to be traced to the equivocal designation of the tower on the Rhine, Mäusethurm, near Bingen, which has been selected as the scene of the occurrence. *Mäusethurm*, "Mouse-tower," is possibly only a corrupted form of *Mauth Thurm*, "Toll-tower," a sufficiently descriptive name; but the modified form of the word might readily suggest a legend of mice or rats. The date at which the Mäusethurm was built is unknown, and it is far from certain that it is not much later than the time of Hatto. See Baring-Gould, 'Curious Myths of the Middle Ages' (1869); Max Beheim, 'Die Mäusethurmsage' (1888).

Hat'ton, Sir Christopher, English statesman: b. at Holdenby about 1540; d. 1591. Lord chancellor of England, a favorite of Queen Elizabeth; was entered a gentleman commoner at Saint Mary Hall, Oxford, but removed without taking a degree, to the Inner Temple in 1560. He was introduced at court some time previous to the middle of the year 1564, and it is said Queen Elizabeth was so much struck with his graceful person and dancing that an introduction to her favor was the result, and gained him the name of "the dancing chancellor." He was a furious enemy of the Jesuits, and did not hesitate to accuse Parry, their defender in Parliament, and secure his execution. He was elected a member of Parliament in 1571, became captain of the Queen's Guard in 1572, vice-chamberlain and a privy-councillor in 1577, lord-chancellor in 1587. He was one of the commissioners for the trial of Mary Queen of Scots, in 1586. His artful speech to the unhappy queen, "If you are innocent you have nothing to fear; but by seeking to avoid a trial you stain your reputation by an everlasting blot," is supposed to have been mainly influential in inducing her to submit to trial. Spenser, whose patron he was, dedicated to him 'The Faerie Queen.'

Hatton, Frank, American journalist: b. Cambridge, Ohio, 28 April 1846; d. Washington, D. C., 30 April 1894. He served through the Civil War in the Army of the Cumberland, being commissioned and was subsequently partner with Robert J. Burdette (q.v.) in the proprietorship of the Burlington *Hawkeye*. He was assistant postmaster-general (1881–4); postmaster-general (1884–5); editor of Chicago *Mail* (1884–8); and editor of the Washington *Post* (1888–94).

Hatton, John Liptrot, English composer: b. Liverpool 1809; d. Margate, Kent, 20 Sept. 1886. Removing to London in 1832 he became famous for his many operas, cantatas, overtures, entr'actes, etc., and was musical director of the Princess Theatre 1853–9. He is now, however, remembered chiefly for his admirable settings of English songs, such as 'Good-bye, Sweetheart,' 'The Tar's Song,' 'The Bait,' etc.

Hatton, Joseph, English journalist, novelist, and playwright: b. Andover 3 Feb. 1841. Beginning journalism on the Derbyshire *Times*, founded by his father, he went to London, where he edited the 'Gentleman's Magazine' (1868–74); and became a newspaper correspondent for the New York *Times* and other journals. Among his numerous novels are: 'Clytie' (1874); 'Queen of Bohemia' (1877); 'John Needham's Double' (1885), dramatized for E. S. Willard; 'By Order of the Czar,' a novel of Russian life; 'Princess Mazaroff'; 'Under the Great Seal'; 'When Greek Meets Greek,' a novel of the French Revolution successfully dramatized; 'When Rogues Fall Out' (1899). Among his miscellaneous publications the best-known are: 'Journalistic London'; 'The New Ceylon'; 'Henry Irving's Impressions of America'; 'Old Lamps and New'; while among his plays may be cited a version of 'The Scarlet Letter' successfully acted in the United States; 'The Prince and the Pauper'; 'Liz'; and 'A Daughter of France.'

Hauck, hâk, Minnie, American vocalist: b. New York 16 Nov. 1852. She appeared in concert in New Orleans at 13, afterward studied with Errani in New York and made her début as an opera singer in 'La Sonnambula' in 1868. She has been uniformly successful both in the United States and Europe, but is best known in the title role of Carmen. She is married to the Chevalier de Hesse-Wartegg.

Haupt, howpt, Herman, American engineer: b. Philadelphia, Pa., 26 March 1817; d. 14 Dec. 1905. He was graduated at West Point in 1855, but became a civil engineer, and joined the staff engaged on the public works of Pennsylvania. For three years he was professor of civil engineering and mathematics in Pennsylvania College but in 1847 became consulting engineer of the Philadelphia Railroad. He was afterward chief engineer of the Hoosac Tunnel and during the Civil War chief of the United States Bureau of Military Railroads. The Royal Polytechnic Society of Great Britain gave him their highest prize for the drilling machine which he invented, and he first made practicable the transportation and distribution of oil from the well side. He wrote 'Hints on Bridge Building' (1840); 'General Theory of Bridge Construction' (1852); 'A Consideration of the Plans Proposed for the Improvement of the Ohio River' (1855); 'Military Bridges' (1864).

Haupt, Lewis Muhlenberg, American engineer: b. Gettysburg, Pa., 21 March 1841. He

was educated at Harvard and West Point. From 1872 to 1892 he was professor of civil engineering in the University of Pennsylvania, and for the year ending 1886 edited the 'Engineering Register.' From 1897 to 1899 he was a member of the Nicaraguan and the Isthmian Canal Commissions. His published works include: 'Working Drawings and How to Make and Use Them' (1881); 'Canals and Their Economic Relation to Transportation' (1890).

Haupt, Paul, American Assyriologist: b. Gorlitz, Germany, 25 Nov. 1858. He was graduated at the Gymnasium Augustum, Gorlitz, in 1876; studied in Leipsic and Berlin, and settled in Göttingen where in 1883 he was appointed extraordinary professor of Assyriology. In the autumn of the same year he accepted the chair of Semitic languages at Johns Hopkins University, Baltimore, Md. He projected and continued to edit the so-called Polychrome Bible. (See BIBLE, POLYCHROME.) Among his many writings in periodical, pamphlet and book form, the most important volumes are 'Das babylonische Nimrod-Epos' (1891); 'Akkadische und sumerische Keilschrifttexte' (1882); 'Prolegomena to a Comparative Assyrian Grammar' (1888).

Hauptmann, howpt'män, **Gerhart,** German dramatist: b. Salzbrunn, Silesia, 15 Nov. 1862. After study at the Breslau Art School, he attended the universities of Jena and Berlin, traveled in Italy and Switzerland, and first appeared in literature with his epic, 'Promethidenlos' (1885). This he followed by a swift succession of dramas — 'Vor Sonnenaufgang' (1889), frankly socialistic and provocative of violent discussion; 'Das Friedensfest' (1890); 'Einsame Menschen' (1891); and 'Die Weber' (1892), a story of an unsuccessful uprising of the Silesian weavers, typifying the hopeless condition of the proletariat. In these works Hauptmann reveals the influence of Tolstoi and Ibsen, and a strong revolt against the conditions imposed, particularly upon the working-class, by a military and plutocratic régime. To this motif he returns in 'Fuhrmann Henschel' (1898). But he strikes a different note in 'Hanneles Himmelfahrt' (1893), a mystic 'dream-poem' as the author styles it, and 'Die versunkene Glocke' (1897; Eng. trans. by Meltzer 1900), which harks back to an indefinite period of the Middle Ages and makes artistic use of the primitive Germanic fairy-lore. In 'Kollege Crampton' (1892), 'Der Biberpelz' (1893) with its inferior sequel 'Der rote Hahn' (1901), and 'Schluck und Jan' (1900) he displays gifts of humor and satire. Other works are 'Florian Geyer' (1895) and 'Michael Kramer' (1900). Hauptmann is the chief figure in modern German drama. He excels less in dramatic structure than in art of characterization, and despite crudity and occasional dulness attains genuine poetic value.

Hauptmann, Moritz, German musician: b. Dresden 13 Oct. 1792; d. Leipsic 3 Jan. 1869. He studied at Gotha; was violinist at the court in Dresden in 1812; in 1815–20 was employed as music teacher in the family of a Russian prince; in 1842 he was appointed cantor of the Thomasschule in Leipsic, and the next year became professor of counterpoint at the Leipsic conservatory, where he was very successful and popular as a teacher. His compositions include motettes, an offertory, and sonatas for violin and piano. In 1853 he published his 'Die Natur der Harmonik und Metrik,' a very important theoretical work.

Haus'mannite, a native manganate of manganese, having the formula $MnO.Mn_2O_3$, and crystallizing in the tetragonal system, with octahedral habit. It is brownish black in color, and opaque with a submetallic lustre. It has a hardness of from 5 to 5.5, and a specific gravity of from 4.72 to 4.86. Hausmannite dissolves in hydrochloric acid, with evolution of chlorine gas. It occurs in Germany, Sweden, and elsewhere, usually in connection with porphyry. It was named in honor of the German metallurgist, J. F. L. Hausmann.

Haussa, how'sä. See HOUSSA.

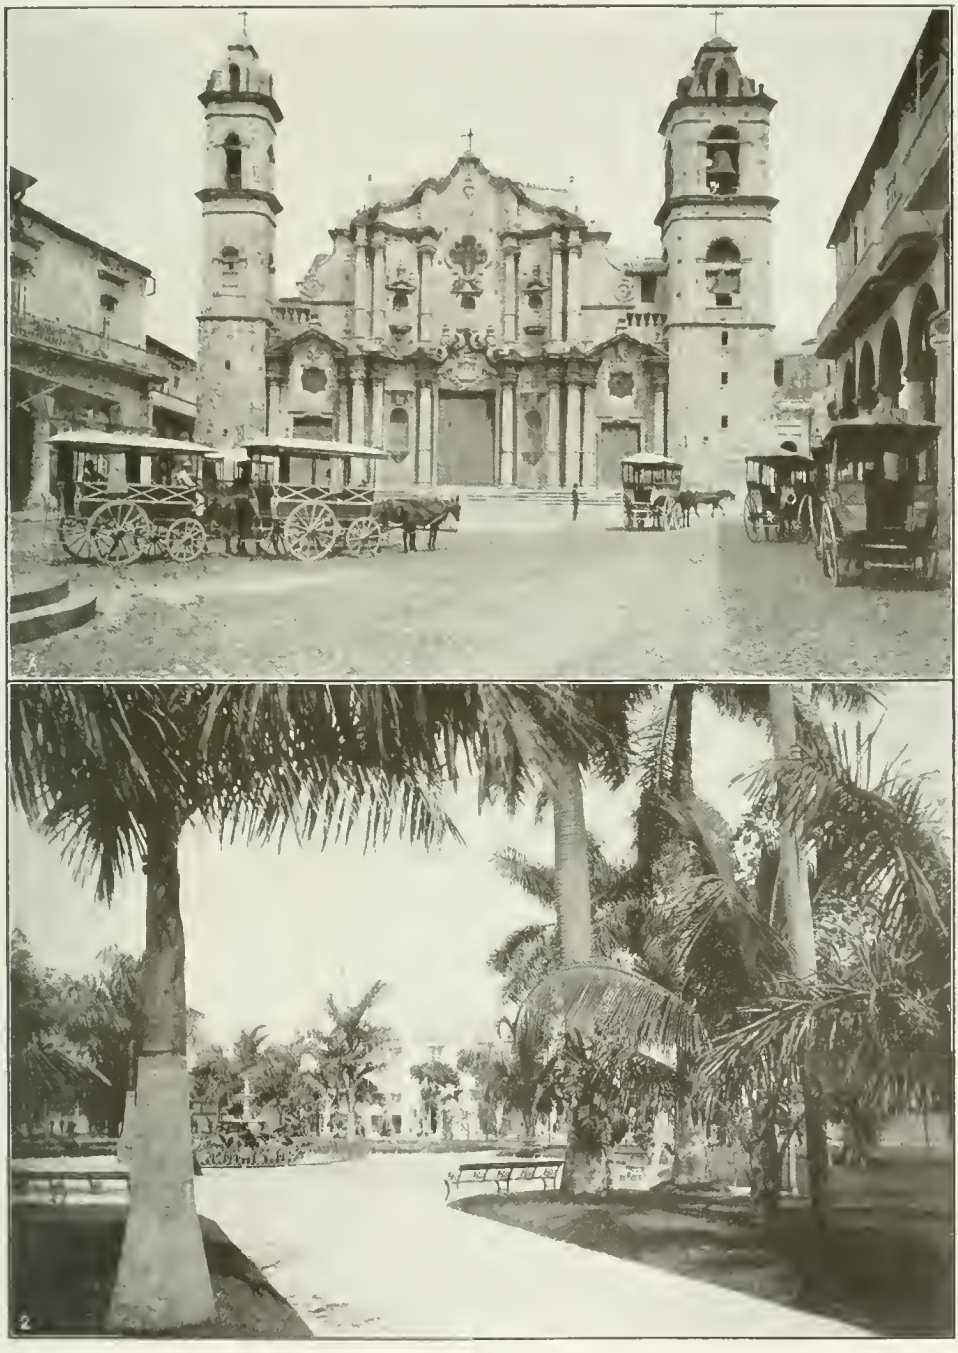
Haussmann, Georges Eugène, zhōrzh ė-zhān ōs-män, BARON DE, French municipal officer: b. Paris 27 March 1809; d. there 11 Jan. 1891. He studied law, and under Louis Philippe was sous-prefect of various places. The February revolution of 1848 caused the forfeiture of his office, but Louis Napoleon in 1853 made him prefect of the Seine, and he applied himself to the improvement and adornment of Paris with such energy that the city became transformed under his administration.

Hautboy, hō'boi (French *hautbois,* "high wood," alluding to its tone); a wooden wind-instrument of two-foot tone, played with a double reed. Also an organ stop, consisting of reed pipes slightly conical, and surmounted by a bell and cap of eight feet pitch. The tone is thin and soft.

Haüy, René Just, ré-nā zhüst ä-ü-ē or ä-wē, French mineralogist: b. St. Just, Oise, 28 Feb. 1743; d. 3 June 1822. He was trained for the Church and took priest's orders, but turned to mineralogy, and acquired a great reputation by a series of important discoveries. Among the chief of these is the geometrical law of crystallization, according to which a given mineral uniformly contains the same primary form as its basis of crystallization. From that time, according to Herschel, mineralogy first ceased to be "a mere laborious cataloguing of stones and rubbish." In 1794 Haüy became keeper of the cabinet of the School of Mines, and in 1802 professor of mineralogy in the Museum of Natural History. His works include: 'Traité de Mineralogie' (1801), and 'Traité de Crystallographie' (1822).

Haüynite, hä'wĭn īt, or **Haüyne,** hä'wĭn, a mineral of the sodalite group, occurring in certain igneous rocks, and notably in the lavas of Mt. Vesuvius. It is a silicate and sulphate of sodium, calcium and aluminum, crystallizing in the isometric system. It is usually translucent with a vitreous lustre, a hardness of from 5.5 to 6, and a specific gravity of about 2.45. Haüynite is commonly blue or green, though red and yellow specimens are also known. It was named in honor of the French mineralogist, R. J. Haüy.

Havan'a (Sp. LA HABANA, lä häbä'nä), Cuba, its capital and the commercial centre of the West Indies, second city of Spanish North America; pop. 242,055. It occupies nine square miles on the west side of the Bay of Havana on the north coast, one of the noblest



1. Cathedral of Havana. 2. Colon Park, Havana

VIEW OF HAVANA FROM CABANAS.

harbors in the world, with deep water up to the quays; entered by a narrow channel ⅛ of a mile long, protected by Punta Castle on the west and Morro Castle and La Cabaña on the east. It is in two sharply distinct sections. The old city, the commercial quarter, was built on the small western peninsula dividing the sea from the harbor, a low plain cut by a small stream on the west, strengthened by a city wall only torn down a generation ago. It is largely, and was entirely till the American occupation, a maze of narrow, crooked lanes traversed by one or two broader streets; the chief of which are the Calle O'Reilly, the main business street, running from the governor's palace to the city wall, and the Calle Obispo (Bishop Street). The new city is on a ring of hills 150 feet high south and west of the old, with the castle of El Principe on the crest, and has a wealth of broad and finely shaded macadamized streets, drives, promenades, parks, plazas, flower-gardens, fountains, statues, etc., which make it one of the handsomest cities in the world. There is no "West End" in Havana, the houses of the wealthy being scattered through every part, usually of classic pattern, with an inner courtyard or patio surrounded by marble or stucco columns, containing a garden of tropical vegetation and a central fountain. The handsomest residence street, next to the new suburb Vedado, is the Cerro, a long thoroughfare running up a hill at the farther end, and bordered by immense old villas in the midst of splendid gardens. The finest drives and promenades are the Malecon, a new thoroughfare along the water front from Prado to the Vedado, the Prado, a boulevard with a double row of shade-trees in the middle, running from Punta Castle outside the old wall, and ending in the largest park in the city, Colón Park or Campo Marte, and the Calle de la Reina (Queen Street) starting west from this park and continued as the Paseo de Tacón to the citadel of El Principe. The Alameda de Paula along the bay is also a favorite promenade.

Among buildings, the most interesting are the palace of the old captains-general, facing the Plaza de Armas near the harbor front, the cathedral, built 1764, and supposed to contain the ashes of Columbus in an urn till it was removed to Spain in 1898 (but the San Domingans claim they have his authentic bones), and the Tacón Theatre, perhaps the largest in the world. There are several other theatres and opera-houses, and many clubs, etc. The chief educational institutions are the University of Havana, founded 1670 by the Dominicans; the Jesuit boys' college de Belén, with a museum, observatory, a library rich in old Cuban history, etc.; College of American Augustinian Fathers, founded 1901. Famous among benevolent institutions are the Casa de Beneficencia, founded by Las Casas for infants. There are three general hospitals, a great lazaretto for lepers, and an insane hospital in the city and vicinity. Over 100 newspapers, etc., are published in the city.

The water supply of the city was installed by a Cuban engineer, Albear, some 40 years ago, and is considered a remarkable specimen of good workmanship. It comes from the Vento by an aqueduct 12 miles long, known as the Canal of Albear. In all other respects the Americans at the conquest found an undescribable state of filth and disease. The city was the prey of yellow fever; the sewers had seldom been cleaned since they were laid down, and some of them were choked with generations of rottenness; the buildings were pest-holes; and in that dungeon of horrors, the military hospital, 70 per cent of the inmates died. The United States forces in their short stay transformed this reeking home of pestilence into one of the healthiest cities in America. In systematic order streets were cleaned, repaved, widened; squads of cleaners were sent from house to house, emptying the Augean stables under them, whitewashing and disinfecting them, and where they were shanties that were nests of infection, tearing them down; the hospital was cleaned, disinfected, and covered deep with whitewash, and turned into a schoolhouse. New business streets were made by widening old lanes; parks were cleared up, and a fine sea-wall along the ocean to the north was built. The average deaths from yellow fever 1887–98 were 440; in 1896 they were 1,262; in 1901, for the first time in its history, only three or four. A Cuban physician of Irish descent, Dr. Carlos Finlay, now chief sanitary officer of Havana, was the originator of the mosquito theory of the yellow fever. Gen. Wood and the American army surgeons, however, deserve much credit for making the theory of practical use.

The climate is not severe. The mean annual temperature is 77°; the range from hottest to coldest 82° to 71°; the highest recorded, 100.6°, the lowest 49.6°. The mean rainfall is 54 inches.

Havana is the market of western Cuba, the head of the island's banking and commercial interests, and the emporium of the West Indies. Besides being the centre of the island railway system and of a great domestic shipping trade, especially with Santiago, it is the focus of a vast foreign commerce with Spain, France, England, and the United States, regular ocean lines running weekly to the first three and semi-weekly to the latter, besides others to the other West Indies. It has excellent covered wharves and a capacious dry-dock to aid this. Regla, on the opposite side of the bay, contains the sugar wharves and railway termini. In 1902 it had exports of about $60,000,000, $43,000,000 to the United States, an increase of $11,000,000 in three years, mainly ours; but its imports had shrunk from $57,000,000 to $45,000,000, most of the reduction from this country, owing to unfavorable customs laws. The entrances and clearances of ocean vessels in that year were over 1,500,000, and of domestic vessels nearly 3,000, with an average tonnage of about 635. The exports are chiefly of sugar, tobacco, cigars, and cigarettes; the imports, flour, rice, lard, and other foods, cotton, and metals. Its manufactures are mainly tobacco products; its cigar factories, of which there are over 100 of the first rank, are the largest in the world, one covering an entire square. It also manufactures confectionery, perfumes, rum, etc. The new electric street railway system is one of the finest of its kind, with 36 miles of track.

Population.— In 1869 it was 242,055, 52,900 being foreign; in 1887 it was about 189,000. About one third were unable to read; and about one third from 5 to 17 attended school.

History.— Havana was founded here (transferred from an older site) by Diego de Velasquez in 1519, and called by him "the key of the

New World." Burnt by buccaneers in 1528, it was rebuilt and made the chief naval station of Spain in this hemisphere, twice sacked in 1555 and 1563, it was a storm centre of wars and piracies for two centuries. In 1762 the English captured it, but restored it to Spain the next year. In 1802 it was partly burnt, but under the famous Governor Tacón, its second founder, commemorated at every turn, it was rebuilt from a straw-thatched wooden town to a city of brick and stone. For its late history, see CUBA. Consult: Norton's 'Handbook of Havana and Cuba' (1900).

Havana, Ill., city, county-seat of Mason County; on the Illinois River, and on the Chicago, P. & St. L. and the Illinois C. R.R.'s; about 39 miles northwest of Springfield. It is situated in an agricultural region and is the trade centre for a large extent of country. The chief manufactures are flour, agricultural implements, drills, gasoline engines, and some factory supplies. Its trade is chiefly in grain, fruit, vegetables, and dairy products. The waterworks are owned and operated by the city. Pop. (1900) 3,268.

Havelock, hăv'ē-lŏk, SIR **Henry,** English soldier; b. Bishop-Wearmouth, near Sunderland, 5 April 1795; d. Dilkusha, India, 24 Nov. 1857. Entering the army, he served with distinction in the Burmese war (1824–6); in 1829 married, became a Baptist, and was distinguished during the remainder of his life by his earnest religious zeal. He participated in the Afghan war, and in the defeat of Mohammed Akbar, 1843. He took part in the Mahratta war, and distinguished himself in the Sikh war of 1845. He commanded a division in the Persian war (1856–7) and on the outbreak of the Indian mutiny was despatched to Allahabad in order to support Sir H. Lawrence at Lucknow and Sir H. Wheeler at Cawnpore. On arriving at Cawnpore he found that Nana Sahib had massacred the prisoners. Pursuing his march to Lucknow, he defeated the rebels at Bithoor, and finally won the battle of Alumbagh. Having captured Lucknow, Havelock and Outram were shut up there until relieved by Sir Colin Campbell 17 Nov. 1857. He was raised to the rank of major-general, made a K. C. B., and (before his death was known) created a baronet. Consult lives by Brock (1858); Marshman (1890); Forbes (1890).

Havemeyer, hăv-ē-mī'ẽr, **William Frederick,** American banker: b. 31 March 1850. He received his education in private schools and entered into commercial business, and as a successful financier became vice-president and director of the National Bank of North America, and of the Queens County Bank of Long Island, and took a place in the board of directors of numerous railroad and banking corporations.

Ha'ven, Alice Bradley, American author: b. Hudson, N. Y., 1828; d. 1863. Her maiden name was Emily Bradley, and while a school girl she sent under the pseudonym of "ALICE G. LEE" many sketches to the Saturday 'Gazette,' then recently established by Joseph C. Neal in Philadelphia. She was married to Mr. Neal in 1846, and at his request assumed and retained the name of Alice. On the death of her husband in 1847, she conducted the 'Gazette' for several years. She published in 1850 'Gossips of Rivertown, with Sketches in Prose and Verse,' and became widely known by her series of juvenile stories, as 'Helen Morton,' 'Pictures from the Bible,' 'No such Word as Fail,' 'Patient Waiting no Loss,' 'Contentment Better than Wealth,' 'All's not Gold that Glitters,' 'Out of Debt Out of Danger,' etc. In 1853 she was married to Mr. Samuel L. Haven.

Haven, Erastus Otis, American Methodist bishop and educator: b. Boston, Mass., 1 Nov. 1820; d. Salem, Ore., 3 Aug. 1881. He was graduated at the Wesleyan University, Middletown, Conn., in 1842, soon after entered the ministry of the Methodist Episcopal Church, was appointed teacher of natural science in the Amenia Seminary, N. Y., and in 1845 was elected principal of that institution. He was professor of Latin and Greek in the University of Michigan 1854–6; editor of 'Zion's Herald' 1856–63, and sat in the Massachusetts Senate 1862–3. He was president of the University of Michigan 1863–7, and of Northwestern University, Evanston, Ill., 1869–72. He was subsequently chancellor of Syracuse University and was elected bishop in 1880. He published 'The Young Man Advised' (1855); 'Pillars of Truth' (1866); 'Rhetoric' (1869).

Haven, Gilbert, American Methodist bishop: b. Malden, Mass., 19 Sept. 1821; d. there 30 Jan. 1880. He was an able writer, and a forceful preacher. In the Civil War he was the first commissioned chaplain in the Federal army. He was editor of 'Zion's Herald' 1867–72, and was elected bishop in the latter year. He published 'The Pilgrim's Wallet, or Sketches of Travel in England, France, and Germany' (1865); 'National Sermons' (1869); 'Life of Father Taylor, the Sailor Preacher' (1871); 'Our Next-Door Neighbor, or a Winter in Mexico' (1875); etc.

Hav'erford College, under the auspices of the Society of Friends founded in 1833 in Haverford, Pa. It was first known as Haverford School, but in 1845 it was suspended for the purpose of collecting an endowment, and in 1856 it was made a college. It was the first collegiate institute in the United States which was founded and conducted entirely within the Society of Friends. Others besides the sons of Friends have been admitted as pupils since 1849. It is well equipped in laboratory requirements and in its library facilities. In 1903 the college reported 20 professors and instructors and 130 students. There were in the library about 37,100 volumes.

Havergal, hăv'ẽr-gal, **Frances Ridley,** English hymn-writer: b. Astley, Worcestershire, 14 Dec. 1836; d. Swansea, Wales, 3 June 1879. She was a frequent contributor to 'Good Words,' and the chief English religious periodicals, and her musical harmonies were praised by the German composer Hiller. Her poems and hymns were collected in several volumes, 'The Ministry of Song' (1870) being the first. Her 'Poetical Works' (1884) appeared under the editorship of M. V. G. Havergal. Of her hymns, which contain her best work and are found in all collections, the most familiar is 'Take my Life and Let it Be.'

Haverhill, hā'vẽr-il, Mass., city in Essex County; on the Merrimac River at the head of navigation, and on the Boston &. M. railroad;

about 30 miles from Boston. It is an important centre of street railway traffic, electric lines radiating from it connecting it with all of the important cities and towns of northeastern Massachusetts and southeastern New Hampshire. Three highway bridges span the river, connecting the city respectively with the Bradford district, with Groveland, and with West Newbury. Haverhill, including Bradford, which was annexed to it, 4 Jan. 1897, is 9 miles long and 3½ miles wide, and covers an area of 32 square miles. Bounding the entire southern length of the original city and separating it from its new adjunct, Bradford, from Groveland, and from West Newbury, flows the Merrimac River, navigable from the sea to the very heart of the city, and affording for freightage or pleasuring a delightful waterway. From the river on both sides the land slopes upward, the lower parts near the river being occupied for manufacturing and commercial purposes, the higher lands for residences. Five large lakes — Kenoza, Round Pond, Saltonstall, Crystal, and Chadwick's Pond — lie entirely within the limits of the city, and three of them, with a large artificial lake at Mill Vale, afford an abundant supply of water for all purposes. The eastern and western parts of the city are known as East Haverhill and West Haverhill, their more thickly settled parts being respectively Rocks Village and Ayers Village; the southern portion, in the Bradford district, is known as Ward Hill.

Government.— The municipal government is administered by a mayor, board of aldermen consisting of seven members, one from each ward of the city, but elected by the votes of the whole city, and 14 councilmen, two from each ward of the city and elected by the votes of the ward. These officials are elected annually and hold office for a single year. The schools are administered by a school board of 21 members, one member being elected annually by each ward and holding office for three years. The administrative officer of the board is the superintendent of schools, and the mayor is, *ex-officio*, chairman of the board. The water board consists of five members, each appointed by the city government for a term of five years; the park commission consists of five members, each appointed by the city government for a term of five years; the trustees of the Public Library, six in number, and the trustees of the City Hospital, five in number, hold office for life, vacancies being filled by the boards of trustees.

Financial.— The assessed valuation of the city, 1 May 1903, was $26,588,292. The tax levy for 1903 was $490,267.94; the state tax, $22,875; the county tax, $28,726.40; and the rate of taxation per $1,000, $17.60. The net bonded debt, 1 Jan. 1904 was: Municipal loans, $470,373.62; water loans, $776,512.43; total, $1,246,886.05. The interests of the business community are served by six national banks, having an aggregate capital of $795,000. There are three savings banks, two co-operative banks with an authorized capital of $1,000,000 each, and a safe deposit and trust company.

Manufactures.— The city has many and varied manufactures, the number of manufacturing establishments of all kinds being (U. S. Census of 1900) 685, with an aggregate capital of $24,937,073. The average number of wage-earners employed is 10,000, to whom is paid an aggregate of $5,035,882. The principal manufactures are those connected with the boot and shoe industry. There are 151 manufactories of boots and shoes, with an aggregate capital of $3,325,717, and an annual production valued at $15,231,440; 98 manufactories of cut stock, aggregate capital, $641,927, value of product, $3,495,433; 22 manufactories of boot and shoe findings, capital, $262,586, value of product, $811,515. The number of cases of shoes annually sent forth is about 450,000, and the market for them is not alone the United States, but England, Germany, Australia, the South American states, and other foreign countries. Other important industries are hat and woolen manufactures, box making, brick making, machine building, etc.

Schools.— The public school buildings are 34 in number, their aggregate value being $649,150. There are 167 teachers employed in the day schools, and an enrollment of 5,552 pupils. There are three parochial schools, Saint James (Irish), with a membership of 921; Saint Joseph's (French), with an enrolment of 372, and the Brothers of the Sacred Heart (French), with an enrollment of 334. Haverhill is also the seat of Bradford Academy, a famous and flourishing school for young ladies, established in 1804.

Board of Trade.— The membership of the Board of Trade includes all of the leading men of business and influence, and its object is "to forward the mercantile interests of Haverhill through the medium of equitable laws and regulations of the General Court and of the municipal government; to procure and spread such information as will conduce to the advancement and elevation of commercial dealings, and the extension of wise and just methods of business."

Parks.— There are 27 public parks in the city. Winnikenni Park, adjacent to Lake Kenoza, is very extensive, diversified, and beautiful, and abounds in delightful drives.

Public Buildings, Institutions, etc.—The Public Library was founded in 1875 by the generosity of E. J. M. Hale, whose gifts to it, including a legacy of $100,000, amounted to more than $175,000. The library contains nearly 100,000 volumes, with an annual circulation of nearly 160,000. There are four branch libraries for the accommodation of the more remote parts of the city, and 12 loan libraries placed in the district schools. Loan libraries are also established in connection with each grammar school, books being sent to and from these schools each week. The Hale Hospital occupies a set of buildings of the most modern type and equipment. The Historical Society occupies the "Buttonwoods," a large old mansion house on Water street, formerly the seat of the Saltonstall family, marking very closely the site of the first settlement of Haverhill. The Whittier homestead, the birthplace of the poet, John Greenleaf Whittier (17 Dec. 1807) and the scene of his poem 'Snow-Bound,' is situated about three miles from the heart of the city on the Merrimac road. The house, with the grounds surrounding it, is owned by the Whittier Association, and it is visited annually by many pilgrims. The Y. M. C. A. occupies a magnificent set of buildings, including a thoroughly equipped gymnasium. The Pentucket Club occupies an elegant mansion, formerly the Duncan residence, more than a century

old, designed by the celebrated architect, Haviland, but harmoniously enlarged to meet the needs of the social club now occupying it. The local military organization is Company F, of Eighth Regiment, M. V. M., organized in 1869, and attached to the Second Brigade. Among the numerous fraternal and other organizations may be mentioned seven Masonic bodies, maintaining a Freemason's Hall Association, with a capital of $50,000; eight lodges of Odd Fellows, maintaining an Odd Fellows' Hall Association, with a capital of $100,000; Elks, Foresters, G. A. R., Sons of Veterans, Woman's Relief Corps, Red Men, Daughters of Pocahontas, Knights of Malta, American Workmen, Knights of Pythias, Patrons of Husbandry, Royal Arcanum, Boot and Shoe Workers' Union, Shoe Workers' Protective Union, etc., while two literary clubs, the Monday Evening Club and the Fortnightly Club, are noteworthy.

History.— The first settlement of Haverhill was made in June 1640, by twelve men from Newbury and Ipswich, the new settlement being known as Pentucket. In the following year (1641) the Rev. John Ward came from Ipswich to be the minister and leader of the colonists, and so pleased were they with his character, attainments, and zeal that they named the place Haverhill from the older Haverhill in England, which was his birthplace. In 1642 title to the tract of land, 14 miles in length, was obtained by purchase and deed from the Indians, Passaquo and Saggahew. In 1660 the first public school was established, its teacher, Thomas Wasse, his salary £10 a year. For many years Haverhill was a frontier town, and suffered from the forays of the Indians. On 15 March 1697 the savages attacked the house of Thomas Duston, carrying away his wife Hannah, her infant child and her nurse, Mary Neff. The child was soon killed, but Mrs. Duston, taken to an island in the Merrimac River above Concord, N. H., in the night, with the assistance of her nurse and a captive youth, killed the Indians who were guarding her, as they lay asleep, scalped them, and escaped in a canoe, carrying the scalps as proof of her deed. A monument to her in City Hall Park commemorates her heroism. On 29 Aug. 1708 the Indians made a murderous foray upon the centre of the town, setting fire to the church and the houses, killing the Rev. Benjamin Rolfe and 15 others, carrying away about 20 captives, but leaving about 30 of their own number dead. These are the more notable among many Indian attacks upon the place. At the outbreak of the Revolution Haverhill contributed to the patriot cause her quota of men, 74 of her sons being engaged in the battle of Bunker Hill. On 4 Nov. 1789 George Washington visited the town, remaining over night at Harrod's tavern, on the site where the City Hall now is, and paying delightful compliments to the town and its beautiful location. In 1793 a stage coach line was established between Boston and Haverhill, "fare, 3d. a mile," running twice a week. 6 Sept. 1793 the first newspaper printed in the town was published. It was called 'The Guardian of Freedom,' and was issued weekly at nine shillings a year. In 1794 the first bridge across the river was erected. In 1827 the Haverhill Academy was opened, one of the students, John G. Whittier (q.v.), writing an ode for the dedication. In 1828 the Rocks Bridge was completed, and in the same year the steamer Merrimac, the first on the river, began running between Haverhill and Newburyport. In 1837 the railroad, now the Boston & Maine, was extended from Andover to Haverhill. In 1842 certain citizens of Haverhill presented to Congress, through John Quincy Adams (q.v.), the famous petition for the dissolution of the Union, the object being to rebuke the Congressional agitators. In the civil war Haverhill contributed to the Union cause about 1,300 men, her first troops leaving for the front on the day when the Massachusetts Sixth was attacked in Baltimore. To those who fell in that war she erected in 1869 on one of her principal squares a beautiful soldiers' monument. Haverhill became a city in 1869. The old place has suffered from several disastrous fires, one in 1775 which destroyed 17 buildings in the little town; one in 1873, which burned out 35 business houses, and the most disastrous one of 17 Feb. 1882, which burnt out about 300 business firms and destroyed about $2,000,000 worth of property. On 6 Nov. 1888 the City Hall, built in 1861, was gutted by fire, but it was immediately rebuilt.

The shoe and leather industry of Haverhill dates back almost to the time of the first settlement, for in 1643 Job Clement established a tannery, and at about the same time Andrew Greeley practised the trade of shoemaker for the little settlement. In 1679 Benjamin Webster and Samuel Parker were permitted to live in the town and to follow the trade of shoemaker. In 1812 Moses Atwood sent a wagon-load of shoes to Philadelphia, probably the first export of this product from the town. In 1818 a special two-horse wagon was regularly run between Haverhill and Boston for the transportation of shoes, and in 1835 the traffic employed 40 horses and two yoke of oxen. The coming of the railroad to Haverhill in 1837 furnished a better means of transportation and gave new impetus to manufacturing. In 1850 about 50,000 cases of shoes were sent out; in 1860 about 94,000, valued at about $3,750,000. The change in 1870 from town government to city government was coincident with an awakening to new life. Old residential streets were changed to manufacturing centres, old farms and pastures became thickly covered with residences, and in manufacturing the city rapidly grew to be one of the three cities leading in the output of shoes. To-day fully 10 per cent of the total output of shoes in the United States and nearly one-fourth of the total number produced in Massachusetts is made in the Haverhill factories. In 1890 Haverhill celebrated the 250th anniversary of its settlement amid a great gathering of distinguished sons and guests, the address being by the Rev. Samuel H. Duncan, the historical poem by Dr. John Crowell, and the beloved and distinguished son of the town, the poet Whittier, sending as a tribute his beautiful poem, "Haverhill."

Population.— The population of Haverhill (U. S. Census of 1900) is 37,175, an increase from 27,412 in 1890. A part of this increase is due to the annexation of Bradford, the population of which in 1895 was 4,736. Of the present population those born in Canada number 4,054; in Ireland, 2,144; in England, Scotland, and Wales, 671; in Russia, 574; in Italy, 444; and in other foreign countries, 643.

ALBERT L. BARTLETT.

Haverhill, N. H., village, county-seat of Grafton County; on the Connecticut River, and on the Boston & M. railroad; about 70 miles northwest of Concord. The town contains several villages, the largest of which is Haverhill. The surrounding region is largely devoted to agriculture, but the granite quarries in the vicinity add to the industrial wealth of the village. Some of the manufactures are flour, lumber, wagons, furniture, whetstones, made from the stone found nearby, and dairy products. Pop. (1890) 2,545; (1900) 3,414.

Havers, Clopton, English anatomist and physician: b. 1650; d. 1702. After study at Cambridge he proceeded to Utrecht, where he graduated M.D. in 1685. He established himself as a practising physician in London, and acquired a reputation by his profound studies on bone structure, which are exhaustively summarized in his 'Osteologia Nova' (1691). His name is perpetuated in osteology by the technical term "Haversian canals." Among his other works are: 'Researches on the Lachrymal Gland' (1691); 'Survey of the Microcosm' (1695); and 'Discourse on the Concoction of Food' (1699).

Haverschmidt, Francis, Dutch poet: b. Leeuwardien 1835; d. Schiedam 1894. Educated for the Church, he completed his studies at Leyden. He became known as "Piet Paaltjens," the pseudonym under which he published 'Snikken en Grimlachjes' (1867), a collection of poems, six editions of which were sold in two years. He published also 'Familie en Kennissen' (1876), a collection of prose essays.

Haversian (hă-vėr'zian) **Canals.** See BONE.

Hav'erstraw, N. Y., village in Rockland County; on the Haverstraw Bay, a part of the Hudson River, and on the West Shore and the New Jersey & N. Y. R.R.'s; about 30 miles north of New York and 35 miles south of West Point. The first settement was made by the Dutch, who established here, about 1710, a trading post. It became a precinct in 1719, but the town was not incorporated until 1854. A short distance north of the village of Haverstraw, and near West Haverstraw, is the "Old Treason House," the house owned in Revolutionary days by Thomas H. Smith, and the place where Arnold and André met in September 1780, and made all arrangements for the surrender of West Point. Except the addition of a wing, the house is to-day about as it was when Arnold visited it. From the room in which the final arrangements were made, may be seen the Hudson and the opposite shore along which André journeyed toward Tarrytown. The "Haverstraw Community" was organized in Haverstraw in 1825, but remained in existence as a community only a few years. The chief industry of the village is brickmaking. Other manufactures are dynamite, baskets and brickmaking machinery. The village has an excellent high school and a public library. Pop. (1900) 5,935.

Havestad, Bernard, German Jesuit and missionary: b. Cologne 1715; d. Munster 1778. In 1748 he was sent as a missionary to Chile, where he rapidly learned the native dialect. He traveled through the lesser known parts of the country, visiting the Araucanians, the Cuenches, the Huillichos, the Guaicurus, etc., and collected a great mass of interesting information on the customs, the natural productions, statistics, etc., of the region. On the expulsion of his order in 1768, he was arrested and conducted to Lima. He escaped death from shipwreck, and returned to Germany, where he published 'Chilidugu, sive Res Chilenses' (1777).

Havet, Ernest Auguste Eugène, French scholar and philosopher: b. Paris 11 April 1813; d. 1889. As a brilliant student, he received several educational appointments, and in 1840 was called to Paris as professor of Greek literature on the staff of the normal school. In 1855 he was appointed professor of Latin eloquence in the College de France. The chief of his many learned works is 'Christianisme et ses origines' (4 vols., 1871–84).

Hav'iland, John, American architect and engineer: b. England 15 Dec. 1792; d. Philadelphia 28 March 1852. He studied architecture with Elmes in London, subsequently went to Russia with a view of entering the imperial corps of engineers, and in 1816 emigrated to the United States. The Pittsburg penitentiary, one of his earliest works, introduced the radiating form of constructing prisons, which was extensively adopted in the United States and in Europe. Among the principal edifices built after his plans are the halls of justice, better known as the "Tombs" (q.v.), in New York, rebuilt in 1902; the United States naval asylum in Norfolk, Va.; the State penitentiaries of New Jersey, Rhode Island, and Missouri; the United States mint, and the deaf and dumb asylum in Philadelphia; the Pennsylvania insane hospital at Harrisburg, besides numerous churches.

Haviland, William, British soldier: b. Ireland 1739; d. 1784. He served in Ireland during the rebellion of 1845. During the years 1757–8 he fought under Abercromby at Ticonderoga, and also under Amherst. In 1760 he fought his way at the head of 34,000 men through the French lines at Lake Champlain to join Murray and Amherst, who were converging on Montreal. After the capture of Montreal he served in the West Indies and was present at the conquest of Havana in 1762. He was made general in 1783.

Havre, ä-vr, **Le,** France (formerly **Le Havre-de-Grace,** lä-vr-dė gräs), an important commercial and seaport town in the department of Seine-Inferieure, on the north side of the estuary of the Seine, 108 miles by rail northwest of Paris. The town, comparatively modern, is built of brick or stone, with regular, straight, wide and well-cleaned streets. The public buildings include the Church of Notre Dame, in bastard architecture, partly Gothic; the townhouse, formerly the governor's palace; the Palais de Justice; the round tower of Francis I.; the theatre, arsenal, exchange, library, and barracks. Havre has a large commerce, for which it possesses great advantages.

Its harbor is entered by a narrow channel, formed by two long jetties stretching from east to west, and kept clear by constant dredging. This channel leads to the outer harbor, an irregular expanse of no great extent, which is left dry at ebb-tide. Within the *avant port* are

capacious wet-docks, lined with fine quays and extensive warehouses. Havre commands the greater part of the import and export trade of Paris, and of the more important towns in the north of France; importing vast quantities of colonial and other produce, among which cotton holds a most important place; and exporting numerous articles of French manufacture. It is the second port in France, being exceeded only by Marseilles. The average annual tonnage arriving from foreign ports is about 2,260,000, the number of vessels being about 2,200. The manufactures consist of paper, starch, lace, oil, refined sugar, cables, and other marine cordage, sulphuric acid, earthen and stone-ware. There are also breweries, gun factories and electrical works. A government tobacco factory employs 300 workmen; and from the building-yards a great number of sailing vessels and steamers are annually fitted out. In the 15th century Havre became of importance to form a new harbor in consequence of the silting up of that of Harfleur. The project was conceived, and some progress made in it, by Louis XII.; but Havre continued little more than a fishing village till the time of Francis I., who erected numerous works, and at immense expense gained the greater part of the present site of the town from the sea. A citadel was afterward built; and Havre, as a place of strength, became the object of repeated contests between French and English. Pop. (1901) 130,196.

Havre de Grace, hăv'ĕr dē grās, Md., city in Harford County; on the Susquehanna River, near its entrance into Chesapeake Bay; and on the Philadelphia, W. & B. and the Baltimore & O. R.R.'s; about 36 miles east-northeast of Baltimore. It is the south terminus of the Tidewater canal. A small settlement was made here in about 1670. The chief manufactures are flour, sash, doors and blinds, lumber, and canned fruits. The fisheries, especially shad and herring, are important. The trade is principally in the manufactured articles, coal, and fish. A government fish hatchery is located on Battery Island. Pop. (1900) 3,423.

Haw, Battle of the, in the Revolution, 21 Feb. 1781. Henry Lee had been commissioned by Greene to prevent Tory reinforcements coming to Cornwallis, who had taken position at Hillsboro and ordered all good citizens to assist him; and in the course of the movement attempted to surprise Tarleton, whose body of troops was much like his own, with cavalry and infantry. Tarleton had moved; but hearing that about 400 Tories under Col. Pyle were on their way to join him, Lee determined to pass off his own "legion" as Tarleton's and capture them all. Forcing two captured British officers to keep up the deception, he moved forward, with Pickens' and Oldham's companies following, and met two young men who had been sent by Pyle to find Tarleton's camp; he was presented to them as Tarleton, and directed them to have Pyle's men drawn up beside the road while his "weary veterans" passed,—his object being to capture and disarm them all, sending them home unless they wished to join him. The plan succeeded perfectly till, just as he had taken Pyle's hand, part of the Tories discovered Pickens' militia and saw the trap, and at once fired on the American rear; the latter poured in a volley that killed 90 of the enemy at the first fire, and in the melée, despite appeals for quarter, a great number of the rest were killed and the majority wounded. Pyle escaped badly hurt, and the rest of the body dispersed unpursued.

Hawaii, a Territory of the United States; geographically the HAWAIIAN (formerly SANDWICH) ISLANDS, the northeasternmost group of the Pacific, lying in the Tropics (lat. 18° 54′ to 22° 15′ N., lon. 154° 50′ to 160° 30′ W.), 2,100 miles southwest of San Francisco (see HONOLULU for various distances). It consists of seven inhabited islands — Hawaii, Maui, Lanai, Molokai, Oahu, Kauai, and Niihau — and one recently deserted, Kahulaui, with 12 islet rocks and coral reefs visited for eggs and guano. They extend in a line 390 miles northwest from the largest, Hawaii, which contains 4,004 square miles of their total 6,538 (one third of the entire land area of Polynesia). The next, Maui, has 721.9; the third, Oahu, 597.8, is the richest per acre, and contains the capital and chief seaport, Honolulu. Pop. (1900) 153,727.

Topography.— The islands are entirely volcanic, the summits of eruptions from the ocean bed, which sinks from their shores to 3½ miles deep near by; and their surface is a mass of overlapping lava-flows. The volcanic action subsided from the northwest: the last but one southeast, Maui, still shows the vast extinct crater of Haleakala, 10,032 feet above sea-level, 30 miles in circumference, and 3,000 feet deep; and Hawaii, the last, composed largely of three great volcanoes,—one of them, Mauna Kea, 13,805 feet high, the loftiest peak in the Pacific, has one still active, in two places 16 miles apart. Kilauea, with an oval crater nine miles in circumference, 6,000 feet above the sea, is the largest active volcano in the world; and Mauna Loa is one of the largest, with a circular crater 8,000 feet in diameter, and nearly vertical walls 500 to 600 feet high on the inner side. The headlands of the islands are sometimes cliffs overhanging the water even to 2,000 feet high; but there are some plains between the mountains and the sea. The shores are mostly lined with coral reefs, which have to be cut through to make entrance for shipping. The only first-rate harbor is Pearl Harbor north of Honolulu, which, owing to the limitations of the latter, is likely to be utilized. The streams are merely mountain brooks.

Climate and Rainfall.— With thousands of miles of even-temperatured water all around it, the climate of Hawaii, though in the zone of warmth, is also equable and mild; the more calculable that it lies in the region of the northeast trade-winds, blowing nine to ten months in the year. These vapor-laden winds have their moisture precipitated by the huge mountain flanks, so that on the northeast coast there is rain sometimes to the amount of 150 to 200 inches a year; the slopes on that side are heavily forested and swampy, and contain enormous reservoirs of water in volcanic hollows; while the opposite sides are arid. From the different elevations and exposures of the islands, there is enormous variety in the conditions of the different islands, and even different elevations of the same plantation: Oahu averages 42 inches; Honolulu upon it, 19; Hawaii, 120, etc.; and one sugar plantation on a mountain side will have perhaps 80 inches at the top and 15 at the bottom.

Production and Industries.— Hawaiian manufactures, from the lack of coal and metals, are mainly confined to local implements and necessities and the making of sugar. The latter is practically the only manufacture for export, though the one cannery put up 6,200 cases last year. But of $24,992,662 total product in 1899–1900, though $1,107,030 in foundry work was turned out, and about $800,000 in rice and coffee cleaned and milled — nearly all for local use, as well as the carpentering, mason-work, carriages, clothing, etc. — $19,254,773 was in sugar, and $1,150,625 in fertilizers made from sugar dregs. The power for the sugar mills is obtained wholly from burning the bagasse or cane refuse; as no other sugar manufacture in the world can do as much, it makes the Hawaiian the most profitable of all — added to the fact that the juice goes so completely to sugar that no molasses is made, the remainder being thrown into fertilizer, and that the yield per acre is the greatest in the world. Only Japan and Cuba have a greater gross product — 720,553,357 pounds exported in the year ending 30 June 1902. Out of a total export of $24,793,735, only $873,622, or a trifle over 3½ per cent, was of other products than sugar. (These, in order of importance, were coffee, wool, hides and tallow, bananas and pineapples, and rice.) Hence the prosperity of the islands advances or declines with the price and market for this one article. In 1902, though the export increased nearly 30,000,000 pounds, the price had fallen off so that there was a money decrease of some $3,000,000. But the acreage of sugar plantations had risen from 66,673 to 78,618; and extensive irrigation systems are employed. On Oahu there are over 200 artesian wells, pumping 44,000,000 gallons a year; and on Hawaii and Maui flumes have been run from huge natural reservoirs in volcanic pits on the mountains, blasted out with dynamite. The future of the industry and the islands, however, is menaced by a peculiar cause: the apparent impossibility henceforward of obtaining cheap labor, a problem which political and social convictions in the United States at present make an *impasse*. The Hawaiian native will not work; the Anglo-Saxon and most Europeans are too expensive; and the earlier plantations were built up on Portuguese labor, imported from the Azores on three-year contracts. These expired, the Portuguese would not generally re-engage; the Polynesians experimented on were too much like Hawaiians; and then low-grade Japanese and Chinese were engaged — the latter for this purpose the ideal workman, all things considered. After the proclamation of the republic in 1894, the Japanese poured in, to the number of some 50,000 in the next six years. But with the annexation of the islands to the United States, its Chinese exclusion laws were made to apply also to Hawaii; and the treaty of this country with Japan in 1899 shut off that stream of immigration also within a year, almost entirely. Barred out from these supplies, the planters have taken to importing Porto Ricans, but cannot obtain enough. Meantime the older Chinese are dying off or re-emigrating; the planters have advanced wages, but even so the laborers, knowing that the masters dare not discharge them, grow lazy and insubordinate. The planters or their representatives have repeatedly petitioned the United States to allow the Chinese entrance as laborers, agreeing to deport them as soon as they cease to be such; but the act of 29 April 1902, extending specifically the exclusion act to all territory owned by the United States, is an answer that seemingly puts an end to hope.

Meantime steps are being taken to diversify the too limited products. Much of the area is occupied by mountain sides or barren lava-plains, and the rains have washed the soil largely from the upper levels, leaving it fit only for grazing ground. Of the 4,164,000 acres, only 2,600,613 in 1900 were in nominal farms: of these, 717,764 were forest land — a valuable asset, the koa-tree furnishing a beautiful cabinet-wood equal to mahogany, though the once famous sandalwoods are exterminated — 1,597,304 untouched natural grazing ground, and only 294,545 improved. But the coast-plains and valleys have an exceedingly deep rich soil, and under this temperate warmth and plentiful moisture an extraordinary variety of products is cultivable. The one specialty, however, has absorbed the foreign capital which alone can develop industries here; and it is one which demands large capital, while the smaller men have been checked from going into side industries by the slender local market, the same labor difficulties, and till recently the political uncertainty — now exchanged apparently for a much worse certainty. High-grade rice is raised to a great amount, but nearly all consumed by the Chinese on the island. Coffee of the best quality is grown, but not largely; tea is a successful experiment, but only such as yet. The Territorial Bureau of Agriculture and Forestry has introduced the hemp culture, but as yet there are slender returns; ramie or vegetable silk does well, but lacks suitable machinery. The castor-oil bean grows wild, and successful attempts have been made to cultivate it; it has produced as high as 275 gallons of oil an acre, worth 80 to 90 cents a gallon in San Francisco. Fruits and vegetables should have a large future. Bananas and pineapples are already exported; the alligator pear makes a delicious salad dressing, and the mango is valuable for chutney sauce. The orange, lemon, and lime, sour-sop and tamarind, and others, are also promising. A very important product for native use is the taro-root, out of which *poi* is made; and another is the *ti*, from which they make an intoxicating drink. The cattle and sheep raising on the upland pastures is increasingly absorbed in local use, though some hides and wool are exported. Honey and wax are also sent out.

Commerce.—The exports have already been mentioned. The imports are mainly of coal, machinery and hardware, lumber, clothing and its materials, and foodstuffs. Over three fourths are from the United States. In 1900, 665 vessels cleared from Hawaiian ports, aggregating 867,905 tons, against 386 with 447,997 tons in 1886.

Transportation.— For steamship lines, see Honolulu. There are about 150 miles of railroad on the islands, in three lines: the chief is the Oahu Railway and Land Company, out from Honolulu, the others on Hawaii and Maui. The three have also telegraph systems, and there is a cable between Hawaii and Oahu. The Marconi system was installed in 1901. Honolulu has telephones, and excellent electric street railways.

Finances.— The United States assumed the most of the Hawaiian debt on annexation. The remainder, on 1 Jan. 1903, was $939,970.31. The assessed valuation varies with the profits of the sugar industry, but was $121,172,929 in 1902, an increase from about $33,000,000 in 1892. The taxes are on real and personal property (limited to 1 per cent), a 2 per cent income tax, and internal revenue and customs dues. The total revenue is upward of $2,500,000 a year; the expenditures included $376,496.26 for schools, and $106,077.25 for judiciary.

Education.— There is a good free-school system, graded, with compulsory attendance from 6 to 15; and there are night, industrial, and high schools. The instruction is in English. Clergymen are ineligible for school commissioners. In 1902 there were 143 public schools, with 380 teachers and 17,518 pupils, and 54 private schools, with 229 teachers and 4,329 pupils. Of the teachers, 329 were American, 56 British, and 149 Hawaiian and mixed blood. The private schools are generally endowed, as Oahu College, or managed by religious orders, as St. Louis College (Catholic). The educational problem is complicated by the extraordinary mixture of races: there were 4,903 Hawaiian children, 2,869 half-breed, 4,124 Portuguese, 1,993 Japanese, 1,395 Chinese, 812 American, 596 Porto Rican, and 337 German.

Charitable Institutions.— The chief is the leper settlement, on a peninsula of Molokai; there are about 900 lepers here, but they are decreasing. Part of them are self-supporting (the settlement manages its own internal affairs), but the government maintains the rest.

Religion.— The Chinese and Japanese retain their own religions; the natives are nominally Christians, but little more than nominally, either in beliefs or morals. The Portuguese are Catholic; the rest of the Europeans and the Americans mainly Protestant. There are some 4,000 Mormons.

Population.— The United States estimates for 1890 and 1900 were as follows:

	1900	1890
Hawaiians	29,834	34,436
Part Hawaiians	7,835	6,186
Caucasians	28,533	21,300
Chinese	25,742	15,300
Japanese	61,122	12,360
Polynesians	407	409
Negroes	254	.....
Total	153,727	89,991

The actual returns in 1900 raise these figures to 154,001; males, 106,369; females, 47,632. The Caucasians consisted of 12,061 born in Hawaii, 4,068 in the United States, 12,357 in other countries, 6,512 being Portuguese. Of the islands, Hawaii had 46,843; Oahu (including the city of Honolulu, 39,306), 54,504; Maui, 25,416; Kauai and Niihau, 20,734; Molokai and Lanai, 2,504. The Hawaiian natives have steadily diminished. Cook in 1778 estimated them at 400,000, not now credited; the missionaries in 1823, 142,000; in 1872 (local census), 49,044; 1900, 29,834.

History.— The islands, though scatteringly seen by white men since 1542, were first discovered and made known as a group by Capt. James Cook in 1778, and named the Sandwich Islands. Their inhabitants were in the feudal stage of semi-civilization. In 1792 Vancouver brought them cattle and taught them ship-building; and early in the 19th century the American fur-ships from the Pacific coast started a great sandalwood trade with them, which furnished them firearms and enabled Kamehameha I. of Hawaii to conquer the other islands. He founded a dynasty only just ended. His widow abolished the heathen rites about 1820; and just then American missionaries introduced Christianity, the Ten Commandments being proclaimed 1825. In 1840 a constitution was granted; in 1846 feudalism was abolished; in 1852 a legislature and full suffrage established, again restricted by a royal proclamation in 1864. In 1872 the direct royal line became extinct. In 1874 Kalakaua was chosen king by the legislature; he headed a native reaction to restore heathenism, and in 1887 the civilized element forced him to sign a new constitution. He and his sister Liliuokalani intrigued to overturn it by violence, and were defeated. In 1891 Liliuokalani succeeded him, and bent her energies to abrogating the constitution and restoring heathen rites; in January 1893 the civilized party dethroned her, by aid of the United States minister, John L. Stevens, who placed the islands under the protection of the United States. President Harrison sent an annexation treaty to the Senate; President Cleveland withdrew it, and sent a commissioner, James H. Blount (q.v.), to the islands, on whose report negotiations were opened to restore the queen; but her own vindictiveness made it as impossible as it was on other grounds undesirable, and on 4 July 1894 Hawaii was proclaimed a republic with Sanford B. Dole President. Negotiations for annexation were renewed; on 7 July 1898 Congress passed a resolution in its favor, and on 12 August it became a part of the United States. On 14 June 1900 it was organized as a Territory, with S. B. Dole Governor. Its difficult political future is shown by the table of populations, though the situation is even worse: of 79,607 adult males in 1900, not above 10,000 or 12,000 are fit for suffrage.

Haweis, hois, **Hugh Reginald,** English author and Anglican clergyman: b. Egham, Surrey, 3 April 1839; d. London 29 Jan. 1901. He was graduated at Cambridge University, in 1859; served under Garibaldi at the siege of Capua and in 1860 became curate of Saint James' Church, Marylebone, London. Here began his striking and somewhat eccentric career as an educational theorist, who sometimes seemed in danger of sacrificing his professional pledges to secularism. His influence was rather that of an intellectualist than of a dogmatic teacher of Christianity, but his sane views of social and moral obligation, his sympathetic philanthropy, his rare literary gifts and powers of exposition did much to quicken the pulse of spiritual life in London and elsewhere. He often lectured at the Royal Institution, and was Lowell lecturer in Boston, Mass., in 1885. His versatile and discursive mind is reflected in the range of his works. He wrote: 'Music and Morals' (1871), which was widely circulated in America; 'American Humorists' (1883); 'Christ and Christianity' (1887); 'The Broad Church' (1891); 'Travel and Talk' (1897); 'Old Violins' (1898); etc.

Hawes' Shop, Cavalry Engagement Near. Gen. Grant had crossed to the south bank of

the North Anna, in Virginia, and finding Gen. Lee too strongly posted to be attacked, and his own army in a false and critical position, he withdrew, on the night of 26 May 1864, to the north bank, and moved down the north bank of the Pamunkey to turn Lee's right. Torbert's and Gregg's divisions of cavalry, under Sheridan, together with the Sixth corps, led the advance. Torbert crossed the Pamunkey at Hanover Ferry on the 27th, after considerable skirmishing in which he took about 60 prisoners, and the two cavalry divisions, supported by Russell's division of infantry, pushed on to Hanover Town and bivouacked for the night. On the morning of the 28th Sheridan was directed to make a demonstration and discover the enemy's position. Gregg's division, advancing on the Mechanicsville road, encountered the two cavalry divisions of Wade Hampton and Fitzhugh Lee and Butler's South Carolina cavalry brigade about a mile beyond Hawes' Shop. The Confederate cavalry was dismounted and had thrown up a barricade of rails covering the road. Gregg attacked, and there ensued one of the most severe cavalry engagements of the War, which continued several hours, neither side yielding ground. Finally, late in the day, Custer's brigade of Torbert's division came up, dismounted, took position in the centre of Gregg's line, formed in close column of attack, the whole line charged and, after a hard struggle at close quarters, the Confederates were driven from position and retreated upon their infantry at the Totopotomoy. Gregg's loss was 256 killed and wounded; the entire Union loss was 44 killed and 306 wounded. The Confederate loss is not known. Consult: 'Official Records,' Vol. XXXVI.; Humphreys, 'The Virginia Campaign of 1864–5'; The Century Company's 'Battles and Leaders of the Civil War,' Vol. IV.

E. A. Carman.

Hawesville, hâz'vĭl, Ky., city, county-seat of Hancock County; on the Ohio River, and on the Louisville, H. & S. T. L. railroad; about 65 miles above Evansville, Ind.; and 80 miles west by south from Louisville. It is situated in an agricultural and coal-mining region. Its chief manufactures are flour, lumber, and furniture. It has a number of tobacco factories or stemmeries, and its trade is chiefly in tobacco, coal, articles of home manufacture, and agricultural products. Pop. (1900) 1,041.

Haw'finch, one of the largest of European finches (*Coccothraustes vulgaris*), so called in England from the belief that it subsisted principally on the fruit of the hawthorn. It resembles the chaffinch in color, but is distinguished by its enormous beak and larger size. It feeds on all kinds of berries.

Hawk, a general name for diurnal birds of prey not eagles or vultures. See Falcon, and the names of various groups and species, as Hen-hawks, Sparrow-hawk and the like: also Falconry.

Hawk-moths, a family of large moths forming the family *Sphingidæ*. They have stout bodies, large heads with prominent eyes, and thick spindle-shaped antennæ, ending in a hook. The fore-wings are long, narrow, more or less pointed, and always much longer than the hind-wings. They are insects of rapid flight, and dart about in the twilight; some species also during the day. Their caterpillars are hairless, smooth, often green, with transverse stripes on the sides and nearly always a horn on the back of the second last segment, and always have ten prolegs. They are leaf-eaters and often greatly destructive to cultivated plants, the tomato-worm (q.v.) being a prominent example. They change to pupæ either on the surface of the ground or in a cell underground, but make no cocoon. Some of the South American species resemble humming-birds so closely, especially when poising before a flower on whirring wings and sucking its nectar, that they can hardly be distinguished, and popular belief asserts that the one is transmutable into the other. A great number of forms exist in all parts of the world, the United States having about 100 species. All are plainly dressed in grays and browns, and one of the most remarkable is the death's-head (q.v.).

Hawkbit, a genus (*Leontodon*) of composite plants closely related to the dandelion, from which they differ in having feathery pappus. The name is due to the peculiar shape of the lacerations of the leaves. Several species are natives of Europe and Russian Asia.

Hawke, Edward, Lord, English sailor: b. London 1705; d. Sunbury-on-Thames 17 Oct. 1781. Early in 1720 Hawke entered the navy and was appointed in 1733 to the command of the Wolf. Being promoted to the command of a squadron in 1847 he totally defeated the French fleet off Belle Isle. In 1759 he was sent in pursuit of the Brest fleet, which he came up with in Quiberon Bay, and signally defeated. He now received a pension of £2,000, and in 1768 became admiral of Great Britain and commander-in-chief of the fleet. From 1766 to 1771 he was first lord of the admiralty. In 1776 he was advanced to a seat in the House of Lords by the style of Baron Hawke of Towton.

Haw'ker, Mary Elizabeth, English novelist: b. 1865. Under the pseudonym of "Lanoe Falconer" she has written the well known novel 'Mademoiselle Ixe' (1890); which was followed by 'The Hotel d'Angleterre' (1891) and 'Cecilia de Noel' (1891).

Hawkesbury, hâks'ber-ĭ, Canada, village in Prescott County, Ontario; on the Ottawa River, and a terminus of a branch of the Canada Atlantic Railway, 50 miles west of Montreal. It has ferry communication with Grenville, across the river. Its chief industrial establishments are flour mills, a woolen factory, and large saw and planing mills. It has an extensive lumber trade. Pop. (1901) 4,150.

Hawk'eye State, Iowa — so named after a famous Indian warrior.

Hawking. See Falconry.

Haw'kins, Anthony Hope, English novelist, known by the pen-name "Anthony Hope"; b. London 9 Feb. 1863. He was educated at Balliol College, Oxford, was admitted to the bar at the Middle Temple in 1887, and practised until 1894 on the London and Midland circuit. He contested South Bucks as a Liberal in 1892, but unsuccessfully. In 1894 he achieved a striking literary success with his 'Prisoner of Zenda,' with scene in an imaginary independent state of South Germany. Other books of his are: 'The Dolly Dialogues' (1894), cited as models of keen if somewhat shallow repartee;

'The Chronicles of Count Antonio' (1895); 'Rupert of Hentzau' (1898); and 'The Intrusions of Peggy' (1902).

Hawkins, Hamilton Smith, American military officer: b. South Carolina 1834. He entered the army in 1861, was made captain in the 6th infantry in 1863, and brevetted major in October 1865. In 1888 he became commandant at West Point, and in 1894 was promoted colonel. When war was declared against Spain (1898) he went to the front as a brigadier-general of volunteers. He led the desperate and now historic charge at San Juan, Cuba, 2 July 1898, and was made major-general of volunteers, 8 July 1898.

Haw'kinsville, Ga., village, county-seat of Pulaski County; on the Ocmulgee River, at the head of navigation, and on a branch of the Macon & B. railroad; about 48 miles south of Macon. It is situated in a fertile agricultural region. It has a cotton factory, cotton compresses, cotton gins, cottonseed-oil mills, barrel factories, carriage and wagon works. Its trade is chiefly in cotton, lumber, fruits, and vegetables. Pop. (1900) 2,103.

Hawksbeard, a perennial composite plant allied to hawkweed, but of the genus *Crepis,* about 150 species of which are known in the northern hemisphere. Several are European weeds which have become naturalized in the United States, and there are several native species. The flowers are dandelion-like and yellow or orange.

Hawksbill, a great marine turtle (*Chelone imbricata*) allied to the green turtle, but which has the plates of the shell overlapping; and these plates form the tortoise-shell (q.v.) of commerce. The flesh is not good for eating, but the eggs are good. The animal inhabits the Indian Ocean, the Pacific, and the warmer parts of the Atlantic. This is one of the sea-turtles called "caret," but that term belongs more properly to the loggerhead. See TURTLE.

Hawkweed, or **Rattlesnake Weed,** a genus (*Hieracium*) of composite plants with mottled, radical leaves, tall hairy stems and yellow or orange flowers. One species, the European orange hawkweed (*H. aurantiacum*) is frequently cultivated for the sake of its fine orange flowers. The name "hawkweed" in English, and various similar names in use among the peasants of continental Europe, are based on an ancient belief that birds of prey used the juice of the species to strengthen their vision. Several species grow numerously in the United States, where they are called "rattlesnake weeds" and are believed to be of value in curing the poison of snakes.

Hawk'wood, SIR **John de,** English soldier: b. Hedingham Sibil, Essex: d. Florence, Italy, 17 March 1394. He was styled by Hallam the first distinguished commander who had appeared in Europe since the destruction of the Roman Empire. It is said that he fought at Crécy and Poitiers, and for his bravery was knighted by Edward III. However that may be, in 1359 he was the leader of a troop of free lances, preying upon France and northern Italy. With this band, the "White Company," he served the Marquis of Montferrat, later the Republic of Pisa, and still later Florence, upon whose side he oftenest fought in the civil disturbances of Italy. As commander-in-chief he directed the successful war against Milan (1390-2). He was pensioned by the Florentines and entombed with great ceremony in the Duomo.

Haw'ley, Gideon, American missionary to the Indians: b. Stratfield, now Bridgeport, Conn., 5 Nov. 1727; d. Marshpee, Mass., 3 Oct. 1807. He was graduated at Yale College in 1749, and commenced his labors at Stockbridge in 1752, opening a school at that place, in which he instructed a number of Mohawk, Oneida, and Tuscarora families. In 1754, under the patronage of Sir William Johnson, he began a mission among the Iroquois, or Six Nations, on the Susquehanna River; but in 1756 was obliged by the disturbances of the French war to leave that region, when he became a chaplain in the army marching against Crown Point. The campaign being over, he re-engaged in his missionary work at Marshpee, where he was installed as pastor in 1758, and there passed the remainder of his life in his benevolent labors.

Hawley, Joseph, American statesman: b. Northampton, Mass., 1724; d. 10 March 1788. He was graduated at Yale College, and followed the profession of law at Northampton, in which he rose to eminence. At the time of the disputes between Great Britain and America, he took a prominent part in advocating the cause of the colonies. "We must fight," he wrote to the delegates of Massachusetts, "if we cannot otherwise rid ourselves of British taxation. The form of government enacted for us by the British parliament is evil against right, utterly intolerable to every man, who has any idea or feeling of right or liberty." He was several times elected a member of the council, but declined, preferring to enter the State legislature, of which he was a member 1764–6.

Hawley, Joseph Roswell, American politician and legislator: b. Stewartsville, N. C., 31 Oct. 1826; d. Washington, D. C., 17 March 1905. He was graduated at Hamilton College, Clinton, N. Y., 1847, and began the practice of law at Hartford, Conn., in 1850. The Republican party in Connecticut was organized in the office of the *Charter Oak,* of which he was the editor. He afterward became editor of the Hartford *Evening Post,* the new Republican paper. When the Civil War broke out he recruited the first company of volunteers raised in the State — Company A of the 1st Connecticut regiment — of which he took command. He saw service throughout the whole war and was mustered out in 1866 with the brevet rank of major-general. He was elected governor of Connecticut the same year. In 1872 he was elected to Congress; at the end of the term, 1879–81, was sent to the United States Senate, to which he was re-elected 1887, 1893, and 1899.

Hawley, Pa., borough in Wayne County; on the Lackawaxen River, and on the main line or branches of the Pennsylvania, the Delaware & H., and the Erie R. R.'s; about nine miles south-southeast of Honesdale. Its chief manufacturing establishments are a glass-factory, a glass-cutting factory and a silk-factory. In addition to its trade in home manufactures, it has an extensive coal trade, and ships a considerable quantity of farm products. Pop. 2,128.

Haworth, Adrian Hardy, English naturalist: b. at Hull in 1767; d. there 16 Jan. 1833. He was educated for the law, but did not

practice, devoting his time to entomology and botany. He was the founder of the Entomological Society of London, a member of the Linnæan Society, and the Hull Botanical Gardens were planned by him, and laid out under his direction. His collections were large and important and his works are still standard. He wrote: 'Observations on the Genus Mesembryanthemum' (1794); 'Prodromus Lepidopterorum Britannicorum' (1802); and 'Synopsis Plantarum Succulentarum' (1812); and many minor papers.

Haworth, hâ'wêrth, **Joseph,** American actor: b. Providence, R. I., 1855; d. 29 Aug. 1903. His first appearance was as a member of Ellsler's stock company at Cleveland, Ohio, and subsequently he supported Edwin Booth, Lawrence Barrett, and John McCullough. From 1883 he toured for several years as a star in 'The Bells,' 'The Leavenworth Case,' 'Hamlet,' and other productions; in 1896–8 was Macbeth to Modjeska's Lady Macbeth, and later Storm in Caine's 'Christian,' Vinicius in Stange's adaptation of Sienkiewicz's 'Quo Vadis,' and Cassius in the Mansfield presentation of 'Julius Cæsar.'

Hawser, a manila or wire rope used in mooring or towing boats, etc., over four or three inches in circumference respectively. The name is now usually applied to all large ropes, though formerly it signified ropes "hawser-laid," that is, with three "plain-laid," three-stranded ropes laid up left-handed, now usually called a cable-laid rope.

Hawthorn, or **White Thorn** (*Cratægus oxyacantha*), a small spiny European tree, rising sometimes to the height of 20 to 25 feet, much admired for the beauty of its foliage. The leaves are smooth, shining, more or less deeply lobed, and of a beautiful green color; the flowers are white, sometimes with a reddish tinge, disposed in corymbs, and possess an agreeable perfume. The species of *Cratægus* are about 50 in number, all shrubs or small trees, spiny, with red fruit resembling in miniature that of the apple, from which plant they are distinguished chiefly by their seeds, and are arranged with it in the family *Rosaceæ*. Fifteen species are recognized in North America. When young the hawthorn springs up rapidly, a shoot of a single year being sufficient for a walking-stick. It thus, if well pruned and kept down, quickly grows into a thick and intricately woven hedge.

Hawthorne, hâ'thôrn, **Julian,** American novelist and journalist, son of Nathaniel Hawthorne (q.v.): b. Boston, Mass., 22 June 1846. He was graduated from Harvard University in 1867 and afterward studied civil engineering in Dresden, but soon forsook this occupation for literature. His first successful story was 'Bressant' (1872), the forerunner of a long list of novels, of which may be particularized 'Garth' (1875); 'Sebastian Strome' (1884); 'Archibald Malmaison' (1884); 'A Fool of Nature' (1896). He has also published 'Saxon Studies' (1876); and 'Nathaniel Hawthorne and His Wife' (1885). His best work suggests more than one element that distinguishes his father's stories. There is a psychologic accent, the touch of mystery, and the avoidance of the stock properties of romance.

Hawthorne, Nathaniel, American novelist: b. Salem, Mass., 4 July 1804; d. Plymouth, N. H., 19 May 1864. The founder of the family in America was William Hathorne (as the name was then spelled), a typical Puritan and a public man of importance. John, his son, was a judge, one of those presiding over the witchcraft trials. Of Joseph in the next generation little is said, but Daniel, next in descent, followed the sea and commanded a privateer in the Revolution, while his son Nathaniel, father of the romancer, was also a sea captain. This pure New England descent gave a personal character to Hawthorne's presentations of New England life; when he writes of the strictness of the early Puritans, of the forests haunted by Indians, of the magnificence of the provincial days, of men high in the opinion of their townspeople, of the reaching out to far lands and exotic splendors, he is expressing the stored-up experience of his race. His father died when Nathaniel was but four and the little family lived a secluded life with his mother. He was a handsome boy and quite devoted to reading, by an early accident which for a time prevented outdoor games. His first school was with Dr. Worcester, the lexicographer. In 1818 his mother moved to Raymond, Maine, where her brother had bought land, and Hawthorne went to Bowdoin College. He entered college at the age of seventeen in the same class with Longfellow. In the class above him was Franklin Pierce, afterward 12th President of the United States. On being graduated in 1825 Hawthorne determined upon literature as a profession, but his first efforts were without success. 'Fanshawe' was published anonymously in 1828, and shorter tales and sketches were without importance. Little need be said of these earlier years save to note that they were full of reading and observation. In 1836 he edited in Boston the 'American Magazine for Useful and Entertaining Knowledge,' but gained little from it save an introduction to 'The Token,' in which his tales first came to be known. Returning to Salem he lived a very secluded life, seeing almost no one (rather a family trait), and devoted to his thoughts and imaginations. He was a strong and powerful man, of excellent health and, though silent, cheerful, and a delightful companion when he chose. But intellectually he was of a separated and individual type, having his own extravagances and powers and submitting to no companionship in influence. In 1837 appeared 'Twice Told Tales' in book form: in a preface written afterwards Hawthorne says that he was at this time "the obscurest man of letters in America." Gradually he began to be more widely received. In 1839 he became engaged to Miss Sophia Peabody, but was not married for some years. In 1838 he was appointed to a place in the Boston custom house, but found that he could not easily save time enough for literature and was not very sorry when the change of administration put him out of office. In 1841 was founded the socialistic community at Brook Farm: it seemed to Hawthorne that here was a chance for a union of intellectual and physical work, whereby he might make a suitable home for his future wife. It failed to fulfill his expectations and Hawthorne withdrew from the experiment. In 1842 he was married and moved with his wife to the Old Manse at Concord just above the historic

bridge. Here chiefly he wrote the 'Mosses of an Old Manse' (1846). In 1845 he published a second series of 'Twice Told Tales'; in this year also the family moved to Salem, where he had received the appointment of surveyor at the custom house. As before, official work was a hindrance to literature; not till 1849 when he lost his position could he work seriously. He used his new-found leisure in carrying out a theme that had been long in his mind and produced 'The Scarlet Letter' in 1850. This, the first of his longer novels, was received with enthusiasm and at once gave him a distinct place in literature. He now moved to Lenox, Mass., where he began on 'The House of Seven Gables,' which was published in 1851. He also wrote 'A Wonder-Book' here, which in its way has become as famous as his more important work. In Dec. 1851 he moved to West Newton, and shortly to Concord again, this time to the Wayside. At Newton he wrote 'The Blithedale Romance.' Having settled himself at Concord in the summer of 1852, his first literary work was to write the life of his college friend, Franklin Pierce, just nominated for the Presidency. This done he turned to 'Tanglewood Tales,' a volume not unlike the 'Wonder-Book.' In 1853 he was named consul to Liverpool: at first he declined the position, but finally resolved to take this opportunity to see something of Europe. He spent four years in England, and then a year in Italy. As before, he could write nothing while an official, and resigned in 1857 to go to Rome, where he passed the winter, and to Florence, where he received suggestions and ideas which gave him stimulus for literary work. The summer of 1858 he passed at Redcar, in Yorkshire, where he wrote 'The Marble Faun.' In June 1860 he sailed for America, where he returned to the Wayside. For a time he did little literary work: in 1863 he published 'Our Old Home,' a series of sketches of English life and planned a new novel, 'The Dolliver Romance,' also called 'Pansie.' But though he suffered from no disease his vitality seemed relaxed: some unfortunate accidents had a depressing effect, and in the midst of a carriage trip into the White Mountains with his old friend, Franklin Pierce, he died suddenly at Plymouth, N. H., early in the morning, 19 May 1864.

The works of Hawthorne consist of novels, short stories, tales for children, sketches of life and travel, and some miscellaneous pieces of a biographical or descriptive character. Besides these there were published after his death extracts from his notebooks. Of his novels 'The Scarlet Letter' is a story of old New England: it has a powerful moral idea at bottom, but it is equally strong in its presentation of life and character in the early days of Massachusetts. 'The House of Seven Gables' presents New England life of a later date: there is more of careful analysis and presentation of character and more description of life and manners, but less moral intensity. 'The Blithedale Romance' is less strong: Hawthorne seems hardly to grasp his subject. It makes the third in what may be called a series of romances presenting the molding currents of New England life: the first showing the factors of religion and sin, the second the forces of hereditary good and evil, and the third giving a picture of intellectual and emotional ferment in a society which had come from very different beginnings. 'Septimius Felton,' finished in the main but not published by Hawthorne, is a fantastic story dealing with the idea of immortality. It was put aside by Hawthorne when he began to write 'The Dolliver Romance,' of which he completed only the first chapters. 'Dr. Grimshaw's Secret' (published in 1882) is also not entirely finished. These three books represent a purpose that Hawthorne never carried out. He had presented New England life, with which the life of himself and his ancestry was so indissolubly connected, in three characteristic phases. He had traced New England history to its source. He now looked back across the ocean to the England he had learned to know, and thought of a tale that should bridge the gulf between the old world and the new. But the stories are all incomplete and should be read only by the student. The same thing may be said of 'Fanshawe,' which was published anonymously early in Hawthorne's life and later withdrawn from circulation. 'The Marble Faun' presents to us a conception of the old world at its oldest point. It is Hawthorne's most elaborate work, and if every one were familiar with the scenes so discursively described, would probably be more generally considered his best. Like the other novels its motive is based on the problem of evil, but we have not precisely atonement nor retribution, as in his first two novels. The story is one of development, a transformation of the soul through the overcoming of evil. The four novels constitute the foundation of Hawthorne's literary fame and character, but the collections of short stories do much to develop and complete the structure. They are of various kinds, as follows: (1) Sketches of current life or of history, as 'Rills from the Town Pump,' 'The Village Uncle,' 'Main Street,' 'Old News.' These are chiefly descriptive and have little story; there are about twenty of them. (2) Stories of old New England, as 'The Gray Champion,' 'The Gentle Boy,' 'Tales of the Province House.' These stories are often illustrative of some idea and so might find place in the next set. (3) Stories based upon some idea, as 'Ethan Brand,' which presents the idea of the unpardonable sin; 'The Minister's Black Veil,' the idea of the separation of each soul from its fellows; 'Young Goodman Brown,' the power of doubt in good and evil. These are the most characteristic of Hawthorne's short stories: there are about a dozen of them. (4) Somewhat different are the allegories, as 'The Great Stone Face,' 'Rappacini's Daughter,' 'The Great Carbuncle.' Here the figures are not examples or types, but symbols, although in no story is the allegory consistent. (5) There are also purely fantastic developments of some idea, as 'The New Adam and Eve,' 'The Christmas Banquet,' 'The Celestial Railroad.' These differ from the others in that there is an almost logical development of some fancy, as in case of the first the idea of a perfectly natural pair being suddenly introduced to all the conventionalities of our civilization. There are perhaps twenty of these fantasies. Hawthorne's stories from classical mythology, the 'Wonder-Book' and 'Tanglewood Tales,' belong to a special class of books, those in

which men of genius have retold stories of the past in forms suited to the present. The stories themselves are set in a piece of narrative and description which gives the atmosphere of the time of the writer, and the old legends are turned from stately myths not merely to children's stories, but to romantic fancies. Mr. Pringle in 'Tanglewood Fireside' comments on the idea: "Eustace," he says to the young college student who had been telling the stories to the children, "pray let me advise you never more to meddle with a classical myth. Your imagination is altogether Gothic and will inevitably Gothicize everything that you touch. The effect is like bedaubing a marble statue with paint. This giant, now! How can you have ventured to thrust his huge disproportioned mass among the seemly outlines of Grecian fable?" "I described the giant as he appeared to me," replied the student. "And, sir, if you would only bring your mind into such a relation to these fables as is necessary in order to remodel them, you would see at once that an old Greek has no more exclusive right to them than a modern Yankee has. They are the common property of the world and of all time" ('Wonder-Book,' p. 135). 'Grandfather's Chair' was also written primarily for children and gives narratives of New England history, joined together by a running comment and narrative from Grandfather, whose old chair had come to New England, not in the Mayflower, but with John Winthrop and the first settlers of Boston. 'Biographical Stories,' in a somewhat similar framework, tells of the lives of Franklin, Benjamin West and others. It should be noted of these books that Hawthorne's writings for children were always written with as much care and thought as his more serious work. 'Our Old Home' was the outcome of that less remembered side of Hawthorne's genius which was a master of the details of circumstance and surroundings. The notebooks give us this also, but the American notebook has also rather a peculiar interest in giving us many of Hawthorne's first ideas which were afterwards worked out into stories and sketches.

One element in Hawthorne's intellectual make-up was his interest in the observation of life and his power of description of scenes, manners and character. This is to be seen especially, as has been said, in his notebooks and in 'Our Old Home,' and in slightly modified form in the sketches noted above. These studies make up a considerable part of 'Twice Told Tales' and 'Mosses from an Old Manse,' and represent a side of Hawthorne's genius not always borne in mind. Had this interest been predominant in him we might have had in Hawthorne as great a novelist of our everyday life as James or Howells. In the 'House of Seven Gables' the power comes into full play: 100 pages hardly complete the descriptions of the simple occupations of a single uneventful day. In Hawthorne, however, this interest in the life around him was mingled with a great interest in history, as we may see, not only in the stories of old New England noted above, but in the descriptive passages of 'The Scarlet Letter.' Still we have not, even here, the special quality for which we know Hawthorne. Many great realists have written historical novels, for the same curiosity that absorbs one in the affairs of everyday may readily absorb one in the recreation of the past. In Hawthorne, however, was another element very different. His imagination often furnished him with conceptions having little connection with the actual circumstances of life. The fanciful developments of an idea noted above (5) have almost no relation to fact: they are "made up out of his own head." They are fantastic enough, but generally they are developments of some moral idea and a still more ideal development of such conceptions was not uncommon in Hawthorne. 'Rappacini's Daughter' is an allegory in which the idea is given a wholly imaginary setting, not resembling anything that Hawthorne had ever known from observation. These two elements sometimes appear in Hawthorne's work separate and distinct just as they did in his life: sometimes he secluded himself in his room, going out only after nightfall; sometimes he wandered through the country observing life and meeting with everybody. But neither of these elements alone produced anything great, probably because for anything great we need the whole man. The true Hawthorne was a combination of these two elements, with various others of personal character, and artistic ability that cannot be specified here. The most obvious combination between these two elements, so far as literature is concerned, between the fact of external life and the idea of inward imagination, is by a symbol. The symbolist sees in everyday facts a presentation of ideas. Hawthorne wrote a number of tales that are practically allegories: 'The Great Stone Face' uses facts with which Hawthorne was familiar, persons and scenes that he knew, for the presentation of a conception of the ideal. His novels, too, are full of symbolism. 'The Scarlet Letter' itself is a symbol and the rich clothing of Little Pearl, Alice's posies among the Seven Gables, the old musty house itself, are symbols, Zenobia's flower, Hilda's doves. But this is not the highest synthesis of power, as Hawthorne sometimes felt himself, as when he said of 'The Great Stone Face,' that the moral was too plain and manifest for a work of art. However much we may delight in symbolism it must be admitted that a symbol that represents an idea only by a fanciful connection will not bear the seriousness of analysis of which a moral idea must be capable. A scarlet letter A has no real connection with adultery, which begins with A and is a scarlet sin only to such as know certain languages and certain metaphors. So Hawthorne aimed at a higher combination of the powers of which he was quite aware, and found it in figures and situations in which great ideas are implicit. In his finest work we have, not the circumstance before the conception or the conception before the circumstance, as in allegory. We have the idea in the fact, as it is in life, the two inseparable. Hester Prynne's life does not merely present to us the idea that the breaking of a social law makes one a stranger to society with its advantages and disadvantages. Hester is the result of her breaking that law. The story of Donatello is not merely a way of conveying the idea that the soul which conquers evil, thereby grows strong in being and life. Donatello himself is such a soul growing and developing. We cannot get the idea without the fact, nor the fact without the idea.

This is the especial power of Hawthorne, the power of presenting truth implicit in life. Add to this his profound preoccupation with the problem of evil in this world, with its appearance, its disappearance, its metamorphoses, and we have a clue to Hawthorne's greatest works. In 'The Scarlet Letter,' 'The House of Seven Gables,' 'The Marble Faun,' 'Ethan Brand,' 'The Gray Champion,' the ideas cannot be separated from the personalities which express them. It is this which constitutes Hawthorne's lasting power in literature. His observation is interesting to those that care for the things that he describes, his fancy amuses, or charms or often stimulates our ideas. His short stories are interesting to a student of literature because they did much to give a definite character to a literary form which has since become of great importance. His novels are exquisite specimens of what he himself called the romance, in which the figures and scenes are laid in a world a little more poetic than that which makes up our daily surrounding. But Hawthorne's really great power lay in his ability to depict life so that we are made keenly aware of the dominating influence of moral motive and moral law.

Bibliography.—Hawthorne's life has been written by G. P. Lathrop (library edition of his works), by Henry James ('English Men of Letters'), and by Moncure D. Conway ('Great Writers' Series'). Consult also: 'Memorials of Hawthorne,' by Rose Hawthorne Lathrop. Criticism will be found in G. W. Curtis, 'Literary and Social Studies'; T. W. Higginson, 'Short Studies of American Authors'; Leslie Stephen, 'Hours in a Library'; W. D. Howells, 'My Literary Passions'; J. T. Fields, 'Yesterdays With Authors'; R. H. Hutton, 'Essays in Literary Criticism.'

Edward Everett Hale, Jr.,
Professor of English, Union College, Schenectady, N. Y.

Hawtrey, Charles Henry, English actor, playwright, and manager: b. Eton, 1858, son of Rev. John Hawtrey. He was educated at Rugby and Oxford, becoming an actor when he was twenty-three years old. His greatest success was in 'The Private Secretary,' adapted from Von Moser's 'Der Bibliothekar,' first produced in Cambridge in 1883, and played 844 consecutive times. Other plays in which he has been unusually successful are 'Jane,' 'Mr. Martin,' 'A Message from Mars,' and 'The Man from Blankley's.' With the last two plays he several times visited the United States. For several years he has controlled the Comedy and Avenue theaters in London.

Haxo's System, a style of fortification introduced by Baron François Nicolas Benoit Haxo, a French military engineer, employed by Napoleon and put in command at the siege of Antwerp in 1832. His casemated batteries have earthen parapets along their front, and their arches are mantled with earth. The apertures in front of the guns open into embrasures formed in an extension of the parapet at these points beyond its ordinary retired position. Being open in the rear the circulation of air obviates the inconvenience of confined smoke. This method of construction is now pretty generally adopted.

Hay, George, Scottish artist: b. Edinburgh. At 17 he entered the architectural profession, which he afterward abandoned for painting, and has been a prolific genre painter since he first attracted attention by his 'Barber's Shop in the Time of Elizabeth' (1863). Other works by him are: 'A Visit to the Spaewife' (1872); 'Caleb Balderston's Ruse' (1874); and 'A Scene at Chatsworth' (1899).

Hay, John, American statesman: b. Salem, Ind., 8 Oct. 1838; d. near Newbury, N. H., 1 July 1905. He was graduated from Brown University in 1858, and on leaving college entered the office of Abraham Lincoln in Springfield, Ill., to study law. In 1861 he was admitted to the bar, but did not practise, as in that same year he went with Lincoln to Washington as one of the President's private secretaries. During the Civil War period he was also Lincoln's adjutant and aide-de-camp, and served in the field for some time under Generals Hunter and Gillmore. He was brevetted lieutenant and lieutenant-colonel.

After the death of Lincoln he was made secretary of legation at Paris, remaining there till 1867, when he became *chargé d'affaires* at Vienna. After holding this post for a year he resigned and returned to the United States, but was sent almost immediately to Madrid as secretary of legation, where he remained till 1870.

During his service abroad he gained a valuable knowledge not only of the language and literature of the chief European nations, but also of foreign diplomacy and politics. On his return to the United States he took up journalism, was for a time on the editorial staff of the New York *Tribune*, and published, mostly in its columns, his 'Pike County Ballads.' After about five years of service on the *Tribune*, he married a daughter of Amasa Stone of Cleveland and went to that city to live. He devoted himself mainly to literary work, and occasionally took part in politics, writing and speaking in presidential campaigns. In 1879 he accepted an offer from President Hayes to become first assistant secretary of state under Mr. Evarts. He held this position till the end of the Hayes administration in March 1881; then he took charge of the *Tribune* during Whitelaw Reid's absence in Europe, and conducted it with marked success through the trying period of Garfield's assassination and death.

In March 1897 President McKinley appointed him United States minister to England, and the selection was declared by all without distinction of party, to be most suitable. In London he was well received, and did much to bring about friendly understanding between England and the United States. His London experience was also most valuable training for the important position to which he was appointed in August 1898, when he became secretary of state. Very few of those who had been at the head of the State Department had dealt with so many important questions as Secretary Hay, and probably none had been more thoroughly trained diplomats. At the time of the Boxer outbreak in China, he was successful in obtaining justice for the Chinese, and preserving the integrity of the Chinese Empire. in 1899 he directed the United States ambassadors at London, Berlin, St. Petersburg, and Paris to propose that each of these governments make a declaration in favor

of the "open door" policy in China. They were invited to give assurances: first, that there would be no interference with any treaty port or vested interest; second, that the existing Chinese customs tariff would be continued without discrimination and administered by Chinese officials; third, that there would be no discrimination in harbor dues and railroad rates. Italy and Japan were afterward included in the negotiations. No treaties were exchanged, but all the governments approached pledged themselves by definite promises to the "open door" policy. He also negotiated and signed the Hay-Pauncefote treaty (q.v.), and several reciprocity treaties, including one with Cuba; gave support to The Hague Conference (q.v.), and induced the Powers demanding indemnity from Venezuela to refer the question to The Hague tribunal; and, in 1903, signed within forty-eight hours of each other a treaty with the Colombian government granting right of way for the Panama canal, and a treaty with Great Britain providing for the submission of the Alaskan boundary question to arbitration. During McKinley's first administration, also, Secretary Hay's position was of peculiar significance, because, owing to the death of Vice-President Hobart, Hay would have become McKinley's successor had the President died or resigned before the end of the term.

Secretary Hay was known as an author also, his publications including 'Pike County Ballads' (1871) and other poems; 'Castilian Days,' one of the best books on Spain in the English language, and 'Life of Abraham Lincoln' (1890), written in collaboration with J. G. Nicolay (q.v.), and ranking as the most comprehensive and authoritative biography of Lincoln.

Hay-Pauncefote Treaty, signed 18 Nov. 1901, which replaced the Clayton-Bulwer Treaty (q.v.) as an Anglo-American agreement of policy regarding an isthmian canal, then supposed to be fixed as across Nicaragua. It was drawn up by John Hay, secretary of state, and Sir Julian Pauncefote, ambassador from Great Britain. Public feeling for some years had been growing so sore over the Clayton-Bulwer Treaty's restriction on the independent action of the United States, that there was grave fear lest Congress might abrogate it by open violence, a great blow to future amicable action. President McKinley voiced the feeling by the declaration, in his annual message for 1898, that the canal had become a national necessity. Fresh negotiations were opened with Great Britain; that country had no wish beyond that of neutralizing the canal, and sent one of her best diplomats with very liberal instructions, to concede whatever did not nullify that essential principle. The draft treaty was sent to the Senate by the President 5 Feb. 1900. It provided that a canal might be constructed by the United States, or under its direction; should be permanently neutralized on the basis of the Suez Canal agreement — to be kept open at all times, either of war or peace, to all vessels, without discrimination, and no fortifications to be constructed commanding the canal or the waters adjacent, and that other powers should be invited to join in this guaranty of neutrality. The provisions excited intense hostility, and Senator Davis offered an amendment adopted by the committee on foreign affairs, canceling the very features for which it was drawn up, and which made the spirit of the previous one. It provided that the neutralization clause should not prevent the United States from any measures it thought needful for its own defense or the preservation of order, declared the Clayton-Bulwer Treaty specifically abrogated, and struck out the third clause inviting the concurrence of other powers. In this form it was ratified by the Senate 20 Dec. 1900, but Great Britain refused to accept the transformed treaty, and it expired by limitation on 5 March 1901. Undiscouraged, the two diplomats set to work on a compromise, which was signed by them 18 Nov. 1901, sent to the Senate by President Roosevelt, and ratified by them 16 December. The chief differences were in dropping as far as possible all specific guaranties, requirements, or prohibitions, leaving its interpretation and application to the chapter of fate and the certainty that the strong hand would decide in any event. The neutrality of the canal is not guaranteed at all except by the terms of the agreement, the Clayton-Bulwer Treaty is abrogated by name, and the United States is not forbidden to construct fortifications, nor required to keep the canal open in time of war.

Hay, or Forage, the stems and leaves of grasses and other plants cut for fodder and dried in the sun. In haymaking the object of the farmer is to preserve the hay for winter use in the condition most nearly resembling the grass in its natural state. Of the various ingredients which compose grass, those portions which are immediately soluble in water are the most fitted for the purposes of nutrition; and therefore the mowing should be done when the plants contain the largest amount of sugar and other soluble matter. During the latter part of the process of fructification, when the seeds have arrived at maturity, the stem and leaves begin to decay; so that if the grass is not cut when in flower, a great amount of nutriment will be wasted. On the third day after mowing, if the weather is fine, the newly-made hay will be ready for gathering into large windrows for carrying and stacking; but otherwise it will have to be put up into large cocks, and the carrying deferred until the next day. It is not desirable that grass should be too rapidly made into hay under a burning sun, as it is liable to scorch and lose its nutritive value. Great care must also be taken to preserve the hay from dew and rain, as water washes away the soluble salts and other matters, and when in the stack will cause fermentation, which, if excessive, destroys some of the most valuable properties of the hay. Some farmers salt their hay in stacking; others do not. Salt is generally commended. A good plan, when the hay harvest has been accompanied by wet weather, is to place a few layers of straw in the stack at intervals to absorb the moisture from the heating hay. On large farms the spreading out of the hay after it is cut down is performed by a haymaking machine drawn by a horse, which will do the work of twelve or fifteen haymakers, and distribute the grass more thinly and evenly as it crosses the field. It is only for the haymaking of the true grasses, however, that it is adapted, as clover must not be shaken so violently. To be transported to markets at a distance, hay is now compactly pressed into bales by presses worked by hand or power. In fact baled hay has increased the importance of haymaking, owing to the readiness with which it can be transported by

rail or water. On the Pacific Coast, especially in California, hay cut from alfalfa grass is very productive and profitable, and as many as three crops a year are frequently obtained. In the United States 61,691,166 acres of land were utilized in cultivating hay and forage in 1900, the entire crop amounting to 84,011,299 tons, valued at $484,256,846.

The average value per acre of the hay and forage crop is $8. Included in the above estimate were 4,759,353 tons of cornstalks which were cut from fields cultivated mainly for the grain. These figures for 1900 show an increase in area since 1889 of 8,742,369 acres, or 16.5 per cent, and in production of 12,420,466 tons or 18.6 per cent.

Of this total area, 6.7 per cent was devoted to clover, 50.7 per cent to tame and cultivated grasses other than clover, 6.3 per cent to grains cut green for hay, 5.1 per cent to forage crops, 3.4 per cent to alfalfa or lucerne, 2.8 per cent to millet and Hungarian grasses, and 25.1 per cent to wild, salt, and prairie grasses.

The North Central division contained 57.8 per cent of the total hay and forage acreage of the country, the North Atlantic 21.0 per cent, the Western 11.4 per cent, the South Atlantic 3.5 per cent, and the South Central 6.3 per cent.

The rate of increase in area devoted to hay and forage since 1889 was greatest in the South Central division, being 103.0 per cent. The Western division shows an increase of 91.4 per cent, the South Atlantic of 12.2 per cent, and the North Central of 10.7 per cent. The North Atlantic division shows a decrease of 2.2 per cent.

The total value of the hay and forage crop of 1900 averaged $135 per farm. The average yield per acre, exclusive of cornstalks, was 1.28 tons, and the average value per ton $6.11. The average yield per acre of the various classes was as follows: Forage crops, 2.62 tons; alfalfa, or lucerne, 2.49 tons; millet and Hungarian grasses, 1.64 tons; grains cut green for hay, 1.28 tons; clover, 1.26 tons; tame grasses other than clover, 1.14 tons; and wild, salt, and prairie grasses, 1.12 tons. In 1902, the United States exported hay to the value of $2,580,622.

Hay Fever, a nervous affection of the mucous membranes of the eyes, nose, mouth, pharynx, larynx, and bronchi, characterized by a profuse flow of secretion from the nose, and of tears from the eyes, and accompanied in some cases by asthma. It is induced by the inhalation of the pollen of the *Gramineæ,* is prevalent during the hay season, but subsides at its close, and varies in its severity according to certain atmospheric conditions and the amount of pollen in the air. The occurrence of catarrhal symptoms in summer separates it from an ordinary "cold in the head"; while their combination with difficulty of breathing prevents it being mistaken for spasmodic asthma, in which there is seldom any catarrh. There are three combining causes of this affection, which is largely nervous: First, a predisposing cause in some nervous disease, with a probable lesion in the fourth ventricle of the brain. Second, deformity, such as a deviating septum, in the nasal region. Third, inhalation of a special pollen. Removal to the seashore or the mountains is beneficial in some cases. Arsenic, iodides, bromides, and other nerve specifics benefit others. For the asthma, iodide of potash, 5 grains with 5 minims of tincture of belladonna in syrup of orange-peel should be taken every two hours. Inhalations of nitre-paper, stramonium leaves, etc., with wine of cocoa internally, are also useful.

These remedies are, however, merely palliative, and scientific men have been for some time making investigations which may eventually lead to the discovery of a radical cure.

Prof. Dunbar, of Hamburg, who has been studying the subject for seven years, is one of those who hold out the hope of curing hay fever by a rational treatment.

According to him, the disease is caused by the pollen of grasses, but not by mechanical irritation. He has extracted from the pollen a poison, or toxin, which is insoluble in ether and alcohol, but soluble in water and weak saline solutions, tears, the mucus of the nose and the serum of blood. A solution of this toxin dropped into the eye or nose at once produces the characteristic symptoms of hay fever. The same symptoms in an aggravated form occur when the solution is injected hypodermically.

This discovery suggested treatment by the serum method and Dr. Dunbar set to work to produce a curative serum by inoculating animals with pollen toxin, and a serum was eventually obtained which, when dropped into the eye or nose together with pollen toxin, completely prevented the attack which the latter alone would have caused.

Experiments looking to the cure of the disease began in the latter part of January of 1903, and there is good reason to believe that the disease can be checked in its earliest stage by applying the serum to the external mucous surfaces. Hypodermic injection of the serum would probably be necessary if considerable quantities of pollen toxin had already passed into the blood.

It is noteworthy that rye, barley, wheat, rice, maize, and every kind of grain and grass which Dr. Dunbar has investigated yield a toxin which causes hay fever, while, on the other hand, he has not succeeded in obtaining such a toxin from any plant not of the grass family (*Gramineæ*).

Hay River, a stream which rises in the Rocky Mountains in Athabasca, Canada, and flows northeast into Great Slave Lake. It is navigable for about 140 miles from its mouth; its entire length is about 360 miles. The two Alexandra Falls (named after Princess Alexandra, now Queen Alexandra of England) are found in the upper course; they average about 250 feet in height and 900 feet in width.

Hay-worm, the caterpillar of a medium-sized pyralid moth (*Pyralis costalis*), injurious to clover hay, and to other hay when mixed with clover. Its depredations can be prevented by keeping the hay dry and well ventilated, as the insect preferably breeds in moist or matted material such as is to be found in the lower parts of stacks; here the hay becomes filled with webbings of the "worms" and their excrement, rendering it unfit for feeding. The webbed material should be burned, and the place thoroughly cleaned.

Hay'den, Ferdinand Vendeveer, American geologist: b. Westfield, Mass., 7 Sept. 1829; d. 22 Dec. 1887. He was graduated from Oberlin College, Ohio, studied at the Albany Medical College, and during the greater part of 1853–62 was employed in surveys in the northwest. He

served as surgeon in the Union army during the Civil War, and was professor of mineralogy and geology in the University of Pennsylvania 1865–72. In 1867–9 he made a geological survey of Nebraska, and was afterward director of the geological survey of the Territories of the United States, until in 1879 the various national surveys were combined in the geological survey of the United States. Till 1886 he remained at the head of the Montana division. He published many papers, besides numerous and valuable government reports, and was a member of many scientific societies at home and abroad.

Haydn, hā'dn (Ger. hī'dn), **Franz Joseph,** Austrian musical composer: b. Rohau, on the borders of Hungary and Lower Austria, 31 March 1732; d. Vienna 31 May 1809. He was sent to school at Hamburg at 6, where he learned reading, writing, singing by note, and to play on such instruments as his childish strength would admit of his handling. His voice attracted the notice of the parish priest, who recommended him as a choir-boy to the chapel-master of St. Stephen's in Vienna, and at 8 Haydn was received into the choir. With exception of some Latin and much practical music he seems here to have been taught nothing; in the theory and science of the art he received but two lessons from his master in eight years. At last in his 16th year, his voice began to break, and he lost his place and took up his abode in an attic in the Austrian capital, intending to live by his art. At that time the first six sonatas of Emmanuel Bach fell into his hands. "I could not leave my instrument," he said in his old age, "until I had played them through; and any one who knows me must perceive how much I owe to Emmanuel Bach, that I studied him carefully, and comprehended him." After a time he became acquainted with Metastasio, the greatest operatic librettist of the time. The poet had charge of the education of a Signora Martinez, and Haydn was employed to give her elemenary instructions in music. This afforded him an opportunity for mastering Italian, and what was of more immediate importance, procured him board and lodging. Metastasio introduced the struggling young artist to Porpora, a celebrated Italian musician, then in Vienna. As Porpora's accompanist he attracted the attention of Gluck and other masters, and his prospects from this time onward grew steadily brighter. He was often engaged to play at the musical entertainments given by the Austrian nobles, was appointed organist of two churches, sang tenor parts in the choir of another, and pupils became rapidly more numerous. He wrote a short comic opera, 'Der hinkende Teufel' (The Limping Devil), which was given three nights with applause, but owing to the satirical character of the libretto was forbidden by the police. Having now the means, Haydn purchased and studied the theoretical works of Emmanuel Bach, Mattheson, and Fux. In 1759 Count Morzin engaged him as music composer and director at a salary of 200 florins, with free lodgings and table with his secretaries and other officials. In 1761 he was appointed "chapel-master" or musical director to Prince Nicholas Esterhazy, in whose service he remained 30 years. Anything like a catalogue of his compositions during this time is impossible; much was destroyed on three separate occasions when his house was burned down, and much was scattered; but we know of 163 pieces for the baryton, an obsolete instrument in size between the viola and the violoncello; about 120 symphonies for full orchestra; more than 100 works of chamber music of the higher forms; and 12 Italian operas performed in his patron's private theatre. On the death of Esterhazy, in 1790, Haydn visited London, where the musical world received him with the greatest enthusiasm, and where he stayed 18 months. Here he produced an opera, the 'Orfeo,' nine symphonies, six quartettes, 11 sonatas, several songs and canzonets, and the accompaniments to more than 100 Scotch songs. He visited London a second time in 1794, his stay lasting a like period, and on his return to Vienna set about composing the music of an oratorio, the 'Creation,' the words adapted by Linley from Milton's 'Paradise Lost.' Haydn thought the text too long, and being not thoroughly acquainted with English, had it translated and curtailed by Baron von Swieten. It was produced 19 March 1799, when its author was in his 66th year. It obtained a great success, and he was induced to undertake the music of another text prepared from Thomson's 'Seasons.' This work wants the freshness and vigor of the previous work; which may have resulted in some measure from the barren unpoetical text. Consult: Pohl, 'Joseph Haydn' (1875); 'Mozart and Haydn in London' (1867); Karajan, 'Joseph Haydn in London' (1861); Reissmann, 'Joseph Haydn' (1879).

Haydn, hā'dn, **Hiram Collins,** American clergyman: b. Pompey, N. Y., 11 Dec. 1831. He was graduated from Amherst in 1856, from the Union Theological Seminary in 1859, held pastorates at Meriden, Conn., and Painesville, Ohio, was pastor of the First Congregational Church of Cleveland, Ohio, in 1874–80 and again from 1884. He was also president of Western Reserve University in 1888–90, and published 'Lay Effort'; 'Death and Beyond'; 'The Bible and Current Thought'; 'The Face Angelic,' and other works.

Haydon, hā'dŏn, **Benjamin Robert,** English painter: b. Plymouth 26 Jan. 1786; d. London 22 June 1846. He had a passion for great historical subjects, and covered immense areas of canvas, but seldom rose beyond mediocrity excepting by exaggeration. His work was, however, admired by many of his contemporaries, including the poet Keats. Among his pictures may be mentioned: 'Judgment of Solomon' (1814); 'Christ's Entry into Jerusalem' (1820), now in Philadelphia; 'The Raising of Lazarus'; 'The Mock Election in the King's Bench'; 'Napoleon at St. Helena'; 'Alexander and Bucephalus'; 'Alfred and the Trial by Jury'; 'Uriel and Satan'; 'The Burning of Rome.' See Life by Taylor (1853).

Hayes, Augustus Allen, American chemist: b. Windsor, Vt., 1806; d. Brookline, Mass., 21 June 1882. He began his studies under Dana, and was successful throughout his career in improving the resources of applied chemistry to a remarkable extent. He was the first to extract the alkaloid sanguinarin from the blood root, *Sanguinaria Canadensis.* He also improved the common method of reducing pig to malleable iron and discovered new processes in copper-smelting. His researches led him also to a new

formula for the production of chloroform. He was for many years employed by the State of Massachusetts as assayer.

Hayes, Isaac Israel, American arctic explorer: b. Chester County, Pa., 5 March 1832; d. 17 Dec. 1881. He was graduated in medicine at the University of Pennsylvania in 1832, and began his arctic experiences as surgeon in the second Grinnell expedition sent out under Captain Kane in 1853, in search of Franklin. Becoming convinced of the existence of an open polar sea, he was enabled to obtain funds for the expedition on which he sailed in the ship United States from Boston in 1860. He had two astronomers on board and according to their observations reached lat. 81° 35′ N., lon. 70° 30′ W., the farthest point north hitherto recorded in any voyage. In 1869 he made a voyage to Greenland. He received gold medals from the geographical societies of Paris and London. His published works comprise 'An Arctic Boat Journey' (1860); 'The Open Polar Sea' (1867); 'Cast Away in the Cold' (1868); and 'The Land of Desolation' (1872).

Hayes, Rutherford Birchard, 19th President of the United States: b. Delaware, Ohio, 4 Oct. 1822; d. Fremont, Ohio, 17 Jan. 1893. His early education was obtained in the common schools of Fremont and the academy at Norwalk, Ohio. At 16 he entered Kenyon College, from which he was graduated in 1842 as the valedictorian of his class. In 1843, he entered the law school of Harvard University and completed the course in 1845. He was admitted to the bar at Marietta, Ohio, and opened an office at Fremont; but, his health failing, he was compelled to go South, establishing himself later at Cincinnati (1849). His ability and industry soon gained recognition and secured him an excellent practice. He was city solicitor of Cincinnati from 1858 until April 1861, an office which brought him prominently before the people.

Hayes' military career began at the outbreak of the Civil War, when he was elected captain of a company formed from the old Literary Club of Cincinnati. A few months later, June 1861, he was appointed major in the 23d Ohio Volunteer Infantry, of which W. S. Rosecrans was colonel and Stanley Mathews, lieutenant-colonel. After the promotion and transfer of these two officers, the regiment was put under his command, and ordered at once to West Virginia; it took part in all of the important battles of Sheridan's campaign. In the battle of South Mountain he was severely wounded in the arm but soon recovered and returned to duty again. At the battle of Winchester, he made the famous charge across the swamp and saved the day. Many fell in that charge, but the day was won. He was no less courageous at Fisher's Hill and Cedar Creek. For meritorious service he was promoted to the rank of brigadier-general of volunteers and later brevetted major-general. He was nominated for Congress in his home district at Cincinnati, and in the fall of 1864, elected by a majority of 2,400; in 1866 he was re-elected. In 1867 he was nominated for governor of Ohio, by the Republicans; at that time a strong reaction against many of the policies of this party was felt in several States of the North, and the party itself in Ohio was divided into two factions. Hayes was one of the few men who could unite these factions, and he was elected by a small majority; and again chosen governor in 1869. At the close of his second term, he returned to Cincinnati determined to retire from public life; and in 1873 he moved to his old home at Fremont. In 1875, however, he was nominated for governor, and was with difficulty induced to accept the nomination. The great issue of the campaign was the money question, which though properly a national issue had been forced into State politics. There were those who believed and publicly contended that all that was needed to make money was the stamp of the government of the United States, that it was not necessary to have back of it any intrinsic value. Hayes, however, stood for "sound money," and after an active campaign won the election, thus becoming governor of Ohio for a third time.

When the National Republican Convention met at Cincinnati in 1876, a number of prominent leaders were candidates for the presidency. It soon became evident that none of the recognized candidates could be nominated and a "dark horse" was looked for. Thus it happened that Governor Hayes was nominated on the seventh ballot. The campaign which followed proved to be one of the most hotly contested in the history of the nation. The results were uncertain, and for the first time in our national life, a commission was created to pass upon the validity of the certificates which had been returned by the different States. This commission refused to go behind the returns of the different governors; and the votes of the Republican electors were therefore admitted from all of the doubtful States. This gave Mr. Hayes a majority of one in the electoral college, and he became the nineteenth President of the United States. (See ELECTORAL COMMISSION.) Two things were uppermost in his mind: the one, the improvement of the political condition of the South; the other, "the restoration of the civil service to the system established by Washington and followed by the early Presidents." In both of these, he was opposed by the machine politicians of his own party. In spite of this opposition, however, the troops were gradually withdrawn from the South and self-government re-established; the people were slow to see the need of civil service reform, and without effective support, the President could do little. He preserved his attitude in regard to sound money, and by his veto prevented dangerous financial legislation.

At the close of his administration, Mr. Hayes returned to private life. His interest in education was shown by the work done as a member of the boards of trustees of the Ohio Wesleyan University at Delaware and the Ohio State University at Columbus. Hayes' Hall at the latter institution bears his name because of his devotion to the cause of manual training. He was also president of the John F. Slater Educational Fund and gave much time to its proper distribution. As president of the National Prison Reform Association he did much to educate the public to a more humane way of thinking about the treatment of convicts, many of his public utterances have become maxims in prison management, and his work along these lines has been exceedingly valuable and permanent in its results.

Hayes River, called Hill River in the upper part of its course, rises near Lake Winnipeg, in Canada, and flows northeast through

RUTHERFORD BIRCHARD HAYES,

NINETEENTH PRESIDENT OF THE UNITED STATES.

Oxford or Holy Lake, Knee Lake, and several other lakes, into James Bay, near the mouth of the Nelson River. The largest tributaries are the Shamattawa and the Fox. The length of the Hayes is about 300 miles.

Hayesine, hā'zĭn, a hydrous borate of calcium, occurring as a sediment consisting of snowy-white, silky flakes, in the waters of hot springs in Chile. It is a somewhat uncertain species, and is perhaps to be referred in part to bechilite, and in part to ulexite. In the United States, specimens are reported from Bergen Hill, N. J. (Named in honor of A. A. Hayes (q.v.), an American chemist.)

Hay'good, Atticus Green, American Methodist bishop: b. Watkinsville, Ga., 19 Nov. 1839; d. Oxford, Ga., 19 Jan. 1896. He was educated at Emory College, Ga., of which he was president 1876–90, becoming in the last named year bishop of the Methodist Church South. He became bishop in 1890. He wrote: 'The Monk and the Prince,' a study of Savonarola and Lorenzo de Medici; 'Our Brother in Black' (1881); 'Pleas for Progress' (1889); etc.

Hay'market Square Massacre, the murder of several policemen in Chicago, 4 May 1886, by a bomb thrown by an anarchist. The labor troubles had long been exploited by the "practical" anarchists (with whom the philosophic anarchists disclaim connection), who denounced the efforts for shorter hours and better wages as tending merely to aggravate capitalistic slavery, and urged instead the general seizure of property and the murder of its owners. In February 1886 the McCormick Reaper Works had been closed on account of a demand for the expulsion of some non-union men, but had reopened. Meantime a great eight-hour strike had left some 50,000 unemployed workmen in the city, and in view of an almost certain conflict with the police, George Engel proposed at a meeting in Bohemian Hall on 2 May, and the meeting indorsed, a plan to blow up the police stations, shoot the emerging police, cut the telegraph wires, fire buildings to engross the service of the fire department, and make a general jail delivery, that the prisoners might aid in a social revolution. The next day August Spies and others incited a meeting of the Lumber-shovers' Union, 16,000 or more, principally Germans and Bohemians, to assail the McCormick Works in order to furnish an opportunity for carrying out this plan, though the works had no connection with this union. The mob attacked the works with stones and revolvers, but were driven off. No one was fatally injured, but Spies immediately issued a circular headed "Revenge!" asserting that six workingmen had been killed, and calling their brethren to arms. He also published a fierce article in his paper, the *Arbeiter Zeitung*, repeating the falsehood, and declaring that there had been a "massacre" to terrorize the workingmen, who should have had dynamite bombs instead of stones. In the evening a meeting was held at Greif's Hall, at which Engel's plan was adopted. Spies, Albert R. Parsons, Samuel Fielden, and Oscar W. Neebe spoke for a mass-meeting to further the plan above mentioned; at Adolf Fischer's suggestion it was fixed for next evening in Haymarket Square, that the dusk and the room for a great crowd might furnish more confusion and better means of escape. Rudolph Schnaubelt wished to have all socialists in other cities notified, so that there might be a general revolution. The signal was to be "Ruhe" (Peace), which was printed in next afternoon's *Arbeiter Zeitung*. Meantime Louis Lingg and others worked all day preparing bombs, of which the newspaper office was found to be an arsenal, along with firearms, and with a confederate carried a satchel of them to a place where others helped themselves. The air was full of rumors of intended violence, and the mayor (Carter Harrison, Sr.) ordered the police to mix with the meeting, and disperse it if incendiary language were used, and 176 were concentrated at the nearest station. Spies and Parsons spoke first, but the mayor was in the crowd, and they used mild language, till his suspicions were lulled and he left. Then Fielden began a frenzied and bloodthirsty harangue, calling for the "extermination" of the capitalists. The crowd grew so wild that shortly after 10 the police in four divisions appeared and covered the street, and while Fielden was speaking, Capt. Ward ordered the crowd to disperse. Fielden called out "We are peaceable" (curiously like "Peace"), and a bomb was at once thrown into the midst of the police, which exploded and caused frightful carnage, killing or mortally wounding eight policemen and injuring a great number more. The mob instantly followed it up with a volley from rifles and revolvers, proving that they had been expecting the signal, but the police, with a nerve as fine as that of trained soldiers, at once rallied and charged the mob, dispersing it in disorder. Most of the leaders who had been urging destruction either did not attend or ran away. Of the police, besides those killed, 68 were wounded by shot or bombs, many maimed for life. Spies, Parsons, Fischer, Engel, Lingg, Fielden, Michael Schwab, and Neebe were arrested and tried as accessories before the fact: the first four were hanged 11 Nov. 1887; Lingg shattered his jaw in prison with a bomb and died; Fielden and Schwab were sentenced to prison for life, and Neebe for 15 years. The last three were pardoned by Gov. Altgeld in 1893, many prominent men of Chicago and throughout the country having petitioned for their release on the ground that the evidence did not connect them with the actual throwing of the bomb, which was true, the evidence pointing strongly to Schnaubelt.

Hayne, Isaac, American patriot: b. South Carolina 23 Sept. 1745; d. Charleston, S. C., 4 Aug. 1781. He was a wealthy planter who took up arms after the invasion of the colony by the English forces, and after the capitulation of Charleston was paroled with the proviso that he might not be ordered to bear arms against his countrymen. He was summoned, however, to the English standard and refusing compliance as a violation of the compact, hastened to the American camp. Being shortly after taken prisoner by the English, he was tried and hanged.

Hayne, Paul Hamilton, American poet: b. Charleston, S. C., 1 Jan. 1830; d. Grovetown, Ga., 6 July 1886. He was a nephew of R. T. Hayne (q.v.) and was educated at the Charleston College, studied law and engaged in journalism. He served in the Confederate army till forced to resign on account of ill health, and lost nearly all his property through the bombardment of Charleston and the subsequent pillage. With the little left to him he retired to Copse

Hill, Grovetown, Ga., where he spent the rest of his life, a partial invalid. His verse is marked by grace and melody and he ranks almost the first among distinctively southern poets. He published 'Poems' (1855); 'Sonnets and Other Poems' (1857); 'Legends and Lyrics' (1872); etc. A complete edition of his poems appeared in 1882.

Hayne, Robert Young, American statesman: b. Colleton District, S. C., 10 Nov. 1791; d. Asheville, N. C., 24 Sept. 1839. After studying law he was admitted to the bar in 1812; and served in the second war with Great Britain, returning at its close to his practice in Charleston. He was a member of the State legislature 1814–18, and became Speaker, was attorney-general of the State in 1818–22, and a United States senator 1823–32. He vigorously opposed protection, and in 1832 boldly supported in Congress the doctrine of nullification. Daniel Webster's reply to Hayne upon this theme is classed among the former's ablest speeches. In November 1832 South Carolina adopted an ordinance of nullification, in December Hayne was elected governor, and the State prepared to resist the Federal power by force of arms. A compromise, however, was agreed to, and the ordinance was repealed. Hayne was mayor of Charleston in 1834.

Hayne, William Hamilton, American poet: b. Charleston, S. C., 11 March 1856. He is the son of Paul Hamilton Hayne (q.v.). He received a secondary education, from 1879 contributed extensively to various periodicals, and published 'Sylvan Lyrics and Other Verses' (1892).

Haynes, hānz, **Arthur Edwin,** American mathematician: b. Van Buren, N. Y., 23 May 1849. After graduation from Hillsdale College, Mich., in 1875 became instructor of mathematics and physics there in the same year; and was professor, 1877–90. He held the same position in Michigan Mining Schools in 1890–3, and was professor of mathematics at the University of Minnesota, 1893–6, and in its engineering department 1896–1901. He has published 'The Desirability of Uniformity in the Use of Mathematical Symbols and Terms'; etc.

Haynes, John, American colonial governor: b. Old Holt, Essex, England; d. Hartford, Conn., 1 March 1654. He came with Hooker and his company to Boston in 1633, was soon after chosen assistant, and in 1635 governor of Massachusetts. In 1636 he removed to Connecticut, being one of the prominent founders of that colony. In 1639 he was chosen its first governor, and every alternate year afterward, which was as often as the constitution permitted, till his death. He was one of the five who in 1638 drew up a written constitution for the colony, which was finished in 1639, the first ever formed in America, and which embodies the main points of all our subsequent state constitutions, and of the Federal constitution.

Hays, Isaac, American physician and editor: b. Philadelphia 5 July 1796; d. there 12 April 1879. He was graduated from the University of Pennsylvania in 1816 and from its medical school in 1820. In addition to his long service as general practitioner he was for 52 years on the staff of the 'American Journal of the Medical Service.' In 1843 he established a monthly, the 'Medical News,' and in 1874 the 'Monthly Abstract of Medical Science.' He edited: 'Wilson's American Ornithology' (1828); 'Hoblyn's Dictionary of Medical Terms' (1846); 'Lawrence on Diseases of the Eye' (1847); and 'Arnott's Elements of Physics' (1848). He was president of the Philadelphia Academy of Natural Sciences (1865–9) and connected with many scientific societies at home and abroad.

Hayes, William Jacob, American painter: b. New York 8 Aug. 1830; d. there 13 March 1875. He studied art under John Rubens Smith, and his 'Dogs in a Field,' exhibited in the Academy of Design in 1850, won him the reputation of an animal painter of remarkable fidelity to nature and spirit in design. He studied the bison in the upper waters of the Missouri and the deer in Nova Scotia. His 'Bison Bull at Bay' and 'Herd of Caribou in Nova Scotia' are characteristic pictures.

Hays, William Shakespeare, American song-writer and composer: b. Louisville, Ky., 19 July 1837. In 1857 he became a reporter for the Louisville *Democrat,* subsequently was clerk and captain of steamboats on the Ohio and Mississippi, and became marine editor of the Louisville *Courier-Journal* and *Times.* He wrote and composed more than 300 songs, among them 'Nora O'Neil,' 'Write Me a Letter from Home,' and 'Shamus O'Brien'; and published 'Poems and Songs.' His songs have sold very extensively in the United States and England.

Hays, Kan., city, county-seat of Ellis County; on Big Creek, and on the Union P. railroad; about 222 miles west of Topeka. It is in a fertile agricultural region. The chief manufactures are flour, dairy products, and machinery. It has grain-elevators, and there are large annual shipments of grain, flour, and live stock. It is the seat of a Normal school and of a State agricultural experiment station. The experiment station is connected with the State Agricultural College, which owns near Hays 2,000 acres of land. Pop. (1900) 1,136.

Hayti. See HAITI.

Hayward (properly "haw-ward," keeper of the haws or hedges, and still so pronounced, or rather as "howard," in country districts; the family name Howard as well as Hayward is from this), a town officer in old New England, whose duty was to keep the cattle on the roads from breaking through the hedges or fences into enclosed grounds and to impound them if they did so. The title came to be generic for a cattle-ward, and the hog-reeve was frequently known as a "hog howard."

Hayward, Wis., town, county-seat of Sawyer County; on the Namakagon River, and on the Chicago, St. P., M. & O. railroad; about 63 miles by rail southwest of Ashland. It is in the vicinity of the lumber region of the State, and the chief industry is lumbering. It has a government Indian school, a public library, and four churches. Pop. (1900) 2,720.

Hazard, hăz'ard, **Caroline,** American college president: b. Peacedale, R. I., 10 June 1856. She was educated in Providence and in Europe, and in 1899 was appointed president of Wellesley College, Mass., receiving the degrees of M. A. and Litt. D. from the University of Michigan and Brown University the same year. She is a

granddaughter of R. G. Hazard (q.v.) and has published 'The Narragansett Friends' Meeting in the 18th Century' (1899); 'Thomas Hazard: a Study of Life in Narragansett in the 18th Century.'

Hazard, Ebenezer, American author: b. Philadelphia 15 Jan. 1744; d. there 13 June 1817. He was graduated from Princeton in 1762, in 1782–9 was postmaster-general, and from 1791 was in business in Philadelphia, where he assisted in the establishment of the North American Insurance Company. He published 'Historical Collections' (1792–4) and 'Remarks on a Report Concerning Western Indians.'

Hazard, Rowland Gibson, American manufacturer and philosopher: b. South Kingston, R. I., 9 Oct. 1801; d. Peacedale, R. I., 24 June 1888. He was a successful business man, being long engaged in the woolen manufacture in Peacedale. He also wrote on philosophical subjects; his works including 'Language, its Connection with the Constitution and Prospects of Man' (1836); 'Essays on the Resources of the United States' (1864); 'Causation and Freedom of Willing' (1869).

Haze, a condition of the atmosphere which deadens the blueness of the sky, and obscures the sharp outlines of distant objects. Haze is due to fine dust in the air or to extreme heat, the latter being known as heat-haze. In certain parts of China the haze is like a thin fog. Extensive forest fires create a smoke-haze, of a dense, blue color, which drifts like rain clouds hundreds of miles from the scene of the fire. Volcanic eruptions throw fine dust into the air in enormous quantities, forming a haze which is carried many hundreds of miles. See DUST.

Hazel-nut, or **Filbert,** a genus (*Corylus*) of shrubs and trees of the order *Cupuliferæ,* confined to the northern hemisphere. The male flowers are in long cylindrical aments or catkins; and the fruit, a nut, is marked at its base with a large cicatrix. The inflorescences of the hazel are developed in the year preceding their appearance; the male flowers last over the winter, naked; the female inflorescence is enclosed in a bud. In early spring the male catkins elongate and produce an abundance of dry pollen, while the female inflorescences are distinguishable from the leafbuds only by their larger size and projecting red stigmas. The nut is enveloped at the base by a sheath of succulent bracts.

The European hazel (*C. avellana*), from cultivation, has produced several varieties, differing in the size, shape, and flavor of the nuts, which are commonly known under the name of filberts. It grows in all situations, and is easily cultivated, but a light and tolerably dry soil is the most suitable. The best nuts come from Spain, where they are baked in large ovens before export, in order to ensure their preservation. Other species occur in southern Europe and Asia. The American hazel (*C. americana*) very much resembles the European, but is lower in stature. It is common in most parts of the eastern United States, but has not been cultivated. A second species (*C. rostrata*) occurs in California.

The oil which is obtained from hazel-nuts by pressure is little inferior in flavor to that of almonds, and chemists employ it as the basis of fragrant oils artificially prepared and used by perfumers, because it easily combines with and retains odors. In many parts of England hazels are planted in coppices and hedge-rows for several useful purposes, but particularly to be cut down periodically for charcoal, poles, fishing-rods, etc. In brewing, the dried twigs were used as a substitute for yeast when they were soaked in fermenting liquor. Being extremely tough and flexible, the branches are used for making hurdles, crates, and springles to fasten down thatch. They are formed into spars, handles for implements of husbandry, and when split are bent into hoops for casks. Charcoal made from hazel is much in request for forges, and when prepared in a particular manner is used by painters and engravers to draw their outlines. The roots are used by cabinet-makers for veneering; and in Italy the chips of hazel are sometimes put into turbid wine for the purpose of fining it. Finally forked twigs of the European hazel were formerly used by diviners to determine the position of water, gold, etc.

Hazeltine, hā'zĕl-tĭn, **Mayo Williamson,** American journalist and literary critic: b. Boston, Mass., 24 April 1841. He graduated from Harvard, studied also at Oxford, practised law until 1878, and was then appointed literary editor of the New York *Sun.* He became widely known as a critic for his reviews in the *Sun,* and has published in book-form: 'Chats about Books' (1883); 'British and American Education'; 'The American Woman in Europe.'

Ha'zen, Marshman Williams, American lawyer and author: b. Beverly, Mass., 1845. He was graduated from Dartmouth in 1866, from 1873 was a manager for the publishing firms successively of Ginn & Company and D. Appleton & Company, in 1882 was admitted to the Massachusetts bar, and in 1885 began the practice of law in New York. His publications include, besides a series of 21 school text-books: 'Observation, Thought, and Expression'; a 'History of the United States'; and 'Government.'

Hazen, William Babcock, American soldier: b. West Hartford, Vt., 27 Sept. 1830; d. Washington, D. C., 16 Jan. 1887. He was graduated at West Point in 1855, went to the front in the Civil War in command of 41st regiment of Ohio volunteers, which he himself had recruited in 1861, served actively in Ohio, Kentucky, and through the Atlanta campaign and in Sherman's march through Georgia, and in 1865, took command of the Fifteenth army corps. He observed the Franco-Prussian war on French territory, and was at Vienna as military attaché to the United States legation during the Turko-Russian war. Appointed chief signal officer in 1880, with the rank of brigadier general, he employed scientists as observers, introduced «cold wave» signals, and suggested the standard-time meridians at present in use. He published: 'The School and the Army in Germany and France, with a Diary of Siege Life at Versailles' (1872); 'Our Barren Lands' (1875); and 'A Narrative of Military Service' (1885).

Ha'zleton, Pa., a city situated in Luzerne County; on the Pennsylvania and the Lehigh Valley R.R.'s; about 24 miles south of Wilkes-Barre. The city was settled in 1820, incorporated as a borough in 1840, and chartered

as a city in 1890. It is situated in the anthracite coal region, and its industrial interests are largely connected with the mining and shipping of coal. Its chief manufactures are foundry and machine-shop products, carriages, lumber, beer, baking-pans, cattle-powder, cigars, coffins and caskets. It has knitting mills, silk mills, three daily and eight weekly newspapers. It contains a State hospital for miners, 30 churches, three banks, a convent, high school, and Saint Gabriel's Academy. The government is vested in the mayor, who holds office three years, and in the council. The subordinate officials are appointed by the mayor, subject to the approval of the council. Some are elected by the council. Pop. (1890) 11,872; (1900) 14,230.

Hazlitt, hăz'lĭt, **William,** English critic and essayist: b. Maidstone, Kent, 10 April 1778; d. Westminster 18 Sept. 1830. In 1793 he became a student in the Unitarian College at Hackney. He devoted more time, however, to literature and art than to theology, and upon leaving college resolved to become a painter. He painted portraits with only tolerable success, and finally renounced art, and in 1805 opened his literary career with an essay 'On the Principles of Human Action,' in which much metaphysical acumen was displayed. In 1811 he settled in London, deriving his principal support from his contributions of political articles and theatrical and art criticisms to the newspapers, and his occasional lectures and publications. In 1813 he delivered at the Russell Institution a course of lectures on 'English Philosophy,' and subsequently delivered courses of lectures on the English poets generally, the comic poets, and the Elizabethan poets. Later in life he contributed to the 'Edinburgh Review' and some smaller magazines. He was a good art critic, but his tendency to prejudice and paradox, and his almost contemptuous regard for the productions of contemporary genius, render him a less safe authority than his knowledge and talents would lead us to expect. It is as a literary critic and essayist that Hazlitt achieved his chief success. Saintsbury has said that "long before Sainte-Beuve, Hazlitt had shown a genius for real criticism." He has probably not been surpassed by any English critic. Yet his recognition, in view of this fact, has been singularly inadequate to his merits. His judgment was, it is true, often marred by prejudice and by his paradoxes. But in the main it was discriminating and duly appreciative. His equipment might not now be thought adequate, but it was almost certainly in most respects superior to that of his Georgian contemporaries. He was able to write interestingly of a wide range of topics. He was bitterly attacked, after the custom of the times, by writers, particularly journalists, of adverse political views. But as a controversialist he was more than the equal of any of these, bold in epigram and invective. His style has been highly praised for its combination of vigor and ease, its rhythm, its clearness, and the aptness of its epithets. Not only in critical analysis, but as well in narrative and description it is excellent. Hazlitt also lectured in 1818–21 at the Surrey Institute. Northcote states that had he continued his art work he would have become a great painter. The best of his essays for the 'Examiner' appeared in 1817 under the title 'The Round Table.' The 'Spirit of the Age, or Contemporary Portraits,' also a significant work and by some critics considered his best, was published in 1825. Further essays are grouped in 'The Plain Dealer' and 'Sketches and Essays.' Among other well-known works of Hazlitt are: 'Characters of Shakspere's Plays' (1817); 'A View of the English Stage' (1818); 'Lectures on the English Poets' (1818); 'Lectures on the English Comic Writers' (1819); 'Lectures on the Elizabethan Age' (1821); 'Life of Napoleon Bonaparte' (4 vols. 1828). There is an edition of the 'Works' by Henley (1902); and a 'Life' by Berrell (1902).

Hazlitt, William Carew, English author: b. London 22 Aug. 1834. He is a grandson of William Hazlitt (q.v.). He was at first a civil engineer, relinquished that profession for journalism, and finally took up that of literature. Among his works are: 'History of the Venetian Republic' (1860); 'Bibliographical Collections and Notes' (1876–92); 'Memoirs of William Hazlitt' (1897); 'Four Generations of a Literary Family' (1897); 'Leisure Intervals,' poems (1897); 'Ourselves in Relation to a Deity and a Church' (1897); 'Coins of Europe' (1893–7).

Hazor, or **Chazor** (Heb., enclosure), the name of several places in ancient Palestine, the best known of which was the seat of Jabin, a Canaanitish king of considerable power, who, with his allies, was defeated by Joshua (Josh. xi. 1–13). Though it recovered and oppressed Israel, it was conquered a second time by Barak (Judges iv.) and remained in the possession of Israel until the invasion of Tiglath-pileser. Solomon made it a northern frontier fortress (1 Kings ix. 15). Its site has been variously placed, by many at Tell Hara, 2½ miles southeast of Kadesh. Consult the 'Journal of Sacred Literature' for 1866, p. 245.

Hazzard, David, American politician and jurist: b. Broadkiln Neck, Sussex County, Del., 18 May 1781; d. 8 July 1864. He served as an ensign in the War of 1812, was elected governor on the American Republican ticket in 1829, and subsequently was State senator and an associate judge. During his administration as governor, a constitutional convention was held at Dover, Del., by which among various revisions, the governor's term was changed from three to four years. Hazzard was a member of the constitutional convention of 1852.

Head, Barclay Vincent, English numismatic scholar: b. Ipswich, Suffolk, 2 Jan. 1844. In 1864 he became an assistant in the British Museum, where in 1893 he was made keeper of the department of coins and medals. He was also appointed joint-editor of the 'Numismatic Chronicle.' His chief work is the 'Historia Nummorum' (1887), a valuable study, and the standard one in its department. Among further publications by him are: 'History of the Coinage of Bœotia' (1881), and 'Guide to the Coins of the Ancients' (1881).

Head, Sir **Edmund Walker,** English colonial administrator and author: b. near Maidstone, Kent, 1805; d. London 28 Jan. 1868. He was educated at Oriel College, Oxford, became a fellow of Merton, studied law, was a poor-law commissioner in 1841, and in 1847–54 lieutenant-governor of New Brunswick. From 1854 to his

retirement in 1861 he was governor-general of Canada. During his administration Ottawa was chosen as the capital of Canada, the Victoria bridge at Montreal was constructed, and the seigniorial tenures (see CANADA — SEIGNIORIAL TENURE) and the clergy reserves (see CANADA — THE CLERGY RESERVES) were abolished. In 1863 he was appointed a civil-service commissioner and in 1867 a privy councillor. He was an art critic of some importance, and published a 'Handbook of Painting of the German, Dutch, Spanish, and French Schools' (1848), and other works. His poetical contributions to 'Fraser's Magazine' appeared in 1868 in book-form.

Head, SIR **Francis Bond,** English colonial administrator and author: b. near Rochester, Kent, 1 Jan. 1793; d. Croydon, Surrey, 20 July 1875. Educated at Woolwich, he became first lieutenant of engineers in 1811, was at Waterloo and at Fleurus, retired from the army in 1825, and went to South America as a prospector in gold and silver mines. Of some of his experiences there he gave an account in 'Rough Notes of a Journey in the Pampas and Andes' (1828). In 1835 he was appointed lieutenant-governor of Upper Canada. His administration was a decidedly unfortunate one. Unfamiliar with the political status of the country, he opposed the union of the provinces, and endeavored to conduct the government without the assistance of a council. This state of affairs may be regarded as the chief cause for the part taken by Upper Canada in the insurrection of 1837. His numerous publications include: 'Bubbles from the Brunnen of Nassau' (1833); 'The Defenceless State of Great Britain' (1850); 'The Horse and His Rider' (1860); 'The Royal Engineer' (1869).

Head, SIR **George,** English writer of travels, etc.: b. Higham Parish, Kent, 1782; d. 1855. He held various posts in the army, and was present at most of the great battles of the Peninsular. In 1814 he proceeded to Canada to be chief of the commissariat of a proposed navy on the Canadian lakes, and subsequently published his experiences in 'Memoirs of an Assistant Commissary-General' and 'Forest Scenes and Incidents in the Wilds of North America.' He was knighted in 1831 by William IV. He also wrote 'Rome, a Tour of Many Days'; 'A Home Tour Through the Manufacturing Districts of England,' and 'A Tour Through Various Parts of the United Kingdom' and other works.

Head, Natt, American politician: b. Hookset, N. H., 20 May 1828; d. there 12 Nov. 1883. He became a railroad and general building contractor, sat in the State legislatures of 1861 and 1862, was adjutant-general of the State in 1864–70, and in that capacity published a four-volume military record of New Hampshire during the Civil War. In 1876 and 1877 he was elected to the State senate and in the latter year was its president. He was governor in 1879–80.

Head, the anterior part of the body of an animal when it is marked off by a difference in size, or by a constriction. The presence or absence of a head was formerly much used as a character in classification. But this line of classification is artificial. The mouth and principal nervous organs are the guides to the anterior end of the body, where the head, when recognizable, is situated. In the protozoa, infusoria, and cœlenterates, such as the hydra and corals, there is no nervous ganglion, and the mouth is not surrounded by special structures. In the inferior vermes the anterior end becomes marked by the presence of ganglia. The so-called head of parasitic animals, such as the tapeworms, is only the end of attachment, but neither mouth nor ganglia exist in it. In the polyzoa, lampshells, ascidians, and lamellibranch mollusks mouth and ganglia exist, but they are not surrounded by special structures. But in the worms proper, the articulated animals, the land and fresh-water gasteropods and the cuttlefishes a head proper is found. That is, the mouth and the anterior nervous ganglia are placed in a segment of the body which, by structure, is different from the rest. Thus in the worms and articulated animals some of the rings or articles of which the body is made up are fused together, the appendages being not walking limbs, but modified into jaws or jaw-like organs. Thus the common shoreworms possess a structural head, though it is not apparent. The head is best defined in the insects. The snail's head has its cavity shut off by a diaphragm from the rest of the body cavity. The cuttlefishes have, in addition, a remarkable cartilaginous box, which, like a skull, protects the ganglia and gives support to the muscles. The head of the vertebrated animals presents a regular series of increasing complexity from the amphioxus upward. In that fish the most anterior part of the nervous cord is lodged in a canal scarcely distinct from that which contains the rest of it. Ascending in the series, it becomes evident that as the anterior nervous mass enlarges, and its ganglia increase in complexity, the anterior vertebræ change their character; as the brain becomes specialized, so does the brain-case or skull. In man the brain attains its highest development and the head its greatest complexity, the difference between skull and face being now most pronounced. The vertebrate theory of the skull, first propounded by Goethe, is now accepted to this extent, that the skull or cranium consists of three vertebræ, which are recognizable in the fish, and that the facial bones are not vertebræ, but developed from cartilage which did not form an original part of the vertebral column. A vertebra consists of a body or centre, from which two processes arch upward and close in the spinal canal with its contents, the spinal cord. The posterior cranial vertebra is the occipital, consisting of a centre, two lateral pieces, and a superior, the next is the parietal, of which the basisphenoid is the centre, and the great wings of the sphenoid and the parietals the lateral arches; the most anterior is the frontal, with its centre, the presphenoid, and its arch, formed by the orbital plates of the sphenoid and the frontals. The centres of the spinal vertebræ are ossifications around a fibro-cartilaginous rod, the *chorda dorsalis*, which ends in the basisphenoid. So far spinal column and skull have a common base; but the spinal vertebræ were preceded by and are in fact modifications of primitive vertebræ, and no representatives of these appear in the development of the skull. It is therefore open to question whether the three divisions just mentioned are really vertebræ, or should not rather be called cranial segments. There is the more reason for this that in fishes the basisphenoid and pre-

sphenoid are represented by a single bone, the parasphenoid, which underlies the skull, but disappears in the higher vertebrates, and that the presphenoid is not properly connected with the chorda dorsalis, but rather belongs to the series of facial bones. The pituitary body which projects from the lower surface of the brain lies in front of the end of the chorda dorsalis: from this latter rod and its surroundings a plate of cartilage passes forward on either side of the pituitary body, and these (the *trabeculæ*) meeting in front of that body, form the cartilaginous axis around which the vomer, ethmoid, and other facial bones are developed, while the presphenoid is an ossification in this axis just where the two portions meet in front of the pituitary. The sense organs, the ear and the eye, are, so to speak, lodged in capsules of bone which are inserted, the ear between the occipital and parietal, the eye between the parietal and frontal segments. They are accidental, not essential parts of the cranium. The hyoid apparatus and the lower and upper jaws are developed from the cartilaginous walls of the embryonic skull, and the jaws come in a secondary manner to take part in the composition of the face. (See RESPIRATORY ORGANS.) The increasingly globular form of skull in the vertebrates is due to the greater increase of the cerebral hemispheres relatively to that of the base of the brain and axis of the skull; hence the brain comes in man to overhang the face. Of course it is to be remembered that while in the vertebrated animals the head is divided by its axis (commencing at the middle line of the upper jaw, and passing backward through the basisphenoid to the vertebral centres) into an upper chamber, lodging the brain, and a lower, lodging the first part of the alimentary canal; in the lower animals the cavity is a single one, the œsophagus piercing the nervous system so as to reach the surface of the body, and thus coming to be surrounded by a pair of ganglia above and a pair below, with the filaments connecting these ganglia. In the vertebrate the head is curved downward, the basisphenoid being the pivot point, so that the mouth is pushed to the lower surface; in the lower animals the under surface of the body curves upward, so as to carry a part of the nervous system past the mouth toward the upper surface. The eyes and feelers of a crab are in fact modified limbs which are thus carried upward; the jaws and sense organs of a vertebrate are entirely distinct from the limbs and other appendages of the trunk.

Head-hunting. See DYAKS.

Head Money, an immigration tax of 50 cents levied by act of Congress 3 Aug. 1882 on every foreigner brought to the United States. Before the passage of this act the State of New York levied a "head tax" on all immigrants arriving at New York, the funds going to the support of the State board of immigration. A test of the legality of the tax being made in the courts, a decision was rendered that the New York statute was void because it infringed on the prerogatives of national government. Subsequently the act of Congress imposing the tax was questioned in the United States Supreme Court, and a decision affirming the constitutionality of the law was made. The national act provides that the tax shall be paid by the master or owner of the vessel bringing the immigrants, to the collector of the port, and by him turned over to the treasury of the United States, to be used by the secretary to defray the expenses of regulating immigration and to relieve immigrants in distress. See IMMIGRATION.

Headache, pain in the head, the result of a variety of causes. It may arise from overfulness of blood, from deficiency of blood or debility, from excited or inflammatory action, from the nerves, etc. If a person who suffers from headache is of full habit generally; if he is sleepy, dull, the vessels of his face full; overfulness is the probable cause, and reduction of the diet, with occasional doses of saline medicine, exercise, bathing the head with cold water, will be beneficial. If the urine is deficient, cream of tartar in some form may be taken with advantage. The above species of headache may also be occasioned by whatever impedes the circulation, such as affection of the heart or liver; when the latter is the case, the pain is frequently most severe at the back of the head. When, on the other hand, headache occurs in a person of weak constitution; when it is produced or aggravated by mental over-exertion; when there is listlessness both of mind and body rather than oppression — the face pale, the pulse weak — debility is the probable cause. This form of headache is often accompanied with indigestion, and is common in students and anxious men of business. Anything like abstraction of blood will certainly prove injurious. Exercise, attention to the state of the bowels, care in diet, rest, and change of scene and air, will be most useful. Headache from excitement or inflammatory causes is such as occurs in the first stages of inflammation of the brain and in some forms of fevers, or it follows violence to the head. Of all kinds of headache that arising from some disorder of the stomach is, however, the most common. The presence of indigestible food in the stomach almost certainly causes dull pain in the forehead; and too acid a condition of the contents of the organ produces the same effect. The various symptoms of indigestion will generally point to the cause. In the first some aperient, such as a saline draught, will probably remove the disorder. When acid eructa-

tions, heartburn, etc., indicate the presence of superabundant acid, a dose of soda, potash, or magnesia will correct the cause. There is a form of headache which consists in throbbing and pain of one part, or sometimes over one side of the head. This is called hemicrania (the migraine of French and the megrim of old English writers), and is often of a distinctly intermittent character. For its permanent cure quinine is in common use; a mustard poultice on the nape of the neck is also of service; and antipyrin has proved of value in affording relief. It should be well understood that the habitual use in headache of strong and swiftly working drugs is likely to undermine the nervous system, and increase liability to attack. Exercise, moderation and cheerfulness are the best preventives.

Headley, hĕd'lĭ, **Joel Tyler,** American historian: b. Walton, N. Y., 30 Dec. 1813; d. Newburg, N. Y., 16 Jan. 1897. Graduated from Union College in 1846, he took a course in theology at the Auburn Seminary, was pastor at Stockbridge, Mass., and in 1846 became assistant editor of the New York *Tribune.* In 1856–7 he was secretary of state for New York. His works, written in a popular vein, had great currency in their day, and include: 'Napoleon and his Marshals' (1846); 'Washington and his Generals' (1847); 'The Adirondacks' (1849), said to be the first book to advocate that region as a health-resort; 'Grant and Sherman, their Campaigns and Generals' (1865); and 'The Great Rebellion' (1864).

Headley, Phineas Camp, American Congregational clergyman: b. Walton, N. Y., 24 June 1819; d. Lexington, Mass., 1903. He was a brother of J. T. Headley, the historian (q.v.). He was admitted to practice at the bar in 1847, but studied theology at Auburn Seminary, held pastorates in various Presbyterian and Congregational churches, and contributed to the New York 'Observer' and *Tribune,* and many other newspapers and magazines. Among his works are: 'Women of the Bible' (1850); biographies of the Empress Josephine (1851), Kossuth (1852), Lafayette (1853), Mary, Queen of Scots (1856), Ericsson (1863), Farragut (1864), and others; 'Half-Hours in Bible Lands' (1867); 'Court and Camp of David' (1868); and 'Public Men of To-day' (1882).

Healy, George Peter Alexander, American painter: b. Boston 15 July 1808; d. Chicago 24 June 1894. He went to Paris about 1836, where he remained several years, alternating his residence there with occasional visits to the United States. Among works executed by him abroad are portraits of Louis Philippe, Marshal Soult, and Gen. Cass. At home he painted Calhoun, Webster, Pierce, and other prominent American statesmen. He occasionally produced large historical pictures, of which 'Webster's Reply to Hayne,' illustrating a well known scene in American legislative history, completed in 1851, now hangs in Faneuil Hall in Boston. At the exhibition of Paris in 1855 he exhibited a series of 13 portraits and a large picture representing Franklin urging the claims of the American colonies before Louis XVI., for which he received a medal of the 2d class. Portraits by him of Buchanan and Lincoln are in the Corcoran Gallery at Washington.

Healy, Timothy Michael, Irish political leader: b. Bantry, County Cork, Ireland, 17 May 1855. He was elected to Parliament for Wexford in 1880, County Monaghan in 1883, South Londonderry in 1885, North Longford in 1887, and County Louth, North, in 1895. In 1884 he was called to the Irish bar. He became known as a leader of the Irish Nationalist party, was a founder of the Dublin 'National Press' (later combined with the 'Freeman's Journal'), and was repeatedly in difficulties because of his public utterances on political matters. He made a lecture tour of the United States with Dillon and Parnell in 1880, and in 1881 participated in the Land League convention at Chicago, when $250,000 were contributed to the Irish cause. The 'Healy Clause' of the Land Act of 1881, providing that no tenant should pay rent on improvements made by him, was introduced by him. He wrote 'A Word for Ireland' (1886).

Heap, David Porter, American engineer: b. San Stefano, Turkey, 24 March 1843. He studied at Georgetown (D. C.) College, was graduated from the United States Military Academy in 1864, served in the Civil War with the engineer corps of the Army of the Potomac, and was brevetted captain for his services. In 1895 he attained the grade of lieutenant-colonel of engineers. He was for years employed in the construction of fortifications and the improvement of harbors, and in 1881 was military representative of the United States at the Paris congress of electricians. In addition to a 'Report on the International Exhibition of Electricity at Paris' (1884), he published: 'Ancient and Modern Light-Houses' (1889); 'Electrical Appliances of the Present Day'; 'Engineer Exhibit, Centennial Exhibition' (1882); and 'History of the Application of Electricity to Lighting the Coasts of France' (1885).

Heard, Franklin Fiske, American jurist: b. Wayland, Mass., 17 Jan. 1825. He was graduated at Harvard in 1848; was admitted to the bar in 1850; and practised in Middlesex County and later in Boston. He attained a reputation as an authority on pleading, and in 1861–6 was an editor of the 'Monthly Law Reporter.' His publications include: 'Libel and Slander' (1860); an edition of 'Stephen on Pleading' (1867); standard books on 'Criminal Pleading' (1879) and 'Civil Pleading' (1880); 'Heard on Criminal Law' (2d. ed. 1882); 'Shakespeare as a Lawyer' (1883); 'Precedents of Equity Pleadings' (1884); 'Precedents of Pleadings in Personal Actions in the Superior Courts of Common Law' (1886).

Hearing, one of the five senses, the physical organ of which is the ear. (See Ear, Acoustics.)

Hearn, hèrn, **David William,** American Roman Catholic clergyman and educator: b. Boston, Mass., 21 Nov. 1861. He was graduated at Boston College in 1880; took postgraduate courses in literature, science and philosophy for five years, and theological courses for four; entered the Society of Jesus, and was ordained priest of the Roman Catholic Church. He was successively professor in Georgetown University, vice-president of Boston College, and vice-president of the College of Saint Francis Xavier, New York. In 1900 he became president of Saint Francis Xavier.

Hearn, Lafcadio, American author: b. Santa Maura (Leucadia), Ionian Islands, 27 June 1850; d. Tokio, Japan, 26 September 1904. Educated in England and France, he came to the United States in 1869, was a journalist in Cincinnati and New Orleans, in 1887–9 was at Saint Pierre, Martinique, French West Indies, and in 1890 went to Japan. He became a Japanese subject with the name Yakumo Koizumi, and was appointed lecturer in English literature at the Imperial University of Tokio. His 'Stray Leaves from Strange Literature' (1884), and 'Some Chinese Ghosts' (1887), were succeeded by 'Chita: A Memory of Lost Island' (1889), story of the destruction of "L'Ile Dernière," once the watering-place of Louisiana fashion, which attracted attention by its descriptive powers; and 'Two Years in the French West Indies' (1890), which gained new interest through the Martinique disaster of 1902. Among his further works, dealing almost exclusively with things Japanese and revealing a thorough comprehension of and sympathy with the art, myth, tradition, and philosohy of the Orient, are: 'Out of the East' (1894); 'Glimpses of Unfamiliar Japan' (1895); 'Kokovo' (1896); 'Gleanings in Buddha-Fields' (1897); 'Exotics and Retrospections' (1898); and 'Kottō, or Japanese Curios' (1902).

Hearst, Phoebe Appersin, American philanthropist: b. 1840. She was for a time a teacher, and in 1861 married George F. Hearst of California. She has been active in charitable and philanthropic enterprises and has given largely, especially to educational institutions. In San Francisco she has established kindergarten classes for the children of the poor, and a manual training school, and has organized a number of working girl's clubs. She has also given money to build a National Cathedral School for girls; has made donations to the American University at Washington; has established and given largely to public libraries in the mining towns of the West; and maintained a school for mining engineers at the University of California. In 1896 she offered to pay the expenses of an international competition of architects to obtain a suitable plan for a campus and buildings for the University of California, and to erect two buildings in accordance with this plan. See CALIFORNIA, UNIVERSITY OF.

Hearst, William Randolph, American newspaper publisher: b. San Francisco. He was graduated from Harvard, and on leaving college took charge of the publishing of the San Francisco *Examiner*, formerly owned by his father, Senator Hearst of California. In 1895 he bought the New York *Journal*, the name of the morning edition of which he later changed to the *American*; in 1900 he started the Chicago *American*; in 1904 the Boston *American* and the Los Angeles *Examiner*. In 1902 he presented the Greek Theatre to the University of California. From 1903–5 he represented the 11th Congressional District (New York) in Congress. In 1905 he was defeated for the office of Mayor of New York on the Municipal Ownership platform.

Heart, The. The heart and the blood-vessels constitute the mechanical means for maintaining the circulation of the blood. In many respects this system is the most readily understood of any in the body, in that it is largely mechanical. There are, however, certain factors not existing in an ordinary system of hydraulics which, while essential to the proper performance of the function in the human body, render the understanding of the subject more difficult. The heart is merely a pump, or rather two pumps fused, for convenience, into one. It derives its power through contraction of the red muscle which forms its wall. It is hollow, alternately filling and emptying, receiving blood from one set of tubes filling its cavities, then emptying its contents into other tubes by contraction of its walls and momentary obliteration of its cavities. The action is analagous to that of the ordinary bulb syringe. The proper direction of the flow of the blood is maintained by valves, similar in structure and like in function to the valves in an ordinary pump.

The heart is about the size of the closed fist. The average dimensions of the adult organ are: length 85–90 millimetres in the male, 80–85 mm. in the female; breadth, 92–105 mm. in the male, 85–92 mm. in the female; thickness, 35–36 mm. in the male, 30–35 mm. in the female. The average weight in men is 300 grams; in women 250 grams. The heart is cone-shaped with the base uppermost. It lies within the cavity of the bony chest, a small portion of its anterior surface being in contact with the chest-wall, the rest covered by the overlapping lungs. The apex of the cone, or "apex," as it is technically called, is in the space between the fifth and sixth ribs on the left side, about 2 centimetres to the inside of a vertical line drawn through the left nipple. The heart reaches no lower and no farther to the left than this. From this point it reaches upward to the second rib, two thirds of its mass being to the left of the middle line of the body, one third to the right. Its long axis is neither vertical nor horizontal but is inclined to an angle of about 30 degrees to the horizontal, hence 60 degrees to the vertical. Therefore it is nearer horizontal than vertical. The position of the apex of the heart can be readily determined by placing the finger in the interspace mentioned and feeling the beat. In the healthy individual when not under excitement of the emotions or exercise no motion of the heart can be felt by the finger upon the chest-wall except at the apex.

Of secondary importance only to the heart is the system of tubes conveying the blood: arteries, capillaries, veins. The arteries are thick-walled, elastic tubes, dividing and subdividing into smaller tubes, but the total sectional area increases as the vessels become smaller in diameter. These end in a fine network of very small, thin-walled tubes called from their resemblance in size to hairs, capillaries. These in turn become veins, enlarging their diameter and diminishing their number, thus reversing the process in the arteries. Veins have very thin walls in proportion to the diameter of the bore and are provided with valves to prevent a back flow of blood.

This arrangement of the blood-vessels may be likened to two cones, base to base, one apex representing the largest artery leaving the heart, the other apex the largest vein entering the heart, and the bases of the cones the wide capillary system. The flow of blood will be naturally fastest in the larger arteries and veins, slower in the smaller arteries and veins, and slowest in the capillaries, due to the fact already men-

tioned that as vessels divide although the branches are smaller in diameter the combined sectional area is larger. The condition is quite like that of the flow of water in a river, the current being swiftest where the banks approach each other, slowest where the river widens into a lake or pond, again to become swifter as the width of the stream lessens.

The two pumps which compose the heart as a single whole are called the right heart and left heart. This designation takes its origin from the fact that one is more to the right side of the body, the other to the left side. Ordinarily the two parts are spoken of as the right side and the left side. The left side is by far the more powerful pump, having a very thick wall, its function being to force the blood under considerable pressure through most of the body, the so-called systemic circulation. The right heart has merely to force the blood through the lungs, a relatively short distance and under low pressure.

Each half of the heart has two cavities, a thin-walled one called the auricle for receiving the returning blood poured into it from the veins, and a thick-walled one called the ventricle which receives the blood from the auricle through an orifice guarded by a valve. The function of the ventricle is to force the blood by contraction of its muscular wall into the arteries through a connecting orifice also guarded by a valve. These four chambers are called the right auricle, right ventricle, left auricle and left ventricle. The walls of the auricles are composed of red muscle and are quite thin, the work required of them being but slight, that is, they force the blood under slight resistance. The walls of the ventricles are also made up of red muscle fibres, the outer surface being smooth, the inner surface crossed by a network of beams of muscle called the trabeculæ. The thickness of the wall of the right ventricle between the trabeculæ is from 2 to 3 millimetres; of the left ventricle 7 to 10 millimetres. The capacity of each ventricle is about 100 cubic centimetres, that is, it forces out about this amount at each contraction.

The function of the valves is to permit the flow of liquid in one direction and to prevent its flow in the opposite direction; in other words, their presence enables a pump to maintain a flow of liquid in one direction with little or no back flow.

The heart has four valves, one between each auricle and ventricle, and one in each ventricle at its point of connection with its outgoing artery. The valve between the auricle and ventricle of the left heart is called the mitral, from its resemblance to a bishop's mitre; that between the right auricle and right ventricle is called the tricuspid from its having three folds or cusps. The left ventricle is connected with the systemic circulation by the great artery called the aorta, its guarding valve is called the aortic valve. The right ventricle is connected with the circulation through the lungs by the pulmonary artery, its valve is called the pulmonic valve. The aortic and pulmonic valves are each composed of three cups of thin, flexible tissue fastened to the inner wall of the blood-vessel, their edges hanging free, and capacious enough to meet in the middle of the orifice they guard. When the ventricles contract, the blood within them under pressure tends to escape through any orifice, it presses upon these cups, forcing them against the walls of the orifice leading to the aorta and pulmonary artery respectively, leaving an opening of full size. In other words they offer no obstruction to the flow of blood in this direction. When, however, the muscle-wall by its contraction has emptied itself of blood through the orifices just mentioned it begins to relax, thus enlarging the cavity of the ventricle. Were there nothing to prevent, the blood just forced into the aorta and pulmonary artery under considerable pressure would flow back again into the relaxing ventricle, and so it does to a very slight degree, but this very back flow fills these three cups with blood, causing them to meet in the middle of the orifice, thus completely blocking it so far as any return of blood is concerned, and what blood has been forced into the aorta and pulmonary artery remains there to be carried on still further with the next contraction of the heart.

