alterations of the vesical mucosa around these orifices, and a very curious alteration of the character of the urine secreted through them. There occur a slight reddening and gaping of the vesical orifice of the inflamed ureter, or there may be an actual eversion of the ureteral mucosa, until in extreme cases the orifice shows a round hole situated on the summit of a little mound of angry-looking mucosa. The vesical mucosa in the vicinity is usually red and injected, or even roughened and eroded. In these cases localized applications of solid silver nitrate give prompt relief of the pain on micturition. When the ulcers or erosions extend into the neighborhood of the urethral opening, or when the nitrate is too freely applied, the application may be followed by a temporary increase of the symptoms; but this increase seldom lasts more than 24 hours, and is then followed by relief. When it is not necessary to approach closely the urethral orifice, and the nitrate is sparingly used, the relief is usually immediate. The regulation of the diet and the ingestion of an amount of bland fluid equal to at least 3 pints of water daily are important adjuncts to the treatment. The diet should be bland, nutritious, and largely albuminous. Asparagus and strawberries should be absolutely interdicted; other fruits should be used but sparingly, and the highly flavored vegetables in general, such as tomatoes, onions, and cabbage, should be tried with caution. General massage is of the greatest benefit, and active exercise, as the use of the bicycle, will be beneficial. As regards medicinal treatment, alkalies and the so-called alterative drugs are indicated, as small doses of potassium iodid with mercury. Acute ureteritis is probably often mistaken for intestinal colic, pain due to renal stone, catarrhal appendicitis, or acute catarrhal salpingitis.

Surgical Injuries to the Ureters.—J. M. Baldy¹ remarks that injuries to the ureters are by no means uncommon accidents, though few of them ever find their way into print. The treatment of the injuries is now practically settled. The adoption of such makeshifts as ligation of the severed ends, formation of a urinary fistula, or nephrectomy, is ancient history. To-day we have but two propositions to consider—*uretero-ureteral anastomosis* and *ureterocystostomy (bladder-implantation)*. Both these procedures have been demonstrated as feasible, first by experimentation (Van Hook, Paoli, and Busachi) upon dogs, and subsequently by various surgeons upon the human subject. There are now on record 7 successful operations of this character. Experience seems to demonstrate more and more that bladder-implantation is applicable to a much larger group than is uretero-ureteral anastomosis; and if any choice must be made between the two methods, this is the method of election. It is necessary for the purpose of performing uretero-ureteral anastomosis that the two ends of the ureter be perfectly free and easily brought together; that the vesical end be more patulous (or capable of being made so) than the renal end; that the injury to the ureter be sufficiently high in the pelvis to enable the surgeon to readily carry out the necessary manipulations. In the case of ureterocystostomy but one point is necessary—that the injury be not too high in the pelvis to enable the kidney-end of the ureter to be approximated with the bladder. Of the 7 operations mentioned, 2 (Kelly and B. Emmet) were of the method of uretero-ureteral anastomosis; 5 (Novaro, Kelly, King, Penrose, Baldy) were of the method of ureterocystostomy. Of these 5 cases in not one was uretero-ureteral anastomosis possible, while of the other 2 cases 1 (Kelly) could have been corrected with equal success by bladder-implantation. If the injury be at or above the level of the ileo-pectineal line, it is exceedingly difficult, if not impossible, to closely approxi-

¹ Am. Gyn. and Obst. Jour., Oct., 1896.

mate the end of the ureter and the bladder. The danger of immediate obstruction in the two operations does not seem to be great. The danger of secondary obstruction after bladder-implantation seems to be absolutely nil, and the dangers of kidney-infection are mythical.

Tuberculosis of the Ureter and Kidney.—H. Kelly¹ describes 3 cases of unilateral tuberculosis of the kidney and ureter which he treated by excision of the kidney and the whole ureter at one sitting (*nephro-ureterectomy*). The three cases were operated upon by three different methods, and represent to his mind three stages in the evolution of the operation. In the first case he opened the abdomen from the front and removed the kidney and ureter. In the second case he removed the kidney by an incision in the back just outside of the quadratus muscle. In the third case the incision was a horizontal or slightly oblique cut between the lower ribs and the crest of the ilium.

A New Method of Obtaining Urine from a Single Kidney.—Rose² describes a method of obtaining urine from a single kidney. In order to accomplish this purpose, which is often of great importance diagnostically, various measures have been proposed. Pressure upon one ureter, either bimanually or through the vagina, or by means of a special clamp, is an uncertain procedure. Hegar proposed to cut down upon the ureter through the vagina and stop for a time its flow of urine. This method is certain, but is in itself an operation. By means of the cystoscope it is sometimes possible to determine that the urine from one ureter contains pus or blood, while that from the other is clear. At times this distinction is made with difficulty, or not at all, and in the most favorable cases no information is gained as to the chemie or microscopic condition of the urine. The catheterization, as proposed by Nitze and Kelly, requires considerable practice, expensive apparatus, and often an unpleasant dilatation of the urethra. Rose's procedure is based upon the fact that the bladder of a woman in the knee-chest position, or with the pelvis elevated in the dorsal position, will distend with air if a speculum is introduced through the urethra. Through this speculum it is possible to see by direct or reflected light the openings of the ureters; and if the speculum is cut obliquely, its inner extremity may be clamped over one ureter, while the urine from the other ureter flows down over the posterior bladder-wall toward the umbilicus. When sufficient urine for examination has collected in the speculum it can be drawn into a syringe, the speculum be withdrawn and cleansed, the bladder irrigated, emptied, and again distended with air, and the speculum placed over the mouth of the ureter of the opposite side. In cases of extreme sensitiveness the use of cocaine is recommended. As the urethra is not dilated, narcosis is unnecessary, and a resulting incontinence of urine is not to be feared.

MENSTRUATION AND ITS DISORDERS.

Puberty.—[The subject of uterine cardiopathies is very generally overlooked in everyday practice.] Kisch³ calls attention to the reflex cardiac disturbances observed in women at certain crises in their lives—at puberty, at the menopause, just after marriage, and also during pregnancy and labor. These are palpitation, abnormal acceleration and slowness of the pulse, precordial pains, dyspnea, and sense of oppression. In young subjects with these symptoms the external genitals may be non-developed; menstruation is established with difficulty, and is scanty and irregular. When these women reach

¹ Boston M. and S. Jour., Sept. 17, 1896.

² Centrabl. f. Gynäk., Feb. 6, 1897.

³ Gaz. de Gynéc., June, 1896.

the climacteric they have a return of the same phenomena which appeared at puberty, especially if they have been weakened by several previous labors and profuse hemorrhages. Simultaneously with the cardiac disturbances they are troubled with marked gastric irritability. These cardiac neuroses are undoubtedly due to the physiologic changes in the ovaries at puberty and the menopause, though they may be attributed to certain chemic changes which occur during the development and atrophy of the Graafian follicles. The condition is doubtless one of hyperesthesia of the cardiac plexuses. To some extent these cardiopathies seem to be hereditary, and are observed most frequently among the better classes. The treatment recommended is hygienic and moral rather than medicinal.

[The question of *bicycling* for women, whether it be potent for evil or for good, is yet discussed. The discussion is passing through its last stage, and it will take some time yet for it to find its perfect equilibrium.] Evans¹ considers that eventually the use of the bicycle will tend to produce placenta prævia. The author thinks that from the physiology, tissue, and function of the perineum it may be looked upon as a supplementary uterus. Prolonged pressure upon the connective tissue can but lead to "condensation and atrophy," and to increased difficulty of perineal dilatation or more frequent laceration. Turner, in a series of papers in recent numbers of the *British Medical Journal*, has treated the whole matter from all points of view. The conditions under which this exercise should *not* be indulged in appear to be—(1) during menstruation, and if possible for 24 hours preceding and 24 hours after the flow; (2) during pregnancy, although experience has shown that even during the first 3 months of that condition no harm has resulted from resort to the bicycle; (3) pelvic tumors, especially fibroids; (4) recent perimetritis, parametritis, or blood-exudations into the pelvis. [These are naturally only the more important conditions. Each case should be judged on its merits. No woman should ride a bicycle without first consulting her medical man, and she should ride only when suitably dressed.]

E. D. Page² believes that the use of the wheel should be conservative. He claims that the principal muscles developed in its use are those of the leg and thigh; that little muscular development of the arms comes from it, as there is comparatively little use for the arms in cycling except in mounting and dismounting, as when one becomes thoroughly master of the cycle very little effort keeps it balanced and guides it, which are the principal uses of the arms in the erect position in which women ride. There is a fascination about bicycling that leads to immoderate exercise, and then it is positively harmful in a general way. As to the advantage to the muscles of respiration, it would appear to be limited and, in a sense, unnatural. These muscles, to receive their fullest benefit, must also have the freedom of action attendant upon the arms being free to move at the side, with the shoulders thrown back or erect; with freedom to take deep inspirations, and with all chest- and arm-muscles free to move in any direction natural to each. With the slight bending forward and the *constant* extending of both arms in grasping the handles, the chest is perforce limited in its freedom; it is bound. The quickened respiration following the exercise of cycling has not, therefore, the benefit claimed for it. The development, if any, would be a cramped, narrower chest, and the training of years of cycling will frequently result in naught else. The plea that those sitting the wheel *aright* would avoid this by keeping the back usually straight and doing all the bending at the saddle or at the junction of thighs and body, is perhaps in a measure true; but the fact remains that the wheel is rarely ridden that way,

¹ Am. Jour. of Obst., Apr., 1896.

² Brooklyn Med. Jour., Feb., 1897.

it may be more frequently, however, by women. That the abdominal viscera may suffer from cycling is true. Page also claims that the bicycle teaches masturbation in women and girls, and that the saddle causes bruising and chafing of the labia. Also, that abortion is liable to be produced by wheeling, and in young girls there is a liability of narrowing the lateral diameter of the pelvis. [The above is an excellent example of what prejudice opposes to every innovation of any use whatever, and is a fair example of the absurd mistakes made in an attempt to criticise something with which one is not practically familiar. The deductions are purely theoretic and have no foundation in fact. To begin with, all these criticisms are based on the supposition that the woman rides in a leaning-forward (faulty) position, when, as a matter of fact, 9 out of 10 ride in the correct position (upright). The criticism that the chest does not expand properly in riding because the hands and arms are partially extended is theoretically untrue, and practically is answered by the fact that with rare exceptions the chest-measurements are increased after a few months' riding. It is unnecessary to point out to any rider the absurdity of the statement that the arms receive no exercise; it simply needs a trial of the instrument to demonstrate the contrary to be true. The efforts incident to balancing bring all the back-muscles into full play in addition. The pleading for a functionally weak heart is specious. Every experienced rider knows that at first the heart is apt to be overcome by climbing very moderate grades. After short practice these same grades are climbed without the knowledge that they exist, and shortly thereafter considerable hills can be taken with small discomfort. This all means that the weak heart has had constant and increasing judiciously arranged exercise, and is gradually strengthened until it is performing its proper functions easily and with increasing strength and vigor. The same thing may be said of the lungs and the quickened respiration.

Of course, the labia are bruised and chafed at first; but so is any other part of the body under similar experience. A loose shoe, an ill-fitting corset, or even a collar, will produce the same thing in other parts of the body; but in bicycling this is only incident to learning. The parts soon become accustomed to the pressure and the discomfort disappears. As to masturbation, the statement in general is untrue. We have investigated this subject closely and are convinced that it does not result.

The pleading that the perineum is a supplementary uterus and that pressure on it causes placenta previa is unworthy of discussion, as not a single fact is advanced in support of it. It is merely the unsupported belief of the author.

The bicycle is the most valuable addition to the therapeutics of women of the age. Properly utilized (proper saddle and proper position, with moderation as to speed and distances) it is worth all the drugs in the pharmacopeia together, especially in that class in which it is in some quarters condemned—neurotic, anemic women with functional heart-diseases. In healthy women there is no contraindication.]

Theilhaber¹ recommends cycling in cases of amenorrhœa, especially when the uterus is undeveloped. Dysmenorrhœa of nervous origin in young girls and sterile women is often relieved. In endometritis the writer has seen no result, either favorable or unfavorable, from this form of exercise; in the hemorrhagic form he advises against it on theoretic grounds. It should be forbidden in chronic as well as in acute gonorrhœa, in salpingitis, and in sub-acute and chronic peritonitis of whatsoever origin. Flexions and versions do not constitute a contraindication; in fact, cycling is often recommended for

¹ Münch. med. Woch., No. 48, 1896.

patients with these conditions with the view of relieving nervous symptoms and strengthening flabby muscles rather than actually relieving the displacement. This may account for the good results claimed in some cases of partial prolapsus. The use of the bicycle is inadmissible by patients with fibroid and ovarian tumors. The writer noted rapid increase in the size of fibroids in 2 women who rode contrary to his advice. Bladder-troubles are usually aggravated by cycling, though on this point there is some difference of opinion. Hemorrhoids are sometimes relieved, but are sometimes made worse, especially when improper saddles are used. Such benefit as may be experienced is usually due to the relief of constipation. Women ought not to ride during menstruation, though the writer admits that several of his patients have done so without injury. Pregnancy is a positive contraindication. Two of the patients who disobeyed his injunction aborted, but a third went on to full term, though she had a retroflexed uterus and prolapsed ovaries. In general, he approves of cycling in moderation. H. Macnaughton Jones¹ calls attention to the fact that cycling may have an injurious effect on women at the time of the menopause, and should not be indulged in except on the advice of a physician, especially if the patient is anemic and has functional cardiac trouble. He doubts the propriety of women with retrodisplacements of the uterus riding, with or without pessaries; this applies especially to anemic young girls. Hemorrhoids are aggravated, and coccygodynia may result. The writer recommends a pneumatic saddle, so constructed as to support the ischia, but not to press upon the external genitals or the coccyx; there should be no projection under the pubes. He approves highly of this form of exercise, which he regards as far superior to massage.

The Influence of Menstruation upon the Excretion of Uric Acid.—At the French Congress of Medicine E. Laval² stated that on the second day of menstruation, when the flow is most profuse, the amount of uric acid in the urine suddenly diminishes. On the following day the proportion is slightly increased, and on the fourth day exceeds the normal proportion. Subsequently the rate of excretion resumes its usual course. The effect produced by the menstrual flow is, therefore, comparable to that produced by a true hemorrhage.

Bathing during Menstruation.—Matwieff publishes a series of observations which demonstrate that saline or mud baths, at 25°, 27°, or 28° C., have a favorable influence on menstruation from the point of view of pain, the quantity of blood lost, and the duration of the flow. Mironiff, who made a number of observations to verify this, is in a position to state that alkaline baths at 27° or 28° C., taken during the menstrual period by patients suffering from gynecologic troubles, act as an excellent sedative; the quantity of blood lost is not affected by them, or perhaps slightly diminished. After these results he wished to know the influence of hot baths in the same conditions, for these are what would be, more than anything else, recommended in gynecologic cases. In affections of the uterine appendages the menses are often increased in frequency, as is also the quantity of blood lost. Patients do not use hot baths during this period for fear of increasing the flow, or, perhaps, bringing on severe hemorrhage. His conclusions on this account are interesting. He finds, as a result of 20 observations, that hot baths, taken during menstruation, do not increase the quantity of blood lost; on the contrary, they often diminish it. At the same time, they soothe the pain accompanying inflammatory affections of the genitals. They are, therefore, of real benefit, not only between the periods, but during the flow.

¹ Med. Press, Nov. 4, 1896.

² Med. Bull., Oct., 1896.

Houzel¹ states that most authors are in accord with the opinion that baths are contraindicated during the menstrual period. This opinion may be correct as regards the women of towns, but his personal observation has shown him that the robust and perfectly natural woman is not in a condition bordering on illness during this period. With her menstruation is a purely physiologic act, silently accomplished and accommodating itself to the fatigues and vicissitudes which the necessities of life impose upon her. *Sea-baths*, far from deranging, favor menstruation, prolong the period of sexual activity, and increase her fruitfulness. He has frequently been surprised to see the fisherwomen, poorly nourished, slightly clad, feet and limbs bare, wade into the sea up to the waist, and sometimes up to the armpits, remaining there for hours. In spring and summer, having filled their nets with shell-fish, they come out of the water, and with their wet clothing and the dripping net on their shoulder, traverse the town selling their fish. In the winter they may be seen, in coldest weather, with a heavy basket of mussels on their backs, from which the icy water constantly drops. Sometimes their clothes are completely frozen during menstruation, yet without causing any ill effects whatever. All this may seem surprising, and may by many be attributed to race and habit, but a study of sea-baths and their effect on the uterus easily explains it, and shows that all women, except those with grave lesions of the appendages, might imitate these fisherwomen to great advantage, provided they allow themselves time to receive the benefit of the sea-air and to become accustomed to sea-baths before going into the water during the menstrual period. Of 123 fisherwomen examined by Houzel puberty occurred on an average at the age of 13 years and 10 months, and the menopause at 49 years and 6 months—a difference in their favor, as regards the period of fecundity, of 3 years and 7 months over women not going into the sea. According to Raciborski,² the average period of sexual life of the Parisian woman is 31 years and 7 months. [The fear of bathing during menstruation is one of the teachings handed down to us for generations, and is purely fictitious. It is, however, so firmly educated into womankind that it will take a generation or two to remove it. There is no reason why any healthy woman should not bathe during menstruation, with proper precautions against subsequent cold. There is no reason why a woman should allow her person to go unclean at the time of all others it needs cleansing. This is just as true of town women as of country women.]

The Relation between Menstruation and Erysipelas.—Salvy,³ from a study of 810 cases, found a direct relation between menstruation and erysipelas in only 5.2%. In 1.62% menstruation could be regarded as a direct etiologic factor. In 57 cases of recurrent erysipelas only 3 were due to menstruation. Erysipelas has no appreciable influence on the duration and amount of the flow. On the contrary, menstruation favors the development of erysipelas through its influence on the nervous system. Recurrences during the flow are due to the peculiar nervous state of the patient and to the persistence of colonies of streptococci in the skin and lymph-spaces, whose virulence has not been entirely destroyed.

Precocious Menstruation.—Interesting cases are recorded by J. W. Irion⁴ and R. Howie.⁵ Irion's case was a baby that menstruated from birth, the flow returning with perfect regularity, and the child being in good health. The skin was fair and clear, the eyes bright and intelligent. The breasts and mons Veneris were considerably developed, and during the flow the breasts

⁵ Brit. Med. Jour., Sept. 12, 1896.

enlarged and were somewhat sensitive to the touch. The mother's menstrual period was established at the age of 13 years. Howie's case commenced to menstruate when 3 years and 14 days old. During menstruation the child complained of pain in the back, and was languid. The pubic hair was quite well grown, though short. The vulva was well formed and large, and the breasts prominent.

Sterility.—Ashby¹ concludes a paper on this subject as follows: the adjustment of the tube and ovary during ovulation is effected in the human female by the most delicate mechanical arrangement, and may be defeated by trivial mechanical interferences. In animals that habitually have multiple pregnancies a more perfect mechanical provision is made for the reception of the ovum by the tube. The number of ova impregnated seems to bear a close relation to the perfection of the arrangement which is provided for their passage into the tube. Thus, in the bird will be found the most perfect type of mechanical adjustment, in women, the most intricate and difficult. The adjustment of the pavilion of the tube to the ovary may be set aside by the most trivial vices of structure and disease, resulting in absolute or relative sterility. Sterility is due to minor diseases of the tubes and ovaries to a greater extent than has been recognized. In an investigation of the etiology of this condition this fact should be considered in connection with an investigation of other causative influences. The highest aim of surgery is to restore and not to destroy function. In the treatment of minor forms of ovarian and tubal disease this fact should be borne in mind. Organs should not be sacrificed to the rule of expediency, but should be preserved in deference to a law of genuine conservatism. Levy² calls attention to the tendency of both physician and patient to ascribe the cure of sterility to some particular method of treatment, either operative or nonoperative. He insists upon the necessity of examining the husband's semen before beginning any course of treatment, even when some obvious pathologic condition is found in the wife. The importance of the psychic factor must never be lost sight of. The assurance given to the patient that she is capable of conceiving may in itself serve to reconcile certain domestic obstacles. In any case the principle *nil nocere* should always be borne in mind, for in performing an operation for the cure of sterility the surgeon may substitute a pathologic for a normal condition.

The Menopause.—W. Armstrong³ calls attention to the frequency of utero-ovarian irritation at the time of the menopause as a factor in the causation of *rheumatoid arthritis*. This disease is much more common in women than in males, a careful analysis of 180 cases giving the following results: males 34, females 146. Of the latter, 120 suffered from uterine or ovarian derangements or change of function in nearly every case before the onset of the arthritis; and in the few instances in which it was not so, the onset of the pelvic irritation was followed by marked increase of the arthritic troubles. In 58 cases the symptoms came on at or immediately after the climacteric period, and in 62 cases there was distinct uterine or ovarian trouble. As regards treatment, there should be careful attention to uterine and ovarian lesions that may be present; remedies to allay nervous irritation are indicated, as are also general nerve-tonics, and hydrotherapeutic measures and massage, including electric baths.

Reinicke⁴ states that *climacteric hemorrhages* are due to arterial sclerosis, in consequence of which the vessels lose their muscular tone and are unable to contract, as they do normally at the time of the menstrual flow; hence the

¹ Brooklyn Med. Jour., Oct., 1896.

³ Brit. Gyn. Jour., xlv., 496, 1896.

² Frauenarzt, No. 11, 1896.

⁴ Arch. f. Gynäk., Bd. 52, H. 2, 1897.

menorrhagia which is so common at the menopause. When the hemorrhages persist in spite of repeated curettement and the administration of ergot (especially if the drug increases the flow), it is safe to infer that these vascular changes are present, especially if endometritis, neoplasms, and disease of the adnexa can be excluded. This diagnosis is confirmed if the uterine body is hard and arterial changes are noted in the extremities. Since these hemorrhages are due to sclerosis of the uterine arteries, no effect can be expected from the use of drugs or electricity—in fact, they are usually aggravated by ergot, which is apt to cause venous congestion rather than arterial anemia. Rest, strict regulation of diet, with the avoidance of alcohol, strong tea and coffee, and the use of laxatives are sufficient in mild cases. Curettement has been advised, but this operation simply opens up the mouths of numerous vessels which are unable to contract, and thus increases the flow. The cause of the hemorrhage is not in the mucosa, but in the muscular substance of the uterus. Dilatation of the cervical canal and intrauterine applications of Monsell's solution are preferable. In obstinate cases in which the patient is really in danger from repeated hemorrhages total extirpation is indicated, the results being quite satisfactory, while the mortality is only a little over 1%. Castration is not a sure means of relief. This radical treatment should be adopted earlier in the case of workingwomen who cannot rest during the flow.

[Among the most interesting and suggestive of the recent innovations in gynecology stands foremost *ovarian therapy* in the treatment of the phenomena of the menopause, induced or physiologic.]

M. F. Jayle¹ states that this consists in the administration of (1) the ovary in its natural condition; (2) ovarian powder obtained by desiccation or a glycerin-extract. The second in 2-gr. doses a quarter of an hour before the noon-day meal is preferred. The indications are against (1) the accidents provoked by castration; (2) certain ovarian lesions; (3) the normal menopause; and (4) Basedow's disease, osteomalacia, and the like. He concludes that (1) the ovary appears to be the source of an internal secretion which is useful to the economy of the woman. (2) This medication appears to be without danger. (3) It is followed by permanent success in the troubles provoked by the artificial menopause. (4) It appears that it can be used to advantage in the different symptoms due to an ovarian lesion (amenorrhea, dysmenorrhea, adiposis, chlorosis). (5) It seems to be useful in certain cases against the symptoms of the natural menopause. Stachow² gives an abstract of the mode of experimentation and the results attained by Mainzer, Chrobak, Mond, Krauer, and Fisher as regards animal ovarian preparations and organo-therapy. F. Mainzer³ used fresh ovarian substance from cows and calves. The patient had had the operation of bilateral oöphorectomy performed, and a few weeks afterward complained of flashes of heat, profuse sweating, also headache, poor appetite, and marked sensations of pressure in the occipital region preceding and during the early part of the menstrual period. Five to 20 gm. of ovarian substance were administered twice a day. The patient improved very much under this treatment; particularly did the attacks of flashes of heat and sweating become less frequent and severe. Chrobak⁴ applied the treatment in patients having exaggerated symptoms of the natural or induced menopause. He considered the treatment applied in two ways: (1) through transplantation of ovarian tissue; as in the experiments of Krauer, and (2) through the administration of ovarian tissue by the mouth. In a case (induced menopause through hysterectomy) he gave the fresh ovaries of the calf. He noticed no influence. In

¹ Presse méd., No. 71, p. 437, 1896.

² Monats. f. Geb. u. Gynäk., Bd. iv., II. 1, 1896.

³ Deutsch. med. Woch., No. 12, June 18, 1896.

⁴ Centralbl. f. Gynäk., No. 20, 1895.

7 other cases (because of severe symptoms during the natural menopause in 1 and the same symptoms in 6 in which the menopause had been induced) he employed pastels made from the dry ovarian substance (cow), each pastel containing 0.2 gm. In the case of the natural menopause and in 3 of the others all the symptoms were very much improved. The remaining 3 cases had not been observed sufficiently long to report results. The treatment causes no symptoms whatever. Mond¹ employed preparations made (tablets of 0.25 gm.—E. Merck) either from the entire ovarian substance, from the precipitate of the follicle-contents, or from the cortical substance of the ovary of the cow. His observations were on 11 patients from whom either part or all of the internal genitalia had been removed; or who complained of symptoms of the natural menopause, or of amenorrhea the result of atrophy of the genitalia, or in cases of rudimentary uterus with a hyperplasia of the ovaries. In 5 of these cases tablets made from the entire ovarian substance were given 3 times a day. The results were generally very encouraging, the symptoms being very much relieved. The urine remained normal. In 5 other cases 10 tablets made from the precipitate of the follicle-contents were given each day. Also in these cases the patient improved very much. In one case, in which the form of preparation is not stated, it was not surely determined that the treatment did good. Krauer² reports the following experimentation: he removed the ovaries from 4 rabbits, and then replaced them by suturing part in the mesentery of the horn of the uterus, and part was implanted between the fascia and muscle of the abdominal wall. In 3 of these rabbits at the postmortems, 3, 4, and 6 months after operation, ovarian tissue (proved microscopically) was still found in the mesentery of the horn of the uterus and in the abdominal wall. From this investigation Krauer comes to the following conclusions: (1) that in rabbits the ovaries can be removed and then transplanted in other than their normal position; (2) that they can be attached to peritoneum as well as implanted between muscle-fibers; (3) that the thus implanted ovary is nourished and continues its function. Fisher³ writes that from the literature and observation it is known that there exists a relationship between the thyroid gland and the genital apparatus in women. As a proof of this he refers to the greater frequency of thyroid disease in women. He then calls attention to the influence of the genital apparatus upon the healthy thyroid gland, as occurs at puberty, during menstruation, birth, the puerperium, lactation, sexual excitement, the menopause, and genital disease. He emphasizes the influence that the removal of part of the thyroid gland has upon the physiologic and pathologic conditions of the female genital apparatus and which investigators have attempted to explain by experimentation. He then considers the changes in the genital apparatus associated with or resulting from goiter, thyroidectomy, hyperthyresis, myxedema, cretinism, morbus Basedowii, and acromegaly. Fisher concludes (1) that certain occurrences influencing the genital apparatus (puberty, pregnancy, fibroid tumor) which cause a distinct change in the metabolism of the entire organism, very frequently cause an enlargement of the thyroid gland; (2) that the deficiency of the normal thyroid secretion (after thyroidectomy in myxedema, cretinism) is often associated with atrophic changes in the genital apparatus. Cheron⁴ holds that thyroid extract is an excellent remedy in threatened abortion with hemorrhage, and is valuable in preventing the arrest of uterine involution after childbirth, and that it is potent against the premature return of the monthly periods. Moreover, it is

¹ Münch. med. Woch., No. 14, 1896.