The mitral and tricuspid valves are simply flat folds or curtains attached to the edges of the orifices between auricles and ventricles. They are thrown back upon the inner walls of the ventricles while the blood is flowing from the auricles into the ventricles, offering little or no resistance to the flow, but when the flow of blood is in the opposite direction, that is, when the ventricles contract, they are floated upward till the free edges come in contact, thus blocking the orifice. The flaps are prevented from going too far by delicate tendinous cords attached to the free edge of the valves at one end and to the inside of the heart wall at the other end. They play the same part that sheets do for a sail. It will thus be seen that while one set of valves — mitral and tricuspid — is closed, the other set — aortic and pulmonic — will be open, and vice versa.

The period of active contraction of the ventricles is called the systole, and its time is often spoken of as the systolic period. The period of dilatation of the ventricles, the time during which they fill with blood from the auricles, is called the diastole or diastolic period. In time the two are nearly equal, the diastole being somewhat longer.

The cause of the heart beat is a matter of great interest. Inasmuch as the skeletal muscles require for contraction a stimulus carried to them through nerves, it was thought that heart muscle required a similar nerve impulse. It was known to physiologists that the heart of a frog severed from its connections went on beating in spite of there being no nerves attached to it to convey an impulse from without. Then certain nerve ganglia were found in portions of the heart wall and it was inferred that these gave out the necessary stimulus. But finally it was found that isolated portions of the heart wall in which there were no nerve ganglia continued to beat if they had a blood supply. Hence it was concluded by Gaskell that the beat of the heart must be due to an inherent rythmical power of the ventricle; the stimulus to the muscle probably residing in some chemical substance in the blood coming to the part. At any rate the ganglion theory is no longer held, while the latter is considered the probable one.

The sounds associated with the periods previously described are readily heard by anyone placing the ear over the heart of another person, or with a stethoscope the individual may hear

his own heart sounds. The contraction of the ventricles occurs at the time the impulse is seen and felt over the apex of the heart in the fifth interspace. It is associated with a booming sound, loud and distinct. Then comes a short period of silence corresponding to the time when the heart muscle ceases its contraction and begins to relax. Then comes a very short, sharp, flapping sound due to the closure of the valves which prevent the return of the blood from the aorta and pulmonary artery to the ventricles. Then follows a longer period of silence and again a repetition of the same set of sounds. The time from the beginning of the first sound to the beginning of the second sound, that is, the time of the "boom" and its short silence, is the systole of the ventricle. The time from the beginning of the second or short, sharp sound through the period of silence following it is the diastole of the ventricle. The whole period occupied from the beginning of the first of the sounds described to its repetition is called a cycle of the heart. Of these there are on an average in an adult 72 per minute. When the successive cycles occupy the same length of time the rhythm is said to be "regular." When the times are unequal the term "irregular" is used. When a beat is dropped the term "intermittent" is applied.

If, when the ear is placed over the heart, the finger be placed over the artery in the wrist, an impulse or beat will be felt in the latter, occurring at a slightly later time, about one sixth of a second, than the apex beat. This is the pulse wave corresponding to that individual heart beat. It varies in frequency, in volume and in tension according to the number of heart beats, the volume of blood thrown into the arteries from the heart, and the tension or tone of the arterial wall. The latter point will be explained later.

The course of the blood after leaving the left ventricle is through the aorta and its branching arteries to the arms and legs and to all the organs of the body, except the main supply to the lungs, through capillaries; thence it is returned by the veins to the right auricle, from there it goes to the right ventricle, from which it is pumped through the lungs for purification to the left auricle and thence to the left ventricle again. The length of time required for any portion of blood to make the complete circuit in the human being is not known with absolute accuracy, but it is probably not less than 15 seconds nor more than 30 seconds.

The work done by the heart may be expressed in units. Assuming the pressure in the left ventricle during contraction to be 130 millimetres of mercury, each square centimetre will receive a pressure of 175.5 grams. Assuming further that the left ventricle forces 100 cubic centimetres of blood at each contraction, the work done will equal 17,880 gram centimetres. The right ventricle does a third as much work as the left, giving a total of 23,840 gram centimetres. The total work of the heart per diem equals 24,000 kilogram metres, equivalent to 56.6 kilo-calories.

The relatively high pressure required of the heart in maintaining the circulation is due to the fact that it has to force the blood into arteries having elastic walls that offer a considerable resistance to stretching. The stream from the heart into the arteries is intermittent, the elastic arterial walls are stretched by the incoming blood absorbing the force during systole and tending to again give out this force when the heart ceases during diastole to supply fresh blood. Even during diastole the pressure within the arteries remains considerable. Hence the heart has to force the blood against the elastic tension of the arterial wall and against the blood already in the vessel from previous heart beats. This force stored up in the arterial wall tends to drive the blood along to the capillaries and veins, making in the capillaries and veins a constant flow, just as a single-cylinder pump provided with an air-chamber delivers a constant stream. The circulation, then, in the arteries is intermittent, in the capillaries and veins constant.

An element of much interest as well as of great importance to the proper maintenance of the circulation in the arteries and to the nutrition of the organs supplied by them with blood is what is called "vascular tonicity," by which is meant the peculiar property inherent in the arterial walls of maintaining a relatively constant blood pressure with varying amounts of blood contents. In an ordinary system of hydraulics maintained through elastic tubes the walls of which are stretched by the circulating contents, the pressure falls if some of the contents escape. In animals, on the contrary, a considerable quantity of blood may be withdrawn from the blood-vessels, yet the blood pressure, after a fall of very short duration, returns to the normal. This tonicity is due to the fact that the walls of the arteries have circular muscle fibres, under control of nerves, that contract down upon the blood remaining in the vessel and so maintain the pressure, a matter of great importance, as an equal pressure in organs is necessary for the proper physiological function.

The muscle in the arterial walls is supplied with two sets of nerves called vasomotor nerves, having opposite actions. One set called vasoconstrictors has the power when stimulated of contracting the vessel, the other set called vasodilators enlarges the vessel. Under normal conditions a certain equilibrium is established between the two sets of nerves and the artery is said to possess "tone." Increased action of one over the other will produce increased amount of blood in the part, as in the familiar example of blushing, or on the other hand pallor as seen in fright. Certain drugs have a powerful effect upon these nerves.

Before considering the diseases of the heart a word may be said of the historical development of the subject. That the blood circulated was not known until Harvey demonstrated it in 1628. Auenbrugger, a Viennese physician, in 1761 invented percussion, the method by which the position, size, and in a measure the changes in organs may be determined by the sound produced when the surface of the body over them is struck or "percussed," as it is technically called. His invention remained unheeded until 1806, when Corvisart, body physician to Napoleon, used it in mapping out the heart in healthy and in diseased conditions. Laennec, the founder of auscultation as used to-day, by means of his newly invented stethoscope, gave to the world in 1819 the first accurate description of the characteristics of the heart sounds and the significance of changes in the sounds in the diagnosis of diseases of the heart. Bouil-

laud in France and Hope in England were also pioneers in this work, practically all that has been done since then being an elaboration along lines laid down by them.

By percussion the size and position of the heart can be accurately determined, and by auscultation variations from the normal sounds and the presence of abnormal sounds enable one to determine what special derangement of the heart exists.

To understand the abnormalities of the heart it should be borne in mind that the work of this organ is done by the muscle of which it is composed; that the nerve stimulus for the muscular contraction comes from within the heart wall, and that the regulatory action, that is, whether it beats faster or slower, depends upon two nerves of opposing action, the vagus and the sympathetic; stimulation of the former slowing the heart, stimulation of the latter increasing the rapidity of action. Under ordinary conditions an equilibrium is established between them, somewhat analagous to the equilibrium in a balance when equal weights are placed in the scale-pans; an equilibrium that is at once disturbed if weights are added to or taken from either pan. Furthermore intact valves are necessary for the proper function of the heart.

Hence changes in the action of the heart are due to changes in the nerve stimulation; changes in the muscle; changes in the valves. They may exist alone or in combination. Changes affecting the nerves are more commonly functional or temporary; while those affecting muscles and valves are organic and usually, though not always, permanent.

Diseases of the valves are the most frequent, the most important and of the greatest interest. A valve to perform its duty properly must be so flexible that it is readily thrown back against the walls of the heart so as not to hinder the passage of the blood through the orifice it should go. It should also quickly fall back into place and meet its fellows, so as to block the passage and prevent the flow of blood in the direction it should not go. Unfortunately these delicate valve segments are prone to inflammation, rheumatic fever being the commonest cause. This inflammation is associated with the formation of new tissue much like that formed in the scar of a wound. It leads to thickening, rigidity, retraction and deformity of the valves, and also frequently to adhesion of the cups along the edges of closure.

These changes affect the function of the valve, causing on the one hand narrowing of the orifice so that the passage of the blood is obstructed, hence the technical use of the term "obstruction," or "stenosis"; on the other hand the segments of valves may be so shortened and puckered that they do not meet each other, and so leakage results. To this condition the term "insufficiency" or "regurgitation" is applied. Either obstruction of a valve orifice or leakage through a valve calls upon the muscle of the heart for more work. In the former case the blood is forced under a greater resistance; in the latter more blood must be forced to make up for the leakage. The muscular wall thickens and the cavity of the heart behind the leaky valve enlarges to "compensate," as the expression is for the valvular defect. This compensation may remain effective for years, the patient having but little inconvenience from the disease.

Sooner or later the heart muscle feels the effect of the prolonged overwork, it weakens, becomes stretched, the cavity enclosed by it enlarges, and the condition known as "broken compensation" follows. The heart can no longer supply a sufficient amount of blood for the needs of the body, the circulation is slowed, stagnation results with the associated symptoms of distress in breathing and frequently dropsy. There is marked impairment in the functions of the organs of the body due to imperfect blood supply. Valvular disease is very common and may occur at any age, but it usually involves the valves of the left heart, mitral and aortic.

With care on the part of the patient life may often be prolonged with comfort for many years. Apart from the benefit derived from rest, the drug digitalis by prolonging diastole and stimulating the heart muscle to better contraction gives the best results. When properly used it is a great boon to the patient.

The muscle of the heart undergoes a degenerative change in acute infective diseases associated with fever, like typhoid fever, pneumonia, and diphtheria, by which its contractile power is lessened. It may reach such a degree as to lead to death from paralysis of the heart wall. If the patient recovers from the disease the heart muscle in time recovers its normal tone.

An important disease of the heart muscle is one occurring usually in males after middle life, frequently associated with the symptom known as angina pectoris. It is a degeneration of the heart wall due to partial occlusion, by thickening of the walls, of the two coronary arteries which supply the heart muscle with blood, thus disturbing the nutrition of the muscle and the nerve ganglia. Angina pectoris is characterized by the sensation of great constriction and pressure and often of a violent tearing of the heart, with intense anxiety and a feeling of impending death. The suffering is often very great, and while the attack may be of short duration the prostration following one is marked.

Fatty degeneration of the heart muscle occurs, but it cannot be diagnosticated with exactness during life. Although the term is often heard its use should be reserved as an anatomical and not as a clinical diagnosis. That is, one can be sure of it only when one sees the exposed heart. On the other hand, collection of fat between the muscle-fibres and around the heart such as occurs in fat people may seriously embarrass the heart by not allowing enough space for it to move freely.

Extreme muscular effort as in lifting or carrying a heavy load or a prolonged march or climbing a mountain may overstrain the heart and lead to feeble action. Rest usually repairs the damage, although sometimes it is permanent.

Prolonged overwork and certain forms of disease of the kidney may lead to marked enlargement of the heart, due mainly to thickening of muscle wall of the left ventricle, to which the term "hypertrophy" is applied.

Disturbances of the heart function, due to some action through its nerves, are of great importance. Such may be physiological or functional, or they may be due to diseased conditions. Among the former are examples familiar to all. The increased frequency and force of the heart beat due to the emotions, to alcohol, to tea, to

coffee, to tobacco, belong in this category. If not used to excess the effect of the above may be merely temporary, the heart resuming its usual frequency and quiet action when the effect of the stimulation has ceased. Prolonged abuse of such substances or long continued nerve worry or excitement may lead to a more permanent disturbance of the heart functions, indicated by palpitation, either permanent or after a trivial cause, or by irregularity in the rhythm. The "tobacco heart" of the milder form is an irritable one, with increased frequency of the beat; in the severer grade marked irregularity is characteristic. In the nervously tired person palpitation is common, while the uncomfortable sensations about the heart due to disturbed digestion with fermentation in the stomach often lead the individual to consult a physician feeling that heart disease exists.

A nervous disorder of the heart of considerable interest is one associated with greatly increased frequency of its beat, but with a regular rhythm, combined with a marked prominence of the eyeballs, enlarged neck (goitre) and tremor of the hands. This complex has received the name of exophthalmic goitre, a neuropathic disturbance associated with irritation of the sympathetic nerve leading to the rapid heart action.

Still more uncommon and as yet unexplained is the condition called Tachycardia (rapid heart) characterized by paroxysmal attacks of very rapid beating of the heart, lasting but a short time and followed by normal frequency. During an attack it may be impossible to count the heart or pulse beats, owing to the rapidity.

WM. WHITWORTH GANNETT, M.D.,
Visiting Physician to the Massachusetts General Hospital, Boston, Mass.

Heart of Midlothian, The, a romance by Sir Walter Scott, published anonymously in 1818. It takes its name from the Tolbooth or old jail of Edinburgh (pulled down in 1815), where Scott imagined Effie Deans, his heroine, to have been imprisoned. The book is notable for having fewer characters than any others of Scott's novels. It has also a smaller variety of incidents, and less description of scenery.

Heart-urchin. One of a group of sea-urchins (see ECHINOIDEA) of elongated form and cordate outline from a lateral point of view. The group is best represented by the genus *Spatangus*, common in Europe, but heart-urchins occur elsewhere, and are known as fossils.

Hearts-ease, a violet (q.v.), especially the common yellow violet of Europe, or a pansy.

Heat. Until the early part of the 19th century, it was generally believed that heat was a substance devoid of weight (imponderable), and diffused through the mass of bodies. This hypothetical substance was called *caloric*. Many phenomena seemed to be explained by the assumption of the existence of caloric, but finally, through the experiments of Davy and Rumford, in which heat was actually created from mechanical energy, the old caloric theory was abandoned. In its place we now have the molecular motion theory. According to this theory heat is nothing but a violent agitation of the molecules of matter. These molecules are extremely minute, but have a definite size and weight for each definite substance. It has been estimated that a molecule of water has a diameter of about one fifty-millionth of an inch. Though molecules are small in size, their velocity, even at ordinary temperatures, is very great. In air, where the molecules dart about in straight lines until they encounter other molecules, they attain a speed of 1,470 feet a second at the freezing temperature. The average length of their path between two encounters — the *mean free path* — is about 1-277,000 inch, and the number of molecules in a cubic inch of air is about 10 raised to the 21st power. Each molecule experiences about 5,000,000,000 collisions a second.

Expansion of Solids, Liquids, and Gases.— The molecules of every substance attract one another with a force called cohesion. It is cohesion that prevents a wire from breaking when it supports a heavy weight. The pressure of the atmosphere also helps to hold the molecules of a body together. Opposed to both of these forces is heat. The effect of the agitation of the molecules is to make them jostle one another apart. Thus it is that in general an increase of temperature results in expansion. In solids, where the cohesion is enormous, the expansion for a given increase of temperature is very slight, especially when the test is made at low temperatures. At higher temperatures, when the molecules have somewhat weakened their mutual hold through having moved further apart, an increase of temperature equal to the previous increase generally results in a somewhat greater expansion. To express such ideas technically we employ the expression *coefficient of linear expansion,* which means the fraction of its length that a bar expands when heated one degree centigrade. As the length varies with the temperature, the length at the freezing point, 0° C., is taken as the standard length. Using then this expression we may say that the coefficient of expansion of a solid generally increases with the temperature. The coefficient of linear expansion of a number of substances will be found in the following table:

COEFFICIENTS OF LINEAR EXPANSION OF SOLIDS.

Aluminium	0.0000233	Wood (soft)	0.000003
Gold	0.0000144	Wood (hard)	0.000006
Iron	0.0000121	Vulcanite	0.000067
Lead	0.0000293	Paraffin	0.00034
Platinum	0.0000090	Quartz	0.0000013
Copper	0.0000168	Rock salt	0.00003
Zinc	0.0000292	Ice	0.00005
Silver	0.0000193	Glass	0.0000083
Steel	0.0000123	Granite	0.0000087
Guillaume's nickel steel (36 per cent nickel)	0.00000087	Porcelain	0.0000025

Two notable cases may be remarked. It is seen from the table that the coefficient for glass is very close to that for platinum. This fact is taken advantage of in the construction of incandescent electric lamps, and of those scientific instruments where it is necessary to have a wire pass through glass and leave an air-tight joint. In making the joint, the glass around the hole is softened by heat until it gathers closely around the hot platinum wire. In cooling, if the coefficient for platinum were higher than that for glass, the platinum would contract more rapidly than the glass and leave a leaky joint. The second case to be noted is that of Guillaume's nickel steel. The coefficient of expansion of this metal is so extremely small that

it is eminently suited to the construction of clock pendulum rods, of surveying instruments, and of standard scales of length, and to many other purposes where much expansion now proves an annoyance. Unfortunately the high cost of nickel will preclude the employment of this wonderful alloy in some cases.

The influence of expansion is seen in railroad tracks. On a cold day 60-foot rails may contract so as to draw apart one half of an inch. The cables of the Brooklyn Bridge support the slightly arched roadway. When they sag down in hot weather through expansion, they tend to make the roadway buckle. This tendency is increased by the expansion of the roadway itself. However, both tendencies were overcome through the foresight of the engineers, who provided a telescoping joint in the roadway at the middle of the span. The parts of this joint play in and out about a foot. On hot days clock pendulums grow longer, and so the clocks lose time. Glass when suddenly and hence unevenly heated, expands more at one point than at another, thus introducing internal strains that cause fracture, but vessels made of vitrified quartz are strong enough to resist this tendency to crack; they will endure without injury the sudden application of a blowpipe flame.

In liquids the molecules are so far freed from cohesion that they are able to roll around one another and to wander from one position to another. The small remaining cohesion is assisted by the pressure of the atmosphere or by any other pressure to which the liquid may be subjected and so the molecules in the body of the liquid are prevented from flying directly apart. It is on account of this small resistance to expansion that we find liquids very much more expansible than solids. The term *coefficient of cubical expansion* is employed to express the degree of expansibility of a liquid. It means the fraction of its volume that a liquid expands when its temperature is raised one degree centigrade. The cubical coefficient of a substance is three times as great as its linear coefficient, because we measure the effect of expansion in length, breadth, and thickness, instead of merely noting the expansion in length. Of course a liquid confined in a tube of unchanging dimension could only expand in length, but the effect in this one direction would be three times as much as it would be if the liquid were allowed to expand proportionally in all three dimensions.

Ether	0.00148		
Olive oil	0.00080		

The expansibility of water is strikingly irregular. Starting at the freezing point, water contracts as the temperature rises until at about 4° C. it has assumed its maximum density. A further increase of temperature now causes the water to expand, which it does at an increasing rate until it begins to boil at 100° C.

Gases surpass even liquids in their expansibility. Because in gases the molecules are relatively very far apart, cohesion counts for nearly nothing, leaving external pressure as almost the sole force restraining expansion. It appears that the coefficient of expansion of a gas is nearly independent of the external pressure, for though a greater pressure tends to restrain expansion more, the greater crowding of the molecules resulting from this pressure causes more frequent blows among the molecules, and makes the expansive force increase in nearly the same proportion as the external pressure. This law is not perfectly complied with because the molecules in a gas are not quite free from cohesion, especially when much compressed, and because the diameter of the molecule is an appreciable fraction of the distance between two molecules. Another law, fulfilled only approximately for the same reasons, is that all gases have the same coefficient of expansion, as will be seen in the following table, which gives the cubical coefficient referred as a standard to the volume the gas has at 0° C.

The Convection of Heat.—When the air in contact with a hot stove becomes warmed, it expands and grows lighter than the other air. Owing to unbalanced forces the hot air rises to the ceiling and then spreads out to the walls. It there becomes cooled, and therefore contracts and becomes dense. As a result it descends at the walls and finally returns to the stove only to start again on the journey. During this process, called *convection*, heat is carried by the air from the stove to the most distant parts of the room. Winds consist of convection currents in the atmosphere. Some parts of the earth's surface become more highly heated by the sun than others. The air over the hot areas expands and becomes specifically lighter than the surrounding air. The general result is that the hot air is forced to rise giving place to the surrounding cooler air which blows toward the hot area as a surface wind. The hot air risen aloft spreads away toward the cool regions as an upper wind. Corresponding to the ascent of air over the hot areas is a descent of air over the cool areas. Much heat is brought from the tropical regions to temperate regions by regular winds.

Convection phenomena also occur in liquids. A large vessel of water supplied with heat at one side of the bottom becomes through the action of convection currents uniformly heated throughout. Much heat is conveyed from the equator toward the poles by means of the Gulf Stream and other ocean currents. It is probable, however, that with ocean currents differences of temperature have little to do with the motion of the water, but that the motion is caused chiefly by the action of winds that blow with great steadiness in a westerly direction across the equatorial portions of the great oceans. Difference in salinity of the ocean at different latitudes may possibly be a partial cause of the phenomenon.

Thermometry.—Before proceeding further in the discussion of heat phenomena, it will be necessary to describe some of the methods employed for measuring temperature or the degree of hotness of a body. Most commonly the methods depend upon the property of expansion. In ordinary thermometers the expanding body is either mercury or colored alcohol. The

liquid, say mercury, is held in a glass tube having a fine bore and at one end a spherical or cylindrical bulb, the other end being simply closed. Above the mercury, which fills the bulb and part of the stem, is a space that is free from air and contains only a small amount of mercury vapor. When the thermometer is warmed, the mercury rises in the tube because the cubical expansion of mercury is greater than the cubical expansion of glass. The glass tube is provided with a scale, sometimes engraved directly on the tube, and sometimes engraved on some other material and mounted at the back of the tube. For a Fahrenheit scale division number 32 is placed opposite the mercury level when the thermometer is placed in pure crushed melting ice, and division number 212 is placed opposite the mercury level when the thermometer is placed in saturated steam over boiling water. As the temperature of the boiling point depends upon the atmospheric pressure, which is ever varying, the standard boiling point is taken to correspond to the average atmospheric pressure, which is measured by a barometric column of 760 millimetres. The space between these marks, the freezing and boiling points, is divided into 180 equal divisions, and then divisions equal to these are extended above the boiling point and below the freezing point. For the centigrade scale, which is generally employed in scientific work, the freezing point on the thermometer is marked 0° and the boiling point 100°. For the Réaumur scale, much used for household purposes in Germany, these points are marked 0° and 80° respectively, and finally for the De Lisle scale, which is used in Russia, the direction of the graduation is reversed, the boiling point being marked 0° and the freezing point + 150°. With this last thermometer, the greater the intensity of the *cold* the higher the number representing the temperature. Mercury thermometers permit of the measurement of rather high temperatures, mercury not boiling until the temperature of about 357° C. (674.3 F.) is reached. Still higher temperatures with mercury thermometers may be reached by checking the vaporization of the mercury through the introduction into the upper part of the tube of a compressed gas such as nitrogen. With such a thermometer the only limitation is the softening of the glass at high heats, and even this trouble is largely lessened by the use of vitrified quartz for the material of the bulb. On the other hand, mercury freezes at about — 39° C. (— 38.2° F.) and so becomes useless for indicating temperatures lower than this. For these lower temperatures alcohol may be employed as the thermometric substance because it resists freezing until temperatures far below any met with in nature are encountered. In addition to this advantage alcohol expands much more rapidly than mercury, thus permitting a much larger bore for the same length of degree. However, for very high temperatures alcohol is not available, as it boils at the moderate temperature of 78.3° C. (173° F.).

In practical work thermometry fairly bristles with errors. For several months after a thermometer is made the bulb gradually shrinks, probably owing to some molecular instability in the glass caused by the excessive heating employed in the process of blowing the bulb. This causes the thermometer to read too high. After each time a thermometer is used for a very high temperature the bulb on cooling fails to contract promptly to the volume proper to the new temperature, and so now the thermometer for a while reads too low; however, prolonged heating at the temperature of boiling mercury tends to put the glass into a more stable state. Also such troubles are much reduced by the use of hard glass instead of soft glass for the bulbs. Errors also arise from the following causes: non-uniformity of the bore; variations of atmospheric pressure, which cause a yielding of the bulb; failure to have the stem of the thermometer at the same temperature as the bulb; the hydrostatic pressure on the bulb due to the liquid being tested, especially when the thermometer is sunk to great depths; a variation in the internal pressure of the mercury itself on the bulb when the thermometer is inclined from the vertical position to the horizontal; a peculiar jerking motion of the mercury when it ascends a very fine bore; the fact that equal volumes of the bore marked off on the tube do not represent equal expansions of the mercury, since at high temperatures the volume of the bore indicating a degree has increased (this is quite distinct from the matter of the relative expansion of glass and mercury); irregularities in the expansion of the glass of the thermometer; and lastly irregularities in the expansion of the fluid itself, be it mercury, alcohol, air, or any other substance. This last source of error is worth much consideration because two thermometers otherwise perfect but containing different liquids, as alcohol and mercury, fail to agree in their indications. Further, we have no right arbitrarily to select any particular fluid as a standard and yet feel that our temperature scale has anything more than an empirical value. It will, however, be explained in the last section how a theoretical definition for temperature measurement can be formulated (the thermodynamic scale), agreeing fairly with ordinary thermometers, very closely with the hydrogen or nitrogen thermometer, and perfectly free from ambiguity.

In the hydrogen thermometer advantage is taken of the increase of pressure of a gas attending an increase of temperature, the volume of the gas being kept constant. The hydrogen is confined in a glass bulb about two inches in diameter which is connected by a thick-walled capillary tube with the top of one side of a U-shaped apparatus consisting of two vertical glass tubes connected by a rubber hose at their lower ends and partly filled with mercury. When the hydrogen in the bulb is warmed it tends to expand and push the mercury down its side of the U and to cause it to rise on the other side, which is open to the atmosphere. This effect is counteracted by raising the glass tube on the open side, the rubber tubing allowing this to be done. The extra back pressure of the mercury forces the hydrogen back to its former volume. In measuring the pressure to which the hydrogen at any time is subjected, the difference in level of the mercury columns must have added to it the length of the barometric column measured at the time. For each degree centigrade added to the temperature, the hydrogen is found to increase in pressure about 1/273 of its pressure measured at 0° C. Similarly for each degree subtracted, the pressure decreases 1/273 of the pressure at 0° C.

If this law held to the limit, we would conclude that at $-273°$ C. the hydrogen would lose all its pressure, thus indicating the cessation of all molecular motion — a veritable absolute zero of temperature. However, at extremely low temperatures the perfect working of this law is interfered with through the dominance of cohesion which reduces unduly the pressure of the hydrogen, and may cause it to assume the liquid or even the solid state. Nevertheless, this limiting temperature as predicted by the hydrogen thermometer agrees almost exactly with the true absolute zero of the thermodynamic scale referred to above. On this absolute scale the temperature of freezing water is approximately $+273°$ Abs., and temperature of boiling, $+373°$ Abs.

Other methods of measuring temperature depend upon change in the electrical resistance of platinum, and upon the electromotive force created when the juncture of two dissimilar metals as platinum and rhodium is heated. Very high and very low temperatures may be measured by such methods.

Conduction of Heat.—When a sterling silver spoon is placed in a cup of hot tea, the handle of the spoon soon becomes uncomfortably warm to the hand. Heat has been conducted through the silver. The molecules in the bowl of the spoon are the first to have their motion accelerated by contact with the tea. This extra motion is communicated to their neighbors which in turn pass it on until, step by step, the motion reaches the molecules in the handle. It appears that in some substances the character of connection between the molecules is more favorable to conduction than in others. As we might have expected, from the mutual grip of the molecules found in solids, that class of bodies furnishes the best conductors; but in gases, where the molecules are very loosely distributed, we naturally find the poorest conductors. Liquids as conductors occupy a position intermediate between solids and gases. Metals surpass all other materials in conducting power, silver standing at the very head of the list, while near the foot of the list of solids are found organic materials and mineral substances especially when in the porous or fibrous state, such as horn, leather, magnesia brick, asbestos fibre, sand, cotton wool, cowhair felt, and down. Great value is attached to poor conductors of heat. They are called insulators. Bone is used in joining the handles to silver tea pots. Our clothes are made of organic material woven so as to leave a multitude of fine pores, a condition favorable to insulation and met with in the fur of animals and in the feathers of birds. Saw dust and mineral wool for the same reason are made to serve as insulators of heat in the outer casing of ice boxes.

In the following table of conductivities the better conductors have the higher numbers. These numbers, called the *coefficient of conductivity*, indicate the amount of heat energy measured in calories (a *calorie* is the amount of heat energy required to raise the temperature of a gram of water one degree centigrade) conducted from one face to the opposite face of a centimetre cube of the substance when one of the faces is maintained one degree hotter than the other. The amount of heat energy conducted is proportional to the difference in temperature between the opposite faces.

Specific Heat.— In the last section the expression "heat energy" was employed, and the "calorie," its unit, was defined. If thin glass vessels containing equal weights at equal temperatures of different materials, mercury and water for example, be placed over equal gas flames so as to receive in a given time equal amounts of heat energy (equal numbers of calories), it will be found that the water will require nearly 30 minutes to get as hot as the mercury does in one minute. The water is said to have a greater capacity for heat than the mercury has. Making allowance for the heat capacity of the glass vessels and for radiation and conduction it is found that the heat capacity of mercury is 0.034 that of water. We say that the *specific heat* of the mercury is 0.034, for water is taken as the standard and its heat capacity is assigned the value 1.0. The value of the specific heat of a number of solids and liquids is given in the following tables:

SPECIFIC HEAT OF SOLIDS.

In the first table the atomic weights (the weight of the atom as compared with the weight of an atom of hydrogen) of some of the elements in the solid state are also given. The product obtained by multiplying the specific heat by the atomic weight is given in the last column. It will be observed that these products are approxi-

mately equal. This equality indicates that if we took as our standard of comparison equal numbers of atoms of a solid instead of equal weights, all elements in the solid state would have the same heat capacity. It takes about as much heat energy to raise the temperature of an atom of gold one degree as it does for one atom of aluminium. This law of Dulong and Petit also applies with some degree of approximation to compounds in the solid state — not equal heat capacity for the molecules, but for the atoms.

In the cases of gases we have two specific heats according as on the one hand the gas is confined to constant volume while being heated, or as on the other hand the gas is allowed to expand so as to keep the pressure constant. This is shown in the accompanying table where it will be seen that the specific heat at constant pressure is greater than the specific heat at constant volume.

SPECIFIC HEATS OF GASES.

Substance	Symbol	Constant volume equal weights	Constant pressure		Ratio of specific heats, equals cal. 4 ÷ cal. 3
			Equal weights	Equal volumes

Ether	C_4H_4O	.467	.4810	1.2296	1.03

This difference in specific heat in the same gas is due to two causes. When the gas expands not only do the molecules acquire greater kinetic energy, but in pushing each other farther apart against the attractive force of cohesion, they require a further amount of energy of the potential sort, and in pushing back the restraining pressure of the atmosphere still another large supply of energy is needed. It appears from several independent considerations that in gases far removed from their liquefying points the cohesion effect is exceedingly small, and so we conclude that the excess of specific heat of an expanding gas is almost entirely due to work done on the external pressure applied to the gas.

In the last column of the table the ratio of the two specific heats of the gases is given. This ratio is found to vary, decreasing from simple gases like mercury vapor, the molecules of which have single atoms, to complex gases like ether vapor, the molecules of which have 15 atoms. With complex molecules a large part of the energy is internal, much being stored up in the rotating motion of the individual molecules, and in the relative motion of their atoms, leaving the energy of translation of the molecules and the energy due to the pushing back of the external pressure about the same as before. It follows then that the energy associated with the external pressure is a smaller fraction of the whole energy, and that therefore, as observed, the ratio between the heat energy imparted to an expanding gas and the energy imparted to a non-expanding gas must be smaller for such complex molecules. The value of this ratio is the principal means of judging of the number of atoms in a molecule of an element in the gaseous state.

Before leaving this subject it should be remarked that the specific heat of water varies slightly with the temperature, and so it is convenient to take as the value of the calorie one hundredth the heat required to raise the temperature of a gram of water from 0° C. to 100° C.

Latent Heat.—If heat energy be imparted to a mass of ice at the point of melting, the ice will proceed to melt, but will not grow any warmer as it does so. The heat energy thus added without increasing temperature is called *latent heat.* Latent heat is devoted only to shaking the molecules of ice asunder, not to increasing their speed. Temperature depends upon the energy of motion (kinetic energy) of the molecules; latent heat only stores up energy of position (potential energy) of the molecules, and so does not produce an increase of temperature. Again, when water is being boiled, a large amount of heat energy becomes latent. The latent heat of vaporization and of melting for a variety of substances is given below.

LATENT HEAT OF VAPORIZATION.

	Calories		Calories
Water	536	Mercury	62
Acetone	126	Carbon disulpbide	90
Ethyl alcohol	206	Sulphur	362
Methyl alcobol	264	Ether	91
Liquid air	47		

LATENT HEAT OF MELTING.

Ice	80.	Silver	21.07
Sulphur	9.37	Mercury	2.82
Paraffin	35.10	Iron	35.
Phosphorus	5.	Platinum	27.
Bees'-wax	42.	Tin	14.
Zinc	28.13	Bismuth	13.
Lead	5.86	Copper	30.

It should be remarked that the latent heat devoted to converting a liquid into vapor besides increasing the internal potential energy of the molecules also does work in pushing back the atmosphere, but with water this external work bears a very small ratio to the internal work against cohesion, namely, a little more than one twelfth.

Heretofore we have supposed the energy for melting or for vaporization to be derived from some external source of heat. It is, however, possible to secure a change of state through the consumption of the heat energy of the body itself. If water be left in an open vessel it will presently have evaporated entirely away. During the progress of this vaporization a thermometer placed either in the water or in the moist air above the water will show a temperature lower than that of the surrounding air. The reason of this is as follows: At the surface of the liquid, with all the irregularities of position and velocity possessed by the molecules, some of them find opportunity to fly off from the liquid surface. On the average it will be the faster going molecules that spring away first, thus leaving the more slowly going ones behind, which is the same as saying that the remaining liquid is cooler. Also in going away, the

molecules fly against the back pull of cohesion, and so their velocity is checked. Indeed many are entirely stopped and drawn back into the liquid, though others escape quite beyond the range of cohesion of the liquid and diffuse among the molecules of the air. The reduced motion of these escaping molecules causes the low temperature referred to above of the vapor. Common illustrations of cold by evaporation are frequently met with. The function of perspiration is a means of regulating the temperature of the human body. In the healthy state when we are overheated the skin becomes very moist and the evaporation of this moisture, assisted by a breeze or by fanning, cools the surface. In disease the proper action of the skin may be interfered with, and becoming dry, may fail through lack of evaporation to provide the normal cooling effect. An exalted temperature of the body ensues; in other words, a fever. Certain drugs tend to promote perspiration and thus reduce the temperature of the patient. Another large factor in the temperature regulation of the body is in the water evaporated from the lungs in the process of breathing. The evaporation of ammonia that has been liquefied by pressure furnishes the cold employed in some ice machines. In the case of liquefaction the necessary latent heat may be derived from the body itself. This occurs when a salt is dissolved in water, a process that is generally accompanied by a fall of temperature, though occasionally a rise in temperature is noted. The factors governing the result in such cases are rather complicated. We have to take account of the work done by the solvent in tearing molecules away from the solid lump and in some cases the tearing of these molecules apart into electrically charged parts called ions. On the other hand a certain amount of kinetic energy is furnished by the attraction of the molecules of the dissolving substance by the molecules of the solvent. According as the back pulls or the forward pulls predominate, will the temperature of the solution be lowered or raised. If much chemical action takes place between the substance and the solvent, the solution is almost always warmed.

The temperature at which melting takes place depends upon external pressure. When a solid like paraffin expands on liquefying high pressure, which resists expansion, stops melting until a temperature slightly higher than the ordinary melting point is reached. Paraffin that under ordinary conditions melts at 46.3° C. melts at 49.9° C. when subjected to the additional pressure of 100 atmospheres. In the case of ice, which contracts on melting, melting is favored by pressure. The addition of one atmosphere of pressure lowers the melting point of ice by 0.0072° C. This fact accounts for the slipperiness of ice especially when being skated upon. The sharp edge of the skate exerts great pressure on the ice below it, which melts and furnishes a lubricating film of water. This film of water is cooler than the ice furnishing it, some of the heat of the ice having become latent, and as soon as the skate has passed over, the water immediately resumes the solid state. This process of freezing again is called regelation. Regelation is an important factor in glacier motion. The ice as it follows down a tortuous valley is continually being cracked. After the settling following this cracking, the great pressure from the upper ice fields melts the ice at the points of contact of opposite sides of a fracture, and the escaping undercooled water freezes again, thus healing the fracture. In this way the glacier appears to follow down the irregularities of a valley as would a very viscous mass.

MELTING POINTS.

Saturated and Unsaturated Vapors.—When a liquid, water for example, is placed in a vacuous enclosure kept at constant temperature by artificial means, it immediately begins to evaporate, the vapor presently attaining a maximum density and pressure. The vapor as well as the space occupied by it is then said to be *saturated.* Before this maximum pressure was reached the vapor was unsaturated. If the temperature of the whole apparatus be now raised, more water will commence to evaporate, and the vapor will increase in density and pressure before it is again saturated. Had the saturated vapor formed in the first place been shut off from the water surface before raising the temperature, it would not become as dense as when it had the water evaporating into it, and so we would then pronounce the heated saturated vapor as unsaturated. On the other hand if a mass of unsaturated water vapor be cooled, the density of the vapor will at a certain temperature be sufficient to cause saturation. Below this particular temperature, called the *dew-point,* some of the moisture will condense. In some cases, however, when there are no nuclei in the form of dust particles, free ions, etc., the vapor may cool appreciably below the dew-point without immediate condensation. The vapor is then said to be supersaturated. The presence of air has only a very small influence on the density and pressure of saturated water vapor in contact with water, especially when the temperature is not high.

When the temperature of water or other volatile liquid is raised so high that the pressure of the saturated vapor becomes as great as that of the atmosphere, bubbles of the vapor begin to form in the body of the liquid. This constitutes the process of boiling. The temperature at which a liquid boils is much influenced by the external pressure. The boiling point is the same as the temperature at which the pressure of the saturated vapor equals the external pressure on the bubble. In the following table these temperatures with their corresponding pressures are given for water.

PRESSURE OF WATER VAPOR.

Temperature degrees centigrade	Pressure in millimetres of mercury	Temperature degrees centigrade	Pressure in millimetres of mercury

Nitrous oxide	— 89.	Aniline	+ 184.4
Carbon dioxide (sub-limes)	— 80.	Sulphuric acid	+ 330.?
Chlorine	— 33.6	Sulphur	+ 448.4
Ammonia	— 32.9	Mercury	+ 356.8
		Zinc	+ 958.

A saturated vapor in contact with its liquid offers a beautiful instance of dynamic equilibrium. We conceive that molecules are ever leaving the surface of the water, adding themselves to the vapor. At the same time molecules of the vapor coming near to the liquid surface or plunging into it are caught by the cohesion of the liquid, thus subtracting themselves from the vapor. A less dense vapor would lessen the latter process and would allow the vapor to grow denser; a denser vapor would increase it and allow the vapor to fall to a state — the saturated state — when the rate of evaporation is just equal to the rate of condensation.

The degree of moistness of air is expressed by the phrase *hygrometric state*. The hygrometric state does not express the density of the water vapor present, but instead expresses the quotient obtained by dividing the density of the vapor present by the density of the vapor required to saturate the air. If pressures were employed instead of densities in getting the quotient, substantially the same result would be obtained. Still another common way of defining hygrometric state is to take the quotient obtained by dividing the pressure of the vapor corresponding to the dew-point by the pressure of vapor saturated at the temperature of the air, a method closely agreeing with the former ones.

The Critical State.—When the temperature rises, the density of a saturated vapor in contact with its liquid becomes denser, while the liquid itself expands and becomes less dense. If the heating of the liquid and vapor takes place in a strong closed vessel containing not too much or too little of the liquid, after a while a temperature is reached at which the saturated vapor becomes as dense as the liquid. At this point they become identical in their physical properties; the line of demarkation of liquid and vapor fades away, and the two fluids begin to mix. The temperature at which this phenomenon occurs is called the *critical temperature*, the corresponding pressure is called the *critical pressure*, and the liquid is said to be at the *critical state*. Above the critical temperature it is impossible to distinguish between a liquid and its vapor. No matter how great the pressure, a gas or vapor cannot be forced into the state of a liquid that is obviously distinct from the vapor unless the vapor be cooled below the critical temperature.

CRITICAL TEMPERATURES AND PRESSURES.

Substance	Critical Temperature Degrees Centigrade	Critical Pressure Atmospheres
Hydrogen	— 225.	15.
Oxygen	— 118.8	50.8

Water	+ 365.	200.
Ethane	+ 34.	50.2
Ethylene	+ 10.	51.7

Radiation.—We have described two methods by which heat energy may be transferred from one place to another — by conduction and by convection. A third method remains to be studied. How does the heat of the sun reach us? By means of waves in the luminiferous ether. Go to a quiet pond in which a piece of wood may be floating. Standing on the shore, vibrate your hand up and down in the water. Waves run from your hand over the surface of the water to the wood and cause it to vibrate up and down. Energy from the hand has been transferred to the wood by means of waves. These waves consist of the successive vibration of successive particles of water, each particle receiving energy from behind and passing it on to the front. It is much the same with heat waves. The ether, which fills all space, is capable of being set into vibration by vibrating molecules and of handing this vibration on step by step in the form of waves. Molecules acted upon by these waves are themselves set into vibration. The vibrating molecoles of the sun generate ether waves, and the ether waves generate vibration of the molecules of bodies on the earth. These ether waves are called *radiant heat*. We now have a very wide range of ether waves under experimental control. From the large waves generated by electrical oscillations used in wireless telegraphy

and sometimes a quarter of a mile long we may pass by insensible gradations with only two breaks to the extremely minute waves supposed to constitute Roentgen's X rays. Dark heat waves or infra-red rays, ordinary light, and ultra-violet light belong to the middle of the series. Quite recently Blondot has discovered a peculiar radiation which he designates as *n rays.* There are indications that n rays are ether waves about one fifth of a millimetre in length. All of these waves behave very much like light. They all have the same velocity as light, namely, 186,300 miles a second (n rays not tested yet). All except Roentgen rays may be reflected, refracted, polarized, and absorbed by transmission to a degree depending upon the substance used for transmission and the particular wave-length of the rays.

Thermodynamics.—The most cogent reason for discarding the caloric theory of heat is that heat may be generated from that which is not in any sense substance — heat may be derived from mechanical energy. Heat is generated when a brass button is rubbed on the carpet, when a bullet is struck with a hammer, and when two pieces of ice are rubbed together, a process resulting in their melting. The relation between mechanical energy and the heat energy generated by its consumption was first carefully investigated by J. P. Joule before 1850. One pound-calorie of heat energy is obtained from 1,400 foot-pounds of mechanical energy. That is to say, the energy due to the fall of 1,400 pounds through the distance of a foot is sufficient if transformed into heat to raise the temperature of a pound of water through one degree centigrade. This number of foot-pounds is called the *mechanical equivalent of heat,* for it has been found that the process is reversible. When by means of an air-engine or a steam-engine one pound-calorie of heat is consumed in generating mechanical energy, 1,400 foot-pounds of the latter are obtained. *The first law of thermodynamics* states that when mechanical energy is converted into heat, or when heat is converted into mechanical energy, the quantity of mechanical energy is equivalent to the quantity of heat energy. *The second law of thermodynamics* states that it is impossible for a machine without the consumption of external energy to make heat pass from a body at a low temperature to one at a high temperature. When external energy is supplied, the transfer of heat becomes possible through the use of a reversible engine. A reversible engine is one that while it may on the one hand take heat from a high temperature source and transfer it to a low temperature escape with a conversion of a definite portion of the heat into mechanical energy, may, on the other hand, when its operation is reversed by the application of external mechanical energy equal in amount to that generated in the first operation, take back the same heat from the low temperature escape and transfer it together with an amount of heat equal to that lost in the first operation to the high temperature source. The fraction of the heat leaving the high temperature source converted into mechanical energy, or when the engine is reversed, the fraction of the heat entering the high temperature source obtained from the mechanical energy applied has been shown by Carnot to be the same for all reversible engines of whatever nature and working with any substance whatsoever, provided they work between the same temperatures. This fraction may be called the *thermodynamic efficiency* of the engine. The thermodynamic efficiency of good steam-engines occasionally exceeds 20 per cent. This means that 20 per cent of the heat energy supplied to engine is transformed into mechanical energy, the remaining 80 per cent escaping unused at the condenser or exhaust.

Using the provisional absolute scale as indicated by a hydrogen thermometer experiment shows that the efficiency, W/H, is roughly represented by the following equation in which W stands for the mechanical energy realized, H for the heat (measured in the equivalent foot-pounds) leaving the high temperature source, T for the temperature of the source, and T^1 for the temperature of the cooler escape.

$$\frac{W}{H} = \frac{T - T^1}{T}$$

This suggests a new definition for a temperature scale, namely that numerical values of temperatures be so adjusted as to fulfil exactly the above formula. Since the formula only fixes a ratio between the temperatures T and T^1 corresponding to a given efficiency, an infinite number of sets of numerical values for these temperatures could be found to satisfy the formula. But if it be decided that a definite numerical range, say one hundred degrees, be comprised between the freezing and boiling points of water, only one set of values becomes possible. This decision makes the value of the freezing point very nearly $+273°$ Abs., and the value of the boiling point $+370°$ Abs. Lord Kelvin was the first to propose this *thermodynamic scale.* Theory shows that its indications would correspond exactly to a thermometer containing a perfect gas. Hydrogen is not quite a perfect gas, for its molecules attract each other slightly and they occupy an appreciable fraction of the space holding the gas. Hence there are small deviations of the hydrogen thermometer from the thermodynamic scale, especially at low temperatures. It should be added that the practical realization of the thermodynamic scale, though much aided by very ingenious mathematical considerations relating to careful experiments made by Regnault on the expansion and the increase of pressure observed when hydrogen and other gases are heated, and by Joule and Kelvin on the temperature changes suffered by gases in expanding through a porous plug, still that realization is far from complete. Nevertheless, the thermodynamic scale offers us a theoretical ideal which is absolutely independent of the thermal properties of any particular substance, but is only related in a definite way to a fixed universal law.

When a *small* amount of heat is transferred from or to a gram of a substance, the heat transferred (measured in calories), divided by the average absolute temperature of the substance at the time of the transference is called the *change* of *entropy* of the substance. For convenience, the zero of entropy is generally taken to correspond to water at the freezing point and under the normal atmospheric pressure. It may be shown that when two bodies at different temperatures are

placed in contact and their temperatures become equalized, the average entropy rises, for from the above definition of entropy, the heat leaving the hotter body must reduce its entropy less than it increases the entropy of the cooler body into which the heat enters. Consequently the average entropy of the universe is constantly rising and tending toward a maximum. At the same time the availability of the energy of the universe is tending toward zero.

Ernest R. von Nardroff, E. M., D. Sc.,
Head Science Department Erasmus Hall High School, Brooklyn, N. Y.

Heath, Daniel Collamore, American publisher: b. Salem, Maine, 19 Jan. 1857. He was graduated from Amherst in 1868, became junior member of the firm of Ginn and Heath, publishers of Boston, and in 1886 established in Boston the house of D. C. Heath & Company, publishers of text-books for schools and colleges, with branch offices in New York, Chicago and London.

Heath, Francis George, English writer: b. Totnes, Devon, 15 Jan. 1843. He entered the civil service as a clerk of the higher division in the customs department in 1862, and was transferred as surveyor to the outdoor division of that department in 1882. In 1896 he founded and in 1897 became editor of the Imperial Press, in connection with which he directed from 1896 the publication of the Imperial library. He was for several years prominent in his activity for the preservation and extension of open spaces in and about London; and published: 'The "Romance" of Peasant Life' (1872); 'The Fern World' (1877; 10th ed. 1902); 'Our Woodland Trees' (1878); 'Where to Find Ferns' (1881), and other volumes.

Heath, Perry Sanford, American journalist and politician: b. Muncie, Ind., 31 Aug. 1857. He learned the printer's trade, in 1877 became a newspaper reporter, in 1878–80 was editor of the Muncie *Times*, and in 1881 established the *Pioneer* at Aberdeen, S. D. In 1881–93 he was a correspondent at Washington, D. C., in 1894–6 president and general-manager of the Cincinnati *Commercial-Gazette* (now the *Commercial-Tribune*), and in 1897–1900 was first assistant postmaster-general of the United States. In 1900 he was elected secretary of the Republican National committee.

Heath, William, American soldier: b. Roxbury, Mass., 7 March 1737; d. there 24 Jan. 1814. When the Massachusetts congress in 1774 voted to enroll 12,000 minute men, volunteers from among the militia, Heath, then a farmer in Roxbury, was commissioned as one of the generals. In June 1775 he received the appointment of brigadier in the Continental army, and in August 1776 was created major-general. When the troops moved to New York Heath was stationed in the highlands near King's Bridge, with orders to throw up fortifications for the defense of that important pass. In 1777 he was transferred to Boston, and the prisoners of Saratoga were entrusted to him. In June 1779 he was again in New York, at the Highlands, with four regiments, and was stationed near the Hudson till the close of the war. He was the last surviving major-general of the war. Consult: 'Memoirs of Maj.-Gen. Heath, containing Anecdotes, Details of Skirmishes, Battles, etc., during the American War' (1798).

Heathcock, Heath-hen. See Blackcock.

Heath'cote, Caleb, American merchant: b. Chesterfield, Derbyshire, England, 6 March 1665; d. New York 28 Feb. 1721. He was successful in a mercantile career in New York from 1692, save for the years 1698–1701, was a councillor of the province, was a petitioner for a license to build Old Trinity, was mayor of New York in 1711-14, and held other posts, among them those of judge of Westchester County; commander-in-chief of the military of the colony; surveyor-general; and receiver-general of customs for North America. His letters and despatches afford interesting glimpses of the history of his time.

Heaths, or Heather, a group (*Ericoideæ*) of the order *Ericaceæ*. The leaves of the heaths are simple and entire; their flowers oval, cylindrical, or even swelled at the base; the anthers of many with horn-like appendages. From 400 to 500 species are known, 12 or 15 of which inhabit Europe, and have small flowers, while all the remainder are natives of South Africa, many of them bearing brilliantly colored flowers, and forming one of the most characteristic genera of that region of dry plains. The common heath of Europe (*Calluna vulgaris*), a low shrub, often covers exclusively extensive tracts of dry land, and is used in domestic economy; mixed with oak-bark it is employed in tanning; and also, when tender, for fodder. This species forms the "heather" of British moorlands; but in Scotland are two other species, whose flowers are the "heather-bells" of Scottish song and story. Many South African species, remarkable for the size and beauty of their flowers, are much cultivated in greenhouses, and have been so improved and hybridized that they exhibit a wonderful richness of color.

Heating and Ventilation. Generally speaking, the methods of heating buildings may be divided into two general classes — the direct and the indirect system, or a combination of the two. Heating by means of an open fire, by a stove, and by radiators placed in the rooms to be warmed are examples of the former method, while furnace-heating and heating by means of a current of air warmed by indirect steam or hot-water coils are examples of the latter method. When a direct radiator is fitted with a connection to the outer air, it is said to be arranged on the direct-indirect principle. Hot water, steam, or electricity may be the vehicle used for conveying heat to radiators. Ventilation is only obtained by supplying air, and in some systems of heating and ventilation the air is made so hot that part of it is available for heating purposes. This is the case in furnace-heating.

It is well known that when two bodies of different temperature exist, heat passes from the warmer to the cooler body until their temperatures are equal. If a building be of a temperature of 70° F. and the outer air of a lower temperature, heat will be transmitted by the walls, windows, and other exposed surfaces, and the temperature of the air in the building will be lowered. It is only by supplying to the building an amount of heat equivalent to that transmitted by the walls and windows that it is possible to maintain the building at constant temperature. If we supply more heat than is

transmitted by the walls, the temperature of the room rises.

Heat is measured in units which have as exact a value as a ton of coal or a pound of sugar. British physicists have selected as the unit of heat that quantity which will raise the temperature of one pound of water one degree on the Fahrenheit scale when the water's temperature is near 39° F. This unit is designated as the British thermal unit. It is known with reasonable accuracy just how many heat-units are transmitted by each square foot of wall, window, and other exposed surfaces of the various materials used in building construction, under such extreme conditions as to building and outside temperature as may exist. With these data and the plans of a building, calculation will show the heat-loss from a building or a room, and the heating-apparatus should be proportioned to supply this amount of heat. Allowances are made for various conditions that may exist, depending upon the judgment and experience of the designer. The heat required can be supplied by radiation from an open fire or from a stove, but this is an unsatisfactory method. Direct radiators supplied with steam or hot water can be placed in a room to furnish the heat necessary, or the heat may be supplied by hot air from a furnace, or by air heated by indirect radiators supplied with steam or hot water.

Heating by hot air is a slightly more expensive method than heating by direct radiation, for to be effective the air must be taken in from outdoors, sometimes at very low temperature, and heated above the temperature of the room to be warmed. If cold air at 40° F. is heated to 100° F., and is supplied to a room at this temperature, it is evident that as soon as this air is cooled from 100° to 70° no more heat can pass from the air to the room if the temperature of the latter remains at 70°. Under these conditions only one-half of the heat that has been supplied to the air is available for heating the room. This will tend to show why heating by hot air is more expensive, estimated from the cost of fuel, than the direct system. When the advantages of the air supply that accompanies indirect heating are taken into account the increased fuel cost becomes insignificant.

Direct heating is usually obtained by steam and hot-water radiators. Although manufacturers have greatly improved the appearance of direct radiators, at best they are unsightly and objectionable from an artistic point of view. This objection may be overcome by concealing the radiators in boxing beneath windows, when the walls of the building are thick enough to permit the boxing to be built in without projecting into the room. A screened opening is provided in the front of the boxing near the floor, and one at the top over the radiator, to permit a circulation of air, so that the radiators can be effective.

In residence-heating it is frequently the custom to heat the first floor by the indirect method and the upper stories by the direct. When an owner will pay for it, the indirect method is used throughout the building. Such a system is much to be preferred to the direct.

The simplest method of connecting steam-radiators is by the gravity system, and it is usually employed unless steam exhausted by engines is available for heating. This system comprises distributing-mains connecting with the top of the boiler, and with vertical riser-pipes from which horizontal branches lead to the radiators. Usually a return pipe is connected to the opposite end of the radiators from that at which steam is admitted, this return connecting, through return risers and mains, with the boiler at a point below the water-line. As the steam in the radiators condenses, the resulting condensation flows back by gravity through the return pipes to the boiler. The flow and return pipes are made sufficiently large to insure a practically uniform pressure throughout the system. The system is simplicity itself, as the fire only needs attention. When the boiler is once filled, no more water is required.

It is only recently that the steam exhausted by engines and pumps has been used for heating. Before this time steam direct from the boilers was used in direct radiators for heating mills and factories. The radiators consisted of coils of pipe suspended from the walls or ceilings. Sometimes the condensation was returned to the boilers by a pump or other device; sometimes it was allowed to go to waste. As the steam exhausted by engines, pumps, etc., contains a very large percentage of the heat that it contained upon entering the engine, someone conceived the idea of utilizing this steam for heating buildings, thereby saving the steam direct from the boilers that would otherwise have to be used. This practice is now almost universal where exhaust-steam is available, and the saving that it has occasioned is very great. By placing what is known as a back-pressure valve in the exhaust-pipe, sufficient pressure is maintained to cause the exhaust-steam to circulate through the pipes and radiators of the heating-system, the latter being connected to the exhaust-pipe between the engine and the back-pressure valve. The condensation that occurs in the heating system can be collected and returned to the boilers by various methods. Usually a pump or similarly acting device is employed.

A hot-water system arranged on the gravity-principle has flow and return pipes similar to the gravity-system of steam-heating described. The entire system is filled with water. As the water is warmed in the boilers it becomes lighter in weight per cubic foot, making a difference in pressure between the flow and return pipes and causing a circulation to begin. The water rises in the flow pipes to the radiators and is there cooled. On its return to the boiler the water is again heated, and so the circulation is maintained. As the difference in weight between the water in the flow and return pipes is very slight, the motive power producing the circulation is very slight also. Hence the pipes have to be relatively larger than for steam-heating and very carefully connected to avoid excessive friction, which would stop or retard the circulation. As large pipes are costly, in some large plants heated by hot water, a circulation is brought about by pumps.

Direct steam-radiators emit about 250 British thermal units per square foot of radiating surface per hour, and hot-water radiators about 180 heat-units per square foot. Consequently about one third more radiating surface is neces-

sary with hot water than with steam. The pipes also must be larger, hence the hot-water system is the most expensive in first cost. Hot water, however, is cheaper to operate, for water will circulate with a very low fire and supply the small amount of heat required to warm a building in mild weather.

With direct steam-heat, operating on the gravity-system, it is impossible to vary to any appreciable extent the temperature of steam in a radiator; hence with this system the alternative is, all the heat the radiator will supply or none at all. This is the principal objection to heating by means of direct steam. Air warmed by the relatively cooler hot-water radiators is thought by some to be more agreeable than air heated by steam-radiators.

With indirect heating the lack of means of regulating the steam-temperature is not of so much moment, for the air-supply can be partly shut off by partly closing a register in mild weather; or else, if the full air-supply is required at all times, arrangements can be made for passing part of the air-supply around the indirect radiators, which is called "by-passing" them. Another method is to divide the indirect radiator into independent sections and place some of the sections under the control of a regulator that automatically shuts off the supply of steam when the room becomes too warm. The method of "by-passing" the radiator, or subdividing it, is used mainly with the fan-system of supplying air.

The cost of indirect hot-water heating is greater than that of indirect heating by steam, as the radiators and pipes must be larger, the same as in direct heating. Hot water is, however, cheaper to operate. The principal objection to its use in indirect heating is the possibility of damage to the indirect radiators through the freezing of the water in them in severe weather, if the circulation should from any cause be arrested.

The direct-indirect system consists of direct radiators connected with the outer air by means of an opening in the building-walls beneath the window-sill, the radiator being set under the window opposite the opening. With this system there is always the possibility of getting too much air when the wind blows strongly. Furthermore, in situations where the air is smoke-laden or dusty, it is not easy to keep the smoke and dust from entering a building supplied with air by this means.

As has been said, a supply of air may be brought about by the gravity-method or by means of fans. In the gravity-method the heated column of air in the flue is lighter than the outdoor air; hence it rises. As in the case of hot-water heating, the motive power is very slight, and it becomes less as the outdoor temperature increases. For this reason the gravity system is not a positive one, and it cannot be depended upon to supply much air in mild weather. Its use for schoolhouse ventilation is therefore to be deprecated. An important advantage of this system is its simplicity, as no machinery is required with it.

With the fan-system some type of fan is employed, to give a positive supply of air. The air is blown over coils, usually steam, and delivered to the room at a temperature slightly above that of the room, if the air-supply is intended to ventilate only, or at a higher temperature if the air-supply is to carry with it the heat necessary to balance that transmitted by the walls and windows. In the former event the indirect coils act as tempering-coils, being sufficient only to raise the air to about 70° F. If the air-supply is to furnish heat for warming the rooms, additional coils, known as supplementary coils, are provided. These raise the air-temperature from 70° to from 100° to 120° F. Sometimes the supplementary coils are combined with the tempering coils, the whole being divided into several independently controlled sections. In some instances the supplementary coils are divided into a number of small coils, one being placed at the base of each air-supply flue, and so arranged that, by adjusting dampers controlled by hand or automatically, the temperature of the air supplied to any room can be regulated independently of that supplied to other rooms. If all of the air is passed through one group of coils, independent regulation of the temperature of the air in the branch ducts and flues is impossible. This independent regulation can be obtained, however, by the double-duct system. The coils are divided into two groups, one for tempering and one for supplying additional heat. All of the air is passed through the tempering coils, but only part of it through the supplementary coils, the balance "by-passing" the latter coils and flowing through a system of ducts, usually located below the system conveying the air of higher temperature, to the base of the flues. At the junction of the two ducts a mixing-damper is provided, so arranged as to open in one duct as it closes in the other. By adjusting this damper the air can be mixed to give the resultant temperature required.

In situations where direct radiators can be used, either exposed or concealed, it is becoming the practice to provide sufficient heat by means of direct radiation to balance the heat transmitted by walls, windows, etc., also a supply of tempered air for ventilation only. As previously explained, when heat is supplied by means of air, the fuel-cost is greater than with direct heating; so that a building can be warmed with less coal with the direct than with the indirect system. Furthermore, with the combined system, heating can be done at night, and at other times when air-supply is not required, at minimum cost. This system is particularly adapted for schoolhouse heating and ventilation.

The withdrawal of impure air from rooms is effected by fans connected to a system of vent-flues extending upward to an attic space, or downward to a cellar or basement, if the latter is more convenient. Another method of accelerating the outflow of air through flues rising to the roof of a building is by the use of aspirating coils. These are simply coils of pipe, or radiators, placed in the vent-flues as low down as possible, the coil heating the air and thus causing it to rise. Theoretically the aspirating-coil is a more expensive method of moving air than the mechanical method, as far as fuel-cost is concerned. It is simpler, however, than the fan-system.

Fans are of two general types — the disk or propeller fan, and the centrifugal blower. The former is constructed somewhat like a ship's propeller, and the current of air that it produces is mainly in a direction parallel with the shaft of the fan. The centrifugal blower, as usually de-

signed, consists of a wheel with blades, something like a ship's paddle-wheel, enclosed in a casing. The air enters at the axis of the fan, and when the fan-wheel is revolved the air is discharged radially to the casing by the action of centrifugal force. Relatively speaking, the propeller-fan will move a large volume of air with small expenditure of power, but the pressure at which it will deliver air is limited. The centrifugal fan will deliver air under a greater pressure and the power required is therefore greater. In some buildings, where the system is of ducts and flues, is long, and the cross-sections are comparatively small, to save space, quite a pressure is required to force the necessary amount of air through them. For such situations the centrifugal blower is best adapted. When the ducts are short and of ample area, it is best to use the propeller type of fan.

Fans are driven usually by small steam-engines or by electric motors. Sometimes gas-engines have been used with success. Where an engine is used, it is necessary for the boilers to operate under a sufficient pressure to drive the engine, or at least under a higher pressure than is commonly used with the gravity-system of connecting radiators. If the steam exhausted by the engine is condensed in the heating-system, as it usually is, a pump is necessary to return the condensation to the boilers. In large office buildings, public buildings, theatres, etc., where a skilled engineman is employed to care for the plant, the use of a pump, an engine, etc., does not present an objection. On the other hand, in the case of schoolhouses, large residences, churches, etc., which are apt to be looked after by less skilled attendants, an engine, pump, and other apparatus that must go with them are open to objection. In such cases electric motors can be used if current can be obtained from an electric-supply company. The entire heating system can then be operated on the simpler gravity-system. Of course the current must be paid for, but in many locations its cost will be more than offset by the greater simplicity of the motor-driven system.

Heating by electricity is not done to any great extent, on account of the excessive cost. When coal is burned under a steam-boiler, it is not uncommon for 60 per cent of the heat in the fuel to be realized in the steam which can be used for heating. If the heat in coal be transformed into electrical energy, and this again transformed into heat, less than 10 per cent of the heat in the fuel will be realized for heating.

HENRY C. MEYER, JR.,
Consulting Engineer.

Hea'ton, Augustus George, American artist: b. Philadelphia, Pa., 28 April 1844. He was the first pupil from the United States to study at the Paris Beaux-Arts, where he was trained by Cabanel. Later (1878–80) he was in the studio of Léon Bonnat, and exhibited considerably at the Salon. Among his paintings are: 'Washington at Fort Duquesne'; 'The Recall of Columbus,' engraved on the 50-cent Columbian Exposition stamp of 1893; a portrait of Bishop Bowman; and 'Hardships of Emigration,' engraved on the 10-cent Omaha Fair stamp. He wrote 'The Heart of David — the Psalmist King' (1900).

Heaton, John Henniker, English publicist: b. Rochester, Kent, England, 1848. He was for some time prominent in Australian journalism and has sat in the House of Commons for Canterbury from 1885. He carried the Imperial Penny Postage Scheme in July 1898, introduced telegraph money orders into England, the parcel-post to France, and has been connected with other progressive schemes. He has published: 'Manners and Customs of the Aborigines of Australia'; 'Australian Men of the Time'; etc.

Heaton, John Langdon, American journalist: b. Canton, N. Y., 29 Jan. 1860. He was graduated from St. Lawrence University in 1880, entered journalism as a member of the Brooklyn *Times* staff in 1881, and in 1897 became assistant editor of the New York *World*. His publications are: 'The Story of Vermont' (1889); 'Stories of Napoleon' (1895); 'The Book of Lies' (1896); 'The Quilting Bee' (1896).

Heaven, in a physical sense, is the azure vault which spreads above us like a hollow hemisphere, and appears to rest on the limits of the horizon. Modern astronomy has taught that this blue vault is, in fact, the immeasurable space in which earth, sun, and planets, with the countless host of fixed stars, revolve. The blue color of the heavens is due to the action of minute particles in the air upon the blue rays in sunlight.

In ancient astronomy, heaven denoted a sphere or circular region of the ethereal heaven. The ancient astronomers assumed as many different heavens as they observed different celestial motions. These they supposed to be all solid, thinking they could not otherwise sustain the bodies fixed in them; and spherical, that being the most proper form for motion. Thus they had seven heavens for the seven planets: the moon, Mercury, Venus, the sun, Mars, Jupiter, and Saturn. The eighth was that of the fixed stars, which was particularly denominated the firmament. Ptolemy adds a ninth heaven, which he calls the *primum mobile*. But others admitted many more heavens, according as their different views and hypotheses required: Eudoxus supposed 23; Regiomontanus 33; and Fracastoro no less than 70.

In theology, this word denotes the upper and nobler region of God's universe, in contrast with the earth, the lower part assigned to men for their habitation. Of the belief in the existence of some special scene of the presence of Deity, the majority of the known religions of the world bear ample evidence. According to Aristotle all men, whether Greeks or barbarians, had a conception of God; and all united in placing the residence of the gods in the most elevated regions of the universe. This idea runs through the Persian, Egyptian, German, Scandinavian, and indeed of all the ancient religions

in which the belief in a supreme being assumes any other form than the pantheistic; and even though the pantheistic philosophers may have denied that any peculiar locality could be regarded as the peculiar habitation of the Deity, we find that the popular belief and worship of the sect is evidently grounded upon a contrary opinion. In addition, however, to its being the special seat of the Deity, heaven also denotes the place, or the state or condition of blessed spirits, and of the souls of just men either immediately after physical death or at some certain period subsequent to it. All the religious systems which include the immortality of the soul involve, at least in substance, the idea of a future state of happiness as a reward for a virtuous life. The delights of the heavens of the various creeds differ greatly in kind. The pleasures of the classical Elysian fields were to a great extent pleasures of sense; the German warrior believed he would be transferred to a region where he would be able to pursue his old fierce enjoyments, and the American Indian cherishes the notion that he quits this world for a happier hunting-ground. Among Christians the general opinion is that heaven is the residence of the Most High, the holy angels, and the spirits of just men made perfect, that this abode is eternal, its joys entirely spiritual; it is believed also by many that the just who are free from sin are admitted into heaven immediately after death; also that the souls of the patriarchs, prophets, and in general the good, were detained, before the new dispensation, in a temporary abode till the coming of the Redeemer. See IMMORTALITY.

Heaves, or Broken Wind, a disease of the horse generally described as unsoundness of the respiratory organs. The disease is not well understood by veterinarians and the treatment is unsatisfactory. It is generally conceded that the disease is incurable. The characteristic symptoms are labored breathing, dilated nostrils, bloodshot eyes and dependent belly. Horses with this disease often drop down while at work and succumb to congestion of the lungs, hemorrhage or suffocation, the direct result of the heaves. Upon post-mortem examination the stomach is found distended and to have thinner walls than in the normal horse.

Hebe, hē'bē, according to Greek mythology, the goddess of youth, and the cup-bearer on Olympus until replaced by Ganymede. She was a daughter of Zeus and Hera, who gave her as a wife to Heracles, in reward of his achievements. At Rome she was worshipped as Juventas. She is described by some authorities as a divinity who had it in her power to make old persons young again. In the arts she is represented with the cup in which she presents the nectar, under the figure of a charming young girl, her dress adorned with roses, and wearing a wreath of flowers. An eagle often stands beside her, which she is caressing.

Heber, hē'bėr, **Reginald,** English Anglican bishop and poet: b. Malpas, Cheshire, 21 April 1783; d. Trichinopoli, India, 1 April 1826. He was educated at Brasenose College, Oxford, distinguished himself by the English prize poem —'Palestine,' was elected to a fellowship in All Souls' College, traveled in Germany, Russia, and the Crimea, entered holy orders in 1807, and became the incumbent of Hodnet, Shropshire. In 1812 he was appointed prebendary of St. Asaph, in 1815 Bampton lecturer at Oxford, in 1822 preacher at Lincoln's Inn. From 1822 until his death he was bishop of Calcutta, at that time constituting one very extensive diocese, in all parts of which he traveled to the furtherance of the mission work in progress. He completed the establishment of Bishop's College, Calcutta, begun by Bishop Middleton. Heber is best known for his hymns, 58 of which, including the familiar 'From Greenland's Icy Mountains,' 'Brightest and Best,' and 'Holy, Holy, Holy!' appear in 'Hymns Written and Adapted to the Weekly Church Service of the Year.' In prose he wrote 'A Life of Bishop Jeremy Taylor' (1822), and 'A Journey Through India' (1828). Consult the 'Life' by Smith (1895).

Hébert, Jacques René, zhäk rė-nā ā-bār, French journalist and politician: b. Alençon, Orne, 15 Nov. 1755; d. Paris 24 March 1794. At the beginning of the French Revolution Lemaire published a journal supporting constitutional principles under the title 'Père Duchesne.' The Jacobins soon established a rival 'Père Duchesne,' of which Hébert became editor. The journal owed its success to the cynical virulence with which it advocated the popular cause, and abused the court and the monarchy, and soon had the field to itself. He was a member of the Revolutionary Commune that approved the massacres in the prisons in September 1792, was soon after substitute attorney of the commune, and employed all his influence in forwarding a project to establish the authority of the commune on the ruins of the national representation. The Girondists, who were at that period contending against the Mountain, had credit enough to procure the arrest of Hébert 24 May 1793. Again restored to liberty, he assisted with all his power and influence in the proscription of the Brissotins. Their downfall hastened his own. With Chaumette he established the 'Feast of Reason,' and afterward accused Danton of having violated the nature of liberty and the rights of mankind. This terrified both Danton and Robespierre, who suspended their mutual jealousies to accomplish his destruction; and Hébert, with the greater part of his associates, was arrested and guillotined.

Hébert, Louis Philippe, Canadian sculptor: b. Sainte Sophie d'Halifax, Quebec, 27 Jan. 1850. He studied for several years in Canada, and later in Paris, where he established his studio. In 1894 he won the Confederation medal awarded by the Canadian government Among his works are historical subjects executed for public buildings in Quebec, Ottawa, and Montreal.

Hebrew Language and Literature, the tongue in which the ancient Jews spoke and wrote, and the books produced by that people during their settlement in Palestine as an independent nation; these latter constitute the Hebrew Scriptures and are looked upon by the Hebrews as containing the inspired word of God. It is impossible not to include in Hebrew literature the immense volume of rabbinical writings produced after the conquest of the Romans and the subsequent dispersion of the

Jews. The destruction of Jerusalem deprived the Israelites of the temple worship, and practically abolished the institution of sacrifice. Hence the importance to them of that literature of the dispersion which did so much in preserving to them their national unity and exclusiveness, and keeping alive the flame of race enthusiasm, amid the new circumstances of their national life as the chosen people.

The Hebrew Language.—The Hebrew tongue belongs to the Semitic family of languages in which are included the Arabic, the Ethiopic, Babylonic and Chaldaic. It is one of the finest, most copious and elastic of this group, and indeed is only inferior in richness and development to the Arabic. It is, however, surpassed by Indo-Germanic dialects such as Greek and Latin, in point of precision, as its want of accidence, in its uninflected nouns and verbs, sometimes leads to confusion and obscurity. In the suggestion of poetic imagery, in gorgeousness of expression and breadth of meaning, it stands alone and pre-eminent.

The alphabet is composed of 22 letters, all consonants, the vowel values being expressed by points of which there are about 40. These are placed above or below the letters they syllabicate. The system of vowel points was introduced so late as the 6th or 7th century by the school of Tiberias when the Masora, a collection of critical, exegetical, and grammatical remarks on the sacred texts, was first committed to writing. There are no capital letters. The writing is from right to left. There are three kinds of Hebrew alphabet now in use—the square or Assyrian (properly called the Babylonian), which is generally supposed to have been introduced by Ezra, the most common in print; the rabbinical, or mediæval, used chiefly in commentaries and notes; and the cursive, in writing.

The Hebrew etymological roots are triliteral, to reckon by consonants. From these roots words are formed by suffixes or prefixes. One of the most remarkable characteristics of the Hebrew language is its apparent fixity of form. After it had been in use for upward of a thousand years there is little variation to be seen in the idiom, vocabulary or literature of its monuments. This has led some critics to dispute the traditional antiquity of the Pentateuch. There is very much less variation from the style of the books of Moses to be found in the latest of the Scriptures than is met with in an English writer of to-day when compared with a writer of the Restoration period. But this may perhaps be explained by the fact that the early Scriptures fixed once for all the Hebrew tongue, which was not allowed to develop or deviate from the standard of a grammar, vocabulary and idiom which were alike inspired of God. The Chinese language furnishes a parallel instance of immutability. The Arabic of the present day is very much the same as in the days of Mohammed, who gave it the form it bears in the Koran, and the Hadiths which supplemented it in subsequent centuries.

Hebrew Literature.—The Hebrew books have had more influence on the religion of the world than any other books of the kind. They afford an example of writings which promulgate a pure monotheism, and depend on none of the variegated and romantic resources of polytheism for their force of persuasiveness. They have been a thesaurus of religious ideas for other sacred books. They may be said to be the golden ore out of which the New Testament was cast as Gideon cast his sacred ephod out of the melted earrings of the Midianites. It is a question whether the Koran would ever have been written but for the boundless material which Mohammed found in the Old Testament Scriptures, and the floating traditions, fables, legends and allegories which resulted from the impression they produced on the minds of a superstitious Western-Asiatic population. The Hebrew writings cover a wide area, whether we consider their literary form as comprising a cosmogony or treatise of primitive science, verses of moral treatises, including a code of civil law, history, poetry, in the form of lyric, drama, and ode; or the time they cover from Moses to Ezra; or the peoples they deal with which include all the ancient monarchies of Western Asia, as well as the most illustrious of Pharaonic dynasties. The ancient books give us a wonderful picture of the pastoral life of the early patriarchs. Tales and poems, items of daily contemporaneous incident abound in them. Poetry among the Hebrews as among all other ancient nations is earlier than prose, and a vein of lyric feelings runs through the Jewish records from the first chapter of Genesis to the Song of the Well in Numbers, and the ode of Deborah and Barak, in Judges. There is the fable of Jotham, and the riddle of Samson. The variety which characterizes even the books of Moses is inexhaustible. But those, such as Joshua, which have been called the Book of the Wars of Jehovah, and the Book of Proverbs, show a still deeper and more prolific vitality in literary and religious ideas. In the age of Samuel there was a new department of literature inaugurated under the influence of religious conviction and emotion. The schools of the prophets favored the cultivation and development of a species of poetry of which the world had never seen the like, and has never yet since equaled. The prophets were poets who stood between Jehovah and his people, interpreting his will, in strains of alternate consolation and rebuke; in words of warning, rebuke, prediction and condemnation. It was in these schools that David learned to be what he styled himself, the sweet singer of Israel. He indeed was the greatest of a line of psalmists, which includes Asaph and the Sons of Korah. His son Solomon became the philosophic moralist of his people, and was as famous for gnomic utterances as his father had been for his psalms. The love idyll followed, and the century of the Hebrew monarchy saw also the rise of Hebrew historic literature.

It is easy to classify the Hebrew literature, which naturally divides itself into origins, legislation, prophecy, history, lyric, proverbs, and moral poetry. The origins and legislation are included in the Pentateuch or five books of Moses, and give us the history of Israel's beginning, and settlement in the holy land. As a sequel to this we have the history of the kings, completed by Ezra. Prophecy as represented by Samuel, Nathan and Gad, Elijah and Elisha, had always existed through the monarchical period, but it reached its highest literary development, in proportion as the national spirit of religion declined, and the days of exile and

dispersion grew nearer. The form the written prophecy takes is that of a rhetorical lyric, frequently a passionate improvisation which often rises in eloquence and power to the pitch of sublimity. Even history sometimes takes the shape of a poetic tale, sometimes of a mere traditional record of events. The early historical books take their tone and color from that of Genesis; the type of the later historian is the book of Samuel and Kings. An appendix to these is furnished by Ezra and Nehemiah. Hebrew poetry is quite different from that of Europe. It has neither the artful arrangement of repeated syllabic metre, like that of Greece and Rome, nor the music of terminal rhymes, like the romantic poetry of the Latin and Teutonic races. It is a wonderful system of strophic parallelisms. This system is shown in its simplest form in the proverbs of Solomon, and revived in the Greek writings of Jesus the son of Sirach. The book of Job excels both of these works in poetic intensity, and wide spiritual sweep. It is largely dramatic in form; occasional lyrical passages occur, while it has an epic prologue and epilogue, that is, the introduction and dénouement have all the direct stateliness of the epic poem. Indeed the foundation of Hebrew poetry is laid in the lyric, and the genius of the national literature are to be looked for in those psalms which were current from the time of David to the Maccabees. The Song of Solomon is a collection of love lyrics, tender and passionate, but more gorgeous and tinged with deeper melancholy than those of the Greek or Persian muse; the village tale of Ruth belongs to the days of pastoral Israel; the novelette of Esther can scarcely claim a place in religious literature; the lamentations of Jeremiah are elegies uttered over the coming downfall of Israel, and the words of the preacher, in Ecclesiastes, which belongs to the Alexandrian periods, are laments over the decline of the people in religious idealism and social virtue. After their return from captivity, the Jewish, or as it is often called, rabbinical literature, grew and flourished with new life. Under the guidance of Ezra the sacred books were collected, authenticated, and arranged into a canon. The Pentateuch was publicly read, taught in schools, explained, and translated into the Aramaic or Chaldee dialect. The traditions explanatory or complementary to the law of Moses were traced through the prophets and elders to that lawgiver, and established as authoritative and binding. They were compiled so as to form what was styled Midrash, divided into the Halacha and the Haggada: the former considered the improvement of the law with a view to practical results; the latter the essence of the religious and historical. To the Maccabean era belong the Apocrypha, various Greek versions of the Bible, and collections of prayers, poems, and proverbs. Following the destruction of Jerusalem (70 A.D.) came the completion of the New Testament, the historical works of Josephus, and various spurious Gospels, all written in the Greek language. On being driven from their capital the Jews founded numerous schools in which their language and literature were taught. The Mishna, which contains traditions and interpretations of the Scriptures, is supposed to have been compiled in the second or third century of our era. The Mishna was considered one of the principal works of Hebrew literature, and the rabbis of Tiberias and Babylon wrote numerous commentaries on it. These were collected into two works, and entitled the Jerusalem and the Babylonian Talmuds. The Jerusalem Talmud was completed about the end of the 4th century; the Babylonian Talmud about a century later. The most brilliant era of modern Jewish literature is that of Moorish Spain. Treated by the conquerors of the Peninsula with mildness, the Jews turned to the culture of science and literature, and soon found themselves at the head of the intellectual world, not excepting the Arabs, whose culture is a subject of admiration among all historians. No science was neglected by the Israelites; astronomy, geography, philosophy, medicine, history, poetry, music, the Spanish rabbis knew and taught. The Jewish school of Toledo was the most renowned of all the schools in the Peninsula. This is the era of the great Moses ben Maimon (Maimonides), the illustrious disciple of Averroes; of the poet and philologist Aben-Ezra; of Kimchi, of Isaac Ben-Sid, etc. The celebrated Academy of Lisbon flourished under Jewish auspices to the end of the 15th century. After their expulsion from Spain, the Jews founded those printing establishments from which issued a great number of works in Hebrew. The 17th century was more fatal to Judaism than even the centuries of persecution. It was the age of Spinoza, the pantheist. But even before his day the Hebrew language had been falling into disuse. In Germany many of the writers of the 18th and 19th centuries were Jews or of Jewish extraction, and are among the brightest names in literature. Moses Mendelssohn, the philosopher; Neander, Heinrich Heine, Berthold Auerbach, Herz, Börne have added much to the literary glory of their age; Disraeli, father and son, Zangwill, Emma Lazarus, are names which will occur to book-lovers of a younger generation.

Jahrhunderts' (1870); Herder, 'Vom Geiste der hebräischen Poesie' (1891); Meier, 'Geschichte der poetischen Nationallitteratur der Hebräer' (1856); 'Bibliographisches Handbuch über die Litteratur der hebräischen Sprachkunde' (1859).

Hebrews. See JEWS.

Hebrews, Epistle to the, one of the longest apostolic letters in the New Testament. The absence of the opening salutation usual in the apostolic epistles has led to some doubt as to its authorship. The immediate successors of the apostles (Clement of Rome, Justin Martyr, etc.) considered it as of canonical authority, while the Gnostics Basilides and Marcion rejected it. No doubt as to its authenticity was expressed by the Church, however, until about the middle of the 2d century, and for two centuries afterward it was generally rejected by the fathers of the Roman and North African churches. Toward the end of the 4th century Jerome reviewed the conflicting opinions as to the canonicity of this epistle. He pronounced in its favor. In 416 a decretal of Pope Innocent I. placed its authority beyond dispute. As to the authorship there is no reason to doubt that

at first everywhere but in North Africa, Paul was recognized as the writer. Clement of Alexandria states that it was written by Paul in Hebrew for the benefit of the Hebrews, and translated by Luke for the benefit of the Greeks. The opinion that it was originally written in Hebrew is strongly advocated by Michaelis; while the opposite one, that Greek is the original language, is supported by Rosenmüller and others. Tertullian mentions Barnabas as the reputed author, according to the North African tradition. Luther conjectured that Apollos was the author.

Hebrides, hĕb'rĭ-dēz, **The, or Western Islands,** Scotland, an archipelago off the west coast, extending from lat. 55° 35′ to 58° 32′ N.; the most southern island being Islay, and the most northern, Lewis. The group is politically divided between the shires of Ross and Cromarty, Inverness, and Argyll, very nearly in the line of their coincidence with the coasts of the respective counties. They number about 400 in all, but many are inconsiderable islets and rocks, and only about 90 are inhabited; area, about 2,800 square miles; pop. (1901) 79,159. They are usually divided into the Outer Hebrides, of which the principal are Lewis and Harris (forming a single island), North Uist, Benbecula, South Uist, and Barra; and the Inner Hebrides — Skye, Mull, Islay, Jura, Coll, Rum, Tiree, Colonsay, etc. The Outer are separated from the Inner, and from the mainland, by a strait or channel called the Minch, which at its narrowest part, between Harris and Skye, is about 12 miles broad.

The climate is mild and salubrious, but variable, tempestuous, and humid. Snow and frost are almost unknown in the smaller islands, and are but little felt in the larger. There is comparatively little wood in the Hebrides, and on many of the islands none at all. In Lewis, Skye, Islay, Mull, and several of the other islands, however, both forest and fruit trees have been planted to a considerable extent, with great success. Oats and barley are almost the only cereal crops raised. Potatoes are extensively cultivated. Cattle constitute the staple product. The native breed are small but handsome. Cheese and butter of good quality are produced. The breed of horses is also small, but hardy and docile. The native breed of sheep is very small, but Cheviots have been introduced with success. The productive land is partly occupied as sheep-farms; much of it is held by "crofters," who occupy holdings usually of a very few acres, sometimes with a right of pasturage in common attached. There are also "cotters" who occupy houses, with or without a patch of ground, on the land of the crofter, the farmer, or the landlord, and who are often mere squatters paying no rent. Grouse-moors and deer ranges cover a considerable area. Owing to the minute division of the arable land there is in many places an excess of population. The condition of the crofters and cotters, especially in the Outer Hebrides and Skye, is very depressed, their dwellings miserable, and their living poor, consisting chiefly of potatoes, milk, and oat or barley bread, and in bad harvests it is often insufficient in quantity. The fisheries are not developed to the extent they might be. Whiskey is manufactured in Skye, Islay, and Mull. Gaelic is the universal language of the Hebrides, which in remote times were subject to the kings of Norway, but in 1264 were annexed to the crown of Scotland. They were held by various native chieftains, in vassalage to the Scottish monarch; but subsequently fell into the hands of one powerful chief, who thereupon (1346) assumed the title of "Lord of the Isles," and began to affect an entire independence of his sovereign. The abolition of hereditary jurisdictions in 1748 secured to these islands for the first time the peace and safety afforded by a just and powerful government. Little was known about the Hebrides until the publication of Johnson's 'Journey to the Western Islands of Scotland' (1775), and of Scott's 'Lord of the Isles,' which invested them with a popular interest which has been increased by the facilities afforded to tourists by the steamers of the Clyde.

Hebron, hē'brŏn (originally KIRJATHARBA, now EL-KHALÎL), Asiatic Turkey, a town of great antiquity in Palestine, 18 miles southwest of Jerusalem, 2,830 feet above sea-level. It lies in the narrow valley of Mamre, has narrow streets, high well-built stone houses with flat roofs, extensive covered bazars, with well-furnished shops, exhibiting glass manufactures, consisting of lamps, colored rings, etc., for which the place has long been celebrated. The chief mosque, El-Haram, built around the Cave of Machpelah, from which Christians are rigorously excluded, is esteemed by Mohammedans one of their holiest places. Hebron is one of the oldest existing towns, having been built seven years before Zoan (Num. xiii. 22), and it is mentioned prior to Damascus (Gen. xiii. 18). Abraham resided here, and acquired the Cave of Machpelah as a sepulchre for Sarah and his family. It was David's royal city for seven years. There is a German Protestant mission here. Pop. about 19,000.

Hebron, Neb., city, county-seat of Thayer County; on the Little Blue River, and on the Chicago, R. I. & P., and the Burlington & M. R.R.'s; about 63 miles southwest of Lincoln. It is situated in an excellent agricultural and stock region. It has a large flour-mill, a creamery, and a planing-mill. There are five churches, a high school, three banks, and three weekly newspapers. The shipments of wheat and live stock are extensive. Pop. (1900) 1,511.

Hecatæus, hek-ą-tē'ŭs, distinguished Greek historian and geographer: fl. about 500 B.C. He was a native of Miletus, and the son of Hegesander, a member of an ancient and illustrious family. Of his public life the only event of which we have any definite knowledge was the part he took in the insurrection of the Ionians against the Persians. Being well acquainted with the resources of Persia, he vainly attempted to dissuade Aristagoras, the planner of the revolt, from his undertaking. Later he went as ambassador to Artaphernes, and prevailed on the satrap to win the confidence of the Ionians by lenient treatment. His two great works were his 'Tour of the World,' and his 'Genealogies.' The latter is little more than a prose version of the legends already given in versified form. He improved the map of the world made by Anaximander; and his writings were highly esteemed by Herodotus. The fragments of his works were published by Müller (1841–70).

Hecate, hĕk'ā-tē, in Greek mythology, a goddess, whose parentage is variously given.

Homer does not mention her. She appears to have been originally a Titan who ruled in heaven, on the earth, and in the sea. She could bestow or withhold at pleasure the blessings of wealth, victory, and wisdom to mortals, and was the only Titan who retained power under the rule of Zeus. She was subsequently confounded with several other divinities, and at length became a mystic goddess having all the magic powers of nature at her command. She was identified with Demeter and Artemis, and was regarded as the mystic Persephone. Magicians and witches prayed particularly for her aid. Sacrifices used to be offered to her at places where three ways met (whence her epithet Τριοδῖτις, or in Latin, *Trivia*), and these consisted of dogs, honey, and black female lambs. Her mysterious festivals were celebrated annually at Ægina. Her appearance was frightful. She had three bodies or three heads, and serpents hung hissing around her neck and shoulders.

Heck, Barbara, one of the founders of American Methodism: b. Ballygarry, County Limerick, Ireland, 1734; d. near Augusta, Ont., 1804. She was one of a colony of German immigrants in Ireland who were among the first to be influenced by Wesley's preaching. In 1760 she came to America with her husband, Paul Heck, and Philip Embury (q.v.). In 1766 she was very active in the organizing of a Methodist society which met at Embury's house, and she also did much toward the building of the Old John Street Methodist Church. Later she and her family removed to the northern part of New York State, and when the Revolution broke out went to Ontario, where they founded another Methodist society.

Heck'er, Friedrich Karl Franz, German-American soldier: b. Eichtersheim, Baden, 28 Sept. 1811; d. St. Louis, Mo., 24 March 1881. After studying law in Heidelberg, he abandoned his profession for political life. In 1842 he was elected to the Chamber of Deputies of Baden. On the outbreak of the revolution in Germany in 1848 he endeavored to convert the preliminary convention into a permanent republican assembly. Frustrated in this attempt, he put himself at the head of a band of revolutionists, and invaded Baden from the south. He was defeated at Käudern 20 May 1848, and fled to Switzerland. In the following year he removed to the United States, and became a farmer near Belleville, Ill. On the outbreak of the Civil War he raised a regiment of Germans, serving in General Fremont's division as colonel; and afterward for a time commanded a brigade.

Hecker, Isaac Thomas, American Roman Catholic clergyman: b. New York 18 Dec. 1819; d. there 22 Dec. 1888. In early life he was a member of the Brook Farm community, near Boston, where for nearly a year he officiated as baker for the establishment. In 1845 he became a Roman Catholic; went to Germany to study for the priesthood, and joined the Redemptorist Fathers in Belgium in 1847. He was ordained priest in London by Cardinal Wiseman in 1849. Returning to New York he founded the order of the Paulists (1858), became their superior; and established the 'Catholic World' (1865), of which he was editor till his death. An anonymous French version of Elliott's 'Life of Father Hecker' led to the noted "American" controversy. He wrote: 'Questions of the Soul' (1855); 'The Church and the Age' (1888); etc. Consult: Sedgwick, 'Father Hecker' (1900).

Heckewelder, hĕk'ĕ-wĕl-dĕr, John Gottlieb Ernest, American Moravian missionary: b. Bedford, England, 12 March 1743; d. Bethlehem, Pa., 21 Jan. 1823. At the age of 12 he came with his father to Pennsylvania. He accompanied Post in 1762 in his expedition to the Indian tribes on the Ohio, and in 1771 took up his residence among them as a missionary. After some 40 years' missionary service, he went to Bethlehem, the principal establishment of the Moravians in America, and there remained till his death. He wrote several memoirs upon the Delaware and Mohegan Indians: 'Account of the History, etc., of the Indian Nations' (1818); 'Narrative of the Mission of the United Brethren' (1820).

Hec'la, or Hekla, Iceland, an isolated volcano in the southwest, about 20 miles from the coast. It is of comical shape, terminating in three perpetually snow-clad peaks, the central and loftiest of which, Heklufjall, is 5,110 feet high. The circumference at the base is about 12 miles. It is composed chiefly of columnar basalt, and of lava, mostly covered by stones, scoria, ashes, and other loose volcanic matter. Since the 10th century there are 43 eruptions on record. One of the most tremendous occurred in 1783, after which it remained quiescent till 2 Sept. 1845, when it again became active, and continued with little intermission for 15 months to discharge itself from three craters, its effects being felt as far as the Orkney Islands, 400 miles distant. The last outbreak was in 1878.

Hectic Fever, a type of fever which is intermittent, and is distinguished by an afternoon or evening quickening of the pulse, and rise of temperature. The eyes of the patient brighten, his cheeks flush, and there is some nervous and cerebral excitement. The fever is succeeded by a profuse perspiration. This affection is frequently associated with phthisis, abscess, or septicæmia, and is of dangerous significance.

Hector, in Homeric narrative, the son of Priam and Hecuba, and the bravest of the Trojans, whose forces he commanded. His wife was Andromache, the daughter of Aëtion. He encountered the Grecian heroes in battle, and often gained advantages over them. By his presence Troy was invincible; but when he had slain Patroclus, the friend of Achilles, the latter, forgetting his dispute with Agamemnon, resumed his arms to avenge the death of his beloved companion. Pierced by the spear of Achilles, the body of Hector was dragged at the chariot wheels of the conqueror; but afterward, at the command of Zeus, was delivered to Priam for a ransom, who gave it a solemn burial.

Hector, Annie French ("Mrs. Alexander"), Irish novelist: b. Dublin, Ireland, 1825; d. London 10 July 1902. She began to write at an early age and was a prolific and popular writer. Among her books, all of which enjoyed a wide popularity in the United States, are: 'The Wooing O't' (1873); 'Ralph Wilton's Weird' (1875); 'Her Dearest Foe' (1876); 'The Frères' (1882); 'A Golden Autumn' (1897); and 'A Winning Hazard' (1897).

Hec'uba, in Greek legend, the second wife of Priam, king of Troy, to whom she bore Hector, Paris, Cassandra, Troilus, and other children. After the fall of Troy she was given as a slave to Odysseus, and, according to one form of the legend, in despair leaped into the Hellespont.

Hed'ding, Elijah, American Methodist bishop: b. Dutchess County, N. Y., 7 Jan. 1780; d. Poughkeepsie, N. Y., 9 April 1852. At 19 he entered the Methodist ministry, and was appointed successor of Lorenzo Dow. He extended his travels to Canada, and preached the Gospel in various parts. He became a member of the New York annual conference in 1801, and was made a bishop in 1824. He was instrumental in the establishment of the 'Zion's Herald' at Boston, the first journal published by the Methodist Church in the United States.

Hedge, Frederick Henry, American scholar: b. Cambridge, Mass., 12 Dec. 1805; d. there 21 Aug. 1890. He studied in Germany 1815–23, was later graduated from Harvard and Harvard divinity school, and after holding Unitarian pastorates in Bangor, Maine; Providence, R. I., and Brookline, Mass.; was professor of German at Harvard University (1872–81). Deeply read in philosophy, ecclesiastical history, and German literature, he was a finished writer and a much admired orator, and ranked as perhaps the foremost German literary scholar in the United States. Among his writings are: 'Reason in Religion' (1865); 'The Primeval World of Hebrew Tradition' (1870); 'Martin Luther and Other Essays' (1888); etc. His 'Prose Writers of Germany' (1848) is a standard work. He translated poems from the German and wrote numerous hymns for the Unitarian Church.

Hedge, a fence formed of living trees or shrubs. Hedges are generally composed of one or more of the following species: Hawthorn, crab, blackthorn, holly, privet, beech, hornbeam, maple, barberry, furze, broom, alder, poplar, willow, yew, box, arbor-vitæ, sweet-briar, etc. When there are so many different species to select from, plants may be found suitable for almost all kinds of soil — such as wet or boggy, and dry or sandy; for all situations, whether sheltered or exposed; and for all purposes, such as fences against cattle, or simply as ornaments for garden and pleasure grounds.

Hedge'hog, a small insectivorous mammal of the Old World family *Erinaceidæ,* and especially of the genus *Erinaceus,* characterized by its coat of stiff spines. The family inhabit temperate Europe and Asia, but are not known on sea-girt islands. The best known of the score of species is the common hedgehog (*E. europæus*). It has a long nose, the face, sides, and rump covered with strong, coarse, yellowish hair, the back with sharp, strong spines; and is about nine inches long plus a very short tail. Hedgehogs, as their name indicates, reside under hedges and in thickets, where they turn over the leaves and root in the mould for insects (especially beetles), snails, lizards, roots, fallen fruit, etc.; they are, indeed, omnivorous. The hedgehog defends itself against attack by rolling itself up, and thus exposing no part of its body that is not furnished with a defense of spines. It may be rendered domestic to a certain degree, and has been employed in Europe to destroy cockroaches, which it pursues with avidity. In the winter, in cold climates, the hedgehog wraps itself in a warm nest, composed of moss, dried hay and leaves, and remains torpid till the return of spring. The female produces four or five young at a birth, which soon become covered with prickles. These animals are sometimes used as food, and are said to be very delicate. The long-eared hedgehog (*E. auritus*) of the East is smaller than the common, and is distinguished by the great size of its ears and shortness of tail. Fossil forms as far back as the Miocene differ little from existing species. No true hedgehogs exist in America; the animals often so called being the very different porcupines (q.v.).

Hedge-hyssop. See GRATIOLA.

Hedge-sparrow, a small brown warbler (*Accentor modularis*), with a sweet plaintive song, very common in Europe about gardens and roadsides in summer. It is not a sparrow at all, but nearly related to the American water-thrushes (*Seiurus*). In Great Britain it goes by many names, as dunnock, etc., and is one of the birds most frequently mentioned in books.

Hedin, Sven Anders, svĭn än'dĕrz hĭ-dēn', Swedish geographer and explorer: b. Stockholm 19 Feb. 1865; was educated at Stockholm, Upsala, Berlin, and Halle, at the latter university receiving the degree of doctor of philosophy. In 1885 he began his first journey of exploration through Persia and Mesopotamia. In 1890 he went to Persia as a member of King Oscar's embassy to the Shah, and the next year journeyed through Khorassan and Turkestan. In 1893 he set out on a remarkable journey from the Russian frontier to Peking, through Tibet and the Lob-nor region. He arrived at his destination in 1897, having experienced four years of exciting and harrowing adventures. His second expedition to Central Asia began in 1899. In 1901, writing from Narkhlik, Dr. Hedin tells of finding the ruins of a beautiful Buddhist temple, some rare specimens of wood carving and 12 complete letters written in Chinese on paper and marvellously well preserved. Dr. Hedin has written five books, four in English: 'A Journey Through Persia and Mesopotamia' (1887); 'King Oscar's Embassy to the Shah of Persia' (1891); 'A Journey Through Khorassan and Turkestan' (1892); and 'Through Asia' (1898). He wrote also a scientific treatise in German, 'The Results to Geographic Science of My Travels in Central Asia.'

Hedonism, hē'dō-nĭzm, the philosophical belief of Aristippus, a disciple of Socrates, who taught that pleasure was the end of life, and that it was the duty of a wise man to enjoy pleasure without being controlled by it. Horace tersely sums up the philosophy of Aristippus: "I purpose to subdue things to myself and not myself to things." The most eminent of the Hedonic school were Arete, the daughter of the founder, her son, surnamed from her teaching Metrodidaktos, Theodorus the Atheist, and his scholars, Bio and Euhemerus.

Heel Fly. See BOT-FLY.

Heer'mans, Forbes, American dramatist: b. Syracuse, N. Y., 25 Oct. 1856. He was graduated from Cornell University in 1878, and is author of the dramas: 'Love by Induction'

(1889); 'The Silent Witness' (1890); 'Between Two Foes' (1899); 'The Vagabond' (1893); 'Jess of the Bar' (1896).

Hegel, Georg Wilhelm Friedrich, gā-ōrg' vĭl'hĕlm frēd'rĭh hā'gĕl, German metaphysician: b. Stuttgart 27 Aug. 1770; d. Berlin 14 Nov. 1831. After attending the gymnasium of his native city he entered the theological institute at Tübingen (1788–93) diligently devoted to the study of theology and philosophy. On leaving the institute he was employed for six years as a private tutor, first at Berne, and then at Frankfort-on-the-Main; but on the death of his father, who left him some property, he took up his residence at Jena, where, through an intimate friendship with Schelling, the strong love which he had always felt for metaphysics was more fully developed. In 1806 he removed to Bamberg, and was employed on a newspaper till 1808, when he became rector of the gymnasium at Nuremberg. This situation he held for eight years, and then was appointed professor of philosophy first at Heidelberg in 1816, and next at Berlin, where in 1818 he succeeded to Fichte's chair. He had here gathered around him a large number of admirers, and was in the zenith of his fame, when he was suddenly cut off by cholera. He was buried beside Fichte. Among his numerous works, the most important, in the order of their publication, are his 'Phänomenologie des Geistes,' which appeared in 1807 as the first part of a system of sciences; 'Wissenschaft der Logik' (1812–16); 'Encyclopädie der philosophischen Wissenschaften' (1817); and 'Grundlinien der Philosophie des Rechts oder Naturrecht und Staatswissenschaft' (1821). The philosophy of Hegel, starting from the same position as that of Schelling, soon departed from it. As there are, according to him, three stages in the process of thought and existence, his system has necessarily a threefold division; first, logic; second, the philosophy of nature; and third, mental philosophy. Hegelianism has exercised a powerful influence on modern thought. For an exposition of his system consult: Stirling, 'The Secret of Hegel' (1865); E. Caird, 'Hegel'; J. Caird, 'Philosophy of Religion'; Wallace, 'Logic of Hegel' (1874); Erdmann, 'History of Philosophy'; W. T. Harris, 'The Logic of Hegel' (1890); Sterrett, 'The Ethics of Hegel.'

Hegira, hĕj'ĭ-ra, **Hejra,** or **Hijra,** an Arabic word meaning "going away," commonly used to indicate Mohammed's flight from Mecca, in 622 A.D. In 639 Caliph Omar instituted a new Moslem calendar, to begin with the first day of the first month of the year in which the flight took place. The Mohammedan year, as a lunar year, is shorter than ours by 10 days, 21 hours, and 14 2-5 seconds. A rough and ready method for finding the year in our calendar corresponding to a given year in the Mohammedan is to subtract from the latter 1/33 of itself and add 622 to the remainder. To find the precise year and day, multiply the year of the Hegira by 970,224, strike off from the product six decimal figures, and add 621.5774; this will give the year of the Christian era; and the day of the year is got by multiplying the decimal figures by 365.

Heidelberg, hī'dĕl'bĕrg, Germany, an old university town in Baden, on the left bank of the Neckar, here spanned by two bridges, 11 miles by rail east-southeast of Mannheim. It stands on a narrow strip between the river and the rock on which the castle is built, and chiefly consists of the Hauptstrasse, the long main street, and less important steeply-sloping cross and parallel street. The city has an electric street railway system. The imposing castle, on a height above the town, an immense ivy-clad ruin begun in the 13th century, exhibits elaborate examples of early and late renaissance architecture. In the town itself the principal buildings are: the Gothic church of St. Peter, the Gothic church of the Holy Ghost, the Roman Catholic Church, the university (q.v.), the town-house, the post-office, gymnasium, real-schule, and other schools. The manufactures, comparatively unimportant, include cement, tobacco, cigars, fire-extinguishing apparatus, shoddy, mathematical and surgical instruments, leather, etc., and there are also several breweries. One of the curiosities of the place is the well-known Heidelberg copper tun, kept in the cellar under the castle, and long ranking as the largest wine cask in the world, being 36 feet in length, 26 feet in diameter, and capable of holding 800 hogsheads. Heidelberg has fine public walks. The gardens around the castle are well laid out, and at every turn present the finest views of the Neckar, and the fertile and richly wooded valley through which it winds to join the Rhine. Behind the town and castle, a carriage-road leads by easy ascent to the top of the Königstuhl, the loftiest hill of the district, from which an extensive view is obtained of surpassing beauty. Heidelberg arose around its 13th century castle and was until 1719 the capital of the Palatinate. In 1622, 1688, and in 1693 the French captured and pillaged the city. In 1802 it was united to the Grand Duchy of Baden. Pop. (1900) 40,121.

Heidelberg Catechism, a religious work published at Heidelberg in 1563 by Zachariah Ursinus for the use of the Reformed Church, and published in the Palatinate. It was approved by the Synod of Dort, and was the model on which the Westminster Assembly framed the Shorter Catechism.

Heidelberg University, Germany, a renowned institution founded by Elector Rupert I. in 1386. It was organized by Marsilius von Inghen on the model of the University of Paris, and at the Reformation, from a Catholic became a Protestant stronghold of learning. It flourished till the period of the Thirty Years' War when it declined. In 1802 under the administration of the Grand Duke of Baden, a new era was inaugurated and the university rapidly became famous. It is very complete in its details, and comprises faculties of theology, law, medicine and philosophy; the famous library has over 500,000 volumes and 4,700 MSS. There are 150 professors and instructors, while the average annual attendance of students in all departments is over 1,450. Many of the most famous German scholars have been professors here — Melanchthon, Ursinus, Olevianus, Reuchlin, Œcolampadius, Spanheim, Puffendorf, Voss, Schlösser, Creuzer, Gervinus, Paulus, Kuno Fischer, Helmholtz, Bunsen, Blüntschli, etc. The quincentenary of the university was celebrated with elaborate ceremonial in 1886.

Heidelberg University, Ohio, a coeducational institution at Tiffin, founded in 1850, under the auspices of the Reformed Church in the United States. It has departments of theology, commerce, oratory, art, and music, and preparatory and summer schools. In 1902 it had 30 professors and instructors; 350 students; a library of over 25,000 volumes: the grounds and buildings were valued at $125,000; the productive funds amounted to $275,000, and the income to $20,000.

Heidenmauer, hī'dn-mow-ĕr. (1) A name given in Germany to the remains of old German and Roman fortresses and ramparts, some of which still exist, especially at Ottilienberg, a hill of the Vosges, in Alsace. (2) The title of a novel by James Fenimore Cooper, who laid the scene of his story in the Vosges during the Middle Ages.

Heights, Measurement of. See HYPSOMETRY.

Heilprin, hīl'prĭn, **Angelo,** American naturalist: b. Satoralja-Ujhely, Hungary, 31 March 1853. He is a son of Michael Heilprin (q.v.), and came with his parents to the United States in 1856, but received his education later in Europe, making a special study of natural history. On his return to America, his scientific ability was speedily recognized and he became successively professor of invertebrate palæontology and geology (1880–1900), and executive curator (1883–91) at the Academy of Natural Sciences, Philadelphia. From 1885 to 1890 he was professor of geology at the Wagner Free Institute. He was for five years president of the Geographical Society of Philadelphia, was leader of the Peary Relief Expedition in 1892 and made a journey of research to investigate the cause of the Mont Pelee (q.v.) disaster in 1902. His published works include: 'Contributions to the Tertiary Geology and Palæontology of the United States' (1884); 'Town Geology'; 'The Lesson of the Philadelphia Rocks' (1885); 'Geographical and Geological Distribution of Animals' (1887); 'Explorations on the West Coast of Florida and in the Okeechobee Wilderness' (1887); 'The Geological Evidence of Evolution' (1887); 'The Animal Life of our Seashore' (1888); 'The Bermuda Islands: a Contribution to the Physical History and Zoology of the Somers Archipelago' (1889); 'Principles of Geology' (1890); 'The Arctic Problem and Narrative of the Peary Relief Expedition' (1893); 'The Earth and its Story' (1896); 'Alaska and the Klondike' (1899).

Heilprin, Louis, American scholar: b. Miskolcz, Hungary, 2 July 1851. He is a brother of Angelo Heilprin (q.v.). In 1856 he came to the United States, where he was privately educated, and where he was connected with various works of an encyclopædic character. He published a valuable 'Historical Reference Book' (1884; 6th ed. 1899) in 'The Concise Knowledge Library.'

Heilprin, Michael, American author: b. Piobrkow, Russian Poland, 1823; d. New York 19 May 1888. Carefully educated by his father, in his 20th year he emigrated to Hungary, chafing under Russian conditions. For a time he had a book-store at Miskolcz and was on intimate terms with Kossuth and his party. When the Revolution was quelled, he went to London, there meeting Kossuth, who advised him to go to America. In 1859 he and his family emigrated to New York, where his literary activity was continuous for nearly 30 years. As co-editor of Appleton's 'Annual Encyclopedia' and reviewer on 'The Nation,' he won a distinct rank for his exact and versatile scholarship, especially in the line of Semitic literature. On the arrival of the Russian Jewish refugees in 1881–2, he took a prominent part in their welfare and personally supervised the colonization of many families. His published works include: 'The Historical Poetry of the Ancient Hebrew,' Vols. I. and II. (1880); 'Bibelkritische Notizen' (1893).

Heimburg, hīm'boorg, **Wilhelmine.** See BEHRENS, BERTHA.

Heine, Heinrich, hīn'rĭH hī'nė, German poet: b. Jewish parents at Düsseldorf 12 Dec. 1799; d. Paris 17 Feb. 1856. He studied law at Bonn, Berlin, and Göttingen, and took the degree of doctor at the last-mentioned place. In 1825 he became professedly a convert to Christianity, and was baptized in the Lutheran Church of Heiligenstadt. His conversion seems to have been a purely secular matter, having no connection with religious convictions, and professed mainly in order that he might be free to practise law now that he had obtained his doctor's degree. Nevertheless he showed no desire to become a practical lawyer, and soon all his energies were devoted to literature. At Bonn A. W. Schlegel had influenced him greatly, and later in Berlin his powers had been stimulated by the brilliant society which frequented the house of Madame Rahel, the wife of Varnhagen von Ense. He engaged in political journalism in Munich and elsewhere, and the revolutionary opinions expressed by him soon made his imprisonment very probable. The fear of such a result helped to strengthen the joy with which he welcomed the Parisian revolution of 1830. In that year he took up his residence in the French capital, and there he lived almost uninterruptedly till his death, and from 1836 till the revolution of 1848 received a pension from the French government. During the last years of his life he suffered much from disease of the spine, but his sufferings could not permanently cloud his spirit, and, so far from impairing his creative power, seem rather to have stimulated him to the production of some of his finest works. He began his literary career with a volume of poems ('Gedichte') (1822), and in the following year he printed two dramas entitled 'Almansor' and 'Radcliff.' Some years later the publication of the first two volumes of his 'Reisebilder' (Pictures of Travel) (1826–7) made him famous, and his fame was enormously increased by the appearance of his 'Buch der Lieder' in 1827. The third and fourth volumes of the 'Reisebilder' appeared in 1830–1, and among the prose writings of his French period, many of them of the *feuilleton* kind, are: 'Zur Geschichte der neuern schönen Litteratur in Deutschland' (1833); 'Französische Zustände' (1833), a collection of papers on French affairs; 'Der Salon' (1835–40), including an account of German literature and philosophy; 'Die romantische Schule' (1836); 'Shakespeare's Mädchen und

Frauen' (1839); and the bitter pamphlet 'Ueber Börne' (1840). His witty and cynical 'Neue Gedichte' appeared at Hamburg in 1844, and in 'Deutschland, ein Wintermärchen' he gives a characteristically satirical account of his last visit to his native country. Other poetical works are: 'Atta Troll' (1847); Romanzero' (1851); and 'Der Doktor Faust' (1851). The three volumes of 'Vermischte Schriften' published in 1854 contained his 'Geständnisse' (Confessions) and 'Lutetia.' His 'Letzte Gedichte und Gedanken' were published posthumously. As a poet, more especially in his earlier productions, Heine is remarkable for the simplicity and pathos of many of his lyric pieces. His powers of wit and raillery were also great, but in the use of these he has often transgressed all the bounds of propriety and decorum. Skepticism and oversensuousness are prominent characteristics of this writer. In private life he displayed many good qualities, showing himself generous and self-sacrificing, and ever ready to sympathize with and relieve distress. Heine has found many English translators. There is a complete translation of all his works by C. G. Leland (12 vols., 1891, et seq.); and among translations of parts may be cited: 'The Prose Writings of Heine,' by Havelock Ellis (1887); 'Travel Pictures,' by F. Storr (1887); 'Poems and Ballads of Heine,' by Sir Theodore Martin (1878). There are 'Lives in English,' by Stigand (1876) and Sharp (1888). See also 'Erinnerungen an Heinrich Heine und seine Familie' (1868), by his brother Max; 'Heines Familienleben' (1892; Eng. trans. by Leland, 1893), by Baron von Embden; and Karpeles, 'Heinrich Heine: Autobiographie' (1888); Eng. trans. by Dexter, 1894); Brandes, 'Heine in Litteratur des 19. Jahrhundert'; Arnold, 'Essays in Criticism.'

Heinemann, hī'nē-man, **William,** English publisher and author: b. Surbiton 18 May 1863. He founded the publishing house which bears his name in 1890. He has published under the pen name of "Kassandra Vivaria": 'Via Lucis'; 'The Garden of Olives'; 'The First Step,' a play (1895); 'Summer Moths,' a play (1898); 'War,' a play (1901).

Heinrich, H. H., American horologist: b. Cranz, Germany, 1822; d. Brooklyn, N. Y., February 1903. He was apprentice to a Hamburg watchmaker, studied with Martin Zeller of Vienna, in Switzerland became a manufacturer of watches and escapements, and there taught for 10 years in a horological school which he had established. He became known as one of the foremost European chronometer-makers, came to the United States and finally set up in business for himself in New York. In 1880 his time-recording instruments excelled all others at the prize tests held in Washington. He also received highest awards from the Berne exposition of 1858, the Paris exposition of 1889, and the Chicago exposition of 1893.

Heintzelman, hīnt'sĕl-man, **Samuel Peter,** American military officer: b. Manheim, Pa., 30 Sept. 1805; d. Washington, D. C., 1 May 1880. Graduated at the United States Military Academy 1826, and served during the Mexican War. In 1861 he commanded a division at Bull Run, where he was wounded 21 July. Afterward promoted brigadier-general of volunteers, Heintzelman, during the organization of the army in the winter of 1861–2, held command of a division. On the moving of the Army of the Potomac, in March 1862, the 3d Army Corps was placed under his command. His corps formed the right wing of Pope's army at the second battle of Bull Run 30 Aug. 1862. During the Maryland campaign he commanded the defenses at Washington, and was afterward appointed to the command of the Department of Washington, and of the 22d Army Corps, which he held during the battles of Chancellorsville and Gettysburg, in May and July 1863. He retired in 1869, with the rank of major-general.

Heir (Lat. *hæres*), in law, one entitled by descent and right of blood to lands, tenements, or other hereditaments. Hence it is an ancient apothegm, that "God only can make an heir." An heir is really one who is born or begotten in lawful wedlock, and on whom the law casts the estate, in lands, tenements, or hereditaments immediately on the death of his ancestor. The rights of heirs in most of the United States are determined by the principles of the common law unless specially modified by statute. It is a matter of judicial decision that the rights of heirs in the United States are statutory only. Hence they cannot plead, for instance, that an inheritance tax is unconstitutional. An heir presumptive is one who will be the heir at the death of the owner, as the elder son of a deceased brother in England, or all the children of a brother in the United States, where the owner has no children; for they will be heirs if he dies without issue. As an heir presumptive may lose his heirship by a change of circumstances, he does not become an heir apparent so long as this change is legally probably, though physically or naturally impossible. Thus the nephew of the owner can never be his heir apparent, however aged or feeble or near to death the owner may be; for in contemplation of law it is always possible that a son may be born to him, who would be an heir apparent, and who would therefore supersede an heir presumptive. An heir apparent is one who must be the heir if he survive the owner, as the eldest son in Great Britain, or all the children in the United States. But the phrase "heir apparent" is not strictly applicable here. In Great Britain the birth of a younger son cannot affect the rights of inheritance of the eldest son, for they are fixed, and he alone can be heir by descent. But in this country the younger son has an equal right with an elder son; and therefore the exclusive right of inheritance can never be fixed in any children living.

Heiss, hīs, **Michael,** American Roman Catholic prelate: b. Pfahldorf, Bavaria, 12 April 1818; d. Milwaukee 26 March 1890. He studied at the University of Munich and at the Catholic seminary at Eichstädt, and was ordained in 1840. In 1843 he came to the United States, and was first assigned to a church in Covington, Ky.; he next went to Milwaukee as missionary priest and secretary to the bishop. In 1868 he was consecrated as the first bishop of La Crosse, Wis.; in 1880 he was appointed coadjutor to the archbishop of Milwaukee, with the right of succession, and two years later became archbishop of Milwaukee. He has taken an important part in American councils, and was a member of the Vatican Council (1869–70). He has written:

'The Four Evangelists,' and a treatise on marriage (in Latin).

Heistand, Henry Olcot Sheldon, American soldier: b. near Richwood, Ohio, 30 April 1856. He was graduated from West Point 1878, and was assigned to 11th United States infantry as 2d lieutenant. He was appointed government inspector and instructor Ohio National Guard in 1892, and during the presidential campaign of 1896 was confidential secretary to McKinley. He was promoted lieutenant-colonel in 1900, and became adjutant-general and chief of staff in the China expedition for relief of Peking 1900. He has written: 'Alaska, Its History and Description' (1898).

Hejra, or Hijra. See HEGIRA.

Helen, in Greek legend, the most beautiful woman of Greece, daughter of Zeus by Leda. By advice of Ulysses her numerous suitors were bound by oath to respect her choice of a husband, and to maintain it even by arms. She chose Menelaus, but was afterward carried off to Troy by Paris, the Trojan war arising from the claim made by Menelaus for the fulfilment of the oath. After the death of Paris she married his brother Deiphobus. On the fall of Troy she returned to Sparta with Menelaus, but at his death was driven from the country, and was murdered at Rhodes by the queen of that island.

Helena, hĕl'ĕ-na, Saint, the mother of the Emperor Constantine the Great. She was of humble origin, probably the daughter of an innkeeper of Bithynia. She captivated Constantius Chlorus, and became his wife; but when Diocletian elevated him to the dignity of Cæsar, in 292 A.D. he was compelled to repudiate her. The succession of her son, and the influence she had exercised in educating him as a Christian, compensated her for previous humiliations, while her piety and zeal for the propagation of Christianity have made her a saint in the Roman Catholic calendar.

Helena, hĕl'ĕ-na or hĕ lē'na, Ark., city, county-seat of Phillips County, on the Mississippi River, and on the St. Louis, I. M. & S., the Yazoo & M. V., the Arkansas M. R.R.'s., and is the terminus of the Arkansas Central; about 75 miles below Memphis and 95 east by south from Little Rock. It has boat communications with all important river-ports. A conflict between the Federal and Confederate forces took place here 4 July 1863. The Union army, about 4,500, was under Gen. Prentiss, the Confederate, about 9,000, under Gen. Holmes. The Confederate loss was about 1,800, including killed, wounded and prisoners. Helena is in an agricultural and lumbering region; the chief manufactures are lumber, cottonseed-oil, and foundry products. It has cotton-compresses, a shingle-mill, brick-yards, and large lumber-yards. Some of its educational institutions are the Jefferson High School, and the Sacred Heart Academy; it has a public library, nine churches, and three banks. Pop. (1900) 5,500.

Helena, Mont., city, capital of the State, and county-seat of Lewis and Clarke County; on the Northern Pacific and the Great Northern R.R.'s; about 70 miles north by east of Butte. The city is surrounded on all sides by the Rocky Mountains; on the south and west the mountains are within two miles of the city, while to the north there is a wide valley between the city and the foothills, and the same condition exists on the east. The city is protected from severe wind storms, and in the winter season there is a difference in temperature between the city and the mountain country of from 10 to 20 degrees. The country tributary to the city is rich in both mineral and agricultural resources. The mines are principally gold-producing, while the products of the farms are cereals and the ordinary vegetables. Tributary to the city are large areas devoted to the raising of cattle and horses, but this industry is gradually being replaced by diversified farming.

Helena is noted as the richest city per capita not only in Montana, but in the entire Rocky Mountain country. It is principally a city of homes; cattlemen, miners, and others engaged in industries elsewhere in Montana have their residence in Helena because of its church, school, and social attractions. It is the best built city in the State; its hotels, office buildings, mercantile establishments and private residences being equal to any found in cities of 100,000 in the east.

The geographical situation of Helena has made it a great distributing centre. Before the days of the railroads, when stage lines and freight wagons drawn by oxen were the only means of transportation, the geographical position of the city brought to it many travelers and great stores of merchandise. From Helena the people and the goods were distributed to other settlements. The Northern Pacific Railroad, the first to reach the city, following the trend of business, built branch lines from Helena, and thus it retained its commercial supremacy. Later the Great Northern was also extended to the capital city, and it likewise reached out for trade in the surrounding country by building branches. The original of Helena was "Last Chance Gulch"; the town came into existence as a result of discoveries of placer gold. The first discovery of gold was made in 1864, by four prospectors, John S. Cowan, John Crab, D. J. Miller, and Robert Stanley. These four men started early in the spring of 1864 from Alder Gulch, now Virginia City, in the southern part of the State, to search for placer gold. They went first to western Montana, and finding nothing there started east, prospecting the streams. They finally found what is now known as Prickly Pear Creek, running through the valley north of Helena, and here they discovered a few traces of gold, but they continued their journey north. Provisions becoming scarce they retraced their steps, intending to return to Virginia City, and again they came to Prickly Pear Creek where they noticed a little gulch. One of them said: "Boys, this is our last chance to strike it. If we do not find gold here we must strike straight for Alder." On 16 July 1864, they sunk two holes to bedrock, and in each they found gold. It was the "last chance" that turned out favorably, and that was the name of the camp until 30 October of the same year. The news of the find spread, and soon there were 500 men in the camp. At the meeting to name the town, Pumpkinville, Squashtown, Tomahawk, and Tomah were suggested. Finally John Somerville suggested Saint Helena. This was amended to Helena, and on a ballot Helena won by two votes over Tomah.

The educational institutions are public and parish schools, the Montana Wesleyan University (M. E.), opened in 1890, Saint Vincent's Academy, and the State, city, and other libraries.

Among the principal buildings at Helena are the Government building, costing $500,000; State capitol, costing $400,000; the county courthouse, costing $100,000; the high school building, costing $150,000, and seven graded school buildings valued at $200,000. There are also Saint John's Hospital, Saint Joseph's Orphanage, and several fine churches. Twelve miles from Helena, on the Missouri River, is located the plant of the Missouri River Power Company. This company furnishes electrical power for operating street cars and lighting the city of Helena, and for manufacturing purposes. It also transmits electrical power to Butte for use in the mines, a distance of 100 miles. Four miles from Helena is located the smelter of the American Smelting and Refining Company. The principal gold mine now operated in the vicinity of Helena is the Big Indian, located in a gulch four miles south of the city. Marysville is the largest mining camp tributary to the city. Here is located the Drum Lummon mine, owned by an English company, and in the near vicinity are other mines which are large gold producers.

In the 20 years after the opening of the "Last Chance Gulch," gold to the amount of $25,000,000 was taken out of the gulch and the town grew to a city of 20,000 and became the capital of the State.

From the discovery of gold until 22 Feb. 1881, when the city government was organized under a charter from the State government, the government of the city was by a committee representing the merchants and bankers.

The government is now vested in a mayor, who holds office two years, and a council. The executive appoints, subject to the approval of the council, all the subordinate officials except the city treasurer and police magistrate, both of whom are chosen at a popular election. The assessed valuation of property in 1903 was $13,000,000.

Helena has been the capital of Montana since 1869. In that year the capital was removed by popular vote from Virginia City. After Montana was admitted as a State two elections were held for the permanent location of the capital, and in 1894 Helena was chosen.

The altitude of Helena is 4,200 feet. The climate is not severe, the average temperature in January and February, the two coldest months in the year, being 20 above zero, with no moisture in the air. In summer the average temperature is 75. The growth of the city from now on may not be as rapid as in the early days; but it promises to be a healthy, steady development. Pop. (1900) 10,770.

CHARLES D. GREENFIELD,
Editor 'The Helena Independent.'

Helena, Battle of. Helena, Ark., is on the west bank of the Mississippi River, about 82 miles below Memphis. Since 13 July 1862, when Gen. Curtis arrived there from western Arkansas, it had been occupied by Union troops, and on 4 July 1863, was held by a division of the Thirteenth corps, under Gen. Salomon, and a brigade of cavalry, in all 4,129 effective men, under command of Gen. B. M. Prentiss. The place is surrounded by hills, and those nearest the city were occupied by strong redoubts; Graveyard Hill in the centre, Fort Righter on the north or right, and Fort Hindman on the south or left, were all connected by a line of bastions and rifle-pits, both ends of which rested on the river. In the river lay a gunboat. Toward the middle of June it was determined by the Confederates to take the place, whereby it was hoped to raise the siege of Vicksburg or, if Vicksburg fell, still to keep the river closed. Gen. Holmes was ordered to move from Little Rock with about 7,600 men, Price's and Marmaduke's divisions, Fagan's brigade of infantry, and Walker's brigade of cavalry. Holmes bivouacked about four miles from Helena on the evening of 3 July, and at midnight advanced to within a mile of the outer works. The assault was ordered at daylight. On the Confederate right Fagan with 1,770 men advanced on Fort Hindman, carried all the outer entrenchments, and made a desperate attempt to take the fort, but was repulsed with a loss of over 400 men. On the Confederate left, Marmaduke's division of infantry and Walker's cavalry brigade, aggregating 2,780 men, attacked Fort Righter and were repulsed. Price, in the centre, with 3,100 men, made a strong assault, carried all the entrenchments in his front, seized Graveyard Hill, and ordered one brigade to move on the town and another to assault Fort Hindman in the rear, but the Union troops checked the advance of the two brigades and drove them back and, the attacks on the right and left being repulsed, the fire of the forts, rifle-pits, and gunboat was concentrated on Price, and at 10.30 A.M. Holmes gave the order to withdraw, and led his troops back to Little Rock. The Union loss was 57 killed, 146 wounded, and 36 missing; the Confederate loss was 173 killed, 687 wounded, and 776 missing. Consult: 'Official Records,' Vol. XXII.; Greene, 'The Mississippi'; The Century Company's 'Battles and Leaders of the Civil War,' Vol. III.

E. A. CARMAN.

Hel'enin, a chemical substance extracted by hot alcohol from the root of the elecampane (*Inula helenium*). It has the formula C_6H_8O, and is nearly insoluble in water, but very soluble in alcohol. The first crystals obtained from the root-extract contain considerable quantities inula-camphor; but this may be removed by repeated crystallization from alcohol. Pure helenin crystallizes in white prisms or needles, melting at 232° F.

Helicidæ, hē-lĭs'ĭ-dē, the family of terrestrial pulmonate mollusks which includes most of the land and many fresh-water snails. See SNAILS.

Heligoland, hĕl'ĭ-gō-lănd, or **Helgoland,** hĕl'gō-lănt (Dan. "holy land"), a small island and popular sea-bathing resort in the North Sea, belonging to Germany, situated about 40 miles northwest of the mouth of the Elbe. It is about a mile long and one third of a mile broad, and has an area of about one quarter of a square mile. It consists of two parts, the Oberland, a flat-topped rock 206 feet high, affording a little soil for pasture and the growth of potatoes, etc., and communicating with the Unterland, a small stretch of shore at its foot, by 192 steps and an

elevator. Most of the houses stand on the Oberland. The Unterland gives partial shelter to the shipping. Steamboats ply between the island and Hamburg. The principal buildings are the church, lighthouse, and a royal Prussian biological station for the study of the fauna and flora of the North Sea. The bathing facilities, which attract so many visitors, are found in a dune or sand-bank separated from the main island by a channel about a mile wide. This Sandy Island, as it is called, is slowly being reduced in size by the inroads of the sea. The inhabitants are chiefly employed in fishing, and speak a Friesian dialect. The island is well fortified, and has cable communication with Cuxhaven and Wilhelmshaven. Christianity was first preached here by St. Willibrod in the 7th century. Taken from the Danes in 1807, it was ceded to Great Britain in 1814, but was transferred to Germany in 1890. Pop. (1900) 2,307, in the bathing season increased by several thousand visitors.

Heliocentric, hē″lĭ-ō-sĕn′trĭk, "having the sun as centre," a term applied to the Copernican system, as in opposition to the Ptolemaic system, which was geocentric, that is, "having the earth as centre" of the solar system. In modern astronomy the word is applied to calculations in which the sun is referred to as centre of the planetary system. Thus the heliocentric place of a planet is the position it would occupy at a given time when calculated from a point of view in the centre of the sun.

Heliodorus, hē-lĭ-ō-dō′rŭs, the earliest of the Greek writers of romance: b. Emesa, Syria, and lived near the end of the 4th century. He became a believer in the Christian religion, and bishop of Tricca in Thessaly. His youthful work, 'Æthiopica (that is, Æthiopic Affairs), or the Loves of Theagenes and Charicleia,' is a tale in poetical prose, with an almost epic tone. It is distinguished by its strict morality from the other Greek romances, and interests the reader by the wonderful adventures it recounts. One of the best editions is that of Hirschig in the 'Erotici Scriptores' (1856). An English translation by R. Smith appeared in 1855.

Heliogab'alus. See ELAGABALUS.

He'liograph, an instrument invented by De la Rue for obtaining photographs of the sun. Also an apparatus for telegraphing by means of the sun's rays. See HELIOSTAT; MILITARY TELEGRAPH.

Heliogravure, hē″lĭ-ō-grā′vūr. See PHOTOGRAVURE.

Heliom'eter, an instrument for measuring small distances on the sky, particularly the apparent diameters of the sun and of the moon. The heliometer of Bouguer is an astronomical telescope provided with two object-glasses, one of which is movable, and which form two distinct images of the same object, visible through the same eye-glass. A single object-glass cut into two parts, which are relatively movable by a screw, is always employed now. If, in contemplating a celestial body, the object-glasses are placed so as to bring the images to touch each other, the distance of the centres of the glasses gives the diameter of the image. In this manner the instrument gives, for instance, the difference of the diameter of the sun in perigee and apogee.

Heliopolis, hē-lĭ-ŏp′ō-lĭs ("City of the Sun"), Egypt, the On of the Hebrew Scriptures, on a site now partly occupied by Matarieh, six miles northeast of Cairo, was one of the most ancient and extensive cities during the reign of the Pharaohs, and so adorned by monuments as to be esteemed among the first sacred cities of the kingdom. During the flourishing ages of the Egyptian monarchy the priests and scholars acquired and taught all the learning of the Egyptians within the precincts of its temples. It may be regarded as having been the university of the land of Misraim, and at the time of Strabo, who visited this town 24 B.C., the apartments were still shown in which, four centuries before, Eudoxus and Plato had labored during 13 years to learn the philosophy of Egypt. Solon and Thales were also reputed to have visited its schools. Here Joseph and Mary are said to have rested with the infant Jesus. Near the village stands the Pillar of On, a famous obelisk, supposed to be the oldest monument of the kind existing in Egypt. Its height is 67½ feet, and its breadth at the base 6 feet. Hieroglyphical characters are sculptured upon it, but are partly illegible. A fierce battle was fought here, 20 March 1800, between the French under Kleber and the Turks, when the latter were defeated.

Heliornithidæ, hē-lĭ-ôr-nĭth′ĭ-dē, a family of tropical birds, the fin-foots or sun-birds, placed by some ornithologists among the *Cecomorphæ*, and by others, more probably, with the rails. They are about a foot long, mottled brown and white, with long pointed wings and long stiff tails; and frequent the borders of forest streams and ponds, in which they spend much of their time swimming and diving well. They feed on small fish, crustaceans, insects and seeds. The best-known species is *Heliornis fulica* of southern South America.

Helios, hē′lĭ-ŏs, in mythology, the god of the sun (Latin, *Sol*) in the Greek mythology; son of Hyperion and Theia, and brother of Eos (Aurora, the dawn) and Selene (Luna, the moon). He is frequently called by the name of his father. He dwells with Eos in the ocean behind Colchis. From the portals of the morning he rides through the air in an oblique curve to the gates of evening, and after having cooled his horses in the ocean, he drives his chariot into a self-moving golden vessel, made by Hephæstus (Vulcan), which with wonderful rapidity bears him during the night along the northern shore of the ocean back to Colchis, where he bathes his horses in the lake of the Sun, and rests till the dawn of the morning. Other accounts represent him as making this nightly passage while slumbering in a golden bed. His horses and chariot are first mentioned in the Homeric hymn on Helios. Among events in the history of Helios the poets relate his contest with Poseidon for the Isthmus of Corinth, his revealing the secret amours of Ares and Aphrodite, and his disclosure to Demeter of Pluto as the ravisher of her daughter. This idea of his omniscience seems to have been the reason why he was confounded and identified with Apollo, though they were originally quite distinct. As he was descended from the race of the Titans he is often called Titan. The famous Colossus of Rhodes was a representation of Helios.

He'lioscope is a telescope behind which the image of the sun is received upon a plane

surface. An astronomical telescope is drawn out a little farther than is necessary for common use, and directed toward the sun, and the image which is formed is received in a dark place. For this purpose a dark chamber is employed, or the telescope is placed in a dark funnel-shaped enclosure, the bottom of which is covered with oiled paper or closed with ground glass, on which the sun's image is formed. Upon the paper or glass a circle is described equal to the image, and it may be divided by concentric circles into rings. With this instrument the spots on the sun, eclipses, etc, may be observed.

Heliostat, hē'lĭ-ō-stăt, an instrument used in optical experiments with sunlight for keeping a beam always falling in the same direction in spite of the motion of the sun. It consists of a mirror mounted equatorially, and carried round by clock-work in such a way as to neutralize the apparent motion of a beam of sunlight reflected from it. This instrument has been employed among other purposes as a means of signaling. A beam of light being directed to the point to which it is intended to convey the signals, the dot-and-dash alphabet is made use of by the device of exhibiting and obstructing the light for longer or shorter periods. A short flash represents one letter, a long flash another, a short quickly followed by a long a third, and so on. As adapted to this purpose the heliostat has received the name of heliograph.

Heliotherapy (Gk. ἥλιος, sun + θεραπεία, service), the treatment of disease by the action of sunlight. See PHOTOTHERAPY.

Heliotrope, hē'lĭ-ō-trōp, a genus (*Heliotropium*) of plants of the borage family, characterized by the undivided ovary prolonged into a style, many of whose species have vanilla-scented blossoms. The one most in repute is a small shrub (*H. peruvianum*), originally South American, which has small fragrant flowers growing compactly together in the spikes. Cuttings taken from the young branches grow readily, and come soon into blossom. The *H. europæum,* or common heliotrope, is a flowering herb indigenous in the south and west of Europe. The heliotropes are natives of warm climates, and very numerous, several growing wild in the United States. Many delightful varieties have been produced as garden and greenhouse flowers.

Heliotrope, the bloodstone, is a variety of quartz partaking of the character of jasper and of chalcedony. It is of a deep green color, and is covered with red spots like drops of blood. Many fine antique Greek and Roman intaglios and cameos, also seal rings carved in bloodstone, are preserved in the great gem collections. It is found in Tartary, Persia, Siberia; in the island of Rum, Scotland, and many other places. It received the name heliotrope, or as some of the older writers give it, elitropia, because it was said that if the mineral be put into water contained in a basin rubbed with the juice of the plant heliotrope, and be exposed to the sun, the water will appear red and the sun blood-like, as if it was eclipsed.

Heliotropism, hē-lĭ-ŏt'rō-pĭzm, or **Phototropism,** the influence and effect of sunlight on organisms. When a seedling plant is placed in a transparent vessel of water within reach of the light of a window, the stem and leaves gradually bend toward, and the roots from, the light. The former phenomenon is termed positive, and the latter negative, heliotropism. The shoots and leaves of nearly all plants turn toward the light, and the turning of the sunflower toward the sun is familiar to every one. In the case of organs which are positively heliotropic the growth of the side next the light is retarded, and that of the opposite side increased; the result of these combined actions is a concavity on the former, and a convexity on the latter, thus causing a curvature toward the light. In the case of roots these actions are reversed. That these results are brought about by the action of light is evident; the cells on the concave side become less, while those on the convex side become more, turgid, thus forcing the organ to bend; but the cause of turgescence is unknown.

In animals a similar heliotropism is operative and is plainly manifested in some low forms, as hydra, where it is of great service in their almost automatic food-getting. Heliotropism is closely allied to, and much modified by chemotropism (q.v.) and other influences.

Heliozoa, hē"lĭ-ō-zō'a, the "sun animalcules," an order of rhizopods (q.v.) with or without silicious skeletons, and having slender and radiant pseudopodia, stable and rarely interlaced. The majority live in fresh water, but some are marine. A common and widespread example is the genus *Actinophrys.*

He'lium, a gaseous element, known to be present in the atmosphere and in certain minerals, and, like argon, characterized by a singular chemical inertness. The discovery of helium was a consequence of the discovery of argon, and on account of the close chemical, physical and historical relations of the two, reference should be made to the article ARGON, and to the references there given. Helium was known to exist in the sun many years before it was discovered upon the earth. During a total eclipse of the sun, in 1868, Jannsen observed a brilliant yellow line in the spectrum of the solar chromosphere, very close to the D lines of sodium, and yet not identical with either of them. The new line was assumed to be due to a previously unknown element, and in the same year Lockyer proposed the name "helium" for this hypothetical element, from the Greek word "helios," meaning the sun. No evidence of the existence of helium upon the earth was adduced until 1882, when an Italian scientist named Palmieri announced that he had obtained the spectrum of helium from certain of the lavas given off by Mt. Vesuvius. He made no attempt to isolate the new body, however, and while it is quite possible that his observations were correct, he can hardly be credited with the actual discovery of helium. No further progress was made in this direction until 1895. When argon had been discovered, and its chemical inertness had been established, Mr. Miers, mineralogist of the British Museum, pointed out that the mineral cleveite (q.v.) had been shown to contain nitrogen gas, apparently in the free state, and made the suggestion that part of what had been assumed to be nitrogen might in reality prove to be argon. Professor William Ramsay examined the gas from this source, and found that while it undoubtedly did contain argon, it also

showed a brilliant yellow line, which did not appear to coincide with either of the sodium lines, though it was very close to them. He sent a specimen of the gas to Sir William Crookes for a more careful examination, and Crookes promptly reported that the new line was indentical with the helium line. It was therefore proved that helium, which had previously not been certainly known except as a constituent of the solar chromosphere, is also a terrestrial element. Subsequent study revealed the presence of helium in several other minerals. It is given off from cleveite when that mineral is heated to about 400° F. in an exhausted tube, or when the mineral is treated with sulphuric acid, or with acid sulphate of potassium. All the minerals which contain any considerable quantities of helium also contain uranium, yttrium or thorium. It is not certainly known whether the helium is chemically combined with the mineral, or whether it is merely occluded by it. The latter supposition would appear to be the more probable, judging from the chemical inertness of the gas, and from the fact (presently to be noted) that radium appears to be generating helium continuously. Certain observations upon the mineral fergusonite, however, appear to give some color to the hypothesis that the helium is present in a state of chemical combination. Helium has also been found in solution in the waters of certain hot springs.

The presence of helium in the earth's atmosphere was established by means of subjecting the apparently pure argon that had been obtained from this source to a process of diffusion through a series of porous partitions of baked clay. Helium, being much lighter than argon, diffuses far more rapidly, and a mixture in which the two gases exist together may be partially separated into its constituents in this manner.

Helium, when pure, has a density of only 1.98, that of oxygen being taken as 8. Its atomic weight cannot be directly determined, because helium has not yet been made to combine with any other substance, although it has been subjected to the same experimental attempts as were tried in the case of argon (q.v.). It has been found, however, that the ratio of the specific heat of the gas at constant pressure to the specific heat at constant volume is about 1.65, and this indicates that helium is a monatomic gas (see GASES, KINETIC THEORY OF), and that its atomic weight is about $2 \times 1.98 = 3.96$; the atomic weight of oxygen being taken as 16. It therefore has the smallest atomic weight of any of the known elements except hydrogen. The chemical symbol He has been assigned to helium, although, as has been already noted, no compounds of it have as yet been obtained.

Dewar thought he had liquefied helium at the temperature of melting hydrogen (about 436° F. below zero), but this was not confirmed by subsequent experiments, and it is now believed that the liquefaction of helium is a problem still reserved for the future. Its critical temperature is probably still nearer to the absolute zero than that of hydrogen, and for this reason the gas is well adapted for use in thermometers intended for the measurement of exceedingly low temperatures. It has, in fact, been used for this purpose with success, in studying the properties of hydrogen.

A most remarkable and previously unparalleled fact in connection with helium remains to be recorded. It has been known for some time that helium occurs in cleveite, and in other minerals in which the newly discovered element radium is found; but whether this was to be regarded as a mere coincidence, or whether it has some actual physical and chemical significance, has been a subject of considerable discussion. The most striking experiment bearing upon this matter, is one that is due to Huggins, who caused the radiation from radium to pass through a spectroscope provided with a quartz prism, and to fall upon a sensitive photographic plate. Upon developing the plate after a prolonged exposure, he found that cold radium gives a line spectrum when treated in this manner; and he made the further discovery that nearly all of the lines in the spectrum so obtained are apparently coincident with lines in the spectrum of helium. The full significance of this fact is not yet known; but when taken in connection with the observations of Soddy and Ramsay, which indicate that helium occurs in the gaseous emanation that is given off by radium, it is considered by no means impossible that we have here an instance in which one element is being slowly but continuously transformed into another one. If this inference is corroborated by future experiments, it will throw an altogether new light upon the nature of the chemical elements, and upon their relation to one another. The case is the more noteworthy, since helium has a smaller atomic weight than any other element save hydrogen, and radium has a greater atomic weight than any other element save uranium and thorium. Radium, moreover, appears to be metallic in nature, while helium, by its chemical inertness, resembles nitrogen.

Helix, hē'liks, a curve generated by winding a line around in a coil of gradually increasing radius. (1) In anatomy, a prominent and incurved margin surrounding the thinner and larger portion of the pinna in the ear. (2) In architecture, the small volute under the abacus of a Corinthian column. Of these there are in every perfect capital 16: two at each angle, and two meeting under the middle of each face of the abacus. (3) In geometry, a curve the tangents to which make, with the horizontal plane, a constant angle. The edge of the path of a screw is a helix, as is also the path described by any point of the surface of the thread when moved in the nut. (4) In zoology, the typical genus of the snail family. See SNAILS.

Hell (A. Saxon, *hel*, from *helan*, to cover), signifies originally the covered or invisible place. In the Bible the word is used to translate the Hebrew *Sheol* (grave or pit), and *Gehenna* (properly the valley of *Hinnom*), as well as the Greek *Hades* (the unseen). In the Revised Version of the New Testament, hell is used only to translate Gehenna, Hades being left where it stands in the Greek. In common usage hell signifies the place of punishment of the wicked after death, its earlier meaning being lost. The distinctive Scriptural term for the place of future punishment of the wicked is Gehenna. The belief in a state of punishment after death for the finally impenitent is held by almost all sects of Christians, as an analogous belief in the future punishment of unexpiated guilt is a tenet of nearly all religions ancient or modern. The nature of the punishment of hell, its locality, and

its duration, have given rise to interminable controversies among Christian writers. The early Christian writers sometimes apply the word hell to a place of temporary purgation, in which the soul is freed from the stains of guilt contracted on earth preparatory to its enjoying the pure bliss of heaven. In this sense it corresponds in some degree with the Roman Catholic purgatory, and with the pagan idea of purification, as illustrated by Virgil in the sixth Æneid. Sometimes it is applied to the place of waiting of the just under the old law, till the coming of Christ should secure for them the completion of their reward; sometimes to the place where unbaptized children are detained because of unremitted original sin; and more frequently to the place of final and everlasting punishment for impenitent sinners. As to the locality of the scene of final punishment none at the present day makes a formal declaration. The terms above and beneath, as applied to heaven and hell, are merely relative, and though conventionally accepted convey no information. The Churches are not fully agreed as to the nature of hell-punishment. The prevailing idea among modern theologians is that the "fire" and the "worm" are significant emblems to give us the most correct and living conceptions of the reality that we can possibly attain in our present circumstances. They are fit emblems of anguish, and as such had laid hold of the Jewish imagination in connection with the word Gehenna, the term used in Mat. v. 22, 29, 30; Luke xii. 5. Gehenna, unlike Sheol and Hades, has never any intermediate signification, but is invariably applied to the place of punishment of the wicked after death. See IMMORTALITY.

Hell Gate, a narrow part of the East River between Long Island and Manhattan and on the east and west sides of Ward's Island. The passage between Ward's and Randall's Island is called Little Hell Gate. The rocks which were in Hell Gate were of such form and so situated as to make navigation dangerous, and the difference in the times and heights of the two tides which enter East River increased the dangers. The East River receives at one extremity the Sound Tide and at the other the tide from off Sandy Hook. "One sailing vessel out of every fifty" was the proportion damaged seriously when trying to pass through the channel between the reefs. Much had been said and written about the necessity of doing something to remove or at least lessen the dangers of Hell Gate, and officials of the United States navy, Lieutenants Davis and Porter, made a survey of Hell Gate in 1848. They reported the necessity of making the channel safe, and suggested the destruction of some of the most dangerous rocks; but nothing was done until the year 1851, when the work of destroying the rocks was begun. The process used was that of surface-blasting introduced by Maillefert. A portion of some of the rocks was removed, but this method of overcoming the dangers to navigation was found practically useless. In 1866 another survey was made by Brevet-Maj.-Gen. John Newton of the United States Engineer Corps, and in 1867 he submitted his report, in which he advised the removal of the reefs — the work to be done by blasting, and the drilling of the surface to be made from a fixed platform. Soon after the work of making Hell Gate safely navigable was resumed and placed in charge of John Newton. For the work Newton invented a steam-drilling cupola scow, which served as a transport and a working platform from which the drilling-engines were operated. The new machine proved satisfactory. A new system of explosion had to be devised in order to protect Ward's and Randall's Islands and Astoria. Diamond, Coenties, and Ways reefs were removed, also Pilgrim Rock, before operations were begun on Hallet's Point Reef. The last mentioned was an obstacle to both large and small vessels. The excavations, begun in October 1869, were completed in June 1875. The drilling was completed 25 March 1876. The area operated upon was about three acres. The method of explosion was most successful. No damage was done to the windows of buildings near; it had no perceptible effect on the air, but little on the water, and the underground shock was slight, but was perceptible on Manhattan and the western part of Long Island. The removal of Flood Rock, which was in the middle of Hell Gate, made the navigable capacity of the channel more than double. The work of removing this most formidable obstruction was begun 7 June 1875. Lack of funds caused delay, and the explosion did not take place until 10 Oct. 1885. For the removal of Flood Rock about nine acres were tunneled and drilled; and the aggregate length of the tunnels was 21,670 feet, and of the drill-holes, 113,102 feet. The object sought to be gained by removing the rocks and reefs was to make a channel of the uniform depth of 26 feet and of sufficient width for the largest steamers. The work as planned and designed by Gen. Newton has not been completed (1904).

Helladotherium, hĕl″ạ-dō-thē′rĭ-ŭm, an extinct genus of giraffes, found fossil in the upper Miocene (Pikermi) rocks of Attica. Its body was about as large as that of the existing giraffe, but the legs were of nearly equal length, and the skull was hornless.

Hellas, hĕl′ạs, the abode of the Hellenes, was first a town, and afterward, under the name of Phthiotis, a district in Thessaly. The ancients applied this name to the whole of Thessaly. With the spread of the Hellenic people the term embraced a gradually increasing territory, till it came to denote the whole of Middle Greece, and then the whole of Greece, with its islands and colonies. The Hellenes received this name in the belief that they were descended from Hellena, a mythical personage, a son of Deucalion and Pyrrha, or, according to others, of Zeus and Dorippe, and the father of Æolus, Dorus, and Xuthus, was said to have been king of Phthia. See GREECE.

Hell'bender, a large salamander (*Cryptobranchus alleghaniensis*) found chiefly in the streams emptying into the Great Lakes and those draining the western slope of the Appalachian Mountains. The hellbender is an ugly looking but perfectly harmless creature from 18 to 24 inches long; with the head and body much flattened and a prominent wrinkled fold of skin along the sides. Although entirely aquatic, no gills are present in the adult, and only a single pair of small pores represents the

gill-clefts; the lungs are simple sacs. The limbs are functional, the anterior with four, the posterior with five digits, and the tail is provided with a wide fin. A wide mouth with teeth in both jaws, very small eyes and a slimy skin of a deep mottled brown color are further external characteristics. The giant salamander (*Megalobatrachus maximus*) of Japan is the only known closely related form. The hellbender is a sluggish animal, active chiefly at night, when its voracity causes great annoyance to fishermen whose bait and fish it devours. It is extremely tenacious of life, and hibernates during cold weather. Although very common, its breeding habits are yet unknown.

Hellebore, a genus (*Helleborus*) of the crowfoot family (*Ranunculaceæ*), consisting of perennial erect herbs with scanty, palmately divided leathery leaves, and yellowish, greenish, or white terminal flowers. They are of interest on account of their poisonous and medical properties. About 10 species are natives of Europe and Asia, one of which (*H. viridis*) has become naturalized in the eastern United States. The Christmas rose (*H. niger*) is the source of the black hellebore of modern pharmacopœias, but the ancient black hellebore, a famous remedy for insanity, was probably obtained from other species. *H. viridis* and *H. fœtidus* have emetic and purgative properties, and the latter, which is poisonous, has become a common introduced weed along the eastern American seaboard. These plants are closely allied to the aconites.

White Hellebore is a very different plant, a species (*V. album*) of the genus *Veratrum* of the lily family, which contains several poisonous plants allied to colchicum. They are profusely leaved tall herbs growing in rich woods, and their roots contain the peculiar alkaloids veratroidin and jervin, to which their poisonous properties are mainly due. North America has a widespread species in the Indian poke (*V. viride*), which, like the European species, enters into the pharmacopœia, while its rootstocks are ground into the powder used as an insecticide.

Hellenes, hĕl'ēnz, a native name for the ancient Greeks.

Hell'enists, a name given the Jewish colonists who settled in Egypt after the destruction of the kingdom of Judah, about 600 B.C. Their number was increased by the many colonies of Jews planted by Alexander the Great (336 B.C.), and later by Ptolemy Lagus. Under the reign of the Emperor Augustus they amounted to nearly 1,000,000. They laid the foundation of a new epoch of Græco-Jewish literature, which, from its prevailing character, received the name of the Hellenistic. The Alexandrian Jews were the most influential in developing Hellenizing tendencies, and to them chiefly is to be referred the formation of the peculiar dialect termed the Hellenistic. In their literature the systems of Pythagoras and Plato were strangely combined with those Oriental phantasies which had been reduced to a system in Egypt, and with which the mystical doctrines of the Gnostics were imbued. The most noted Jewish Hellenistic philosopher was Philo of Alexandria, and the chief of the learned labors of the Alexandrian Jews was the Greek translation of the Old Testament.

Hellespont, hĕl'ĕs-pŏnt. See Dardanelles.

Hellgrammite, hĕl'grą-mīt, the large black aquatic larva of the insect Corydalus (q.v.), much used as bait for black bass and other game fish. It lives in streams, preying upon smaller animals, and just before pupation crawls under large stones, where it can be found at about the same time as the bass are biting. It is also called "Dobson" after a maker of artificial baits.

Helm, Israel, Swedish colonist in America: b. 1615; d. 1695. He settled on the Delaware River, in 1649; was collector of customs at Philadelphia 1659, and became a member of Captain Carr's council 1668. He was chief interpreter between the colonists and Indians, and rendered valuable service at the meeting of the New Jersey Indians, Governor Andros, and the Swedish authorities, in 1675.

Helmet-shell, a large gasteropod of the genus *Cassis*, family *Cassidæ*. Most of the species inhabit tropical shores, but a few are found on the coast of the Mediterranean. The shells of *C. rufa*, *C. cornuta*, and *C. tuberosa* (the queen conch), are the material on which shell cameos are usually sculptured.

Helmholtz, Hermann Ludwig Ferdinand von, hĕr'män lood'vĭg fĕr'dē-nänd hĕlm'hōlts, German scientist: b. Potsdam 31 Aug. 1821; d. Charlottenburg 8 Sept. 1894. He studied medicine in Berlin, and received the appointment of assistant-surgeon in the Charité Hospital there in 1842. Next year he went to Potsdam as a military surgeon, but in 1848 he returned to Berlin to assume the duties of teacher of anatomy at the Academy of Art and assistant in the Anatomical Museum. He was called to the chair of physiology at Königsberg in 1849, and six years later went to Bonn as professor of anatomy and physiology. In 1858 he was appointed professor of physiology at Heidelberg, whence he returned in 1871 to Berlin as professor of physics. In 1888 he was appointed to the post of president of the new Physikalisch-Technische Reichsanstalt (Imperial Physico-Technical Institute) in Charlottenburg. Helmholtz was distinguished alike in physical science, in mathematics, and in physiology; but his most valuable and most original work was done in those departments of physics which stand in intimate relations with physiology, especially acoustics and optics. He had an eminently philosophical mind, and his works are no less valuable for their masterly exposition of the methods of experimental science than for the important results contained in them. His scientific fame was securely established as early as 1847, when he published 'Über die Erhaltung der Kraft' (On the Conservation of Energy). This subject was pursued further in 'Über die Wechselwirkungen der Naturkräfte' (On the Interactions of Natural Forces) (1854). His greatest works are the 'Handbuch der Physiologischen Optik' (Handbook of Physiological Optics) (1856–66); and 'Die Lehre von den Tonempfindungen' (1862; 5th ed. 1896), translated into English by Ellis under the title 'Sensations of Tone as a Physiological Basis for the Theory of Music' (1875). A collection of 'Vorträge und Reden' reached a fourth edition in 1896, and has been translated into English as 'Popular Lectures on Scientific Subjects' (1873–81). An edition of his scientific treatises was pub-

lished at Leipsic in three volumes (1882–95), and in 1897 his 'Lectures on Theoretical Physics' appeared in one volume. In his 'Beschreibung eines Augenspiegels' (1851) he described the ophthalmoscope he had recently invented. In 1883 he was ennobled by the German emperor.

Hel'mont, Jan Baptista van, Flemish physician and chemist: b. Brussels 1577; d. near Brussels 30 Dec. 1644. He devoted his attention to scientific research, and although he put forth some visionary theories on the constitution of man, and on diseases, made some genuine discoveries in chemistry. He was probably the first to introduce the term "gas" into science, and was the earliest observer of the acid reaction of the gastric juice. He published 'Ortus Medicinæ' (1648); and 'Opuscula Medica Inaudita' (1644), works which still possess interest for students.

Hel'muth, William Tod, American physician: b. Philadelphia 30 Oct. 1833; d. New York 15 May 1902; graduated Homeopathic Medical College, Philadelphia, 1853; Hahnemann College, San Francisco, 1866. In 1877 he became professor of surgery and dean of the New York Homeopathic College and Hospital. He was an officer in numerous medical associations and a member of the Société Medicale Homeopathique of France. Among his published works were: 'Treatise on Diphtheria'; 'Medical Pomposity'; 'System of Surgery'; 'Scratches of a Surgeon'; 'Suprapubic Lithotomy.'

Heloderma, hē-lō-dĕr'mą. See GILA MONSTER.

Heloïse, ā-lō-ēz, or **Eloise.** See ABELARD.

Helots, hē-lŏts, were the lowest of the four classes into which the population of ancient Sparta was divided. They are generally supposed to have been the aboriginal population of the country, and to have been reduced to bondage by their Dorian conquerors, their numbers being swelled from time to time by the addition of peoples conquered in war. The name is generally derived from the town of Helos, the inhabitants of which were carried off and reduced to slavery by the Heraclidæ about 1000 B.C., though a more probable derivation is the Greek *helein*, to take, making the name signify captives. They were the property of the state, which alone had the disposal of their life and freedom. The state assigned them to certain citizens, by whom they were employed in private labors, though not exclusively, as the state still exacted certain services from them; and they were attached to the soil — that is, each citizen received the number that belonged to his allotment, without any power to sell or free them. Agriculture and all mechanical arts at Sparta were in the hands of the Helots, since the laws of Lycurgus prohibited the Spartans from all lucrative occupations. But the Helots were also obliged to bear arms for the state, in case of necessity. Their dress, by which they were contemptuously distinguished from the free Spartans, consisted of sheep's skin and a leather cap of a peculiar shape. They were sometimes liberated for their services or for a sum of money; but they were not admitted to the full dignity of citizenship. In 424 B.C. 2,000 of the Helots, who had conducted themselves with distinguished bravery in war, were treacherously put to death. They several times rose against their masters, but were always and finally reduced.

Helper, Hinton Rowen, American author: b. near Mocksville, N. C., 27 Dec. 1829. He published in 1857 'The Impending Crisis of the South,' which the Republican party used as a campaign document with great effect. Later works by him are: 'The Three Americas' Railway' (1881); 'Nojoque' (1867); 'The Negroes in Negroland' (1868); 'The Land of Gold'; 'Oddments of Andean Diplomacy.'

Helps, Sir Arthur, English essayist and historian: b. Streatham 10 July 1813; d. London 7 March 1875. He was educated at Eton and Cambridge; became private secretary to Lord Monteagle as chancellor of the exchequer, and was afterward commissioner of French, Danish, and Spanish claims. In 1860 he was appointed clerk of the privy council, and held this post till his death. He was created K.C.B. in 1872. As an essayist he was one of the most popular writers of his day, and his historical works had an extended reputation. He possessed very wide and general culture and sound judgment, was painstaking and accurate in details, and in his historical works displayed considerable breadth of view. His principal works are: 'Thoughts in the Cloister and the Crowd' (1835); 'Essays Written in the Intervals of Business' (1841); 'Friends in Council' (1847–57); 'Conquerors of the New World and their Bondsmen' (1848–52); 'Companions of my Solitude' (1851); 'History of the Spanish Conquest of America' (1855–61); 'Oulita the Serf, a Tragedy' (1858); 'Life of Pizarro' (1869); 'Realmah' (1869); 'Casimir Maremma' (1870); 'Brevia, Short Essays and Aphorisms' (1870); 'Life of Hernando Cortes and Conquest of Mexico'; 'Thoughts upon Government' (1871); 'Life and Labors of Mr. Brassey' (1872); 'Social Pressure' (1874).

Helsingfors, hĕl'sĭng-fŏrs, Russia, a seaport town, capital of Finland, on a small peninsula in the Gulf of Finland, 180 miles by rail west-northwest of St. Petersburg. It is defended by the fortress of Sveaborg about three miles distant, and is the residence of the governor of Finland, the seat of important courts and public offices. Its university, removed from Abo in 1827, has a library of over 190,000 volumes. There are manufactures of linen, sail-cloth, tobacco, etc., and an important trade is carried on. Pop. (1903) 94,000.

Helve'tian Republic, the designation of the republic established in Switzerland by France in 1798. See SWITZERLAND.

Helvet'ic Confession, the name of a document drawn up by Martin Bucer in 1536 to settle the controversy between the Lutherans and the Zwinglians; and also of one drawn up by Bullinger (1566) at the request of Friedrich III., elector of the Palatinate, and adopted in Switzerland, the Palatinate, France, Hungary, Poland, and Scotland.

Helvetii, hĕl-vē'shĭ-ī, a former Gallic or Celtic nation living between the Rhone and the Rhine, the Jura, and the Rhætian Alps. They were more numerous and warlike than the neighboring Gallic tribes. They first appear in history 107 B.C., but were not known to the Romans until the time of Julius Cæsar, who, as governor of Gaul, prevented their intended emigration, and

HERMANN LUDWIG FERDINAND VON HELMHOLTZ.

after many bloody battles, in which even the Helvetian women fought, pressed them back within their frontiers. The story of their meditated irruption into and seizure of southern Gaul is circumstantially related in the First Book of the Commentaries of the Roman general, who not only repulsed them with terrible slaughter, but almost exterminated them. Not a third of those who left their homes on this ill-fated expedition ever returned. Helvetia, which was less extensive than the present Switzerland, was divided into four districts, which had an entirely democratical constitution. Cæsar subjected the country to the dominion of the Romans, who established several colonies there. After the death of Nero, the Helvetii, for refusing to acknowledge Vitellius as emperor, were mercilessly punished by Cæcina, one of his generals, and thenceforth they almost disappear as a people.