² Centralbl. f. Gynäk., No. 20, 1896.

³ Wien. med. Woch., Nos. 6 and 9, 1896.

⁴ Rev. méd.-chir. des Mal. des Femmes, Nov. 25 and Dec. 25, 1896.

a valuable galactagogue. Thyroid extract, in other words, stimulates the mammary secretion, whilst it lessens the functional activity of the uterus. In gynecology it has proved valuable in the control of all forms of uterine hemorrhage, whether this be due to endometritis, tumor, or lesions of the adnexa. The contraindications to the employment of the drug are: tuberculosis, since this seems to be stimulated rather than arrested. In heart-disease, even though thyroidin is strongly indicated, it should be administered with the utmost care, and should be stopped at once upon the first suggestion of tachycardia. The symptoms of thyroid-intoxication are tachycardia, oppression, exophthalmos, and irritability. In certain cases the drug produces rapid emaciation. Sometimes gastric vertigo has been observed. Because of the difficulty experienced in procuring the fresh gland and the repugnance which patients exhibit in consuming it, it is well to administer it in the dry form prepared by druggists—this may be obtained in tablets, pastilles or capsules—in doses of $1\frac{1}{2}$ gr. twice daily before meals. After a month there should be an interval of 8 days during which the drug is discontinued, followed by a 3 weeks' course of the medicine. If indications still exist for its employment, a rest of 2 weeks is given, followed by 2 weeks of the drug. Landau¹ has been employing organotherapy at his clinic for several months, as suggested originally by Mainzer, and subsequently by Mond and Chrobak. Cases were carefully selected, in order to control the experiments, with especial reference to the effect of the remedy upon the characteristic "hot flushes" so common at the menopause, both natural and artificial. The isolation of the active principle of ovarian tissue has not yet been effected. The writer believes that it is probably a nucleo-albumin, or perhaps an albuminous body like spermin. He used the ovaries of cows and pigs, dried at a temperature of 60° to 70° C. for 12 hours, then pulverized and made into tablets, each of which contained $7\frac{1}{2}$ gr. Although not prepared to present any positive results, the writer believes that the remedy does possess the power of modifying the unpleasant phenomena of the climacteric, whether physiologic or anticipated, without producing any evil effects, and deserves careful consideration.

Lissac² reviews the various phenomena noted in women after castration, which are more severe in young, neurotic females than in normal subjects who are near the menopause. These are flushing, psychic symptoms, congestions and hemorrhages, disturbances of nutrition, and modifications of the sexual passion. Flushing is a phenomenon that presents wide variations in regard to its appearance and severity. In some women it is noted only once a month, at the time when menstruation should occur; in others it may recur every half-hour or hour during the day or night. Sometimes the face alone is affected; sometimes the entire body seems to be congested and is covered with perspiration. The sensation of heat may be felt during sleep, the patient awaking in terror to find herself bathed in sweat. This symptom may persist for 10 or 15 years. Among the reflex symptoms are headache, insomnia, neuralgia, cardiopathies, and muscular asthenia. Marked changes in the disposition are common, such as irritability, loss of memory, and mental depression, which may persist for many years. Insanity is noted in a certain proportion of cases of castration. Among the congestive phenomena are the irregular uterine hemorrhages and vicarious bleeding from various organs. Increase in adipose has been generally observed, due to profound disturbance of nutrition of vasomotor origin and probable deficient oxidation. The apparent improvement in health, as evidenced by increase in weight, is often misleading. Sexual feelings are more or less changed in about one-half of

¹ Berlin. klin. Woch., No. 25, 1896.

² Gaz. hebdom. de Méd. et de Chir., Nov. 15, 1896.

the cases. The effect of administration of ovarian extract upon women after castration has been to modify, in many instances, the before-mentioned disturbances. In 16 cases thus treated by Jayle¹ the flushing was more or less relieved, but returned after cessation of the treatment. Crude ovarian tissue and ovarin were given by the mouth, and ovarian liquid was injected hypodermically. Ovarin was found to be most convenient, though it sometimes caused indigestion. The first effect noted in the case of highly neurotic subjects was that the insomnia from which they all suffered was relieved. Cephalalgia was generally relieved or cured, and many psychic symptoms were ameliorated, especially mental depression. In one instance marked genital hyperesthesia was notably relieved. In 4 cases uterine hemorrhages ceased under treatment. In general, nutrition was improved and the patients expressed themselves as feeling much better; but it must be admitted that the treatment should be continuous. [A careful consideration of this subject, both theoretic and from the reports, forces one to the conclusion that it is destined quickly to follow in the steps of the testicular injections urged several years ago with the object of renewing youth. The late P. T. Barnum is reputed to have said that "the people wanted to be fooled"—he fooled them and grew rich. There seems to be a considerable element of this kind in the medical profession.]

Atrophy of the Uterus following Castration.—Gottschalk² concludes that the atrophic changes seen in the uterus after the normal or artificial climacteric are due neither to the diminished blood-supply, nor to nerve-degeneration, as shown by experiments in animals. So long as healthy ovarian tissue is preserved the spermatic vessels on both sides may be ligated without causing atrophy of the uterus; in other words, while ovulation persists this change is absent. The normal size and consistence of the organ are due to periodic vasomotor paralysis. When ovulation ceases, normally or artificially, this periodic increase in the blood-supply does not occur, the vessels lose their tone, and general atrophy results. Gottschalk further states that after removal of the adnexa for disease due to gonorrhœal infection the endometrium in the specimens examined by him, as well as the mucosa lining the stumps of the tubes, showed no evidence of such disease. Even when a profuse uterine discharge persisted after castration it contained no specific micro-organisms.

Amenorrhœa and Chlorosis.—L. G. Baldwin³ reports a case of amenorrhœa due to complete occlusion of the os uteri following labor in a multipara of 33 years. There was no appreciable accumulation of blood in the uterine cavity, though the os was not dilated until 29 months after labor. Heim and Dalché⁴ laud the merit of ragwort as an emmenagogue. They say that groundsel (*Senecio vulgaris*) and ragwort (*S. Jacobæa*) have long been in popular use as emollients in England, and lately as emmenagogues. Two alkaloids, *senecïn* and *seniöcïn*, can be obtained from the plants. The authors, in experiments with extracts, have found that they have no definite effect on the sensory nerves. A small dose of ragwort diminishes the excitability of the motor system, and a large one produces effects like curare; the action of the heart is slowed by a small dose and arrested in systole by a large one. The extract caused no symptoms of gastrointestinal irritation or utero-ovarian congestion in animals. In trying its effects on 15 patients Dalché found reaction absent in 3, and doubtful in 3 others, but the results in the remaining 9 were excellent as regards dysmenorrhœa and amenorrhœa not depending on

¹ Loc. cit.

⁴ Soc. de Théor. Paris, June 24, 1896.

inflammation of the uterus or adnexa, but otherwise when these organs were affected. Pain was not directly modified. In the discussion Bolognesi stated that he had tried the effect of this drug in 20 cases, 14 cases being amenorrhœa from various causes and 6 dysmenorrhœa. He had found it a valuable emmenagogue, effective even in small doses and in cases of long standing. It brings on or regulates the catamenia, but must in some cases be repeated at the menstrual periods; it does not modify pain; but never aggravates the causal malady of the amenorrhœa, whatever that may be. In large doses it did seem to cause utero-ovarian congestion. Bardet insisted that the drug caused contraction of the muscular tissue of the genital organs, instancing a woman of 38 who some hours after taking the medicine suffered from nausea and such uterine contractions as resembled labor-pains; moreover, it had in a case which he related caused abortion. Blondel agreed as to the dangers of causing abortion; he had found potassium iodid an absolutely safe and effective emmenagogue. As to the etiology of amenorrhœa L. Garner¹ says that the normal menstrual flow depends upon the condition of the ovaries, uterus, and tubes; any disorder, either functional or organic, of these organs results usually in amenorrhœa. One of the most common causes of this disorder is the non-ripening of the ovules. Again, the menstrual flow may cease in consequence of chronic perioöphoritis, the ovaries being enclosed in a firm mass of exudate. The increased sexuality developed by constant association of young girls with men is largely accountable for amenorrhœa and dysmenorrhœa, but in most cases the causes may be traced to convalescence from typhoid fever, pneumonia, one of the acute exanthemata, tuberculosis, or generally defective hematosis. Gastric catarrh, fright, great anxiety—especially when of long duration—predispose to amenorrhœa. In the treatment of the condition Garner urges the use of apiolin.

The Treatment of Chlorosis with Ovarian Substance.—Spillmann and Etienne² state that the ovaries have the following functions: (1) ovulation; (2) through the menstrual hemorrhage organic toxin is removed from the body; (3) they are important in the general nourishment, similar to the testicles in man. If chlorosis is a disease of the ovaries, these functions must be disturbed; if the body is by any method supplied with ovarian substance, these functions must be restored. With this aim the writers have administered ovarian substance, as described by Brown-Séquard. After the first treatment the patients complained of pain in the lower abdomen, discomfort, headache, and muscular pain. Two had fever and rapid pulse. In three patients the result was good; the general health was improved, the anemia disappeared, the number of blood-corpuscles was increased, and the menses returned.

Menorrhagia and Metrorrhagia.—In treating of menorrhagia in virgins Laroyenne³ distinguishes the majority of cases of profuse menstruation in young girls, which require no local treatment, from a minority in which the use of the curet is advisable. If after long attention to hygiene and a course of suitable tonics menorrhagia persists, interrupted by occasional amenorrhœa, granular or fungous endometritis probably exists. This disease is yet more safely diagnosed when the patient has been perfectly healthy and quite free from anemia before profuse menorrhagia appeared, and equally free from evidence of diseased appendages after the local symptoms become marked. When the excessive menstruation causes debility it is right to dilate and use the curet. A single application (immediately after the scraping) of cotton-

² Gaz. méd. de Paris, No. 35, 1896.

³ Lyon méd., June 28, 1896.

wool soaked in equal parts of water and zinc chlorid is sufficient. Repeated cauterizations may easily cause atresia.

G. Foy¹ extols the value of digitalis in menorrhagia; he uses the infusion in half-ounce doses every 3 hours until 8 doses have been taken. He has used the drug in 8 cases with excellent results.

Dysmenorrhœa.—A discussion on dysmenorrhœa is reported in the *Brit. Med. Jour.*, Oct. 24, 1896. M. Cameron regards the spasmodic variety as by far the most common. For its relief rapid dilatation is preferable. C. Martin states the causes of dysmenorrhœa as extrauterine and intrauterine. The treatment differs markedly in the two classes of cases, and what would relieve in the one would be worse than useless in the other. Three factors are concerned in the production of the pain of dysmenorrhœa: (a) contraction of the muscular fibers of the uterus or Fallopian tubes; (b) increased spasm or blood-pressure in the tissues of the uterus or its appendages—congestion; (c) neuralgia of the uterus or the appendages. Nearly all cases are benefited by rest at the periods, hot vaginal douches during and between the periods, and, in inflammatory cases, tampons of glycerin and ichthyol, and saline aperients. The drugs he has found most useful are bromids, belladonna, antipyrin, and cannabis indica (in the form of suppositories); both viburnum prunifolium and viburnum opulus are excellent ovarian and uterine sedatives. In cases of dysmenorrhœa due to chronic pelvic peritonitis binding down and matting together the uterus, ovaries, and tubes, he recommends conservative operations on the appendages. I. Parsons said that a great many cases occurred in anemic young women, and full doses of iron would cure the anemia, and with it the dysmenorrhœa. J. D. Williams believes that the pain of so-called obstructive dysmenorrhœa is probably due to irregular abnormal contractions, set up by a diseased condition of the mucous membrane at the seat of flexure. A. Routh in spasmodic dysmenorrhœa first treats the constipation, the anemia, or other constitutional state, and then, if need be, examines by the rectum, and if the perimetrium be involved or the ovary enlarged, their state is attended to. As a rule, antispasmodics are very beneficial; the best of these is phenacetin (gr. x) in cachets, antipyrin, and nitroglycerin. J. Connel drew attention to the fact that in sterile married women prescription of abstinence from marital relations for a longer or shorter time, followed by free dilatation immediately before their resumption, would often prove successful in curing dysmenorrhœa. He believes in the advantages of cycling, and if growing girls, especially when anemic, were systematically encouraged to practise that exercise in moderation, there would be much less spasmodic dysmenorrhœa. G. R. Cadell thought that dysmenorrhœa seldom occurred at puberty except in cases of infantile uterus, and that it was often due to some cold or over-exertion, easily cured if taken in time, but, if neglected, extremely intractable. In conclusion, Cameron referred to the marked increase of dysmenorrhœa resulting from the too common custom of using preventives against conception. For the form of dysmenorrhœa occurring at or soon after puberty J. E. Langstaff² injects 10 minims of a 3% mixture of Churchill's tincture of iodine and water into the uterine cavity every 4 or 5 days during the intermenstrual period. This allows about 3 treatments, beginning about 5 days after the flow has ceased and giving the last treatment about 5 days before the next period begins. In cases of dysmenorrhœa complicated by pelvic inflammation or by diseases of the ovaries or tubes this treatment is of no value.

UTERINE ANOMALIES.

Interesting cases of **congenital defects** of the female generative organs are recorded by P. J. McCann,¹ Chavannaz,² J. W. Leech,³ R. B. Hall,⁴ F. Edge,⁵ J. Ramage,⁶ and W. L. Burrage.⁷ McCann remarks that in reality a so-called malformation is a non-formation of one part involving a relative disproportion. Malformations represent stages of development that have remained permanent. Before an organ has reached the mature or fully developed state, we are enabled to distinguish two processes at work—namely, development and growth. The period of development in the uterus extends up to the time of puberty; the period of growth is much longer, probably lasting until the 20th year. He records a case of rudimentary vagina and uterus, the former measuring $1\frac{1}{2}$ in., and the uterus $1\frac{1}{4}$ in.; there was an associated hernia of the left ovary into the inguinal region. He also reports a case of entire absence of all generative organs, vagina included; the pubic hair was normally developed. He remarks that, owing to their distinct origin, ovaries may be present in the absence of the uterus and vagina. Uterine defects may be grouped as follows: 1. Cases in which no uterus is present, the vagina being a cul-de-sac. 2. Cases in which, at the blind end of the vagina, a nodule is found occupying a central position; this nodule has no canal in its interior. 3. Cases in which the nodule previously mentioned forms the lower portion of a small central body admitting the point of a probe. 4. Cases in which the probe can be passed for a distance of $\frac{1}{2}$ to $\frac{3}{4}$ in. into a body, cord-like or spindle-shaped, occupying a position corresponding to the normal uterus. The last group forms a transitional stage preliminary to what is called the *infantile uterus*, which may persist throughout adult life, and is the normal condition in the female child at full term.

As regards general development, patients exhibiting abnormalities of the genital apparatus may be divided into 3 types: masculine, feminine, and infantile. 1. *The Masculine Type*.—Here there is an approach to the characters distinctive of the male sex. A growth of hair on the upper lip, chin, and cheeks may exist; the voice is masculine; the breasts resemble those of the male sex; nevertheless, well-developed mammary glands are frequently noted. Hair around the nipples is occasionally seen. The pubic hair is continued up the linea alba to the umbilicus, thus resembling the distribution in the male. The shoulders are broad, and the pelvis corresponds to the masculine type. These characters, although possessed by certain females whose genital organs are abnormally formed, are also found when the genitalia are well formed. Many females of the masculine type (with well-formed genitals) bear children despite the popular belief to the contrary. 2. *The Feminine Type*.—Under this head are included those cases in which in appearance and general development there is no departure from that of the human female excepting the abnormality of the genital organs. 3. *The Infantile Type*.—The characters of this type resemble those of the infant, hence the name. There is frequently feeble general development, with smallness of stature. The breasts are poorly developed; the axillary hair is absent, also the hair covering the pubis; the pelvis is small. Burrage records a case of congenital absence of the uterus and vagina in which a plastic operation for artificial vagina was performed, the flaps being taken from the nymphæ and perineum.

¹ Am. Jour. Med. Sci., Oct., 1896.² Jour. de Méd. de Bordeaux, No. 32, 1896.³ Brit. Med. Jour., Oct. 10, 1896.⁴ St. Louis M. and S. Jour., Apr., 1897.⁵ Brit. Med. Jour. Oct. 31, 1896.⁶ Lancet, Dec. 12, 1896.⁷ Am. Jour. Med. Sci., Mar., 1897.

Burrage has collected references to 360 cases of absence of the uterus reported by 239 authors from earliest times up to the present; roughly speaking, about 300 cases in the last century. In this number there were but 35 autopsies, 24 of which were on the bodies of adults, 2 on girls 10 and 12 years old respectively, the rest being on monstrosities and fetuses with absence of other organs, making prolonged life impossible. In all of the autopsies on the bodies of adults and girls there were noted in every case rudimentary tissues representing the uterus, generally one or two little knobs of tissue the size of hazelnuts or a thin band between the rectum and bladder. The ovaries were found to be present in all the cases but 6; the tubes were present in all cases except 6, though often without any canal.

The derivation of the hymen is still in dispute. It was formerly held to be formed from the lower end of the vagina, but the many cases of absence of the uterus and vagina in which a well-formed hymen exists would seem to disprove this view. So, also, the absence of smooth muscular fibers in the hymen would tend to show its anatomic dissimilarity to the vagina. Pozzi holds that the hymen is developed entirely distinct from the vagina, and is derived from the urogenital sinus. He accounts for the prolongation of the rugæ and pillars of the vagina on to its posterior aspect as a later developmental change. He thinks that complete atresia of the hymen is generally due to a terminal imperforation of the vagina. It is known that the hymen develops late in fetal life—the nineteenth week, and there seems every reason to believe that it is formed from the same embryonic structure as the vestibular vagina—namely, the urogenital sinus. Ramage reports a case of congenital absence of the ovaries with a rudimentary uterus in a woman of 23 years, who had never menstruated. The uterus measured $1\frac{1}{4}$ in. Edge's case was one of uterus bicornis septus in a woman of 34 years. Leech's patient presented a complete absence of the vagina and uterus. Hall's case was one of double uterus with congenital closure of one cervix, the uterus being distended with menstrual fluid.

UTERINE INFLAMMATION.

Significance of Pelvic Pain.—Dolèris and Pichevin¹ conclude an article on this subject with practical deductions concerning the clinical significance of various pains referred to the pelvis. In *acute metritis* the pain is deep-seated, diffuse, and radiates toward the loins, hips, and hypogastrium. It is principally intrapelvic and is accompanied by vesical and rectal tenesmus. It is most severe in *acute endometritis*, being least in the puerperal form. The pain, however, is only agonizing when the adnexa, peritoneum, or parametrium are inflamed. *Chronic metritis* is characterized by attacks of uterine colic, mostly confined to the menstrual period. In these cases traction on the cervix gives rise to lumbar pains due to stretching of the sacrouterine ligaments. The *pains in retroversion* are of several different types. If complicated by adhesions and disease of the adnexa, the pain is characteristic of these conditions. When retrouterine exudates are present the pain is less severe, except when attempts at replacement are made. It usually radiates toward the rectum, and is often accompanied by severe tenesmus, especially during defecation; this is quite pathognomonic. In simple retroversion the pain may be in the uterus, at the base of the broad ligaments, and in the neighboring organs. The posterior surface of the organ at the fundus is the seat of greatest tenderness, which is to be distinguished by palpation from that caused by pressure of a

¹ La Gynéc., No. 6, 1896.

prolapsed ovary or tube. Lumbar and inguinal pains are often present, due to traction on the sacrouterine and round ligaments. The characteristic pain in *prolapsus uteri* is lumbosacral, from traction on the sacrouterine ligaments, to which are often added painful sensations in the flanks due to dragging on the broad ligaments, and also in the epigastrium from ptosis of the abdominal viscera. Vesical tenesmus is more constant than in retroversion; but rectal tenesmus, on the contrary, is absent. *Carcinoma of the corpus uteri* is often painless until the perimetrial tissues have been invaded. Attacks of uterine colic are characteristic of corporeal, as contrasted with cervical malignant disease. *Rapidly growing fibroids* are attended with more pain than are those that develop slowly. Cystic degeneration increases the pain, which is also most marked in connection with multiple growths within the muscular wall of the uterus. The pains are aggravated by the menopause and often disappear temporarily or permanently after the climacteric. Complications—disease of the adnexa, adhesions, and the like—aggravate the distressing symptoms. The painful sensations due to pressure are readily explained. *Cirrhotic ovaries* are most painful, especially when adherent. Attention has often been called to the intermenstrual pain caused by this condition. When both ovaries are diseased the pain often alternates, being on one side in one month, and on the opposite side the following month. The pain in *chronic salpingitis* is twofold, and is due, first, to traction on the nerves within the tube; and, secondly, to distention of the tubal wall, especially during menstruation. The mere presence of adhesions is not sufficient to explain the pain in these cases; the occurrence of an actual infective inflammation is necessary. Pain due to tubal disease is aggravated at the menstrual periods, but the intermenstrual pain noted in ovarian trouble is absent. The pain in *salpingo-oöphoritis* is referred to the lower abdomen and to the affected side, being deep seated and increased by direct palpation. It is usually paroxysmal and lancinating during exacerbations, dull and heavy during the interval between the acute attacks. It is often entirely out of proportion to the extent of the lesions; the amount of displacement of the affected organs rather than the size of the inflammatory mass seems to govern the severity of the pain. [This ingenious attempt to refer certain distinct pelvic pains to recognized pathologic conditions shows keen observation and analysis. Practically, there are so many exceptions to the rules laid down by the writers that they must be regarded as suggestive rather than positive. They are absolutely worthless for diagnostic purposes; in fact, they are dangerous in that they would in 90% of cases lead astray anyone placing dependence upon them.]

The Condition of the Endometrium following Castration.—

Eekardt¹ calls attention to the fact that, while the condition of atrophy of the endometrium following the menopause has been carefully studied, little attention has been paid to the similar atrophy after removal of the ovaries. The difficulty of obtaining suitable specimens from the human subject has compelled investigators to study the subject experimentally in animals. Krukenberg found that in the uteri of rabbits examined 9 or 10 months after castration there were marked atrophy and fatty degeneration of the uterus, with disappearance of the ciliated epithelium. Eekardt had the opportunity of examining a uterus removed from a woman, aged 43 years, whose ovaries had been extirpated 2 years before; transverse section through the organ showed that the endometrium was poor in cells, the ciliated being replaced by cubic epithelium with granular nuclei. In some cases the epithelial was directly continuous with the muscular layer, while in others the mucosa was

¹ Centrabl. f. Gynäk., No. 30, 1896.

$\frac{1}{2}$ mm. in thickness. The glands were small and often cystic, rarely without external openings; a few were seen in the muscular layer. The latter was atrophied, with an increase in the connective tissue. Neither fatty degeneration nor round-cell infiltration was observed. The openings of the tubes were obliterated. The writer summarizes as follows: the endometrium of the human uterus after castration undergoes retrograde changes, as in senile atrophy, which are indicated by disappearance of the ciliated epithelium, atrophy of the interglandular cells, and destruction or cystic degeneration of the glands.

Classification and Etiology of Endometritis.—Döderlein¹ says that the hitherto general belief that inflammations of the uterus are divided into metritis and endometritis can no longer be considered correct, since it has been shown that the uterus is always diseased *in toto*. The causes of metro-endometritis are very numerous. Up to the present time they can only be separated into 2 chief groups: such inflammations as are caused by the introduction of microorganisms—therefore infectious—and those in which there is no bacteric influence. To the first group belong the septic and saprophytic, gonorrhœal, tuberculous, syphilitic, and diphtheritic endometritis. That there is an endometritis that results from fungi or amœbæ, the writer believes is not proved. The second group can have its origin in diseases of the tubes and ovaries, in the tumorous growths (fibroid and carcinoma), in nervous irritation and circulatory disturbances, in anomalies in the development of the ovum, or in puerperal subinvolution. From the microscopic anatomic characteristics of the various forms of endometritis nothing definite can be gained regarding their separate causes. It is, however, proved that interstitial endometritis is caused only by infection, and the glandular and hyperplastic forms through various other uterine inflammations.

Pinkuss,² from a very exact study of 115 cases, separates the benign changes of the uterine mucous membrane into glandular (24 cases) and interstitial hyperplasia (91 cases). These two changes, however, may be combined in the same mucous membrane. The pure glandular hyperplasia is never caused by inflammation, but through indirect irritation, due to circulatory disturbance. Such irritation is associated with nervohysteria, arises from masturbation or impotence, or is oöphorogenic in origin. Interstitial endometritis is always due to previous infection. Glandular hyperplasia of the endometrium is found in cases of true dysmenorrhœa, particularly in those in which there is a mucous discharge, or in which the periods are long delayed and the menstrual hemorrhage slight. Interstitial endometritis causes purulent leukorrhœa, which may be associated with hemorrhage. Atrophy of the endometrium is associated with atypical, profuse hemorrhage without leukorrhœa.

Heuck,³ from a microscopic study of portions of endometrial tissue removed by the curet from 70 women, comes to the following conclusions: (1) That except when there exist new-growths or adnexal disease a very important and frequent cause of endometritis is the presence of long-retained portions of chorion and decidua. (2) In cases of long-continued hemorrhage following abortion almost always endometritic processes are to be found, and usually the endometritis is diffuse. (3) In the greater number of cases of hemorrhage after abortion the endometritis antedates the pregnancy. (4) The determination of the presence of chorionic villi is not always possible and not always necessary to prove the etiologic relation between hemorrhage and abortion. (5) In a few cases in which there is a history of hemorrhage and abortion the microscope alone cannot determine a diagnosis. (6) Metrorrhagia is observed

¹ Centrallbl. f. Gynäk., No. 45, 1896.

² Zeit. f. Geb. u. Gynäk., Bd. xxxiii., H. 2.

³ Centrallbl. f. Gynäk., No. 6, 1897.

both after abortion and when a small portion of chorion or decidua has been retained. (7) In a very large number of cases of hemorrhage after abortion giant cells are to be found for a long time, but they are of no particular pathologic importance.

Gottschalk and Immerwahr¹ have studied the bacteria contained in the female genital canal with special reference to their relations to endometritis. They made bacteriologic examinations in 60 cases of corporeal endometritis. In 21 cases the secretion from the uterine cavity was free from bacteria. In $\frac{2}{3}$ of these cases the secretion was sterile for many months. In 7 cases bacteria were found during the treatment; but they were not pathogenic, and only a few colonies were seen upon the plates; the greater number of these were fungoid endometritis. In 7 other cases (11% primarily) at the first examination staphylococci were found. Two of these, they conclude, were a particular form of purulent endometritis, since the organism was the staphylococcus pyogenes albus, the pus clinically had a bad odor, and the secretion was now and then bloody—the symptoms thereby having a great similarity to those of gonorrhœa. In 4 of the cases the staphylococci were found secondarily, immediately after an acute gonorrhœal endometritis. In the remaining 28 cases, which were a chronic catarrhal form of disease, the microorganisms found were not pathogenic; they are known as skin-fungi, since they are found on the skin of the perineum, in the pubic hairs, and in the vulva. Their inflammatory action is explained through their chemotactic influence upon the circulation. If, therefore, diplococci, short bacilli, sarcinae, and saccharomyces are not found as the primary cause of the inflammation, they can secondarily cause extensive inflammation of the mucosa. Contrary to the investigations of others, the writers found that the bacteria disappeared during menstruation. They, however, explain that this was probably the result of the washing and disinfectant vaginal douching which is their routine treatment during the menstrual period. In 2 cases of endometritis exfoliativa, and in 2 of endometritis hæmorrhagica, occurring as a result of influenza, a bacteriologic examination gave negative results.

Virginal Endometritis.—This condition is discussed by P. F. Mundé² and E. A. Benn.³ Mundé claims that this form of chronic endometritis is undoubtedly of frequent occurrence. As a result of this condition the lips of the external os become so widely separated by the growth of the endocervical mucosa as to present a condition almost identical with that found after well-marked puerperal laceration of the cervix. He suggests that this might be the true etiology of the so-called congenital laceration of the cervix of Leopold, Ahlfeld, Fischel, and Penrose. In some of these cases there is present a profuse, thick, yellow leukorrhœal discharge, associated with marked menorrhagia. The curet in these cases may remove an abundant quantity of adenoid vegetations, which would account for the profuse hemorrhages. The treatment consists in excising the hypertrophic cervical mucosa, curetting the whole of the endometrium with the blunt, and the cervical canal with the sharp instrument, and, if the eversion is thought sufficient, of paring the lips and uniting them with silver sutures, precisely as is done for puerperal laceration. After-treatment by intrauterine alteratives may be necessary to effect a permanent cure, as would be the case in ordinary endometritis. According to Latour,⁴ endometritis fungosa may sometimes be found in virgins. The clinical symptoms do not differ from those seen during the sexual life of women—fungoid growth

¹ Arch. f. Gynäk., Bd. 50, H. 3, 1896.

² Chicago Med. Rec., Sept., 1896.

³ Physician and Surgeon, Mar., 1897.

⁴ Rev. Internat. de Méd. et Chir. prat., No. 18, 1896.

of the endometrium and profuse menstrual hemorrhage. The first characteristic symptoms appear with the first menstruation. Infection with microorganisms, masturbation, and traumatism are, he believes, etiologic factors. The treatment should be ergot, hydrastis canadensis, and hot-water douching. Ordinarily no operation is required, but one should not wait too long before resorting to dilatation, curettement, and the application of zinc chlorid. [The tendency to interfere in virgins is already too great, and the utmost caution should be practised in selecting cases, all doubtful cases being considered non-operative.]

Senile Endometritis.—In speaking of postlimacteric endometritis Mundé¹ remarks that he has for many years noticed that women who have passed the change of life were subject to a certain extent to a disagreeable mucoserous, pungent discharge which in course of time brought about an erosion of the lips of the cervix and of the vaginal vault, and a chronic vulvovaginitis. His explanation of these cases was that, the pelvic organs having undergone a gradual atrophy after the menopause, the nutrition of the various tissues was insufficient, and in consequence there was a breaking-down of the cell-elements in the uterine mucosa and in the vagina, and a serous discharge was the result. He found that not only women who had passed the natural menopause, but also those in whom that condition had been artificially brought on by the removal of the uterine appendages, were subject to senile endometritis. In some of these cases the discharge may become bloody, brown or blackish, and yet careful curettage and microscopic examination fail to show any signs of malignancy. The treatment consists in the use of the curet, caustics, chiefly nitric acid, followed by a solution of silver nitrate and drainage; and, finally, when the erosion has healed, a contraction of the secreting surface by the frequent application of iodoform and tannin powder. G. E. Herman² remarks that the pain in this disease may be so severe as to keep the patient awake at night; there is also sometimes noted wasting. There is little or no tendency to spontaneous cure. If the usual treatment fails, hysterectomy should be performed. [Before such advice is acted upon the opinion of one or more experts should be received in each individual case.] S. E. Sheldon³ remarks that the skin in many cases is dry, harsh, and shrivelled, with the peculiar sallow appearance that indicates malignant trouble. The physical signs as shown by inspection are usually more or less vaginitis and redness of the cervix without much erosion or ulceration; the absence of the epithelium, Nabothian glands, and follicles gives the mucosa a smooth, glistening appearance more like fibrous or cicatricial tissue.

Endometritis Decidua Polyposa et Tuberosa.—Bulius⁴ reports the case of a primipara, aged 21 years, who gave birth to a dead child in Feb., 1895, and suffered for 6 weeks after with a continuous discharge of blood. The menses then were regular till September. In the beginning of December she again suffered from hemorrhage, and on the 7th experienced pains similar to those of labor, which were accompanied with the expulsion of clots and shreds. Included among these were a fragment of decidua and an ovum surrounded with reflexa. The curet removed more decidua, after which she made a good recovery. Bulius regards the case as one doubtless of hyperplasia of the decidua vera, which was expelled as an almost quadrangular patch, 6 cm. broad and 11 cm. long.

Endometritis Chronica Malignans.—Under this name J. M. Van

¹ Rev. Internat. de Méd. et Chir. prat., No. 18, 1896.

² Treatment, Mar. 11, 1897.

³ Medicine, Apr., 1897.

⁴ Münch. med. Woch., p. 537, 1896.

Cott¹ describes a condition characterized by profuse proliferation of gland-structure, together with a multiplication of capillaries in the endometrium. There is a superficial proliferation merely, and the growth is limited to the tissues of the endometrium. He says that pathologic conditions of the endometrium must be classed under 2 general heads: 1, correlation; 2, coalescence. The former concerns those changes that occur in the form and relation to each other of the component elements of the endometrium. The latter those changes whereby the part has failed of complete development during intrauterine gestation, being fused together or with other tissues. The lesion under consideration is one of correlation. Correlation is a term that embraces two principal conditions in pathology: 1, development in excess—hyperplasia; 2, regressive changes—atrophy. These two conditions are often associated in such a manner that one portion of a complex tissue may be the seat of progressive changes that occur either at the expense of other portions of the same tissue, thus producing atrophy of its elements, or synchronously with primary atrophy. Hyperplastic changes in the endometrium frequently originate as a result of primary inflammatory changes, and it is probable that what may have originated as a simple inflammation may assume all the form of malignancy, and eventually destroy even life itself. True hyperplasiae endometria, which have lost the characteristics of inflammation, result in multiplication of the gland-elements, or the stroma, or both together, in which latter case the lesion is either a total diffuse hyperplasia, or circumscribed diffuse hyperplasia—polypus. When the glands alone are the seat of the hyperplastic process the stroma often almost totally disappears, giving to the mass an appearance which microscopically resembles closely those new-formations which must be regarded as true neoplasms. The diagnosis between the malignant and non-malignant condition is difficult, and Van Cott regards it the lesser of two evils to remove a uterus in which simple hyperplasia glandularum existed than to leave unoperated upon a uterus in which are the elements of malignancy. There seems to be general agreement that originally harmless glandular hyperplasiae may retrograde into more lawless growths,—*i. e.*, adenomata. The malignant endometritis has continuous growth and is never metastatic; therefore, it is positively susceptible of radical cure as long as it remains within the confines of the corpus uteri. The uterus is regularly enlarged, somewhat globular, and a trifle soft in consistence.

Treatment of Endometritis.—[The treatment of chronic inflammations of the uterine cavity may be said to include 3 methods of procedure, namely, douching by the vagina and the uterine cavity, topical applications to the endometrium, and curettage and uterine drainage.] As regards hot vaginal douching A. E. Giles² remarks that it should be regarded as a temporary measure merely, in order to avoid chronic pelvic congestion which will follow a long continuation of hot douching; as the symptoms improve it should be replaced by tepid, cool, and even cold irrigations. The fluids to be used for vaginal douching fall into 3 categories: 1. *Neutral or aseptic solutions*: of these, the first is plain or sterilized water. 2. *Mild antiseptic solutions*: among these we may mention boracic acid or borax, zinc sulphocarbonate, carbolic acid, tincture of iodin, Condy's fluid, kreosol, lysol, mercuric chlorid or biniodid, or chinisol. 3. *Powerful antiseptics*: these are required after operations, in obstetric practice, under septic conditions, and in the treatment of gonorrhœa and septic conditions of the vagina and uterus. The most important are: carbolic acid, iodin liniment, mercuric chlorid, and chinisol.

¹ Brooklyn Med. Jour., Sept., 1896.

² Lancet, May 15, 1897.

In giving hot water vaginal injections J. H. Burtenshaw¹ suggests the following rules: 1. Use a large-sized fountain-syringe, preferably one holding 4 quarts, attached to a support 3 or 4 feet above the body. 2. The patient should always lie upon the back with the hips slightly elevated and the shoulders depressed. 3. Use at least 3 gallons of water as hot as can be borne—at a temperature of 110° F. 4. Give the injection twice daily, morning and evening, except on the 2 days preceding and the 2 days following the menstrual flow.

Breslau² has made a study of the antibacterial action of ointments with particular reference to the value of their constituents as disinfectants. He refers to the work of the Neisser school upon this subject, and the fact, determined by Koch, that carbolic acid in oil is worthless. He says that carbolized oil is now rarely used in obstetrics or by practising physicians. He believes, however, that a combined ointment and disinfectant is often wished for. He concludes that a 1 : 1000 bichlorid lanolin is the most effective disinfectant ointment. Two remedies that have been attracting considerable attention in gynecology are irol and formol. *Irol* has been employed by Högler in more than 2000 cases in the form of powder, gauze, vaselin, colloidion, and emulsion. It has been found especially efficacious in the treatment of ulcers and boils. *Formol* is powerfully antiseptic and non-toxic. Legen and Levy state that they have obtained excellent results from these medicaments in the treatment of blennorrhagia. The usefulness of solid glycerin ovules of irol, formol, dermol, aristol, iodol, di-iodoform, ichthyol, microscidin, and thiol commends itself at once to all those whose line of work brings to them many cases of infection of the genital tract. [These form but a few of the innumerable drugs forced on the profession by drug-houses and too-willingly convinced physicians. They are one and all useless for practical work.]

In old inflammatory processes of the genitalia Grammaticatis³ injects daily into the uterus by means of a Braun syringe a gram of the following liquid: alumnol, 2.5 gm.; tincture of iodine and alcohol, each 25 gm. Each case requires about 40 injections, which should be continued, although the first few injections are followed by a serosanguinous discharge from the uterus. The author has made over 3000 injections without an accident of any kind. The injections, he claims, are indicated in all acute or chronic inflammations of the uterus, adnexa, or pelvic peritoneum. They give the best result in acute cases. The temperature falls, the pain disappears, and resorption takes place rapidly. In cases of pyosalpinx the injections modify the condition of the adnexa so that an operation is performed much more easily and there is no danger of a recurrence. The injections cure completely chronic perimetritis, and the secondary complications, such as retroflexion, are relieved more easily. They also cure the most rebellious cases of endometritis. [It is such tampering as this, especially in acute cases, that causes many subsequent operations, and in no possible manner can it render the operation easier as stated. To follow the author's advice will be to set up many an attack of acute pelvic peritonitis, if not worse.] Sordes⁴ recommends the use of vapors medicated with resorcin in the treatment of endometritis. He claims excellent results from their use.

R. C. Norris⁵ treats upon the indications, dangers, and technic of uterine

curettage. The indications he groups as follows: A. Curettage of the puerperal uterus: (a) incomplete abortion; (b) puerperal sepsis after labor at term; (c) subinvolution. B. Curettage of the uterus uninfluenced by or remote from the puerperal period: (1) Uterine hemorrhages: (a) polypoid or fungous endometritis, (b) uterine fibromyomata, (c) malignant diseases (diagnostic and therapeutic uses); (2) uterine discharges (purulent or mucopurulent): (a) acute septic or gonorrhœal endometritis, (b) chronic septic or gonorrhœal endometritis, with or without tubal and ovarian inflammation; (3) dysmenorrhœa and sterility. He states that the curet accomplishes the best results in puerperal sepsis only when it is used early and thoroughly. Clean obstetrics will almost banish the curet from the obstetric bag and from the lying-in hospital. In subinvolution the results of curettage are always brilliant if, when required, mechanical or surgical measures are utilized to correct displacement and to give support to the uterus. The usefulness of the curet decreases in direct proportion to delay. In exfoliative or membranous dysmenorrhœa the curet affords the only method of treatment of value [and even it fails, as a rule]. A. Donald¹ insists upon the employment of the flushing curet, a modification of which he has devised.

J. W. Boycé² believes that curettage is often a valuable alternative for abdominal section. If pus be present in the adnexa or other surrounding parts, it would be dangerous to curet and leave the pus. If adhesions exist between the uterus and adjacent structures, or if large intrauterine or submucous fibroids be present, curettage is hazardous, on account of the danger of subsequent sepsis. J. D. Emmet³ remarks that this operation is universally recognized as the best and most efficient agent at our command for the cure of the acute onset of every form of sepsis, for retained placental and other post-partum remains, and for the relief of inoperable carcinoma. As regards packing and draining the uterus after curettage, he believes the two procedures are practically contradictory. If the uterus be properly packed, it cannot properly drain. [The author is evidently at fault: the uterus packed with gauze will most assuredly be drained by capillary action; in addition, the pressure of the packing will in great part eliminate the throwing out of the serum to be drained.] Only in those conditions that are the immediate effects of the puerperium, in septicemia from traumatism, or in conditions of specific inflammation by continuity, as in gonorrhœa, is drainage indicated. He would also drain in simple uncomplicated endometritis. In all other cases in which he curets he does so in order to change the character of the endometrium and to enable its glandular structure to recover its normal anatomic and functional condition; secondly, in order to effect a local bloodletting for its immediate effect upon the periuterine circulation; thirdly, he packs the uterus (after thoroughly removing all debris and applying a powerful styptic), in order to produce a counterirritant effect upon the endometrium itself and upon the pelvic circulation outside the uterus. For drainage to be effectual, according to J. H. Richmiller,⁴ it must afford a ready exit for the secreted material, and so prevent reabsorption. He recognizes the fallacy of packing the uterine cavity in aseptic cases that have no functional disturbances. Experience has demonstrated that *the average temperature after curettage is lower without than with gauze-packing*. [This statement is somewhat puzzling, as after curettage and packing, *properly* performed, there is practically no temperature other than the normal in the vast majority of cases.] In tamponing, the uterus is stimulated to contraction, tending to expel the gauze through the cervical canal,

¹ Brit. Med. Jour., Nov. 21, 1896.

² Va. Med. Semi-monthly, Dec. 11, 1896.

³ Am. Gyn. and Obst. Jour., May, 1897.

⁴ Ibid., Oct., 1896.

and by so doing it presses the gauze over the internal os, forming a plug, which dams back the secretions. The wedge of gauze is always covered with a thick, tenacious mucus, tinged with blood, which resembles uterine catarrhal secretion. This mucus is the result of uterine irritation and inflammation, kindled by the presence of a foreign body. The meshes of the gauze become occluded, and drainage cannot take place; the retained secretions are forced back into the Fallopian tubes, lymphatic sinuses, and blood-vessels, and as a result salpingitis or pyosalpinx develops. *More cases of pyosalpinx are produced from the injudicious use of uterine gauze-tamponade than from the use of the curet.* [These statements *in toto* are absolutely unsupported by facts.] Firm uterine tamponade, on the contrary, is indicated in sterility depending upon flexion of the uterus, in uterine hemorrhage when the muscular walls are flabby and inert, and in some cases with sluggish circulation of the pelvic viscera. The absorption of parametritic exudation is favored by thorough tamponade; likewise phlegmatic nodulations in the broad ligaments, and boggy congestions immediately involving the surrounding structures of the uterus. Capillary drainage, according to R. R. Kime,¹ may be secured by gauze or wicking tubes, or by the use of soft-rubber, hard-rubber, or aluminum drainage-tubes. The strip of gauze drains for a few hours only; the uterine drainage-tube is more efficient. H. Rothstein² says that the best time to introduce the tube is about 4 days after the termination of menstruation. The nearer to the termination of a catamenial period the better, as it permits of letting the tube remain longer in the cervix, and consequently favors obtaining a better result. The tube should not remain *in situ* for a longer period of time than 10 days. It may then be removed and reintroduced within a day or two.

UTERINE DISPLACEMENTS.

Anteflexion of the Uterus.—B. Gordon³ has devised a stem-pessary made of brass gold-plated. It can be sterilized by boiling and can remain in the uterine canal for a long period without becoming corroded. Since there has been no operation yet invented for anteflexions nor for anteverted retroflexion of the uterus, and since many patients absolutely refuse operative intervention, Gordon claims that this instrument is an invaluable addition to the gynecologic armamentarium. [How can an instrument which attempts to correct perfectly normal conditions be of value to gynecology or any other branch of medicine?]

Uterine Prolapse.—Winter,⁴ in speaking of the pathology of uterine prolapse, describes 2 forms. One is the result of a relaxation of the peritoneum and ligaments, with retroversion and descent of the uterus (through the latter an inversion of the vaginal walls results); in the other form the prolapse begins with a relaxation and descent of the vaginal walls. In the treatment of the first form, vagino- or ventrofixation is to be considered, while in the second form the various plastic operations of the perineum and vagina are indicated. [Ventrofixation is never of itself to be considered—it must always be accompanied by thorough plastic work in the vagina.]

T. A. Helme⁵ reports a case of so-called prolapsus uteri (cervical hypertrophy) in a virgin of 21 years. The treatment adopted was carried out with a twofold object: 1. Removal of the hypertrophic tissues—to reduce the uterus to its normal length; 2. Cutting off of the blood-supply to the cervix to prevent a

⁴ Univ. Med. Mag., Apr., 1897.

⁵ Brit. Med. Jour., Dec. 26, 1896.

recurrence of overgrowth—that is, dissection of the broad ligaments and ligation of the uterine arteries, simple amputation of the cervix being deemed not sufficient.

G. H. Noble¹ reports a case of hypertrophic elongation of the cervix uteri, with complete eversion of the vagina, resulting from a fibroid tumor of the cervix, occurring in a multipara (Fig. 37). A supravaginal amputation of the neck was performed and the everted vagina replaced, the supports being equal to the task of sustaining the parts.

Jacobs² recommends the following operation, which he calls “collopxie

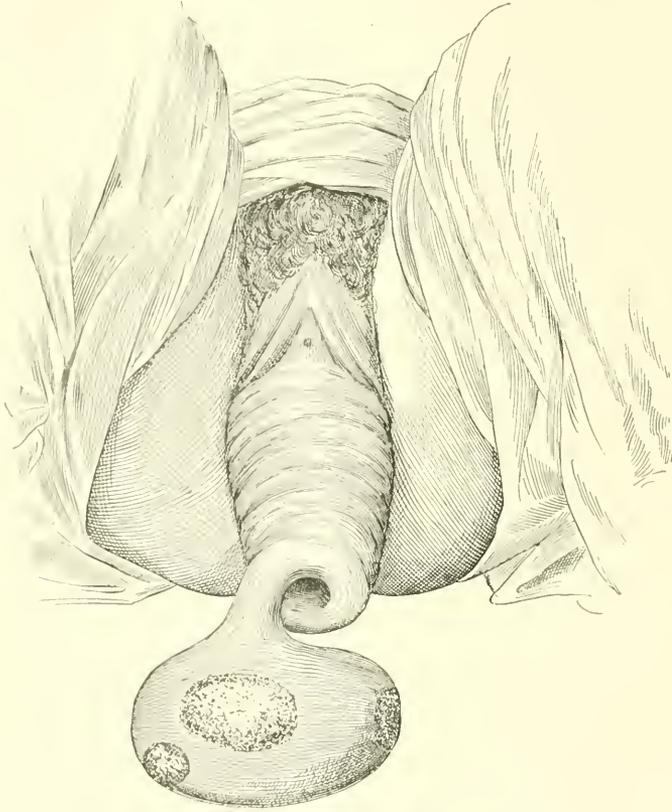

FIG. 37.—Case of cervical hypertrophy and eversion of the vagina, showing tumor and everted vagina before operation (South. Med. Rec., Feb., 1897).

ligementaire,” for prolapse in women of 40 to 50 years, who have been too frequently confined. After disinfection of the vagina and curettage of the cervix the vagina is plugged, and he performs a partial abdominal hysterectomy by amputating the uterus a little above the internal os, not circularly, but by an anterior and posterior flap, leaving enough peritoneum to cover the stump. After applying zinc chlorid to the collum, the flaps are united by a continuous suture and the peritoneum by another. The upper part of the stump is then secured on either side to the upper part of the broad ligament by several sutures, so as to draw the collum well up in the pelvis. In the single instance in which he operated in this way the uterus was sound;

¹ South. Med. Rec., Feb., 1897.

² Centralbl. f. Gynäk., p. 415, 1896.

but if desirable the collum might be amputated before the celiotomy, or after total abdominal hysterectomy the broad ligament might be fastened directly to the vagina. [The operation is almost identical with that devised by Baldy and demonstrated on many patients.]

Prolapse of the Uterus in Young Girls.—Stepkowski¹ reports the case of a woman, aged 25 years, who suffered from complete prolapsus uteri et vagina brought about by vomiting of 12 years' standing. Karczewski² cites the case of a girl, aged 13 years, who had complete procidentia of gradual development, due to carrying heavy burdens. Five days before entering the hospital the rectum also prolapsed.

Retrodisplacement of the Uterus.—H. Robb³ makes mention of the following factors as being concerned in the causation of retrodeviations of the uterus: 1. Congenital defects. A short vagina necessitates a forward position of the cervix; this tends to bring the fundus and anterior surface of the uterus under the direct line of abdominal pressure. The ordinary distention of the bladder, which, as a rule, slightly elevates the fundus, now throws it backward, thus causing a displacement. 2. If extreme distention of the bladder happens often, the malposition is liable to continue. 3. Impacted feces in the rectum change an anteversion into a retroversion. 4. A sudden severe strain put upon the abdominal muscles brings about a retroflexion. 5. Of all causes of retropositions, by far the most frequent is a relaxation of the vaginal outlet. 6. Finally, inflammatory changes in the uterine supports may also cause retrodeviations.

Gottschalk⁴ reports several cases to support his assertion that amputation of the uterine neck is resorted to too frequently, since the operation not only often fails to meet the indications, but is even productive of harm by establishing a true pathologic condition. In the 5 cases reported retroflexion afterward developed, the uterus being previously in a normal position. He attributes this condition to the fact that with the removal of the portio the relations between the cervix and corpus uteri are changed, and at the same time cicatrices are formed anterior to the stump, which tend to draw it forward and thus to throw the fundus backward. Unfortunately, these cases cannot be treated by pessaries, and the cicatricial contraction often gives rise to so much disturbance that subsequent ventrofixation becomes necessary.

Treatment of Uterine Retrodisplacements.—[The treatment of this form of displacement is, as it ever has been, the *bête noire* of the gynecologist. During the year there has been made, by its admirers, a very strong attempt to revive the flagging interest in the Alexander operation, while the methods of anterior fixation have commanded considerable space in the various periodicals. The dangers of vaginofixation are more generally appreciated and the operation is practically obsolete, while the limits of ventrofixation have been considerably restricted.] H. A. Kelly,⁵ in a comprehensive paper, states that the correct method of dealing with any given case of retrodisplacement will fall under one of the following heads: 1. Cases in which no treatment is required. 2. The use of a pessary. 3. Manual reposition and massage. 4. Operation upon the vaginal outlet. 5. Operation on the uterus at the vaginal vault. 6. Shortening the round ligaments. 7. A suspensory abdominal operation, or ventrofixation. 8. An operation upon the vaginal outlet and a suspensory operation combined.

³ Cleveland Med. Gaz., xi, No. 9.

⁴ Deutsch. med. Woch., No. 18, 1896.

⁵ Am. Jour. Med. Sci., Dec., 1896.

No treatment is required when the discovery of the flexion is the accident of an examination and there are no symptoms.

He insists that retroversions and retroflexions are but rarely cured by the use of the *pessary*, and this in spite of the numerous statements to the contrary. In speaking of the mode of action of pessaries J. C. Webster¹ says that the Hodge pessary acts in two ways: (a) It helps to keep up the uterus as a whole, thus tending toward the relief of the congestion of the organ. (b) The upper end of the pessary affords a support over which the posterior vaginal wall pulls on the cervix in an upward and backward direction, the body of the uterus consequently tending to be kept forward. Ring pessaries act merely as a means of support. They lie between the pubic and sacral ligaments, stretching the vagina somewhat transversely. They tend to prevent the vagina and uterus from becoming prolapsed. Ball pessaries act merely by distending the vagina. Vagino-abdominal pessaries keep up prolapsing parts by means of the suspension from an abdominal band. *Manual reposition and massage* may be of service when there is no lateral disease of the pelvis, and when the uterus is movable and the vaginal outlet is not broken down. According to G. T. Harrison,² the technic of pelvic massage is as follows: the patient being on her back, 1 or 2 fingers are introduced into the vagina, the cervix is pressed backward, while the other hand above the promontory, executing rotary movements, endeavors to attain between the promontory and fundus to the posterior uterine wall. At the same time the effort is made to enlarge the distance between the uterine fundus and posterior pelvic wall; these efforts should not provoke pain. This maneuver may be practised daily, the object being to relax the adhesions and to lift the fundus and bring it forward. [If adhesions really exist, pelvic massage is utterly useless and harmful.]