Helvétius, Claude Adrien, klōd ā-drē-oṅ ĕl-vā-sē-ŭs, French metaphysician: b. Paris Jan. 1715; d. there 26 Dec. 1771. At the age of 23 he obtained the lucrative post of farmer-general, where he was distinguished by his mildness and indulgence from his colleagues, whose base practices filled him with indignation. He therefore resigned his office, and purchased the place of *maître d'hôtel* to the queen. Aspiring after literary fame he first directed his efforts to mathematics, then attempted to rival the dramatic fame of Voltaire by writing a tragedy. In 1758 he published 'De l'Esprit,' the materialism of which drew upon him many attacks. It was condemned by the doctors of the Sorbonne, and publicly burned in accordance with a decree of the Parliament of Paris. Helvétius went in 1764 to England, and the year afterward to Germany, where Frederick the Great and other German princes received him with many proofs of esteem. A complete edition of his writings was published at Paris in 1795.

Hem'ans, Felicia Dorothea Browne, English poet: b. Liverpool 25 Sept. 1793; d. near Dublin, Ireland, 16 May 1835. She displayed the bent of her genius when a mere child, and wrote some tolerable poetry in her 9th year. She first appeared as an author, in 1808, in a volume entitled 'Early Blossoms,' but it was subjected to harsh criticism, which she took very seriously to heart. A second volume, published in 1812, 'The Domestic Affections,' was much more successful. The same year she married Captain Hemans, from whom she was separated in 1818. She then resumed her literary pursuits, made herself acquainted with Latin and modern languages, and wrote much in the periodicals of the time. At the suggestion of Reginald Heber, afterward bishop of Calcutta, she wrote a tragedy entitled 'The Vespers of Palermo,' which, owing partly to Sir Walter Scott, who wrote an epilogue for it, was favorably received at the Edinburgh theatre, though it had previously, in 1823, proved unsuccessful at Covent Garden. Before this time she had added greatly to her popularity by her poems entitled 'The Restoration of the Works of Art to Italy'; 'The Skeptic'; 'Modern Greece'; and 'Dartmoor.' Later works were 'Lays of Many Lands'; 'Forest Sanctuary'; 'Records of Woman'; and 'The Songs of the Affections' (1830). She visited Sir Walter Scott at Abbotsford, and Wordsworth at Rydal Mount, and left with each the impression of a singularly graceful and gifted woman. Her poetry is essentially lyrical and descriptive, and is always sweet, natural, and pleasing. In her earlier pieces she was imitative, but she ultimately asserted her independence, and produced many short poems of great beauty and pathos. Mrs. Hemans had no dramatic power, her effusions being always intensely subjective.

Hem'atin, or **Hæmatin.** See Hæmoglobin.

Hem'atite, native sesquioxide of iron, Fe_2O_3, a mineral widely distributed, and constituting a valuable ore of iron. It crystallizes in the rhombohedral system, and also occurs in massive form, sometimes forming beds of great thickness. It has a hardness of from 5.5 to 6.5, and a specific gravity ranging from 4.9 to 5.3. It is usually dark gray or black in color, with a metallic lustre, and is sometimes slightly magnetic, occasionally even showing magnetic polarity. Hematite occurs in the rocks of every age. The extensive masses that occur in metamorphic rocks are believed to have been deposited, originally, in marshes, undergoing metamorphosis at the same time as the rocks with which they are now associated. Fibrous and columnar forms of the mineral, brownish-red or black in color, are also known, and to these the name "red hematite" is sometimes applied In crystalline and metamorphic rocks a variety known as "specular iron" is met with, which is distinguished by the presence of crystals having a splendent lustre. Hematite occurs in vast quantities in various parts of the United States, notably in upper Michigan, in the Marquette district, and in Menominee and Gogebic counties; in Northern Wisconsin; and in St. Louis County, Minnesota. Iron Mountain, Missouri, is a hill about 200 feet high, the surface of which consists of loose blocks of hematite, many of which weigh as much as 10 or 20 tons. The name "hematite" is from a Greek word signifying "blood," and was given to the mineral by the ancients from its fancied resemblance to coagulated blood. Hematite is sometimes called "bloodstone" at the present time, though that name is more properly applied to a green variety of quartz, which contains small spots of red jasper. An allied mineral, consisting of hydrated sesquioxide of iron and known to mineralogists as limonite, is often popularly called "brown hematite."

Hemianæsthesia, hĕm-ĭ-ăn-ĕs-thē'sĭ-ạ, loss of sensation on one half of the body, right or left.

Hemiplegia, hĕm-ĭ-plē'jĭ-ạ (lit. "half a stroke," that is, of paralysis), paralysis of one side of the body. It is usually caused by hemorrhage in the brain cavity, commonly known as apoplexy; often a local accumulation of serum, or a tumor is the cause. The paralysis falls on the side of the body opposite to the lesion in the pyramids of the brain, unless the lesion occurs below the decussation of brain fibres. The treatment of hemiplegia requires the services of a physician. It is amenable to timely remedies, and a cure is generally obtained after the first attack, if it result from apoplexy; but the patient is liable to subsequent attacks.

Hem'ipode. See Button-quail.

Hemiptera, hē-mĭp'tē ra, an order of insects. It contains two leading groups, the *Homoptera* and *Heteroptera.* In the former the two pairs of wings when present are applied in rest pent-house fashion to the sides of the body. Several families are wingless. Cicadas, plant-lice (*Aphis*) and the like come here. In the second group the wings, when at rest, placed horizontally across the body, the second pair covered by the upper, which are *hemielytra,* that is, the basal half is leathery, the distal portion membranous. See Bug.

Hemlock, one of various plants. (1) A highly poisonous umbelliferous herb of the genus *Conium,* one species of which is European and the other African. The well-known officinal European one (*C. maculatum*) has become extensively naturalized as a weed in the United States. It is easily recognized by the wavy, crenate ridges of its short, laterally compressed fruit, and also by the disagreeable mouse-like odor when bruised (see Conium). (2) The water hemlocks or cowbanes of the closely allied genus *Cicuta,* which is also both European and American. The common American species is *C. maculata,* which grows in swamps and wet places, and is also dangerously poisonous, especially in its turnip-like cavernous root. See Cicuta.

Hemlock-spruce, an American coniferous tree of the genus *Abies* (or *Tsuga*) of which two species are recognized, the common northern one (*T. canadensis*), and a lesser one of the Southern Alleghanies (*T. Caroliniana*). The wood is too soft, weak, and brittle to be of extensive use as lumber, but the bark is of great importance in tanning. See Fir.

Hemlock, Water. See Hemlock.

Hem'meter, John Cohn, American physician: b. Baltimore, Md., 25 April 1864. He studied at the Royal Gymnasium, Wiesbaden, Germany; Baltimore City College; and University of Maryland; and became clinical professor of medicine in the last named institution, and director of the clinical laboratory. He is associate editor of 'Archives for Digestive Diseases,' Berlin, and author of: 'The Special Pathology and Treatment of Diseases of the Digestive Organs' (1896); 'Diseases of the Stomach' (1897); 'Diseases of the Intestines' (1901); 'Theodore Billroth, a biography' (1900). He is also a composer, and has composed 'Hygeia' (cantata); 'Prelude and Choral Music to the 23d Psalm' and other works.

Hem'orrhage. See Bleeding.

Hemp. The hemp plant proper, or "common hemp," is *Cannabis sativa,* an annual shrub belonging to the *Urticaceæ.* The term hemp, however, is used to designate many other kinds of fibre which are in no way related to the species of common hemp, such as Manila hemp, from a plantain, sisal hemp from an agave, bow string hemp, from a liliaceous plant, and 30 or more other kinds. The different kinds of common hemps are also specially designated, with prefixes, as Breton hemp, Piedmontese, Russian, English, China, and Japanese hemps, and many others, some of these being trade names, or the names of varieties. The hemp plant proper is a native of that part of Asia which includes India and Persia, though, like flax, its culture has been extended to many portions of the world in both temperate and tropical climes. It was used by the Scythians 2,500 years ago, and it was probably known to the Chinese and Europeans many centuries earlier. The Romans used it for sails and cordage, but not until after the dawn of the Christian era. It grows wild in many parts of India, where it is regarded more for its product known as chang or hasheesh than for its fibre. It flourishes on both the east and west coasts of Africa, and has been naturalized in Australia, as well as in several South American countries. In Europe it is cultivated chiefly in France, Italy, Germany, and central and southern Russia, and it will grow in Great Britain and Sweden. The plains of Hungary are peculiarly adapted to its culture. It is a favorite textile in China and Japan, the fibre from the last named country being particularly strong and fine, and at the same time, better prepared than many European hemps. The plant is an annual shrub, the fibre being produced in the bark of the straight stiff stalks or stems, and is therefore a bast fibre. In the experiments of Roxburgh and others, Russian hemp is taken as the standard of comparison for all other fibres. The stems vary from 3 to 20 feet long, dependent upon the variety and the soil in which grown. The best kinds have a hollow stem, the wood of which breaks down readily when cleaned for the fibre. While hemp is produced commercially in very few localities of the United States, it will thrive from ocean to ocean, and from the Gulf to Canada. Its cultivation as a fibre crop is confined chiefly to Kentucky, Illinois, Missouri, Nebraska, and California, though considerable hemp, in past time, has been produced in New York. Lately it has been experimented with in the South, notably in Mississippi and Texas. The bulk of the crop is grown at the present time in Kentucky and California.

The Kentucky hemp industry is very old, for the fibre was cultivated in the early part of the last century. The annual production, in 1859, reached a total of 75,000 tons, but 20 years later it had fallen off to such an extent that 5,000 tons only were recorded for the entire country. Since that time it has fluctuated between 5,000 and 12,000 tons as the total crop of the country, the annual production at the present time being less than the smaller figure. In late years the price has ruled at about 3½ cents per pound, though now it is quoted at 4½ cents. American hemp was at one time used to some extent for the rigging of vessels, although its largest use was for bagging. As early as 1824 it was employed in the navy, and efforts were made later by the government toward the production of better grades of hemp by water retting. The fibre has also been used for twines, and for woven fabrics. In late years the demand has been largely for a low grade fibre that could be manufactured into binder twine, though the bulk of the binder twine is made from manila and sisal. Very recently there has been a demand for a better grade of fibre, which has resulted in more careful methods, particularly on the Pacific coast, where a fibre has been produced fit for fine twines and cordage. Kentucky, Illinois, and Nebraska hemps are coarse, dark in color, and are not carefully prepared, which is the reason for the low price of 3½ cents against 8 and 10 cents per pound for finer imported hemps. The best hemp comes from Italy,

chiefly from the provinces of Bologna and Ferrara, the fibre being very white, very well prepared, and of superb strength. Breton hemp from France is almost as good, but rarely imported. Russian comes in several grades, some light, but not as light as the Italian, some dark like the native fibre, and low in grade. Some good hemp comes from Austria-Hungary, and a trifle from other portions of Europe. Little if any of the Japan fibre reaches this market, though the best Japanese is as good as the Italian. We consume annually less than 10,000 tons, including both the native and imported.

There are many varieties of the hemp plant, four or five having been grown in the United States, though it is said that the bulk of the seed at present sown is the China hemp and a Japanese variety. Five varieties are cultivated in Europe, a common form reaching a height of 5 to 7 feet; Piedmontese or Bologna, an Italian variety that averages 12 feet in height; China hemp, introduced in 1846; a small hemp found in the valley of the Arno, and around Tuscany, and Arabian hemp, cultivated for the resinous principle or drug.

Limestone soils and the alluvial soils of the river bottoms are best adapted to hemp culture, and the seed bed should be almost as carefully prepared as for flax. One to three bushels of seed are sown per acre broadcast, and lightly covered. The planting, in Kentucky, usually begins in April, and the crop may be harvested in 100 days. For further particulars regarding the culture and preparation of this fibre, see Special Reports Nos. 1, 8, and 11, office of Fibre Investigations of the Department of Agriculture, and Hemp Culture in the United States, Year-book of Agriculture for 1901. See also the 'Dictionary of the Economic Products of India.'

While some 300 patents have been issued in this country for hemp machines, the bulk of the fibre is extracted by means of the old-fashioned, clumsy wooden "slat brake" that has been employed from time immemorial and without improvement or change. With one of these brakes a Kentucky negro can extract perhaps 150 pounds of fibre in a day. The brakes used in European hemp countries are little better, though they are smaller and less clumsy. The best foreign hemps are water retted, the stalks dried with great care, often in kilns, and therefore are more evenly prepared, and the fibre soft, strong, and light in color — almost white as in the Italian and French hemp. On the contrary most of the American hemps are dew retted, and are exposed to alternate freezing and thawing, as the stalks lie on the ground, giving an inferior product, uneven, and very dark in color, often a slate gray. See CORDAGE; CORDAGE INDUSTRIES; FIBRE; FLAX; MANILA HEMP; RAMIE; SISAL.

CHAS. RICHARDS DODGE.

Hemp-agrimony. See EUPATORIUM.

Hemp-nettle, a genus (*Galeopsis*) of European plants of the mint family, two species of which have become naturalized as weeds in the eastern United States.

Hemp'hill, James C., American journalist: b. Due West, Abbeville County, S. C., 18 May 1850. Was graduated at Erskine College in his native town in 1870 and entered journalism as editor of the Abbeville, S. C., 'Medium' in 1871. In 1880 he joined the staff of the Charleston *News and Courier*, of which since 1888 he has been manager and editor.

Hempl, George, American philologist: b. Whitewater, Wis., 6 July 1859. He was graduated at the universities of Michigan in 1879 and of Jena in 1889, and was appointed instructor in German at Johns Hopkins University in 1884. After spending three years abroad (1886–9) in study at Göttingen, Tübingen, Strasburg, and Berlin, he became junior professor of English in the University of Michigan, where he has been professor of English philology and general linguistics since 1897. He has been a voluminous writer, and among his technical works may be mentioned 'German Orthography and Phonology' (1897); 'German Grammar' (1901).

Hemp'stead, N. Y., village, in the town of the same name, in Nassau County; on the Long Island Railroad; about 15 miles east of the borough of Brooklyn, and 10 miles from the ocean. The village was settled in 1643 by people from New England. The Presbyterian Society of Hempstead claim the oldest Presbyterian organization in the country, dating their beginning in this village in 1644. Hempstead is located in a section of Long Island in which there are many summer homes. During the war with Spain an encampment for State troops was located at Hempstead; it was called Camp Black after the then governor of the State. The chief industrial interests are market gardening, farming, and the manufacturing of cork insoles, phosphates, and carriages. Pop. (1900) 3,582.

Hempstead, Texas, town, county-seat of Waller County; on the Houston & T. C. railroad; about 50 miles northwest of Houston and 113 miles east by south of Austin. It is situated in a fertile agricultural region, noted for its cotton fields and its vegetable products. It has a cottonseed-oil mill, cotton-gins, and its trade is chiefly in cotton, grain, fruits, and vegetables. Pop. 1,978.

Hems, or Homs, hōms (Lat. *Emesa*), Syria, an ancient city, near the Orontes and the Lake of Homs, 86 miles northeast of Damascus. Its temple of the sun-god Elagabalus was famous, and one of its priests became emperor of Rome, assuming its title, in 218. Here in 272 Zenobia was defeated by Aurelian, and in 1832 the forces of the sultan of Turkey by Ibrahim Pasha. The town is still surrounded by its ancient walls now in a ruinous condition. It has some manufactures of silk goods and gold ornaments, and a trade in oil and agricultural produce. Pop. est. 30,000.

Hem'street, Charles, American journalist and author: b. New York 20 Sept. 1866. He entered the profession of journalism as a reporter in 1886, and was connected with the City Press Association until 1900, when he resigned to devote himself to literature and historical research. He has published: 'Manhattan' (1888); 'Nooks and Corners of Old New York' (1899); 'The Calendar of Old New York' (1900); 'History of New York City' (1901); 'When Old New York was Young' (1901).

Hem'yng, Bracebridge, English author: b. London 1832; d. 1891. In early life a journalist he began at the age of 35 a series of sensational tales for boys known as the 'Jack Hark-

away' stories, which for a dozen years had great vogue in Great Britain and the United States. He wrote not only some 20 serial stories having to do with the adventures of 'Jack Harkaway,' but upward of 40 volumes of sensational fiction, none of which, however, found readers in America.

Hen-hawk, or **Chicken-hawk,** any kind of hawk which attacks poultry, or is supposed to do so. Two or three large buzzard-hawks are popularly so called in the eastern United States, and at least two smaller falcons. In the West, and in other parts of the English-speaking world, are other species of the same repute, more or less well-deserved. In England the analogue of the American marsh-hawk (q.v.) is known as "hen-harrier." Certain owls everywhere kill much poultry where it is not safely housed at night. In North America the best known hen-hawks are the broad-winged, red-tailed, and red-shouldered (q.v.; also BUZZARD). They are comparatively harmless to poultry, however, feeding mainly on squirrels, mice, frogs, etc. The broad-wing (*Buteo pennsylvanicus*) is one of the most familiar of our hawks, breeding numerously in the woods all over the country. It is 16 inches long, with the tail 7 inches, and the wing 11 inches. The upper parts are dull umber-brown, the tail almost black, crossed by two to four pale brown bands; the lower parts are dull rufous brown, nearly unbroken on the breast. It is rather sluggish in temperament, though capable of swift and bold action, and feeds mainly on mice, but will now and then seize young chickens, ducklings, etc. On the whole, as in the case of the other buzzard-hawks, it is of more service than injury to the agriculturist. The real culprits are two small, swift, agile falcons, Cooper's (*Accipiter cooperi*), and the sharp-shin (*A. velox*). The former is nearly two feet long, grayish-brown on the upper parts and white below, with the sides and breast barred with dusky red-brown, and tail barred with blackish. The sharp-shin has much the same colors, but is little more than half as large, and is further distinguished by the triangular shape of the tarsus, giving it an edge in front. These bold and active falcons live mainly on birds, and on farms prey largely on chickens and house-sparrows, compensating somewhat for the former by killing the latter. Consult Fisher, 'Hawks and Owls of the United States' (Washington 1893).

Henbane, a dangerous plant (*Hyoscyamus niger*) of the order *Solanaceæ*, which contains the tobacco, stramonium and other plants abounding in narcotic poisons. The black henbane (*Hyoscyamus niger*) represents some 15 species of the Mediterranean region, and springs up in waste places throughout Great Britain and the eastern United States, where it has become naturalized. It is an annual, somewhat bushy, about two feet high, with large sinuated or sharply lobed leaves without leaf-stalks, and large dingy yellow flowers with purplish veins. The whole plant is covered with unctuous hairs, and has a nauseous smell. The seeds contain in largest quantity the specific alkaloid hyoscyamin, which crystallizes in stellated acicular crystals of a silky lustre. The symptoms of poisoning by henbane are similar to those produced by other narcotic poisons, and the proper treatment is the same as in cases of poisoning by opium. In medicine henbane is employed both externally and internally. The leaves are the part commonly used; they are gathered and quickly dried when the plant is in full flower. Fomentations of henbane are applied to painful glandular swellings, parts affected with neuralgia, etc., and are often found to afford relief. An extract of henbane is sometimes employed instead of belladonna to dilate the pupil of the eye. Tincture and extract of henbane are often administered in cases of annoying cough, spasmodic asthma, and other diseases requiring sedatives and anti-spasmodics. For many cases it has one great advantage over laudanum, in not producing constipation. The other species of henbane possess similar properties. The dried stalks of *H. olbus* are used by smoking in Greece to allay toothache.

Hen'derson, Charles Hanford, American educator and author: b. Philadelphia 30 Dec. 1861. He was graduated from the University of Pennsylvania in 1882, was lecturer at the Franklin Institute 1883–5, 1885–6; lecturer on education at Harvard 1897–8; and director of Pratt Institute, Brooklyn, 1898–9. He has published 'Elements of Physics' (1900); 'John Percyfield: the Anatomy of Cheerfulness' (1903); 'The Children of Good Fortune' (1904).

Henderson, Charles Richmond, American educator: b. Covington, Ind., 17 Dec. 1848. He was graduated from the University of Chicago in 1870, and has been professor of sociology there since 1892. He was president 26th National Conference of Charities 1898–9, and vice-president National Prison Association. He has published 'Social Spirit in America' (1896); 'Social Settlement' (1897); 'Social Element' (1898).

Henderson, David Bremner, American statesman: b. Old Deer, Scotland, 14 March 1840; d. Dubuque, Iowa, 25 Jan. 1906. He was educated in the public schools and Upper Iowa University; in 1861 entered the army as lieutenant of the Twelfth Iowa regiment; lost a leg at Corinth (1863), and was discharged from the service. He then became commissioner of the board of enrolment in the 3d Iowa district, but re-entered the army as colonel in 1864. He studied law and was admitted to the bar in Iowa in 1865, and was United States district attorney in the northern division of Iowa 1869–71. He early became prominent in the local politics of his district, and was a delegate to three Republican national conventions. In 1882 he was elected to the House of Representatives, and was re-elected biennally till 1902. He was for many years one of the leaders of the Republicans in the House, served on the committee of appropriations for 10 years, and was chairman of the judiciary committee and a member of the committee on rules in the 54th and 55th Congresses. He assisted Speaker Reed (q.v.) in the making of the "Reed rules," was consistently an advocate of sound money, and a strong supporter of President McKinley's Cuban policy. At the organization of the 56th Congress in 1899 he was chosen speaker of the House, and re-elected in 1901; he was an impartial presiding officer and took important part in shaping the legislation made necessary by the Spanish war and the acquisition of new territory. In 1902 he

declined a unanimous renomination from his district, because he could not support the policy of tariff revision then made a prominent issue by Iowa Republicans.

Henderson, Isaac, American journalist and novelist: b. Brooklyn, N. Y., 13 Feb. 1850. He was graduated from Williams College in 1872, and the same year joined the staff of the New York *Evening Post*, of which journal he became publisher in 1876. He sold his interests in 1880, and went abroad in 1888, making his home in London and Rome. Author of 'The Prelate' (1898); 'Agatha Page' (1900).

Henderson, James Pinckney, American soldier and politician: b. Lincoln County, North Carolina, 21 March 1808; d. Washington, D. C., 4 June 1858. He practised law in Mississippi; went to Texas in 1836, and became secretary of state of the Texan Republic 1837–9. In the latter year he was sent as a minister to England and France to secure the recognition of Texan independence, and went to Washington in 1844 to secure annexation. He was a member of the Texas constitutional convention 1845, and the following year was elected first governor of the State. In 1857 he was appointed senator from Texas as a State Rights Democrat. Henderson fought in the Mexican War and Congress gave him a sword for his gallantry.

Henderson, Mary N. Foote, American writer on domestic science: b. New York 1842. She was married to J. B. Henderson, and in 1876 organized the St. Louis School of Design. She is the author of 'Diet for the Sick,' 'Practical Cooking and Dinner Giving.'

Henderson, Peter, American horticulturist: b. Porthead, Scotland, 1823: d. Jersey City, N. J., 17 Jan. 1890. He came to America in 1843, and opened a seed-store in New York city in 1862. He has been called "the father of horticulture and ornamental gardening in the United States." He published 'Practical Floriculture' (1867); 'Gardening for Profit' (1866); 'Gardening for Pleasure' (1875); 'Garden and Farm Topics' (1884); 'How the Farm Pays' (1884).

Henderson, Richard, American pioneer: b. Hanover County, Virginia, 1734; d. North Carolina 1785. He studied law and in 1769 was appointed associate justice of the superior court of North Carolina. After the adoption of the Declaration of Independence he declined re-election to the bench, in order to participate in the scheme of the Transylvania Land Company. By this scheme the company organized as a political community with president, legislature, and judges, all the territory lying between the Cumberland River, the Cumberland Mountains, and the Kentucky River. The State of Virginia annulled the deed of sale of this tract of territory which the Cherokee Indians had given to the Transylvania Land Company, but as a reward for the pioneer work of the company, granted them an area 12 miles square on the Ohio River, below the mouth of the Greene River.

Henderson, William James, American musical critic and author: b. Newark, N. J., 4 Dec. 1855. He was graduated from Princeton College in 1876, and joined the staff of the New York *Tribune*, the following year becoming musical critic of the New York *Times*. He was associate editor of 'The Standard Dictionary' (1892–4), and has published: 'The Story of Music' (1889); 'Preludes and Studies' (1891); 'Sea Yarns for Boys' (1894); 'Afloat with the Flag' (1895); 'Elements of Navigation' (1895); 'The Last Cruise of the Mohawk' (1897); 'What is Good Music?' (1898); 'How Music Developed' (1899); 'The Orchestra and Orchestral Music' (1899); 'Richard Wagner' (1901).

Henderson, Ky., city, county-seat of Henderson County; on the Ohio River, and on the Illinois C., the Louisville & N., the Louisville, H. & St. L. R.R.'s; about 10 miles below Evansville, Ind., and 103 miles, in direct line, southwest of Louisville. It has regular steamboat connection with Louisville, Evansville, Memphis, and other river ports. It is one of the oldest settlements on the Ohio River, but it was not incorporated until 1797. It is situated in a fertile agricultural region, rich in timber and coal. The chief manufactures are cotton and woolen goods, flour, hominy, lumber, tobacco products, furniture, carriages and wagons, foundry products, car-works, and agricultural implements. Large shipments are made of corn, wheat, and tobacco. It has large coal and lumber yards, grain-elevators, tobacco-stemmeries, fine fairgrounds, and Atkinson Park, the area of which is about 100 acres. It has a sanatorium and a number of well-built churches and schools. The charter of 1893 provides for a mayor, who holds office four years and is not eligible for re-election, and a common council. The city owns and operates the electric-light and gas plants and the waterworks. Pop. (1900) 10,272.

Henderson, N. C., town, county-seat of Vance County, on the Southern and the Seaboard A. L. R.R.'s; about 12 miles east of Oxford and 42 miles north of Raleigh. Henderson was settled in 1820, but was not incorporated until 1842. It is situated in a cotton and tobacco region of the State. The chief industrial establishments are cotton-gins, cotton-seed oil mills, cotton-mills, knitting-mills, tobacco warehouses, wagon-factories, flour-mills, and lumber-yards. Its chief trade is in cotton and tobacco. Pop. (1890) 4,191; (1900) 3,746.

Henderson, Texas, town, county-seat of Rusk County; on a branch of the International & G. N. railroad; about 122 miles southeast of Dallas and 165 miles north by east from Houston. It is situated in an agricultural section, and the chief industries are connected with agricultural products. Its chief industrial establishments are a foundry, a pottery, and cotton-gins. The trade is in manufactured articles, live-stock, cotton, and vegetables. It is the seat of a normal college.

Hen'dersonville, N. C., town, county-seat of Henderson County; on the Southern Railway; about 21 miles south of Asheville and 100 miles west of Charlotte. It is situated in a mountainous portion of the State, but in the valleys are fertile farm lands. The chief industrial establishments are a furniture factory, a tannery, a canning factory, and a lumber yard. Apples and vegetables are among the agricultural products shipped to other markets. Hendersonville has a large number of summer

guests owing to the healthfulness of the climate and the beauty of the scenery. Pop. (1900) 1,917.

Hen'dricks, Thomas Andrews, American politician, 21st Vice-President of the United States: b. near Zanesville, O., 7 Sept. 1819; d. Indianapolis, Ind., 25 Nov. 1885. He was graduated at South Hanover College, Indiana, in 1841; studied law and was admitted to the Indiana bar in 1843. In 1845 he was elected to the legislature, and in 1850 and 1852 to Congress. In 1860 he was the Democratic candidate for governor of Indiana, but was defeated. He was a United States senator 1863–9; and at the Democratic National Convention of 1868 received 132 votes for the Presidential nomination. In the same year he was again defeated for the governorship of Indiana, but in 1872 was elected. In the Democratic National Convention of 1876 he was nominated for the Vice-Presidency, but the ticket, headed by Tilden, was defeated. Hendricks was again nominated for the Vice-Presidency in 1884, however, on the ticket with Cleveland, and on this occasion was elected.

Hen'drix, Eugene Russell, American Methodist bishop: b. Fayette, Mo., 17 May 1847. He was graduated from Wesleyan University, Middletown, Conn., 1867; and the Union Theological Seminary 1869. Appointed bishop of the Methodist Episcopal Church South, in 1886, he has since made official visits to China, Japan, Korea, Mexico, and Brazil. He is the possessor of John Wesley's manuscript 'Journal' written in America 1736–7. He has written 'Around the World' (1878); 'Skilled Labor for the Master' (1900).

Hengist, hĕng'gĭst, Saxon founder of the kingdom of Kent in Great Britain: d. about 488. He and his brother Horsa were renowned among the Saxons for their bodily strength and the antiquity of their family, which derived its origin in a direct line from Odin. In 449 the Britons sued for aid from the Saxons against the inroads of the Scots and Picts. Under command of Hengist and Horsa the Saxons landed at the mouth of the Thames, attacked the enemies of the Britons, and defeated them near Stamford in 450 A.D. As soon as they had received reinforcements from home they sought occasion for a quarrel, and uniting with the Scots and Picts they attacked the Britons, who were forced to flee or submit to the Saxons. Some fled to Armorica (Haute-Bretagne), to which they gave their name. Hengist, who had lost his brother in the battle near Eglesford (now Aylesford) in 455 A.D., founded the kingdom of Kent. He established his residence in Canterbury. By some of our writers Hengist and Horsa are regarded as mythical personages.

Hening's Statutes, the first complete collection of the laws of any American State, including those of its colonial times, those repealed and those dropped in revision. These were the "Statutes at Large of Virginia, 1619–1792," in 13 volumes, published at Richmond 1809–23, by William Waller Hening, clerk of the court of chancery; Jefferson is said to have suggested the publication. It is highly valued as a historical source.

Hen'ley, William Ernest, English poet, critic, and journalist: b. Gloucester 23 Aug. 1849; d. Woking 12 July 1903. He entered on a journalistic career in London, and in 1877 became first editor of the magazine 'London.' He was then editor successively of the 'Magazine of Art' (1882–6), of the 'Scots'— later the 'National Observer'— (1888–93), and of the 'New Review' (1893–8). His first publication, 'In Hospital: Rhymes and Rhythms' (1888), was inspired by his own experiences as a patient in Edinburgh Infirmary. Its contents were subsequently included in 'A Book of Verses' (1888). A second volume of poems, 'The Song of the Sword,' appeared in 1892 (2d ed. as 'London Voluntaries' 1893). Both of these books were incorporated in the collection of his 'Poems' (1898). Later poetical works were: 'For England's Sake' (1900); and 'Hawthorn and Lavender, and Other Verses' (1901). Henley collaborated with Stevenson four plays, 'Deacon Brodie,' 'Beau Austin,' and 'Admiral Guinea' and 'Macaire.' He also edited, either alone or in cooperation with others, the following anthologies and collections: 'Lyra Heroica' (1891), an anthology of English patriotic verse; 'A London Garland: from Five Centuries of English Verse' (1895); 'Book of English Prose' (1896); 'English Lyrics, 1340–1809' (1897); 'The Works of Lord Byron' (1897); 'The Poetry of Wilfrid Blunt' (1896); and 'London Types' (1898), and was editor of a series of 'Tudor Translations.' The 'Centenary Burns' (1896–7) is an important work edited by him with the cooperation of T. F. Henderson. The fourth volume contains an elaborate estimate by Henley of Burns as poet and man, published separately in 1898. His critical work appears at its best in 'Views and Reviews: Literature' (1890), and 'Views and Reviews: Painting and Sculpture' (1901). Both as poet and critic he was prejudiced and aggressive, but keen, vigorous, and often distinguished in style. A paper on Stevenson contributed to the 'Pall Mall' in 1901 aroused much unfavorable comment by its arraignment of Balfour's 'Life.'

Henley-on-Thames, England, a market-town and municipal borough of Oxfordshire, on the Thames, 35 miles by rail west of London. The town is especially famous for its annual regatta in July, a notable event in the British sporting world. The university boat races are held on the river here, and Americans frequently take part in the various open events. Pop. (1901) 5,984.

Henlopen. See CAPE HENLOPEN.

Henna, a shrub (*Lawsonia inermis*) resembling the privet, but of the order LYTHRACEÆ. It grows in moist situations throughout the north of Africa, Arabia, Persia, and the East Indies, and has acquired celebrity from being used by the inhabitants of those countries to dye the nails of their fingers and the manes, hoofs, etc., of their horses. For this purpose the leaves are dried, powdered, and made into a paste with hot water, which imparts a yellow color, requiring renewal every three or four weeks. It is cultivated extensively in Egypt, and the powdered leaves form a large article of export to Persia and Turkey. Henna is supposed to be the *kopher* of the Hebrew, translated *camphire* in the Song of Solomon.

Hennepin, Louis, loo-ē ĕn-păn or hĕn'ĕ-pĭn, French Franciscan missionary and explorer in North America: b. Ath, Belgium, about 1640; d. Utrecht, Holland, about 1706. He entered a convent, and being sent by his superiors to Calais and Dunkirk, the stories he heard from the sailors inspired him with a desire to visit distant countries. At length he embarked for Canada, and arrived at Quebec in 1675. In 1676 he went to the Indian mission at Fort Frontenac, whence he visited the Five Nations and the Dutch settlement at Albany. In 1678 he was attached to La Salle's expedition, and, in company with the Chevalier de Tonty and the Sieur de la Motte, was ordered to sail from Fort Frontenac to Niagara, and there construct a vessel for navigating the Lakes above the falls. This accomplished, La Salle joined the party, and on 7 Aug. 1679 the adventurers began their voyage on Lake Erie. They passed through Lakes Erie, Huron, and Michigan, to the mouth of the St. Joseph's River, ascended this in canoes to the portage, carried their frail barks several miles by land to the Kankakee, and floated down this stream and the Iroquois to the Illinois, on the banks of which they built Fort Crèvecœur near the present site of Peoria. After a delay of two months at this place, La Salle returned to Fort Frontenac for supplies, charging Father Hennepin with a voyage of discovery to the sources of the Mississippi, which had never been explored above the mouth of the Wisconsin. Accompanied by Picard du Gay and Michel Ako, he set out in a canoe 29 Feb. 1680, followed the Illinois to its mouth, and ascended the Mississippi to the Falls of St. Anthony, which he was the first European to see, and which he named in honor of his patron saint. This was on 30 April. Arriving at the mouth of the St. Francis River, in what is now the State of Minnesota, he traveled by land about 180 miles along its banks, naming it in honor of the founder of his order, and visited the Sioux Indians, whom he mentions by the names Issati and Nadouessioux. He stayed with them three months, being, according to his own account, held in captivity, and then, meeting a party of Frenchmen who had come into the country by way of Lake Superior, returned with them to Canada, descending the Mississippi to the Wisconsin, and passing up that river and down the Fox, and so through Green Bay to Lake Michigan. From Quebec he sailed for France, where he published in 1683 his 'Description de la Louisiane Nouvellement Découverte au Sud-Ouest de la Nouvelle-France, etc.,' containing the fullest published account of La Salle's first expedition, a history of his second voyage, and of Hennepin's own explorations, with a description of the upper Mississippi. Notwithstanding the writer's vanity and fondness for exaggeration, the work is valuable. He put off his clerical dress in Holland about 1697, but to the end of his life seems to have written himself: "Recollect missionary and apostolic notary." In 1697, 10 years after La Salle's death, Hennepin published his extraordinary 'Nouvelle Découverte d'un Très-Grand Pays Situé dans l'Amérique entre le Nouveau Mexique et la Mer Glaciale, etc.,' reprinted the next year under the title 'Nouveau Voyage dans un Pays Plus Grand que l'Europe, etc.' In this work, which embodies his 'Description de la Louisiane,' written anew and enlarged, he claims to have descended to the mouth of the Mississippi, and to have been the first European who floated on that river. He gives a description of the scenery, Indian tribes, and distances along the route, with a minuteness which easily gained him credit for veracity, and explained his long silence on this important point by saying that he feared the enmity of La Salle, who had ordered him to follow a different course, and who prided himself upon his own claims as the first who descended the Mississippi to the Gulf of Mexico. Notwithstanding the utter impossibility of reconciling the dates given in Hennepin's narrative, the story obtained general credence until its falseness was exposed by Jared Sparks. (See 'Life of La Salle' by Sparks in the 'Library of American Biography.') Consult: Saint-Genois, 'Les Voyageurs Belges du XIII. au XIX. Siècle' (1867); Van Hulet, 'Notice sur le Père Louis Hennepin' (1845); Shea, 'Discovery of the Mississippi' (1852); Parkman, 'La Salle and the Discovery of the Great West'; Winsor, 'Narrative and Critical History of America,' Vol. IV. (1884).

Hen'nessey, William J., Anglo-American artist: b. Thomastown, County Kilkenny, Ireland, 1839. He was brought to New York when 10 years of age, and became a student of the Academy of Design in 1856. He paints in oil and water colors, with a preference for landscape, and draws in black and white as an illustrator. In 1863 he was elected a National Academician, and since 1870 has lived in London, England.

Hennessy, John, American Roman Catholic bishop: b. Ireland 20 Aug. 1825; d. Dubuque, Iowa, 4 March 1900. He came to the United States in 1847, and pursued his theological studies in Carondelet Seminary, near St. Louis. After serving several years as a missionary in Missouri he became professor in Carondelet Seminary in 1854, and its president in 1857. He was afterward pastor in St. Joseph, Mo.; became bishop of Dubuque in 1866, and archbishop in 1893.

Hennessy, John Joseph, American Roman Catholic bishop: b. County Cork, Ireland, 19 July 1847. He came to America in early life and was graduated at the Christian Brothers' College, St. Louis, Mo., in 1862. He was ordained priest in 1869; founded the Railroad Men's Benevolent Union 1871; established the Ursuline convent, Arcadia, Mo., 1877; and edited 'The Youth's Magazine,' St. Louis, 1880–6. He was consecrated bishop of Wichita, Kan., in November 1888.

Hen'niker, Hon. Mrs. **Arthur,** English novelist. She is a daughter of Richard Monckton Milnes (q.v.), 1st Baron Houghton, and was married to Hon. Arthur Henniker in 1882. Her books, which have had an American as well as English circulation, include: 'Sir George' (1891); 'Foiled' (1893); 'Outlines' (1894); 'In Scarlet and Gray' (1896); 'Sowing the Sand' (1898); etc.

Hen'ningsen, Charles Frederick, American military officer: b. in England, of Swedish parents, 1815; d. Washington, D. C., 14 June 1877. He joined the Carlists in Spain in 1834, and later was a follower of Kossuth in the Hungarian Revolution. He went to Nicaragua in 1856, where he distinguished himself in the de-

fense of Granada, and in the victory at Quer-esma. During the Civil War he served in the Confederate army, becoming a brigadier-general. He directed the construction of the first Minie rifles manufactured in the United States. His publications include 'Eastern Europe'; 'Past and Future of Hungary'; 'Sixty Years Hence'; 'Personal Recollections of Nicaragua'; 'The White Slave'; etc.

Henri, Robert, American painter: b. Philadelphia, Pa., 1865. He began his art studies in his native city and became an instructor in the Philadelphia School of Design. He has exhibited in Paris, and his picture 'Snow' was purchased by the French government and hangs in the Luxembourg. While in Paris he gathered round him a group of pupils in his studio, and as a landscape painter did much to impress younger men with his breadth and vigor of style. While he is a landscape painter of notable attainment, his portraits also are admirable for the power of individualization and the directness which characterizes them.

Henriet'ta, Duchess of Orleans: b. Exeter 16 June 1644; d. St. Cloud, France, 30 June 1670. She was the daughter of King Charles I. Her mother fled with her to France where she was educated a Roman Catholic. Her marriage with the brother of Louis XIV., Philip of France, Duke of Orleans, was celebrated in March, 1661. Louis XIV. was desirous of detaching her brother, Charles II., from the triple alliance with Holland and Sweden, in order to accomplish his plan of obtaining possession of a part of Holland. She went, therefore, in 1670, with the court to Flanders, and, under pretense of visiting her brother, passed over to Dover, where Charles was awaiting her arrival, and there succeeded in obtaining his signature to the secret treaty of Dover. Shortly after her return she died so suddenly as to excite the suspicion of her being poisoned. Bossuet pronounced her funeral oration.

Henrietta Maria, queen of Charles I. of England: b. Paris 25 Nov. 1609; d. Colombes, near Paris, 31 Aug. 1669. She was the youngest child of Henry IV. of France. Her marriage ceremony was celebrated by proxy at Paris in 1625. On Henrietta's first arrival in England she enjoyed great popularity with her husband's subjects, but her attachment to the Roman Catholic faith, combined with her hauteur and despotic ideas as to divine right, soon dissipated these favorable prepossessions. Much of Charles' subsequent arbitrary and injudicious procedure, may be traced indirectly to the influence of his queen. On the breaking out of the civil war Henrietta proceeded to Holland, where she procured money and troops for the assistance of her husband, and afterward joined him at Oxford. She again returned to the Continent, and took up her abode in France.

Henriet'ta, Texas, town, county-seat of Clay County; on the Little Wichita River, and on the Missouri, K. & T., and the Fort Worth & D. R.R.'s; about 90 miles northwest of Fort Worth and 128 miles northwest of Dallas. It is situated in an agricultural and stock-raising region, and the building-stone quarries in the vicinity add to the industrial wealth of the town. The chief manufactures are flour and lumber. The town has cotton-gins, grain elevators, lumber-yards, and stock-yards. The trade is chiefly in live stock, grain, flour, lumber, cotton, and building-stone. Pop. (1900) 1,614.

Hen'rotin, Ellen M., American social reformer; b. Portland, Maine, July 1847. She was educated in Europe and in 1869 was married to Charles Henrotin, Belgian consul at Chicago. In 1893 she was vice-president of the Congress Auxiliary of the World's Columbian Exposition; the same year she was decorated by the Sultan of Turkey with the order of Chafkat and made an Officier de l'Academie by the French Republic, 1899. She was president from 1894 to 1898 of the General Federation of Women's Clubs.

Henry I., king of England, surnamed Beauclerc, youngest son of William the Conqueror: b. Selby, Yorkshire, 1068; d. Rouen, France, 1 Dec. 1135. He was hunting with William Rufus in the New Forest when that prince received his mortal wound in 1100, and instantly going to London, caused himself to be proclaimed king, to the prejudice of his elder brother Robert, then absent in the Crusade. To reconcile the people to his usurpation Henry issued a charter containing concessions to public liberty, and also performed another popular act, by recalling Anselm, archbishop of Canterbury. In November 1100 he married Matilda, daughter of Malcolm III., king of Scotland. This union strengthened his party, when his brother landed an army in 1101, with a view of asserting his claim to the crown. Actual hostilities were prevented by Anselm, who induced Robert to accept a pension; and it was agreed that in the event of the death of either of the brothers without issue, the other should succeed to his dominions. He subsequently invaded Normandy, and in 1106 took Robert prisoner, and reduced the whole duchy. His usurpation of Normandy involved him in continual war, but although William, son of Robert, escaped out of custody, and was assisted by the king of France, Henry maintained possession of the duchy. His only son William was drowned in 1120 in returning from Normandy, and Henry was never seen to smile afterward. He married his only daughter, Matilda, to the Emperor Henry V., and when she became a widow married her a second time to Geoffrey Plantagenet, son of the Count of Anjou. Henry was succeeded by Stephen.

Henry II., king of England, the first of the line of the Plantagenets, b. Normandy 1133; d. Castle of Chinon, near Saumur, France, 6 July 1189. He was the son of Geoffrey, count of Anjou, and the empress Matilda, daughter of Henry I. He was invested with the duchy of Normandy, by the consent of his mother, in 1150. The next year he succeeded his father in the possession of Anjou and Maine, and by a marriage with Eleanor of Guienne, just divorced from Louis VII., king of France, annexed that province with Poitou to his other dominions. He succeeded Stephen as king of England in 1154. Although involved with his brother Geoffrey, who attempted to seize Anjou and Maine, and in a temporary dispute with France, he reigned prosperously till the memorable contest with Thomas Becket. Anxious to dominate the clergy, Henry in 1164 summoned a general council of nobility and prelates at Clarendon, which assembly passed the famous

constitutions named from that place, the effect of which was to render the church and ecclesiastical dignitaries subject to the temporal authority. (See CLARENDON, CONSTITUTIONS OF.) After the murder of Becket Henry receded from his position and restored the Church to its rights. Before this matter was terminated, Henry, in 1171, undertook an expedition into Ireland, and having left Earl Richard in the post of seneschal of Ireland he returned to England — proceedings so important to the future destinies of both countries having occupied only a few months. Being an indulgent father Henry had assigned to each of his four sons a provision out of his extensive territories. The eldest son, Henry, was not only declared heir to England, Normandy, Anjou, Maine, and Touraine, but actually crowned in his father's lifetime. On paying a visit to the court of his father-in-law, Louis VII. of France, the prince was induced by the French monarch to demand of his father the immediate resignation either of the kingdom of England or of the dukedom of Normandy. This request being refused he withdrew from his father's court, and was openly supported in his claim by Louis. Henry's various gallantries, exemplified in the popular and not altogether unfounded legend of fair Rosamond, or Rosamond Clifford, also embroiled him with his queen, Eleanor, who incited her other sons, Richard and Geoffrey, to make similar claims. A general invasion of Henry's dominions was in this way concerted, and began in 1173 by an attack on the frontiers of Normandy, but the king presently subdued his opponents and entered into an accommodation with his sons on less favorable terms than they had previously rejected. Henry now employed himself in regulations and improvements which equally manifest his capacity and love of justice. He partitioned England into four judiciary districts, appointed itinerant justices to make regular excursions through them, revived trial by jury, discouraged that by combat, and demolished all the newly erected castles as shelters of violence and anarchy. The turbulence of his sons still disquieted him; but Henry, the eldest, was cut off by fever in 1183, and three years after the death of the equally restless Geoffrey occurred. Philip Augustus, then king of France, however, continued to foment the differences between Henry and his sons, and Richard was again prompted to rebel. A war followed, the event of which was so unfavorable to Henry, that he was at length obliged to agree that Richard should receive an oath of fealty from all his subjects. He also stipulated to pay a sum of money to the French king, and to grant a pardon to all Richard's adherents. The mortification of Henry at these humiliating terms was aggravated to despair when he saw the name of his favorite son John at the head of the list of delinquents whom he was required to pardon. Henry II. ranks among the greatest kings of England. His wisdom and love of justice were acknowledged by foreign potentates, who made him arbiter of their differences, and regarded him as the first prince of the age. Consult: Stubbs, 'The Early Plantagenets' (1876); Mrs. J. R. Green, 'Henry II.' (1888); Norgate, 'England Under the Angevin Kings' (1887).

Henry III., king of England: b. Winchester 1 Oct. 1207; d. Westminster 16 Nov. 1272. He was the son of John, whom he succeeded in 1216. As Henry approached to manhood he displayed a character wholly unfit for his station. One of his first false steps was to discard his most faithful and able minister Hubert de Burgh. In 1236 Henry married Eleanor of Provence, which increased the dislike which his subjects already felt toward him; for she brought a train of foreigners to the court, and encouraged her husband in extravagant courses which forced him to all kinds of oppressive exactions to raise money. He received frequent grants of money from Parliament, but always on condition of confirming the Great Charter, which had been extorted from King John. Henry at length raised the national discontent to such a pitch that the nobles rose in rebellion under Simon de Montfort, the earl of Leicester, the husband of the king's sister; and in 1258, obliged the king to sign a body of resolutions, which threw all the legislative and executive power into the hands of an aristocracy of twenty-four barons, assisted by a lower house, consisting of four knights chosen from each county. By the aid of his son Edward, Henry was gradually restored to authority; on which Leicester, calling in Llewellyn, prince of Wales, involved the kingdom in a civil war. The power of the barons was by this means partially restored; but both parties agreed to abide by the award of Louis IX., king of France. This being favorable to the king, Leicester and the barons refused to submit to it, and a battle was fought near Lewes, in which Henry was taken prisoner, and the person of Prince Edward also ultimately secured. A convention provided for the future settlement of the kingdom; but in the meantime Leicester ruled without control. To him, however, was owing the first example of a genuine House of Commons in England; for in a Parliament summoned by him in 1265, deputies from boroughs were sent, as well as knights of shires. Prince Edward at length escaped, and, assembling an army, defeated Leicester's son. The decisive battle of Evesham (1265) quickly followed, in which Leicester himself was slain. Replaced upon the throne Henry remained as insignificant as ever. He died in the 64th year of his age, and the 56th of his reign, the longest in English history, except those of George III. and Victoria. He was succeeded by his son, Edward I.

Henry IV., king of England, first king of the house of Lancaster: b. Bolingbroke 3 April 1367; d. 19 March 1413. He was the eldest son of John of Gaunt, duke of Lancaster; fourth son of Edward III. by the heiress of Edmund, earl of Lancaster, second son of Henry III. In the reign of Richard II. he was made Earl of Derby and Duke of Hereford, and while bearing the latter title appeared in the Parliament of 1398, and preferred an accusation of treason against Mowbray, duke of Norfolk. The latter denied the charge, and offered to prove his innocence by single combat, which challenge being accepted, the king appointed the lists at Coventry; but on the appearance of the two champions at the appointed time and place, Richard would not suffer them to proceed. Both were banished the kingdom, Norfolk for life, and Hereford for 10 years, shortened by favor to four, with the further privilege of immediately entering upon any inheritance which might accrue to

him. On the death of John of Gaunt in 1399 he succeeded to the dukedom of Lancaster, and laid claim, according to agreement, to the great estates attached to it; but Richard retained possession of the estates. The duke, therefore disregarding the unfinished term of his exile, landed with a small retinue at Ravenspur in Yorkshire, where he was quickly joined by the Earls of Northumberland and Westmoreland, and soon found himself at the head of 60,000 men. Richard falling into the hands of his enemies, was brought to London by the duke, who now began openly to aim at the crown. A resignation was first obtained from Richard, who was then solemnly deposed in Parliament; and Henry unanimously declared lawful king under the title of Henry IV. The death of Richard soon removed a dangerous rival; yet a short time only elapsed before the nobles rebelled against the king of their own creation. The first plot, in 1400, was discovered in time to prevent its success, but an insurrection in Wales, under Owen Glendower, proved more formidable. That chieftain having captured Mortimer, earl of March, who was descended from Lionel, duke of Clarence, the second son of Edward III., and therefore the lineal heir to the crown, Henry would not suffer his relation, the Earl of Northumberland, to treat for his ransom. He thus offended that powerful nobleman, who, with his son, the famous Hotspur, soon after joined Glendower. The king met the insurgents at Shrewsbury, and a furious battle ensued, 21 July 1403, which ended in the death of Percy, and the defeat of his party. A new insurrection, headed by the Earl of Nottingham and Scrope or Scroop, the archbishop of York, broke out in 1405, which was suppressed by the king's third son, Prince John. The archbishop afforded the first example in this kingdom of a capital punishment inflicted upon a prelate. The rest of this king's reign was comparatively untroubled. Henry was succeeded by his son of the same name.

Henry V., king of England: b. Monmouth 19 Aug. 1387; d. Vincennes, France, 31 Aug. 1422. He succeeded his father, Henry IV., in 1413. His dissipated youth, and fondness for joviality and low company, gave his father much uneasiness; but circumstances occurred, even in the midst of his wildness, which showed that better principles were latent in his mind. His conduct when he ascended the throne justified the best expectations. The circumstances of France, torn asunder by the opposing factions of the dukes of Orleans and Burgundy, afforded a tempting opportunity to an ambitious neighbor, and Henry was easily induced to revive the claims of his predecessors upon that country. He accordingly assembled a great fleet and army and landed near Harfleur, 14 Aug. 1415. He took that town after a siege which so much reduced his army that he was advised to return to England by sea. But Henry determined to march on Calais, and on his way was met on the plain of Agincourt by a French army ten times as numerous as his own. A battle took place there on 25 October, in which the French host was totally defeated, with a comparatively trifling loss on the side of the English. In 1417, the liberal grants of the Commons enabled Henry once more to invade France with 25,000 men. By the famous Treaty of Troyes (21 May 1420), Henry engaged to marry the Princess Catharine, and to leave Charles in possession of the crown, on condition that it should go to Henry and his heirs at his decease, and be inseparably united to the crown of England. Henry, after espousing Catharine, took possession of Paris, and then went over to England to raise recruits for his army. All his great projects seemed about to be realized, when he was attacked by a disease which carried him off at the age of 34, and in the 10th year of his reign. He was succeeded by his son Henry VI. Henry V., as the gallant, youthful, and successful conqueror of France, is a favorite name in English history; but he was inferior in wisdom and solid policy to many of his ancestors.

Henry VI., king of England: b. Windsor 6 Dec. 1421; d. London 21 May 1471. He was crowned at Westminster in November 1429, and at Paris in December 1430. As he was not nine months old at the death of his father Henry V., John, duke of Bedford, a brother of the late king, was appointed Regent of France; and Humphrey, duke of Gloucester, another brother of the same, Protector of the realm of England, with a council at his side appointed by Parliament. A few weeks after Henry's succession, Charles VI. of France died, when, according to the provisions of the Treaty of Troyes, Henry was proclaimed King of France. But the French did not quietly submit, and a war began at first favorable to the English, but in the end, after they had been roused to more effectual efforts by the heroism of Joan of Arc (q.v.) (1428–30), resulted in the almost total loss to the English of their possessions in France. In 1453 nothing remained to them in that country but Calais. In April 1445, Henry married Margaret of Anjou, daughter of René of Provence. Two years later the Earl of Suffolk acquired the chief power in the kingdom, and was created first marquis and then duke. His government was very unpopular, which caused the people to look to the claim of Richard, duke of York. The insurrection of Cade followed, and the Duke of York was by Parliament declared Protector of the kingdom. The York and Lancaster parties were now in such a state that the sword only could decide between them; and that course of civil contention commenced, the first bloodshed in which occurred at St. Albans in May 1455, and as far as the reign of Henry was concerned, the last in the battle of Tewkesbury in 1471. When the latter took place the king was a prisoner in the Tower, where he soon after died, but whether by a natural or violent death is uncertain. Henry was gentle, pious, and well-intentioned, but weak. Eton College reveres Henry as its founder, as does likewise King's College, Cambridge.

Henry VII., king of England, first sovereign of the house of Tudor: b. Wales 28 Jan. 1457; d. Richmond, Surrey, 22 April 1509. He was the son of Edmund, earl of Richmond, son of Owen Tudor and Catharine of France, widow of Henry V. His mother, Margaret, was the only child of John, duke of Somerset, grandson of John of Gaunt. After the battle of Tewkesbury he was carried by his uncle, the Earl of Pembroke, to Brittany, to seek refuge in that court from the jealousy of the victorious house of York. On the usurpation of Richard the young Earl of Richmond was naturally turned to as the representative of the house of Lan-

caster. In 1485 Richmond landed at Milford Haven, where he was immediately joined by some leaders of rank, but had only 6,000 men when Richard met him at Bosworth, with an army twice as numerous in appearance; but the defection of Lord Stanley with his forces, who joined Richmond during the battle, obtained for the latter a complete victory. Henry was proclaimed king on the field of battle, and his right was subsequently recognized by Parliament. In 1486 he married Elizabeth, daughter of Edward IV., and heiress of the house of York, and thus united the claims of the rival houses of York and Lancaster. The reign of Henry VII. was troubled by repeated insurrections. The project of France for annexing the province of Brittany, by marriage with the heiress, induced Henry to declare war, but his measures were so tardy and parsimonious that the annexation was effected. He then raised large sums on the plea of the necessity for hostilities; and landing a numerous army at Calais in 1492, almost immediately accepted a large compensation for peace. The Duchess-dowager of Burgundy, governess of the Low Countries, now advocated the cause of Perkin Warbeck, a youth who gave himself out to be Richard Plantagenet, the younger of the two sons of Edward IV., supposed to have been murdered in the Tower of London, and the justice of his claim has been maintained even by some historians of a recent date. The duchess professed to be satisfied with the proofs of his identity, and acknowledged him as her nephew. He was so far successful as to secure a large following, with which he marched to Taunton; but there his heart failed him, and he fled. Captured by Henry he confessed himself an impostor, and was sent to the Tower, where he became acquainted with the Earl of Warwick, and persuaded him to accompany him in an attempt to escape. They were both retaken, and Warwick was recommitted to the Tower and Perkin Warbeck hanged at Tyburn (1499). Soon after, the king ordered the Earl of Warwick also to be executed. After a long negotiation he brought about a match between the Infanta Catharine, daughter of Ferdinand of Aragon and of Isabella of Castile, and his eldest son Arthur; and on the death of the latter, in order to retain the dowry of this princess, caused his remaining son Henry to marry the widow by Papal dispensation, an event which, in the sequel, led to a separation from the See of Rome. He married his eldest daughter to James IV., king of Scotland, from which union there ultimately resulted the union of the two crowns. His reign was, upon the whole, beneficial to his country. Being conducted upon pacific principles it put a period to many disorders, and gave an opportunity to the nation to flourish by its internal resources. His policy of depressing the feudal nobility, which proportionably exalted the middle ranks, was highly salutary; and it was especially advanced by the statute which allowed the breaking of entails and the alienation of landed estates.

Henry VIII., king of England: b. Greenwich 28 June 1491; d. Westminster 28 Jan. 1547. He succeeded his father, Henry VII., in 1509. His disposition for show and magnificence soon squandered the hoards of his predecessor. James IV., king of Scotland, having made an incursion with a numerous body of troops into England, was completely defeated and slain at the battle of Flodden Field. Henry, however, granted peace to the Queen of Scotland, his sister, and established an influence which rendered his kingdom long secure on that side. The aggrandizement of Cardinal Wolsey now began to give a leading feature to the conduct of Henry, that prelate being appointed chancellor in 1515. His favor was now sought by Maximilian I., emperor of Germany, who hoped to secure the support of England against France, and as Wolsey was at first neglected by the French king the German emperor gained his point; but when Maximilian was succeeded by Charles V., hereditary king of Spain as well as emperor of Germany, Francis found it expedient to gain Wolsey, and for that purpose entered into an amicable correspondence with them. In order to cement this new friendship the two monarchs had an interview near Calais, the magnificence of which gave the place of meeting the denomination of the Field of the Cloth of Gold (1520). Notwithstanding these indications, a prospect of the papacy being artfully held out to the cardinal by the young emperor Charles, his interest at length gained a preponderance in the English councils. The principles of the Reformation were now making rapid strides, and Henry himself wrote a Latin book against the tenets of Luther, which he presented to Pope Leo X., who favored him in return with the title of defender of the faith. After being married to Catharine for about 18 years, Henry began to feel some scruples as to the validity of the marriage, on the ground that she had previously been his brother's wife, and his scruples were no doubt increased by the fact of his having conceived a passion for Anne Boleyn, one of the queen's maids of honor. He accordingly applied in 1527 to Pope Clement VII. for a divorce, and the Pope appointed cardinals Wolsey and Campeggio to try the case. Wolsey had at first been favorable to the project of a divorce, but when he perceived the desire of Henry to marry Anne Boleyn, fearing that this marriage would result in winning over Henry to the side of the reformers, since Anne Boleyn's friends belonged to that party, he did all in his power to prolong the inquiry, until the commission was at last withdrawn, and it was decided by the Pope that the case should be tried at Rome. This procrastination on Wolsey's part led to his own ruin. Henry, disgusted at these delays, eagerly caught at the advice of Thomas Cranmer (q.v.), afterwards archbishop of Canterbury, to refer the case to the universities, from whom he got the decision desired. In May 1533 his marriage with Catharine was declared null, and as he had by that time privately married Anne Boleyn, this second marriage was a few days later declared lawful. As these decisions were not recognized by the Pope, an act of Parliament was obtained in the following year (1534), setting aside the authority of the chief pontiff in England, which was followed by another in 1535 declaring Henry the supreme head of the church. Thus was effected the great revolution by which, in ecclesiastical annals, this reign is so much distinguished. The birth of a daughter by the new queen produced a bill for regulating the succession, which settled it on the issue of this marriage, and declared

the king's daughter by Catharine illegitimate. But although Henry discarded the authority of the Roman Catholic Church, he adhered to its theological tenets. While he executed Bishop Fisher and Sir Thomas More (who had been appointed chancellor after the fall of Wolsey) for refusing the oath of supremacy, he displayed an aversion to the principles of the reformers, and brought many of them to the stake. Finding that the monks and friars in England were the most direct advocates of the papal authority, he suppressed the monasteries by act of Parliament. The fall of Anne Boleyn was, however, unfavorable for a time to the reformers. Henry then married Jane Seymour, and the birth of Prince Edward in 1537 fulfilled his wish for a male heir, although his joy was abated by the death of the queen. Henry now resolved to marry again, and Thomas Cromwell, a Protestant, who had succeeded More as first minister, recommended Anne of Cleves. The marriage took place in January 1540, and Henry created Cromwell Earl of Essex; but his dislike to his new wife hastened the fall of that minister, who was condemned and executed upon a charge of treason. At the same time Henry procured from the convocation and Parliament a divorce from Anne of Cleves. He then married Catharine Howard, niece to the Duke of Norfolk, but Henry now found that his new queen, of whom he was very fond, had proved false, and on further inquiry her conduct before marriage was discovered to have been loose and criminal. She was therefore accused and brought to the block in 1542. In 1543 he married his sixth wife, Catharine Parr, widow of Lord Latimer, a lady of merit, secretly inclined to the Reformation.

Henry was succeeded by his son, Edward VI. The complete union of Wales with England, and the conversion of Ireland into a kingdom, date from the reign of Henry VIII. Consult: Histories of England by Lingard (1854–5); Froude (1870); and Green (1879 and 1884); also Brewer, 'History of the Reign of Henry VIII. to the Death of Wolsey' (1884); Dixon, 'History of the Church of England from the Abolition of the Roman Jurisdiction' (1884–91); Froude, 'The Divorce of Catharine of Aragon' (1891).

Henry I., king of France: b. 1005; d. Vitri, 4 Aug. 1060. He was the third son of Robert II. He succeeded to power in 1031. His reign was a continuous series of difficulties with the nobility and with the growing power of the clergy. His younger brother, Robert, led a revolt against him, but this he suppressed with the aid of Duke Robert of Normandy.

Henry II., king of France: b. St. Germain-en-Laye 31 March 1519; d. 10 July 1559. He succeeded his father, Francis I., 31 March 1547. He severely persecuted the Huguenots, and was involved in wars with the Emperor Charles V. and Philip II. of Spain. The Constable de Montmorency was defeated at St. Quentin (10 Aug. 1557); the Marshal de Thermes at Gravelines (13 June 1558), and the peace of Cateau-Cambrésis (3 April 1559) lost to France most of the advantages previously gained. Henry was a monarch of slight capability, despite his regal bearing.

Henry III., king of France: b. Fontainebleau 19 Sept. 1551; d. by assassination St. Cloud 2 Aug. 1589. He was the third son of Henry II. He fought, as Duke of Anjou, against the Huguenots, was elected king of Poland in 1573 and crowned 15 Feb. 1574, but in June 1574 left Poland and succeeded his brother, Charles IX., as king of France. The Peace of Beaulieu (1576), confirmed by the Edict of Poitiers (1577), granted to the Huguenots so many privileges that the Holy League was formed, seeking openly Catholic supremacy and secretly the elevation of Henry of Guise to the French throne. When all privileges granted to Huguenots were repealed by the Edict of Nemours (1585) war broke out. Henry of Navarre was victor at Coutras, while Henry of Guise drove the king from Paris. The king then caused the murder of Guise and Guise's brother, the Cardinal of Lorraine, in consequence of which the doctors of the Sorbonne absolved the people from obedience to him. He then joined cause with Henry of Navarre, with whom he marched against Paris; but in camp at St. Cloud was stabbed by Jacques Clément, a fanatical Dominican, 1 Aug. 1589. Henry III. was the last of the branch of Orléans-Angoulême of the stock of the Valois.

Henry IV., known as Henry of Navarre, king of France: b. Pau 13 Dec. 1553; d. 14 May 1610. He was a son of Anthony of Bourbon, Duke of Vendôme, and of Jeanne d'Albret, daughter of Henry, king of Navarre, and herself afterward queen of Navarre. Educated by his mother in the Calvinistic faith, he early joined, at her wish, the Protestant army of France, and served under Admiral Coligny. In 1572 he married Margaret of Valois, sister of Charles IX., and after the massacre of St. Bartholomew, which took place during the festivities in connection with this marriage, adopted the Roman Catholic creed. For the next four years he was compelled to reside in Paris, but 3 Feb. 1576 succeeded in making his escape, and after retracting, at Tours, the abjuration of Calvinism which he had made at Paris, put himself at the head of the Huguenots, and took a leading part in all the subsequent religious wars. He occupied a still more important position, when, in 1584, the death of the Duc d'Anjou, brother of the king (Henry III.), made him presumptive heir to the crown, as descended from Robert, Count of Clermont, the sixth son of Louis IX. Rejected by the Roman Catholic party and the League as a heretic, Henry found himself obliged to resort to arms to assert his claims. On 20 Oct. 1587 with an inferior force, he defeated the army of the League at Coutras. In 1589 he became king through the assassination of Henry III. (q.v.)., but found innumerable difficulties in establishing his claims. His Protestant religion was brought forward by all the competitors to prejudice the Catholics against him. At the head of the opposite party stood the Duke de Mayenne. Philip II. of Spain also claimed the French throne, and sent aid to the League. Henry IV. defeated his enemies in the celebrated engagement of Ivry (14 March 1590). In consequence of this victory Paris was besieged, and Henry IV. was upon the point of compelling the citizens to surrender by famine, when the Spanish general, Alexander, Duke of Parma, by

a skilful maneuver, obliged him to raise the siege. Convinced that he should never enjoy quiet possession of the French throne without professing the Catholic faith, Henry at length yielded to the wishes of his friends, was instructed in the doctrines of the Roman Church, and professed the Catholic faith, 23 July 1593, in the church of St. Denys. He was anointed king at Chartres in 1594; and entered the capital amid the acclamations of the people. He quickly brought France entirely into subjection, and concluded the war against Spain in 1598, by the Peace of Vervins, to the advantage of France. The same year was signalized by the granting of the Edict of Nantes, which secured to the Protestants entire religious liberty, and freed them from all political disabilities. Henry made use of the tranquillity which followed to restore the internal prosperity of his kingdom, and particularly the wasted finances. In this design he was so successful, with the aid of his prime minister Sully, that the national debt of 350,000,000 livres was diminished by 125,000,000, and 41,000,000 livres were laid up in the treasury. As Henry was riding through the streets of Paris he was stabbed by the fanatic Ravaillac. The great benefits which Henry IV. bestowed upon France entitle him to the designation which he himself assumed at an assembly of the Notables at Rouen in 1596, the Regenerator of France. His benevolent mind, his paternal love to his subjects, his great achievements, his heart, always open to truth, though it exposed his own faults, have preserved his memory in the hearts of the nation. To the end of his life he had to contend against the governors of provinces, Protestant as well as Catholic, who had rendered themselves almost independent under the last kings of the house of Valois. Many of the acts of his internal government show that, while he aimed at restoring the prosperity of the nation by encouraging agriculture, commerce, and manufacturing industries, he was determined by all means in his power to strengthen the authority of the crown. In his foreign policy Henry IV. revived the projects of Francis I. and Henry II. against the house of Austria, and re-established the influence of France in the Catholic states of Italy. He supported Holland in its revolt against Spain; allayed the bitterness of feeling between the Lutherans and the Calvinists, and induced them to form the Evangelical Union. Consult: Lacombe, 'Henri IV. et sa Politique' (1878); and Willert, 'Henry of Navarre and the Huguenots in France' (1893).

Henry V. (of France). See CHAMBORD, COMPTE DE.

Henry I., emperor of Germany: b. about 876; d. Memleben 2 July 936. He was the son of Otho I., the Illustrious, duke of Saxony, who had refused the regal dignity offered him in 912. Henry, on the death of his father, became duke of Saxony and Thuringia. He was chosen king of the Germans by the Franks and Saxons, April 919, at Fritzlar. The surname DER FINKLER or DER VOGLER (the Fowler), sometimes applied to him, did not arise until the 12th century, and is based upon the unauthentic legend that the princes who notified him of election found him at fowling. He subdued Duke Giselbert of Lorraine, and in 924 concluded with the Hungarians a nine-years' treaty of peace, with the condition that he should pay a yearly tribute. This tribute he finally refused (933), whereupon the Hungarians invaded his realm with two large armies which he defeated, the one near Göttingen, the other at Riade (Riethenburg). In 934 he waged a victorious contest against the Danes. He thoroughly reorganized the German defensive military system, built fortified cities, and fortified others. Though he did not technically possess the title of emperor, he was the real founder of the mediæval German empire, and is recognized as a wise ruler and skilful military leader.

Henry II., THE LAME, emperor of Germany: b. 6 May 973; d. Grona, near Göttingen 13 July 1024. He was the last of the Saxon line, a son of Henry the Quarreler of Bavaria, and great-grandson of the Emperor Henry I. He inherited Bavaria on the death of his father in 995. On the death of Otho III. in the beginning of 1002 he laid claim to the kingdom, and was crowned at Mainz 7 June. He was for a time busily occupied in wars with Duke Boleslav II. of Bohemia, the Margrave Henry of Schweinfurt, and the Margrave Ernest of Austria. In 1004 and 1013 he was obliged to make expeditions to Italy, where Arduin of Ivrea was twice chosen king. Having thoroughly defeated his opponent, he was invested with the imperial insignia at Rome by Pope Benedict VIII. 14 Feb. 1014. His somewhat protracted struggle with Boleslav of Poland ended without any considerable success. At the call of the Pope he fought against the Greeks in lower Italy. For his zeal in the interests of the Church he was canonized by Eugenius III. in 1146.

Henry III., variously surnamed the OLD, the BLACK, and the PIOUS, emperor of Germany: b. Osterbeck, Netherlands, 28 Oct. 1017; d. Botfeld 5 Oct. 1056. He was the second of the house of the Salian Franks, son of the Emperor Conrad II., whom he succeeded in the imperial dignity 1039. He had already been chosen king in 1026. He weakened the power of the nobles by keeping the great fiefs when they became vacant for himself or members of his family, or by bestowing them upon less powerful nobles than had previously possessed them. He also extended the power of the empire by forcing the duke of Bohemia in 1042, and the king of Hungary in 1044, and again in 1047, to accept their dominions as imperial fiefs. His influence was paramount in Italy, especially in the south, where the Normans in Apulia and Calabria paid homage to him as their feudal chief. On the occasion of his first visit to Italy (1046) he put an end to the contention between Benedict IX., Sylvester III., and Gregory VI. for the papacy, causing them all to be deposed, and Suitger, bishop of Bamberg, to be elected in their stead with the title of Clement II. His efforts were now directed toward rooting out the evils which were rife among the clergy, but not less toward securing the permanence of the influence of the empire over the See of Rome. Henry III. was not only a powerful ruler, but also a patron of arts and sciences. He founded numerous schools in connection with the monasteries, and built the cathedrals of Worms, Mainz, and Spires.

Henry IV., emperor of Germany: b. 11 Nov. 1050; d. Liège 7 Aug. 1106. He was the

son of Henry III. He was crowned at Aix-la-Chapelle in 1054. His reign was from the first disturbed by contests with his vassals. The Saxons joined with the inhabitants of Thuringia, drove Henry from Saxony (1073), and destroyed many of the castles which he had built to overawe the inhabitants. But some churches having been destroyed by the populace, Henry accused the Saxons to the pope of sacrilege, and thus gave him an opportunity to interfere as umpire. The Saxons offered to make every satisfaction; but Henry suddenly invaded their territory with a powerful army, and attacked them 9 June 1075, at Hohenburg, on the Unstrut, where they suffered a total defeat. He imprisoned nobles and ecclesiastics, and aroused the attention of the papacy. Gregory VII. (Hildebrand), who had been elevated to the papal chair some years before, without the consent of the imperial court, eagerly seized this opportunity to challenge Henry's usurpation of the power of investing bishops with the spiritual insignia of office, and in December 1075 presented to the king a list of charges, and demanded proofs of obedience to the Church. Henry then instigated the bishops, assembled by his order at Worms, to renounce their obedience to the pope (24 Jan. 1076). Gregory, however, pronounced the sentence of excommunication against him (22 Feb.), and absolved his subjects from their allegiance, and Henry soon found himself deserted. In this state of affairs he was obliged to go to Italy and make his submission to the pope. He found Gregory at Canossa, not far from Reggio, a strong castle belonging to Matilda, countess of Tuscany, whither he had retired for security. Three days successively, in the depth of winter, Henry appeared in a penitential dress, in the court of the castle, before the intercession of Matilda obtained for him an audience of the pope (28 Jan. 1077), when he was, after all, released from the sentence of excommunication only upon submitting to the most humiliating conditions. Some of the Italian princes, who had long been dissatisfied with Gregory, and were desirous of deposing him, gathered round Henry, who was not disposed to fulfil the hard conditions imposed upon him, and offered him their assistance. The German princes, however, at the instigation of the pope, assembled at Forchheim in 1077, and elected Rudolf, Duke of Swabia, king. Henry hastened back to Germany and overcame his rival, who lost his life in battle at Merseburg, in 1080. Gregory again excommunicated Henry; but at the councils of Brixen and Mainz in 1080, he was declared deposed by the German bishops as a heretic and a sorcerer, and Guibert, archbishop of Ravenna, set up in his place, with the title of Clement III. In 1081 Henry marched into Italy to take vengeance on Gregory, and appeared at Easter before Rome. He was not able in that year, however, to pursue the siege of the city, which did not fall into his hands till 1084. He was forced by a conspiracy of the majority of the nobles, led by his son, Henry V., to abdicate at Ingelheim 31 Dec. 1105.

Henry V., emperor of Germany: b. 11 Aug. 1081; d. Utrecht 23 May 1125. He was the son and successor of Henry IV. He was crowned emperor in 1111. His reign was continually disturbed by troubles with the papacy. He was excommunicated no less than four times, and finally in the concordat of Worms (23 Sept. 1122) conceded the advantage to the pope. He also carried on wars with Flanders, Hungary, and Poland, and with various German nobles. He was the last of the Salic or Frankish family of emperors, which was succeeded by the Swabian house.

Henry VI., the CRUEL, emperor of Germany: b. 1165; d. Messina 28 Sept. 1197. He was the son of Frederick I. (Barbarossa), was crowned king in 1169, and succeeded his father as emperor in 1190. He was involved in wars in Italy to assure his possessions there. It was during his reign that Richard Cœur de Lion, returning from Palestine, was imprisoned by Leopold of Austria and surrendered to the emperor, who exacted a heavy ransom.

Henry VII., OF LUXEMBURG, emperor of Germany: b. 1269; d. Buonconvento, Italy, 24 Aug. 1313. He was son of the Count of Luxemburg, and was chosen king of the Romans 27 Nov. 1308, and crowned at Aix-la-Chapelle 6 Jan. 1309. In 1311 he received the iron crown of the Lombards, and 29 June 1312 was crowned emperor at the Lateran. His march into Italy at the head of a Ghibelline army (October 1310) was hailed by Dante, who did homage at some time and place unknown. His sudden death immediately after reception of the Eucharist led to the unfounded rumor that he had been poisoned.

Henry, prince of Portugal, surnamed the NAVIGATOR: b. 4 March 1394; d. 13 Nov. 1460. He was a grandson of old John of Gaunt; nephew of Henry IV. of England; and great-grandson of Edward III. His father, King João or John, who formed a close English connection by marrying Philippa of Lancaster, was the first king of the house of Avitz, under which Portugal, for two hundred years, rose to its highest prosperity and power. The career of Portugal in exploration and discovery, due to the genius and devotion of Prince Henry, his biographer characterizes as "a phenomenon without example in the world's history, resulting from the thought and perseverance of one man." Prince Henry had become one of the first soldiers of his age when, in 1420, he refused offers of military command, and undertook to direct, at Sagres (the extreme point of land of Europe looking southwest into the Atlantic Sea of Darkness), plans of exploration of the unknown seas of the world lying to the west and south. His idea was to overcome the difficulties of the worst part of that immense world of storms, that lying west of Africa, and thereby get round Africa to the south and sail to India, and China, and the isles beyond India. Every year he sent out two or three caravels; but his great thought and indomitable perseverance had yielded only "twelve years of costly failure and disheartening ridicule," when, in 1434, the first great success was achieved by Gil Eannes, that of sailing beyond Cape Bojador. Prince Henry made his seat at Sagres, one of the most desolate spots in the world, a school of navigation, a resort for explorers and navigators. His contemporary Azurara says of him: "Stout of heart and keen of intellect, he was extraordinarily ambitious of achieving great deeds. His self-discipline was unsurpassed; all his days were spent in

hard work, and often he passed the night without sleep; so that by dint of unflagging industry he conquered what seemed to be impossibilities to other men. His household formed a training-school for the young nobility of the country." Consult: Major, 'Life of Prince Henry the Navigator' (1868).

Henry, prince of Prussia, German naval officer: b. Berlin 14 Aug. 1862. He is a brother of Emperor William, and married Princess Irene, daughter of the late Grand Duke Ludwig IV. of Hesse, in 1888. He succeeded Vice-Admiral von Diederichs in command of the German fleet in Chinese waters, in March 1899. In January 1902, Emperor William requested that the president's daughter, Alice, should christen the royal yacht then building in the United States. After receiving the consent of President Roosevelt, the Emperor informed the President that he had ordered his yacht, the "Hohenzollern," to be present at the ceremony, and had appointed his brother, Admiral Prince Henry of Prussia, to represent him on the occasion. The Prince arrived in New York city on 23 February and left on 12 March, after receiving many national, municipal, and social honors.

Henry, surnamed THE LION, duke of Saxony and Bavaria: b. Ravensburg 1129; d. Brunswick 6 Aug. 1195. He was the son of Henry the Proud, and the head of the Guelphs. He greatly enlarged his domains, and so increased in power as finally to become a dangerous rival of the Emperor Frederick I., Barbarossa. His refusal to support Frederick was among the chief causes of the latter's defeat at Legnano (29 May 1176). He was summoned to appear at three diets, and, having failed to attend was placed under the imperial ban (1180). Later he was allowed to retain Lüneburg and Brunswick upon condition of going for three years into exile. He was finally reconciled with Henry VI.

Henry, Alexander, American traveler: b. New Brunswick, N. J., 1739; d. 1824. He joined the Canadian expedition under Amherst against the French (1760) and when peace followed he went to Michilimackinac and engaged in the fur trade. After the massacre of the English by the Indians in that place he being one of the few survivors, remained a captive among the Ojibways at Sault Ste. Marie for 12 months, when he escaped and resumed the fur trade. In the pursuit of this business he traveled between Montreal and the Rocky Mountains. He also interested himself in the copper mines on Lake Superior and for many years made an effort to establish a company for their exploitation.

Henry, Edward Lamson, American painter: b. Charleston, N. C., 12 Jan. 1841. He began his artistic studies at the Philadelphia Academy and in 1860 went to Paris where he studied for three years under Saisse and Courbet. In 1869 he was elected a member of the National Academy. He has frequently revisited Europe for the purpose of sketching the scenery, although his specialty is domestic genre, and history. In the Corcoran Gallery at Washington is one of his most characteristic pictures, which shows his careful grouping of figures, his attention to detail as well as the stiffness of his drawing and his deficiency in the sense of color which recalls Wilkie, whose swing and movement he lacks, though he exhibits some of the humor of the Scottish master. The picture referred to is a crowded canvas of fifty figures with the title 'Initial Excursion of the First Railway Ever Constructed in New York State.' Among his historical pictures the best are 'Battle of Germantown,' owned by William Astor, 'Declaration of Independence,' owned by J. W. Drexel, and 'Reception to Lafayette.'

Henry, Guy Vernon, American soldier: b. Fort Smith, Indian Territory, 1839; d. Ponce, Porto Rico, 1899. He was graduated at West Point 1861, and went to the front in the Civil War, taking part in four years of the hardest fighting, from Bull Run to Cold Harbor. At 23 he was commissioned colonel of the 40th Massachusetts volunteers. After the Civil War he was transferred to the 3d Cavalry, and in 1874 was in Arizona. He continued his Indian campaign, though severely wounded on one occasion, and compelled to be invalided. He served through the outbreak of the Sioux in 1890, and was also on service at Porto Rico during the Spanish-American War, where he died of typhoid fever.

Henry, Joseph, American physicist: b. Albany, N. Y., 17 Dec. 1797; d. Washington, D. C., 13 May 1878. He was educated at the Albany Academy, after graduation undertook the study of chemistry, anatomy and physiology with a view to adopting the medical profession. During the years 1824–5, he contributed occasional scientific papers to the Albany Institute, his especial subjects being chemistry and mechanics, and was appointed assistant engineer on the survey instituted for a road between Lake Erie and the Hudson. In the spring of 1826 he was elected teacher of mathematics and natural philosophy in the Albany Academy and in the latter part of 1827 read a very important paper before the Albany Institute, 'On Some Modifications of the Electro-Magnetic Apparatus.' He made his first public demonstration of his magnetic discoveries in exhibiting before the Institute small electro-magnets wound with silk-covered wire. These magnets had a greatly multiplied lifting power over any that had yet been known. In this lay the essential point of his first discovery, for he was undoubtedly the earliest physicist to adopt insulated or silk-covered wire for the magnetic coil, and to employ spool winding for the limb of the magnet. He demonstrated also for the first time, by a very intelligent experiment, the difference of action in a quantity magnet excited by a quantity battery of a single pair, and an intensity magnet with a long fine wire coil excited by an intensity battery of many elements, having their resistances suitably proportioned. The first of these two forms was not capable of being employed for telegraphic purposes, while the intensity magnets with their attachments could be so applied. The quantity magnets which he exhibited caused a good deal of excitement in the scientific world. Their attractive power was at that time quite unprecedented. One of them had sufficient power to raise as much as 3,500 pounds.

Henry was the first to show that iron could be magnetized at a distance, and to invent a suitable combination of magnet and battery for the production of this result. In 1831 he made this experimental demonstration. He suspended a mile of insulated copper wire round a chamber in the Academy, and so placed a bell at one extremity of it that it was struck by the polarized

armature of an intensity battery connected with the other extremity. This was the earliest example of the magnetic telegraph, for the galvanometer or needle had been the principle on which all preceding experiments had been conducted. It was not long after that he invented a machine, and finally constructed it, which is recognized as the first electro-magnetic engine with automatic pole-changer. In 1832 after repeated experiments he discovered how to give greater intensity to a magnetic discharge by the induction of a current on itself in a long spiral or helical wire. These progressive steps in magnetic science gained for him an extended reputation, and soon after the publication of the last experiment in Silliman's 'American Journal of Science' Henry was elected professor of natural philosophy in Princeton College. The discovery of the spiral or helical conductor suggested to him further experiments, and his extended researches and their results were announced by him in a paper published 1834, under the title 'On the Influence of a Spiral Conductor in Increasing the Intensity of Electricity from a Galvanic Arrangement of a Single Pair.' He supplemented these discoveries by many others, and by his experiments produced electrical combinations which were undoubtedly precursors of later relay and receiving magnets, while his demonstration of the conditions and range of induction from electrical currents, and the successive orders of induction in the passage of frictional electricity, as well as his discovery of the oscillatory nature of electricity, paved the way for that great scientific and practical resolution which was to consummate by the genius of Morse and his confrères.

In 1846 Henry was called to a new sphere of activity, in which he exhibited his usual zeal and enthusiasm. The Smithsonian Institution had just come into existence, and during the formative period of the great museum, he was appointed to be its secretary. The office did not so far engross his attention as to make him neglectful of practical work in science. He found time to investigate the acoustics of public buildings, meteorological changes of the atmosphere and methods for telegraphic transmission of meteorological observation from all points of the continent. From 1868 up to his death he was president of the National Academy of Sciences, and of the Philosophical Society of Washington from 1871, when it was first organized.

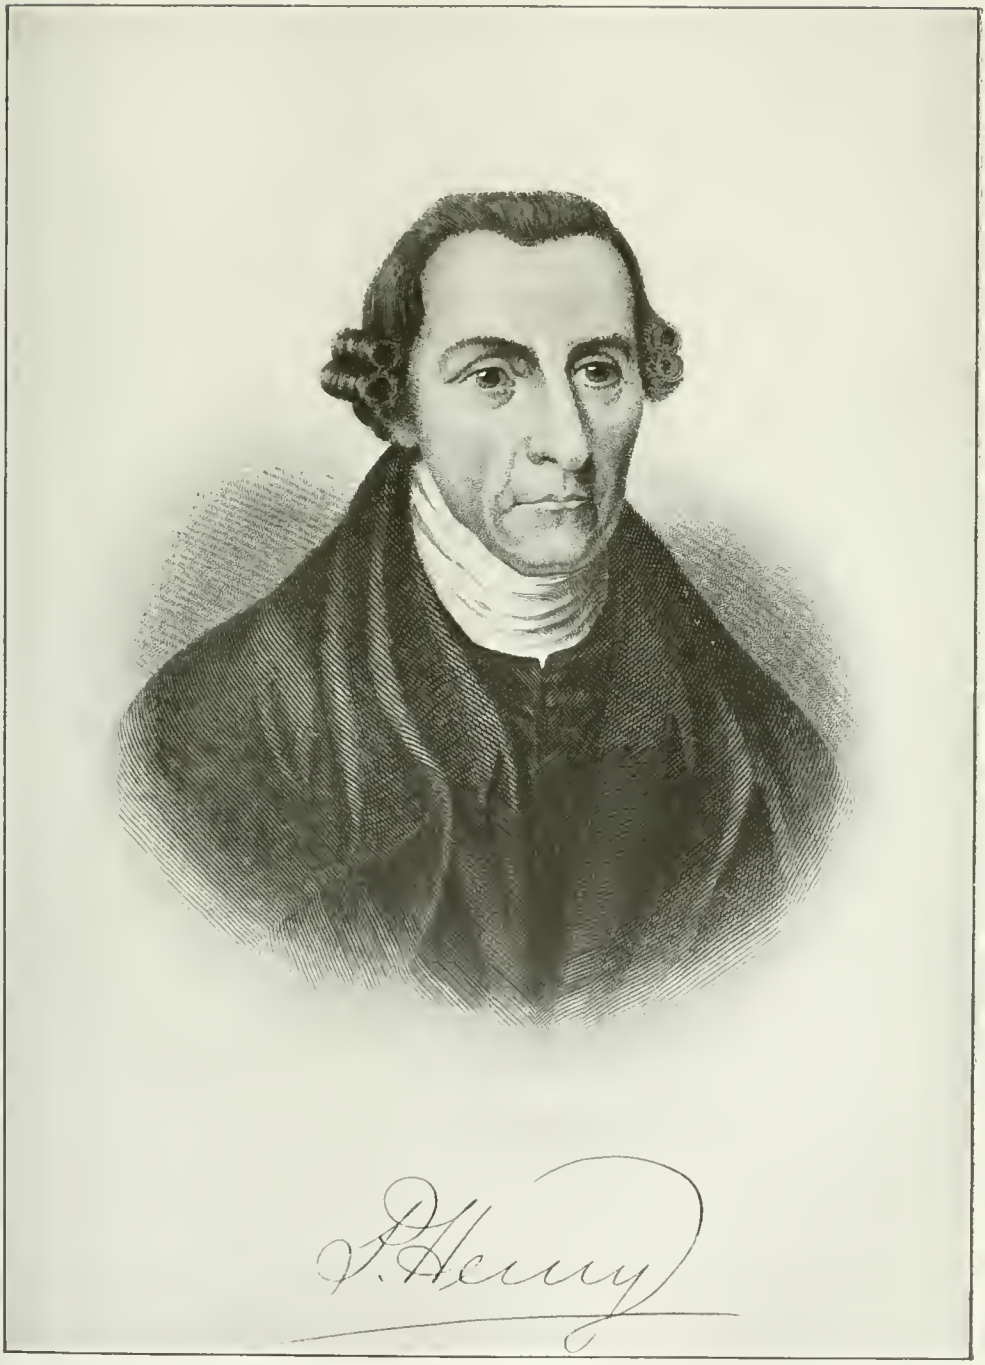
Henry, Matthew, English Nonconformist clergyman: b. Broadoak, Flintshire, Wales, 18 Oct. 1662; d. Nantwich, Cheshire, 22 June 1714. In 1686, having qualified himself for the ministry, he began to preach: and in the succeeding year he was settled as pastor to a congregation at Chester, and continued to discharge the duties of his office for 25 years, when he removed to Hackney, London, where his clerical labors were still more extended. Besides his greatest work, 'Expositions on the Bible' (1710), he was the author of 'A Discourse on Schism'; 'A Scripture Catechism'; 'Family Hymns'; etc.

Henry, Patrick, American orator and statesman: b. 29 May 1736, in Hanover County, Va., within a few miles of the birthplace of Henry Clay; d. 6 June 1799, in Charlotte County, Va. His father, John Henry, was a well-educated Scotchman, presiding judge of the Hanover court. He was a cousin of William Robertson, author of the 'History of the Emperor Charles the Fifth.' Another relative of his was Henry Brougham, the radical Scotch writer, who became lord chancellor of England. Of Patrick Henry's mother, "a portly, handsome dame," a pleasing portrait is left us by William Byrd, of Westover, the genial litterateur of colonial Virginia.

Poor as were the schools in his neighborhood, Patrick seems to have profited little by them. From his uncle, the rector of the parish, he gained a rudimentary knowledge of the classics and mathematics. He was a frolicsome and vagrant youth, fond of hunting and frontier life in general. At 18 years of age, and without money or employment, he married Sarah Shelton, a poor girl of the neighborhood. He kept a store and failed; he tried farming, and failed; then he returned to the store, only to fail again. He now turned to law, and spent a few weeks in reading upon that subject. Having received his license, he began to practise in his native county, while he assisted in the tavern kept by his father-in-law.

In 1763 Henry singled himself out as a born orator by his impassioned plea in "The Parsons' Cause." The king had annulled a statute of the Virginia burgesses, which compelled the clergy to accept the depreciated currency of the colony in payment of their annual salaries, in lieu of 16,000 pounds of tobacco as theretofore, a product which was then selling at a high price. Henry startled the court and the countryside by asserting "that a king, by annuling or disallowing acts of so salutary a nature, from being the father of his people, degenerates into a tyrant, and forfeits all right to his subjects' obedience." Henry's utterance on this occasion was in keeping with the bold address, two years previous, of James Otis, who declared that the tyranny lurking in general search warrants had "cost one king of England his head and another his throne."

Henry became a member of the House of Burgesses in May 1765, just at the time of the arrival of the Stamp Act. Unabashed by his rustic appearance and inexperience in legislative matters, he brought forward a series of resolutions to the effect "that the general assembly of this colony have the only sole and exclusive right and power to lay taxes." In the bloody debate which followed he was "opposed by Randolph, Bland, Pendleton, Nicholas, Wythe, and all the old members, whose influence in the House till then had been unbroken," so we learn from Jefferson, then a college student, who was present at the session of the burgesses. In pleading the injustice of the Stamp Act, Henry used the famous words: "Caesar had his Brutus; Charles the First, his Cromwell; and George the Third ['Treason!' shouted the Speaker. 'Treason,' 'treason,' echoed others. After a moment's pause, the orator completed the interrupted sentence in a manner that showed no less defiance than adroitness] and George the Third may profit by their example. If this be treason, make the most of it." As the royal governor of Massachusetts wrote the ministry: "The Virginia resolves proved an alarm bell to the disaffected." By his intrepidity, his oratory, and his intuition, at once patriotic and prophetic, Patrick Henry became henceforth the protag-



P. Henry

onist of the colonial cause, sharing with Otis, Gadsden, and Samuel Adams the high honor of launching the American Revolution.

Henry represented Virginia in the first colonial congress, which met at Philadelphia 5 Sept. 1774, when he gave final expression to the feeling of nationality: "The distinctions between Virginians, Pennsylvanians, New Yorkers, and New Englanders are no more. I am not a Virginian, but an American." With this speech compare Christopher Gadsden's remark nine years before at the Stamp Act congress in New York: "There ought to be no New England men, no New Yorkers, known on the continent, but all of us Americans."

On 23 March 1775, Henry, as a member of the second Virginia convention, which met in St. John's Church, Richmond, moved that the colony be armed, and again electrified the patriots with his eloquence in support of this radical measure. "Gentlemen," said he, "may cry peace, peace — but there is no peace. The war is actually begun! The next gale that sweeps from the North will bring to our ears the clash of resounding arms! Our brethren are already in the field! . . . Is life so dear, or peace so sweet, as to be purchased at the price of chains and slavery? Forbid it, Almighty God! I know not what course others may take; but as for me, give me liberty, or give me death." Col. Edward Carrington, listening at a window in the east end of the church, was so transported by the eloquence of Henry, that he exclaimed, "Let me be buried at this spot," a wish that was respected at his death in 1810. Such was the universal testimony of those present as to the overmastering effect of Henry's speech at that crisis.

On 5 Aug. 1775, Henry was made commander-in-chief of the Virginia troops. In May of that year he had made a dash against Lord Dunmore, on account of the governor's secret seizure of some powder belonging to the colony. Deeming himself slighted by the Committee of Public Safety, which acted during the interim as the executive of Virginia, Henry, with some heat, threw up his military commission, 28 Feb. 1776.

Fortunate was it for the colonial cause that Henry was again at liberty to exert his forensic powers in the councils of the State. Representing Hanover County in the convention which met at Williamsburg 6 May 1776, he contributed greatly to the constructive work of that celebrated body, notably the motion for a declaration of American independence and the framing of a constitution for Virginia. Among the convention papers in the State Library at Richmond were found three endorsed by the clerk, "Rough Resolutions. Independence." William Wirt Henry, after minute comparison of the handwriting of these, concluded that the first was penned by Patrick Henry; the second by Meriwether Smith; and the third by Edmund Pendleton; and that the resolution actually introduced by Nelson was the one written by Henry. On the other hand, Edmund Randolph, who was a member of the convention, says that the resolution declaring for independence "was drawn by Pendleton, was offered in convention by Nelson, and was advocated on the floor by Henry."

On 29 June 1776, the natal day of the commonwealth of Virginia, Patrick Henry was elected governor, took the oath of office 5 July, and served for three annual terms in succession. As governor he commissioned, on 2 Jan. 1778, Col. George Rogers Clark to enlist seven companies of men for the expedition against the British garrisons in the Northwest Territory. After leaving the executive office, Henry settled in Henry County, on an estate of about 10,000 acres, called Leatherwood, where he lived until he became governor for the fourth time, on 30 Nov. 1784. In the Virginia convention of 1788, which was called to ratify the Constitution of the United States, Henry led the opposition on the ground that such a federal government encroached too far upon the rights of the several States. While the arguments of Madison and the influence of Washington happily prevailed on that critical occasion, Henry was a chief agent in securing the amendments which constitute a bill of rights in the national instrument. His objection to the Constitution was stated concisely in his first speech before the convention: "That this is a consolidated government is demonstrably clear; and the danger of such a government is, to my mind, very striking. . . . Who authorized them (the framers) to speak the language of *we the people*, instead of *we the States?* States are the characteristics and the soul of a confederation. If the States be not the agents of this compact, it must be one great, consolidated, national government of the people of all the States." Such was his clear discernment of the real nature of the government established by the Constitution of the United States.

S. C. Mitchell,
Professor of History, Richmond College, Richmond, Va.

Henry, William Arnon, American educator: b. Norwalk, Ohio, 16 June, 1850. He obtained his early education in the Holbrook Normal School at Lebanon, Ohio; studied at Ohio Wesleyan University from 1867–9, and at Cornell University from 1876–80, receiving the degree of B. S. Agr. He was appointed professor of botany and agriculture in the University of Wisconsin in 1881, professor of agriculture in 1883, director of the agricultural experiment station in 1887, and since 1891 has been dean of College of Agriculture in that university. He has had charge, from the beginning, of the agricultural college and experimental station of the University of Wisconsin, which now has buildings valued at $300,000 and 450 pupils. He has written: 'Rush's Special Report on Diseases of Cattle and Cattle Feeding' (Part II. 1892); 'Handbook on Northern Wisconsin' (1895); 'Feeds and Feeding' (1898), etc.

Henry, William Wirt, American historian and lawyer: b. Red Hill, Va., 14 Feb. 1831; d. 5 Dec. 1900. He was educated at the University of Virginia, and took up the practice of law, later being elected to the legislature for four terms. He preferred, however, historical research to his law practice, and spent much of his time in that pursuit. He was president of the American Historical Association and of the Virginia Historical Society. He is chiefly noted for his 'Life, Correspondence, and Speeches of Patrick Henry' (3 vols. 1890–1).

Henry College, a coeducational institution, founded in 1892, in Campbell, Texas. At the close of 1902 there were connected with the school 10 professors and instructors, with 150

students in attendance. The estimated value of the grounds and buildings is $125,000.

Henry Documents, 26 letters of 1809 between John Henry and several British officials — Sir James H. Craig, governor of British North America, his secretary Ryland, and the English foreign secretary Lord Liverpool, with related papers. Tempted by the hostility of the New England Federalists to the Embargo (q.v.), and the threats of secession by the extremists, Craig sent the adventurer Henry in January 1809 to sound the people as to reunion with Great Britain. Henry remained till June, and sent back the most extravagant reports of the secession feeling, but the British ministry not paying him as he thought fitting, he sold the copies of the letters and other documents to the United States government in February 1812 for $50,000. Madison used them to hurry forward the War of 1812, by sending them to Congress on March 9 with a special message, in which he accused Great Britain of attempting to dismember the Union by intrigue and annex the North to itself. So far as the New Englanders were concerned, however, the papers contained nothing incriminatory of secession movements.

Henry Phipps Institute, The, for the study, treatment, and prevention of tuberculosis, was founded at Philadelphia, 1 Feb. 1903 by Henry Phipps. The incorporators were Henry Phipps, George E. Gordon, Lawrence F. Flick, Miss Amy Phipps, and S. P. Harbison. The scientific work of the Institute is in the hands of a medical staff, consisting of a medical director, an assistant medical director, clinicians, bacteriologists, and pathologists. In the Institute's organization there are a number of paid fellowships open to any member of the staff and a number of honorary fellowships open to any person throughout the world who has done distinguished work in the cause of the study, treatment, or prevention of tuberculosis. The eleemosynary work of the Institute contemplated is the care of the consumptive poor in their homes, the care and treatment of consumptives in hospital beds, and the care and treatment of consumptives in a sanatorium. Consumptives in their homes are to be cared for and treated through a dispensary. The patients come to the dispensary where they are prescribed for and given medicines and supplies for the prevention of tuberculosis. They are instructed in preventive measures, and during the intervals between their visits to the dispensary are supervised in the carrying out of these instructions by a visitor from the dispensary. The consumptive who is entirely destitute and who cannot be cared for in his home even with such assistance as can be given is brought into the hospital and treated as a ward of the Institute. The scientific work of the Institute contemplated is education in preventive measures, study of the disease, dissemination of knowledge about the disease among physicians, stimulation of effort on the part of scientific men throughout the world, and encouragement of workers in the cause. This work is to be pursued through lecture courses, laboratory and clinical experiments, distribution of literature, organization of the workers in the cause of prevention of tuberculosis, and public receptions to persons who have done distinguished work. The Institute will seek to aid all workers in the crusade against tuberculosis. It will act as a bureau of information and with this end in view will index literature on the subject of tuberculosis and collect objects of various kinds which have a bearing upon the prevention or treatment of the disease. The Institute has inaugurated an international course of lectures by the foremost workers in the crusade against tuberculosis. One lecture a month is given during the fall and winter months. The Institute will publish annually a report of its work which will be distributed gratuitously to the libraries of the world.

LAWRENCE F. FLICK,
Of the Henry Phipps Institute.

Henschel, Georg, gā-ōrg' hĕn'shĕl, German composer and concert singer: b. Breslau, 18 Feb. 1850. He began his musical education under the pianist Moscheles, the contrapuntist Richter, and the vocal teacher Gosse in the Conservatory at Leipsic. In 1870 he sang with great success at the Beethoven celebration at Weimar, and toward the end of the same year went to Berlin to complete his studies in musical science and vocalization. He met with a brilliant reception in his professional tour through Cologne, Düsseldorf, and the lower Rhine provinces, and his fame spread over all Germany, Austria, Holland, and Russia (1874–7). He was received with immense applause in London, and crossing the Atlantic was appointed musical director in Boston (1883–5); when he returned to London and became teacher of singing in the Royal College of Music. He wrote among his numerous compositions many songs and duets, such as 'Wanderlieder'; 'Duette in Kanonform,' 'Serbisches Liederspiel'; etc. He married in 1881 Lilian Jane Bailey (d. 1901) a well known American singer.

Hens'ley, Sophia Almon, American lecturer and author: b. Nova Scotia 31 May 1866. She studied in England and Paris, and moved to New York in 1889. She has been interested in the study of social problems and actively identified with the work of the "Mother's Congress." She has served as president of the Society for the Study of Life in New York city and as vice-president of the New York City Mothers' Club, and lectures frequently. She is author of 'Woman's Love-Letters' and 'Souls.'

Hen'son, Herbert Hensley, English Anglican clergyman: b. London 8 Nov. 1863. He was graduated at Oxford and elected fellow of All Souls College in that university 1884. He was head of the Oxford House at Bethnal Green, 1887–8, and since 1900 has been canon of Westminster Abbey and rector of St. Margaret's. He has attracted wide attention as a fresh and powerful preacher by his utterances on national topics of social and political interest, and among his published works may be noted: 'Light and Leaven' (1897); 'Cross Bench Views of Current Church Questions' (1902).

Henson, Josiah, American negro slave and clergyman: b. Port Tobacco, Md., 1787; d. 1883. His early life was one of great hardship, but he finally escaped to Canada (1828), where he became a Methodist clergyman with a charge at Dresden, Bothwell County, Ontario. He also

lectured in the United States. Upon the story of his slave career was based the character of Uncle Tom in Harriet Beecher Stowe's 'Uncle Tom's Cabin' (1852).

Henty, George Alfred, English writer of novels and stories for boys: b. Trumpington, Cambridgeshire, 8 Dec. 1832; d. Weymouth, Dorsetshire, 16 Nov. 1902. He was educated at Westminster and Cambridge; he went to the Crimea during the war with Russia, and served there in the purveyor's department of the army. Soon afterward he went to Italy to organize the hospitals of the Italian legion. As special correspondent of the *Standard* newspaper he went through the Austro-Italian, Franco-German, Turco-Servian, Abyssinian, and Ashanti campaigns, besides accompanying Garibaldi in the Tyrol. He described two of these campaigns in the works 'The March to Magdala' (1868) and 'The March to Coomassie' (1874). He wrote eight novels, among which are: 'A Woman of the Commune' (1895); 'The Queen's Cup' (1897); and 'Colonel Thorndyke's Secret' (1898); but he is much more widely known as the author of a large number of stimulating stories of adventure for boys, many of them based on famous historical events. Among these are: 'The Young Franc-Tireurs' (1871), a story of the Franco-German war; 'The Young Buglers,' a tale of the Peninsular War (1879); 'In Times of Peril,' a tale of India (1881); 'Under Drake's Flag' (1882); 'The Lion of the North' (1885), a story of Gustavus Adolphus; 'With Lee in Virginia' (1889); 'By Pike and Dyke' (1889), a story of the Dutch War of Independence; 'In the Irish Brigade' (1900); and 'Out with Garibaldi' (1900).

Hepat'ica, a genus of plants, the liverworts, of the crowfoot order (*Ranunculaceæ*), closely related to *Anemone.* The best-known species is *H. hepatica,* found wild throughout North America as well as Europe in woods, and widely cultivated for its attractive and fragrant star-like blue, white, or purple-red flowers, which open in early spring. It is, indeed, the earliest of American spring flowers. Sometimes even under the snow its buds, well wrapped up in a warm down, lie upon the broad, furry liver-shaped leaves, awaiting the first warmth to induce them to open. In the southern Alleghanies its leaves are dried and steeped into a medicinal tea. A more southern species is *H. acuta.*

Hepburn vs. Griswold, 1869: the great case in which the Supreme Court of the United States decided that the government had no power to make its own notes legal tender; reversed through a change in the constitution of the court in Knox *v.* Lee and Juilliard *v.* Greenman. Mrs. Hepburn of Kentucky had given Henry Griswold a note for 11,250 "dollars," payable 20 Feb. 1862; it was not paid when due, and five days subsequently the government passed the act authorizing $150,000,000 in notes (see GREENBACKS), receivable for public and private debts. In 1864 Griswold brought suit in the chancery court of Louisville for principal and interest; $12,270 in greenbacks was tendered in settlement, but refused, on the claim that the act did not extend to debts contracted before its passage. The court decided for Mrs. Hepburn; Griswold carried the case to the Kentucky court of appeals, which reversed the decision; Mrs. Hepburn carried it to the Supreme Court, which on account of the far-reaching importance of the case, and at the request of the attorney-general, laid it over till 1868, when it was reargued, and finally decided in the December term 1869. Chief Justice Chase, for five justices against three, decided that the act extended to all debts, contracted as well before as after its passage, and that the question therefore must be whether the government had the power to make anything but coin a legal tender; that it could not do so, under the Constitution, because at the time of its adoption no money but gold and silver was recognized; that as paper money never rose above coin and almost always fell below it, each particle of depreciation was so much abstracted from the value understood by the parties to the contract, and was therefore an unlawful deprivation of private property; that the power of Congress to use "necessary means" to carry out its power of making war did not convey this right, because this was no more a special means of carrying out war powers than any other powers, and would enable it to issue bills of credit and make them legal tender just as much in the post-office business or the patent business as the war. The minority admitted that it was so impairing the obligation of contracts, but asserted that Congress was given the power to do so; and this is now law. See LEGAL-TENDER CASES.

Hephæstus, hĕ-fĕs'tus, a god of the ancient Greeks, identified by the Romans with their Vulcanus. He presided over fire, and was the patron of all artists who worked in iron and metals. He was the son of Zeus (Jupiter) and Hera (Juno). Homer says that his mother was so disgusted with the deformities of her son, that she threw him into the sea as soon as born, where he remained for nine years. He afterward returned, but for taking the part of his mother on one occasion against Zeus was thrown down by the latter a second time. He was a whole day in passing from heaven to earth, and fell in the island of Lemnos. He broke his leg by the fall, and ever after remained lame of one foot. He fixed his residence in Lemnos, where he built himself a palace, and raised forges to work metals. The Cyclopes of Sicily were his ministers and attendants; and with him they fabricated not only the thunderbolts of Zeus, but also arms for the gods and the most celebrated heroes. His forges were supposed to be under Mount Ætna, in the island of Sicily, as well as in every part of the earth where there were volcanoes. Aphrodite (Venus) was the wife of Hephæstus. Her infidelity is well known. Her amours with Ares (Mars) were discovered by Phœbus, and exposed to the gods by her own husband. He appears on some monuments with a long beard, disheveled hair, half naked, and a small round cap on his head, while he holds a hammer and pincers in his hand.

Hep'tarchy, seven Anglo-Saxon kingdoms into which England was at one time or other supposed to be divided, although the kingdoms were founded at different times, and at no one time were they all independent monarchies together. In 827 King Egbert of Wessex united

them into one kingdom, and claimed the title King of England. See ENGLAND.

Hep'tasophs, Improved Order of, a benefit society, organized in 1878 as an independent branch of the Order of Heptasophs (q.v.). At the time of secession the Heptasophs had not adopted the benefit system. The constitution and ceremonies are identical with those of the parent order. At the close of 1902 it had 722 conclaves, a membership of 52,825, and since its organization had disbursed in benefits nearly seven million dollars.

Heptasophs, Order of, a benevolent society in the United States founded in New Orleans 1852 by Alexander Leonard Saunders, and other Freemasons, originally called "The Seven Wise Men." The ritual of its ceremonial is elaborate; the membership of each chapter is seven, or a multiple of that number. In 1872 the adoption of a death benefit system was agitated, and the discussion led to the secession in 1878 of the Zeta Conclave of Baltimore, which organized the Improved Order of Heptasophs (q.v.). In 1880 the Order of Heptasophs adopted the benefit system. Members must be white males and profess a belief in the Supreme Being. Their number in 18 States amounts to about 4,000.

Hep'worth, George Hughes, American clergyman, journalist, and author: b. Boston 4 Feb. 1833; d. 7 June 1902. He was brought up a Unitarian, and after leaving the Harvard Divinity School held Unitarian pastorates at Nantucket, Boston, and New York. He advocated preaching in theatres and conducted theatre meetings in various cities, but being not wholly at ease in the Unitarian denomination, entered the Congregationalist ministry in 1872. He subsequently quitted the ministry and became attached to the editorial staff of the New York *Herald*. He published: 'The Whip, Hoe, and Sword' (1864); 'The Criminal, the Crime, the Penalty' (1865); 'Starboard and Port' (1876), record of a yacht cruise; a book entitled '! ! !'; 'Rocks and Shoals'; 'Brown Studies'; 'Hiram Golf's Religion'; 'They Met in Heaven'; 'Through Armenia on Horseback' (1899). Consult S. H. Ward, 'George H. Hepworth; the Story of his Life' (1903).

Hera, hē'rä or -rē, a mythological goddess of the Greek pantheon, identified by the Romans with their Juno, the sister and wife of Zeus (Jupiter), and daughter of Kronos (Saturn) and Rhea (Cybele). The poets represent Zeus as a faithless husband, and Hera as a violent, jealous and vindictive wife. She was worshipped in all Greece, but her principal seats were at Argos and at Samos. The companions of Hera were the Graces and Hours. Iris, a personification of the rainbow, which seems to stretch from heaven to earth, was her messenger. Her usual attribute is a royal diadem. The temples built in her honor were called Heræa. The principal one was at Argos, which city was considered to be especially under her protection. She is represented by Homer as taking the part of the Greeks in the Trojan war, being actuated by revenge for the slight passed on her by the Trojan Paris, who gave the golden apple inscribed "To the Fairest" not to her, but to Aphrodite.

Her'acles. See HERCULES.

Heracli'tus, Greek philosopher: b. Ephesus, who flourished about 513 B.C. He traveled in different countries, particularly in Africa. On his return to Ephesus he was offered the chief magistracy, but refused it. He left a work on nature, in which he treats also of religion and politics. Some fragments only of this work remain. He is considered as belonging generally to the Ionic school of philosophers, though he differed from it in important particulars. He considered fire as the first principle of all things, describing it as an ethereal substance, "self-kindled and self-extinguished," from which the world is evolved (not made) by a natural operation. It is also a rational principle, and the source of the human soul. Phenomena exist in a constant state of flux, always tending to assume new forms, and finally returning again to their source.

Heraclius, hĕr-ạ-klī'ŭs, Roman emperor of the East, from 610 to 641: b. Cappadocia about 575 A.D. He was the son of Heraclius, exarch of Africa, who had gained great renown by his victories over the Persians, the elder Heraclius of the East was applied to by a powerful body of insurgents to claim the throne for himself. This he declined, but sent his son Heraclius to do so. Heraclius the younger therefore ascended the throne, and though he undoubtedly possessed considerable talents, the Roman Empire in the East was tottering to its fall, and nothing he was able to do could save it. Before his death Mohammed had carried his victorious arms on every side, and Syria, Palestine, Mesopotamia, and Egypt had fallen under the dominion of the caliphs. He was permitted, however, to die in peace, and to transmit the succession to his son, who mounted the throne under the title of Constantine III.

Heraldry is the whole group of ceremonial duties discharged by the heralds of a court, an army, a great noble, or the like, with the assistance of their pursuivants, and under the direction of the Earl Marshal, King-at-Arms, the College of Arms, or other chief of the confraternity. These duties are generally divisible into heraldry proper, or the business of regulating ceremonial occasions such as coronations, marriages among princes, proclamations of important events, and the like; and armory, or the art or quasi-science of armorial bearings. In the first of these divisions but little remains of any interest at the present day, for only in Great Britain is the herald of any consequence. There, however, he still has some direction, as at the eventful proclamation of 1 Jan. 1877, when the Queen of Great Britain assumed the title of Empress of India. In the second branch of the subject, the order and marshaling of arms, the Germans are perhaps at the head of modern writers, though the English and Scottish treatises on the subject are more numerous and more widely used. The Germans' thoroughness of investigation has marked their treatment of this subject, which is eminently a branch of mediæval and subsequent history serving to elucidate genealogical research.

Modern heraldry is no older than the tournaments of the Middle Ages. No linking evidences of the science occur during the Dark Ages, although badges and emblems are found

of shields and helmets discovered in the ruins of antiquity, while in Biblical times the men of Israel were directed to pitch their tents, every man by his own camp and standard with the ensigns of his father's house. Greek and Roman writers describe devices on shields and helmets; the golden eagle on the shields of the kings of Media; the standards and brilliantly colored shields borne by the ancient Germans in battle. The office of herald is as ancient as that of priesthood. Spartans, Greeks, and Romans had heralds, the Roman officers being divided into three classes: *caduceatores*, heralds of peace; *fetiales*, heralds of war and peace; and *præcones*, judicial criers or messengers. The *caduceator* on a mission carried a wand of laurel or olive (*caduceus*, q.v.), as a symbol of his office and for his security. The *fetiales* are thought to have had a college of 20 members founded by Numa, who formulated the procedure and ceremonies connected with the declaration of war and the making of treaties. The *præcones* were employed to proclaim matters of public interest to the people at religious ceremonies, in the *comitia*, at public sales, judicial trials, in the senate, on the publication of laws which they read, at funerals, at games, in the army when a general wished to address his men, at executions, and at all public meetings. The heralds of the Middle Ages had duties which in part resembled those of the heralds of antiquity. Thus, they carried messages of peace and of defiance, and yet even in the earlier years of feudality their office was an inferior one, they being replaced by ambassadors, diplomats almost in the modern sense, statesmen in whose suite the heralds and pursuivants went to the foreign court. So it was that the chief duty of the herald came to be the care of armories.

The first known tomb or monument with escutcheons in the period of modern history is stated to be the eleventh century tomb in the Church of St. Emmeran at Ratisbon, where are the bearings of Varmond, a count of Vasserburg; but this may be a later addition. Another very old specimen and certainly genuine is the shield at Le Mans of Geoffrey Plantagenet, who died in 1150. The use of coats of arms seems to have first become general in the 12th century. Rolls of arms in England are extant in the reigns of Henry III., Edward I., and Edward II. Surcoats displayed armorial bearings in the reign of Henry III. The Roll of Caerlaverock, a poem in Norman-French, contains the names and armorial bearings of the knights and barons who attended Edward I. at the siege of the Castle of Cærlaverock, Dumfriesshire in 1300, and exhibits heraldry already in a developed form. On coins also, no armorial ensigns are found till the 13th century; but then both coins and the seals of nobles and monasteries display them; the use of arms on the Great Seal of England was introduced by Richard I.

The study of armory became essential when at mediæval tournaments aged knights were appointed, whose duties were to act as arbiters, and to pass judgment on coats of arms and the right of knighthood. Whenever a new knight appeared at a tournament, the herald had to *blasen* — that is to blow — the trumpet, and proclaim and explain the bearing of his shield or coat of arms. Hence to blason (*blasen*) came to mean, to describe and explain a display of bearings. The heralds were also the chroniclers of the times and were present on all occasions of public ceremony. In France the first herald — *roi-d'armes* — was crowned and consecrated with religious ceremonies, and was called *Montjoie*, from the war-cry of the French royal armies. The heralds were united in associations, and their duties formed a branch of science which was communicated only to the members. If any person pretended to the character of a herald, who on examination was found not to belong to the corporation, he was driven away with insults and frequently with violence. The heralds in modern courts are masters of ceremonies. In England there are now three kings at arms; the highest is the Garter king at arms; the second, known as *Clarencieux*, is for the southern counties; the third, styled *Norroy*, for the northern provinces. These three kings at arms with six subordinate heralds and four pursuivants form under the presidency of the Earl Marshal, always the Duke of Norfolk, the herald's college or herald's office, established in 1340. The use of arms by private persons in the British Isles was forbidden by proclamation in the reign of Henry V. All persons who had not borne arms at Agincourt were prohibited from assuming them unless by hereditary descent, or with the sanction of the constituted authorities. Periodical circuits called visitations were held afterwards by the provincial heralds to take cognizance of the arms, pedigrees, and marriage of such as were entitled to the use of armorial bearings. These visitations continued till about the end of the 17th century; their records, many of which are preserved in the British Museum and elsewhere, contain much genealogical information and are still consulted for evidence of the hereditary right to bear arms.

The practice of *blazoning the arms* is frequently referred to in the poetry of the Troubadours of the 12th and 13th centuries. Those knights who asserted a right to appear at tournaments did so by the blazoning of their arms, and from the Germans this custom was transmitted to the French, for tournaments were held in Germany before they became general in France. The French, however, carried to far greater perfection the tournament, and the blazon of heraldry connected with it, as they did the whole system of chivalry; the French language prevailing at the court of England after the Norman Conquest, pure French expressions came to be preserved in British heraldry. German heraldry, on the contrary, contains almost pure German expressions.

The whole display of any person's arms is called an achievement, also spelled atchievement. Only the escutcheon, however, is of vital importance. This is the broad surface upon which the bearings are charged. It is always assumed to be a shield in the case of a man not an ecclesiastic; but churchmen's arms are charged upon an oval or other architectural form, a sort of cartouche, and women's bearings are charged upon a lozenge set vertically. The arms of husband and wife, however, may be charged on a shield divided vertically in the middle, and are then said to be dimidiated or impaled; thus we might say that such an escutcheon bears the arms of Smith impaling the arms of Jones — Smith and Jones standing

for the two spouses. It is rare to charge the wife's arms unless she was an heiress, that is to say, the owner of real estate in her own right. These rules, however, are those of Great Britain; they differ widely in other countries.

A single escutcheon may be complete with one simple division. Thus, a horizontal line divides the chief or top of the field at one third of its height from the remainder of the field. If that chief is, say, of gold, while the rest of the field is blue, that by itself makes a very respectable and honorable heraldic statement. The chief is one of the honorable ordinaries, and others are almost as simple. They are the pale, the vertical stripe in the middle of the shield and one third of its width; the fess, a horizontal stripe; the bend, which goes diagonally from the left hand upper corner to the right hand lower part, stopping against the rounded border of the shield; the bend sinister, which is a bend turned the other way (but see below, dexter and sinister); the chevron, which is a pair of stripes meeting in the middle, forming a figure like the letter A without the cross-bar; the cross, the two arms of which are usually of one quarter the width of the escutcheon; and the saltire, which is a diagonal cross. A shield upon which there is any one of these honorable ordinaries and nothing else, is most respectable. In general the simpler shields are the older; thus the old family Erskine, with a black pale on a silver field, or the family of Beauchamp with a gold fess on a red field, occupy the most enviable position in having such a plain escutcheon. There are ordinaries of the second rank, such as the quarter or canton, the orle, and besides these there are very many bearings in common use, especially those which are diminutives of the honorable ordinaries. Thus, the pallett is a smaller pale, and the shield of Aragon has four red palletts side by side on a gold ground. These again may be used to charge upon the greater ordinaries. Thus, the escutcheon of Loreyn bears a blue bend sinister on a gold field and the bend itself is charged with three golden six-pointed stars. That also is a simple and presumably ancient armory.

In describing the escutcheon the side on the left of the spectator is called the dexter and that on his right is called the sinister side; that is because the shield, when carried on the arm with the man-at-arms behind it would be to him so disposed. The escutcheon is supposed to be divided into a certain number of imaginary points or divisions for the fixing and placing of the bearings when they are described in words. When there are nine points, the three at the top following each other from the dexter to the sinister side are dexter chief, middle chief and sinister chief, and a similar nomenclature is used throughout. A modern and fuller arrangement is to give eleven points, the honor point interposed between the top horizontal row and the middle one; and the nombril point spaced between the middle row and the lowermost one. A small bearing as a mullet (a five-pointed star) may be located as being in the dexter chief or the like.

The main business of armory is to present simple patches of bright colors which can be recognized at a great distance. The tinctures used in Great Britain are nine — two metals, *or* and *argent* (gold and silver); five colors, *gules* (red); *azure* (blue), *sable* (black), *vert* (green), *purpure* (purple); though this last is very rare and green is not very common. There are also two furs, which are represented by curious conventional patterns supposed to represent the patchwork of small skins sewed together which make a garment or the lining of a garment. These furs are ermine and vair, but each has many curious variations known by different names. Thus "ermine" shows black tails on a white field, or in modern times a flower-like pattern suggested by the real ermine; but erminois has the same pattern in black on a gold field.

Dimidiation and impaling, mentioned above, are varieties of the great general subject of marshalling. The more elaborate form of marshalling is to divide an escutcheon into quarters. Thus, the son of a married pair who have borne their arms impaled, may divide the escutcheon into four quarters and will put his father's arms on the first and fourth quarters (dexter chief and sinister base) and those of his mother on the second and third quarters. This quartering may be quartered again, and so on indefinitely. Thus, the escutcheon of the Prince of Wales during the reign of Queen Victoria (of him who is now King Edward VII.) is too elaborate to describe fully here. This is because his bearings as Duke of Rothsay, Lord of the Isles, Duke of Cornwall, Baron Renfrew, and the like are all charged together, so that the number of small subdivisions is remarkable. Now, there are different ways of charging these. Those which his escutcheon must bear are the royal arms of England differenced (see differencing above) with the label of the heir apparent, which is a label of three points *argent*, and this escutcheon will bear in the middle a small shield with the arms of Saxony. Even in this the inescutcheon is out of place when we are considering his arms as heir to the crown. It is held by many that the Prince of Wales should display two shields: the first as simple as possible, with only the quarters for England, Scotland, and Ireland; while the second should display all his primary and secondary arms, including those of his wife, who, in the case assumed above, was the Princess Alexandra of Denmark. Again, a system is adopted by which a large shield bears those royal arms upon it, an inescutcheon with the secondary arms of Cornwall, Rothsay, Chester, Dublin, Lordship of the Isles, Carrick, Renfrew, Wales as a principality, and over all a small escutcheon of pretense charged with the arms of Saxony for Saxe-Coburg-Gotha. But even these do not include the arms of the Princess, his wife, which should rightly occupy the sinister side of the shield, while all the achievement described above should be charged upon the dexter side. It is evident, then, that a person whose family has formed many dignified alliances may have an indefinitely great number of quarterings. But let us take the escutcheon of a king of the House of Hanover, as George IV., and we shall find that the four quarters of the shield are filled in this way: the first quarter (dexter chief) in *gules*, bearing three lions *passant gardant*, and the fourth quarter (sinister base) exactly the same. These two quarters are England. The second quarter (sinister chief) is Scotland, a field *or*

with a lion *rampant gules*, framed in a *bordure fleur-de-lisée*, also gules. The third quarter (dexter base) is Ireland, the Irish harp *or* on a ground *azure*. Upon this shield is set an inescutcheon, divided in a curious way into three parts, for Hanover, and having above it a royal crown. Upon this inescutcheon is still a second inescutcheon, very small, simply *gules* with a bearing *or*, which is supposed to stand for the imperial crown of Charlemagne, this in commemoration of the electoral dignity of the sovereign of Hanover, who was called the elector until after the Napoleonic wars. It is a rule never to place metal upon metal or color upon color. Thus, if your shield is argent, any bearing put upon it must be in one of the colors — never in *or*. But there is one curious exception; that of the Latin Kingdom of Jerusalem (which lasted only from 1099 to 1187, but which is perpetuated by the addition of its bearings to many private shields) was *argent*, a cross potent between four crosses *or*. This means a large gold cross, at the end of each arm of which is a cross head like the handle of a crutch; and in the little corners left by the cross, four small Greek crosses; all these in gold on a silver ground.

No two persons should bear the same arms at the same time, therefore a distinction is made between the escutcheons of younger children. Even the heir may distinguish his bearings from his father's by a special mark, apart from the quartering described above. The term marks of cadency is used for these distinctions. Many different plans have been followed, and one which has been much accepted is the label. This is a band with pendant strips hanging from it, usually three; and this is laid right upon the escutcheon near its head, and crosses it, partly concealing all the bearings. This label will be plain for the oldest son, differenced by a bearing like a crescent, *or*, a mullet for the second son, another bearing for the third son, and so on.

The practical functions of the herald developed into blazoning, historifying, passing judgment on, and marshalling coats of arms. Blazoning is the methodical description of a bearing. In the first place the shield is described according to its tinctures, figures and partitions. The inferior parts of an escutcheon are then blazoned — the helm with its insignia which are trumpet, wings and plumes, men and animals, or their members; then the wreath and its tinctures; after which the coronet, cap, etc.; finally the supporters, the mantle, the device and other secondary addenda. To historify in heraldry is to explain the history of a coat of arms, its origin, and the changes it has undergone. If the herald is to explain a bearing historically, he must show that this figure is the proper emblem of the family or country. He derives, for instance, from historical sources the proof that the double-headed eagle of the German king was first introduced in the beginning of the 14th century under Albert I., and that previously from the time of Otho II. the royal eagle had but one head; and he records the privilege given to wear that eagle on a private escutcheon. So he shows that the three leopards (lions passant gardant) in the English arms were first derived in 1127 under Henry I. from the Norman house. The marshalling of arms is especially important in the preparation of new escutcheons. In this matter, the herald either follows the orders of the sovereign, or he invents the idea, and makes the plan of the escutcheon according to his own judgment, or he composes a new escutcheon from several coats of arms.

When color is not used, a system of conventional expression is substituted; thus, *argent* is plain white, *or* is white with black dots, *azure* by horizontal black lines on white, *gules* by vertical black lines, *sable* by crossing black lines horizontal and vertical, *vert* by lines from the dexter chief to the sinister base, *purpure* by lines from the sinister chief to the dexter base. The furs have peculiar patterns and surfaces of their own.

The crest is the highest part of an achievement of arms and is set above the escutcheon. It is called crest from the Latin word *crista*, which signifies a comb or tuft, such as many birds have upon their heads. Crests were anciently marks of honor, because they were worn only by heroes of valor and high rank that they might be the better distinguished in an engagement, and thereby rally their men if dispersed; or else they were of the nature of badges worn by all the followers of a chieftain and serving to identify them. They are at present considered as mere ornaments; and they may be assumed without authority; obviously they should not be used by women. Supporters are figures placed on each side of the shield and perhaps originated from the custom of pages in fantastic dresses guarding the achievements of arms of their masters while the latter were taking part in the exercises of the tournament. The scroll is an ornament usually placed below the shield and supporters, containing a motto or short sentence alluding to the crest, or to the bearing or to the bearer's name. The motto had its origin in the war cries of knights, though in some instances mottoes were borne differing from the war cry of the wearer. The badge is not subject to heraldic rule, though it may be a part of the heraldic achievement, used separately. The porcupine was the badge of Louis XII. of France, and the salamander was chosen by Francis I. when he came to the throne, but neither of these was included in the escutcheon or worn as a crest. The reader may consult Palliser, 'Historical Devices, Badges and War Cries' (London 1870). The most recent large and important book on heraldry in English is 'The Art of Heraldry,' by Arthur Charles Fox-Davies, which is based upon the Heraldischer Atlas of H. G. Ströhl. An excellent book for persons who are making a serious study of the matter is Berry's 'Encyclopædia Heraldica,' in three volumes, n. d. (about 1820). The treatise on Heraldry by Woodward and Burnett, two volumes, 1892, is a very full and up-to-date manual. Smaller books are numerous. To name English ones alone Cussan's 'Handbook of Heraldry,' Planche's 'The Pursuivant at Arms,' Worthy's 'Practical Heraldry,' and especially Charles Boutell's two books, 'English Heraldry,' second edition, 1871, and the very remarkable essay, 'Heraldry, Historical and Popular,' third edition, 1864, now scarce, but nevertheless the most suggestive book that can be found.

Revised by Russell Sturgis.

Herat, hĕr-ät', Afghanistan, a city in the northwest near the Heri-Rud River, about 370 miles west of Cabul. It is enclosed by a broad deep moat and an earthen mound surmounted by a lofty wall of unburned brick, and defended by a strong citadel. The caravansaries, public baths, and mosques are numerous. The trade, almost entirely in the hands of Hindus, is greatly favored by the situation of the town on the great thoroughfare from India westward. Herat was long the capital of the empire founded by Tamerlane, and was once much larger and more splendid than now. Its possession has been repeatedly contested among the peoples of central Asia, and, being regarded as a key to Afghanistan on the side next Persia and Russia it is of great importance politically. Its capture by Persia in 1856 led to a short war between Britain and Persia. Pop. about 45,000.

Hérault de Séchelles, sā'shĕl, **Marie Jean**, French revolutionist: b. Paris 1760; d. there 1794. He became imbued with the teachings of Diderot, but, after his election to the Legislative Assembly in 1791, being rather a philosopher than a revolutionist, he at first paid little attention to the radical element there. He soon, however, joined the extreme left, and later on supported Danton in the revolution of August and September 1792. He was a deputy from the department of Seine-et-Oise to the Convention of 1792 and voted for the king's death. He became a member of the Committee of Public Safety, and as such gained the enmity of Robespierre, who, claiming that he had betrayed certain secrets to the army of the Rhine, caused him to be arrested and executed. His best writings were published under the title 'Voyage à Montbard' (last ed. 1890).

Herb Paris, a poisonous plant of the lily family (*Paris quadrifolia*), resembling and related to white hellebore (q.v.), the toxic principle of which is a specific alkaloid called paradin.

Herbarium, a collection of dried plants, leaves, and fruit or seeds, arranged for preservation between sheets of bibulous paper; it is sometimes called *hortus siccus*, "dry garden," and is an indispensable adjunct to the apparatus of the systematic botanist, and microscopist. The most famous public herbariums are those of Kew, London; those of the British Museum and the London Linnæan Society. Those in Paris, Leyden, Berlin, and Vienna are also very full and complete.

In the United States there are three herbaria both copious and of the first order, namely, the Gray Herbarium of Harvard University, the Herbarium of the New York Botanical Garden, and the United States National Herbarium at Washington.

Herbart, Johann Friedrich, yō'hän frēd'rĭH hĕr'bärt, German philosopher: b. Oldenburg 4 May 1776; d. Göttingen 14 Aug. 1841. At 17 he became the pupil of Fichte at Jena, in 1805 was appointed extraordinary professor of Philosophy at Göttingen, and in 1809 went to Königsberg as Kant's successor; but in 1833 returned to Göttingen, where he remained till his death.

Herbart starts from the Kantian position by analyzing experience: logic, metaphysics, and æsthetics ranking as co-ordinate elements in his system. The first of these deals with the formal elements of thought, metaphysics and æsthetics with its content. Of these latter the former investigates those of our empirical conceptions arising from experience, and which cannot be alienated from our thought, whilst the latter are concerned with those conceptions which involve judgments of approval or disapproval. The most characteristic features of his thinking, however, are these: He posits a multiplicity of "reals," or things which possess in themselves absolute existence apart from apperception by the mind of man. He rejects the notion of separate mental faculties, substituting in their place the conception of primordial presentations or forces, from whose action and interaction all psychical phenomena result. From the conditions determining the equilibrium and movement of these presentations he deduces a statics and a dynamics of mind, both amenable to mathematical manipulation, and thus introduces psychology to a place among the exact sciences. Ethics he ranks as a branch of æsthetics; it investigates the agreement or disagreement between volition and the fundamental moral ideas.

Consult: works on Herbart by Thilo (1875), Zimmermann (1877), and Wagner (17th ed. 1894); De Garmo, 'Herbart and the Herbartians' (1895); Felkin's translation of Herbart's 'Science of Education' (1895); Ufer, 'Pedagogy of Herbart' (trans. 1896).

Herbelot, Barthélemy d', bär-tāl-mē dĕr-blō, French Orientalist: b. Paris 4 Dec. 1625; d. there 8 Dec. 1695. Having gone through a course of study in the university of his native city, he applied himself particularly to the eastern languages, with a view to the elucidation of the Hebrew Scriptures. He visited Italy, and while there commenced his great work, the 'Oriental Library.' Recalled to Paris by Colbert, a pension was given him, that he might be at liberty to proceed with his undertaking. It was his first design to have published his collection in Arabic, and types were cast for the purpose of printing it. But the death of Colbert having interrupted this plan, he recomposed his work in the French language, as likely to prove more generally useful. He was appointed to the royal professorship of Syriac in 1692. His book was published in 1697, under the title of 'La Bibliothèque Orientale.' The best edition of the 'Oriental Library' is that of The Hague (1777), with the supplements of Galland and Visdelou.

Herbert, Edward, Lord Herbert of Cherbury, English philosopher: b. Eyton-on-Severn, near Wroxeter, 1583; d. London 20 Aug. 1648. He was a famous soldier and diplomatist in his day, but at the present is remembered as an author and philosopher. At Paris, in 1624, he printed his famous book, 'De Veritate prout Distinguitur a Revelatione, a Verisimili, a Possibili et a Falso,' the object of which was to assert the sufficiency, universality, and perfection of natural religion, and thereby prove the uselessness of revelation. In 1624 he returned from France, and was created an Irish peer; and in 1629 became an English baron with the title of Lord Herbert of Cherbury. In the civil war he at first tried as far as possible to play a neutral part, but afterward sided with

the Parliamentary party chiefly with a view, it appears, to save his property. The character of Lord Herbert is strongly marked in his memoirs, which show him to be vain, punctilious, and fanciful, but open, generous, brave, and disinterested. The 'De Veritate' was followed by works entitled 'De Causis Errorum' (1645); and 'De Religione Gentilium' (1663; Eng. trans. 1709). In 1649 was published his 'Life and Reign of Henry VIII.' The English style of Lord Herbert is strong, manly, and free from the quaint pedantry of the age. He was one of the first to attempt a systematic proof of the sufficiency of natural religion. "Herbert's religious doctrine," says Sidney Lee, "starts with the assumption that religion, which is common to the human race, consists merely of the five innate ideas or axioms that there is a God, that He ought to be worshipped, that virtue and piety are essential to worship, that man ought to repent of his sins, and that there are rewards and punishments in a future life. He regards Christianity as on the whole the best religion, because its dogmas are least inconsistent with his five primary articles." His autobiography remained in manuscript till 1764, when it was published by Horace Walpole. There is a recent critical edition by Sidney Lee (1886).

Herbert, Lady **Elizabeth,** English writer, mother of Sir Michael Herbert, British ambassador at Washington 1902–3. She is well known as an authoress, and has written books of travel in Spain, Algeria, and many other countries, as well as novels and biographies. Among these may be noted: 'Rambles Round the World'; 'Wayside Tales'; 'Lives of Monsignor Dupanloup, Gascia Moreno, Alexis Clerc,' etc.

Herbert, George, English Anglican clergyman and poet; a brother of Lord Herbert (q.v.): b. Montgomery Castle, Wales, 3 April 1593; d. Bemerton, England, February 1632. He was educated at Westminster and Cambridge. After taking orders he was made prebendary of Leighton Bromswold, or Layton Ecclesia, in 1626. In 1630 Charles I., at the request of the earl of Pembroke, presented him with the living of Bemerton, near Salisbury, and here he remained till his death. As a pastor he was most exemplary and zealous, and he is generally known as "holy George Herbert." His verses are quaint and full of imagery, but with many beautiful thoughts and holy precepts. They are of the same school as those of Quarles and Donne. George Herbert was the intimate friend of Sir Henry Wotton, Dr. Donne, and Lord Bacon. Indeed the latter, whose acquaintance he made at Cambridge, is said to have had so high an opinion of his judgment as to have submitted his works to him before publishing them. Herbert's principal works are: 'The Temple; Sacred Poems and Private Ejaculations' (1631); 'Outlandish Proverbs, Sentences, etc.' (1640); 'Quadripartit Devotions' (1647); 'The Priest to the Temple, or the Character of a Country Parson' (1647); 'Remains,' prose writings (1652). His life was written by Izaak Walton (q.v.).

Herbert, Henry William, "Frank Forester," American author: b. London, England, 7 April 1807; d. New York 17 May 1858. He was graduated from Caius College, Cambridge, in 1828; removed to the United States in 1831; and until 1839 was instructor in the Greek and Latin languages in a private school of New York. In 1833 he established and until 1836 was editor of the 'American Monthly Magazine,' during a portion of that time with Charles Fenno Hoffmann (q.v.) as associate. From 1834 he became largely known as the first important American writer on sports and out-of-door subjects. He wrote also on French and English history, and made excellent translations from Dumas and Sue. His volumes include: 'Cromwell' (1837); 'Marmaduke Wyvil' (1843), 'The Cavaliers of England' (1852); 'The Chevaliers of France' (1853); 'The Puritans of New England' (1853); 'Field-Sports of the United States and the British Provinces' (1848); 'Sporting Scenes and Characters' (1857); 'Horses and Horsemanship of the United States and British Provinces' (1859).

Herbert, Hilary Abner, American lawyer and politician: b. Laurensville, S. C., 12 March 1834. He was educated at the universities of Alabama and Virginia, studied law and was admitted to the bar. He began practice at Greenville, Ala., but served in the Confederate army as captain and colonel of the 8th Alabama regiment; being disabled at the battle of the Wilderness (1864), he retired from the army, and continued the practice of his profession, first at Greenville, then at Montgomery (1872). He was elected to Congress in 1877, and seven times re-elected; in three Congresses he was chairman of the committee on naval affairs. In March 1895, he was appointed secretary of the navy by President Cleveland, an office which he held till 1897, when he began to practise law in Washington.

Herbert, Sir **Michael Henry,** English diplomatist: b. England 25 June 1857; d. Davos-Platz, Switzerland, 30 Sept. 1903. He went to Paris as attaché in 1879; was *chargé d'affaires* at Washington (1888–9); secretary to the British legation at Washington (1892–3); at The Hague (1893–4); and at Constantinople (1894–7). On 4 June 1902 he was appointed British ambassador to the United States at Washington, in succession to the late Lord Pauncefote, and the following year was compelled by ill health to return to Europe.

Herbert, Victor, American musical director and composer: b. Dublin, Ireland, 1 Feb. 1859. After studying music from his childhood in Germany, he was appointed principal 'cello player in the court orchestra, Stuttgart, from which time he appeared in concerts throughout Europe. In 1886 he took the position of solo 'cellist in the Metropolitan orchestra, New York, and has since been connected as soloist and conductor with the principal orchestras of the United States. As a composer he has written: 'The Captive,' an oratorio; and the comic operas, 'Prince Ananias'; 'The Wizard of the Nile'; 'The Serenade'; 'Cyrano de Bergerac.'

Herbiv'ora, a group of mammals characterized by their herbaceous diet; the grazers or ruminants. The term is no longer in scientific use.

Herbs, Culinary, fragrant or aromatic plants used to add flavor to food, especially stews, soups, dressings and salads. They usually owe these qualities to essential oils, which, being readily soluble or easily volatilized by heat,

quickly permeate the mass of food in which they are mixed. The seed of some, as caraway, anise (qq.v.) and dill, is employed; the foliage of others, as parsley, sage, thyme, is more frequently used. The former plants are cut and placed loosely upon sheets as soon as the seed reaches maturity; allowed to dry a few days; lightly thrashed and the seed cleaned; still further dried and stored in air-tight packages. The latter are gathered just before the first blossoms would open, because they are then richest in flavor. With parsley the leaves are gathered as soon as mature, several cuttings being made in a season. They are then dried upon trays at a temperature below 120 degrees and in freely circulating air until crisp, when they are rubbed to powder and stored as above. Paper or pasteboard packages are bad, because they allow the flavors to escape. Both seeds and leaves may be used in decoction, being covered with vinegar or alcohol in stoppered bottles. Fresh herbs, which are always preferable to dried or decocted, are especially useful in salads; dried and decocted in dressings, stews, etc., and at seasons when fresh ones cannot be obtained. In the United States the species most in demand are parsley, sage, thyme, savory, marjoram, spearmint, dill, fennel, tarragon, balm and basil (qq.v.) in nearly the order named. Parsley is beyond question the most popular because of its double use as a garnish and flavoring plant but sage is perhaps more frequently used in the latter capacity. It is most esteemed with pork, goose, duck, and similar rich meats. Spearmint is used mainly with roast lamb; tarragon with boiled fish; dill with pickles; and the other kinds mentioned with mild meats, such as turkey, chicken, veal, venison, etc. The kind, quantity and mixture used with each sort of food depends upon personal preference.

In general, herbs are of simplest cultivation. They usually prefer rather light, moderately rich, well drained soil, and sunny exposures. Since the seeds of many are small or slow to germinate they are frequently started in a greenhouse, hotbed or window, and transplanted to the garden when they are large enough and when conditions are favorable. Clean cultivation and the removal of weeds is essential. The perennial kinds, such as sage, are often propagated by stem cuttings, divisions or layers; tarragon always thus because it does not produce seed; spearmint usually by cuttings of the rootstock. The great majority are grown as annuals, being replaced each spring with fresh plants. Commercially they follow such crops as early cabbage, peas, etc., thus permitting a double use of the same soil annually. They are easily grown for winter use in the borders of benches in the greenhouse or in boxes placed in sunny windows.

Consult articles such as *Sweet Herbs* by Kains in Bailey's 'Cyclopedia of American Horticulture' (New York 1900–2).

Herculaneum, hĕr-kū-lā'nē-ŭm, or **Herculanum,** Italy, an ancient buried city, about five miles southeast of Naples. Strabo says it was first occupied by Oscans, afterward by Tyrrhenians and Pelasgians, and then by the Samnites. It took part in the social war against the Romans. In the time of Sulla it was a *municipium* and a fortified town. It was situated between Neapolis and Pompeii, on elevated ground between two rivers, and its port was one of the best on the coast. It suffered in 63 A.D. in the same earthquake that nearly destroyed Pompeii. In the greater irruption of 79 A.D. it was buried under a volcanic tuff formed of sand and ashes, partly consolidated by the agency of water. The site of Herculaneum, though well described, had been long sought in vain, when in 1713 three female statues (now in the Dresden Museum) were found in digging a well at Portici, a village situated on the ancient site. After this discovery further excavation was prohibited by the government, until in 1738 the well was dug deeper, and the theatre of Herculaneum was discovered. In 1750 a long, narrow passage, sloping down into the theatre, was opened, and is still the only way by which travelers descend to examine this structure. The excavations were continued more or less industriously for 50 years; but comparatively little progress was made, as the work was difficult and also dangerous to the houses in the populous villages of Resina and Portici, situated above. As soon as one part was excavated and explored it was filled up with the rubbish from a new digging. The theatre is the only building to be seen underground, and it is encumbered with the supports built to sustain the rock above it. It is a noble edifice, massively built of solid stone, and seated 8,000 persons. Bronze statues of Drusus and Antonia and of the Muses were found in various parts of the building. In a square on the south of the theatre a temple was found which was connected with another temple, to the east of it, by a wide street lined with porticoes. One of these temples, dedicated to the mother of the gods, had been restored by Vespasian after the earthquake of 63 A.D. On the north of the theatre was a basilica 228 feet long and 132 broad, surrounded by a portico of 42 columns, and adorned with paintings. Many beautiful paintings and works of art were removed from these buildings to the museum at Naples. A sumptuous private villa was disinterred, containing a number of statues, and in one of the rooms a quantity of papyrus manuscripts. Some of the statues are excellent as works of art, such as those of Agrippina, Aristides, the Sleeping Faun, and the Mercury. Other precious relics discovered here, and now in the museum, are busts of Plato, Demosthenes, Scipio Africanus, Augustus, Seneca, etc., beautiful mosaics, and articles of furniture. New excavations were carried out in 1828–37, and since 1868. The chief discoveries made were those of the forum, a small and elegant temple, a basilica, a dilapidated building supposed to have been an inn, dwelling-houses, tombs, etc. One of the houses discovered at Herculaneum contained a quantity of provisions, dates, chestnuts, large walnuts, dried figs, almonds, prunes, corn, oil, pease, lentils, pies, and hams, none of which had been disturbed for 18 centuries, for the doors remained fastened, in the same state as they were at the period of the catastrophe which buried the town. The internal arrangement of the house, and the manner in which it was ornamented, proved that it had belonged to a rich family, admirers of the arts; for it contained many pictures, vases, articles in glass, bronze, and terra-cotta. Few skeletons comparatively have been found either in Pompeii or Herculaneum, so that it is probable most of the

inhabitants saved themselves by flight. At the door of a villa in Herculaneum were found two, one of which held a key in one hand, and in the other a bag with coins and cameos. Near them were silver and bronze vessels.

Among the most interesting objects discovered here are the papyri above mentioned, over 1,750 of which are now in the Naples Museum. The rolls are of cylindrical form, and much charred. Hardly a third of them have been unrolled. The process presents great difficulties, from the tendency of the MSS. to crumble. One of the works is a treatise by Epicurus on Nature; there are some writings of Philodemus, a Syrian philosopher; but on the whole they are of little value. There have been published 11 volumes of the 'Volumina Herculanensia,' containing engraved transcripts of the unrolled papyri (folio, Naples, 1793–1855), and since 1861 several volumes of a continuation of the same.

Consult: Furcheim, 'Bibliografia di Pompei, Ercolano e Stabia'; Ruggiero, 'Storia degli Scavi di Ercolano.'

Her'cules, hér'kū-lēz, called by the Greeks HERAKLES, and also ALCIDES, al-sī'dēz, after his grandfather, Alcæus: a mythological hero of Greece, typified by poets, sculptors, and artists of later ages, as a model of human perfection, physical and mental. According to the traditions of the heroic age, he united the finest qualities of mind and heart, as understood at that period, with the highest development of bodily vigor, and under a ceaseless succession of labors and sacrifices, strove perpetually after divine excellence. His indomitable perseverance was crowned with victories which showed the triumph of the divine part of man's nature over the earthly, while his death secured him immortality, a seat among the gods, and the homage of divine honors.

The legends relate that he was the son of Zeus or Jupiter, king of the gods, and of Alcmena the Theban, daughter of Alcæus, son of Perseus. Knowing that the child born on a certain day would rule over the descendants of Perseus, Hera or Juno, wife of Jupiter, consumed with jealousy, contrived to prolong the travail of Alcmena, and hasten that of the wife of Sthenelus, another son of Perseus, who gave birth to Eurystheus, subsequently chief of the Persidæ. Hercules was brought up at Tirynthus, or according to Diodorus, at Thebes. Jupiter sought to protect his favorite son in every manner, and to make him worthy of immortality. On one occasion, while Juno was asleep, he laid the infant on her breast, that he might feed on the milk of the goddess. She awoke, and cast the hated babe from her, and the drops that then fell from her are said to have formed the Milky Way. Under the care of Amphitryon, Alcmena's husband, Hercules received the best instruction in all arts. Castor, the son of Tyndarus, taught him how to fight; Eurytus, archery; Autolycus, driving; Eumolpus, singing; Linus, to play the lyre; and under the centaur Chiron, he perfected his training, and became the most valiant and accomplished hero of the age.

In his eighteenth year he slew a huge lion in the neighborhood of Mount Cithæron which had preyed on the flocks of Amphitryon and of the king of Thespis. The king, desirous that his 50 daughters might have children by such a hero, entertained him at his court for 50 days, and Hercules became the father of their sons, the Thespiadæ. Hercules next freed his native city from the annual tribute of a hundred oxen, paid to Erginus, king of the Orchomenians. Creon, king of Thebes, rewarded Hercules by giving him his daughter Megara in marriage, and intrusting him with the government of his kingdom. Subjected to the power of Eurystheus owing to priority of birth, the latter acquainted with Hercules' successes and rising power, ordered him to appear at Mycenæ, and perform the labors which he was empowered to impose upon him. Hercules refused, and Juno to punish him, afflicted him with melancholic madness, during which he killed his own children by Megara, supposing them to be the offspring of Eurystheus. When he recovered he was so horrified by the misfortunes which had proceeded from his disobedience and insanity, that he consulted the oracle at Delphi; he was told that he must be subservient to the will of Eurystheus and perform ten labors imposed by the king, after which he would attain immortality. Hercules thereupon went to Mycenæ, where Eurystheus, apprehensive of so powerful an enemy, commanded Hercules to achieve a number of enterprises, the most difficult and arduous ever known. The favors of the gods, however, had completely equipped him for their performance; from Minerva he had received a coat of arms and helmet, a sword from Mercury, a horse from Neptune, a shield from Jupiter, a bow and arrows from Apollo, and from Vulcan a golden cuirass and brazen buskin with a celebrated brass club.

The first labor was to destroy the lion which infested the forests of Nemea and Cleonæ near Mycenæ, and was invulnerable to mortal arrows. Hercules attacked him with his club, chased him to his den, and after a sharp and fierce struggle choked him to death. He carried the dead beast on his shoulders to Mycenæ, and ever after clothed himself with the skin. The second labor was to destroy the Lernæan hydra, which he accomplished with the assistance of his friend Iolaus, who burnt with a hot iron the root of each head as Hercules crushed it to pieces with his club. The third labor was to catch the hind of Diana, famous for its swiftness, golden horns, and brazen feet. The fourth labor was to bring alive to Eurystheus a wild boar which ravaged the neighborhood of Erymanthus. In this expedition he destroyed the Centaurs, and caught the boar by closely pursuing it in the deep snow. In his fifth labor Hercules was commanded to clean the stables of Augeas, where 3,000 oxen had been kept for many years; this he accomplished in one day by turning the rivers Alpheus and Peneus through the stables, receiving as payment a tenth of the cattle, and concealing the fact that he had been commanded to perform the service. The sixth labor was to destroy the carnivorous birds, with brazen wings, beaks, and claws, which ravaged the country near Lake Stymphalis in Arcadia. In his seventh labor he brought alive into Peloponnesus the wild bull, a gift of Poseidon to Minos, king of Crete, which had laid waste the island. In his eighth labor he was commissioned to capture the mares of Diomedes, which fed upon human flesh. He killed Diomedes, and gave him to be eaten by his mares, which he brought to

Eurystheus. For his ninth labor he was commanded to obtain the girdle of the queen of the Amazons. In his tenth labor, he killed the monster Geryon, king of Gades, and brought to Argos his numerous flocks, which fed upon human flesh. Adjudging the second and fifth labors as unlawfully performed, Eurystheus imposed two others. These were: the eleventh, to obtain the golden apples from the garden of the Hesperides; and the twelfth, to bring from hell the three-headed dog Cerberus. Pluto promised him Cerberus on condition that he should use no weapons but force. Eurystheus, pale with fright when Hercules brought the monster to him, ordered its immediate removal. This ended what are generally known as the Twelve Labors of Hercules, and relieved the hero from bondage.

Besides these, Hercules achieved other labors equally great and celebrated, such as his war with Jupiter against the giants, his expedition with the Argonauts to Colchis, the pillage of Troy, the liberation of Prometheus and Theseus, etc. During three years' slavery, imposed by the Delphian oracle for plundering the temple to avenge supposed neglect, Hercules' mistress, Omphale, queen of Lydia, married him. Hercules afterwards married Dejanira, daughter of Œneus, king of Ætolia, and when Iole, daughter of the king of Œchalia, a princess formerly refused to Hercules, became his captive, Dejanira sent Hercules the tunic given her by the dying centaur Nessus, as having the power to recall a husband from unlawful love. The tunic had been infected by the poisoned arrow shot by Hercules at the centaur, when he offered violence to Dejanira, after carrying her across the river Evenus. When Hercules put the tunic on, the poison penetrated his system and he suffered untold torments; in remorse Dejanira killed herself. In his agony Hercules had himself conveyed to Mount Œta and laid on a funeral pyre which at his commands was set on fire. In the midst of a dark cloud, accompanied by lightning and thunder, his immortal spirit was transported to Heaven, where he took his place among the gods, became reconciled to Juno and married her daughter Hebe.

While the myth of Hercules is of Greek origin, counterparts of the legend appear among many nations. Some scholars regard Hercules as a solar hero, and the twelve labors to represent the 12 zodiacal signs. Artists represent him under a variety of forms, as a child, a youth, and man, in his numerous adventures and exploits. The principal ancient statue is the Farnese Hercules at Naples, by the Athenian Glycon. In the Vatican, the Torso di Michelangelo, so called because that artist studied it during several years, is a remarkable fragment of an ancient statue of Hercules.

Hercules, in astronomy, one of Ptolemy's northern constellations. It is within this constellation that the point toward which the sun, with its accompanying system of planets, is traveling at present is situated. The constellation contains the finest globular cluster of stars in the northern heavens, and the bright double and variable star Ras Algethi.

Hercules-beetle, a very large South American lamellicorn beetle (*Dynastes hercules*). An enormous horn projects from the prothorax of the male, and a smaller one from the head; they act together like a pair of forceps. The length of the male is about six inches, but the female is smaller and lacks the horns. Numerous related species are known, of which *D. tityrus,* found in the southern United States, is 2½ inches long.

Hercules' Club, a North American shrub or tree growing to height of 12 feet and sometimes to 40 feet. See ARALIA.

Hercules, Pillars of, name of the Straits of Gibraltar among the ancients. Hercules is said to have erected a pillar on each side of the strait between Europe and Africa, upon the mountains Calpe and Abyla, as the limits of his wanderings toward the west. The earliest Greek writer by whom the Pillars of Hercules are mentioned is Pindar. On the other hand the Phœnicians called the strait the Pillars of Melkant (q.v.), whom the Greeks knew as Melicertes.

Herder, Johann Gottfried von, yō hän gŏt'frēd fŏn hĕr'dĕr, German critic and poet: b. Mohrungen, Prussia, 25 Aug. 1744; d. Weimar 18 Dec. 1803. He was the son of a poor schoolmaster, but friends procured him an appointment in Frederick's College, where he was at first tutor, and at a later period instructor. During this period he became known to Kant, who permitted him to hear all his lectures gratis. His unrelaxing zeal and diligence enabled him to become acquainted with science, theology, philosophy, philology, natural and civil history, and politics. In 1764 he was appointed an assistant teacher at the cathedral school of Riga, with which office that of a preacher was connected. In 1769 he went to Paris; he became traveling tutor to the Prince of Holstein-Oldenburg, but in Strasburg he was prevented from proceeding by a disease of the eyes; and here he became acquainted with Goethe, on whom he had a very decided influence. Herder had already published his 'Fragments on the More Modern German Literature,' his 'Critical Woods' (Kritische Wälder), etc., which had gained him a considerable reputation, though he had not published anything of importance in theology; yet, while in Strasburg, he was invited to become court preacher, superintendent, and consistorial counsellor at Bückeburg, whither he proceeded in 1771. He soon made himself known as a distinguished theologian, and in 1776 received an invitation to become court preacher, general superintendent, and consistorial counsellor at Weimar. This appointment was through the influence of Goethe. In 1801 he was made president of the high consistory, a place never before given to a person not a nobleman and was subsequently made a noble by the Elector of Bavaria. As a theologian Herder contributed to a better understanding of the historical and antiquarian part of the Old Testament. His 'Geist der hebräischen Poesie' is highly valued. He did much for the better appreciation of the classical authors, and his philosophical views of human character are full of instruction. His greatest work is his 'Ideen zur Philosophie der Geschichte der Menschheit' (1785 *et seq.*). In poetry Herder effected more by his various accomplishments, his vast knowledge, and fine taste, than by creative power; yet he has produced some charming songs; and

his 'Cid,' a collection of Spanish romances into a kind of epic, is one of the most popular poems of Germany.

Heredia, José Maria, Spanish-American poet: b. Santiago de Cuba 31 Dec. 1803; d. Toluca, Mexico, 7 May 1839. He was graduated from the law department of the University of Havana in 1819; for taking part in the attempted revolution of 1823 was banished from Cuba, lived for two years in the United States, and in 1825 removed to Mexico, where he held various civil, judicial, and journalistic positions. His poetic works have been to some extent rendered into other languages. The 'Ode to Niagara' is well known. Heredia has been considered by many the greatest of Spanish-American poets. One of the best editions is that of Ponce de Leon, 'Obras Poeticas de Don José Maria de Heredia' (1875).

Heredity, the transmission of parental characteristics to the offspring. The child possesses the mean between the character of each parent, that is, the father and mother share equally in transmitting their peculiarities. Yet it should be borne in mind that no two individuals are exactly alike, and besides the resemblances to the parents, every child differs in certain respects from the parent. We speak of the force of heredity, and this, whatever be its nature, is very wonderful. Thus the Egyptian of to-day inherits the features and mental characteristics of his ancestors who lived 10,000 years ago. One cause of this is the fact that the physical features and climate of Egypt have remained unchanged for that period. Did heredity act rigidly we should have no modification of type from one geological age to another. The inheritance of one set of characters may, owing probably to profound changes in the environment, lapse, and the original peculiarities be replaced by others. Thus civilized man has thrown off certain habits and tendencies of his savage ancestors, and acquired new and higher culture — modes of action and feeling. Heredity has its limits, and in certain highly specialized types of animals has lapsed or ceased to act as at first. Hurst remarks: "Heredity is merely a likeness of effects due to the likeness of the causes producing them."

There are four types or forms of inheritance: (1) Continuous or normal inheritance, that is, where the children resemble the father and mother. (2) Interrupted inheritance, where the offspring resemble the grandparents. (3) Collateral inheritance, where the offspring inherit the qualities of their uncle or aunt. (4) Atavism or reversion, which is inheritance from a remote ancestor. Thus when individuals of two domesticated races are crossed, the offspring may resemble neither parent, but are like the supposed ancestral or wild species. This is called "throwing back" by breeders. Galton speaks of alternative heredity, and illustrates it by the color of the human eye. "If one parent," he says, "has a light eye-color and the other a dark eye-color, some of the children will, as a rule, be light and the rest dark, they will seldom be medium eye-colored, like the children of medium eye-colored parents." What is called particulate inheritance is common in the color of the hair of horses, dogs, mice, and other mammals, and in the hairs on the leaves of certain plants.

Galton's Law.— We do not know why certain characters are transmitted and others are not, and we cannot foretell, says Bateson, which individual parent will transmit characters to the offspring, and which will not, yet this problem may at some time become solved. From his studies on human stature, and on the transmission of colors in Bassett hounds, Galton has shown that the expectation of inheritance is such that a simple arithmetical rule is approximately followed. He deduced the rule that of the whole heritage of the offspring the two parents together on an average contribute one half, the four grandparents one quarter, the eight great-grandparents one eighth, and so on, the remainder being contributed by the more remote ancestors.

This rule does not in many cases apply, and Galton points out that it takes no account of individual prepotencies. Moreover, says Bateson, there are numerous cases in which on crossing two varieties the character of one variety almost always appears in each member of the first cross-bred generation. For example, the offspring of the polled Angus cow and the shorthorn bull is almost always polled or with very small loose "scurs." Seedlings raised by crossing *Atropa belladonna* with the yellow-fruited variety have without exception the blackish-purple fruits of the type. These are now recognized as instances of Mendel's principle of dominance.

Mendel's Law.— As far back as 1865 an Austrian monk, Mendel, made prolonged experiments in crossing varieties of the pea (*Pisum sativum*). His paper was overlooked until attention to his remarkable results was called by De Vries in 1900; he and also Correns and Tschermak at the same time independently rediscovered Mendel's law. Mendel selected seven pairs of characters, such as the shape of the ripe seed, of the cotyledons, of the seed-pod, color of the seed-skin, length of stem, etc. Large numbers of crosses were made between peas differing in respect of one of each of these pairs of characters. It was found, says Bateson, that in each case the offspring of the cross exhibited the character of one of the parents in almost undiminished intensity, and intermediates which could not be at once referred to one or other of the parental forms were not found. "In the case of each pair of characters there is thus one which in the first cross prevails to the exclusion of the other." This prevailing character Mendel called the dominant character, and to the other he gave the name of recessive character.