Operative Treatment of Retroflexion.—Kuestner,³ after an exhaustive review of the statistics of various operators, using all the different methods of treatment, arrives at the following conclusions: 1. Although none of the operations for the cure of retroversion restore the uterus and adnexa to an absolutely normal position, the new relation of the pelvic organs is preferable to former displacement. 2. A sharp distinction must be drawn between cases of movable and adherent retroversion. The adhesions must first be separated, after which the treatment in both cases is the same. 3. The abdominal cavity should not be opened for the purpose of separating adhesions unless these are too fine to permit detachment of the uterus by massage or Schultze's method. 4. Celiotomy is preferable to anterior or posterior colpotomy, since adhesions may be more thoroughly and safely separated by the abdominal route, and, moreover, conservative operations on the adnexa can be carried out more satisfactorily. 5. The test of the value of any given method of fixing the uterus anteriorly is that it should keep the organ in a normal position, and that its functions should not be interfered with. 6. The results obtained by retrofixation and vaginofixation and by Alexander's operation prove that the uterus may be maintained in a good position, but it has been shown that after vaginofixation the functions of the organ are disturbed. 7. The latter operation should, therefore, not be performed in the case of women who are likely to conceive subsequently; in those who are not liable vaginofixation has given excellent results, especially when supplemented by kolporrhaphy. 8. When the adhesions are extensive the best operation is celiotomy with ventrofixation. Conservatism should be practised as far as possible, especially in young sub-

¹ Am. Medico-Surg. Bull., Oct. 10, 1896.

² Va. Med. Semi-monthly, Nov. 29, 1896.

³ Wien. klin. Woch., No. 15, 1896.

jects, in whom a portion of ovarian tissue should be left. If the tubes and ovaries are not seriously affected, it is sufficient merely to separate adhesions. 9. Alexander's operation is preferable in cases of movable retroversion, since it restores the uterus as nearly as possible to a normal position. 10. The indications for the operative treatment of retrodisplacement are furnished by the duration of the trouble, the negative results from the use of pessaries, and the aversion of the patient to palliative measures. A condition of the vagina which prevents the use of pessaries furnishes a positive indication. 11. Since prolapse is generally the result of retroversion, the maintenance of the uterus in a normal position is the essential object to be aimed at. This is best attained by ventrofixation, supplemented by a plastic operation on the vagina. [With the exception of proposition 3 the preceding summary is sound.]

Vaginal Operations.—(a) *Kolpotomy, Anterior and Posterior.*—J. Phillips¹ gives the credit of bringing this operation into notice to Dührssen. He has done the operation 4 times successfully. He claims that when practicable this operation appears to have some marked advantages over the abdominal method. These are: (1) Avoidance of the risk of subsequent adhesions of the cicatrix to the omentum or intestines, which so frequently lead to intestinal obstruction; (2) The absence of ventral hernia; (3) There is no post-operative sickness, and the convalescence is much more rapid. The operation is quite unsuitable for large pelvic tumors. It must be remembered that the peritoneum is opened, and hence every precaution should be taken as in the abdominal operation. W. J. Gow² says that anterior kolpotomy is performed with one of three objects in view: (1) As a means of exploring the condition of the ovaries and tubes in certain cases when their condition is doubtful; (2) For the purpose of removing the uterine appendages on one or both sides, provided that the diseased appendages are not greatly enlarged or very firmly adherent; (3) For the purpose of overcoming retroversion and retroflexion by means of vaginal fixation. The incision, which may be either transverse or longitudinal, gives great scope for the exploration of the pelvic organs. Steffek³ says that anterior kolpotomy is indicated: 1. In small ovarian tumors that lie in the anterior portion of the pelvis; 2. In small interstitial and subserous myomata requiring operation; 3. In diseases of the tubes without suppuration. It is contraindicated: 1. In all diseases of the posterior pelvis; 2. In all adherent ovarian and tubal tumors; 3. In adhesive posterior perimetritis. Posterior kolpotomy is indicated: 1. In small ovarian tumors lying behind the uterus; 2. In adherent ovaries when they lie close to the vaginal vault; 3. In tubal tumors adherent to the vagina, when incision and drainage without extirpation can be accomplished; 4. In adhesive posterior perimetritis. It is contraindicated: 1. In all diseases of the anterior pelvis; 2. In ovarian and tubal diseases in which the organs do not lie close to the vagina.

(b) *Vagino-fixation.*—A. Dührssen⁴ thinks that dystocia following vagino-fixation is due to faulty technic, and can be avoided. The fundus of the uterus should be attached to the peritoneum only, and not to the vagina. F. H. Wiggin⁵ believes that in all cases thought to require this operation the vesico-uterine fold of the peritoneum should be divided, and the exact condition of the adnexa determined by aid of sight as well as by touch. This addition to the original technic does not in any way increase the slight risk of the operation.

(c) *Fixation of the Shortened Round Ligaments upon the Anterior Abdom-*

¹ Tr. London Obst. Soc., June 3, 1896.

² Lancet, July 4, 1896.

³ Berlin. klin. Woch., Nov. 2, 1896.

⁴ Centrabl. f. Gynäk., No. 22, S. 584, 1896.

⁵ N. Y. Med. Jour., Aug. 8, 1896.

inal Wall per Vaginam.—The reported cases of dystocia following vaginofixation have resulted in various modifications of the technic. Wertheim and Mandl¹ combine the two procedures for vaginal fixation of the retroverted and prolapsed uterus recently recommended, their method being as follows: a free opening is made in the vesico-uterine pouch and the uterus is drawn well downward into the vagina with a volsella, aided by external manipulation. Backward traction on the cervix then enables the operator to see nearly all the posterior surface of the organ, including the tense sacro-uterine folds. The intestines are held upward by a gauze compress, posterior adhesions are separated, and the sacro-uterine ligaments are drawn backward with forceps until the "slack" is taken up and the fundus is kept well forward; the points at which the ligaments are seized are then united with silk or silkworm-gut to their uterine origins, the amount of shortening varying from $2\frac{1}{2}$ to 3 in. The gauze is removed and the uterus replaced; the round ligaments are exposed by inserting a retractor in the opening, and are drawn down and shortened in the manner already described by the authors. The danger of complications during pregnancy and parturition, noted after Mackenrodt's operation, is not present, since the portio is not directed backward, nor is ascent of the fundus in the pregnant uterus prevented. Vesical and rectal disturbances have not been noted in the cases (3) successfully operated upon by the authors. E. Bode² has done this operation 3 times and recommends it. F. Kiefer³ stitched together a fold of the round ligament through the vaginal incision very much as Mann does through the abdominal incision. Guenther⁴ put a silk suture in each round ligament near the uterus and pierced the abdominal wall over each tuberculum ossis pubis with the needles, and thus brought out the threads, pulled the uterus forward by them, and tied them on the skin. H. T. Byford⁵ passes two chromicized catgut threads about 1 in. apart through that portion of the peritoneum which lies behind the tubes and attaches the fundus of the uterus to the bladder; the round ligaments are then drawn down until the inguinal ends become taut, when catgut sutures are passed through them as far from the uterine end as possible and secured to the uterus just above the normal uterine insertion. Kocks⁶ doubles each broad ligament over the front of the uterus, and then sutures the edge of the one on the left side to that on the right side. Godinho⁷ opens the vesico-uterine pouch by a transverse incision, after detaching the bladder from the cervix; two fingers are introduced, adhesions are separated, and the uterus is replaced bimanually. A silk suture is then passed through one of the round ligaments near its base, is tied, and is then passed through the same ligament 3 in. below the former point. The same procedure is carried out on the opposite side. The sutures are then tied, thus shortening the ligaments, and with the same needles the resulting loop is sewed together on either side. The wound is then closed.

(*d*) **Vesicofixation.**—A. Dührssen⁸ performs anterior fixation as follows: he opens the anterior vaginal fornix by a transverse incision, dissecting up the tissues until the peritoneum comes into view, then seizing it with artery-clamps and dissecting off the peritoneum from the posterior surface of the bladder. The peritoneum is opened by a sagittal incision, and the upper angles of the peritoneal flap are held by clamps. The uterus is then anteflexed and fastened to the peritoneum of the bladder by 2 catgut sutures. The upper suture passes through the vesical peritoneum $\frac{1}{2}$ cm. above the end of the incision and

through the fundus at the level of the insertion of the tubes. The peritoneum is then sewed by a continuous catgut suture and the vaginal incision closed.

Alexander's Operation.—M. C. McGannon¹ reports 91 cases without a death, and 4 subsequent pregnancies with 3 normal deliveries. Kelly² states that the disadvantages of the operation are that the ligaments are sometimes found with great difficulty or not at all, and that relapses are not infrequent. To these A. H. Goelet³ adds the time the operation requires; the doubt about finding the ligaments sufficiently strong in their long overstretched and atrophied condition to bear the strain thrown upon them; the prolonged convalescence necessary before the shortened ligaments can be regarded sufficiently strong to support the uterus; the risk of hernia; and the cicatrices that may become the seat of keloid. Of the 37 patients on whom S. Stoeker⁴ has performed Alexander's operation, 16 were either single women, widows, or women who had passed the childbearing age. Of the remaining 21, 10—3 of them for the 2d time—have become pregnant. One of these aborted in the 2d month, the other 9 were delivered at term; 7 of the 10 he examined and found the uterus in good position, the 8th was 5 months pregnant for the 2d time; 2 of these women had been sterile for the 2 years of their married life, but became pregnant within 6 months after the operation. From his experience he concludes that Alexander's operation causes no disturbances in the course of future labors, and gives brilliant results in favoring conception.

G. M. Edebohls⁵ says that when a round ligament tears in drawing it out the retracted end should be sought for and recovered, if possible, at the internal ring. If this should prove impossible, the peritoneum should be incised at the internal ring and the ligaments sought for and brought out of the abdomen with the aid of a finger or two, assisted, if necessary, by slender forceps. When the ligament tears out of the uterus, or so near the latter as to leave a stump too short to be drawn out and properly fastened, 3 courses are open: the first is to shorten the opposite ligament and trust to one shortened ligament to keep the uterus forward. The second is to open the abdomen in the median line, unite the torn ends of the round ligament, or attach the pulled-out end to the uterus by suture, and complete the operation in the usual way. The third is to substitute immediately the next best retroversion operation. He has operated on 116 cases, with only 4 failures; 12 of the cases became pregnant, with 2 abortions, 6 normal labors, and 4 not yet delivered. Calmann⁶ describes the following ingenious procedure: after drawing out the ligament as far as necessary on both sides it is kept on the stretch by an assistant while 2 sutures of fine catgut are passed through it and through the pillar of the external ring on either side. Then sutures are passed on both sides through the aponeurosis, then through either half of the ligament parallel with its long axis, and out through the aponeurosis again near the point of entrance. When tied, these unite the ligament firmly to the aponeurosis without constricting the former. Finally, the redundant portion of the ligament is excised and the distal end is sutured to the stump of the ligament. The wound in the skin is closed with a continuous catgut suture. F. H. Martin⁷ performs Alexander's operation without buried sutures as follows: the ordinary incision on either side is extended until the lower ends are about an inch and a quarter apart. After exposing and drawing out the round ligaments, closed, pointed artery-forceps are passed

¹ Am. Gyn. and Obst. Jour., Aug., 1896.

from the bottom of the lower end of the wound on the right side beneath the suprapubic tissues to the corresponding point in the lower end of the wound on the left side; the left round ligament is grasped and drawn beneath the skin, fat, and superficial fascia, to the lower end of the right wound. The pubic attachments of both round ligaments are then freed, the uterus drawn well forward, and the 2 ligaments securely fastened by tying them together with a double knot, as advised by Duret, of Lille. The wounds are closed with fine silkworm-gut sutures, allowing every other one to include a small amount of the ligaments and the edges of the external inguinal rings. [The unique feature of this method of operating is the suspension of the uterus by tying the 2 ligaments together over the symphysis.]

Suspension of the Uterus.—*Ventrofixation.*—In stating the indications for suspensio uteri A. H. Goelet¹ writes that vaginal fixation deserves condemnation. Alexander's operation for shortening the round ligaments is appropriate when the retroflexed organ is freely movable and the adnexa are not diseased. In this condition another more simple procedure will accomplish as much in a much shorter time and with less inconvenience to the patient. This procedure aims at a cure of the metritis and endometritis, the maintaining cause of the displacement in a majority of cases in which the organ is movable. This places shortening of the round ligaments in the category of unnecessary operations, though there may be certain cases in which it is appropriate and even necessary. Ventral suspension should be reserved for those cases in which the organ is bound down by adhesions, the adnexa are irreparably diseased and require removal, and the retroflexed organ, though movable, is prolapsed, and for prolapsus without retroflexion.

E. F. Ross² suggests an improvement in the technic of ventrosuspension; it consists in the preliminary introduction into the vagina of a plug of absorbent salicylic wool, which pushes the fundus well up out of the pelvis and keeps it there, so that it becomes unnecessary to use forceps for this purpose. C. Beck³ suggests suspending the uterus to the fascia and peritoneum by means of the round ligaments.

FIBROID TUMOR OF THE UTERUS.

Interesting cases are reported as follows: T. S. Cullen,⁴ a case of adenomyoma of the round ligament; he states that while adenomyomata of the uterus are not so rare, similar tumors of the round ligaments have apparently never been reported. While admitting the probability of the glands in this case being due to remains of the Wolffian body, still, from the striking resemblance to those of the uterine mucosa and from the fact that their stroma resembled that of the mucosa, he suggests the possibility that they may be due to an abnormal embryonic deposit of a portion of Müller's duct. Hansemann⁵ describes the case of a myoma of the round ligament in an inguinal hernia, discovered at the necropsy of a woman, aged 66, who died of aortic aneurysm. Rendu⁶ records a case of soft myoma that closely simulated an ovarian cyst, in a single patient of 40 years. Depla⁷ records a case of death from intra-uterine infection of a myomatous uterus by the bacterium coli commune in an unmarried woman 37 years of age. The removed tumor was found to be completely decomposed. Cultures were made from the tumor, and a pure

⁶ Lyon méd., June 14, 1896.

⁷ Sem. gynéc., No. 10, 1896.

culture of the bacterium coli commune was gained. Depla believes the bacteria were introduced into the vagina through defecation; then the uterine cavity was infected, resulting finally in most extensive sloughing of the tumor. Hartmann and Mignot¹ also report a fatal case of general suppuration and necrosis of a uterine fibroid, which they attributed to infection by anaërobic microbes, appearing in the form of short bacilli, frequently joined together, which were found in large numbers on the surface of the uterine mucosa as well as in the pus within the tumor. M. Heurtaux² reports a case of myofibroma of the uterus with torsion of the pedicle, cured by operation. E. Van de Warker³ records a uterine fibroid complicated with adenolymphangitis and phlebitis cured by hysterectomy. J. B. Sutton⁴ records a case of large myoma of the neck of the uterus in a sterile woman of 40 years. W. C. Wood⁵ records a case of multiple fibroids of the uterus associated with hydrosalpinx cured by hysterectomy.

The Microscopic Relations of the Myometrium in Pathologic Enlargements of the Uterus, with Particular Reference to the Muscle-cells.—Bertelsmann,⁶ from a careful microscopic study of 22 enlarged uteri, comes to the following conclusions: hypertrophy of the muscle-cells of the uterine wall is frequently associated with interstitial fibroids. Hypertrophy of the muscle-cells always occurs with submucous fibroids, and in every instance in which the uterine cavity contains an abnormal substance (pyometra and hematometra). Hyperplastic changes, also increase of the connective tissue and muscle-cells, were found, particularly in metritis and in carcinoma and interstitial fibroids. [These results correspond with those of Ritschl and Herezel.]

The Relationship between Myoma of the Uterus and Sterility.—Hofmeier⁷ is led to conclude that myoma of the uterus does not in itself cause sterility. He finds in a number of cases that sterility was present during the first 5 years after marriage before a myomatous tumor could be detected. It is only exceptionally that the direct influence of the presence of the tumor in producing sterility can be proved. He reports a number of cases in which the tumor disappeared without interference during the puerperal state.

Indications in Fibroid Tumors of the Uterus.—Kessler⁸ says but a short time has elapsed since it was considered advisable to operate upon only a small percentage of the cases of fibroid tumor of the uterus, but that now, on the contrary, one goes so far as to question whether it is not advisable to operate in every instance. It was believed that fibroid tumors, unlike carcinoma and sarcoma, were always benign growths, and, therefore, they were only treated for the hemorrhage, and when this was not present it was thought best to wait for the menopause in the hope that the patient would then be cured. By degrees we have come to know these tumors better. He concludes: (1) It has been determined that the menopause does not always result in a favorable influence, but often the tumor first begins to grow after the menopause. (2) Through continued irritation circumscribed peritonitis is easily developed, and strong and very vascular adhesions are formed. (3) The hemorrhage results in an undermining of the constitution, and particularly in fatty degeneration of the heart-muscle, "the fibroid-tumor heart." (4) Frequently gangrene or sloughing of the tumor occurs. (5) Now and then they become telangiectatic and cystic; also more rarely torsion occurs. (6) A fibroid tumor easily degenerates into a

⁸ St. Petersburg. med. Woch., No. 19, 1896.

sarcoma. (7) Finally, local compression of neighboring organs occurs. The mortality-statistics of the operation for fibroid tumors have become extraordinarily favorable, and one can now definitely speak of the degree of danger. Kessler believes that all fibroid tumors should be removed as soon as they cause symptoms, at least as soon as the symptoms have a tendency to increase, are pronounced or progressive.

Treatment of Fibroid Tumors.—(a) *Non-operative Treatment.*—Cheron¹ speaks highly of intrauterine injections of sterilized glycerin in cases of fibromyoma. A little over a dram is slowly injected every two or three days, the vagina being subsequently tamponed with cotton or gauze saturated with boroglycerid. The effect of the drug is to cause dryness and atrophy of the endometrium, and hence diminution of the tumor. A marked decrease in the flow is observed at the following menstrual period. The writer affirms that the ease and safety of this method of treatment should recommend it in cases in which operative interference is inadvisable, or is refused.

The use of thyroid extract in the treatment of uterine fibroids is treated of by Jouin.² Having had occasion to administer thyroid extract to a stout woman for the purpose of reducing her weight, he noticed that not only was the obesity diminished, but a large uterine fibroid which extended above the umbilicus rapidly lessened in size until it attained only one-fourth of its former dimensions. He accordingly selected 17 cases of fibroids, which were treated by the internal administration of thyroid, with the following results: in 12 cases in which hemorrhage was a marked symptom there was a noticeable diminution in the size of the tumor, while the hemorrhage practically ceased; of 5 large tumors, in feeble subjects, 2 were decidedly affected, 2 but slightly, and 1 not at all. Five other patients with profuse menorrhagia attributed to the climacteric, 2 with bleeding due to carcinoma, and 1 with an intrauterine polypus were treated with the same remedy. The writer concludes that thyroid extract does cause a marked reduction in the size of uterine fibroids, while the symptoms—pain, pressure, general weakness, and especially hemorrhage—are certainly relieved. Moreover, it causes a diminution of the menorrhagia in women at the climacteric.

(b) *Surgical Treatment of Uterine Fibroids.*—[During the 43 years that have elapsed since Burnham first successfully removed a uterine fibroid by abdominal section a very large number of operations and modifications of these have been suggested by surgeons both in this country and abroad.] According to J. Wallace,³ surgical interference is demanded in: (a) fibrocystic growths; (b) sarcomata in the early stages if possible (the longer the tumor is left the greater the risk of recurrence); (c) when the tumor permanently interferes with the action of the bowel or the bladder, with or without pain, and causes inflammation which may give rise to adhesions to superincumbent and pelvic viscera; (d) when ascites is a sequel or when there is overdilatation from the size of the growth, and direct or reflex symptoms indicate danger to life (cardiac collapse). Hemorrhage alone does not demand extirpation. In the experience of G. E. Shoemaker,⁴ patients with valvular heart-disease, if without atheroma, withstand operation well, provided there is good compensation in the heart-muscle. An irregular or intermittent pulse is a far greater contraindication for operation than a heart-murmur. The use of strychnin and whiskey before the operation, careful preparation of the kidneys and skin, and the avoidance of too severe preparatory purgation, the early supply of liquid nourishment by the bowel after the operation (*i. e.*, beef-tea or peptonized milk by the rectum in the first

¹ Rev. internat. de Méd. et Chir. prat., No. 6, 1896.

⁴ Univ. Med. Mag., Aug., 1896.

24 hours) will forestall the failure of a heart which might not otherwise stand a strain. Hysterectomy should not be considered in advanced phthisis. In the incipient stages it may be indicated to remove a drain, and thus enable nature to effect a cure. Chronic coughs not due to phthisis will often disappear marvellously after the removal of abdominal tumors. In hopeless kidney disorganization with purulent urine, large granular casts, and constitutional symptoms, no operation is advisable. It must be remembered, however, that solid abdominal tumors often predispose to kidney-disease by obstructing the ureter or interfering with bladder-drainage, and unless the kidney-lesion is too far advanced relief of pressure and lessened kidney-work may enable restoration to take place.

Methods of Operation.—(1) *Vaginal Ligation of the Uterine Arteries.*—A. H. Goelet¹ states that Martin, the originator of this method, believes that in order to have success in this operation it is very important to include the nerves as well as the blood-vessels in the ligature of the base of the broad ligament. Goelet claims that this is not enough, since permanent obliteration of the vessels is by no means certain; he contends that in order to secure complete obliteration of the vessels they should be divided between double ligatures. He operates in this manner in suitable cases with considerable success.

(2) *Abdominal Enucleation.*—This method is the enucleation of fibroid tumors of the uterus after abdominal section. According to Témoïn,² the operation is as follows: after opening the peritoneal cavity the uterus is drawn forward and the broad ligaments clamped and ligated. An incision is then made over the fibroid tumor, and it is enucleated with the fingers, which is very easily accomplished even in the deeper growths. A necessary portion of the uterine tissue is then excised and the wound closed by a deep, superficial, and peritoneal continuous suture. The last suture includes wounds in the broad ligaments. The uterus is then replaced, the peritoneal cavity washed out with warm water, and the abdominal wound closed. When the tumor is very large it is advisable also to include the uterine artery in the clamp. The clamp-blades should be covered with drainage-tube to prevent injury to the tissues. If there are a number of tumors, each one is enucleated, and the wounds treated with a strong carbolic-acid solution before introducing the sutures. Engström³ strongly recommends this operation. He has performed it in 100 cases in which the tumor varied from the size of a hazelnut to that of an adult head, with but 5 deaths. He believes, with all modern observers, that although these growths may in a few instances remain stationary in the uterine wall without causing symptoms, trouble is apt to develop at any time during life. He believes that the ideal operation is the one that removes the isolated fibroids and allows the uterus, ovaries, and tubes to remain. In his series 63 times there was but 1 tumor, and 37 times multiple tumors; from 2 to 5, and once 22 growths were enucleated. Tumors which extended into the uterine cavity, intramural, subperitoneal, intraligamentous, and one which distorted and thinned out the cervix uteri, were removed; also those with marked development of the blood- and lymph-vessels, and those with more or less necrotic or calcareous change; also those with intestinal and omental adhesions, and sometimes with extensive pathologic changes in the ovaries and tubes. In 3 cases small tumors have since developed. In 113 cases reported by Martin tumors have since been found in 3. This Engström believes is not a contraindication to the operation. Four patients have become pregnant since operation; 1 aborted at 6 months during an attack of typhoid

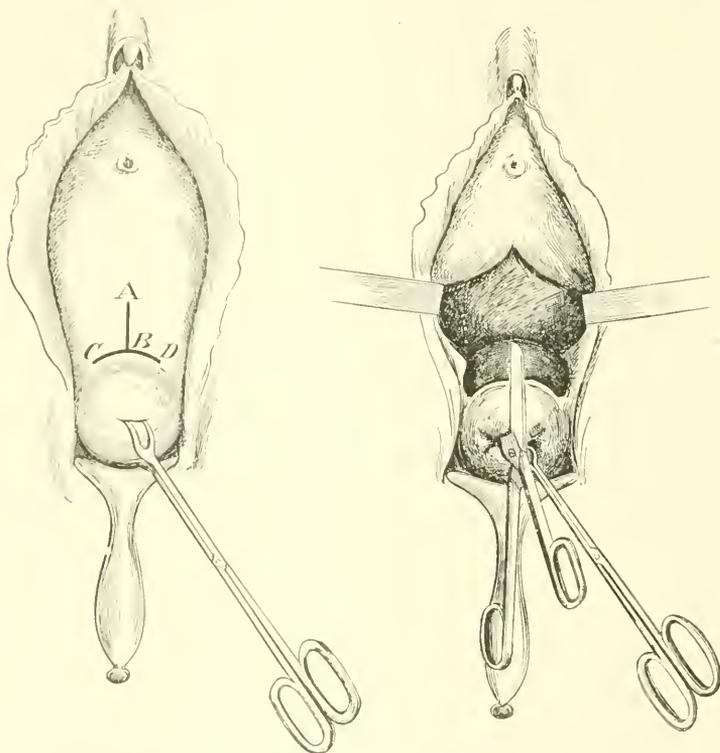

¹ Med. Rec., Mar. 6, 1897.

² Arch. provinciale de Chir., No. 7, 1896.

³ Monatsch. f. Geb. u. Gynäk., Bd. v., H. 4, 1896.

fever; another in the fourth month; 1 went to term and was delivered of a living and healthy child; and 1 is now in the third month of pregnancy. Of Martin's 113 cases 2 became pregnant; 1 aborted, and the other was delivered of a living child.

(3) *Vaginal Enucleation.*—*Vaginal Myomectomy.*—This method, according to E. C. Dudley,¹ has usually been reserved for the smaller tumors of a size not larger than the capacity of the small pelvis. Latterly, however, the vaginal method has been often and successfully used by certain French surgeons for the removal of much larger tumors, by the operation known as *traction and*

FIGS. 38 and 39.—Dudley's operation (Jour. Am. Med. Assoc., Aug. 15, 1896).

morcellement. One strong contraindication to this operation for large tumors must always be the constant possibility of pus-tubes or ovarian abscesses. The technic of the operation is as follows: the tumor is usually made more accessible and its enucleation or morcellation is facilitated either by dilatation or more frequently by deep lateral (or, what is safer, posterior) incisions of the cervix even to the internal os. These incisions having been made, the cervical lips are drawn well down to the vulva and held widely apart by means of strong double-tooth forceps in the hands of an assistant. Dudley proposes as an improvement on the other method a simple median incision through the anterior wall of the uterus after having made a circular incision in front of the uterus, which shall separate the vaginal wall from the cervix at the uterovaginal attachment in the line *C D* (Fig. 38). The anterior vaginal wall is then incised from the point at the middle of the first incision

¹ Jour. Am. Med. Assoc., Aug. 15, 1896.

for a distance of $\frac{1}{2}$ to $\frac{3}{4}$ of an inch (line *AB*, Fig. 38), care being taken not to invade the bladder and to avoid the ureter on either side. The bladder is dissected up and the anterior wall of the uterus is exposed (Fig. 39), which is then divided longitudinally in the median line by means of scissors to whatever extent may be necessary to render the tumor accessible (Fig. 39). If necessary, the peritoneum may be opened and the incision carried high up into the corpus uteri. With the finger as a guide a long-bladed knife is passed to the highest point of the tumor, and an incision is made parallel with the long axis of the uterus. The mucosa is pushed away from the incision on either side, the myoma seized and firmly held by vulsellum forceps, and traction made as described by Emmet, while the dissection is made close to the capsule. Laceration of the uterine tissue must be avoided as far as possible, because it is apt to give rise to troublesome hemorrhage. If the myoma is too large to remove entire, it is to be done by morcellement. The cervix and uterus may then be sutured.