This law of dominance has been found by Bateson and by Castle to apply to animals as well as plants, and thus is a most important biological law. Thus when mating occurs between two organisms, whether vegetable or animal, differing in some character, the offspring frequently all exhibit the character of one parent only, in which case that character is said to be "dominant." For example, on crossing white mice with gray mice, Castle found that the offspring are gray, that color-character being dominant. The character which is not seen in the immediate offspring is called recessive, for though unseen it is still present in the young. white in the experiment being the recessive color.

The law of dominance has its exceptions; the hybrid often possesses a character of its

own, instead of the pure character of one parent, as is true in cases of complete dominance. The hybrid form often resembles a supposed ancestral condition, when it is usually regarded as a reversion. Examples are the gray hybrid mice, which are indistinguishable in appearance from the house mouse; also slate-colored pigeons resulting from crossing white with buff pigeons.

One result of Mendel's discovery is the purity of the germ-cells. As stated by Castle: "The hybrid, whatever its own character, produces ripe germ-cells which bear only the pure character of one parent or the other." To breeders Mendel's law is of great importance because, as remarked by Castle, it reduces to an exact science the art of breeding in the case most carefully studied by him, that of entire dominance. "No animal or plant is 'pure' simply because it is descended from a long line of ancestors possessing a desired combination of characters, but any animal is pure if it produces gametes (germ-cells) of only one sort, even though its grandparents may among themselves have possessed opposite characters."

The bearings of Mendel's discovery, confirmed by De Vries' experiments, on the origin of species is of great interest and moment. The problem is whether aberrations, sports, or discontinuous variations may not sometimes result in the formation of new species and types, or whether species are all the result of slow, continuous variations. As stated by Castle, "A sport having once arisen affecting some one character of a species, may by crossing with the parent form be the cause of no end of disintegration on the part of any or all of the characters of the species, and the disintegrated characters may, indeed must, form a great variety of new combinations of characters, some of which will prove stable and self-perpetuating.

Mendel's discoveries also explain the principle that new types of organisms are extremely variable, whereas old types are subject to little variation. A new type which has arisen as a sport will cross with the parent form. The offspring, says Castle, will then inherit some dominant character, others latent, and this will result in polymorphism of the race. Thus the suggestion of Galton that species may arise from sports is confirmed, while added cases are afforded by the recent remarkable experiments of De Vries, resulting in the origination of seven new species of primrose by sudden variations, or what he calls "mutations."

Homochronous Heredity.— This is a form of heredity called by Darwin "inheritance at corresponding periods of life." It is exemplified in animals with a metamorphosis, whose larvæ lead a different life and differ greatly in structure and form from the parent. Thus the butterfly inherits in its infancy the caterpillar stage, then the pupa, finally the features of the imago; one character or set of characters appear by heredity, are cast aside, and new features arise, those of the pupa stage, and so on. Each butterfly, beetle, or bee, as well as the fluke-worms, tapeworms, etc., inherit at different periods of their lives stages which have become fixed by homochronous heredity.

The Physical Basis of Heredity.— A number of biologists from Spencer to Jaeger and Weismann have supposed that heredity is due to the transmission from parent to offspring of particles developed in the reproductive cells of the parent, whence arose the theory now generally held that the nucleus of the spermatozoon and of the egg is the bearer of heredity. Even in the protozoa, if one be divided into nucleate and enucleate halves, the portion without a nucleus degenerates, while the part containing the nucleus lives and regenerates the lost parts. The nucleus contains a portion which stains readily with reagents, and is called the "chromatin," which consists of particles called "chromosomes." Now the nucleus of the egg and that of the spermatozoon contain the same number and quantity of chromosomes, to what are called the cleavage-spindles, hence the chromatin, that is, the chromosomes, are regarded as the bearers of heredity, some of these passing down from one generation to another.

Consult: Weismann, 'The Germ-Plasm' (New York 1893); Bateson, 'Mendel's Principles of Heredity' (Cambridge, England, 1902); Castle, 'Mendel's Law of Heredity' (Cambridge, Mass., 1903); with the earlier works of Darwin, Brooks, Galton, Hertwig, and others.

ALPHEUS S. PACKARD,
Late Professor of Zoology, Brown University.

Hereford, hĕr'ĕ-fōrd, England, a city and parliamentary borough, capital of Herefordshire on the Wye, 120 miles northwest of London. The chief building is the cathedral, built in 1012–56, rebuilt in 1072, and restored in 1863. It is of early Norman architecture, 335 feet long and 174 feet wide, contains many fine monuments, some as ancient as the cathedral, and its accessory features include a lady chapel, charterhouse, cloisters, an episcopal palace and a library containing valuable MSS., Wyclif's Bible, and a 13th century map of the world. A musical festival of the united choirs of Gloucester, Worcester, and Hereford is given in the cathedral triennially. The see dates from 673; the city was incorporated in the reign of King John. Pop. (1901) 21,382.

Her'esy (Gr. *hæresis*) primitively means a choice or election, and in its application to religious belief is used to designate as well the act of choosing for one's self, and maintaining opinions contrary to the authorized teaching, as also the heterodox opinions thus adopted. In the Acts of the Apostles the word seems to be used of a sect or party, apart from the consideration of its character, whether good or bad; but in the Epistles and in the early Christian writers it is almost invariably used in a bad sense, which is the sense uniformly accepted in all subsequent theological literature.

Even in the apostolic times heresies had arisen in the Church, and before the Council of Nice the catalogue of sects had already swelled to considerable dimensions.

From the very date of the establishment of Christianity in the Roman empire heresy appears to have been regarded as a crime cognizable by the civil law; and Constantine enacted several severe laws for its repression, which were continued and extended by his successors, and were collected into a single title, 'De Hæreticis,' in the Justinian code. The penalties of heresy ordained by these enactments are very severe, extending to corporal punishment, and even to death; and they all proceed on the distinct assumption that a crime against religion

is a crime against the state. These enactments of the Roman law were embodied in the various codes of the European kingdoms; in English law heresy consisted in holding opinions contrary to the faith of Holy Church. By common law the offender was to be tried in the provincial synod by the archbishop and his council, and, after conviction, was to be given up to the king to be dealt with at his pleasure. But the statute 2 Hen. IV. chap. 15 (*De hæretico comburendo*) empowered the diocesan to take cognizance of heresy, and, on conviction, to hand over the criminal directly, and without waiting for the king's writ, to the sheriff or other competent officer. This statute continued practically in force, with certain modifications, till the 29 Charles II. chap. 9, since which time heresy is left entirely to the control of ecclesiastical legislation.

The doctrines considered heretical by the Christian Church may be found in the 'Dictionnaire des Heresies,' by the Abbé Pluquet, with the history, progress, nature, and also the refutations of their errors.

Her'etic, in ecclesiastical terminology, one who embraces a heresy. It is evident that the word heretic can have only the relative meaning of heterodox. The early Christian Church always made a distinction between heretics who obstinately persisted in their heresy, and heretics merely through error, or who had been born in heresy. The fathers of the Church declare themselves ignorant of the final condition of the latter. Again, peaceable heretics are distinguished from those whose doctrines produce public confusion and disorder. However, the general view is that all heresies lead, sooner or later, to disturbances and bloodshed.

Hereward, hĕr'ĕ-wȧrd, a Saxon yeoman who flourished about 1070. He was practically the last to withstand the Normans, holding the Isle of Ely against William the Conqueror 1070–1. After William had succeeded in reaching the refuge of the Saxon patriots, Hereward, scorning to yield, fled to the fastness of the swampy fens to the northward. He was commonly styled HEREWARD the WAKE, and his character and adventures form the theme of Charles Kingsley's popular historical romance, 'Hereward.'

Her'ford, Oliver, American humorous author and illustrator: b. England. He is at present on the staff of the 'Criterion.' Among his works are: 'Artful Antics'; 'The Bashful Earthquake and Other Fables and Verses' (1898); 'Alphabet of Celebrities' (1899); 'A Child's Primer of Natural History' (1899); 'Wagner for Infants' (1899); 'Overheard in a Garden' (1900).

Hering, Ewald, German psychologist: b. Altgersdorf, Saxony, 5 Aug. 1834. He studied medicine, and settled at Leipsic as physician in 1860; in 1862 he was lecturer in physiology at the Leipsic University, and in 1865 was professor of physiology and medico-physics in a medical school at Vienna, and in 1870 held the same chair at Prague. Hering is best known for his work in the field of psychophysics, especially for his investigations of visual space perception and for the color theory which he originated. This theory is opposed to the empiristic theory of Helmholtz and is most generally accepted by psychologists at the present time. His writings include: 'Die Lehre vom Binocularen Sehen' (1860); 'Zur Lehre vom Lichtsinne' (1872–4); 'Der Raumsinn und die Bewegung des Auges'; 'Das Gedächtniss als eine allgemeine Funktion der organisierten Materie' (1870).

Her'ing, Rudolph, American hydraulic and sanitary engineer: b. Philadelphia, Pa., 26 Feb. 1847. He was graduated at the Dresden (Germany) Polytechnic School, 1867, and became assistant engineer of Prospect Park, Brooklyn, N. Y., the following year. He was assistant engineer of Fairmount Park, at Philadelphia, 1869–71, and astronomer at Yellowstone National Park in 1872. After serving as assistant city engineer 1873–80 he opened an office for private practice in engineering and has furnished designs for sewerage and water supply for numerous towns and cities in the United States, Canada and South America. He is member of many professional societies both in Europe and America, and has written many published reports on sewerage and water supply of cities.

Heriot, hĕr'ĭ-ŏt, George, Scottish philanthropist: b. Edinburgh 1563; d. London 12 Feb. 1624. His father was a goldsmith in Edinburgh, and the son followed his father's profession, and was admitted a member of the Incorporation of Goldsmiths in May 1588. In 1597 he was appointed goldsmith to the queen by a charter from James VI., and on the accession of the latter to the English crown followed the court to England. From the period of Heriot's settlement in London little is known of his history. He died on 12 Feb. 1624, and was buried at St. Martin's-in-the-Fields. By his will he left nearly the whole of his fortune toward the founding and erecting of a school for poor boys in Edinburgh, styled in the bequest a "hospital." The foundation of the present structure, known as Heriot's Hospital, was laid in July 1628; and the expense of the erection exceeded £30,000 sterling. From the rise in value of property the yearly revenue of the hospital has very greatly increased; and the governors were empowered in the reign of William IV. to establish elementary schools within the city for the gratuitous education of poor children, 16 day schools being ultimately established, besides evening schools. In 1885, however, an entirely new scheme was introduced and a great part of the funds are now devoted to the support of Heriot's Hospital School and the Heriot-Watt College. The former is a day school for boys of 10 and upward, and the Heriot-Watt College is a college giving a thorough technical, commercial, and literary education chiefly by evening classes, though there are also day classes. The annual revenue is now about $150,000.

Her'kimer, Nicholas, American military officer: b. about 1715; d. Danube, N. Y., 17 Aug. 1777. He became a lieutenant of militia, served in the French and Indian war, and defended Fort Herkimer in 1758. Promoted brigadier-general of militia in 1776, he directed operations against Sir John Johnson, and when Fort Stanwix was threatened by a combined force of Indians, Tories, and regulars, advanced to its relief. He was ambushed by Col. Saint Leger at Oriskany, and one of the most closely-fought battles of the Revolutionary War followed.

Herkimer having lost a third of his force, was unable to continue, and Saint Leger's army was rendered thoroughly ineffective. Herkimer himself was wounded, and died as the result of an unskilful operation. The town and county of Herkimer, N. Y., were named in his honor.

Herkimer, N. Y., village, county-seat of Herkimer County; on the Mohawk River, the Erie Canal, and on the New York C. & H. R. railroad; about 25 miles east of Utica and 68 miles northwest of Albany. The chief manufactures are flour, furniture, mattresses, knit goods, beds, paper, creamery products, and cigars. The city owns and operates the electric plant and the waterworks. It is the seat of Folts Mission Institute. Pop. (1900) 5,555.

Her'komer, Hubert, English painter: b. Waal, Bavaria, 26 May 1849. His father, a wood carver, went to America in 1851, but returned to Europe and settled in Southampton in 1857. Hubert studied at the School of Art in that city, where he assisted in founding a life school for drawing. In 1867 he exhibited in the Dudley Gallery. From this time he gradually gained recognition as a painter in water colors, and in 1871 was elected a member of the Institute of Water Color Painters. His first picture exhibited at the Royal Academy, 'After the Toil of the Day' (1873), a German subject, attracted attention; and two years later he gained a great reputation by his famous picture representing 'The Last Master — Sunday at the Royal Hospital, Chelsea,' to which a grand medal of honor was awarded at Paris in 1878. Later pictures are: 'Eventide: a Scene in Westminster Union' (1878), "a worthy companion of the other realistic yet more heroic study of old age, which the artist made in his Chelsea Pensioners"; 'Missing: a Scene at the Portsmouth Dockyard Gates' (1881), "a masterpiece in its way"; 'On Strike' (1891), his diploma work; 'Back to Life: a District Nurse Taking out a Child for the First Walk after a Long Illness' (1896); and 'The Guards' Cheer' (1898), representing a scene in the Diamond Jubilee procession. Among many portraits painted by him the best known are those of Wagner, Ruskin, and Tennyson. His best water-color pictures are: 'Im Walde'; 'The Woodcutter's Rest'; 'The Poacher's Fate'; and 'At the Well.' Mr. Herkomer was elected associate of the Royal Academy in 1879, and full member in 1890, and from 1885 till 1895 held the Slade professorship of fine art at Oxford in succession to Mr. Ruskin. He holds a life professorship at Munich, superintends an art school founded by himself at Bushey in Hertfordshire, and for the theatre connected with it has written several plays. Herkomer also occupies a high place as an etcher and mezzotint engraver. He has published: 'Lectures on Etching and Mezzotint Engraving' (1892). See Courtney, 'Life' (1892).

Hermandad, ĕr-män-däth', a confederation of the cities of Aragon, formed to defend themselves against the usurpations and the rapacity of the feudal nobility. This object was most clearly apparent in the brotherhood (Hermandad) formed about the middle of the 13th century in Aragon, and that formed about 1282 in Castile. In 1295, 35 cities of Castile and Leon formed a joint confederacy for the same object. These fraternities were the model of the later Hermandad of the municipal communities, which was formed in Castile under the reign of Ferdinand and Isabella. It was established in 1486 with the approbation of the king. The city authorities raised a military force, and appointed judges in different parts of the kingdom. Neither rank nor station protected the offender against the tranquillity of the country, nor could he find safety even in the churches. The Santa Hermandad (holy brotherhood) which readers of Don Quixote will be acquainted with, had, like the earlier institution, of which it was a continuation, the object of securing internal safety, and seizing disturbers of the peace and highway robbers, but did not act except in case of offenses actually committed. It consisted of a company of armed police officers, who were distributed in the different provinces of the kingdom of Castile, and whose duty it was to provide for the security of the roads outside of the cities. One of their strictest regulations was not to use their power within the cities. They were subject to the Council of Castile. The principal divisions of the company had stations at Toledo, at Ciudad Rodrigo, and at Talavera.

Hermann, hĕr'mạn, **Alexander,** American conjurer: b. Paris, France, 10 Feb. 1844; d. near Great Valley, N. Y., 17 Dec. 1896. From his brother Carl, Alexander took his earliest lessons in sleight-of-hand and the brothers then traveled in Europe and became widely known as skilled conjurers. Coming to the United States in 1867 they met with great success. The elder presently returned to Europe, but Alexander became a citizen of the United States, made a tour of the world and had few equals in his profession.

Hermann (hĕr'män) **und Dorothea,** dŏr-ō-tā'ä, a pastoral poem by Goethe, published in 1797. It contains about 2,000 hexameter lines. The scene is the broad Rhine plain, and the time the poet's own. The standard English translation is that by Miss Ellen Frothingham (1870).

Hermann, Mo., a town in Roark Township, the capital of Gasconade County, on the south bank of the Missouri River, here crossed by a bridge, 81 miles west of St. Louis, and on the Missouri Pacific railroad. It is in a grape-vine-growing region and manufactures wine, beer, flour, tools and cigars. Pop. (1900) 1,575.

Hermannstadt, or **Nagy-Szeben,** Austria, the capital of a county in Transylvania. See Szeben, Nagy.

Hermaph'roditism, the occurence of both kinds of sexual glands in one and the same animal. The differentiation of the sexes begins with the polyps, when for the first time in the animal kingdom we meet with individuals which are male and female. The lower plants and in the animal kingdom the sponges and Hydra (q.v.) are monœcious, that is, sexual cells occur in the same individual. In the more highly specialized animals, the sexual glands exist in different individuals, and the form is said to be bisexual, or diœcious, as opposed to hermaphroditic forms.

True or Natural Hermaphroditism.— This is found in many flowering plants, in sponges, most cœlenterates, many worms, including the earthworm, many mollusks, and in most barna-

cles, and this appears to be in relation with their more or less fixed mode of life. As a rule testes and ovaries occur in the same animal, but situated in different regions of the body, while in land snails there is a hermaphroditic gland which produces spermatozoa and eggs in the same follicle. Certain animals, or frogs, which are bisexual as adults, pass through an embryonic hermaphroditism. Normal hermaphroditism is very rare in insects and vertebrates; in the latter only two cases are known, that is, a sea-perch (*Serranus scriba*) and the hagfish (*Myxine*).

Abnormal Hermaphroditism.— What in man is called hermaphroditism is a misnomer, as it arises from malformation of the external reproductive organs. In insects occurs lateral hermaphroditism in which one half of the moth or butterfly, for example, is male and the other female. In some of these cases dissection has shown that only male or female sexual glands alone occur in an undeveloped condition. This is called *gynandromorphism.* Abnormal hermaphroditism sometimes occurs in fishes and batrachians where an ovary is found on one side and a testis on the other. It is curious that in a threadworm (*Angiostomum*) and in certain isopod crustacea (*Cymothoidæ*) the reproductive glands are first male, the same gland afterward producing eggs.

Hermes, Georg, gā-ōrg' hĕr'mĕs, German theologian: b. Dreyerwalde, Westphalia, 22 April 1775; d. Bonn 26 May 1831. He studied theology at the University of Münster, became a teacher in the gymnasium of that city, and in 1807 professor of dogmatic theology in the university. When the Prussian government established the University of Bonn, Hermes was appointed to the chair of Catholic theology (1819). Here he began to distinguish himself by his attempts to found a speculative, philosophic, and dogmatic school in the church itself, delivering a series of lectures which caused great sensation by aiming at an alliance between Protestants and Catholics. This attempt to base the positive theology of the church (a doctrine known as Hermesianism) drew around him great numbers of followers. Many of these in time filled chairs of theology and set forth their views in conjunction with their master in a magazine, the 'Zeitschrift für Philosophie und katholische Theologie,' published at Cologne from 1832. The method which Hermes advocated insisted that the truth of revelation and of the Catholic Church should first be tested by reason, and that revelation should then be followed. He did not go so far as to declare that all the dogmas in themselves could be proved *a priori,* but endeavored to found the right of the church to teach them on the ground of reason. Hermesianism was in fact an ingenious effort to base the doctrines of the church on Kant's system of philosophy. It aroused powerful opposition, being condemned as heretical by a papal letter of 26 Sept. 1835. Hermes' scholars stoutly defended their orthodoxy, many of them repeatedly appealing to the pope, but without success.

Hermes, hĕr'mēz (called by the Romans *Mercurius,* and identified with their own god of that name), in Greek mythology the son of Zeus and Maia. According to legend his birthplace was in the mountains of Cyllene, Arcadia. Four hours after his birth he invented the lyre, which he made by killing a tortoise, and stringing the shell with three or seven strings. He then sang to it the loves of Zeus and his mother Maia. Having concealed the lyre in his cradle, he was seized with hunger, went in the dark evening to Pieria, and stole 50 oxen from the sacred herd of Apollo which he drove backward and forward to confound their tracks; then walking backward himself, he drove them backward also; and after having killed two of them near the river Alpheus roasted and sacrificed a part to the gods. He concealed the remainder in a cavern. He also carefully destroyed all traces of them. The next morning Apollo missed his oxen, and went in search of them, but he could discover no traces of them until an old man of Pylos told him that he had seen a boy driving a herd of oxen in a very strange manner. Apollo now discovered that Hermes was the thief. He hastened to Maia, and accused the infant, who pretended to be asleep, and, not terrified by the threat of the god that he would hurl him into Tartarus, steadily maintained his innocence. Apollo, not deceived by the crafty child, carried his complaint to Zeus. Hermes lied even to him. But Zeus perceived him to be the offender; but was not angry with him, and smiling at his cunning, ordered him to show the place where the oxen were concealed. To secure him Apollo bound his hands, but his chains fell off, and the cattle appeared bound together by twos. Hermes then began to play upon his newly-invented lyre, at which Apollo begged the instrument of the inventor, learned of him how to play on it, and gave him a whip to drive the herd, thenceforth belonging to both in common.

They then concluded a contract with each other: Hermes promised never to steal Apollo's lyre or bow; the latter gave him the *caduceus.* The ancients represent Hermes as the herald and messenger of the gods. He conducts the souls of the departed to the lower world, and is therefore the herald of Pluto, and the executor of his commands. His magic wand had the power to close the eyes of mortals, to cause dreams, and wake the slumbering. The qualities requisite for a herald he possessed in the highest perfection, and bestowed them on others — grace, dignity, and insinuating manners. He was also the symbol of prudence, cunning, and fraud, and even of perjury, and was the god of theft and robbery. In the wars of the giants he wore the helmet of Pluto, which rendered him invisible, and slew Hippolytus. When Typhon compelled the gods to fly before him and conceal themselves in Egypt, he metamorphosed himself into an ibis. He is also mentioned by Homer as the patron of eloquence, and still more particularly by Hesiod. Of his inventions Homer makes no mention. Later writers ascribe to him the invention of dice, music, geometry, the interpretation of dreams, measures and weights, the arts of the palæstra, letters, etc. He was also regarded as the patron of public treaties, as the guardian of roads, and as the protector of travelers. He was represented in art as a boy in the prime of youth, sometimes with the caduceus, and sometimes with a winged cap, standing, sitting, or walking. The artists of later times placed him among the youthful and beardless gods. The most prominent traits of his character are vigor and dexterity. In the

representation of Hermes of a later date the relations of corporeal beauty and mental dexterity are wonderfully preserved. Artists made the cock his symbol, on account of its vigilance or love of fighting (in allusion to gymnastics); the tortoise, on account of his invention of the lyre; the purse, because he was the god of traffic; a ram and a goblet, because he was the director of religious ceremonies and sacrifices; the trunk of a palm-tree, upon which his statues lean, because he was the inventor of arithmetic and writing (upon palm-leaves); the *harpe* or sickle-shaped knife, because he was the slayer of Argus.

Hermes Trismegistus, trĭs-mĕ-jĭs'tŭs, the Greek title of the Egyptian moon god, Thoth, one of the most interesting figures in Egyptian mythology. He is represented as Ibis or with the ibis head, and is fully illustrated in the monuments and papyrus rolls from time to time brought to light. He is the god of time and of its divisions; he is the measurer and the god of measurements. He is the conductor of the dead. He is also the god of human intelligence, to whom are attributed all the productions of human art. All the literature of Egypt is attributed to him — all the writings that relate to the different sciences, mathematics, astronomy, medicine, music. These were called by the Greeks the Hermetic Books. Thoth is also credited with the invention of alchemy and magic. The Hermetic art is used to mean alchemy. The secrets of this art were handed on from teacher to pupil orally and in secret and this transmission was termed the Hermetic chain. For these reasons the Greeks identified him with their Hermes, and besides called him Trismegistus, "thrice great." By later writers, Euhemerists, Neoplatonists (q.v.), and Christians, Thoth was considered a great Egyptian king, a teacher of mankind, who had left books of magic and mystery behind him. Numerous books of such a sort once existed in Egypt. Clement of Alexandria knew of 42, and so-called Hermetic fragments are still extant in the works of Stobæus, Cyrillus, Suidas and Lactantius. The Hermetic books as we know them belong probably to no earlier date than the 3d or 4th century of our era, and are in Greek and Latin.

Her'mit (Gr. *eremitēs*), a solitary ascetic, who, with a view to more complete freedom from the cares, temptations, and business of the world, took up his abode in a natural cavern or a rudely formed hut in a desert, forest, mountain, or other solitary place. Hermits began to appear in the Christian church in the 3d century. The advocates of asceticism (q.v.) were the first to set the example of retiring from cities to rural districts and villages. But the hermits sought to withdraw altogether from mankind, that they might give themselves up to holy contemplation. The earliest hermit is said to have been Paul of the Thebaid (Egypt), who during the Decian persecution fled to the desert (250); there he lived for the rest of his life, dying, 113 years old, about 342. The fame of his sanctity quickly incited others to imitate his mode of life. The most famous amongst these successors was St. Anthony (q.v.). At the time of his death (365) hermit cells existed in considerable numbers in the deserts of Egypt, Syria, and Palestine. The fame of their sanctity drew many to visit these hermits partly out of curiosity, to get religious advice from them, partly also in the belief that diseases were cured by their blessing. Sometimes they returned for a short time to the midst of their fellow-men to deliver warnings, instruction, or encouragement, and were received as if they had been inspired prophets or angels from heaven. But the number of hermits gradually diminished as the cenobite life of convents grew into fashion. Indeed the institution at no time secured the same footing in the Western Church that it did in the Eastern; and perhaps the reason may in part be found in the difference of climate, which renders a manner of life impossible in most parts of Europe that could be pursued for many years in Egypt or Syria. Partial revivals of the practice continued to be made, however, during some centuries, St. Cuthbert (q.v.) being a case in point. See Monachism, and Charles Kingsley's 'Hermits' (1869).

Hermit-crabs, crabs that shelter themselves in spiral sea-shells, for the protection of the soft-skinned and unsymmetrical abdomen. They are members of the *Macrura* (see Decapoda), and have very large and generally unequal claws, one being used to close the entrance of the shell into which the hermit can wholly retract himself. The abdominal appendages are practically aborted, with the exception of those at the tip of the tail, which hold firmly to the spire of the inhabited shell. The hermit-crabs belong to three families, namely: *Paguridæ,* or common marine hermit-crabs; *Parapaguridæ,* or deep-sea hermit-crabs; and *Cenobitidæ,* or terrestrial hermit-crabs. Two species are numerous on the American Atlantic coast running actively about in rock pools and shallows. The little hermit-crab (*Eupagurus longicarpus*) generally inhabits the shells of dog-whelks (*Ilyanassa*), while the larger species (*E. pollicaris*) occupies those of *Lunatia* or sometimes of the winkles and conchs. As they grow they must move to larger and larger shells, and the search for new tenements and dangerous change of abodes in the presence of enemies makes the life of one of these animals more than ordinarily exciting. The habits of these and other hermit-crabs are of great interest, generally, and especially on account of the various hydroids, anemones and mollusca which associate with them as commensals. The palm or robber-crab (q.v.) of the East Indies, and the land-crabs of the West Indies, are good examples of terrestrial hermit-crabs. Consult J. R. Henderson, 'Challenger Report on Anomura'; Verrill, 'Invertebrates of Vineyard Sound' (1875); Arnold, 'Sea Beach at Ebb-tide' (1901). See Commensalism, Crab, Crustacea.

Hermit Thrush. See Thrush.

Her'mitage, The, Andrew Jackson's home at Nashville, Tenn., from about 1804, when he removed there from Hunter's Hill. In 1819 the house was built in which he lived till his death in 1845. The Hermitage is now the property of the State of Tennessee.

Hermite, Charles, shärl ār-mēt, French mathematician: b. Dieuze, Meurthe, German Lorraine, 24 Dec. 1822; d. Paris 14 Jan. 1901. He entered the Ecole Polytechnique in 1842, but left it to devote his attention wholly to mathematics. From 1876 to his death he held the chair of higher algebra in the University of

Paris. His principal claim to be considered a great and original mathematician rests on his investigations in the line of functions, and his first important work on this theory won for him election to the Academy of Sciences. He proceeded to make discoveries in the theory of algebraic forms and in the theory of numbers. He finally settled the question of the solubility of the quintic equation, and really led the way to Lindemann's further investigations. For a list of his writings see 'Catalogue of Scientific Papers of the Royal Society of London,' Vols. III. and VII.

Hermosillo, hār-mō-sēl'yō, Mexico, capital of the state of Sonora, on the river Sonora, about 60 miles from the Gulf of California, and 78 by rail north from the port of Guaymas, with which it has a large traffic, being the principal entrepôt for the trade with the interior. Large quantities of fruit are grown in the vicinity, especially grapes, from which much brandy is made. Pop. (1903) 17,800.

Hern'don, William Henry, American lawyer: b. Greensburg, Ky., 28 Dec. 1818; d. near Springfield, Ill., 18 March 1891. He studied at Illinois College, was admitted to the bar in 1844, and in the same year formed a law partnership with Abraham Lincoln, which continued formally till the latter's death. He was mayor of Springfield, Ill., in 1855. With J. W. Weik, he wrote the well-known 'Herndon's Lincoln: The True Story of a Great Life' (in a new ed. 1891), which is particularly valuable for the study of Lincoln's personality and the details of his early career.

Herne, James A. (JAMES AHERNE), American actor and playwright: b. Troy, N. Y., 1 Feb. 1840; d. New York 2 June 1901. He first appeared in a traveling company, and later in various roles and organizations throughout the United States. Later he was actor-manager at San Francisco, and in 1878 presented his first play, 'Hearts of Oak,' which won immediate success. 'Drifting Apart' (1885), 'The Minute-Men' (1886) and 'Margaret Fleming' (1890) were less favorably received, although the last was highly ranked by the critics. In 1883–4 Herne wrote his most successful work, 'Shore Acres,' which was first performed as 'The Hawthornes' at Chicago in 1892, and in 1892–3 in Boston under its present title. He himself appeared as 'Uncle Nat' Berry. 'Shore Acres' was followed by 'The Rev. Griffith Davenport' (1899), a dramatization of Helen Gardner's 'An Unofficial Patriot,' and 'Sag Harbor' (1900). As both actor and dramatist Herne was a skilful delineator of types of everyday life.

Her'nia (Latin, a rupture, a burst, a descent), a swelling formed by the displacement of a soft part, which protrudes by a natural or accidental opening from the cavity in which it is contained. The three great cavities of the body are subject to these displacements. The brain, the heart, the lungs, and most of the abdominal viscera may become totally or partially displaced, and thus give rise to the formation of hernial swellings. Displacements of the brain and of the organs of the chest are, however, extremely rare, and are in general the result or symptom of some accident or disease. Many parts of the abdominal wall may become the seat of hernias, but they most commonly appear in the front lower regions, which, being destitute in great measure of muscular fibres, and being the site of many of the openings leading from the abdomen to the limbs, offer less resistance to the displacement of the viscera. Hernias are most common in the groin, at the navel, more rarely in the vagina, at the interior and upper part of the thigh, and at its lower and posterior part. They have received different names from their positions. All the abdominal viscera, with the exception of the duodenum, the pancreas, and the kidneys, may form a hernia, but they are not all displaced with the same facility. The omentum and intestinal canal escape easily; the stomach, liver, and spleen rarely form hernias. Most of the viscera, when displaced, push the peritoneum forward before them; this membrane thus forms a covering to the hernia, which is called the hernial sac. If the hernia, with its sac, can be entirely replaced, it is said to be reducible; if, from its size or other cause, it cannot be restored to its former place, it is irreducible.

Among the predisposing causes of hernia may be ranked any circumstance which diminishes the resistance of the abdominal walls, whether natural or accidental; such as muscular weakening of those walls by a forced distention, as in pregnancy, by accidents, by lifting heavy weights, or by excessive standing. Any prolongation of the viscera which tends to bring them in contact with points at which they may protrude, and articles of dress which push the organs toward the weaker parts of the abdominal wall (as corsets), may also produce hernia. The efficient causes of hernia are all circumstances which may break the equilibrium existing between the abdominal walls and the viscera, which react and mutually press upon each other. The simultaneous contraction of the abdominal muscles and of the diaphragm, which takes place on every violent effort, is one of the chief of these cases. Hence sneezing, coughing, leaping, playing on wind-instruments, etc., may be the direct cause of a hernia.

The symptoms of a hernia are the existence of a tumor or swelling at any point of the abdomen, but more particularly in the region of the groin. A reducible hernia is not a very troublesome disease, but may become so by acquiring an increase of size, and by strangulation. A hernia is said to be strangulated when it is not only irreducible, but also subjected to a continual constriction; this constriction may be produced by different causes, but it is generally a constriction at the opening through which the hernia protrudes. As soon as a patient perceives that he is affected with a hernia he should have recourse to medical advice, for the disease is then in its most favorable state for treatment. The hernia is immediately reduced, and must then be subjected to a constant compression. This is done by means of a truss (q.v.). An irreducible hernia must be supported with great care. All violent exercises and excess in diet must be avoided. Strangulated hernia, presenting greater danger, requires more prompt relief. The object of treatment is to relieve the constriction. If the reduction cannot be effected by other means, an operation will be necessary. This consists in dividing the parts which produce the constriction. The longer this opera-

tion is delayed, the more dangerous it will become. After the parts are healed, the opening must be subject to compression, as in the case of a simple hernia. Radical operation for hernia is the most advisable form of treatment. It is safe in the hands of a competent surgeon.

Hero, a priestess of Aphrodite at Sestos. The loves of Hero and Leander, a youth of Abydos, on the other side of the Hellespont, are related in a poem by Musæus. No difficulties could discourage Leander. He swam every night across the Hellespont, guided by a torch which shone across the strait from the tower of Hero, and even continued his visits during the winter. On one occasion, however, the guiding light was extinguished, and his strength failed him, and the waves carried his body to the foot of the tower, where Hero anxiously awaited him. Overcome with anguish at the sight, she threw herself from the tower and perished.

Hero of Alexandria (Gr. *Herōn*), Greek mathematician and natural philosopher; fl. perhaps in the 1st century A. D. He seems to have invented a number of machines, among which are "Hero's fountain," and a steam-engine on a principle similar to that of Barker's mill (q.v.). He also made some contributions to pure mathematics. Hultsch edited the remaining fragments of his geometrical works in 1864, and Schmidt began in 1899 an edition of his complete extant writings. See HERO'S FOUNTAIN.

Herod, called THE GREAT, king of the Jews: b. about 62 B.C.; d. 4 B.C. He reigned from 37 B.C. until his death. He was the second son of Antipater the Idumean, who, being made procurator of Judea by Julius Cæsar, appointed him to the government of Galilee. He at first embraced the party of Brutus and Cassius, but after their death reconciled himself to Antony, by whose interest he was first named tetrarch, and afterward king of Judea. After the battle of Actium Augustus confirmed him in his kingdom. As a politician and commander, his abilities were conspicuous. He rebuilt the temple at Jerusalem with great magnificence, and erected a stately theatre and amphitheatre in that city, in which he celebrated games in honor of Augustus, to the great displeasure of the more zealous of the Jews. He also rebuilt Samaria, which he called Sebaste, and adorned it with very sumptuous edifices. He likewise, for his security, constructed many strong fortresses throughout Judea, the principal of which he termed Cæsarea, after the emperor. On his palace, near the temple of Jerusalem, he lavished the most costly materials, and his residence of Herodium, at some distance from the capital, by the beauty of its situation, drew around it the population of a great city. Such, indeed, was his magnificence, that Augustus said his soul was too great for his kingdom. Herod was the first who shook the foundation of the Jewish government, by dissolving the national council, and appointing the high-priests, and removing them at pleasure, without regard to the laws of succession. His policy, ability, and influence with Augustus, however, gave a great temporary splendor to the Jewish nation.

Herod Agrip'pa I., king of Judea: d. Cæsarea 44 A.D. He reigned from 37 A.D. until his death. He was son of Aristobulus. At Rome with Drusus, son of Tiberius, on whose death he left Rome for Idumæa; but returned some years after. On the accession of Caligula 37 A.D. he was honored with the title of king, and received the tetrarchies of Philip and Lysanias, and later that of Antipas. Upon the accession of Claudius his rule was extended to include all the dominions of Herod the Great. It was this Herod who, to please the Jews, caused St. James to be put to death, and St. Peter to be imprisoned. His power and opulence acquired him a great reputation, and he really did much for the benefit of the Jews. His death is described in Acts xii. 20–3.

Herod Agrippa II., king of Judea: d. 100 A.D. He reigned from 53 A.D. until his death. He was son of Herod Agrippa I. He resided much at Jerusalem, and here, together with his sister, Berenice, heard the defense of Paul, addressed to the Roman governor Festus (Acts xxv. 13–xxvi. 32). A great builder, he improved his capital city of Cæsarea Philippi; renamed by him Neronias. It was in his reign that the Temple was completed. Being driven from Jerusalem in the revolt which proved so fatal to the Jews, he joined Cestius, the Roman commander, and, when Vespasian was sent into the province, met him with a considerable reinforcement. During the siege of Jerusalem he was very serviceable to Titus.

Herod An'tipas, tetrarch of Galilee. He reigned from 4 B.C. to 37 A.D. He was son of Herod the Great. This was the Herod who put to death St. John the Baptist (Mark vi. 14–29), in compliment to his wife Herodias, and it is he who is the familiar 'Herod' of the New Testament narrative. Accused of having been concerned in the conspiracy of Sejanus, and of being in secret league with the king of Parthia, he was stripped of his dominions, and sent (39 A.D.) with his wife into exile at Lugunum (Lyons), or, as some say, to Spain, where he died.

Herodes, Atticus. See ATTICUS HERODES.

Hero'dias, a granddaughter of Herod the Great and Mariamne, daughter of Aristobulus and sister of Herod Agrippa I. She was first married to her half-uncle Herod Philip, whom she abandoned to connect herself with his half-brother Herod Antipas. It was by her artifice that Antipas was persuaded to order the death of John the Baptist (Matt. xiv. 3–12; Mark vi. 17–29).

Herod'otus, Greek historian, called the "father of history": b. at Halicarnassus in Asia Minor about 484 B.C. Before writing his history he traveled extensively, visiting the shores of the Hellespont and the Euxine, Scythia, Syria, Palestine, Babylon and Ecbatana, Egypt as far as Elephantine and other parts of northern Africa, everywhere investigating the manners, customs, and religion of the people, the history of the country, productions of the soil, etc. On returning home he found that Lygdamis had usurped the supreme authority in Halicarnassus, and put to death the noblest citizens, and Herodotus was forced to seek an asylum in the island of Samos. Having formed a conspiracy with several exiles he returned to Halicarnassus and drove out the usurper, but the nobles who had acted with him immediately formed an

aristocracy more oppressive than the government of the banished tyrant, and Herodotus withdrew to the recently founded colony of Thurii, in Italy, where he seems to have spent most of his remaining life. Here, at an advanced age, we are told by Pliny, he wrote his immortal work, a statement strengthened by the fact that events are noticed in the body of the book which occurred so late as 409 B.C., while its abrupt ending proves almost beyond question that he was prevented by death from completing it. The history is divided into nine books, each bearing the name of a Muse, and is written in the Ionic dialect. The object of the historian is to narrate the conflict between the Greeks and Persians, and he traces the enmity of the two races back to mythical times. Passing rapidly over the mythical period he comes to Crœsus, king of Lydia, of whom and of his kingdom he gives a comparatively full history. The conquest of Lydia by Cyrus induces him to relate the rise of the Persian monarchy and the subjugation of Asia Minor and Babylon. The history of Cambyses and his Egyptian expedition leads him to introduce the valuable details of the history, geography, and manners and customs of Egypt, occupying the second book. The Scythian expedition of Darius causes the historian to treat of the Scythians and the north of Europe; and the subsequent extension of the Persian kingdom affords him opportunity for an account of Cyrene and Libya. In the meantime the revolt of the Ionians breaks out, which eventually brings on the conflict between Greece and Persia. An account of this outbreak and of the rise of Athens after the expulsion of the Pisistratidæ, is followed by what properly constitutes the principal part of the work, and the history of the Persian war now runs on in an uninterrupted stream until the taking of Sestos. There are English translations of his history by Macaulay (1890); Beloe, Cary, and Rawlinson, the last with important notes and dissertations. The 'Life of Homer,' attributed to Herodotus, and printed at the end of several editions of his works, is now universally believed to be a production of a later date. The best editions of the history of Herodotus are by Wesseling (1763); Schweighäuser (1806); Bähr (1855-61); Stein (1871).

Heroin, hĕr'ō-ĭn, $C_{17}H_{17}NO_3.(CH_3CO)_2$, the diacetic ester of morphine. It occurs as a faintly bitter, colorless, odorless, crystalline powder, which is nearly insoluble in water. It is soluble in dilute acids, however, and is precipitated by alkalies. Its hydrochloric dissolves freely in water and in alcohol, but is insoluble in ether. Heroin was first prominently introduced to the medical world in 1898.

Herold, Louis Joseph Ferdinand, loo-ē zhō-zĕf fĕr-dē-năñ ā-rōld, French musical composer: b. Paris 28 Jan. 1791; d. Thernes, near Paris, 19 Jan. 1833. A pupil of the Conservatoire, he also studied composition under Catel, Méhul, and Cherubini, and in 1812 won the Prix de Rome with the cantata 'Mlle. de la Vallière.' His first opera, 'La Gioventú di Enrico Quinto' (1815) was received by the Neapolitan public with applause. His first serious début as composer for the French stage was with his comic opera 'Les Rosières' (1817). This very successful work was followed in quick succession by numerous others of varying fortune. At last in 1831 appeared his 'Zampa,' and in 1832 his 'Le Pré aux Clercs,' the operas on which his fame chiefly rests, and which have gained a permanent place, the former especially being still produced with acceptance in the principal cities of the Continent. Consult: Jouvin, 'Herold sa Vie et ses Œuvres' (1868).

Her'on, Matilda, American actress: b. Draperstown, near Londonderry, Ireland, 1 Dec. 1830: d. New York 7 March 1877. She was brought to the United States as a child, and appeared on the stage for the first time in Philadelphia as Bianca in 'Fazio.' Her chief parts, in which she met with great success throughout the United States, were Camille in 'La Dame aux Camélias'; and Ulah in 'De Soto.'

Herondas, or **Herodas,** Greek poet, probably flourishing about the latter half of the 3rd century B.C. Little positive information is obtainable concerning the place of his birth, but it was probably in the island of Cos. Prior to 1891 only a few fragments of his verses had been found, but in that year an Egyptian papyrus was found containing several poems (mimes or mimianibi) and these were published by F. G. Kenyon, thus bringing to light a phase of Greek life and times of which the history has been meagre. Seven of the poems are in comparatively complete form, and, besides giving an insight into Heronda's life and work, they picture the every day life of the times in extremely realistic terms, though the satirical portions of them are not personal in their nature. In composition the mimes are in choliambic verse or iambic trimeter and are written in the Ionic dialect. The latest edition containing additions by O. Crusius was published in 1898, entitled 'Untersuchungen zu den Mimiamben des Herondas.' See MIME.

Herons, wading birds of the order *Herodii*, forming, with egrets and bitterns, the family *Ardeidæ*. The family is characterized by a thin, compressed body; a long, thin neck; a straight, narrow, pointed beak; fully feathered head; longish, slender legs; three toes in front, the two outer united by a membrane, the middle claw pectinate; large, blunt wings; extensive development of powder-down tracts; and often by elongated feathers of the top of the head and other parts. Upward of 70 species of herons and their immediate allies are known, of which 14 inhabit North America. The bitterns (q.v.), with 10 tail-quills, form the sub-family *Botaurinæ*, the herons and egrets (q.v.), with 12 tail quills, the *Ardeinæ*. Egrets are simply white herons. The great blue heron (*Ardea herodias*) to which *A. cinerea* of Europe is closely related, inhabits all parts of North America and northern South America. It is a large bird with a length of about four and a spread of nearly six feet, and of beautiful slate-blue color, with the long flowing plumes black. It is to be found by the side of streams, lakes and the seashore, usually alone. Fish form the bulk of its food, but it also devours frogs, small reptiles, insects, and almost any kind of animal which it can capture. It roams in search of food mostly in the morning and evening. The heronry, or breeding-place, is usually found among high trees, and the same breeding-place is used by successive generations if they are unmolested: frequently several species of herons consort together at a favorite breeding-place. The large

nest is made of twigs and sticks, and is lined with rushes, grass, and various similar materials. The eggs, usually three or four in a nest, are of a fairly uniform greenish blue color. Many nests are usually found in one heronry, and sometimes the nests are built on the ground or on a cliff. The cry is a sort of "crank, crank," uttered in a hoarse voice. In the North the blue heron is migratory, elsewhere it is resident. The little blue heron (*A. cærulea*) is found in the eastern United States from the Middle States southward and in the West Indies and Central America. It is scarcely more than one half the size of *A. herodias* and exists in two color phases, the one dark slate-blue with purplish reflections on the head and neck, the other white with traces of blue, especially constant on the unfeathered parts. This species formerly bred with other southern species in great heronries, most of which have been decimated by plume-hunters.

The little green heron or fly-up-the-creek (*Butorides virescens*) ranges throughout temperate North America and somewhat beyond southward, breeding nearly everywhere. Northward it is migratory and is the familiar heron about the streams and ponds of the Middle and New England States, where it usually nests in pairs or small communities and mostly in thick bushes or cedar trees; in other localities it sometimes breeds with larger species in heronries. The pale greenish elliptical eggs are from three to six in number. Its foods consist chiefly of small frogs, minnows and snakes, for which it searches by day as well as by night along the shallows of streams, where its harsh cry of alarm is often the first intimation of its presence. The name refers to the beautiful deep bronze green color of the upper parts.

The night-herons (*Nycticorax nævius*, and *N. violaceus*), which are closely related to the *N. grisea* of Europe, are easily distinguished from other herons by the thick, stout beak. The former, known as the black-crowned night-heron or squawk, is common throughout the United States and Canada in summer, and in the winter migrates far into South America, while the latter, or yellow-crowned species, is much less frequent and chiefly confined to the sea-coast of the warm parts of America. The squawk is about two feet long, the young brownish, the adults deep green and blue-gray above with two or three very long filamentous white occipital plumes. The night-herons are more active after dark than any other species, and are seldom seen abroad, except in the dusk or on cloudy days.

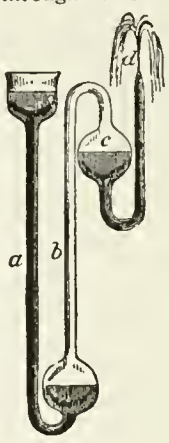
Many species of herons reside in the warm parts of Africa and Asia, among them being the largest of all, the *A. goliath*.

Consult Baird, Brewer and Ridgway, 'Water-birds of North America' (1884); Reichenow, 'Journal of Ornithology' (1877); Job, 'Among the Waterfowl' (1902). See BITTERN; EGRET.

Heroöpolis, an ancient Egyptian city found by excavation in the eastern Delta region. Maps made prior to 1880 generally located the city near the present city of Suez, but the excavations of Naville in 1883 under the auspices of the Egypt Exploration Fund tend to show that the city was farther north. Heroöpolis is given in the Septuagint version of the Old Testament as the meeting place of Joseph and Jacob. The Coptic translation is Pethom, very similar to the Hebrew Pithom, or "House of Tum," and for some time it has been known from Egyptian geographical lists that Pithom was situated in the land of Theku-t. This name has been identified with Succoth, the second resting place of the Children of Israel in their flight from Egypt. The Naville excavations brought to light the old site of Pithom and Succoth, the excavations being made at Tell el-Mashhutah, twelve miles west of Ismailah. A mile-stone which was recovered then showed the distance between Heroöpolis and Clysma to have been nine miles. This would confirm the view taken by Strabo that the city was at the head of the Red Sea navigation and was situated on what he called "Heroöpolitan Gulf," but if his view be correct, then it can only be inferred that the Red Sea extended at that ancient date further north than it now does and that the place where the Israelites crossed was not where it is generally supposed to be, but considerably further north.

Herostratus. See EROSTRATUS.

Hero's Fountain, a pneumatic apparatus, through which a jet of water is supported by condensed air. A simple mode of constructing it by means of glass tubes and a glass-blower's lamp is shown in the annexed figure. The column of water in the tube *a* compresses the air in *b;* this presses on the surface of the water in *c,* and causes it to gush out at *d*.



Hero's Fountain.

Herpes, an acute, non-contagious, inflammatory disease of the skin, characterized by an eruption of one or more clusters of vesicles upon a reddened base. Several forms of the disease are recognized by dermatologists, of which the commonest are facial herpes, and herpes zoster. Facial herpes constitutes the common fever blister, or cold sore, and is usually seen about the mouth, though it also occurs on other parts of the face. There is often some slight constitutional disturbance preceding the eruption, which first makes its advent known by a sensation of burning or itching in the part, followed by reddish discoloration of the skin and after a few hours by a number of pin-head to pea-sized blisters filled with clear or turbid fluid. After a few days these dry up and form a yellowish crust, which then falls off, leaving a red spot that soon disappears. The usual duration of the disease is about a week and it shows a strong tendency to recur. Herpes often accompanies febrile conditions such as pneumonia and malaria, and a similar lesion is not rare about the genitals. Herpes occurs mostly in those whose skin is irritable or delicate, and is usually the result of some derangement of the mucous membrane of the respiratory, digestive or genito-urinary tract. It sometimes is the unfailing harbinger of the menstrual period. Cold, mental depression, and injury or irritation of the skin are other causes. The disease belongs to the class of the neuroses, and in some instances its presence

can be explained only on the basis of nerve disturbance. In most cases no treatment is required, as the lesions promptly heal of their own accord, but soothing ointments or lotions tend to relieve the irritation. Herpes zoster, or shingles, is a special form remarkable for the fact that the eruption follows the course of certain nerves, and is usually disposed around one side of the body like a half belt. In rare cases it encircles the body. Its onset is preceded by stinging neuralgic pains, and by languor, lassitude, loss of appetite, shiverings, headache, nausea, quickened pulse, etc., after which the eruption appears in irregular patches. The vesicles become enlarged to the size of small peas in twenty-four to thirty-six hours, and fresh clusters occur for three or four days, completing the belt-like appearance. As the eruption recedes, by the fifth or sixth day, the vesicles become white and opaque, and the red margins grow livid or purple. Sometimes the vesicles burst, and several of the patches run together, forming irritable sores, discharging a thin serous fluid, which concretes and forms a crust that falls off as the parts beneath heal. The disease occasionally follows injuries to the nerves, and it is common in damp, cold weather of spring or autumn, when it sometimes occurs in epidemics. It is sometimes produced by sudden exposure to cold after violent exercise, and sometimes follows acute affections of the respiratory organs. The treatment consists in attention to any systematic derangement present and in the local use of soothing applications, and protective dressings to prevent rupture of the vesicles. The duration of shingles is usually from ten days to three weeks. Most cases run a favorable course and second attacks are rare.

Herpestis, a genus of dicotyledonous gamopetalous plants, of the natural order *Scrophularineæ*, of the tribe *Gratioleæ*, native to the tropical sections of both hemispheres. It may be distinguished by its calyx, as the upper segment is large and ovate, and covers the rest, the other lobes narrow or linear, its cylindrical corolla, four stamens, and two or four-valved capsule. The genus comprises about fifty species of small, creeping herbs, having opposite, or toothed leaves, and generally flowering solitary or in axillary clusters of yellow, blue or white flowers. *H. Monniera* is the common water hyssop, and the natives of India find the juice of this plant, when mixed with petroleum, of great benefit to parts of the body affected with rheumatism. *H. colubrina*, a native to Peru, is used, under the name of *yerba de colubra*, as a remedy for the bites of poisonous animals.

Herpetology, hĕr-pĕ-tŏl'ō-jĭ, the study of reptiles. In its earlier days it included under the term "reptile" not only those now properly so named, but the amphibia (q.v.) and some other "creeping things" not in either group. Cuvier's classification, the first approach to a scientific one, put both the true reptiles and the amphibians as co-related groups under *Reptilia;* but their formal distinction was soon perceived. Huxley showed that in their descent, embryology and structural relations, the amphibians were more closely related to fishes than to the reptiles (lizards, serpents and turtles). He therefore united the two in a superior group *Ichthyopsida*, while he joined the birds to the reptiles in a group of similar rank called *Sauropsida*. Thus the limits of herpetology have been restricted to truly scientific limits,— the chordate class *Reptilia*, a definite group distinguished by the following characters:

Reptiles are cold-blooded, the temperature of the body not greatly exceeding that of the surrounding medium; the heart is three-chambered, except in crocodilians, where four chambers first occur; mostly venous blood goes from the heart to the anterior viscera, and mixed blood to the posterior region, only the head and anterior regions receiving purely arterial blood; the body is covered with scales, with which subjacent bony plates or scutes are sometimes associated; the vertebræ are absolutely gastrocentrous (biconcave); the skull articulates by a single condyle with the backbone, and the lower jaw works against the quadrate bone; the great majority are oviparous, while in some the eggs are hatched within the mother.

This characterization unites into the one class, many orders of wholly extinct types, one order represented by a single living example (the tuatara "lizard"), and the existing tortoises and turtles, lizards, snakes, and crocodiles; and none other is a reptile, properly speaking. The group occupies a central position in the vertebrate series. Above it on the scale of organization are the birds and mammals; beneath it the amphibians and fishes. Similarly reptiles stand in a middle position in geological history, as the Mesozoic, or Secondary Period, was that in which the group flourished, and of which the existing forms are, on the whole, the diminished and degraded remnants. In respect to their phylogeny: "On the one hand, there is not the slightest doubt," declares Gadow, "that they are evolved from some branch of the Stegocephali (q.v.), whilst on the other hand the reptiles, probably through some branch of the Theromorpha, have given rise to the mammals; some other reptilian branch, at present unknown, blossomed out into birds."

Classification.—The most recent classification of the reptiles, perfected since about 1875 by the enormous amount of information collected in all parts of the world, and especially in the western United States, in regard to fossil forms (see PALÆONTOLOGY), is that formulated by H. Gadow ('Amphibia and Reptiles,' 1901), expressing substantially the consensus of all specialists, and is as follows:

CLASS REPTILIA.

SUBCLASS I. *Proreptilia.*—Permian reptiles in which the components of the vertebra remain separate; well developed limbs and girdles fitted for a terrestrial life. The fragmentary remains of these animals are hard to separate definitely from the Stegocephali.

SUBCLASS II. *Prosauria.*—Chiefly extinct reptiles with deeply amphicœlous vertebræ whose parts are still unfused; movable chevron bones occur in the tail and frequently, with intercentra, in the trunk.

Order I.—*Microsauri.*—Small Carboniferous and Permian reptiles with dermal armor on the dorsal and ventral side of the trunk and tail; and ribs with head and tubercle. The armor of the skull, and the flat ischia and pubes of the pelvis resemble the condition in Stegocephali.

Order 2.— Prosauri.— Permian to recent, terrestrial, unarmored, generalized reptiles, of which one species (*Sphenodon,* or *Hatteria, Punctatum*) still persists in New Zealand (see TUATARA). This animal is distinguished from the lizards with which it was formerly placed by many skeletal characters, such as the fixed quadrate bone and the broad bony roof of the mouth.

SUBCLASS III. *Theromorpha.*— Fossil reptiles with fixed quadrate bone, only one temporal arch, and having pubes and ischia united ventrally in one broad symphysis. This group has an especial interest because it is probably the one from which mammals sprang, and flourished between the Permian and Triassic ages. See THEROMORPHA.

SUBCLASS IV. *Chelonia.*— Reptiles with an upper and lower bony shield, four feet, and toothless jaws — the turtles. There are two orders, *Athecæ* and *Thecophora.* See CHELONIA.

SUBCLASS V. *Dinosauria.*— Mesozoic reptiles, having a long tail, powerful hind legs, fixed quadrate bones, and bifurcated ribs. It is divisible into several orders. See DINOSAURIA.

SUBCLASS VI. *Crocodilia.*—Four-footed, long-tailed reptiles, with fixed quadrate bone, teeth in alveolæ and confined to jaws; ischia not united by a symphysis. The group had its origin in the Dinosauria, from which it is difficult sharply to separate it, arose in the Mesozoic era, and the early forms were marine. The strict *Crocodilia* first appeared in the lower Jura, and have evolved along two parallel lines of advance, one of which ends in the recent long, sharp-snouted gavials, and the other in the broad, short-snouted crocodiles and alligators (qq.v.). The skin is covered with horny scales or scutes which, in some fossil species formed an osseous armor. The front nasal openings lie on the dorsum of the snout near its apex, and their hinder ends are carried by the broad and deep palate far back into the throat. By this means the alligator can lie submerged with its mouth open so as to bring the nostrils to the surface and thus breath without carrying water into the windpipe. The lungs are large and of complicated structure. The heart has practically four chambers as in mammals. There are three orders: *Pscudosuchia,* early generalized forms, expiring in the Jurassic age; *Parasuchia,* extinct forms of the Jurassic and Triassic periods (See CROCODILE, FOSSIL; BELODON); *Eusuchia,* modern crocodilians. See CROCODILE.

SUBCLASS VII. *Plesiosauria.*—Mesozoic reptiles, with pentadactyle appendages adapted to life in water; fixed quadrate bones, numerous alveolar teeth, and ribs without tubercles. They apparently filled the place of the dolphins of to-day, except that the neck is in most species extremely long. See PLESIOSAURIA.

SUBCLASS VIII. *Ichthyosauria.*— Mesozoic, marine, whale-like, viviparous reptiles, with appendages transformed into paddles. The teeth are conical, lie in a groove and are very numerous. See ICHTHYOSAURIA.

SUBCLASS IX. *Pterosauria.*— Mesozoic aërial reptiles with fixed quadrate and anterior appendages forming wings — the pterodactyls. See PTEROSAURIA.

SUBCLASS X. *Pythonomorpha.*—Elongate marine cretaceous reptiles with movable quadrate bones; appendages shaped like paddles, teeth fused with jaws. Two orders, *Dolichosauri* and *Mosasauri.* See MOSASAURS.

SUBCLASS XI. *Sauria.*— Reptiles with movable quadrate bones and transverse cloacal opening; the most recent of the reptiles, probably originating in the *Prosauria.* It contains two orders: *Lacertilia* (geckos, lizards, and chameleons); and *Ophidia* (snakes).

Bibliography.— Huxley, 'Anatomy of Vertebrated Animals' (1879); Hoffmann in Bronn's 'Klassen und Ordnungen des Thierreichs' (Leipsic, in progress); Duméril and Bibron, 'Erpétologie Générale' (9 vols. Paris, 1834–54); British Museum Catalogues by Boulenger, etc.; Holbrook, 'North American Herpetology' (1836–42); Zittel-Eastman, 'Text-book of Paleontology' (1902); Gadow, 'Amphibia and Reptiles' (1901).

Herrera, Francesco de, frän-thēs'kō dā ār-rā'rä, called EL VIEJO (the Elder), Spanish painter: b. Seville 1576; d. Madrid 1656. He broke with the Italian traditions of Spanish painting and became the founder of the Spanish national school. He also worked in bronze, and it was this probably which gave rise to the charge that he was connected with counterfeiters. He had a disposition so very detestable that his pupils, of whom Velasquez was one, all left him. The Louvre contains some of his works, among others 'The Israelites Gathering the Quail in the Wilderness.' But the best are at Seville, including the 'Last Judgment,' in the Church of San Bernardo; 'Saint Peter,' in the Cathedral; and 'Moses Smiting Water from the Rock,' one of four large canvases in the archiepiscopal palace. His frescoes at both Madrid and Seville have quite disappeared.

Herrera, Francesco de, called EL MOZO (the Younger), Spanish painter: b. Seville 1622; d. Madrid 1685. He studied art under his father, Francesco, called El Viejo (q.v.) (to whom he was very far inferior as a painter), and remained some years at Rome. He was a founder of the Seville Academy (1660), and became its vice-director. Subsequently he was appointed court-painter to Philip IV. In the Seville Museum is his 'Four Doctors of the Church Adoring the Host'; in the Prado Museum, 'Saint Hermenegild.' During his residence in Italy he painted fish with such success that he was known there as 'Lo Spagnuolo dei Pesci.'

Herrera, José Joaquin de, hō-sā' hō-ā-kēn, Mexican military officer: b. Jalapa 1792; d. Tacubaya 10 Feb. 1854. He joined the Mexican army in 1809, and in 1821 was promoted brigadier-general. He aided in overthrowing Iturbide, when the latter became emperor, and was successively minister of war and president of the supreme court. President for a brief period in 1845, he again held office in 1848–51. During the war with the United States, he was aide to General Santa Anna.

Herreshoff, hĕr'rĕs-hŏf, **John B.,** American shipbuilder: b. Bristol, R. I., 1841. Under his management the Herreshoff Manufacturing Company succeeded Edward Burgess in designing and building the fastest yachts in the world. Although he has been blind since the age of 15, he has always been active in business.

Herreshoff, Nathaniel Greene, American shipbuilder: b. Bristol, R. I., 1848. He was

educated at the Massachusetts Institute of Technology, and was graduated Sc. M., at Brown University. He is superintendent of the Herreshoff Manufacturing Company, and has designed many torpedo-boats and yachts, notably those sloops which have engaged in the international races of recent years.

Her'rick, Christine Terhune, American writer on domestic economy: b. Newark, N. J., 1859. She is a daughter of M. V. Terhune (q.v.) and has published: 'Housekeeping Made Easy' (1888); 'The Little Dinner'; 'Liberal Living Upon Narrow Means'; 'First Aid to the Young Housekeeper' (1900); etc.

Herrick, Clarence Luther, American college president: b. Minneapolis, Minn., 21 June 1858. He was graduated from the University of Minnesota in 1880, and after holding professorships at Denison University, Ohio, and the University of Chicago, became president of the University of New Mexico at Albuquerque.

Herrick, Myron T., American capitalist and politician: b. Huntington, Lorain County, Ohio, 1854. He studied at Oberlin College and Ohio Wesleyan University, went to Cleveland in 1875, and taking up the study of law was admitted to the bar in 1878. He soon gave up the profession of law, however, and organized the Euclid Avenue National Bank, from this time onward being prominent in financial circles. At first secretary of the Society for Savings Bank in Cleveland, he became its president in 1894, and has been connected with various railroad and other large financial enterprises. He has taken a keen interest in national and local politics from a Republican standpoint, in 1903 was elected governor of Ohio, but in 1905 was defeated by John M. Pattison.

Herrick, Robert, English lyric poet: b. London 20 Aug. 1591; d. Dean Prior, Devonshire, October 1674. He was educated at Cambridge, at one time studied law, but entered the Church, and in 1629 received the living of Dean Prior, Devonshire. Previous to this he had written much poetry, and had also indulged in the gayeties of London, where he had become a friend of Ben Jonson and other kindred spirits. In common with many others of the Episcopal clergy, he was ejected from his living in 1647, whereupon he returned to London, and lived there on scanty means till he was restored in 1662. The first collected edition of his poems was published in 1648, under the title of 'Hesperides, or the Works, both Humane and Divine, of Robert Herrick.' Herrick sank for a considerable time into unmerited neglect. From this he was rescued by Nott, who, in 1810, published a selection of poems from his 'Hesperides.' There are complete editions by W. C. Hazlitt (1869) and Grosart (1876). Notwithstanding his frequent coarseness in his secular pieces, his sacred poems appear to be the outcome of sincere piety. He has been pronounced by Campbell a writer of delightful Anacreontic spirit, and by many critics he is ranked as the best of English lyric poets. Some of his songs, as 'Cherry Ripe,' 'Gather the Rosebuds while ye May,' etc., are still popular favorites.

Herrick, Robert Welch, American novelist: b. Cambridge, Mass., 26 April 1868. He was graduated at Harvard in 1890, and in 1895 became assistant professor of rhetoric at the University of Chicago. His literary style displays much finish, while his studies of character are both keen and discriminating. He has published: 'The Man Who Wins' (1895); 'Literary Love Letters and Other Stories' (1896); 'Love's Dilemmas' (1898); 'Composition and Rhetoric' (1899); 'The Web of Life' (1900); etc.

Herrick, Sophie McIlvaine Bledsoe, American microscopist, daughter of Albert T. Bledsoe (q.v.): b. Gambier, Ohio, 26 March 1837. She was editor of the 'Southern Review' 1875–8, and has since been connected with the editorial staff of 'Scribner's Magazine' and its successor, 'The Century.' She has published 'Wonders of Plant Life under the Microscope' (1883); 'The Earth in Past Ages'; 'Chapters in Plant Life.'

Herring. The typical fishes of the family *Clupeidæ* (q.v.), to which also belong the shad, alewife, sardine (qq.v.), and other food-fishes, the numbers of which consumed makes this the most important economically of all families of fishes. The true or sea-herrings belong to the genus *Clupea*. The common herring (*C. harengus*) of both sides of the North Atlantic swims in enormous schools containing countless numbers of individuals packed as closely as possible over areas of often 6 to 20 square miles. The herring is a migratory fish, but its movements are so complicated that much mystery still clings to them. The most satisfactory conclusions have been arrived at by a German commission appointed to study the natural history of the Baltic, etc., which concluded that the herrings live in the deep water off the coasts which they approach periodically chiefly for the purpose of spawning; that there exist a large number of distinct races, differing in size, form, times of spawning, and various other peculiarities, and that each of these races swims in separate schools, which move independently and have different seasons and grounds for spawning. Spawning takes place at various seasons, according to locality, some schools spawning in the late winter, others in the spring, and still others during the autumn months. The eggs are small and adhere in masses to seaweeds, stones, etc., on the bottom. Vast numbers are thus deposited in certain favored localities to which haddock and other fishes are attracted for the purpose of devouring them. The number of eggs produced by each fish is not especially large, being from 10,000 to 50,000, but nevertheless the natural productiveness of the herring has been sufficient to overcome inroads caused by the fisheries and the much greater destruction due to the hordes of bluefish, sharks, porpoises, gulls, and other enemies which accompany the schools in order to prey upon them. Having only few and small teeth, the herrings cannot capture active living creatures, but, as they swim with quick, nervous movements, water is being continually taken into the mouth and strained through the gill-rakers. By this means great numbers of copepods and other minute forms of life, especially larval crustaceans, annelids, and mollusks, are retained within the mouth and swallowed.

The herring fishery is of stupendous importance to the countries of northern Europe, whose prosperity is as much dependent upon this industry as ours is upon the wheat crop.

This is especially true of the Scandinavian countries, whose hardy fishermen take from the sea annually not less than 1,500,000,000 pounds. Scotland takes from 150,000,000 to 200,000,000 pounds, and the other maritime nations usually smaller quantities. On this side of the Atlantic the fishery is much less extensive, but is growing, and is no doubt destined to reach a great magnitude, especially in the waters of British America, which furnish each year about 250,000,000 pounds. Although found as far south as North Carolina, the herring has a commercial importance only north of Cape Cod, the New England fisheries, which are chiefly confined to Maine, yielding in 1898 64,589,000 pounds, worth $600,000. Most of these were sold fresh, either for food, or, early in the season, for cod bait; of the remainder, about 7,000,000 were salted and nearly 4,000,000 smoked. A favorite preparation is the partly smoked form of "bloaters." Large quantities of young herrings are packed and sold as sardines. In the prosecution of the American fisheries use is made chiefly of several forms of drift or gill nets and seines; under favorable conditions of great tidal movements, as in the Bay of Fundy, great numbers are captured in weirs.

A closely similar species (*C. pallasii*) is found on the Pacific coast of America, and is the object of a rapidly extending fishery. Of the anadromous river-herrings or alewives (*Pomolobus*), two species are of great commercial importance on the Atlantic coast of the United States, particularly southward, though the fisheries extend from Maine to Florida. They enter the rivers to spawn about the same time as the shad, with which they are caught chiefly in pound nets and seines. In 1896, 2,500 persons were employed in the fishery, the product of which was about 50,000,000 pounds, valued at $460,000. The greater number are smoked.

To the extensive literature of the herring, the following references will serve as an introduction: Goode, 'Fishery Industries of the United States' (1884); Smith, 'Alewife Fisheries of the United States,' in Report of United States Fish Commission for 1898; Cunningham, 'Marketable Marine Fishes'; 'Report of the Commission for the Scientific Investigation of the German Seas' (a very important contribution in German); 'Annual Reports' of the United States Commissioner of Fisheries.

Herring Gull, the most numerous and widely spread of gulls, common in the breeding season throughout all the northerly parts of the world, and migrating southward in winter. The silvery sheen of white and pearl-blue plumage are indicated in its technical name (*Larus argentatus*); and its habit of following schools of fishes and picking them up gives it the name of herring-gull. The same name is often given, however, to several others of the smaller gulls. See GULLS.

Herrnhut, hĕrn'hoot, a small town or village in the kingdom of Saxony, in the circle and 18 miles southeast of Bautzen. It is situated at the foot of Hutberg Mountain, 1,054 feet above the level of the sea. It was founded by Count Zinzendorf 1722, for the use of the Moravian Brethren, and it afterward became the metropolis and centre of that sect of Christians, who, from this town, are often called Herrnhuters. (See UNITED BRETHREN.) The town is built with great regularity, and distinguished by the order, cleanliness, and stillness which prevail in it. It has a great variety of manufactures, principally of linen, calico, tobacco, and of articles in gold, tin, leather, etc. The objects of curiosity are the observatory and the burial-ground on a neighboring hill, resembling a garden, and called by the brethren "Garden of Peace." Pop. 1,200.

Her'ron, Francis Jay, American soldier: b. Pittsburg, Pa., 17 Feb. 1837; d. New York 8 Jan. 1902. He was graduated at the Western University of Pennsylvania in 1854, and on the breaking out of the Civil War commanded the Governor's Grays in the First Iowa regiment. In 1861 he was made lieutenant-colonel of the Ninth Iowa regiment. In 1862 he received the commission of brigadier-general of volunteers. Early in 1863 he joined Gen. Grant at Vicksburg and commanded the left wing of the besieging forces as major-general (1862), until the capture of the city. He subsequently captured Yazoo City, with its boats and supplies; commanded the Thirteenth army corps, and broke up the traffic along the Rio Grande, assisted President Juarez against Maximilian's forces, and in June 1865 received the surrender of the Confederate forces west of the Mississippi. In 1873 he took up his residence in New York, where he practised law until his death.

Herron, George Davis, American clergyman and social reformer: b. Montezuma, Ind., 21 Jan. 1862. He was educated at Ripon College, Wisconsin, and also studied in Europe. He became pastor of the Congregational Church in Lake City, Minn., and while there made an address ("The Message of Jesus to Men of Wealth") before a Minneapolis club, which attracted much attention; he subsequently received a number of calls from important churches, and went as pastor to Burlington, Ia. Here he organized a club for the discussion of social questions, which was largely attended, especially by workingmen. In 1893 he accepted the chair of applied Christianity at Iowa College, resigning in 1900 on account of the objection to his teachings; he then organized a religious and socialist movement known as the "social crusade." In 1901 he divorced his wife, and married a second time, an action which aroused much criticism. He has written: 'The Larger Christ' (1891); 'The Call of the Cross' (1892); 'A Plea for the Gospel' (1892); 'The New Redemption' (1893); 'The Christian Society' (1894); 'The Christian State' (1895); 'Social Meaning of Religious Experiences' (1897); 'Between Cæsar and Jesus' (1899).

Herschel, hĕr'shĕl, **Caroline Lucretia,** sister of Sir William Herschel (q.v.), German astronomer: b. Hanover, Germany, 16 March 1750; d. there 9 Jan. 1848. In her 22d year she went to England to reside with her brother, then organist in Bath. When William abandoned his former profession in favor of astronomy she became his helpmate, and when he was appointed private astronomer to George III. she discharged efficiently all the duties of an assistant astronomer, for which she was allowed a small salary. Although these duties were very arduous, she yet found time to conduct a series of observations of her own with a small Newtonian telescope her brother had made for

HERRING GULL (*Larus Argentatus*).

her. She devoted special energy to the discovery of comets, and was so successful as to be entitled to claim the priority of discovery of at least five. Several remarkable nebulæ and clusters of stars included in her brother's catalogue were described from her original observations. In 1798 her valuable work, 'A Catalogue of Stars taken from Mr. Flamsteed's Observations, with Introductory Remarks by W. Herschel,' was published by the Royal Society. On her brother's death in 1822 she returned to her native country, where she died after an unusually protracted life, distinguished by useful scientific labors. The Royal Society recognized the value of her labors by bestowing upon her in 1828 their gold medal, and some time afterward by conferring upon her the privileges of honorary membership.

Herschel, Sir John Frederick William, English astronomer; only son of Sir William Herschel (q.v.): b. Slough, near Windsor, 7 March 1792; d. Collingwood, Kent, 11 May 1871. He was educated at Eton and Cambridge. His first publication was 'A Collection of Examples of the Application of the Calculus to Finite Differences' (1820), but it was not until the death of his father that he devoted his special attention to those astronomical researches which have made the name of Herschel so famous. He limited his first exertions to a re-examination of the nebulæ and clusters of stars discovered by his father, and in 1824, with James South, reported to the Royal Society the position and apparent distances of 380 double and triple stars, obtained by more than 10,000 measurements. This memoir attracted the notice of the French Academy, and they voted it their astronomical prize; and two years later the gold medal of the Royal Society was awarded to each of the astronomers. The results of the re-examination were given in 1833 to the Royal Society in the form of a catalogue of stars in order of their right ascension. The catalogue contained observations on 525 nebulæ and clusters of stars not noticed by his father, and on a great number of double stars, between 3,000 and 4,000 in all. His 'Treatise on Sound' appeared in the 'Encyclopædia Metropolitana' in 1830, as did his 'Treatise on the Theory of Light' in 1831, in which year also appeared his well-known 'Preliminary Discourse on the Study of Natural Philosophy,' one of the most charmingly written books on science. In 1831 he was created a knight of the Royal Hanoverian Order. In 1833 Herschel published in Lardner's 'Cabinet Cyclopædia' a 'Treatise on Astronomy,' subsequently enlarged into 'The Outlines of Astronomy,' of which several editions have been published. Before this, however, he had undertaken a private expedition to the Cape of Good Hope for the purpose of carrying out in the southern hemisphere observations similar to those he had made in the northern. Four years were spent near Cape Town (1834–7). His great object was to discover whether the distribution of the stars in the southern hemisphere corresponded with the results of his father's labors, prosecuted mainly on the opposite side of the Galactic Circle. That the observations might be strictly comparable they were made by the same method as Sir W. Herschel, and with a telescope of the same optical power. The whole number of stars counted in the telescope amounted to 68,948, included within 2,299 fields of view. By a computation based on the star-gauges in both hemispheres relative to the Milky Way, Sir John found that the stars visible in a reflecting telescope of 18 inches aperture amounted to 5,331,-572; and, more than this, the number really visible in the telescope was vastly greater, for in some parts of the Milky Way the stars were found to be so crowded in space as to defy all attempts to count them. The results of this vast labor were published in 1847, expense being borne by the Duke of Northumberland. On Herschel's return to England in 1838 he was received with every public honor, and on the queen's coronation was created a baronet. In 1848 he was president of the Royal Astronomical Society. He was buried in Westminster Abbey.

Herschel, Sir William, Anglo-German astronomer: b. Hanover, Germany, 15 Nov. 1738; d. Slough, near Windsor, England, 25 Aug. 1822. He went to England in 1757, and at first was employed in the formation of a military band. Although enthusiastically fond of music, he devoted his leisure hours to mathematics and astronomy; and being dissatisfied with the only telescopes within his reach, he set about constructing one for himself, in which undertaking he succeeded, having in 1774 finished a reflecting instrument of 5½ feet. Encouraged by his success he proceeded to complete larger telescopes, and from this period gradually withdrew from his musical engagements. Late in 1779 he began a regular survey of the heavens, star by star, with a 7-foot reflector, and after 18 months labor discovered, 13 March 1781, a new primary planet, named by him the *Georgium Sidus*, but now known as *Uranus*. George III. gave him a pension, enabling him to devote the rest of his life to astronomy. At Slough, he commenced the erection of a telescope of the dimensions of 40 feet, and completed it in 1787. Its diameter was 4½ feet, and it weighed 2,118 lbs. With this powerful instrument he continued to prosecute his discoveries, regularly communicating the results to the Royal Society till 1818. In 1783 he thought he had discovered a volcanic mountain in the moon, and from further observations made with his large instrument in 1787 found he was the victim of an optical illusion. He discovered two of the satellites of Saturn, and the fact that his system of rings revolved, and he measured his rotation and that of Venus, announced to the world that there were binary stars in the heavens, etc. Herschel received much assistance in making and recording observations from his sister Caroline (q.v.); and latterly his brother, a skilful optical instrument-maker, lent him valuable aid. In 1802 he laid before the Royal Society a catalogue of 5,000 new nebulæ, nebulous stars, planetary nebulæ, and clusters of stars he had discovered. See 'Herschel, his Life and Works,' by Holden (1881).

Her'schell, Farrer, Lord, English lawyer and statesman: b. London, England, 2 Nov. 1837; d. Washington, D. C., 1 March 1899. He was educated at University College, London, and the University of Bonn. He became a barrister of Lincoln's Inn in 1860; was recorder of Carlisle 1873–80; solicitor-general 1880–5; and lord high chancellor in 1886, and again 1892–5. He was a member of the Venezuela and British Guiana boundary arbitration tribunal in 1897,

and was subsequently appointed one of the high joint commissioners from Great Britain, on the Anglo-American Commission, designed to settle existing differences between the United States and Canada, of which he became president. During the sitting of the commission in Washington, D. C., in February 1899, he had a severe fall, from the effects of which he died shortly after.

Hertel, hĕr'tĕl, **Albert,** German painter: b. Berlin 19 April 1843; studied at the Berlin Academy, where he became professor in 1875, and was made a member in 1901. Among his landscapes are 'Olive Harvest in Capri' (1872); 'After the Storm on the Coast of Genoa' (1878); 'Road Between Rapalla and Santa Margherita' (1892); and 'View in the Roman Campagna' (1896).

Hertel de Rouville, ār-tĕl dė roo-vēl', **Francis,** Canadian soldier: b. Three Rivers, Maurice County, Quebec, 1643; d. 1722. He was captured in 1681 and tortured by the Iroquois who were so struck by his fortitude that they adopted him into their tribe, from which he escaped and as one of Frontenac's lieutenants performed some remarkable exploits against the English from whom he captured Falmouth, now Portland. Louis XIV. tardily rewarded him with a patent of nobility.

Herter, Albert, American artist: b. New York 2 March 1871. He studied painting at Paris in the studio of Jean Paul Laurens. He has twice visited Japan and the years spent there have strongly influenced the character of his work. He is member of the Society of American Artists, of the Water Color Club, and of the Water Color Society.

Hertz, Heinrich, hīn'rĭH hĕrts, German physicist: b. Hamburg 22 Feb. 1857; d. Bonn 1 Jan. 1894. He studied at the University of Berlin, and in 1880 became assistant to Helmholtz there. In 1883 he was lecturer on theoretical physics at the University of Kiel; in 1885 was professor of physics at a technical school in Karlsruhe; and in 1889 succeeded Clausius as professor of physics at the University of Bonn. His most important work was his experiments with electricity, by which he proved that electricity can be transmitted in electromagnetic waves with the same rapidity as light, these waves showing the same phenomena of refraction, polarization, etc., as light waves. He thus further developed and attested the truth of Faraday's electro-magnetic theory of light. It is by means of the Hertzian waves also that wireless telegraphy (q.v.) is made possible.

Heruli, hĕr'ū-lī, a Teutonic tribe first heard of in history about the middle of the 3d century, who passed south from the coast of the Baltic and swept with the Goths into the eastern provinces of Rome and founded an empire on the Danube. They appear as reinforcements of Odoacer in his invasion of the western provinces of Rome in 476. Their king Rudolph formed an alliance with Theodoric the Great, but they were afterward conquered by the Longobardi. A part of them were driven toward Scandinavia, a part lingered on the borders of the Roman empire. They did good service to the Byzantine empire, but after encountering the Vandals in Africa, and the Ostrogoths in Italy, they vanished from history.

Herzel, Theodor, Jewish leader of political Zionism: b. Budapest 2 May 1860; d. 3 July 1904. He was educated in Vienna for the law, but devoted himself almost exclusively to journalism and literature. He was at first Paris correspondent and later literary editor of the *Neue Freie Presse,* and wrote comedies and dramas. In 1896 he published his 'Judenstaat,' the English translation of which ('A Jewish State') made him the political leader of the Zionist movement; and his efforts were at once centred in this propaganda. 'Die Welt' of Vienna was established by him in 1897, and in that year he planned and was elected president of the first Zionist Congress held at Basel. At every subsequent congress (the sixth having been held in August 1903) he was unanimously re-elected. In 1898 he inaugurated a series of diplomatic interviews with various sovereigns and statesmen. At the Hague Peace Conference he was received by many of the delegates. In the Zionist movement he was officially the chairman of the Grosses Actions Comité, and of the Vienna executive committee, and a member of the council of administration. Among his further works are: 'Das Neue Ghetto' (1903), directed against the Jewish element that combated his views; 'Altneuland' (1903), a fictional presentation of Zionistic ideas.

Herzegovina, hĕrt-sĕ-gō-vē'nä, Austria-Hungary, a province of the Balkan peninsula nominally belonging to European Turkey, but since 1878 administered along with Bosnia (q.v.) by Austria. It is bounded on the north by Croatia and Bosnia, on the east by Bosnia, on the southeast by Montenegro, and on the south and west by Dalmatia; length, northwest to southeast, 140 miles; breadth, 50 miles; area, 700 square miles. The surface is generally mountainous, covered by ranges belonging to the Dinaric Alps, sloping gradually to the Adriatic, which receives all its drainage chiefly by the Narenta. It contains many fertile valleys, and raises excellent tobacco. The exports consist chiefly of hides, tallow, cattle, wool, wax, and fruit. Mostar is the chief town. The province was conquered by the Turks in 1465. An insurrection, caused by Turkish misgovernment, broke out in July 1875, and was the cause subsequently of war between Russia and Turkey. In accordance with the Treaty of Berlin (1878) the province was occupied by Austrian troops, and is now ruled by an Austrian military governor. Pop. about 250,000.

Hesiod, hē'sĭ-ŏd, Greek poet: b. Ascra, a village of Bœotia, at the foot of Mount Helicon, whence it is called the *Ascræan.* But little is known of Hesiod with certainty. Even the age in which he lived cannot be precisely determined. A very common tradition relates that, in a poetical contest with Homer at Chalcis, he came off victorious. Herodotus calls him a contemporary of Homer, and says they lived 400 years before himself (about 900 B.C.). In his 'Works and Days' (172) Hesiod says that he belonged to the period immediately following the Trojan war; but there are many reasons for supposing that he lived at a later period. Of the numerous works attributed to him three only remain. These are the 'Theogony,' a collection of the oldest fables concerning the birth and achievements of the gods, arranged so as to form a connected whole. It is the most

important and difficult of all his works. With it was probably connected the lost 'Catalogues of Women' (or the *Eoiai megalai*), to the fourth book of which the second fragment (the 'Shield of Heracles') must have belonged. This is evidently composed of three distinct parts, only one of which is occupied with the real description of the shield. The third fragment is a didactic poem, 'Works and Days' (*Erga*, or *Erga kai Hemerai*). It treats of agriculture, the choice of days, etc., with prudential precepts concerning education, domestic economy, navigation, etc. The Hesiodic poems are inferior to the Homeric in almost every respect. Hesiod's complete works have been translated into English verse by Elton, and Bohn's Classical Library contains a prose version.

Hesperides, hĕs-pĕr'ĭ-dēz (daughters of Hesperis), the guardians of the gold apples which Ge (the Earth) had given to Hera on her marriage. They were the daughters of Atlas and Hesperis, but their parentage is differently represented by other writers. They were four in number and their names were Agle, Arethusa, Erytheia, Hesperia, or Hesperarethusa. They were assisted in the charge of their garden by the sleepless dragon, Ladon. It was the twelfth labor of Heracles to bring the golden apples of the Hesperides to Eurystheus.

Hesperornis, hĕs-pē-rôr'nĭs, a remarkable extinct form of bird, the remains of which are met with in the cretaceous deposits of Kansas. As described by Prof. Marsh, it possessed small pointed reptilian teeth, which were implanted in a deep continuous groove, somewhat like those of Ichthyosaurus. Its brain was small and more reptilian in type than that of any adult bird as yet examined. It appears to have been a large diving-bird, measuring over five feet from the point of the bill to the end of the toes. Its wings were rudimentary, its legs powerful, and its feet well adapted for rapid progression in water. The tail was broad, could move up and down, and was probably used as a rudder or swimming-paddle. The long slender jaws were united in front only by cartilage, as in serpents, and had on each side a joint which admitted of some motion, so that "the power of swallowing was doubtless equal to almost any emergency." Consult: Lucas, 'Animals of the Past' (1901).

Hesperus, hĕs'pē-rŭs, among the Greeks the planet Venus, when it appeared as evening star, personified as the divinity that at weddings leads the bride to the arms of her husband. He is called Phosphorus or Lucifer as a morning star, and is styled the son of Eos (Aurora) and Cephalus. He was also known as son or brother of Atlas, and brother of the Hesperidæ.

Hesperus Peak, an elevation of the La Plata Mountains, in the southwestern part of Colorado. Gold and silver have been mined in the vicinity. This peak is one of a group of high peaks in this part of the State; the height is about 13,135 feet.

Hesse, hĕs, or **Hessia** (German, HESSEN, hĕs'sĕn), Germany, an ancient territory inhabited in the time of the Romans by the Catti or Chatti, an old Germanic tribe. Under the Frankish kings Hesse was governed by counts, the principal of whom were the Counts of Gudensberg of the name of Giso. Philip I. the Generous, who succeeded to the sovereignty of the whole country in 1509, and who was the earnest and zealous friend of the Reformation, divided his dominions among his four sons. The eldest, William IV., obtained one half, including the capital, Cassel; Louis IV. one fourth, comprising Marburg; Philip II. one eighth, with Rheinfels; and George I. also an eighth, with Darmstadt. But Philip dying in 1583, and Louis in 1604, without children, there remained only the main branches of Hesse-Cassel and Hesse-Darmstadt (qq.v.).

Hesse, Grand Duchy of, formerly HESSEN-DARMSTADT, Germany, a state consisting of 13 divisions. Eleven of these are small, six surrounded by Prussian territory, and five on the borders of Baden and Würtemberg. The other two portions, forming about nine tenths of the whole, are separated by a belt of land stretching east to west, and including part of the Prussian dominions. The more southerly of these portions forms the two provinces of Rheinhessen and Starkenburg. The northern portion, forming the province of Oberhessen, is surrounded by the Prussian province of Hesse-Nassau; area of whole grand duchy, 2,964 square miles. Oberhessen is generally mountainous; Starkenburg and Rheinhessen are also mountainous; in the southwest the Donnersberg, a northern ramification of the Vosges, rapidly subsides to the extensive plains belonging to the valleys of the Main and the Rhine. To the latter river the whole surface of the grand duchy belongs, with exception of a small portion in the north, drained by the Eder and Fulda, affluents of the Weser. The climate is greatly diversified, varying with the altitude. The soil, particularly in the provinces of Starkenburg and Rheinhessen, is fertile, and grain of all kinds is raised in large quantities. Hemp, flax, potatoes, and rape-seed also are extensively grown, and in particular districts tobacco and hops. The vine forms an important object of culture, and fruit is abundant. Horses, cattle, sheep, and swine are numerous. The minerals include iron, coal, lignite, and salt; and there are good quarries of sandstone, limestone, whetstones, basalt, and roofing-slate. The most important manufacturing industry is linen. The principal towns are Darmstadt, the capital; Mainz, Giessen, Bingen, and Worms. The grand duchy is an hereditary monarchy. The constitution dates from 1820, but was somewhat modified in 1856 and 1872. The legislative power is vested partly in two chambers — an upper, composed chiefly of nobility and citizens, appointed for life by the grand-duke; and a lower, composed chiefly of deputies from the towns, villages, and rural districts. About two thirds of the inhabitants are Protestants. Pop. (1900) 1,119,893. The grand-ducal line was founded in 1567 by George I., son of Philip the Generous. By the death of the landgrave of Hesse-Homburg, in 1866, Louis III., grand-duke of Hessen-Darmstadt, succeeded to his dominions. In the German war of that year Hessen-Darmstadt joined Austria. Its army was nearly annihilated at Friedberg, and it was deprived of the newly-acquired landgraviate and other districts. In 1870 the grand duchy of Hesse entered the German empire. Louis IV., who succeeded Louis III., died in 1892. He was the husband of Princess

Alice of Great Britain, and their son, Ernest Louis, is now the reigning sovereign.

Hesse-Cassel, hĕs-kăs'ĕl, or **Electoral Hesse,** Germany, a former electorate and independent member of the Germanic Confederacy, between Rhenish Prussia and Bavaria, containing 4,430 square miles, with about 850,000 inhabitants, mostly Protestants. It was founded by the eldest son of Philip the Generous, the Landgrave William IV., surnamed the Wise (1567–92). For a long period the history of Hesse-Cassel was a narrative of conflicts between the people for political freedom and the elector for absolute rule. The demands of the people were on several occasions strengthened by appeals to the elector from the Prussian government. On the outbreak of the German war of 1866, the elector joined Austria, and his territory was occupied by Prussian troops. On the conclusion of the war Hesse-Cassel was annexed to the Prussian territories, and now forms part of Hesse-Nassau (q.v.).

Hesse-Nassau, hĕs'năs'â, or **Hessen-Nassau,** hĕs'sĕn-năs'sow, Germany, a province of Prussia, which includes the former principality of Hesse-Cassel (except some small districts), the greater part of the former duchy of Nassau, that portion of the former landgraviate of Hesse-Homburg which lies on the right bank of the Rhine, the territory and town of Frankfort, and some small districts ceded by Hessen-Darmstadt and Bavaria. The province is bounded by the Prussian provinces of Westphalia, Hanover, Saxony, and the Rhineland, the principality of Waldeck, the grand duchy of Saxe-Weimar, and the kingdom of Bavaria; area, 6,018 English square miles, divided into the two governments (Regierungsbezirke) of Cassel and Wiesbaden. The greater part of this province has a rugged surface, partly covered by branches of the Harz Mountains. The principal rivers are the Werra, Lahn, Ohm, Rhine, and Main. Arable land is limited, and cultivation is chiefly confined to the narrow valleys and lower hill slopes, amounting to about two fifths of the whole surface. The principal crops are rye, barley, and oats. Potatoes also are extensively grown. Fruit is tolerably abundant, and a great part of the loftier districts is covered with extensive forests, which employ a considerable number of the inhabitants, and furnish one of the most valuable sources of revenue. There are various minerals, and valuable mineral waters at Homburg, Wiesbaden, etc. The manufactures consist chiefly of woolens, cottons, and linens. The principal towns are Cassel, the capital, Wiesbaden, and Frankfort. Pop. (1900) 1,897,310.

Hessen-Darmstadt, hĕs'sĕn-därm'stät. See HESSE, GRAND DUCHY OF.

Hessian Fly. See WHEAT INSECT PESTS.

Hessians in the Revolution, The. In the 18th century Germany was divided into nearly 300 sovereignties, each maintaining a court and a military force. The possible revenue was often very limited, the burdens were almost intolerable, and the princelings were often profligate and cruel; they did not need their forces for home defense, and were glad to make money for themselves by letting out their regiments for hire, though except in one case they remitted no taxes on the people from the receipts. There was also a lingering tradition that soldiering was an honest trade like any other, and that it was useful for helping sovereigns to keep order; especially to put down insurrections, which were wicked. This, however, did not apply to rulers hiring out their troops and pocketing the money; and not only the liberal school of writers and public men, but enlightened despots like Frederick the Great, denounced it. But England had not sufficient army for the American War, and wished drilled troops rather than raw recruits, and after vainly endeavoring to hire 20,000 Russian soldiers, turned to the German princes, with some of whom she had dynastic relations, and all of whom were so eager to sell their wares that two of them offered soldiers for hire immediately after Bunker Hill, without waiting to be asked. Only those which could furnish considerable numbers were worth treating with, and all the German auxiliaries were finally hired from six states; about half being from two Hessian states, and by far the largest (more than three times greater than any other) from one. All were indiscriminately termed "Hessians," as all German immigrants were formerly called "Palatines." The first treaty was made with the Duke of Brunswick, 9 Jan. 1776, for 4,300 troops; reinforcements or replacements were sent year by year, till the total had amounted to 5,723, only 2,708 of whom ever returned. The second was with the Landgrave of Hesse-Cassel, 15 Jan. 1776, for 12,805; finally increased to 16,992, of whom 10,492 returned. The contingents from the others, under various treaties, amounted to — Hesse-Hanau, 2,038; Anspach-Baireuth, 2,353; Waldeck, 1,225; Anhalt-Zerbst, 1,152. Total sent to America, 29,867, of whom 17,313 returned; the rest either died or remained as citizens. There were about 20,000 in America at any one time after 1776. These forces cost Great Britain in subsidies and incidentals about £1,770,000; besides the lump sum, it was obliged to replace the dead, and at least in one case count three wounded men as one dead one.

About 18,000 were shipped in 1776; the commander-in-chief was Lieut-Gen. Philipp von Heister, a veteran of the Seven Years' War. The first division of some 8,000 landed at Staten Island, 15 August; they included a body of chasseurs and grenadiers under Lieut. E. W. F. von Donop, an able and daring officer. They took a leading part in the battles of Long Island and White Plains, and all the operations for capturing New York; and stormed Fort Washington with a loss of 56 killed and 276 wounded. During this time the second division of about 4,000, under Lieut-Gen. Wilhelm von Knyphausen, joined them. Washington's surprise at Trenton fell on Col. Rall's brigade of Germans. Rall was a regular officer whose contempt for the ragged Americans surpassed that of the most arrogant Briton, and he refused to take the most elementary precautions; he was mortally wounded. Early in 1777 Heister was superseded by Knyphausen; Howe finding the former intractable, and the Landgrave of Hesse laying the blame of Trenton upon him. Meantime the Brunswickers and a Hanau regiment under Baron von Riedesel had made a clearance of Canada; and in 1777 they were

joined to the expedition of Burgoyne, in whom Riedesel had no faith. It was from this division that Baum's detachment was sent off to raid Vermont, and to meet its fate at Bennington, with Breymann's sent to support it; 365 of Baum's 374 Germans did not return, and 231 of Breymann's were killed, wounded, or captured. Riedesel and his remaining men shared in Burgoyne's surrender. Around Philadelphia, at Brandywine and Germantown, Knyphausen's command was of the first importance; and at Red Bank Donop tried to storm the American fort and was mortally wounded, his command losing 82 killed and 229 wounded, besides 60 prisoners. In the three years' occupation of Rhode Island, from the fall of 1776 to that of 1779, about half of the British corps was Hessians; and they liked, and were liked by the inhabitants,— when they departed, all persons, but especially women, were prohibited from appearing at the Newport windows, in fear that the soldiers might not wish to go. In the South, at Savannah, Charleston, Pensacola, Baton Rouge, etc., they left many dead; and shared in the bloody drawn battle of Guilford Court House. Finally, at Yorktown, they bore the brunt of the actual fighting, losing 53 killed and 131 wounded.

The Germans did their duty bravely and faithfully, with loyalty to a service they had been sold into to no profit of theirs. Very few deserted, in spite of constant inducements held out to them; a policy which Washington strongly deprecated. Probably one reason was, that they were at once recognizable from their speech. Nor were they in the least inhumane or rapacious: the charge that they were cruel barbarians was a mere political weapon of the time. In a strange country, they would have run the risk of being murdered in reprisal had they been such: but in fact they appear to have been well-meaning men. Of the 29,867 who came over, only 17,313 returned to Germany. Of the 12,554 remaining, 548 were killed; some of the total 1,652 wounded died; some disappeared; but a great number are known to have remained and settled in the country. Grants were given them in Nova Scotia, but many scattered as chance directed. See Lowell, 'The Hessians in the Revolution' (1884).

Hestia. See VESTA.

Hesychius, hĕ-sĭk'ĭ-ŭs, the author of a Greek lexicon, which has probably come to us in an abridged form, and which he partly collected from former dictionaries, and partly enlarged by many new words and examples from Homer, the dramatic and lyric poets, the orators, physicians, and historians, was a native of Alexandria, and according to the best authorities flourished about the end of the 4th century after Christ. Of the circumstances of his life nothing is known. His lexicon possesses great value, especially of an antiquarian kind, and is the most useful for the study of the Greek language of all the ancient critical writings that are extant. The best editions of his lexicon are Alberti and Ruhnken's (Leyden 1746–66, two vols. folio), and that prepared by Schmidt (Jena, five vols. 1867–68; in a smaller form, two parts, 1864; second edition, 1867).

Hetæra, hĕ-tē'ra (Greek *hetaira,* a female companion), the name given by the Greeks to a mistress, as opposed to a lawful wife. But the word had various shades of meaning, from a mistress, who might be a wife in all but the legal qualification of citizenship, down to a harlot. The beauty and accomplishments of many of the hetæræ occasioned their society to be sought by men of the highest eminence, even Plato and Socrates. No shame was attached to associating with them. Aspasia, the mistress of Pericles, is the most renowned of these hetæræ. (See ASPASIA.) Hetæræ, less intellectually famous, were Lais, whom Aristippus the philosopher loved, Phryne, and others. They also became famous for their connection with the works of art. Praxiteles made a marble and gold statue of the latter, and she was also the model for his statues of Aphrodite.

Heterog'amy. See METAGENESIS.

Heterogenesis, hĕt"ĕ-rō-jĕn'ĕ-sĭs, or **Heterogeny.** See METAGENESIS.

Heteropoda, hĕt-ĕ-rop'ō-da, a group of small, pelagic, pectinibranch mollusks, which dwell together in the open sea, have the foot modified into a swimming organ, and are provided with a ventral sucker. The shells are spiral or shaped like that of an argonaut and seem as if composed of thin glass; indeed, the whole animal is beautifully transparent. Heteropods occur in enormous abundance at the surface of the sea in all the warmer parts of the world, and their dead shells sinking to the bottom form a large constituent of the abyssal ooze. They are highly organized, have well developed eyes and other organs of sense, are bisexual, and produce eggs in long cylindrical cords. The young in their development pass through a trochosphere and then a veliger stage. All are predatory, seizing and feeding on the numerous minute forms of life about them. They are most active in the early evening, darting about with twisting motions like worms, usually on their backs. They use the ventral sucking-disk for attaching themselves to any object they may encounter. Three families, containing many species, are known, and their closest affinities are with the pteropods. Consult Kingsley, 'Standard Natural History,' Vol. I. (1885).

Heterop'tera. See HEMIPTERA.

Het'man (Russian, Ataman), chief of the Cossacks, formerly elected by that people. He had the power of life and death, and was head of the army in time of war. Mazeppa in 1708 revolted against Russia, taking the side of Charles XII. of Sweden, and Peter the Great abolished in consequence the power and authority of the hetman. Catharine II. suppressed the office and title in the province of Ukraine; it still exists among the Cossacks of the Don. In Poland the commander-in-chief of the army was styled hetman, and was appointed by the sovereign. The last elective hetman of the Cossacks in Russia was Platorf 1812–14. On his death the grand duke, heir to the throne, was made hetman.

Hetty Sorrel, in George Eliot's 'Adam Bede' (1859), a dairymaid whose unfortunate career, condemnation to death, and final reprieve form an important part of the story.

Hevelius, Johannes, yō-hän'nĕs hā-fā'lē-oos, or hĕ-vē'lī-ŭs, known also as JOHANNES HEVEL, Polish astronomer: b. Dantzic 28 Jan. 1611; d. there 28 Jan. 1687. After visiting the principal countries of Europe he settled in his native city, and from 1639 till his death applied himself almost exclusively to the study of astronomy. His 'Selenographia,' or description of the moon, published in 1647, was the first of numerous astronomical works of great value and authority on his favorite science. Halley, who visited Hevelius at Dantzic at the request of the Royal Society of London, of which Hevelius had been elected a member in 1664, reported favorably of the correctness of his observations. In 1661 he observed a transit of Mercury, a triumph confined to Gassendi alone of all preceding astronomers. Hevelius ranks next to Flamsteed among the men of his day as a diligent and accurate observer of the heavens.

Hewes, hūz, **Joseph,** American patriot; a signer of the Declaration of Independence: b. Kingston, N. J., 1730; d. Philadelphia, 10 Nov. 1779. He was educated at Princeton College, and about 1760 he removed to Edenton, North Carolina. He soon became a member of the colonial legislature, and was a delegate to the General Congress at Philadelphia 1774–7 and again in 1779. After taking his seat he was appointed on a committee to "state the rights of the colonies in general, the several instances in which those rights are violated or infringed, and the means most proper to be pursued for obtaining a restoration of them," and aided in the preparation of its report.

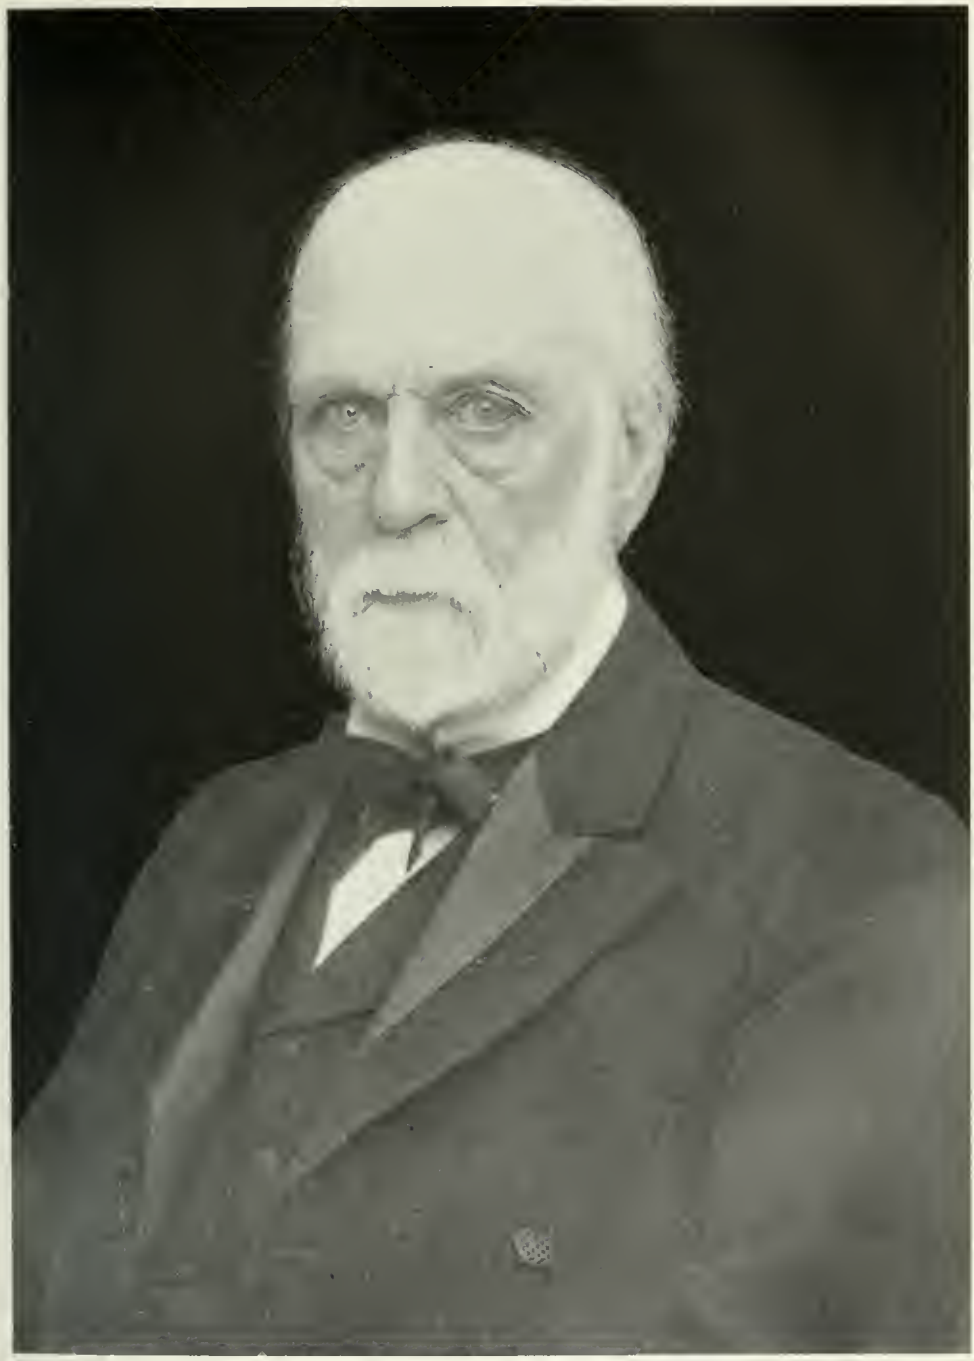
Hewett, hū'ĕt, **Waterman Thomas,** American Germanic scholar: b. Miami, Mo., 10 Jan. 1846. He was graduated from Amherst College in 1869 and has been professor of German language and literature at Cornell University from 1870. He has been general editor of Macmillan's 'German Classics' since 1895, and beside frequent contributions to periodicals has published among other works 'The Friesian Language and Literature' (1879); 'History of Cornell University' (1894).

Hewit, hū'ĭt, **Nathaniel Augustus,** American Roman Catholic clergyman: b. Fairfield, Conn., 27 Nov. 1820; d. New York 3 July 1897. He was graduated from Amherst College in 1839 and was for several years in the Episcopal ministry. He became a Roman Catholic in 1846 and joined the Order of Redemptorists. He was later one of the founders of the Congregation of Saint Paul (Paulists) taking the religious name of "AUGUSTINE FRANCIS," and subsequently becoming professor and superior in the Paulist Seminary, New York. He wrote 'Life of Princess Borghese' (1856); 'Problems of the Age' (1868); 'Light in Darkness' (1871); etc.

Hewitt, hū'ĭt, **Abram Stevens,** American manufacturer and politician: b. Haverstraw, Rockland County, N. Y., 31 July 1822; d. New York 18 Jan. 1903. He was graduated from Columbia in 1842 at the head of his class, and in 1843 he was made acting professor of mathematics there; he also began the study of law, and was admitted to the bar in 1845. He did not practise, however, but shortly after went into the iron and steel business with his father-in-law, Edward Cooper. By careful and skilful management he built up the financial success of his firm (Cooper & Hewitt); which was the first to manufacture iron girders and supports for fire-proof buildings and bridges, and also furnished the government with large quantity of material during the Civil War. In dealing with his employees, he was particularly successful, never having any serious trouble; it was his policy to keep the works running and the men employed, at least part of the time during dull seasons, though the business was sometimes carried on at a loss. At the time of his death he was recognized as one of the foremost iron masters in the country, his firm controlling the Trenton Iron Co. and the New Jersey Iron and Steel Co. He organized the Cooper Union Institute (q.v.), and as the secretary of the board of trustees largely shaped and controlled its policy for a number of years. He also gave largely to the institution. He was first active in politics at the time of the reorganization of Tammany Hall after the overthrow of the Tweed Ring. He served in Congress 1874–8, and again 1880–6 and was always especially prominent in all matters pertaining to finance, advocating a low tariff and the gold standard. In 1876 he was chairman of the Democratic National Committee, and immediately after the election issued a proclamation to his party stating that Tilden had been elected; later he supported the policy of Tilden which resulted in the appointment of the Electoral Commission (q.v.). In 1886 he was nominated for mayor of New York by Tammany and other Democratic organizations and after a hard campaign won the election over Henry George and Theodore Roosevelt. As mayor he gave the city a most efficient administration, but his independent policy often antagonized the Tammany leaders, especially his strict enforcement of the excise law. He was not renominated by his party, and was defeated as a candidate on an independent ticket in 1888. While mayor he urged in one of his annual messages the need of improvement of the city's rapid transit, and advocated municipal ownership; though his suggestions were not heeded at the time, he continued his interest in the subject, and it was largely due to his efforts that recent improvements in that direction were undertaken; in recognition of his services the Chamber of Commerce presented him with a gold medal in 1901. In February 1903 a number of prominent citizens of New York set on foot a movement to raise a memorial fund of $500,000 to be presented to Cooper Union as the "Abram S. Hewitt Endowment of the Cooper Union."

Hewitt, John Napoleon Brinton, American ethnologist and linguist: b. on the Tuscarora reserve, Niagara County, N. Y., 16 Dec. 1859. For several years he assisted Mrs. Erminnie Smith (q.v.) in the linguistic researches she was making for the Bureau of Ethnology on the Tuscarora reserve, and he is now employed in linguistic work at the Smithsonian Institution.

Hewitt, Peter Cooper, American capitalist and inventor: b. New York 1861. He is the son of Abram S. Hewitt (q.v.), was educated at Stevens Institute, Hoboken, and Columbia College. He entered business with his father and invented improvements in the processes of the Peter Cooper glue factory, which the Hewitt firm controls. Turning his attention to electricity



ABRAM STEVENS HEWITT

he invented the Cooper Hewitt lamp and static converter. The lamp in its present form consists of a glass tube of any desired shape with a bulb at one end which contains a small quantity of mercury. All air is exhausted from the tube, which thereupon fills with vapor from the mercury in the bulb. Electrodes are provided at each end of the lamp, the negative electrode in the bulb of mercury and the positive electrode at the opposite end. On passing a direct current through the lamp the vapor which fills the tube is rendered incandescent and gives off a steady, blue-white light. Owing to the great resistance at the negative electrode to the initial flow of current, it is necessary to use a high voltage to start the lamp. This is commonly done by passing a spark from a "choking" coil through the negative electrode, which when once penetrated offers but slight resistance to the flow of current. If for any reason the current is interrupted, the high resistance is immediately resumed and must be broken down again before permitting further flow of current.

The light given off by this lamp is entirely lacking in red rays, and consequently does not reveal the real color of the objects it falls upon. It is, however, of great value as a photographic illuminator being rich in actinic rays, which most affect the photographic plate. Mr. Hewitt is investigating with a view to discover means to turn some of the rays of the incandescent vapor into red rays. This discovery will be a means of great economy, because the Cooper Hewitt lamp is probably the cheapest artificial light in the world. The mercury vapor lamp consumes one half watt per candle-power, as against 3½ watts in the incandescent lamp.

Hewlett, hū'lĕt, **Maurice Henry,** English author: b. London 22 Jan. 1861. He was the son of Henry Gay Hewlett, a writer of some little note, and was educated at the London International College, Isleworth. He was admitted to the bar in 1891, and in 1896–1900 was keeper of the land revenue records and enrolments. His reputation was made as an interpreter of the more recondite phases of the life and thought of the Middle Ages, especially in Italy. His style is a skilful medium for his purpose, but frequently so archaized as to be somewhat difficult. His books are: 'Earthwork out of Tuscany' (1895), a collection of Italian studies; 'The Masque of Dead Florentines' (1895); 'Songs and Meditations' (1897); 'Pan and the Young Shepherd' (1898); 'The Forest Lovers' (1898), his first popular success; 'Little Novels of Italy' (1899); 'Richard Yea-and-Nay' (1900); 'New Canterbury Tales' (1901); 'Fond Adventures' (1904).

Hexam'eter (from the Greek ἕξ, six, and μέτρον, a measure), a verse of six feet. It is the heroic or epic measure of the Greeks and Romans, the finest examples of which are the two poems ascribed to Homer, the Iliad and the Odyssey, and the Æneid of Virgil. The sixth foot is always a spondee (two long syllables) or a trochee (a long and a short). The five first may be all dactyls (one long syllable and two short), or all spondees, or a mixture of both. The scheme of this verse then is —

—◡◡, —◡◡, —◡◡, —◡◡, —◡◡, — —
— —, — —, — —, — —, — —, — ◡

with all the varieties which the mingling of the two kinds of feet, as mentioned, affords; as,

—◡◡, — —, — —, —◡◡, —◡◡, — —
Forte sub arguto consederat ilice Daphnis;
or, —◡◡, — —, —◡◡, —◡◡, —◡◡, — —
Qui Bavium non odit amet tua carmina, Mævi;

and so on. The variety of which the hexameter is susceptible, its great simplicity, its harmony, and its numerous pauses, constitute the charm of this verse, and adapt it to the most various subjects. A spondee is rarely used in the fifth foot, and then in Latin the word with which the verse ends is generally composed of four syllables, and the fourth foot at least must be a dactyl; as,

Cara deûm soboles, magnum Jovis incrementum.

The prevalence of the dactyl or spondee in the hexameter depends much upon the genius of the language; thus the dactyl is more frequent in Greek than in Latin, and in German than in Greek. It is evident that the hexameter cannot be formed in such languages as Italian, French, Spanish and English, whose prosody is regulated by the accent and not by the *quantity* of the words.

The French and Italian writers, however, early attempted the hexameter, as well as Sidney and Southey in English; but without success. More recent English poets have also tried it, as Clough and Kingsley. Longfellow has made use of the hexameter in his 'Evangeline.' But in no modern European language have hexameters become naturalized, except in German, to which this measure seems as well adapted as to the Greek. Fischart attempted the German hexameter in the 16th century. In the middle of the 18th century it was used by Klopstock, Uz, and Kleist. Goethe's hexameters are very often as poor as their sense is beautiful. John Henry Voss improved the German hexameter by the excellent translation of Homer and his valuable 'Zeitmessung der deutschen Sprache' (Königsberg 1802).

Hexapoda, hĕk-săp'ō-dạ, a group name for the six-footed arthropods, or true insects (*Insecta*), excluding spiders, myriapods and other forms often popularly included in the term "insects."

Hexoic Acid, an organic acid having the formula $C_6H_{12}O_2$, or $C_5H_{11}.COOH$, and occurring in fats, in cheese, among the products of the butyric fermentation of sugar, and in the fruit of *Heracleum sphondylium* and in the flowers of *Satyrium hircinum*. It is best prepared by the fractional distillation of crude fermentation butyric acid. It is an oily substance, very clear and mobile, solidifying at about 29° F., and boiling at 400° F. It has a specific gravity of 0.95, and is oxidized by nitric acid to acetic and succinic acids. It is also known as "caproic acid," and its salts are sometimes called caproates, and sometimes hexoates.

Heyse, Paul, powl hī'zĕ, German poet and novelist: b. Berlin 15 March 1830. He studied classics in his native city, in 1852 traveled in Switzerland and Italy, and two years later he settled in Munich on the invitation of King Maximilian II. of Bavaria, who granted him a pension. He has lived mainly in Munich ever since, devoted almost exclusively to literature. His first work was 'Jungbrunnen, Märchen

eines fahrenden Schülers' (Tales of a Traveling Scholar) (1850); and to the same year belongs his tragedy 'Francesca da Rimini.' 'Die Brüder' (1852) and 'Urica' (1852), were narrative poems, and formed part of the volume entitled 'Hermen' (1854), later 'Novellen in Versen,' which did much to establish his reputation. Heyse's genius has found its most perfect expression in his tales or novelettes (Novellen), and in this department of literature he holds almost a unique place among German writers. His work is almost throughout highly finished and artistic, and shows a rich imagination and great fertility in invention. His tales have been published in more than 20 collections, and a selection appeared in 1890 under the title 'Auswahl fürs Haus.' His early successes in narrative verse were followed by such works as: 'Die Braut von Cypern' (1856); 'Thekla' (1858); 'Rafael' (1863); 'Syritha' (1867); 'Der Salamander' (1879); 'Die Madonna im Ölwald' (1879); 'Liebeszauber' (1889). His best plays are those of his third period, and some of them, especially 'Hans Lange' and 'Kolberg,' have been acted with great success. 'Mary of Magdala' was well received in America. Among them are: 'Die Hochzeit auf dem Aventin' (1886); 'Gott schütze mich vor meinen Freunden' (1888); 'Hans Lange' (1866); 'Kolberg' (1868); 'Die Weisheit Salomos' (1887); 'Weltuntergang' (1889); 'Die schlimmen Brüder' (1891); 'Wahrheit?' (1892); and 'Jungfer Justine' (1893). His larger novels, 'Kinder der Welt' (1873); 'Im Paradiese' (1875); 'Merlin' (1892); and 'Über allen Gipfeln' (1895), have met with great success. Among other works are: 'Skizzenbuch' (1877); 'Verse aus Italien' (1880); 'Spruchbüchlein' (1885); 'Gedichte' (Poems, 5th ed. 1895); and 'Neue Gedichte und Jugendlieder' (1897).

Heyward, hā'ward, **Thomas, Jr.,** American patriot: b. St. Luke's Parish, S. C., 1746; d. there 6 March 1809. He was of much prominence in North Carolina during the Revolution, was a delegate to the Continental Congress 1775–8 and one of the signers of the Declaration of Independence. In later years he was a judge in his native State.

Heywood, John, English dramatist of the first half of the 16th century. He was a paid musician at the court of Henry VIII., with whom he became a favorite on account of his skill in music. Heywood's dramatic works may be classed as interludes, standing between the miracle-plays and the drama proper. The earliest of them, 'A Merry Play between the Pardoner and the Frere, the Curate and Neybour Pratte,' was written before 1521. Another famous piece is 'The Four P's, an interlude in which figure a Palmer, a Pardoner, a Potycary, and a Pedlar.' His allegory of the 'Spider and the Fly' (1556) fully reveals Heywood's religious proclivities. By spiders, the Protestants are meant; by flies, the Catholics.

Heywood, Thomas, English dramatist: b. Lincolnshire. He was educated at Cambridge and appears to have been writing plays as early as 1596. Of all the old dramatists he was the most prolific. We learn from the preface to 'The English Traveller' that down to 1633 he had "had either an entire hand, or at the least a main finger," in the composition of 220 plays; and he continued for some years after that date to write for the stage.

Twenty-four of Heywood's plays have been preserved. The best is 'A Woman kilde with Kindnesse' (1607). His work is usually distinguished by naturalness and simplicity; but he wrote at the beginning of his career one absurdly grandiose play, 'The Foure Prentises of London' (1615), which was parodied in Beaumont and Fletcher's 'Knight of the Burning Pestle.' 'The Rape of Lucreece' (1608) is chiefly noticeable for its songs; 'Love's Maistresse' (1636), dealing with the story of Cupid and Psyche, is fanciful and ingenious; and there is much tenderness in 'A Challenge for Beautie' (1636). 'The Captives, or the Lost Recovered' an interesting play acted in 1624, was first published in 1885.

Hezekiah, hĕz-ę-kī'a (*Hizkiyah,* generally *Hizkiyahu,* strength of Jehovah), the 12th king of Judah. At 25 he succeeded Ahaz about 726 B.C., d. about 698 B.C. He had no sooner mounted the throne than he initiated a system of reform, on the injunctions of Isaiah, and broke up the idolatrous customs into which the people had fallen during the life of his father. He also endeavored to repair the injury done by national defeats and losses. He purged, repaired, and reopened the temple with magnificent sacrifices and a splendid ceremonial. So extreme was his indignation against idolatry that he destroyed the brazen serpent which was said to be the one used by Moses in his miraculous healing of the Israelites. With patriotic zeal he assumed the aggressive against the Philistines, and not only rewon the cities lost by his father, but dispossessed them of most of their own. In the 14th year of Hezekiah's reign he had a dangerous illness, which threatened serious complications, and the kingdom was in a difficult crisis, for the king had no heir, Manasseh not being born till long afterward. The greater part of the Scripture records bearing on the reign of Hezekiah is occupied by the two invasions of Sennacherib. Several of the Psalms are supposed to allude to the discomfiture of Sennacherib, for example, xlvi.-xlviii., lxxvi. Hezekiah did not long survive this deliverance, dying after a reign of nearly 29 years. Among the many highly useful works executed by him, the aqueducts of Jerusalem are of especial importance.

Hiawatha, hī-ą-wâ'tą or -thą, the hero of an American Indian legend known by this name among the Iroquois and among the other tribes. He is mentioned in various works on the aborigines, and in 1855 was immortalized in the poem, 'Hiawatha,' by Longfellow.

Hiawatha, Kan., city, county-seat of Brown County; on the Saint Joseph & G. I. and the Missouri P. R.R.'s; about 70 miles northwest of Kansas City and 55 miles north of Topeka. It is situated in a rich agricultural region. Its chief manufactures are flour, foundry products and agricultural implements. Its trade is principally in wheat, corn, fruit, livestock, flour, and lumber. It has the Morrill Public Library and an academy. The city owns and operates the waterworks and an electric-light plant. Another electric-light plant is

owned by a private corporation. Pop. (1900) 2,829.

Hib'bard, George Abiah, American writer of short stories: b. Buffalo, N. Y., 1858. He has written 'Iduna, and Other Stories'; 'Nowadays'; 'The Governor'; etc. His work is marked by finished style and much insight into character.

Hib'ben, John Grier, American logician: b. Peoria, Ill., 19 April 1861. He was graduated from Princeton 1887 and is now professor of logic there. He is author of 'Inductive Logic' (1896); 'The Problems of Philosophy' (1898).

Hiberna'tion, the winter sleep of warm-blooded animals. Under this term is also included the torpidity of frogs, toads, reptiles, certain fishes, insects, the horseshoe crab and snails, which is mainly due to prolonged cold. Among the mammals which hibernate are the bear, dormouse, badger, bat and hamster; a number are incomplete hibernators, as the prairie dog, while squirrels fall into a winter sleep during the coldest weather, but may be seen in warm spells in winter. The males of the black and white bear are more or less active during the winter months, while the females are hibernating. The same species, like the skunk, may in the southern portion of its range not hibernate at all. Neither do the hibernators all retire to their holes or dens or under fallen trees at the same date, but the time varies with the temperature, and different degrees of torpidity are exhibited. It also appears that continuous hibernators do not lay in a supply of food, as do intermittent ones like squirrels; yet the Arctic fox is said to store up a supply of dead lemmings, ermines, geese, etc.

Hibernation is like sleep, and has been compared with trance. During this period the animal functions are nearly suspended, the excretions are greatly diminished and in the bears the rectum is closed by a resinous plug, called by the Swedes "tappen," and by American hunters "seal." The animal heat is lowered to that or nearly that of the air, the action of the heart being slight; there is an increased muscular irritability, and the animal loses from 30 to 40 per cent of weight.

Snakes, lizards, the toad, frog, salamanders, and certain fishes hibernate, burying themselves in the earth below the reach of frost, the aquatic forms digging into the mud at the bottom of streams. The few fishes which are known to lie dormant and take no food sink into the mud of streams or of the sea. The horseshoe crab burrows in the mud beyond the reach of oyster dredges in November, remaining in deep water until the middle of spring. Most insects hibernate in the larva or pupa state, a few as moths or butterflies. Caterpillars hide under moss, the bark of trees, etc., but they freeze solid and may be broken into two pieces like an icicle. They gradually thaw out in spring; when the changes are sudden, great numbers die. Spiders and snails hibernate under stones, moss, etc., while slugs bury themselves in the mud, and those mussels and other mollusks living in streams and lakes descend into the mud.

Estivation.— In the tropics there is a corresponding period of torpor during the hot, dry season, when food is scarce, and vegetation is taking a rest. Alligators, snakes, certain mammals, as the tanrec, insects and land snails become dormant, the latter closing the mouth of their shells with a membrane-like substance (epiphragm), leaving a small opening in it for the admission of air in breathing, yet after a prolonged shower they become active. Thus it is seen that heat, dryness and the lack of food operate in causing estivation, while cold and famine appear to be the cause of hibernation; though all species are by no means affected alike. Among the lowest organisms the dormant vitality of resting spores, seeds of plants, winter eggs of sponges, of polyzoa, the dormancy of certain adult forms, are connected with a lowered temperature, and a resting period is necessary both in plants and animals. The simultaneous shedding of the leaves of deciduous trees is certainly connected with if not caused by cold, and it is undoubtedly true that changes of temperature as well as lack of food, and the need of rest, cause hibernation and summer dormancy.

Hibernia, the ancient name applied to Ireland (q.v.).

Hiber'nians of American, Ancient Order of, an Irish-American secret society founded in 1836. It has one general or national board, with 2,002 subordinate divisions. There were 139,453 members in 1902. The benefits disbursed the same year amounted to $429,000. National president (1902), J. T. Keating, Chicago, Ill.

Hibiscus, hī-bĭs'kŭs, a genus of plants of the mallow family (q.v.), distinguished by a double calyx and fruit of three or more many-seeded carpels united into a many-seeded capsule. The species are numerous, natives of warm climates, some trees or shrubs, but most of them large herbaceous plants. Many bear very beautiful flowers, much used in the South Sea Islands in wreaths, etc., for personal adornment. The rose-of-Sharon (*Hibiscus syriacus*), a native of Syria and Carniola, has long been in cultivation as an ornamental shrub. Several other species have become favorite hothouse plants. The scarlet hibiscus (*H. coccineus*) and the rose-mallow (*H. moschcutos*) are among the most striking and beautiful of North American wild flowers, glowing among the reeds of marshes in late summer in flame-color and pink. The characteristic mucilaginous and fibrous properties of the Malvaceæ are very strongly developed in this tribe. The fruit of *H. esculentus,* called gumbo, okra, etc., is in general use for food in the East and West Indies and the United States. It is an annual plant, with a soft herbaceous stem, three to five feet high, crenate leaves, axillary sulphur-colored flowers, and pyramidal, somewhat podlike capsules. The fruit is used in an unripe state, and is generally much esteemed, but is disliked by some on account of its viscidity. It enters as an important ingredient into the pepper-pot of the West Indies, or is used in soups. It also produces a coarse fibre. The bark of *H. tiliaceus,* a tree 20 feet high, with a very thick bole, abounds in mucilage. This tree is one of the most abundant trees of the South Sea Islands; and the wood, being light, tough, and durable, is much used for many purposes. From its fibre the Tahitians manufacture matting. Many other species yield fibres, some coarse, some fine and beautiful, which are used in dif-

ferent countries; but the most important in this respect is *H. cannabinus*, the Deccan hemp of western India (see HEMP). *H. sabdariffa* is very generally cultivated in warm countries, on account of its calyx, which, as the fruit ripens, becomes fleshy, and acquires a very pleasant acidity. It is much used for making tarts and jelly, and a decoction of it, sweetened and fermented, affords a refreshing beverage, well known in the West Indies as sorrel cool drink, the plant being called red sorrel; and in Madras it is used for similar purposes, and is named rozelle or rouselle. Musk-seed (*H. abelmoschus*) is cultivated for its seeds, which have a fragrance between that of musk and that of amber. They are much used by perfumers, and are called *graines d'ambrette*. In Egypt and Arabia they are mixed with coffee, and stimulant and stomachic qualities are ascribed to them. The petals of *H. rosa-sinensis* possess astringent properties, and they are also used by the Chinese to stain their eyebrows and their shoes black.

Hic'cup, or **Hiccough**, is a spasmodic affection of the diaphragm caused sympathetically by the irritation of structures supplied by nerves communicating with the phrenic nerve. Though generally a slight and passing inconvenience, its occurrence in the last stages of acute disease is a grave symptom, indicating general collapse of the nervous system. It may last only a few minutes or may continue for weeks without being capable of being subdued by any kind of treatment. Fasting or a stimulant suddenly swallowed is one of the commonest causes of hiccup, which generally passes off of its own accord. Nothing removes it more effectually than some active emotion of the mind suddenly excited. Hiccup is a common attendant of dyspepsia, and is often observed in abdominal diseases when terminating fatally, and is especially a symptom in some forms of hernia. Many remedies have been suggested for it, such as holding the breath as long as possible, tying a belt tightly round the waist, and the frequent swallowing of small rounded pieces of ice.

Hich'born, Philip, American naval officer: b. Charlestown, Mass., 1839. In 1869 he entered the United States navy as assistant constructor, in 1875 was made constructor, and in 1881 a member of the naval advisory board. From 1893 until his retirement 4 March 1901, he was chief constructor, and as such was identified with the reorganization and enlargement of the new United States navy. He attained rear-admiral's rank, and published a valuable report on foreign dockyards.

Hich'ens, Robert Smythe, English journalist and novelist: b. Speldhurst, Kent, 14 Nov. 1864. He was educated at Clifton College and the Royal College of Music, and after a short career as a musician turned to journalism. In 1893 he visited Egypt for his health, and there conceived the idea which materialized in the 'Imaginative Man' (1895) 'The Green Carnation' (1894), however, epigrammatic and keenly satirical in tone, first brought him into public notice. Later works of his are: 'After To-Morrow' (1895); 'New Love' (1895); 'The Folly of Eustace and Other Stories' (1896); 'The Londoners' (1897); 'Byeways' (1897); 'The Prophet of Berkeley Square' (1901); etc.

Hick'ey, Emily, English poet: b. Macine Castle, County Wexford, Ireland, about 1845. She was co-founder in 1881 of the Browning Society with F. J. Furnivall (q.v.) and has lectured on English literature. She has published among other volumes 'A Sculptor and Other Poems' (1881); 'Verse Tales, Lyrics, and Translations' (1889); 'Our Lady of May and Other Poems' (1902). Her verse has been highly praised by critics.

Hickey Plot (1776), a conspiracy of the British officials and Loyalists of New York to end the Revolutionary war by the murder or capture of its leaders and the seizure or destruction of its supplies. The heads and probable devisers of it were Governor Tryon, who had fled from the city but remained on a man-of-war in the harbor, and sent supplies of money for bribery, etc.; and Mayor Mathews. The scheme was to kill or seize the patriot generals, and at all events to deliver Washington alive to Sir William Howe, blow up the magazine and secure the passes to the city. Several hundred New York Loyalists were involved. Two of Washington's guard were bought, but a third pretended to accede and revealed the plot. Mathews, a gunsmith named Forbes, and a dozen others were arrested and sent to Connecticut, Mathews carrying the mayoralty flag with him. Thomas Hickey, one of the treacherous guards, was hanged in New York 27 June 1776, the first military execution in the American army.

Hick'man, Ky., town, county-seat of Fulton County; on the Mississippi River, and on the Nashville, C. & St. L. railroad; about 35 miles below Cairo, Ill. It has steamboat connections with the river ports. It is the seat of Hickman College. Its chief industrial establishments are a flour-mill, wagon-factory, two spoke-factories, saw- and planing-mills. Its trade, in addition to its own manufactured articles, is principally in grain and tobacco. Pop. (1900) 1,589.

Hick'ok, Laurens Perseus, American metaphysician: b. Danbury, Conn., 29 Dec. 1798; d. Amherst, Mass., 6 May 1888. He was graduated at Union College in 1820, was licensed as a preacher in 1822, and was pastor successively at Newton and Litchfield, Conn., till in 1836 he was elected professor of theology in the Western Reserve College, Ohio, where he remained eight years. He was professor in the Auburn Theological Seminary 1844–52, and then became professor of mental and moral science, and vice-president in Union College. In 1866 he was formally made president of that institution of which, however, he had been in sole charge for eight years previous. His publications include among other works 'Rational Psychology' (1848); 'Moral Science' (1853); 'Empirical Psychology, or the Human Mind as Given in Consciousness' (1854); 'Rational Cosmology,' (New York 1858), in which he attempts to demonstrate *a priori* the laws of the universe; 'Creator and Creation' (1872); 'Humanity Immortal' (1872); 'Logic of Reason' (1875).

Hick'ory (formerly HICKORY TAVERN), N. C., town in Catawba County; on the Southern railway; near the headwaters of the Catawba

River; about 43 miles northwest of Charlotte and 50 miles west of Salisbury. The chief manufactures are flour, foundry products, wagons, lumber, leather, boots and shoes. It has several private educational institutions: Claremont Female College, opened in 1880; Saint Paul's Lutheran Seminary; Lenoir College, opened in 1891, under the auspices of the Lutheran Church. Pop. (1900) 2,535.

Hickory, a group of trees of the walnut, forming the genus *Hicoria,* and exclusively North American. They are large strong trees, 60 to 80 feet high, with close shaggy bark and large pinnately divided leaves, pistillate flowers on a terminal peduncle and staminate flowers in long, drooping aments. The fruit is a thick-shelled nut in a tough green husk. There are about 10 species, all natives of the eastern United States and Canada except a Mexican species. The best known of these are the following: Shag-bark, shell-bark or white hickory (*H. ovata*), leaflets 5 to 7, whose bark scales off in great plates curving outward at both ends, and whose nuts are sweeter and better than those of any other species; the northerly "big shag-bark" or king-nut (*H. laciniosa*), leaflets 7 to 9, with narrower "shags," darker wood and big nuts in husks often three inches long; white-heart, or fragrant hickory, or mocker-nut (*H. alba*), noted for the hardness and toughness of its wood; the pignut or broom hickory (*H. glabra*), leaflets 3 to 7, which represents a group of moisture-loving species whose nuts are thin-husked, elongated and bitter and astringent to the taste. Associated with these is the pecan (*H. pecan*), of the Southern States, whose oblong, thin-shelled nut is one of the most delicious of all nuts, and is now being cultivated in a few places in order to supply the increasing demand. The water hickory (*H. aquatica*) is sometimes called the bitter pecan.

Uses of Hickory-wood.—As timber this wood is of great value for articles requiring great strength with lightness and elasticity; but it is liable to quick decay when exposed to the atmosphere, and for this reason is little used in building, and should be painted. It was the most serviceable of all woods to the aboriginal Americans; and the axe, pick, and tool handles made from it are exported to all parts of the world. It enters into the manufacture of rakes, cradles, and many forms of farm-implements; is largely used in carriage-making, especially for thills, shafts, and the parts of racing-sulkies, the lighter American vehicles owing their acknowledged pre-eminence largely to the availability of this wood. The wood of the various species differs in quality, however; that of the pecan is hard and brittle, and the water hickory soft and comparatively light. The wood of the others is exceedingly strong and tenacious, and weighs about 50 pounds to the cubic foot.

Insect Pests.—A. S. Packard recorded in 1890 170 species of insects attacking the hickories; and Chittenden declared in 1903 that this number could be easily doubled. Hickory appears to be an especial favorite of borers. Prominent among them are the painted hickory-borer, one of the long-horned beetles (*Cyllene picta*); the hickory twig-girdler (*Oncideres cingulata*), twig-pruner (*Elaphidion villosum*), and hickory-bark beetle (*Scolytus quadrispinosus*). This bark-borer is the most important economic species, and during recent years has been the cause of considerable injury in hickory forests in the State of New York. Consult Packard, 'Insects Injurious to Forest and Shade Trees,' published in 1888 as the fifth report of the United States Entomological Commission.

Hickory Shad. See GIZZARD SHAD.

Hicks, Elias, American preacher of the Society of Friends: b. Hempstead, L. I., 19 March 1748; d. Jericho, L. I., 27 Feb. 1830. While a youth he manifested a talent for public speaking, and at 27 was a well known preacher. For many years he labored zealously in advancing the generally accepted doctrines of the Friends; but having as he believed discovered errors in these tenets, put forth views of his own which he defended with energy and ability. To advance these views he traveled extensively in the United States and in the British provinces, attracting large congregations by his oratory. The result was a schism in the body of Friends; those adhering to the old doctrines being specially termed orthodox, while the followers of Hicks were called after him Hicksites. (See FRIENDS.) He was an active abolitionist and with others was instrumental in inducing the State of New York to pass an act which, on 4 July 1827, liberated all slaves within its borders. He was the author of 'Sermons' (1828); 'Observations on Slavery' (1811); 'The Letters of Elias Hicks' (1834); etc. See 'Elias Hicks, Journal of his Life and Labors' (1828).

Hicks, Thomas, American painter: b. Newton, Pa., 18 Oct. 1823; d. 1890. He studied at the Philadelphia Academy, at the National Academy, New York, and afterward in Paris under Couture. Settling in New York he became one of the favorite portrait painters of his day. His pictures in the rooms of the New York Historical Society form an interesting gallery of historic figures, executed with more than ordinary artistic skill.

Hicks, Thomas Holliday, American politician: b. Dorchester County, Md., 2 Sept. 1798; d. Washington, D. C., 13 Feb. 1865. After successively occupying the positions of sheriff, member of the State legislature, member of the State electoral college, and member of the Governor's council, he was in 1858 elected governor of the State. When war was threatened between North and South, although sympathizing with the South and condemning the North's attitude on the slavery question, he sided with the party of neutrality in Maryland and opposed the secession of that State. When there were rumors of a plot formed by 6,000 men of his State to prevent Lincoln's inauguration and seize the city of Washington he suspended the writ of habeas corpus, and planned the arrest of suspected persons. He was the only prominent State official who stood by the Federal government, and at the expiration of his term as governor the new Legislature passed resolutions thanking him for having saved the State from joining the Confederates. In 1862 he was appointed to the senate of the United States and served in it till his death.

Hicks-Beach, SIR Michael Edward, English politician: b. London 1837. He was educated at Eton and Oxford, entered parliament

in 1864, and was made chief secretary for Ireland in 1874, and secretary of state for the colonies in 1898. In 1885 he was appointed chancellor of the exchequer and leader of the Conservative party in the House of Commons. He was president of the board of trade from 1888 to 1892. On the fall of the Gladstone ministry in 1895 he again became chancellor of the exchequer. In October, 1902, he caused a sensation by charging the Balfour government with wasteful expenditure of war appropriations, and in 1903 ably defended the British policy of free trade.

Hick'son, Sydney John, English zoologist: b. London 25 June 1859. He was educated at Cambridge and has been professor of zoology at Owens College, Manchester, England, from 1894. He has published 'A Naturalist in North Celebes'; 'The Fauna of the Deep Seas'; 'The Story of Life in the Seas' (1898).

Hidalgo y Costilla, Miguel, mē-gĕl' ē-dăl'-gō ē kōs-tēl'yä, Mexican revolutionist, first leader in the Mexican war of independence: b. State of Guanajuato 8 May 1753; shot in Chihuahua, Mexico, 27 July 1811. He was a priest, and in earlier life was simply a man of great acquirements, anxious to promote industry in Mexico, and noted for conscientious fulfilment of his ecclesiastical functions. He is said to have introduced the silkworm into Mexico, and did much to promote the culture of the vine. This conflicted with the policy of the Spanish government, which was to discourage all manufactures or agriculture which could interfere with the revenue, and the vines Hidalgo had planted were destroyed. This drove him to rebellion. Possessing much influence among the Indians, he formed the plan of a general insurrection, which was to take place 1 Nov. 1810; but the plot having been disclosed by one of the conspirators, some of his party were arrested, and he was obliged to precipitate his movements. On 10 September having been joined by three officers of the garrison of Guanajuato, he raised the standard of revolt. His eloquence had a remarkable effect on the multitude who heard him, and when after his oration he unfurled a rude copy of the picture of Our Lady of Guadalupe, the patroness of Mexico, the war assumed the character of a crusade. On 29 September with an army of 20,000 men, mostly Indians, he captured Guanajuato. He took Valladolid and several small places, and soon after was proclaimed generalissimo of the Mexican army, and advanced against Mexico; but finding himself almost without ammunition, was obliged to retreat. During this war the government party declared that the ordinary rules of warfare need not be observed as regarded the insurgents, while the latter retaliated with the most horrible atrocities. On one occasion Hidalgo is said to have massacred 700 prisoners because they were Europeans. After several defeats the insurgents were left at Saltillo under charge of Rayon, while Hidalgo and others went to the United States to obtain arms and military aid. On their way they were captured by a former friend, and finally shot in Chihuahua. He was after his death regarded as a saint by the people, and within a few years the place of his execution was shown to travelers as a holy spot. The town of Goliad, Texas, was named in his honor, the H, as silent in pronunciation, being omitted and the other letters rearranged. At the founding of the town the name of Hidalgo was still proscribed by the Spanish rulers and the transposition of the letters of his name was made in order to avert the attention of the authorities.

Hid'denite, a yellowish-green or emerald-green, transparent variety of spodumene, discovered by W. E. Hidden, in 1880, in Alexander County, N. C. The emerald-green varieties have been used as gems. They resemble the emerald, but show a greater wealth of color on account of their pleochroism.

Hides and Leather. There are few arts, among the many that are used for the benefit of mankind to-day, that are of such ancient origin as that of tanning. It is only necessary to study the carvings upon the monuments that the modern archæologist has unearthed to ascertain the fact that the old Egyptians were not only acquainted with several processes of tanning and working in leather, but that its preparation was one of the most important branches of Egyptian industry. So far as our knowledge of their methods of work extends, we know that these ancient workmen prepared their tan in earthen vessels and that they were able to preserve skin either with or without the hair attached. Among the Hebrews, who undoubtedly derived their knowledge of the art of preparing leather from the Egyptians, the trade of the tanner was despised, largely because of the bad odor connected with it, and those who followed this source of livelihood were obliged to locate their working places outside the limits of the city. Often they were situated by the side of streams, or on the shore of the sea, as was the case in Joppa, where the building said to have been the house of Simon the Tanner was located on the shore south of the city.

According to the most authentic records the first tannery to be operated in this country was established in Virginia, about the year 1630. A year or two later another tannery was established in New England, in the village of Swampscott, or Lynn, Mass., by Francis Ingalls, a colonist who had learned his trade in Lincolnshire, England. As it was impossible not to recognize the importance of the industry it was greatly encouraged by the colonial authorities, in evidence of which fact there are many laws on the old statute books regulating, not only the manufacture of leather, but the saving of skins needed by the tanners, under serious penalties for noncompliance. For example, a law was passed in Massachusetts, in 1646, prohibiting the exportation of raw hides, or unwrought leather, under heavy penalties which not only affected the shipper, but reacted upon the master of the vessel that attempted to sail with such freight, for these were the days when the small tanners who had shops scattered throughout the country were entirely dependent upon the surrounding neighborhood for their hides, but so effective were the restrictions placed upon importations of skins by the authorities, that leather was relatively more plentiful in the American colonies than it was in England.

One of the most prominent leather manufacturers of the old days was Colonel William Ed-

wards, who sent the first tanned leather to the Boston market in 1794. Beginning his business in Hampshire about 1790, when he was less than 20 years of age, he immediately inaugurated a series of improvements in the mechanical branch of the art, which, as they were afterward adopted and extended by others, were the means of infusing a much-needed spirit of enterprise into the business. In fact, it was the new ideas in mechanism and in the arrangement of the tannery which he evolved that paved the way for the most important improvements which have since been made in the manufacture of leather. The first company in the business to be incorporated also owed its existence to Colonel Edwards' enterprise, for it was his extensive tanneries at Northampton, Cummington, and Chester that were purchased by the men who incorporated the Hampshire Leather Manufacturing Company of Massachusetts, with a capital of $100,000, in 1809. These works then had a capacity of 16,000 full-grown hides per annum.

By 1810, the tanning industry had extended so widely that there were tanneries in operation in almost every portion of the country. Bark was so plentiful that it was much cheaper than in England, and, as the result, it was not long before the exportations of American leather had attained an aggregate of 350,000 pounds per annum, while the importations were confined to morocco, and some peculiar kinds of English leather which could not then be produced in this country. At this time (1810) the value of all the manufactures of hides and skins was stated by the census office to be $17,935,447, but, owing to the fact that the census at that time was so crudely conducted that it was very incomplete, it is safe to say that $20,000,000 would be much closer to the correct figure. From that date, however, the business increased, slowly at times, perhaps, but steadily, until, in 1840, it was reported that there were about 8,000 tanneries in the country, with a capital of $16,000,000, and employment for fully 26,000 hands. By 1850, the capital had increased to more than $20,000,000, while the value of the annual product had reached the quite respectable figure of $38,000,000. In 1860, this product, including the making of morocco and patent leather, had almost doubled, being in excess of $72,000,000, while, in 1870, the 7,569 establishments in the country were employing no less than 35,243 persons, at an aggregate wage of $14,505,775, to produce an annual output that was value at $157,237,597. At this time the capital invested in this business was reported as being more than $61,000,000.

As the establishments engaged in the making of leather were enumerated very differently by the census of 1890 and 1880, it is quite impossible to obtain a reliable basis of comparison from the published statistics. In preparing the census of 1880, the government's enumerators not only counted all the smaller businesses, but they must have reckoned twice all that were engaged in both tanning and currying, with the result that they were able to make an aggregate of 5,628 establishments. As the later census enumerators have confined their attention solely to the large establishments the discrepancy is too great to be readjusted by estimate. Thus, for example, the 1890 census reports 1,787 establishments, while the 1900 census has but 1,306. The other census figures follow:

THE LEATHER INDUSTRY, 1880 TO 1900.

	1880	1890	1900
Capital	$73,383,911	$98,088,698	$173,977,421
Number of employees	40,282	42,392	52,109
Wages paid	$16,503,828	$21,249,989	$22,591,091
Cost of material used	156,384,117	122,946,721	155,000,004
Value of product	200,264,944	172,116,092	204,038,127

Among the first patents taken out for the application of any special process in the making of leather was in 1823, when an inventor patented a method of forcing the tanning liquor through the skin by hydrostatic pressure. In 1831, William Drake devised a modification of this method. According to his process two skins were sewed together and the liquid, which was placed in the receptacle thus formed, was permitted to remain until the tanning had been completed. Some years prior to that time a patent had been issued for a method which provided for the suspension of the hides in a closed vessel, in which their conversion into leather would be much accelerated by the removal of

LEATHER PATENTS.

Purpose for which Issued	Date of First Patent	Approximate Total Number of Patents to Date
Processes and apparatus for leaching and making extracts from tan-bark	Aug. 10, 1791	100
Bark-mills	July 19, 1794	100
Processes employing apparatus for tanning leather	July 9, 1808	100
Leather-splitting machine	July 9, 1808	75
Unhairing-machine	July 12, 1812	75
For rolling leather	Oct. 19, 1812	25
Scouring and setting machine	Nov. 21, 1831	70
Tanners' vats and handling appliances	Jan. 9, 1834	75
Machines for boarding and graining leather	March 25, 1835	35
Compounds for depilating hides and skins	June 30, 1836	60
For fleshing machines	June 17, 1837	25
Compounds for bating hides and skins	Feb. 3, 1838	40
Whitening, buffing, and shaving leather	May 10, 1838	30
Compounds and materials for tanning and tawing leather and preparing raw hides	July 12, 1838	175
Processes for tanning leather	Aug. 1, 1838	275
For currying leather	Aug. 1, 1838	25
Machines for stoning, polishing, finishing, glassing, glazing, flinting, creasing, and dicing leather	March 15, 1845	75
Compounds for coloring and polishing leather	Oct. 9, 1847	40
Methods for manufacturing enameled, japanned, and patent leather	Jan. 9, 1855	20
For stuffing leather	Feb. 6, 1855	20
For pebbling leather	May 6, 1856	30
For employing mineral substances for tawing hides and skins	Aug. 4, 1857	20
For stretching leather	Feb. 8, 1859	40
Bark-rossing machines	Jan. 9, 1863	10
For preserving hides	Sept. 11, 1866	15
Machines for shaving or making leather of uniform thickness	Sept. 24, 1867	5
Apparatus for blacking leather	Sept. 20, 1870	15
Measuring-machines	Aug. 28, 1877	25
Striking-out machines	March 27, 1883	4

all the air by an air-pump. To enumerate all, or even the most important of these inventions within any brief space would be impossible, but the preceding table gives the dates when the first patent was issued for each of the details which enter into the manufacture of leather, as well as an estimate of the number of patents that have been issued in each division of the industry up to the present time.

Hides, as the term is generally accepted today, may be conveniently divided into three classes: (1) Hides proper, which consist of the skins of the larger and more common animals, such as oxen, cows, and horses; (2) kips, which comprise the skins of small, or yearling cattle, which are too large to be classified as calfskins, and (3) skins, including those of calves, sheep, goats, deer, pigs, seal, and the various kinds of fur-bearing animals, many of which, including most of the latter, retain their hair after tanning. The heavy hides are converted into sole, belt, and harness leather; the calfskins are chiefly used for material for the manufacture of the uppers for leather shoes and boots, and are also in much demand by bookbinders; the sheepskins are used for a large variety of purposes, including linings for shoes, aprons, cushions, and covers, gloves, women's shoes, bellows, whips, etc.; the goatskins are used almost exclusively in the making of gloves and ladies' shoes — the morocco leather so extensively manufactured until recent years having now given place to the cheaper and more durable "glazed kid"; the hogskins are utilized in the making of saddle-leather, traveling bags, etc., while dogskins, because of their thin and tough characteristics, are particularly useful in the manufacture of gloves. The durability of the porpoise-skin has recommended its use in the making of shoe-strings, while the buffalo, alligator, kangaroo, deer, elephant, hippopotamus, rhinoceros, walrus, and shark, are among the many other creatures whose skins are utilized in various fields of manufacture after they have left the hands of the tanner.

There is probably no vegetable growth containing tannin that has not been tried by those who are interested in discovering the best and most economical methods of tanning leather, but, while nearly all of them have met with some favor, oak-bark is now held to be the best agent obtainable for this purpose. Among the other tannages that have been utilized with success, however, one may mention hemlock-bark, union, Dongola, alum, chrome, combination, electric, sumac, and gambier.

Practically the only change that has taken place in the tannage process of sole-leather is represented by a slight diminution in the time required for the work, but as experiments are constantly being made along these lines it is believed that the day will come when such leather will be turned out in as many days — perhaps hours — as it now takes weeks. The change that has already been made along these lines in the preparation of the lighter skins has been almost as radical. The introduction of Dongola kid, in 1880, completely revolutionized the manufacture of kid or morocco. It was the discovery of James Kent, of Gloversville, N. Y. The system of tanning, or tawing, by the use of chromium compounds was discovered as early as 1856 by a German chemist, but each of the many experiments which followed this discovery had failed because there was no known method by which the tannage could be made permanent. At last it was found that hyposulphite of sodium contained the long-sought remedy, and by this process the tannage was made lasting. It was due to this discovery, and to its successful application, that some of the largest and best equipped leather manufactories in the world have since been established in the United States.

Hierarchy, hī'ē-rär-kĭ (from Gr. *hieros,* sacred, and *arche,* government), sacred government or "the administration of sacred things," first used by the pseudo-Dionysius in the 5th century in his work on the Celestial and Ecclesiastical Hierarchies. It is now generally used to signify the body of officials in the Church organically graduated in their ranks and orders from the supreme head to those in the most subordinate position. In the Roman Catholic Church a threefold distinction is recognized: (1) A hierarchy of divine right, which embraces, under the primacy of the popes, bishops, priests, and deacons. This hierarchy is held by Church to be of divine institution. (2) A hierarchy by ecclesiastical right, consisting of the Roman pontiff and the three original divine orders and of the five minor orders (two in the East), subdeacons, acolytes, exorcists, lectors, and porters (ostiarii). (3) A hierarchy of jurisdiction, which includes all the judicial and administrative authorities, ordinary and delegated, charged with the maintenance of the faith among Christians, its union, its discipline, and its general care and supervision. All its powers proceed from the pope as primate, either expressly or by implication. In this category are ranked cardinals, patriarchs, exarchs, metropolitans, and archbishops, and as deriving their powers from these, archpriests, archdeacons, rural-deans, vicars-general, etc. The Anglican Church also recognizes a hierarchical rank in its body, comprising bishops, priests, and deacons. The other Protestant bodies practically reject hierarchical government.

Hiero I., hī'ērō, king of Syracuse in Sicily: d. Catania, 467 B.C. He was brother and successor of Gelon. Hiero's reign, though less glorious than the preceding, was marked by a peculiar splendor on account of his generous encouragement of learning. Though some blemishes tarnish the first years of Hiero's reign, he compensated for his first faults by the noble actions which signalized the remainder of his life. A long sickness was the main cause of this alteration. Since he could no longer occupy himself with the cares of royalty, he collected around him a society of learned men, and thus becoming acquainted with the pleasures of learning, he never afterward ceased to value it. His court became the rendezvous of the most distinguished men of his time. The names of Simonides and Pindar appear among those of his most constant companions, and when Æschylus left Greece, he betook himself to Hiero, to close his days in his kingdom. He was several times victor in the Grecian games.

Hiero II., king of Syracuse: b. before 306 B.C.; d. 216 B.C. He was the son of Hierocles, a noble Syracusan, who claimed a descent from the family of Gelon. During Hiero's reign began the first Punic war, and he was able, by his

adroitness, to preserve the friendship of both Romans and Carthaginians. The glory of Hiero and the prosperity of Syracuse culminated in the period which intervened between the first Punic war and the second; for in that season of peace Hiero enacted wise laws, and was devoted to the happiness of his subjects. His encouragement of agricultural pursuits enriched him and doubled the revenues of the state. He left the crown to his grandson Hieronymus.

Hieronymus. See JEROME, SAINT.

Hieroglyphics, hī″ē-rō-glĭf′ĭks (from Gr. *hieros*, sacred, and *glypho*, engrave), the inscriptions sculptured on buildings in Egypt, with the implication that the writing was confined to sacred subjects, and legible only by the priests. The term has also been applied to picture-writing in general, such as that of the Mexicans and the still ruder pictures of the North American Indians. Two different modes of hieroglyphic writing were used by the ancient Egyptians., the hieratic, and the demotic. Pure hieratic writing is the earliest, and consists of figures of material objects from every sphere of nature and art, with certain mathematical and arbitrary symbols. Next was developed the middle hieratic or priestly writing, the form in which most Egyptian literature is written, and in which the symbols almost cease to be recognizable as figures of objects. Hieratic writings of the third millennium B.C., are extant. In the demotic or enchorial writing, derived directly from the hieratic, the symbols are still more obscured. The demotic was first used in the 9th century B.C., and was chiefly employed in social and commercial intercourse. Down to the end of the 18th century scholars failed in find a clue to the hieroglyphic writings. In 1799, however, M. Bouchard, a French captain of engineers, discovered at Rosetta the celebrated stone which afforded European scholars a key to the language and writing of the ancient Egyptians. It contained a trilingual inscription in hieratics, demotic characters, and Greek, which turned out to be a decree of the priests in honor of Ptolemy V., issued in 195 B.C. The last paragraph of the Greek inscription stated that two translations, one in the sacred and the other in the popular Egyptian language, would be found adjacent to it. In deciphering these inscriptions the discovery of an alphabet was the first task. The demotic part of the inscription was first examined by De Sacy and Akerblad, and the signification of a number of the symbols ascertained. The hieratic part was next carefully examined and compared with the demotic and Greek. At last after much study Champollion and Dr. Thomas Young, independently of each other, discovered the method of reading the characters (1822), and thus provided a clue to the decipherment of the ancient Egyptian writing.

Cartouche of Cleopatra, i.e. Kleopatra.

Cartouche of Ptolemy, i.e. Ptolemaios.

Hieroglyphic characters are either ideographic, that is, using well-known objects as symbols of conceptions, or phonetic, that is, representing words by symbols standing for their sounds. The phonetic signs are again divided into alphabetical signs and syllabic signs. Many of the ideographic characters are simple enough; thus the figure of a man, a woman, a calf, indicate simply those objects. Others, however, are less simple, and convey their meaning figuratively or symbolically. Water was expressed by three zigzag lines, one above the other, to represent waves or ripples of running water, milk by a milk-jar, oil by an oil-jar, fishing by a pelican seizing a fish, that is, fishing; seeing and sight by an eye; and so on. The nature of the phonetic hieroglyphs, which represent simply sounds, will be understood from an explanation of the accompanying cuts.

(1) The first hieroglyph in the name of Kleopatra is a knee, which is *kne* or *kle* in Coptic, and represents the K of Kleopatra. (2) The second hieroglyph in Kleopatra is a lion couchant, which is *laboi* in Coptic, and *labu* in the old Egyptian, and represents the L of both names. In Kleopatra it occupies the second place, and in Ptolemaios the fourth. (3) The third hieroglyph in Kleopatra is a reed, which is *aké* in Coptic and *aak* in the old Egyptian, and represents the E of Kleopatra. The reed is doubled in Ptolemaios and occupies the sixth and seventh places, where it represents the diphthong *ai* of Ptolemaios. (4) The fourth hieroglyph in Kleopatra is a noose, which represents the O of both names and occurs in the third place of Ptolemaios. (5) The fifth hieroglyph in Kleopatra is a mat, which represents the P of both names, and is the initial of Ptolemaios. (6) The sixth hieroglyph in Kleopatra is an eagle, which is *akhoom* in Coptic, and represents the A, which is found twice in the name of Kleopatra. (7) The seventh hieroglyph in Kleopatra is a hand, which is *toot* in Coptic, and represents the T of Kleopatra, but does not occur in Ptolemaios, where it might be expected to occupy the second place. The second place of Ptolemaios is occupied by a semicircle, which is found at the end of feminine proper names, and is the Coptic feminine article T. The researches of Champollion satisfied him of the existence of homophones, or characters having the same phonetic value and which might be interchanged in writing proper names. (8) The eighth hieroglyph in Kleopatra is a mouth, which is *ro* in Coptic, and represents the R of Kleopatra. (9) The ninth hieroglyph in Kleopatra is the eagle, which is explained in No. 6 above. (10) The semicircle is the T of Ptolemaios, which with (11) the egg found at the end of proper names of women, is a feminine affix. In the name of Ptolemaios there is still the M and the S to account for. The fifth hieroglyph in the cartouche of Ptolemaios is a geometrical figure, consisting of three sides of (probably?) a parallelogram, but now called a hole, because the Coptic *mu* has that signification, and represents the M. The hook represents the S of the word Ptolemaios. Vowels were only regarded by the Egyptians as they were needed to avoid ambiguous writing. There are groups of hieroglyphs of which one element is an ideographic sign, to which a phonetic complement is added to indicate the pronunciation of the ideographic sign. The

words of a text could be written in hieroglyphs in three ways — (1) by phonetic hieroglyphs; (2) by ideographic hieroglyphs; and (3) by a combination of both. According to Ebers, in the perfected system of hieroglyphics the symbols for sounds and syllables are to be regarded as the foundation of the writing, while symbols for ideas are interspersed with them, partly to render the meaning more intelligible, and partly for ornamental purposes. Consult: Brugsch, 'Ægyptologie' (1891); Erman, 'Life in Ancient Egypt' (1894); and 'Egyptian Grammar' (1894).

Hierosolyma. See JERUSALEM.

Hig'gins, Anthony, American politician: b. Red Lion Hundred, Del., 1 Oct. 1840. He was educated at Yale and after studying law at the Harvard Law School was admitted to the Delaware bar in 1864. From 1869 to 1876 he was United States attorney for Delaware, and becoming interested in politics was chairman of the Republican State Convention in 1868. In 1881 he secured the vote of the Republican members of the Delaware legislature for the National Senate and in 1884 was defeated as a Republican candidate for Congress. He was United States Senator 1889–95.

Hig'ginson, Ella Rhoads, American novelist and poet: b. Council Grove, Kan., 1862. She was married to R. C. Higginson and has passed her life mainly in the vicinity of Puget Sound, Wash. She has contributed much to periodicals, and her work, which has a distinctly original flavor, has attracted much attention from its vigorous presentation of life on the upper Pacific slope. Her most noteworthy book is 'Mariella, or Out West,' an extremely strong novel (1902); and other works of hers are 'The Flower that Grew in the Sand' (1896); 'From the Land of the Snow Pearls' (1897); 'A Forest Orchid' (1897); and several collections of poems.

Higginson, Francis, English clergyman in colonial America: b. 1587; d. Salem, Mass., 6 Aug. 1630. He was educated at Cambridge, England, and subsequently became rector of a parish in Leicester, but becoming gradually a Nonconformist, was deprived of his benefice, and was employed among his former parishioners as a lecturer. While apprehending a summons to appear before the high commission court, he received an invitation from the Massachusetts Company to proceed to their colony, which he accepted. He embarked in May 1629, and it is related by Cotton Mather that as the ship was passing Land's End, he called the passengers about him and exclaimed: "We will not say, as the Separatists were wont to say at their leaving of England, 'Farewell, Babylon; farewell, Rome!' but we will say, Farewell, dear England! farewell, the church of God in England, and all the Christian friends there. We do not go to New England as Separatists, though we cannot but separate from the corruptions of it. But we go to practise the positive part of church reformation, and propagate the gospel in America." He arrived at Salem 29 June, and on 20 July was chosen teacher of the congregation established there. Subsequently Higginson drew up "a confession of faith and church covenant according to Scripture," which on 6 August was assented to by 30 persons, who associated themselves as a church. He wrote 'New England's Plantations, or a Short and True Description of the Commodities and Discommodities of the Country' (1630), and an account of his voyage, printed in Young's 'Chronicles of the First Planters' (1846). Consult: T. W. Higginson, 'Life of Francis Higginson' (1891).

Higginson, Francis John, American rear-admiral: b. Boston 19 July 1843. He was graduated from the United States Naval Academy in 1861 and served in the United States navy during the Civil War becoming lieutenant-commander in 1866. He was commander of the Massachusetts during the Spanish-American War 1898, was promoted commodore that same year, and rear-admiral in March 1899.

Higginson, Henry Lee, American banker: b. New York 18 Nov. 1834. He was educated at Harvard, studied music abroad and served in the Federal army during the Civil War and was brevetted lieutenant-colonel. He has been long connected with the Boston banking firm of Lee-Higginson & Co., and has contributed large amounts toward the organization and support of the Boston Symphony Orchestra.

Higginson, Mary Thacher, American author, wife of T. W. Higginson (q.v.): b. Machias, Maine, 27 Nov. 1843. She has written 'Seashore and Prairie' (1876); 'Room for One More' (1879); and 'Such as They Are' (1893), poems written in collaboration with her husband.

Higginson, Sarah Jane Hatfield, American writer: b. Philadelphia 15 Jan. 1840. With her first husband, a Dutch jurist, she lived for several years in the Dutch East Indies, and after his death returned to the United States, where she was married to Stephen Higginson, a former American consul in the Dutch East Indies. She has written: 'A Princess of Java: a Tale of the Far East' (1887); 'Java, the Pearl of the East,' a book of travel (1890); 'The Bedouin Girl.'

Higginson, Thomas Wentworth, American author: b. Cambridge, Mass., 22 Dec. 1823. He is descended from Rev. Francis Higginson (q.v.) and was graduated from Harvard in 1841, and from Harvard Divinity School in 1847. He became pastor of a Unitarian church in Newburyport, Mass., in 1847, but resigned from the pastorate in 1850, his anti-slavery views being unacceptable to his congregation. In the year last named he was the unsuccessful "Free Soil" candidate for Congress, and he was pastor of a Free (unsectarian) church at Worcester, Mass., 1852–8. In the interim he had been prominent in anti-slavery agitation, and for his share in the attempted rescue of the fugitive slave Anthony Burns (q.v.), was indicted for murder in 1854 with Wendell Phillips, Theodore Parker and others, but owing to a flaw in the indictment the defendants were discharged. He also aided in the Kansas Free State efforts, and during the Civil War was captain of the 51st Massachusetts regiment of volunteers, becoming colonel in November 1862, of the 1st South Carolina volunteers, the earliest regiment of freed slaves in the Federal service. He resigned from the army in October 1864, by reason of disability, and has since given his attention to literature, residing at Cambridge, Mass., since

1878. He has been almost a life-long advocate of woman suffrage and of the higher education of woman, and was a member of the Massachusetts legislature 1880–1, serving on the State board of education, also, 1881–3. He is a polished, graceful speaker, and has frequently appeared on the lecture platform, his latest appearance being as Lowell lecturer on American literature in Boston in 1902. As an after-dinner or occasional speaker he is especially happy, his felicitous sentences being almost always illuminated by the play of a very delicate humor. He is president of the Round Table, a social Boston club, and vice-president of the Boston Authors Club, as well as a member of many other organizations, social and literary. He has been for a generation a constant contributor to periodicals of the highest class and has figured in literature as essayist, novelist, poet, and historian. His principal work in fiction is 'Malbone' (1869), in which his first wife is outlined as Aunt Jane. As an essayist he is perhaps seen at his best, the essay form seeming peculiarly adapted to his genius. Among collections of essays by him may be cited: 'Outdoor Papers' (1863); 'Atlantic Essays' (1871); 'Women and Men' (1887); 'The New World and the New Book' (1891); and 'Concerning All of Us' (1892). His 'Young Folks' History of the United States' (1875) has been widely popular, and other histories by him are 'Larger History of the United States' (1885); 'English History for Americans' (1893); 'Massachusetts in the Army and Navy, 1861–5' (1895–6). His verse is included in 'The Afternoon Landscape' (1889); 'Such as They Are' (1893). Yet other important works by him are 'The Monarch of Dreams,' a strikingly original sketch (1886); 'Army Life in a Black Regiment' (1869); 'Cheerful Yesterdays' (1898); 'Old Cambridge' (1899); 'Contemporaries' (1899); and lives of Margaret Fuller (1884); Francis Higginson (1891); Henry W. Longfellow (1903); John Greenleaf Whittier (1903); 'History of the United States' (1905). He translated the complete works of Epictetus (1865, revised edition 1891). With Samuel Longfellow (q.v.) he completed a well-known anthology of seaside verse, 'Thalatta' (1853), and with Mrs. E. H. Bigelow 'American Sonnets' (1890). Several of his works have been translated into French, German, Italian, and even modern Greek. He was the friend of very many of the older New England writers and has been especially helpful to many of the younger ones, not a few of whom owe him much in the way of kindly criticism or suggestion, the fruit of ripe scholarship.

High Church, a term applied to a faction in the Church of England. It was applied first to the younger clergy during the latter part of the reign of Elizabeth who asserted that Calvinism was inconsistent with the ancient doctrine and constitution of the primitive church, and who claimed a divine right for episcopacy. Bishop Andrews was the chief writer of this faction, and Laud became its most active leader. The term now generally refers to those who exalt the authority and jurisdiction of the church, and attach great value to ecclesiastical dignities and ordinances, being more or less identified with the ritualistic party. See RITUALISM.

High Bridge, Engagement at. See FARMVILLE.

High-Frequency Oscillating Current. This term is especially applicable to electrical currents, the high frequency interruptions of which are obtained by means of condenser discharges in contradistinction to those produced by a disrupted static current, without the interposition of a metallic condenser in series with one or both terminals. The latter differs in several characteristics and is essentially a high potential current, 10,000 to 50,000 volts, with a minimum amperage, usually about .0005.

To generate a high-frequency current it is usual to charge two Leyden jar condensers with a high potential current, the source of which may be a static machine or induction coil, shunting the two wires with a spark-gap for the purpose of disrupting the current. The external armatures of the condensers are short-circuited through a solenoid or helix consisting of a few turns of coarse copper wire (D'Arsonval). The helix may be substituted by a straight copper bar (Sheldon). By prolonging the helix from 50 to 100 turns, this constitutes the resonator of Oudin. The upper part of the helix resonates in unison with the lower, when properly in tune, as would a tuning-fork resonate with another of the same pitch. The office of the extended helix is to amplify the current.

Another arrangement is after Tesla: The primary of a specially constructed induction coil is energized by an alternating current. The secondary terminals, giving a potential of 15,000 volts, are connected, one to each side of a suitable condenser. From each of these terminals a shunt is taken. One leads to one end of the primary of a Tesla coil; the other, broken by a spark-gap, is connected to the second terminal of the primary. The frequency obtained from the Tesla apparatus is fabulously high — millions a second. The potential may be hundreds of thousands or millions of volts. The amperage is sufficient to light to full candle-power several incandescent lamps. The primary of the induction coil consumes 15 to 25 amperes. For maximum high frequency effects this type of apparatus seems to be essential. The brush discharge from the terminals may be 20 or even 50 inches in length. There are many modifications of this apparatus.

The one characteristic of the high-frequency oscillating current is its lack of power to excite the motor, and, aside from a slight sensation of warmth, the sensory nerves at the point where the electrode touches the body. The accepted explanation for this fact is, that the nerves respond to certain frequencies of stimulus; for the motor nerves, reaction takes place up to about 5,000 frequencies; if these are gradually increased muscular contraction diminishes and finally ceases. This theory is in line with reasoning as to the cause for action of the special senses — sight and hearing.

At the terminals of a working high-frequency apparatus is seen a beautiful brush discharge or effluve of a peculiar blue color, which will leap to any object brought near it. Interpose a plate glass one half inch thick (or more), and

the effluve will penetrate it. If the object be a vacuum tube it will glow almost as brightly as if nothing intervened. It is an ideal current for igniting Geissler and low-vacuum X-ray tubes; only one terminal need be connected.

The high-frequency discharge is a rich ozone generator, and, applied to unhealthy granulations and various skin diseases, acts as an oxidizer, antiseptic, and disinfectant. Applied to the skin before incision, it will render the site aseptic.

For general effect the patient is placed upon an auto-condensation couch or in the centre of an auto-conduction cage. In the treatment of sub-acute and chronic rheumatism, sciatica, neurasthenia, etc., it is most useful.

JOHN M. GARRATT, M.D.

High Priest, the head of the Jewish priesthood. In the books of Moses the holder of this dignity is simply designated the priest, the epithet high occurs on one or two occasions, but as a distinctive epithet it appears to have been added subsequently. The formal consecration of Aaron, the brother of Moses, together with his sons, to a hereditary priesthood, is recorded in Ex. xxviii. The high-priesthood continued in the line of Aaron, sometimes in one, and sometimes in another branch of it, until the coming of Christ. After the subjugation of the Jews by the Seleucidæ, the Ptolemies, and the Romans, it was often arbitrarily conferred by the foreign masters. The dignity of the priest's office is indicated by the splendor and costliness of his garment, which was among the most beautiful works of ancient art. To the high priest belonged the regulation and superintendence of the worship of God, the declaration of the oracles of Jehovah to the people (he alone being permitted to consult them on important public occasions), and the preservation of the national sanctuary. Although the administration of justice was committed to particular judges, yet to him the last appeal was made in difficult cases, even in temporal affairs, and nothing important in war or peace could be undertaken without his assent.

High Schools, the term applied in the public school system of the United States to the institutions for secondary and higher education preparatory to a college course. They were generally established at public expense between 1820 and 1850, to correspond in grade to the academies or schools maintained by endowment or at private expense in which young men were prepared for college.

The European representatives of the American high schools are the public schools and colleges of Great Britain, the lyceums of France, Spain, and Italy, and the gymnasia of Germany; the universities in Germany are officially called high schools (Hochschulen).

The term "high school" was applied as early as the 16th century to a celebrated educational establishment of a liberal character, a grade below the university, in Edinburgh, Scotland.

In 1647 the Massachusetts Colony enacted a law that every town of 100 families should maintain a school, the teacher of which should be "able to instruct youth, so far as they may be fitted, for the university." This law, though imperfectly obeyed, introduced very early into Massachusetts and New England a small number of classical schools, and subsequently prepared the way for the endowment of a few academies in which young men were prepared for the colleges. Of these especially endowed academies, many of which rendered eminent service, the more notable are the Hopkins Grammar Schools of Hartford and New Haven, Conn.; the Hopkins Academy in Hadley, and Phillips Academy at Andover, Mass.; Phillips Exeter Academy at Exeter, N. H., and Amherst Academy, Mass. Among the public schools of the country, the Boston Latin School, a colonial foundation, was for a long time almost the only classical school supported by public taxation at which students could be prepared for college. It was pre-eminent alike for the thoroughness of the education which it gave, and the freeness with which this was proffered to all the residents of Boston. In 1821 the English High School, supplementary to the Latin School, was established in Boston. In Philadelphia the corresponding institution still bears the name of the Central High School, while in New York city the original Free Academy has developed into the College of the City of New York. With the reorganization of the public school systems of the older States, and the foundation of such systems almost simultaneously with the redemption of the soil from the forest and wild prairie in the newer States, provision was made for a system of high schools, to give a thorough preparation for the college curriculum. These high schools are now in vigorous operation from one end of the United States to the other. See EDUCATION, SECONDARY.

High Seas. Among maritime nations both in ancient and modern times the necessity for some international regulations to govern their communications by sea has been found a necessity. The views of jurists on this subject have fluctuated between two opposite principles. Nations possessing a powerful marine, are disposed to push their privileges to the utmost, and to claim exclusive accession to, or a superiority and protective rights over, extensive tracts of the ocean highway. The weaker maritime nations, on the other hand, and the commercial rivals of these most especially privileged, have contended for the liberty of the seas. The most memorable instance of this controversy occurred in connection with the claims arising out of the great maritime discoveries of the Portuguese at the close of the 15th century. Under the grant of Pope Alexander VI. the Portuguese claimed the right to exclude other nations from the seas between the eastern coast of Africa and the coasts of India. Against this claim Grotius wrote his celebrated treatise, the 'Mare Liberum,' which appeared in 1609. The English, who had their own claims of jurisdiction, were not then, or for long after, prepared to admit the liberty of the seas. The general principle of international law now accepted is that the jurisdiction of maritime nations extends only for three miles, or within cannon range of their own coasts; the remainder of the seas being high seas, accessible on equal terms to all nations. Inland seas and estuaries, of course, are excepted.

High Treason (Fr. *trahison,* betrayal), is defined in English law as the most heinous of all offenses against the law, and consists in imagin-

ing or devising the death of the ruling monarch, or proposing to kill, maim or restrain the king or queen; or levying war against him; adhering to his enemies; killing his wife or eldest son, or heir; violating his wife, or daughter, or heir's wife; killing the lord chancellor; killing the chancellor of the exchequer, or a justice in office. High treason against the United States consists in levying war against them; adhering to their enemies, or giving their enemies aid and comfort. Treason against a State is generally defined as hostility to a State only. The former punishment of treason in English law was death by hanging, drawing and quartering. The penalty is now hanging or imprisonment. This crime is punishable in the United States according to the act of 1862 by death or imprisonment with hard labor for a period of not less than five years, a fine of not less than $10,000 and a perpetual disability to hold any office under the United States. The act of 1862 adds: "No person shall be convicted of treason unless on the testimony of two persons to some overt act, or on confession in open court. The Congress shall have power to declare the punishment of treason, but no attainder of treason shall work corruption of blood (q.v.) or forfeiture except during the life of the person attainted."

Highbinders, a name given to a secret organization among the Chinese in the United States which has caused much bloodshed in the Chinese quarter of San Francisco, Cal., necessitating intervention on the part of the authorities. The Chinese call these societies "hatchet" societies, and the members "hatchet men." The organization seems to be an offshoot of the Six Companies (q.v.), though some claim that it is merely a revival of one which originated over 200 years ago in China.

Higher Criticism, The. The higher criticism is a science whose aim is the determination of the literary history of books and writings. It sets forth the facts and principles by which we must determine, in the case of any writing, its literary form, its unity, its date, the place of its composition, its authorship, the method of its composition or construction, its integrity, and the amount and character of any subsequent editing it has received, so far as these matters can be discovered by the use of such internal evidence as is presented in the writing itself. It is thus the science for ascertaining the literary form and the literary history of any writing by means of internal evidence. These same matters may also be determined, in part or in whole, by external evidence in many cases; that is, by history or tradition. This latter method will not necessarily be either better or worse than the method which employs internal evidence. The greater probability of the result, in every case, will depend upon the amount and the character of the evidence which is attainable. Sometimes external evidence may be more abundant and trustworthy than the internal evidence, and sometimes the reverse may be true.

The science under consideration is termed higher criticism to distinguish it from the related science of lower, or textual, criticism. This latter science has for its object the ascertaining of the history of writings as the work of penmen and printers. It seeks to determine just the words and the letters which the author himself wrote, and what are the changes which his work has suffered in transmission. Since the literary history of a writing is, on the whole, of more importance than the history of the written or printed text, the science of the literary history is justly termed the higher criticism.

The higher criticism is a science which is equally applicable to all literatures. It may be used to determine the literary history of a writing of any age, language, or people. But, of late, it has been especially brought into notice in its application to the literature of the Bible. On this account, it is sometimes spoken of as if it were a science belonging to Biblical study only. But the fact is that Biblical higher criticism is only one department of higher criticism in general.

As employed in Biblical study, higher criticism adopts the following method: (1) it sets forth the principles by which, according to the teachings of general literary criticism, we may correctly determine the literary form, the unity, the date, the place of composition, the authorship, the method of composition or construction, the integrity, the amount and character of subsequent editing, of each of the Biblical books and writings; (2) it then presents the evidential facts to be found in each of the Biblical books and writings, to which these principles will apply; and (3) finally it gives the conclusions which result from the application of these principles to the evidential facts. In practice, however, different schools of Biblical higher critics come to very different conclusions upon the same basis of evidential facts, while using the same principles of criticism. This results from the varying opinions held by these critics in relation to the value and significance of the evidential facts, due to their differing views about the history of Israel, and their philosophical convictions concerning the place of the supernatural in that history. Those critics who refuse to allow the existence of any supernatural element in the history of Israel, and hold that this history was the product of only those forces which shape and determine all human history, so that it was exactly like the history of every other people, cannot put the same value and meaning upon the historical testimony and references to be found in the Biblical books, as those critics must who believe that the history of Israel was, to no inconsiderable extent, a supernatural history, and, therefore, different from the history of every other people. In the case of the Old Testament, for example, some critics hold, because of their philosophical opinions in regard to the supernatural, and the universality of the working of the evolutionary forces of history, that the historical material of the Old Testament, as we now have it, is not to be accepted as the true basis of Old Testament history, and that this history must be constructed out of this material, under the guidance of some philosophical theory. Other critics accept the historical material which is now to be found in the Old Testament, as furnishing in itself the true Old Testament history. Since the evidential facts used in higher criticism receive their value and meaning from their evident relation to a previously determined history, it is clear

that each of two so different histories cannot be a basis for the same critical conclusions. But it is to be noted that the determination of the histories is not a work of higher criticism, but is a matter which results from the philosophical opinions held by historians. The consequence of these facts is that the only results which have thus far been reached by Biblical higher criticism, which all schools of critics would accept, seem to be: (1) The existence of different documents in the Pentateuch, which have been used in its compilation, although there is, among critics, quite a little difference of view in relation to the age of these documents and the time of their compilation into the Pentateuch; (2) the plural authorship of the books of the Old Testament known as the books of Isaiah and Zechariah; and (3) the fact that older sources have been used in the making of the synoptic gospels and the book of Acts. From all that has been said, it will be seen that it is not the duty of higher criticism to assert or deny anything in relation to the inspiration of the Scriptures, or their authority for belief or conduct. With these matters this science has absolutely nothing to do.

S. Burnham, D.D.,
Dean of the Hamilton Theological Seminary, Colgate University.

Higher Law, a famous phrase used by William H. Seward (q.v.) 11 March 1850, in the United States Senate, on the admission of California as a State, which was held up by the Southern element to force the Congress to admit it as a slave State, or at least to divide it on the line of the Missouri Compromise (q.v.). Seward denied that the principle of compromise applied only to slavery, which was only one of many institutions, and held it equally applicable to the Territories, which were a possession to be enjoyed and administered in common by the States; and declared that the older States had no arbitrary power over them. He went on: "The Constitution regulates our stewardship; the Constitution devotes the domain to union, to justice, to defense, to welfare, to liberty. But there is a higher law than the Constitution, which regulates our authority over the domain, and devotes it to the same noble purposes. The territory is a part . . . of the common heritage of mankind, bestowed upon them by the Creator of the universe. We are his stewards, and must so discharge our trust as to secure in the highest attainable degree their happiness." And to Webster's assertion that it was absurd to re-enact the laws of God, he answered that "there is no human enactment which is just that is not a re-enactment of the law of God." It was his first set speech in the Senate, and at once made him the recognized leader of the radical section. The conservatives denounced it as treasonable, implying that no one was under any obligation to support the Constitution if he believed it in opposition to the law of God, and making the execution of any laws impossible.

Higher Plane Curves. See Curves, Higher Plane.

High'land Cattle, a variety of small, rough-coated, usually red or black cattle, with upturned horns, kept half wild upon the moors of the Scottish Highlands, and believed to represent in part the cattle of the aboriginal Britons, which are replaced in the south of Great Britain by the short-horned breeds introduced by the Roman conquest. Compare White Cattle.

Highlanders, Scotch, in the United States. After the Jacobite risings in England in 1715 and 1745, in favor of the Old and Young Pretenders, which were zealously supported by the Highlanders (who indeed formed their backbone), the English government exerted itself to drain their strength by colonizing them elsewhere; and many who were in danger of vengeance came to America voluntarily. The chief movement was after 1745, when the government thoroughly reorganized the Highlands, broke up the clans, and deported large numbers to the colonies; but after 1715 many, in bands or as individuals, had come over, especially to the Carolinas. Some settled in western South Carolina, as farmers or Indian traders; a considerable body near Fayetteville, N. C., where their descendants still speak Gaelic in preference to English, and have their church ministrations in that language; and a number of different colonies in the future Georgia, where Oglethorpe found them when he came over in 1733 with a patent for a new colony. Especially he won the hearts of a settlement at Darien, under a Capt. Mackay. These Highlanders gave him priceless help in his incessant fights with the Spaniards and constant negotiations with the Indians; but they strongly opposed the slave trade or the introduction of slaves into Georgia. Some Highland companies sent to the Mohawk Valley, during the French and Indian war, were disbanded there, and remained as settlers, a recognizable element during the Indian troubles of the early Revolution.

Hil'da, Saint, Anglo-Saxon abbess: b. about 614; d. 680. She was consecrated as a nun by Bishop Aidan, and was successively head of the abbey of Hartlepool, and of the famous monastery founded by her in 657 at Whitby, Yorkshire. This continued for several centuries a religious house of great power and influence, in the time of its founder perhaps the strongest in Great Britain. Cædmon (q.v.), the Anglo-Saxon poet, was attached to the monastery during her rule, and it was there that the celebrated synod took place in 664 in which the Celtic ritual was condemned. Consult: Bede, 'Ecclesiastical History.'

Hil'debrand. See Gregory VII., Pope.

Hil'dreth, Richard, American historian: b. Deerfield, Mass., 22 June 1807; d. Florence, Italy, 11 July 1865. He was graduated at Harvard in 1826, studied law at Newburyport, entered practice in Boston, and abandoned it in 1832 to become editor of the 'Boston Atlas.' In this position a series of articles by him in 1837, relative to the separation of Texas from Mexico, did much to stimulate the resistance which that movement encountered in the free

States. In 1834 his anti-slavery novel, 'The Slave,' was written. This work was republished and favorably received in England, and in 1852 an enlarged American edition appeared under the title of 'The White Slave: Memoir of Archy Moore' (1837). In 1837–8 he was Washington correspondent of the 'Boston Atlas,' and resumed his editorial post as an advocate of the election of General Harrison, of whom he wrote a campaign biography. He then abandoned journalism, and in 1840 published, under the title of 'Despotism in America,' a volume on the political, economical, and social aspects of slavery, to which in the edition of 1854 was appended a chapter on the 'Legal Basis of Slavery.' In 1840–3 he resided in Demerara, British Guiana, and at Georgetown edited two free labor newspapers. Later, for several years, he was a member of the New York *Tribune* staff, and in 1861 was appointed United States consul at Triest. His best known work is his 'History of the United States' (1849–56), which extends from 1492 to the end of President Monroe's first term. The author sought an authentic presentation of the conspicuous figures of earlier American history. His work is accurate and careful, though with a Federalistic viewpoint; but so uninteresting in manner as to be ill-adapted for continuous reading. Hildreth also wrote: 'Theory of Morals' (1844); 'Theory of Politics' (1853); 'Japan as it Was and Is' (1855); and 'Atrocious Judges' (1856).

Hilgard, hĭl'gärd, **Eugene Woldemar,** German-American chemist and geologist: b. Zweibrücken, Bavaria, 5 Jan. 1833. He came to the United States in 1836, returned to Europe for purposes of study and was graduated (Ph. D.) at Heidelberg, 1853. In 1858 he became State geologist of Mississippi, in 1873 was appointed professor of geology and natural history in the University of Michigan, and in 1875 was made professor of agricultural chemistry and director of the agricultural experiment station in the University of California. He received the Liebig medal from the Munich Academy of Sciences in 1894, and his investigations into the chemistry and physics of soils have done much to promote agricultural science.

Hill, Adams Sherman, American educator: b. Boston, 30 June 1833. He was graduated from Harvard College 1853 and Harvard Law School 1855, and in 1875 became Boylston professor of rhetoric and oratory at Harvard University. He has written: 'Principles of Rhetoric' (1878); 'Our English' (1889); 'Foundation of Rhetoric' (1892).

Hill, Ambrose Powell, American military officer: b. Culpeper County, Va., 9 Nov. 1825; d. 2 April 1865. He was graduated at the United States Military Academy 1847; served in the Mexican War, but resigned from the army in March 1861, and was made colonel of the 13th Virginia regiment of the Confederate army. Having distinguished himself in service, he was promoted major-general in May 1862, and lieutenant-general 20 May 1863, and placed in command of one of the three corps of the army of Northern Virginia. He led his corps at Gettysburg and later at Bristow Station and the assault on the Weldon railroad in 1864. He was killed in the attack on Petersburg, Va.

Hill, Benjamin Harvey, American legislator: b. Jasper County, Ga., 14 Sept. 1823; d. 16 Aug. 1882. He was graduated at the State University of Georgia in 1844 and chose law as a career. In 1851 he was elected to the State legislature. He in vain attempted to withstand the secession sentiment of his State, but at last yielded to the movement, and was elected to the Provisional Confederate Congress, and from the assembly promoted to the Confederate Senate. He supported Greeley for the presidency in 1872, and was defeated for the United States Senate the following year, but after being elected to the House of Representatives in 1875, was given a seat in the United States Senate 1876 and held it for the remainder of his life.

Hill, Daniel Harvey, American military officer: b. Hill's Iron Works, York district, S. C., 12 July 1821; d. Charlotte, N. C., 24 Sept. 1889. He was graduated at the United States Military Academy in 1842, and served in the Mexican War; became professor of mathematics and military tactics in Washington College, Va., in 1849, professor of mathematics in Davidson College, N. C., in 1854; and was made president of the North Carolina Military Institute in Charlotte in 1859. At the outbreak of the Civil War he entered the Confederate army as colonel; was promoted to lieutenant-general in 1863, and commanded a corps at the battle of Chickamauga. After the close of the war he resumed his educational work, and in 1877 became president of the Arkansas Industrial University, where he remained until shortly before his death.

Hill, David Bennett, American lawyer and politician: b. Havana, N. Y., 29 Aug. 1843. He entered a law office in Elmira, N. Y., as clerk and student in 1862, and after admission to the bar in 1864, rapidly built up a law practice and was an acknowledged leader of the local bar. He was active in politics, and acquired a leadership there also, through his genius for organization. He was a member of the State assembly 1870–1, and president of the Democratic State convention in 1877 and 1881. In 1882 he was elected mayor of Elmira, and lieutenant-governor in the same year, with Cleveland as governor. In 1885, when Cleveland resigned to take up his duties as President, Hill became governor. He was subsequently twice elected governor, serving till January 1892, when he took his seat in the United States Senate. During his first administration as governor, the legislature was Republican, and he was involved in a number of partisan struggles. As senator, he opposed on some issues the policy of President Cleveland; he was also opposed to the income tax clause of the Wilson Tariff Bill. In 1892 he was a prominent candidate for the presidency at the Democratic National convention, and at the convention of 1896 was one of the chief leaders of those who favored the gold standard and were opposed to radicalism in the party. In 1894 he was again candidate for governor of New York State, but was defeated by Levi P. Morton. In 1902 he practically dominated the Democratic State convention, and was active throughout the campaign.

Hill, David Jayne, American educator and diplomat: b. Plainfield, N. J., 10 June 1850. He was educated at Bucknell University, where he became professor of rhetoric 1877–9, and then president of the institution. He was elected president of Rochester University, N. Y., in 1888, resigning to spend three years in Europe studying international law and diplomacy. He became first assistant United States secretary of state in October 1898, and in 1903 was appointed United States minister to Switzerland. He has written biographies of 'Washington Irving' (1879); and 'William Cullen Bryant' (1879); 'Principles and Fallacies of Socialism' (1885); 'International Justice'; 'A Premier of Finance'; etc., and several school and college textbooks.

Hill, Frank Alpine, American educator: b. Biddeford, Maine, 12 Oct. 1841; d. Brookline, Mass., 12 Sept. 1903. He had long been prominent among New England educators, and after being head-master of high schools in Milford, Chelsea, and Cambridge, Mass., became secretary of the Massachusetts State Board of Education in 1894. He was a trustee of the Massachusetts Institute of Technology, of the State Agricultural College at Amherst, and of the Boston Museum of Fine Arts, as well as a commissioner of the State School Fund.

Hill, Frank Pierce, American librarian: b. Concord, N. H., 22 Aug. 1855. He was graduated from Dartmouth in 1876. In 1881 he became librarian of the Lowell public library, and in 1885 he organized the first free public library in New Jersey at Paterson. He also organized the Salem public library, and the Newark library in 1889. At Newark a new building was erected under his administration and the library brought to a high degree of efficiency so that it is recognized as one of the model public libraries. In 1901 he was appointed chief librarian of Brooklyn, under the new system established upon the receipt of Mr. Carnegie's gift.

Hill, Frederic Stanhope, American sailor and author: b. Boston, 24 Aug. 1829. He went to sea when a boy, and during the Civil War was an officer in the United States navy. He was with Farragut at the capture of New Orleans and Vicksburg, and was also in command on the Texas coast and in the Mississippi squadron. He has written: 'Twenty Years at Sea' (1896); 'Story of the Lucky Little Enterprise'; 'Twenty-six Historic Ships' (1903); and has been editor of the Cambridge 'Tribune.'

Hill, George Birbeck, English educator and author: b. Tottenham, Middlesex, 7 June 1835; d. Hampstead, London, 24 Feb. 1903. He was a nephew of Sir Rowland Hill (q.v.), was educated at Oxford, and was head-master of Bruce Castle School 1859–76. Since the latter date he had devoted his attention to literature and was well known in the United States through his 'Harvard College, by an Oxonian' (1894). Other works by him are: 'Talks about Autographs' (1896); 'Dr. Johnson: his Friends and his Critics' (1878); 'Life of Sir Rowland Hill' (1880); 'Foot-steps of Dr. Johnson in Scotland' (1890); 'Memoirs of the Life of Edward Gibbon' (1900).

Hill, Henry Wayland, American lawyer: b. Isle La Motte, Vt., 13 Nov. 1853. He was graduated from the University of Vermont in 1876, was principal of Swanton, Vt., union school 1877–9, and of Chateaugay, N. Y., academy 1879–83. He was admitted to the bar at Albany, N. Y., in 1884, and entered upon the practice of his profession at Buffalo. He was a member of the New York assembly 1896–1900, and has been State senator since 1901, representing each time a constituency in Buffalo. He is the author of several constitutional provisions and of several general statutes now in force. During his public career he has secured for Buffalo large State appropriations for the new 74th and 65th regiment armories, for the Historical Society building, for harbor improvement and other public purposes. He also advocated measures designed to provide home rule for cities, reform in election methods, etc., and many important State measures, such as the Primary Election law, the Civil Service law, the Franchise Tax law, the Pharmacy law, and the Canal Improvement referendum of 1903. He has made a study of waterways in this and other countries, and contributes the article on that subject in this encyclopedia. He is the author of 'The Development of Constitution Law in New York,' and a contributor to the 'Bibliophile Edition of the Odes and Epodes of Horace.'

Hill, James J., American capitalist: b. near Guelph, Ont., 16 Sept. 1838. At 18 in the village of St. Paul, Minn., he became check-clerk and caretaker of freight at the steamboat landing. At that time there was not a mile of railroad in the State. In 1862 the first 10 miles of railroad were finished from the levee in St. Paul to the riverside in St. Anthony, and known as the St. Paul and Pacific railroad, of which Hill later became the agent. After the Civil War, Hill clearly discerned the great resources and possibilities of the Red River country—Western Minnesota and Eastern Dakota. He went East, contracted for his boilers and machinery, and on the bank of the river built a flat-bottomed steamer called The Selkirk, which in the summer of 1870 began to run between Winnipeg and the head of navigation, to rival the line operated by the Hudson Bay Company. The same year, 1872, Hill consolidated his transportation interests with those of the Hudson Bay Company, forming the Red River Transportation Company. The St. Paul and Pacific railroad now reached the western boundary of the State at Breckenridge. For several years the St. Paul and Pacific system of railroads, consisting of 437 miles of completed track, was in poor condition. The stockholders, mostly Holland capitalists, were weary with delay and misfortune. Because of his faith in the future of the region Hill formed a syndicate of five persons which soon gained possession of the road, and in June 1879, the system was consolidated into a single ownership as the St. Paul, Minneapolis and Manitoba Railroad Company. In 1880 the road was extended to the Pacific coast, traversing vast tracts of land without human habitation. The track was well laid, but the stations were often only freight cars, remote from one another, and from other human settlements. The road is now known as the Great Northern. Coal fields were discovered, a branch road carried their product for the use

of the main line and settlements formed for preparing the lumber for shipment. To ship valuable lumber eastward was an excellent plan; but to send empty cars after it was out of the question; and Hill conceived the idea of shipping grain for the Japanese steamers to carry to the Orient. An agent was sent to China and Japan to find out what the price of wheat must be to compete with rice, and the result was that the Japanese Navigation Company, the third largest steamship company in the world, began to carry large shipments of grain to China and Japan. Large docks for these steamers were built at Seattle, Wash., the western terminus of the road. The original 437 miles of completed road of which Hill took charge as manager, developed into the Great Northern system of 6,000 miles. In 1883 he became president of the company. The road extends from Puget Sound to St. Paul, or during the season of navigation to Duluth and Superior, where it connects for Buffalo with its own steamers. A fleet of six freight vessels are added to these. The grain ships moving through the "Soo" give that canal rank over the Suez in point of tonnage.

In developing this scheme the plan increased enormously in the process. Besides laying the foundation of a great fortune, it opened a very rich and vast new country, reached out to new markets for many American products, and brought benefit to great numbers of people. All along the line of the road Hill encouraged the most diversified and productive farming, and introduced new methods and labor-saving devices.

Hill, Octavia, English social reformer: b. about 1838. She began work among the London poor under F. D. Maurice (q.v.); and in 1864, supported by Ruskin, began her great work of improving the homes of workingmen in the slums of London. Her methods were based upon the principle of teaching the people to help themselves, by inculcating in them right notions of cleanliness, order, and self-respect. Her efforts have been crowned with great success; the houses which have been improved yield a good percentage on the money spent in effecting the improvements; and through her hundreds have been helped to lead more comfortable and better lives. She has written 'Homes of the London Poor' (1875); 'Our Common Land and other Essays' (1878).

Hill, Robert Thomas, American geologist: b. Nashville, Tenn., 11 Aug. 1858. He was graduated from Cornell University in 1886; and was immediately given a position on the United States Geological survey. He was also a lecturer in the school of economics at the University of Michigan, and professor of geology at the University of Texas for two years, which position he resigned to return to the United States Geological Survey. He has been engaged in geological and geographical explorations in the southwestern States, Mexico, Central America, and the West Indies. His work in the two last-mentioned localities has been the investigation of the origin of the land forms, and the problem of the union of the continents. Among his most valuable contributions to geological science have been the proof of the existence of the lower cretaceous formation in the United States and the announcement of the possibility of artesian wells in Texas. In May 1902 he was sent by the National Geographical Society at the head of the expedition to investigate the volcanic eruption of Mount Pelée in Martinique. His publications include 'On Occurrence of Artesian and Other Underground Waters in Texas' (1892); 'Cuba and Porto Rico with other Islands of the West Indies' (1898); and numerous contributions to the bulletins of the geological survey and periodicals.

Hill, Rowland, English popular preacher: b. Hawkstone, Shropshire, 13 Aug. 1744; d. London 11 April 1833. He was ordained in the Anglican Church, but embracing the views of the Calvinistic Methodists, soon began to preach in barns and meeting-houses, and when they were too small or too distant, or not to be procured, in streets, fields, and highways. In 1783 he laid the foundation of Surrey Chapel, Blackfriars Road, London, where he preached with great success every winter for about 50 years, making summer excursions to the provinces, where his eloquent but eccentric preaching attracted immense crowds. He published sermons and other theological works, of which the best known are his 'Village Dialogues.'

Hill, Rowland, Viscount, English soldier: nephew of Rev. Rowland Hill (q.v.); b. Prees, Shropshire, 11 Aug. 1772; d. near Shrewsbury, England, 10 Dec. 1842. He entered the army in 1790 and served with distinction from Toulon to Waterloo. In 1812 he was made a K. B., and in 1814, a peer by the title of Baron of Almaraz and of Hawkstone. At the battle of Waterloo, Lord Hill commanded the right wing of the British. In 1828 he was appointed general commanding-in-chief of the British army. This important office he continued to hold under several successive ministries, and only resigned it a few months before his death. He was made a viscount in 1842. He was often styled "the right arm of Wellington." See Sidney's 'Life of Lord Hill' (1845).

Hill, Sir **Rowland,** English postal reformer: b. Kidderminster, 3 Dec. 1795; d. 27 Aug. 1879. He was engaged as a schoolmaster till 1833, shortly after which he was appointed secretary to the commissioners for the colonization of South Australia. In 1837 he published a pamphlet recommending the adoption of a low and uniform rate of postage throughout Great Britain and Ireland. The scheme was approved by a committee of the House of Commons, and early in 1840 the penny postage system, which seems to have been originally proposed by James Chalmers of Dundee, was carried into effect with the assistance of Rowland Hill, who, for this purpose, received an appointment in the Treasury. In 1846 he received a public testimonial of the value of upward of £13,000. In 1846, he was made secretary to the postmaster-general, and in 1854 chief secretary to the Post-office. In 1860 he became K. C. B.

Hill, Thomas, American Unitarian clergyman and mathematician: b. New Brunswick, N. J., 7 Jan. 1818; d. Waltham, Mass., 21 Nov. 1891. Left an orphan at 10 years; at 12 he was apprenticed to the printer of the 'Fredonian' newspaper, where he remained four years. He then entered an apothecary's shop, after a year's attendance at school, and served in it several years. He was graduated from Harvard College in 1843; and from the Divinity School in 1845,

and was settled as pastor at Waltham the same year. He was president of Antioch College, Ohio, 1859–62. He accompanied Agassiz on his expedition to South America and was pastor of the Unitarian Church at Portland, Maine, 1873–91. He published 'Elementary Treatise on Arithmetic' (1845); 'Geometry and Faith' (1849); 'First Lessons in Geometry' (1855); 'Treatise on Curves' (1855); 'The Natural Sources of Theology' (1875); 'In the Woods and Elsewhere', verse (1888); etc.

Hill, Thomas, American painter: b. Birmingham, England, 11 Sept. 1829. He came to the United States in 1841. Returning to Europe he studied under Paul Mayerheim for several months, but is practically a self-taught artist. He painted the 'Yosemite Valley' which was chromo-lithographed by Prang. He has continued to confine himself to the grander aspects of American scenery, and notable among his productions are 'The Home of the Eagle'; and 'Grand Cañon of the Sierras.'

Hill, Walter Barnard, American lawyer and educator: b. Talbotton, Ga., 9 Sept. 1851: d. Athens, Ga., 28 Dec. 1905. He was graduated from the University of Georgia in 1870, and from the law school in 1871, with the degree of A.M. He was admitted to the bar, and practised law in Macon, Ga., from 1871 to 1899. He was a member of the Georgia Bar Association, and was its president in 1888; a member also of the American Bar Association and the chairman of the committee on judicial administration. He also was actively interested in educational progress, being trustee of Vanderbilt University at Nashville, Tenn. In 1899 he was appointed chancellor of the University of Georgia; as an educator he strongly approved the work of the Tuskegee and similar institutions for the negro. He wrote articles on legal and educational subjects and compiled the law code of Georgia (1873, 1882).

Hill, Walter Henry, American Roman Catholic priest and educator: b. near Lebanon, Ky., 21 Jan. 1822. He was graduated from St. Mary's College in 1843, was tutor there for a time, and also studied medicine at St. Louis University. In 1847 he became a member of the Jesuit order, taught at St. Joseph's College and at St. Louis University and completed his theological studies. In 1861 he was ordained a priest; in 1865–9 he was president of St. Xavier College at Cincinnati; he was socius of the provincial at St. Louis University in 1869 and professor of mental and moral philosophy there in 1871. From 1884 to 1896 he was pastor of the church of the Sacred Heart in Chicago, and in 1896 retired from all active duties. He has written 'Elements of Philosophy, comprising Logic and Ontology' (1873); 'Ethics of Moral Philosophy' (1877); 'Historical Sketch of St. Louis University' (1879); and valuable contributions to the 'American Catholic Quarterly.'

Hill River. See HAYES RIVER.

Hillard, hil'ard, **George Stillman,** American author and lawyer: b. Machias, Maine, 22 Sept. 1808; d. Boston 21 Jan. 1879. He was graduated from Harvard in 1828, and from the Harvard Law School four years later. He was a member of the Massachusetts senate in 1850, where his policy as a legislator was warmly commended by Daniel Webster; a member of the Massachusetts constitutional convention in 1853; and United States district attorney in 1866–70. Though successful as a lawyer his tastes were largely literary; he was well known as a lecturer; was editor of the 'Christian Register' with George Ripley, and associate editor of the Boston *Courier;* wrote 'Six Months in Italy' (1853); 'Life of George Ticknor' (with Mrs. Ticknor); 'Life of George B. McClellan' (1864), and edited a series of school readers which bore his name, and the works of Spenser.

Hillebrand, Karl, kärl hĭl'lĕ-brănt, **German** critic and historian: b. Giessen, 17 Sept. 1829; d. Florence 19 Oct. 1884. For participation in the insurrection in Baden (1849) he was imprisoned, but escaped to France, where he was graduated at the Sorbonne, and in 1863 became professor of foreign languages at Douai. On the outbreak of the Franco-Prussian War, he removed to Italy and passed the remainder of his life there. Among his publications in French, German, Italian, and English, are: 'On Good Comedy' (1863); 'Contemporary Prussia' (1867); 'Italian Studies' (1868); 'Times, Peoples, and Men' (1875–85); 'History of the Government of Normandy' (1863–73); 'Public Instruction in the United States' (1869); 'Lectures on German Thought during the Last Two Hundred Years' (1880). Consult Homberger, 'Karl Hillebrand' (1884).

Hil'legas, Howard Clemens, American journalist and author: b. Pennsburg, Pa., 30 Dec. 1872. He was graduated from Franklin and Marshall College, Lancaster, Pa., in 1894, and after being connected with several Pennsylvania journals was war correspondent of the New York *World* in South Africa 1899–1900. He has published 'Oom Paul's People' (1899); 'The Boers in War' (1900); 'With the Boer Forces' (1900).

Hillern, Wilhelmine von, vĭl-hĕl-mē'nĕ fŏn hĭl'ĕrn, German novelist: b. Munich 11 March 1836. In early life she was an actress at Coburg, and in 1857 married Baron von Hillern who died in 1882. Her novels began to appear in 1862 and became rapidly popular. Among them are: 'Double Life' (1865); 'A Physician to the Soul' (1869); 'The Geyer-Wally' (1873). Translations of her novels have been widely circulated in America. Her efforts as a dramatist have not endured, but one or two of her novels have been adapted for the stage.

Hill'house, James, American politician: b. Montville, 21 Oct. 1754; d. New Haven, Conn., 29 Dec. 1832. He was graduated in 1773 at Yale, of which institution he was treasurer from 1782. He studied law, and took an active part in the struggle of the Revolution; was a Federalist member of Congress in 1791, and in 1795–1810 a member of the United States senate. He was also a member of the Hartford Convention of 1815. It was chiefly through his initiative in the planting of trees that New Haven came to obtain the title of 'Elm City.'

Hillhouse, James Abraham, American poet: b. New Haven, Conn., 26 Sept. 1789; d. near there 4 Jan. 1841. He was the son of James Hillhouse (q.v.). He was graduated at Yale College in 1808, entered commerce in New York, and published in London his drama of 'Percy's Masque,' reprinted in New York with

changes in 1820. In 1822 he removed to a country seat near New Haven, where he passed the remainder of his life. In 1825 he published his second drama, 'Hadad'; and in 1839 a collected edition of his writings appeared under the title of 'Dramas, Discourses, and other Pieces.' His dramatic writings, once greatly praised, now appear grandiose and dull.

Hilliard, hĭl'yard, **Henry Washington,** American lawyer: b. Fayetteville, N. C., 4 Aug. 1808; d. Atlanta, Ga., 17 Dec. 1892. He was graduated at South Carolina College in 1826, was admitted to the bar in 1829, in 1831–4 was a professor in the University of Alabama (Tuscaloosa), in 1838 was chosen to the Alabama legislature, in 1842–4 was United States *chargé d'affaires* in Belgium, and in 1845–51 represented an Alabama district in Congress. Though opposed to secession, he became a brigadier-general in the Confederate army. He was United States minister to Brazil, in 1877–81. He wrote: 'Speeches and Addresses' (1855); 'De Vane, a Story of Plebeians and Patricians' (1865); and 'Politics and Pen Pictures' (1892).

Hillis, hĭl'ĭs, **Newell Dwight,** American Presbyterian clergyman: b. Magnolia, Ia., 2 Sept. 1858. He was educated at Iowa College and Lake Forest University, studied theology at McCormick Theological Seminary, entered the ministry of the Presbyterian Church, and held pastorates at Peoria, Ill. (1887–90), and Evanston, Ill. (1890–4). In 1894 he was appointed pastor of the Central Church, Chicago, an independent congregation, and in 1899 of Plymouth Church of Brooklyn. He became known also as a lecturer, and has published: 'The Investment of Influence'; 'A Man's Value to Society'; 'How the Inner Light Failed'; 'Foretokens of Immortality'; 'Great Books as Life Teachers'; 'The Influence of Christ in Modern Life'; 'The Quest of John Chapman' (1904); and many other books.

Hills'boro, Ill., city, county-seat of Montgomery County; on the Cleveland, C., C. & St. L. railroad; about 45 miles south by west of Springfield, and 52 miles northwest of East Saint Louis. Its chief manufactures are flour, furniture, woolen goods, carriages and wagons, and dairy products. There is a coal-mine nearby. It is the commercial centre of an agricultural section of the State. Pop. (1900) 1,937.

Hillsboro, Ohio, village, county-seat of Highland County; on the Norfolk & W. and the Baltimore & O. S. R.R.'s; about 60 miles southwest of Columbus and 50 miles east by north of Cincinnati. It is in an agricultural and stock-raising region. The chief manufactures are furniture, foundry products, flour, lumber, dairy products, and cigars. It is the trade centre for a large part of Highland County. It has a public library containing about 8,000 volumes, and a number of fine public and private buildings. The city owns and operates the waterworks. Pop. (1900) 4,535.

Hillsboro, Texas, city, county-seat of Hill County; on the Missouri, K. & T. and the St. Louis S. R.R.'s; about 52 miles southwest of Dallas and 38 miles north of Waco. It is situated in an agricultural and stock-raising region. Its chief manufactures are cottonseed-oil, cotton goods, hosiery, flour, candy, men's clothing, agricultural implements, and lumber. The trade is largely in live stock, cotton, hides, grain, hay, and lumber. It has cotton-gins, cotton-compresses, planing-mills, and hay presses. The city owns and operates the waterworks. Pop. (1890) 2,541; (1900) 5,346.

Hills'dale, Mich., city, county-seat of Hillsdale County; on the Lake Shore & M. S. railroad; about 88 miles southwest of Detroit and 60 miles west of Toledo, Ohio. The first permanent settlement was made about the year 1840. It is situated in a rich agricultural region in which are raised large quantities of fruit. The chief manufactures are flour, fur garments, screens for doors and windows, wagon-wheels, tables, furnaces, furniture, and canned fruits The trade, in addition to the manufactures, is chiefly in grain, fruits, vegetables, and live-stock. Baw Beese Park, outside the city limits, is owned by the city. Hillsdale is the seat of Hillsdale College (q.v.). The electric-light plant and the waterworks are owned and operated by the city. Pop. (1900) 4,151.

Hillsdale College, a coeducational institution founded in 1855 under the auspices of the Free Baptist Church, in Hillsdale, Mich. Since its establishment it has graduated about 1,000 students. The number of professors and instructors in 1903 was 24, the number of students 350. Special attention is given to the classical and scientific work, but the modern languages are not neglected.

Hilo, hē'lō, Hawaii, town on the Hilo Bay, on the eastern coast of the island; about 38 miles from Mauna Loa, 36 miles from Mauna Kea (the highest peak of the group), and 28 miles from Kilauea. Hilo is the second town in size in the Hawaiian Islands. It has the best harbor belonging to the group. The lighthouse in the harbor can be seen many miles. Large lava-fields are near; on the northwest side of the town and in the vicinity are extensive forests. The craters of Loa and Kilauea, the largest in the world, are visited annually by many tourists who land at Hilo. The inhabitants of the town include many races; but people from the United States who have engaged in business in Hilo are quite prominent. Hilo has good schools to which attendance is compulsory. The population of the town, which is co-extensive with the district of the same name is (1900) 19,785.

Hilongos, hē-lŏng'ōs, Philippines, pueblo of Leyte, on the southwest coast at the mouth of the Salog River, 62 miles southwest of Tacloban. It has a good harbor. Pop. 13,813.

Hilprecht, Herman Volrath, hĕr'măn fōl'rät hĭl'prĕHt, American Assyriologist: b. Hohenerxlehen, Germany, 28 July 1859. He was graduated at Leipsic in 1883 and was curator of the Semitic section of the museum of the University of Pennsylvania, to which he presented the greater part of the 27,000 original cuneiform inscriptions which it contains. He was made professor of Assyrian and Comparative Semitic philology in the same institution 1886. In 1888-89 he was Assyriologist and scientific director of the University of Pennsylvania's expedition to Nippur, Babylonia, and editor-in-chief of its publications. Among his works may he mentioned: 'Old Babylonian Inscriptions, chiefly from Nippur'; 'History of the Babylonian Expedition of the University of

Pennsylvania to Nippur'; 'Recent Researches in Bible Lands'; 'Explorations in Bible Lands during the 19th Century' (1903).

Hilton Head, an island, at the mouth of the Broad River, off the southeast coast of South Carolina; a part of Beaufort County. Fort Walker, a Confederate fortification, was erected here during the Civil War. On 5 Nov. 1861, the fort was attacked by a Union fleet, under Commodore Dupont; Commodore Tatnall, with a Confederate flotilla, or "mosquito fleet," assisted Fort Walker, but it was captured by Dupont. The reports gave Union loss 8 killed and 23 wounded; Confederates, 10 killed and 10 wounded.

Himalaya, hĭm-ä'lā-yạ or hĭm-ạ-lā'yạ (from the Sanskrit signifying the abode of snow), a mountain system of Asia containing the highest peaks in the world, the principal mass of which is near the southern edge of the central section of the continent, between lon. 65° and 110° E., and lat. 28° and 37° N. The system extends approximately from northwest to southeast for about 2,000 miles, while its breadth varies from 100 to between 500 and 600 miles. The elevated plateau of Tibet, between the Himalaya proper and its extension, the Kuen-Lun range, is the widest part of the system. While the term Himalaya is usually confined to the range forming the northern barrier of India, the Hindu-Kush, on the northwest, and the Karakoram with the Kuen-Lun to the north are not distinct chains as frequently represented, but are all portions of the same connected mountain mass, having very little to distinguish them from the rest of the elevated system to which they belong. The Himalaya is connected on the east with the mountains of China and the Indo-Chinese peninsula, and on the west with the mountains of Baluchistan and Afghanistan. The Pamir Plateau described as a "huge boss or knot" north of the Hindu-Kush connects the Himalayas with the Thian-Shan, another mountain system which extends northeastward for about 1,200 miles. From the Ganges-watered plain of northern India which has an elevation of about 1,000 feet above the sea, the Himalayas ascend by successive slopes. The transition from this plain to the ascent of the range is marked in the northwest by a belt of dry, porous ground, broken up into numerous ravines. East of this is the "Terai," a belt of sloping marshland covered with forest and jungle, very malarious and crowded with wild animals. Beyond this lies the "Bhabar," a belt of gravelly and sandy nature covered with forests of valuable timber trees. The "duns," "maris," or "dwars," longitudinal valleys partly cultivated and partly yielding forest growth, occupy the space between the Bhabar and the slopes of the Himalayas. The principal passes are the highest in the world and include the Ibi-Gamin pass in Garwhal 20,457 feet, the Mustagh 19,019 feet, the Parangla 18,500 feet, the Kronbrung 18,313 feet, and the Dura Ghat 17,750 feet. The greatest elevations of the Himalayan system are Mt. Godwin-Austen 28,250 feet in the Karakoram range, and in the Himalayas proper the Gaurisankar or Mount Everest 29,002 feet, the highest peak in the world, Kunchinjinga 28,176 feet, and Dhawalagiri 26,826 feet. On the north the limit of the snow line is 17,400 feet, on the south 16,200 feet. From the southern slope of the central portion of the great chain flow the various streams which unite in the Ganges; from the southern slope of the northwestern portion spring the rivers of the Punjab or "Five Waters," which unite to swell the Indus which rises on the northern slope and flows southwestward to the Arabian Sea; also on the northern slope not far from the source of the Indus springs the Brahmaputra which flows east, southwest, and south to the Bay of Bengal; and also from the plateau of Tibet north of the main Himalayan range flow the Salwin, Mekong and other rivers of the Indo-Chinese peninsula, the Yangtse, Hwang-ho, and other rivers of the Chinese Empire. The whole system is of granitic formation associated with gneiss and mica-slate, followed in descending by metamorphic and secondary rocks, until the alluvial deposits are reached. Minerals abound; copper and lead have been mined from ancient times, iron more recently, coal is found at the foot of the mountains, gold in the beds of the mountain torrents, zinc, sulphur, plumbago and salt are also obtained, and there are numerous mineral springs. The vegetation is luxuriant; rhododendrons are in rich profusion, and there are forests of pine, spruce, silver-fir and deodar cedar at varying altitudes. Consult Schlagintweit, 'Scientific Mission to India and High Asia'; Waddell, 'Among the Himalayas.'

Hinck'ley, Thomas, American colonial governor: b. England, about 1618; d. Barnstable, Mass., 25 April 1706. In 1635 he emigrated to America, and settled at Scituate, but four years later removed to Barnstable. He was deputy governor of Plymouth Colony in 1680 and afterward governor.

Hincks, Sir Francis, Canadian statesman: b. Cork, Ireland, 14 Dec. 1807; d. Montreal, 18 Aug. 1885. He went to Canada in 1831, set up in business at Toronto, and there became editor of the 'Examiner.' In 1841 he entered the first United Parliament as a prominent Liberal. He undertook the editorship of the 'Pilot' of Montreal in 1844. From 1851 to 1854 he was Canadian premier, and as such developed the railway facilities and mining resources of the country, and negotiated a treaty of commerce with the United States. In 1855–62 he was governor of Barbadoes, in 1862–9 of British Guiana, later minister of finance, and from 1873 editor of the Montreal 'Journal of Commerce.' Among his publications are: 'Canada: Its Financial Position and Resources' (1849); 'The Political History of Canada between 1840 and 1855' (1877); 'The Boundaries Formerly in Dispute between Canada and the United States' (1885).

Hind, hīnd, John Russell, English astronomer: b. Nottingham 12 May 1823; d. Twickenham 23 Dec. 1895. In 1840 he obtained a situation in the Royal Observatory at Greenwich. He was a member of the commission appointed to determine the exact longitude of Valencia (1844), and on his return was appointed the observer in Bishop's Observatory, Regent's Park. There he calculated the orbits of more than 70 planets and comets, noted several new variable stars and nebulæ, and discovered 10 minor planets. In 1851 he obtained from the Academy of Sciences at Paris the Lalande medal, and was elected a corresponding member; and in 1852 received the Astronomical

Society of London's gold medal, and a pension of $1,000 a year from the British government. In 1857–91 he was director of the 'Nautical Almanac,' and in 1880 president of the Royal Astronomical Society. He wrote: 'The Solar System' (1846); 'Astronomical Vocabulary' (1852); 'The Comets' (1852); 'Elements of Algebra' (1885); 'Introduction to Astronomy' (1871), and other works.

Hindman, hĭnd'măn, **Thomas Carmichael,** American soldier: b. Tennessee 1818; d. Arkansas 1868. He studied law, entered practice in Mississippi, fought in the Mexican War as a lieutenant of Mississippi volunteers, and in 1858–61 was a Democratic representative in Congress. Not long after the outbreak of the Civil War, he was commissioned brigadier-general, was defeated at Newtonia and Prairie Grove, was promoted major-general at Shiloh, and later served in Arkansas.

Hin'doos, in American history, a nickname given in New York State in 1854 to the American (q.v.) or Know-Nothing Party, from a charge that its candidate for governor, Daniel Ullmann, was born in Calcutta. He was in fact a Delaware man and a graduate of Yale.

Hinduism, in its widest sense, the religion and religious philosophy of the inhabitants of Hindustan, which is professed by nearly half of mankind. Hinduism, historically considered, presents three periods of development. The first is the Vedic age. The Vedas (q.v.) are hymns of worship, and the study of them reveals very clearly the nature worship of primitive Hindustan. In these hymns the elements of nature are addressed as divine beings. Agni, fire, lightning; Surya, the sun; Indra, the cloudless firmament; Maruts, the winds; Ushas, the dawn, are the principal deities of this poetic pantheon. They are addressed in high and sometimes beautiful language, as the senders of temporal blessings. Offerings of delicious viands are made to them; but they are not to be propitiated by bloody sacrifices of beasts, much less by human sacrifices. Libations are poured to them of soma, an exhilarating drink, made from the fermented juice of the soma (q.v.) or milk-plant. Throughout the Vedic hymns runs the under-notion of a supreme being, the creator and ruler of all. This is less discernible in the Brahmana or the Veda than in the Upanishads (q.v.). The Brahmana is a later class of Vedic hymn in which the henotheism suggested in the Upanishads has given place to a highly artificial classification of the divine powers, with a careful estimate of the rank of each. In the Upanishads, Agni, Indra, and Surya become symbols whose united significance may help the mind to understand the existence of one supreme and absolute being, and in this class of Vedic hymn we see the principles of the most enlightened form of native religion in India. The one world soul, in all its manifestations, is reflected in the soul of man, whose destiny is to be reunited with it. The moral responsibility of man, and the judgment of the supreme being against wrong-doing, are plainly taught in these hymns; but there is no trace in them of the later doctrine of moral purification through reiterated metempsychosis.

The second period in the development of Hinduism may be called the epic period. It receives full illustration in the great epic poems, the Ramayana, and the Mahabharata. Side by side with the pictorial teaching of these poems, in which an attempt is made to present the working of the divine economy in relation to specific human lives, there rises a philosophical system, rudimentary indeed, but laying foundations for the later Sankhya, Nyaya, and Vedanta systems. In the Mahabharata, with all its episodes and fantastic incidents, is vividly put forth the doctrine that the union of the human soul with the great, divine soul of the world is aided and expedited by penances of various sorts, such as are detailed with systematic prolixity in the Yoga. In the epic period the doctrine of metempsychosis is clearly enunciated. The soul, after the death of its temporary possessor, must be born again in some material semblance, in order that it may complete the work left unfinished in some previous state of existence, and must repeat the same experience until its task be accomplished and perfection be attained. A decided change is apparent in the popular Hinduism of the third or Puranic period (see PURANAS; TANTRAS). In the Puranas there is almost a Götterdämmerung discernible: no longer do peace and concord prevail in the pantheon where Brahma, Vishnu and Siva still reign supreme, but all is discord, confusion, and destruction. The legends of the epic poems are amplified with childish variations. The simple ideas of the Vedic hymns have vanished. The unbridled imagination of imitators and commentators has overstepped the limits of reverence, dignity, and even poetic beauty in the Puranas, which do not show any advance even in philosophical earnestness, acuteness, or profundity. Worship has become an empty ceremonial. The Vedanta philosophy is now the intellectual creed of the thoughtful and learned (see VEDANTA), and this philosophy is a sort of Deistic agnosticism, only slightly more definite than that of Herbert Spencer, as propounded in his 'First Principles.' For it is the main tenet of the Vedanta that there is one supreme divinity, but, however imagination and speculation may seek to invest this first principle with all the perfections which the human mind is capable of conceiving, the essence of the one divine being lies far beyond the grasp of human thought.

The philosophical creed and henotheism of the educated Brahmin is a sort of esoteric Hinduism which has not supplanted among the general people the influence of a wild polytheism. While it is said that the inferior gods of India make up a pantheon of 330,000,000 divinities, the most important among them are but few in number. These are styled "Guardians of the World," and comprise the elemental gods worshipped in the Vedic hymns. Next in rank to Vishnu, Siva, and Brahma, the supreme triad, are Indra, Agni, Yama (the god of hell), Surya, Varana (the god of water), Purana (the god of wind), Kuvesa (the god of wealth), Soma or Chandra (the moon god), etc. Among sacred animals are bulls; snakes, whose union with the demigods produced monkeys, and some birds, such as the ganada. Among trees, the banyan is held to be divine.

The sects of Hinduism are numerous, and their existence illustrates a principle which is

found to have prevailed in the mythological religion of Greece. Each of these sects worships a particular divinity, and teaches that this divinity possesses all the attributes of a supreme being. Thus polytheism does not mean in India, generally, the worship of many gods by each devotee, but very often merely the worship of one god under many names. For example, the Saivas worship Siva; the Sauras, Surya the sŏn; the Ganapatyas, Ganesa, the god of wisdom, and so on to an almost indefinite length. They ask from each of these gods the same gifts, and the exercise of the same powers. Other sects are Buddhists, Jainas (q.v.), and Sikhs (q.v.). These last profess a pure theism, yet blended with all the absurdities of Hindu mythology and the monstrous fables of Islam; nevertheless they despise Hindus and Mussulmans alike and do not recognize the distinctions of caste. They reject all the Hindu sacred books and look upon warfare as a religious deity. This sect was founded at the beginning of the 16th century A.D. by Nanak Shah.

The philosophy of Hinduism is almost altogether occupied with those questions for which a religious solution is generally sought, namely, the origin and destiny of man, and his relation to the supreme being or the absolute. There are six schools of this philosophy, namely, the Nyaya, Vaiseshika, Sankhya, Yoga, Mimansa, and Vedanta. They all agree in essential points. Their object is to prescribe rules by which man may be delivered from the bondage of ignorance, and be absorbed into the deity. Their doctrine of the soul as something eternal and inextinguishable, distinct from mind, senses, and body, yet sharing in the merit or guilt of good or bad deeds, the latter of which are caused by ignorance of what is best and highest, is identical. They all teach the doctrine of metempsychosis and accept the authority of the Vedas. There is complete agreement among them as to how ignorance is to be gradually illuminated and right apprehension acquired; to this end the Scriptures must be studied and clearness of intellect and heart secured by sacrifices, alms giving, pilgrimages, the repetition of sacred words. The Sankhya are atheistic in their belief, but all the other schools teach the existence of one supreme being.

Hindustan, hĭn-doo-stän', **Hindostan,** hĭn-dō-stän', or **Indostan,** signifying "the land of the (river) Indus," a word of Persian derivation, formerly applied to India (q.v.).

Hingham, hing'am, Mass., town in Plymouth County; on Massachusetts Bay, and on the New York, N. H. & H. railroad; about 15 miles southeast of Boston. In the town are the villages of South Hingham, West Hingham, and Hingham Centre. The first permanent settlement was made in 1633, and it was then called Barecove. In 1635 it was incorporated under its present name. Its chief manufactures are awnings, cordage, wooden-ware, toys, boot-heels, furniture, leatherette and upholstery. It has a meeting-house which was built in 1681. It contains a public library and is the seat of Derby Academy. Some of the noted people who have lived in Hingham are John A. Andrew, John D. Long, Benjamin Lincoln, and James Hall, the famous geologist who for a number of years was State geologist of New York. Joshua Hobart, the Puritan ancestor of the Hobarts of New York State, lived in Hingham. Pop. (1900) 5,059. Consult: 'History of the Town of Hingham.'

Hink'son, Katherine Tynan, Irish novelist and poet: b. Dublin, Ireland, 3 Feb. 1861. She was educated in a convent at Drogheda and since her marriage to H. A. Hinkson in 1893, has lived in Ealing, a suburb of London. She is a voluminous writer of prose and verse, and her books are well known in the United States. Among them may be named: 'Shamrocks,' verse (1887); 'The Way of a Maid' (1895); 'Oh! What a Plague is Love' (1896); 'Three Fair Maids' (1900); 'That Sweet Enemy' (1901).

Hinman, Russell, American editor of text-books: b. Cincinnati 23 Jan. 1853. He was educated at Antioch College, Ohio, went into business as a civil engineer; and later became editor of geographical text-books for Messrs. Van Antwerp, Bragg & Co. of Cincinnati. Since 1890 he has been in charge of the editorial office of the American Book Co. He has written 'Eclectic Elementary Geography'; 'Eclectic Complete Geography'; 'Eclectic Physical Geography.'

Hinoyossa, hē-noi-ŏs'sä, **Alexander d',** Dutch colonial governor in America: b. and d. Holland. He came to America in 1650 as lieutenant in a small military force sent to accompany 150 immigrants. In 1659 he became director of Nieuer Amstel, a Dutch colony on the eastern bank of the Delaware River. Although, owing to disagreements and illness, this colony was not at first a success, it was greatly developed by Hinoyossa's wise rule. Hinoyossa was for a time involved in a conflict of authority with Director Petrus Stuyvesant of New Amsterdam, who had general superintendence of the commissioners constituting the government of Nieuer Amstel. In 1663 he obtained autnority over all the settlements on the Delaware. The Swedish colonists submitted, and Stuyvesant relinquished his control. Upon the conquest of New Netherland by England, Hinoyossa returned (1674) to the continent where he fought in the Dutch army against the French invasion by Louis XIV.

Hin'ton, Richard Josiah, American author: b. London, England, 25 Nov. 1830; d. 20 Dec. 1901. He settled in the United States in 1851; studied topographical engineering at the Columbia School of Mines; and removing to Kansas in 1856 became a supporter of the cause of John Brown. He served in the National army in 1861–5; and was the first white man appointed to raise and lead colored troops. After the war he engaged in newspaper work in Washington, New York, and San Francisco. He was the author of 'Life of William H. Seward'; 'Life of Gen. P. H. Sheridan'; 'John Brown'; etc.

Hip, that part of the trunk comprised between the abdominal wall and the lower limb,

particularly the region over the hip-bone (the crest of the ilium).

Hip Joint, the joint of the upper leg or thigh (femur) where it joins the trunk. It is a ball and socket joint, formed by the sinking of the smooth globular cap into the deep hollow, called acetabulum (vinegar bowl), of the os innominatum. Its movements are controlled by five ligaments: the capsular; the ilio-femoral; the teres; the cotyloid; and the transverse. These movements are more wonderful than even those of the arm, being flexion, extension, abduction, adduction, and rotation inward and outward. It is the most powerful joint in the body and hardest to dislocate.

Hip Joint, Disease of, a disease of the ball and socket of the hip. It often results from scrofula; comes on in children or young persons, from very slight causes; is often traced to a long walk, a sprain in jumping, or a fall. In the early stage of the disease the whole of the structures of the joint are inflamed and after proper treatment may be sometimes subdued with no worse consequences than a more or less rigid joint. Usually, however, abscesses form around the joint, and often communicate with its interior; and the acetabulum and the head and neck of the thigh-bone become disintegrated, softened, and gritty. In a still more advanced stage, dislocation of the head of the thigh-bone commonly occurs, either from the capsular ligament becoming more or less destroyed, and the head of the bone being drawn out of its cavity by the action of the surrounding muscles, or from a fungous mass sprouting up from the bottom of the cavity, and pushing the head of the bone before it.

As the disease advances, abscesses occur around the joint. True shortening of the limb now takes place, which at the same time becomes adducted and inverted. From this stage, if the health is pretty good, and the lungs are sound, the patient may be so fortunate as to recover with an anchylosed (or immovable) hip-joint; but the probability is that exhaustion and hectic will come on, and that death will supervene, from the wasting influence of the purulent discharges occasioned by the diseased bone.

Hipparchus, hĭ-pär'kŭs, Greek astronomer: b. Nicæa in Bithynia. He lived about 160–125 B.C.; resided for some time at Rhodes, but afterward went to Alexandria, then the great school of science. A commentary on Aratus is the only work of his extant. He first ascertained the true length of the year, discovered the precession of the equinoxes, determined the revolutions and mean motions of the planets, prepared a catalogue of the fixed stars, etc.

Hipparion, hĭ-pā'rĭ-ŏn, a genus of fossil three-toed *Equidæ*. See HORSE. EVOLUTION OF.

Hippel'ates, a genus of midges to whose agency is ascribed the spread in many instances of the southern ophthalmic disease of cattle called pink-eye. See FLIES; PINK-EYE.

Hippocrates, hĭ-pŏk'ra-tēz, Greek physician, the father of medicine: b. in the island of Cos 460 B.C.; d. Larissa, Thessaly, 357 B.C. Besides practising and teaching his profession at home he traveled on the mainland of Greece. His writings, which were early celebrated, became the nucleus of a collection of medical treatises by a number of authors of different places and periods, which were long attributed to him, and still bear his name. The best edition is that of Littré (in 10 vols. Paris, 1839–61). He has the great distinction of having been the first to put aside the traditions of early ignorance and superstition, and to base the practice of medicine on the study of nature. He maintained, against the universal religious view, that diseases must be treated as subject to natural laws; and his observations on the natural history of disease, as presented in the living subject, show him to have been a master of clinical research. His accounts of phenomena show great power of graphic description. In treating disease he gave chief attention to diet and regimen, expecting nature to do the larger part. His ideas of the very great influence of climate both on the body and the mind, were a profound anticipation of modern knowledge. He reflected in medicine the enlightenment of the great age in Greece of the philosophers and dramatists.

Hippodrome (from the Greek, *Hippos,* a horse, and *Dromos,* a race course), the name given by the Greeks to places where races were held. This included both chariot and single horse racing, but the hippodrome later took the form of a circus, other games, such as wrestling, boxing, running, etc., being added, and for a short time after the introduction of Roman customs and manners it became the scene of gladiatorial combats, but as sights of this nature did not find favor in the sight of the Greeks, these combats were eventually eliminated and the main feature of the games, as in the beginning, was the chariot race. To the brutal taste of the Roman populace flowing blood acted as an elixir, but to the more refined Eastern people the amphitheatre was abhorrent. Though numerous amphitheatres were scattered throughout western Europe very few were ever built within the limits of the Eastern empire and then only where the influence and manners of the Romans were most powerful.

The first mention of a hippodrome is made by Homer, but it is believed that the term then applied to any course over which a race of any kind was run and that it did not necessarily have a fixed location. As the chariot-racing became the national game, the proper courses for the holding of such events became necessary, as in these races, though much of the success depended upon the courage and skill of the driver, the loss of life was often great, through collision, the overthrow of the chariot in turning caused by rough ground, the breaking of an axle, or numerous other accidents. The hippodrome was built for the purpose of avoiding, as much as possible, the possibility of such mishaps, by providing a wide and smooth track, thus leaving plenty of space for the contestants. Of the ancient hippodromes (as distinguished from circus, amphitheatre, etc.), probably the most famous are those of Olympus and of Constantinople, and while the Circus Maximus of Rome may to a great extent have been more of a circus than race course, it was planned after the Greek race courses, was used by the Romans for this purpose, and thus may properly be classed with the other two.

The origin of the hippodrome at Olympus tradition gives to Hercules, but the only de-

scription of it obtainable is found in the passages of Pausanias (v. 15 φ 4; vi. 20 φ 7 foll.) though from the explorations of the German archæologists the ground plans of most of the structures described by Pausanias have been traced. Of its length and breadth there is no precise information, the overflow of the Alphus River having washed away the indications of its limits, though probably the distance from the starting place of the races to the goal, or from one goal to the other, was 770 metres or 4 Olympic stradia, and it was about one fourth as wide, or the same as each side of the starting place.

In general form the hippodrome was an oblong, one end of which was semicircular; on three sides having seats for the populace and on the fourth, where the races were started, seats for the royalty and nobles. The right side, formed by an artificial mound, was a little longer than the left side, which was built on the natural slope of a hill, the base of the fourth side being formed by the portico of Agnaptus, named after its builder. The form of the starting place was not unlike the prow of a ship, each side being 400 feet long, and containing stalls for the chariots and their horses. In the arena were two goals around which the chariots passed several times to complete the race; one of these goals having a bronze statue of Hippodameia upon it, the other an altar dedicated to "Taraxippus, the Terror of the Horses." The principal difference between the Greek hippodrome and the Roman circus was in the width of the arena, in the latter only four chariots being able to race at one time; there was also some slight difference in the arrangement of the carceres.

The erection of the hippodrome of Constantinople was due to two Roman emperors, Septimus Severus and Constantine the Great, who each in turn captured Byzantium by storm. About six years after its capture by him (197 A.D.) Severus commenced operations a little to the west of Byzantium, but in that year was called away by a rebellion in the West and never returned to the city. For over a hundred years it remained untouched, until 323, when Constantine, having conquered the city, pushed the work to completion after changing the details in the original plans. On 11 May 330 it was inaugurated.

The external appearance of the hippodrome was imposing for its vastness, its height, and even for its beauty. The walls were of brick, laid in arches, and faced by a row of Corinthian columns 260 in number and standing 11 feet apart. There were four entrances from the city each flanked with towers, but of the stairways leading to these entrances no description has come down to us.

Some idea of the immensity of this prodigious structure may be given by the fact that its dimensions were 1,400 feet in length by 400 feet in width, covering an area of 535,866 square feet, or 12.3 acres. On the north was a structure containing the apparatus for the games, the servants' and attendants' apartments, the chariots and horses, the arsenal, etc., called by the Romans the *carceres* and by the Greeks μάγγανα. This apartment was separated from the arena by pillars with latticed gates, 12 in number. Next to these gates was the little church or oratory, where the rival contestants prayed before the games.

The ground story was 20 feet high. On it rested the palace of the Kathisma or Tribunal, in the centre of which, supported upon 24 marble pillars was the platform in Kathisma proper, on the front of which was the emperor's throne. On either side and a little below the emperor were the seats for courtiers, ambassadors, etc. Far down the western side of the hippodrome and nearly opposite the built column was the gorgeous chamber of the empress, this supported upon four porphyry pillars and hence called the tetrakion.

The eastern, western, and southern portions were occupied by parallel rows of seats, appropriated to the spectators according to their rank. Behind these rose tier upon tier of benches until nearly half way to the top where was a broad promenade bounding the entire extent of the hippodrome except on the northern side. This promenade was without roof or covering, and, standing nearly 40 feet above the ground, protected by a solid marble railing reaching to the breast, the spectator had a spacious avenue 2,766 feet long. It is estimated that the hippodrome would seat 60,000 persons and have comfortable standing room for 20,000 more, while with a little crowding 100,000 might be accommodated.

The arena was 211 feet wide by 1,190 feet long and was bounded by a narrow walk called the Euripus, paved in tesselated stone. The semicircular southern portion of the arena, that included in the curve of the Sphendone, was reserved for the criminals and there too was the place for executions. In the centre of the arena and lying parallel to it was the Spina; a stadium, 607 English feet in length, it marked and governed the beginning, duration, and end of each course of a race. At each end of the Spina was a high, narrow framework, surmounted by seven poles, on one group being placed seven fish, on the other seven eggs; one of each was taken down upon the completion of each circuit during the race until the race finished. Toward the southern end of the Spina was the Phiale, a broad basin of running water devoted to the victims of accidents. The space between the northern goal and the carceres was called the Stama, where wrestlers and acrobats performed.

Many additions to the works of art already gathered by Constantine were made during the 700 succeeding years, but in 1203 the hippodrome was sacked by the Franks and Venetians and all were either carried off or destroyed. The most famous of these was the 'Four Golden Steeds,' which was stolen by the Venetians and which in turn was brought to Paris by Napoleon, and is now standing guard over the main entrance of the cathedral of Saint Mark. Among the others are the statues of Hercules, the Shewolf and Hyæna, the Virgin Goddess Diana, the Brazen Ass, the Caledonian Boar, Helen of Troy, the God of Wealth, and eight Sphinxes, beside the statues of the early Roman emperors, martyrs, teachers, philosophers, etc. In the early days of the city games were of frequent occurrence, but as time went by they became less and less frequent owing probably to the great cost (it is estimated that a single celebration cost 1,000,000 francs) and at last were celebrated only on 11 May and 25 December, the birthdays of the city and Christ respectively.

It is not known precisely when this hippodrome was entirely destroyed, but as there is no definite reference to any chariot race later than the reign of Isaac Angelus, who was dethroned

2. The auditorium, the front stage or apron, and the proscenium arch.

in 1105, and as the place was sacked in 1203–4 it is probable that it did not survive the beginning of the 13th century.

The Circus Maximus at Rome was for a long time the only structure of its kind in the world, taking its form from the Greek hippodrome and furnishing the model for all later *circi*. In the Vallis Murcia, between the Palatine and Avantine hills, wooden seats were first constructed by Tarquinius Priscus (Liv. I., 35); were frequently burned and rebuilt until the time of Julius Cæsar, when the steps were constructed of stone and greatly improved. At that time it probably accommodated about 100,000 people. After its destruction by fire in 31 B.C. Augustus completely restored it, making several magnificent additions. The upper tier of seats on the Aventine side was again destroyed by fire in 36 A.D., but Claudius not only restored these, but greatly enlarged the entire circus. These additions were supplemented by others made during the reigns of Trajan and Constantine until it was estimated that the circus held 385,000 spectators, while the 'Notitia' places the possible number at 485,000.

The general plan of the Circus Maximus compared favorably with the Greek hippodromes, the main difference being in the arena around which Cæsar had constructed a moat 10 feet wide and 10 feet deep to prevent beasts from injuring the spectators, and in the width of the arena as before stated. Before the reign of Augustus the circus was used for gladiatorial fights with wild beasts and other forms of butchery, but after the erection of the amphitheatre of Statilius Taurus the circus was no longer used for such purposes. The popularity of this as of the Greek hippodrome also declined and it gradually decayed, now only a few of the remains standing.

The term hippodrome has also been applied to race tracks in England and on the continent, the most famous of these so called hippodromes being those at Vincennes, Longchamps, Chantilly in France, Newmarket and Epsom in England, and Curragn in Ireland. The modern hippodrome, or indoor circus, had its beginning in Paris, where the first was constructed in 1845. It was built entirely of wood, the arena was 108 metres long and 104 wide, and it had a seating capacity of 15,000 persons. This was destroyed in 1870 by fire. The word hippodrome was first utilized in this country when Franconi conducted a circus where now stands the Fifth Avenue Hotel, at 23d Street and Fifth Avenue, New York.

The first hippodrome of the accepted type to be built in America was the New York Hippodrome, which occupies an entire block on Sixth Avenue, between 43d and 44th streets. This structure was begun on 1 July 1904 and finished in five months, the opening performance occurring 12 April 1905. The main façade has a length of 200 feet, and the building extends 240 feet east on 43d and 44th streets. It is built of brick, marble, and steel, and rises to a height of 72 feet on Sixth Avenue, and 110 feet in the rear, the total cost being $1,750,000. It is the largest playhouse in the world, having a seating capacity of 5,200.

In the interior decorations the general scheme of coloring is a Roman red as a background, with all the structural features done in ivory, gold, and silver. The carpetings are of the same color, and the wall hangings, draperies, and upholstery are executed in a Roman red velvet enriched with heavy gold and silver embroidery and tassels.

The auditorium is about 160 feet long and 160 feet wide in the first story, and the balcony and gallery occupy the building in front of the stage above the first story. At the rear of the balcony is the mezzanine floor, below the rear seats of the balcony being the wide segmental promenade with main entrances and flights of shallow stairs at each end leading to the street. Behind the promenade the space, 20 to 50 feet wide and 200 feet long, is occupied by smoking rooms, parlors, waiting rooms, and cloak rooms. The promenade and lobbies are finished in marble and cæn-stone, relieved by rich illuminations of the ornamented parts in gold and silver. A special feature of the auditorium is the arrangement and construction of cages for animals of the feline kind. Their dens are arranged in a segmental curve in the promenade floor, and have plate glass fronts with iron bars behind.

The chief point of interest in the hippodrome centres the stage and the entirely novel mechanical arrangements for operating the movable platforms, filling and emptying the tank, raising and lowering the stage, and handling the scenery. The depth of the stage from the extreme front to the back wall is 110 feet, or 50 feet from the back wall to the proscenium opening and 60 feet from the arch to the front of the stage. This latter part of the stage lying forward of the proscenium arch is known as the "apron." It is large enough to contain two regulation circus rings, each 42 feet in diameter. Beneath the "apron" is built a huge steel and concrete tank, over 14 feet in depth, and large enough for the whole "apron" to sink within it. When aquatic performances or naval pageants are given the tank is filled with water and the movable "apron" is submerged below the water to the bottom of the tank.

Bibliography.—As before stated, the only description of the Olympia as it originally stood is contained in 'Pausanias' (v. 15 ϕ 4; v. 120 ϕ 7 foll.). From results of excavations the best descriptions of the old hippodromes of the world may be had in the following: Curtius, 'Olympia' (Berlin 1852); Grosvenor, 'Hippodrome of Constantinople' (London 1889); Lehndorf, 'Hippodromos' (Berlin 1876); Pollack, 'Hippodromica' (Leipsic 1890). For descriptions of chariot races consult: Homer's 'Iliad,' and Livy, and "Lew" Wallace, 'Ben Hur' (New York 1880). Of the New York Hippodrome probably the best description is contained in the 'Scientific American' (Vol. XCII., No. 12; 25 March 1905). For a study of the architectural features of the structures of those times consult Sturgis, 'European Architecture' (New York 1896).

Hippopot'amus, the generic and popular name of a great amphibious ungulate, allied to the swine, of which two species are known. One (*H. amphibius*) is common throughout the greater part of Africa; the other (*H. liberiensis*) is not only smaller, but has other important differences, and is found only in the African west coast rivers, and those flowing into Lake Tchad. The former species has a thick and square head, a very large muzzle, small eyes

and ears, thick and heavy body, short legs terminated by four toes, a short tail, two ventral teats, skin about two inches thick on the back and sides, and without hair, except at the extremity of the tail. A curious feature of the skin is the reddish exudation which pours from its pores when the animal is excited or in pain. It is called "bloody sweat," but the blood has no part in it. The incisors and canines of the lower jaw are of great strength and size, the canines or tusks being long and curved forward. These tusks sometimes reach the length of two feet and more, and weigh upward of six pounds. The animal is killed by the natives partly as food, but also on account of the teeth, their hardness being superior to that of ivory, and less liable to turn yellow. The hippopotamus has been found as much as 14 feet long, and nearly 5 feet high, but usually measures much less. It delights in water, living in lakes, rivers, and estuaries, and feeding on water-plants or on the herbage growing near the water, where it can walk as well as swim. It often leaves the water after nightfall, and goes, sometimes long distances, to grassy pastures to feed; regular paths are worn through the reeds, and here the Africans often arrange pits, deadfalls, or other traps for their capture. These animals are quick of sense, timid and anxious to escape danger; but when brought to bay or enraged prove formidable antagonists and often destroy canoes. They are excellent swimmers and divers, and can remain under water eight or ten minutes. The behemoth of Job is considered to be the hippopotamus. Several extinct species are found in Old World Tertiary formations, and modern species formerly inhabited not only Madagascar, but southern Europe and India, where they were contemporary with the men of the Stone Age.

Hippuric (hĭ-pū′rĭk) **Acid**, an organic acid, $C_9H_9NO_3$, existing in the urine of herbivorous animals, and, in small quantities, in that of human beings. It is increased by a vegetable diet, and by the disease called diabetes, and may be caused to appear in the human urine in considerable quantities by the administration of benzoic acid with the food. It is most conveniently prepared by boiling horse urine with milk of lime, filtering, neutralizing with hydrochloric acid, and evaporating to about one eighth of its volume. The concentrated urine is then acidified with hydrochloric acid and allowed to stand, when impure hippuric acid comes down as a yellowish-brown precipitate. To purify the crude product, it is heated to 212° F. with not quite enough water to entirely dissolve it, and chlorine gas is passed through the solution until the unpleasant smell has entirely disappeared. The solution is then filtered while hot, and the crystals which separate upon cooling are isolated and subjected again to the same treatment, the chlorine being passed through the solution, in this second treatment, until the solution is bright yellow. When thus prepared, hippuric acid crystallizes from water in the form of large prismatic plates, belonging to the trimetric system. Its crystals are colorless or white, free from odor, and have a slightly bitter taste. Hippuric acid has a specific gravity of about 1.308, and melts at 369° F.; it begins to boil at about 465° F., giving off benzoic acid and benzonitrile. It is insoluble in benzene, carbon disulphid, and cold chloroform, and is but slightly soluble in ether and in cold water. It is very soluble, however, in boiling water, and in hot alcohol. With bases, hippuric acid forms salts that are remarkable for the beauty of their crystalline forms. When boiled with dilute hydrochloric, sulphuric, nitric or oxalic acid, it yields benzoic acid and glycocoll.

Hiram College, a coeducational institution, founded in 1850, in Hiram, Ohio, under the auspices of the Christian Church. It was first called the Eclectic Institute, but was incorporated as a college in 1870. In 1903 there were in attendance about 400 pupils in the departments of oratory and music and in the preparatory department and college. There are about 6,200 volumes in the library.

Hiroshima, hē-rō-shē′mä, Japan, a town on the island of Hondo, about 160 miles from Kobe, and after Osaka the most important port on the inland sea. Pop. (1899) 122,306.

Hirsch, Emil Gustav, American rabbi: b. Luxemburg, Germany, 22 May 1852. He studied at the University of Pennsylvania and at Berlin, was rabbi successively in Baltimore, Md. (1877) and Louisville, Ky. (1878–80), and in 1880 was chosen minister of the Sinai congregation of Chicago, Ill. In 1880–7 he was editor of the 'Zeitgeist' of Milwaukee, Wis., and later became editor of the 'Reform Advocate' of Chicago. He was appointed professor of rabbinical literature in Chicago University in 1892. He appeared as an orator on various patriotic and other occasions, and wrote several monographs on religious and Biblical topics. He was also prominent in Republican State politics, and in 1896 was presidential elector-at-large for Illinois.

Hirsch, Maurice, Baron de (Baron Maurice de Hirsch de Gereuth), Austrian Jewish capitalist and philanthropist: b. Munich 9 Dec. 1831; d. Ogyalla, Hungary, 21 April 1896. His fortune was computed to be $200,000,000, and his yearly income at about $20,000,000. His benefactions equaled nearly $100,000,000, the most of this sum being directed toward the improvement of the condition of the Jews in all parts of the world. The De Hirsch trust for the United States is a fund of $2,500,000 for the Americanizing and education of Rumanian and Russian Jews. Other large gifts were those of $5,000,000 for the endowment of schools in Galicia, and of $50,000,000 to the Jewish colonization association for the establishment of colonies in Argentina. In 1888 he offered to the Russian government $10,000,000 for schools, with the condition that in the distribution of the amount no discrimination as to race or religion be made. This offer was not accepted. Baron de Hirsch made extensive sums through the construction of railways in Turkey.

Hirth, Friedrich, German-American educator: b. Gräfentonna, Saxe-Coburg, Germany, 1845. He studied at Leipsic, Berlin, and Greifswald, entered the Chinese customs service in 1870; retired in 1897, and in 1902 was called to the newly created professorship of Chinese in Columbia University. In the summer of 1902 he was in St. Petersburg, cataloguing a collection of manuscripts taken at Peking. He made a valuable collection of Chinese porcelains, now in the museum at Gotha, and one of printed

HIPPOPOTAMUS (*Hippopotamus Amphibius*)

books and MSS., now in the Berlin Royal library. Among his publications are: 'China and the Roman Orient' (1885); 'Ancient Porcelain' (1888); 'Chinesische Studien' (Vol. I., 1890); and 'Ueber fremde Einflüsse in der Chinesischen Kunst' (1896).

His'cock, Frank, American legislator: b. Pompey, Onondaga County, N. Y., 6 Sept. 1834. In 1855 he was admitted to the bar, in 1860–3 was district attorney of Onondaga County, and in 1867 a member of the State constitutional convention of New York. He was a Republican representative in Congress in 1879–87, and obtained recognition as a party leader and speaker. In 1887 he was United States senator from New York and then returned to professional practice.

Hispania, hĭs-pā'nĭ-a. See SPAIN.

Histol'ogy, the science of animal and vegetable tissues. It investigates by means of the microscope the various tissues of man, animals and plants in their anatomical relations and compositions. Topographical histology considers the more minute structures of the organs and systems of the body; normal histology deals with the healthy tissues; and pathological histology investigates the changes they undergo in disease. Marie François Xavier Bichat (1771–1802) is generally credited with the foundation of the science of histology. Unfortunately the imperfect condition of the microscope in his time prevented Bichat and his contemporaries from carrying their investigations to the point which Schleiden, Schwann, Johann Müller, Virchow, Von Recklinghausen, Cohnheim, etc., have reached. It has been found that all structures however complex are made up of cells, and that the parts of a body may be resolved into a small number of elementary tissues now grouped as: (1) epithelium, which lines almost all the cavities of the body and is directly or indirectly in communication with the atmosphere; (2) the nervous tissues, which as nerve cells originate and as nervous fibres transmit all nervous impulses; (3) muscle, which produces motion whether voluntary or involuntary; (4) glandular tissue which consists of cells standing in close relation with the blood-vessels which take from the blood certain substances and secrete them; (5) connective substances which support and hold together the more delicate and important structures, especially forming the cartilages and bones. See CELL; ANATOMY, COMPARATIVE; ANATOMY OF PLANTS.

Many tissues have the power of repairing injuries that happen to them. This power is called regeneration, and is found especially in the lower animals, in polyps, worms, and in many amphibious creatures and reptiles. In other cases the lesion is supplied by a new growth of connective substance. In diseases the tissues undergo many changes and many of these diseases in the organism are shown also by the changing of color. The science of such changes is generally called pathological histology. It is a comparatively young science and has been cultivated by Virchow, who was the founder of cellular pathology.

Vegetable histology is that department of botany which deals with microscopic phytotomy or the anatomy of plants, especially investigating the plant cells and plant tissues. It is properly subordinate to morphology and is a distinctively descriptive science. It deals with the question in what relation the cells or forms of tissue stand to the vital activity of plants, what functions they perform, and in what respect they are constituted for the fulfilling of those functions. (Compare CYTOLOGY.) Owing to the excessive minuteness of the cells which form the tissues of all plants the investigation relies almost entirely on the microscope, and naturally has made its advance in proportion as the microscope has been made more perfect. Microscopes that are now used magnify at least 1,000 diameters, and the materials used have to be carefully prepared and mounted. Many of them have to be colored with hæmatoxylin, fuchsin, saffranin, and other alcoholic or aqueous dyes. Consult Delafield and Prudden, 'Handbook of Pathological Anatomy and Histology' (1901).

Historical Societies in the United States. John Pintard, of New York, deserves the credit of being the first who endeavored to organize historical societies in the United States. He was born 18 May 1759, received his education at Princeton College, and became actively identified with several military expeditions in the War of the Revolution, being also deputy commissary for American prisoners. He was especially zealous in the study of American history, and appreciated the need of preserving the literature, muster-rolls, private and public documents, relics, and other material of the colonial period, at that time uncollected. In 1789 he visited the Rev. Jeremy Belknap, in Boston, who writes: "When Mr. Pintard was here he strongly urged forming a society of antiquarians." In August 1790 Mr. Belknap, following this suggestion of Mr. Pintard, drew up an outline for such a society, in which was the following clause, "Letters shall be written to gentlemen in each of the United States requesting them to form similar societies and a correspondence shall be kept up between them for the purpose of communicating discoveries and improvements to each other," and quaintly concludes, "When ye societie's funds can afford it salaries shall be granted to the secretaries and other officers." In February 1791 Mr. Belknap writes: "We have now formed our society and it is dubbed, not the Antiquarian, but the Historical Society. It consists at present of only 8, and is limited to 25. We intend to be an active, not a passive, literary body; not to be waiting like a bed of oysters for the tide (of communication) to flow in upon us, but to seek and find, to preserve and communicate literary intelligence, especially in the historical way." In 1794 the membership was increased to 60, and by act of legislature in 1857, the limit of resident members was placed at 100. Associated with Jeremy Belknap in the new society were Rev. John Eliot, Rev. James Freeman, James Sullivan (later governor of Massachusetts), Rev. Peter Thatcher, William Tudor, the noted lawyer, Thomas Wallcut, the antiquary, James Winthrop, for years librarian of Harvard, Dr. William Baylies, a physician of Dighton, and George R. Minot, the author. The position held to-day by the Massachusetts Historical Society is so well recognized at home and abroad that it would be futile to attempt to describe either its valuable contributions or its stimulating example to similar societies, during its unqualified success of over 100 years. Its

officers in 1903, were: President, Charles Francis Adams; vice-presidents, Samuel Abbott Green, M.D., Thomas Jefferson Coolidge; recording secretary, Edward James Young; corresponding secretary, Henry Williamson Haynes; treasurer, Charles Card Smith; librarian, Samuel Abbott Green, M.D.; cabinet-keeper, Henry Fitch Jenks.

To John Pintard is due the credit for the first meeting, 20 Nov. 1804, of the New York Historical Society. Those present included John Pintard, Judge Egbert Benson, DeWitt Clinton, Rev. Wm. Linn, Rev. Samuel Miller, Dr. David Hosack, Rev. John M. Mason, Rev. John N. Abeel, Samuel Bayard, Peter G. Stuyvesant and Anthony Bleecker. These patriotic founders organized "for the purpose of discovering, procuring, and preserving whatever may relate to the natural, civil, literary, and ecclesiastical history of the United States in general, and of this State in particular." The valuable library of John Pintard was acquired in 1807, thus forming the nucleus of the 100,000 volumes owned by the society in 1903. The first gift from outside sources, recorded in the minutes of the Society, came in 1810, when 10 volumes of the publications of the Massachusetts Historical Society were presented. The society is now erecting a new home on Central Park West, 76th and 77th streets, where its thousand members may more adequately enjoy its collections; including the galleries of American portraits and old masters; the famous Egyptian collection of Dr. Henry Abbott, the Nineveh sculptures presented by James Lenox, the original Audubon water colors, together with countless original papers, engravings, prints, broadsides and relics of the Colonial and Revolutionary periods. Meetings are held the first Tuesday of each month, October to June inclusive, at which papers, dealing with American history, are read. The society established a fund for printing its proceedings and collections; 28 volumes have been issued since 1868, as follows:

Vol. I.—'The Continuation of Chalmer's Political Annals of the American Colonies' (1685–96); 'The Colden Letters on Smith's History of New York' (1759–60); 'Documents Relating to the Administration of Jacob Leisler' (1689–1769).

Vol. II.—'The Clarendon Papers, Relating to New York and New England' (1662–7); 'The Destruction of Schenectady' (1690); 'Montague's Arguments on Acts of New York Assembly' (1701); 'Colden's Letter on Smith's History of New York' (1759); 'Plowden's New Albion' (1632–50); 'Gardiner's History of East Hampton, New York' (1798); 'Collection of Evidence and Vindication of the Rights of New York to the New Hampshire Grants.'

Vol. III.—'Territorial Rights of New York Against the Government of New Hampshire,' a brief by James Duane; 'Old New York and Trinity Church' (1730–90); sermon by the Rev. Francis Makemie (1707).

Vol. IV., Vol. V., Vol. VI., Vol. VII.—'The Papers of Major-General Charles Lee' (1754–1811).

Vol. VIII.—'Letters of General Pattison, Commandant of New York City' (1779–80); 'Letters to General Lewis Morris (1775–82).

Vol. IX., Vol. X.—'Official Letter-Books of Lieutenant-Governor Cadwalader Colden' (1760–75).

Vol. XI.—'Papers of Charles Thomson, Secretary of the Continental Congress' (1765–1816); 'Letters of Colonel Armand' (1777–91); 'Letters to Robert Morris' (1775–82).

Vol. XII.—'Trial of General Schuyler' (1778); 'Trial of General Robert Howe' (1781); 'Journal of Commissary Rainsford, Enlistment of Hessian Troops' (1776–78).

Vol. XIII.—'Trial of General St. Clair' (1778); 'Journal of Occurrences at Quebec' (1775–76); 'Case of William Atwood, Chief Justice of New York' (1703); 'Vesey's Sermon in Trinity Church, at the Funeral of Lord Lovelace' (1709); 'Letter of Dominie Michaelius, First Minister in New Netherland' (1628); 'Records of the Court of Lieutenancy, New York Militia' (1686–96).

Vol. XIV.—'Journals of the Engineer Officers, Colonel James and Captain John Montressor, of Services in America' (1757–78).

Vol. XV.—'Journal of Lieutenant Von Krafft, of the Hessian Army' (1776–84); 'Letter-Book of Captain Alexander McDonald, of the Royal Highland Emigrants' (1775–79).

Vol. XVI., Vol. XVII.—'Papers of Lieutenant-Colonel Stephen Kemble, Adjutant-General of the British Army in America, Journals and Correspondence (1775–89); 'General Orders of the British Army in America' (1775–8); 'Journals, Documents, and Correspondence of the Expedition to Nicaragua' (1780–1).

Vol. XVIII.—'The Burgher Right and Roll of Burghers of New Amsterdam' (1648–61); 'Roll of Freedom of New York City' (1675–1866); 'Register of Indentures of Apprentices of New York City' (1694–1708).

Vol. XIX. to XXIII.—'The Deane Papers, Correspondence, Official and Private, of Silas Deane' (1774–89).

Vol. XXIV.—'Muster Rolls of New York Provincial Troops' (1755–64).

Vol. XXV.—'Abstracts of Wills on File in the Surrogate's Office, City of New York' (1665–1707).

Vol. XXVI.—Same (1708–29), with Appendix.

Vol. XXVII.—Same (1730–44).

Vol. XXVIII.—Same (1744–).

The officers of the New York Society for 1903 are: President, Samuel Verplanck Hoffman; first vice-president, Frederic Wendell Jackson; second vice-president, Francis Robert Schell; foreign corresponding secretary, Archer Milton Huntington; domestic corresponding secretary, George Richard Schieffelin; recording secretary, Sydney Howard Carney, Jr., M.D.; treasurer, Charles Augustus Sherman; librarian, Robert Hendre Kelby.

Following in the steps of these two oldest societies hundreds of a similar character exist to-day. Indeed, hardly a city or county in each State of the Union but has had its own local historical society. A casual glance at a few local societies in Massachusetts and New York will give an idea of the spirit which prevails for the preservation of the historic past:

The American Antiquarian Society, Worcester, Mass., was incorporated 24 October 1812; this inland city being selected as less exposed to possible invasion from the sea, with the consequent loss of historical collections.

The Essex Historical Society, Salem, Mass., was originally started by Dr. Edward A. Holyoke, of Salem, and incorporated in 1821. Some 15 years later the Essex County Natural History Society was incorporated, and in 1848 both of these societies united, forming the Essex Institute. Of other societies in Massachusetts a few will suffice. The New England Historic Genealogical Society, Boston; The Quoboag Historical Society, Brookfield; Historical Society, Nantucket; Old Residents' Association, Lowell; Old Colony Historical Society, Taunton; Pocumtuck Valley Memorial Association, Deerfield; The Pilgrim Society, Plymouth; The Rumford Historical Society, Woburn. Rehoboth, Watertown, Westborough, Weymouth, and Winchester have each local societies.

In New York State mention may be made of the Long Island Historical Society, Brooklyn; Suffolk County Historical Society, Sag Harbor; Oneida Historical Society, Utica; Onondaga Historical Association, Syracuse; Rochester Historical Society; Buffalo Historical Society; Westchester Historical Society, and Tarrytown Historical Society. In many States the various religious denominations have historical societies and there was organized recently the American Jewish Historical Society, New York.

The various organizations in the several States have assumed so much usefulness that there now exists an "American Historical Association," organized at Saratoga, N. Y., 10 Sept. 1884, incorporated by Act of Congress, approved 4 Jan. 1889, and reports annually to Congress through the Smithsonian Institution. The more recent

patriotic societies, such as the Sons of the Revolution, Society of Colonial Wars, Mayflower Society, Daughters of the Revolution, Colonial Dames, and Huguenot Society, are largely indebted to the historical societies for their existence. Indeed, the Sons of the Revolution was formed in the hall of the New York Historical Society.

The following list of historical societies existing in 1903, is arranged in alphabetical order of States, with the information furnished, in so far as replies have been received, from the secretaries of States, or officers of historical societies:

Alabama.— The Alabama Historical Society, organized 8 July 1850 at Tuscaloosa, Chancellor Alexander Bowie being first president. Incorporated by Act of the General Assembly 5 Feb. 1852. During Civil War all work was suspended, many documents being lost. 1874 revived by Dr. Joshua H. Foster, its first secretary. 10 Dec. 1898; The Alabama History Commission was created at Montgomery, Hon. Thomas M. Owen being secretary and treasurer.

Alaska.— Society of Alaska, Natural History and Ethnology, incorporated 11 April 1888 at Sitka. Alaska Historical Library and Museum incorporated 6 June 1900, at Sitka.

Arizona.— The Arizona Pioneer Historical Society, located at Tucson, was established some years ago.

Arkansas.— There are two historical societies in the State, both styled "Arkansas Historical Society," one at Little Rock, Fay Hempstead, secretary; the other at the University of Arkansas, Fayetteville, J. H. Reynolds, secretary.

California.— The California Historical Society, organized in 1886, San Francisco.

Colorado.— The State Historical and Natural History Society, Denver; incorporated 11 July 1879. Charles R. Dudley, secretary.

Connecticut.— The Connecticut Historical Society, Hartford, organized 1825; revived by the general assembly 1839; Albert C. Bates, secretary; New Haven Colony Historical Society, New Haven, 1862; New London County Historical Society, New London, 1870; Fairfield County Historical Society, Bridgeport, 1881; and the Middlesex County Historical Society, Middletown, 1902.

Delaware.— The Historical Society of Delaware, Wilmington, incorporated 1868; Hon. Chas. B. Lore, president; Wm. Hall Porter, recording secretary.

District of Columbia.— The Columbia Historical Society, organized 9 March 1894; Mrs. Mary Stevens Beall, recording secretary; and also the American Historical Society.

Georgia.— The Georgia Historical Society, Savannah; Hon. William Harden, secretary.

Idaho.— The Historical Society of the State of Idaho, Boise City; Hon. Wm. A. Goulden, secretary.

Illinois.— The Illinois State Historical Society, organized 30 June 1899. Local organizations in the State cooperate with the Society. The last legislature made the society a part of the Illinois State Historical Library, which library has heretofore issued publications of the society. Mrs. Jessie Palmer Webb, librarian of State Historical Library, and secretary and treasurer State Historical Society.

Indiana.— The Indiana Historical Society, organized 1830.

Iowa.— The State Historical Society of Iowa, Iowa City; organized 1857; present articles of incorporation date April 1892; F. E. Horack, secretary. The historical department of the State Library, Des Moines, should not be confused with this society.

Kansas.— The Kansas State Historical Society, Topeka; organized 14 Dec. 1875; Geo. W. Martin, secretary; "this library contains 24,424 books; 72,789 pamphlets; 25,926 volumes of newspapers; 25,977 manuscripts; 6,696 relics; 5,751 pictures; and 5,129 atlases and maps.

Kentucky.— The Kentucky Historical Society; organized 1839–40. The legislature donated rooms to the society 1879–80. In August 1902 it became a department of the State. Gov. J. C. W. Beckham, president; General Fayette Hewitt, first vice-president; W. W. Langmoor, second vice-president; Mrs. Jennie C. Morton, secretary and treasurer.

Louisiana.— The Louisiana Historical Society; organized 15 Jan. 1836; Judge Henry A. Bullard, president; reorganized 1846 with Judge F. X. Martin, president; incorporated 1847 and a new charter given 30 April 1877, transferring it from Baton Rouge to New Orleans. From 1860 to 1888 Judge Charles Gayarré, president, being succeeded by Judge W. W. Howe. Since 1894 Prof. Alcée Fortier has been president.

Maine.— The Maine Historical Society, Portland; organized 1822; H. W. Bryant, recording secretary; The Bangor Historical Society, Bangor; The Kennebec Antiquarian Society, Augusta; York Institute, Saco; The Sagadahoc Historical Society, Bath; The Lincoln County Historical Society, Wiscasset; The Skowhegan Historical Society, Skowhegan; The Waterville Historical Society, Waterville; and The Eliot Historical Society, Eliot.

Maryland.— The Maryland Historical Society, Baltimore; Geo. W. McCreary, librarian; The Frederick County Historical Society, Frederick; The Harford County Historical Society, Belair, Dr. Archer, president.

Massachusetts.—See data previously given.

Michigan.— The Michigan Pioneer and Historical Society, Lansing; organized 22 April 1874; issues each year a volume of historical collections; Henry R. Pattengill, secretary.

Minnesota.— The Minnesota Historical Society, St. Paul, is the only society in that State.

Mississippi.— The Mississippi Historical Society; organized 1898; Dr. F. L. Riley, secretary; Dunbar Rowland is director of the department of archives and history of the State of Mississippi, Jackson. This department was created 26 Feb. 1902 and is under the auspices of the historical society.

Missouri.—The Missouri Historical Society, St. Louis; chartered in 1875; The State Historical Society, Columbia, in 1899.

Montana.— The Montana Historical Society, Helena; organized December 1864; incorporated February 1865 and is a part of the State Library; Miss Laura E. Hovey, secretary and librarian.

Nebraska.— The Nebraska State Historical Society, Lincoln.

New Hampshire.— The New Hampshire Historical Society, Concord.

New Jersey.— The New Jersey Historical Society, Newark; organized 1845; William Nelson, corresponding secretary; Bergen County Historical Society, Hackensack, 1902; New Brunswick Historical Club, New Brunswick, Hunterdon County Historical Society, Flemington; Salem County Historical Society, Salem; Princeton Historical Association, Princeton; Woodstown and Pilesgrove Historical Society, Woodstown.

New Mexico.— The Historical Society of New Mexico; incorporated 5 Feb. 1881; home office, Santa Fe.

New York.— See previous references.

North Carolina.—The Historical Society of North Carolina was chartered in 1833; rechartered 22 March 1875; Dr. K. P. Battle, department of history University of North Carolina, Chapel Hill, secretary; The North Carolina Literary and Historical Society, Raleigh; W. J. Peele, secretary; and The Trinity Historical Society, Durham; Dr. J. S. Bassett, secretary.

North Dakota.— The North Dakota Historical Society; incorporated 8 March 1895; Col. C. A. Lounsberry, secretary, Fargo.

Ohio.— The Ohio State Archæological and Historical Society, Columbus; incorporated 13 March 1885, E. O. Randall, secretary. There are many local societies in Ohio: The Western Reserve Historical Society, Cleveland; The Fireland Historical Society, Norwalk; The Ohio Philosophical and Historical Society, Cincinnati; and others.

Oklahoma Territory.— The Oklahoma Historical Society, founded by the Oklahoma Press Association at Kingfisher, May 1893. By act of territorial legislature 21 Feb. 1895 it became trustee of the Territory "for the care, collection and preservation of all kinds of historical matter, and for the expending of any appropriation made by the Territory for such historical purposes, and located the society at the University building at Norman." In June 1901 the society accepted the offer of the entire upper floor of the Carnegie Library, Oklahoma City, pending the erection of a capitol building. Lincoln McKinlay, president; Sidney Clark, custodian.

Oregon.— The Oregon Historical Society, organized 17 December 1899; F. G. Young, secretary, University of Oregon.

Pennsylvania.— The Historical Society of Pennsylvania, Philadelphia; organized 1824; John W. Jordan, librarian; Bucks County Historical Society, Doylestown; Montgomery County Historical Society, Norristown; York County Historical Society, York; Lancaster County Historical Society, Lancaster; Wyoming Historical and Geological Society, Wilkes-Barre; Washington County Historical Society, Washington; Lebanon County Historical Society, Heilman Dale; Chester County Historical Society, West Chester; Delaware County Historical Society, Chester; Berks County Historical Society, Reading; Tioga Point Historical Society,

Athens; and the Presbyterian, Baptist, and Methodist Historical Societies. Philadelphia.

Rhode Island.— The Rhode Island Historical Society, Providence; founded in 1822; The Newport Historical Society, Newport, R. I.

South Carolina.— The South Carolina Historical Society, Charleston: organized 1855; Gen. Edward McCrady, president; A. S. Salley, Jr., secretary.

South Dakota.— The Department of History in the State of South Dakota; administered by the State Historical Society; was organized by act of legislature 21 Jan. 1903; located at Pierre; Doane Robinson, secretary.

Tennessee.— Tennessee Historical Society, Nashville; Robert T. Quarles, corresponding secretary.

Texas.— The Texas State Historical Society; organized 2 March 1897; Hon. John H. Reagan, Palestine, president.

Utah.— The State Historical Society of Utah; organized 31 Dec. 1897; Salt Lake City.

Vermont.— The Vermont Historical Society; organized 1838; Montpelier; Joseph A. Deboer, recording secretary.

Virginia.— The Virginia Historical Society, Richmond; organized 1831; William G. Stanard, corresponding secretary and librarian.

Washington.— The Washington State Historical Society, Tacoma; Hon. Ezra Meeker, president; E. N. Fuller, secretary.

West Virginia.— State Historical Society, Charlestown.

Wisconsin.— The State Historical Society of Wisconsin, Madison; organized 1849; re-organized 1853, this latter date being considered the real date of organization.

Wyoming.— The Wyoming Historical Society; organized 1895; Robert Morris, secretary, Cheyenne.

SYDNEY H. CARNEY, JR., M.D.

History is a record of events which have occurred among mankind; embracing an account of the rise and fall of nations, and other great mutations which have affected the political and social condition of the human race. In a more limited sense, history is a record of the progress of mankind in civilization; and, therefore, deals especially with those nations which have performed great achievements and exerted a commanding influence upon the fortunes of the human race.

History is generally divided into three great epochs — Ancient History, Mediæval History, and Modern History. Ancient History begins with the first appearance of historic records, and ends with the fall of the Western Roman Empire 476 A.D. Mediæval History, or the History of the Middle Ages, extends from the fall of Rome 476 A.D., to the discovery of America 1492 A.D. Modern History embraces the period from the discovery of America to the present time. Sometimes, however, the world's history is divided into only two great periods — Ancient and Modern; Ancient History embracing the whole period before the fall of Rome, 476 A.D., and Modern History comprising the entire period since that event.

The three sources of history are written records, architectural monuments and fragmentary remains. Several races of men have disappeared from the globe, leaving no records inscribed upon stone or parchment. The existence and character of these people can only be inferred from fragments of their weapons, ornaments and household utensils, found in their tombs or among the ruins of their habitations. Among these races were the Lake-dwellers of Switzerland; the prehistoric inhabitants of the Age of Stone and the Age of Bronze of the British Isles; the builders of the shell-mounds of Denmark and India; and the Mound-builders of the Mississippi Valley.

The discovery of monuments of great antiquity has aided vastly in ascertaining the date of ancient events. The Parian Marble, brought to England from Smyrna by the Earl of Arundel, contains a chronological arrangement of important events in Grecian history from the earliest period to 355 B.C. The Assyrian Canon, discovered by Sir Henry Rawlinson, the great English antiquarian, consists of a number of clay tablets, constructed during the reign of Sardanapálus, and containing a complete plan of Assyrian chronology, verified by the record of a solar eclipse which must have occurred 15 June 763 B.C. The Fasti Capitolini, discovered at Rome, partly in 1547 and partly in 1817 and 1818, contains in fragmentary records a list of Roman magistrates and triumphs from the beginning of the Roman Republic to the close of the reign of Augustus. The Rosetta Stone, discovered by a French military engineer during Bonaparte's expedition to Egypt in 1708, contains inscriptions in the Greek and Egyptian languages, the deciphering of which has led to the discovery of a key to the meaning of the hieroglyphic inscriptions on the Egyptian monuments. The fragmentary writings of Sanchoniathon give us some light on Phœnician history; those of Berosus on Babylonia and Assyria; Manetho's lists of the 30 dynasties of Egyptian kings afford us valuable information; and the works of Herodotus, the «Father of History,» have given us a graphic account of the ancient nations — their annals, manners, and customs, as well as a geographical description of the countries which they inhabited.

Herodotus was the first of Grecian historians. Other Greek writers of history were Thucydides, the great philosophic historian; Xenophon, the writer of charming historical romances; Ctesias; Diodorus Siculus; Polybius; and Plutarch, the charming biographer of antiquity. Ancient Rome produced Livy, Tacitus, Sallust, and Cornelius Nepos, who have given us the facts of Roman history. For the history of the ancient Hebrews we are indebted to the books of the Old Testament and the works of Josephus, the celebrated Jewish historian, who wrote a complete history of his countrymen in Greek. Among early Christian Church historians were the Roman Eusebius and the Anglo-Saxon, the Venerable Bede. The Frenchmen Comines and Froissart were celebrated chroniclers of the Middle Ages. The Italian Macchiavelli achieved fame by his historical writings. Among modern historians have been many who have acquired celebrity by their works. Such were the great trio of British historians — Hume, Gibbon, and Robertson, whose works have always been regarded as standards. England has produced many famous writers of history; such as Macaulay, Carlyle, Grote, Thirlwall, Froude, Lingard, Arnold, Allison, Freeman, Rawlinson, Green, Knight, Merivale, Milman, Hallam, and others. France produced Rollin, Voltaire, Thiers, Guizot, Sismondi, Mignet, Michelet, and the brothers Thierry. Germany has given the world a great ecclesiastical historian in the person of Mosheim; and a number of German historians have given the world the benefit of their scholarly researches, among whom we may mention Niebühr, Neander, Rotteck, Heeren, Schlosser, Mommsen, Curtius, and Leopold von Ranke. Among American historians the most renowned

have been Hildreth, Prescott, Bancroft, Motley, Lossing, and Parkman.

The origin of nations has been involved in obscurity, which has only quite recently been removed by the diligent study and the patient research of modern European scholars. Investigation into the affinities of the various languages has given us some new knowledge upon this interesting and important subject. Comparing the languages of most of the modern European nations with those spoken by the ancient Romans, Greeks, Medes, and Persians, and Hindus, we observe that all these languages had a common origin, entirely different from those spoken by the ancient Chaldees, Assyrians, Phœnicians, Hebrews, Arabs, and Egyptians; these latter being related to each other, but not to those of the nations previously named. The former of these languages are called *Aryan*, the latter *Semitic* and *Hamitic;* while the Central Asian Tartar nomads have a language called *Turanian*.

The Aryan branch is called Japhetic, because it has been supposed to be descended from Japheth; while the Semitic branch is regarded as the posterity of Shem, and the Hamitic branch as the children of Ham. The name Aryan means "tiller of the soil"; wherein this race has differed from the Turanian, or nomadic races of Central Asia.

In the course of time nations became divided into civilized and uncivilized, as their intellectual development was furthered by talents and commerce, or retarded or cramped by dullness and by isolation from the rest of mankind. Uncivilized nations are either wild hordes under an absolute and despotic chief who wields unlimited power over his followers, or wandering nomadic tribes, guided by a leader, who, as father of the family, exercises the functions of lawgiver, governor, judge and high priest. Neither the wild hordes under their despotic chiefs, occupying the unknown regions of Africa (negroes), the steppes and lofty mountain ranges of Asia, the primeval forests of America (Indians), and the numerous islands of Oceanica (Malays), nor the nomadic races with their patriarchal government, find any place in history.

The oldest civilizations were those found in the Tigris-Euphrates and Nile valleys, in the Hindu peninsula, and in the remote empire of China. The exact origin of the ancient nations and civilizations is lost in the dimness of their remote antiquity. These regions were richly endowed by nature with the resources necessary for sustaining a dense population; and the oldest historic empires accordingly took their rise in the rich alluvial lands watered by the Tigris and the Euphrates in southwestern Asia and by the Nile in northeastern Africa.

Historical Asia is southwestern Asia; where the great Hamitic and Semitic empires of Chaldæa, Assyria, and Babylonia successively flourished, in the Tigris-Euphrates valleys; where the Hebrews and the Phœnicans played their respective parts in the world's historic drama; and where the Aryan race finally came upon the scene in the appearance of the great Median and Medo-Persian empires and the Græco-Macedonian empire of Alexander the Great and his successors, followed by the Parthian, Eastern Roman, and new Persian empires; after which the Semitic race again prevailed in the sudden rise of Mohammed's religion and the great empire founded by his successors; followed by the conquests of the Seljuk Turks from Tartary, the two centuries of warfare between Christendom and Islam for the possession of the Holy Land as represented in the Crusades, the terrible scourges of the conquering Mongol and Tartar hordes of Genghis Khan and Tamerlane; and, lastly, the rise of the now-decaying Mohammedan empires of the Ottoman Turks and the modern Persians.

Southern Europe was the seat of the greatest two nations of antiquity—the Greeks and the Romans—the former by their literature and philosophy and their political freedom, and the latter by their laws and political institutions influencing all future European nations. The other nations of ancient Europe were barbarians, many of whom were conquered and civilized by the Romans. The overflow of the Roman dominion in the 5th century after Christ entirely changed the current of European history by a redistribution of its population through the migrations and conquests of its vast hordes of northern barbarians, who 14 centuries ago laid the foundations of the great nations of modern Europe. America and Oceanica were wholly unknown to the ancient inhabitants of the Old World, and have only occupied the field of history since their discovery and settlement by Europeans within the last four centuries.

The cradle of civilization — if not the cradle of the human race — was the fertile alluvial Tigris-Euphrates and Nile valleys, where, with the dawn of civilization, flourished the old Chaldæan and Egyptian empires—the most remote of historical states of antiquity. History begins with Egypt, the oldest of historical nations.

Asia is the birth-place of the great religions and the home of absolute despotism. The two great pantheistic religions — Brahmanism and Buddhism; also the great monotheistic religions — Judaism, Christianity, and Mohammedanism — arose in Asia; while Asiatic governments today are what they have been from time immemorial — absolute monarchies, or despotisms; no republic or constitutional monarchy ever having flourished on Asiatic soil.

Europe, on the contrary, inhabited by the progressive Aryan race, has carried political institutions to the highest state of development; civil, political, and religious liberty having had a steady growth. Asiatic civilization has been stationary, while European civilization has been progressive. The Asiatics are passive, submissive, given to contemplative ease and disinclined to active exertion. The Europeans are active, energetic, vigilant and aggressive. Europe has also colonized other portions of the globe; the greater part of the present populations of North and South America being the descendants of Europeans who settled in the New World, and drove away, or assimilated with, the aborigines; while Europeans have also settled in portions of Africa, Asia, and Oceanica. The Asiatics, on the other hand, do not colonize.

History, Ancient. Objectively history is a succession of past events connected with one another as cause and effect; subjectively it is a record of such events as determined by the processes of investigation included in historical method. The history of mankind treats not so

much of individuals as of the progress and decline of communities and states with especial reference to morality, religion, intelligence, social organization, economic condition, refinement and taste, government, and the peaceful and military relations of governments to one another (cf. Andrews, 'Institutes of General History,' p. 3). Strictly there are no periods; the life of mankind flows continuously, never wholly changing the direction of its current at any definite time. But for the convenience of study history is more or less arbitrarily divided into periods, during each of which the resultant of changes in the life of mankind, or of a particular part of it, is supposed to be a determinable movement of progress or decline which the historian takes as characteristic of the period.

The familiar division of general history into ancient, mediæval, and modern may be accepted as the most practical, though it is exceedingly difficult to define these long and complex ages. Most obvious is the geographical characteristic. Leaving out of account India and the farther East, which have contributed little to the progress of the rest of the world, ancient history has to do (1) with the fertile river-valleys adjoining the east end of the Mediterranean; (2) with the Mediterranean basin itself; for the few outlying countries which had a share in ancient history depended upon this area for their civilization. Or taking race and religion as the basis of division, we may define ancient history as the development of pagan, non-Germanic civilization; for with the thorough establishment of Christianity and the coming of the Germans the Middle Age begins. Although ancient history includes many nations and numberless movements of growth and decay, it shows nevertheless remarkable unity. From simple though diverse beginnings the various peoples of the area above defined developed into the one complex political and social organization known as the Roman empire; and when with the wreck of this system the ancient world passed away, there began under new conditions that fresh life of mankind which in its earlier stage we call mediæval and in its more mature growth modern.

History does not concern itself with ultimate origins; it begins with man in the lowest condition in which it actually finds him, and with the help of anthropology, archæology, and kindred sciences it traces his improvement from that point upward through the earlier known stages of his existence. The prehistoric age, which precedes contemporary written records, is taken into account in so far as, by furnishing relative beginnings, it affords an explanation of later developments. Even when the historian reaches the period of contemporary documents and literature, he continues to use all available auxiliary sciences, principally epigraphy, archæology, numismatics, philology, and geography. In testing the genuineness and the historical value of sources he makes use of critical principles which are becoming more and more definite and effective with the growth of historical method into a science.

Nowhere has source material accumulated so rapidly in recent years as in the Orient. As a result of continued explorations there our knowledge of Oriental life has been vastly increased, and the beginnings of Oriental history have been pushed much farther back into the past. We are now able to study the Egyptians of the paleolithic age (cf. Petrie, 'History of Egypt' (4th ed. i. p. 5 ff), although no date can yet be assigned to that primitive culture, nor have yet been discovered all the links which connect it with the historic age. Beginning with the earliest appearance of written records in the Orient, we may divide ancient history into the following periods:

I. *The Dawn of Civilization; the old Egyptian Kingdom and the Chaldean and Syrian City-States, 5000–3000 B. C.*—Whether mankind first emerged from the Stone Age in the valley of the Nile or in that of the Tigris and Euphrates rivers is disputed, and the date of this event has not been even approximately determined. There can be no doubt, however, that early in the fifth millennium B.C. civilization in both these regions had reached a comparatively high development. People irrigated their fields, built cities, in which they lived under kings, and were acquainted with the elements of practical science as well as with the art of writing. The Egyptian alphabet of this period was hieroglyphic, the Chaldean cuneiform. Egypt achieved political unification under a monarch near the beginning of the period; Chaldea and Syria remained divided among rival city-states.

Through the most brilliant part of the period the Egyptian capital was Memphis, whose Pharaohs of the fourth dynasty (about 4000–3725 B.C.) constructed the great pyramids at Gizeh. This epoch is unique in the world's history for the bold attempt to surpass nature in the grandeur and strength of its buildings, which at the same time indicate the high centralization in the hands of the monarch. The people of Egypt, devoted to agriculture and the industrial arts, were peace-loving, submissive to authority, and intensely religious. Prominent among the Chaldean cities were Ur, Nippur, Agade (Accad), and Babylon, under independent kings who strove with one another for the mastery. In spite of their military occupation the people, like the Egyptians, engaged their best thought and energy in creating the elements of civilization. Among their early achievements were the science of astronomy, the calendar, and a system of weights and measures, which with some modifications afterward passed to Europe. Early in the fourth millennium Chaldean civilization began to affect Syria.

II. *The Middle Kingdom of Egypt; the Political Unification of Chaldea; the Neolithic and Æncolithic Ages in Greece, about 3000–2000 B. C.*—In the beginning of the period Thebes supplanted Memphis as the political centre of Egypt. The most brilliant dynasty was the twelfth (about 2775–2550 B.C.). The Pharaohs of this family with a firm hand controlled the feudal lords who since the sixth dynasty had been growing strong over all Egypt, and to whom most of the famous rock-graves of the period belong. The same dynasty conquered Ethiopia (Nubia), carried on a lively trade with Syria, and had commerce with countries as far west as Crete. They built splendid temples, and regulated the waters of the lower Nile by means of a great reservoir in the Fayûm. Their utilitarian works contrast strikingly with the grand though selfish idealism of the pyramid-builders. Meanwhile in Chaldea the strife among the cities continued till the whole country was unified under Babylon (2250 B.C.).

In the industries both nations reached a high stage of technical skill. The Egyptians excelled in inlaid work, the Babylonians in the engraving of gems. The architecture was massive, the Chaldean in brick, the Egyptian in stone. The sculpture, too, though lacking grace, showed great strength. The literature was looked upon by after ages as classic. In government we find a centralized monarchy with a bureaucratic administration regulated by written law (cf. the Code of Hammurabi (q.v.), about 2250 B.C.). The family was monogamic, and society was definitely organized in classes. The prime motive power in life was religion, which, manipulated by the priests, was already reducing the activities of man to a system of conventions and thus putting an end to originality.

In the region about the Ægean Sea the period is represented by the first settlement at Troy, of neolithic culture (3000–2500 B.C.), and by the second or "burnt" city, which was æneolithic (2500–2000 B.C.). Crete, in communication with Egypt, seems to have taken the lead in the civilization of this region.

III. *The Earliest Empires and Their Struggles; the Beginnings of Assyria, Phœnicia, and the Hebrews; the Bronze Age in Greece, 2000–1000 B. C.*—After the twelfth dynasty Egypt weakened; from the beginning of the second millennium the Hyksos (q.v.) a barbarous people from Asia, controlled the lower Nile valley for several, possibly five, centuries. After their expulsion the Egyptians became a conquering people. The eighteenth dynasty (about 1600–1325 B.C) extended their dominion on the south to the centre of Ethiopia and on the northeast to the Euphrates River. Cyprus and the "isles of the Great Sea" sent as tribute and gifts vases of Mycenæan manufacture.

Chaldea, ruled by Cossæan — Kassite — kings (1717–1140 B.C.), was not only unable to prevent these conquests, but even lost her hold upon Assyria, which now began a long winning struggle with Babylon for supremacy. Both countries courted the favor of the powerful Pharaohs. For the first time in history we have great states in relations of war and peace with one another — the beginning of diplomacy and "world-politics." Assyria (1125 B.C.) suddenly created an empire which extended northward to the sources of the two rivers and westward to the Mediterranean. She advanced beyond Egypt in the organization and administration of conquered countries, but her empire soon fell to pieces, partly from internal exhaustion and partly because of invasions from Arabia.

Before the rise of the Assyrian empire the Hittites had conquered eastern Asia Minor and had wrested northern Syria from Egypt; but their power was as speedily overthrown by swarms of invaders of unknown race from Asia Minor, who then made a fierce assault upon Egypt.

Before the end of the millennium the Phœnicians had planted many trading-stations on the islands and coasts of the Mediterranean and had created a "world-commerce." Sidon was at first the leading city, and afterward Tyre. Their civilization, with that of all Syria, was fundamentally Chaldean, affected to some extent by Egyptian commerce and conquest. About 1000 B.C. the Greeks adopted their phonetic alphabet.

Among the immigrants from Arabia into the civilized districts of Hither Asia were the Aramæans, who established themselves in northern Syria with their capital at Damascus, and the Hebrews, who conquered the country in southern Syria now known as Palestine (1150 B.C.). At first their government was a theocracy represented by prophets and "judges," but soon (about 1050 B.C.) they established a kingship.

In this period the creative energy of the Egyptians had exhausted itself. Life became artificial; wealth, flowing in from conquests, substituted magnificence for taste, and in the end enfeebled the national spirit. On account of the wars the military class came into great prominence; the king, more than before, became the proprietor of the state, and the priests gained control of the material as well as of the spiritual activities of the nation. In Hither Asia, also, artistic and industrial civilization suffered through the decline of Chaldea; for the Assyrian genius was chiefly political and military rather than artistic or intellectual. The Hebrews, however, were moving in the direction of monotheism, and Phœnicia was spreading Oriental civilization abroad over the Mediterranean lands.

Of enormous importance for history was the development of civilization in the Ægean region. The beginnings of the Bronze Age — proto-Mycenæan — are represented by the third, fourth, and fifth cities at Troy (2000–1500 B.C.), followed by the fully developed Mycenæan civilization, represented by the sixth city at Troy, by Tiryns, Mycenæ, and many other cities on the Greek peninsula, in Crete and the Ægean islands. Characteristic of the civilization are massive fortifications, large palaces, immense tombs, wonderfully skilful work in gold, in vase-making, gem-cutting, and inlaying with precious metals, also excessive ornamentation of apparel and effeminate luxury. Toward the close of the millennium this culture began rapidly to decline.

Parallel to this development in the Ægean, yet little affected by it, the Etruscans of central and northern Italy were creating a peculiar civilization,— less artistic and less grand than the Mycenæan,— which did not reach its height till the following millennium.

IV. *The Growth and Decline of the Syrian Kingdoms; the Rise of the Assyrian Empire; the Epic Age in Greece, 1000–700 B. C.*— Tyre, taking the place of Sidon, became the centre of the world's commerce. Under king David the Hebrews developed a great political power; but after the death of Solomon they split into two kingdoms, Judah and Israel. Damascus, which had belonged to the realm of David, again became the capital of an independent Aramæan kingdom. Near the end of the period, however, all Syria excepting Tyre fell under the Assyrian yoke. The people of Damascus (about 730 B.C.) and Israel (722 B.C.) were carried into captivity, and Judah became tributary. Babylon, too, was definitely conquered (728 B.C.). Egypt, again declining, divided into many small principalities, while Ethiopia rose to a power of the first importance. Her king conquered the Nile valley to its mouth in 728 B.C. But the greatest political event of the period was the rise of the Assyrian empire. Through persistent warfare carried on by a line of able

kings for crushing frequent rebellion as well as for new conquests, the empire reached the height of glory, though not yet its widest extent, under Sargon (722–705 B.C.).

Great progress was made in civilization. The Hebrews, afflicted by Assyria, were purging themselves of polytheism, and under the lead of inspired prophets were learning to look upon Jehovah as the only God, almighty, pure, and jealous, who demanded of his worshippers not only ceremonial exactness but clean hearts and spiritual devotion. With the Assyrians, notwithstanding their strong religious nature, political motives were dominant. For strengthening their empire they adopted the plan (1) of recruiting their armies partly from conquered peoples, (2) of transplanting populations from one part of the empire to another, to break up local attachments and weaken the power of resistance, (3) of organizing some of the conquered countries into provinces ruled by Assyrian officials, though many were still left under their native rulers. In government and administration, accordingly, Assyria was at this time the most progressive of nations.

The centre of interest in the growth of civilization, however, shifted to the Ægean region, where in this age the Ionic Greeks produced the first European literature — the 'Iliad' (q.v.) and the 'Odyssey' (q.v.) Colonists in a strange country, the Ionians were not in a condition to cultivate the Mycenæan arts, but drew their subsistence from grazing, agriculture, and war. With a high degree of refinement, mixed with barbarity, they possessed remarkably virile, elastic minds. In contrast with the slavish Orientals, the Greeks, represented by the Ionians, were in spirit free. To them neither nature nor religion was terrible; their gods were intensely human, generally the helpers, never the implacable enemies of man. Combined with this intellectual liberty and boldness was a rare sense of fitness and proportion, manifested in the Homeric poems referred to above. In Greek manhood, virility, freedom, intelligence, and taste combined to produce a civilization which was already rapidly advancing beyond that of the Orient.

V. *The Fall of Assyria and the Rise of the Persian Empire; in Greece Colonial Expansion and the Awakening of a National Consciousness; the Struggle Between Asia and Europe, in which Greece Becomes the Centre of Interest in the World's Politics; in the Central Mediterranean Region the Political Growth of Carthage and Etruria; at Rome the Primitive Kingship and the Beginning of the Republic, 700–479 B. C.*— Early in the period Lydia became a conquering state, and reached the height of its imperial power under Crœsus (560–546 B.C.), who ruled nearly all Asia Minor west of the Halys River. Egypt fell under the Assyrian power (664 B.C.); but soon throwing off the yoke, it enjoyed a long period of independence (645–525 B.C.). Before the loss of Egypt the Assyrian empire reached from Thebes on the Nile nearly to the Caspian Sea, and from the Persian Gulf nearly to the Black Sea — the greatest extent of country yet united under one ruler. In Nineveh, their new capital, the kings built magnificent palaces of brick, adorned with representations of their wars in sculptured reliefs. They established libraries, too, of Babylonian learning. But they had already ceased to make political progress, and they failed to give their empire an organic unity, and to inspire the conquered nations with loyalty to the central government. Suddenly the empire was overthrown by a combination of the Babylonians and the Medes, who destroyed Nineveh in 606 B.C. With this event Assyria disappeared from history.

Two empires — the Median and the Babylonian — divided between them the Assyrian domain. The former lay in the north of Hither Asia, the latter in the south. Under Nebuchadnezzar (606–562 B.C.). Babylon became the largest and wealthiest city in the world, a brilliant seat of industry and commerce. He destroyed Jerusalem, carried Judah into captivity (586 B.C.), and conquered Tyre. Of the other empire the ruling people were the Medes, who inhabited the plateau between the Tigris Valley and the Caspian Sea. Their sway extended westward, on the north of Babylonia, to the Halys River, and southward over their Persian kinsmen. Both empires, however, were short-lived; in 550 B.C. Cyrus, an Elamitic prince, at the head of a Persian revolt, established himself master of the Median realm. This event made the empire Persian. After conquering Lydia (546 B.C.) and Babylon (538 B.C.), Cyrus proceeded to subdue the countries to the east and northeast of Persia; so that at his death (529 B.C.) his empire extended from the Ægean Sea to the Indus River, and from the Persian Gulf to the Jaxartes River — an area perhaps five or six times as great as that of the Assyrian empire. His son and successor Cambyses added Egypt (525 B.C.), and Darius, the following king (522–485 B.C.), completing an organization begun by Cyrus, divided the empire into twenty satrapies (provinces), each under a governor termed satrap. This magistrate, appointed by the king, exercised full military and civil authority over his province, subject to royal regulations and commands. Though checked by the continual presence of a royal secretary and by the occasional visits of the king's "eye" (inspector), the satrap enjoyed the splendor and nearly all the power of a sovereign. Darius also built roads throughout the empire, distributed the taxes equitably, and established a system of gold and silver coins. He annexed Thrace to his empire, and made an unsuccessful attempt to conquer Greece.

In the beginning of this period the Greeks were extending the sphere of their influence through colonization. About 750 B.C. they had begun to settle in southern Italy and Sicily: and for two centuries the movement of expansion continued, till their settlements extended from Naucratis, Egypt, to the Pillars of Hercules, and from the northern coast of the Black Sea to Libya. With colonial enterprise the industries and commerce kept full pace. They manufactured armor, artistic bronze-ware, and tastefully painted vases. From Lydia they learned the art of weaving and dyeing fine woolens as well as of coining money; from Egypt they derived the elements of astronomy, of surveying, and of the other practical sciences. Great intellectual progress took place; lyric poetry flourished in all parts of Greece — a kind of poetry which shows that the Greeks were actively thinking on all subjects suggested by their expanding environment. They made a

beginning of geography, history, and philosophy. Thinking led to religious and moral progress; the Greeks began to exercise self-restraint and moderation in life. Their sympathies widened with their intelligence; they discovered that they were all of one blood, one speech, and one religion, and began to call themselves by the common name of Hellenes. They became aware, too, of the differences between themselves and foreigners, whom they termed "barbarians," and of their own superiority to all other races. Conflicts with foreigners made the Greeks feel that they ought to combine for mutual defense. In the preceding age (1000–700 B.C.) their whole country was divided among a multitude of small city-states, each under an independent king. While in the more progressive parts of the nation in the period now before us the government was rapidly developing from kingship through aristocracy, oligarchy or timocracy, and tyranny in the direction of democracy, a corresponding movement was going on toward political unity. The city of Sparta, after uniting by conquest Laconia, Messenia, and Cynuria in the strong military state of Lacedæmon, built up the Peloponnesian league with herself as leader. The basis of her superior military organization was the phalanx. Under the fear of Persian invasion this power expanded into an Hellenic league of all the loyal Greek states on the peninsula and on the neighboring islands. In Sicily a similar league grew up under Syracuse for defense against two formidable powers, Etruria and Carthage. The Etruscan dominion extended from the Alps to the vicinity of the present Naples, and probably included the then insignificant city of Rome, which after having been ruled from the earliest times by kings set up a republic in 509 B.C. The Etruscans, now at the height of their development, were equally powerful by land and sea. Even more formidable to the Greeks was Carthage, the greatest Phœnician colony, which united under its leadership all the other Phœnician settlements in the western Mediterranean region. By means of enormous wealth, accumulated through commerce, this city recruited a vast army of mercenaries, with which she hoped to overwhelm the western Greeks.

Checked by the growth of foreign powers, Greek colonial expansion came to an end about 550 B.C. Then the boundary of free Hellas on the east was pushed back by the Lydian and Persian conquests in Asia Minor. A revolt of the Ionians against Darius,— in which the insurgents were aided by the mother country,— precipitated between Asia and Europe a conflict destined to affect the whole future history of the world. An army sent into Greece by Darius, was beaten back by the Athenians at Marathon in 490 B.C. Ten years afterward, Xerxes, son and successor of Darius, led a vast host into Greece, hoping to overwhelm the free little country by the sheer force of numbers. But his fleet was shattered in the battle of Salamis (480 B.C.) and his army destroyed at Platæa by the forces of the Hellenic league (479 B.C.). Meantime at Himera, Sicily, the despot of Syracuse destroyed the invading mercenary army of Carthage (480 B.C.). The Greeks met with brilliant success both in the East and in the West: those of their race in Asia Minor were liberated; all were relieved from fear of foreigners; Greek civilization was free to develop without the restraint of alien rule; Greece came out of the struggle strong, proud, self-conscious, ready for great achievements in peace and in war.

VI. *The Culmination and Decline of Greek Political Power and of Greek Civilization; the Hellenization of the Orient; the Unification of Italy Under Rome, 479–264 B. C.*—The splendid naval force which Athens furnished for the war, together with superior statesmanship, placed her at the head of a new league of maritime Greek states, known as the Delian Confederacy (organized 477 B.C.). Rivalry for the headship of Greece between democratic Athens and oligarchic Sparta led to the Peloponnesian war, which involved a great part of the Greek world (431–404 B.C.), and which ended in the establishment of Spartan supremacy (404–371) over eastern Greece, while nearly all western Greece was united under Syracuse. Oppression on the one hand, and on the other the love of the Greeks for city-autonomy, caused the downfall of both political powers. For a short time under Epaminondas (371–362 B.C.) Thebes attempted to take the place of Sparta, but in vain; the Greek state-system,— consisting of leagues and hegemonies of cities,— was rapidly crumbling. Meanwhile Macedon, a territorial state under King Philip, taking advantage of the political disunion and mutual jealousies of the city republics, began to encroach on free Hellas. After defeating the combined forces of Athens and Thebes at Chæronea (338 B.C.) he imposed his protectorate upon the Hellenic state-system. His son Alexander the Great in a series of brilliant campaigns (334–331 B.C.) conquered the Persian empire, and afterward extended its boundaries to the northeast and the east. His empire was the largest the world had known. Among his improvements was the specialization of administrative functions, financial, judicial, and military. When he died, the empire after a long struggle among his generals ultimately divided into three great states,— Egypt, Asia (the Seleucid empire), and Macedon, including Greece. To regain and preserve their liberty many of the cities of eastern Greece entered into two federal unions, the Ætolian and the Achæan. These institutions, though long known to the Greeks, came into favor too late to save them from the domination — not of Macedon but of Rome. The western Greeks, however, were first to meet their fate.

After adopting a Republican constitution Rome engaged with her neighbors in a long, desperate struggle for existence (509–431 B.C.). Then by securing the headship of Latium (431–406 B.C.) and by the conquest of Veii she became one of the strongest powers in Italy. A series of wars with the Latins, Samnites, and Italiot Greeks (343–290 B.C.) gave her control of all Italy south of the Rubicon River. The success of the Romans was due to their improvement on the Greek phalanx, their strict discipline and obedience to authority, their laborious patience in fortifying acquired territory, and their liberality in the treatment of conquered peoples. The political system which in this period they gradually built up on the basis of Italian nationality recognized various gradations of rights and obligations among the communities of the system from the tributary subjection of the Gauls to the full Roman citizenship. Though

partly federal, the system left to Rome absolute control of foreign and military affairs. At the close of the period (264 B.C.) Rome and Carthage were the great powers of the western Mediterranean; those of the East were Macedon, Egypt, and the Seleucid empire.

The century and a half (479–322 B.C.) following the Græco-Persian war was in some respects the most brilliant in the history of civilization. The tremendous energy roused in Greece by the war displayed itself under the guidance of taste and reason in every field of activity. A wave of independence, overthrowing tyrannies and oligarchies, established popular governments in many cities, and intensified the democracies already existing. In Periclean Athens, which depended economically upon the labor of slaves and tributes from dependent allies, the citizens enjoyed a more liberal education and a wider range of political and social privileges than have ever fallen to any other community known to history. In close relation with this political and social development architecture, sculpture, and literature reached ideal perfection. The fifth century produced the Attic drama (Æschylus, Sophocles, Euripides, and Aristophanes), the noblest historical writing (Herodotus and Thucydides), and the inimitable Parthenon and Erechtheum. But the Peloponnesian war exhausted the energy and resources of eastern Greece. The growing refinement and love of peace which characterized the following century is indicated by the fact that the inhabitants of the city-states shirked military service, so that war came largely into the hands of mercenaries drawn from the less cultured territorial states. Thought prevailed over action; and in art strength was to some extent sacrificed to beauty and finish. While poetry declined, oratory and philosophy reached the height of their development in Demosthenes, Plato, and Aristotle, who brought classic Greek literature to a close.

Following the conquests of Alexander, commerce, colonization, and administrative policy spread Hellenic civilization over the Orient. In the post-classic period (after 322 B.C.) Pergamum and Alexandria became the most famous seats of Hellenistic culture, which was distinguished for painstaking scholarship rather than for creative power. The West, too, was falling under Hellenic influence. Rome adopted from the Greeks not only the phalanx, but also various deities and religious ideas, the alphabet,—either directly or through the Etruscans,—and other rudiments of civilization. From the Etruscans chiefly came the impetus to the building of public works,—temples, sewers, roads, bridges, fortifications,—in which the Romans showed creative genius. But to the end of the period they paid little attention to learning; they were without literature and had few if any schools. A realistic, practical people, they were narrow and unamiable in private and business relations, but excellent warriors and citizens. Duty and Discipine were the great commandments to which the family and society, citizens and soldiers, yielded religious obedience. These heroic virtues were not the least important factor in the creation of their empire.

VII. *The Expansion of the Roman Power over the Mediterranean World; the Growth of Plutocracy and the Decline of the Republic, 264–27 B. C.*—The extension of the power of Rome over the peninsula brought her into collision with Carthage, which had occupied nearly the whole of Sicily and was now threatening southern Italy. Not only did Rome feel bound to protect Italy, but her growing commercial class desired by conquest to extend its opportunities for trade and speculation. The First Punic War (264–241 B.C.) may be compared in character and importance with the recent war between the United States and Spain, which resulted in the occupation of the Philippine Islands by the former power. To meet the Carthaginians on their own element, Rome built a navy, and thus equipped herself for transmarine conquests. As a result of the war, Carthage surrendered Sicily to Rome in addition to paying a heavy indemnity. This island became the first Roman province (227 B.C.). Sardinia and Corsica, acquired soon after the war, were organized into a second province. Then by conquering the Gauls in the north of Italy (225–222 B.C.) the Romans extended their sway to the Alps. In the Second Punic War (218–201 B.C.) the Carthaginian Hannibal, one of the most eminent generals of all time, invaded Italy, defeated one Roman army after another, desolated the country, and came near wrecking the power of Rome. Her preservation was due to the wisdom of the senate, to the solidity of Roman character, and to the tie of common interests and of kindred blood which bound the Italians together against the alien intruder. This war of defense shows Rome at her best. Peace brought her two provinces in Spain and the destruction of her rival's navy. So greatly superior was now her strength that the conquest of the civilized world had become merely a question of a few years. In another series of successful wars (200–146 B.C.) she acquired Macedon, Greece, Asia Minor, and the country about Carthage. Corinth and Carthage were destroyed, and most of the acquired territory was organized into provinces. At this date (146 B.C.) Rome was the only great power in the entire Mediterranean basin. The further growth of her empire consisted mainly in the conversion of protected and dependent countries into provinces and an occasional conquest. To Pompey belongs the subjugation of Syria (65–62 B.C.), which alone remained of the Seleucid empire, and to Julius Cæsar the more important conquest of Gaul (58–50 B.C.). Egypt, long dependent, became a province in 30 B.C. The Roman empire, consisting of provinces and dependent allies, now included the whole circuit of the Mediterranean.

Some advantages came to the world from Roman rule: while in the East Græco-Oriental culture continued undisturbed, Latin civilization, which was falling more and more under Hellenic influence, gradually permeated the provinces of the West; throughout the empire the cities retained their own laws and self-administration under the government of their wealthy class; all parts but the frontiers enjoyed lasting peace. The evil effects of the system, however, soon began to outweigh its advantages. To secure a monopoly of commerce for themselves, the Romans restricted or even prohibited trade among the subject communities. Over all the empire they acquired vast estates, which they worked by slave labor, thus destroying everywhere the free peasantry. Their policy of farming the taxes was also unjust and oppressive.

The governors, too, with rare exceptions made office a means of amassing fortunes. In these ways the administrative and capitalist classes recklessly exploited the provinces for their own profit. At the same time commercial restrictions and the competition of slave labor were ruining the farmers and business men of Italy, and a worthless, dangerous mob was growing up in the capital.

The early government of Rome by magistrates, senate, and assemblies, although admirably adapted to a small community, proved unequal to its new and complex functions. The assemblies, now becoming corrupt, were in the hands of magistrates, ministers of the senate, which as a whole was controlled by a small knot of members, the curule ex-magistrates. This inner circle formed in the beginning a nobility of merit; it saved the state from Hannibal and conquered the Mediterranean world. But it soon transformed itself into an hereditary caste, which, monopolizing the domestic and imperial offices, used them as a means of absorbing the wealth of the world. In brief the nobility degenerated into a corrupt, self-seeking plutocracy. As to the general condition of the world at this time it should be noted that the want of competition, such as exists among nations of approximately equal power, by reducing the vitality of mankind, stopped progress, and decay was already setting in. Thorough reform was needed even to postpone the collapse of ancient civilization.

The Gracchi sacrificed their lives in a vain attempt to regenerate the peasantry and to restore Italy to its old condition of economic health; at the same time they showed the enormous power of the plebeian tribunate for purposes of reform or revolution. Far preferable to government by the corrupt aristocracy or by the mob, which Gaius Gracchus organized, would be the strong rule of one man; and the task of creating in the army a solid foundation for a government of the kind was accomplished by Gaius Marius. After him the governor (proconsul) of a military province employed his position as a means of acquiring an army for political use; and the proconsuls became rivals for the mastery of Rome. Finally Gaius Julius Cæsar, an aristocrat by birth but a champion of the people, allying himself with the tribunes, overthrew the republic and created a virtual monarchy. By radical reform of the entire administration this great creative statesman arrested the decay of civilization and gave the institutions of the ancient world a new lease of life. The assassination of the monarch, far from restoring the republic, was followed by a war of succession, in which his grand-nephew Octavius —after 27 B.C. Augustus — won the imperial prize (31 B.C.).

VIII. *The Empire at Its Height, 27 B. C.–180 A. D.*— Instead of recurring to the autocracy of Cæsar, Augustus hit upon a compromise between republic and monarchy (27 B.C.). The senate through its magistrates and promagistrates was still to govern Rome, Italy, and the peaceful provinces, while Augustus as holder of the military authority (*imperator*, hence emperor) was to rule directly the exposed and unquiet provinces and to exercise supervision even over those administered by the senate; the republic was to continue for Italy, the monarchy was established for the subject countries. In Rome Augustus held the tribunician power, and was sometimes elected to republican offices; but his chief influence over the home government was exercised not through office but in the capacity of political "boss,"— a position which the Romans dignified with the name of *princeps* (foremost citizen). The prince and the senate had not only their separate fields of administration but also separate treasuries and separate sets of officials. Augustus concealed the independent position of the prince; Tiberius brought the dyarchic antithesis into bold relief; the Claudian and Flavian princes, by gradual encroachment on the senatorial prerogatives, aimed to convert the dyarchy into a monarchy. As the senate declined, the officials of the prince, originally his friends and household servants, developed into an imperial bureaucracy. After the tyranny of Domitian the "Good Emperors" (96–180 A.D.), in reconciling the nobility to the principate, laid more firmly the constitutional basis of their power. The government may now be termed a monarchy, although some elements of the dyarchy remained, and though the senate, with its republican traditions, continued to be a material check upon the powers of the prince.

The emperors made few permanent conquests,— chiefly Britain and the Danubian provinces. Their fundamental task was to extend Latin civilization to the un-Hellenized parts of their dominion. In Africa west of Egypt, notwithstanding the survival of the Phœnician language in private life, Latin civilization took deep root. Spain and southern Gaul became perhaps even more thoroughly Latinized. Northern Gaul was less affected, and Britain still less, by the Romans, while the northern provinces east of Gaul varied greatly in their receptivity of Latin culture. The principal factor in the work of civilization was the city; in most of their European domains the Romans superseded the old tribal organization by the Italian municipal system, which gave the nations the refining and disciplining influence of comfortable homes, useful and artistic public works, schools, courts of justice, and local self-government. Each city was a centre from which Latin modes of life and Latin ideas radiated. Imperial rule cured most of the ills of republican administration. Abolishing the farming of direct taxes, it placed their collection in the hands of imperial officials, and distributed them on the basis of a careful census. The governors, now drawing their salaries from Rome, and deprived of their former unlimited opportunity for extortion, were held responsible to the emperor. The armies, placed under strict discipline and controlled by one will, no longer wasted the empire by civil wars. For the vast extent of the frontier the soldiers were few, and the burden of their support was light. The republic had looked upon the provinces as its estates; in the 2d century A.D. the emperor came to regard himself as the parent of the subject peoples, whom he was in duty bound to treat with love as well as with justice. Though oppression was not wholly eradicated, the imperial government was in a high degree efficient, just, and humane. The progress of civilization was followed by the extension of the Roman citizenship. The liberal policy of Claudius in bestowing it was continued by his successors, till shortly after the period

under discussion all freemen of the empire became Romans by the edict of Caracalla (212 A.D.).

In this period was tried the experiment of maintaining profound and lasting peace over the large area comprising the interior provinces. Prominent among the results was a material prosperity far greater than has ever blessed those countries in any other age. Another result was the development of the "feminine virtues." Men "became chaste, tender-hearted, loyal, religious, capable of infinite endurance in a good cause" (Seeley, 'Roman Imperialism'). They began to regard women as their equals, to treat children and slaves humanely, to show kindness even to animals, and in spite of gladiatorial contests, to abhor bloodshed. Morals, at their lowest ebb in the Rome of Nero, were rapidly purified by the coming in of the best families from the provinces, so that under the Good Emperors morality in the capital reached a high level. The spirit of the age expressed itself not only in the private and social virtues, but also in the Civil Law, which rested upon the principles of justice, kindliness, and equality among men.

The unimaginative Romans failed to produce a literature of the highest rank. In the late republic lived Lucretius, a poet of real genius, and Cicero, the versatile author of orations, philosophic works, and private correspondence. The Augustan age created the epic and rural poetry of Virgil, the 'Odes' and 'Satires' of Horace on social and moral topics, and Livy's stately history of the republic. The most splendid Latin writers of the age of the Good Emperors were the satirist Juvenal and Tacitus, the historian of the early empire. Among the most famous writers in the Greek language at this time were Pausanias, author of a 'Tour of Greece,' Appian, the historian, and Plutarch, the biographer of eminent men. Hellenism continued to be the chief liberalizing and refining force in the empire. Its highest intellectual product from Roman soil was Stoicism, which found its best expression in the writings and character of Marcus Aurelius.

IX. *From Limited Monarchy to Despotism; the Reorganization of Diocletian and Constantine; the Barbarian Invasions and the Decline of the Empire, 180–500 A. D.*— Writers generally agree in making the decline begin with the reign of Commodus (180–192 A.D.), though disintegrating forces had long been in operation and though for generations afterward the empire at times, as under Septimius Severus and Diocletian, showed great recuperative power. The century which intervened between the death of Marcus Aurelius and the accession of Diocletian (180–284 A.D.) we may regard as a period of revolution. The happiness of the Roman world under the Good Emperors had been chiefly due to the wisdom of a succession of rulers who were able to secure the good will of the senate and of the populace of Rome, the subordination of the pretorians and of the army, and the respect of surrounding nations. The weak, brutish Commodus allowed these nicely adjusted forces to conflict, and the result was civil war and anarchy. The revolution, sweeping away the influence of pretorians, populace, and senate, almost of Rome itself, brought new principles of government into play. The emperor was to be a despot of the Oriental type,— a God on earth,— who surrounded himself with stately splendor, and governed through a complex bureaucracy. He appointed a colleague, and two Cæsars were named as heirs of the emperors, all four dignitaries being men of eminent military ability. The empire was reorganized in prefectures, dioceses, and provinces under appropriate magistrates. These arrangements, chiefly the work of Diocletian (284–305 A.D.) and Constantine (sole emperor 324–337 A.D.), were in the main permanent. In making better use of the resources of the empire for the purposes of defense the new organization brought fresh strength, but rivalry between the emperors again caused civil wars with all their evil consequences. Under Constantine, who removed the capital to Byzantium, thereafter called Constantinople, the two imperial offices were again vested in one person, and were not definitely separated till the accession of Arcadius and Honorius, sons of Theodosius (395 A.D.). Even then the theory of a single empire ruled by two colleagues continued; and when in 476 A.D. Romulus "Augustulus" was deposed at Rome and the imperial trappings were sent to Constantinople, people understood merely that the collegial government had once more given way to monarchy.

Meanwhile from the heart outward through every limb the empire was falling to decay. The underlying cause, already referred to, was declining vitality, fundamentally due to lack of interest in the welfare of the state, of the community, of future generations. As the civilized part of the human race lost love of life and hope for the future, it began to die out. A related cause was slavery, which long before Marcus Aurelius had been destroying the free population; in his time the plague, and after him foreign and civil wars, continued to waste life, while the burden of taxation, always increasing, made life every day more wretched. The wealth of the empire flowed to the East in exchange for useless luxuries; and for want of gold and silver the coinage was debased; at the same time the cost of living became excessive. Then, too, the growing splendor of the imperial courts added to the burden. With their scant means many found it impossible to support families, and even the slaves grew fewer. In these conditions most of the lower population, free and slave, became hereditary serfs — *coloni* — bound to the soil and to the payment of fixed dues to their lords. But it was not only the poor who suffered. The municipalities had once enjoyed freedom in local affairs, each governed by a senate, whose members — *decuriones* — were the wealthier men of the community. Gradually the emperors encroached upon the liberty of these cities, till they had converted even the privileges of the senators into intolerable burdens. For as these officials were responsible for the taxes due from their districts, many of them, unable to wring the required amount from the poorer classes, were themselves reduced to poverty. Nevertheless they could in no way shirk their duty, but were held for life by an iron hand to the unenviable task of collecting and of paying oppressive taxes. Artisans and traders, too, were bound strictly to their hereditary vocations, in order that the government might be sure of the dues to which they were subject. In brief, society was forced into a rigid caste-like system, which crushed freedom and made the life of rich and poor, bond and free, almost

equally wretched. As under these circumstances the population grew unwarlike, the government found it more and more necessary to make up the armies of Germans, who consequently settled in the empire in ever increasing numbers. Although they readily adopted Roman civilization, their independent spirit, out of harmony with the conditions above described, acted as a new disintegrating force. Another power, which while aiming to make the world over on its own model tended to destroy ancient ideas and institutions,— including the empire itself,— was Christianity. Rome, essentially polytheistic, always tolerated the religions of the nations which she conquered; in the adoption of their gods into her pantheon she found a means of political centralization. Judaism, however, she regarded with disfavor, and attempted to suppress Christianity. These exceptions to her policy of toleration were due to the irreconcilable conflict between monotheism and polytheism and to the leveling tendency of the Christian religion. The apostles of Christ taught that the gods of Rome were demons, that the worship of the emperor was sinful, that all men from the emperor to the slave were equal before God, that the heaping up of wealth was an abomination; in brief their religion seemed to the Romans subversive of all the principles on which the empire rested. But although Christianity and Germanism were disintegrating the empire, they were destined in combination to make the old world new. The estimate of their value as creative agencies belongs to the mediæval period.

In appearance more formidable than internal decay were the hostile nations outside the empire. In the 3d century the Germans, who had long been threatening, began to break through the northern frontier. The Franks flung themselves upon Gaul; the Goths occupied Dacia and crossed the Danube, to defeat and kill an emperor. In the East, too, a new danger appeared; on the ruins of the old Seleucid power had arisen the Parthian empire, which in the 3d century was supplanted by a new, vigorous Persian empire. The warlike Persian monarchs nearly made good their threat to drive the Romans from Asia.

Early in the 5th century the Germans began to establish their states within the empire,— the Visigothic kingdom in Gaul and Spain (415 A.D.), that of the Vandals in Africa, and of the Burgundians in the Rhone valley. About the middle of the century the Angles and Saxons began to overrun Britain; a little later the Franks, who long before had crossed the Rhine, began the conquest of Gaul (486 A.D.); and in 493 A.D. the Ostrogoths conquered Italy. Before the end of the century the western branch of the empire had fallen into the hands of Germanic chiefs, who while vaguely recognizing the emperor at Constantinople as their lord were in reality sovereign kings of the countries they ruled. Here ancient history ends; the interaction between Roman and German life under Christian influence is the subject of mediæval history.

Literature.— For the method of history see Bernheim, 'Lehrbuch der historischen Methode' (4th ed., Leipsic 1903); for an elementary sketch, Botsford, 'Ancient History' (New York 1902), a philosophic view may be found in Andrews, 'Brief Institutes of General History' (6th ed., Boston 1900); by far the best detailed work is Meyer, 'Geschichte des Altertums' (I.–V., reaching to the middle of the 4th century B.C., Stuttgart and Berlin 1884–1902); for a satisfactory treatment of the period following this date it is necessary to depend on the histories of special countries and periods, for example, Holm, 'History of Greece' (III., IV., translated from the German, New York 1896–8); Mommsen, 'History of Rome' (translated from the German, 5 vols., conformed to the 8th ed., New York 1895); 'Provinces of the Roman Empire,' 2 vols. (New York 1886); Duruy, 'History of Rome' (8 vols., Boston), valuable for the imperial period; cf. also Duncker, 'Geschichte des Altertums' (3d–6th ed., 9 vols., Leipsic 1874–86); 6 vols. translated by Abbott (London 1877–86); Oncken, 'Allgemeine Geschichte in Einzeldarstellungen,' by various authors (Berlin 1878–90); Helmholt, 'History of the World' (Vols. I.–IV., New York 1902); Philippson, 'Das Mittelmeergebiet: seine geographische und kulturelle Eigenart' (Leipsic 1904), valuable for physical environment; Cunningham, 'Western Civilization in its Economic Aspects' (Cambridge 1898); Webster, 'General History of Commerce' (Boston 1903); Perrot et Chipiez, 'Histoire de l'Art dans l'Antiquité' (8 vols., Paris 1882–1903); for general tendencies, Freeman, 'Chief Periods of European History' (New York 1886); especially fresh and suggestive are the articles by E. Meyer, Diels, Wilamowitz-Möllendorff, Soltau, and Hirschfeld in the 'Historians' History of the World,' III.–VI. (New York and London 1904); the best encyclopedias for Greece and Rome, containing much information also regarding the Orient, are Daremberg et Saglio, 'Dictionnaire des Antiquités grecques et Romaines' (3 vols. ready, Paris 1873–1904); Pauly-Wissowa, 'Real-Encyclopädie der cl. Altertumswissenschaft' (4 vols. ready, Stuttgart 1894–1901); the best periodical is 'Beiträge zur alten Geschichte,' edited by Lehmann (Leipsic 1901—); for bibliography past and current, 'Jahresbericht über die Fortschritte der cl. Altertumswissenschaft,' including 'Bibliotheca philol. cl.,' edited by Bursian (Berlin); for bibliographies of special countries see the articles on Egypt, Chaldea, Babylonia, Assyria, Greece, and Rome.