(4) *Hysterectomy.*—(a) *By the Vaginal Route.*—According to F. H. Wig-

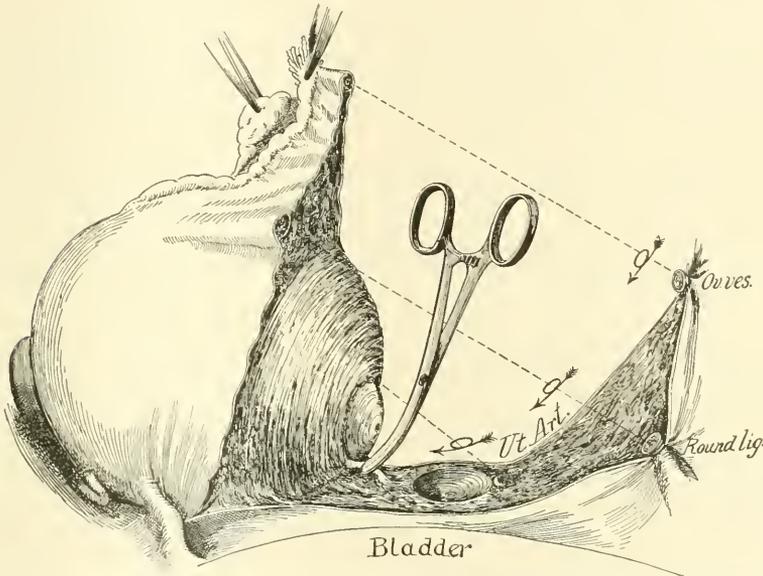

FIG. 40.—Left ovarian vessels tied; left round ligament tied; vesical peritoneum divided and pushed down; left uterine vessels ligated. Cervix amputated and uterus pulled up and out, exposing right uterine artery, which is clamped an inch above the cervical stump. The two following steps are clamping the right round ligament and right ovarian vessels, when the mass is removed (Bull. Johns Hopkins Hosp., Feb.-Mar., 1896).

gin,¹ the selection of the method, whether vaginal, abdominal, or a combination of the two, by means of which the diseased uterus shall be removed, will at the present time depend largely upon the size, benignity or malignity of the tumor, and upon the character of the adhesions that exist in a given case, as well as upon the personal experience and predilection of the individual operator. One of the objections to the operation is, according to H. T. Nelson,² that the plastic exudate thrown out upon the surface of the packing which is introduced into the opened vaginal vault for purposes of drainage, as well as to prevent the descent of portions of the abdominal contents, makes a mass of cicatricial tissue in which portions of the bowel are necessarily involved.

¹ N. Y. Med. Jour., Aug. 22, 1896.

² Am. Gyn. and Obst. Jour., Nov., 1896.

A certain amount of intestinal adhesion will take place, with the probability of becoming in the future a source of great trouble to the patient. The causes of death after vaginal hysterectomy, as stated by T. Wilson,¹ are: 1. Shock, hemorrhage, and exhaustion; 2. Septic conditions; 3. Cardiac, renal, and other organic complications. He believes that half of the cases of death ascribed to exhaustion and to ileus are due to sepsis. This is also probably a factor in the production of death in some cases ascribed to shock. Intestinal obstruction is a common sequela, immediate and remote, of vaginal hysterectomy. Cases of ileus following soon after the operation are usually due to sepsis. In many cases local signs of infection in the wound are not very marked, and in many cases an exhausted condition of the patient consequent on the length of the operation and hemorrhage is a most important factor in determining reflex paralytic distention of the intestine. Obstruction of the bowel beginning after the first few days following operation is usually due to adhesion of the intestine. Fistule connecting the vagina with the bladder, ureter, rectum, or intestine, are common and distressing sequelæ of vaginal hysterectomy.

(b) *By the Abdominal Route.*—Abdominal hysterectomy by amputation, as described in the *Year-Book* for 1897, has, in the hands of skilled surgeons, become the method of selection. The accompanying illustration (Fig. 40) shows far better than could any verbal description the method of procedure. The hysterectomy spud employed in the operation is also shown (Fig. 41).

FIG. 41.—Hysterectomy spud. Used instead of a knife for amputating the uterus at the cervix. The curved blade enables the operator to work easily in a deep pelvis cupping out the stump (Bull. Johns Hopkins Hosp., Feb.-Mar., 1896).

The reasons why the extraperitoneal method of abdominal hysterectomy was so long the only method employed, and why it was so slowly relinquished are, as shown by A. Donald,² not far to seek. It possesses two great advantages—the comparative simplicity and the rapidity with which in most cases it may be accomplished. L. Tait³ still adheres to this method, stating that he now gets runs of success of 30, 40, and even as high as 52 consecutive cases, while with every kind of intraperitoneal treatment of the pedicle which he has tried the mortality has been terrible, and “he is done with it forever.” [So many other operators have as good or better results with the supravaginal amputation than Lawson Tait has with the neud method that the only conclusion to draw from his remarks is that he does not know how to do the amputation operation or his patients die from lack of antiseptic precautions—he is well known to oppose all antiseptics.] However, as Donald points out, the intraperitoneal method, when successfully carried out, does away with many drawbacks attendant upon the extraperitoneal method, as the traction on the stump or broad ligaments, the strangulated and sloughing stump, the pit-shaped wound in the abdominal wall after separation of the necrosed stump, the sinus leading to the pelvis, the adhesions of the stump to the abdominal wall, and the weakness of the abdominal cicatrix at the lower angle where the stump was fixed. It has, on the other hand, the great disadvantage of being a rather complicated operation, requiring a long time for its performance. Its weak point is also the stump.

¹ Birmingham Med. Rev., Apr., 1897.

² Brit. Med. Jour., Oct. 24, 1896.

³ Ibid., Mar. 27, 1897.

Altuchoff and Sengiroff¹ describe their new method of reaching the uterine artery after abdominal section by drawing the round ligament well forward and the Fallopian tube backward, and making a broad triangular space between the two structures. An incision 3 cm. long is then made behind (above) the round ligament and parallel to it. By dissecting down from 12–16 mm. in the loose connective tissue, keeping near the anterior layer of the broad ligament, the artery is easily found and ligated. Sengiroff has ligated the uterine artery 8 times by this method, and in 7 of the cases removed complicated tumors of the uterus and adnexa bloodlessly. Once the ligation was performed for menorrhagia due to fibroids. The ligation is usually performed easily, though large tumors and other complications may greatly increase the difficulty.

Drainage of the Stump in Abdominal Hysterectomy.—Byford² says that in 46 cases he turned the uterine stump into the vagina through an opening made into the anterior vaginal fornix. In 18 cases he sutured the stump with chromieized catgut, shutting off the peritoneal cavity and draining through an opening made into the anterior vaginal fornix; in 1 case he did not shut off the peritoneal cavity, but drained the cul-de-sac of Douglas; and in 3 cases he removed the whole uterus and drained the stump through an opening left in the upper part of the vagina. Out of this total of 68, 3 died. It is his opinion that if he had not drained, there would have been at least twice as many deaths. [A mere matter of opinion without a particle of proof accompanying it.] His present method consists in sewing up the stump with catgut and draining through an opening made in the anterior vaginal wall just in front of the cervix.

Doyen's method of abdominal panhysterectomy for large uterine fibromyomata is thus described by F. Edge:³ A sufficiently large median incision is made, the tumor is fixed by a wire corkscrew of large size, drawn out of the pelvis, and delivered through the incision. Large compresses are placed so as to cover the intestines and each one is held by forceps. The assistant then passes a large pair of forceps into the vagina and up into the posterior fornix; the operator then cuts down in the middle line with scissors upon the elevation in the floor of Douglas's pouch, and having made a free incision into the vagina the anterior lip of the cervix is seized with a volsella and drawn strongly upward. With scissors the mucosa is snipped round the cervix and pushed up in front bluntly with the finger, thus separating the bladder. Having freed the cervix sufficiently all around, the assistant grasps between the finger and thumb of the right hand the base of the broad ligament; starting from behind in the median line the operator cuts upward on the right side so as to leave all the broad ligament with the tubes and ovaries and a free flap of peritoneum and the capsule of the uterine mass. Practically he cuts through the whole broad ligament as near the mass to be removed as possible. The other broad ligament is held by the assistant's left hand and similarly cut through. The tumor is removed, leaving a flap of peritoneum and broad ligament on each side and behind the bladder, on which are the tubes and ovaries. This flap is large enough to easily form the new pelvic floor; the apices of the two flaps are transfixed and doubly ligated, the ovaries and tubes being removed by cutting off the parts beyond the ligatures. The open rectovaginal and vesicovaginal cellular spaces are closed by a continuous catgut suture uniting peritoneum and vaginal walls. The flaps are pulled down over the raw surfaces of the broad ligaments by the ligatures which had been left long after tying off

¹ *Monatsch. f. Geb. u. Gynäk.*, Bd. iii, H. 6.

² *Am. Jour. of Obst.*, Aug., 1896.

³ *Birmingham Med. Rev.*, Nov., 1896.

the tubes and ovaries. A continuous catgut suture is now passed, picking up peritoneum all around—*i. e.*, from both flaps and from the rectal and vesical peritoneum. This is tied and pulled into the vagina, and another similar suture, about $1\frac{1}{2}$ in. higher, is passed and tied, absolutely shutting off the peritoneal cavity of the vagina. The abdomen is then closed. Doyen has performed this operation 35 times, with 1 death. A similar operation is done by Le Bee.¹

MALIGNANT DISEASE OF THE UTERUS.

Etiology of Carcinoma Uteri.—Baecker,² from an analysis of 705 cases of carcinoma of the uterus, arrives at the following conclusions with reference to the etiology of the disease: 1. The true origin of malignant disease of the uterus is as yet unknown, nor can it be referred to a specific micro-organism. 2. The indirect cause is endometritis, generally of puerperal origin, which furnishes a suitable nidus for its development. This is shown by the fact that carcinoma is common in women who have borne children, while it is comparatively rare in single and in sterile women, as well as in those who have had gonorrhœa. Moreover, in nearly every case of carcinoma there is a chronic catarrh of the endometrium. Endometritis is the primary condition, malignant degeneration being secondary. Hence, the practical importance of treating endometritis actively from the outset as a prophylactic measure.

G. L. Mullins³ has made a study of carcinoma in New South Wales, and finds that of 585 females who died of cancer, 202 were affected in the uterus. The period of life at which death occurred was between 25 and 85 years, but it was not common before the 40th year. It occurred most frequently between the 45th and the 60th year. The average number of children borne by each female dying of carcinoma of the uterus is 5.07. Two single females died of the disease, and 17 who were married but had no issue. There is no information as to whether any of these women had ever had miscarriages. He concludes: (1) that although New South Wales has one of the lowest death-rates in the world from carcinoma, the disease is undoubtedly increasing in the colony; (2) the carcinoma-age is from 35 upward; (3) carcinoma is slightly more prevalent among males than females; (4) climate appears to have little or no effect on the production of the disease; (5) the stomach is the organ most affected in males; the uterus in females; the stomach is also largely affected in females; (6) heredity is the chief cause of the production of carcinoma. Chronic irritation is an important factor, but its true significance is still a matter of dispute.

The Origin of Malignant from Non-malignant Uterine Neoplasms.—W. R. Williams⁴ remarks that considering the great frequency of both diseases (carcinoma and fibroma) in women of a certain age, one need not be surprised to find them coexisting rather frequently in the same uterus. In 78 uterine carcinoma necropsies he found in 5 concomitant fibroids; of 45 similar necropsies tabulated by Lebert 6 were associated with fibroids—*i. e.*, in 125 carcinoma patients fibroids coexisted in 11, or in 9%. In the immense majority of cases the two neoplasms are quite separate and independent of one another, the fibroid having sprung from the corpus and the carcinoma from the cervix or portio, so that in these cases there is no question of the latter disease having originated from the former. In the remaining cases the coexisting neoplasms are much more closely associated, most of them arising

¹ Brit. Med. Jour., Oct. 31, 1896.

³ Australasian Med. Gaz., Jan., 1897.

² Arch. f. Gynäk., Bd. liii., H. 1, 1897.

⁴ Ann. of Surg., Sept., 1896.

in the corpus. A common condition is to find one or more small subperitoneal or intramural fibroids with carcinoma of the adjacent mucosa. Under these circumstances the fibroid is seldom cancerous. Many instances have been recorded of fibroids projecting into the uterine cavity and bearing on their surfaces a cancerous growth or ulcer. In cases of this kind the latter disease usually spreads from the mucosa to the fibroid by way of the perivascular lymphatics. In like manner uterine fibroids projecting into the abdomen sometimes become cancerous through extension of the disease from adherent neighboring organs, as the ovary, intestine, and omentum. There is yet another way in which fibroids may possibly be secondarily invaded by carcinoma, and that is by dissemination from a primary focus elsewhere, as in the lung. In such cases as the foregoing there is no question of the cancerous disease having primarily originated in the fibromyoma. This is, however, an event of such rarity that only about a dozen instances of it have hitherto been recorded; and in most of these the evidence adduced is far from being thoroughly convincing. Uterine fibroids, instead of having any special proclivity to become cancerous, are very much less liable to originate this disease than are the glandular elements of the uterus itself. [The foregoing is contrary to the teachings of the vast majority of textbooks and teachers; it seems to us, however, to be so true that no man can candidly look over his own experience and fail to accept it in great part if not *in toto*.] As to the association of uterine fibroma and sarcoma Williams's analysis of 2649 consecutive cases of uterine neoplasms showed 883 uterine fibromyomata and only 2 sarcomata; while of 205 hysterectomies for fibroids of the corpus, Martin found 4 of the tumors sarcomatous. These figures prove, therefore, that uterine fibroids seldom become sarcomatous, although the occasional origin of sarcomatous disease in uterine fibromyomata has been clearly established. In this connection it must be remembered that fibroids are of composite build, including connective tissue, muscle-elements, blood-vessels, and lymphatics, from either of which the sarcomatous metaplasia may arise; hence corresponding varieties of the disease (myosarcoma, myomyxoma). By far the commonest variety of the disease is the myosarcomatous.

Primary Carcinoma of the Corpus Uteri.—Käpelli,¹ from the investigation of 15 cases at the University of Basel clinic for women, comes to the following conclusions: (1) the frequency of carcinoma of the corpus uteri as compared with cervical carcinoma is 5.3%; (2) it occurs after the menopause, and perhaps more frequently in unhealthy married than in single women; (3) carcinoma of the corpus uteri can be associated with myoma of the uterus or follow abortion; (4) chronic irritation and inflammatory diseases of the endometrium act as predisposing causes of carcinoma; therefore displacements of the uterus are a relatively frequent cause; (5) the hemorrhage resists treatment and is atypical; pain is present in only a few cases, but its character is pathognomonic; (6) in a typical case it is possible, from the symptoms and clinical examination, to determine the diagnosis. An absolute diagnosis can only be gained through microscopic examination of tissue removed by the enret.

According to H. D. Beyea,² the history of primary carcinoma of the uterine body is almost entirely confined to the last 15 years. During the last 2½ years he has seen 7 positive cases. The disease occurs most frequently during the post-climacteric period and between the ages of 50 and 60 years, but it may occur as early as the twentieth year; it is more often found in multiparæ.

¹ Dissert., Luzerne, 1896; Centralbl. f. Gynäk., No. 29, 1896.

² Therap. Gaz., Aug. 15, 1896.

In Beyea's experience there is a form of malignant uterine disease which primarily appears as a malignant adenoma—or, better, adenoma destruens—and which progresses as an atypical glandular form of disease, which can destroy and perforate the uterine wall, and, if not removed early, will result in the death of the patient. Anatomically, there are 3 forms of growth—that which projects in polypoid masses in the uterine cavity, that which grows diffusely over the corporeal endometrium, and that which appears as a nodule in the uterine wall. Every one of these forms of growth, primarily beginning in the endometrium, must soon infiltrate the endometrial tissue to a greater or less extent. The polypoid and diffuse forms of the disease are by far the most frequent. The only method of diagnosis that can give positive results is that of microscopic examination of tissue removed by the curet.

Adenoma Cervicis Malignum Cysticum.—Knauss and Camerer¹ report the following case of cervical polyp and malignant adenoma of the cervix uteri. A polyp the size of a hazelnut, having a pedicle, was found protruding from the cervical canal and was excised. The woman returned a month later, and at the site of insertion of the pedicle of the previously removed polyp there was found a small round tumor, which proved to be a malignant adenoma. The uterus was removed. Two and a half years later the patient was perfectly well. The microscopic characteristics of the disease are thoroughly described. The writers were able to find only 6 cases of malignant adenoma of the cervix reported in the literature. Smith² also reports a case of malignant adenoma of the cervix uteri in an unmarried woman 34 years of age. The diagnosis was made by microscopic examination of tissue removed by the curet. The uterus was removed, and after 6 months there were no signs of a return of the disease. An additional case is recorded by M. H. Richardson.³

Carcinoma Uteri in the Young.—Pilliet and Delaunay⁴ record a case of cervical carcinoma in a woman of 30 years; Tschop,⁵ a case in a girl 19 years of age; and W. L. Little,⁶ a case in a girl of 14 years, resulting fatally.

Diagnosis of Uterine Carcinoma.—[The early recognition of uterine carcinoma is probably as difficult as it is important.] W. B. Chase⁷ remarks that any escape of blood from the vagina at a period subsequent to the menopause is a matter of deep significance, and, except in rare cases, is the concomitant of malignant disease. An ichorous, foul-smelling discharge, more or less mingled with blood, is almost pathognomonic of carcinoma. If, associated with these symptoms there are those of pain and cachexia, the diagnosis is practically established. Still, according to Masse,⁸ it must be remembered that hemorrhagic endometritis, without malignant disease, may arise suddenly in old women 7 or 8 years after the menopause. Most of such cases occur, strange to say, in large and fleshy patients. [Does obesity, which is very frequent after the menopause, cause a modification in the mucosa of the senile uterus? Hermann and Fournieux, while studying this subject, found the muscular tissue lax and pliable, and the vessels atheromatous. Delert has proved the absence of the glands of the mucosa, and this tissue is very vascular in women who have had endometritis. This senile degeneration of the

⁸ Sem. gynéc., Apr. 7, 1896.

mucosa probably predisposes to the uterine hemorrhages; the etiology, however, is still very obscure. It is evident that they may occur without the presence of a malignant growth or fibroid.] Dorland¹ urges that hemorrhage after the menopause should be regarded as a most ominous sign of grave organic disease, and its cause investigated. Other clinical manifestations of undoubted value are the characteristic sacral pain—a very common symptom—and the offensive and acrid leukorrhœa, often resulting in an uncontrollable pruritus. W. R. Williams² states that carcinoma is often ushered in by certain vague premonitory indications, as malaise, lassitude, anorexia, uneasy sensations in the lumbosacral and genital regions, and leukorrhœa. Physical examination is important, and the condition of the lymph-glands in the groin should be ascertained, for in more than one-fourth of all cases those of one or both sides become obviously enlarged in the course of the disease. This may occur at a comparatively early date, when the disease starts at or near the fundus. The left supraclavicular region should also be examined, as in advanced cases of uterine carcinoma the lymph-glands in this situation are apt to become enlarged (*Troisier's symptom*); it must be remembered, however, that any intra-abdominal carcinoma may cause this adenopathy. Edema of one or both legs—owing to pressure of enlarged glands on the iliac veins—is met with in about 15% of the cases. The symptoms of uterine tuberculosis closely resemble those of carcinoma, but hemorrhage is a less marked feature. In tubercle of the corpus the part is much enlarged, its walls are thickened, and its cavity is distended with yellowish fluid containing curdy, caseous flakes or thick magma. On removing this, irregular patches of rather deep, sharply punched-out ulceration are seen, each ulcer being covered by a deposit of yellowish caseous matter. The adjacent parts are thickened by tuberculous infiltration, in which yellow opaque granules are often noticeable.

To effect an accurate diagnosis, however, in any case resort must be had to the curet and microscope. Gessner,³ at a meeting of the Berlin Obstetric and Gynecologic Society, on March 13, 1896, read a paper comparing the advantages and worth of curettement, and the microscopic examination of tissue removed, over digital palpation of the uterine cavity in malignant diseases. He says that, although microscopic diagnosis in gynecologic diseases has been known for the last 20 years, the method has not as yet received general acknowledgment. Particularly in England has this method been almost condemned. The only other method of diagnosis of malignant diseases of the corpus uteri which can be considered to compare with this is digital palpation of the uterine cavity. He believes there are 3 factors which a method of diagnosis of these diseases of the corpus uteri must have, as follows: it must be without danger, easily applied, and, most important, it must be positive. In order to digitally palpate the uterine cavity the cervical canal must be dilated. This is always, whether rapid or gradual, dangerous for the patient. Recently, cases have been reported in which death resulted from this procedure. As compared with this, curettement is less dangerous if infection and perforation be isolated. For dilatation and digital palpation, except when rapid dilatation is practised, two sittings and frequently two anesthetics are necessary, while in curettement only one sitting is required. In various complications (senile vaginae, long or constricted cervical canal, ridged pelvic floor, and enlarged myomatous uterus) digital palpation is difficult or impossible, and thus no positive results can be gained. It is also not true that the surface of the endometrium always becomes roughened or nodular in carcinoma. This occurs

¹ Univ. Med. Mag., Sept., 1896.

² Lancet, Oct. 17, 1896.

³ Centralbl. f. Gynäk., No. 18, 1896.

only when the disease is far advanced. Not rarely carcinoma causes soft polypi which digitally cannot be differentiated from benign polypi. On the other hand, endometritic processes can result in hard growths, as in suppurating myomata. In the cases in which digital palpation gives a positive result a careful curettement in which considerable tissue is removed would also afford a positive diagnosis through microscopic examination. This is also possible in cases in which digital palpation would never have led to any result because the disease was too much localized. In the Berlin University clinic for women, since January 1, 1890, the diagnosis of malignant disease of the corpus uteri has been made and the uterus removed 58 times. In 11 of these cases a carcinomatous, and in 3 a sarcomatous new-growth was directly palpated. In 3 excised polypi sarcoma was diagnosed through microscopic examination. In the remaining 44 cases the diagnosis was made by curettement and microscopic examination alone. During 5 years in this clinic it has never been necessary to employ digital palpation as a means of diagnosis in malignant disease of the endometrium. In 4 cases the carcinoma, although giving the symptoms, was not situated in the corpus uteri, but in the cervix. He therefore believes that the curettement is useful as a method of making an early diagnosis of carcinoma of the cervix. In another case, from the changes occurring in the endometrium, malignant disease of the ovary was diagnosed. He advises that the curettement be done under anesthesia, and the cervical canal be slightly dilated.

Pick¹ describes a rapid method of permanently staining microscopic sections for diagnosis, employed in the Landau clinic. It is as follows: (1) The portions of tissue are washed free from blood and immediately frozen and cut with the small Young microtome. (2) The sections are carried by the finger-tip into a 2% formalin solution, and allowed to remain 2 or 3 minutes (the formalin solution should be made with boiled water). (3) They are then washed for a half minute in water. (4) They are then placed 3 or 4 minutes in a 4% solution of alum carmin. (5) They are washed 1 minute in water. (6) They are placed in 80% alcohol for 10 seconds. (7) They are placed in carbol-xylol for 1 minute. (8) They are mounted in Canada balsam.

Treatment of Carcinoma.—(1) *Palliative.*—R. M. Stone² reports the only case of malignant uterine disease treated by the crysipelas and prodigious toxins followed by favorable results. The case was undoubtedly malignant and inoperable, and the patient apparently near to death. The initial dose of the unfiltered toxins was 3 minims, injected between the shoulder-blades; the next day, 3 minims; the next, 10; the next, 14, and the next, 20 minims were injected. The patient's condition was improving steadily. The next day 19 minims were injected into the vagina, the patient shortly falling into collapse, and being saved only by active stimulation. Under a renewal of the treatment the carcinomatous growth entirely disappeared, and the patient made a complete recovery. [This method of treatment has been tried quite extensively, with little or no success. Extreme caution should be observed in its use].

N. G. Bozeman³ suggests as the indications for treatment in inoperable cases: 1. To keep the seat of the disease in an aseptic condition; 2. To prevent or counteract any narrowing of the vagina in front of the disease; 3. When the bladder becomes involved to use effective irrigation and drainage to carry off the urine as soon as it is secreted. E. Duvrac⁴ calls attention to the favorable action exerted on malignant neoplasms of the uterus by

¹ Centrabl. f. Gynäk., No. 40, 1896.

² Med. Rec., Nov. 21, 1896.

³ Jour. Am. Med. Assoc., Jan. 16, 1897.

⁴ Am. Medico-Surg. Bull., Sept. 12, 1896.

the administration of sodium chlorate internally and its simultaneous application to the cervix uteri. Under this treatment the metrorrhagia and fetid discharge decrease and ultimately disappear more or less completely; the pain is alleviated, rendering the use of morphin unnecessary; the puffiness of the cervix subsides, the sores heal, appetite and digestion are restored, and the general condition improves. [It seems necessary periodically to repeat the warning that carcinoma has but one cure—the knife. It is hardly fair to the patient to waste time over will-o'-the-wisps.] M. A. Guinard¹ has employed carburetted calcium (calcium carbid) in several cases of inoperable cervical carcinoma, with good results.

A piece of the material the size of a nut is introduced and placed in contact with the growth. The vagina is then packed with iodoform-gauze, which is left in place for 4 days. After it is removed a vaginal douche is given and the pieces of calcium oxid remaining in contact with the cervix are removed with the fingers. The main objection to this treatment is the moderate amount of pain caused by the application of the drug, but this disappears in a few hours. Although not a curative procedure, the application has a beneficial effect on all of the 3 cardinal symptoms of carcinoma of the cervix—namely, pain, hemorrhage, and fetid discharge. Moreover, the excrescences of the carcinoma dry up and fall off, leaving in their place a smooth, even surface. Calcium carbid, discovered by Moissau, has the property of changing into calcium oxid and acetylen gas, so that one sees the gas bubbling out of the vagina after an application of the drug. The acetylen acts as a hemostatic and the calcium as a caustic, but the fluids of the vagina cause the latter to become hydrated and limit its caustic action.

R. Bell² speaks of the treatment of uterine carcinoma and fibroma and certain forms of ovarian disease by means of thyroid, parotid, and mammary gland therapeutics. He asserts that the parotid gland exerts a most powerful influence upon the ovaries, and uterine fibroids are benefited by the employment of mammary glands of healthy animals. He has benefited cases of uterine carcinoma by administering thyroid elixir and palatinoids.

(2) *Radical (Operative) Treatment of Uterine Carcinoma.*—F. W. Johnson³ has employed Clark's method (see *Year-Book*, 1896) in 10 cases, with the following results: 3 died from the immediate effects of the operation; 3 are alive and in perfect health 16 months after the operation, 1 of these has gained 100 pounds, and at the time of the operation she was the most unpromising of the three; 1 is alive, with no return of the disease, 12 months after the operation; 1 is alive, with no return of the disease, 8 months after operation; in 2 the disease has returned in scar-tissue at the vault of the vagina. [These results speak very ill for such an extensive operative procedure; the removal of the uterus by the usual methods gives far better results. The mortality is something startling, and it would require an exceedingly bold man to continue with the method.]