GEORGE WILLIS BOTSFORD,
Adjunct Professor of Ancient History, Columbia University.

History, Mediæval. *Definition.*— Mediæval history may be most easily defined as the middle period between ancient and modern history. Some scholars have wished to do away with the term entirely, and to use only two divisions, ancient and modern. In fact, in Oriental history there is no mediæval period. But most students prefer to keep to the threefold division for European history. This is due largely to the fact that the mediæval period can be presented with greater unity than either ancient or modern.

Mediæval history began with the disintegration of the Roman Empire in the 5th century, the ruin of paganism, and the migrations. Without arguing the merits of the various dates which may be assigned for the end of the Middle Ages (q.v.), we shall here discuss the history to about 1500 A.D. During this period of

one thousand years, the most marked characteristic is the dominant influence of the Church. The most important peoples are the Germanic races, who emerged slowly from barbarism, and gradually assimilated some of the features of the Roman civilization. Based upon the ruins of the older rose a new civilization, which caused a radical transformation in political, social, and religious ideals.

Contrast Between Romans and Germans.— The Romans had a highly developed and very complex civilization. From their Greek subjects, they had acquired the knowledge of art, literature, science, and philosophy. Under the Roman peace, an active commerce had grown up throughout the empire, supplying to each province the products of all of the others. In law and administration the Romans had reached such excellence that we still imitate them. Moreover, Christianity had become the state religion.

The Germans were barbarians, having the virtues and vices of their savage state, and resembling, in many respects, the North American Indians. But they were a vigorous race, with a great capacity for learning. Some of them had been converted to Christianity before they entered the Roman Empire, but most of them were still pagans.

Migrations.— The Roman Empire had for centuries held the barbarians in check, by the prestige of its name, by the payment of tribute, or by the policy of exciting dissension among its enemies. This last is well summed up in the Roman proverb, *Divide et impera*, which may be paraphrased, "Cause divisions and strife among those whom you fear and thus rule over them." In the latter part of the 4th century, however, the terrors inspired by the advance of the Huns (q.v.) into Europe, the knowledge of the weakness of the Roman Empire, and their own desire for more fertile lands, caused the Visigoths (q.v.) to enter upon their great migration. Their example was followed by other German tribes, and the movement continued throughout the 5th and 6th centuries. By the year 600, all the European portion of the Western Empire, except a few positions in Italy, was held by the Germans.

During the period of the migrations, there was a great destruction of life and property. But the conquered inhabitants were neither exterminated nor driven out. The German invaders were relatively few in number, and, in many sections, they found unoccupied lands sufficient for their needs. The conquerors and the conquered lived in constant contact with one another, and the resultant civilization was partly Roman and partly German. See MIGRATIONS.

Fusion of the Two Civilizations.— The 7th and 8th centuries were the period of fusion. By the year 800, the terms *Roman* and *Barbarian* were no longer used. The inhabitants formed a single people, with a civilization much lower than the Roman but much higher than that of the Germans when the latter had entered the Empire. In this new composite civilization, the Roman influence was greater in language, mechanical arts, business arrangements, and municipal, intellectual, and ecclesiastical affairs. The German influence was greater in military matters and judicial procedure.

The fusion was practically completed by the time of Charles the Great. He realized clearly the task of the Middle Ages, and did all in his power, on the one hand to retain all that was best of the older German customs, and, on the other hand, to introduce from Italy such Roman customs as his subjects were able to adopt. He did much to foster education, which followed Roman models. By his wars, he brought under his sword all of the German peoples.

The New Empire.— In 800, Charles's services received fitting recognition in his election as emperor of the Roman Empire. The idea of a Roman empire which embraced all Christians had never been lost. After 476, when Romulus Augustulus was deposed by Odoacer, the people in the West, Germans and Romans alike, had regarded the emperor at Constantinople as the head of the Christian world. Even barbarians like Clovis (q.v.) had been proud to secure recognition and obtain a title from the emperor. The popes had looked to the emperors for support. In the last years of the 8th century, the East was ruled over by Irene (q.v.), who was both despised because she was a woman and for her crimes and heresy, so that it seemed to many that the imperial office was vacant. Consequently, Charles was crowned emperor and was considered the successor of Augustus, Trajan, and Constantine (qq.v.). Under his strong rule, the Western world was governed firmly, and the western nations were held together.

Disintegration of the Empire.— After Charles's death, his son was unequal to the task of ruling the empire. Under the combined effects of civil strife and constant invasions by the Northmen, the Mohammedans, and the Slavs (qq.v.), the central power was weakened, and the last Carolingian rulers were unable to protect their subjects. The whole frontier was exposed to attacks and the raids of the enemy even extended far into the interior. In each district the strongest man came to be regarded as the natural leader and protector. Sometimes it was a royal official, holding a fortification; sometimes it was an abbot or a bishop; at other times, a bold adventurer, who usurped authority. In the absence of a strong central government, each leader had to police his land and administer justice. Naturally, he demanded to be paid for his services, and exacted tribute from all under his control.

Because of the lack of money, the Carolingians (see CARLOVINGIANS) had always furnished to their counts and other official estates from which they obtained their living. Under the weak kings, the temporary grants of both land and office became hereditary, with or without the rulers' consent. The rulers, however, soon recognized the necessity of allowing this, and sought merely the recognition of their own overlordship and ultimate ownership of the lands. Consequently, they granted the benefices to the heirs and conferred, in addition, the immunity, or right of independent jurisdiction. Thus almost all land and power came to be held feudally. See FEUDALISM.

Feudal Anarchy.— There was constant warfare as each strong lord sought to obtain greater power or a more independent position. On the other hand, each king or suzerain tried to increase his own feudal holdings by conquest or marriage. Every vassal was anxious to avoid

all the feudal services that he could, and, at the same time, to exact as much as possible from the people subject to him. Commerce was burdened with excessive tolls in each fief and exposed to the depredations of the robber barons. Little attention was paid to maintaining roads and bridges, consequently travel was difficult as well as dangerous. As a whole, the feudal régime tended to isolate each fief and to reduce the peasantry to misery. It is significant that the term "Dark Ages," formerly applied to the whole of the Middle Ages, is often used now for the 9th and 10th centuries.

The Church.— The great cohesive and educating force was the Church. Soon after they entered the Roman Empire, each tribe of Germans had been converted to Christianity. In every barbarian kingdom the bishops were important officials. They often obtained great wealth, and ruled over vast estates. On their possessions, the serfs were treated somewhat better than on the lay fiefs. Monasteries had been founded throughout Western Europe, and often these served both as schools and as model farms. Boniface did much to bring the tribes of Germany into direct connection with Rome, and he held frequent church councils at which the clergy and nobles of a whole district came together. These councils were very important for their effect in unifying the Church and making its work more effective.

From this time the Church gained steadily in power and influence. Charles the Great did much to increase its wealth by enforcing the payment of tithes. He insisted that the clergy should be better educated themselves and should do more for the education of the people. In the 9th century the growing power of the papacy and the weakness of the kings enabled the popes to bring the bishops more directly under their own control. Thus the clergy of Western Christendom were brought into intimate association with Rome. Latin was the common language of all churchmen. Their feeling of membership in the Church was frequently stronger than any local attachment. Consequently the more able men were equally at home in every country and the Church had a greater unity than any lay power. This all-pervasive Church was the great unifying element amid the divisions of the feudal period.

Investiture Struggle.— After periods of weakness in the first half of the 10th and again in the first half of the 11th century, the Church at Rome was purified and strengthened by the support of the German emperors. About the middle of the 11th century, the strong personalities of Pope Leo IX. (q.v.) and of Hildebrand (later Gregory VII.) (q.v.) led to a great reform movement, and also to an effort to make the pope's power more effective. One feature of this movement was an attempt to secure entire control of appointment to church offices. This brought the papacy into conflict with the kings who considered that they had a right to nominate the bishops in their own kingdoms. The struggle was most acute between the German emperors and the popes, and resulted in the long investiture conflict, which was ended in 1122 by a compromise. See INVESTITURE.

Roman Empire of the German Nation.— But the investiture struggle was only a single phase in the relations between the empire and the papacy (q.v.). In order to understand this it is necessary to study the fortunes of the empire after Charles the Great. Under his successors, the emperors had gradually lost their power, so that by the end of the 9th century, the title of *emperor* had become almost a meaningless designation, either conferred by a pope on anyone of whom he wished to make use, or else usurped by any ruler who chanced to be temporarily the strongest personality in Italian affairs. This continued to be the fate of the imperial title until Otto the Great (q.v.) was summoned to Italy, because of the discord reigning among the various Italian nobles. In 963 he was crowned emperor, and became the ruler of both Germany and Italy. Under his son and grandson, Otto II. and Otto III., "the Roman Empire of the German nation" was a very effective power in controlling both the imperial lands and the papal policy. After the death of Otto III. in 1002, the German rulers paid little attention to Italian affairs until 1046, when Henry III. was summoned to Rome because of the contest which was being waged between three rivals for the papal office. For 10 years he wielded a power similar to that of the Ottos. But at his death, as the heir was a young child, the reformed and strengthened papacy was able to assert its independence. When Henry reached manhood and desired to regain his father's power, the contest began and took the shape of the already mentioned investiture struggle. After the Concordat of Worms (q.v.) there was a truce which was broken by the accession of Frederick Barbarossa (q.v.), who was determined to be emperor in fact as well as in name.

Empire and Papacy.— On the other hand, the papacy was strong and was determined to assert its paramount authority. There ensued a struggle of one hundred years between the Hohenstaufen emperors and the popes. In spite of the ability of the rulers and the brilliancy of their reigns, the popes triumphed, largely by means of the assistance of the Lombard cities, which had grown rich and powerful and claimed to be independent of the imperial control. The death of Frederick II. in 1250 really marks the end of the mediæval empire, as a strong international power, although it continued, under a changed form, to be a factor in European politics for centuries longer, and came to a close only in the 19th century.

The Crusades.— The increasing power of the popes was also marked by their desire to extend their authority over the Eastern Church as well as the Western. This was in part the cause of the crusades, which were the most important manifestation of the strength and influence of the Church. The spirit of asceticism (q.v.) had long been inculcated as the most distinguishing mark of Christianity. The consciousness of their own sins and the teachings of the Church led many to do penance. One of the favorite forms, especially for heinous crimes, was a pilgrimage to some hallowed spot. The most difficult pilgrimage and the one to which greatest sanctity attached was the journey to Jerusalem. In the 11th century, one hundred and sixteen separate pilgrimages to Jerusalem are recorded, and, in some of these expeditions, hundreds and even thousands took part. Thus attention was directed to the Holy

Land. Moreover, in spite of the disorders of the feudal régime, the population was increasing, especially in France. The people were hard-pressed to get food, and were anxious for a change of any kind. Consequently, when the Emperor Alexius appealed for aid and Pope Urban II. preached the crusade at Clermont thousands took the cross. The movement spread rapidly and affected every country in Europe. Although Jerusalem was in the possession of the Christians for little more than a century, the crusades to the Holy Land, which continued for 200 years, produced great results. In order to understand these, it is necessary now to take up the Byzantine and Muslim civilizations. See CRUSADES.

Byzantine Civilization. — Until a half-century ago, the Byzantine history was misunderstood. It was looked upon as the long death struggle of a society in which all progress had ceased, and despotism, tempered by assassination, crushed out all vitality. Gibbon styled the history "a tedious and uniform tale of weakness and misery." It is known now that this was unjust. The most striking fact about the Byzantine Empire is its "constant vitality and power of recuperation." It was threatened by invaders, but it repelled them all. At times it lost some of its most fertile provinces, but at other periods it would rise triumphantly and recover its lost possessions. Throughout the period between 700 and 1100, Constantinople was the bulwark of Europe, against which the waves of invasions rolled in vain. In addition to being a bulwark, Constantinople was, throughout the Middle Ages, the great storehouse of the Greek and Roman civilizations, where it was preserved until the European nations were sufficiently advanced to profit by it. Constantinople (q.v.) was also the most important commercial centre of the Middle Ages. The city was marvelously wealthy and excited the admiration of every traveler. Most of the crusaders passed through Constantinople and the Greek lands on their way to Jerusalem; by them the influence of its civilization was widely spread throughout the West. See BYZANTINE EMPIRE.

Muslim Civilization. — No less important was the influence of the Mohammedans. After the death of the prophet in 632, his followers had conquered with wonderful rapidity the greater part of the civilized world. From Persia and India they held all Asia to the Hellespont. Egypt and the whole north coast of Africa, Spain, and about one third of Gaul, were under their sway within a century. Their advance in civilization was equally rapid. The Arabs had wonderful acquisitive ability and were taking almost the first step in their education. In each country they learned the arts and sciences known by the inhabitants, and they carried this knowledge wherever they ruled. The Greek philosophy, which they acquired from the peoples in the lands formerly under Greek sway, the mathematical knowledge of India, the irrigation practised in Egypt, are illustrations of their acquisitions, which enabled them in the 10th and 11th centuries, to develop a civilization far in advance of any other, with the exception of the Byzantine. From Bagdad to Spain this culture was spread throughout the Mussulman world. In Syria, the crusaders were in contact with this civilization for two centuries. By their agency and by the association of Christians and Mussulmans in Spain, Sicily, and other points, much of the Muslim learning was conveyed to the Christians of Western Europe.

Changes in the 12th and 13th Centuries. Enrichment of Europe. — In addition to this fructifying intercourse with other civilizations, many elements in their own contributed to cause a rapid advance in the 12th and 13th centuries. Among these may be noted the increase in population, the cultivation of waste lands, the revival of commerce, the general progress along educational lines, and the rise of strong kingdoms. But as it is impossible to isolate each factor and to determine the part which it played, the results will be considered as a whole and the changes which took place in Western Europe after 1100 will be described.

The hundreds of thousands of crusaders had to procure large sums of money for their equipment and journey. Consequently the precious metals which had been hoarded came into circulation as money. Instruments of credit were devised and the money circulated rapidly. Contact with other civilizations gave birth to new tastes and these were gratified by means of a greatly increased commerce which extended to all parts of Europe and even to the extreme East. The merchants became numerous and prospered. Cities increased rapidly in population and new ones were founded. The Italian cities, because of their position, prospered the most of all. The merchants became an important class because of their wealth, and by the end of the 13th century became a political factor which was recognized by their inclusion in the new parliamentary bodies.

Intellectual Advance.—The investiture struggle had caused scholars to study history in order to find precedents in support of the imperial or the papal claims. The contact with other peoples broadened the intellectual horizon of the Western people. The new points of view with which they became acquainted led them to question the traditions which had ruled their lives. The new books, especially the works of Aristotle (q.v.), which fell into their hands, were studied eagerly. The new wealth gave leisure. Students flocked to the centres where teachers were to be found, and gradually universities arose. Roman law was fostered by the emperors; canon law, by the Church. Scientific knowledge, especially in medicine, was acquired from the Greek and the Arabic works. Gothic cathedrals of exquisite beauty were built in western Europe. The deeds of the crusaders furnished new material to literature. The old tales were re-worked and given a literary form.

Growth of Monastic Orders. Temporal Power of the Popes.—No less marked were the changes in the Church. At the close of the 11th century a great wave of asceticism spread over western Europe. The idea of sacrifice caused thousands to enter monasteries, and many new orders of monks were founded. These orders vied with one another in austerity and asceticism. Their reputation for sanctity and their services to the community brought to them great donations from the pious. Their knowledge enabled them to increase their wealth. But this wealth led many to enter the monasteries from unworthy motives, and thus caused a gradual

decline in their lofty morals. The wealth of the Church, as a whole, caused many, both monks and laymen, to attack it as having departed from its Christian ideals. Heretics became numerous and had to be repressed by persecutions and the inquisition. In the 13th century the mendicant orders became prominent, partly as a protest against the wealth of the Church, and partly as an agency to combat heresy. The ideal of service to others for which they stood became dominant in monasticism, and later orders were founded, almost universally, for some special service. See MONACHISM; ORDERS, RELIGIOUS.

The papacy, engaged in a struggle with the monarchs, felt the need of temporal power and strove for it. Innocent III. had monarchs as his vassals, and wielded a temporal authority greater than that of any previous pope. After the popes had triumphed over the Hohenstaufens they seemed to have achieved success. Their struggle with the French king, at the beginning of the 14th century, however, led to defeat and to the "Babylonian captivity" at Avignon. Then ensued the schism and the conciliar period when many felt that the general councils and not the popes should be supreme. Finally the papacy emerged triumphant, but with a changed ideal, laying less stress upon temporal power (q.v.) than upon control over the conscience of the individual.

Chivalry. Decadence of the Knights.—In the 12th century, the clergy and the knights formed the aristocracy. The latter, too, had their period of great splendor. The ideals of chivalry, which became prominent in the 12th century, were inculcated by the Church, and the knights were often likened to the clergy as a class specially set apart by their religious vows. These ideals were also inculcated by the new literature, which glorified not only bravery and loyalty, but also generosity and luxury. The latter led to the ruin of many of the knights. Their income, arising from feudal dues, was relatively fixed. As their tastes expanded and they expended more upon luxuries, they fell into debt. The rate of interest was ruinous and they were unable to pay. Consequently many were compelled to alienate their fiefs, the monarchs and other lords of large fiefs absorbed the lesser fiefs, and there was a tendency for the knights to become retainers of the more wealthy. Their consequence as a class declined in comparison with the growing importance of the merchants. The development of strong infantry forces finally deprived them of their pre-eminence in military matters. See CHIVALRY.

Rise of the Nations.—The contact with other peoples led to the rise of a national consciousness. In the earlier days, when each feudal castle or village was practically isolated and often at strife with its neighbors, there had been little feeling of common interests. Association with foreigners brought a sense of national feeling in opposition to the foreigners. This is very marked in the armies of the second and third crusades. This movement was coincident with, and one cause of, the growth of the strong monarchies. The merchant class was also an important element in the development of the king's powers. Commerce was heavily burdened with feudal tolls and exposed to depredations by the knights. The merchants sought privileges and protection from the kings. In return they furnished them money, which aided them in extending their power at the expense of that of their nobles. The kings came to depend largely upon the cities for support in all struggles with the nobles. By their wealth the citizens were able to rival the nobles in luxury and ostentation. The sons of the merchants frequented the universities and developed into officials of the kings. More and more the kings came to depend upon the third estate and to withdraw power from the nobles.

The French Monarchy.—The development of the monarchical power took different forms in the several countries, but took place about the same time in the leading nations. In France, the Capetian kings (see CAPET) had at first little power. They had only a small territory directly under their control, and consequently only a small income. But by fortunate marriages and by confiscations they enlarged their feudal domains. Several of the kings had long reigns and the evils of a minority or a change of dynasty were avoided. Gradually all the fiefs were brought under the control of the king, and feudal usages were made the basis for the assertion of a really monarchical power. Under Saint Louis (1226–1270) and his successors France was centralized and the kings became supreme. The prosperity of France was checked for a time by the Hundred Years' war (1328–1461). This was due in part to a failure of male heirs in the direct line, which enabled the English kings to make a claim to the throne on the ground that they were the most direct heirs. But France finally emerged triumphant and England lost all her territory in France. The kings, supported by the third estate, became practically absolute.

The English Monarchy.—In England the Norman Conquest (q.v.) made William supreme lord. Following the Norman feudal usages, he insisted upon an oath from each one of his subjects, and did not allow the intervention of the feudal nobles. In spite of the civil wars of the 12th century, Henry II. was able to retain the supreme control. The tyranny and incompetence of John led to a revolt on the part of the barons and the extortion from him of the Great Charter. (See ENGLAND—*Civil History.*) The efforts of the kings to evade the provisions of the charter caused the union of the nobles and third estate, the distinctive feature of the English constitution as contrasted with that of France or of Germany. The loss of its continental possessions really strengthened England and enabled it to develop a strong government in its own island.

The German Monarchy.—Germany was a kingdom made up of great duchies. The king was strong only when he had all these duchies under his immediate control. The imperial title which he held was usually a source of weakness, because of the necessity of maintaining his authority outside of Germany. Those kings who neglected the imperial interests in Italy and Burgundy were strongest at home. Frederick Barbarossa, Henry VI., and Frederick II. (qq.v.), who attempted to build up strong empires, were compelled, as the price of support from their German subjects, to make constant concessions. Thus they bartered away most of their German lands and royal rights. The towns

and cities, in particular, acquired privileges and practical independence in payment for their support in men and money. On the extinction of the Hohenstaufen house, Germany was divided up into many separate entities, varying in size from a duchy to a village or to a knight's fee, all claiming independence of all control except the imperial. The weak emperors of the 14th and 15th centuries were unable to maintain any effective control or order. Each emperor was intent only upon retaining his position and securing such property for his family as he could. Consequently Germany became a prey to internal dissension and division.

The Other Monarchies.—The other countries were more backward. In Spain, the Christian kings were engaged in conquering Muslim territory or else in warring with one another. These movements were going on for several centuries, and culminated just at the close of the Middle Ages. In 1492, the Moors were conquered in Granada, their last stronghold. The two most powerful kingdoms, Castile and Leon, had already been united, and 20 years later the Spanish portion of Navarre was added. In Scandinavia powerful monarchies were growing up. In the eastern portions of Europe new Christian kingdoms had arisen, especially Russia and Hungary, which were destined to play an important role in the later centuries.

The Period of the Renaissance: Discoveries.—The last period of the Middle Ages is often spoken of as the Age of the Renaissance (q.v.). The name is to a certain extent a misnomer. But it is sanctioned by general usage, and there are certain factors that may be brought together, which serve to mark the transition from the mediæval to the modern world.

The travel and commerce of the 12th and 13th centuries caused an interest in foreign lands which never abated. In particular, the taste for spices, which had become common, led to attempts to secure these more easily and more cheaply. After the loss of the Christian possessions in Syria, the importation of spices into Europe was burdened with heavy tolls by the Muslim rulers through whose territories they had to be carried. To the men of the 15th century there seemed to be two possible routes by sea to the spice islands, one by sailing around Africa, the other by sailing directly west to India. Attempting the latter led to the discovery of America; attempting the former, to the doubling of the Cape of Good Hope. The result of these discoveries was to make the nations on the ocean the leaders in commerce. The Mediterranean ceased to be the centre of the world's commerce and the Italian cities lost their pre-eminence as commercial centres.

Inventions: Compass, Printing-press, Gunpowder.—This exploration was possible only by the use of the compass (q.v.). This had been known in the West by the 12th century; in the East, centuries earlier. But it was perfected as a real aid to navigation only in the 14th century. About the middle of the 15th century came an even more important invention, that of printing (q.v.). This resulted at once in increasing enormously the number of books in existence and in cheapening their cost to one fifth or less, so that books were readily accessible to a much larger number than before. At about the same time the manufacture of gunpowder was being perfected. Compositions similar to gunpowder (q.v.) had long been known in the East, and the knowledge of the composition of "Greek fire" had been brought to the West. But it came into general use only in the 15th century, and the guns long after that were held by many to be inferior to the cross-bow. But gunpowder, before 1500, was revolutionizing the art of war and rendering the mediæval knight obsolete.

Classical Literature and Pagan Spirit.—Contemporary with these discoveries and inventions was the awakening of an interest in classical literature. In the 12th century there has been at some centres an eager study of the Latin classics, but, in the 13th, this had been superseded to a great extent by the branches considered more practical, especially law, mathematics, and science. In the 14th and 15th centuries men turned again to the classics, and Greek, which had long been neglected, became a favorite study. Along with the study of the pagan authors developed a new feeling for art, which resulted in the wonderfully natural works of the Renaissance artists. Other sides of this new activity were manifested in the more scholarly spirit of criticism and in scientific study. In fact, with the period of the Renaissance modern history had dawned.

Bibliography.—Lavisse et Rambaud, 'Histoire Générale du IVe siècle à nos jours' (Paris 1893 ff.; the first three volumes form the best general history of the Middle Ages); Gibbon, 'Decline and Fall of the Roman Empire' (edited by Bury, 7 volumes, London and New York 1896–1900); Milman, 'History of Latin Christianity' (9 volumes, 1867; a general favorite). Of the many Church histories, two may be mentioned: Alzog, 'Manual of Universal Church History' (3 volumes; a scholarly treatise from a Roman Catholic standpoint); Schaff, 'History of the Christian Church' (4 volumes, to Gregory VII.; voluminous, scholarly, from a Protestant standpoint). Three volumes in the 'Periods of European History'; Oman, 'Dark Ages'; Tout, 'Empire and Papacy'; Lodge, 'Close of the Middle Ages' (New York 1893–1901), furnish a detailed, but somewhat uninteresting, summary of the political history. Hodgkin, 'Italy and Her Invaders' (8 vols.), and Bury, 'Later Roman Empire' (2 vols.), are the best guides for the periods before 800. Bryce, 'Holy Roman Empire' (new ed. 1904; wonderfully compact and useful); Symonds, 'Renaissance in Italy' (7 vols.); Burckhardt, 'Civilization of the Italian Renaissance'; Voigt, 'Wiederbelebung des classischen Alterthums' (2 vols., 3d edition); these works are to be commended for the period of the Renaissance. For special subjects: Montalembert, 'Monks of the West' (6 vols.); Lea, 'History of the Inquisition' (3 vols.; the masterpiece of a great historian); Oman, 'History of the Art of War' (Vol. II.), for military matters; Heyd, 'Geschichte des Levantehandels im Mittelalter' (2 vols.), very important for the commerce; Levasseur, 'Histoire des classes ouvrières avant 1789' (2 vols.), admirable for economic conditions; Gregorovius, 'Rome in the Middle Ages' (8 vols.), very scholarly and interesting; Rashdall, 'History of the Universities of Europe in the Middle Ages' (2 vols.), the best treatise on the subject; Saintsbury, 'Flourishing of Romance,' the best brief account of the literature in the 12th and 13th centuries; Munro,

'Syllabus of Mediæval History' (3d ed., 1903), contains references by topics to about 250 works, mainly in English.

DANA CARLETON MUNRO,
Professor of History, University of Wisconsin.

History, Modern.—*General Characteristics.*—When History is divided merely into Ancient and Modern, the term Modern applies to history subsequent to the 4th century A.D. The *Americana*, however, keeps to the more usual triple division into Ancient, Mediæval, and Modern; and with this classification Modern History begins about the year 1500.

At that date, as for several centuries preceding it, the scene of human progress was confined to Western Europe, and the actors were the Latin and Teutonic peoples. Nations, in the proper sense, were not made; and the political map bore faint resemblance to that of to-day. There was one Latin Christendom, binding in feeble union the several geographic units. But most of the units themselves were broken into fragments under local rulers; and these fragments, sometimes of widely separated lands, were recombined, with kaleidoscopic confusion, in loose, shifting aggregates which possessed not even permanent names. Out of this feudal chaos, strong monarchies were just emerging, to organize states, in France, England, and Spain; but there was hardly a prophecy of a Germany or an Italy. Except for Poland with its Latin church and borrowed German culture, Eastern Europe was outside the pale of civilization. The barbarous northern Slavs seemed doomed to Tartar domination, and the somewhat less barbarous southern Slavs with the neighboring Magyars were enslaved by the Turk. From the devouring victorious march of the Turk even Central Europe was in imminent peril.

This dismal political picture had its counterpart in social and economic conditions. Society was hopelessly aristocratic and predominantly militant, and it was crystallized in strata. The skilled industry of the towns was managed upon the guild system; and agricultural labor, except in England and some other small districts, was carried on by serfs.

But Europe had been astir with dim impulses to change for four hundred years,—ever since the Crusades broke the torpor of the Dark Ages and prepared the way for the rise of towns and the Renaissance. Near the close of the 15th century the tendency to progress became more pronounced, and the lines of activity more varied. Louis XI. in France, the Tudors in England, Ferdinand and Isabella in Spain, prepared the way for new consolidated political societies, and for new principles of government; the invention of printing made possible the preservation and utilization of the recently rediscovered Greek learning and the rapid dissemination of new ideas; the discoveries of Columbus and Vasco da Gama set free undreamed-of energies among the lands of the Atlantic seaboard, and summoned commercial Europe to a right-about from east to west; the adoption of gunpowder in the wars between Francis I. and Charles V. marked the passing of the military superiority of the knight in armor, and undermined the citadel of aristocracy in politics; the opening of the Protestant Reformation (1520) shattered the old unity of Christendom, and, together with the Catholic Counter-Reformation, called out new energies in the fields of morals and intellect. Within two generations, the one just before and the one just after the year 1500, there stood revealed not merely a new physical hemisphere and new continents in the old one, but also a new universe of thought and feeling. Europe had passed into a new age.

The four centuries of Modern History have been a period of constant, marvelous, increasingly rapid transformation,—intellectual, political, industrial. The stage itself has widened from a corner of the smallest continent into wellnigh the whole surface of the globe. The actors have multiplied, until they promise in the near future to include all branches of the human race. The drama has become infinitely complex, with the interaction of countless streams of influence. As compared with Ancient or Mediæval History, Modern History deals with a brief time, but with vast spaces, complex relations, and accelerated progress. The separate movements that make up the bewildering maze are discussed severally in some detail, under appropriate headings, in the *Americana*. This article attempts only to marshal them in such order as to bring out the essential relations between them.

It is convenient to divide the four centuries of Modern History into the *age of monarchic states* and the *age of nation-states*. The American and French Revolutions make the transition from one to the other, and the most satisfactory dividing date is 1789.

FROM THE REFORMATION TO THE FRENCH REVOLUTION.—*Monarchic States.*—The constant warfare of the 16th, 17th, and 18th centuries is the simplest thread by which to connect the other movements of the age. Speaking broadly, the contests of the first half of the period, to 1648, are "religious wars," Catholic against Protestant, while after 1648 the struggles grow out of dynastic and commercial rivalries.

The declaration of the war which split Christendom into opposing camps for over a century came in 1520, when Luther burned the Pope's bull. The Diet of Worms at once pronounced against the rash monk the ban of the Empire; and the decree would have been enforced, and Protestantism stifled at its birth, if the young Emperor, Charles V., had had a free hand. But Charles had just become involved in strife with Francis I., over the claims of Spain and France in Italy, and he was kept busy with war against France and the Turks until 1544. For a generation, therefore, the new faith was left to spread itself unchecked over Germany and Scandinavia, while during the same period the English church cut itself off from Rome, and Presbyterian heresy made headway in France and Switzerland. For a time, indeed, Protestantism threatened to conquer even the south of Europe; but the Catholic Counter-Reformation, with equal zeal and superior skill, finally saved the Romance lands to the old faith.

Religious Wars, 1546–1648.—Meanwhile, entangled in his strife for European sovereignty, Charles could not strike at Protestants in Germany until 1546. It was then too late. In 1555, after brief struggles, the princes of the Schmalkald League forced upon him the Peace of Augsburg; and, though troubled with incessant bickerings, Germany had no further civil war for sixty years. Just that period, how-

ever, was filled with terrible religious contests in the Netherlands and France; and then the age of religious wars closed with another civil war in Germany,— the most destructive in European history. The century of strife from the opening of the Schmalkald War to the close of the Thirty Years' War (1546–1648) did not materially alter religious frontiers. Catholicism, to be sure, made some conquests with the sword, — Bohemia, South Germany, and the southern Netherlands,— but in most of these districts, as in the Latin countries of Southern Europe, the Counter-Reformation was making rapid gains before war began.

The close of the period of religious war is marked by the decay of Spain, the continued disruption of the Holy Roman Empire, and the rise of France and of the Dutch Republic. To explain these changes it is needful to dwell somewhat further upon the wars.

In 1556–7, after his failure in Germany, Charles V. resigned his crowns,— the Austrian possessions passing to his brother, and the Spanish to his son, Philip II. Despite the division, Philip was far the most powerful monarch in the world. Each year the "gold fleet" filled his coffers from the exhaustless wealth of the Americas, and in 1580 Portugal with her East India empire fell into his hands. This was the power,— supreme in Europe and sole mistress of the New Worlds east and west,— against which the petty, disunited Netherland provinces dared to rebel. Beginning as a political revolt in 1568, the struggle soon became a religious war; and it was waged for more than forty years with a relentless fury which made it a byword for ferocity even in that brutal age. The ten southern provinces finally returned to Spanish allegiance; but the northern provinces,— Dutch in blood and Protestant in religion,— fought on with desperate courage until they won independence. At the same time they preserved political and religious liberty for the world. Midway in the struggle, Elizabeth of England sent some tardy aid. Philip then turned upon England; but the destruction of his "Invincible Armada" in the splendid sea-fight in the Channel not only saved England at home but also paved the way for the English colonization of North America. The war closed in 1609. Spain had sunk into a second-rate power, never again to play an important part in European politics; but the United Provinces, through the stage of the desolating war, had grown prosperous. They drew wealth, not from the wasted land, but from the sea, plundering the new possessions of Spain in the East Indies and building there a colonial empire for themselves. For most of the century, in intellectual, commercial, and industrial activities, the Dutch held the first place in Europe.

In France the Edict of Nantes (1598) closed the wars of religion by guaranteeing toleration and handing over certain garrisoned towns to the Huguenots as security. During the next half century, under the wise administration of Henry IV. and then of Richelieu, the industry of the people restored prosperity with marvelous rapidity. Richelieu crushed the feudal nobles and recaptured from the Huguenots their garrisoned towns. In other respects, however, he kept toward the Protestants the pledges of the Edict of Nantes; and as he warred upon the Protestants within France in order to strengthen the royal power, so he aided the Protestants of Germany in the Thirty Years' War in order to make France supreme in Europe. France had long been in real peril from the Hapsburg powers of Spain and Austria, which ringed her about in hostile embrace; but the failure of Spain against Holland and Richelieu's policy of weakening Austria in the German war removed the peril, and, as Spain declined from the first place in Europe, France stepped into it.

Meantime the Thirty Years' War (1618–48) was desolating Central Europe. The princes of North Germany proved timid and incapable; and the cause of Protestantism was saved only by foreign intervention, by Denmark, by Sweden, and finally by Catholic France. At the close of the struggle, the first European Congress reorganized Europe. By the Peace of Westphalia, France received most of Alsace and some other Rhine districts. The independence of Switzerland and of the United Provinces was formally recognized. Sweden, already reaching down both west and east shores of the Baltic, secured much of the south shore also, with command of the mouths of the German Oder, Elbe, and Weser. On the other hand, the Empire lost more than territory. The political rearrangements within that state reduced the imperial Diet to the level of a useless debating society and put an end to whatever had persisted of national unity. From this time until it vanished, a century and a half later, the Holy Roman Empire was a meaningless survival, cumbering the earth, and the Hapsburg "Emperors" derived their only real importance from their position as hereditary archdukes of Austria. To most of Germany the war had brought blasting ruin. Half the population and two thirds the movable property were swept away. Land tilled for centuries became waste, and men became savages. Not till the middle of the nineteenth century did large districts again contain as many homesteads and cattle as in 1618; while the low position of the German peasantry, until 1850, was due in great measure to this war.

American Colonization.—Before the religious wars closed, the continent of Europe had ceased to be the sole scene of important historical development. American colonization was well advanced, and political liberty had received a remarkable development both in England and in English colonies. These topics demand attention before the student enters upon the consideration of the next period of European wars.

Spain made her first settlement upon the American continent at the Pearl Coast in 1513. Then sweeping to north and south, she took swift possession of all South America except Brazil, all Central America, and of the Floridas and Californias, far up both coasts of North America, while plans were afoot to plant her flag over the rest of that continent. But the ruin of the Armada, together with Spain's decay at home, came in time to leave room for other colonization. France seized upon the mouths of the Mississippi and the St. Lawrence, the apparent gateways to the continent; and English colonies stretched themselves in patches along the fringe of the North Atlantic coast. The Dutch spent their colonizing energies main-

ly in the Orient; and, despite some ambitious beginnings, Sweden soon grew too weak to be a serious factor in North America. Thus that continent was left in dispute between Spain, France, and England. The contest was to be interwoven with the European wars of the last half of the seventeenth century and of the eighteenth century, and the outcome was big with consequence to the world. All European countries except England governed their colonies on despotic plans. The English colonists took to the New World institutions and principles of freedom, and soon gave them a wider development there than had been possible even in the old home. Besides the rights of free speech and jury trial and *habeas corpus*, each English colony had from the first, or very quickly inaugurated, a representative legislature with full parliamentary privileges and with control over taxation. In several colonies, local government also was conducted on extreme democratic principles. Not until two hundred years later did any of these free principles appear in the colonies of any other people,— and then only because of the success of the English colonies.

England in the Seventeenth Century.— In England itself the seventeenth century saw an important development in free government. Through the Stuart period, from 1603 to 1688, England was engaged in a critical struggle between the royal claims of "Divine Right" government and the rising spirit of popular government. Except for brief intervals the conflict was parliamentary, not military, but it was constant and stubborn. Much of the time it was confused with ecclesiastical questions, which, to the men of the time, often seemed the chief issue; and it was fortunate, indeed, that the stern heroism of Puritanism became engaged on the side of political liberty. During this century, too, England was the last remaining battle ground in Europe for free government. In the other large states,— in Spain, France, Austria, in the Scandinavian lands, even in the petty principalities of Italy and Germany, — despotism was triumphant. In England, popular principles not merely maintained themselves against the Stuart attack; they came out of the conflict with increased vitality. The great experiment of a Puritan Commonwealth failed; but after the Stuart Restoration it became apparent that the body of the monarchists themselves were now thoroughly devoted to parliamentary government, and the attempt of the later Stuarts to set up a personal absolutism called forth the "Glorious Revolution" of 1688, which established the supremacy of Parliament over the king.

Dynastic and Commercial Struggles, 1648–1783.— We now return to the general development of Europe after 1648. On the continent the period from the Peace of Westphalia to the French Revolution (1648–1789) is marked (1) by absolutism within the several states and (2) by dynastic interests in their foreign relations,— with incessant selfish war, as the result. The famous phrase ascribed to Louis XIV. of France, —"I am the State,"— might have been used appropriately by any monarch of the time outside of England. A few great rulers dominate the period. Indeed the stage is largely filled by three monarchs,— Louis XIV. (1643–1715), Peter the Great (1689–1725), and Frederick the Great (1740–86). The influence of Peter was restricted for the most part to Russia; but the other two belong to all Europe, and the period divides itself naturally into the Age of Louis XIV. and the Age of Frederick II. The chief aim of statesmen was to prevent any one country from becoming too strong for the safety of its neighbors. The Peace of Westphalia had transferred political predominance from the Hapsburgs to the Bourbons. Thus, during the first half of the period France threatened the "balance of power," and league after league of other powers was organized against her. International morality, however, was low; and commonly rulers were willing to let a strong power rob a weaker one if they could find "compensation" by robbing some other state themselves. In the last wars of Louis XIV., just before and after 1700 (known in American history as King William's War and Queen Anne's War), the dynastic interests of European ruling families became merged in a titanic, century-long struggle between France and England for world dominion,— though neither country was yet fully conscious of the import of the strife.

In Europe, France was no longer in peril, as she had been in the period preceding Richelieu; and Louis the Fourteenth's half-century of war was merely a struggle to enlarge his dominions. For a generation the victories of Turenne dazzled Europe; and France annexed some important strips of territory on the east, at the expense of Spain and of the decaying Empire. But in the closing period, when the Allies also had found great generals, in the English Marlborough and the Austrian Prince Eugene, even success in the field deserted Louis; and to a comprehensive view his failure was profound. Exhausted France was crushed by taxation to pay the interest of the war debt; while, in attacks upon petty provinces in Europe, she had wasted energies and opportunities that might have made her supreme in Asia and America. Within, the economic reforms of the great Colbert were abandoned; and the revocation of the Edict of Nantes (1685) drove into exile more than two hundred thousand of the best citizens of France. The effect corresponded in a measure to the effect upon Spain of the expulsion of the Moriscoes somewhat earlier. The Huguenots had comprised the skilled artisans and the enterprising merchant classes; and their flight added to the terrible economic demoralization and deprived France of all chance at industrial leadership.

To men of the time, however, the failure was partially disguised by the glamor that surrounded the court of the *Grand Monarque*. French literature, brilliant and sparkling, was in its first splendid period; and French intellectual leadership survived for more than a century. Until after 1800, the court of Louis XIV. remained the model for every court in Europe; and French thought, French fashions, and the French language were the common property of all polite society.

The Treaty of Utrecht (1713), while it left France still one of the three greatest powers, marks her recession from predominance. Spain resigned her territories and claims in Italy and on the Rhine, and, except for her decaying

colonies, withdrew finally within her own peninsula. England gained Newfoundland and Nova Scotia from France, and in Europe she secured command of the Mediterranean by the conquest of Gibraltar and Minorca. By the same treaty and by the rearrangements that immediately followed, the old Spanish Netherlands, the Duchy of Milan, and the Kingdom of Naples and Sicily fell to Austria. The Duke of Savoy (one of the faithful allies against France) acquired Sardinia, with the title of a kingdom for his enlarged state. A little before, in 1701, the Elector of Brandenburg had secured the title of King of Prussia. Thus, out of the wars of Louis, at the beginning of the eighteenth century, arose the two kingdoms, Prussia and Sardinia, which in the latter part of the nineteenth century were to make modern Germany and modern Italy against the will of modern France.

About 1700, other important changes took place in the map of Europe. For three centuries, Austria had been one of the chief bulwarks of Christendom against Mohammedanism. In 1683 Vienna had been besieged by the Turks, and had been saved only by the arrival of the gallant Sobieski with his Polish chivalry. But thereafter Austria took the offensive. She won back Hungary, and then, step by step, extended her dominions down the Danube valley and the Illyrian coast. In the latter part of the reign of Louis XIV., the Austrian Hapsburgs, turning away from the Rhine, definitely adopted a Danubian policy and sought to aggrandize themselves by seizing Slav territory from Turkey.

This new policy of Austria gave Louis XIV. a freer hand on the Rhine than he otherwise would have had, and so helped on the decline of Holland. In 1640, Dutch vessels carried the commerce of the world,—even the greater part of that between England and her colonies. Soon after that date, however, England attacked the Dutch commercial supremacy by navigation laws, and at last by war. Fearful of French conquest, and deserted or timidly defended by Austria, Holland had no choice but to ally herself to her commercial rival. After 1689 in particular (when William of Orange became King of England), Holland followed the lead of England in politics, while that country drew to herself the Dutch carrying trade.

In the north of Europe the former great powers, Sweden and Poland, were declining before the rise of Russia and Prussia. Peter the Great (1689–1725) consolidated the government in Russia, introduced a veneer of Western civilization, and started his country on its deliberate march toward distant seas, west, south, and east. Peter himself secured the western "window" by seizing from Sweden the southeastern Baltic provinces. In the middle of the century, the Empress Elizabeth (1741–62) robbed Sweden of the rest of the Baltic coast up through southern Finland. The northern half of Finland remained Sweden's until Alexander I. seized it in the Napoleonic wars; but toward the close of the eighteenth century, under Catherine II., Russia began her advance along the Black Sea at the expense of Turkey. Under the same ruler occurred the Russian gains in the partitions of Poland,—a story which can be understood only in connection with the rise of Prussia.

For three centuries the Hohenzollern Margraves of Brandenburg had been patiently adding scrap by scrap to their realms. Soon after 1600 these dominions lay mainly in three widely separated groups,—Cleves on the Rhine, Brandenburg on the Elbe, and East Prussia beyond the Vistula. The object of Hohenzollern politics was to consolidate these provinces by acquiring intermediate territory. Toward the close of the Thirty Years' War, Frederick William, the Great Elector, made important headway in this respect and accomplished still more for his country after the close of that struggle by persistently maintaining peace and fostering industry. It was his son who in 1701 secured the title of King. The second king of Prussia built up a magnificent army and reared a son who was to use it magnificently. Frederick II. ascended the throne in 1740 and began his long reign by an unjust but profitable war. The Hapsburg realms had just fallen to a woman, and, disregarding solemn treaties, Frederick took unscrupulous advantage of the supposed weakness of the Archduchess, Maria Theresa, to seize from Austria the rich province of Silesia. The heterogeneous Hapsburg realms seemed about to fall to pieces; and Spain, France, Savoy, and Bavaria hurried to join Prussia in dismembering the carcass. But England and Holland threw themselves into the struggle on the Austrian side, and the Treaty of Aix la Chapelle (1748) closed the War of the Austrian Succession without further territorial changes. Frederick kept Silesia, reaching far down into the heart of Germany, and Prussia stood forth as one of the great powers.

The significance of the contest, however, lay in its wide extension into India and America. Indeed, colonial war between England and Spain had already begun before Frederick appeared on the stage, and France must soon have joined Spain in any event. In the New Worlds, too, the Peace restored the former boundaries; but the war marks a clear consciousness in England and France that the two were rivals for vast realms outside Europe. The family interests of monarchs as a cause for war were giving place to the commercial interests of English and Dutch merchants as opposed to those of French and Spanish merchants, while back of these selfish motives lay the mighty question, big with consequence to the world, whether French or English political ideas should hold the New World.

In 1756, Austria fortified herself by alliance with Russia, Sweden, and even her old enemy France, and prepared to destroy Prussia. Frederick's supreme military genius saved his country for the moment, and the next year England came to his aid. During the brief interval between the European wars, England and France had practically remained at war in America; and now that France had joined Austria, England was constrained to support Prussia. In all the period from 1689 to 1815, no matter what the origin of the wars, England and France soon became the chief factors; and though they were at one time or another on every side of every question, they were never on the same side at the same time.

This Seven Years' War (1756–1763), or Great French War, as it is commonly known in

America, was literally a world-wide struggle. Red men fought by the Great Lakes of North America, and black men fought in Senegal, while Englishmen and Frenchmen grappled in India as well as in Germany, and their fleets engaged on every sea. The showy battles took place in Germany, and on the whole the European conflict determined the wider results. Pitt, with vision fixed upon a coming British empire, declared that in Germany he would conquer America from France. This he did. England furnished the funds, and her navy swept the seas. Frederick, supported by British subsidies, furnished the generalship and most of the troops for the German battlefields. The striking figures in the struggle are (1) Pitt, the English imperialist and the directing genius of the war; (2) Frederick, the military genius, who won Pitt's victories in Europe; (3) Wolfe, who won French America from the great Montcalm; and (4) Clive, the East India Company's clerk, who laid the basis for England's supremacy in India.

Changes in the World-Map; the American Revolution.— The Treaty of Paris (1763) left Europe without change; but in India France lost all except a few unfortified trading posts, while in America England received Florida from Spain, and Canada and the eastern half of the Mississippi valley from France. France ceded to Spain the western half of the Mississippi valley, in compensation for the losses Spain had incurred as her ally; and, except for her West India islands, she ceased to be an American power. Spain still held South America and half North America; but her huge bulk was decaying day by day. Holland, too, with widespread empire, was plainly in decline. England, having dispossessed France in both Asia and America, stood forth as the leading world-power.

The American Revolution, a few years later, did not lessen this pre-eminence; but it had other results of supreme significance. The war came because the American colonies had really become a nation, and because the English government unwisely insisted upon managing American affairs after the Americans were quite able to take care of themselves. English interference in economic matters had long been irksome, and the danger of interference in ecclesiastical matters was feared. England had just relieved the colonies from fear of French conquest. External bonds were gone, and internal ties were dissolving. Then George III. and his ministers supplied the necessary jar to effect separation by trying to raise revenue in America by Acts of Parliament. Astute patriots rallied the majority of the Americans by an old English shibboleth; and after a bitter eight-years conflict (1775–83), the thirteen English colonies became the first free American nation.

The Revolution "split the English race and doubled its influence." It paved the way for a more enlightened economic science, since, contrary to all expectations, the trade of free America from the first proved more valuable to England than that of colonial America had been. It reacted upon England, so that, when the great wars were over, both that country and its remaining colonies made new advances in political liberty. It set up the standard of independence for the states of Spanish America in both continents. But its supreme importance lay in the birth into the family of nations of the United States itself, though the full significance of the new nation hardly began to impress Europe for more than two generations.

England's European enemies had seized the opportunity to attack her in a war of revenge. England came out of the contest with glory little tarnished. She had been fighting, not America alone, but France, Spain, and Holland, as well; and though she had lost the best part of her old American empire she was not without compensating gains. She seized Dutch colonies at will; she strengthened her grasp upon India; she won back the undisputed sovereignty of the ocean by shattering the navy of France; she rebuffed all assailants from the rock of Gibraltar, the key to the Mediterranean; and in some measure she made good even her American loss by the acquisition of Australia just afterward.

The Partitions of Poland.— To return to continental Europe in the closing half of the Age of Frederick the Great:— one more territorial change calls for attention. Poland had fallen into anarchy under its elective, figurehead king and its oligarchic nobles. This anarchy gave the neighboring powers excuse for plunder. Catherine II. determined to seize a large part of the country. Frederick II. persuaded his old enemy, Austria, to join him in compelling Russia to share her booty. The First Partition of Poland (1772) pared off a deep rind. The Second and Third Partitions, which "assassinated the kingdom," had not even the pretext of misgovernment in Poland, for the Poles had earnestly taken up the work of reform. These final divisions took place in 1793 and 1795, after the death of Frederick, amid the wars of the French Revolution. Prussia gained large extent of territory, with valuable sea coast; and, most important of all, the additions brought the principal Prussian provinces,— formerly scattered,— into a compact body. But Russia gained far the greatest part of the territory, and she now bordered Germany on the east, as France had come to do earlier on the west, after the destruction of the Burgundy of Charles the Bold. The wise policy of the Germans, early and late, would have been to support the buffer states against the greed of Russia and France. Failure to do so has left Germany exposed ever since to direct attack by powerful enemies, and has compelled her to build up artificial frontiers of fortresses and bayonets, and to accept an undue militant character for all her civilization.

The Beneficent Despots of the Eighteenth Century.— In foreign relations, the Age of Frederick the Great saw little improvement over that of Louis. In the government within the several states, however, there was a beneficent and significant change. Frederick of Prussia, Catherine of Russia, Charles III. of Spain, Leopold of Tuscany, Ferdinand of Naples, Joseph II. of Austria, all belonged to a new class of "crowned philosophers" and "benevolent despots" who sat upon the thrones of Europe in the latter half of the eighteenth century. In Sweden and Portugal, also, great ministers sought to impose a liberal policy upon the monarchs, as

Turgot succeeded in doing for a while, even in France. A remarkable school of French writers,— Diderot, Voltaire, Rousseau,— had created a new, enlightened sentiment in the ruling classes, and a new sense of responsibility. Government was no more *by* the people than before, but despots did try to govern *for* the people, not for themselves. Sovereigns spoke of themselves no longer as privileged proprietors, but, in Frederick's phrase, as "the first servants of their states." All these rulers planned far reaching reforms,— the amelioration or abolition of serfdom, the correction of abuses in the church, the building up of popular education. In Prussia, for a time, much was accomplished. The condition of the peasantry was improved; the administration was rendered economical and efficient; and wealth and comfort began to increase by bounds. But these happy results were secured only by the tireless energy of one of the world's greatest geniuses. On the whole the liberal monarchs made lamentable failures. One man could not lift the weight of a nation. It remained to see what the people could do for themselves. The age of enlightened despots was the prelude to the French Revolution.

The Age of Nation States.— *The French Revolution, 1789–99.*—In the latter part of the Middle Ages, Italy had given the world an intellectual revolution; Germany began Modern History with a religious revolution; and France now introduced the last great division of the Modern period by a political and social revolution. Pre-eminently among political revolutions, the French Revolution deserves the name. The English Revolution of 1688 swept away temporary interference with ancient principles of English politics; the American Revolution made the Americans politically independent, but did not directly change the character of their society; the French Revolution cut loose from the past, and started France, with all the world, upon new lines of growth.

But if it destroyed the old, it also built the new. The work of destruction was needlessly horrible and bloody; but as a whole the Revolution was a vast and fruitful reform. The really significant thing is not the temporary mob-rule and bloodshed; the significant thing is the great national awakening which swept away an absurd society, founded on ancient violence and warped by time, to replace it with a simpler social system, based more nearly on equal rights.

The chief institutions of France were: (1) a monarchy, centralized, despotic, and irresponsible; but in weak hands, incumbered by complex survivals of ancient local institutions, and hampered by its respect for the good opinion of the privileged classes; (2) an aristocracy, wealthy, privileged, corrupt, skeptical; and (3) an established church, wealthy and often corrupt. Below these spread the masses, a necessary but ugly substructure. Over the continent, similar conditions held sway. In France the nobles had fewer duties, the peasantry had more completely risen out of serfdom, and more of a middle class had grown up, than in the other large countries of the continent. Feudal society was more decayed, and industrial society more advanced. The great European revolution broke through at the weakest spot.

The fundamental cause of the Revolution was the unjust privileges of the favored classes and the crushing burdens of the masses. The evil was no greater than for centuries, but the consciousness of it was greater. The masses began to demand reform; and the privileged classes had begun to distrust their rights.

The Revolution is usually dated from the meeting of the States-General in 1789. The king had summoned that body, hoping to induce the privileged orders to give up their exemptions from taxation, and so relieve the bankrupt treasury. The Third Estate, representing the middle class, and the liberal nobles and clergy had assembled with the determination to secure far-reaching reforms and to establish a "constitution." A sharp contest, with a brief period of anarchy, left power in the hands of these liberal elements, where, despite some attempts at counter-revolution and some danger of mob predominance, it remained for two years. The Constitution fashioned during this period provided for a weak kingship and abolished nobility and all special privileges before the law; but it carefully entrenched middle-class supremacy against democracy by graded property qualifications and a complex system of indirect elections.

Further changes were inevitable; but, if France had been left to herself, they might have come about as quietly as these first ones. Instead, foreign war gave the movement a new character. War was inevitable. Emigrant nobles gathered their forces on the Rhine under the protection of German princes. The Emperor, Leopold, brother-in-law of Louis of France, called upon the sovereigns of Europe to recognize the cause of Louis as "the cause of kings," and demanded from France such changes in her government as should protect Europe against the spread of revolution. This presumptuous dictation in their internal affairs roused a tempest of righteous wrath in the French nation; and in 1792 war began between "the cause of kings" and "the cause of peoples." For twenty-three years Europe was engaged in strife, upon a greater scale than ever before in history.

France was girdled with foes. The Empire, Prussia, and Sardinia, were at once in arms. Naples and Spain joined the coalition. Sweden and Russia both offered to do so, if needed. Ere long England and Holland were added to the enemies who expected to partition France. Vast armies invaded France; and the French forces were demoralized by treachery of officers and by fear of royalist plots. If France was to be saved, it could not be done by half-measures, nor with a king in secret alliance with the enemy. Control fell to extremists; and, while the mighty Danton roused and organized the national energies, the frenzied mob, unhindered, answered the victories and boastings of the invaders by the attack on the Tuileries and the Massacres. In September, the Convention established the French Republic with extreme democratic features and with manhood suffrage. Then revolution within revolution transferred power to more and more radical factions. The defeated Girondists raised the provinces against the capital; and for a time Paris and a score of central departments faced the remaining three fourths of France and

united Europe. Out of this crisis, in 1703, grew the great Committee of Public Safety, which ruled France for a year with despotic power. The Revolution now became constructive, and never has the French genius for organization shown itself more triumphantly. The Committee deliberately adopted a policy of "Terror" to crush plots and dissension and to secure united action. Revolt was stamped out. A million soldiers were sent to the front. The invaders were rolled back in rout, and the ragged but devoted French armies swarmed victoriously across all the frontiers, to sow civil liberty over Europe with fire and sword. France was not again in serious danger from foreign foes until the fall of Napoleon, twenty years later.

Meantime, while the grim, crime-stained men of the Committee in war and tumult were organizing order within and victory abroad, the Convention was laying anew the foundations of French society and advancing the progress of the human race. It adopted the projects of Cambarcères for the codification of French law, and the plans of Condorcet for a system of national education; it accepted Argobast's metric system of weights and measures; it abolished slavery in the French colonies, created provision for the public debt, instituted the first Normal School, the Polytechnic School, the Conservatory, the Institute of France, the National Library, and began the improvement of prisons and hospitals, and the reform of youthful criminals. Meantime the peasants had become free landholders, and the whole laboring class was rising rapidly in standard of living.

In 1794 the Jacobins split into factions, and these turned the "Terror" upon one another. The following year a conservative reaction gave the Republic a new constitution, which restored property qualifications and indirect voting. But the new plural executive (the Directory) proved incompetent and corrupt, and kept itself in power only by a series of *coups d' état*. It was assailed by conspiracy, radical and royalist; and France breathed more easily, when, in 1799, Bonaparte overthrew it with his troops and set up a firm military despotism, veiled by plebiscites.

Napoleonic Period, 1800–15.—For fifteen years, as First Consul (1800), Consul for Life (1802), and Emperor of the French (1804–14), Napoleon was sole master of France. He preserved the principle of civil equality and all the economic gains of the Revolution, but political liberty for a time was lost. True, his rule was a denial of the old doctrine of Divine Right: each new usurpation received the sanction of a popular vote, and he boasted that he was chief by will of the people. But every form of constitutional opposition was crushed or muzzled. The legislative chambers existed only to speak when and as he chose; free speech, free press, and all security for personal liberty were suppressed by a system of spies and secret police and by arbitrary imprisonment of suspects; local administration was centralized more highly than even under the old monarchy, "nor did there exist anywhere independent of him authority to light or repair the streets of the meanest village in France."

This all-pervading absolutism was directed by the penetrating intelligence and indomitable energy of the world's most "terrible worker"; and it conferred upon France great and rapid benefits. Order, precision, symmetry were introduced into every branch of the administration. The interrupted work of the Convention was resumed. Education was organized; law was simplified and codified; the church was again brought into alliance with the state; industry was fostered, and magnificent public works were carried out. But in all this, Napoleon was merely the last and greatest of the beneficent despots. And in the outcome, his rule fixed more firmly than before in the mind of the nation the dangerous willingness to depend upon an all-directing central power; so that in our own day, after many revolutions, the supremely difficult task of the Third Republic has been to create the spirit of local self-government.

No doubt, in 1800, when Napoleon came into power, he sincerely desired peace, in order to reconstruct France. By the brilliant victories of Marengo and Hohenlinden he dissolved the hostile coalition, and a series of treaties, closing with the Treaty of Amiens (1802), gave Europe a breathing spell. But soon Napoleon again desired war. His victories in Italy, as a general of the Directory, had first brought him to the world's notice, and only military glory could keep France from murmuring at his rule. Moreover, he aspired frankly to European empire. On the other hand, the nations felt that there could be no lasting peace with him except by complete submission to his will. In 1803, England and France renewed their strife, and between these powers there was to be no more truce until Napoleon's fall, eleven years later. In that time Napoleon fought also three wars with Austria, two with Prussia, two with Russia, a long war with Spain, and various minor conflicts. From 1792 to 1802, the unceasing European wars belong to the Revolutionary movement. From 1803 to 1815, they are properly Napoleonic wars, due primarily to the ambition of a great military genius. In the first series, Austria was the chief opponent of the Revolution; in the second series, England was the relentless foe of Napoleon.

Napoleon's insight readily divined his true enemy; but Nelson's great sea fight put an end to all possibility of directly invading England. On the continent, however, victory followed victory. After Austerlitz (1805), Austria gave up her remaining Italian and Illyrian territory, and many of her possessions in Germany. After Jena (1807), humiliated Prussia was reduced half in size, thrust beyond the Elbe, and bound to France by a shameful treaty. Less decisive conflict with Russia was followed by the diplomatic victory of Tilsit (1807). Emperor and Tsar entered into friendly alliance. France was to have a free hand in Western Europe; Russia was to be permitted to aggrandize herself at the expense of Sweden, Turkey, and Asia; and the two were to join in ruining England by enforcing Napoleon's "continental system."

The refusal of Portugal to obey Napoleon's command for the confiscation of English commerce led to the seizure of that state. Then followed a like seizure of Spain, out of which grew the long Peninsular War, which, as Napoleon confessed afterward at St. Helena, was

really the canker that destroyed him. At the time, however, it seemed trivial, and for five years after Tilsit Napoleon was master of the continent. At its greatest extent the huge bulk of France filled the space from the ocean to the Rhine, including not only France as we know it, but also Belgium, half of Switzerland, and large strips of Germany, while from this central body two outward-curving arms reached toward the east, one along the North Sea to the Danish peninsula, and the other down the coast of Italy past Rome. The rest of Italy and half the rest of Germany were under Napoleon's protection, ruled as vassal states by his brothers and generals. Denmark and Switzerland were his willing allies, and Prussia and Austria were unwilling ones. Sweden and Russia, though nominally his equals, were allowed that dignity only because they upheld his policy. Only the extremities of the continent,— the islands of Sicily, Sardinia, and England, and the mountainous Spanish peninsula,— kept their independence, at the cost of wasting war.

The period was filled with important rearrangements for Europe, territorial, political, and social. Many of these were designed in selfishness; but nearly all were to bear good fruit. In particular, the Germany and Italy of to-day were made possible by Napoleon's fearless clearing away of old institutions, and by the vigorous impulse he gave to the new forces of political unity and social reform.

In Germany, even the territorial rearrangements paved the way for later national unity. Not only the twelve hundred anarchic territories of the "knights," but also the three hundred petty, scattered, despotic principalities, ecclesiastical states, and oligarchic city-republics (with a few exceptions) were absorbed in larger neighbors; so that the multitudinous, ill-governed states of the vanished "Empire" were consolidated into less than forty. Most of these reorganized states, outside Austria and Prussia, were further combined in the Confederation of the Rhine; and in this Confederation, as well as in the German and Italian territory annexed to France, and in the various vassal states over Europe, serfdom and feudalism were abolished and civil equality and the Code Napoleon were introduced. The administration of justice was made cheap and simple, and the old clumsy and corrupt methods of government gave way to order and efficiency.

Most important of all, similar reforms were adopted in Prussia, not from French pressure, but by the influence of the Prussian minister, Stein, who sought to make his country strong enough to throw off the French yoke and to regenerate Germany. Napoleon's insolence had at last forced part of Germany into a new national patriotism; and that patriotism began to arm itself by borrowing weapons from the arsenal of the Revolution.

Napoleon's "continental system," if embarrassing to England, was ruinous to Europe. Moreover, Tsar Alexander began to suspect Napoleon of intriguing against him in Finland and Turkey; and in 1811 he refused longer to follow Napoleon's commercial policy. Napoleon declared war. The destruction of his Grand Army amid Russian snows was the signal for the rising of the peoples of Central Europe in the Wars of Liberation. Napoleon, like a desperate gamester, refused all terms, and finally was crushed and deposed. The Bourbon dynasty was restored to the throne of France, and the powers met in the Congress of Vienna (1814–15) to reconstruct the map of Europe.

The Congress of Vienna.— In its desires, that Congress stood for reaction. Says Fyffe, "It complacently set to work to turn back the hands of time to the historic hour at which they stood when the Bastille fell." It ignored peoples, and considered only princes. Its work, therefore, had to be slowly undone through the next half-century.

Still, its power for restoration was less than its wish; and even its most selfish work contained seeds of progress. Nobody thought of restoring the old ecclesiastical princes, nor of undoing the consolidation of Germany. That country was left in thirty-eight states, and Italy in twelve. Austria, which had lost territory in Central Europe, received its compensation in Italy, so that its despotic energies were more than ever drawn away into Italian and Danubian questions. Renovated Prussia, in return for Slav lands, which it ceded for the Tsar's new Kingdom of Poland, received German territory,— half of Saxony, the Pomeranian sea coast, and German provinces on the Rhine taken from France. Thus, reaching down into the heart of Germany, and with distant isolated districts to defend on the Rhine and on the Niemen, Prussia stood forth the natural champion of Germany against Slav and Gaul. In like manner, Sardinia's gain of Genoa was one more step in the consolidation of Italy. In return for the vast national debt incurred in supporting coalitions against Napoleon, England added still further to her colonial supremacy by holding South Africa, Cyprus, Malta, and other important stations. Despite its brief welcome to Napoleon at his return from Elba, France was wisely left with the boundaries she had when the Revolutionary wars began. The most serious disappointment to the liberals was the failure to secure a national union in Germany. Reactionary Austria secured instead the Germanic Confederacy — a loose league under Austrian presidency, with a Diet which was merely a meeting of ambassadors,— "a polite and ceremonious means of doing nothing."

It was worth much to Europe merely to recognize that it had common interests which could be arranged by a peaceful congress. Even this gathering of despots was an advance from eighteenth century politics toward a better international organization. Some of its work, moreover, was distinctly progressive, such as the declaration against the African Slave Trade, the opening to commerce of the rivers flowing between or through different countries, and especially the neutralization of Switzerland under the protection of the powers.

From 1815 to the Revolutions of 1820.— For more than thirty years after the Congress of Vienna, reaction held sway. The restored princes, who "had learned nothing and forgotten nothing," strove to ignore the progress from 1789 to 1815. In Sardinia, serfdom was restored; in Spain and the Papal States, the Inquisition and other mediæval institutions; in some places, even street lamps were abolished along with other hateful French reforms. Five states,— Russia, Austria, Prussia, England, and

France,— determined the policy of Europe. The first three were divine-right despotisms; and though the Tsar and the King of Prussia played for a time at liberalism, the first disorders enabled Austria to draw them over to her own frankly reactionary program. At first, France and England were not much better than these Eastern powers. Louis XVIII. had found it necessary to give France a charter; but in that document itself the theory of divine right was preserved, until the revolutionary changes of 1830. That theory could have no place in England; but even there the government was for many years in the hands of an extreme Tory party. The evil genius of the whole period was the subtle Austrian statesman, Metternich, with his motto, "Government is no more a matter for debate than religion is." The one good thing to be said for Metternich's long supremacy is that he permitted no great war; and this was because he felt it necessary to hold the powers in friendly alliance, so as better to arrest progress within the lines drawn at the Congress of Vienna.

However, beneath the tide of reaction, the principles of the Revolution survived. The two positive forces in politics for the 19th century were to be democracy and nationality. The league of princes compelled them to work underground; but before the middle of the century they emerged in three series of revolutions — in 1820, 1830, and 1848.

The revolutions of 1820 started in Spain, to re-establish the Constitution of 1812, which had been adopted first during the war for Independence. Completely successful there for the time, the movement spread swiftly over the southern peninsulas — to Portugal and to the states of North and South Italy, while it stimulated the Greek rising against the Turks. Metternich found a weapon of repression ready. After Waterloo the four great allies, Russia, Prussia, Austria, and England, had agreed to preserve their union against revolutionary France by holding occasional congresses. Metternich now summoned these powers to the Congress of Troppau. Here the despotic masters of Russia, Austria, and Prussia signed an agreement to unite in putting down revolution against any established government. England protested and withdrew from the alliance; but her place was taken by France, and the united despots, popularly known as the "Holy Alliance," proceeded to carry out the Troppau programme. With overwhelming armies they crushed constitutionalism in Naples and Piedmont, and a little later, in Spain. England's fleet preserved the little sea-coast country of Portugal from attack; and the Tsar's sympathy for his Greek coreligionists held Metternich from aiding Turkey. Portugal and Greece were the only European lands to reap good from the widespread risings of this period.

American Progress.— Greater gain there was, however, outside Europe. The "Holy Alliance," successful in Spain, wished to restore monarchic control over revolted Spanish America. Here they failed. When Napoleon seized Spain (1808), the Spanish colonies, nominally loyal to the old Spanish dynasty, began to taste the sweets of economic and political freedom. They were powerfully influenced, too, by the success of the United States; and soon they began, one after another, to avow independence not only of Napoleon, but also of the mother country. The United States had recognized their independence. England had not done this; but now she interposed her sea-power to shield them against the proposed attack by the "Holy Alliance." England, indeed, urged the United States to join in a formal alliance to protect Spanish America. The United States chose to act separately, but it did act along the same line: in 1823 President Monroe's message announced that this country would oppose any attempt of the despotic powers to extend their political system to America. Thus was born a group of new nations. For more than fifty years, it is true, the best of the new states manifested anarchic tendencies; but before the close of the nineteenth century some of them began to make steady and promising progress in government and society. Their constitutions have been modeled generally upon that of the United States.

Before returning to Europe, brief attention should be given to the progress of the United States itself in the generation following the French Revolution. The Constitution of 1787 saved the thirteen States of that time from falling apart into jangling, insignificant units, and gave the world an advanced type of federal government. The Louisiana Purchase (1803) doubled the territory of the country and confirmed its destiny as the home of a mighty continental nation. During the closing Napoleonic struggles, the contemptuous disregard of England for the rights of neutrals, together with the treacheries of Napoleon, involved America in war with England; but, beyond this, except for the enunciation of the Monroe Doctrine, the United States, busied with its marvelous growth at home, had kept free from foreign complications. At the moment of the European revolutions of 1820, the great American Republic was entering on the forty years of anti-slavery debate which preceded the Civil War.

Revolutions of 1830.—The year 1830 is one of the notable dates in the 19th century. In America the victory of Jackson had just marked a fresh advance in popular government. In England the First Reform Bill began its two-year struggle in Parliament. On the continent of Europe, revolution struck a new blow at the system of Metternich. This time the movement started in France, where the July Revolution replaced the divine-right Bourbon monarchy with the constitutional, bourgeois monarchy of the Orleanists. Explosions followed over Europe. The Belgians rose against their Dutch masters; the Poles against Russia; Italian risings seemed for a moment to have some chance in the papal states and the duchies; and, while Russia and Austria were busied in Poland and Italy, liberal gains were secured in several German states. But soon Metternich, his hands free once more, set himself patiently to restore the old order in Germany. France, it is true, was lost to the "Holy Alliance," and joined England in defending liberal Belgium against despotic intervention. But in the final result, France and Belgium were the only gainers from this period. It was to take the third great "year of revolutions," to sweep away Metternich's shattered system.

To appreciate in any measure the wonderful progress of the remaining two thirds of the 19th century, it is needful to grasp the conditions of the world of 1830, or, we may say, of 1837, when the Victorian era began. It was still a small, despotic world, far more remote from the great, progressive world of 1900 than from the world of 1600. Civilization held only two patches on the globe,— western Europe and eastern North America. In the latter, the real frontier of the United States reached less than one third the way across the continent, and politics and society were dominated by the slave power. Europe knew "Germany" only as a pious aspiration of revolutionaries, and "Italy" as a "geographical expression." Metternich stood guard over central Europe. On the east hung Russia, an inert mass, in the chains of her millions of serfs. Under the contemptible Orleans monarchy, France was taking breath between spasmodic revolutions. England herself had only begun to stir under the long oligarchic rule of her landlord class. The rest of the globe hardly counted; a fringe of Australia held a convict camp; eastern Canada was a group of jealous, petty provinces, learning to agitate in disorderly fashion for self-government; Spanish America, prostrate in anarchy, gave as yet little hope of the coming renaissance; Japan was to sleep a generation longer; while the two largest continents were undisturbed in their native barbarism, except for England's grasp upon the hem of India and South Africa.

England in the 19th Century.—In Europe, England was to lead the van of progress; and in England, almost alone in Europe, reform was to come without revolution. But the England of 1830 was still mediæval. During the great French wars from 1690 to 1815, except for the one development of ministerial government, England had retrograded politically and socially. Her society was marked by extreme inequalities between rich and poor, intensified by cruel class legislation; her government, superficially representative, had really fallen into the hands of a selfish landlord class; her boasted local self-government was intensely aristocratic: her established church was aristocratic and unspiritual. In the last half-century had come an industrial revolution — the growth of the factory system — with marvelous increase of population and growth of city life, calling imperatively for new adjustments; but the great Tory party met all calls for reform with sullen denunciation and repressive legislation which made free speech a crime.

Under the system of rotten and pocket boroughs, more than half the House of Commons were the appointees of less than 200 landlords, while most of the rest represented small fantastic constituencies. Thus, reform necessarily began with Parliament itself. This parliamentary reform was accomplished by three great measures: that of 1832 placed power in the hands of an intelligent middle class, the landed and mercantile interests; 35 years later, the Second Reform Bill (1867) gave power to the artisan class of the towns; and the bill of 1884 once more doubled the electorate and left England a democracy.

The Reform Bill of 1832 was followed at once by social reform, in response to the swelling tide of humanitarianism in literature and society. Legislation swept away negro slavery in the colonies, and the hideous white slavery of women and children in English factories and mines; reformed the barbarous and fantastic criminal code; abolished the worst abuses of the pauperizing poor-law; began the protection of workmen in factories against carelessness or wilful neglect of capitalists; gave women legal rights; adjusted taxation more equibly; swept away the corn laws and introduced the free-trade era; removed the press gang, and brought in the penny post; enlarged the self-government of the colonies; and established a wonderfully efficient system of democratic self-government in cities at home. Subsequent political reform, despite the Irish difficulties after 1870, added to the rate of social reform. In particular should be noticed the complex industrial legislation, and, for dependencies where the nature of the population forbids self-government, the adoption of efficient, unselfish colonial administration, in which England has set an example for all world powers. Even India and Egypt, with their tremendous difficulties, have been touched with new life; while the great provinces of the English-speaking colonies, Canada and Australia, have organized themselves into two mighty federal states (1867 and 1901). In the rural units of England, too, the local government bills of 1888 and 1894 established true democracy.

Revolutions of '48.—Meantime, on the Continent, the next great progress after 1830 came with the revolutions of '48. A general explosion had been preparing; but again the signal was given by France. The Orleans monarchy had become reactionary; and the socialistic February revolution set up the Second Republic. March saw Metternich himself a fugitive, escaping from Vienna in a laundry cart, while thrones were tottering everywhere between Russia and Turkey on one side and England on the other. Even England trembled with a Chartist movement and the threat of an Irish rebellion. The kings of Holland, Spain, Denmark, and Sweden made constitutional concessions. In Germany and Italy there were complex movements, working (1) for constitutional liberty and social reform within the several states; (2) for the union of the fragments of the German race into a nation; and (3) for the independence of Italians, Slavs, and Hungarians, held in subjection by Austria.

The third movement resulted in wars, out of which Austria finally emerged triumphant; and her victorious army was a ready tool to restore absolutism at home. In Germany the undisciplined Liberals had wasted opportunity, Austria dispersed the Frankfort National Assembly, and, after humiliating unready Prussia at Olmütz, restored the old confederation (1850). A year later (1851) the *coup d'état* of Louis Napoleon closed the revolution in France and prepared the way for the Second Empire of the next year.

But there had been great gains. Feudalism and serfdom were gone forever, even from Austria. Sardinia, Prussia, and the minor German states kept their new constitutions. Switzerland had become a true federal republic upon the American type. Sardinia, by her sacrifices, and Prussia, in spite of the past mistakes of her timid government, were clearly marked out as

the champions of Italy and Germany against Austria. Victor Emanuel of Sardinia recognized his mission to unite and free Italy; and Prussia, so recently shamed, had statesmen who would see that next time she should be ready.

Europe from 1850 to 1880.—The next 25 years (1850–75) saw not only the advance toward democracy in England, the victory of nationality and the abolition of slavery in the United States, the formation of the federal Canadian Dominion, on the American model, and the awakening of Japan under American constraint, but also a new federal German Empire, a united, constitutional Italy, a stable French republic, a constitutional Spain, and a constitutional, federal Austria-Hungary. The period was one of "blood and iron." Napoleon III., who had drawn England into the Crimean war (1854) to humiliate Russia, was himself drawn by the statesmanship of Cavour into the Austrian war of 1859 to help free Italy. Within a year after the resulting campaigns in Italy had closed, the American Civil War began; and before it ended, Bismarck had entered upon his trilogy of wars. In 1864 he robbed Denmark of the Schleswig-Holstein duchies, with the great harbor of Kiel for Prussia's projected navy, and so made trial of the new army he was at once to use (1866) in driving Austria out of Germany by the Six Weeks' War. The North German Confederation, then formed, was expanded into the German Empire by the Franco-Prussian war (1870–1), into which Bismarck next tricked French vanity and the despairing ambition of the decaying French government. These struggles completed also the unity of Italy. In 1866 Italy recovered Venetia from Austria, and in 1870, when France could no longer interfere, it at last marched its troops into its ancient capital, Rome. Even for conquered countries, during this period, did reform grow out of war. The Crimean catastrophe struck the chains from Russia's serfs; the shock of defeat in '59 and '66 woke Austria to constitutional progress; only when Germany shivered the sham of the Second Empire did France enter upon true republican life; and it was in the ashes of her old social system that our own South found regeneration.

Out of the Russian-Turkish war of 1877–8 a new group of Balkan nations was born, mainly Slav in blood, with at least the forms of constitutional government. But since 1871 political progress for the most part has been peaceful. The various monarchies of Europe, except Russia and Turkey, had already all adopted constitutions modeled upon the English government, though in none of them were the ministries so truly dependent upon popular will as in England. Indeed, in some states the formal constitutional monarchy really merges into a practical despotism. Progress in politics since 1871 has been of two kinds: (1) a growth in ministerial responsibility, and (2) rapid extension of the franchise toward a manhood basis. Actual administration, in most European countries, is still highly aristocratic; but in the matter of ultimate control democracy is generally triumphant, and it is training itself everywhere, by compulsory school systems, for the closer management of affairs.

International Relations Since 1880. Europe in Africa and Asia.—International relations since 1880 require brief statement. France longing to recover her lost provinces from Germany in a war of revenge, drew close to Russia. Bismarck offended Russia by supporting Austria in the Balkans. Italy was angered by the French seizure of Tunis in 1880. Thus new combinations of the powers appeared. In 1881, Germany, Austria, and Italy (all old enemies) leagued in the Triple Alliance; while a little later, France and Russia formally adopted a dual alliance. The Continent was thrown into two hostile camps, and has rested ever since under an armed peace. France became "the tail to the Russian kite." England, unwilling to join the Triple Alliance, as Bismarck wished, has been left in a position her statesmen have chosen to characterize as one of splendid isolation.

In the '90s, all these arrangements were threatened by the active appearance, in the field of international politics, of two non-European powers. The Chinese war of 1894 revealed Japan as a modern and powerful state; and the Spanish-American War (1898) made it apparent that the United States had abandoned its exclusively American policy. Moreover, since about 1880, European politics had been merging more completely than ever before in world politics. The questions at issue ceased to be Rhenish or Danubian, and became African and Asiatic. The 19th century, indeed, had been one of expansion of civilized powers, but that expansion had hardly been conscious of its own importance. The United States had quietly filled its borders from ocean to ocean with a homogeneous population. Russia had spread across northern Asia to the Pacific, and was reaching down in the Trans-Caspian region toward the Persian Gulf. And England had continued annexation of the keys to empire in waste spaces of the earth. These three were the world-powers. Far behind came France, with some important possessions in North Africa and some ancient claims in southeast Asia. Until 1884 Germany had no thought of colonial empire.

About 1880 a new, conscious greed for colonial territory seized Europe. Africa, some Pacific islands, and the helpless Asiatic empires of Persia, Turkey, Siam, and China were the only unappropriated lands. There followed a swift, peaceful division of Africa. In 1880, only patches here and there on the coast were European; in 1891, except for the native states of Abyssinia, Liberia, and Morocco, the continent was mapped out between European claimants. The three important African powers are England, France, and Germany, though Belgium, Spain, Portugal, and Italy are also represented. England is far in the lead. Her ambition has been to unite her two main possessions, in the Nile Valley and in South Africa, by acquiring intermediate territory; but the Congo Free State and German East Africa were thrust between too soon. France comes second in extent of territory; but, except for Algeria and Madagascar, her districts are less valuable than those of England or Germany. France would have liked to join her holdings on the east and west of the continent; but she found English territory thrust in between. German ambition was frustrated in similar manner. The three powers seem to have mutually stale-mated one another's attempts to dominate Africa.

The occupation of Asia by European states has proceeded more slowly, but has moved with increasing rapidity in recent years. England, Russia, Japan, and France are the chief powers concerned, though Germany has shown an active disposition to take a hand in any partition, and though the commercial interests of the United States make it certain that that country will be an important factor in any further changes.

In 1894, Japan and China engaged in war over the control of Korea. With amazing rapidity, Japan overcame her bulky antagonist; but Russia, backed by France and Germany, stepped in to rob her of the fruits of her victory. Japan, owning not even one modern ship of war, was forced to yield — to spend all energies for the next 10 years in preparing for further conflict. Russia secured from China the right to extend her Siberian railroad through Manchuria, and in 1898 she also obtained the powerful fortress of Port Arthur. Germany and England then compelled China to grant them important districts, which, like the Russian acquisitions, seemed to command the heart of China and to doom that power to partition. In 1900 the Chinese resentment against "western barbarians" culminated in the Boxer massacres. The powers sent armies to rescue their beleaguered embassies at Peking; but, largely through the policy of the United States, no territorial indemnities were demanded. During the campaign, however, Russia occupied Manchuria, and, despite repeated solemn promises, it soon became plain that she meant to keep it. The powers apparently acquiesced; but when Russia in 1903 encroached also upon Korea, Japan foresaw danger to her own independence, and, in 1904, she began war. The struggle has been tremendous, almost beyond parallel; but Japanese victory has been swift and overwhelming, and has changed the whole face of world politics. Russian aggression in the East has been checked for a long period. See MANCHURIA; PORTSMOUTH, TREATY OF.

Summary.—The three mighty agents in the 19th century transformation have been democracy in politics and industry, humane sentiment in morals, and scientific progress. The first of these has been the main theme of the latter part of this article. The gentler spirit of recent society, likewise touched upon, has abolished slavery, ameliorated law, and brought about organized, zealous, and intelligent effort to lessen misery and crime. But perhaps the most marvelous phase of the "Wonderful Century" is the scientific advance. Since the primitive inventions of making fire, of the bow, of domesticating animals, of smelting iron, and of the alphabet, all the inventions of man up to the year 1800 probably count for less than those since that year. In civilized lands, life has been lengthened over a fourth, and the population of the civilized world has trebled. This larger amount of life has been lifted to a higher level. Wealth is more abundant; and the laboring masses, though still getting too little of it, get far more than formerly. The area of civilized life has been wonderfully expanded, but steam and electricity bind the most scattered portions together more closely than adjacent villages were joined in the near past. And this new solidarity is not merely in material interests: it has its intellectual and moral side. There is a growing unity of sympathy and opinion.

The picture, of course, has its dark side. Crowded populations live and work under conditions of misery and disease and often of sin. Civilized nations show callous disregard for the rights of weaker or barbarous people. And over the civilized world itself there still broods the danger of annihilating war, more terrible because of the inventions of this scientific age.

Happily this survey may close with a chronicle of a great step toward removing this last danger. The Hague Conference of 1899, called in the interests of peace, did not find it possible to make any advance toward disarmament, but it did provide for a permanent international tribunal for arbitration between such nations as may choose to avail themselves of it. It is of supreme consequence that machinery is ready so that two nations at difference may escape war without loss of dignity, if they both desire. Even more significant and hopeful, however, is a long series of arbitration treaties between nations, two and two, beginning with the Anglo-French treaty of 1903. Despite the terrible Russo-Japanese war, the first years of the 20th century have seen remarkable progress toward the federation of the world.

Bibliography.—Within the space at command, no detailed bibliography is possible. Since the dawn of the scientific study of history, writers have shunned the attempt to cover the complex field of modern history except in co-operative "series." Of such series the most important in English are 'The Cambridge Modern History,' edited by Ward (1903, 12 vols., of which only 5 have appeared by 1905); and 'Periods of European History,' edited by Hassall (1890–2, 8 vols., of which the last 5 belong to our period). Andrews' 'Historical Development of Modern Europe' (1896), Fyffe's 'Modern Europe to 1878' (1884), and Seignobos' 'Europe Since 1814' (1899) deal with the 19th century. Cunningham's 'Western Civilization' (1900), and McVey's 'Modern Industrialism' (1904) treat special phases. For further references the reader may consult the special bibliographies at the close of the articles on leading countries and movements. West's 'Modern History' (a high-school manual, 1904) in an appendix gives a classified bibliography of 150 standard English works.

Hitchcock, hĭch'kŏk, **Charles Henry,** American geologist: b. Amherst, Mass., 23 Aug. 1836. He was son of Edward Hitchcock,

geologist (q.v.). He was graduated from Amherst College in 1856, was assistant State geologist of Vermont in 1857–61, State geologist of Maine 1861–2, and of New Hampshire 1868–78. In 1868 he was appointed professor of geology in Dartmouth College. In connection with his survey of New Hampshire, he maintained, during the winter of 1870, a meteorological station on Mount Washington, the earliest high-mountain observatory in the United States. He became known as a compiler of geological maps, and for his investigations regarding the geology of the crystalline schists, ichnology, and glacial geology. The location of the terminal glacier in the United States was first suggested by him. He was a founder of the Geological Society of America, and in 1883 president of the American Association for the Advancement of Science. His publications include: 'Elementary Geology' (1861, with E. Hitchcock); 'Mt. Washington in Winter' (1871); and a 'Report on the Geology of New Hampshire' (1873–8), with folio atlas, his most valuable work.

Hitchcock, Edward, American Congregational clergyman and geologist: b. Deerfield, Mass., 24 May 1793; d. Amherst, Mass., 27 Feb. 1864. He was principal of the academy in his native place 1815–18; pastor of the Congregational Church in Conway, Mass., 1821–5; professor of chemistry and natural history in Amherst College 1825–45, and president of Amherst College and professor of natural theology and geology 1845–54. He was appointed State geologist of Massachusetts in 1830, of the First District of New York in 1836, and of Vermont in 1857. In 1850 he was commissioned by the government of his native State to examine the agricultural schools in Europe. His life was in a great measure identified with the history of Amherst College. Connected with it almost from the beginning, in his own presidency he procured for it buildings, apparatus, and funds to the amount of $100,000, doubled the number of students, and established it on a solid pecuniary as well as literary and scientific basis. His earliest scientific publications were the 'Geology of the Connecticut Valley' (1823), and a 'Catalogue of the Plants within Twenty Miles of Amherst' (1829). Later works were: 'Lectures on Diet, Regimen, and Employment' (1831); 'Lectures on the Peculiar Phenomena of the Four Seasons' (1850); 'Reports on the Geology of Massachusetts' (1833–35–38–41); 'Illustrations of Surface Geology' (1857); 'Elementary Geology,' which passed through 25 editions in America, and one third of that number in England; 'Religion of Geology and its Connected Sciences' (1851); and 'Reminiscences of Amherst College' (1863). Dr. Hitchcock suggested as well as executed the geological survey of Massachusetts, the first not only in the long series of scientific surveys in the United States, but the first survey of an entire State under the authority of government in the world. He was the first to give a scientific exposition of the fossil footprints of the Connecticut Valley, and with him ichnology as a science began.

Hitchcock, Ethan Allen, American soldier: b. Vergennes, Vt., 18 May 1798; d. Sparta, Ga., 5 Aug. 1870. He was a grandson of Ethan Allen (q.v.), and was graduated at West Point in 1817, entering the corps of artillery as a third lieutenant. In 1829 he became the military commandant of the corps of cadets, in which office he continued until 1833. He served in Florida against the Indians, and in the war with Mexico, where he received two brevets, one as colonel and another as brigadier-general. In 1855 he printed for private circulation a pamphlet in support of his opinion that genuine alchemy was not an art for making gold, but that the alchemists were students of man, whose perfection was symbolized by their "philosopher's stone." He subsequently published: 'Remarks upon Alchemy and the Alchemists' (1857); 'Swedenborg a Hermetic Philosopher' (1858); 'Notes on the Vita Nuova of Dante' (1866).

Hitchcock, Ethan Allen, American politician: b. Mobile, Ala., 19 Sept. 1835. He received a secondary education, was in mercantile business at St. Louis, Mo., in 1855–60, then went to China to enter a commission house, of which firm he became a partner in 1866. In 1872 he retired from business, in 1874 returned to the United States, and in 1874–97 was president of several manufacturing, mining, and railway companies. He was appointed envoy extraordinary and minister plenipotentiary to Russia in 1897, and in February 1898 ambassador extraordinary and minister plenipotentiary, the first ambassador accredited from the United States to the court of Russia. In 1898 he was nominated and confirmed as secretary of the interior, and 20 Feb. 1899 entered upon his duties.

Hitchcock, James Ripley Wellman, American art critic: b. Fitchburg, Mass., 3 July 1857. He was graduated at Harvard in 1877, and was art critic of the New York *Tribune* 1882–90. He has written: 'The Western Art Movement' (1885); 'A Study of George Inness' (1885); 'Madonnas by Old Masters' (1888), the text to photogravures; 'The Future of Etching'; 'Some American Painters in Water Colors'; 'Etching in America'; 'Notable Etchings by American Artists'; etc.

Hitchcock, Roswell Dwight, American Congregational clergyman: b. East Machias, Maine, 15 Aug. 1817; d. Somerset, Mass., 16 June 1887. Graduated from Amherst College in 1836 and from the Andover Theological Seminary in 1838, he also studied at Halle and Berlin (1847), in 1845–52 was pastor of the First Congregational Church at Exeter, N. H., and in 1852–5 professor of revealed religion in Bowdoin College. In 1855 he became professor of church history at the Union Theological Seminary, of which institution he was elected president in 1880. He became president of the Palestine Exploration Society in 1871, and vice-president of the American Geological Society in 1880. An editor of the 'American Theological Review'; he wrote: 'The Life, Character, and Writings of Edward Robinson' (1863); 'Complete Analysis of the Holy Bible' (1869); and 'Socialism' (1879). With Eddy and Madge, he compiled 'Carmina Sanctorum' (1885); and 'Eternal Atonement,' a volume of sermons, appeared in 1888.

Hittell, Theodore Henry, American historian: b. Marietta, Pa., 5 April 1830. In 1852

he was admitted to the bar at Cincinnati, in 1855 removed to California, in 1855–61 was connected with the *Bulletin and Times* of San Francisco and from 1862 practised law. He was State senator in 1880–2. He wrote a 'History of California,' his chief work; and compiled 'The General Laws of California,' known as 'Hittell's Digest,' and 'Hittell's Codes and Statutes of California.'

Hittites, hit'its, the name of several peoples mentioned in the Old Testament, and in Egyptian and Assyrian inscriptions. In the Old Testament the name is applied to three more or less distinct groups, namely, the "children of Heth" from whom Abraham purchased a burying-place; a people or group of peoples which inhabited Palestine before the Hebrews and resisted their invasion; a kingdom in northeastern Syria, with which Solomon formed marriage alliances. The first group dwelt around Hebron in southern Palestine, and the Hittites mentioned in connection with David, of whom the chief was Uriah, may be their descendants. The second group of Hittites dwelt among the mountains of central Palestine, and the third group, united in some sort of empire, had their seat still farther north. Of this Hittite empire we learn more from the Egyptian and Assyrian records than from the Old Testament. The Heta, according to the hieroglyphic inscriptions, offered a vigorous resistance in northern Syria to the Egyptian king Thutmosis III. (18th dyn.: c. 1560 B.C.), and to his successors of the 19th dynasty, Sethos I., Rameses II. and III., c. 1350–1200 B.C. Carchemish, Kadesh, and Hamath were among their chief cities. The cuneiform inscriptions contain notices of a people called Hatti who frequently fought with the Assyrians from the time of Tiglath-pilesar I. (c. 1100 B.C.) till that of Sargon II. (721–704 B.C.), after which they are no more heard of. The Hittite monuments and inscriptions which have been found in Carchemish, Hamath and neighboring places, as well as throughout Asia Minor, appear to belong to the Assyrian period.

Hittorf, Jacques Ignace, French architect: b. Cologne 1792; d. 1867. He studied his profession in Paris and was employed on many public buildings and places, doing work on the Bois de Boulogne, the Champs-Elysées and the Church of Saint Vincent de Paul. Among his publications may be mentioned 'Architecture Antique de la Sicile'; 'Architecture Moderne de la Sicile' and 'Architecture polychrome chey les Grees.'

Hitzig, Ferdinand, German theologian: b. Hauingen, Baden, 23 June 1807; d. Heidelberg, 22 Jan. 1875. He was educated at Heidelberg, Halle and Göttingen. He went to Zurich in 1833 as professor of theology, where he remained until 1861, when he returned to Heidelberg. He was quite a voluminous writer on the Old Testament, composing commentaries on the Minor Prophets (1838); Jeremiah (1841); Ezekiel (1847); Ecclesiastes (1847); Daniel (1850); Song of Solomon (1855). He made a translation of the Psalms in 1835.

Hive-bee. See HONEY-BEE; BEE-CULTURE.

Hives. See URTICARIA.

Hoactzin, hō-ăkt'zĭn or -ăk'zĭn, a singular South American bird (*Opisthocomus cristatus*) of the size of a pheasant. It is brown streaked with white, and the head has a movable crest. It is interesting principally from the extraordinary way in which the fledglings, as soon as they leave the nest (in a tree), scramble about the branches by aid of their wings used like hands, by reason of the fact that they have a temporary claw on both the index and pollex. The food of these birds is mainly leaves and fruit; and a strong musky odor is given off by the adults, so that in British Guiana they are called "stinking pheasants."

Hoadley, hōd'lĭ, **George,** American lawyer: b. New Haven, Conn., 31 July 1826; d. Watkins, N. Y., 27 Aug. 1902. He was graduated at Hudson College, Ohio, in 1844; studied law at Harvard, was admitted to the bar in 1847 and joined a law firm in Cincinnati of which Salmon P. Chase (q.v.) was the leading member. He was appointed judge of the superior court of Cincinnati in 1859, and re-elected in 1864. He took a leading part among the "Barnburners" (q.v.), was a War Democrat, and during the War joined the Republican party. He defeated Foraker in a contest for the governorship of Ohio in 1883, but failed of re-election in a struggle against the same candidate.

Hoadly, Benjamin, English Anglican prelate: b. Westerham, Kent, 14 Nov. 1676; d. Chelsea 17 April 1761. He was educated at Cambridge; took orders in 1700, and after being settled in London distinguished himself in controversy with Bishop Atterbury and others. A staunch Low-Churchman, he was appointed bishop of Bangor in 1715. A sermon preached before the king of 1717 gave rise to the "Bangorian Controversy" regarding the divine authority of the king and the church. He was translated to the see of Hereford in 1721, to Salisbury in 1723, and Winchester in 1734.

Hoang-ho. See HWANG OR HOANG-HO.

Hoar, Ebenezer Rockwood, American jurist: b. Concord, Mass., 21 Feb. 1816; d. there 31 Jan. 1895. He was the son of Samuel Hoar (q.v.), was graduated at Harvard (1835), and subsequently admitted to the bar. He rose to be judge of the court of common pleas (1849), judge of the State supreme court (1859), and attorney-general of the United States (1869), and was a member of the Joint High Commission that framed the Treaty of Washington (1873–5).

Hoar, George Frisbie, American statesman: b. Concord, Mass., 29 Aug. 1826; d. Worcester, Mass., 30 Sept. 1904. Senator Hoar's paternal and maternal inheritance was very remarkable. His grandfather was an officer in the Revolutionary army and his father, Samuel Hoar, was one of the ablest lawyers and statesmen of his time, a member of Congress from Massachusetts, and a man of great learning and force of character. Senator Hoar's mother was a daughter of Roger Sherman, a signer of the Declaration of Independence. He was graduated from Harvard in 1846, studied law there, and began his law practice in Worcester, Mass. The young man was early attracted to politics and identified himself with the Free Soil party, and his purpose in 1895 — so characteristic of his whole career — is thus stated by himself: "All of us Free Soilers were drawn into politics by a great issue. It

was to prevent slavery being extended into the new territory between the Mississippi and the Pacific. We were all ardent advocates of freedom. The party and the movement were new, and we were stirred by high ideals. Among the young men who went into the new movement at that time were my brother, Ebenezer Hoar, Erastus Hopkins, Anson Burlingame, Whittier, Lowell, Longfellow, and many others that became well known. There were no offices to gain. There was simply a cause to work for. In the campaign of 1850 the Free Soilers did not carry a single State, only a few Congressional districts.» He was a member of the Republican party from the first, and in 1852 was elected to the Massachusetts house of representatives; in 1857 to the State senate. In the intervals of service he practised law. In 1860 he was city solicitor. He presided over the Republican conventions in Massachusetts in 1871, 1877, 1882 and 1885; was a delegate to his party's national conventions in 1876, 1880 (the chairman in that year), 1884, 1888, 1892 and 1896. He served in the national House of Representatives for four successive Congresses, 1869–77, elected as a representative of the Worcester district; in 1877 he was elected to the Senate, and was re-elected in 1883, 1889, 1895, and 1901, serving his country continuously as a national legislator since 1869, having represented Massachusetts for a longer period in the national Congress than any other representative from that State. In 1876, he was one of the managers on behalf of the House in the Belknap impeachment trial, and was also a member of the Electoral Commission (q.v.), which decided the Hayes-Tilden contest for the Presidency, the other Republican members of that famous body being Senators George T. Edmunds, O. P. Morton and Frederick T. Frelinghuysen, and Representative James A. Garfield. In the Senate he was chairman of the judiciary committee, and of the committee on privileges and elections, and a member of other important committees. He was known as the old man eloquent of the Senate, having served in that body for 37 years and taken part in all the great questions that have been before the country during that time. He was a determined opponent of the retention of the Philippines, and independent enough to state his views fearlessly in the support of his own theory that the United States should leave the islands to the control of the Filipinos and prevent interference from foreign nations, but his honesty and sincerity were unquestioned and he always retained the confidence of his party and the respect of all. He was a thorough American and believed in the future of his country and placed its welfare above all personal considerations. «The lesson which I have learned in life, which has been impressed upon me daily and more deeply as I grow old,» he said in his autobiography, «is the lesson of Good Will and Good Hope. I believe that to-day is better than yesterday, and that to-morrow will be better than to-day. I believe that, in spite of many errors and wrongs, and even crimes, my countrymen of all classes desire what is good, and not what is evil.»

Senator Hoar was an idealist, and was not to be turned aside, even by his loyal love of party, from following his sincere convictions. He demanded justice for the negroes and the Indians, openly declared his sympathy for Cuban and Filipino, and as firmly opposed religious intolerance in Massachusetts because his actions were controlled by reasons which he considered were founded in righteousness and truth, and therefore not subject to change.

Senator Hoar was a man of considerable scholarship and took great delight in literary and historical studies. He was a member of several historical and scientific societies, and took much interest in their work. He was president of the American Historical Society, president of the American Antiquarian Society, regent of the Smithsonian Institution in 1880, and trustee of the Peabody Museum of Archæology. He received the degree of LL.D. from the College of William and Mary, Amherst, Yale and Harvard. In 1903 he published 'Autobiography of Seventy Years,' which first appeared in 'Scribner's Magazine' as a serial. The same year, in a speech in his home city of Worcester, Senator Hoar, as if in anticipation of his approaching dissolution, thus summed up the creed of his career:

«If my life has been worth anything, it has been because I have insisted, to the best of my ability, that these three things — love of God, love of country, and manhood — are the essential and fundamental things, and that race, color, and creed are unessential and accidental.»

Although 78 years of age, he was in good health until the death of his beloved wife in 1903; their devotion had led many to predict that neither would long survive the other. Senator Hoar was taken seriously ill in June 1904, but lingered until 30 September, when he died at Worcester, Mass.

His death was the occasion of a remarkable display of panegyric in the press of both Republican and Democratic parties. It possessed the peculiar quality of reconciliation, one party regretting what the other considered his noblest quality. The only flaws in his judgment, said the Republican press, were his disagreements with the party leaders on the Philippine and Panama issues; but to the Democratic press his noble loyalty to the right on these occasions was convincing proof of his lofty statesmanship. The Democratic press regretted his inability to see any good in their party, while to Republican journals this virtue redeemed his errors of judgment on the matters of party policy.

One journal said: «As long as the confidence and affection of all the people are given to such a man, it is foolish and false to assume that the old standards are departing and the old ideals becoming broken. The people still know a man when they see him. Still they respect and honor the statesman who loves the republic better than he does himself, who never falters in his service, to whose fingers gold does not cling, and whose never-forgotten ideal is the people's welfare. While they honor such qualities above all others, pure and able statesmen will continue to come to their service,» sentiments which were summarized in Ex-President Cleveland's statement that «Senator Hoar's ability, his high-mindedness, and his freedom from political trickery, furnish an example of a useful life which may well be imitated by all those entrusted by their countrymen with public duties.»

George Edwin Rines,
Editorial Staff 'Encyclopedia Americana.'

Hoar, Samuel, American lawyer and legislator: b. Lincoln, Mass., 1778; d. 1856. He was graduated at Harvard in 1802 and three years later entered upon a highly successful career as a lawyer. He served two terms as a State senator and was chosen by the Massachusetts legislature to challenge the constitutionality of certain laws in South Carolina relating to the imprisonment of free negroes. He was subsequently excluded from South Carolina courts by the State legislature.

Hoarhound. See HOREHOUND.

Ho'bart, Garret Augustus, American lawyer and politician: b. Long Branch, N. J., 1844; d. Paterson, N. J., 2 Nov. 1899. He was gradated at Rutgers College, New Jersey, in 1863, and admitted to the bar in 1866. At Paterson, where he made his home till his death, he enjoyed a successful law practice. He became successively city attorney, prosecuting attorney for Passaic County, a member of the State Assembly 1873–8, and of the State Senate 1879–85. During his several terms he was speaker of the Assembly and president of the Senate. In 1896 he was nominated at St. Louis for vice-president on the ticket with William McKinley, whose intimate friend he was, and was elected to that office.

Hobart, George Vere, American journalist, playwright, and author: b. Cape Breton, N. S., 16 Jan. 1867. He was educated in Nova Scotia, later coming to the United States as a telegraph operator for the United Press. He became editor of the Cumberland Sunday 'Scimitar,' later writing for the 'Herald,' *Evening News* and 'American' of Baltimore. Since then he has been writing for the Hearst newspapers the humorous sketches, 'John Henry' and 'Dinkelspiel.' He has written 'Many Moods and Many Meters' (1899), and 'Li'l Verses for Li'l Fellers' (1903), both poems; the 'Dinkelspiel' series (1900); the 'John Henry' books (1901–4), and the plays, 'After Office Hours,' 'Miss Print,' 'Hodge, Podge & Co.,' 'Sally in Our Alley,' etc.

Hobart, John Henry, American Protestant Episcopal bishop: b. Philadelphia 14 Sept. 1775; d. Auburn, N. Y., 10 Sept. 1830. He was educated at the College of Philadelphia (now the University of Pennsylvania), and the College of New Jersey (now Princeton), and after trying commercial life in his brother-in-law's counting house, went back to Princeton as a tutor for two years, and was ordained deacon in 1798 and priest in 1801. After brief periods of pastoral service in Pennsylvania, New Jersey, and Long Island, he became assistant in Trinity Parish, New York, where he remained until his elevation to the episcopate, combining with his other duties a prominent share in the legislative councils of the church, as deputy to the General Conventions of 1801 and 1804, and secretary to the House of Deputies in the latter year. In 1811 he was consecrated as bishop-coadjutor in the diocese of New York, and upon the death of Bishop Moore in 1816, succeeded him both in the full charge of the diocese and in the rectorship of Trinity Church. He also gave provisional episcopal care at different times to New Jersey and Connecticut. He was very active in promoting the establishment of the General Theological Seminary, and upon its location in New York became professor of pastoral theology. Hobart College also owed much to him, a debt recognized by the taking of his name, when, in 1852, the original title of Geneva College was changed to Hobart Free College. He wrote or edited a number of theological works, some of which, especially his 'Companion for the Festivals and Fasts' (1805), reached several editions. His 'Apology for Apostolic Order' (1802) is still used as a text-book.

Hobart, the capital of Tasmania, and up to 1881 called HOBART TOWN, is situated at the foot of Mount Wellington (4,166 feet high), on the Derwent River, 12 miles from its outlet in Storm Bay on the south coast. It has handsome public buildings, including government house, the government offices, parliament houses, Episcopal and Catholic cathedrals. There are important domestic manufactures, and in connection with its considerable shipping interests, a fine harbor with modern accommodations. Hobart is connected by rail with Launceston. Pop. (1903) 31,400.

Hobart College, a Protestant Episcopal institution, located at Geneva, N. Y. In 1825 it was chartered as Geneva College; but in 1852 the name was changed to Hobart Free College, and in 1860 to Hobart College. Bishop Hobart (q.v.) had aided the school by advice and by money. An endowment from Trinity Church, New York, had greatly assisted the institution. The college offers scholarships and prizes to worthy students, and the departments are all well sustained. The courses lead to the degrees of A.B., B.S., and Ph.B. There are about 44,000 volumes in the library. In 1904–5 the school had 17 professors and instructors and 105 students. The graduates number nearly 1,500. LANGDON C. STEWARDSON,
Registrar.

Hobart Pasha, AUGUSTUS CHARLES HOBART-HAMPDEN, third son of the Earl of Buckinghamshire, English sailor: b. Waltham-on-the-Wolds, Leicestershire, 1 April 1822; d. Milan, Italy, 19 June 1886. He entered the English navy as midshipman 1836 and retired as captain at the conclusion of the Crimean War in 1863. During the American Civil War he took the name of "CAPTAIN ROBERTS" and was given command of a blockade runner, an account of which is to be found in his 'Sketches of My Life' published posthumously. In 1867 he entered the Sultan's service, reorganized the Turkish navy, and fought the Russians on the Black Sea in the War of 1877–8. He was made Pasha (1869) and marshal of the Turkish Empire (1881).

Hobbema, Meindert, mīn'dĕrt hŏb'ĕ-mā, Dutch landscape painter: b. Amsterdam, 1638; d. there 7 Dec. 1709. He was considered, next to J. Ruysdaal, the best of the Dutch landscape-painters, and as a colorist reckoned even superior to Ruysdaal. The figures in his landscapes are painted mostly by Berchem, Van de Velde, Lingelbach, and J. Van Loo. His paintings consist chiefly of forest scenes, ruins, villages, etc. Some of the most celebrated works of this master are to be found in public or pri-

vate galleries in France, Germany and Holland. His greatest painting is 'A View in Holland,' with figures painted by Adrien van de Velde.

Hobbes, John Oliver. See CRAIGIE, PEARL MARY TERESA.

Hobbes, Thomas, English moral and political writer and philosopher: b. within the borough of Malmesbury, Wiltshire, 5 April 1588; d. Hardwicke, Derbyshire, 4 Dec. 1679. He was educated at Oxford, and resided several years in the Devonshire family as secretary to Lord Hardwicke. During this period Hobbes became acquainted with Lord Bacon (some of whose works he translated into Latin), Lord Herbert of Cherbury, and Ben Jonson. In 1642 first appeared his treatise 'De Cive.' His writings on mathematics are not important, yet he was employed to teach Prince Charles (afterwards Charles II.) the elements of mathematical philosophy. In 1650 was published a small treatise by Hobbes, entitled 'Human Nature'; and another, 'De Corpore Politico, or Elements of Law, Moral and Politick.' But the most remarkable of his works is his 'Leviathan, or the Matter, Form, and Power of a Commonwealth, ecclesiastical and civil' (1651). This greatly alarmed the ecclesiastics of those days, and drew on the author much literary hostility. In 1654 he published a 'Letter about Liberty and Necessity.' In 1658 appeared his 'Dissertation on Man,' which completed his philosophical system, a work containing some singular notions relative to the moral and intellectual faculties of the human species. After the Restoration Hobbes was favorably received by the king, who settled on him a pension of £100 a year out of his privy purse. In 1666 his 'Leviathan' was censured in Parliament, and a bill was introduced into the House of Commons to provide for the punishment of atheism and profaneness, which gave him great uneasiness. On this occasion, it is supposed, he composed his work, entitled a 'Historical Narration concerning Heresy and the Punishment thereof,' to show that he was not legally chargeable with heresy in writing and publishing his 'Leviathan.' His 'Decameron Physiologicum, or Ten Dialogues of Natural Philosophy,' was published in 1678; as was also a 'Dialogue between a Philosopher and a Student of the Common Law of England,' and in 1679 he consigned to the care of a bookseller his 'Behemoth, or a History of the Civil Wars from 1640 to 1660,' which did not appear till after his death. The first collected edition of his Latin works was published at Amsterdam in two vols. 4to, in 1668. His complete works, in Latin and English, were first published in the edition of Sir William Molesworth (1839–45).

Few authors have encountered more opposition than the philosopher of Malmesbury. Both with respect to religion and government he ascribes great weight to the will of the civil magistrate. And his sentiments on this point, together with his doctrine that a state of nature must be a state of perpetual hostility, in which brute force must supersede law and every other principle of action, have perhaps been most generally objected to. Yet his claim of obedience to existing authorities is qualified by the assertion that it is no longer due than while they can afford protection to the subject. He says expressly, '*Obligatio civium erga eum qui summam habet potestatem, tandem nec diutius permanere intelligitur, quam manet potentia cives protegendi.*' The philosophy of Hobbes, so depreciated among his contemporaries, was more or less adopted by Locke, Hartley, Hume, and Priestley.

Hob'ble-bush, a viburnum (*V. aluifolium*) of the southern interior of the United States, whose branches often stretch along the ground and root at the other end, tripping up the unwary; hence it has such other names as warfaring-tree, tanglefoot and devil's-shoestrings. See VIBURNUM.

Hobkirk's (hŏb'kĕrks) **Hill, Battle of,** in the Revolution, 25 April 1781. After Guilford Court-house (q.v.), Greene marched toward the British position at Camden under Rawdon, and encamped at Hobkirk's Hill, about 1½ miles north. He had 940 men in line, prudently encamping in order of battle; and some militia just arrived who took no part in the battle. His trains and artillery had not come up, and a renegade drummer boy informing Rawdon of this, the latter took 960 men, and making a detour to the right through the woods in front of Greene, drove in Greene's pickets with so sudden an onslaught that the Americans had barely time to form. Greene ordered the First Maryland to charge bayonets and William Washington to take the British in the rear with his cavalry, while Ford and Campbell executed flanking movements on Rawdon's wings. But Ford was killed, one of the First Maryland's captains was shot, the men fell into disorder, and Col. Gunby ordered the regiment to form on the rear companies instead of moving the latter forward; the retiring men were seized with a panic, the famous veterans broke, and though soon re-formed, the position was dangerous and Greene had to retreat. Gunby was court-martialed, but acquitted of anything but grave misjudgment. Greene's loss was 135, besides missing militia; Rawdon's 220 (his own figure) or 258 (Tarleton's).

Hoboken, hō'bō-kĕn, N. J., city in Hudson County; on the Hudson River. It is the terminus of the Delaware, L. & W. R.R. It is opposite New York city, north of and adjoining Jersey City, and has on the north and west the Palisades. Its area is about one square mile. It has electric railway connections with a number of the cities and towns of the State, and by direct ferries with the business district of New York. The principal streets run north and south, nearly parallel with the river. Its long waterfront gives it excellent shipping facilities; and here are located the docks of the ocean steamship lines; the North German Lloyd, the Thingvalla, the Netherlands-American, and the Hamburg-American. The land upon which Hoboken is located as well as much of that adjoining, once formed a part of the territory of New Netherlands. It was early known as Hobocan Hacking, which means "the land of the tobacco-pipe." The tobacco-pipes which were made by the Indians from the stone found in the vicinity gave rise to the name. In 1630 Michael Pauw, of Holland, purchased from the New Netherlands Company a tract of land a part of which is the site of the present city of Hoboken. The land around was soon cultivated and as New Amsterdam grew in numbers and importance, the gardens across the river became

more valuable. John Stevens (q.v.), in 1804, purchased the land upon which the city now stands, and began the town. At this time and for some years after the Elysian Fields of Hoboken were much used as pleasure grounds by New Yorkers. At first Hoboken was a part of the town of North Bergen, but on 28 March 1855 it was incorporated as a city. The disastrous fire at the wharves of the North German Lloyd Steamship Company, which occurred in 1900, destroyed considerable of the city property and three steamers. The estimated number of lives lost was 200. The chief manufactures of Hoboken are iron products, leather, silk, lead-pencils, caskets, wall-paper, beer, shipbuilding and repairing, and chemicals. It has extensive coal yards, and large lumber and brick yards. The drainage of the lowlands is now (1903) under consideration, and by this means a large tract of land will be reclaimed and the sanitary conditions of the city improved. The city is the seat of the Stevens Institute of Technology (q.v.), and of the Sacred Heart Academy. It has Saint Mary's hospital, public and parish schools, and several fine church buildings. The government is vested in a mayor, who holds office two years, and a city council. The mayor appoints the school, library, fire, and health commissioners, also the assessors. The police commissioners are appointed by the mayor and approved by the council. The council elects the inspectors, the city clerk and his assistants. Pop. (1890) 43,648; (1900) 59,364; (1905) about 65,000.

Hob'son, John Atkinson, English social economist: b. Derby, England, 6 July 1858. He was graduated at Oxford University, and from 1887 to 1897 taught English literature and economics for the University Extension Delegacy, and the London Society for the Extension of University teaching. He is one of the foremost of economic writers in England and, as a socialist, advocates the monopolistic control of industries by government, whether municipal, or national. Among his works are 'The Physiology of Industry: Being an Exposure of Certain Fallacies in Existing Theories of Economics' (with A. F. Mummery, 1889); 'The Evolution of Modern Capitalism' (1894); 'The Social Problem: Life and Work' (1901); and 'Imperialism' (1902).

Hobson, Richmond Pearson, American naval constructor: b. Greensboro, Ala., 17 Aug. 1870. He was graduated at Annapolis Naval Academy in 1889 and took a post-graduate course at the Ecole Nationale Supérieure des Mines, and the Ecole d'Application du Gènie Maritime in Paris. During the war with Spain he was present at the bombardment of Matanzas and distinguished himself by his heroism in sinking a collier across the entrance to Santiago Harbor, on the night of 3 July 1898, for the purpose of preventing the exit of Cervera's fleet. He resigned from the navy in 1903.

Hobson's Choice, a proverbial expression, denoting "without an alternative." It is said to have had its origin in the practice of Hobson, a carrier at Cambridge, England, in Milton's time, who let horses to the students, and obliged his customers to take the horses in rotation, that they might be worked equally. Milton wrote two epitaphs upon him.

Hoche, Lazare, lä-zär ōsh, French soldier: b. Montreuil 25 June 1768; d. Wetzler 19 Sept. 1797. He took service in the French guards when 16 years old, and at the revolution joined the popular party. He greatly distinguished himself at the siege of Thionville and the defence of Dunkirk, and shortly afterwards, when scarcely 25 years of age, received the command of the army on the Moselle. In 1793 he drove the Austrians out of Alsace, and soon after was arrested by the Jacobins and imprisoned at Paris. In 1794 he was released, and appointed commander of the army destined to quell the rising in the west, and afterwards to that in La Vendée. In 1796 he conceived the plan of attacking Britain, and making a descent on Ireland, but expired suddenly while in camp with his army of invasion.

Hockey, a game of ball known as hurley in Ireland and shinty in Scotland, dating in its present form from about 1883, when a definite code of rules was drawn up by the Wimbledon Club. According to standard rules the game is played between two teams of 11 players each, on a ground 100 yards long by 50 to 60 yards wide. A goal is erected at each end of the field, and consists of two uprights 12 feet apart supporting a horizontal bar 7 feet from the ground. In front of each goal a line 12 feet long is drawn parallel to the goal-line and 15 yards from it; and from each end of this line, with the corresponding goal-post as centre, a segment of a circle is drawn outwards to meet the goal-line. Thus, a kind of semicircle flattened at the top is drawn in front of each goal, and no goal is scored unless the ball is hit from within this line or striking-circle. The ball used is an ordinary cricket ball painted white; and each player is provided with a stick, curved at the end, without any metal fittings, and not too thick to be passed through a ring two inches in diameter. The players are arranged on the field as in Association football, namely, goal-keeper, two backs, three half-backs, five forwards. The game is started by one player of each side bullying the ball in the centre of the ground, that is, by first striking the ground with his stick and then striking his opponent's stick three times, after which either may strike the ball. When the ball is driven between the goal-posts under the bar by a stroke from within the striking-circle, a goal is scored, and the game is won by the side with a majority of goals scored. The ball may be caught or stopped with any port of the body, but it must not be carried, kicked, or knocked on except with the stick; it must be played from right to left only. The goal-keeper is allowed to kick the ball away in defending his goal. Ends are changed at half-time.

Hock'ing, Joseph, English nonconformist clergyman and novelist: b. St. Stephens, Cornwall, 1859. He was educated at Owens College, Manchester, and entered the nonconformist ministry in 1884. Among his many published books are: 'Story of Andrew Fairfax' (1903); 'The Scarlet Woman' (1899); 'The Purple Robe' (1900); 'The Madness of David Baring' (1900); 'Greater Love' (1901); 'Lest We Forget' (1901). He is a brother of S. K. Hocking (q.v.).

Hocking, Silas Kitto, English Methodist clergyman and novelist: b. St. Stephen's, Corn-

wall, 24 March 1850. He was ordained a minister in the Methodist Free Church in 1870, and after holding pastorates in Liverpool, Manchester, and elsewhere, resigned from the ministry in 1896. He is a prolific writer and several of his books have been much read in America. Among them may be named 'Alec Green' (1878); 'For Light and Liberty' (1890); 'One in Charity' (1893); 'A Son of Reuben' (1894); 'God's Outcast' (1898); 'The Awakening of Anthony Weir' (1901) 'Gripped' (1902).

Hocking River, a stream which has its rise in Fairfield County, Ohio, and flows southeast into the Ohio River. The whole length is about 80 miles; it is navigable for about 70 miles. Along the shore, in the upper part of the course, is the Hocking Canal.

Hocking Valley Railway Company, The. The Mineral Railroad Company was incorporated 14th April 1864, to build a railroad from Columbus to Athens, Ohio, but beyond making preliminary surveys and securing some rights of way, nothing was done toward the construction of the line. Mr. M. M. Greene, who was operating salt works at Salina (now Beaumont), Ohio, in the Hocking Valley, seven miles north of Athens, in 1867, took up the project, and on 26 June of that year, by decree of the Franklin County Common Pleas Court, the name was changed from Mineral Railroad Company to Columbus & Hocking Valley Railroad Company. In 1868 the line was opened for traffic from Columbus to Lancaster, and in 1869 was completed as far as Nelsonville, where it reached the coal field.

Construction was finished 25 July 1870, to Athens with a branch from Logan to Straitsville, in the coal district. The annual report of the president for the year 1870 stated: "That the company owned 12 locomotives, eight passenger cars, three baggage cars, 279 coal, 60 box, and 26 flat cars, in addition to which, private parties furnished 403 coal cars, and that with all this equipment, together with 150 other cars furnished by connecting lines, the company was unable to supply the demand for coal and would have to provide more coal cars." The gross earnings of the line for 1870 amounted to $372,229.

In the year 1871, the gross earnings increased to $548,942 and the president's report for that year stated that a valuable trade for coal had been commenced through Cleveland to points on the Lakes. The report further stated that the heavy traffic made it necessary to renew some of the rails, and that, in order to have a test between iron and steel, 50 tons of steel rails were purchased as an experiment and laid in sidings in Columbus yard under the heaviest wear of any part of the road.

The coal business of the line developed rapidly, the gross earnings for the year 1872 being $854,892. The company trebled its number of coal cars and began to feel the need of proper outlets for traffic to points beyond Columbus, connecting lines being either unable or unwilling to furnish cars for the business offered their lines. It was thereupon determined to undertake the construction of a line to supply the great demand of the Lakes and the Northwest for Hocking Valley coal, and Toledo was selected as the most appropriate port. Accordingly on 28 May 1872, the Columbus & Toledo Railroad Company was incorporated by M. M. Greene, P. W. Huntington, B. E. Smith, W. G. Deshler, James A. Wilcox, and John L. Gill, and a preliminary survey was at once made.

The line was permanently located from Columbus to Toledo on 15 Oct. 1873. The financial panic of 1874, however, made it necessary to defer for nearly a year the construction, which was commenced 17 Aug. 1875; on 15 Oct. 1876, the line from Columbus to Marion was opened for traffic, and on 10 Jan. 1877, the first regular train ran through to Toledo, where the company had acquired valuable frontage on the Maumee river for the construction of docks.

The Columbus & Hocking Valley and Columbus & Toledo Railroad companies entered into a contract 22 Feb. 1877, providing for the joint management of the two lines and for the joint use of terminal property and facilities in Columbus.

During the year 1877, extensive docks were constructed at Toledo, and connecting lines at Toledo furnished an outlet to points in Michigan and Canada. In the meantime, the Columbus & Hocking Valley Railroad had continued to prosper. In 1877, the Monday Creek and Snow Fork branches in the coal field were partially constructed and opened and seven iron furnaces were in blast in the coal region.

The Ohio & West Virginia Railway was incorporated 21 May 1878, to build from Logan, in the Hocking Valley, to Gallipolis, on the Ohio river, and some little grading was done upon this line, but no further progress was made until one year later, 21 May 1879, when Hocking Valley interests took up the project, amended the charter to extend from Gallipolis to Pomeroy, and commenced construction. The line was opened for traffic 15 Oct. 1880, from Logan to Gallipolis, and 1 Jan. 1881, to Pomeroy.

The Columbus & Hocking Valley, and Columbus & Toledo Railroad companies, and The Ohio & West Virginia Railway Company were consolidated 20 Aug. 1881, under the name of the Columbus, Hocking Valley & Toledo Railway Company.

In 1895, the Wellston & Jackson Belt Railway was built by the Hocking Valley Company from McArthur Junction to Jackson, through the Jackson County coal field, affording a valuable feeder to the line, and was opened for traffic to Wellston 1 Dec. 1895, and to Jackson 10 Feb. 1896.

During the past few years radical improvements have been made in the capacity of the line for handling traffic; 40 ton coal cars to the number of nearly 6,000 have been added to the equipment, mogul freight engines have been superseded by consolidation engines of greater capacity, making a large increase in the loading of freight trains; improved machinery for handling coal and iron ore has been placed on the company's docks at Toledo, and the yards, sidings, and station facilities of the line have been increased to take care of the constantly growing traffic.

Of the five seams of bituminous coal mined in the State of Ohio, four are to be found on the line of the Hocking Valley Railway, and through its connection with the Kanawha & Michigan Railway at Athens it also receives shipments of coal and coke from the Kanawha

& New River districts of West Virginia. Through its control of dock facilities at various points on the Great Lakes it has been enabled to transport coal for shipment by lake to the amount of nearly 2,000,000 tons during the navigation season of the year 1904.

The Hocking Valley is the longest line of railway entirely within the limits of the State of Ohio, and occupies a central position from the Ohio river to Lake Erie, passing through the capital, with branches in the populous regions of the coal fields. In 1905 the total mileage of the Hocking Valley Railway was 344.7, made up as follows: Toledo to Pomeroy, 256.8 miles; Athens branch, 26.9 miles; Jackson branch, 17.3 miles; other branches, 43.7 miles. For the year ending 30 June 1905, the gross earnings were $6,013,214. The operating expenses were $4,067,901, thus showing net earnings of $1,945,313, which with other income of $382,230 shows the total net income of the company for that year, $2,327,543.

F. B. Sheldon,
Assistant to President.

Hodder, Alfred, American author: b. Celina, Ohio, 18 Sept. 1866. In 1886–9 he read law in the office of Senator Teller, in 1889 was admitted to the bar at Denver, Colo., studied in the Harvard graduate school in 1890–1, and was Morgan fellow there 1891–2. He was for a time lecturer in English literature and drama at Bryn Mawr College, contributed extensively to the New York 'Nation,' and published 'The Powers that Prey' (with Josiah Flynt, 1900), a collection of stories of the criminal classes, and 'The Specious Present' (1901), a metaphysical treatise.

Hodge, Archibald Alexander, American Presbyterian divine: b. Princeton, N. J., 18 July 1823; d. Princeton 11 Nov. 1886. He was the son of Charles Hodge (q.v.) and was graduated at Princeton College 1841, where he became assistant professor. In 1847 after graduation in the Theological Seminary of the same place he went to Allahabad, India, as a missionary. He stayed in Asia for three years and returning home held pastoral charges in Maryland, Virginia, and Pennsylvania until 1877, when he became his father's assistant at Princeton Seminary, succeeding in 1878 to the chair of didactic and exegetical theology made vacant by his father's death. Among his works the most important are 'Outlines of Theology' (1879); 'The Atonement' (1886).

Hodge, Charles, American Presbyterian theologian: b. Philadelphia 28 Dec. 1797; d. Princeton, N. J., 19 June 1878. He was educated in Princeton College, graduating in 1815. In 1816–19 he studied in the theological seminary at Princeton, in 1820 was appointed instructor there, and two years later made professor of Oriental and biblical literature. In 1840 he was transferred to the chair of didactic and exegetical theology in the seminary, and 12 years afterwards appointed to the additional chair of polemical theology. In 1825 he founded the 'Biblical Repertory,' afterwards was renamed 'Biblical Repertory and Princeton Review,' and merged in 1872 in the 'Presbyterian Quarterly and American Theological Review.' From the foundation till 1872 he was editor of and chief contributor to the 'Review,' and two of his works, 'Princeton Theological Essays' (1846–7); and 'Essays and Reviews' (1857), were compiled from his numerous articles in that periodical. Other works are: 'Commentary on the Epistle to the Romans' (1855; enlarged, 1866); 'Constitutional History of the Presbyterian Church in the United States' (1840–41); 'The Way of Life' (1842); 'Systematic Theology' (1871–2), a comprehensive treatise giving an exposition of Calvinistic theology; and 'What is Darwinism?' (1874).

Hodge, Frederick Webb, American ethnologist: b. Plymouth, England, 28 Oct. 1864. He was brought to this country at the age of seven years, and was educated at Washington, D. C. In 1884 he received appointment to the United States Geological Survey, in 1886 became secretary of the Southern Archæological Expedition, and in 1889, was appointed to the Bureau of Ethnology, Smithsonian Institution. He has written various papers on the Indians of the southwest.

Hodge, John Aspinwall, American Presbyterian theologian: b. Philadelphia, Pa., 12 Aug. 1831. He was graduated from the University of Pennsylvania (1851) and from Princeton Theological Seminary (1856). After 35 years of pastoral work he was appointed in 1893 professor of biblical instruction and church polity in Lincoln University. Among his works are 'What is Presbyterian Law?' (1882); 'Theology of the Shorter Catechism' (1888); 'The Ruling Elder at Work' (1897).

Hodges, George, American Episcopal clergyman: b. Rome, N. Y., 6 Oct. 1856. He was graduated from Hamilton College, Clinton, N. Y., in 1877, and from the Berkeley Divinity School, Middletown, Conn., in 1881. He was assistant rector of Calvary Church, Pittsburg, Pa., 1881–9, and rector 1889–94, in the year last named becoming dean of the Episcopal Theological School in Cambridge, Mass. He has published among other works: 'Christianity Between Sundays' (1892); 'The Heresy of Cain' (1894); 'In the Present World' (1896); 'Faith and Social Service' (1896); 'The Battles of Peace' (1897); 'The Path of Life' (1897); 'William Penn' (1900). He is one of the most prominent members of the Low Broad Church School in the Episcopal Church.

Hodgetts, hŏj'ĕts, **Edward Arthur Brayley,** English journalist: b. Berlin, Germany, 12 June 1859. He has been connected with several influential London journals in the capacity of correspondent and was foreign editor of the New York *World* in 1894. Among his published books are 'Liquid Fuel' (1890); 'Round About Armenia' (1896); 'A Russian Wild Flower' (1897); and a translation of 'The Swiss Family Robinson' (1897).

Hodgkin, hŏj'kĭn, **Thomas,** English historian and banker: b. Tottenham, Middlesex, 29 July 1831. He has been for many years the senior partner in a banking firm at Newcastle-on-Tyne, but since 1874 has given his time to historical writing. He has published 'Italy and her Invaders,' a work of much importance, of which eight volumes have already appeared (1880–99); 'Dynasty of Theodosius' (1889); 'Life of George Fox' (1896); 'Life of Charles the Great' (1897); etc.

Hodgkin's Disease. See PSEUDOLEUCÆMIA.

Hodgkinson, hŏj'kĭn-sŏn, **Eaton,** English engineer: b. Anderton, Cheshire, 1789; d. 1861. After a somewhat desultory education, and the pursuit of independent investigations in mechanics he was appointed in 1847 professor of the mechanical principles of engineering at University College, London. He was one of the royal commission appointed in 1847 to inquire into the application of iron in railroad building. His principal experiments led him to the determination of the "neutral line" in the section of fracture, an important step in the progress of engineering science. Among his many writings is 'Researches on the Strength and Other Properties of Cast Iron' (1846).

Hodgson, hŏj'sŏn, **Shadworth Hollway,** English metaphysician: b. Boston, Lincolnshire, 25 Dec. 1832. He was educated at Rugby and Oxford and is the author of 'Time and Space' (1865); 'Principles of Reform in the Suffrage' (1866); 'The Theory of Practice' (1870); 'The Philosophy of Reflection' (1878); 'The Metaphysic of Experience' (1898); etc.

Hodograph, hŏd'ō-grăf, the term for a velocity diagram which facilitates the study of kinematics. It signifies the curve along which the extremities of lines drawn from a fixed point pass and exhibit in direction and magnitude the velocities of a moving object at the different points of its orbit or path.

Hoe, Richard Marsh, American inventor: b. New York 12 Sept. 1812; d. Florence, Italy, 7 June 1886. He was the son of Robert Hoe (q.v.). In 1846 with his brother Peter S. he perfected a rotary printing-press which was called "Hoe's lightning press." Subsequently the two brothers invented the Hoe web-perfecting press. These were especially adapted to newspaper printing and made a revolution in that art. The sons of Richard M. Hoe and of Peter S. Hoe conducted the business after the death of the brothers, and added various improvements to the original Hoe printing-press. The factory in New York in 1903 was said to be the largest printing-press works in the world.

Hoe, Robert, American inventor: b. Leicestershire, England, 1784; d. 1833. He came to the United States in 1803, was for a time a joiner, and later entered partnership with his brothers-in-law, Matthew and Peter Smith, for the sale of a hand printing-press, the invention of the latter. He took over the business in 1823. The original Hoe printing-press was designed and built by him.

Hoe, Robert, American manufacturer: b. 1839. He is a nephew of Richard M. Hoe (q.v.). He became the head of the Hoe firm, and maintained its high position among establishments of its class. A founder of the Grolier Club of New York, he was also its first president. He published an edition (1880) of Maberley's 'Print Collector.'

Hoe'ber, Arthur, American artist: b. New York 23 July 1854. He studied under Beckwith in New York and under Gérôme at the Ecole des Beaux Arts, exhibited for the first time at the Salon in 1882, and is a contributor to most American exhibitions. He is art critic to the *Commercial Advertiser.* Among his writings are 'Treasures of the Metropolitan Museum of Art'; and 'Painting in the 19th Century in France, Belgium, Spain and Italy.'

Hoey, Frances Sarah Johnston, Irish novelist: b. near Dublin 1830. She was married to A. M. Stewart in 1846, and to John Cashel Hoey in 1858. Among her books, which have circulated in America as well as in England, are: 'A House of Cards'; 'A Golden Sorrow'; 'No Sign'; 'A Stern Chase'; 'His Match and More.'

Hofer, hō'fĕr, **Andreas,** Tyrolese patriot: b. Sankt Leonhard 22 Nov. 1767; d. Mantua 20 Feb. 1810. He was landlord of the inn "Am Sand" at Sankt Leonhard, and hence often known as "Sandwirt." In 1796 he led a rifle company against the French on Lake Garda, and after the Peace of Lunéville was prominent in the organization of the Tyrol militia. In 1809 he led in an insurrection of the Tyrolese for shaking off the yoke of Bavaria, to which their country had been transferred by the Treaty of Presburg. In a short time, with intermittent assistance from the Austrians, he defeated the French and Bavarian troops, and nearly the whole country was liberated. Hofer then carried on the military and civil administration, till the Peace of Vienna was proclaimed. Misled by false reports he commenced hostilities anew, and thus forfeited the protection of the amnesty. He remained concealed for some time, but was at last betrayed to the French, and carried to Mantua, where he was tried by a court-martial and shot. His family was indemnified for the loss of their property by the Emperor of Austria in 1819, and his son ennobled. The career of Hofer furnished material for tragedies by Immermann and Auerbach. Consult the studies by Heigel (1874) and Stampfer (1891).

Hoff, hŏf, **William Bainbridge,** American naval officer: b. Philadelphia, 1846; d. Washington, D. C., 23 May 1903. He entered the naval service in 1860, and in 1863 was graduated from the Naval Academy. He took part in several naval campaigns during the Civil War, and at the torpedo school and on the United States steamship Dale he gave his attention to the instruction of seamen in gunnery. In 1893 he was marine commissioner to Great Britain for the World's Fair at Chicago, and was retired in 1897. He was the author of 'Elementary Naval Tactics'; and 'Avoidance of Collisions at Sea.'

Hoffman, hŏf'măn, **Charles Fenno,** American poet and novelist: b. New York 1806; d. Harrisburg, Pa., 7 June 1884. He entered Columbia College, and studied law at Albany, being called to the bar in 1827. In 1830 he became joint-editor of a New York journal, and three years later started the 'Knickerbocker Magazine.' For many years he edited the 'American Monthly Magazine,' also. In 1849 his mind began to give way, and from that time till his death he was an inmate of Harrisburg lunatic asylum. His first separate publication was 'A Winter in the West' (1835), followed in 1837 by 'Wild Scenes in Forest and Prairie,' and in 1840 by the novel 'Greyslaer: a Romance of the Mohawk,' which met with immediate and remarkable success. An earlier novel, 'Vanderlyn,' appeared in the 'American Monthly Magazine' during 1837. Several of his songs have

gained great popularity. His published volumes of verse include: 'The Vigil of Faith' (1842); 'The Echo' (1844); 'Lays of the Hudson, and other Poems' (1846); 'Love's Calendar, and other Poems' (1848).

Hoffman, Eugene Augustus, American Episcopal clergyman: b. New York *21* March 1829; d. near Plattsburg, N. Y., 17 June 1902. He was educated at Rutgers and Harvard colleges and at the General Theological Seminary. He held successive rectorships at Elizabeth, N. J., Burlington, N. J., Brooklyn, N. Y., and Philadelphia, and in 1879 was appointed dean of the General Theological Seminary, New York, and with others of his family, heavily endowed that institution. Dean Hoffman built Christ Church and rectory at Elizabeth, N. J., and also churches at Woodbridge and Milburn, N. J. He was the author of 'Free Churches' (1858); and 'The Eucharistic Week' (1859 and 1893).

Hoffman, Murray, American jurist: b. New York 29 Sept. 1791; d. Flushing, L. I., 7 May 1878. He graduated from Columbia College in 1809; was admitted to the bar, became assistant vice-chancellor of the superior court of New York in 1839, serving till 1843, and was elected judge in 1853, holding that position for eight years. He wrote: 'Office and Duties of Masters in Chancery and Practice in the Master's Office' (1824); 'A Treatise on the Practice in the Court of Chancery,' in three volumes (1834–40); 'Reports of Cases, Court of Chancery' (1839–40); several treatises on Church Law and numerous other works.

Hoffman, Richard, American pianist and composer: b. Manchester, England, 24 May 1831. He came to New York in his 16th year. He received early instruction from Rubinstein, Liszt, Thalberg, Döbler and Meyer. After his arrival in America he made a tour of the country as a soloist, and later accompanied Jenny Lind on her tours; he also played with Gottschalk and Von Bülow in New York in 1875. Later he became an important figure in American musical life. He has composed music for the piano, songs, anthems, ballads and church music.

Hoffman, William M., American inventor: b. Buffalo, N. Y., 1853. He received only a limited education and began to earn his living when nine years of age. He prospered until he was 20, when misfortune overtook him and he became a fireman on the Erie Railroad. The clumsiness in the action of the piston rod which runs to the driving-wheels of an engine, involving such a waste of power, attracted his attention and decided him to build an engine in which there should be no such starting and stopping, but in which the power should create a direct rotary movement. He studied for eight years the technical branches of engineering, and at the end of this period became chief engineer of a large tannery in Buffalo. He there invented a new set of "fleshing" and "putting out" machinery for use in a tannery, and sold the invention to obtain funds with which to experiment on his engine. He went to Detroit in 1886 and organized a company to produce his engines. He spent the first funds in experiments, and built five models, all of which refused to stir when connected up, nor were they in any way operative. In the winter of 1898–9 he went to Buffalo, there producing No. 6, which was a partial success. It was of a type in which the piston revolved in the cylinder, and showed a great advance over his previous models in control and speed and in sustaining varying loads. The internal friction made in this "annular cylinder" type was too great, and he set out to lessen it or do away with it altogether. Hoffman worked day and night, and when exhausted would ride on a trolley car all over the city till his brain became clear again, then would go back to work. It was on one of these rides that he thought out the principle which, with a few perfections, achieved the long-sought end. Hoffman thought that if the piston would not revolve inside the cylinder, the cylinder might revolve around the piston, and he immediately designed an engine in which the cylinder revolved around the eccentric abutment by introducing radial wings extending from the shell toward and against the stationary eccentric core. This engine, though proved by actual test of 18 months to be a success, was such a disappointment to Hoffman that he mortgaged all his property and returned the money which he had borrowed from financiers in August 1902 to further his investigations. Hoffman's son Bertram and Randl Riehl then joined him, and together, in July 1904 they brought out a 28 h.p. engine which was put into operation in the basement of the Ellicott Square Building in Buffalo and which has proved a success. He then made a twelfth and last design in a 300 h.p. compound engine, which is the largest of its type ever built and which, it is claimed, shows an economy of 33 per cent and a saving in floor space of 80 per cent as compared with the highest type of reciprocating engine, while the friction load has been reduced to 1.1 per cent. All of Hoffman's patents have now been merged into one company, of which he is president.

Hoffmann, August Heinrich, ow'goost hīn'-rih höf'män, usually known as HOFFMANN VON FALLERSLEBEN, German poet and philologist: b. Fallersleben, Hanover, *2* April 1798; d. Corvei 19 Jan. 1874. He studied at Göttingen and Bonn, was appointed in 1823 custodian of the university library at Breslau, and in 1830 became extraordinary, in 1835 ordinary professor of the German language and literature in the university of that city. He resigned his librarianship at Breslau in 1838, and in 1842 was removed from his chair without a pension because of the liberal political views represented in his 'Unpolitsche Lieder' (1840–1). He led a wandering life till 1845, when he obtained the right of domicile in Mecklenburg. In 1848 he was granted a pension by the Prussian government, and from 1860 he was librarian to the Duke of Ratibor. Of his original writings the best known are his songs, not a few of which, especially that beginning 'Deutschland, Deutschland über Alles' (1841), have long received emphatic popular approval. For several of them he composed tunes. They were published in several volumes, among these being: 'Gedichte' (1827); 'Alemannische Lieder' (1827); 'Hundert Schullieder' (1848); 'Deutsches Volksgesangbuch' (1848); 'Soldatenlieder' (1851); 'Kinderwelt in Liedern,' and 'Alte und Neue Kinderlieder' (1873). A complete edition of his 'Kinderlieder' was prepared by von Donop in

1877. 'Mein Leben' (1868; abridged edition continued to his death, by Gerstenberg, 1892-4), is autobiographical. Consult also the 'Life' by Wagner (1869).

Hoffmann, Heinrich, German painter: b. Frankfort-on-the-Main, 18 Oct. 1814. Beginning life as a room decorator, in 1843, he adopted landscape painting as his profession and studied under Jacob Becker with that end. Long wanderings and careful studies of nature in the Taunus Mountains, in Obenwald, and the Black Forest, as well as in the valleys of the Rhine and Mosel, were followed by extensive travels in Switzerland and the Tyrol. The results of this preparatory training appeared in his first large canvas in which the old romantic spirit was blent with an independent and realistic presentation of nature which at once attracted public attention. He has produced numberless Alpine and forest landscapes, moonlight and street scenes, most of which are in private collections at Frankfort.

Hofmann, August Wilhelm, von, German chemist: b. Giessen 8 April 1818; d. Berlin 5 May 1892. He studied law, obtained the degree of doctor of philosophy, became assistant under Liebig in the Giessen Laboratory, and in 1845 became professor of chemistry in the University of Bonn. The same year he was appointed superintendent of the new Royal College of Chemistry in London, and in 1853 became professor of chemistry in the Royal School of Mines, though still remaining at the head of the College of Chemistry. In 1861 he was elected president of the London Chemical Society, and in 1863 was appointed to the chair of chemistry in the University of Berlin, where he remained till his death. In 1864 he built a laboratory at Bonn and became its director, and in 1868 founded the German Chemical Society. He was judge of several industrial expositions and was a member of many scientific societies, and for his valuable services was ennobled in 1888. A statue of him is in the National Gallery of Berlin. He wrote: 'A Handbook of Organic Analysis' (1853); 'Introduction to Modern Chemistry' (1865); 'Zur Errinnerung an vorangegangene Freunde' (1889); etc.

Hofmann, Heinrich, German painter: b. Darmstadt 19 March 1824. In his native town he began his studies as a copper-plate engraver, but subsequently under Schadow and Hildebrande turned his attention to painting, to which henceforth he devoted his life. After extensive travels in Europe, which included a residence of four years in Italy, he settled at Dresden as professor of painting in the Academy there. The most famous of his pictures are: 'The Burial of Christ'; 'King Enzio in Prison'; 'The Betrayal of Christ,' in the Darmstadt Gallery; 'The Finding of Christ in the Temple,' in the Dresden Gallery; 'Christ Preaching on the Lake,' in the Berlin National Gallery; 'Venus and Cupid'; 'Romeo and Juliet'; 'Othello and Desdemona'; and 'Christ in Gethsemane.' All the creations of Hofmann testify to his sense of refined beauty and are rather remarkable for harmonious coloring and delicacy than for originality of design or composition, as he clings to the tradition of the classic period in the ideal character of his conceptions. His works are popular and have been engraved and photographed more extensively perhaps than those of any contemporary German painter of his order.

Hofmann, Josef, yō'sĕf, Polish pianist: b. Cracow 20 Jan. 1877. He studied with his father, a professor in the Warsaw Conservatory and director of the Warsaw opera, appeared as a pianist in public at the age of six, became known as one of the most notable of musical prodigies, visited the United States in 1887-8, and was there prevented from playing through the action of the Society for the Prevention of Cruelty to Children. After a period of study, two years of which were spent as a pupil of Rubinstein, he made his début as a virtuoso at Dresden in 1894. His recitals in New York in 1901 showed him to be one of the leading modern pianists. His compositions include some interesting works for the pianoforte.

Hog-feeding. See NUTRITION OF FARM ANIMALS.

Ho'gan, John Joseph, American Roman Catholic bishop: b. Bruff, County Limerick, Ireland, 10 May 1829. He came to St. Louis, Mo., in 1848, studied at the Roman Catholic theological seminary there, was ordained priest in 1852, and built and became pastor of St. Michael's Church of St. Louis. In 1868 he was consecrated bishop of St. Joseph, Mo., and in 1880 was transferred to the see of Kansas City.

Hogarth, hō'gärth, **David George,** English archæologist: b. Barton-on-Humber, Lincolnshire, 23 May 1862. He was educated at Oxford and has since conducted excavations at Paphos, Alexandria, Fayum and elsewhere in the East. He was director of the British School at Athens 1897–1900 and has published: 'Devia Cypria' (1890); 'Modern and Ancient Roads in Asia Minor' (1892); 'A Wandering Scholar in the Levant' (1896); 'Philip and Alexander of Macedon' (1897); 'The Nearer East' (1902).

Hogarth, William, English painter and engraver: b. London 10 Nov. 1697; d. there 25 Oct. 1764. He studied art at Sir James Thornhill's school, James Street, Covent Garden. About 1720 he set up for himself, and designed plates for booksellers, the chief of which are the illustrations to Gray's edition of 'Hudibras' (1726). He had ample employment for what are called "conversation pieces," that is, groups of family portraits, united by some common occupation or interest, but never cared greatly for this branch of art. In March 1729 he married clandestinely the daughter of Sir James Thornhill, and shortly afterward began to display his extraordinary faculty for depicting the vices and follies of his time. In 1730–1 he painted 'A Harlot's Progress,' a series of six pictures, like many of his other works, engraved by himself. It was published in April 1732. The 'Harlot's Progress' was followed by other satiric delineations, such as 'A Midnight Modern Conversation' (1734), 'Southwark Fair' (1735), 'A Rake's Progress' (1735), 'The Distressed Poet' (1736), 'The Four Times of the Day,' and the 'Strolling Actresses Dressing in a Barn' (1738). With less success he also produced the large canvases still in St. Bartholomew's Hospital — the 'Pool of Bethesda' and the 'Good Samaritan,' both executed in 1736; and also painted several portraits. The series of graphic satires was, however, continued

by the 'Enraged Musician' (1741) and the famous 'Marriage à la Mode' (his masterpiece), six pictures now in the National Gallery, and engraved by various hands in 1745. 'Industry and Idleness,' 12 plates, followed these in 1747; 'Calais Gate' (1749) came next, and in 1750 the fine plate known familiarly as the 'March to Finchley.' The minor plates of 'Beer Street' and 'Gin Lane' and the set called 'The Progress of Cruelty' belong to 1751. In 1752 Hogarth published his 'Analysis of Beauty,' a treatise containing many shrewd remarks, but confused and illiterate in its style, and the cause of much ridicule. After this he produced (with the aid of Grignion and others) the four prints of the 'Election Series' (1755–8), the 'Cockpit' (1759), etc. In 1762–3 he became involved in a miserable quarrel with Wilkes and Churchill, the result of which, on his side, was the well-known portraits of Wilkes, and of Churchill as a bear ('The Bruiser').

Most of Hogarth's pictures, which now enjoy a much higher repute for technique than formerly, are preserved in public or private collections in Britain. He was entirely uninfluenced by foreign art. His powers of invention and combination were extraordinary; and as a humorist and social satirist with the pencil he has never been surpassed. There can be no doubt also that he genuinely desired to assist by his work in the reformation of manners. Consult the biographies by Sala (1866) and Dobson (1879).

Hoge, hōg, **Moses Drury,** American Presbyterian clergyman; b. Hampden-Sidney, Va., 17 Sept. 1819; d. Richmond, Va., 1899. He was graduated at Hampden-Sidney College and Seminary and was pastor of the Second Presbyterian Church in Richmond, Va. (1845–85). He ran the blockade in a ship from Charleston during the Civil War and secured from England a large number of copies of the Holy Scriptures for distribution among the Confederate soldiers, the British and Foreign Bible Society making a special grant at his request. After the war he was instrumental, especially during the session in 1874 of the Southern Presbyterian Church, in reconciling differences with the Northern Presbyterian Church.

Hogg, James, Scottish poet, familiarly known as "The Ettrick Shepherd"; b. Ettrick, Selkirkshire, 25 Jan. 1770; d. Altrive, on the Yarrow, 21 Nov. 1835. After receiving a very scanty education, he began to earn his bread by daily labor as a shepherd. His early rhymings brought him under the notice of Sir Walter Scott, by whose advice he published a volume of ballads called 'The Mountain Bard.' He then went to Edinburgh, where he published the 'Forest Minstrel' (1810), and started a weekly periodical entitled 'The Spy.' The appearance of the 'Queen's Wake' in 1813, with its charming ballad of Kilmeny, established Hogg's reputation as a poet. In 1815 he published 'Pilgrims of the Sun,' followed by 'Mador of the Moor'; the 'Poetic Mirror' (a collection of imitations of living poets); 'Queen Hynde,' and 'Dramatic Tales,' as well as by 'The Brownie of Bodsbeck,' etc. From 1817 he held the farm of Altrive from the Duke of Buccleuch at a merely nominal rent; but his farming schemes never throve, and he was generally in narrow circumstances.

Hogg, James Stephens, American politician and lawyer: b. near Rusk, Tex., 24 March 1851; d. Houston, Tex., 3 March 1906. He took up the practice of law, and was justice of the peace in Wood County 1873–5, and county attorney 1878–80. In 1880 he was district attorney in the 7th judicial district of Texas; in 1886 became attorney-general of the State and from 1890 to 1895 was governor. He was one of the Democratic governors who objected to the use of United States troops by President Cleveland at the time of the Pullman strike in 1894. After serving as governor he returned to the practice of law, and remained active in politics, being prominent as a public speaker.

Hog'nose, a North American colubrine serpent (*Heterodon platyrhinus*), so-called because of its upturned pig-like snout. It is usually about two feet long, gray marked with brown bars, but sometimes is so dark that the whole surface appears blackish; and dwells and seeks its prey mainly in the woods and thickets. When alarmed — and it is extremely timid — it hisses violently (whence other rustic names such as "blowing-adder"), and expands and flattens the head and neck by inhaling air and stretching out the ribs, giving itself a most ugly aspect. If these tactics do not succeed in terrifying the enemy sufficiently, the snake begins a series of astonishing contortions and twistings which end in the animal throwing itself upon its back and seeming dead until a chance of escape offers. Two or three other species are known in the South and West, all of which are regarded as poisonous by most country people, but are really quite harmless.

Hogs, or **Swine,** hoofed quadrupeds of the family *Suidæ*, including several genera and many species and domesticated races. The males are called "boars," the females "sows," the young "pigs," and the flesh "pork." The hogs proper, both wild and tame, belong to the genus *Sus*, represented in the wilderness of the Old World by the wild boar (*S. scrofa*), which is, or was, known throughout southern and central Europe, Algeria, Asia Minor, and southwestern Asia; and by the Indian boar (*S. cristatus*) of India and Indo-China. The wild boar stands from 30 to 40 inches high at the shoulder and will weigh on the average about 250 pounds. His snout is longer, his ears shorter than those of the domestic hog. He roots up the ground in a different manner, ploughing it in furrows; his tusks are larger, some of them being 10 inches in length, bent circularly, and exceedingly sharp at the points. The young wild boar, for the first three years of his life, follows the sow, the whole litter living in a herd together, and although the adults are plain iron gray (the male exceedingly large and shaggy) the young are striped and spotted. Old boars range the forest alone and unsupported, dreading no single creature, not even man himself. Hunting this animal has always been a favorite amusement, and in Europe is usually pursued on foot by the aid of large dogs, the hunters armed with strong pikes termed *boarspears*. A chase seldom terminates without the maiming or destruction of some of the dogs, and tests the courage of the men, for a charge from an enraged or wounded

boar is a formidable thing. In India the chase is pursued on horseback, the rider using a long spear. Hence the sport is known as "pig-sticking," and it involves much risk and danger, and the death of many horses ripped open by the boar's tusks. In addition to these, a small wild pig inhabits western equatorial Africa; there are two lesser species in India, one not much bigger than a hare; and several in the islands stretching from Sumatra to Japan.

Domestic Races.— Swine everywhere have seemed easily tamable and susceptible to domestication, breeding fertilely in confinement and easily adapting themselves to new environments. Since prehistoric times, therefore, the animal has been raised by man in many parts of the world to supply food. The process of domestication seems to have gone farther toward producing a good pork-making animal in the Orient than in Europe until the revival of agriculture there following the decay of the feudal system. In Great Britain there was early introduced eastern blood called Chinese stock, and it is from the union of these two strains — one derived from the European wild boar and the other from some or many Oriental species — that European and American farmyard swine are descended. The foremost breed, in general popularity, is the Berkshire, which originated in the English County of Berks, but is now universal. The Berkshire hog is of large size, yields pork of great fatness and excellent flavor, grows rapidly and is hardy. It is usually black in color. An American breed, developed first in Ohio, and known as Poland-China, is very similar to the Berkshire, and has been perfected until it has become the principal pork-producing hog of the Mississippi Valley. The English white breeds are led by the Yorkshire, which reaches a larger size than any other kind; and from which has been developed an American strain, called Chester Whites, after the county in eastern Pennsylvania where it originated. New Jersey has a local breed called Durocs, or Jersey red hogs, which have the advantage of great hardiness. For these breeds regular stock-registers have long been maintained. Various other well-known strains of swine in Great Britain and America are the Tamworth, Victoria, Essex, etc. The domestic hog has run wild in various parts of the world. In many of the South Sea islands, and in parts of South America, they have practically returned to a feral condition, and are public game. In the southern part of the United States large numbers of pigs, nominally under ownership, range the woods, picking up their own food of herbage, roots and mast; these become gaunt, thin, high-backed, bristly and develop great running powers, cunning (the intelligence of the whole race is comparatively high), and savagery of disposition; they are locally known as "razor backs."

For the proper care and treatment of hogs raised for their pork see NUTRITION OF FARM ANIMALS.

Domestication has changed the form and proportions of the body, the color, etc.; thus the skull is higher and broader in proportion to its length, and it is more upright in the occipital region. The sow brings forth from the 16th to the 20th week after conception, and has usually two litters in a year. Her offspring are very numerous, a litter consisting of from 10 to even 20; but she can bring up no more than she has teats, which are 12 in number. The natural term of the life of these animals is from 15 to 30 years, and they continue to increase in size and strength until they are from four to five years of age. As might be supposed from their habits, they are much infested by vermin of different kinds, and are also liable to many disorders, particularly those arising from gluttony. Notwithstanding repugnant qualities the hog is of incalculable benefit to mankind. Its flesh is pleasant, substantial and nutritious. Pork takes salt better than almost any other meat, and may be cured and preserved in many ways. The fat (lard) is one of the most important culinary articles; the bristles are used in large quantities in the manufacture of brushes, while the skin is in demand among saddlers, trunk-makers, and manufacturers of small articles of leather, calling for great durability with flexibility and a handsome appearance.

The family includes various wild species more or less closely related to the typical swine, such as the babirussa, peccaries, river-hogs, wart-hogs, etc., elsewhere described.

The principal English works on swine are Long's 'The Book of the Pig' (1889), and Spencer's 'Pigs, Breed and Management' (1897). American works of note are Coburn's 'Swine Husbandry' (1889); Harris' 'On the Pig' (1896), and pamphlets issued by the Department of Agriculture. See NUTRITION OF FARM ANIMALS; PORK; PACKING INDUSTRY.

Hogs'head, a liquid measure formerly in use in England. Its capacity varied in different cases. For beer it was 54 gallons, for rum 45 to 50 gallons, for brandy 45 to 60 gallons, and for different kinds of wine it varied from 46 to 93 gallons. In the United States the measure is still in use, being equivalent to 63 American gallons or 52.485 imperial gallons; for tobacco it varies from 750 pounds in some States to 1,200 pounds in others.

Hohenlinden, hō-ĕn-lĭn'dĕn, Germany, a village of Bavaria, 20 miles east of Munich, celebrated for the victory gained by the French under Moreau over the Austrians under the Archduke John, 3 Dec. 1800. The French took nearly 80 pieces of cannon, 200 caissons, and more than 10,000 prisoners, with three generals officers.

Hohenlohe-Schillingsfürst, hō-ĕn-lō'ĕ shĭl'-lĭngs-fürst, **Chlodwig Karl Victor,** PRINCE VON, German chancellor; b. Rotenburg-an-der-Fulda March 1819; d. Ragatz, Switzerland, 6 July 1901. He took courses in law and political science at Heidelberg, Göttingen and Bonn. He entered public life and became in 1866 prime minister of Bavaria. In 1874 he was German ambassador at France and in 1885 became governor-general of Alsace-Lorraine. In 1894 he was appointed chancellor and resigned in 1900.

Hohenstaufen, House of, a German dynasty reigning from 1138 to 1254. After the death of the Emperor Henry V. (1125), his two nephews, Frederick II., duke of Swabia, and Conrad, duke of Franconia, aspired to the German crown; but were opposed by the directors of the election, the Archbishop of Mayence and the papal legate; and Lothaire of Saxony was elected. This circumstance, with the demand made by the new emperor of the

restitution of all the possessions acquired by the lords of Hohenstaufen during the preceding reign, produced a fierce war between the emperor and the two brothers. Lothaire preserved himself by a union with Henry the Proud, duke of Bavaria, to whom he gave his daughter and the Duchy of Saxony. The Peace of Mühlhausen (1135), between Lothaire and Conrad, put an end to this Ten Years' war. Conrad renounced his title of King of Italy which he had taken, but received the first rank among the dukes, and both he and his brother regained all their lands. After Lothaire's death (1137) Conrad, duke of Franconia, of the house of Hohenstaufen, was raised to the throne of Germany, with the title of Conrad III.

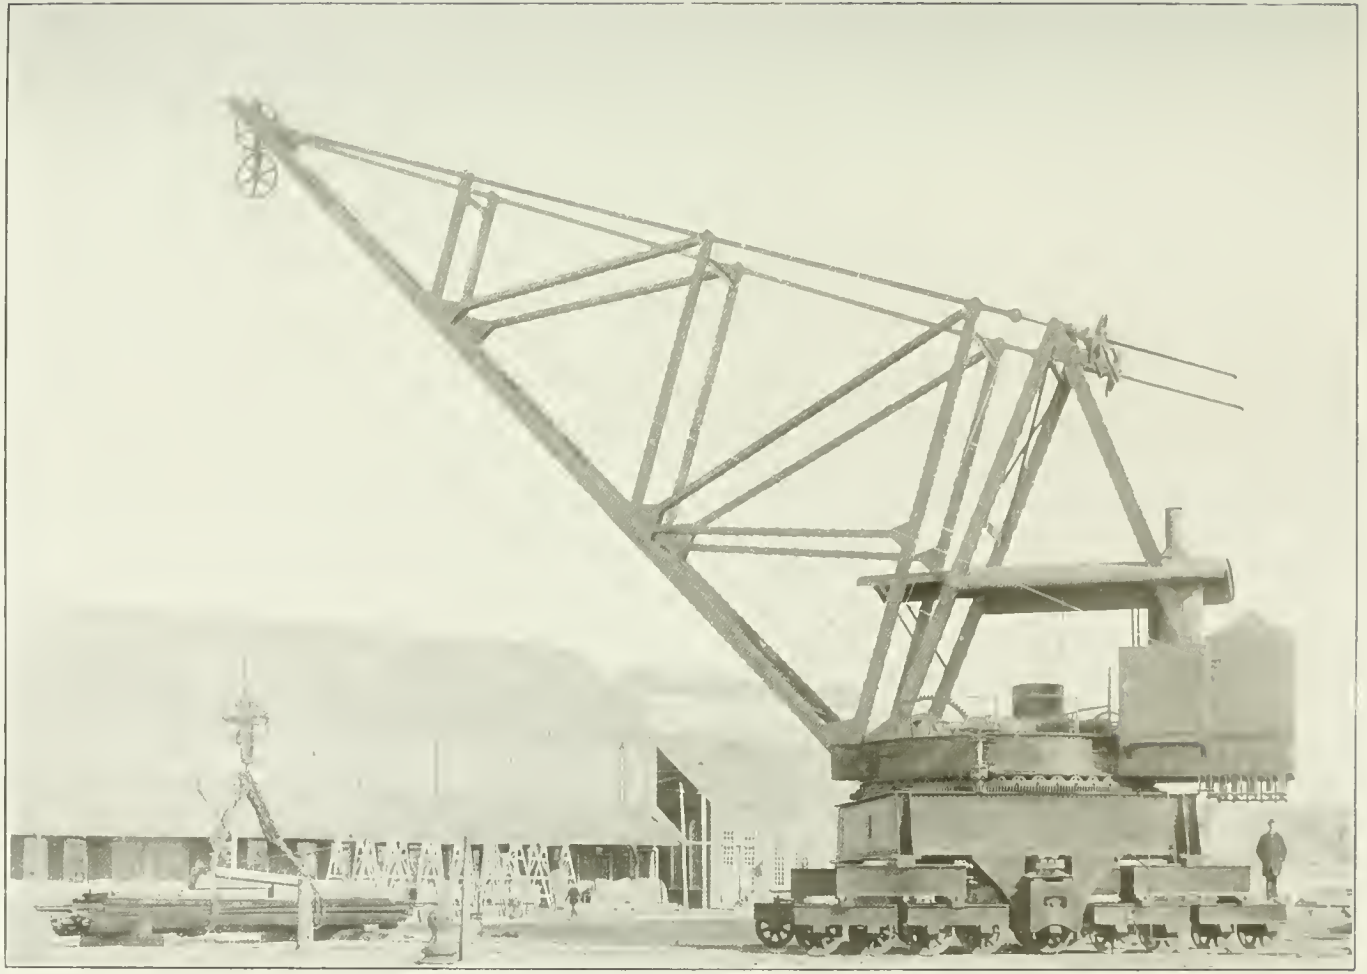
After the death of Conrad III. (1152) the confidence which was felt in the Hohenstaufen family caused the choice to fall on his nephew, Frederick III. of Swabia, called Barbarossa (the Red-beard), who was followed by Henry VI. (1190), and he again by Otto IV. (1197) and Frederick II. (1215–50), all belonging to the same house. After the death of Frederick II. his son Conrad was acknowledged as his successor, with the title of Conrad IV., by most of the states of the empire; but Innocent IV. laid him under an interdict, and declared him to be deprived of all his lands. The conflict between Conrad and the Pope lasted until the latter's death in 1254. The fame of the house of Hohenstaufen is based upon the political greatness to which the Fredericks in particular attained; their success in reducing to order all the states of the empire; the encouragement which they gave to commerce and trade, and their efforts to promote the sciences and arts.