Supravaginal excision of the uterus by the galvanocautery in place of total or partial hysterectomy is advocated by J. Byrne⁴ and W. J. Corcoran.⁵ They claim for this method the following: it is aseptic and nearly bloodless; post-operative shock is absent; it has no primary mortality; its ultimate results challenge any and every other method; its action extends beyond the immediate field of operation, thus probably killing or rendering inert the cancer-elements not accessible to the knife. Byrne has employed this method for

¹ Sem. méd., No. 18, 1896.

² Internat. Med. Mag., July, 1896.

³ Boston M. and S. Jour., Dec. 31, 1896.

⁴ Am. Gyn. and Obst. Jour., July, 1896.

⁵ Brooklyn Med. Jour., Sept., 1896.

nearly 25 years, and is convinced that *there is positively no place in legitimate surgery for colpohysterectomy, or high or low amputation in carcinoma of the cervix, except when performed through the agency of the galvanocautery.* Corcoran states that the operation of Byrne is practically painless, there is no such thing as shock, and the convalescence is absolutely afebrile. There is, however, considerable danger of hemorrhage if not properly performed.

Penrose¹ writes that he has performed complete hysterectomy for carcinoma by a combined method of operation through the abdomen and vagina during the last year. In the combined operation, as usually performed, the vaginal part of the operation is done first, the abdominal part last. The method which he has followed was begun through the abdomen and finished by way of the vagina. The advantages claimed for this method of combined operation are as follows: the dirty part of the operation is done last. The septic cervix is withdrawn through the vagina and not through the peritoneal cavity.

[*Vaginal hysterectomy* for carcinoma is not in as great favor as formerly.] As stated by J. H. Croom,² for this operation to be successful mobility of the uterus, freedom of the fornices, and, as a result, the possibility of pulling the cervix well down to the vulva, are the essential points. Without these conditions the operation can, of course, be performed; but whether it relieves suffering or prolongs life is questionable. According to J. E. Janvrin,³ vaginal hysterectomy should be confined to cases in which the disease is limited to the cervix or the cervix and mucous membrane only of the upper part of the vagina, or to those in which the disease, having involved these points, has also begun to develop upon the mucous lining of the uterus itself. To this may be added cases of adenoma and carcinoma uteri in their early stages. In all cases in which there is suspicion of extension of the disease beyond the limits previously mentioned, whether into the parametrium, the folds of the broad ligaments, the ovaries or the cul-de-sac, the combined abdomino-vaginal operation is the most appropriate, if we resort to any radical operation. As to the results of the operation, T. Wilson⁴ remarks that of 100 suitable cases of carcinoma of the cervix submitted to vaginal hysterectomy, 40 patients may be reasonably expected to be alive and free from recurrence 2 years after operation. The duration of life after operation in patients dying from recurrence was found by Leopold in 50 cases to average 19.7 months. From the most complete statistics and reports of cases from Great Britain Wilson collects 283 cases of hysterectomy for carcinoma, with 34 deaths (a percentage-mortality of 12). Schramm⁵ reports 33 cases of vaginal hysterectomy, with a mortality of 15.1%. He prefers clamps to ligatures for the following reasons: 1. The operation is shorter and easier. 2. Less blood is lost and there is less risk of secondary hemorrhage. 3. In cases of carcinoma the resulting necrosis causes the destruction of the diseased tissue not removed at the time of operation. 4. Even in advanced cases the operation is free from danger. 5. The after-treatment is simpler and there are no ligatures to be removed subsequently. According to Olshausen,⁶ in Germany during 1887-1888 only 28% of cases of carcinoma of the uterus were regarded as suitable for a radical operation, while during 1895-1896 the number rose to 40%. The difference is attributed to the greater intelligence of general physicians and the earlier recognition of the initial symptoms. He condemns the sacral and parasacral methods of operation, since they are neces-

¹ Am. Jour. Obst., vol. xxxiv., No. 6, 1896.

⁴ Birmingham Med. Rev., Feb., 1897.

⁵ Arch. f. Gynäk., Bd. lii., H. 2, 1896.

⁶ Berlin. klin. Woch., No. 23, 1896.

sary only in cases which he regards as unsuitable for extirpation. In 139 vaginal hysterectomies performed by him since April, 1894, there were only 3 deaths, while in his last 100 cases there was only 1 death, due to pyæmia, from which the patient was suffering before the operation. As regards the technic of the operation T. A. Helme¹ prefers, instead of the usual circular incision around the cervix, a barleycorn-shaped or elliptic incision—similar to that usually employed in excision of the breast—which gives more room and greater freedom for subsequent manipulation. The greater diameter of this ellipse coincides with the transverse of the vaginal roof, and its extremities may at times with advantage be prolonged in an outward direction along the lateral fornices. He divides the lateral ligaments gradually and on each side alternately from below upward; delays opening the peritoneal cavity; completely closes the peritoneum after removal of the uterus; cuts short the intra-peritoneal ligatures and leaves the others long; partially obliterates the pericervical space by buried sutures; and removes by scissors (if necessary) all ligatures after the third day.

AFFECTIONS OF THE PELVIC VISCERA.

The Diagnosis of Pelvic Disease.—[The ability to properly diagnose affections of the pelvic viscera is by far more important to the general clinician than is a most comprehensive knowledge of the refinements of technic of abdominal or vaginal section. A number of able men have devoted their energies to the perfection of the methods of diagnosis at our command.] Thus Mare Sec² describes a new and very original method of palpating the abdomen, which he names “hydrostatic exploration.” It consists in palpation of the abdomen while the patient is in a bath sufficiently deep to cover its surface with water. The relaxation of the parietes thus produced is explained by the fact that, more or less loaded with fat, they tend to rise toward the surface. Thus, this ascending movement, counteracting their elastic and contractile force, which tends to keep them in close relation with the viscera, gives them a laxity which is highly favorable to exploration of the deep parts. The whole of the abdominal organs, even in stout subjects, are thus rendered peculiarly accessible to touch, and the fingers readily make out even the vertebral column and the sacrovertebral angle. Adolphi³ speaks highly of the Brandt-Dührssen method of examination, which, it is claimed, allows one to practise bimanual examination as thoroughly as if the patient were anesthetized. The essential point is that the thighs should be strongly flexed as the woman lies upon her back, while the examining-finger is introduced under the left thigh, instead of between the thighs. Adolphi employs a low couch, the head and foot of which can be raised by means of screws. The patient lies upon her back with her arms extended, her mouth being slightly open. The physician sits on her left side and places his right hand upon the abdomen, while the left forefinger is inserted into the vulva. If the abdominal muscles are not sufficiently relaxed, the patient is drawn downward and the thighs are flexed still more by raising the lower segment of the table. The symphysis and thorax are approximated and the recti are relaxed, thus favoring the most satisfactory practice of the bimanual method. W. R. Pryor⁴ suggests a method of examining the pelvic contents which renders exploratory section unnecessary in inflammatory conditions of the appendages, and in certain other diseased states of the pelvic viscera. It consists in opening Douglas’s

¹ Brit. Med. Jour., Oct. 31, 1896.

³ St. Petersburg. med. Woch., No. 43, 1896.

² L'Union méd., No. 25, 1896.

⁴ Med. Rec., July 11, 1896.

cul-de-sac by a transverse incision through the vaginal mucosa, downward traction being made upon the cervix; a digital exploration of the pelvic cavity is then made and a knowledge obtained as to the state of affairs. It is in doubtful cases—possible hydrosalpinx, broad-ligament cyst, enlarged ovary with adherent inflamed tube—that there exists the indication for this, as for the abdominal exploratory incision. The advantages of the method are, its rapidity (the cul-de-sac is entered in from 1 to 5 minutes), bloodlessness, and safety. Should a vaginal hysterectomy be indicated the exploratory vaginal incision completes the first step of the radical operation. Should it be deemed wise to open the abdomen the vaginal incision affords the rational drainage-space. [This method is open to all of the objections of the original section, and cannot be recommended as an absolutely safe procedure.]

In considering the value of *rectal exploration in children* G. Carpenter¹ pays considerable attention to the female pelvic organs. The sacrum is almost straight, as is the course of the rectum. The bladder is egg-shaped, with the larger extremity downward; it is almost entirely an abdominal viscus owing to the shallowness of the pelvic cavity. When the girl begins to assume the upright position and walk the bladder tends to sink into the pelvis; at the same time the attachments are so lax that when distended it lies almost completely in the abdominal cavity. This condition exists until puberty. The uterus is almost entirely composed of cervix, the body being very small, and is situated high up in the pelvis. It is found at birth that the ovaries have descended as far as the brim of the true pelvis, while a little later in life there is a further descent. The uterus is 1 in. long and $\frac{1}{2}$ in. broad at the fundus; the Fallopian tubes measure just under 2 in. in length; the right ovary is $\frac{5}{8}$ in., the left $\frac{1}{2}$ in. in length, and both are $\frac{1}{6}$ in. in diameter. As the child approaches puberty the ovary measures $1\frac{1}{2}$ in. in length by $\frac{1}{2}$ in. in breadth. The important anatomic guide to the Fallopian tubes when making a rectal examination appears to be the falciform ligament, or, in other words, the uterosacral ligaments, which form together a sickle-shaped curve surrounding the rectum, being attached posteriorly to the sacrum and anteriorly to the junction of the vagina and cervix.

Salpingitis.—E. Reymond and W. S. Magill² have made an exhaustive experimental study of the pathologic anatomy and bacteriology of salpingo-ovaritis.

The authors assert that the usual classification of salpingitis, although clinically useful, is no more founded upon the successive stages of the affection than upon the different forms of the infection. The *salpingitis productiva vegetans* of Savinoff is the same form as that described by Cornil as *vegetating catarrhal salpingitis*; it is in reality a parenchymatous form, the parenchyma having assumed the preponderance in relation to the other tissues. *Salpingitis papillomatosa* and the *nodular salpingitis* would appear to constitute a special form due to a particular agent of infection. According to Doran, the papillomata invade the salpinx in the same manner as gonorrhoea, the contagion being due to direct contact. These papillomata determine a secretion which varies according to its location. The vulva and vagina give rise to a fetid and abundant secretion; in the uterus this affection causes frequent metrorrhagia, sometimes excessive in quantity; in the salpinx the irritation caused by this infection may be so violent as to produce an obliteration of the pavilion, and thus prevent an extension of the affection to the peritoneum; but if the adhesion of the pavilion is not obtained and its permeability persists, there flows into the peritoneal cavity a serous liquid of slight irritating quality, caus-

¹ Pediatrics, June 1, 1896.

² Ann. of Surg., Sept., 1896.

ing, perhaps, a little ascites, but incapable of provoking adhesions; papillomata of the peritoneum and ovaries may then appear. The nodular variety has two principal characteristics: (1) nodules formed by the muscular tissue itself; (2) culs-de-sac of mucous follicles isolated in this muscular mass. The authors believe that both forms should be united and more advantageously considered as the exaggeration of a usual disposition of the tissue in salpingitis rather than a definite variety. A careful revision of the various elements would seem to explain the formation of the nodulofollicular salpingitis in the following manner: By agglutination of the fringes cysts are formed in the mucosa of the salpinx. The walls of these cysts are very vascular, and this vascular tissue has a strong tendency to transformation in the external coats of the mucosa in contact with the muscular. It may give place to fibrous tissue, but its change into muscular tissue invading the mucosa is often seen. Such transformation would appear analogous to that which Klebs describes for the formation of myomata; the large capillaries first surround themselves with spheric cells that ultimately become fusiform. The cysts included in the wall are crowded out by the formation of muscular tissue on the inside. These transformations could take place in all points of the salpinx in regular sequence, and in this case the salpingitis would deserve the designation parenchymatous. But in a patient predisposed to fibromata the production of muscular fibers may be so accentuated in a single point as to form a myocystic nodulus; and as the muscular tissue tends toward a transformation into fibrous tissue, a fibrocystic formation would finally be realized in this way.

Under the influence of inflammation the fringes first become enlarged, and their ramifications more numerous, the cellular infiltration distends the connective tissue, separates the epithelial surfaces, tends to obliterate the fine ramifications, and gives the fringe a globular appearance.

In speaking of the symptoms of salpingitis L. G. Baldwin¹ states that it is the general opinion among the profession that pus-tubes spontaneously discharge through the uterus, a cure resulting; and, in case they do not empty themselves, that they may be drained by dilating and curetting the uterus. He would place himself on record as saying that he does not believe that a pyosalpinx ever discharged through the uterine end of the tube into the uterus, either spontaneously or as a result of dilatation and curetting of the uterus. His reasons are, first, the normal size of the lumen of the tube at the isthmus, together with the large amount of muscular tissue it contains at that point, rendering during pathologic conditions narrowing, if not complete occlusion, almost certain as a result of the preceding inflammatory process; and, secondly, the careful observation of a large number of removed specimens in not one of which could pus be squeezed through the uterine end without considerable force being applied. [The author has reached the same conclusion as have a large number of other surgeons in this matter.]

Septic inflammation of the tubes and pelvis is, according to W. Duncan,² in the great majority of cases the result of parturition, though a few cases may be due to the use of sponge or laminaria tents or to operations performed on the uterus with dirty instruments. Bernutz analyzed 99 cases of peritonitis as follows: 43 occurred in puerperæ; 28 after gonorrhœa; 20 during menstruation; and 8 were traumatic. Duncan believes that almost all the cases of peritonitis occurring in women, apart from labor, are most likely secondary to specific infection from gonorrhœa. When a purulent collection in the tube leaks into the peritoneal cavity peritonitis follows; and this may be either (a) serous, (b) plastic, or (c) suppurative; it may be quite localized, or affect

¹ Am. Gyn. and Obst. Jour., Nov., 1896.

² Lancet, Jan. 2, 1897.

the whole pelvis, or even in very severe cases it may become general. Usually it is limited in extent, the ostium of the tube becoming closed, and the ovary matted to the tube; then ovaritis follows or an abscess may be formed in the ovary. The form most often met with is the plastic, where lymph is thrown out, matting the parts together. The chief symptoms of chronic disease of the tubes and ovaries associated with slight peritonitis are pain, hemorrhage, and yellow discharge. The pain varies; in catarrhal salpingitis it is slight, as there are no pelvic adhesions; but in purulent salpingitis and ovaritis (especially when the ovary and tube are matted together) there is more or less constant pain in the back and iliac fossæ, extending down one or both thighs, and aggravated by coitus, walking, or jolting. Menorrhagia is pretty constant in these cases, with a mucopurulent uterine discharge in the intervals. Deguy¹ records a case of infectious endocarditis following pyosalpinx, and W. R. Lincoln² a case of double salpingitis in which lime-salt concretions were found in both tubes.

The Bacteriology of Diseased Adnexa.—Kiefer³ sought to determine the question as to the presence of bacteria in pyosalpinx; what method of examination is of the greatest practical value, the cover-glass preparation or culture; the proportion of the different species, and the average virulence of the pyogenic bacteria found. He made cover-glass preparations and cultures from 40 cases of pyosalpinx or ovarian abscess, in all of which the pus had soiled the peritoneum during operation. Although cover-glass preparations reveal the presence of bacteria, they do not give information regarding their vitality or degree of virulence. The gonococci were largely in majority, next the bacteria coli, the latter being mainly found in ovarian abscesses. None of the 40 cases died from purulent infection of the peritoneum, which again proves the fact that bacteria confined encapsulated in closed cavities soon lose their virulence; they die from their own products—the toxins. The average time determined from the formation to the sterility of the pus is about 9 months.

Tuberculosis of the Fallopian Tubes.—Cases of tubal tuberculosis are recorded as follows: C. Cone,⁴ encysted dropsy of the peritoneum secondary to uterotubal tuberculosis and associated with tuberculous pleurisy, generalized tuberculosis, and pyococcal infection in a colored woman 30 years of age; J. A. Robison,⁵ a case of focal tuberculosis in the right Fallopian tube, with general miliary tuberculosis, in a single woman of 22 years; Heydenreich,⁶ a case of tuberculous salpingitis in a woman 39 years of age; and G. Carpenter,⁷ a case of tuberculosis of the uterus and adnexa in a girl of 9 years, who also had tuberculous peritonitis, and subsequently died of general tuberculosis. [Tuberculosis of the uterus and adnexa is extremely rare in children.] Robison⁸ remarks that tuberculosis of the tubes may develop at any age, but rarely before puberty. It is most common during menstrual life, and often arises during pregnancy. It often follows tuberculosis of the genital organs or of the lungs, rectum, and peritoneum. Many authors believe that tuberculosis of the uterus is frequently due to primary tuberculosis of the tubes with extension to the uterus. The diagnosis of tubal tuberculosis is comparatively easy if the abdominal walls are thin and the vagina large, as is taught by Chiari, the tubes being felt as irregular tumors external to the uterus.

Carcinoma of the Fallopian Tubes.—Hennig⁹ considers the diffi-

culty of diagnosis due to the very great infrequency of the disease. When gonorrhœal affections are excluded, the diseases to be thought of are sacculated growths, tuberculosis, carcinoma, or abnormal pregnancies. The diagnosis of carcinoma is made more easy than others in that a fluid (increasing in amount) is encapsulated by a ridged wall; sometimes also there is a vaginal discharge of bloody water or cloudy mucus. The statistics regarding its frequency widely differ. Wagner states that in northern Germany 5% of uterine carcinoma are associated with carcinoma of the tube, while Kiwisch, in southern Germany, found the tube carcinomatous 25 times with 100 uterine carcinomata. It very rarely occurs with carcinoma of the cervix, is more frequent with ovarian carcinoma, and most frequent with carcinoma of the uterine body. Primary tubal carcinoma may infect either the uterus or peritoneum, and is most frequently bilateral. Eighteen cases have been reported. *Sarcoma of the tube* is excessively rare—only 4 cases having been reported. The form of carcinoma, according to Sanger, is always medullary; sometimes it is infiltrating, and sometimes villous. The climacteric and catarrhal inflammation are predisposing causes (Sanger). The diagnosis *per vaginam* must be made by exclusion and by rectal and bimanual examination under ether. Cachexia is not present—at least not early. The presence of ascites, disease of neighboring organs, stomacic, urinary, and rectal symptoms are important. When the growth breaks through into the peritoneal cavity marked symptoms result. The appearance of the posterior wall of the bladder is often important. In 6 cases the diseased organ has been removed and the patient provisionally restored. In 4 cases the disease returned—in Thornton's case after 3 years. Doran advises the removal of uterus and both tubes. Four patients died either during or immediately after operation. In the case in which the growth was least advanced the uterus and tubes were removed *per vaginam*. The left tube showed beginning villous carcinoma.

Eckardt¹ reports a case of primary alveolar carcinoma of the tube, the fifth on record. Twelve other reported cases were of the papillary variety. E. Ries² reports what he claims is the 7th case of primary papilloma of the tube, and the 20th case of primary carcinoma of the tube, the tables of Doran (in Allbutt and Playfair's *System of Gynecology*, 1896) and Sanger (in Martin's *Krankheiten der Eideiter*, 1896) containing 19 cases. Godart³ observed a case of papilloma of a Fallopian tube in a sterile woman of 32 years.

Echinococcus of the Tubes.—Doleris⁴ reports the case of a multipara, aged 36 years, who had suffered with severe abdominal pain for 11 years. The diagnosis of uterine fibroid was made. On opening the abdomen a tumor was found extending above the umbilicus. It consisted of both Fallopian tubes enormously enlarged and adherent to one another and to the omentum. They contained numerous echinococcus cysts. There were no metastases. The patient was cured. [The formation of a hydatid cyst in the pelvis is very rare. Davaine considered that they formed 7.9% of all cases, but it is probable that this estimate is far too high. The danger caused by their presence in this situation depends to a large extent on their pressure on the surrounding parts, especially on the urinary canals. They may also cause obstruction to delivery in pregnant women. Porak collected a series of 17 cases, in some of which delivery was impossible. No fewer than 6 died. Of the cases recorded in England the majority have been males. Kenwick found 90 cases of the disease recorded in 200 years. The majority appear to have originated

between the muscular coat of the bladder and the peritoneum.] G. Herman¹ records an additional case forming a retrouterine tumor in a woman of 66 years, and causing retention of urine. [Pelvic hydatids show a tendency to suppurate, and also to erode and mine the pelvic bones.]

Tuberculous Peritonitis.—Abbé² states that the stages of tuberculous peritonitis are divided as follows: There may be (1) an eruption of miliary tubercles on the surface of the peritoneum so acute that acute infectious diseases or even strangulated hernia have been suspected; or there may be (2) an enormous accumulation of ascitic fluid, with rapid wasting, slight pain, and no fever—here a slow deposition of tubercles, widely scattered over the peritoneum, has occurred. There may be (3) persistent pain or tenderness of the abdomen, with moderate tympanitic distention and irregular areas of dullness, associated with slight afternoon temperature and loss of appetite or flesh, indicating diffuse tuberculosis of the peritoneal cavity without fluid, but with a varying amount of plastic exudate partially sealing its walls together; or there may be (4) wasting of the body with irregular tympanitic distention, fever, anorexia, and sweats, associated with huge cakes of matted lymph and omentum, or sacculated ascites or pus, which illustrates the latest steps of tuberculous development; or there may be (5) the mishaps incident to degeneration of caseating patches ulcerating into the bowel, causing fistulae or extravasations of feces into the peritoneum, or bowel-obstruction by lymph-adhesions; and, finally, (6) a retrograde course in the life of the bacillus and its products may leave an abdominal cavity partly sealed by atrophied tuberculous elements, which may give the patient years of comparative health. Abbé believes that the bacillus enters less often through the circulation than through perforation of the intestinal wall or through transmission from the Fallopian tube.

Treatment of Pelvic Disease.—The prevention of pelvic disease is discussed by R. Peterson.³ He states that the causes of pelvic disease are: (1) *Imperfect development of the sexual organs.* At no period of life will prophylactic measures prove of so much avail as during the few years prior to puberty. Prolonged hours in the school-room and ignorance as to the functions of the generative organs are responsible for much of the disease of later life. (2) *Gonorrhœa.* (3) *Lacerations due to childbirth.* The improved obstetrics is doing away with much of the pelvic disease consequent upon unrecognized and unrepaired lacerations of the cervix and perineum. (4) *Sepsis following childbirth and abortions.* W. R. Pryor⁴ suggests that suppuration may be prevented by curetting the uterus in all cases of acute salpingitis and peritonitis. He has done this in nearly 100 cases of acute first attacks, and he has never seen failure result from it when early applied. The causes of failure in the hands of others are the use of strong antiseptics within the uterine cavity, partial removal of debris, and incomplete packing of the uterus.

Abdominal Section.—Interesting cases are recorded as follows: J. H. Galton,⁵ a case of successful second ovariectomy at the age of 70 years, the first operation having been performed 12 years before. [Many instances have been recorded of cases of ovariectomy above the age of 70 years. J. R. Morison recorded 5 cases, and of these only 1 died. Homans recorded 12 cases, of whom 3 died. M. Sherwood collected 38 cases, with 5 deaths. Spencer Wells's oldest case was 71 years of age, and Keith's 73 years. Terrier removed both ovaries from a woman aged 77. Several cases have been recorded

⁴ Med. News, Sept. 5, 1896.

⁵ Lancet, Aug. 15, 1896.

of ovariectomies on patients over 80 years of age. Schroeder's and Owens's cases were each 80 years old. Edis records a case over the age of 81 years. H. Spencer's case was 82 years 3 months old. Homans's case was 1 month older. J. P. Bush performed an ovariectomy on a patient who had commenced her 85th year. All these patients over 80 years of age recovered from the operation.] G. Carpenter¹ records an ovariectomy on a child 9 years of age suffering with tuberculous Fallopian tubes. [The youngest ovariectomy on record is that reported by Chiene in 1884, on a child aged 3 months.] Carpenter tabulates 35 cases of ovariectomy on children performed for cystic disease, dermoids, fibromyoma, sarcoma, and carcinoma.

The *technic of abdominal section* is discussed by J. G. Clark,² T. J. Watkins,³ and I. S. Stone.⁴ The method of preparing sponges at the Johns Hopkins Hospital, as recorded by Clark, is as follows: 1. Reef sponges are pounded with a wooden mallet until freed from gritty particles; 2. They are then immersed in HCl solution (5ij to Oj) over night; 3. They are then washed in pure water until the latter is perfectly clear; 4. They are immersed for a few minutes in a saturated solution of potassium permanganate; 5. They are transferred from this solution with sterile hands to a saturated solution of oxalic acid, and left there until decolorized; 6. They are then rinsed through sterile water; 7. They are next immersed in mercuric chlorid solution (1:1000) for 24 hours; 8. They are transferred to a 1:20 solution of carbolic acid, where they are permanently preserved until ready for use.

The *vagina* is carefully cleansed in the following manner: 1. It is thoroughly washed with green-soap and warm water; 2. It is then douched with a 10% creolin solution; 3. It is further washed with sterile water; 4. Finally, it is douched with mercuric chlorid solution (1:1000), followed by sterile water.

Sterilization of Ligatures.—Clark and Miller,⁵ after a thorough bacteriologic investigation and a practical experience of a year with the cumol method of sterilization of catgut, conclude that it is the most reliable. The sterilization by Krönig's method is perfect, but the transference from boiling cumol to benzene is open to serious objection. Clark and Miller have found from this investigation that benzene is not a germicide; also that it cannot be rendered sterile by heat without danger, and, therefore, they have found it necessary to modify the method of Krönig as follows: (1) The catgut, 12 strands, is rolled in a figure-of-8 form, so that it can be slipped into a large test-tube. (2) The catgut is brought up to a temperature of 80° C., and held at this point for 1 hour. (3) It is placed in cumol, which must not be above 100° C.; this temperature is raised to 165° C., and held at this point for 1 hour. (4) The cumol is then poured off, and either the heat of the sand-bath is allowed to dry the catgut, or it is transferred to a hot-air oven, at a temperature of 100° C., for 2 hours. (5) The rings are transferred with sterile forceps to the test-tubes previously sterilized, as in the laboratory. In drying or boiling, the catgut should not come in contact with the bottom or sides of the vessel, but should be suspended on slender wire supports, or placed upon cotton loosely packed in the bottom of the beaker-glass.

Bröse,⁶ at the meeting of the Berlin Obstetric and Gynecologic Society on November 13, 1896, advised the following new method for sterilizing catgut. The catgut, wound on glass rollers, is first placed in juniper oil or tur-

⁵ Bull. Johns Hopkins Hosp., Nos. 59 and 60, 1896.

⁶ Centralbl. f. Gynäk., No. 52, 1896.

pentine, in a vessel having a stopper that will not allow steam to enter. The vessel is then placed on a water-bath (the water being cold) and heat is applied for one-half hour. These ethereal oils, which boil at a temperature of from 155° to 160° C., reach a temperature of from 99° to 100° C. in the half hour. In these thus heated ethereal oils all bacteria, including the anthrax-bacillus, are destroyed. This the writer proved by a thorough bacteriologic investigation. The catgut retains the strength, and, besides, it is free from fat and water. These oils are also strong disinfectants. Since catgut taken directly from the oil would be difficult to handle, and, again, since the oil would irritate the tissue, he advises that the catgut be placed, just before operation, in a 1:1000 alcoholic solution of the mercuric chlorid. Bröse has employed catgut thus prepared for 3 months with perfect satisfaction. Schaffer, in the discussion, stated that only fresh juniper oil should be employed, as this alone has the power to disinfect.

Tretrop¹ has been experimenting with formol as a means of sterilizing catgut and other ligatures. Soaking in a 2% solution for 24 hours will kill all bacteria except staphylococci. A 5% solution (by volume) rendered catgut, silk, silkworm-gut, and rubber tubing absolutely sterile. The experiments included tests with streptococci, staphylococci, anthrax, bacterium coli, Löffler's bacillus, and the bacillus pyocyaneus. The sterilized material was kept in common alcohol (94%), and was found to be sterile after 4 weeks. An experiment on a dog showed that the catgut was completely absorbed after 4 days, so that no trace remained of No. 4 gut.

Closure of the Abdominal Wound.—In discussing this subject before the International Congress at Geneva² Bantock offered the following conclusions: 1. Suppuration of the abdominal wound is due, not to the presence of bacteria, but to foreign bodies or to strangulation by tight sutures. 2. In many cases simple through-and-through sutures are sufficient. 3. In stout patients it is better to close the peritoneum separately and the remaining layers of the wound with 1 or 2 series of sutures. 4. Silkworm-gut is the best for interrupted sutures and catgut (*not* chromicized) for buried sutures. Le Torre thinks that it is not sufficient to unite the fascial edges alone; the edges of the muscle should also be included in the sutures. Howitz believes that just as little of the peritoneum as possible should be included; in fact, he approves of the plan of some operators not to suture the peritoneal edges at all, but to allow them to unite toward the abdominal cavity. Patients should not be allowed to leave their beds until 3 weeks have elapsed. Condamin recommends a tier-suture in the form of corset-lacing, especially in large wounds.

At the Johns Hopkins Hospital³ the following method is employed: 1. Continuous catgut sutures to the peritoneum; 2. Silver mattress-sutures, which are passed only through the aponeurosis of the separated recti muscles, and closely twisted 5 times. The wires are cut smoothly with dull scissors, and the point turned down upon the aponeurosis of the recti muscles, projecting neither upward nor downward; 3. Continuous catgut to the fat; 4. Subcutaneous catgut suture. No. 24 sterling silver wire is used. It is sterilized by boiling with the instruments. After the abdominal dressing is applied the patient is elevated to the medium high Trendelenburg posture, and a liter of warm salt-solution (0.6%) is injected well up into the sigmoid flexure. In order that the patient may retain the enema *she must yet be under the anesthetic when it is given*, otherwise the bowel will not tolerate such a large quantity of fluid. This means of alleviating thirst was first employed 2

¹ Centralbl. f. Gynäk., No. 15, 1896.

² Ann. de Gynéc. et d'Obstét., No. 9, 1896.

³ Clark, *Loc. cit.*

years ago and has proved remarkably effective. Goelet¹ unites the peritoneum by a continuous suture of fine (No. 0) chromicized catgut, which is made to include the muscle as well. Next, deep interrupted sutures of silkworm-gut are inserted about $\frac{1}{2}$ or $\frac{3}{4}$ in. apart and $\frac{1}{2}$ in. from the margin of the wound. They include skin, fascia, and muscle, and are not tied at once. The

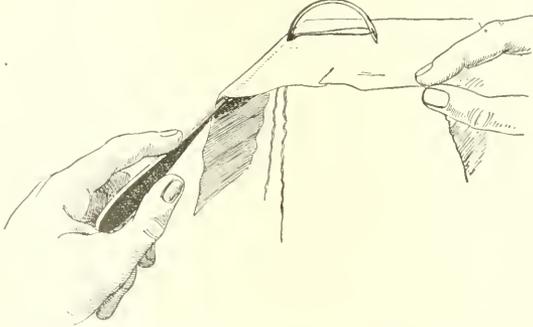

FIG. 42.—Shimonek's figure-of-8 ligature (Jour. Am. Med. Assoc., Sept. 26, 1897).

fascia is then united separately by means of a continuous suture of the same size chromicized catgut as before. The interrupted silkworm-gut sutures are now tied. C. P. Noble² has employed the buried silkworm-gut suture in 297 abdominal sections; of these cases suppuration occurred in 7, or 2.3%. The silkworm-gut should be carefully selected, and should be light in weight and

FIG. 43.—Shimonek's figure-of-8 ligature (Jour. Am. Med. Assoc., Sept. 26, 1897).

absolutely aseptic. To secure the best results the abdominal incision should pass through one rectus muscle rather than through the linea alba. F. Shimonek³ describes a new figure-of-8 ligature. An armed needle is passed through the pedicle, as shown in Fig. 42. That part of the ligature passing through the eye of the needle is withdrawn from it, as shown in Fig. 43. We

¹ Clinical Record, July, 1896.

² Am. Gyn. and Obst. Jour., Dec., 1896.

³ Jour. Am. Med. Assoc., Sept. 26, 1897.

now have the needle and ligature passing through the same opening in the pedicle, and yet they are independent of each other. Take that part of the

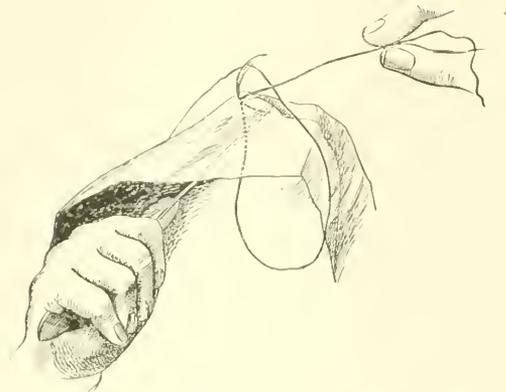

FIG. 44.—Shimonck's figure-of-8 ligature (Jour. Am. Med. Assoc., Sept. 26, 1897).

ligature corresponding to the handle of the needle, carry it half-way around the pedicle, and pass it through the eye of the needle, as shown in Fig. 44.

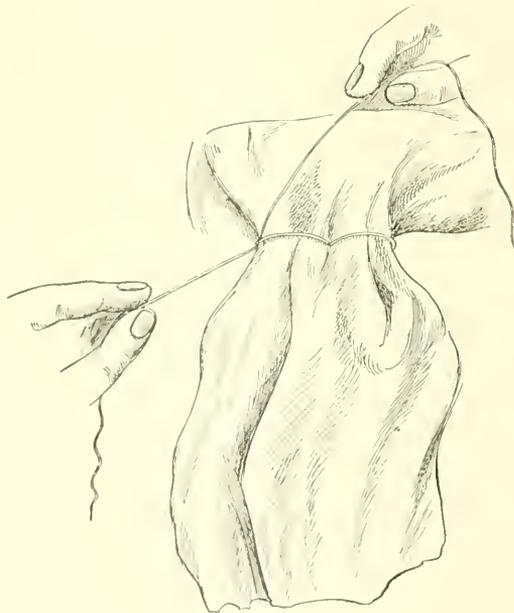

FIG. 45.—Shimonck's figure-of-8 ligature (Jour. Am. Med. Assoc., Sept. 26, 1897).

Now withdraw the threaded needle from the pedicle, thereby forming a loop upon one side of the latter; the ends passing and crossing through the same opening appear upon the other side and may be tied, as shown in Fig. 45; or,

in a very broad pedicle that cannot be securely tied with one figure-of-8, the needle may be passed through the pedicle at a distance of $\frac{1}{2}$ in. or more, threaded with one of the free ends, then unthreaded at that end and again threaded with the other one, and so on, until the entire pedicle is encompassed and the free ends tied.

Schaffer¹ writes that silk as a suture-material has greatly replaced the smooth, hard silkworm-gut and silver wire because of its flexibility, elasticity, and strength. The reason why silkworm-gut and silver wire are still frequently employed is that when silk is employed stitch-hole abscesses are apt to result. The great trouble which every one has experienced in the sterilization of the silk suture, chemical as well as physical disinfection, has continually become less and less; also the physical quality of the silk itself is now considered—the construction of the Ihle silk suture-carrier, which has the object of exposing each strand directly to the sterilization. As experimentation has shown, these methods are sure enough in rendering the bacteria in suture-material unharmed, except as regards catgut, which sometimes contains an irritating toxin which will develop in water, but not in the preparing alcohol or ether. He says that in order to prevent the invasion of the stitch-canal with bacteria two conditions must be considered: (1) the site of introduction of the suture must be free from bacteria, and (2) the suture-material should not absorb fluids, so that the stitch-canal remains dry; no bacteria are then introduced as, at least, a favorable culture-medium is not prepared. This, however, is not usually attained, for during the manipulation of the wound and skin the suture-material is saturated with fluid. The first condition is prevented, or, at least, greatly prevented through thorough mechanical (the brush, soap, water, and alcohol) and chemical (mercuric chlorid) disinfection. The mechanical disinfection not only removes a large amount of fat, but also partially empties the glands of the skin. The second condition as regards the silk suture is not gained; for, although sterile, it is very hygroscopic. If the silk suture is introduced in the abdominal wall in the ordinary manner, particularly in fat women, it is very easily removed, and Ihle believes this is true of the figure-of-8 ligatures in the abdominal cavity. The silk ligature absorbs the wound-matter and continues saturated, and such saturated suture at the body-temperature constitutes a most favorable culture-medium for pus-organisms which may have been introduced from the skin-surface or its glands. Considering this factor as important, the writer sought to get a silk suture which would act as a capillary drain, and therefore now advises the use of silk suture-material which is impregnated with gutta-percha, prepared by Evens and Piston, of Kassel. Its advantages are that it is as soft, elastic, strong, and as easily sterilized as before; it receives a satin luster, a proof that it has the consistency of vessels; if dry, ordinary and impregnated portions be placed in water, the impregnated is unchanged while the other becomes soft and saturated; and if the end of each be placed in colored water at the body-temperature, the impregnated remains dry and the surface only is slightly discolored.

T. J. Watkins² performs abdominal salpingo-oöphorectomy without leaving a pedicle. This is done by passing a ligature under the infundibulopelvic ligament just deep enough to include the ovarian artery; the suture is tied, the short end is cut off near the knot and the long end is left to suture the broad ligament. The tube and ovary are then separated from the broad ligament by dividing the latter close to the tube from a point just external to the tube and ovary, and by continuing the division until the uterus is reached, when the tube is excised flush with the uterus. The wound is then closed

¹ *Centralbl. f. Gynäk.*, No. 46, 1896.

² *Med. News*, Aug. 8, 1896.

with the long end of the suture by the glover's stitch. The advantages of this method are: (1) no pedicle is made; (2) the entire tube and ovary can be excised; (3) very little tissue is included in the suture and very little tension is made on the broad ligaments; (4) little or no raw surface remains to form adhesions or cicatrices; (5) absorbable sutures may be used without fear of hemorrhage; (6) blood-vessels are ligated while in normal location, which protects against retraction and hemorrhage; (7) when the broad ligaments are friable hemorrhage can be more easily controlled by suture than by ligature *en masse*; (8) bleeding points in the posterior surface of the broad ligament are more accessible after suturing than after the broad ligament has been puckered by ligature. In order to remove pus-tubes without rupture, I. S. Stone¹ prefers to make a longer incision, tie the ovarian and ovario-uterine arteries and free the specimen at one or both ends or sides before attempting enucleation.

Drainage.—Baldy² remarks that the tendency of the day is to as much as possible eliminate drainage, and experience is daily proving that this procedure is less and less necessary in abdominal surgery. He has drained very little of late and has not seen a fistula occur, nor does he know of but 1 or 2 hernias during the past 3 years' work. Not over 5% of cases require drainage. J. G. Clark³ endorses the postural method of draining the peritoneal cavity after abdominal operations. The method consists in introducing 500 to 1000 c.c. of salt-solution into the peritoneal cavity after thorough irrigation; the patient is then returned to her room, and the foot of the bed elevated about 20°, which gives sufficient inclination of the posterior pelvic wall to assist the flow toward the general peritoneal cavity. This posture should be maintained for 24–36 hours, after which the bed may be lowered. This method of drainage is offered as a prophylactic measure against postoperative peritonitis, but *not as a curative measure* after the peritonitis is established. It should, therefore, not be employed when an operation is performed for the relief of purulent peritonitis or for inflammatory conditions associated with general peritonitis. According to Watkins,⁴ drainage should be employed: (1) when general septic peritonitis exists; (2) when septic matter has escaped into the general peritoneal cavity; (3) when necrotic or septic tissue is left in the pelvic cavity; (4) when hemorrhage exists which cannot be readily controlled by ligature, suture, or temporary pressure; (5) when an intestine has been so injured that fecal fistula is liable to occur.

After-treatment of Abdominal Section.—According to Clark,⁵ thirst may be controlled by saline enemata; if, however, the fluid is expelled, as is occasionally the case, water in small sips, cracked ice, or small saline enemata may be used to alleviate it. For the *vomiting*, a mustard-plaster over the epigastrium, hot or cold water bags to the nape of the neck, 20 drops of a 5% solution of cocaine, cerium oxalate in 1 gr. pill, or chloroform-water may be tried. Rectal feeding must be the only means of alimentation. The treatment of *tympanites* consists in the free administration of purgatives, usually calomel or salts, large high enemata, and the insertion of a rectal tube well up into the colon. The very light application of the Paquelin cautery to the abdominal surface has been of the greatest value in many cases. The platinum point is heated to a dull red and so lightly applied that it makes not a distinct burn, but a decided erythema; this is accomplished by just touching the tips of the short hairs on the abdomen.

⁴ Loc. cit.

⁵ Therap. Gaz., Dec. 15, 1896.

Complications during and after Abdominal Section.—1. *Stitch-hole Abscesses.*—Clark¹ employs large flaxseed poultices made up with 1:1000 mercuric chlorid solution until localization of the pus occurs, when the abscesses are freely opened. Subsequently the abscess-cavity is kept clean with boric-acid irrigations and hydrogen peroxid. W. E. Ashton² employs a snare of silkworm-gut to remove infected ligatures from sinus-tracts in the abdominal wall.

2. *Phlebitis.*—Clark³ lightly touches the line over the inflamed vein with a Paquelin cautery, after which the leg is elevated and enveloped in rolls of cotton and a gauze bandage.

3. *Parotitis.*—W. S. Morrow⁴ reports 3 cases occurring during the course of pelvic disease and W. Krusen⁵ 2 cases following abdominal sections. [Paget has collected 101 cases of parotitis following injury to the abdominal or pelvic organs, and due not to pyemia, but to reflex nervous action. Fifty of these were due to slight injuries, as a blow or the introduction of a pessary. It may occur during pregnancy. In 78 of the cases 45 were suppurative and 33 resolved without suppuration.]

4. *Peritonitis.*—Michoux⁶ during the last 3 years has employed the intravenous injection of serum in 25 to 30 cases of septic peritonitis, obtaining very good results, even though the symptoms were severe, as when there existed tympanites, small and rapid pulse, and subnormal temperature. The serum was that advised by Hayem, and when this could not be procured he employed boiled water containing 105 to 150 gr. of sea-salt to the quart. The quantity of serum used was usually 32 to 48 oz., but in 2 cases 80 and 96 oz. The amount of urine was always very much increased. With this treatment he combines hypodermic injections of ether, caffeine, and alcohol. Monod, in 7 patients with septic peritonitis, practised intravenous injections of serum, with the result that 4 died and 3 recovered.

5. *Pulmonary Embolism.*—Gessner⁷ believes that the production of thrombosis and the resultant pulmonary embolism is always brought about through the concomitant action of several causes. The origin of the thrombosis is inflammatory disease acting either directly within the blood-channel, or the inflammatory process arises in the tissue surrounding the blood-vessel, and then it extends to the blood-vessel wall. Further important factors that favor thrombosis are the presence of anemia and changes in the heart. These last conditions are most often found with fibroid tumors, which accounts for the greater number of instances of thrombosis and pulmonary embolism associated with this disease. Besides fibroid tumors the malignant new-growths may predispose the patient to thrombosis. The writer considers mechanical causes to be of very little moment. The characteristic increase of the pulse-frequency which Mahler has described in these cases Gessner has not observed in all cases. The careful observation of the pulse after operation is always of the greatest importance. He agrees with Mahler and Wyder that in fatal pulmonary embolism the thrombosis usually occurs in the large pelvic veins. The separation of emboli is without doubt mechanical. The treatment should be chiefly prophylactic. If, in spite of this, pulmonary embolism does occur, the patient is best treated with hypodermic injections of ether and elevation of the upper part of the body. For the subjective symptoms morphin hypodermically has a favorable influence.

⁷ Centralbl. f. Gynäk., No. 6, 1897.

6. *Psychoses*.—Jacobs¹ believes that mental derangements that appear immediately after operation offer a more favorable prognosis than those that develop after a considerable lapse of time.

7. *Emphysema of the Abdominal Wall*.—Heil² reports this interesting case, 9 others having been recorded: on the third day after a Porro operation (the abdominal incision having been closed with deep and superficial sutures) emphysema developed along both edges of the wound. By the eighth day it had disappeared on the left side, but on the right it extended to the iliac region, when it gradually subsided, no trace of it remaining 4 days later. Madlener affirms that Trendelenburg's position favors the development of emphysema, as air is drawn into the abdominal cavity by the upward movement of the intestines and diaphragm; hence he advises that the sutures should not be tied until the patient has been lowered to a horizontal posture. Gräfe advises that the abdomen should always be compressed by an assistant before sutures are tied. However, in cases reported by Leopold and Brosin the patient remained in the horizontal position throughout the operation. The writer believes that emphysema is due entirely to imperfect approximation of the deeper layers of the abdominal wall, with firm union of the skin. This he demonstrated clearly by experiments on rabbits. To avoid emphysema, he concludes, as well as hernia, exact approximation of the recti and their sheaths is all-important, the position of the patient being a minor consideration.

8. *Opening of the Abdominal Wound*.—Switalski³ reports a case in which the wound opened a week after operation as a result of severe and persistent coughing. The suture-material employed in the primary operation was catgut, 3 separate layers being introduced. [This accident is very rare; Rosner has been able to collect but 31 cases during the last 3 years.]

Vaginal Prolapse.—Baldy⁴ describes a method of preventing vaginal prolapse after abdominal hysterectomy. He includes both the ovarian artery and the round ligament in the first ligature on either side; this ligature is placed as near the pelvic wall as possible, so as to leave but a small amount of broad ligament behind with the stump; one ligature is placed on each side of the uterus, including the uterine artery, with as little other tissue as possible; this leaves both broad ligaments open; the uterus is amputated as low on the cervix as possible. The sutures employed are of heavy silk, and include both the ovarian and uterine stumps, deeply placed well back of the ligatures; they include the sides of the cervical stump, and when tied lift this together with the vagina and bring it in close approximation with the ovarian stumps, doubling the open broad ligaments together, between which folds firm adhesions take place.

Hysterectomy for Suppurative Disease of the Pelvic Organs.—

R. Peterson⁵ suggests that after 3 years' work in this line it would be well to pause and ask ourselves not, How many uteri have been removed during this period? but, How much has been learned from careful microscopic and bacteriologic examinations of these removed organs? In other words, do the pathologic lesions found in the ablated uteri confirm the correctness of the reasoning of those who, mainly upon clinical grounds, advocate hysterectomy in certain inflammatory pelvic diseases? He claims that the surgeon has no right to remove the uterus after removal of the appendages unless he is convinced that the organ is diseased beyond the hope of cure by less radical methods.

¹ La Policlinique, No. 4, 1896.

² Arch. f. Gynäk., Bd. lii., H. 3, 1897.

³ Monats. f. Geb. u. Gynäk., Bd. v., H. 4, 1897.

⁴ Am. Jour. Obst., Jan., 1897.

⁵ Jour. Am. Med. Assoc., Aug. 8, 1896.

He believes that the prediction of Baldy made $2\frac{1}{2}$ years ago that uteri would be removed that might safely be left has proved true to a far greater extent than one could have predicted. F. H. Martin¹ gives some reasons why the uterus should not always be removed with bilateral disease of the appendages. In the first place, he believes that many of the cases of apparently incurable diseases of the appendages can be cured without mutilation if time be given, stimulated by rational treatment, for the organs to exert their own powerful natural reparative capabilities. Frequently macroscopically, and, reasoning from analogy, microscopically, the uterus appears absolutely healthy when a septic process has destroyed the integrity of the appendages. Here he would remove the appendages thoroughly and institute a course of treatment for the uterine cavity. In the next place, it is not consistent to remove the body of the uterus and not the cervix, which is the portion most liable to be infected with the primary disease—in its deep glands—and which is also most liable to be infected with carcinoma. The removal of the cervix, however, causes a considerable shortening of the vagina from cicatricial contraction, and, thereby, interferes with the marital relations. In the third place, the nervous phenomena during convalescence from hysterectomy are far greater than from simple removal of diseased appendages.

Hysterectomy in Puerperal Sepsis.—J. H. Croom² believes that vaginal hysterectomy for other than malignant disease is much more limited than the present literature of the profession would lead us to believe, for 3 reasons: 1. That in acute septicemia the onset is so sudden and the general systemic infection so rapid that no purely local measures are of any avail. 2. In those cases in which the absorption from septic foci is slow satisfactory results may be obtained by antiseptic irrigation or by curettage. 3. The conditions under which puerperal hysterectomy is undertaken must always be unfavorable, since the woman is exhausted by labor and sepsis. [Practically, there has been no change in the status of this question during the past 2 years and the conclusions advanced in the 2 preceding volumes of the *Year-Book* hold good at the present time.]

Vaginal Incision for Pelvic Disease.—[Those advocating the vaginal methods of operating have during the past year notably receded in their claims and in many instances are returning to the abdominal methods.] Coe³ states that the *abdominal method* is to be elected in: (1) neoplasms or obscure enlargements which are situated in the abdominal cavity, or have risen above the pelvic brim, especially if such be more or less adherent; (2) ascites of doubtful origin, more particularly when tuberculous or malignant disease is suspected; (3) disease of the adnexa in which the latter are situated near or above the pelvic brim, as established by bimanual palpation; (4) when the history and symptoms point to general intestinal adhesions, and, above all, when appendical complications are suspected; (5) ectopic gestation before rupture, when the sac is high up, at the side or in front of the uterus, instead of in Douglas's pouch; (6) intractable pelvic and abdominal pain of obscure origin, including the so-called *neuroses*. On the other hand, *explorative vaginal section* is preferred in: (1) cases in which the presence of pus within the pelvis is suspected, as in pyosalpinx, pelvic abscess proper, suppurating dermoids and cysto-adenomata, and hematocele; (2) small intrapelvic tumors situated in the pouch of Douglas, or at least readily accessible from below; impacted ovarian cysts, dermoids, and fibroids belong to this category; (3) adherent adnexa situated in

¹ N. Am. Pract., June, 1897.

² Brit. Med. Jour., Aug. 1, 1896.

³ N. Y. Polyclinic, No. 6, 1896.

the true pelvis ; (4) unruptured ectopic sacs in the same locality ; (5) circumscribed exudates and indurations in the broad ligaments or behind the uterus, especially when associated with displacement and fixation of the latter organ. Fehling,¹ in spite of the ease with which the vaginal operation can be performed, and the absence of an external cicatrix and subsequent hernia, regards it as unsatisfactory, since one must always be prepared to perform abdominal section or even to remove the uterus. He believes that anterior kolpotomy for the removal of diseased adnexa must have a limited application. I. S. Stone² gives as the most suitable cases for vaginal operation the following : (1) when the patient demands the vaginal extirpation ; (2) when she has borne several children and has a roomy pelvis and vagina ; (3) when the case is of very serious nature, the pulse weak, and the surgeon is in doubt as to her ability to withstand the greater shock of the abdominal operation ; (4) when the sigmoid and rectum are thought to be greatly involved. W. D. Haggard, Jr.,³ gives as the especial indications for vaginal section : (1) early cases of acute suppurating salpingitis ; (2) incipient post-puerperal peritonitis ; (3) large pyosalpinx and true pelvic abscess.

DISEASES OF THE OVARIES.

Position of the Normal Ovary.—Waldeyer⁴ states that the ovary lies normally in a triangular fossa formed by the round ligament, umbilical artery, and ureter. Hernial protrusion of the fossa with the ovary may occur either at the greater ischiatic foramen, or beneath the pyriformis muscle, and in the lesser ischiatic foramen.

The Internal Secretion of the Ovary.—Curatulo⁵ publishes the following conclusions in regard to this question: 1. The ablation of the ovaries exercises a considerable influence on metabolism. 2. The quantity of phosphates eliminated by the urine is notably diminished after removal of the ovaries. 3. The curve of nitrogen, after ovariectomy, ascertained either by Kjeldahl's method or by Yvon's, presents a slight oscillation, without a very distinct tendency to elevation or to lowering. 4. After oöphorectomy the quantity of carbonic acid eliminated by the respiration, and that of the oxygen absorbed, diminish considerably up to a certain limit, from which time it remains stationary. 5. In animals from which the ovaries have been removed the curve of the weight is progressively elevated until it attains considerable proportions from five to six months after the operation. 6. When a certain amount of ovarian juice is injected subcutaneously into sluts deprived of the ovaries the quantity of phosphates eliminated by the urine, which diminishes considerably soon after the operation, tends to increase and even to become superior to that which was ascertained before the operation ; when still larger amounts are injected the quantity of phosphates increases in a very marked degree. Hysterectomy performed in conjunction with oöphorectomy does not seem to cause modifications other than those ascertained after simple removal of the ovaries. [This fully accords with observations on the human subject.] The author advances the following theory : the ovaries, like other glands of the animal economy, have, according to Brown-Séguard's general doctrine, a special internal secretion. These glands continually throw into the blood a peculiar product, the chemical composition of which is completely unknown, and the essential properties of which tend to favor the oxidation of phosphor-

¹ Centralbl. f. Gynäk., No. 30, 1896.

ized organic substances, of carbohydrates, and of fatty substances. It results therefrom that, when the function of the ovaries is suppressed, whether because oöphorectomy has been practised or because these organs do not act, as is the case before puberty and after the menopause, there should be produced, on the one hand, a more considerable retention of organic phosphorus, whence there is a greater accumulation of calcareous salts in the bones, and, on the other hand, the very manifest corpulency which is ordinarily seen after oöphorectomy or after the menopause.