Hohenzollern, hō'ĕn-tsŏl-lĕrn, Germany, a province of Prussia, formed in 1849 by the union of the two principalities of Hohenzollern-Hechingen and Hohenzollern-Sigmaringen. It consists of a narrow irregular strip of country encircled by Würtemberg and Baden. Area 441 square miles; pop. (1900) 66,783. The princely family of Hohenzollern dates from Thassilo, Count of Zollern, who died about 800 A.D., after having founded a castle near Hechingen, on the Zollern hill in the Swabian Alb. The fine Hohenzollern castle of 14th century architecture, built in the latter half of the 19th century, occupies the site of the ancient family-seat. There have been several lines and branches of the Hohenzollerns, the first separation taking place about 1165, when Frederick IV. founded the elder or Swabian and Conrad III. the younger or Franconian line. The elder line was subdivided, in 1576, into the branches of Hechingen and Sigmaringen. Frederick VI., the representative of the younger line, in 1415 received from the Emperor Sigismund the investiture of the electorate of Brandenburg, thus founding the reigning dynasty of Prussia. The two branches of the elder line continued unbroken till 1849, when the reigning princes ceded their respective rights and principalities to the king of Prussia, who in 1871 became emperor of Germany. The main branch of the Hohenzollerns is now represented by the imperial family of Germany. See GERMANY.

Hoisting Apparatus, mechanical devices for lifting and moving laterally heavy weights. They are known under various names and include cranes, derricks, overhead trolleys, crane-derricks, etc. The smaller are operated by hand power, the larger by steam or electric power. By their aid the heaviest weights may be readily lifted to any desired height and "slewed" into any desired position. Their use dates from the most ancient times, and they are now in constant and general use all over the world.

Derrick.— This is the simplest form of a machine for hoisting. The name is derived from a family by that title who adapted its form from the early English style of gallows, and the name has now come into common use. In form the derrick is like the letter V, one side being fixed immovably by guy ropes, the other hinged to the bottom of this fixed upright, so that it can be raised or lowered at will. This movable jib is somewhat shorter than the upright and the whole apparatus is on a platform which can turn laterally in a circle. Through the top of the jib is run a pulley block, a rope passing through this and down to the base of the upright, where it is wound about a cylinder, or winch. This, when revolved by hand or other power, winds up the rope or cable, thus raising the weight attached to the other end of the rope. The jib is lowered or raised to get the proper angle for picking up the article to be lifted. This simple form of hoister is in constant use by builders in constructing modern high buildings. By its use, heavy or light weights can be quickly lifted from the ground to the top of even 30-story structures. Derricks are commonly made of wooden spars, unless the work to be done is very heavy or the jib exceedingly long. In such case, a tubular iron spar is used. Hoisting engines of such power and facility of control are now made that they enable the operator to move the jib up or down or sideways easily and quickly. The "stiff-leg" derrick has its upright firmly braced by timbers running from the top to the ground, but this form is not common except in stone quarries or in some work where the derrick is stationary. The more common form is the guy-rope derrick, where strong wire cables extend from the top of the upright to the ground. With this arrangement, the hoisting machine can be moved and located in a fresh position easily. Derricks that will lift and swing to position weights of from 5 to 50 tons are now made in this country. In the contemplated work on the Panama Canal, derricks capable of moving 100-ton loads of stone and rock are to be built, with a radius of over 100 feet for the jib.

Crane.— Thus named because the arm or boom resembles the neck of the crane, which raises and lowers its neck to lift objects from the ground. It differs from the derrick in not having any mast or upright, usually. In the common form of crane the whole apparatus is centered upon a heavy platform which is itself on wheels. The engine which operates the winch also slews the boom in a circle, and, in some cases, moves the whole outfit along the rails upon which the wheeled platform rests. At the base of the boom, on the platform, is an inverted "V" horse, to which are attached the pulley blocks through which run the ropes for raising and lowering objects to be lifted. In large foundries, ship-yards and like places, the locomotive crane runs upon a track which usu-



FORTY TON LOCOMOTIVE CRANE.

IN USE BY THE U. S. GOVERNMENT AT PORT ROYAL, S. C.

ally extends the length of the yard or shop, or perhaps clear around it. Under its own steam, the ponderous machine runs along this track to the object it is desired to move. Steam power then slews the machine laterally so that the end of the jib or boom is over the object, when the latter is attached to the rope running over the end of the jib, the winch turned by the engine and the object lifted into the air. A second rope over another winch then raises the jib to the desired height and the machine runs back over the track to the point desired, where the object is deposited. The utmost expertness and delicacy of handling is acquired by the operator of this steam locomotive crane, which will thus grasp and carry where desired objects weighing often 50 tons or more. The common size is the one capable of lifting five tons only, though there are at Port Royal, in the United States navy yards, several large cranes which just as easily lift 50 tons. This latter machine has a boom 85 feet long and will travel under its own steam along the track 50 feet per minute. It will hoist a 40-ton load seven feet per minute and slew, or turn, a complete revolution in two minutes. The smaller cranes are much used on flat cars as wrecking apparatus for railroads, in excavating and dredging and in heavy construction work. Scores were used in digging the subway for New York city. A small 5-ton locomotive crane costs about $7,500. This style of hoisting apparatus is peculiarly the product of American genius and machines made in America are found in all large contracts for bridge building, railroad construction and like work in every corner of the world. A new machine for placer mining installed in New Mexico in the summer of 1903 adopts this form of crane, using the water over and over for sluicing the sand. It also operates a clam-shell shovel. In more difficult digging the "orange peel" form of shovel is used, the crane raising a ton or more of earth in the shovel and depositing it where desired.

Overhead Trolleys.—In the yard of a shipbuilding company at New London, Conn., has been installed a system of overhead hoisters which combine the advantages of both the derrick and the crane advantageously. The two enormous steamships, Minnesota and Dakota, were constructed by its aid solely. The two ships were built side by side and one trolley system served for both. By this method there are three steel spars, each 120 feet long, each supporting a steel cross-yard 174 feet long. These masts are braced by immense steel guy ropes or cables. The distance between the masts is 300 feet and the tops of the yards, or jibs, are 84 feet from the ground. The working field of the trolleys is a rectangle 600 feet long and 174 feet wide. Along the jibs a track made of wire rope is laid, on which a carriage is swung, suitably centred and controlled. On the main mast, just below the yard, is the house containing the operator and engine. This one man controls the trolley carriages on all the jibs, the raising or lowering and slewing of the jibs and masts and the return of the trolley carriages to the point desired. All is done swiftly and accurately, each carriage being capable of carrying 5,000 pounds. This system can operate four of these trolleys when desired.

Crane-derrick.— This is a combination of the crane and the derrick, as its name indicates. It resembles a figure 4 in construction. The mast can be slewed, but the yard or jib is a fixture and cannot be raised or lowered. Near the juncture of the jib and mast is the house in which sits the operator and where the engine is located. Along the under side of the jib is suspended a wire cable track on which runs a grappler carriage. The jib is usually very long, at least 60 feet, and the grappler runs to the end of this or to such point as is desired to be attached to the object to be lifted. This form of hoister is much used in bridge building and in places where a long reach of jib is desired.

At least 25,000 hoisting machines of these various types are made annually in the United States, one fifth of which are exported. About $25,000,000 is the annual expenditure for this class of machines, aside from the cost of hoisting engines, ropes, wire cable and the other appurtenances of the trade. The largest locomotive cranes cost $50,000 and the small wooden derrick $300 to $1,000. The industry has grown to enormous proportions and new improvements in methods of hoisting are constantly being made for special purposes. PUTNAM DREW.

Holacan'thus. See BUTTERFLY-FISH.

Holbach, Paul Heinrich Dietrich, powl hīn'rĭH dēt'rĭH hōl'bäH (Fr. ōl-bäk), BARON VON, German philosophical writer: b. Heidelsheim, in the Palatinate, 1723; d. Paris 21 June 1789. He was educated in Paris, where he passed the greater part of his life. He was the centre of a circle of men of wit, but of free thinking principles, using his great fortune, says Rousseau, generously, and appearing to advantage in the learned society which he gathered round his table. He was the author of a great number of works, most of which were anonymous or pseudonymous. The principal work attributed to him, which appeared in 1770 under the name of M. Mirabaud, and excited much attention in the learned world, is the 'Système de la Nature ou les Lois du Monde physique et moral.' He afterward published 'Système social, or Principes naturels de la Morale et de la Politique'— a development of the previous work, showing the application of the principles promulgated in it to morals and politics; 'Bons Sens, or Idées naturelles opposées aux Idées surnaturelles'; 'Eléments de la Morale universelle'; etc. According to Holbach matter is the only form of existence, and everything is the effect of a blind necessity.

Holbein, Hans, hänts hōl'- or hōl'bīn, the Elder, German painter: b. Augsburg 1460; d. Alsace 1524. His art training began under the influence of Martin Schongauer, but he quickly launched out into a new style, which left ancient precedents behind. He developed a dramatic energy, a clear and lifelike coloring and pre-eminent distinction of expression which rendered him the acknowledged head of a new school. His figures took the attitude of life. The pictures over the altar in the Cathedral at Augsburg, painted in 1493, are good specimens of his best work; in them are portrayed incidents in the life of Virgin Mary. To the same class belong the remains of an altarpiece in the Dominican Church at Frankfort-on-Main, representing scenes of the Passion (1501); 16 paintings of the Passion in the Munich Gallery; the

portrait of the artist with his two sons, in the gallery at Augsburg. His later pictures show traces of the influence exercised by the Italian renaissance, and those painted about 1512 and later are vastly superior to his early work. Among them is his 'Fount of Life' (1519), now in the royal gallery at Lisbon; the altarpiece 'St. Sebastian' (1515), at Augsburg; the altarpiece 'St. Katharine,' in the same gallery; etc. In such works the bold and devotional conception, delicacy and directness of expression, ease of drawing and splendor of coloring, are beyond praise. Excellent also are some of his preliminary sketches and outlines, and in Basle, Berlin, and Copenhagen are collections of his pencil sketches, the most remarkable of which is that at Berlin. Consult: Woltmann, 'Holbein und seine Zeit' (1866).

Holbein, Hans, the Younger, German painter: b. Augsburg 1497; d. London Nov. 1543. He probably received instruction in painting from his father, and about 1515 went to Basle, where he engaged in illustrating books. At Basle he also painted his earliest portraits, and in 1517 went to Lucerne. Here he painted the house of Jacob von Hertenstein, designed windows, and executed other works. Returning to Basle in 1519, he became a burgher in the following year, and during a seven years' residence in that city he executed many works of great importance. In 1526 he went to England. Letters from his friend Erasmus, whose famous 'Praise of Folly' he had illustrated, procured him the patronage of the chancellor, Sir Thomas More, who employed him to delineate the portraits of most of his own personal friends about the court, and introduced him to the notice of Henry VIII., who was a liberal encourager of the fine arts. Among the portraits produced by him during this period are those of More, Archbishop Warham, Bishop Fisher, and several other distinguished persons. From 1528 till 1532 he was again in Basle, but in the latter year he returned to England, where he was destined to spend nearly all the remainder of his life. Holbein painted most of the principal English nobility, whose portraits place him among the world's greatest portrait-painters. Some of his earlier productions, especially his 'Dance of Death,' are also celebrated. In 1538 he completed and published this series. Among the pictures of Holbein's last period are 'The Ambassadors' (1533), and portraits of Hans of Antwerp (1532), English Lady and Gentlemen (1534), Sir Richard Southwell (1538), Duke of Norfolk (1539), Thomas Cromwell, Lady Jane Seymour, Henry VIII. (1542, unfinished), and others. Comparatively few of Holbein's pictures are still extant in England, great numbers of them having been destroyed by Puritan fanatics, or sold and dispersed over Europe. Many of them also perished in the great fire in London in 1666. Holbein also excelled in wood-engraving, and before his visit to England had produced a large number of wood-cuts. He was one of the earliest to paint portraits in miniature. See Woltmann, 'Holbein und seine Zeit' (1874); Wornum, 'Life and Works of Holbein' (1867); Knackfuss, 'Holbein der Jüngere' (1896).

Holberg, Ludwig, lood'vĭg hōl'bĕrg, Baron, Danish author: b. Bergen, Norway, 3 Dec. 1684; d. Copenhagen, 28 Jan. 1754. He studied at Copenhagen, Oxford and Paris, and after paying a six months' visit to Rome returned to Copenhagen in the end of 1716. In 1718 he was appointed to an ordinary professorship in the university of that city, where after this date he chiefly resided till his death. In 1735 he was unanimously elected rector, and in 1737 treasurer of the university, and in 1747 was raised to the rank of baron. Holberg's numerous productions in various departments of literature as well as the important and salutary influence which he exercised upon his countrymen, place him in the front rank of the literary men of his age. He was extremely versatile — now devoted to history, now to poetry, and now to the drama; but during his whole life he was a sworn enemy to pedantry, theological disputatiousness, and scholastic metaphysics. His works may be divided into four classes — poems, stage pieces, philosophical treatises, and historical works. His poems are chiefly of a satirical nature. The most celebrated among them is 'Peder Paars,' a comic heroic poem in 14 cantos, still regarded throughout the Scandinavian countries as a masterpiece, and the hero of which has become the national comic impersonation in Denmark. It has been translated into several languages. Almost equally famous is his 'Nicholas Klimm's Subterraneous Travels,' a satirical romance in prose, originally written in Latin, but translated into seven modern European languages shortly after it appeared, into Danish first by Baggesen (1789). His numerous stage pieces are either comedies or farces, and nearly all characterized by true comic power. Among his philosophical writings the most important is his 'Moral Reflections' (1744). His historical works include: 'The Political, Ecclesiastical, and Geographical Condition of the Danish Monarchy,' a work of great value as a source of reference; 'A General History of the Jews,' and 'A History of Famous Men and Famous Women' (1739–45).

Hol'brook, John Edwards, American naturalist: b. Beaufort, S. C., 30 Dec. 1794; d. Norfolk, Mass., 8 Sept. 1871. He was graduated from Brown in 1815, from the medical school of the University of Pennsylvania in 1818, began practice at Charleston, S. C., in 1822, and in 1824 was appointed to the chair of anatomy in the Medical College of South Carolina, a post he held for over 30 years. In the Civil War he was head of the South Carolina examining board of surgeons. His 'American Herpetology, or a Description of Reptiles Inhabiting the United States' (1842), won for him recognition among European scientists. He published but 10 numbers of his 'Ichthyology of South Carolina' (1854 *et seq.*), when the Civil War compelled its discontinuance.

Hol'comb, Silas Alexander, American jurist: b. in Gibson County, Indiana, 25 Aug. 1858. He received a common school training, studied law in Nebraska, and in 1891 was made judge of the 12th judicial district. He was governor of Nebraska from 1894 to 1898, having been elected by fusion of the Populist and Democratic voters. He has been justice of the supreme court of Nebraska from 1900.

Hol'combe, Chester, American diplomatist and author: b. Winfield, N. Y., 16 Oct. 1844. He was graduated at Union College in 1861; and served as interpreter and secretary to the United States Legation in China, 1871–85. Becoming an authority on the Chinese and Chinese

affairs, in 1896 he acted for the Chinese government in its financial embarrassments. He has published: 'Travels in Western China' (1875); 'The Practical Effect of Confucianism upon the Chinese Nation' (1882); 'The Real Chinaman' (1895); 'The Real Chinese Question' (1899).

Holden, hōl'dĕn, **Albert J.,** American musician: b. Boston 1841. He studied music in New York, and since 1855 has been organist at the Church of the Divine Paternity and at the Church of the Puritans. He has composed more than 300 anthems, hymns and other church music, but his compositions are not confined to sacred music; they include songs, ballads, and choruses; he has also edited and compiled numerous collections.

Holden, Albert W., English painter: b. London 6 July 1848. He studied drawing and antiquities at the British Museum, and gained a studentship at the Royal Academy of Arts, where he afterward exhibited. He has painted historical and humorous genre pictures, and has a high reputation as a portrait painter. Since 1887 he has been professor of fine arts, King's College, London. Among the well known works he has exhibited are: 'A Bank Holiday' (1883); 'Naughty Polly' (1898); 'The Annunciation' (1896); etc.

Holden, Edward Singleton, American astronomer: b. St. Louis, Mo., 5 Nov. 1846. He was graduated at Washington University in 1866, and at the United States Military Academy in 1870; was professor of mathematics at the Naval Academy in 1873–81; and director of the Washburn Observatory (Madison, Wis.) in 1881–5. In 1885–7 he was president of the University of California, and in 1888–98 director of the Lick Observatory, on Mount Hamilton, San José, Cal. It was in connection with the Lick Observatory that his most important work was done, and his services to astronomy found recognition in America and from European states. Among his publications are: 'Index Catalogue of Nebulæ' (1877); 'Life of Sir William Herschel' (1881); 'Astronomy' (with S. Newcomb, 1892); 'Mountain Observatories' (1896); 'Essays in Astronomy' (1900).

Holden, Sir **Isaac,** English inventor: b. Hurlet, near Paisley, 7 May 1807; d. Reighley, Yorkshire, 13 Aug. 1897. While a worker in a cotton mill in Paisley he fitted himself for the post of a teacher. While conducting an experiment he discovered the lucifer match, but he secured no patent on the invention, the financial benefit of which fell to others. Subsequently he was manager, then owner of a wool-combing establishment, and by his mechanical improvements made significant changes in that industry. His shops at Bradford, with branches at Croix and Rheims, eventually became the largest of the kind in the world. He was several times elected to Parliament in the Liberal interest.

Holder, hōl'dĕr, **Charles Frederick,** American naturalist: b. Lynn, Mass., 5 Aug. 1851. He studied at the United States Naval Academy, but resigned in 1871; in 1871–5 was assistant curator of the American Museum of Natural History, from that time turned his attention to lecturing and literary work, and became known as a leading writer on popular science. At Pasadena, Cal., whither he removed in 1885, he became president of the board of education, professor of zoology in Throop University, and honorary curator of the university museum. Among his publications are: 'Elements of Zoology' (1885); 'Living Lights' (1887); 'Louis Agassiz, his Life' (1892); 'Along the Florida Reef' (1892); 'Stories of Animal Life' (1900); 'Half-Hours with Nature' (1901).

Holds'worth, Annie E., English novelist: b. Jamaica. She was married to Eugene Lee-Hamilton, the poet, in 1898. She has been co-editor of 'The Woman's Signal,' with Lady Henry Somerset, and is the author of the popular novels: 'Joanna Traill, Spinster'; 'The Years that the Locust Hath Eaten'; 'Spindles and Oars'; 'The Gods Arrive' (1897); etc.

Hole, Samuel Reynolds, English Anglican clergyman: b. 5 Dec. 1819; d. Rochester, Eng., 27 Aug. 1904. He was educated at Oxford, took orders, was ordained in 1845 and was vicar of Caunton, 1845–87. From 1887 he was dean of Rochester Cathedral. He visited the United States on a lecture tour in 1896, where his humorous, anecdotical lectures were very popular. He was a recognized authority on rose culture and wrote: 'A Book about Roses,' which has reached its 15th edition; 'The Memories of Dean Hole'; 'More Memories'; 'Addresses to Working Men'; 'A Little Tour in America'; 'Our Gardens' (1899); 'Then and Now' (1901); etc.

Hole, William, English painter: b. Salisbury 7 Nov. 1846. He was destined for the profession of engineering but after a journey to Italy turned his attention to art. He studied at the Edinburgh school of art, and in 1889 was elected member of the Royal Scottish Academy. His versatility is shown by the excellence of his work in portrait, genre and fresco, while as an engraver he has made many famous plates after such masters as Millet, Constable and Millais. Among his best known paintings are: 'The End of Forty-Five' (1879); and 'News of Flodden' (1886).

Holguin, ōl-gēn', Cuba, city in the province of Santiago de Cuba; about 25 miles by rail south by west of Gibara, its port; and 70 miles northwest of the city of Santiago de Cuba. Fertile agricultural lands are in the vicinity, also on the southwest is a hilly section bordering on the interior mountain range. A noted cave is in the vicinity. The trade is chiefly in sugar-cane and tobacco. Pop. 6,500.

Hol'ibut. See Halibut.

Hol'iday, any day set apart as a religious or national festival. (See Festivals.) Certain days are fixed by law as bank-holidays for England and Scotland, and it is enacted that all business transactions which would have been valid on any such holiday shall be held as valid if performed on the day following. Thus, when a bill of exchange becomes due, or notice of dishonor falls to be given, on a bank-holiday, the bill is payable, or the notice stands good on the following day. The days fixed for England are Easter Monday, the Monday in Whitsun Week, the first Monday in August, and the 26th of December if a week-day. These are in addition to Christmas Day, Good Friday, and other holidays previously established. The days fixed as bank-holidays for Scotland are New Year's

Day, Good Friday, the first Monday of May, the first Monday of August, and Christmas Day; and if either New Year's Day or Christmas Day falls on a Sunday, the Monday after is held as a holiday. The same act empowers the sovereign to appoint by proclamation a special day to be observed as a bank-holiday, and to alter by order in council any of the days settled by the act.

In the United States there is no national holiday, not even 4 July. The 53d Congress passed an act making Labor Day a public holiday in the District of Columbia, and various States have followed with a similar act. The proclamation of the President designating a day of Thanksgiving only makes it a legal holiday in the District of Columbia and in the Territories. New Year's Day is a legal holiday in all the States except Massachusetts, Mississippi, and New Hampshire. Lincoln's Birthday (12 Feb.) is a legal holiday in Connecticut, Illinois, Minnesota, New Jersey, New York, North Dakota, Pennsylvania, Washington, and Wyoming. Washington's Birthday (22 Feb.) is a legal holiday in all the States except Mississippi. Decoration Day (30 May) in all the States except Alabama, Florida, Georgia, Idaho, Louisiana, Mississippi, North Carolina, South Carolina, and Texas. Independence Day (4 July) in all the States and Territories. Labor Day (in general, the first Monday in September) in all the States except Arizona, Mississippi, Nevada, and North Dakota. Election Day and Christmas Day are generally observed as legal holidays in all the States and Territories. There are various States holidays, such as Patriot's Day (19 April) in Massachusetts, Pioneer's Day (16 Aug.) in Utah, All Saints' Day (1 Nov.) in Louisiana, Admission Day (9 Sept.) in California, and Confederate Memorial Day (10 May) in North and South Carolina. Every Saturday after 12 o'clock noon is a legal holiday in New York, New Jersey, Pennsylvania, Maryland, Tennessee, Virginia, in the city of New Orleans and in Newcastle County, Delaware.

Holinshed, hŏl'ĭnz-hĕd, **Raphael** or **Ralph,** an English chronicler: d. about 1580. He is only known by his 'Chronicles of Englande, Scotlande, and Irelande,' the first edition of which, known as the "Shakespeare edition," because it is the one the poet is supposed to have used in collecting material for his historical plays, was published in London in 1577. In the preparation of this work Holinshed was assisted by several of the most learned men of the day.

Holl, Frank, English portrait and genre painter; son of Francis Holl, an eminent engraver: b. London 4 July 1845; d. there 31 July 1888. He was a very successful student at the Royal Academy, and exhibited constantly from his student days. Among his best-known pictures are: 'Faces in the Fire'; 'Fern-Gatherers'; 'No Tidings from the Sea'; 'Leaving Home'; and the 'Gifts of the Fairies.' In the later portion of his career he devoted himself to portraiture, in which he greatly excelled, and painted many of the celebrities of the day.

Holland, Edmund Milton, American actor: b. New York 7 Sept. 1848. He began his professional career at Barnum's Museum in 1866, was later for 13 years a member of Lester Wallack's company, and as a member of the Madison Square company from 1882 created the parts of Captain Redwood in 'Jim the Penman,' Colonel Moberley in 'Alabama,' and the title-role in 'Colonel Carter of Cartersville.' In 1895–7 he starred with his brother Joseph, and later (1901) appeared as Eben Holden in the dramatization of Irving Bacheller's book of that name.

Holland, Frederic May, American author: b. Boston 2 May 1836. He was graduated from Harvard in 1859, entered the ministry of the Unitarian Church in 1862, but resigned in 1874. His publications include: 'The Reign of the Stoics' (1879); 'Frederick Douglass, the Colored Orator' (1895); and 'Liberty in the Nineteenth Century' (1899).

Holland, Henry Richard Vassall Fox, 3d Lord, English statesman: b. Wiltshire 21 Nov. 1773; d. 22 Oct. 1840. He succeeded to the peerage by the death of his father when less than one year old. In 1798 he took his place in the House of Lords, and as the nephew of Charles James Fox was at once acknowledged as a Whig leader. In 1806 he was commissioner for settling disputes with the United States; was lord privy seal in 1806–7; and chancellor of the duchy of Lancaster. He made Holland House the resort of the wit, talent, and beauty of his day. He was the author of: 'Life of Lope de Vega' (1806); 'Three Comedies from the Spanish' (1807); 'Foreign Reminiscences' (1850); 'Memoirs of the Whig Party' (1852).

Holland, John P., American inventor: b. 1841. As one of the most successful designers in the interesting field of submarine navigation, Holland is well known. His first boat was built in 1875; a second was launched in 1877, and a third in 1881. After a series of severe tests, the Holland boat was ordered by the United States government for the navy in 1900. In 1903 eight of the submarines were put in commission. These have a speed varying from 8.87 to 8 knots, a horse-power of 160 (with one exception), and a displacement in general of 122.55 tons. For some time the inventor was interested in the Holland Submarine Boat Company, but from this he has now retired to devote his time independently to submarines and flying devices. His more recent designs call for smaller and more compact vessels, with much less complicated mechanism, power of remaining longer submerged, and increased safety in operation. See Submarine Navigation, History of.

Holland, Josiah Gilbert, American editor and author: b. Belchertown, Mass., 24 July 1819; d. New York 12 Oct. 1881. He began the study of medicine in 1840, in 1844 was graduated from the Berkshire Medical College, and entered practice at Springfield, Mass. The years that followed were discouraging, for patients did not come to the young doctor. With true Yankee versatility he turned his hand to anything,—taught district school, was a traveling writing-master, and a daguerreotypist. Of his boyish mortification at being a mill hand he has written in 'Arthur Bonnicastle.' He tried editorial work, and started 'The Bay State Weekly Courier,' which ran for six months. Subsequently he taught at Richmond, Va., and for 16 months

was superintendent of public schools at Vicksburg, Miss. All these varied experiences gave him the knowledge of American life and appreciation of workaday struggles which later made the value of his poems, essays, and novels. In 1849–66 he was assistant editor of the Springfield *Republican*, and from 1851 also part owner of that journal. It was largely due to his influence that the *Republican* became so widely known and popular a journal. In it his 'Letters to Young People Married and Single: By Timothy Titcomb' first attracted readers by their vivacious style, moral sincerity, and good common sense. Later, in book form (1858) they had a great and immediate success.

In 1870 Dr. Holland was one of the founders and became editor of 'Scribner's Monthly,' later the 'Century Magazine,' and the editorship of this periodical he retained till his death in 1881. Holland's novels: 'Arthur Bonnicastle' (1873); 'Sevenoaks' (1876); and 'Nicholas Minturn' (1877), although showing his quick and sympathetic observation and containing fine passages, have been less popular than his poems. The latter, in their constant appeal to the moral sense, and in their accurate portrayal of the homely and picturesque in New York life, found many admirers. Several of the short lyrics, with 'Bittersweet' (1858); 'Kathrina' (1868), and 'The Mistress of the Manse' (1871), came as messages of an American poet who understood and honored his own people. Consult the 'Life' by Plunkett (1894).

Holland, Thomas Erskine, English jurist: b. Brighton 17 July 1835. He studied at Oxford, was called to the bar in 1863, in 1874 became a reader in English law at Oxford, and shortly afterward professor of international law. The University of Perugia appointed him to an honorary professorship in recognition of his attainments. His best-known work is his 'Elements of Jurisprudence' (1880; 9th ed. 1900), to which was awarded the Swinney prize (1894), decennially bestowed for the best book published on jurisprudence, and which is now a standard text-book in England and the United States. He wrote further: 'An Essay on Composition Deeds' (1864); 'Essays on the Form of the Law' (1870); 'The European Concert in the Eastern Question' (1885); 'Studies in International Law' (1898), and other works.

Holland, William J., American Presbyterian clergyman and educator: b. Jamaica, W. I., 16 Aug. 1848. He was graduated from Amherst College in 1869, from the Princeton Theological Seminary in 1874, entered the ministry of the Presbyterian Church, and was a pastor at Pittsburg, Pa., in 1874–91. In 1891–1901 he was chancellor of the Western University of Pennsylvania (Allegheny), and in 1897 was appointed director of the Carnegie Museum at Pittsburg. In 1887 and 1889 he was naturalist of the United States eclipse expeditions to Japan and West Africa respectively. A recognized authority on museum administration and zoology, he wrote numerous scientific papers in learned publications, and 'The Butterfly Book' (1898).

Holland, a popular designation for the Kingdom of the Netherlands, derived from the provinces of North and South Holland, formerly constituting a feudal countship allied to the Holy Roman-German Empire, and from 1806–10 with other parts of the Netherlands, Hanover, and Oldenburg, ruled by Louis Bonaparte as the Kingdom of Holland. The region is the seat of the hardy and industrious Dutch race and of the Dutch language called by the natives *Neder-duitsch*, a dialect of Low German phonology, with evolutionary periods of Old, Middle, and Modern, and an interesting historical and varied literature. See NETHERLANDS.

Holland, Mich., city, in Ottawa County, at the head of Black Lake, which is really an arm of Lake Michigan, and on the Père Marquette railroad; about 80 miles west of Lansing and 25 miles southwest of Grand Rapids. It has direct communication by steamers with Chicago, Milwaukee, and other lake ports. Holland was settled in 1847 by a Dutch colony, and many of its inhabitants are of Dutch descent. In 1867 it was chartered as a city. It is located in an agricultural region, once a lumber section. The manufactures are largely articles made of wood, but the beet-sugar industry is growing in importance. The chief manufacturing establishments are planing-mills, furniture, tub, and basket factories, flour-mills, tanneries, wood-working machinery shops, pickling-plants, beet-sugar factory, grain elevators, and creameries. The manufacture of launches is also an important industry of Holland. The trade is chiefly in the manufactures, and in grain and vegetables. The city owns and operates the electric-light plant and the waterworks. Holland is the seat of the Western Theological Seminary and of Hope College, both under the auspices of the Reformed Church in America. It has a number of fine public buildings, and a free public library. The summer resorts on Black Lake add to the industrial wealth of the city. Pop. (1890) 3,945; (1900) 7,790.

Holland-linen, a fine and close fabric, so called from its first being manufactured in Holland; also a coarser linen fabric, unbleached or dyed brown, used for covering furniture, carpets, etc.

Hol'lander, Jacob H., American economist: b. Baltimore, Md., 23 July 1871. He was educated in the Baltimore schools and graduated from Johns Hopkins University in 1891, receiving his Ph. D. degree in 1894. His ability as economist and financier was soon recognized, and he became associate professor of finance at Johns Hopkins. In 1897 he was appointed secretary of the Bimetallic Commission abroad and was chosen chairman of the Baltimore municipal lighting commission in 1900. In the same year the secretary of war appointed him special commissioner to revise the laws relating to taxation in Puerto Rico, and while engaged in this service he was made treasurer of Puerto Rico by President McKinley.

Hollar, Wenzel or **Wenceslaus,** vĕnt'zĕl or wĕn'sĕs-lâs hŏl'lär, Bohemian engraver: b. Prague 13 July 1607; d. London 28 March 1677. He accompanied the Earl of Arundel, English ambassador to Germany, to London, who employed him to engrave some of the pictures of his collection. Among his numerous works, which are greatly esteemed for their delicate,

firm, and spirited execution, and which include some 2,740 plates, are the set of 28 plates, entitled, 'Ornatus Muliebris Anglicanus,' representing the dresses of Englishwomen of all ranks and conditions in full-length figures; Holbein's 'Dance of Death,' etc.

Holleben, hŏl'lā-bĕn, **Theodore von,** German diplomat: b. Stettin, Pomerania, 16 Sept. 1838. He was educated at the universities of Heidelberg, Berlin, and Göttingen; became an officer in the Body-Guard Hussar Regiment; and took a distinguished part in the Franco-Prussian War. He entered the diplomatic service in 1872; was *chargé d'affaires* at Peking, China, 1873–4, and at Tokio, Japan, in 1875; minister at Buenos Ayres in 1876–84; at Tokio 1885-9; and at Washington, D. C., 1892-3. In 1897 he became ambassador extraordinary and plenipotentiary to the United States. At the command of Emperor William he, together with Secretary Hay, of the State Department, had charge of the arrangements for the official reception of the emperor's brother, Admiral Prince Henry, in February 1902. Failing health caused his resignation, and in 1903 he was succeeded by Baron Speck von Sternberg.

Hol'ley, Alexander Lyman, American engineer: b. Lakeville, Conn., 20 July 1832; d. Brooklyn, N. Y., 29 Jan. 1882. He was graduated at Brown University in 1853, and became editor of 'The Railroad Advocate' in 1856, changing its name to 'The American Engineer.' He introduced into the United States in 1865 the Bessemer steel process, erecting the first Bessemer works in the country at Troy, N. Y. He was lecturer on the manufacture of iron and steel at Columbia University 1879–82. Holley secured many patents, the most important probably being that for the detached converter-shell, an improvement in the Bessemer process. He published with Z. Colburn: 'Railway Economy: a Report on European Railways' (1858); 'American and European Railway Practice' (1860); 'A Treatise on Ordnance and Armor' (1865); etc. In 1890 a bronze bust of Holley was placed in Washington Square, New York, by the mechanical engineers of the United States and Europe.

Holley, Marietta, American author, known by her pseudonym, "Josiah Allen's Wife": b. near Adams, Jefferson County, N. Y., 1844. She began her literary career as a contributor to the 'Christian Union,' the 'Independent,' 'Peterson's Magazine,' and other periodicals; and in 1873 published her first book, 'My Opinions and Betsy Bobbet's,' which in a measure recalled the 'Widow Bedott Papers' of F. M. Whitcher. This was followed by a series of works containing many touches of distinctive and genuine humor: 'Samantha at the Centennial' (1876); 'My Wayward Pardner' (1880); 'Miss Richard's Boy' (1882); 'Sweet Cicely' (1885); 'Miss Jones's Quilting' (1887); 'Samantha at Saratoga' (1887); 'Poems' (1887); 'Samantha Among the Brethren' (1891), considered by many her best volume; 'Samantha at the World's Fair' (1893), and others. Her writings have had large sale, and been translated into several foreign tongues.

Hollidaysburg, hŏl'ĭ-dāz-bĕrg, Pa., borough, county-seat of Blair County: on the Juniata River, and the Pennsylvania railroad; about 82 miles east of Pittsburg and five miles south of Altoona. Rich coal-fields, iron-ore beds, and limestone quarries are in the vicinity. The chief manufactures are foundry products, agricultural and mining implements, nails, and furniture. Hollidaysburg Female Seminary is a prosperous institution. Pop. 3,000.

Hol'lins, Alfred, English musician: b. Hull 1865. He was born blind, and was educated at an institution for the blind in York, and at the Royal Normal College for the Blind in Upper Norwood, where he specialized in music (piano and organ); he also studied music in Germany. He was popular at the English and German courts, where he gave recitals; and was for a time organist at the United Free Saint George's Church in Edinburgh. He visited America in 1886 and 1888, and his organ compositions are widely known and liked throughout the United States.

Hollins, George Nichols, American naval officer: b. Baltimore, Md., 20 Sept. 1799; d. there 18 Jan. 1878. He entered the navy as midshipman in 1814, and while assigned to the President, Stephen Decatur, was captured by the English and held prisoner at Bermuda until the conclusion of peace. He served also in the Algerine war of 1815, later assumed command of an East Indiaman, and in 1844 attained commander's rank. In 1855, on complaint of American residents who claimed they had been injured by the local officials, he bombarded Greytown, Nicaragua. At that time Nicaragua was under English protection, and the property and lives of English residents having been imperilled, international complications with Great Britain arose. Hollins was commissioned commodore in the Confederate navy at the outbreak of the Civil War, attacked the Federal blockading squadron at the passes of the Mississippi River, and was appointed flag-captain of the New Orleans station. He was superseded in 1862.

Hol'lister, Cal., town, county-seat of San Benito County; on the Southern Pacific railroad; about 80 miles southeast of San Francisco, and 35 miles east by south of Santa Cruz. It is situated in a rich agricultural region, noted for its fruit. The chief industrial interests of the town are connected with dairying, fruit-growing, and the shipment of grain and live-stock. Pop. (1900) 2,315.

Holloway, hŏl'ō-wā, **Laura Carter,** American author: b. Nashville, Tenn., 22 Aug. 1848. She was at one time editor of the 'Home Library Magazine' of Chicago, Ill., was for 12 years associate editor of the Brooklyn *Daily Eagle*, and collaborated with Anton Seidl in the preparation of musical terms for the 'Standard Dictionary.' She wrote: 'Ladies of the White House' (1870); 'The Mothers of Great Men and Women' (1884); 'The Home in Poetry' (1884); 'Chinese Gordon' (1885); 'The Buddhist Diet Book' (1887); and other volumes.

Holloway, Thomas, English patent medicine proprietor and philanthropist: b. Devonport 22 Sept. 1800; d. Tittenhurst 26 Dec. 1883. About 1837 he began to sell his well-known ointment, and soon afterwards brought his pills to the notice of the public. He ultimately

succeeded in amassing a very large fortune which he partly devoted to benevolent objects. The Royal Holloway College for Women, on the equipment and endowment of which he expended about $4,000,000 was opened on 30 June 1886. It contains a collection of pictures valued at $500,000. Near it is a sanitorium founded by him for the mentally afflicted of the lower middle class.

Holls, hōlz, **George Frederick William,** American lawyer and statesman: b. Zelienople, Pa., 1 July 1857; d. Yonkers, N. Y., 23 July 1903. He was graduated from Columbia in 1878, and from the law school there two years later. He was admitted to the bar and established a large law practice in New York city, becoming senior member of the firm of Hollis, Wagner & Burghard; in his later life he visited Europe frequently and became widely known there, especially in Germany where he established a branch of his law firm. He was prominent in philanthropic work, being for years an officer of the Legal Aid Society and a director of the Charity Organization Society. He was also an active member of the Republican party, and much in demand as a campaign speaker, especially as he could address the Germans in their own language. In 1893 he was a delegate-at-large to the New York Constitutional Convention, where he was chairman of the committee on education, a member of the committee on cities, and author of several amendments. His frequent visits abroad gave him a wide and intelligent interest in international questions, and at the time of the Hague Conference he was very influential in arousing interest and obtaining a large delegation from the United States. He was secretary of the American delegation at the Conference (1899), was the American member of the committee which drafted the arbitration treaty, and author of the clause on "Special Mediation." He was afterward appointed a member of the permanent international court of arbitration. A few months before his death President Roosevelt asked him to umpire the adjustment of claims between Germany and England and Venezuela, but he declined. He has written: 'Sancta Sophia and Troitza' (1888); 'Compulsory Voting' (1891); and 'The Peace Conference at the Hague and Its Bearings on International Law and Policy' (1900).

Hol'ly, James Theodore, American Protestant Episcopal bishop: b. Washington, D. C., 3 Oct. 1829. He was of African Roman Catholic parentage, but withdrawing from the Roman Catholic Church, entered the Episcopal Church in 1851, studied for the ministry and in 1856 became rector of St. Luke's, New Haven, Conn. In 1874 he became missionary bishop of Haiti.

Holly. See AQUIFOLIACEÆ.

Holly Springs, Miss., a point on the Mississippi Central Railroad, about 40 miles southeast of Memphis and about 25 miles south of Grand Junction, on the Memphis & Charleston Railroad, and an important strategical point. After the battle of Iuka, 19 Sept. 1862, and the Confederate defeat at Corinth, 3-4 Oct. 1862, the Confederates fell back to Holly Springs. Early in November Gen. Grant had concentrated an army of 30,000 men in the vicinity of Grand Junction to make a movement along the line of the Mississippi Central Railroad in the direction of the rear of Vicksburg. On 8 November Gen. McPherson, with 10,000 infantry and 1,500 cavalry, advanced from Grand Junction southward and pushed the Confederates under Gen. Pemberton back to Holly Springs. The main body of Grant's army moved forward, and Pemberton, abandoning Holly Springs, fell back to Grenada, Grant following to Oxford, 30 miles beyond Holly Springs. There he arrived 5 December, and arranged with Gen. Sherman a combined movement on Vicksburg. Grant was to move directly south on the line of the railroad and take the place in rear; Sherman to move a force from Memphis, accompanied by a gunboat fleet, to descend the Mississippi and attack in front. A depot of supplies was established at Holly Springs, guarded by Col. Murphy, with two regiments of Wisconsin infantry and a regiment of Illinois cavalry, and Grant was about to move forward from Oxford, when Gen. Earl Van Dorn, at the head of 3,500 cavalry, dashed into Holly Springs at daylight, 20 December, and attacked Murphy, who had been warned of the impending danger on the 19th, but neglected to take the necessary precautions and was surprised. He made a feeble resistance and surrendered his infantry; the cavalry cut its way out and escaped with the loss of only seven men. Van Dorn took about 1,500 prisoners, destroyed stores to the value of $1,500,000, and left town in the afternoon. This disaster, in connection with Forrest's raid into West Tennessee, which destroyed Grant's communication, forced him to abandon his movement on Vicksburg and fall back to Grand Junction, leaving Pemberton at liberty to concentrate his forces at Vicksburg against Sherman. Sherman was informed of Grant's failure, but the information reached him after his bloody repulse at Chickasaw Bluff, 27–28 Dec. 1862. Consult: 'Official Records,' Vol. XVII.; Greene, 'The Mississippi.'

E. A. CARMAN.

Hol'lyhock, a tall and rather coarse flowering plant (*Althæa rosea*) of the mallow family, said to be a native of China, but now cultivated all over the world as an ornament of old-fashioned gardens. It rises in a single leafy stalk, sometimes to the height of six or eight feet, studded with large single or double flowers, in varieties from white to yellow, scarlet and purple. Although rather difficult to start and slow of growth, it remains a hardy and easily nurtured perennial of highly effective beauty when suitably placed.

Holm, Saxe, a pseudonym affixed to a collection of 'Stories' (1st series 1874; 2d 1878), originally published in 'Scribner's Monthly' and generally believed to be by Helen Hunt Jackson (q.v.).

Holman, hōl'man, **William Steele,** American politician: b. Veraestau, Dearborn County, Ind., 6 Sept. 1822; d. Washington, D. C., 22 April 1897. He studied at Franklin College (Ind.), was admitted to the bar, and began practice at Aurora, Ind. In 1847–9 he was prosecuting attorney, in 1850 a member of the State Constitutional convention, in 1851–2 of the State legislature. He was a judge of the court of common pleas in 1852–6, in 1856 was elected as a Democratic representative to Con-

gress, where with the exception of eight years, he served until his death. His vigilance in opposing unnecessary appropriations and doubtful measures obtained for him the sobriquets of "The Watchdog of the Treasury," and "The Great Objector."

Holman-Hunt, William. See HUNT, WILLIAM HOLMAN.

Holmes, hōmz, **Abiel,** American Unitarian clergyman and annalist: b. Woodstock, Conn., 24 Dec. 1763; d. Cambridge, Mass., 4 June 1837. He was graduated at Yale College in 1783, and became subsequently a tutor in the college, pursuing at the same time his theological studies. In 1785 he was settled over a parish at Midway, Ga., where he remained till 1791. Returning north he became pastor of the first parish in Cambridge, and continued to fill the office till 26 Sept. 1832. Besides publishing a 'Life of President Stiles' in 1798, he was the author also of 'Annals of America' (1805), which gave him a high reputation for care and accuracy. It was republished in England in 1813. He contributed frequently to the collections of the Massachusetts Historical Society, in Vol. XXVII. of which will be found a complete list of his publications.

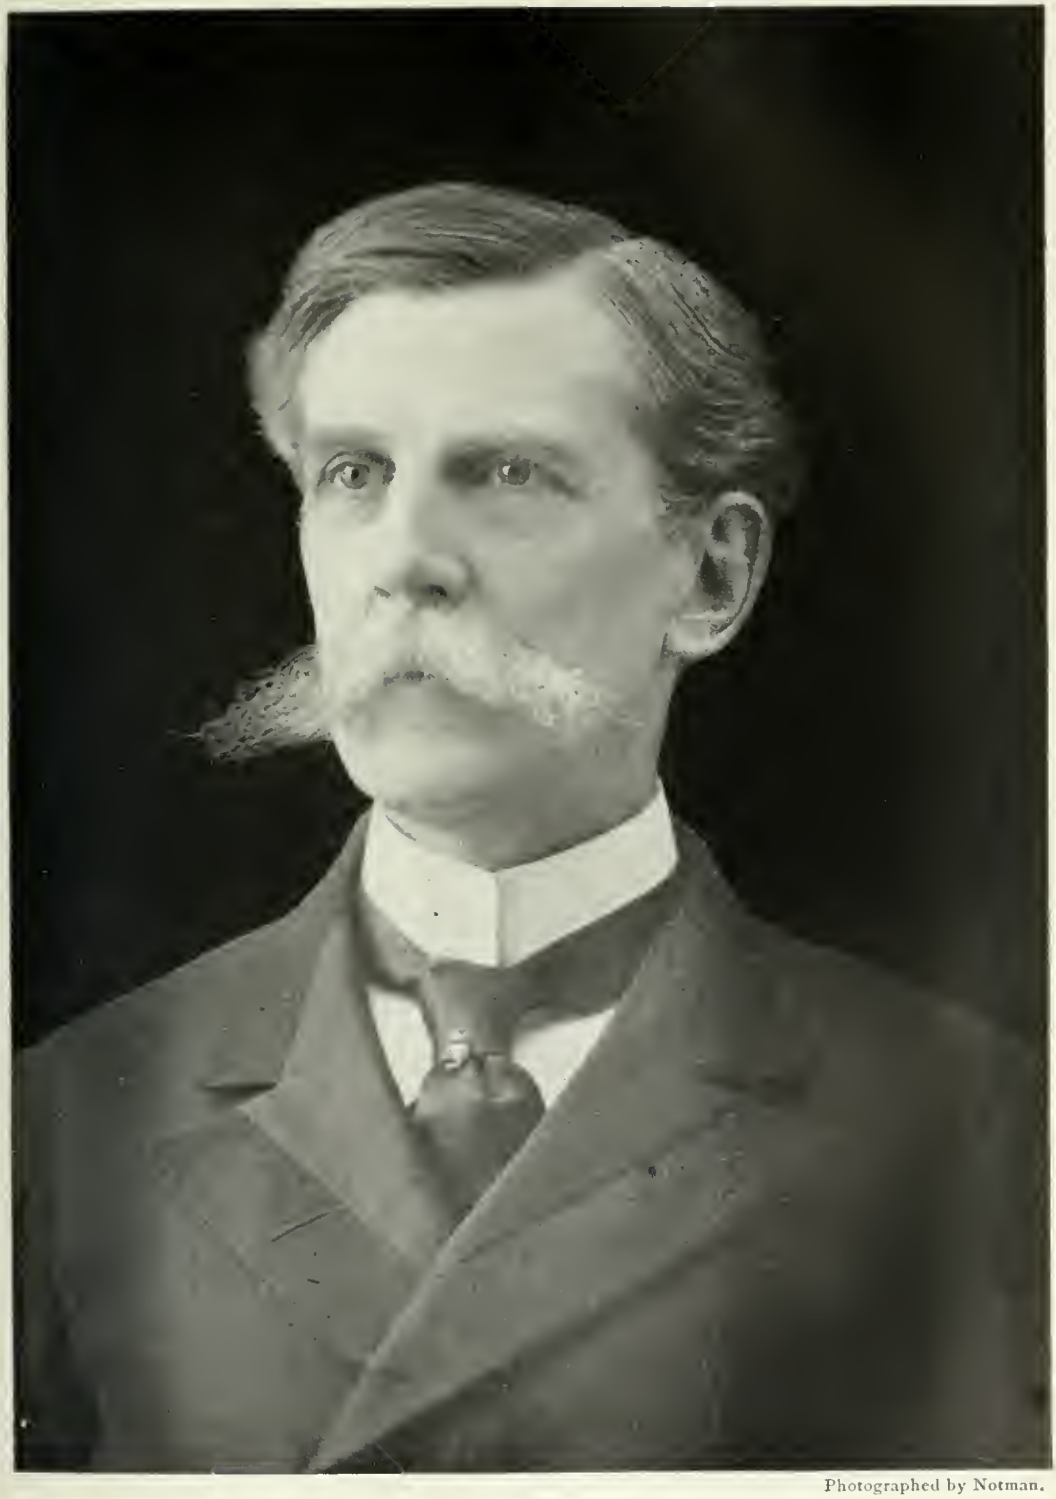
Holmés, ō-mēs', **Augusta Mary Anne,** French composer: b. Paris 1847; d. there Jan. 1903. She studied composition with Lambert, Klose, and César Franck, and began her career as a pianist. Her first work of magnitude was a setting of the psalm 'In Exitu,' sung for the first time in 1873. She later wrote considerable music, including 100 songs, characterized by much grace of expression. In the larger forms her compositions include the well-known symphony 'Hero et Léandre'; three other symphonies, 'Lutèce,' which in 1879 won third prize in an open competition directed by the Paris municipality. 'Les Argonautes' and 'Irlande'; the symphonic poems, 'Les Sept Ivresses,' 'Roland,' 'Pologne,' 'Au Pays Bleu'; an ode of triumph, 'Patrie'; a four-act lyric opera, 'Le Montagne Noire' (Grand Opera 1895), and an allegorical cantata, 'La Vision de la Reine.'

Holmes, Burton, American traveler and lecturer: b. Chicago 8 Jan. 1870. After a secondary education at Chicago he traveled in all the countries of continental Europe, as well as in Japan, Algeria, Tunis, Morocco, Corsica, Greece, and Thessaly, Hawaiian Islands, the Yellowstone Park, the Grand Cañon of the Colorado, the Philippines, and China. About 1890 he became known as a platform lecturer, giving in popular form the results of his observations.

Holmes, Mary Jane Hawes, American novelist: b. Brookfield, Mass. She was married to Daniel Holmes, a lawyer of Brockport, N. Y., where she has since resided. She has published many volumes of domestic fiction which have had an extraordinarily wide circulation but in which the literary element is slight. Among her novels are: 'Tempest and Sunshine' (1854) (perhaps the best known of them all); 'Lena Rivers' (1856); 'Marian Gray' (1863); 'Milbank' (1871); 'Queenie Hetherton' (1883).

Holmes, Nathaniel, American jurist and Shakespearian scholar: b. Peterboro, N. H., 2 Jan. 1815; d. Cambridge, Mass., 26 Feb. 1901. He was graduated from Harvard in 1837 and after admission to the bar in 1839 began to practise in St. Louis. He was judge of the supreme court of Missouri 1865–9, and Royall professor of law at Harvard 1868–72. He retired from his profession in 1883 and henceforth devoted himself to study and authorship. He was a strong believer in the Baconian theory of the origin of Shakespeare's plays, which he defends in his work, 'The Authorship of Shakespeare' (1866). In 1888 he published 'Realistic Idealism in Philosophy Itself.'

Holmes, Oliver Wendell, American poet, essayist and physician: b. Cambridge, Mass., 29 Aug. 1809; d. Boston, Mass., 8 Oct. 1894. He was the son of Rev. Abiel Holmes (q.v.), minister of the first parish in Cambridge, and on the maternal side was a descendant of Anne Bradstreet (q.v.) and related to the orator Wendell Phillips, the poet Richard Henry Dana, and the theologian, Dr. Channing. He was educated at Phillips Academy, Andover, and at Harvard, and was graduated from the latter in 1829 in a class which contained several who afterward became famous. In the next year he became well known through his poem 'Old Ironsides,' first published in the Boston *Advertiser,* and which prevented the breaking up of the famous frigate Constitution. He spent a year in the Harvard Law School but soon turned his attention to medicine and after studying in Paris three years returned to America where he received his degree of M.D. in 1836, the same year in which his first volume of poems appeared. He was professor of anatomy and physiology at Dartmouth College 1839–40. He married in the last named year and established a practice in Boston, becoming in 1847 professor of anatomy and physiology in the Harvard Medical School, a post which he resigned in 1882, when he was at once made professor emeritus. In 1849, and for several succeeding years, he made his summer home at Pittsfield, Mass., the scene of his novel 'Elsie Venner.' He was one of the first contributors to the 'Atlantic Monthly' when it was established in 1857, the opening chapter of his 'Autocrat of the Breakfast Table' appearing in the first issue. It is this work, which has found innumerable readers both at home and abroad, by which he will be longest remembered. These brilliant, conversational papers were followed in 1859 by a similar series, 'The Professor at the Breakfast Table.' and these in 1872, by 'The Poet at the Breakfast Table.' Many of his best poems were scattered through these volumes. In 1861 appeared his novel 'Elsie Venner: a Romance of Destiny,' and in 1868 'The Guardian Angel,' a less striking fiction than its predecessor, but like that exhibiting a remarkable series of studies of character. 'A Mortal Antipathy' (1885) was his only other essay in fiction. His volumes of verse 'Urania' (1846), and 'Astrea' (1850), had made him well known as a poet ere he appeared before the public as the kindly breakfast table autocrat, and he continued to write poetry at frequent intervals for the rest of his life. He was especially happy as the poet of occasions, but much of his verse, witty and sparkling as it is, is ephemeral from its very nature and not destined to endure. In such serious poems,



Photographed by Notman.

OLIVER WENDELL HOLMES,

ASSOCIATE JUSTICE OF THE UNITED STATES.

however, as: 'The Chambered Nautilus'; 'The Voiceless'; 'The Last Leaf'; 'The Iron Gate'; and one or two hymns, he takes high rank among the poets of his time, while such poems as 'The One Hoss Shay'; 'Evening, By a Tailor,' and 'Parson Turell's Legacy,' to name no others, are inimitable examples of humorous verse. His later collections of poems comprise: 'Songs in Many Keys' (1861); 'Songs of Many Seasons' (1875); 'The Iron Gate' (1880); and 'Before the Curfew' (1887). As a physician and medical lecturer he was very successful, and among his purely professional works may be named: 'Lectures on Homeopathy and Its Kindred Delusions' (1842); 'Currents and Counter Currents in Medical Science' (1861); 'Border Lines in some Provinces of Medical Science' (1862); 'Medical Essays,' a reissue of some of his earlier work (1883). Still other volumes by Dr. Holmes are: 'Soundings from the Atlantic' (1864), a series of essays originally contributed to the 'Atlantic Monthly,' where the bulk of his writing first appeared; 'Mechanism in Thought and Morals' (1871); lives of 'John Lothrop Motley' (1879); and 'Ralph Waldo Emerson' (1884); 'Our Hundred Days in Europe' (1888); a sprightly record of a short visit to England in 1886, on which occasion honorary degrees were conferred upon him by the universities of Cambridge, Oxford and Edinburgh; and 'Over the Teacups' (1891). His 70th birthday was celebrated by a breakfast given in his honor by the publishers of the 'Atlantic Monthly,' and on this occasion the poet read his poem 'The Iron Gate,' which many persons have considered even finer than 'The Chambered Nautilus' which Holmes himself preferred to any other verses of his. At its best Holmes's prose style is thoroughly admirable, characterized as it is by an unerring sense of the value of words and their fitness for conveying a desired impression, and illumined by the interfused play of a delicate fancy and the most sparkling humor. Next to 'The Autocrat' must be ranked 'The Guardian Angel' among his prose works, the same kindly tolerant spirit being dominant in both, and the same shrewd, wholesome perception of character. In much of his earlier poetry, excepting in his lyrics, Holmes uses the formal ten-syllabled iambic pentameter of the 18th century, but in his hands the measure seems at times more flexible than when used by Pope and his school, and it is at all events relieved from solemnity by his ever present humor. 'Urania' is the best-known of his earlier efforts in this manner, and 'The Schoolboy' (1878) his most notable later one, this latter having been written for the centennial anniversary of Phillips Academy at Andover. Holmes's special characteristic was kindliness, which found its expression as well in his verse as in his prose, and in his ordinary living. He could be keenly satirical on occasion but he never became in the least cynical. Perhaps no American writer, not even Longfellow or Lowell, ever won the English heart so completely as Holmes. Longfellow found a wide hearing in England for his poetry, it is true, and Lowell was thoroughly appreciated by the upper class Englishman of his time, but Holmes was the most generally beloved of the three. In his own country Holmes's gentle, tolerant writing did not a little toward softening the asperities of controversy and liberalizing unconsciously the heart of Puritan New England. Consult: Morse, 'Life and Letters of Oliver Wendell Holmes' (1896); and lives by Kennedy (1883); E. E. Brown (1884).

Holmes, Oliver Wendell, Jr., American jurist: b. Boston 8 March 1841. He was graduated from Harvard in 1861, and in the same year entered the army as lieutenant of the 20th Massachusetts regiment. He was wounded at the battles of Ball's Bluff, Antietam, and the second battle of Fredericksburg, and was mustered out of the army in 1864, with the rank of brevet lieutenant-colonel. He then studied at the Harvard Law School, and was admitted to the bar in 1866, beginning his practice in Boston. He was editor of the 'American Law Review' (1870–3); became professor at the Harvard Law School in 1882, and in the same year justice in the Massachusetts supreme court; in 1899 he was appointed chief justice of the same court. His decisions in this position gave him wide fame among lawyers, and were characterized by originality and literary finish. In several cases his decisions were in favor of organized labor; his position being that workingmen had a right to combine and to "support their interests by arguments, persuasion, and the bestowal or refusal of those advantages which they otherwise lawfully control, so long as they do no violence or threaten no violence." In August 1902, he was appointed a member of the United States Supreme Court. He has published: 'The Common Law' (1881), lectures delivered before the Lowell Institute; and a collection of speeches (1900); he also edited the 12th edition of Kent's 'Commentaries' (1873).

Holmes, Theophilus Hunter, American soldier: b. Sampson County, N. C., 1804; d. near Fayetteville, N. C., 21 June 1880. He was graduated from the United States Military Academy in 1829, served in the Florida war, the occupation of Texas, and the Mexican War, and at the beginning of the Civil War was major and superintendent of the general recruiting service. On 22 April 1861, he resigned his commission in the United States army, forthwith was appointed brigadier-general in the Confederate forces, and organized several North Carolina regiments. He was in command at Aquia Creek, and, promoted major-general, was in command of the trans-Mississippi department from September 1862 to March 1863, was commissioned lieutenant-general, and 3 July 1863 lost heavily in an unsuccessful attack on Helena, Ark.

Holmes, William Henry, American geologist: b. Harrison County, Ohio, 1 Dec. 1846. He was graduated at the McNeely Normal College in 1870, in 1872 was made an assistant on the United States geological survey, and in 1880–9 was a geologist on the survey. In 1889–98 he was archæologist to the United States bureau of ethnology, directing explorations, and in 1894–8 also curator of anthropology in the Field Columbian Museum of Chicago, and professor of anthropic geology in Chicago University. In 1898 he was appointed head curator in the department of anthropology in the United States National Museum. His chief works are: 'Archæological Studies among the Cities of Mexico'

(1895); and 'Stone Implements of the Potomac-Chesapeake Tidewater Province' (1897).

Holocaine. See COCAINE.

Holocephali, hŏl-ō-sĕf'a-lī, or **Chimæroidea,** a group of small shark-like fishes of bizarre appearance occurring in the deeper portions of all colder seas, including in all about seven species, five in American waters. They have a cartilaginous skeleton, are of no value as food, and are known to fishermen as rat-fish and elephant-fish (q.v.). The name Chimæra, given to one genus, emphasizes the strange appearance of these fishes. See ICHTHYOLOGY.

Holophytes, hō'lō-fīts. See FUNGI.

Holostei, hō-lŏs'tē-ī, a group of fishes, the bony ganoids, largely fossil, represented by the garpikes. See ICHTHYOLOGY.

Holothuria, hŏl-ō thū'rĭ a, echinoderms of the class *Holothuroidea,* popularly called "sea-cucumbers," from their resemblance in shape and rough skin to that vegetable, in which the body is long, cylindrical, somewhat worm-like, less radiated than other echinoderms with a thick muscular body-wall of longitudinal and transverse muscles. The skin is usually thick, tough, and imbedded in it are in certain forms calcareous plates, wheels and anchors. The mouth is surrounded with a circle of ten branched tentacles, adapted both for respiration and for seizing the food, which consists mainly of foraminifera. The intestine is very long and slender, thus in *Thyone briareus,* which lives in mud and sand on the coast south of Cape Cod, the intestine in an individual three or four inches long is nearly seven feet in length; it opens at the end of the body, and connects with the "respiratory tree," by which the water is introduced into the interior of the body. Unlike other echinoderms the so-called madreporic body is internal. Holothurians move by tubes or ambulacra feet which are filled with water, and when distended act as suckers to drag the animal over the bottom. These suckers are either arranged in five rows or with three rows on the ventral surface, and two above, the latter in some form obsolete, or they are scattered irregularly over the surface of the body, while in *Caudina arcnata* of the New England coast there are no suckers. A tendency to bilateral symmetry is seen in a form like *Psolus,* which has a creeping disk and three rows of suckers on the flattened disk-like under side.

The holothurians undergo a metamorphosis, somewhat like that of the starfish: but the transparent larva called "auricularia," is barrel-shaped; what corresponds to the hoops of the barrel being bands of cilia, while the ear-like projections in certain forms give it the name auricularia. Before the larva is fully grown, the body of the young holothurian begins to bud out from near the side of the larval stomach, the calcareous cross-like plates are deposited, and the tentacles begin to grow out. Finally after the larval body is absorbed the young holothurian sinks to the bottom. The degree of metamorphosis is less marked than in other echinoderms, while in two forms development is direct, the young growing in a marsupium or brood-pouch. A form (*Cladodactyla crocea*) living in the south seas at the Falkland Islands, carries its young in a sort of nursery where they are densely packed in two continuous fringes adhering to the dorsal tubes. Holothurians are remarkable from the fact that when captured they eject their intestine, a new one in time being regenerated. The large forms lying about on the coral reefs are known to harbor a small slender fish (*Fierasfer*) which lodges in their cloaca or in the branchial tree. Many of the species are very large, being nearly two feet in length. A common species on the Florida keys and reefs is *Holothuria floridana;* it lives in water only a few inches deep and can be picked up in large numbers; it is fully 15 inches in length, and lives on foraminifera. It has been collected, dried and a shipload exported to China, but the trepang or beche-de-mer of commerce is either of two species (*H. edulis,* and *H. tremula*) inhabiting the Pacific Ocean (see TREPANG). A California species is also dried and exported by the local Chinese.

The class of *Holothuroidea* is divided into two orders: (1) *Actinopoda* represented by *Holothuria, Cucumaria, Thyone, Psolus,* etc.; and (2) *Paractinopoda,* of which *Synapta* is an example, the common form living in sand at low water on the New England coast being *Leptosynapta girardii.* A few forms inhabit great depths. Remains of holothurians have been found fossil; certain calcareous plates attributed to them occurring in the Carboniferous, Lias, Jura, and Cretaceous strata. Minute calcareous bodies referable to *Synapta,* etc., have been detected in the Paris Eocene limestones.

Holst, hōlst, **Hermann Eduard von,** German-American historian: b. Fellin, Livonia, Russia, 19 June 1841; d. Freiburg, Germany, 20 Jan. 1904. He studied history in Dorpat and Heidelberg and in 1865 traveled through France, Italy, etc. His writings were looked upon with suspicion by the Russian authorities and his further stay in that country becoming unsafe, he removed to the United States in 1866. Here he became American correspondent of the 'Kölnische Zeitung,' and sub-editor of the 'Deutsch-amerikanischer Conversations-Lexicon.' In 1872 he was appointed extraordinary professor of history in the University of Strasburg and in 1874 ordinary professor at Freiburg-im-Breisgau. In 1876 he undertook, with means furnished by the Baden government, a journey to London for the purpose of study and in 1878–9 a similar journey to North America at the expense of the Prussian Academy of Science. In 1892 he accepted an appointment in the University of Chicago. He has published: 'Constitutional and Political History of the United States' (1873); 'The French Revolution Tested by Mirabeau's Career' (1894), etc.

Holstein, hōl'stīn, Germany, a former duchy of Denmark, and member of the Germanic Confederation, since 1866 united to Schleswig-Holstein (q.v.), Prussia.

Holstein Cattle. See DAIRY CATTLE.

Holston, hōl'stŏn, a river which rises in the southwestern part of Virginia, flows south and southwest into Tennessee and unites with the French Broad River about five miles east of Knoxville. The Holston and the French Broad are the head-streams of the Tennessee River. The course of the Holston is through a mountainous country, noted for its beautiful scenery.

It has as tributaries many small mountain streams. Its length is about 200 miles.

Holt, Joseph, American jurist: b. Breckinridge County, Ky., 6 Jan. 1807; d. Washington, D. C., 1 Aug. 1894. He began legal practice at Elizabethtown in 1828, and in 1857 was appointed commissioner of patents. In 1859 he became postmaster-general and in 1860 secretary of war. He was made by Lincoln a judge-advocate general of the army, with colonel's rank, was promoted brigadier, brevetted major-general for distinguished service in the bureau of military justice, and was retired in 1875. With the exception of Cass, he was the only member of Buchanan's cabinet that was not a Confederate sympathizer. Among the courts over which he presided were those before which Fitz-John Porter and Lincoln's assassins were tried.

Hol'ton, Kan., city, county-seat of Jackson County; on the Missouri P., the Chicago, R. I. & P., and the Union P. R.R.'s; about 28 miles north of Topeka and 30 miles west of Atchison. It was settled in 1859 and received its charter in 1870. It is situated in a section noted for good farms. The chief manufactures are flour, wagons, cigars, creamery products, and planed lumber. Its trade is chiefly in wheat, corn, hay, live-stock, and local manufactured products. The government is vested in a mayor, who holds office two years, and a common council. Pop. (1900) 3,082.

Hölty, Ludwig Heinrich Christoph, lood'-vĭg hĭn'rĭH krēs'tŏf hĕl'tĭ, German lyric poet: b. Mariensee, near Hanover, 21 Dec. 1748; d. Hanover 1 Sept. 1776. In 1769 he went to Göttingen to study theology. Here, falling in with Bürger, Voss, the Stolbergs, and other poets of kindred tastes, he became one of the founders of the Göttingen "Hainbund." This league of young enthusiasts was aflame for Klopstock, then considered the greatest German poet for patriotism and for friendship, detested Wieland's sensual poems and his Frenchified manner, read the classics together, and wrote poetry in friendly emulation. Hölty's poems reveal a lovable personality. The strain of sentimentality that runs through all his work is not affectation, as it was with so many of the younger poets of that age in which Rousseau had made sentimentality fashionable, but the true expression of his nature. His range was small; but within its limits his work was excellent, and many of his songs have become the common property of the people. Consult: Voigts, 'Hölty, ein Roman' (1844); Reute, 'Hölty, Sein Leben und Dichten' (1883).

Holub, ho'loob, Emil, Austrian explorer: b. Holics, Bohemia, 7 Oct. 1847; d. Vienna 21 Feb. 1902. At 25 he went to South Africa, where he practised in Kimberley and elsewhere as a physician. Later he became engaged in African exploration and in recognition of his services as an explorer received from the Austrian emperor the Order of the Iron Crown. He published 'Beiträge zur Ornithologie Südafrikas'; 'Sieben Jahre in Südafrika' (1881); 'The Colonization of Africa'; and 'From Cape Town to the Maskukulumbe.'

Holy Alliance, an international league proposed by Alexander I., emperor of Russia, 26 Sept. 1815, after the defeat of Napoleon at Waterloo had cleared the way for the execution of his desire of establishing a settled peace in Europe. Alexander, Francis of Austria, and Frederick William III. of Prussia, signed with their own hands, and without the countersign of a minister, the act establishing this alliance, which is said to have been sent to the two latter in the handwriting of the first. It was not wholly published till 2 Feb. 1816, when the text was given in full in the Frankfort *Journal.* It consisted of a declaration, that, in accordance with the precepts of the gospel of Jesus Christ, the principles of justice, charity, and peace should be the basis of their internal administration, and of their international relations, and that the happiness and religious welfare of their subjects should be their great object. Its real aim, however, was to maintain the power and influence of the existing dynasties. It was also stipulated that the three sovereigns should invite others to become members of the Holy Alliance. In Russia and Germany its principles were not discussed except in a spirit of eulogy, but they were uncompromisingly condemned in Britain by many of her foremost statesmen. On 4 Feb. 1823 both Lansdowne and Brougham openly condemned its doctrines in their places in Parliament. Sir James Mackintosh said of the doctrine of legitimacy, in the sense in which it was used by the Holy Alliance, "Sophistry lent her colors to the most extravagant pretensions of tyranny." The events of 1848 broke up the Holy Alliance. It had previously lost much of its authority from the death of Alexander, and the French revolution of 1830. By a special article of the treaty the members of the Bonaparte family were declared incapable of occupying any European throne.

Holy Cross, College of the, an institution in charge of the Fathers of the Society of Jesus, situated at Worcester, Mass. The school was founded in 1843. It has a preparatory department; and the college grants the usual degrees given by classical and scientific institutions. It is self-supporting; up to 1903 it had received no State aid nor any endowments. It has established six fellowships. In 1903 there were connected with the school 28 professors and instructors, and nearly 400 students. The library contained about 25,000 volumes.

Holy Cross, Mount of the, a peak of the Rocky Mountains, in Eagle County, in the State of Colorado. The peak is about 75 miles southwest of Denver, and 20 miles north by west of Leadville. It is 14,006 feet high.

Holy Day, a day set apart in the Catholic Church for the commemoration of some saint or mystery. It is called "of obligation" when attendance at Mass and abstention from servile works are prescribed.

Holy Ghost, or **Holy Spirit,** the third person in the Holy Trinity. The Roman Catholic Church declares the Son to be begotten by the Father, and the Holy Ghost to have proceeded from both. The Orthodox Greek Church maintains that the Holy Ghost proceeds from the Father only; and this is one of the main points of doctrine on which Roman and Greek Catholics differ. The history of the controversy is shortly this: Tertullian and Origen, two distinguished Fathers of the Church in the 3d century, maintained that the Holy Ghost was begotten by the Father through the Son.

Macedonius, bishop of Constantinople in the middle of the 4th century, denied that the Holy Ghost was equal in essence and dignity to God the Father. The Council of Alexandria in 362 declared this bishop and his adherents, the Pneumatomachists, teachers of heresy; and the general council at Constantinople in 381 declared expressly to the whole Christian Church, that the Holy Ghost was the third person of the Trinity, proceeding from the Father, and to be worshipped equally with the Father and the Son. Augustine taught that the Holy Ghost proceeds from the Father and the Son; and the Council of Toledo, in 589, condemned all who believed otherwise. This new formulation of the dogma occasioned a controversy which lasted from the 8th to the 11th century, between the Western or Latin, and the Eastern or Greek Churches, and finally led to their complete separation. The Anglican Church and the Protestant Episcopal Church in the United States use the Greek form of the Nicene Creed. The worship of the Holy Ghost as the third person in the Godhead is common to both Roman and Greek churches, and to the Protestant Trinitarians, being essential to the faith in the divine Trinity. See CREED: TRINITY.

Holy Ghost Flower, or Holy Spirit Plant. See DOVE PLANT.

Holy Ghost, Order of, a former order of Hospitalers, founded by Guy, son of William, Count of Montpellier, in the 12th century, for the relief of the poor, the infirm and foundlings. In the 18th century it was united with the order of St. Lazarus by Clement XIII. Also the name of the principal military order in France instituted in 1578, abolished in 1789, revived at the Restoration, and finally abolished in 1830.

Holy Land, a name given by Mohammedans to Arabia because it was the birthplace of Mohammed; also by Buddhists to India because it was the country of Sakya Muni. It is a common name of Palestine, because the place where Christ lived when upon earth. See PALESTINE.

Holy Orders, the several ranks of the ministry of a church; also the power or authority to exercise that ministry.

In the Roman Catholic Church Holy Orders is one of the sacraments and there are seven orders of the ministry, viz.: priesthood, deaconate, and sub-deaconate: these are the greater or sacred orders; and the four minor orders of lector, acolyte, exorcist, and doorkeeper. Usually the episcopate is classed, not as a separate order, but as the completion and extension of the priesthood. Though every candidate for the priesthood is inducted into the four minor orders and the sub-deaconate and deaconate before he receives priestly ordination, it happens very seldom that a man enters any of those inferior orders intending to remain therein: they are simply steps to the priesthood.

In the Oriental churches, both those in communion with the Roman See — as the Greek Uniate, the Maronite, the United Armenian, etc., and those which are separated from Rome by schism or by heresy, the number of orders is less than in the Latin Church: in all the foregoing churches only four orders, or, counting the episcopate as a distinct order, five orders are recognized; those of bishop, priest, deacon, and lector: and of these the first three, at least, are held to be of divine institution and sacramental.

By the Anglican Church and the Protestant Episcopal Church of the United States three orders are recognized; those of bishops, priests and deacons: but in the 25th of the Articles of Religion those orders are expressly declared to be no sacrament.

The orders of the Oriental churches are generally recognized as valid by the Church of Rome; and when a priest of any of those churches is received into the Roman Catholic Church he is still regarded as a priest: but an Anglican or a Protestant Episcopal minister enters the Latin Church as a simple layman even though he were in Anglicanism a bishop; for Anglican orders have ever been held by Rome to be invalid.

Other Protestan churches, whether episcopal (as the Lutheran) or presbyterial or congregational, do not regard holy orders (or clerical order) as of divine institution or as setting up any essential difference between minister and layman. See CLERGY.

Holy Roman or German-Roman Empire, a title conferred on the German empire in 962 by Pope John XII. at the coronation in Rome of Otho I., who considered himself the lineal representative of the rulers of the ancient Roman Empire which practically had ceased to exist in 476. The designation ended in 1804 with the accession of Francis II. as hereditary emperor of Austria. See HAPSBURG.

Holy Water, in the Greek and Roman Catholic Churches, water which has been consecrated by prayers, exorcism, and other ceremonies to sprinkle the faithful and things used for the church. Some antiquaries think that the use of holy or lustral water was borrowed from the Jews. The Roman Catholic Church considers holy water not only symbolical of the purity of the soul, but in certain cases as effectual in exorcism. At the entrance of all churches is kept a font of holy water, in which those going in and out dip the fingers and bless themselves. The consecration of holy water takes place on Holy Saturday before Easter Sunday.

Holy Week, or Passion Week, is that which immediately precedes Easter. The name Passion Week rather refers to the days following and exclusive of Palm Sunday, since this day, strictly speaking, does not commemorate any incident of Christ's passion, but his triumphant entry into Jerusalem. The three chief days of the week are Maundy Thursday (or Holy Thursday), Good Friday, and Holy Saturday, the most sacred of all being Good Friday. The observance of Holy Week is of very early origin, and it was known as Great Week, Silent Week, Penitential Week, etc. In the ancient Church of Rome, when any of the ordinary Church festivals falls on this week, it is not observed till after Easter. In Rome it used to be observed with much greater solemnity and penitential rigor than now; for the shops are kept open, concerts and other amusements are given, though the theatres are closed. The washing of the feet of poor men is still practised in Roman Catholic churches; and the pope washes the feet of 13 poor persons, all of whom are priests. In Austria the emperor keeps up the old rite of feet-washing with much ceremony.

Holyoake, hōlī-ōk, **George Jacob,** English political reformer: b. Birmingham 13 April 1817; d. Brighton 22 Jan. 1906. He early became connected with various advance movements in Birmingham. In 1841 he was one of the lecturers chosen to explain Robert Owen's social theories, and next year was imprisoned on a charge of atheism. He supported the Chartist demands, but did not sympathize with their hostility to the Whigs. He took an important part in the agitation for the repeal of the corn laws, and for the repeal of the so-called "taxes upon knowledge." He was the founder of a purely ethical religion, without theistic element (secularism); and was active as a lecturer and writer in the co-operative movement. His works include: 'The Logic of Death'; 'The Logic of Life'; 'The Trial of Theism'; 'Nature and the Origin of Secularism'; 'Thirty-three Years of Co-operation' (1872); 'History of Co-operation in England, Its Literature and Its Advocates' (1875); 'Among the Americans' (1881); 'Self Help One Hundred Years Ago' (1888); 'The Co-operative Movement of To-day' (1891), a short, useful account of the history of co-operation; 'Sixty Years of an Agitator's Life' (1892), an autobiography; and 'Jubilee History of the Leeds Co-operative Society' (1897).

Holyoke, hōl'yōk, Mass., city in Hampden County; on the Connecticut River, and the New York, N. H. & H. and the Boston & M. R.R.'s; about 75 miles southwest of Boston and 8 miles north of Springfield. Holyoke was settled in the last part of the 17th century by people from Ireland, and for some time it was called Ireland Parish. It was incorporated as a part of West Springfield in 1786; but in 1850 it became a distinct town, with its own government, and it was chartered as a city in 1873. Like the other settlements along the shore of the Connecticut, the inhabitants saw the advantages to be derived from the water-power. At first only the small streams flowing into the Connecticut were dammed, and used for turning machinery; the main stream itself was the great route whereby trade intercourse was established with settlements along its shores. In 1847 the Hadley Falls Company began to devise ways and means of using the water-power of the Connecticut River, which at Holyoke had a fall of about 60 feet. In a few years the dam, 1,000 feet in length, was placed across the river, and the water-power thus obtained gave Holyoke great opportunities for the establishment of manufacturing industries, and they have been well utilized. For some years it was noted for the number and magnitude of its paper-mills; but other industries now enrich the city. Its chief manufactures are paper, paper-products, thread, cotton and woolen goods, knit goods, alpaca, silk, automobiles, machinery, bicycles, wire, belting, screws, bricks, furniture, and school supplies. Some of the public institutions are the College of Music, public library, House of Providence hospital, city hospital, two orphanages located outside the city limits, St. Vincent's for girls and Holy Family for boys. A large percentage of the people are of foreign birth or foreign descent. The school census of 1902 shows the following: Public schools, 3,500 Irish, 3,200 French, 800 German, and 900 American. In the parish schools there were enrolled that same year 3,500 pupils. The law which declares: "No minor who cannot read and write the English language can be employed in any factory or commercial enterprise" is rigidly enforced. Evening schools are provided for those who cannot attend school in the day time. The Holyoke Scientific Society has done special and excellent work in American archæology. It owns a valuable collection of Indian relics. Some of the places of interest near the city, and which may be reached by the electric railway, are Mount Holyoke (q.v.), Mount Tom (q.v.), and Springfield. In 1896 the city charter was revised, and the government is now vested in a mayor, who is elected annually, and a city council. Pop. (1890) 35,637; (1900) 45,712.

Holyoke College, Mount. See MOUNT HOLYOKE COLLEGE.

Holyoke, Mount, a narrow ridge of greenstone, the highest point of which is about 1,120 feet above the sea. It is in Hampshire County, Mass., about one mile east of the Connecticut River, five miles southeast of Northampton, and eight miles northeast of Holyoke. On the summit is a hotel, built in 1821. The hotel can be reached by a carriage road which winds to the top, or by a railway which runs up a steep incline.

Holyrood, hō'lī-rood, **Palace and Abbey of,** Scotland, the ancient royal residence at Edinburgh (q.v.).

Homatropin, hō-măt'rō-pĭn. See ATROPINE.

Home, Henry, LORD KAMES, Scottish lawyer and author: b. Kames, Berwickshire, 1696; d. Edinburgh 27 Dec. 1782. He studied law at Edinburgh, and, called to the bar in 1724, soon acquired reputation by a number of publications on the civil and Scottish law. In 1752 he became a judge of session, and assumed the title of Lord Kames. In addition to legal works he published 'Essays on British Antiquities'; 'Essays on the Principles of Morality and Natural Religion,' in which he advocates the doctrine of philosophical necessity; 'Introduction to the Art of Thinking'; and his best-known work, 'Elements of Criticism,' in which, discarding all arbitrary rules of literary composition, he endeavors to establish a new theory on the principles of human nature. In 1776 he published the 'Gentleman Farmer'; and in 1781 'Loose Thoughts on Education.'

Home Education. From the earliest recorded school the conception of education has steadily broadened, till now careful thinkers recognize that education should be for adults as well as for the young, carried on at home as well as in school and through life instead of for a limited course. The agencies for this broader education are in five distinct groups, and workers in this special field after mature deliberation have given to it the name "Home education" because it differs from school education in being carried on at home while the students are engaged in their regular callings, instead of in schools as a chief occupation. The five groups of schools (elementary schools, high schools and academies, colleges, professional and technical schools, universities) might be called the five majors of education, while libraries, museums, study clubs, extension teaching, tests and credentials might be called the five minors.

1. *Libraries.*— This includes reference and lending libraries, magazine and news rooms and all reading of the conventional symbols called print. Reading courses, circles, clubs, and home study from books without instructors belong to this library group, which is the cornerstone of all home education. See LIBRARIES; TRAVELING LIBRARIES.

2. *Museums.*— This includes museums and laboratories of science, art, history, etc. As the library group includes education through the eye by means of conventional symbols, so in its broadest sense the museum group represents education also through the eye from reading the interesting and beautiful language of nature and art; and as reading may often have no direct connection with the public library, so also the museum group may include detached monuments, statues, busts, pictures, and other works of art. See MUSEUMS.

3. *Extension Teaching.*—This includes all agencies which extend personal help or teaching to those who cannot attend regular schools; for example, summer, vacation, Saturday, night schools or classes, extension lectures, correspondence teaching, home study under direction, classes in libraries, Y. M. C. A. or Y. W. C. A. and other organizations. Mere lectures or addresses not accompanied by class or paper work, or instruction in the more limited sense, should be sharply distinguished from extension teaching. They represent the platform and perhaps should be counted as an independent group. Some so-called extension teaching is really little more than lectures, while under the name lecture some excellent instruction is given. The group should perhaps be called "extension teaching and lectures," to keep prominent the difference between the two, while it recognizes as their common distinguishing quality the personal aid and inspiration given by the teacher or lecturer to his class or audience. Lecturers give the inspiration and magnetism of personal contact which cannot be transmitted in print. This personal element, however, is chiefly on the side of the lecturer; the audience is a mass. In extension teaching where the lecturers are to stimulate to personal study and are supplemented by class and written work, the personal element is reciprocal; for the teacher, dealing with each student as an individual, answers his questions, solves his difficulties and is his personal teacher, guide and friend. The lecture is chiefly for inspiration; the teaching, for instruction.

The chief factors in extension teaching are:

Summer Schools.—In the last decade skepticism as to the practical value of summer schools has given way to official recognition by the leading American universities of the demand for such instruction and of the duty to supply it of institutions with buildings, libraries, laboratories, reputation and faculty. Fortunately, many weak institutions, some of them started or maintained from commercial motives and others lacking funds for proper work, have been discontinued as one by one the strongest institutions have offered the needed instruction and thrown open to the public during the summer months their great facilities. See SUMMER SCHOOLS.

Correspondence Teaching.— Commercial experiments have proved that there is a large demand for instruction in many subjects, especially those which add most directly to wage-earning capacity, from those wholly unable to leave their positions to attend any of the established schools. The growth of this demand is evidenced by the great number of advertisements of such instruction and by the marked success of some of the more prominent schools. One of these schools in 1903 had 650,000 students and 114 professors, and upward of 2,000,000 persons were taking correspondence courses in this country. The method having been proved efficient is beginning to be adopted by the endowed institutions; and inevitably as they offer better instruction at less cost and with it their established reputation, correspondence teaching with full recognition of its limitations but also of its possibilities, will become an established and creditable educational factor.

Extension Courses.— In America for the few years near the end of the 19th century hundreds of university extension centres were established, most of them with insufficient knowledge of what a real extension course was and with inadequate facilities and teachers inexperienced in this peculiar but important work. The result predicted naturally followed and most of the organizations which sprung into existence died out. The University of Chicago won first place by the excellence of the work it offered and still carries on. The American Society for the Extension of University Teaching in Philadelphia has been most active and successful of all the voluntary organizations. The New York State extension work was from the first announced to be wholly subsidiary to the more important function of the public library and study clubs. Experience has proved the great merit of the extension method in the hands of skilful teachers with a gift for this difficult kind of teaching, where inspiration is more important than instruction. See UNIVERSITY EXTENSION.

Lectures.—In most cases lecturers have been desultory and have been intellectual entertainments rather than entitled to rank as educational factors. Students of home education, however, recognize the inspirational lecture as a strong lever in their work and are using it more carefully and effectively, and organizing into courses which give better results. The Brooklyn Institute has maintained for many years a remarkable system, giving each year hundreds of lectures from recognized authorities, and in connection with its library and museum affords the best existing example of a great metropolitan home education centre. In New York the free lectures for the people have grown steadily from year to year and exert a great influence for good on the hundreds of thousands who hear them annually. Progressive librarians are more and more feeling the responsibility of guiding the local demand so that the lectures shall become a still more efficient ally of the library in its broad work of giving information, inspiration and intellectual recreation. See also ADULT EDUCATION.

4. *Associations or Clubs.*— This includes all forms of mutual help through associated effort, from the club of two friends in a single house to the great summer schools like Chautauqua, where each July and August thousands gather

from all parts of the country. This work with one's fellows supplies something of the element of residence, which is as valuable a part of the usual college course as are the studies. A certain subtle mental chemistry of the greatest practical value results from contact with other minds pursuing the same studies. If this gives a few weeks actual residence away from home, with daily student life, and a course in such company and surroundings as our best summer schools now offer, the student gets an invaluable taste of real college residence. This mutual help element in home education is chiefly supplied by the numerous literary and study clubs, many of which are coming to give their annual programs, a definite educational value by limiting them to a single worthy subject and supplying members with books, pictures and, if needed, specimens or other aids.

5. *Tests and Credentials.*— The great problem in popularizing education is to secure continuous and systematic study from those lacking the stimulus of the schools. Experience shows that a goal is needed by most people to hold them to completion of what they begin, by giving tests and official recognition, with suitable credentials for work well done. Differing from the other groups their field is to stimulate, test, record, and certify, rather than to give instruction. In spite of the criticisms and abuses of examinations, no satisfactory substitute for the good they accomplish when properly used has yet been found. They are last and least of the minors, but necessary to a complete system.

Educational Factors.— Most well equipped schools have all the factors of home education in active operation, but it is the use of these factors by those who cannot attend schools that constitutes home education. Schools imply residence and are attended consecutively, students advancing stage by stage from kindergarten to university. In home education the student will often use all five minors at once, and in well organized extension courses with lectures, syllabus, class, paper work, directed reading, student club and final examination we have four of the five minors, and in many subjects the museum or laboratory element is also added. A town that aims to provide educational facilities for both old and young at home, through life must make all five groups available. For most places the ideal would be to combine in a single building suitably arranged, the public library, museum, extension, examination, and association or club rooms, thus massing in a single institution, for which the best name is institute, all the essential educational agencies outside regular schools.

While there should be constant co-operation and the utmost harmony between the agencies for home and school education, experience constantly proves that the best results cannot be obtained by putting home education work in charge of school authorities. The obvious reason is that school trustees naturally and properly feel that the school system is the vital part, while libraries, museums, clubs, and extension teaching are only incidentals. The best results are always reached with independent trustees, who regard home education as quite as important as school education, and who devote all their energies to promoting their own work. While two governing boards are thus a necessity, a larger number is more costly and less efficient in administration, so that most close students of this problem advise in all ordinary circumstances the massing of the five minors together under a single board with headquarters in a single building. While in theory the library is one of the five home education factors, in fact the rapidly growing practice is wisely making home education a part of the library. This is because the country is being rapidly dotted with library buildings supported by taxation and endowments and receiving private gifts and public appropriations and support to a degree never equaled in educational history. The public library is already one of the most popular of American institutions and is rapidly gaining ground in all civilized countries. With buildings, endowments, trustees and public sympathy and support, it is the most economical, natural and best centre for the other elements of home education. In New York the official title now used is "New York State Library and Home Education," but it is frankly stated that the words "home education" will be dropped when the public learns that library means not a mere collection of books, but the home of all this closely allied work.

At the national meeting of American librarians in 1898 the entire program was given to impressing as strongly as possible the fact that small as well as large public libraries had the privilege and duty of giving stimulus and aid not alone to readers of books, but to all citizens, young or old, who were seeking intellectual advancement. Libraries are rapidly introducing the museum element in collecting and lending pictures as they do books. Many have started collections in art, science, or history. Laboratories are sure to follow, where persons without such facilities at home may pursue investigations and supplement their reading with experimental work. Even small towns now consider a library building inadequate which does not provide rooms for literary, scientific and similar societies for mutual improvement, and lecture halls, large and small, for the various phases of extension teaching. In the last few years this development has become less a matter of discussion than the rapidity with which individual libraries may take on their new and broader functions.

MELVIL DEWEY,
Formerly Director New York State Library.

Home Rule, the domestic control of local affairs in a province, colony, or dependency of an empire. The term has been employed in recent history most especially with regard to Ireland, which has been a dependency of England ever since Pope Hadrian, as is averred, handed it over to Henry II. of England in 1155, on condition that a certain portion of its revenue should flow into the treasury of the Holy See. Since that time Ireland has been more or less subject to the government of England. English viceroys have ruled at Dublin, and English troops kept the peace. The Irish are a high-spirited and proud nation, and the history of their subjugation has been a bloody one. For many years, however, they had their own parliament, and managed their own domestic affairs. Then came what was called the Union. The Irish

parliament was abolished, and Irish boroughs elected representatives to seats at Westminster. This was in 1801, when it is said that the Irish parliament which passed the bill for its own destruction was bribed or cajoled into what Irishmen of to-day consider a fatal and suicidal act. The first Irishman of note to attempt a remedy for Irish grievances was Daniel O'Connell. Catholic emancipation had been won largely through his agitation, seconded by the strong and clear-headed statesmanship of Wellington. In 1834 O'Connell brought forward in the House of Commons his motion for a repeal of the Union. By recent act of Parliament the municipal councils of Ireland had been thrown open to Roman Catholics. O'Connell was elected lord mayor of Dublin, and while his motion for appeal was supported with but 40 votes in parliament, he carried it by 45 to 15 votes in the municipal chamber at Dublin. This was undoubtedly the earliest step in the movement toward home rule, which from that time to the present moment has convulsed Ireland. In the town council at Dublin one of the 15 who had voted against O'Connell's motion for the repeal of the union was a brilliant young lawyer named Isaac Butt. In 1871 he was elected member of Parliament for Limerick and with him the Home Rule party in the English Parliament was born. The party struggled along for many years striving by obstruction and agitation in several quarters to maintain the rights of Ireland, and obtain for her better terms in her relations with the mother country. Mr. Butt, who was a true home ruler, though a conservative, was at length incensed by the obstructionist tactics of Parnell and Biggar, which he thought beneath "the dignity of Parliament," and practically surrendered the leadership of his party, in which he was succeeded by Parnell. In 1877 Parnell was elected president of the Home Rule Confederation of Great Britain. Parnell very quickly showed that he not only had very definite views, but possessed also the courage of his convictions. He became an advocate of peasant proprietorship. For the realization of this idea the Land League was constituted. At a meeting held in London 21 Oct. 1879 it was declared that the objects of the league were, first to bring about a reduction of rack-rents; second to facilitate the obtaining of the ownership of the soil by the occupiers. It was very remarkable to see how English opinion was gradually molded by the great Land League and Home Rule Party. In the elections of 1885 many Conservative candidates almost echoed the words of Parnell in declaring for a "liberal measure of home rule for Ireland." In the elections of 1885 the Liberals came in for a majority and Mr. Gladstone was premier for the third time. He was not long in bringing in a bill providing for "the constitution of an Irish parliament sitting in Dublin with the Queen as its head." He urged the passing of the bill with one of the most powerful, the most effective, and most touching speeches which he ever delivered. But his eloquence was in vain, the measure was defeated by a majority of 30. This was not the last time that Gladstone was to attempt the liberation of Ireland. But bold as had been his change of opinion in putting forth a measure he had in earlier life condemned, his conception of Home Rule for Ireland was quite inadequate compared with what O'Connell contemplated in his agitation for repeal. Such as it was, Gladstone again staked the existence of his ministry on its realization in 1893. The bill passed the House of Commons, but was rejected in the House of Lords, and since that time Home Rule for Ireland has been a dead issue in English politics.

Home Rule, Municipal. See MUNICIPAL GOVERNMENT.

Homer, hō'mėr, a poet to whom was attributed in ancient Greece the authorship of the two epic poems, the 'Iliad' and the 'Odyssey,' which form the foundation of Greek, and consequently of European literature. Of Homer's personality, birth, place, and time, we have no certain knowledge. His very existence has been brought into doubt, and in accordance with the etymology of his name Homer, which means the same as Vyasa, to whom the Mahabharata has been attributed, he is sometimes taken merely for the "arranger" or "compiler" of the works that go by his name. Seven cities, however, contended for the honor of being his birthplace; their names form the hexameter line

Symrna, Rhodos, Colophon, Salamis, Chios, Argos, Athenæ.

These names cover almost the whole geographical area of Greece and at least point to the extent of the poet's fame and influence. Although the dates of his birth and death are equally doubtful, critics have placed him anywhere in the 9th and 10th centuries before Christ, though some have thought these dates 500 years too early. He is traditionally said to have been blind, like Demodocus, the minstrel of the Odyssey. Some in ancient times attributed to him also the Batrachyomachia, and the so-called Homeric hymns, but it is at least doubtful whether these were written by the author of the 'Iliad,' as the Batrachyomachia seems a century later than the epics, and the hymns to Apollo, Demeter, Hermes, Aphrodite, and minor divinities were probably preludes or introductions which the rhapsodes or minstrels sang or chanted before beginning the serious business of the epic recitation.

The 'Iliad' and 'Odyssey' deal with the war waged by European Greece against Asiatic Troy.

The Iliad.— This 'Poem of Ilium' or Troy describes some phases of the war waged by Agamemnon and his brother Menelaus against Priam, whose son Paris had carried off Helen, the beautiful wife of Menelaus. The subject of this epic is called the wrath of Achilles, the representative Greek hero, a romantic and dazzling figure. He remains in his tent without helping in the war because Agamemnon has taken from him the captive slave girl Briseis. At length Hector, the champion of the Trojans, slays in fight Patroclus, the bosom friend of Achilles, who is roused by this from his sullen inactivity, and rushes forth to the battlefield, where he meets and slays Hector, whose funeral rites form the closing incidents of the poem.

The Odyssey.— The 'Odyssey' describes the return of Odysseus from the siege of Troy to his island kingdom, Ithaca, where he is restored to his faithful wife, Penelope, and takes vengeance on the suitors who have sought her hand and wasted her husband's substance in

revelry and debauchery during his absence. The first four books describe Odysseus detained in the magic isle of Calypso, and the despatch of his son Telemachus to bring him home. The following eight are taken up with the hero's homeward voyage with his various adventures. In books 13–19, Odysseus in the attire of a beggar is found unrecognized at the door of his home; books 20–24 describe his vengeance on the suitors.

There were some critics of Greece, notably Xenon and Hellanicus, who held that the so-called Homeric epics were written by different men. This school of grammarians were called chorizontes, or separators. There is much indeed to give color to such a view. As has been said, the 'Iliad' was written for men, the 'Odyssey' for women. But what principally distinguishes the 'Odyssey' from the 'Iliad' is the fuller and more complete individualization of the Greek divinities, the higher tone of religious and social life. The knowledge of foreign lands and their products and the means of travel by sea seem also to have reached a more advanced stage.

It remained for F. A. Wolf in his famous 'Prolegomena ad Homerum' (1795) to make the keenest and most searching analysis of these epics, as regards their unity of composition and identity of origin. He relies upon the statement in Greek history that Pisistratus in 540 collected and arranged the Homeric poems in something like their present form. The epics are thus made up of separate ballads, sung by rhapsodes, probably written by different poets, and Wolf has shown much acuteness in pointing out that long epic poems could not have been transmitted from such early antiquity without handwriting, which did not then exist, and in indicating what portion of each epic originally formed individual and distinct songs or lays. Consult: Jebb, 'Introduction to Homer' (1887); Monro, 'Homeric Grammar' (1891); Ebeling, 'Lexicon Homericum' (1885); Leaf, 'The Iliad' (1888); Hayman, 'The Odyssey' (1882).

Homer, Winslow, American painter: b. Boston 24 Feb. 1836. He studied in the National Academy of Design and was also a pupil of Frederic Rondel. He was sent to the front during the Civil War as special artist to 'Harper's Weekly' and on his return to New York exhibited his first important work, 'Prisoners from the Front' (1864), which won him recognition. In 1865 he was elected Academician. Taking up his residence in Scarboro, Maine, he painted for many years a series of pictures which indicated a marked development in style, sentiment, and power. There was a trace of conventionality at least in the subjects of such pictures as 'Home, Sweet Home,' which he painted between 1864 and 1884. From the latter date he began his portrayal of the fisher population of New England. Dramatic and realistic in the highest degree is the series of seven canvases from the 'Life Line' (1884) to the 'Lookout' (1897). But this artist has reached his finest vein in his pure marines, of which by far the greatest is 'The Maine Coast.'

Homestead, hōm'stĕd, Pa., borough, in Allegheny County, on the Monongahela River and on the Pittsburg & L. E. and the Pennsylvania R.R.'s; about seven miles south of Pittsburg. It was settled in 1871 and incorporated and chartered in 1880. The chief manufactures are foundry-products, glass, machinery, and steel products. It is noted for its large steel plants, which employ over 6,000 men. The borough owns and operates the waterworks. At one time Andrew Carnegie (q.v.) was the principal owner of the Homestead steel works. Pop. (1890) 7,911; (1900) 12,554.

There occurred in Homestead a serious strike which began 6 July 1892. Reductions in wages, change in time of signing the schedule, and refusal to recognize the Amalgamated Iron and Steel Association, or to hold any conferences with the men, had brought on a general strike to date from a certain time, and enraged the men into burning H. C. Frick, the manager, in effigy; whereupon the works were at once shut down, 1 July, two days ahead of the agreed time, and the men armed themselves and prepared to resist by violence any attempt to supply their places with non-union men. The advisory committee of the union took charge of the town with regular armed companies, and allowed no one to enter the mills without their permission. On 5 July the company announced an intention to make repairs, and appealed to the sheriff for protection; he sent a small squad, who were at once driven from town by the strikers, the latter denying that any damage was intended and offering to be sworn in as deputies themselves. The company then hired a body of 300 Pinkerton detectives, who came up the river in barges; but the strikers broke through the fence surrounding the mill, intrenched themselves behind a barricade of steel rails and billets, and whenever the Pinkerton men attempted to climb the steep bank (which they began at 4 A.M. of 6 July), shot them down. Next day they procured a 10-pounder brass cannon and bombarded the boat, splintering her wooden sides, but failing to pierce the steel plates within. They then sprayed the boats with oil from a hose, and emptied barrels of it on the river, setting it on fire to float down and fire the boats. The detectives repeatedly ran up flags of truce, which were at once shot down. At length the advisory committee sent delegates to offer a safe-conduct to the detectives, if they would leave their arms and ammunition and quit the town under guard; they were forced to submit, but when leaving under escort, the mob stoned, shot, and clubbed them shockingly, one having an eye struck out by a woman in the mob. Seven were killed first and last, and 20 to 30 wounded; and 11 strikers and spectators were killed by their return fire from the boats. The governor (Pattison) refused to use the State power to quell the riot till the 10th, insisting that the local authorities must do their utmost first, and the sheriff must summon the citizens; and the troops did not arrive till the 12th, when the town was put under martial law. A committee of Congress was appointed to investigate the case; and later, a Senate committee in the interest of the strikers was appointed to inquire into the hiring of private armed parties to maintain public order. On 21 July Mr. Frick was shot and stabbed in his office, but recovered. On the 18th a number of the strikers were arrested for murder; and

retorted by indicting the Carnegie Company, the Pinkerton brothers, and five of their men, for murder. The advisory committee was also charged with treason and usurpation, in taking military possession of the town. The mills were soon supplied with new men, but the strike was not officially declared "off" till 20 Nov. 1892.

Homestead and Land Laws. Under the United States laws any citizen or person who declares intentions to become a citizen, male or female, 21 years old, or head of a family, may become the possessor of a homestead of 80 or 160 acres, by occupation and cultivation, to be taken from unreserved public lands, surveyed or unsurveyed. A fee of $5 or $10 is required to be paid for filing affidavit of settlement, citizenship, age or family status. Total fee is from $26 to $34, according to the land district. Five years' residence and cultivation are required, but only three are demanded where 5 or 10 acres of forest trees have been cultivated. Ex-Union veterans or their heirs obtain patent one year after residence. Benefits are limited to one claim, except that veterans who have made one land settlement may also take a homestead claim. Under timber-culture provisions homestead locators may secure another 160 acres, including timber area, by cultivating 40 acres of trees. A homestead is free from debt liability before patent issues. Locator may, on proof of settlement six months after occupancy, buy said land at pre-emption price.

Homestead discussion began in 1852 by the Free-Soil party demanding reservation for settlers. It was presented first in Congress by Galusha Grow, 1854. A bill was first offered in 1859, and passed the House; an act passed in 1860, granting homestead on payment of 25 cents an acre, was vetoed by President Buchanan. The present law was signed by President Lincoln, 20 May 1862. Homestead law initiated the national land policy. It marks the third step in definite change from purchase to settlement. Pre-emption policy, granting preference to occupancy over speculating purchases, was the second step. First was sale or grants *en bloc*. It began in 1801 when an act was passed granting pre-emption to Miami Valley settlers on Ohio-Symmes tract. Sixteen acts were passed before that of 1832, which fixed the price at $1.25 and $2.50, and divisions at 40, 80, 120, and 160 acres. Under Pre-emption Laws, a locator having civic rights and also able to testify that he or she does not possess 320 acres of land in the United States, or has not abandoned any to settle on public lands, can hold for cultivation and residence up to 160 acres. After a limited period a locator may on satisfactorily proving settlement, purchase and obtain patent at minimum or maximum rate, the latter, $2.50, being paid for government land within railway grant. No restriction is placed on pre-emptor's acquirement of private lands. Under timber-culture acts entry additional to pre-emption or homestead may be made of legal subdivision, one fourth of which must be devoted for eight years to timber culture. On proof, a patent will issue for tracts; the total fee is $18.

Timber acts are in the nature of a land bounty for forest culture in sub-humid areas. Desert land acts are designed to encourage reclamation by irrigation of arid lands. Entry is of 640 acres permitted on "dry lands" within California, Nevada, Oregon, Arizona, New Mexico, North and South Dakota, Wyoming, Utah, Idaho, Montana, and Washington. Three years are allowed to bring water thereon. On proof of this, same may be purchased at 25 cents an acre. Under present laws mineral lands are held for industrial development, miners' customs being recognized by Congress and upheld by the federal judiciary. Locators form district, lode, or placer, adopt regulations, and elect recorder. Quartz or lode claims permitted of 1,500 lineal by 600 lateral feet, 300 on each side of lode. Boundaries must be marked plainly, entry recorded, and work to the value of $100 or more be performed each 12 months in order to hold claim. Qualifications as to persons or associations are the same as in other land entries. No alien is permitted to hold, occupy, work, or possess public lands. Placer claims of 20 acres to the individual, or not over 160 to associations, are similarly permitted. Patents issue on proving up and payment of fees.

The mineral land policy of the United States fluctuated till the act of 1866 was passed. Lands were sold or leased at different periods, and the procedure was wasteful both to miners and people. Mill sites and right of way for ditches are provided for. Coal lands are pre-emptible on civic and occupancy requirements by payment of from $10 to $20 per acre. First priced land is not within 15 miles of a railway; the other is within such distance. The individual limit is 160 acres; association 320 acres. An association on proof of $5,000 expenditure may enter one section. Only one entry is permitted. Saline lands being exempt from settlement, are offered for sale at $1.25 an acre, and then become subject to private entry. Public land for town site purposes is arranged for (1) by Interior Department setting aside suitable area and selling lots of definite size; (2) by town associations, filing plats of 640 acres or less therein. Town associations failing to file plats, lots may be sold publicly after 12 months at increase of 50 per cent. on minimum price. The actual occupant of a town lot may prove up and pre-empt by time of sale, paying minimum price for same. Stone and timber lands designated as unfit for cultivation, within California, Oregon, Nevada, and Washington, may be purchased by persons having required civic qualifications as follows: Affidavit and proof of non-mineral character and non-speculative purpose required, and they must be sworn to as for personal use and benefit. Notice of application to be published for 60 days in land-office and nearest newspaper. Penalties are provided for perjury or for trespass on timber lands.

The domain is also subject to various land-grant and bounty laws. These include State grants for internal improvements, institutions, common schools, seminaries, and agricultural colleges; land bounties, naval and military; canal, wagon, and railway grants; military and Indian reservations. Under graduation act, land unentered privately can be sold at public sale at minimum figures. The public domain area was acquired by cessions from original States, 259,171,787 acres; by purchase from Spain,

France, Mexico, Texas, and Russia 1,580,900,800 acres; total, 1,840,072,587 acres.

Public lands are surveyed into "hundreds," 10 miles square: then into "sections," of 1 mile square, again subdivided into quarters, and down to eighths. This is known as the rectangular system. A general land-office, forming a bureau of the Interior Department, is in charge of land administration. Each State and Territory has a surveyor-general, and each congressional district a land-office. In the Territories these are provided as required. A large portion of the domain acquired from Mexico still remains subject to private grants. The land laws of Hawaii were drawn up to protect small holders. See PUBLIC DOMAIN.

GORHAM D. GILMAN,
Ex-U. S. Consul to Hawaii.

Homicide, hŏm'ĭ-sīd, is either justifiable, excusable, or felonious. Of the first sort are such cases as arise from unavoidable necessity or accident, without any imputation of blame or negligence in the party killing. So where a crime is punishable capitally according to the laws, the judge is bound to condemn the criminal to death, and the sheriff or other executive officer to carry the sentence into effect in the manner prescribed by the sentence of condemnation. But the judge must have jurisdiction of the offense, and be duly commissioned; and the executive officer must be empowered to carry the sentence into effect, and must perform the execution in the manner prescribed by law, otherwise the execution of the criminal will make the judge or the officer, as the case may be, guilty of criminal homicide. So, too, where an officer of justice is resisted in the execution of his office, in his attempt to arrest a person in a criminal, or, as is maintained, even in a civil case, he is not obliged to give back, but may repel force with force; and if the person resisting is unavoidably killed, the homicide is justifiable, for few men would quietly submit to arrest if, in case of resistance, the officer was obliged to give back. It is, however, laid down as law that if a felony be committed, and the felon attempts to flee from justice, it is the duty of every private citizen to use his best endeavors to prevent an escape, and if in the fresh pursuit the party be killed where he cannot be taken alive, it will be deemed a justifiable homicide. The same rule applies to cases of an attempt on the part of a felon to break away and escape after he has been arrested, and is on the way to jail. So if a party has been indicted for felony, and will not permit himself to be arrested, the officer having a warrant for his arrest may lawfully kill him if he cannot be taken alive. But this is to be understood only of officers, and not of private persons. Magistrates and officers authorized to suppress and disperse mobs are justified by the common law in taking the requisite measures and using the requisite force for this purpose, though it extend to the killing of some of the rioters. The law arms every private citizen in the community with the power of life and death for the prevention of atrocious felonies accompanied with violence and personal danger to others, as in case of an attempt to murder or rob, or commit burglary or arson, the person making the attempt may, by the common law, if he cannot be otherwise prevented, be killed on the spot, and the law will not recognize the act as a crime. In cases of this sort, in order to justify the homicide, it must appear that there were good grounds for a suspicion that the person killed had a felonious intent. A woman is justifiable in killing one who attempts to ravish her, and the husband or father may be justified in killing a man who attempts a rape on his wife or daughter.

The cases already mentioned of justifiable homicide are those in which the public authority and laws are directly concerned. The laws of society, however, leave every individual a portion of that right of personal defense with which he is invested by those of nature. If one may interpose to prevent an atrocious crime against society, where he is not himself in any personal danger, the laws will, *a fortiori,* permit him to defend himself against attacks upon his own person. Murder is the killing of a person who is under the protection of the laws, with malice prepense, either express or implied. Malice is the distinguishing characteristic of murder, and may be either aforethought, or expressed, or implied. It is not necessary in order to constitute the crime of murder that the slayer should have the direct intention of killing. If the act be done with a wicked, depraved, malignant spirit, a heart regardless of social duty, and deliberately bent upon mischief, it is characterized by what the law denominates malice, though it may not result from any enmity or grudge against the particular victim. So if a man wantonly discharges a gun among a multitude of people, whereby any one is killed, the act will be done with that depravity of disposition which the law considers malice. Murder can be committed only by a free agent, for the crime presupposes a will, motive, or disposition on the part of the perpetrator. An idiot or insane person cannot commit this crime. But drunkenness is in general no excuse for homicide, though the act be done under its immediate influence.

The manner of killing is not material. Whether it be by sword, poison, beating, imprisonment, starvation, or exposure to the inclemency of the atmosphere, it will be equally murder. This crime may be committed by mere advice and encouragement. An infant unborn is within the protection of the law, and it is laid down that if, in consequence of poison given or wounds inflicted before the birth of a child which is afterward born alive, it dies soon after its birth, the act is murder. The act of suicide is considered by the law to be murder, and the person making away with himself is accordingly styled a "self-felon."

The lines of distinction between felonious and excusable or justifiable homicide, and between manslaughter and murder, are in many cases difficult to define with precision. But in general the accused has the advantage of any uncertainty or obscurity that may hang over his case, since the presumptions of law are usually in his favor. The characteristic distinction laid down in the books between murder and manslaughter is the absence of malice in the latter. Sudden provocation may be an excuse for striking another without the intention to give a deadly blow; and though death ensue, the party may not be guilty of murder. One circumstance, showing the degree of malice, or rather showing its presence or absence, is the kind of weapon

used in giving a wound on a sudden provocation; and another circumstance of importance is the fact of the weapon's being already in the hand or not, for going to seek a weapon gives time for deliberation. The ground of excuse of homicide, in case of provocation merely, is the supposed sudden passion, some influence of which the law concedes to the frailty of human nature. But the excuse of self-defense goes still further; and where a man is attacked, so that his own life is endangered, or in such way that he may reasonably suppose it to be so, he may repel the attack with mortal weapons. One of the most frequent cases of manslaughter was that occasioned by single combat, and on account of the firm hold which the point of honor had taken of European nations, was long among the most difficult subjects of legislation. (See DUEL.) The crime of murder in its most aggravated degree is punished with death in most parts of the civilized world.

Hom'ily (Greek, *homilia*, intercourse), as an ecclesiastical term, a discourse addressed to an audience on some subject of religion. The homily was so called to distinguish it from the speeches of profane orators. The ancient homily was sometimes simply a conversation, the prelate talking to the people and interrogating them, and they in turn talking to and interrogating him. The difference between the homily and the sermon was the entire absence of oratorical display from the former, and the elucidation of the Scriptural text in natural order, without throwing the exposition into the form of an essay.

The earliest existing examples of the homily proper are those of Origen in the 3d century. In the schools of Alexandria and Antioch this form of discourse was sedulously cultivated, and Clement of Alexandria, Dionysius, and Gregory Thaumaturgus are among the names most eminent in this department. Augustine and Gregory the Great were among the western composers of homilies. Later still Bede, several of the popes, and foreign ecclesiastics still adhered to the homiletic form of exposition as the most suitable to impress the truths of Scripture with efficacy on the popular mind.

In the Church of England there were two books of homilies that were long authoritative, and are still sometimes appealed to to settle disputes as to what the Anglican doctrine is in points on which they bear.

Homing-pigeon, a variety of the common pigeon in which the love of home and power of flight have been developed to make the bird useful and reliable as a bearer of messages; also a fancy variety characterized by the possession of certain definite points, but not necessarily useful as a homer. The show carrier-pigeon is a large, long-necked variety, with abnormally developed wattles about the base of the beak and round the eyes, but the true homer is of smaller size, and lacks the enormous tuberculated growth.

The training and breeding of homing-pigeons were long almost confined to Belgium, and two main types of the Belgian homer have been distinguished as the Antwerp and the Liège varieties, the former being larger but less graceful in form than the latter. American pigeon fanciers breed mainly from the Antwerp type, and the birds are commonly designated Antwerps.

The training of a homing-pigeon begins when it is about three months old. It may then be taken to a distance of about a mile from its loft in a suitable direction and liberated in order that it may fly back. After an interval of a day or two it should be carried three miles from home in the same direction and set free, and on the third occasion, a few days later still, the distance is usually increased to six miles. This mode of training is continued steadily during the season, the successive distances above those already mentioned being 12, 25, 50, 75, 96, 125, 155, and 200 miles. The intervals of rest must be carefully preserved, especially in times when the weather is unfavorable. During the bird's second season it is made to repeat something of its first year's performances and to extend its flight to 250 miles or possibly to a greater distance. During the following three seasons good birds will be at their best, and even for some few years later they may do good work. During the training period and also at other times the housing and feeding of the birds must be carefully attended to.

Velocities of over 30 yards per second have been recorded for various pigeons, but the average velocity is rather less than half that amount. One bird, in 1896, actually covered the distance from Thurso to London, just over 500 miles, within one day, its average velocity being about 24 yards per second. In unfavorable weather the height attained varies from about 320 to rather over 400 feet, but in good weather some birds will reach a height of about 1,000 feet. The distance from Algiers to Paris, fully 1,100 miles, is one of the longest on record as having been traveled by a pigeon.

There has been much discussion regarding the means by which pigeons return to their homes over such long distances. Untrained birds often fail to return, and during training young birds are often lost.

Many instances are recorded of the employment of pigeon messengers by ancient peoples. During the first half of the 19th century pigeons were widely used in Great Britain for the rapid communication of intelligence, and in particular many stockbrokers obtained early information of the state of the markets by this means. The introduction of the electric telegraph, however, soon led to the complete disuse of the pigeon post. The siege of Paris during the Franco-German war of 1870–1 first brought the carrier-pigeon into prominent notice as a valuable means of communication in time of war. During that siege more than 350 birds were sent out of the city in balloons, and of these some 300 were liberated with messages. Only some 70 returns were made, and these were effected by 57 birds. By the adoption of microphotography the space occupied by a message was so reduced that a single pigeon could carry a very large number of messages without having its movements hampered in the least. One of the pigeons that succeeded in returning to Paris carried no less than 40,000 messages on eighteen collodion films which were enclosed in a goose-quill attached to the tail. Since that time the leading Continental powers have established elaborate pigeon systems for use in time of

war. During the war with Spain, in 1898, the fleet of vessels that patrolled the Atlantic coast was supplied with a number of carrier-pigeons' cotes, but happily there was no occasion for testing their effectiveness, though in times of peace messages are frequently successfully carried from war vessels to points on the shore. Consult books mentioned under PIGEONS.

Hominidæ, hō-mĭn'ĭ-dē, the family to which man was assigned in the earlier systems of animal classification; but many modern zoologists refuse him so great a distinction, making man, zoologically considered, only a species (*Homo sapiens*) of a genus of the family *Simiidæ*, which also includes the genera of the anthropoid apes. See MAN.

Homœopathy (Greek ὅμοιος, like, and πάθος, suffering or disease). The term signifies similar affection, passion, suffering or disease. As employed in Medicine, and as understood by Hahnemann and physicians of the homœopathic school, it is properly defined as follows: (1) The treatment of disease by means of its similimum; (2) treatment of disease by a medicine capable of causing, in a healthy person, symptoms similar to those manifested by the patient. This definition can refer only to the symptoms producible by the drug, and the symptoms exhibited by the patient. It makes no direct reference to the name or type of the disease, nor to the type or class of the drug administered, nor to the size or strength of the dose. Nevertheless, homœopathy does hold important incidental relationship to the classification of drugs, to the facts and principles of dosage, and to diagnosis and all other departments of pathology. Under this definition, the experimental application of homœopathy requires that the drug shall cover the *tout ensemble* — or, as Hahnemann expresses it, the "totality" of the symptoms as exhibited by the patient; and not merely one, or a few, of the dominant or diagnostic symptoms or conditions. Neither does it imply that the homœopathic remedy can overcome any and all the adverse conditions and circumstances under which it may be administered.

As a system of medical practice, Homœopathy recognizes this principle of similarity as between the symptoms of the curative drug and the symptoms appearing in the patient. In this form of practice, the symptoms exhibited by the patient are carefully ascertained and studied with reference to their significance and relations, and these furnish the indications upon which the selection of the "similar remedy" is then made with equal care. Whether the object of the prescriber be immediate and complete restoration to health in a curable case, or mere alleviation of suffering in a case not curable, the same course is pursued; since, in the experience of the profession, the similimum possesses peculiar efficacy in either class of cases.

In homœopathic practice, the finding of the curative remedy is of *first* importance, as a matter of course. But, the diagnosis of the case is a most urgent consideration, because it materially aids the physician in his quest for the "totality" of the symptoms, suggests his general management of the case, prompts the sanitary precautions to be taken, guides him in his prognosis, etc. Moreover, it sometimes calls to his mind a group of medicines among which the curative similimum will probably be discovered, and in this indirect way may assist in the medical treatment. Yet is must be distinctly understood that in homœopathic prescribing, the final choice of the remedy is always made, not by the name of the disease, nor even by the symptoms usually present in the disease, but only by those occurring in the individual patient. Pathology, both structural and functional, is also a subject of careful research in connection with homœopathic practice, as under other systems; but never for the purpose of formulating "theories" of the nature of the disease, on which to base treatment.

In common with all other modern "schools" of physicians, homœopathists hold that whenever the originating or "exciting" cause of the disease can be discovered, it should be removed if possible; and they claim that when this is done the disease will often disappear spontaneously. When the disease does not so disappear after removal of the cause which had apparently produced it, homœopathic physicians are convinced that some other ("maintaining") cause has been developed. In most cases this perpetuating cause is occult and its nature altogether undiscoverable. They also hold the view that if this latter cause be removed, the continuance of the malady is inconceivable. Equally incredible is it that the disease can be actually "cured" so long as the cause remains operative; if it could be, it would be immediately reproduced; unless meantime the bodily susceptibility to the disease were also removed. Hence, the homœopathic profession does not concede a "cure" in any case in which the operative cause remains active, and therefore, in the view of these practitioners, the word "cure" has a much narrower meaning, and actual cures are accomplished much less frequently than is generally supposed; the majority of such so-called cures being merely recoveries — recoveries facilitated, or perhaps made possible, by the skilful efforts of the medical practitioner — but recoveries nevertheless.

Under this view, that the disease has a central morbific cause, it is impossible that homœopathists can accept the opinion that the malady can be cured by the mere lopping off of one or a few of its principal symptoms, or of its prominent pathological processes or conditions. How, then, do homœopathists explain their ability to reach with their remedies the perpetuating or "maintaining" cause of disease, conceding, as they do, their inability to determine its nature, or even its location?

Starting out with the accepted principle that "like causes operating under like conditions produce like effects," the homœopathist assumes the converse of the proposition to be likewise true; namely, that like results appearing under like conditions and circumstances, indicate the operation of like causes. When two patients in similar conditions of health manifest similar morbid symptoms, the phenomenon is, by all pathologists, considered as indicating the operation of causes in corresponding portions of the two organisms, and acting in a similar manner. This view is not peculiar to any medical school, but is held by all physicians alike. To this doctrine, the homœopathist adds the belief that it also applies to the effects of drugs, as well as to those of natural (?) diseases; and that when similar

morbid manifestations result, in one case from disease and in the other from the effects of a drug, the phenomenon still indicates a physiological or (pathological) cause operating in a similar part or parts of the organisms involved, and operating in a similar manner in both. So much as to the *locality* of the cause — the "seat of the disease," upon which the "similar" drug acts. What of the *manner* in which it acts?

It was long ago shown by Hahnemann and others that the effects of almost any drug upon the human body are of two kinds, primary and secondary, direct action and reaction; and that these two actions are, in a measure, the opposite, one of the other. This view has been advocated by numerous physicians, not always of the homœopathic school. Of late years the phenomenon has attracted more attention from medical writers than formerly, and is generally spoken of as "the dual action of drugs." To illustrate: a drug may first stimulate, and afterward depress, a certain organ of function. Another may first depress and then stimulate; and the symptoms will, of course, take their character from the action or reaction of the drug. Some homœopathists are of opinion that this dual quality of drug action is the proper explanation of the curative potency of the similimum. Others, Hahnemann included, explain it on other grounds. Others consider it likely that the different effects of large and small doses — a fact observed by many practitioners — may account for the cures made by the similar remedy. All homœopathists agree, however, that the question turns upon the curative *fact*, and not upon its explanation; and hold that one and all of these explanations may yet prove to be erroneous; yet firmly convinced that the main fact will remain unaffected through all changes in theory and doctrine.

Homœopathy, like any other principle or art, has its own particular field of application and operation. Thus it does not cure *directly*, a mechanical injury to the tissues, or any impairment wrought by chemical means; though it does cure the functional diseases and disorders caused by the irritation of such injuries. The homœopathic remedy acts *directly* only upon function. It never alters a structure except by first modifying a function. Nor does a drug ever act homœopathically upon a function unless that function be disordered. When a drug acts on a healthy function, or when it causes disorder in a function, such action is never homœopathic, whatever may be the mode of its selection and whatever the form or quantity in which it is administered. *The homœopathic medicine is a specific-restorative-stimulant, only and always.* Such, in brief, is an exposition of homœopathic belief and practice, and of its underlying principles and doctrines as taught by Hahnemann and held by the profession as a body. The small dose used by homœopathic prescribers is considered in another part of this article.

Homœopathy as a mode of medical practice is usually said to have originated in 1796, when Dr. Christian Friedrich Samuel Hahnemann published in 'Hufeland's Journal,' at Jena, an 'Essay on a New Principle for Ascertaining the Curative Powers of Drugs.' In this essay he criticizes the state of the medical art, and especially urges that the chemical properties and powers of drugs are not adapted to the work of curing disease, but that cures must be accomplished by an entirely different property resident in medicinal substances. Having read of cures in medical literature and observed, in his own patients, recoveries occurring under the evident influence of the "similar" remedy, he offers the following theory of the phenomenon: "Every powerful medicinal substance produces in the human body a kind of peculiar disease; the more powerful the medicine, the more peculiar, marked, and violent the disease. We should imitate nature, which sometimes cures a chronic disease by superadding another, and employ, in the (especially chronic) disease we wish to cure, that medicine which is able to produce another very similar artificial disease, and the former will be cured; *similia similibus.*" Hahnemann further explains his conception of a homœopathic cure in his 'Organon,' section 26, in the following language: "A weaker dynamic affection is permanently extinguished in the living organism by a stronger one, if the latter (while differing in kind) is very similar to the former in its manifestations." This language he designates the "homœopathic law of nature." The term "homœopathy" or "similar disease," as representing the new medical practice, may have been suggested not alone by the fact of cures produced by the similar drug, but also by Hahnemann's theoretical explanation of the phenomenon.

A correct and adequate conception of homœopathy, of the difficulties necessarily encountered in its propagation and establishment, and of the place it holds and the influence it exerts in the development of therapeutics can be obtained only through knowledge of the conditions of general medicine down to the close of the 18th century. It is essential, therefore, that reference be made to certain points in the progress of medical history from its beginnings to and including the period of the investigations that resulted in the discovery of homœopathy as a general therapeutic principle. This reference does not need to embrace all the departments of medical science — anatomy, physiology, pathology, etc. — but the department relating to treatment, or therapeutics only. It is requisite for us to know and appreciate the mental conception — the basis of reason — upon which the "art of healing" was established prior to the advent of homœopathy as a system of medical practice.

The earliest efforts of men to alleviate the sufferings caused by illness and mechanical injury were chiefly instinctive. Water, moist earth, the fleshy portions of plants, and other cooling substances, were employed by men, as well as by the lower animals, to mitigate the pain, heat, and discomfort of local inflammation; and other simple expedients were instinctively resorted to for various disordered conditions. In time the number and variety of known remedial agents, as well as of the diseases for which they were used, must have been rapidly extended by experience. And thus began the "empirical method" of treatment — the natural second step in the progress of medicine.

Inefficient as were these modes of treatment, they were far more rational than most of those that occupy the pages of medical history for many succeeding centuries. These later methods were based, not on observation and experience,

but upon pure assumptions having, as John Stuart Mill expresses it, "no limitations other than those of the imagination." (The construction of medical theories, or philosophical explanations of observed facts, was a still later development.)

Among the large number of these hypotheses are the following: (1) That disease is a punishment sent by some malevolent deity; (2) that it is due to the influence of a comet, a planetary conjunction, an earthquake, or some other celestial or terrestrial phenomenon; (3) that it is caused by abnormal preponderance of some one of the four elements (fire, air, earth, and water) of which the human body was said to be composed; (4) that it originates in a disturbance of the bodily states of heat, coldness, moisture, and dryness; (5) that it arises from disproportion in the four humors which supply the organism — blood, mucus, black bile, and yellow bile; (6) that it is produced by a *materia peccans*, or offending matter, which must needs be expelled; (7) that the body contains multitudes of "invisible pores" through which circulate infinitesimally minute atoms or corpuscles, and that disease has its cause in obstruction or relaxation of these pores; (8) that disease is based upon three possible states of the organism — "strictum," "laxum," or "mixtum" — which must be treated with laxatives, astringents, or a combination of both, as might be needed; etc., etc. All these hypotheses, and many others, arose prior to the close of the 2d century A.D. Their absurdity is not more grotesque than that other hypothesis which underlies each and all of them; namely, that a knowledge of the cause or nature of disease can indicate the means and method of its cure; a view not held at present by any homœopathic or other scientific physician.

The period between the 2d century and the 15th presents little record of therapeutic art; but with the invention of the printing-press came a stronger impetus to all forms of research, medical included. Since that time increasing knowledge of anatomy, chemistry, and physiology has led to the elaboration of therapeutic theories based upon certain facts relating to these natural sciences. The advances in anatomy had suggested a mechanical basis for therapeutics; pneumatics, friction of fluids in vessels, the diameters, curvatures, and angles of blood-vessels were brought forward to explain the phenomena of disease and to suggest measures for its cure. Physiology and chemistry brought out a renewal of the ancient doctrine of "four elements" and the substitution of the three "alchymistic symbols" represented by mercury, salt and sulphur, whose union is health, and their separation disease. The author of this doctrine, Paracelsus, also ascribed to the "vital force" not only the power, but also the intelligence, to resist disease and to provide for its cure. About the middle of the 18th century, or near the time at which the discovery of the general principle of similars was made, physiological hypotheses became largely identified with therapeutics; and the same might be said of chemical theories. Health and disease were the results of a contention between the acids and the alkalies. Haller held to the view that disease was due to change in the "irritability" of the tissues. Cullen revived an old doctrine that disease was caused by "spasm" and "atony," and required to be treated in accordance with that view. Brown, the rival of Cullen, concluded that diseases were either "sthenic" or "asthenic," and required asthenic, or sthenic medication, as the case might be.

Before the close of the 18th century the medical profession had acquired knowledge of a number of drugs possessed of "specific" properties for the cure of particular diseased conditions; among them Peruvian bark for intermittent and other malarial fevers, mercury for syphilitic diseases, sulphur for itch, etc. These specifics exerted their curative effects by virtue of properties not at all understood at that time, and but imperfectly known a century later. These specific cures were limited to comparatively few diseases. For the treatment of the conditions with which the medical practitioner is contending daily, which constitutes almost his entire duty, he had nothing but fallacious assumptions and hypotheses to depend on. Such was the condition of the medical art at the time when Hahnemann began his independent researches in therapeutics.

Hahnemann possessed unusual linguistic attainments, which gave him access to the publications not only of Germany, but of England, France, Spain, Italy, Austria, Greece, and Arabia. He was not only a literary scholar. He was also a practical expert in the fields of chemistry, pharmacy, and industrial technology. He made many discoveries in industrial chemistry, and introduced scores of improvements in the details of manufacturing chemical products. At the period of his earliest responsible connection with medicine, "there was," says Rapou, "complete anarchy in the domain of therapeutics." Hahnemann, unwilling to trust the lives of his patients to the tender mercies of this conglomeration of assumptions, adopted the use of the class of remedies known as specifics, whose effects were easily ascertainable, though their *modus operandi* was altogether unknown.

Homœopathy was not an invention, like some of the "systems" of medicine that preceded it; neither was it a sudden discovery. It was an evolution extending from 1790 to 1835, a period of 45 years. The earlier portion of the process is described by Bradford, who in speaking of its beginning says: "We now come to the translation of a very important book (Cullen's 'Materia Medica'), from which must be dated the discovery of the Law of Similars. It has been asked why Hahnemann at this time happened to translate this particular book, and it has been asserted that he used it as a blind to foist on the world his peculiar theories. It is not probable that when he commenced upon Cullen Hahnemann had any particular medical theories, but only a growing disgust for the medical fallacies of the day. This is clearly evidenced by his writings at that time. It is not to be wondered at that he should translate the work at that particular time. He was translating for money, for the booksellers and publishers of Leipsic, and it is not likely that he selected the books which he was to translate. Dr. Cullen was an authority on the subject of the materia medica of his day, an experienced lecturer, a talented chemist, and a brilliant and popular teacher in Edinburgh. Naturally the Germans wished to learn of his new and peculiar theories regarding disease, as well as to obtain the use of his 'Materia Medica,' which at this time was a standard work.

"Hahnemann was the most accomplished translator of medical works of the time, and

what more natural than that the task should be given to him. Cullen published the first edition of this book, in London, in 1773. Another edition was issued in 1789, in two volumes, and it was this edition that Hahnemann used in his translation. In this book, Volume II., Cullen devotes about 20 pages to *Cortex Peruvianis* (Peruvian Bark), gives its therapeutical uses in the treatment of intermittent and remittent fevers, advises its use to prevent the chill, and gives minute directions for the safest period of the disease in which to use it. Hahnemann was impressed with the use of this drug, with which he as a physician had before been familiar. Something in the manner in which Cullen wrote decided Hahnemann to experiment with it upon himself and to see what effect it would have upon a person in perfect health. The result of this experiment will be given in Hahnemann's own words. In the translation of William Cullen's 'Materia Medica,' Leipsic, Schweikert, 1790, page 108 of Volume II., appears the following foot-note by Hahnemann: 'By combining the strongest bitters and the strongest astringents, one can obtain a compound which, in small doses, possesses much more of both these properties than the bark, and yet no specific for fever will ever come of such a compound. This the author (Cullen) ought to have accounted for. This perhaps will not be so easily discovered for explaining to us their action in the absence of the Cinchona principle.

" 'I took, by way of experiment, twice a day, four drachms of good *China*. My feet, finger ends, etc., at first became cold; I grew languid and drowsy; then my heart began to palpitate and my pulse grew hard and small; intolerable anxiety; trembling (but without cold rigor); prostration throughout all my limbs; then pulsation in my head, redness of my cheeks, thirst, and, in short, all those symptoms which are characteristic of intermittent fever, made their appearance, one after the other, yet without the peculiar, chilly, shivering rigor.

" 'Briefly, even those symptoms which are of regular occurrence and especially characteristic — the stupidity of mind, the kind of rigidity in all the limbs, but above all, the numb, disagreeable sensation which seems to have its seat in the periosteum, over every bone in the body — all these made their appearance. This paroxysm lasted two or three hours each time, and recurred *if I repeated this dose, not otherwise;* I discontinued it, and was in health.'

"The next note in the German translation is as follows: 'Had he (Cullen) found in bark traces of a power to excite an artificial antagonistic fever, he certainly would not have persisted so obstinately in his mode of explanation.' " ('Life and Letters of Dr. Samuel Hahnemann,' by T. L. Bradford, M.D., pp. 35–7.)

These experiments seemed to show that Peruvian bark is capable of producing in the healthy human organism a series of symptoms quite closely resembling those of that peculiar form of fever which it is known to cure. Instead, however, of solving any questions in the mind of Hahnemann, it only served to suggest several others. Does Peruvian bark then produce the same symptoms that it specifically cures? Is its specific curing property dependent on its power to cause the symptoms which it cures? If so, is this power peculiar to *Peruvian bark,* or is it to be discovered in other drugs? And do all drugs possess the power to cause symptoms similar to those they cure?

To obtain light upon these questions occupied his efforts during the six years between the translation of Cullen's 'Materia Medica' and the publication of the 'Essay' above mentioned. To quote from a writer in the British 'Homœopathic World,' 1875, p. 234: "Drug after drug, specific after specific, was tested on himself and on healthy friends with one unvarying result — each remedy of recognized specific power excited a spurious disease resembling that for which it was considered specific. But many more symptoms than those diagnostic of any one disease resulted from almost every medicine, and aroused a hope in the experimenter's mind of specifically treating a greater number of diseases than had ever been so treated before. Besides discovering many valuable phenomena undreamt of, he verified his discoveries and observations by ransacking the volumes of recorded experiments in materia medica and the whole history of poisoning." The members of his family and his personal and professional friends aided in the work of experimentation, and tests of each medicine were made with different doses, and on many different persons, all the work being conducted under his own supervision.

Dr. Bradford tells us that at the time of Hahnemann's translation of Cullen's 'Materia Medica,' that is, at the beginning of his independent investigations in 1790, he had no preconceived theories or opinions to sustain. This view of his biographer is corroborated by the absence from Hahnemann's writings of even remote reference to any *a priori* conception or suspicion of a general curative relation between drugs and diseases. Nor does it appear that he then possessed the faintest conception of the magnitude, or of the quality, of the task he was gradually assuming. His original object evidently was to ascertain why Peruvian bark cures intermittent fever, and to learn if the view held by Cullen — that its curative property resides in a combination of bitter (tonic) and astringent qualities — was indeed true. There is no historic evidence that before 1790 the general therapeutic principle of similars had even dawned upon his mind. But we may be quite sure that the logical and philosophical principles that must necessarily govern his researches had been well thought out before the work had very far advanced.

Hahnemann and his disciples claim that in the discovery of homœopathy as a general principle of organic science, and in its conception and development as a system of medicine, assumption, speculation and hypothesis have had no place; but that observation, experimentation, and inductive classification constitute the scientific and solid foundation of fact upon which it rests. They assert that all its essential doctrines are susceptible of demonstration, that they have been verified and reverified times without number, and that for the first time in the history of intellectual development the establishment of the homœopathic principle showed that the Baconian method of research is as applicable in the realm of therapeutics as in any other department of scientific investigation. If we look over the records of the processes leading to its discovery, it appears that these processes were

under the guidance of the following principles of scientific philosophy, all of which are distinctly set forth by Hahnemann in his 'Organon':

1. That in the study of disease with a view to its cure, the only safe dependence is upon the manifestations (symptoms) perceptible to the senses, and that no safe conclusions can be drawn from mere theories erected upon these signs and symptoms. The signs and symptoms constitute the only side of the disease that is turned toward the physician, and the totality of these signs furnishes the only true expression or portrait of the disease.

2. That the specifically curative power of a drug resides not in its physical, nor yet in its chemical properties, but in its capacity to produce changes in the functions of the organism.

3. That the dynamic properties of a drug — in other words, its power to specifically cure disease — can be ascertained only by observing the signs and symptoms which it can produce in the organism, and that these specifically curative properties cannot be inferred from the physical or chemical properties of the drug substance.

4. That experiments for the purpose of ascertaining the pathogenetic properties (signs and symptoms) of drugs must be conducted under the precautions necessary in other researches; and the tests must be repeated and varied with a view to eliminate every influence and agency that can vitiate the experiment. The drug experimented with, and the person experimented upon, must both be "standard." That is, the drug must be pure and unmixed with any other substance capable of disguising, modifying, or otherwise affecting its own specific activity, and the person experimented upon (prover) must be possessed of good health, and free from any unhealthful occupation or habit, and from any mental, moral, or other influence or agent that can modify the pure effects of the drug upon his organism. Also, that the experimentation with the drug must be continued until its whole pathogenetic effect has been elicited.

5. That the observations made from such experiments as those here indicated constitute the only source of a pure and "standard" materia medica, and supply the only material from which general therapeutic principles can be discovered or deduced.

6. That effects observed from the action of a drug upon diseased persons (clinical effects) or those obtained from a combination of drugs (polypharmacy) are not "standard" effects and cannot serve as reliable guides in a search for therapeutic principles.

In the opening sections of the 'Organon,' Hahnemann mentions as among the physician's essential acquirements:

(1) Knowledge of diseases; (2) knowledge of the dynamic properties of drugs; (3) knowledge of the curative relations between the two. This knowledge he holds essential both to the development of therapeutic science and to enable the physician to prescribe the curative remedy.

In order to qualify the physician for his work his knowledge of disease must be composed of facts perceptible to the senses. Our physiological and pathological deductions in reference to a case of disease are more or less uncertain and theoretical. Absolute knowledge of disease is limited to its signs and symptoms, besides which there can be no certain and assured foundation for a science of therapeutics.

The knowledge of drug-properties must be equally certain and substantial. All drugs possess three classes of properties — physical, chemical, and specific or "dynamic." The physical and chemical properties can be ascertained by physical and chemical methods. The specific or dynamic properties, that is, the properties which alone impart the power to accomplish specific cures of disease, can be learned only by observing their power to cause changes in the health of the organism as shown by their capacity to produce signs and symptoms. Here again the signs and symptoms constitute the only sure basis of classification and induction in the construction of a science of therapeutics.

Having possessed himself of so much of such knowledge as was within his reach, Hahnemann then began the investigation of the great and dominating question: Given a knowledge of diseases as expressed by signs and symptoms, and a knowledge of drug properties as expressed by signs and symptoms, can we discover between them any general relation that will guide the physician in his search for the curative drug? In this work of "interrogating nature" he had already been led to infer what her reply might be. His experiment with Peruvian bark had given him a somewhat emphatic hint. Then followed the six years of experimentation upon himself, his family, and friends; with what result we have already seen. Accompanying and following these experiments came the "ransacking of the libraries" — a work for which few men were so well fitted. This literary search resulted in two important discoveries. First, that when two diseases manifesting quite similar symptoms appear in the same organism, they antagonize or annihilate each other. This subject is carefully outlined in the 'Organon,' sec. 42–45, and in sec. 46 the writer cites a score of illustrative instances obtained from the pages of contemporaneous literature, the authority being carefully mentioned in every citation.

The second result of this literary search is that it corroborates the view with which Hahnemann set out; namely, that even under the modes of treatment in vogue before his day, undoubted cures frequently resulted from the action of drugs possessed of the power to cause symptoms similar to those of the cases cured. Some of these cases are well worthy of study by those interested in medical subjects. In the earlier editions of the 'Organon' and in the 'Essay on a New Principle for Ascertaining the Curative Powers of Drugs,' these published cures are reported *in extenso*, the literary source being given, together with the name of the physician in each case. In the Dudgeon translation of the 5th German edition the same list occupies 31 pages of the appendix. In practically all of the cases reported, the mere name of the disease is sufficient to suggest the fact of similarity between the symptoms of the malady cured and the symptoms of the drug prescribed. In other cases the symptoms themselves are given with more attention to detail than was customary at that period of medical history. If we sum up the remedies named in the 'Essay,' together with those mentioned in the 'Organon,' we have a total of 63 drugs to which Hahne-

mann was able to ascribe homœopathic cures occurring in the practice of physicians who had no knowledge of the homœopathic principle.

In presenting this list of cases successfully treated with the similar remedy, Hahnemann has made nearly 500 citations of writers who had no suspicion that any general law of therapeutics was involved in the operation of their prescriptions. The degree of similarity shown between the pathogenetic properties of the drugs administered and the symptoms manifested by the patients seemed, in most cases, to be positive and emphatic, and in some instances striking. In what he has to say regarding the curative effects of opium this fact is graphically shown. He says:

"A condition of convulsions without consciousness, resembling the death-agony, alternating with attacks of spasmodic and jerky, sometimes also sobbing and stertorous, respiration, with icy coldness of the face and body, lividity of the feet and hands and feebleness of the pulse (precisely resembling the symptoms of opium observed by Schweikert and others), was at first treated unsuccessfully by Stütz with potash, but afterward cured in a speedy, perfect, and permanent manner by opium. According to Vicat, J. C. Grimm, and others, opium produces an extreme and almost irresistible tendency to sleep, accompanied by profuse perspiration and delirium. This is the reason why Osthoff was afraid to administer it in an epidemic fever which exhibited similar symptoms, for the system he pursued prohibited the use of it under such circumstances. It was only after having employed in vain all the known remedies and seeing that death was imminent that he resolved to try it at all hazards, and behold, it was always efficacious. J. Lind also avowed that opium removes the head troubles, and the burning sensation in the skin and the difficulty of perspiring during the pyrexia; under opium the head becomes free, the burning febrile heat disappears, the skin becomes soft, and its surface is bathed in a profuse perspiration. But Lind was not aware of the circumstance that opium produces very similar morbid symptoms in the healthy. Alston says that opium is a remedy that excites heat, notwithstanding which it certainly diminishes heat where it already exists. De la Guérène administered opium in a case of fever attended with violent headache, tension and hardness of the pulse, dryness of the skin, burning heat, and hence difficult and debilitating perspirations, constantly interrupted by the extreme restlessness of the patient. He was successful with this case because opium possesses the faculty of creating an exactly similar feverish condition in healthy persons, of which he knew nothing, though it is stated by many observers. In a fever where the patients were speechless, eyes open, limbs stiff, pulse small and intermittent, respiration labored, snoring, and stertorous, and deep somnolence (all of which are symptoms perfectly similar to those which opium excites), this was the only substance which C. L. Hoffmann saw produce any good effects. Wirthenson, Sydenham, and Marcus have in like manner cured lethargic fevers with opium. C. C. Mathai, in an obstinate case of nervous disease, where the principal symptoms were insensibility and numbness of the arms and legs, after having for a long time treated it with inappropriate remedies, at length effected a cure by opium, which, according to Stütz, Young, and others, causes similar states in an intense degree. Hufeland performed, by the use of opium, the cure of a case of lethargy of several days' duration. How is it that opium, which, as everyone knows, of all vegetable substances is the one which in its primary action (in small doses) produces the most severe and obstinate constipation, should be one of the most efficient remedies in constipation of the most dangerous character, if not by virtue of the homœopathic therapeutic law, so long unrecognized? The honest Bohn was convinced by experience that opiates were the only remedies in the colic called 'miserere'; and the celebrated F. Hoffmann, in the most dangerous cases of this nature, placed his sole reliance on opium combined in the anodyne liquor called after his name. Can all the 'theories' contained in the 200,000 medical books which cumber the earth furnish us with a rational explanation of this and so many other similar facts?"

The great German physician and philosopher was careful to credit other medical men with having obtained foregleams of his great discovery. "How near," he says, "was the great truth sometimes of being apprehended!" And again: "There have been physicians here and there across whose minds this truth passed like a flash of lightning without ever giving birth to a suspicion of the homœopathic law of nature."

From Hahnemann's literary and experimental investigations alone, both he and his disciples have unhesitatingly justified their belief in a general curative relation between drugs, as represented by their symptoms, and diseases as represented by their symptoms, and their belief that this curative relation is properly set forth by the word "similarity." The proofs herein presented are considered conclusive, although similar evidence has been constantly accumulating in the writings of medical men of all schools, and in the practice of hundreds and thousands of homœopathic physicians for more than a century.

In Hahnemann's foot-note (see Dudgeon's Appendix to the 'Organon,' p. 207) it is shown that he early became aware of the "danger which is to be anticipated from large doses of homœopathic remedies." He says, however, that "it often happens, from various causes which cannot always be discovered, that even very large doses of homœopathic medicines effect a cure, without doing any particular harm." In most instances homœopathic physicians came to regard the small dose as a necessity to homœopathic practice. Thus, a full dose of belladonna, or of opium, administered to a patient already suffering with symptoms like those producible by one of these drugs, might be perilous. Experience also taught them that the curative action of the homœopathic drug could be secured as well or even better through the small dose. The results claimed for these small or minute doses naturally aroused the skepticism of physicians and laymen alike, and became a serious hindrance to the spread of the homœopathic system. The very nature of the homœopathic principle, however, carries with it the necessity for the use of the diminished dose.

Homœopathic physicians, when prescribing minute doses of their remedies, are under the necessity of employing great care in securing absolute purity and simplicity in the preparation of their medicines; and this has led to the need of a special pharmacy for homœopathic prescribers. Another corollary of the homœopathic law of cure is the "single remedy," without which no prescription can be strictly homœopathic. Still another principle follows from the application of this law: namely, that a homœopathic prescription can never be made from the *name* of the disease. The similarity must be traced between the symptoms of the drug and those of the individual patient. This fact is fortunate in that it at once brands the advertised "homœopathic" proprietary medicine as a fraud and a pretense, no matter in what form it may be put upon the market.

The spread of homœopathy in the country of its birth, and in other countries of Europe, has been slow. The delay in securing its establishment has been due partly to the cause already mentioned — an unwillingness on the part of both physicians and laymen to accredit the little dose with curative potency. But the chief obstacle to its advancement is to be sought in inimical legislation and the lack of facilities and authority to educate young men and women for homœopathic professional life, and the consequent inability to supply the public need of homœopathic physicians.

Homœopathy was introduced into the United States in 1825 by a physician named Hans B. Gram, who at that time settled in New York. In this country, with its free institutions and its asserted freedom of opinion, the new medical thought found less antagonism to overcome, although there were many obstacles to be encountered, chiefly of a social and legislative character. The physicians of America, less conservative, perhaps, than those of Europe, were more disposed to inquire into the scientific and practical aspects of homœopathy, with the result that in less than 20 years more than 300 of them were engaged in its practice. These physicians speedily conceived the necessity for having their own students educated under teachers of their own faith and practice, and in 1848 organized and equipped a medical college for this purpose. This school was almost immediately succeeded by others; and these institutions have very largely contributed to the rapid spread of homœopathic practice in all parts of the United States.

When Dr. H. B. Gram arrived in New York in 1825, the only homœopathic literature in the English language was Hahnemann's 'Geist der homöopathischen Heilkunst,' a pamphlet of 24 pages, translated by himself and published by J. & J. Harper, of New York. The remaining homœopathic literature was all in the German language, and it is recorded that such was the interest felt in the subject that numerous converts to Hahnemann's system, some of them past middle life, pursued the study of German in order to facilitate their investigations in homœopathy. At the close of the first quarter-century of the new practice, more than 25,000 pages in the English language had been published by the homœopathic press, and at the end of 50 years the aggregate reached more than 150,000 pages. (See 'Transactions of the World's Homœopathic Convention of 1876, Vol. II., pp. 1020–65.)

The progress that homœopathy has made in the United States can be best shown by the records of its organizations and institutions. The American Institute of Homœopathy, the national society of homœopathic physicians, organized in 1844, now has a membership of over 2,000. There are six other national organizations, formed to promote various departments of medical and surgical interest. State societies are organized in 36 of the commonwealths, and at the present rate of increase these bodies will in a few years exist in every State. To these may be added 150 local societies of various kinds. In the United States homœopathic physicians are in charge of 220 hospitals, general and special, 66 other institutions — asylums, homes, etc., and 65 dispensaries, 20 medical colleges, and 32 medical journals.

The exact number of physicians practising homœopathy in this country cannot be ascertained with accuracy, but it is known to be not less than 12,000, and has been estimated as high as 18,000. The number of people employing these physicians, regularly or irregularly, cannot be less than 15,000,000. Thus has the influence of homœopathy extended during its American career of 75 years.

The influence of homœopathy upon public and professional sentiment has been beneficent and pronounced. Laymen and physicians have alike learned from the practice, that large quantities of potent and dangerous drugs are not often necessary to determine recovery from disease, and physicians have reached the wise conclusion that cures sometimes occur under the influence of small doses, as well as quantities with larger.

Bibliography.— Ameke, 'History of Homœopathy'; Boericke, 'A Compend of the Principles of Homœopathy'; Bradford, 'Homœopathic Bibliography of the United States from the Year 1825 to 1891 inclusive'; 'Life and Letters of Dr. Samuel Hahnemann'; 'The Pioneers of Homœopathy'; Dake, 'Therapeutic Methods'; Dudgeon, 'The Lesser Writings of Hahnemann'; 'Lectures on Homœopathy'; Dunham, 'Homœopathy the Science of Therapeutics'; Hahnemann, 'Organon of the Art of Healing'; 'Materia Medica Pura'; 'The Chronic Diseases: Their Peculiar Nature and Their Homœopathic Cure'; Mack, 'The Philosophy of Homœopathy'; 'Transactions of the American Institute of Homœopathy' (1844–1903); 'Transactions of the World's Homœopathic Convention' (1876).

PEMBERTON DUDLEY, M.D., LL.D.,
Professor of Institutes of Medicine, Hahnemann Medical College, Philadelphia.

Homol'ogy, a principle first enunciated by E. Geoffrey St. Hilaire. It is the anatomical or morphological identity of parts or organs, which may have entirely different functions. Thus the wing of a bird is homologous with the fore limb of a dog or the arm of man. On the other hand analogy involves the idea of physiological identity, or use. Thus the wing of a bird is analogous to the wing of an insect. Homologous organs are also present in groups of animals which have had a common origin; thus the swimming-bladder of a fish has given origin to the lungs of the higher vertebrates, the physiological differences arising from change of function. See ANATOMY, COMPARATIVE; ANALOGY.

Homoousian, hō-mō-oo'sĭ an (Greek *homo-,* "the same," and *ousia,* "substance") and **Homoiousian** (Greek *homoios,* "like," and *ousia,* "substance"). The Council of Nice adopted the word homoousian to express that the Son was of the same substance with the Father, while the followers of Arius adopted the term homoiousian, as a sort of middle and reconciling theory, to express that the Son, though not of the same, was yet of a similar substance with the Father. The doctrine of Arianism was not only that the Son was subordinate to the Father, but that he was totally unlike him, being a mere created being.

Homoplasy, hō'mō-plăs-ĭ, the effect of the influences of convergence (q.v.), upon homologous structures. The term was proposed by E. Ray Lankester and used at first with a rather broader meaning subsequently restricted and defined by Osborn. See Analogy.

Homop'tera. See Hemiptera.

Homs, hōms. See Hems.

Hondo, hŏn'dō (signifying "chief island"), the largest island of Japan (q.v.), for a long time erroneously known as Nippon or Niphon, the Japanese name for the whole empire.

Honduras, British, or **Belize,** a colony in Central America, bounded on the north and northwest by Yucatan (Mexico), on the east by the Caribbean Sea and Gulf of Honduras, and on the south and west by Guatemala. Its chief town, Belize, has 9,113 inhabitants. The Cockscomb Mountains in the southern district rise to the height of 3,700 feet. Principal rivers are the Old, the New, and the Sibun. The northern part of the colony contains many lagoons, and a chain of cays stretches along the coast. The forests yield mahogany and logwood in large quantities; cattle raising and the cultivation of coffee and fruits receive some attention. The value of exports since 1897 has been decidedly greater than that of imports. During the year ending 31 March 1902 exports reached $1,427,500 in value: imports for the same period, $1,262,500. In 1901 exports of mahogany amounted to 6,485,952 superficial feet; logwood, 19,682 tons. Registered shipping: 6 steamers and 204 sailing vessels. Vessels entering and clearing in 1901, 414,795 tons. The total number of letters, books, postal cards, parcels, and newspapers transmitted by the post-office in 1901 was 245,694. That is to say, proportionately to the population, from 100 to 350 per cent more than in the neighboring Guatemala and Honduras. The standard of currency since 15 Oct. 1894 has been United States gold. In common use are silver coins and government notes. British Honduras is governed as a crown colony, by a governor, assisted by executive and legislative councils, the former composed of five members and the latter of eight. Expenditures since the close of 1899 have been less than the revenue, the latter being derived from customs duties, excise, land-tax, licenses, and the sale or leasing of lands. Total expenditure in the year ending 31 March 1902, about $256,050; revenue, $300,750; public debt, $173,680. There are 36 primary schools, with 3,423 pupils, receiving aid from the government: also a few denominational secondary schools. Population, according to the latest census, 37,479, an increase of about 17 per cent since the previous census. For origin and early history of the settlement, see Belize: also Central America.

Consult: 'Consolidated Laws of the Colony of British Honduras' (London 1887); Gibbs, 'History of British Honduras'; and Henderson, 'An Account of the British Settlement of Honduras.'

Marrion Wilcox,
Authority on Spanish America.

Honduras, Gulf of, a spacious inlet of the Caribbean Sea, having on the west British Honduras, and on the south Guatemala and Honduras. In it several smaller bays of which the Gulf of Amatique, with its inner recess, the bay of St. Tomas, are spacious and deep. Several large rivers, the Belize, Chamelicon, Dulce, Motagua and Ulua, flow into the gulf. Along the shores are the islands of Turneffe, Manabique, the Bay Islands including Ruatan, Utila, and Bonacca, and numerous islets and reefs called cays.

Honduras, Republic of, a country of Central America, bounded on the north and northeast by the Gulf of Honduras and the Caribbean Sea; on the southeast and south by Nicaragua; and on the southwest and west by Fonseca Bay, Salvador, and Guatemala. Estimated area, 46,250 to 46,400 square miles. The departments of the republic, with the population of each as shown by official statistics of 1901, are as follows: Tegucigalpa, 81,800; Copán, 62,398; Gracias, 48,242; Choluteca, 45,340; Olancho, 44,496; El Paraiso, 39,918; Santa Bárbara, 36,228; Valle, 33,450; Comayagua, 29,023; La Paz, 27,384; Intibucá, 26,348; Cortéz, 21,801; Yoro, 19,988; Colón, 13,791; Atlántida, 8,797; Bay Islands, 4,737. The capital, Tegucigalpa, has 12,000 inhabitants. Mountain ranges, which rise to heights of 5,000 or even 10,000 feet, are massed in the western half of the republic; the Juticalpa, Camasca, and Tompocente ranges, however, are near the frontier of Nicaragua in the east. Rivers emptying into the Caribbean Sea or Gulf of Honduras are the Coco or Wanks, and Patuca, in the east, and the Ulua, Chamelicon, etc., in the west. The Choluteca flows southward from the Misoco Mountains near Tegucigalpa, and empties into Fonseca Bay, on the Pacific coast. Large lakes are the Caratasca, on the Mosquito coast, and Yojoa, among the western mountains. The chief port on the Pacific is Amapala; other ports of entry are Puerto Cortez (on the Gulf of Honduras), La Ceiba, Truxillo, Roatan, and Iriona.

Minerals, Woods, and Agricultural Products. — Gold is found between the south and centre; silver in almost all sections. Lead, copper, saltpeter, iron, coal, platinum, zinc, and antimony are also widely distributed. The value of ores produced in 1902 was approximately $1,000,000 (that is, 23,234 ounces of gold, 1,010,204 ounces of silver, and a considerable quantity of copper). Only about 5 per cent of the mines of the country are being worked. The forests from sea-level to an altitude of 1,000 feet, contain mahogany, ebony, dyewoods, sarsaparilla and other medicinal plants, and cabinet woods, cedar, etc. At an elevation of 1,800 feet are dense and very extensive forests of pine and similar woods. Agriculture receives more attention than formerly, and the leading product is the native maize, of which 509,049 bushels were raised in 1902, chiefly in the departments of Copán, Gracias, and Santa Barbara. Bananas and plan-

tains are grown on 42,840 acres of territory in the departments of Cortéz, Atlántida, the Bay Islands, etc. The wheat crop in 1902 was 15,813 bushels; rice, 3,914,219 pounds. Nearly 20,000 acres are devoted to the cultivation of plantains. Cocoanuts, lemons, and oranges are produced for export on a large scale. The coffee crop in 1902 amounted to 4,494,826 pounds, and tobacco to 1,378,573 pounds. Sugar-cane is cultivated on 13,263 acres; indigo on about 9,000 acres. The total value of agricultural products in 1902 was about $2,482,449.10. The number of cattle is estimated at 571,120; horses, 43,549; mules, about 14,000, etc.

Commerce and Manufactures.— The total value of imports in 1902 was 4,377,161.42 *pesos*, or about $1,750,684.68 in United States currency; of exports, 6,170,353.27 *pesos*. Imports came chiefly from: the United States (60 per cent), Germany, Great Britain, Belize, Central America, and France. Exports were sent to: the United States (two thirds of total), Great Britain, Central America, Cuba, and Germany, with comparatively small amounts to other countries. The articles exported, together with their values (in *pesos*), follow: Metals, 2,319,070.49; fruits, 1,943,168.06; cattle, 560,411; coffee, 275,826.68; hides and skins, 257,598.10; woods, 217,459.70; tobacco and cigars, 200,851; indigo, 105,425; sarsaparilla, 80,602.50; rubber, 77,552.50; wheat and flour, 66,992; salt, 22,716.20; hats, 14,150; miscellaneous, 28,529.04. Exports to the United States were valued at 1,235,624.79 *pesos* more than imports from that country. Native industries include the manufacture of cigars, flour, hats, and candles.

Railways, etc.— A contract for the completion of an interoceanic railway was entered into by an American syndicate in 1897; in 1902 the government's concession to the syndicate lapsed, but a prorogue was requested. The line from Puerto Cortéz runs southward to San Pedro and La Pimienta. Tegucigalpa is to be connected with the Pacific coast, at San Lorenzo, by a line which is now being constructed. Roads in the country, with a few exceptions, are mere mule-paths. A cart-road from the capital to San Lorenzo is completed as far as La Venta. There are 245 post-offices, and the number of letters (both internal and foreign correspondence) is not more than 1,250,000 in a year. The republic has 3,249 miles of telegraph wire; the capital and some other towns telephone services.

Money, Weights, Measures, and Banking.— The standard dollar, or silver *peso*, is worth about 40 cent, United States currency. Gold coins of the value of 20, 10, and 5 dollars, and silver pieces, fractions of one dollar, are also in circulation. While the metric system is authorized by law, the chief measures and weights in commercial use, as in the other countries of Central America, are: Centaro = 4.2631 gallons; fanega (dry) = 1.5745 bushels; libra = 1.043 pounds; and vara = 33.874 inches. Note also, manzana = 1 5-6 acres, and arroba = 2¾–3½ gallons. The capital of the Bank of Honduras, 30 June 1902, was 600,000 *pesos;* bank-bills in circulation, 60,242 *pesos*.

Government, Finances, Army and Navy.— The president and vice-president of the republic, nominated and elected by vote of the people, serve for four years; the former is assisted by the ministers (chiefs of departments) of finance, interior, foreign relations, public works, war, public instruction, and justice. The legislative body is composed of deputies elected by the people, there being one deputy for each 10,000 inhabitants. The budget for the fiscal year 1903–4 gives, as the total of receipts from all sources, 2,637,724.20 *pesos*, the largest items being, customs duties, 1,100,000 *pesos*; tax on aguardiente, 805,000 *pesos;* and lottery and wharfage, 223,500 *pesos*. The estimate of expenditures in the same budget is 2,625,985.45 *pesos*, the largest item being for the war department — 941,853.85 *pesos*. The foreign debt of the republic (that is, the loans of 1867–70, with arrears of interest amounting nearly to two and a half times the principal sum) was determined by calculation to be about $96,124,940 in United States currency; and the internal debt was put at 1,332,400 *pesos* in 1900. But in the annual message of the retiring president, Sr. Sierra, sent to Congress 1 Jan. 1903, the assertion was made that the total "recognized" debt had been only $1,704,124.67 silver in 1899, and that this amount was reduced to $1,221,298.09 silver by 31 Oct. 1901. President Sierra completely ignored the large foreign loans, speaking of the 1,704,124 *pesos* as "the entire amount of the debt existing at the beginning of my term of office," "the public debt," etc. The army on 31 July 1902 comprised, according to a statement in the same message, 480 *jefes*, 2,608 officers, and 47,841 men. The permanent force consisted of 87 *jefes*, 226 officers and 2,481 men. Two small steamers belong to the government, and are used as revenue vessels.

Population, Education, and Religion.— The total number of inhabitants, as shown (by departments) in the first paragraph of this article, is 543,741, exclusive of forest tribes. Very few of this number are of Spanish descent, the great mass of the people being Indians or Mestizos. Between 1899 and 1903, new schools to the number of 136 were founded, making a total of 851; and 30,025 pupils received instruction in 1902. There are 13 national "colleges" and one private school for higher education; professional schools with faculties of jurisprudence and political science, and medicine and surgery, at Tegucigalpa; the Escuela de Derecho at Comayagua; a national library with 6,854 volumes; and an art school. Primary instruction is compulsory, gratuitous, and secular. Freedom of worship is secured by constitutional guaranty; the government does not contribute to the support of any church; the prevailing religion is Roman Catholicism.

History.— The first place of debarkation of Christopher Columbus on the American mainland was near the present Cape Honduras, where he landed on Sunday, 14 Aug. 1502. On the following Wednesday Bartholomew Columbus landed at the mouth of Rio Tinto. They sailed thence along the coast to Cape Gracias á Dios (see CENTRAL AMERICA). The conquest of the country was effected by Hernan Cortés, who found the natives manageable, but their land "covered with awfully miry swamps," as he wrote to the Spanish emperor 3 Sept. 1526. "I can assure your majesty," he adds, "that even on the tops of the hills our horses, led as they were by hand, and without their riders, sank to their girths in the mire." The most important fact in the history of Honduras — the fact that the Indians remained in possession of so large a portion of the country that their descendants

constitute the bulk of the population to-day — is a consequence of the policy observed by Cortés and his successors. The natives were tractable; without their assistance it would have been impossible to move about among the dense forests, swamps, and mountains; therefore the Spaniards realized that more was to be accomplished by diplomacy than by force. Massacres occurred, but extermination was not attempted; on the contrary, Honduras became in time a nation of Spanish-speaking Indians, those of pure or nearly pure blood being more numerous now than before the conquest. For the era of independence, confederation with the neighboring states, etc., see CENTRAL AMERICA.

Bibliography.— American Republics, International Bureau of the, 'Monthly Bulletin' (1902–3); Cortés, 'Fifth Letter of Cortés to the Emperor Charles V.'; Diaz, 'Historia Verdadera de la Conquista de la Nueva España'; Sierra, 'Mensaje,' etc., in 'Pabellon de Honduras,' Tegucigalpa 10 Jan. 1903; Squier, 'Honduras,' and 'Honduras Interoceanic Railway'; Wells, 'Explorations and Adventures in Honduras.'

MARRION WILCOX,
Authority on Spanish America.

Hone, hōn, **Philip**, American merchant: b. New York 1781; d. there 4 May 1851. He was a successful auctioneer in New York, established there the first savings bank (1816), was mayor in 1826, and one of the founders of the Mercantile Library Association. Prominent in national political affairs, he aided in the formation of the Whig party. His diary, a portion of which, edited by Tuckerman, appeared in 1889, contains important side-lights on the early history of the Whigs. Hone was also at one time naval officer of New York port.

Hone, a strop or stone for sharpening knives and razors. See WHETSTONE.

Honesdale, hōnz'dāl, Pa., borough, county-seat of Wayne County; on the Lackawaxen River; the Erie, and the Delaware & H. R.R.'s; about 15 miles northeast of Carbondale and 30 miles northeast of Scranton. The first locomotive used in America, the "Stourbridge Lion," made its trial trip from this city. It is situated in a coal-mining region, with good farming land in the valleys. Its manufactures are silk and woolen goods, boots, and shoes, machine-shop and foundry products, axes, electric elevators, green, cut, engraved, and decorated glassware, men's clothing, and wheels for polishing glass. Large quantities of coal are shipped annually from Honesdale. Pop. (1900) 2,864.

Honesty. A flowering herb. See SATIN-FLOWER.

Honey, a sweet sticky liquid obtained by bees and other insects from flowers (see HONEY-BEE; and FLOWERS AND INSECTS) as food, or taken home to be stored as food for the young. The care with which the honey-bee (q.v.) collects and stores this substance in its hive has led to bee-culture (q.v.). Honey is highly nutritive, especially as a fuel for the energies of the body, as four fifths of its components are carbohydrates, the remainder being water with a trifle of protein. The saccharine elements are mainly grape-sugar and some fruit-sugar, which are so readily affected by yeast that various fermented drinks are made with honey as their basis, of which the best known are the mead and metheglin in great demand among all Teutonic peoples a thousand years ago, and the equivalents of which are still made in Russia, Abyssinia and elsewhere. Before the general manufacture and use of cane-sugar, honey was largely depended upon for purposes of sweetening, and was put into a great number of cakes and confections now rare or only locally manufactured. Of the place which it took among the ancients in the household, in ceremonials, worship, and folk-lore a large amount of curious information may be gathered from such books as Beckman's 'History of Invention' (1846); Dutt's 'Materia Medica of the Hindoos' (1877), and similar works, of which lists may be found in Warring's 'Bibliography of Therapeutics' (1868), and in the 'Catalogue of the United States Army Medical Museum.' The importance of honey was, indeed, much greater to the ancients than to us; as might be inferred from its frequent mention in the Bible as a sign of abundance or the resource of the destitute. It has well-recognized medicinal properties, especially as a demulcent against hoarseness, catarrh, etc., in promoting expectoration in disorders of the breast, and as an ingredient in cooling and detergent gargles. Its effect is usually laxative also. It is used to sweeten certain medicines; and is sometimes mixed with vinegar in the proportion of two pounds of clarified honey to one pint of the acetic acid, boiled down to a proper consistence over a slow fire, and thus forms the oxymel simple of the shops. It enters into the composition of various sweetmeats, especially in the East, such as the genuine Oriental nougat. These properties and the flavor and color of honey vary with the qualities of the flowers from which it is made. Thus in Europe the white Narbonne honey of France, is said to owe its peculiar and delicious flavor to the rosemary and other labiate flowers on which the bees feed. The Grecian honey also stands in high estimation. Mt. Hymettus in Attica has been famous since classic times for this product; but that yielded by the bees who range the thyme-covered hills of Corinth is said to excel it. Another famous ancient source of supply was Sicily, especially about Mt. Hybla; and Corsica is yet celebrated for its honey and wax, which in ancient times were the chief exports of that island. In the eastern United States the early light-colored honey obtained from the blossoms of the white clover, is especially esteemed; also that derived from raspberry plantations, bass-wood flowers and the like; while that made later in the summer from buckwheat is in favor among darker varieties. California is an extensive producer of honey from various flowers.

As the aromatic agreeable flavors and healthful qualities of special flowers (fortunately in the majority) are kept and apparent in ordinary good honey, so certain bad qualities are retained and spoil some honey, which thereby becomes deleterious to the human system, acting as a nauseant, a purgative, affecting the nerve-centres or even seriously poisoning those who eat it. This is the case in the United States with honey made from the flowers of the mountain laurel (*Kalmia*) and some other toxic plants. Some persons are unable to eat any

kind of honey, without disarrangement of the digestion or nerves, or both; and all should use it in moderation.

The industry of bee-keeping is for the purpose of supplying the market demand for honey. Modern hives are so constructed that the bees build separate combs each filling a box with glass sides, which are taken out and sent to market as the bees finish them. Another method of marketing is in the form of "strained" honey, the liquid pressed from the comb after warming, through sieves of linen cloth, or by other means. There is no reason why this should not be as good as that left in the comb, if properly prepared and preserved, and it permits of saving the material of the combs for wax (q.v.); but it makes possible adulteration, which is freely taken advantage of. The chief adulterant is commercial glucose, which occasionally is substituted to the extent of three fourths of the volume, leaving only enough real honey to flavor the mass. As glucose (grape-sugar) is a large constituent of this substance in nature no great harm results (when the glucose is good), beyond the deception; and wholly artificial honey has been largely sold in the past as the product of bees.

The United States is probably the greatest honey-producing region of the globe, and exports a vast quantity to Europe annually. The census of 1900 reported 4,149,426 swarms of bees, valued at $10,186,513; and the annual production of honey at 61,196,160 pounds, which, together with 1,765,315 pounds of wax was worth $6,664,904.

Honey Ant, a true ant of the family *Formicidæ,* fifth sub-family *Camponotinæ,* and allied to the typical ants (*Formica*). The honey ant (*Myrmecocystus melliger*), is so called from certain of the wingless individuals being so many honey-pots, their abdomens being distended with honey fed to them by the normal workers, including both dwarfs and majors. It occurs from central Colorado (Garden of the Gods) to New Mexico and as far south as the city of Mexico. It erects mounds six or seven inches across and two or three inches in height, of the shape of a truncated cone. In the interior is the "honey chamber" or a rough dome-roofed vault or fissure, the honey-bearers (600 in a large colony) clinging by their feet to the roof. Their yellow bodies are stretched along the ceiling, their swollen, round, amber-colored abdomens of the size of currants hanging down. The "honey" is obtained in the night time by the workers which go in long processions to some distant scrub-oak bearing nectar-producing galls. The workers return with distended abdomens, and feed the honey-bearers with the nectar. C. McCook thinks the honey-bearers are not a distinct caste, but simply workers "with an overgrown abdomen." The honey is thus stored, as bees store their honey, for food in winter or times of famine. Consult McCook, 'The Honey Ants of the Garden of the Gods,' etc. (Philadelphia 1882).

Honey-badger, a small mustiline burrowing animal (*Mellivora indica*) of India, which eats insects, frogs, birds' eggs, and small animals generally, and is fond of honey. The natives believe it robs graves, but destruction of poultry is its worst sin. It is nearly related to the South African ratel.

Honey-ball, or **Globe-flower,** the flower of an American shrub (*Cephalanthus occidentalis*) of the madder family, which grows in wet places, where it is called button or river bush, and bears extremely fragrant flowers whose small florets are folded or packed into balls, while "the long styles and capitate stigmas remind us of pins stuck in a cushion."

Honey Bear, the sun-bear (q.v.).

Honey-bee. Bees in general are *Hymenoptera,* of the family *Apidæ.* Bees are distinguished from wasps and other hymenoptera in the first place by the long, broad, flattened basal joint of the hind tarsus, which is adapted for carrying pollen to the nest. Bees are also more hairy than others of their order, and some of the hairs are plumose or feathery. The mouth-appendages are long and highly specialized, especially the long flexible proboscis or tongue (hypopharynx). There are no wingless adult forms. While the more primitive genera are solitary, in the more specialized or social kinds, besides the males and females, there are workers, which are, as a rule, sterile females in which the ovaries are undeveloped. Of the bee family there are now known to be about 150 genera and 1,500 species.

Original Home of the Honey-bee.— Although the honey-bee (*Apis mellifica*) has followed the white man in his migrations from the Old World to the New, and to Australia, New Zealand, etc., its original birthplace is in southern Asia, probably including the eastern shores of the Mediterranean Sea. Besides *A. mellifica* there are seven or eight other species, all except one southern and eastern Asiatic, including the islands of Timor and Celebes; the exceptional one (*A. adamsoni*) inhabiting tropical Africa and Madagascar. We know little of the honey-bees of China and Japan.

Like other domestic animals (and the honey-bee is the only domestic insect we possess), this bee is divided into races of which the Ligurian bee (variety *ligustica*), originally inhabiting Italy and adjoining regions, is a well-marked one, and another is the Egyptian honey-bee (variety *fasciata*). There are several sub-varieties of the northern form of *A. mellifica* in Germany. The English naturalist Ray, who published before Linné gave the name *A. domestica* to the northern dark form, our common honey-bee. This dark, northern form is the one which has been carried by the European race to various parts of the world, in some of which it is now wild. It occurs in the West Indies, in North America, including Mexico, in central and southern Africa, and in Australia and New Zealand. The variety *ligustica* has also been found at the Cape of Good Hope.

Besides the honey-bee there are other social forms in Central and South America, as well as other tropical countries, including Australia, which store up honey; these are small bees, exceedingly numerous in individuals, which belong to the genera *Melipona* and *Trigona,* and are stingless, though the sting exists in a rudimentary state. *Trigona mosquito* is known to send off swarms and to have but a single queen in a colony. The nests are built in hollow trunks of trees, in banks of clay or earth, and they gather pollen, nectar, and resin. On the

whole, the honey-bee stands at the head of the hymenopterous series, and, in fact, at the head of the class of insects, though the house-fly is in some respects more extremely specialized.

Structure of the Honey-bee.— Besides the males or drones, and the female or queen, the colony consists of workers; these carry on the work of the society, gathering nectar, pollen, building the cells and feeding the young. The colony is permanent, differing in this respect from that of bumblebees, which come to an end each autumn. We will first describe the chief points in the external anatomy of the insect. The body is divided into three regions, the head, thorax, and abdomen. The eyes are of two kinds, simple and compound, the male differing from the queen and the workers in the large compound eye meeting in the middle of the top of the head. The mouth-appendages consist of three pairs,— first the jaws or mandibles; these in the queen and drone are notched, but in the worker the edge is entire and serves for biting, and in comb-building for thinning out wax shreds, also for scooping and molding the wax, while the next pair of appendages, or accessory jaws, are called maxillæ, and are used as a trowel. In the bumblebee the maxillæ are also used for piercing the corolla of flowers like the wistaria and honeysuckle, but those of the honey-bee appear to be too weak for this purpose. They also ensheathe the proboscis. The so-called tongue (ligula, lingua or hypopharynx) is the long, slender, hairy appendage adapted for gathering the nectar of flowers. It is an outgrowth of the under lips (labium or fused second maxillæ), is situated in a tube formed by the maxillæ and labial palpi, and can be partially withdrawn into the memtum, or base of the under lip. It can move up and down in the tube thus formed. It is covered by a hairy sheath, and is very elastic, this being due to a rod extending through its centre, enabling it to be used as a lapping tongue. Cheshire states that the rod on the under side has a gutter or trough-like hollow, which forms a false tube by the intercrossing of black hairs. There are also two side-ducts, which extend along to the end of the tongue, where the "spoon" or "bouton" is situated. This is provided with very delicate split hairs, "capable of brushing up the most minute quantity of nectar, which by capillarity is at once transferred by the gathering hairs to two side groove-like furrows at the back of the bouton." The central duct, because of its smaller size and consequent greater capillary attraction, receives the nectar, if insufficient in quantity to fill the side ducts. "But," says Cheshire, "good honey-yielding plants would bring both centre and side into requisition. The nectar is sucked up until it reaches the paraglossæ, which are plate-like in front, but membranous extensions, like small aprons, behind; and by these the nectar reaches the front of the tongue, to be swallowed as before described. The process of gathering the nectar is not exactly either a sucking or a licking process; but, as Cheshire shows, the action is primarily due to capillary attraction.

Organs of Smell and Taste.— Bees are guided to flowers chiefly by smell, rather than by the color of the flowers they visit. (See Flowers and Insects.) The olfactory organs are multitudes of microscopic pits in the antennæ — the organs of smell. The sense of taste is lodged in a minute soft baggy fold on the under side of the upper lip, which is rich in taste-cups; and, besides, there are a few taste-papillæ or cups found by Packard at the base of the paraglossæ and on the base of the labial palpi. These sites of the gustatory organs are situated where the food or nectar will come in contact in passing down the throat into the stomach.

Formation of Honey and the Honey-Stomach.— In insects there is the fore stomach (proventriculus) and the true or chyle-stomach. The former is called by apiarians the "honey-sac" or "honey-stomach." "If," says Cheshire, "it be carefully removed from a freshly killed bee, its calyx-like 'stomach-mouth' may be seen to gape open and shut with a rapid snapping movement." The entrance to the stomach is guarded by four valves, which open to allow the passage of food from the honey-sac to the chyle-stomach. It is closed at will by circular muscles. Thus the bee can carry food for a week's necessities, either using it rapidly in the production of wax, or eking it out if the weather is unfavorable for the gathering of a new store. By means of a complicated mechanism a bee in sucking up from composite and other flowers nectar together with much pollen (1) can either eat or drink from the mixed diet she carries, gulping down the pollen in pellets, or swallowing the nectar as her necessities demand; (2) when the collected pollen is driven into the chyle-stomach, the tube-extension prevents the pellets forming into plug-like masses just below, for by its action these pellets are delivered into the midst of the fluids of the stomach to be at once broken up and digested; (3) "while the little gatherer," says Cheshire, "is flying from flower to flower, her stomach-mouth is busy in separating pollen from nectar, so that the latter may be less liable to fermentation and better suited to winter consumption. She, in fact, carries with her, and at once puts into operation, the most ancient, and yet the most perfect and beautiful, of all honey-strainers.' "

How the Honey is Made.— Honey is made of nectar, and is due to a chemical change in the honey-sac. The bee gathers the nectar with its "tongue," swallows it; it then passes into the honey-sac, and is regurgitated as honey. The nectar when gathered is almost entirely pure saccharose, and, according to Bertrand, when regurgitated it is found to consist of dextrose and levulose; this change appears to be practically the conversion of cane-sugar into grape-sugar. A little salivary fluid is poured out into the mouth as the bee sucks the nectar, and this effects the chemical change. Cheshire thinks that the salivary fluid is added while the nectar is being sucked, and is passing over the middle parts of the under lip, so that the nectar may be honey when swallowed by the bee.

Many and probably all bees eat the pollen while gathering it. The plumose hairs of bees are of use in collecting the pollen grains which adhere to them, but the exact method of accumulation of the pollen and the mechanism of its conveyance from hair to hair till it reaches the part of the body it must attain in order to be removed for packing in the cells, is not fully understood, but the head and front legs scratch up the pollen-grains, and the honey-bee has a pollen-basket on each hind leg, the basal joint of the tarsus being broad and slightly hollow,

with nine rows of short hairs to which the pollen-grains adhere.

Life History and Social Life.— In founding a new colony the young swarms consist of a queen-bee and a number of workers, a surplus population of the old colony. The swarming is not a nuptial flight, but an act of emigration. After the new swarm has been housed, the workers begin their labors by secreting wax. This is formed in glands on the inside of the ventral plates of the abdominal segments, appearing outside as thin projecting plates, which are removed by the wax-pincers on the hind legs; after being molded by the jaws they form the hexagonal cells in which the young or larvæ live and the food is stored, and thus the comb is gradually built up. The queen then lays an egg in each cell, and the larvæ (grubs) on hatching are fed by the workers. This they do by eating honey and pollen, which is formed in the digestive organs, into a kind of pap. This pap looks like arrowroot made with water, and the very young grubs partly float in it, besides absorbing it by the mouth. The young grubs, as they increase in size, are weaned from this glandular secretion or pap, pollen, honey and water being added, while the pap or glandular secretion is gradually withdrawn. The queen larvæ, according to Cheshire, is not weaned, but the secretion or pap (the so-called "royal jelly"), which is a rich, highly nitrogenous food, is added unstintingly to the end, and owing to this the queen becomes larger and fertile. When the colony is progressing well and young bees emerge, these act as nurses, the old ones going out of the hive to forage. When the grub is full-sized the worker bees seal up the cell with a cover made of pollen and wax, but pervious to the air. In this cell the grub spins a cocoon in which it pupates, finally biting its way out; the bee developing in three weeks from the time the egg is laid.

The new queen arises from an egg laid in the royal cell, which is large and slipper-shaped. She develops in 16 days. Only one queen is allowed in the hive at one time. The males (drones) arise from unfertilized eggs. The drone cells are a little larger than the ordinary worker cells. A drone is developed in about 24 days. When a swarm leaves the hive the old queen quits with it, but when a second swarm goes off from a hive it is accompanied by a young queen, who is frequently and perhaps usually, unfertilized.

The young queens will usually mate when five to seven days old, flying from the hive for this purpose. In a day or two after mating the queen generally begins to deposit eggs, and is then ready for use in the hive or to be sent away as an "untested queen."

Bee-Culture.— Spring is the best season to start a hive or apiary. In April a good colony situated in the Central States ought to have brood in five or six combs. The Langstroth hive with its modern improvements is the best, and the novice should select those holding 10 to 12 frames in each story.

Swarming is the result of an abundant secretion of honey, and combs crowded with bees and brood, that is, overpopulation. Just before swarming there is a partial cessation of field-work, the workers clustering or loitering about the entrance to the hives. Suddenly those which happen to be in the hive at this time rush forth, accompanied by the old queen, and cluster on some tree or shrub near by. Hiving the new swarm can be done after a little experience and the use of smoke. Swarming may be prevented by giving abundant room for the storage of honey early in the season, before, as Benton says, the bees get fairly into the swarming notion. The honey also should be frequently removed. Also the hives should be well ventilated and shaded in hot weather. To successfully winter bees the colony must have a good queen, and young workers, also good and abundant food. Those colonies having the most honey compactly stored in the brood department and close about the very centre when the last brood of young bees should emerge, are the ones which will winter best. A good substitute for honey is a syrup made of granulated sugar, to be fed early in autumn. The bees should be kept dry and warm, and there should be no manipulation out of season. (Benton.)

Diseases and Enemies.— Diarrhœa is due to sour or fermented honey, dampness, and chilling of the bees. Foul-brood is a germ-disease, occasioned by *Bacillus alvei;* it affects both the brood and the adult bees. Of insect enemies the caterpillar of the wax or bee-moth is the most destructive, but with care it can be kept out of well-regulated hives.

Agency of Bees in Cross-Fertilization of Plants.— A hive is an essential thing in an orchard, and were it not for the visits of bees the fruit in many cases would not set. Also in hothouses where cucumbers are raised, a small hive of bees is indispensable for fertilizing the flowers. See BEE-KEEPING; FLOWERS AND INSECTS.

Consult: Cheshire, 'Bees and Bee-Keeping' (2 vols., London 1886); Benton, 'The Honey Bee'; Bulletin No. 1, new series, U. S. Department of Agriculture, Division of Entomology, Washington, 1896, contains a list of the best books on bee-keeping.

ALPHEUS S. PACKARD,
Late Professor of Zoology, Brown University.

Honey-bird, or **Honey-guide.** See GUIDEBIRDS.

Honey Bloom, one of the American species (*Apocynum androsæmifolium*), the "spreading dogbane" of the family *Apocynaceæ* (q.v.). It grows in fields and thickets all over temperate North America, and has the medicinal qualities characteristic of the family.

Honey-buzzards, a genus (*Pernis*) of Old World hawks, formerly called "perns," which subsist mainly on insects, especially burrowing wasps, and bees, with their young and food-stores, which they dig out of the ground.

Honey-creepers, a group of small warbler-like birds (the family *Cœrebidæ*) of gay plumage, numerous in the West Indies and neighboring lands, where they are known about gardens and plantations and admired for their agility in searching flowers for small insects, and their cheery notes. Among them are the "banana-birds" (q.v.).

Honey-dew, the sweet secretion of certain plants and insects. (1) Some trees in warm climates yield from their leaves in very warm moist weather a saccharine liquid which may fall in drops, or may form a sticky film over each leaf. This exudation, dried, is one form of

manna. (2) Certain minute insects, chiefly plant-lice, leaf-hoppers, and related bugs, yield a sweetish secretion, sometimes so copiously as to bedew a whole tree, and even fall in drops, giving the phenomena called weeping trees. The usual cause in this case is the presence of a tree-hopper (*Proconia undata*). Honey-dew in both cases attracts insects in large numbers, who feed upon it or upon the lesser insects gathered to the feast: and these, in turn, attract larger predatory animals, as birds, lizards, etc. Moreover dust sticks to it, closing the pores of the leaves to the injury of the tree; and, still worse, the honey-dew forms a highly favorable culture-ground for the spores of smuts and other pernicious fungi.

Honey-eater, or **Honey-sucker,** any of various small and somewhat thrush-like long-billed birds of the family *Meliphagidæ,* which inhabit the Australian regions, and seem to feed upon the nectar of flowers. They do so to some extent, but mainly are in search of insects within the corolla, collecting them easily by means of a peculiar tongue, which is divided near the end into a sort of fringe. They also eat soft fruit, and spend much of their time hunting insects on the ground. Well-known examples are the soldier-bird, parson-bird, pimlico, friar-bird (qq.v.) and others familiar in Australia and New Zealand.

Honey-guides. See GUIDE-BIRDS.

Honey Hill, Battle of. On the night of 28 Nov. 1864 Gen. Foster, commanding the Federal troops in the Department of the South, left Hilton Head, S. C., with 5,000 infantry, cavalry, and artillery, and about 500 sailors and marines, for Boyd's Neck on the south side of Broad River, the object of the movement being to cut the railroad connecting Savannah and Charleston, and otherwise co-operate with Sherman, who was marching to the coast. Owing to a thick fog many of the boats lost their way, and it was late in the afternoon of the 29th before the troops got ashore. Gen. Hatch was put in command, with orders to push forward and cut the railroad. Hatch marched immediately; the guides and maps proved worthless, and, after marching and countermarching the greater part of the night, he went into bivouac about 2 o'clock on the morning of the 30th. Information of Foster's appearance at Boyd's Neck was carried to Gen. Hardee at Savannah on the evening of the 29th, and next morning at 2 o'clock, the advance of G. W. Smith's Georgia militia arriving at Savannah, Hardee directed Smith to hasten it to Grahamsville Station on the Charleston & S. railroad. The station was reached at 8 A.M., and the men marched out on the road leading to Broad River landing, about three miles where, on the crest of the north bank of a small stream, a work for light guns had been thrown up and trenches for infantry prepared. These works were about 100 yards from the little stream, and upon Honey Hill, 10 or 12 feet above the water level. On the right of the battery of five guns was a dense forest, on the left an open pine wood. The ground in front was open. Preparations were completed by 10 o'clock, at which hour about 1,000 militia filled the trenches on the right and left of the battery. Early in his march Hatch encountered the Confederate outposts, drove them in, and, soon after 10 o'clock, came under fire of the guns. Hatch attempted a flanking movement, but failed, and made several direct assaults during the day, all of which were repulsed, and at dusk he began his retreat to Boyd's Neck. His loss was 711 killed and wounded, and 43 missing. During the action Smith was reinforced by the 47th Georgia, but at no time did he have more than 1,400 men. He lost 8 killed and 42 wounded. Consult 'Official Records,' Vol. XLIV.

E. A. CARMAN.

Honey-locust, or **Honey-shucks.** See LOCUST TREE.

Honeysuckle, a genus of plants, *Lonicera,* belonging to the natural order *Caprifoliaceæ.* Upward of 100 species are native to the northern hemisphere. The honeysuckle family is represented in the North American flora by different species, among which are *L. sempervirens,* the trumpet honeysuckle; *L. grata,* American woodbine; *L. flava,* yellow honeysuckle, etc. "Coral honeysuckle" is another name in the United States for *L. sempervirens.* It is much valued in the South, where it is native, for its flowers of beautiful color and grateful perfume. In the eastern United States the Japanese honeysuckle has escaped from cultivation. The common honeysuckle, *L. periclymenum,* with distinct leaves and red berries, is indigenous in Great Britain; but two others have been naturalized, *L. caprifolium,* distinguished by its upper leaves being united (connate) and perfoliate, and by its smooth orange-colored berries; and *L. xylosteum,* an erect shrub, with small, yellowish, scentless flowers and scarlet berries. There are many other species in America, Europe, and Asia, and the name honeysuckle is often given to shrubs with sweet flowers of quite different genera.

Honey-sweet. See MEADOW-SWEET.

Hongkong, hŏng'-kŏng', or **Hian-Kiang,** hē'ăn-kē'ăng (signifying "the place of sweet streams"), an island off the southeast coast of China, forming with Kau-lung on the mainland, a British crown colony and naval station. The island is on the east side of the estuary of the Chu-Kiang or Canton River, 90 miles south of Canton, and is separated from the mainland by the narrow Lyemun strait. About 10 miles long and about 7½ miles broad, the island is of rocky formation, attaining in Victoria Peak a maximum altitude of 1,809 feet. While almost treeless it is noted for its profuse flora. Good water is abundant. Hongkong is a great entrepôt for the foreign commerce of China, and Victoria (q.v.) the chief town and centre of its commerce is a free port. The foreign commerce is carried on mainly with Great Britain and Germany, whence considerable quantities of goods are imported, cottons being the principal item,—and to which tea, silks, hemp, etc., are exported.

In 1902 Hongkong exported, in vessels of European construction, goods to the value of $3,963,463, besides $2,372,397 worth of goods in transit, making a total of $6,335,860, and showing an increase of $720,288 over the previous year.

Comparing 1902 with 1901 the number of steamships which entered the port of Hongkong and their classification by the flags they carried, is as follows:

Courtesy of the Philadelphia Commercial Museums.

QUEEN STREET, HONGKONG.

Flag	Ships		Total Tonnage	
	1901	1902	1901	1902
British	321	324	2,894,519	2,965,030
German	122	123	1,242,499	1,360,524
Japanese	65	56	692,981	865,400
Norwegian	3	3	78,004	263,379
French	22	27	209,094	219,111
Chinese	4	17	3,349	163,396
Austrian	20	20	128,483	125,929
American	19	23	130,476	121,939
Others	33	37	119,498	131,518
Totals	609	630	5,498,903	6,216,226

In 1901 the vessels entered the port 3,510 times, and in 1902 4,000 times.

The currency is chiefly in silver dollars. The revenue of the government is derived from land rents, licenses to sell opium, spirits, etc., taxes, postage, office fees, fines, etc. The colony's prosperity is due chiefly to the presence of large numbers of Chinese engaged in trade or in working building stone, one of the island's principal products. Exclusive of the naval and military establishments which numbered 5,597 and 7,640 respectively, the population in 1901 was 283,905 of which 274,543 were Chinese and one third of these by birth, British subjects. Hongkong was ceded to Great Britain in 1842; some 376 square miles on the mainland, with 100,000 Chinese inhabitants, were leased in 1898.

Honolulu, Hawaii, capital and principal city of the Hawaiian Islands (now a United States Territory), and commercial metropolis of Polynesia; the business heart of the central Pacific. It is 2,089 miles southwest of San Francisco, in lat. 21° 17′ 56″ N., lon. 157° 51′ 48″ W. It lies on the southwest side of Oahu (the third island of the group in size, and northwest of Hawaii, with a safe harbor formed by a natural breakwater of coral reef, pierced by a broad opening. A fine lighthouse here throws a light visible for 25 miles. With its natural advantages, and the absence of rivals, the city occupies a unique position. From its central location it is a common point of touch for the three great trans-Pacific steamship routes — from the United States and British Columbia to New Zealand and Australia, from the same to Japan, China, and the Philippines, and from South America to Japan and China. Several independent steamship routes also run from it. It has regular communication with San Francisco, Vancouver, and Seattle, Peru, Auckland, and Sydney, New York and Boston, Yokohama and Hongkong, Liverpool, Glasgow, and Bremen, besides other places. The steamship line to Sydney touches at the Fijis; the line to Auckland, at Apia, Samoa. From Honolulu it is 3,850 miles to Auckland, about 4,000 to Sydney, and 3,445 to Yokohama. It is the port of foreign trade for the archipelago; hundreds of vessels and some $20,000,000 worth of products pass in and out of it annually. There are numerous wharves and warehouses here and a government custom-house. (For the items of the trade, see Hawaii: the great items are sugar and molasses, rice, coffee, hides, and wool.)

Honolulu lies at the mouth of the valley of Nuuanu, which runs back between two high ridges to a pass between two peaks about 3,000 feet high in the great eastern range of mountains; the view from the brink of the *pali* or precipice at this pass, is one of the notable sights of the neighborhood. The climate is mild and equable, and many sufferers from lung troubles in the United States seek it for a sanatorium. The extreme range of temperatures is 52° to 88°, average 70°. The rainfall is very irregular, but never slight; from 40 to 60 inches annually. The island is volcanic, the bordering reefs coral; hence the city streets are macadamized with coral and lava, porous rock making good surface drainage. The city is well laid out in American fashion, being indeed a modern American place; the old one-story wooden huts, mingled with grass huts among the trees, have mostly given place to cottages, unpretentious indeed, but neat and comfortable, and making parts of a beautiful and picturesque whole of luxuriant gardens and surroundings of tropical trees, with which also some of the streets are abundantly shaded — the great Norfolk pine, papaya, bread-fruit, mango, and monkey-pod, umbrella-tree, tamarind tree, algaroba, bamboo and koa, date and cocoa palms, candle-nut, royal-palm and poinciana regia, alligator-pear, china-rose bush, blooming all the year round, etc., many with rich and fantastic blossoms, others with great parasitic ferns, besides peach, oleander, banana, guava, orange, citron, and others. The flowers are also of great beauty and luxuriance.

The city has nearly 200 acres of public parks. There are all modern appliances and services for civilized work and comfort; several first-class hotels, physicians, lawyers, daily and weekly newspapers, four banks and two theatres, insurance offices, several hospitals, a public library, etc. There are 22 public schools, including a high school and normal school, with a total attendance of over 4,000 pupils, besides 37 private schools, with an attendance of 2,700 pupils. There are a number of churches, Protestant and Catholic; the city is the seat of a Roman Catholic and an Anglican bishop. It is also the residence of the government officials, and the consular agents of many European powers. It has waterworks owned and operated by the Territorial government, and furnishing excellent water, pumped from artesian wells, supplemented by water from the adjoining valleys. Ice is made by machinery. There is an electric street lighting system operated by the government, and an electric street railway system, built and conducted by a chartered company; a telephone system; and there is a submarine cable to San Francisco and wireless telegraph to the neighboring islands. Of manufactures the number of different lines is upward of 30, of course chiefly for local needs; the largest branch is foundry and machine-shop manufacture, which is carried on in large works, and turns out some $650,000 a year of product. Next to this is rice-milling, with some $150,000 a year. Minor industries are ice, harness, leather, jewelry, soap, and shipbuilding. The total number of all employees in 1900 was 1,854, and the total annual wages paid $1,201,648.

The chief building is the former royal palace, now the executive building, in the Italian style, finished in 1882. The judiciary and other government buildings are near it. The most interesting place is the museum, with many curious

relics of early Hawaiian history, corals, and shells and other native curiosities, land and marine. The chief in interest and value is the great feather war-cloak of Kamehameha I., the founder of the monarchy, valued at $150,000. This was the chief treasure of the former sovereignty, and was used as a mantle of state by the sovereigns. It was made of yellow feathers from the *mamo* bird, found only in the mountains, each bird furnishing only two small tufts of feathers for it, one from under each wing. It is four feet long, and has a spread at the bottom of 11½ feet. Nine generations were employed in making it.

Honolulu harbor was discovered by Capt. Brown in November 1794. The city as a modern foundation dates only from 1816, when John Young, an Englishman, and a faithful counsellor of the king, Kamehameha, advised its fortification. Previously it had been only a native village of huts, of little commercial importance. In 1820 it was made the capital of the archipelago, and afterward became the seat of government. Population (1870) 14,852; (1890) 22,907; (1900) 39,306. Since the annexation of Hawaii to the United States, it is rapidly increasing. Of the population in 1900, 24,746 were males and 14,560 females; the total being divided as follows: 11,690 Hawaiians, 9,061 Chinese, 7,229 whites, 6,179 Japanese, 5,000 Portuguese, and 147 negro. Of these, 21,871 were born in Hawaii and 17,435 born in foreign countries. (This classification is based upon a census taken by the plague inspectors during the spring of 1900, and is believed to be approximately correct. Of the 7,229 whites about 2,000 are classed as foreigners.)

W. D. Alexander,
Surveyor-General Hawaiian Islands.

Honor, Knights of, a secret, beneficiary order founded in 1873. In 1902, there were in the United States 36 grand lodges, 1,960 sub-lodges and 54,029 members. Since its organization the order has disbursed over $79,000,000 in benefits, and in 1902 the amount was $3,074,649. The order is incorporated under the laws of Missouri, with headquarters in St. Louis.

Honor, Knights and Ladies of, a fraternal, benevolent society founded in 1877 at Louisville, Ky. In 1902 there were 16 grand lodges, 1,160 sub-lodges, and 63,000 members. Since its organization over $19,000,000 has been disbursed in benefits, and during 1902, the amount was $1,173,000.

Honorius I., hō-nō′rĭ-ŭs, Pope: d. 12 Oct. 638. He was elected pope in 625. In the hope of allaying a controversy he temporized with the leaders of the Monothelite heresy, which, while recognizing the twofold nature of Christ, declared he had but one will, a doctrine condemned by the sixth council of Constantinople. He was anathematized by the council that condemned the heresy. Pope Leo II., in confirming the acts of this council, says that Honorius was condemned for "not extinguishing the flames of incipient heresy." For a full account of the case of Honorius, consult Parson, 'Studies in Church History,' Vol I.

Honorius II., Pope: d. 14 Feb. 1130. He was elected pope in 1124, and was at the time of his election bishop of Velletri. A part of the bishops and cardinals had previously invested Cardinal Thibaut with the papal dignity; but both candidates having resigned Honorius was re-elected.

Honorius III., Pope: d. 18 March 1227. He became pope in 1216, on the death of Innocent III. He at once wrote to the King of Jerusalem to assure him of his support; to the bishops of France, to encourage pilgrims, and to the Emperor of Constantinople to promise him assistance. John, king of England, had left to his successor, Henry III., the burden of a war with the French Prince Louis, who laid claim to the English throne, and had been encouraged in his pretensions by Innocent. Honorius reconciled the barons with Henry, and obliged Louis to renounce his pretensions. He then turned his attention to the crusades, and crowned Frederick II. emperor of Germany, on condition that he would go to Palestine within two years. In France he instigated Philip Augustus and Louis VIII. to support the war against the Albigenses. He was succeeded by Gregory IX.

Honorius IV., Pope: d. 3 April 1287. He was elected pope in 1285, and supported the French king, Philip the Bold, in the war against Peter of Aragon.

Honorius, Flavius, Roman emperor, son of Theodosius the Great, b. Constantinople 9 Sept. 384 A.D.; d. Ravenna, Italy, 26 Aug. 423 A.D. On the death of his father in 395 the empire was divided into two parts, Honorius receiving the western half, with Rome as his capital. The principal events of his reign are the adoption of rigorous measures against paganism in 399; the devastation of Northern Italy by Alaric in 400–403; another irruption of barbarians under Rhadagasius 405–6. Both invasions were repelled by his able minister Stilicho, who, however fell under the displeasure of his weak and indolent master, and was assassinated at Ravenna in 408. Taking advantage of the death of the defender of Rome, Alaric marched upon the city and plundered it in 410.

Hooch, or Hoogh, Pieter de, pē′tĕr dē hooh, or hōg, Dutch painter: b. Utrecht 1630; d. Amsterdam soon after 1677. His early art training was much influenced by Rembrandt. In 1655, he was enrolled in the Painters' Guild of Delft, where he resided, but later removed to Amsterdam. He was the chief representative of Dutch genre painting, and his specialty was the delineation of Dutch interiors, with their semi-darkness, suffused by the witchery of sunlight. Sometimes he set out two or more rooms in perspective, the vista of which was drawn and lit up with extraordinary skill.

Hood, John Bell, American soldier: b. Owingsville, Ky., 29 June 1831; d. New Orleans, La., 30 Aug. 1879. He was graduated at West Point in 1853, and bore a commission in the United States Army till 1861 when he joined the army of secession. The part he took in the Virginia campaign gained for him the rank of major-general, and at Gettysburg his division made a gallant record in its position at the extreme right of the Confederate line. He took part in the battle of Chickamauga on 19–20 Sept. 1863, having come to Tennessee to the support of General Bragg. When General Johnston was endeavoring in the spring of 1864 to impede Sherman's advance on Atlanta, Hood was a lieutenant-general in his army and his corps on

Courtesy of the Philadelphia Commercial Museums.

THE HARBOR OF HONOLULU.

25 May 1864, was attacked by Hooker at New Hope Church. He succeeded Johnston the following July in the command of the Army of Tennessee, fought the battle of Peach Creek with Sherman 20 July 1864, but was compelled to retire behind the fortifications of Atlanta. After the battle of Jonesboro he retired from Atlanta, which was entered by Sherman. His attack on the forces under Schofield at Franklin being repulsed, he proceeded to Nashville, where he met General Thomas. Thomas advanced from his entrenchments on 15 December, and a two-days' battle ensued. Federal preparation had been carefully and deliberately made. A general attack on the afternoon of 16 December caused the entire Confederate line to give way. Soon Hood's army was in full retreat toward Franklin, the larger part of it "in great confusion," according to Hood's official report. After a nine-days' pursuit by the Federals, the remnant of the Confederates, now largely disintegrated, crossed the Tennessee. Hood, at his request, was relieved of his command. Subsequent to the war he was a commission merchant at New Orleans. He wrote 'Advance and Retreat: Personal Experiences in the United States and Confederate States Armies' (1880), and articles for 'Battles and Leaders of the Civil War' (1887). Consult these works; see also NASHVILLE, CAMPAIGN AND BATTLE OF.

Hood, Robin, English outlaw: said to have been b. 1160 and d. 1247. According to the popular account, with his followers, he inhabited Sherwood Forest, in Nottinghamshire, and also the woodlands of Barnsdale in the adjoining West Riding. They supported themselves by levying toll on the wealthy, and more especially on ecclesiastics, and by hunting the deer. The principal members of his band were his lieutenant Little John, his chaplain Friar Tuck, William Scadlock, George-a-Greene, Much the miller's son, and Maid Marian. His skill with the long-bow and quarter-staff was celebrated in tradition. What basis of fact there is for the story of Robin Hood is doubtful. Grimm maintained that he was one with the Teutonic god Woden. Other theories suppose him to have been a rebel yeoman in Lancaster's rebellion under Edward II.; a Saxon chief who defied the Normans; and a fugitive follower of Sir Simon de Montfort after the battle of Evesham. He figures prominently in Scott's novel 'Ivanhoe,' and in 'The Foresters,' a drama by Tennyson. The earliest known mention of him is in 'The Vision of Piers Plowman,' version B. (about 1377), in which Sloth says he knows "rymes of Robin Hood." 'The Gest of Robin Hood' (assigned to 1400), almost epic in length, consisting of 456 four-line stanzas, is the oldest extant ballad on this theme. Others of the more important ballads are 'Robin Hood and the Monk,' 'Robin Hood and Guy of Gisborne,' and 'Robin Hood's Death.' The remaining ballads are, in general, of inferior merit. It seems probable that there were what may be called a Sherwood cycle and a Barnsdale cycle, respectively. Many proverbs and sayings exist in connection with Robin Hood. Consult: Child, 'English and Scottish Ballads' (1883); Fricke, 'Die Robin Hood Balladen' (1883); and Ritson, 'Robin Hood' (new ed. 1885).

Hood, Samuel, VISCOUNT, British naval officer: b. Thorncombe, Devonshire, 12 Dec. 1724; d. Bath, Somersetshire, 27 Jan. 1816. He entered the navy in 1740, was promoted lieutenant in 1746, commander in 1754, and post-captain in 1756. While commanding the Vestal in 1759 he took the French Bellona after a three-hours' fight. From 1767 to 1771 he was commander-in-chief in North America. Having served as commissioner of the Portsmouth dockyard in 1778–80, he was made admiral of the blue in 1780, and almost immediately was sent in command of a squadron to reinforce Rodney on the North American and West Indian stations. He remained on that duty until the signing of the peace, and distinguished himself in several battles. Despatched in 1781 to blockade Martinique, he was intercepted by De Grasse and the French fleet, against which he fought in April and in July (under Admiral Graves). Again in the West Indies in 1782, after an absence along the North American coast, he outmaneuvered De Grasse in several minor contests, and later, on 12 April, took an important part in the victory of Dominica, when he led the rear of the British line. In 1784 he was elected to Parliament for Westminster, and in 1788 made a lord of the admiralty. He took command of the British fleet in the Mediterranean in 1793, and occupied Toulon. Hood had a great reputation as a tactician, and a high tribute was paid him by Nelson, who had been one of his subordinate officers. Consult James, 'The Naval History of Great Britain' (1822–4; new ed. 1837).

Hood, Thomas, English poet and humorist: b. London 23 May 1799; d. there 3 May 1845. In 1821 he became sub-editor of the 'London Magazine,' and from that time appears to have resolved on devoting himself entirely to a literary life. In 1826 he published 'Whims and Oddities.' This was followed by 'National Tales' in prose, and a volume of serious poetry, which, though favorably received, did not obtain much popularity. In 1830 he started the 'Comic Annual,' which, during the eight years of its existence, was made the vehicle of many of his most remarkable productions. At the same time his pen was diligently employed on other subjects, and he published the powerful poem called 'Eugene Aram's Dream,' 'Tylney Hall,' a novel, which, though defective in its plan and structure, abounds in fine strokes of wit and humor. His health had begun to fail, and in consequence he lived on the Continent 1835–40. He continued his 'Comic Annual' during his residence at Coblentz and Ostend, and in 1838 published 'Hood's Own.' His continental experiences also furnished materials for his 'Up the Rhine' (1839), a series of imaginary letters after the manner of Smollett's 'Humphrey Clinker.' The whimsical cuts inserted in the work, as well as its combination of good sense and humor, made it very popular. Shortly after his return, he undertook the editorship of the 'New Monthly Magazine,' and continued it until 1843. His principal contribution to it was the famous tragi-comic story in verse of 'Miss Kilmansegg.' His last periodical, entitled 'Hood's Magazine,' was commenced in 1844. It contains some of his best productions, though several of them were written after his health

had completely given way, and while he was propped up by pillows in bed. Hood is unrivaled as a punster, and seems to have been almost equal master of the comic and the pathetic. In the latter style his 'Song of the Shirt' is universally known, and as a burst of poetry and indignation is not surpassed by anything in the English language.

Hood, Thomas, generally known as Tom Hood, English miscellaneous writer; son of the preceding: b. at Wanstead, Essex, 19 Jan. 1835; d. Peckham Rye, Surrey, 20 Nov. 1874. He was educated at Oxford in 1853, with a view to a clerical career, but edited the 'Liskeard Gazette' in 1858–9, and from 1860 till 1865 was a clerk in the accountant-general's department at the War Office. In 1865 he became editor of the comic paper called 'Fun.' His first separate publication was 'Pen and Pencil Pictures' (1857), and among his subsequent works are: 'The Daughters of King Daher, and other Poems' (1861); 'Jingles and Jokes for the Little Folks' (1865); 'Captain Masters's Children' (1865), his best novel; 'A Golden Heart' (1867); 'The Rules of Rhyme: A Practical Guide to English Versification (1869), a work which has gone through two later editions; 'From Nowhere to the North Pole' (1874). From 1867 he produced 'Tom Hood's Comic Annual.' A volume of his 'Favourite Poems,' with a memoir by his sister, Mrs. Broderip, was published in the United States in 1877.

Hood of Avalon, Arthur William Acland Hood, Baron, English naval officer: b. Somersetshire 14 July 1824; d. Glastonbury 15 Nov. 1901. After service on the coasts of Spain and of Syria, he was made lieutenant in 1846, and in 1854 commander in recognition of his services with the naval brigade before Sebastopol. Assigned to the China station, he participated in the capture of Canton (December 1857), and in 1858 received the commission of post-captain. In 1862–6 he was in command of the Pylades of the North American station, in 1866–9 of the Excellent and the Royal Naval College at Portsmouth, and in 1869–74 director of naval ordnance. He was promoted rear-admiral in 1876, was first sea lord of the admiralty in 1885–9, and became admiral in 1886. His attitude in connection with the development of the British navy was strongly conservative.

Hood, Mount, a peak of the Cascade Range, in the northern part of Wasco County, in Oregon. The height is usually given as over 11,225 feet, but the latest explorers claim it is nearly 12,000 feet. Mount Hood was at one time an active volcano; the lava is found on the slopes and some distance from its base.

Hood River, a name applied to a valley, town, and river in Wasco County, Oregon. The town is situated on the Columbia River and on the line of the Oregon Railway & Navigation Company, 66 miles east of Portland and 22 miles below The Dalles, the county-seat. The Hood River strawberry has acquired a reputation almost phenomenal, and is distributed over an immense area of country extending from Denver and Omaha on the south to Winnipeg in the province of Manitoba to the north and east. The output in 1903 was 150 carloads. The apple industry is also rapidly assuming large proportions, grades of superior excellence are produced, and the highest priced Spitzenburgs and Yellow Newtown Pippins found in the markets of New York and London were grown in Hood River. The valley proper extends south from the Columbia River to Mount Hood, some 20 miles, and is protected and cradled by the Cascade range of mountains on the west and a high divide putting out from Mount Hood on the east. The amount of land adapted for fruit culture in this unique valley exceeds 50,000 acres. The river itself drains all of the north side of Mount Hood, has a large and constant flow of water, and for the last 10 miles of its course before entering the Columbia has an average fall of over 60 feet per mile, affording 10,000 measured horse-power per mile. There are immense forests of fir and cedar about the head-waters of this stream, and one of the largest saw-mills in the State is conveniently situated near its confluence with the Columbia. The climate is a happy mean between the moist section of western Oregon and the semi-arid plains of the Columbia. The scenery is grand in the extreme and yearly attracts the attention of many visitors. The town is pleasantly situated, overlooking the Columbia River, is supplied with electric lights, while the telephone is universally present in both town and country. It is, however, the superlative excellence of its fruits that has given Hood River a reputation almost world-wide. The population of town and valley (1904) is about 6,000.

E. L. Smith.

Hooded Crow, a crow native in northern Europe (*Corvus cornix*), so termed in allusion to markings on the head. Head, wings, and fore parts are jet black, the rest of the bird ash-gray; bill and feet are black. It retires to the southward from its more northerly haunts at the time of the crow migration. In England it is known as the gray, dun, or Royston crow. The hooded crow found in India is similar in general appearance, but is a smaller species.

Hooded Seal, a large dark-gray spotted seal of the North Atlantic, closely related to the common harbor seal, and named *Cystophora cristata.* It reaches a length of about 10 feet, and is especially distinguished by a large inflatable sac upon the face, the expansion of which is thought to be a defensive device, calculated to terrify enemies. It is occasionally seen on ice-floes along the Labrador coast.

Hooded Warbler, a fly-catching warbler (*Sylvania mitrata*), common in the southern United States in summer and making its nest in low bushes. It is bright yellow except a solidly black crown, neck and breast, comparable to a hood, leaving the face golden yellow.

Hoodoo. See Mascot.

Hoof, a toe-nail which is large, envelops the terminal phalange, and is of material assistance in walking, as in the case of horses, cattle and other ruminants, and in the elephant, rhinoceros, etc. It is most highly developed in the horse, where the whole terminal part of the foot is reduced to a single, well-booted toe. In split-hoofed or cloven-hoofed animals there are two toes approximately equal, and booted with hoofs flat on their inner sides and closely appressed. The small non-functional

toes hanging behind the hock-joint in most split-hoofed animals are often called "false hoofs." Accidents and diseases affect the hoofs of domestic animals (see FOOT-ROT, etc.), and require careful attention, especially in the case of horses. The soundness of a horse's foot is mainly preserved by permitting it to grow uninjured by the rasp and knife, and kept clean by being washed with cold water; all other applications are injurious and destroy the toughness of the "horn surface." Softness and brittleness of the hoof, which are fruitful sources of cracks and corns, may be remedied by placing the feet for several hours daily in thick woolen swabs, kept cool and moist by frequent applications of cold water, and by encouraging a more healthy growth of horn by occasional mild blisters round the coronary band. Cracks (or sand-cracks) mostly occur among horses much upon the road, cause lameness, and constitute unsoundness. When serious and recent, poulticing, thinning away of the crust about the crack, and perfect rest are essential. After the earlier heat and tenderness are removed a hot iron should be drawn at right angles to the crack, both above and below, so as to separate the diseased from the sound horn. Waxed thread or fine wire should be wound round the hoof, and a sound growth of horn stimulated by a blister round the coronet.

Hooft, Pieter Corneliszoon, pē-tĕr kor-nā'-lēs-zōn hōft, Dutch poet and historian: b. Amsterdam 26 March 1581; d. The Hague 21 May 1647. He was son of that Cornelius Hooft who did much to procure Elizabeth's recall of the incompetent and tyrannical Leicester in 1587. He traveled through France, Italy, and Germany in 1601, and on his return began with patriotic ardor to improve and purge the speech of his mother country. With this aim in view he translated Tacitus into Dutch, and made that Latin writer the model of his style, as a historian. His historical writings are vivid and comprehensive. His poems are chiefly in the erotic vein. He also produced dramas in the form of pastoral, tragedy, and comedy. In his comedies the domestic life of the Netherlands is admirably portrayed. In the castle of Moritz, Prince of Orange, at Muiden, where he lived as high bailiff, he used to gather round him a coterie of brilliant men and women, and this intellectual circle famous as the "Muiderkring" included the poets Huygens, Vondel, and Baerle. His principal works are 'Hendrik (IV.) de Grote zijn leven en bedrijf' (1671); 'Nederlandsche Historien' (1656); the poems 'Minneliederen'; 'Afbeeldinglien van Minne'; the pastoral drama 'Granida' (1605); the tragedies 'Geraerdt van Velzen' (1813); and 'Baeto' (1616); and the comedy 'Warenar.'

Hook, Theodore Edward, English novelist and journalist: b. London 22 Sept. 1788; d. 24 Aug. 1841. For some years Hook led a life of gaiety in London, and became notorious for practical jokes and similar escapades. In 1812 he was appointed accountant-general and treasurer of the island of Mauritius; but, owing to his gross carelessness, a large deficiency in the military chest was discovered, and in 1818 he was sent home under arrest, but no proceedings were taken against him. From 1820 to 1841 he was editor of the 'John Bull,' and at intervals from 1824 to 1828 published his 'Sayings and Doings,' while in 1836 he became editor of the 'New Monthly Magazine.' His other principal works are a series of novels, among which may be mentioned 'Love and Pride'; 'Jack Brag'; 'Gilbert Gurney'; 'Gurney Married.'

Hooker, hůk'ĕr, **Edward,** American sailor: b. Farmington, Conn., 1822; d. Brooklyn, N. Y., 1 May 1903. He followed the sea in the merchant service until the outbreak of the Civil War when he joined the United States navy as acting master, and served with distinguished bravery. He was commissioned as lieutenant-commander in the regular naval service in 1884 and full commander two years later, when he retired.

Hooker, Isabella Beecher, American philanthropist: b. Litchfield, Conn., 22 Feb. 1822. She is a daughter of Dr. Lyman Beecher (q.v.) and in 1841 married Joseph Hooker, a lawyer. She has made a special study of the right of women of the United States to vote; has been active in various reform movements, and is known as a public speaker. She has written 'Womanhood, Its Sanctities and Fidelities.'

Hooker, Joseph, American soldier: b. Hadley, Mass., 13 Nov. 1814; d. Garden City, N. Y., 31 Oct. 1879. He was graduated at West Point in 1837 and received a commission in the 1st artillery. He served in Florida and on the northeast frontier 1837–40 and during the Mexican War was aide to Generals Smith, Harmer, Butler and Pillow. He saw much service in both the northern and southern campaigns, and resigned from the army in 1853. From that date to the breaking out of the Civil War he was successively farmer, engineer and militia colonel. In 1861 he went to the front as a brigadier-general of volunteers. In 1862 he was commissioned major-general of volunteers and was present at the battle of Williamsburg, Va., and was subsequently conspicuous in the Peninsular campaign and in the battles of Bristoe Station and Chantilly. He also took part in the Maryland campaign, and in September of 1862 was appointed brigadier-general in the regular army. Two months later he was placed in command of the Fifth corps, and at the battle of Fredericksburg commanded the Third and Fifth corps. In 1863 he was put in command of the Army of the Potomac, but although very successful in refitting and reorganizing his troops, failed to show, as head of an army, those qualities which had characterized him in the field as corps and division commander. At Chancellorsville the defeat of the Federal troops by General Jackson was largely due to Hooker's vacillation and his want of power to cope with the sudden surprise of his right flank by the Confederate general.

In 1863 he was despatched in command of the Army of the Cumberland to reinforce Rosecrans at Chattanooga and distinguished himself on 24 November in the so-called "Battle among the Clouds" on Lookout Mountain. He was brevetted major-general in the regular army in 1865, and a paralytic stroke forced him to retire from active service with that rank in 1868.

An equestrian statue of General Joseph Hooker by the sculptor French, was unveiled on Beacon Hill, Boston, 25 June 1903, with imposing ceremonies. The day was made a State holiday.

Hooker, Sir Joseph Dalton, English botanist; son of Sir William Jackson Hooker (q.v.)

b. Halesworth, Suffolk, 30 June 1817. He was educated at the University of Glasgow, accompanied Sir James Clark Ross's Antarctic expedition of 1839–43 as assistant-surgeon and naturalist, and in 1847 published an account of its botanical results in two volumes, entitled 'The Botany of the Antarctic Voyage of H.M. Discovery Ships Erebus and Terror in the years 1839–43.' He went to India in 1847, in order to investigate the botany of part of the Himalayan region, and in 1854, three years after his return issued his 'Himalayan Journals, or Notes of a Naturalist in Bengal, the Sikkim and Nepal Himalayas, the Khasia Mountains,' etc. In his work on the 'Rhododendrons of the Sikkim Himalaya' (1849), he first introduced to the notice of European gardeners many splendid and now familiar species of these favorite shrubs. In 1871 he set sail for Morocco, and in May of that year he and his companions reached the summits of the Great Atlas, which till then had never been trodden by any European foot. A record of this journey is contained in the work written with John Ball, 'Journal of a Tour in Morocco and the Great Atlas' (1879). He traveled in the Rocky Mountains and California in 1877. In 1855 was appointed assistant to his father in the directorship of Kew Gardens, and on his father's death in 1865, succeeded him as director. He retired in 1885. He was president of the Royal Society during the five years 1873–8. Among his other works are: 'Introductory Essay to the Flora of New Zealand' (1853); 'Introductory Essay to the Flora of Indica' (1855); 'Flora Novæ Zealandæ' (1853–5); 'Flora of Tasmania' (1856–60); 'The Flora of Australia: its Origin, Affinities, Distribution, etc.' (1859); 'Genera Plantarum' (1862–83), with George Bentham, an epoch-making revision of the natural system of classification; 'The Student's Flora of the British Islands' (1870; new ed. 1883), an excellent and popular work; 'The Distribution of the North American Flora' (1878); and the great 'Flora of British India' (1875–97).

Hooker, Richard, English theologian: b. Heavitree, near Exeter, March 1554; d. Bishopsbourne, 2 Nov. 1600. He was educated at Oxford. In 1581 he took orders, and was shortly after made preacher at St. Paul's Cross, in London. In 1584 he became rector of Drayton Beauchamp, Buckinghamshire. The following year he was appointed by Archbishop Whitgift Master of the Temple for life. Here he became engaged in a controversy with his colleague Walter Travers, whose sympathies were strongly puritanical, and to this controversy we owe his celebrated work 'Of the Laws of Ecclesiastical Polity.' The first four books were printed in 1594. The fifth book of his great work appeared in 1597; the last three in 1600. 'The Ecclesiastical Polity' written in defense of the Church of England, is no less remarkable for learning and extent of research than for the richness and purity of its style, which entitles its author to be regarded as one of the classics of the Elizabethan age. See Lives by Walton, and Keble.

Hooker, Thomas, American colonial clergyman: b. Markfield, Leicestershire, England, probably 7 July 1586; d. Hartford, Conn., 7 July 1647. After being graduated at Cambridge he took orders, preached in London, and was chosen lecturer at Chelmsford in 1626. Having been silenced by Laud for nonconformity, he established a grammar school, and about 1630 went to Holland, where he preached at Delft and Rotterdam. In 1633 he came to New England with Cotton and Stone, and was settled with the latter at Newtown, now Cambridge, being ordained by the brethren of the church. In 1636 he removed with about 100 others to what is now Hartford, Conn., where he and Stone were the first ministers of the church. He was a remarkably animated and able preacher, of commanding presence and earnest zeal, and he has been called the Luther of New England. It was his custom to preach without notes. Some 200 of his sermons were sent to England, where about half of them were published. His most celebrated work, 'A Survey of the Summe of Church Discipline,' written with John Cotton, was published in England (1648). Many of his works have gone through repeated editions. See Walker, 'Life of Hooker' (1891).

Hooker, Sir William Jackson, English botanist: b. Norwich 1785; d. 12 Aug. 1865. He applied himself to the study of botany at an early age, and in search of botanical specimens visited Scotland and the Scottish islands, France, Switzerland, and Iceland. His investigations on the British 'Jungermanniæ and Mosses' drew attention to his attainments, and he was elected to the chair of botany in the University of Glasgow, a position he filled for 20 years. In 1836 he was knighted, and in 1841 was appointed director of the Royal Gardens at Kew, a post which he held up to the time of his death. Under his management these gardens increased their area from 11 acres to 270. They are well laid out, and contain hot-houses and conservatories far superior to anything of the kind on the Continent, and include museums filled with objects derived from the vegetable kingdom, botanical libraries, and a most extensive and excellently arranged herbarium. Among his works may be mentioned 'Tour in Iceland' (1811); 'The British Flora'; 'Flora Boreali-Americana'; 'Illustrations of the Genera of Ferns, Icones Plantarum'; 'British Ferns'; etc.

Hooker, Mount, Canada, a peak in the Rocky Mountains; 15,690 feet high; near the eastern boundary of British Columbia.

Hoonoomaun, hoo'noo-män. See Entellus Monkey.

Hoop Ash. The black or water ash (*Fraxinus nigra*). See Ash.

Hooper, hüp'ėr, **John,** English reformer and martyr: b. Somersetshire, about 1495; d. Gloucester 9 Feb. 1555. He embraced the principles of the Reformation and in 1539, to avoid the persecution consequent on refusing to sign the new articles of faith put forth by Henry VIII., withdrew to the Continent. On the accession of Edward VI., in 1547, he went to London, and contributed greatly to the progress of the Reformation. In 1550 he was nominated bishop of Gloucester. On the accession of Mary, in 1553, he was one of the first victims fixed upon, and being imprisoned in the Fleet, was treated with great severity. In 1555 he was required formally to recant his opinions. This he refused to do and was burned at the stake near his own cathedral. His works con-

sist chiefly of a 'Godly Confession and Protestation of the Christian Faith'; 'Lectures on the Creed'; 'Sermons on the Book of Jonah'; 'Annotations on the Thirteenth Chapter of the Romans.'

Hooper, William, American patriot: one of the signers of the Declaration of Independence: b. Boston, Mass., 17 June 1742; d. Hillsboro, N. C., October 1790. He was graduated at Harvard College in 1760, studied law with James Otis in Boston, and removed permanently to Wilmington, N. C., in 1767, where he soon rose to professional eminence and was noted for his social qualities and hospitality. He was delegated to the Continental Congress in 1775, and was till his death a leader in the councils of North Carolina.

Hoopeston, hoops'tŏn, Ill., city in Vermilion County; on the Lake Erie & W. and the Chicago & E. I. R.R's.; about 85 miles south of Chicago and 48 miles south by east of Kankakee. It is situated in an agricultural region, and its chief industries are connected with agricultural products. It has large sweet-corn canning establishments, and factories for making the cans and the canning machinery. There are manufactured other canned goods, also horsehoe nails and agricultural implements. Grain and hay are shipped to the larger markets. The government, in accordance with the charter of 1877, is vested in a mayor who serves for two years and in a city council. The city owns and operates the waterworks. Pop. (1890) 1,911; (1900) 3,823.

Hooping-cough, a series of coughs ending in a long-drawn breath, during which a shrill whistling sound, the hoop, is produced. Several fits of coughing succeed one another, until some phlegm or mucus is expelled. Vomiting not infrequently follows a fit of coughing. It has recently been discovered that the cause of the complaint is a poison acting as an irritant on the pneumogastric nerve. Hooping-cough is contagious, and most commonly attacks children, generally but once in their lives. The first symptoms are a difficulty of breathing, and other slight febrile affections, which are succeeded by hoarseness, cough, and difficulty of expectoration. After a fortnight or more the cough becomes convulsive, and is attended by the hoop. In four or five weeks the expectoration becomes loose, and the fits of coughing gradually diminish in frequency and duration. Hooping-cough is seldom fatal to adults, but is most fatal in the first year of childhood. Bronchitis and pneumonia are the most serious complications.

Hoopoe, hoo'pō, a peculiar bird of the Old World, which takes both its vernacular and scientific name (*Upupa*) from its whooping cry. It is of the group *Coccygomorphæ* (q.v.) and represents a family (*Upupidæ*), many species of which inhabit southern Asia and Africa, while one (*U. epops*) is a well known migrant in Europe. It is about 12 inches long, is brown above and white beneath, with black, white-barred wings, and a very large cinnamon-red black-tipped crest and a long, sharp, curved bill. It seeks its food on the ground, nests in holes in trees, crannies in walls, etc., and has many curious traits and habits which have caused the bird to take a prominent place in the folk-lore of all countries. The African hoopoes belong to the genus *Irrisor*, and are called wood-hoopoes. They have brilliant plumage, but no crest. They go about in noisy flocks, and have much the appearance and habits of woodpeckers.

Hoorn, hōrn, or **Hoorne,** hōr'nė, or **Horn,** or **Hornes,** ŏrn, Count of (Philip II., De Montmorency-Nivelle); Flemish soldier and statesman: b. about 1520; d. Brussels 5 June 1568. His father was a descendant of the French family of Montmorency, and on the mother's side he was related to Lamoral Egmont, with whose fate his own was linked. His mother becoming a widow when he was about eight, was married again to John, Count van Horn, one of the wealthiest nobles of the Netherlands, who, left his estates to his wife's children on condition that they should assume his name. Philip was thus at the outset of his career one of the most influential of his order, and received from Charles V. and Philip II. important trusts and distinctions. He accompanied Philip II. to Spain, where he is supposed to have received information of the designs of the Spanish court against the Netherlands, and to have communicated them to the Prince of Orange. Returning to the Netherlands he joined Orange and Egmont in resisting the aggressive policy of Philip; yet continued loyal to the crown. He was, however, suspected by the Spanish court, and upon the arrival of Alva in Brussels was enticed with Egmont to that city, and arrested in September 1567, on a charge of high treason. Ceaseless but vain efforts were made to obtain for him a fair trial, and appeals for clemency on his behalf were made by potentates in all parts of the Continent. He was executed with Egmont in June 1568.

Hoosac (hoo'sak) **Mountain,** the name given to a spur of the Green Mountains (q.v.) which is in the northwestern part of Massachusetts, on the east side of the valley of the Hoosac River. The whole length is about 16 miles. The mountain is noted for its beautiful scenery.

Hoosac Tunnel, in the towns of Adams and Florida, in Berkshire County, in Massachusetts, and piercing the Hoosac Mountain. It is on what is now known as the Boston and Maine railroad, the route from Boston to Troy, N. Y., by way of Greenfield. From the west entrance of the tunnel to Troy is 54 miles; from the east entrance to Boston, 137 miles. The tunnel is nearly five miles in length, the longest tunnel in the United States. Before the general introduction of railroads, and, as early as 1825, the project was broached of making a canal across Massachusetts from Boston to the Hudson River. This plan was abandoned when railroads were built across the State. In 1851 the tunnel question had advanced so far that surveys of various routes were made and some experiments were begun. The work of tunneling began in 1856 and was completed in 1873. For so long a tunnel the ventilation is good owing to the shaft, 1028 feet, sunk near the centre. The width is sufficient for two tracks. The total cost, including 39 miles of adjoining railroad, was about $13,000,000.

Hoo'sic Falls, N. Y., village in Rensselaer County; on the Hoosac River and on the Boston & M. railroad; about 28 miles northeast of Albany. The first permanent settlement was

made in 1688, and the first charter was received in 1827. The charter has been revised and the last revision was in 1890. The village has excellent water-power. The chief manufactures are agricultural implements, paper and paper-making machinery, shirts, cotton and woolen goods, and flour. The government of the village is vested in a president who holds office three years, and a board of trustees. Pop. (1890) 7,014; (1900) 5,671.

Hoosier (hoo'zhêr) **Schoolmaster, The,** a story by Edward Eggleston (q.v.) published in 1875, and the most popular of its author's works. It is descriptive of the life of the Middle West in the pioneer days of the early 19th century.

Hoosier State, a popular name for Indiana. The word is said to be a corruption of «husher,» formerly a colloquial name for a fighter or a bully.

Hop-hornbeam. See IRON-WOOD.

Hopatcong, hō-păt'kŏng, **Lake, in Sussex** County, New Jersey; about 33 miles northwest of Jersey City and 25 miles west of Paterson. The lake is 725 feet above the sea, and eight and one-half miles long and three and one-half miles wide. Its outlet is the Musconetcong River which flows into the Delaware. Lake Hopatcong is a favorite summer resort, its beautiful scenery is one attraction. It is surrounded by hills and low mountains, all well wooded, and many of the trees are evergreens.

Hope, Anthony. See HAWKINS, ANTHONY HOPE.

Hope, Ascott R. See MONCRIEFF.

Hope College, in Holland, Mich., a co-educational institution, founded in 1866, by Dutch settlers, and under the auspices of the Reformed Church in America. At the close of 1902 there were connected with the school 14 instructors and 200 students.

Hope Diamond, a famous blue diamond weighing 44¼ carats, in possession of the family of H. T. Hope, of England, until 1903, when it was sold to an American.

Hope'dale, the name of a community founded by Rev. Adin Ballou, in 1841, at Milford, in Worcester County, Mass. At the beginning there were 28 persons who wished to lead lives in accordance with high ideals of Christianity. They formed themselves into a joint-stock company, purchased a farm of 238 acres, established a settlement, and proceeded to cultivate the soil, and to manufacture their own breadstuffs and clothing. At first a board of trustees were the chief governing power and had entire control of the industries. Later more responsibilities were given to the members, and the industries were, in different ways, apportioned among them. In 1854 there were 200 members; but the community had become a financial failure and dissensions had crept in. In 1856 they were in debt, and as a joint-stock company they disbanded; but continued as a semi-communistic community until about 1862, when they gave up the industries they had established to private individuals, and formed themselves into Hopedale Parish with their founder as pastor. Consult: Adin Ballou, 'Hopedale Community.'

Hop'kins, Alphonso Alvah, American author and lecturer: b. Burlington Flats, N. Y., 27 March 1843. He was for three years professor in the American Temperance University; from 1867–86 was editor of three agricultural papers successively. Since 1868 he has lectured on temperance and other social and political subjects; in 1882 he was the prohibition candidate for governor of New York. He has written 'Geraldine, a Romance in Verse,' a popular poem in the style of Owen Meredith's 'Lucille' (1881); 'His Prison Bars' (1878); 'Sinner and Saint' (1880); 'Wealth and Waste' (1896); 'Ballads of Brotherhood' (1900).

Hopkins, Edward, American colonial governor: b. England 1600; d. London March 1657. He was a prominent merchant of London, and came to Boston in 1637, but soon after removed to Hartford, where he was chosen a magistrate in 1639, and governor of the colony of Connecticut every other year from 1640 to 1654, alternating with Haynes. He afterward went back to England, where he was chosen warden of the English fleet, commissioner of the admiralty and navy, and member of Parliament. But he never lost his interest in the colonies, and at his death bequeathed much of his estate to New England, giving £1,000 for the support of grammar schools in Hartford and New Haven, which are still flourishing, and £500 which went to Harvard College and the grammar school at Cambridge.

Hopkins, Edward Washburn, American philologist: b. Northampton, Mass., 8 Sept. 1857. He was graduated from Columbia in 1878, and going to Germany to study took the degree of Ph.D. at the University of Leipsic. In 1895 he became professor of comparative philology and Sanskrit at Yale. He has written 'Caste in Ancient India' (1881); 'Manu's Lawbook' (1884); 'Religions of India' (1895); 'The Great Epic of India' (1901); and 'India Old and New' (1901).

Hopkins, Esek, first commodore of the American navy: b. Scituate, R. I., 1718; d. North Providence, R. I., 26 Feb. 1802. In November 1775 he received a commission from the Continental Congress as commodore and «commander-in-chief» of the navy, soon after which he put to sea with the first squadron sent out by the colonies. The fleet sailed for the Bahama islands, and captured the forts at New Providence, and with them 80 cannon, and a large quantity of ordnance, stores, and ammunition. On his return, when off Block Island, the commodore took the British schooner Hawke and the bomb brig Bolton. For this act the president of congress complimented Hopkins officially. Commodore, or Admiral Hopkins, as he was generally called (even by Washington, who so addressed him in his official letters), performed other remarkable exploits, though he had great difficulties to contend with. His name became a synonym for heroism, and for American patriotism. In June 1776, Hopkins was ordered by Congress to appear before the naval committee in Philadelphia to reply to charges which had been preferred against him for not annoying the enemy's ships on the southern coast. He was defended by John Adams, and was acquitted. The unavoidable delays at a later period in getting his ships ready for sea gave another chance for his enemies to complain; and neglecting a

citation to appear at Philadelphia, because no specific charges were made against him, and on account of his general disgust at the conduct of his opponents, he was dismissed the service, 2 Jan. 1777. He resided near Providence, and exerted during a long life a great political influence in Rhode Island, being often elected to the general assembly of that State. Consult Field, 'Esek Hopkins' (1898).

Hopkins, John Henry, American Protestant Episcopal bishop: b. Dublin, Ireland, 30 Jan. 1792; d. Rock Point near Burlington, Vt., 9 Jan. 1868. At the age of eight, he was brought to America, his father settling in Philadelphia. He became a successful member of the bar in Pittsburg, where his interest in church work was so earnest that the vestry of Trinity Church unanimously elected him rector of the parish though he was not even a candidate for orders. He accepted the call, was ordained in 1823, and remained in Pittsburg until 1831, when he went to Trinity Church, Boston, as assistant, and became at the same time professor of systematic divinity in a theological school. He was consecrated bishop of Vermont in 1832 and combined with the episcopate the rectorship of St. Paul's Church, Burlington. Though at the head of a small diocese, he exerted a widespread influence as a learned theologian and a controversialist of uncompromising bravery and great versatility. He is said to have been the first to suggest the idea out of which grew the important Lambeth Conferences of the entire Anglican Communion, and it is unquestionably to his prudent and charitable efforts that the happy reunion of the northern and southern dioceses after the Civil War was largely due. Besides controversial works, which at the time had great effect, he published 'The Primitive Creed' (1834); 'The Primitive Church' (1835); 'The American Citizen' (1857); and 'The Law of Ritualism' (1866). See 'Life of Bishop Hopkins by One of his Sons' (1873).

Hopkins, Johns, American financier and philanthropist: b. Anne Arundel County, Md., 19 May 1795; d. Baltimore 24 Dec. 1873. His parents, Quakers, gave him a fair education and the training of a farmer. At 17 he went to Baltimore, there became a grocer, and in 1822 founded the house of Hopkins & Brothers. He built up a trade in Maryland, Virginia, and North Carolina, having practically a monopoly in his line. His credit and counsel were highly valued in financial and mercantile affairs. He retired in 1847 with a large fortune, which he employed in banking and railway operations. In 1873 he gave property worth $4,500,000 to found a free hospital; he presented Baltimore with a public park, and also gave over $3,000,000 to found the Johns Hopkins University in Baltimore.

Hopkins, Lemuel, American physician and political writer: b. Waterbury, Conn., 19 June 1750; d. Hartford, Conn., 14 April 1801. He practised medicine at Litchfield 1776–84, when he removed to Hartford, where he sustained a high reputation, and had an extensive practice till his death. He was singular in his appearance, manners, and opinions; a man of talents and learning, and also a poet. He was associated with Trumbull, Barlow, Alsop, Theodore Dwight, and others (called the "Hartford wits"), in the 'Anarchiad,' the 'Echo,' 'Political Greenhouse,' the 'Guillotine,' and similar satirical compositions; and is said to have written for Barlow the beautiful and well known version of the 137th psalm beginning, "Along the Banks where Babel's Current Flows."

Hopkins, Margaret Sutton Briscoe, American author: b. Baltimore 7 Dec. 1864. She married Prof. A. J. Hopkins of Amherst College, and has been engaged in literary work since 1890. She has written under the pen name of "Margaret Sutton Briscoe" 'Perchance to Dream and Other Stories' (1892); 'Links in a Chain' (1893); 'Jimty and Others' (1898); 'The Sixth Sense and Other Stories' (1899).

Hopkins, Mark, American college president: b. Stockbridge, Mass., 4 Feb. 1802; d. Williamstown, Mass., 17 June 1887. He was graduated at Williams College, Mass., in 1824, and having filled a tutorship in the college two years received in 1828 the degree of M. D., and in the same year commenced the practice of medicine in New York. In 1830 he was recalled to Williams College to fill the chair of moral philosophy and rhetoric, and in 1836 became president of the college, a position which he held till 1872. In addition to his labors as an instructor, he lectured before the Lowell Institute of Boston, the Smithsonian Institution, and various scientific and literary associations. Presiding over a college which has been called the cradle of foreign missions, he took an active part in the deliberations of the American board of commissioners for foreign missions, of which he was president from 1857. He published 'Lectures on the Evidences of Christianity' (1846); 'Miscellaneous Essays and Discourses' (1847); 'Lectures on Moral Science' (1862); 'The Law of Love and Love as Law' (1869); 'Outline Study of Man' (1873); 'Scriptural Idea of Man' (1883); 'Teachings and Counsels' (1884). See Carter, 'Life of Mark Hopkins' (1892).

Hopkins, Pauline Bradford Mackie, American novelist: b. Fairfield, Conn., 1874. In 1899 she married H. M. Hopkins; she has been in literary work since 1896. Her works include 'Mademoiselle de Berny, a Story of Valley Forge' (1897); 'Ye Lyttle Salem Maide, a Story of Witchcraft' (1898); 'A Georgian Actress, an Historical Romance' (1900).

Hopkins, Samuel, American Congregational clergyman: b. Waterbury, Conn., 17 Sept. 1721; d. Newport, R. I., 20 Dec. 1803. He was graduated at Yale College in 1741, studied theology under Jonathan Edwards (q.v.), and in 1743 was ordained at Housatonic, now Great Barrington, Mass., where he continued until 1769, when he removed to Newport, R. I., and was pastor there till his death. He possessed almost incredible powers of application, and is said to have been sometimes engaged during 18 hours of the day in his studies. He published 'Dialogue, Showing it to be the Duty and Interest of the American States to Emancipate all their African Slaves' (1776); 'System of Doctrines Contained in Divine Revelation, Explained and Defended' (1793); etc. His theological opinions gave rise to the famous Hopkinsian Controversy. Hopkins differs from orthodox Calvinism in his opposition to the doc-

trines of original sin and of the atonement; moreover, he put particular stress on the virtue of altruism and unselfishness, even claiming that selfishness, of whatever nature, was inherently and essentially sinful. Consult: West, 'Life of Hopkins' (1805); Park, 'Memoir' (1852). See also Mrs. Stowe's novel, 'The Minister's Wooing,' in which Hopkins is the central figure.

Hopkins, Stephen, American statesman; a signer of the Declaration of Independence: b. Scituate, R. I., 7 March 1707; d. Providence 13 July 1785. In 1733 at Providence he was elected a member of the general assembly, and in 1739 became chief justice of the court of common pleas. In 1755 he was elected governor of the State, and remained in office, with the exception of four years, until 1768. In 1754 he was appointed a member of the board of commissioners assembled at Albany, N. Y., to concert a plan of union for the colonies. In 1765 he was elected chairman of a committee appointed at a special town meeting held in Providence to draft instructions to the general assembly on the stamp act. In August 1774, he was, with Samuel Ward, elected to represent the State in the general Congress held at Philadelphia, and was also chosen in 1775 and 1776. On the naval committee he was placed next after John Hancock, the chairman, and greatly assisted in the formation of a navy. For 50 years he filled some public station; he was for many years chancellor of Brown University. In 1765 he commenced a 'History of the Planting and Growth of Providence,' published in the 'Providence Gazette.' In the same year he published 'The Rights of the Colonies Examined,' which was reprinted in London.

Hopkins, Tighe, English author: b. 8 Dec. 1856. He is a frequent contributor to English and American periodicals and among his numerous works are 'Twixt Love and Duty' (1886); 'For Freedom' (1888); 'Dungeons of Old Paris' (1898); 'An Idler in Old France' (1889); 'The Man in the Iron Mask' (1901).

Hop'kinson, Francis, American jurist; one of the signers of the Declaration of Independence: b. Philadelphia 21 Sept. 1737; d. there 9 May 1791. He was graduated at the College of Philadelphia (now the University of Pennsylvania), having been the first student who entered that institution at its opening, and afterward studied law. In 1776 he was sent from New Jersey as one of her representatives in Congress. During the Revolution he distinguished himself by satirical and political writings, which attained such popularity that it has been said that few pens effected more than Hopkinson's in educating the American people for political independence. He also ridiculed in prose and verse most of the social follies of his time. In 1779 he was made judge of the admiralty of Pennsylvania, which office he held for ten years, until the organization of the federal government, when it expired. As soon, however, as Washington became President of the United States, he addressed to Hopkinson a letter enclosing a commission as United States district judge for Pennsylvania. He was skilled in painting and music, composing highly popular airs for his own songs. Of his political writings the most prominent were: 'The Pretty Story' (1774); 'The Prophecy' (1776); 'The Political Catechism' (1777). The best known of his poems are: 'The Battle of the Kegs,' a humorous ballad, and 'The New Roof, a Song for Federal Mechanics.' The 'Miscellaneous Essays and Occasional Writings of Francis Hopkinson' were published in 1792.

Hopkinson, Joseph, American jurist and poet: b. Philadelphia 12 Nov. 1770; d. there 15 Jan. 1842. He was a son of Francis Hopkinson (q.v.). He was educated at the University of Pennsylvania, studied law, and began to practise at Easton, Pa., in 1791, whence he returned to Philadelphia. From 1815 to 1819 he was a member of the House of Representatives from Philadelphia. He opposed the recharter of the United States bank, and made a noted speech on the Seminole war. At the close of 1819 he retired from Congress, declining a re-election. Having gone to Bordentown to reside, he was elected to the legislature of New Jersey. In 1828 he was appointed judge of the United States court for the eastern district of Pennsylvania, an office which had been filled by his father under Washington. In 1837 he was chairman of the judiciary committee of the convention to revise the constitution of Pennsylvania. He is, however, best known as the author of the national song 'Hail Columbia,' written in 1798 for the benefit of an actor named Fox.

Hop'kinsville, Ky., city and county-seat of Christian County, on the Louisville and Nashville, and the Ohio Valley R.R.'s. Here are Bethel Female and Southern Kentucky colleges, Western Kentucky insane asylum, and manufactures of tobacco, lime, brick, wagons, and carriages, a national bank and the Hopkinsville high school. The city has an assessed property valuation of over $2,000,000. Pop. (1900) 7,280.

Hop'per, De Wolf, American actor: b. New York 1858. He made his first professional appearance in 'Our Boys' (1878), and later appeared in 'Hazel Kirke' and other plays. He studied vocal music for several years and became a star in comic opera and musical comedy.

Hopper, Isaac Tatem, American philanthropist: b. Deptford, N. J., 3 Dec. 1771; d. New York 7 May 1852. He was a member of the Society of Friends, and in the division which took place in 1827–8, joined the anti-orthodox or "Hicksite" branch. In 1829–41 he was director of a New York shop for the sale of Hicksite books, in 1841–5 was treasurer and book-agent of the Anti-Slavery Society, and from 1845 devoted his efforts to the work of the New York Prison Association. He was widely known for his interest in benevolent objects, especially negro emancipation and the assistance of discharged prisoners. At Philadelphia he was a founder and the secretary of a society for the employment of the poor, teacher in a colored school, and otherwise interested in philanthropic measures. He was an eloquent speaker. Consult the 'Life' by Child (1853).

Hop'pin, James Mason, American scholar and author: b. Providence, R. I., 17 Jan. 1820. He was graduated from Yale in 1840, studied law at the Harvard law school (1841–2), theology at the Union and Andover seminaries (1843–5) and the University of Berlin (1847–9), was ordained to the Congregational ministry in 1850, and was

pastor at Salem, Mass., in 1850–9. In 1861–79 he was professor of homiletics at Yale, in 1861–3 also pastor of the College church, and from 1879 until his retirement as professor emeritus in 1899 professor of the history of art. His publications include 'Notes of a Theological Student' (1854); 'Old England: Its Art, Scenery, and People' (1867); 'The Office, and Work of the Christian Ministry' (1869); 'Homiletics' (1881); 'Pastoral Theology' (1889); 'The Early Renaissance' (1892); and 'Greek Art on Greek Soil' (1897).

Hoppner, hŏp'nėr, **John,** English portrait painter: b. London 4 April 1758; d. 23 Jan. 1810. He entered the schools of the Royal Academy in 1775; and became a fashionable portrait painter and the rival of Lawrence. He was a member of the Royal Academy in 1795. His paintings have suffered from his use of bad mediums; but his repute has risen, and in 1896 a portrait by him was sold for 1,800 guineas.

Hopps, John Page, English Unitarian clergyman: b. London 6 Nov. 1834. He was educated at the Baptist College in Leicester, and first entered the Baptist minstry. Becoming a Unitarian, he held pastorates in Unitarian churches in Sheffield, Dukinfield, Glasgow, Leicester, and Croydon. He was a member of the first school board of the city of Glasgow. He was proprietor and editor of 'The Truth-seeker,' 1863–87, and became editor of 'The Coming Day' in 1891; he has written 'Pilgrim Songs'; 'A Scientific Basis of Belief in a Future Life'; 'The Alleged Prophecies concerning Jesus Christ in the Old Testament'; 'The Plain Truth about the Bible'; 'First Principles of Religion and Morality.'

Hops (*Humulus lupulus*) are a climbing plant, often met with in the wild state in northern Europe and in North America. The hop belongs to the hemp family (*Cannabinaceæ*) and it is the sole representative of its genus, but is cultivated in many varieties. It is a dicœcious plant, that is, the pistillate (female) and staminate (male) inflorescence is borne by different plants. In American and English hop-gardens it is customary to grow a sprinkling of male plants, but these are rigorously excluded on the Continent. In the former case the pistillate inflorescence becomes impregnated and forms seeds, in the latter they do not. In good hops the seeds are scarce, small, shrunken and sterile, that is incapable of propagating the plant. Many believe that the formation of seed ought to be prevented, as the seeds are useless to the brewer, the main consumer of hops, and besides they only add weight to the hops. Hop-plants are not raised from seeds, but are propagated by cutting off and transplanting portions of the underground stem or root. Only the pistillate plant is cultivated, because its ripe flower is the part of the hop-plant used in brewing. It has been introduced into Brazil, Australia and the Himalayas.

The hop is a perennial herbaceous plant, which produces each year several long twisting, striated stems, 15 to 20 feet in length, which clamber over hedges, brush, etc., with ease. The leaves are stalked, opposite, three to five lobed, and coarsely serrate. They are, like the stem, rough to the touch. The male inflorescence forms a panicle; the flowers enclose five stamens in a small greenish five-parted perianth. At an early stage the female inflorescence is less conspicuous. The strobile or catkin consists of several small acute bracts or leaves at whose base are situated two sessile ovaries, each subtended by a rounded bractlet. These bracts are attached to the extremity of the stem in such a way as to form a cone, and are shaped similar to roofing tiles, being one half to three quarters of an inch long.

The ovary and the base of the bracts are covered with a yellowish powder, the "hop-meal" or lupulin, which is the active principle of the plant.

Only a very slight amount of hops is used in medicine, being chiefly employed as a stomachic in dyspepsia; a pillow stuffed with hops is said to induce sleep. Nevertheless by far the largest portion of the hops produced is used in the manufacture of various beers, so that here this subject is treated with that idea in view.

The pistillate plant alone is cultivated, because hop growers on the Continent, especially Germany and Austria, find that unfertilized pistillate plants produce strobiles richer in aroma, more plenteous in lupulin, and in general better than where the plants were fertilized through the pollen of the staminate plant. In the United States we always find the strobiles containing much seed, while the choice imported Bohemian and Bavarian hops are seedless. The pistillate plant flowers in August, and its strobiles are ready for harvesting during September.

The continental European growers always strive to have early, medium and late hops, so that there the hop-picking begins late in August and lasts through the early part of October. In the United States the picking is usually over in two weeks. The time at which the strobile is fit to pick is indicated by the change of color from a light golden to a somewhat deeper hue, also by the closing up at the tips and making a rustling sound when touched. The seeds should be firm and dark in appearance before the hops are gathered. Much loss can occur by too early picking, while too late harvesting is also detrimental to the value and quality of the product.

For about 1,000 years hops have been added to beer or wort, in former times to prevent its spoiling and also to give it its pleasant and characteristic flavor and aroma; and its cultivation has progressed as the manufacture of beer became more widespread. Germany and England had hop gardens in the 8th and 9th centuries, but the cultivation was not rationalized until the 16th century, and at the present is a very important agricultural product.

Abroad the finest hops are raised in Bohemia, its "Saazer" hops being known throughout the world. Next to this ranks the Bavarian "Spalter hops," and the product of the so-called "Hallertau." As a rule the Bavarian hop is stronger than the Bohemian, but somewhat inferior in quality. Würtemberg, Saxony, Baden, Prussia and Alsace also raise a good quality of hops; and Belgium, northern France and Burgundy cultivate it on a large scale. England's most famous hops are the "Farnhams," the "Golony" and "Grape" varieties. Owing to the high import taxes, Russia has also begun to raise hops. Of all these only the "Saazer" and the "Spalter" are imported to the United States. The follow-

ing table gives an idea of the size of the world's production during the years 1900 and 1901:

WORLD'S PRODUCTION OF HOPS IN HUNDREDWEIGHTS.

COUNTRIES	1901	1900
United States	451,000	528,000
German Empire	283,580	523,600
Austro-Hungary	308,000	214,500
France	49,500	55,000
Belgium and Holland	93,500	55,000
Russia	88,000	88,000
Great Britain	726,000	385,000
Australia	3,300	13,200
	2,002,880	1,862,300

In the United States, the culture of hops was introduced as early as 1625 in New Netherlands, and 23 years later in Virginia, but although encouraged by special legislation in 1657, never assumed its present important agricultural role until 1800. During the first half of the 19th century Vermont produced seven eighths of the entire United States crop; since then New York has held first place. It has always been the tendency of hop cultivation to concentrate in well-defined districts, but in spite of this accumulative tendency, the centre of cultivation has slowly but surely moved westward. At first Massachusetts, Vermont and Maine were the chief hop States, but as the quality of the New York hops was far superior, and the quantity three times as great, the former States soon abandoned hop culture. The result was that during 1850-65 a small portion of New York, lying south of the New York Central Railroad between Rochester and Albany, monopolized the hop raising of the United States. Small patches were planted in Wisconsin and Michigan in 1860 and in 1866, when the New York crop was completely destroyed by vermin, Wisconsin hop-growers obtained exorbitant prices for their excellent product, which induced many to plant hops, expecting to realize a fortune in a few years, but the prices speedily declined owing to an overproduction. During 1870 and 1880 New York again was at the head, but at that time fresh competition began to develop on the Pacific coast. The "Russian River" hops of California were a marvel; their texture was "fine as silk"; their color "bright golden"; they were "clean picked"; their "contents of lupulin" second only to the best German brands, so that it was no wonder that hop-culture there advanced quickly to 40,000 bales, the yield of 1902. The first of the three following tables shows the yield in pounds of the various States from 1849 to 1899. The next table gives a comparison between the acreage, yield and value of the hop crop for 1899, 1889, and 1879; and in the third table this comparison has been calculated to

percentages of the total United States crop, in order to give a clearer idea of the hop industry during these years.

New York hops are almost entirely consumed in the United States, while the greater amount of the Pacific coast hops (especially Oregon) is exported. The English production is scarcely ever sufficient for its needs, so that Great Britain must import some and mostly takes Oregon hops, because they are especially adapted to the English ale brewer's requirements.

The hop plant is subject to many diseases, due mostly to parasites, among which are the hop plant-louse (*Phordon humuli*), the hop-grub (*Gortyna immanis*), the hop-vine snout-moth (*Hypena humuli*), the hop-merchants (*Polygonia interrogationis*), the zebra caterpillar (*Mamestra picta*), the common woolly bear caterpillar (*Spilisonma virginica*), the saddle-back caterpillar (*Empretia stimulca*), hop vine leaf-hopper (*Tettigonia confluenta*); various beetles, the "red spider" or spinning mite, and the needle-nosed hop-bug (*Calocoris fulmomaculatus*), which mostly produce red smut, etc., and even destroy entire crops. Fungus pest, blight and mold (black smut), are extremely rare in the United States, although widespread in England and Europe. It is almost impossible to eradicate these pests, except by extreme measures. The best remedies for the destruction of the animal parasites is the use of bisulphide of lime or a heavy spraying of soap and tobacco emulsion. Sulphur in any form is a good remedy, and a spray of kerosene soap emulsion, to which a small quantity of flowers of sulphur is added, is generally effective. In extreme cases the affected plants are cut down and burned to prevent a spread of the disease.

The elements also play havoc with the development of the tender hop-vine. High winds will tear the vine from its support; drouth will tend to change the color of the light yellow strobile to the objectionable "pole redness"; and too much water will produce a lack of lustre, when the hops are said to be "blind." This is due to the fact that the entire energy of the plant is spent in the formation of leaves, the strobile being scarcely developed.

Hops contain hop-oil, hop-resins, acids, hop-tannin, hop-bitter, hop-wax, nitrogenous bodies, carbohydrates and mineral substances. Diastase (an enzyme) has also been found, which is especially valuable in ale brewing. Hop-oil, the principal constituent of the lupulin, present in 0.2 per cent to 0.8 per cent, is obtained by distilling the hops with water. It is colorless and hardly soluble in water. The characteristic agreeable aromatic flavor of the hops depends on this oil. If exposed to air the oil turns to resin, passing to valerianic acid, to which the cheesy odor of old hops can be traced. According to Hayduck, there are three resins in hops, the α, β, and γ, of which the first two are soft and the latter hard. The preserving, antiseptic effect of hops is due to the two soft resins, as they are distinctly prejudicial to the growth of butyric acid and many other bacteria, but do not have much effect on acetic acid bacteria and sarcina. In old hops valerianic acid, malic acid, citric acid and succinic acid are present. Hop-tannin is chiefly stored in the leaves of the strobile and is a pale brown amorphous powder soluble in dilute alcohol, which through oxidation passes into phlobaphen. The hop-bitter is obtained from the two soft resins, and imparts a pleasant bitter taste to the beer, without which it would be flat and insipid. Hop-wax is present in considerable proportions in hops, but, since it is insoluble in water and even in 90 per cent alcohol, it has no value in beer. Nitrogenous constituents of hops are about 2 per cent to 4 per cent, which calculated to albumen are 12 per cent to 24 per cent, of which 0.75 per cent to 1.6 per cent are soluble. Bungerer maintains that 30 per cent of the nitrogenous substances are asparagin. Behrens says that trimethylamin and free ammonia are also present. Griess and Harrow have discovered cholin in hops. Brown and Morris have shown the presence of an enzyme similar to diastase, which will saccharify starch, that is, change it into sugar. This enzyme is chiefly accumulated in the seeds. The carbohydrates contained are cellulose, sugar, dextrin. According to Brown and Morris there is present 1.55 per cent dextrose and 2.10 per cent levulose, together 3.65 per cent of inverted sugar. According to Thausing hops contain 5.3 per cent to 15.3 per cent of ash and an average of 7.54 per cent, of which over one third is potash, one sixth phosphoric acid, one sixth silica, and some sodium, lime, magnesia, iron oxide, sulphuric acid and chlorine. The presence of an alkaloid in the seed has been ascertained by Dr. Ernst Hantke, but research on this point is still progressing.

Although it is possible to estimate with a fair degree of accuracy the several constituents of hops, it has not been so far found possible to establish any definite relation between the value of the hops and the amounts of hop-oil, resins, tannin, etc., which they contain. Consequently up to the present time, chemistry has not afforded much assistance in this direction. Hence the value of hops is still judged according to its general properties. The color, size and appearance and lustre of the strobile, the quantity and color of the lupulin, the amount of seed, the odor, taste and cleanliness, are the essential points in the valuation of hops.

Fine hops possess a silky lustre which is lacking in inferior grades. The color is greenish yellow, varying with the origin. New York hops have a somewhat paler color of a stronger greenish shade, while the Pacific coast hops have a more pronounced yellowish color. A reddish tint may indicate pole-redness, or, what is worse, that the hops have become overheated in the bale, which implies a darker coloration of the lupulin and deterioration of quality. The form and size of the strobile is also characteristic of the origin. Small strobiles are preferable to big ones, as they contain on an average more lupulin; and the fewer the seeds the better. The bracts ought to lap over one another and hold firmly together, whereby the lupulin is kept in better. The odor and aroma should be strong, fine, free from any off-smell such as odors of fruit, garlic, etc. Only very slight amounts of stems, foliage, or stripped cones should be present, as they impart a coarse taste to the beer. The amount of lupulin present in the strobile is an indicator of the value of the hops, because it contains those resins, volatile oils and bitter substances, which are so essentially valuable to the brewer. In fresh hops,

slight pressure will force out the contents of the strobile in a transparent droplet, but in old hops the contents of the lupulin granule will not flow, due to resinification, and the expressed juice is more syrupy, wax-like and opaque. In short, the preparation of the strobiles for the market should be as follows: After the crop has been harvested, it is dried. The largest part of the German crop is merely air-dried or sun-dried, and it is claimed that this "natural cure" preserves far more of the essential oils and other active principles than is possible by the artificial hot-air cure used in the United States and England, and that this at least in part accounts for the peculiarities of Spalt hops that command such extraordinary prices. The kiln in which the hops are dried resembles in some respects the drying kiln of the maltster. This process requires great care, as much of the hops may be easily damaged. When the moisture has been completely removed, sulphur is placed on the fire, which has the effect of brightening the color; the evolved sulphurous acid also acts as an antiseptic, destroying to some extent the germs of mould-fungi and other organisms. After drying, the hops are stored three or four days, whereupon they are baled and are then ready for the market. They are easily affected by warmth, moisture, air and light, and for this reason must be protected in storage against these influences. For brewing purposes it is almost impossible to pass off a substitute for hops, although lupulin and hop-extract are now manufactured. The lupulin is separated from the strobile, and inasmuch as it contains the essential constituents for which hops are used in brewing, it can be better utilized, although it is impracticable and impossible to replace the entire quantity of hops with lupulin alone because it contains very little tannin, which also is essential. The same remark is applicable to hop-extract.

DR. ERNST HANTKE,
President of the Industrial Chemical Institute of Milwaukee.

Horace (QUINTUS HORATIUS FLACCUS), Roman poet of the Augustan Age: b. Venusia, Italy, 8 Dec. 65 B.C.; d. Rome 27 Nov. 8 B.C. Our information about Horace's life is derived in the main from his own writings, which are supplemented in a few details by a brief biography attributed to Suetonius. He was born at Venusia, a small town in Apulia, near the boundaries of Lucania and Samnium. His father was a freedman, and, according to Horace's own statement, followed the trade of a *coactor*, or collector. He seems to have prospered, for he was able to purchase a small farm. He was not satisfied to send the boy to the local school of Flavius, which was patronized by the aristocracy of Venusia, but moved to Rome to give his son the best possible educational advantages. It is to his credit that he did this, not that Horace might better his position in life, but for the sake of the education itself. At the capital he supplied his son with the means of making a creditable appearance, and he himself accompanied him to and from his classes, giving him moral instruction in a shrewd and homely way by pointing out men who offered examples to be followed or shunned. To this training Horace owed both his habit of self-examination and his consequent temperance and self-control, and that keen observation of men and things which is one of his marked characteristics. He nowhere makes mention of his mother, who very likely died while he was an infant.

At Rome Horace pursued the usual grammatical studies under the notorious "flogging Orbilius," and doubtless supplemented them by more advanced work in rhetoric and literature. It is, however, in marked contrast to the fulness of our information about the other details of his life, that we know little or nothing about the masters who influenced him or about the particulars of his education, except that he implies that he attended the classes of several teachers. We may, however, infer something from the results. He certainly acquired a taste for reading, both in the literature of Greece and that of his native land, a habit which he continued to follow throughout his life. Somewhere about 46 B.C., in his 19th year, Horace went to Athens to study philosophy but he does not seem to have been especially attracted by any particular school. In his early life he leaned toward the Epicurean doctrine, but as time went on he turned more and more to that of the Stoics, without, however, committing himself to either sect. The assassination of Cæsar and the arrival of Brutus in Athens in September 44 B.C., put an end to his quiet student life. He joined the army of the liberators, and received a commission as tribune, though he was in no way fitted for the post. At Philippi he fled from the field with the rest of the routed forces, and, as he himself says, "left his shield behind." His humble estate was confiscated, but on his return to Rome in 41, when a general amnesty was granted by Octavian, he in some way secured a position as clerk in the quæstor's office, which furnished him the means of livelihood.

Horace freely admits that it was lack of money which first led him to write verse, and it was to his efforts in this line that he owed his advancement. He soon made the acquaintance of Vergil and of Varius, by whom he was introduced to Mæcenas. After a delay of several months, during which the astute statesman doubtless took the young man's measure, his position was established by his admission to the select circle of Mæcenas' literary friends. This honor, as he says with pardonable pride, was due not to high birth, but to his personal character. In 33 he received from his patron a small estate, the famous Sabine farm, situated in the valley of the Digentia, a small stream flowing into the Anio, about 30 miles northeast of Rome. Through Mæcenas he became intimate with the most eminent men of the day, both in literary and in political life, including Augustus. Toward the emperor his attitude was one of dignified independence. He was quick to recognize the advantages of the peaceful and established order of things which Augustus had brought about, and he celebrates it in many of his odes; but he did not hesitate to decline the position of private secretary which the emperor offered him. This he did without giving offense, for Suetonius quotes extracts from letters of Augustus which indicate a cordial and even an intimate friendship. Horace also preserved his independence in his relations with his benefactor Mæcenas, as appears from several pas-

sages in his works, although he showed a proper gratitude for his many favors.

In the year 35 Horace issued his first book of satires, to which he himself gave the title of 'Sermones,' or familiar talks. On this branch of literature, which the Romans claimed as their own creation, see SATIRE. He took as his model Lucilius, and at first seems to have followed him closely, but he soon found himself out of sympathy with the earlier poet's severity in invective and disregard of form. In the fourth and tenth Satires he subjects the work of his predecessor to a thorough criticism, and defines his own ideal of what satire should be. This book was complete in itself, and begins with an essay addressed to Mæcenas. That the reception given to his first effort, which did not lack serious defects, was not wholly favorable, and that Horace had not satisfied himself, is evident from the poet's own words in the introductory essay of the second book, which seems to have appeared in the year 30. This book marks a great advance on the first, from which it differs in its externals in having no formal dedication and in being cast almost wholly in dialogue form, whereas in the first book Horace himself had been the chief speaker. In the following year, urged by Mæcenas, Horace published his first collection of lyrics, some of which doubtless represent his earliest attempts at verse. It was a volume of 17 Epodes, or 'Iambi,' as he himself named them. He chose as his model the Greek iambic poet Archilochus, and followed him closely in form. His work, however, has little of the bitter invective for which the Greek poet was notorious, and Horace shows no little originality both in his choice of themes and in his treatment of them. Six years later Horace, now a man of 42, published the first three books of the Odes, which form a work complete in itself, opening with a dedication to Mæcenas and closing with an epilogue in which he predicts his own immortality. In his choice of metres he followed especially Alcæus and Sappho, from whom he also took many of the subjects of his odes. But he shows the influence of many other Greek poets, as well as considerable independence. Although this work did not wholly escape hostile criticism, it at once placed Horace in the front rank of Roman poets. This position was formally recognized in 17 B.C. through his appointment by Augustus to write the ode, the well-known 'Carmen Sæculare,' which was sung at the celebration of the secular games in that year.

His next work was a return to the field of satire, for the 'Epistles' belong with the 'Sermones' to that branch of literature in the Roman sense of the term. They differ from the 'Sermones' in their greater finish and in their external form. Horace regarded the hexameter as the conventional form for satire, and the poetic epistle represents his third and final choice of form for his essays in that measure. The first book was apparently issued in the year 20. Horace was then a mature man, who had made his mark, and his tone is more assured and his self-appreciation is greater, though without any trace of egotism. The practical philosophy of life seemed to him the thing most worthy of serious consideration, and to teaching this he proposed to devote the rest of his literary work. This book, which consists of 20 letters, of which some are genuine and some fictitious, is also dedicated to Mæcenas. The second book is devoted wholly to literary criticism, a subject which lay within the domain of satire and had already been handled in some of the 'Sermones.' The chronology of the book is somewhat difficult. It was probably published in the year 14. Whether the *Ars Poetica* formed the third letter of the second book or not is uncertain. It has been assigned to various years from 20 to 8 B.C., and if it really belongs to the latter date, it must have been published separately, perhaps after Horace's death, and is the latest of his works. The title which Horace gave it seems to have been 'Epistula ad Pisones,' but it received its present designation at an early period. The second book of epistles begins with a letter addressed to Augustus, who is said by Suetonius to have taken Horace to task for dedicating none of his works to him. In his epistles, Horace had formally renounced lyric poetry. Nevertheless, at the express request of the emperor, he published a fourth book of odes in 13 B.C. This collection, though admirable in form and containing some of Horace's best work, is characterized by a certain perfunctoriness and lack of spontaneity. It was not addressed to Mæcenas, but is without a formal dedication. This was, however, not due to any diminution of his regard for his patron, but to the fact that the book was published by the special request of Augustus.

Of the remaining years of the poet's life we know very little. Suetonius says that he died 27 Nov. 8 B.C., and there seems to be no ground for rejecting this testimony. No authentic portrait of Horace has come down to us. From his own allusions to his personal appearance, and from a letter of Augustus, quoted by Suetonius, we learn that he was stout and short, with dark eyes and hair, but prematurely gray. He further tells us that he was quick to anger, but easily appeased. He never married, and of all the loves of which he sings, Canara alone seems to be other than imaginary.

It is probably safe to say that Horace has been the most widely read of all Roman writers, not excepting Vergil, and that he has appealed to a more varied circle of readers than any of his countrymen. This statement applies especially to his odes, since it is to them that his popularity with the general public is for the most part due. It has been said that the odes are not poetry of the highest type, and that when they are analyzed and their contents subjected to searching criticism, the sum total of poetic material is scanty. This is unquestionably true, yet it is equally true that their influence and popularity have none the less been great. This is due in part to the personality of the man and the sympathetic feeling which he rouses in his readers on account of his broad humanity; and in part to the fact that the very simplicity of the odes and their ease of comprehension appeal to readers of all classes. As Mackail says, he realized that limited as was his own range of emotions, that of mankind at large was still more so. In some cases, notably in the love poems and the convivial odes, we are conscious that he did not always feel even the emotions which he describes. In spite of all criticism, the one undoubted fact remains, that the odes of Horace have pleased readers of all epochs and all sorts and conditions of men.

Horace's claim to originality is greater than is usually admitted. In his day the question of imitation of Greek models had ceased to exist, and the question was, rather, which model to choose. In the Augustan Age we find two schools, those who followed the Alexandrine writers, and those who went back for their inspiration to the Greeks of the classical period. Horace belonged to the latter class. His contempt for the followers of Alexandria is outspoken, and so undiscriminating as to include such really great poets as Calvus and Catullus. He certainly knew how to make what he borrowed his own, and many of his odes are so thoroughly national in character that they can have owed little except their external form to Greek sources. In his Satires, in spite of his avowed imitation of Lucilius in the beginning, his originality is far greater, and these are in reality his greatest works. While less popular with the general reader, they are of great interest for the light which they throw on Horace's life, personality, and habits, as well as for the vivid pictures which they set before us of the complex Roman life. In his daily walks about the city, Horace used his powers of observation, and drew material from all sides and from all classes of society. Above all we can trace in them his own self-improvement and the development of his character, and the gradual growth of that sound judgment and good taste which characterize the work of his mature years. The Satires are further characterized by a genial and good-natured humor. Like Dickens, he chose appropriate names for many of his characters — such as *Novius*, or Newman, for the parvenu, though, like those of Dickens, they were not always of his own coinage. The Satires also abound in the familiar phrases of every-day life, in puns and plays upon words, in proverbs and homely fables and stories.

Horace's works, as he himself humorously predicted, became school text-books at an early period. Juvenal implies that this was the case in his day. This fact and his general popularity led to the numerous commentaries on his works, which began to appear as early as the days of Nero, of which those of Porphyrio, of the early part of the 3d century, and the collection falsely attributed to Helenius Acron, have come down to us. The great number of manuscripts which exists testifies to his popularity in the Middle Ages. His fame at that time was, however, much less than that of Vergil, and, though he also was regarded as a magician, it was only at Palestrina and at Venusia that such legends were current. In modern times his influence on French and English satire has been great, as well as on modern poetry in general.

The date of the first edition is uncertain, but is earlier than 1471. Since then the editions of Horace's works, or of parts of them, have been legion. Of these may be mentioned as epoch-making that of Richard Bentley (Cambridge 1711), which has often been reprinted (the reprint at Berlin in 1869 contains a word-index by C. Zangermeister). The standard critical text is that of O. Keller and A. Holder (Leipsic 1864–70, a second edition of the first volume containing the 'Odes,' 'Epodes,' and 'Carmen Sæculare,' appearing in 1899). A commentary on this edition is furnished by Keller's 'Epilegomena zu Horaz' (Leipsic 1879–80). Of editions with notes may be mentioned: J. G. Orelli, 4th ed. by W. Hirschfelder and W. Mewes (Berlin 1886–92), containing a complete word-index; A. Kiessling (Berlin, 2d ed. 1890–8); H. Schutz (Berlin 1880–3); these two appear in new editions from time to time; L. Müller, 'Odes' (Leipsic 1900), 'Satires and Epistles' (Leipsic 1891–3); E. C. Wickham, 'Odes and Epodes' (3d ed. Oxford 1896), 'Satires and Epistles' (Oxford 1891); Page, Palmer, and Wilkins (London and New York 1896). The edition of the 'Odes and Epodes' by P. Shorey (New York 1896) is of special interest to the general reader on account of its large number of parallel passages from English poetry.

The simplicity and directness of Horace's thought have been a constant temptation to translators, and the number of English versions, particularly of the 'Odes,' is very great. But his care in composition and his inimitable skill in the use of words, his *curiosa felicitas*, as Petronius terms it, make him exceedingly difficult to translate, and, while some brilliant successes have been achieved with single odes, no one has done justice to him as a whole. Many of the attempts which have been made are reviewed in two articles in the 'Quarterly Review' (Vol. CIV., 1858, and Vol. CLXXX., 1895). The following may be mentioned: Lord Lytton, 'Odes and Epodes' (London 1869); Cooper, 'Horace's Odes Englished and Imitated by Various Hands' (London 1880); Martin, 'Works of Horace' (Edinburgh 1888); Conington, 'Odes and Epodes' (3d ed., London 1885), 'Satires and Epistles' (London 1892); Gladstone, 'Odes' (New York 1894); Green, 'Odes and Epodes' (London 1904). An edition of Horace's works, in six volumes, containing both text and translations, has recently been issued by the Bibliophile Society of Boston. To give an adequate literary criticism of Horace is nearly as difficult as to translate him, and is out of the question within the limits of a brief article. Consult: the various histories of Roman literature, especially that of Mackail (New York 1900); Sellar, 'Roman Poets of the Augustan Age — Horace and the Elegiac Poets' (London 1892); Nettleship, 'Lectures and Essays' (Oxford 1885); Patin, 'Etudes sur la poesie latine' (3d ed., Paris 1883); Tyrrell, 'Latin Poetry' (Boston 1895); Boissier, 'The Country of Horace and Virgil' (London 1896); Lang, 'Letters to Dead Authors' (London 1886).

JOHN C. ROLFE,
Professor of Latin Language and Literature, University of Pennsylvania.

Horæ, hō'rē, in Greek mythology, goddesses of the seasons. They were generally regarded as attendants of the gods, and guardians of the Olympian gates. Their characteristics, however, varied, and their number was variously represented as two, three, or four. Hesoid names three — Euxomia (good order), Dike (justice), and Eirene (peace), and thus makes prominent their attributes as also guardians of social and political conditions.

Horatii, hō-rā'shĭ-ī, three Roman brothers, who, in the reign of Tullus Hostilius, engaged the same number of Alban brothers (the Curiatii), in order to decide the contest between the two nations. A sister of the Horatii was

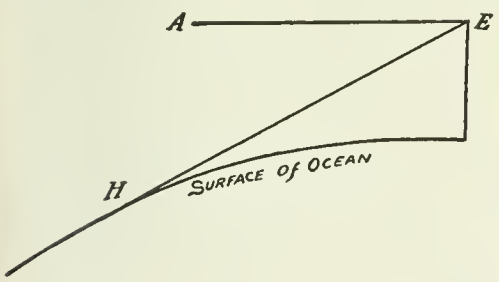
betrothed to one of the Curiatii; but both sides forgot their private relations in the service of their country. Two of the Romans soon fell. The contest was unequal, but Horatius saw his antagonists faint with the loss of blood. In order therefore to separate them from one another, he feigned flight, and, while they pursued him as well as their wounds would permit, at unequal distances, he suddenly turned and slew one after the other. He was conducted back to the city amidst the rejoicings of the Romans, adorned with the spoils of the slain. There he saw, in the crowd, his sister in tears for the death of her betrothed. Angered that her lamentations for her lover should mingle with the rejoicings of the nation on his victory, the brother plunged his dagger into her breast. He was condemned by the duumviri to be scourged to death, but he was later pardoned.

Horeb, hō′rĕb, a mountain in the northern part of Arabia, of the same ridge as Mount Sinai, which lies not far distant from it, memorable in the history of Moses. The monks on Mount Sinai still point out the rock on Horeb from which water issued at the blow of Moses.

Horicon, hŏr′ĭ-kŏn. See GEORGE, LAKE.

Hori′zon. In its most familiar sense the horizon is the line or circle around which earth and sky seem to meet. On the ocean this circle is smooth and easily visible, and is then called the *sea horizon.*

In astronomy the horizon is defined by a plane at right angles to the direction of gravity, extending out indefinitely on all sides, and called the *plane of the horizon.* The circle in which this plane cuts the celestial sphere is called the *astronomical horizon.* All points of it are apparently on a level with the eye of the observer. Owing to the rotundity of the earth



the sea horizon is lower than this astronomical horizon — a narrow strip of sky separating the two. The angular distance between them is called the *dip of the horizon.* The higher the observer is above the ocean, the greater is the dip. To an eye on the surface of the water, the sea horizon and the astronomical horizon coincide, so that there is no dip. The geometrical principle which determines both the dip and the distance of the visible horizon, are seen in the figure. The circular arc is here the surface of the ocean. The eye of the observer is situated at the point E, a short distance above the surface of the water. A tangent drawn from the eye to the surface meets the latter at the visible horizon, H. Let a horizontal line E A be drawn from the eye, the angle A E H is then the geometric dip of the horizon. The geometer will readily see that this is equal to the angle at the surface of the earth between O and H. Since one minute of arc in the curvature of the earth's surface corresponds to one nautical mile, it follows that, geometrically, the dip of the horizon in minutes is equal to its distance in nautical miles. But, in the actual case, the line of sight is curved in consequence of the refraction of the air. The result of this is that the actual horizon is further than given by the geometric theory, and the dip somewhat smaller. The following table shows the relation between the apparent dip and the height of the eye above the water and the distance of the sea horizon.

Height in Feet	Dip of Horizon	Distance of Horizon Miles
1	1.0	1.3
2	1.4	1.8
3	1.7	2.3
4	2.0	2.6
9	2.9	4.0
16	3.9	5.3
25	4.9	6.6

On board a steamship the eye of an observer on the promenade deck is generally from 15 to 20 feet above the water. It follows that the distance of the horizon is about five miles. A ship farther away than this will have more or less of her hull below the horizon. At double the distance the entire hull will be below the horizon, and only smokepipe and masts visible. As she goes yet further, these also will disappear, as if sinking below the water.

SIMON NEWCOMB.

Horn, a tough, flexible, semi-transparent substance derived from the epidermis, which may be developed morbidly as a corn, or naturally, as in the callosities on the legs of a horse; or in connection with important functions, as when it forms the outer sheath of the outgrowths upon the heads of ungulate animals, called "horns," the "shell" of the tortoise, the nails, claws, and hoofs of animals, the beak of bird and turtle; and the hairs and feathers of mammals and birds, or their modification into spurs, scales, spines, bristles, whalebone, nasal horns, etc. This epidermal tissue consists largely of keratin, an albuminoid composed mainly of carbon (about one half), oxygen, nitrogen, and sulphur.

The horns of mammals are in effect modifications of the hairy integument covering parts liable to great wear, or needing to be hard and sharp, especially the outgrowths of the skull characteristic of male ruminants. Hollow horns are usually unbranched and persistent, but in the pronghorn (q.v.) they are shed annually while the bony cores grow and their vascular coverings persist and give rise to the new horns. Hollow horns are found usually in both sexes, but in some genera of antelopes only in the male. In the pronghorn the horns of the female are almost hidden in the hair of the head, and are small, short, and unbranched. Such horns as these are called hollow or sheath horns, and are very different from antlers (q.v.). Another form of true horn is that on the snout of the rhinoceros (q.v.) where, when more than one appears, the projections stand one behind the

other in a median line, and not side by side. This nasal rhinoceros-horn is not a hollow sheath clothing a bony core, but a solid mass of coarse agglutinated hairs, arising from the skin and supported by a thickening of the underlying bone.

Utility of Horn.— In their natural form, the horn-sheaths of oxen, sheep and antelopes have been put to a great variety of use, as weapons, receptacles, handles, and musical instruments — the latter surviving in certain ceremonial usages and in the general term "horn" for a wind instrument. Cleaned and polished it served many additional needs, forming the primitive drinking cups; and it is from this ancient usage that the general name of "horns" has been given to a species of drinking cup, and its spirituous contents. The horns of victims sacrificed to the gods were often gilded by the Romans and suspended in the temples, more especially in those of Apollo and Diana. From the most remote times the altars of the heathen divinities were likewise embellished with horns, and such as fled thither to seek an asylum embraced them. Originally the horns were doubtless symbolical of power and dignity, since they are the principal feature of gracefulness in some animals, and instrument of strength in others. Hence these ornaments were frequently bestowed in imagination and art upon gods, and were actually worn by heroes. In more modern times ox-horns have been used the world over for carrying gunpowder; and museums abound in quaint relics of this kind elaborately ornamented by soldiers and hunters. Small bottles (ink-horns) of this substance were the first receptacles for ink, and are still used in the East, where opium for smoking is usually kept in horn-boxes. Before the general adoption of glass panes in windows thin plates of horn were often used, as they still are in barbarous parts of Asia; lanterns were made of them; and the faces of the mediæval horn-books were so protected. The material now lends itself to manufacturing into many other articles by reason of its toughness, pliability and capability of being softened by heat and then molded. The heat is applied in the form of hot water; and splitting into thin sheets, or welding pieces together, or molding fragments into various forms, may all be accomplished under combined moisture, heat and pressure. Both the natural horn and the molded substance may be carved, or impressed with a die, polished and dyed. Hence an enormous variety of useful and ornamental articles may be made, and the horns of cattle have commercial value.

Horn, a musical instrument, originally formed, as the name denotes, from the horn of an animal. The name includes a large family of wind-instruments, many of which have fallen into disuse. The hunting-horn was long the chief form extant. The French horn consists of a metallic tube of about 10 feet in length, very narrow at top, bent into rings, and gradually widening toward the end whence the sound issues, called the bell, or in French the *pavillon.* It is blown through a cup-shaped mouth-piece of brass or silver, and the sounds are regulated by the player's lips, the pressure of his breath, and by the insertion of the hand in the bell of the instrument. The compass of the instrument is three octaves. Music for the horn is always written on the key of C, an octave higher than it is played, with the key of the composition marked at the beginning of each movement. Great improvements have been made in the instrument by C. J. Sax of Paris, whose saxhorn gives a greater volume of sound than the old instrument. The buglehorn is a tube of 3 feet 10 inches in length bent into small compass. It is usually provided with keys, and has a range of two octaves, and notes commencing with the upper B of the bass clef.

Horn, Cape. See CAPE HORN.

Horn-fly, a European fly (*Hæmatobia serrata*), since about 1890 become widespread in North America, which have a curious habit of clustering in masses about the base of the horns of cattle. It is closely related to the house-fly and stable-fly, and although annoying does no serious harm to the cattle or their horns.

Horn'aday, William Temple, American naturalist: b. Plainfield, Ind., 1 Dec. 1854. He studied zoology and in 1875–9 visited as a zoological collector South American countries, India, Ceylon, the Malay Peninsula, and islands. In 1882–90 he was chief taxidermist of the United States National Museum, and in 1896 was appointed director of the New York Zoological Park. His publications are: 'Two Years in the Jungle' (1885); 'Free Rum on the Congo' (1887); 'The Extermination of the American Bison' (1887); 'Taxidermy and Zoological Collecting' (1892); 'The Man who Became a Savage' (1895).

Horn'beam (*Carpinus*), a genus of trees of the natural order *Cupuliferæ,* of which the species *C. betulus* is common in Europe, in some places growing to nearly 100 feet in height, although in Great Britain, where it is much planted, it is a small tree. It is also called horn-beech, hardbeam, and yoke-elm. It has barren flowers in a cylindrical catkin; fertile flowers in a lax catkin; nuts in pairs. It grows in woods and hedges, often in a damp tenacious soil, and forms a principal part of the ancient forests on the north and east sides of London. The wood is white, tough, and hard, and burns like a candle. It is used in turnery, for cogs of wheels, etc. The inner bark yields a yellow dye. The American hornbeam (*Caprinus Americana* or *Caroliniana*) is a small tree rarely attaining the height of 30 feet, sparingly diffused over most of the United States. It is also called water-beech, blue beech and ironwood. The wood, fine-grained, tenacious, and very compact, is used for handles, as of carpenter's tools, ets., its serviceability being restricted by reason of its inferior size. See IRONWOOD.

Horn'bill, a genus (*Buceros*) and of a family (*Bucerotidæ*) of birds now placed in the division *Coraciiformes,* and related to the hoopoes and owls. The species are numerous, and are found in Africa, India, and throughout the Malayan region as far as New Guinea, are mostly large birds, the largest being more than four feet long, the smallest rather smaller than a magpie. They are bulky birds of heavy, noisy flight; their large bills are surmounted by bony crests or "helmets" of varied shape and sometimes of great size, but rendered light by the presence of numerous air-cells. Their food

is principally fruits, but in certain circumstances they become to a great extent omnivorous. Thus a well-known South African ground-hornbill devours snakes, and is highly regarded by the negroes because of its enmity to them, and ability to overcome the largest and deadliest vipers. Several are mainly terrestrial in their habits. The most curious fact regarding these birds is that during the breeding season the female is imprisoned on her nest in a cavity in a tree-trunk, she herself apparently gradually plastering up the entrance by the use of her excrements, until there is left only a small aperture through which the male supplies her and her offspring with food until the young ones are nearly full grown. In captivity the male bird has been observed to disgorge at intervals the lining of his gizzard in the form of a bag, and it is supposed that the food supplied to the female during her term of captivity in the breeding season is enclosed in this structure. Consult: Newton, 'Dictionary of Birds' (1896).

Hornblende, hôrn'blĕnd, or **Amphibole,** an abundant and widely diffused mineral, remarkable on account of the various forms and chemical compositions that it exhibits, and its diversified colors. Almost numberless varieties of it are recognized, to many of which distinct names have been given. It crystallizes in the monoclinic system, and is brittle, with a hardness of from 5 to 6 and a specific gravity of from 2.9 to 3.4, according to its composition. It has a vitreous or pearly lustre, and its fibrous varieties often have a silky appearance. The variety most commonly known as "hornblende" is usually black or greenish black, and occurs in many rock formations, notably in granites and basalts, and in certain schists and slates. The strongly colored varieties are pleochroic. Common hornblende is a silicate of iron, aluminum, magnesium and calcium. The various hornblende minerals are now collectively known as the "amphibole group." See AMPHIBOLE.

Hornbook, an elementary school book in use in England down to the time of George II. It was made up of a single leaf on which was written the alphabet in large and small letters; the Roman numerals, and the Lord's Prayer. The leaf was sometimes set in a frame and sometimes pasted against a piece of sliced transparent horn; hence the name. There was a handle through which a string was inserted whereby the book might be tied around the waist.

Horne, C. Silvester, English Congregational clergyman: b. Sussex 1865. He was educated at Glasgow University and Mansfield College, Oxford, and after leaving the latter institution was pastor of the Kensington Congregational Church until 1903, when he became pastor of the Whitefield Tabernacle in Tottenham Court Road, London. He has been active in many social and religious enterprises and is one of the most prominent men in his denomination in England. He has published 'History of the Free Churches.'

Horne, Richard Henry, or **Hengist,** English poet and essayist: b. London 1 Jan. 1803; d. Margate 13 March 1884. He was educated at Sandhurst, and entered the Mexican navy as midshipman, serving till the close of the Mexican war of independence. He then returned to London to begin a literary career. To his early period belong two tragedies, 'Cosmo de' Medici' (1837), and 'The Death of Marlowe' (1837), both of which contain fine passages. A poem sent to him for criticism by Elizabeth Barrett opened the way to a cordial friendship and a correspondence of seven years. In 1852 Horne removed to Australia, and remained there until 1866; his book, 'Australian Facts and Principles,' being one outcome of this residence. Again returning to England, he continued literary work until his death. His last publications were tragedies, including 'Judas Iscariot: A Miracle-Play' (1848), and a curious prose tract, 'Sithron the Star-Stricken' (1883), which he pretended to take from the Arabian. His best known work, however, is his epic poem 'Orion' which Poe said might be called "a homily against supineness and apathy in the cause of human progress, and in favor of energetic action for the good of the race."

Horned Dace, Rattlesnake, Screamer, Viper, etc. See DACE, RATTLESNAKE.

Horned Toad, lizards of the family *Iguanidæ,* popularly called toads from a certain general resemblance in form and manner to those animals. The body and head are broad, thick, and flattened, the tail short and the usual attitude a sort of squatting posture with the head elevated. About a dozen species of the genus *Phrynosoma* occur in the arid parts of the southwestern United States and in Mexico. The best known are *P. cornutum* and *P. coronatum,* which, because of the bizarre appearance, quaint ways and tolerance of captivity, are often brought back as souvenirs by visitors to those regions. The scales on the body bear prominent conical spines, and the long horns of the head are supported by bony cores. Their mottled brown and gray colors harmonize well with their natural surroundings. The horned toads love to bask in the sunshine in the hottest weather and to bury themselves in the burning sand. Never very active, they become extremely sluggish in cool or dull weather and hibernate in the winter. They feed on all kinds of insects, for which they search only during the hottest hours of the day, and drink copiously of water when sprinkled in the form of drops. Like many other lizards, but unlike most of the *Iguanidæ,* they are viviparous.

Horned Viper. See VIPER.

Hornellsville, hôr'nĕlz-vĭl, N. Y., city in Steuben County; on the Canisteo River, and on the Erie and the Central N. Y. & W. R.R.'s; about 57 miles south of Rochester and 46 miles northwest of Elmira. The first settlement was made in 1790, but it was a part of Canisteo and was called Upper Canisteo until 1820. The present name was given in honor of George Hornell, who had done much for the early development of the town. It was incorporated as a city in 1890. Hornellsville is situated in a fertile agricultural region, noted for fruit. Its chief manufactures are sash, doors, and blinds, railroad supplies, furniture, leather, carriages and wagons, silk, bricks, tiles, wire-fencings, gloves, and agricultural implements. It has a good public high school, St. Ann's Academy, St. James Mercy Hospital, and a number of fine

public and private buildings. The government is vested in a mayor, who holds office two years, and a city council. The subordinate officers are appointed by the mayor subject to confirmation by the council. Pop. (1900) 11,918.

Horner, William George, English algebraist: b. 1786; d. Bath, 22 Sept. 1837. He was educated at a private school near Bristol, and later taught there, becoming head master in 1806. In 1809 he established a school at Bath, which he conducted until the time of his death. His only work of importance was his discovery of a method of solving numerical equations of any degree, which he first announced in a paper read before the Royal Society in 1819, and afterward published in the 'Philosophical Transactions.' The method is still in use, and is known by Horner's name. See ALGEBRA, HISTORY OF THE ELEMENTS OF.

Hor'net. The true hornet is a European wasp (*Vespa crabro*); but in America the term is applied to almost any form of large stinging wasp, especially such as make papery nests. In some portions of the United States this is considered the only "hornet," but in the vicinity of New York the European hornet also occurs; and southward a somewhat smaller species (*V. carolina*) goes by this name.

Hornet, The, the name of two sloops-of-war in the American navy during the War of 1812. The chief was a ship-rigged 18-gun sloop, and did brilliant service. Through December and January 1812–13, under Master-Commandant James Lawrence, she blockaded the 20-gun English sloop Bonne Citoyenne in the harbor of Bahia, Brazil, till overmatched by a 74; Lawrence was surprised and himself had to take refuge in the harbor, but instead of being blockaded, slipped out the next night under the very guns of the man-of-war. After capturing a merchantman, on 24 February he fell in with the English sloop-of-war Peacock, Capt. William Peake, each at this time having 20 guns; they engaged at 5.25 P.M., and in eleven minutes the Peacock was a sinking wreck and surrendered. Her captors made every effort to keep her afloat, but in a few minutes she sank, carrying down 13 of her own crew and three of the Hornet's. Peake and four men were killed and three wounded; the Hornet had one killed and two wounded, besides two more hurt by an exploding cartridge. "A vessel moored for the purposes of experiment could not have been sunk sooner," said an English paper of the time; "it will not do for our vessels to fight theirs single-handed." On 22 Jan. 1815, under Capt. James Biddle, she encountered off Tristan d'Acumba, in the South Atlantic, the English brig Penguin, Capt. James Dickinson, with 19 guns of about the same metal as her own 20; in 22 minutes the Penguin surrendered, but on Biddle going forward, two British seamen shot him in the neck (not vitally), and were immediately shot down themselves. The Penguin lost her captain and 9 others killed, and 38 wounded; the Hornet, one killed and 11 wounded. The Penguin was shot to pieces, and could not be taken away, so she was scuttled; the Hornet was almost uninjured. On 28–9 April she had a long chase from the British ship of the line Cornwallis, the rear-admiral's flagship, and only escaped by thoroughly dismantling herself.

Horol'ogy. See CLOCK; CLOCK-WORK.

Hor'oscope. See ASTROLOGY.

Horrocks, hŏr'ŏks, Jeremiah, English astronomer: b. Toxteth, near Liverpool, about 1617; d. 3 Jan. 1641. He was educated at Cambridge and was appointed in 1639 to the curacy of Hoole, Lancashire, and in that village made his famous observation (24 Nov. 1639, O. S.) of the transit of Venus, the first on record. Newton, in the 'Principia,' bears honorable testimony to the value of Horrocks' astronomical work. The observation of the transit is by no means regarded as his sole astronomical achievement, as he added to our knowledge of the physical cause of celestial motions, deduced the solar parallax, corrected the solar diameter, and, made tidal observations. Hevelius printed the 'Venus in Sole Visa,' which was first published in Germany (1662); a translation of this work, with memoir by Whatton, appeared in 1859.

Horschelt, Theodor, German painter: b. Munich 1829; d. 1871. He began his early studies in the Munich Academy, and later became a pupil of Albrecht Adam. At first he painted horses, among which is 'The Poacher' (1850), and then turned to military scenes, painting 'The Seizure of Shamyl' and 'Cossacks Returning from a Razzia.'

Horse, in a general sense, a member of the ungulate family *Equidæ* (q.v.); but in ordinary use the word designates the single domestic species (*Equus caballus*), the wild original of which is unknown. It is not decided, in fact, whether a single species, or more than one, was the source, nor where the domestication of the horse was first effected. The evolution of the species, elsewhere sketched, took place in the American continent, and the writings of some of the earliest voyagers to the eastern coast of South America contain allusions which some commentators regard as evidence that horses survived and were known to the people who occupied the La Plata valley at that time, but this is open to doubt. It is probable that at the dawn of civilization the wild ancestors of our modern horses roamed in bands over the whole extent of grassy uplands stretching from northern Africa to eastern Manchuria, on the steppes of Russia, and wherever in Europe open country might be found; and it is also probable that they were among the first animals which men killed for food and afterward captured and tamed in order to keep a supply of food under control. This act must have been one of the earliest steps toward community life and civilization. The oldest paintings and carvings left by the ancient inhabitants of the valley of the Euphrates show that saddle-horses were familiar to them; and it is fair to suppose that the supremacy primitively gained by the people of central Asia over other parts of the world was largely due to their use of horses in war, giving them a great advantage over unmounted tribes; but it was not until much later — probably no earlier than 2000 B.C. — that the animal came into use in Arabia and Egypt, where before had been only camels and asses. So far as can be judged, these early Assyrian war-horses were rather small, robust, large-headed and shaggy beasts, much like Przewalsky's horse or the kiang (q.v.). A very similar animal was domesticated by the men of the Polished Stone Age in Europe, excellent portraits of which

were etched by neolithic artists upon pieces of bone, and have come down to us among the contents of graves opened by archæologists in France, Switzerland and elsewhere. Later, but still in the prehistoric period, Europe was repeatedly invaded by Asiatic hosts who brought with them eastern horses. These modified, if they did not supersede, the local stock. When Rome conquered the barbarous inhabitants of Europe its horses, which were of Asiatic stock, with perhaps some African mixture, largely superseded those of the conquered tribes, and from the mingling there sprang the big heavy breeds which characterized the Middle Ages, and were intended for strength and weight-carrying, rather than for nimbleness and speed. It was not until near the end of the 17th century that the introduction into France and England of certain sires of Arabian breed — a clean-limbed, small-headed, agile, hardy race, which arose in Arabia and Palestine about 2,000 years ago — began the improvement of British stock, which has reached its highest development in the modern European racehorse, hunter and hackney. From this stock was derived the American horses which have been perfected in at least one new direction — that of the trotter.

Horse, Care and Diseases of the. *Breeding.*—As *heredity* is the basis of all permanence in breeding, and *variation* the condition of advancement, we can, under intelligent selection, environment, and control, attain to a constant improvement. In selecting horses for breeding, certain leading principles must guide. These may be shortly stated as: (1) adaptability to the use of the breed; (2) quality, style; (3) strength, endurance; (4) good conformation; (5) good constitution; (6) good pedigree; (7) prepotency; (8) no violent crossing of equally prepotent animals; cross the desirable prepotent animal on a non-prepotent cross-bred animal; (9) a speedy amelioration of a large number is most certainly obtained through a prepotent stallion, which leaves a large number of his offspring every year; (10) sound, vigorous health; the prepotent parent must be at his best, and no non-prepotent one should be bred to him, none that is old, feeble, or reduced by disease, overwork, underfeeding, etc; the lack of prepotency will not prevent the transmission of the systemic weakness to the offspring; (11) secure an environment calculated to enhance the qualities we seek in the progeny. Systematic exercise that is not exhausting, generous tissue forming, but not fat forming regimen, and pure, dry, genial but bracing air are especially important.

Contagion Through Sexual Congress.—Many maladies may be transmitted during coition, but some are especially liable to be so. Dourine, glanders, genital eczema, contagious acne, horse-pox, mange, and contagious abortion are to be specially guarded against. Some, like strangles, influenza, and contagious pneumonia, may be transmitted by an animal that has already passed through the disease and acquired immunity. Special care, therefore, or even veterinary supervision of horses devoted to breeding is a desideratum.

Care of the Pregnant Mare.—Exercise is a valuable provision too often neglected. Free range on breeding ranches, or, for valuable mares, separate paddocks, secure this, while working mares are better to continue the work, provided it is not unduly straining nor jarring, nor productive of excessive fatigue, exhaustion, or debility. This maintains appetite, digestion, assimilation, muscular tone, and vigor, favors the development of a stronger, better foal, and keeps the dam fitter for foaling and nursing. Feed well, avoiding what is hard of digestion, or liable to cause impaction, indigestion, fermentation, or, above all else, diarrhœa. On good pasture grain may be omitted, unless in the last month of gestation, or if the mare is visibly running down. Good, clear, sound oats or barley, or bran mash with some boiled flaxseed may be given, and heating agents like maize, buckwheat, or wheat avoided. During gestation violent purgatives and active diuretics are liable to bring on abortion.

Care of the Foal.—To avoid danger to both mare and foal in parturition, provide a roomy box-stall with door opening outward, or a paddock. The foal born indoors is always in danger of infection through the raw surface of the navel. The common or box-stall swarming with microbes is more to be dreaded than exposure to storms outside. When severe weather forbids foaling outdoors, the box should be thoroughly cleansed, disinfected, and whitewashed to obviate this danger. Navel infection may cause simple inflammation, swelling, and abscess, or the germ may propagate itself through the inactive umbilical vein to the liver, causing infective hepatitis with abscesses or necrosis; or, reaching the bowels, it causes infective diarrhœa (white scour); or it may colonize the joints, as infective arthritis (joint ill); or again it may cause pneumonia, or multiple abscesses in different organs. The gravity of the resulting disease varies with the infection, and a deadly germ, located in a stable, is liable to attack all foals that come later in the season. Both stable and navel should be disinfected. The foal should be delivered on clean straw, which may be sprinkled with carbolic acid. The navel-string may be severed with an emasculator previously cleaned and boiled, or tied with a carbolized new cord painted with tincture of iodine, and, when dry, dusted with tannic acid impregnated with iodine and carbolic acid.

The new-born foal may have the back (flexor) tendons contracted so as to stand over at the knee and fetlock, and in the worst cases the extensor pedis tendon, the opponent of these, is found to be divided across and the muscle wasted and degenerated. A succession of such cases in the same stable suggests infection. Slight cases will recover under splints and bandages, while for more severe ones an aseptic surgical operation may be required. The foal should have the first milk (*colostrum*) to clear away tenacious bowel contents and prepare for healthy function. A mild laxative of raw linseed or olive oil may be requisite in the absence of colostrum. In the absence of the dam's milk the foal may be raised on cow's milk reduced by adding one third boiled water and sugar to sweeten. After two or three weeks the undiluted cow's milk may be allowed. The cow should be free from tuberculosis.

For the pure bred racer or trotter the foal should have half a pint of oats daily at a month old, to be increased with his growth. Even draft breeds are benefited by such early grain-feeding.

Exercise is essential to the growing foal. The quality of bone, muscle, brain, and other parts depends largely on physiological use, and rich blood, active digestion, and assimilation, vigorous health, strength and endurance are incompatible with confinement and inactivity. This may at first be secured by freedom to play in pasture, or by careful handling and training by a judicious manager. But to put the two-year-old into a severely contested race, or full training, or to devote the draft colt to regular work, is but to invite disaster. The bones are as yet too soft, they contain too much organic matter and too little mineral, the muscles lack firmness and power of endurance, the whole system is immature and imperfect, and over-taxing exhausts or deranges the functions, and direct injury or impaired development is the natural result.

CARE OF THE FEET.

Overgrown Hoofs.—With unlimited exercise on firm ground, the unshod foot is sufficiently worn down, but when confined for months indoors or in a limited straw yard overgrowth occurs, especially at the toe, and a dangerously increased strain is thrown on the joints, ligaments, and back tendons. Distorted and twisted feet, bruises of the sole by the ingrowing heels and quarters, ringbones, ossified cartilages, sprains of the flexor tendons, and diseases of the fetlock, pastern, and coffin joints are common, and irreparable results. The feet exposed to this should be frequently pared and adjusted. Remove excess of toe, reduce and balance the inner and outer sides of the wall, file or cut to the level the incurving heels and quarters, and round off the sharp outer edge of the hoof. Dry, imprisoned plates of horn pressing up on the sole must be set free and removed. But do not file the surface of the hoof-wall. This removes nature's protective covering and exposes open horn tubes to exhale moisture, and conduces to dryness, brittleness, shrinking, compression, and inflammation of the sensitive parts, atrophy, and lameness.

Defective Growth of Hoof.—Imperfect growth of hoof may arise from shoeing, pinching, filing, paring, etc., to excess, but also from compulsory idleness. The circulation inside the hoof is greatly accelerated by the ascent and descent of the foot within the horny box in action, and a free blood supply in a healthy tissue favors growth. Life at pasture on firm ground tends to abundant, strong, tough, durable hoof, while close confinement in a stall makes for a thin, friable, brittle, and shrunken horny covering. Constant soaking in water softens the hoof, reducing its tenacity, and tending to flattening of both wall and sole. The Belgian and other horses bred on wet, swampy ground generally show large, flat, pliant, and most undesirable hoofs. Such feet are especially liable to thrush, canker, corns, bruises, grease, and laminitis. Feet habitually resting on piles of reeking manure in stalls, sheds, or yards suffer the additional injury of softening and disintegration from the ammonia gas, and attacks by the swarming putrefying microbes which abound in such material.

Good hoofs, beside use and care, depend on generous living. The fuller growth on the spring and summer grass, forming a permanent ring, illustrates this. Daily washing of the hoof is important, and a subsequent smearing with an ointment of tar and vaseline or oil is useful in preserving the natural moisture and preventing the attacks of microbes.

Shoeing.—For good feet, shoes may be dispensed with on soft ground or mud roads, but they become necessary on hard roads and for hard-worked animals. Tips, extending back to the broadest part of the foot only, are the least objectionable. Full sized shoes are too often made to pinch, distort, bruise, or injure the foot beyond repair; and a poor foot is as injurious to a horse as an unstable foundation to a building. The first consideration is the preparation of the foot, giving due balance to heel and toe, inner side and outer, sole and wall, heel and bars. While removing all overgrown wall and bars, and all sole-plates that have become detached from the tough living horn beneath and now act as foreign bodies, the tough horn itself should not be exposed, nor removed except as a thin margin around the outer edge, where it is smoothed to the same level as the wall, to which it acts as a support, and the bearing surface of which for the shoe it slightly extends. The outer surface of the wall must be spared abrasion by the file, with consequent drying and contracting as already noticed. Shoes should be removed and reset every four weeks at the utmost, to avoid pinching, setting in, bruising, and other injuries. Intelligent shoeing, conserving the feet, goes far to obviate diseases of the feet, the most common and harmful of equine diseases. Among these may be specially named corns, bruises, pricks, quittors, sandcracks, thrush, canker, sidebones, laminitis, navicular disease, contracted hoof, cleft hoof, wry hoof, crooked hoof, loose wall, hollow wall and graveling. As the integrity and easy normal function of the foot is further one of the best means of protection against distortions and diseases of the various joints of the limb, it follows that the preservation of sound feet by good shoeing and intelligent care is one of the greatest desiderata in horse management.

FEEDING AND DIGESTIVE DISORDERS.

The natural food of the horse is *grass* and though charged with excess of water, and at first liable to scour, and always to cause flaccid muscles and lack of energy and endurance, yet a run at pasture, with pure air, normal, easy exercise, and stimulation of stomach, liver, bowels, metabolism, and excretion will often improve or arrest infirmities of digestion, assimilation, elimination and even innervation. Heaves (broken wind), chronic bronchitis, various forms of nasal discharges, indigestion, torpid liver, gall stones, and kidney affections are examples of maladies which improve at pasture. Dried grass in the form of hay is the standard food of the domesticated horse. This is best from natural pastures with a mixture of grasses, to be followed by blue grass, timothy, ryegrass, and clover, the latter being the most dangerous as a horse fed. Upland hay is more aromatic and choice than that from low, damp or irrigated meadows, and the first crop is always the best. New hay will sometimes disagree, while the old, though lacking aroma and less palatable, is less likely to cause digestive disorder. At a year old and over it is brittle, dried, more fibrous and less nutritive. Daily

cured hay is always innutritious, and often directly poisonous, when altered by bacterial ferments, molds and their products. The results are shown in heaves, gastric disorders, liver troubles, brain affections (staggers), kidney and skin diseases. Second crop hay, clover and alfalfa hay are especially dangerous in this sense, the excess of protcids in the last two, and especially of foliage, delaying curing and favoring the multiplication of ferments. Oats are the standard grain feed for horses. But like hay they must be well matured on good soil, and well cured. Mustiness brings essentially the same evils as in hay, and newly harvested they are liable to disagree. Kiln-dried oats are to be avoided, also those that have sprouted. The composition of oats and hay shows the excess of proteids, carbohydrates and fats in the first.

	Water	Proteids	Carbohydrates	Fats	Cellulose	Salts
Meadow hay	14.59	10.11	40.90	2.34	25.52	6.54
Oats	14.3	12.0	60.9	6.0	10.3	3.0
Maize	10.6	10.3	70.4	5.0	2.2	1.5

Maize is notorious for the deficiency of proteids relatively to the carbohydrates and fat. With a great excess of heat and energy producing constituents and a deficiency of earthy salts it is less calculated to foster growth and development, and predisposes rather to fat. It tends more to impactions of the bowels and indigestion, with resulting skin eruptions, and above all to the destructive recurrent inflammation of the eyes, which ruins so many young horses. Yet it is fed over large areas as the exclusive grain feed, and such is the adaptability of the living system that the minimum evil results. To obviate the evils it can be fed with cooling, laxative agents as wheat bran, carrots, or turnips, or an ounce of Glauber salts may be given daily.

Barley, rye and wheat have been successfully fed to horses but are not equal to oats in supporting the animal and fitting for hard work.

Beans, peas and other leguminous seeds are fed when a horse is subjected to an extraordinary strain of work or endurance, being especially valuable for the excess of proteids they contain. They should be thoroughly matured and dried as the fully formed and partially ripened seeds of several species contain a narcotic poison.

The relative amount of hay and oats for a horse of 1,000 pounds live weight may be stated as follows: *Cavalry horse:* Oats 12 pounds, hay 14 pounds. *Carriage horse:* Oats 10 pounds, hay 12 pounds. *Draft horse:* Oats 15 pounds, hay 12 pounds. The horse at rest can live on a mere maintenance ration sufficient to keep up bodily temperature and repair waste. A horse in active work will need about one half more. For very severe or rapid work about one third more must be added. For hard work a broad ration-proteids 1, to carbonaceous matter 6, is preferable to a narrow ration-proteids 1, to carbonaceous matter 3. An economical feed can often be made of a number of agents compounded from their known chemical composition, to form such a balanced ration, but mere chemical ingredients are not final, as palatability and adaptability have still to be reckoned with and a given weight of oats is of more value than an equal amount of similar nutritive elements in wheat or barley.

Good judgment and regularity in feeding and watering are essential to success with any feed. Feeding in irregular amounts at varying intervals, and with uncertain watering will undo the good effects of a generous ration. The small stomach (16 quarts) cannot admit a large feed of oats and saliva without suffering, and, if overdistended, it becomes paretic or torpid, and dangerous fermentation and gaseous distension may ensue. Again, if feeding is delayed the hungry craving and nervous excitement cannot be undone by a generous feed later. Then again, if the perspiring and exhausted animal is allowed to slake his thirst with a bucket of ice-cold water, he may have heart failure, or colic, or gastric congestion with sympathetic skin eruption or laminitis, or inflammation may attack any organ that has been previously weakened.

An excellent appetizing food is molasses. This has been largely neglected because of the mistaken idea that it contained heat producing elements only. But corn carbohydrates furnish energy to the acting muscles and other tissues as fuel does to an engine, and sugar, having no need of digestion, can supply force with less loss than can starch or fat. Not the least of its good qualities is the relish with which it is taken and that it imparts to other less attractive food taken with it. For the horse, otherwise healthy, but debilitated by poor or faulty feeding or overwork, molasses is to be depended on to restore weight and energy alike. For this purpose it may be given in the amount of two pounds per day, and even in double that amount if subjected to severe work.

Overdistension of the Stomach.—Sudden inflation of the stomach with gas, the product of fermentation in unwholesome contents (frosted grass, roots, apples, green potatoes, overripe ryegrass, millet, vetch, etc., irritant plants); from overfeeding (at the cornbin, in ripe grain, etc.), from violent exertion on a full stomach, or from a full feed when debilitated from starvation, disease, or overwork, is liable to cause death in two hours or a little more. The horse can rarely vomit, or belch gas, the stomach does not absorb, and the outlet by the bowels is one hundred feet long, so that the organ is usually ruptured with fatal results. Among the other less rapid disorders are catarrhal inflammation of the stomach, intestinal colic, congestion, inflammation, impaction, twisting, invagination, calculi and worms. Of poisons may be named: lead through water, etc.; molds, fungi, and bacteria in food (causing gastric, intestinal, hepatic, pulmonary, nervous, cutaneous or kidney diseases); ergot, smut (causing gastric disorder, ulcers of the mouth, abortions, etc.); lupines, Senecio Jacobœa (causing cirrhosis of liver); astragalus, oxytropis (loco, brain disease); equisetum (gastric and intestinal catarrh); to

which may be added cicuta, conium, œnanthe, aconite, rhus, ranunculus, larkspur, anemone, digitalis, wild cherry, wild onion, camas, helenium, hyacinth, clematis, thorn apple, colchicum, belladonna, hyoscyamus, bitter sweet, euphorbium, hellebore, wild parsnip, laurel, oleander, etc.

Liver Diseases.—These are notoriously prevalent in hot, damp regions in horses kept in close stables on rich, abundant feeding, in such as have dry feeding and scarcity of water in winter, and in such as have a poorly balanced ration with excess either of proteids or of heating carbohydrates. In damp tropical regions special care is needed as to the site, exposure, ventilation and purity of stables, the dietary, exercise and grooming to obviate liver complaints. Transient fevers, nervous digestion, skin and kidney disorders often originate from troubles in the liver.

Grooming is most important in the finer breeds of horses in clearing off oil and dandruff, rendering the skin pliant, and favoring secretion, exhalation, cooling and elimination. On the contrary, animals at pasture and exposed to cold and wet find a measure of protection in the sebaceous and thick hairy covering. When, however, drenched with perspiration or rain, and in a warm air, the relaxing effect on the skin and general system is very debilitating, hence clipping may become a necessity to be followed by special precautions against cold. The active friction (massage) of grooming renders circulation active, especially that of the lymph, relieving fatigue, favoring elimination and improving the tone of the muscles and general system. The heels need particular care. Clipped heels are irritated by the stubby hair in the folds back of the pastern often precipitating chaps and grease which would have been escaped in the unclipped. The heel is normally protected by the abundance of sebaceous secretion, but when this is rubbed off by dust, clay, sand, etc., the part suffers readily from cold, wet, dried gritty mud or other irritants. Washing the heels, above all with caustic soap, and leaving them to dry in cold air or draft is hurtful. Prompt drying of the heels will obviate the danger, and, if there is already any swelling, gentle massage with a little vaseline will improve the condition. In obstinate cases the source of the trouble may be sought in disorder of digestion, liver or kidney.

Many disorders of the nervous system, lungs, skin, eye and kidneys are due to constitutional troubles which cannot be dealt with here in general terms. Such diseases are usually manifested by elevated body temperature and accelerated or modified breathing or pulse. The temperature of the healthy, mature horse, at rest in a cool or moderate environment, is 99° to 100° F., respirations 10 to 12 per minute, and pulse 35 to 45.

Contagious Diseases.— These agree in one fundamental feature that each is due to a microbe, which passes more or less directly from the affected animal to the sound one, thus propagating the disease. The arrest of the epizootic and even its complete and final extinction, is merely a question of preventing such transmission and of destroying every infecting germ. This truth is not yet duly appreciated by stock-owners, legislators nor sanitary officers, but when it is fully realized we shall be near the total extinction of most animal plagues to the unspeakable profit of humanity. The *Contagious diseases* may be divided into two classes: (1) Those in which the infection is either confined to solipeds, or mainly propagated by the equidæ, so that its extinction in these would mean the final extinction of the disease, and (2) those which are propagated in other genera as well, so that the extinction of the germ in other species also would be essential to its complete eradication.

To the first class belong strangles (distemper), contagious pneumonia, equine influenza, glanders, tetanus, vesicular exanthema, contagious acne, petechial fever, gastro-enteritis of the new born, South African horse sickness, dourine, surra, Nagana, Mal de Caderas, infectious paraplegia. The first four of these affections are constantly spread in the United States through sales, public stables, stockyards, railroad cars, ships, and sale-stables, and no radical measure is taken to destroy the germs in such infected places, or to prevent the infection of all solipedes that pass through them.

In the second class must be included: Horse-pox, contagious abortion, thrush of the mouth, infectious ophthalmia, tuberculosis, rabies, malignant œdema, anthrax and emphysematous anthrax. The first six of these are propagated more by other genera than the horse, so that the burden of the work for their extinction would have to be expended on these other classes. The last three are caused by germs which can live out of the animal body in the soil, and their extinction would involve the drainage and sanitation of the infected soils as well.

Parasitic Diseases.—A number of parasites that prey upon solipeds can live indiscriminately in other animals as well. Among these may be named the *Tricophyton* of ringworm; *Aspergillus* of pneumomycosis; *Actinomyces:* different species of wood ticks; *Dermanyssus* of poultry acariasis; *Trombidium Americanum* (and *T. Holosericium*); *Linguatula Denticulata; Eustrongylus Gigas; Filoria Medinensis; Distoma Hepaticum* and *D. Lanceolatum.* By reason of their variety of hosts these would be less easily got rid of. But another list includes the obligato parasites which must live in the soliped at some stage or perish. These accordingly can be extinguished on the same principle as can the microbes of exclusively equine plagues. They include the larvæ of four species of botfly (*Œstrus Equi, Œ. Hæmorrhoidalio, Œ. Pecorum* and *Œ. Nasalis*); three lice (*Hæmatopinus Macrocephalus, Trichodectes Pilosus,* and *Tr. Pubescens*); four mange acari (*Sarcoptes Scabei V. Equi, Psoroptes Communis V. Equi, Symbiotes Communis V. Equi,* and *Demodox Folliculorum V. Equi;* three tapeworms (*Tœmia Perfoliata, T. Mamillana,* and *T. Plicata*); two stomach worms (*Spiroptera Microstoma* and *Sp. Megastoma*); five intestinal worms (*Ascaris Megalocephala, Oxquris Curvala* and *O. Mastigodes, Sclerostoma Equinum* and *Sc. Tetracanthum*); one of the serous cavities (*Filaria Papellosa*); one of the lungs (*Strongylus Arnfieldi*); and four of the blood (*Filaria Hæmorrhagica, F. Irritans, F. Sanguinis Equi,* and *F. Reticulata*). For the obligato parasites their extinction on the victim, and his removal from the source of a fresh supply means a final extinction of the parasite,

as the worm cannot be perpetuated without its host. In the case of worms, which survive as eggs and embryos in damp earth and water, the exclusion of solipeds for a year or two from infested stables and fields, from waters (ponds, lakes, wells, streams) that receive drainage from infested places, and from food derived from such verminous localities, entails the inevitable destruction of these parasites in such habitat outside the body. An essential condition of complete success is that the infested animals must be themselves cleared of the worms, to prevent their colonizing new places with the parasite, and, in the case of such as are entertained in the blood, or serous cavities or in cysts in the tissues, this takes time to allow of their migrating into the bowels or reaching their limit of life and perishing. The mere use of anthelmintics or vermifuges alone is no radical treatment for these parasites. A veterinary sanitation which is far reaching enough to do away for all time with the class of contagious and parasitic epizootics, is the only one worthy of twentieth century knowledge, or which will fulfill the duties of the age.

James Law,
Director New York State Veterinary College, Cornell University.

Horse, Evolution of the. As a domestic animal the horse is to be found almost everywhere that man can live. He is spread all over the world — from torrid to arctic climates, in all the continents, in remote oceanic islands — he is completely cosmopolitan. But as a wild animal the horse is limited to the Old World, and is found there only in the open arid or desert plains of Central Asia and Africa. There are two species in Asia, the Asiatic wild ass (*Equus hemionus*), and the little known Przewalsky's horse (*E. przewalskii*), while in Africa there are the African wild ass (*E. asinus*) and the several species of zebra (*E. zebra, E. burchelli, E. quagga*). In the Americas and Australia there are no true wild horses, the mustangs and broncos of the Western plains and South America being feral (domesticated animals run wild) and descended from the horses brought over from Europe by the early white settlers. When the Spaniards first explored the New World they found no horses on either continent. The Indians were quite unfamiliar with them and at first regarded the strange animal which the newcomers rode with wonder and terror, like that of the ancient Romans when Pyrrhus and his Greeks brought elephants to fight against them.

The horse is distinguished from all other animals now living by the fact that he has but one toe on each foot. Comparison with other animals shows that thi toe is the third or middle digit of the foot. The hoof corresponds to the nail of a man or the claw of a dog or cat, and is broadened out to afford a firm, strong support on which the whole weight of the animal rests. Behind the "cannon-bone" of the foot are two slender little bones, one on each side, called *splint-bones*. These represent the second and fourth digits of other animals, but they do not show on the surface, and there is nothing like a separate toe. So that the horse may be said to be an animal that walks on its middle finger-nail, all the other fingers having disappeared.

The teeth of the horse are almost equally peculiar. The molars are long, square prisms which grow up from the gums as fast as they wear off on the crowns. Their grinding surface exhibits a peculiar and complicated pattern of edges of hard enamel between which are softer spaces composed of dentine and of a material called "cement," much like the dentine in quality but formed in a different way. The dentine is formed on the inside surfaces of the enamel while the tooth is still within the jaw-bone; the cement is deposited on the outside surfaces of the enamel after the tooth has broken through the jaw-bone and before it appears above the gums.