Cystomata.—According to J. Fabricius,¹ the following are the different varieties of cysts that occur about the female genitalia: 1. In the broad ligament, about the middle of the tube, is usually found a small cyst not larger than a pepper-corn, which evidently belongs to the broad ligament, as it is not connected with the tube. 2. The hydatid of Morgagni, a cyst usually about the size of a cherry, which is attached to one of the fimbriæ of a tube. Embryologically, this comes from the upper end of Müller's duct. 3. Cysts in the broad ligament between the tube and Gärtner's canal. These cysts have the same characters as those described under 1. They do not seem to have any connection with the epoöphoron. 4. Cysts from the tubes of the parovarium. These cysts always develop interligamentously, but may reach such a size that they press out the peritoneum, and may finally become pedunculated. They are usually not larger than a bean. They are lined on the inside with ciliated cylindric epithelium, and contain a thin serous fluid. The cysts often reach a large size. Kossmann has recently pointed out that the cysts of the broad ligament do not all come from the parovarium, but a great many of them originate from secondary tubes (*Nebentuben*), which may be situated anywhere in the broad ligament. The cyst-wall gives no indication as to the origin of the cyst, as muscular tissue occurs in the walls of both parovarian cysts and those from the secondary tubes. The fimbriæ of the secondary tubes become adherent and form little pedunculated cysts which Kossmann calls *hydroparasalpinx*. Cysts may also originate from the epoöphoron. The different tubes of this organ are often separated widely from one another by the development of the broad ligament, and cysts originating from them occupy different positions. 5. There are also cysts found in the broad ligaments, uterus, or vagina which owe their origin to the Wolffian or Gärtner canals. The termination of these canals has not been definitely determined. Some claim they terminate at the uterus, others think they end at the cervix, while still others believe they extend down the vagina. 6. Cysts are often found between the layers of the broad ligament, which reach the size of a pigeon's egg. They are often symmetric—*i. e.* situated in both ligaments—and are situated near the larger vessels. They are lined with a simple layer of endothelial cells. The author believes them to be merely dilated lymph-spaces, while Pozzi considers them cysts of the Wolffian ducts. According to Brigidi,² such women are apt to be sterile, because of the frequency with which both ovaries are found in an abnormal position. 7. Chiari has described some little cysts which he has seen about the uterine end of the tube. They were evidently diverticula of the mucous membrane of the tube, caused by a chronic catarrh which had destroyed the muscular coat of the tube. 8. Zedel has described a cyst the size of an apple, into which the right tube opened. The cyst was probably formed by a growing together of the layers of peritoneum about the tube, forming a peritoneal sac into which the tube opens. 9. In addition to the above, the author has found another kind of cyst situated under the serosa of the tube, always multiple, and placed along the whole

¹ Arch. f. Gynäk., v., No. 3, S. 385.

² Ann. di Ost. e Gin., No. 3, 1896.

length of the tube. Two cases were observed. In both the cysts were about the size of an oat, and were lined with cylindric epithelium, which was often found undergoing degeneration.

The author thinks that they are formed by a folding in of the serous covering of the tube due to inflammatory processes. The process is exactly similar to that which takes place in the ovary in the formation of Graafian follicles. The flat epithelium of the tube is changed to cylindric epithelium under the influence of the inflammation. This change can readily take place, as is declared by several observers. Thus Paltanuf has seen a similar change take place in the pericardium after a pericarditis.

Burekhard¹ has investigated the origin of *multilocular* ovarian cysts, and concludes that all arise in the germinal epithelium, or from Pflüger's tubes. The cysts appear to develop in fetal life as a true malformation. Burekhard cannot find any evidence that a cystoma may develop in a normally formed adult ovary. The cutting off of the cysts from the epithelial tubes is brought about by the underlying connective tissue, and not by an active growth of the epithelium. When a cyst is already developed it does not increase by the pressure of its contents, but by active hyperplasia of its connective-tissue wall with a similarly secondary growth of the epithelial elements.

T. Wilson² treats of intermittent cysts of the ovary, those in which there occurs a more or less periodic bursting of the cyst-wall. In some cases after bursting the cyst may be permanently cured. In this event a permanent breach in the wall is supposed to allow the cystic fluid to escape as it is formed into the peritoneal cavity, whence it is at once absorbed by the lymphatics and discharged by the kidneys. In by far the majority of cases the hole in the cyst-wall becomes closed and the fluid re-collects, sometimes in a few weeks, or it may be not for 6 or 8 years.

Semb³ concludes that the true *papillary cystoma* is a distinct growth, to be separated from the papillary cysto-carcinoma, and also from the papillary colloid cystoma. They are most benign new-growths; the epithelial covering of the papilla is always infiltrative, never shows atypical growths; they do not cause cachexia; never give metastasis; are not destructive, are free from return, and are only dislodged and implanted. The implantation on the peritoneum is also benign. Semb says that carcinomatous degeneration of papillomatous cystoma has never been proved. Usually the papillary growths arise from the superficial epithelium. In one of the cases investigated by the writer the papilloma appeared to develop from the primary follicles. The prognosis in the disease after operation is always good; the remaining papillary growths on the peritoneum disappear. If the growths are extensive, they always follow the course characteristic of benign growths. In elderly persons the writer removes both ovaries, as sometimes a similar growth later develops in the remaining ovary which appears healthy. Frequently the disease is bilateral, and often they grow intraligamentous. Dirner⁴ reports a case of ovarian papilloma which on microscopic examination was found to be histologically innocent. Elischer considered that these innocent papillomata are more frequent than is generally suspected. Tauffar insisted that some papillomatous growths of the ovaries are essentially innocent, others distinctly malignant. J. Oliver⁵ records a case of pelvic cyst containing cholesterin, and remarks that cholesteatomata originating in the pelvis have evidently no very decided malignant tendency. H. Cripps⁶ records a case of ovarian cyst communicating

⁶ Brit. Med. Jour., Jan. 2, 1897.

with the rectum; W. H. Baker,¹ an ovarian cyst of 12 years' duration, having a wall 1 in. in thickness; and Ehrendorfer,² a tuberculous ovarian cyst.

Doran³ points out the anatomic difference between real and apparent encapsulation of ovarian cysts, and shows how important it is for the operator to recognize the true condition before beginning the enucleation of the sac. In the case of an intraligamentous cyst the capsule consists entirely of the mesosalpinx, presents a dull-red appearance, and moves freely over the cyst-wall. After tapping, the sac can be drawn out readily and a pedicle can be obtained without enucleation. This is to be distinguished from false encapsulation, in which the cyst is firmly adherent to the floor of the pelvis and to the posterior layer of the broad ligament, and is covered with a pseudocapsule, with the tube apparently lost on its surface, as in the former case; but here the uterus is flattened against the anterior aspect of the tumor, instead of being pushed over to the opposite side. The anatomic relations are apparently identical with those in the former case, and the surgeon often finds out his error only after removing the cyst and finding that no capsule remains, while the tube and mesovarium are intact. The important practical point is that if the intraligamentous development of the growth is recognized at the outset, the surgeon can begin the process of enucleation cautiously, working between the folds of the broad ligament, and thus avoiding important structures, instead of lacerating the peritoneum and injuring ureters or larger veins by trying to tear up a cyst which he erroneously supposes is bound down in Douglas's pouch. Moreover, the after-treatment of the true capsule (by suturing or drainage) will be entirely different from that of a case of false encapsulation.

Suppuration of Ovarian Cysts.—Bouilly,⁴ in a clinical paper on this subject, devotes considerable space to the question of etiology. Owing to the infrequency of tapping at the present day, it is rare that a cyst becomes infected from without. Infection usually comes from an adjacent septic focus, either through the lymphatic channels or bloodvessels, or by direct continuity through the medium of new-formed adhesions. In cases of suppuration of the cyst-contents following labor septic germs are doubtless conveyed through the lymphatics of the broad ligaments from the infected endometrium. The writer has never observed a case of suppuration that could be attributed to coitus during menstruation, as suggested by Mangold. Infectious general diseases may serve as etiologic factors. Two cases of suppuration following typhoid have been reported by Werth, in one of which the characteristic bacilli were found in the cyst-contents. Here the infection is doubtless through the medium of the circulation. In many cases the cause of the suppuration is unknown, especially in dermoids, so that Mangold has advanced the hypothesis that it may result purely from chemical changes in their contents. Infection of ovarian cysts may be distinguished as saprophytic, due to the presence of saprophytic staphylococci, bacterium coli, and similar germs, and septic, caused by pyogenic microorganisms, as the streptococcus pyogenes, gonococcus, bacterium coli commune, and typhoid- and tubercle-bacilli. The clinical symptoms and prognosis are much graver in the latter case, being those of general, as contrasted with those of local, infection.

Rupture of Ovarian Cysts.—Causes of rupture of ovarian cysts may, according to M. Storer,⁵ be divided into (1) those arising within the tumor itself, and (2) external causes. The first produce the spontaneous ruptures of frequent observation. In the advancing growth of a proliferating cystoma,

¹ Boston M. and S. Jour., Nov. 19, 1896.

² Wien. klin. Woch., No. 15, 1896.

³ Brit. Med. Jour., Apr. 18, 1896.

⁴ La Gynéc., June, 1896.

⁵ Boston M. and S. Jour., Nov. 19, 1886.

as the walls of the daughter-cysts are absorbed they may rupture outwardly as well as inwardly. So, too, papillary excrescences, as they impinge against the inner wall of a cyst, may cause pressure-necrosis and perforation. External causes of rupture all come under the general head of traumatism. Storer makes a study of 108 cases collected from literature. In about 30% rupture occurred as the result of sudden, constrained, or violent movement. Rupture may follow torsion, and it has frequently been seen associated with labor. Tapping may cause it.

Torsion.—M. Storer¹ has made a special study of this accident. He states the frequency of rotation as from 25% to 35% of all ovarian tumors and of torsion 8% to 11%. Bilateral rotation is not uncommon. Dermoid tumors are especially liable to the accident. The seat of the torsion is usually in the middle of the uterine third. Sometimes there are 2 or more distinct points of strangulation. The number of twists depends upon the length of the pedicle.

Dermoid Cysts of the Ovary.—Sant Anna² records a dermoid cyst in an infant 1 year old; it weighed 2 pounds. Nine other cases are reported in which the ages of the patients varied from 20 months to 7 years, 4 terminating fatally. C. S. Kalb³ records a case in a girl 3 years 10 months old, and Dandois⁴ one in a girl of 5 years; it weighed 15 pounds. E. Knauer⁵ records a case in which the sac was filled with perfectly symmetric spheres, surrounded by a yellowish, turbid fluid, and a coil of hair. The balls varied in size from a pea to a nut; were soft, friable, and of a smooth, shining surface. Microscopically they were found to consist of epithelial cells with a small amount of fat interspersed. [This spheric formation of dermoid cyst contents is rare, but 4 similar cases having thus far been described—2 by Rokitsansky, 1 by Routh, and 1 by E. Fränkel.] S. Keith⁶ records an ovarian dermoid weighing over 100 pounds successfully removed, and W. R. Williams⁷ one containing about half a gallon of thick pea-soup fluid with large masses of putty-like substance in which balls of hair were imbedded, the whole being the size of a large football. Rendu⁸ removed a dermoid cyst from the round ligament.

Solid Ovarian Tumors.—H. M. Jones⁹ and H. Briggs record cases of ovarian fibromata; Gessner,¹⁰ a pure myoma of the ovarian ligament; and G. Seymour¹¹ a sarcomatous ovary, forming a hernia in the right inguinal region.

D'Urso¹² concludes as follows a comprehensive study of 21 observations of ovarian tumors, most of them personal: 1. In the cortical substance of the normal ovary there are remains of germinal epithelium in the form of cystic formations, which sometimes present the appearance of modified sweat-glands. 2. The Kobelt tubes of the mesosalpinx in the adult have sometimes irregular and papillary outlines. 3. The tubes of the epoöphoron penetrate into the hilus and the medullary substance, and produce cavernous papillary formations, besides the isolated tubule. 4. There are also found in the mesosalpinx, altogether at the abdominal end, small knobs of epithelial tubes, which proceed from the remains of the Wolffian body. 5. The cysts of the ovaries and broad ligaments can be classified into: (a) cystic adenoma, glandular neoplasms formed from the epithelial remains of the cortex; (b) simple Wolffian

cysts ; (e) papillary Wolffian cysts, developing from the epithelial remains in the hilus and mesosalpinx, without glandular formations. 6. Malignant papillary cysts present a peculiar proliferation of the epithelium, contrary to malignant papillary Wolffian cysts. 7. Dermoid cysts show evidences of transformation from simple cysts to true teratomas. Some can be traced to fetal contents, others probably to embryonal development from the ovum cell. 8. Ovarian fibromas can develop in the connective tissue of the corticalis, independently of the corpora lutea and the regressive metamorphoses of the Graafian follicles. 9. Among the simple, connective-tissue ovarian tumors, endotheliomas often occur, not infrequently malignant, which cannot be explained by peculiarities in the histologic structure. He has nothing to say in regard to the histogenesis of alveolar sarcoma and endothelioma except the query whether the theca folliculi may not be the matrix. 10. There is a simple true epithelioma of the ovary ; it develops very slowly and probably originates in the epithelium of the papillary embryonal remains of the hilus.

Angiodystrophia Ovarii.—Bulius¹ refers to a chronic diseased condition of the ovaries in which there is no very distinct enlargement ; the pathologic anatomy shows nothing of importance ; there are definite functional disturbances and other phenomena. The characteristics of these changes are : (1) Macroscopically, enlargement of the ovaries, particularly in their greatest diameter, the formation of deep furrows on the surface, remarkable density of the entire organ, and the formation of cysts. (2) Extensive disease and increase in the number of blood-vessels. The arteries and capillaries are separated in the medulla and cortex. The disease is an extensive thickening and hyaline degeneration of the walls with obstruction of the lumen. (3) Marked reduction in the primary (developing) follicles ; developing to the completely developed follicles are seen, with small cystic degeneration of the Graafian follicles ; decisive pathologic occurrences in the retrograde metamorphosis of the misplaced, augmented, and destroyed follicles. The clinical symptoms, which are dependent upon the amount of anatomic changes, are very profuse menstrual hemorrhage, lasting sometimes 3 weeks ; and pain in the abdomen and back, occurring paroxysmally, the paroxysm often being so long that the patient is free from pain only a few days. Also there are severe nervous symptoms. Endometritis is constantly associated. There is comparatively little change in the remaining genital organs. Bulius believes the changes in the ovaries must be regarded as primary. As to the cause of the disease nothing definite up to the present time has been determined. The results after oöphorectomy in 4 cases were good, in 3 others the hemorrhage ceased and the pain disappeared. Herff, in the discussion of this paper, stated that he doubted the belief that the disease is primary in the ovaries. The fact that patients had not been improved through oöphorectomy seemed to prove that it is a neurosis. Bulius replied that in only one of his cases could the disease possibly be considered a neurosis, and therefore it must be primary in the ovary.

Tuberculosis of the Ovaries.—Wolff² concludes an elaborate article on this subject by denying the probability of primary infection of the ovaries, since the changes in the ovisacs are so slight as compared with the advanced degeneration in other organs. He believes that there is direct infection of the peritoneal covering of the ovaries, transmitted either through the tubes or from the pelvic peritoneum. It is, of course, impossible to exclude as an etiologic factor the entrance of bacilli, carried through the blood-vessels from distant organs, though this mode of infection must be exceptional. In all the writer's cases there was no doubt as to the fact of direct infection. The ques-

¹ Centralbl. f. Gynäk., No. 44, 1896.

² Arch. f. Gynäk., Bd. lii., H. 2, 1896.

tion of the transmission of tuberculosis from the mother to the fetus through the medium of the infected ovum is an interesting one. Although it must be admitted that the development of such an ovum is arrested, it is possible that the tubercle-bacilli from an infected Graafian follicle after the rupture of the ovum may, together with the latter, enter the uterus and infect it during the development of the ovum.

The Anatomy of the Ovaries in Osteomalacia.—Heyse,¹ from a careful microscopic study of ovaries removed from osteomalacic women, decides that there is no reason to infer that there is a marked decrease in the number of primordial follicles. This is also proved by the well-known fertility of these subjects. He believes that the ovarian nerves play an important part in the process, and that future investigations will disclose pathologic changes in them; but whether these changes are primary or secondary is not clear. Unfortunately, ovaries have not been examined in an early stage of the disease.

Hernia of the Ovary in an Infant.—Lockwood² reports the following interesting case: a female infant, aged 6 months, suddenly became ill, drawing up its legs as if suffering from severe abdominal pain. Two days later a swelling was noticed in the right inguinal region, tender, and disappearing on pressure. When brought to the hospital an examination of the little patient showed a tense, oval swelling, 3 in. long and 1½ in. broad, the skin covering it being inflamed. There was no impulse on crying. Obstinate constipation and occasional vomiting were present, but flatus and later fecal matter were passed. The diagnosis of strangulated inguinal hernia was made. On incising the swelling a quantity of dark grumous fluid escaped, and a mass appeared which was at first supposed to be the cecum, but proved to be the fimbriated end of the Fallopian tube and a hemorrhagic ovary, the pedicle of which emerged from the internal abdominal ring being twisted half around its axis, but not constricted at the ring. The pedicle was transfixed and tied, the tube, ovary, and sac excised, and the stump attached beneath the internal oblique and transversalis muscles. The inguinal canal was sutured and the external wound closed with silkworm-gut. The patient's convalescence was normal. The cause of the torsion was obscure, but was probably due to the fact that, as the ovary and tube slipped through the internal ring, the ovary lay in front of and above the tube and slipped down in front of it, thus producing the twist. A similar case has been reported by Owen.

PEDIATRICS.

BY LOUIS STARR, M. D., AND THOMPSON S. WESTCOTT, M. D.,

OF PHILADELPHIA.

The Year's Work.—It is almost impossible to single out any one department of pediatrics for special mention, with the advance that has been made along the whole line. The fields in which there was greater room for work and in which, perhaps, more was accomplished, were those of etiology and pathology. In these lines the contagious diseases offer abundant opportunity, and we need only refer to the investigations on pertussis and parotitis to indicate the activity that is being shown. The success which has attended serum-therapy in diphtheria has been a great stimulus to all methods of treatment, but especially in the same line, although we do not expect a second antitoxin to be developed (we are considering only pediatrics, and therefore exclude tetanus and its antitoxin) until the etiology and pathology of the different diseases are more thoroughly worked out. With reference to the antitoxin of diphtheria, its value is so well established that we have not deemed it necessary at this time to go into the question of statistics as thoroughly as before. Those that have been given in the preceding issues of the *Year-Book* should convince any unbiassed reader that it has value; and if he will then observe the effects of a proper dose given in the early stages of a severe case of the disease, he will be convinced that no case of diphtheria should be allowed to run its course without the injection of antitoxin. In our review we have noticed only one article opposing its use, not because there have been no others, but because they are merely reiterations of what had been mentioned in the preceding issues, and seem to consider the antitoxin an empiric remedy rather than a specific, as it is in almost the highest sense of the term. As J. McFarland stated in the discussion before the American Medical Association, a definite amount of antitoxin (a) will render inert a certain amount of toxin (t); n times a will render inert n times t . The fact that some cases of diphtheria die after injections of antitoxin is no argument against its use. The activity in pediatrics has not been limited to the field as covered by the articles in the journals. Many treatises on pediatrics or some of its branches have appeared; and while it is impossible to mention all that deserve it, the following are some of the noteworthy ones: in Germany Baginsky's *Lehrbuch der Kinderkrankheiten* is in its fifth edition, and Henoeh's *Vorlesungen über Kinderkrankheiten* is in its ninth. In France A. B. Marfan has written a book on artificial feeding, and J. Grancher, J. Comby, and A. B. Marfan are editing a *Traité des Maladies de l'Enfance* in two volumes. In this country we must go back beyond the past year to mention A. Jacobi's *Therapeutics of Infancy and Childhood*, and J. L. Smith's *Diseases of Childhood*; during the past year L. E. Holt's *Diseases of Infancy and Childhood* has been published.

INFANT-FEEDING.

Bunker's Modification.—H. A. Bunker¹ suggests a method of increasing the digestibility of the proteids of cow's milk which seems to be similar to that originally recommended by Jacobi in 1876, to boil milk with dilute hydrochloric acid. The method of procedure is simple: a solution of hydrochloric acid in milk is secured by adding from 20 to 30 drops of a 10% acid to 1 pint of water and then mixing thoroughly with 1 quart of milk. The mixture is then boiled, with constant stirring, for 20 minutes, or is kept at a boiling temperature for that length of time in an Arnold sterilizer. If the milk shows decided activity to litmus, the milk-acids should be neutralized with lime-water before further preparation. The loss by evaporation in boiling in an open vessel may be made up, if desired or found necessary, by a fresh addition of water; or further dilution may be made to meet the demands or limitations of any special case. No addition of sugar is necessary except when heavily sweetened foods, like condensed milk, have previously been used, and under these circumstances the amount can be rapidly lessened. His experience has been that such milk is easily digested and gives full nutrition after failure with plain sterilization or partial peptonization. L. Grant Baldwin,² who has made use of the method, considers it far superior to any artificial food he has tried. [In the discussion Golding stated that the method was proposed by Ruddisch, one of Jacobi's assistants, but was abandoned because no milk in the market could be found sufficiently fresh to remain uncoagulated.]

Infant Foods Compared.—R. H. Chittenden³ has made a careful comparative analytic study of a number of the most widely known manufactured infant foods, standardizing their products as prepared for the nursing-bottle in accordance with directions for infants of 6 months; and these are compared with the analysis of mother's milk, according to Leeds. The table is of considerable interest:

	Mothers' milk.	Malted milk.	Nestlé's milk food.	Imperial granum.	Mellin's food.	Peptogenic milk powder.
Specific gravity	1031	1025	1024	1025	1031	1032
Water	86.73	92.47	92.76	91.53	88.00	86.03
Total solid matter (by direct determination)	13.26	7.43	7.24	8.47	12.00	13.97
Inorganic salts	0.20	0.29	0.13	0.34	0.47	0.26
Total albuminoids	2.00	1.15	0.81	2.15	2.62	2.09
Soluble albuminoids	2.00	1.15	0.36	1.67	2.62	2.09
Insoluble albuminoids	0	trace.	0.45	0.48	0	0
Fat	1.13	0.68	0.36	1.54	2.89	4.38
Milk-sugar	6.93	1.18	0.84	2.71	3.25	7.26
Cane-sugar	0	0	2.57	0	0	0
Maltose	0	3.28	trace.	trace.	2.20	0
Dextrin	0	0.92	0.44	0.58	0.53	0
Soluble starch	0	0				
Starch	0	0	1.99	1.22	0	0
Reaction	alkaline.	alkaline.	alkaline.	alkaline.	alkaline.	alkaline.

If, as Chittenden observes, mother's milk is to be accepted as the standard, it will be seen from the table that cow's milk, modified by the addition of water, cream, and peptogenic milk powder, offers a product containing to the full extent all of the proximate principles present in human milk and wholly free

¹ Brooklyn Med. Jour., Nov., 1896.² *Ibid.*³ N. Y. Med. Jour., July 18, 1896.

from extraneous admixtures. The process of modification takes into account the radical difference between cow's casein and human casein, and affords a method by which the former can be modified to a closer resemblance to the latter without the addition of any substance that will permanently interfere with the purity of the final product. [Partial peptonization by this method may be quite satisfactorily employed with milk mixtures of other proportions, according to the methods of laboratory modification, and also with cream and condensed milk mixtures in the rare cases in which condensed milk seems to be the only form of milk that can be borne.]

Dufour¹ gives the following method for **humanizing cow's milk**: put the quantity of milk suitable for one day at the child's age into a large graduate with a corked spout at the bottom. Set aside tightly covered and at proper temperature for about 4 hours to allow the cream to rise. Draw off one-third the lower milk and add the same amount of water. Add 35 gm. milk-sugar and 1 gm. of salt per liter. Shake and pour into sterilized bottles.

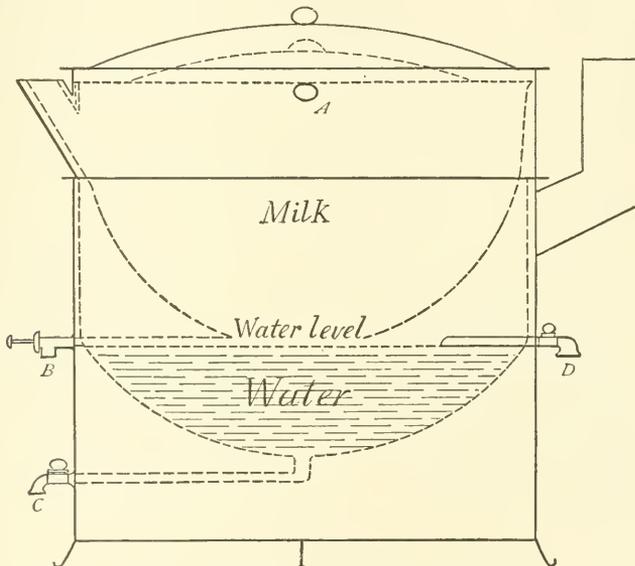

FIG. 46.—Aymard's milk-sterilizer, large size.

If the child's gain in weight is unsatisfactory, add a teaspoonful or two of cream to the whole amount of milk. [The replacement of one-third of the bulk of milk by an equal quantity of water reduces the proteids and salts of the milk, but does not reduce the proteids of the cream.] More definite results are obtained in the wholesale manipulation advised by Dufour, in which the milk is diluted with one-third of water, and to each liter of mixture are added 15 to 20 gm. of fresh cream, 35 gm. milk-sugar, and 1 gm. sodium chlorid. The amount of cream here added produces 4% or more of fat. This preparation is used in all cases, the amount at a feeding alone varying with the age of the child.

Aymard's Sterilizer.—One of the recent additions to sterilizing apparatus is Aymard's,² two sizes of which are here pictured. It differs from the usual form in having the receptacle for the milk shut off tightly from the

¹ Rev. mens. des Mal. de l'Enfance, Sept., 1896.

² Brit. Med. Jour., Oct. 10, 1896.

steam-chamber, though exposed partly to the air by a narrow spout. In the small sizes about 10 minutes are required to raise the milk to a temperature of 200° F., after the water has begun to boil. It is claimed that there is no separation of cream or formation of scum on the surface, which is partly accounted for by the fact that the milk-chamber is entirely closed during

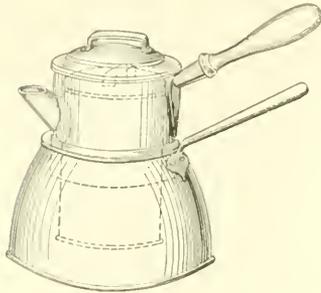

FIG. 47.—Aymard's milk sterilizer, small size.

heating and cooling, thus keeping the whole bulk of milk at an equable temperature. There is said to be but slight alteration in the taste and smell of the milk, and the loss by evaporation is reduced to a minimum. It is not claimed to produce absolute sterilization by this apparatus, and it is not adapted to purposes of storage; but it can be counted upon to destroy all adventitious pathogenic microorganisms. Larger sizes of the apparatus are made for use in institutions.

An Improvement of the Dresden Modification.—Hesse¹ describes in detail an improvement on the so-called Dresden modification, a description of which from an English

observer, Worcester, was given in the *Year-Book* for 1897 (p. 749). Using Lehmann's analyses of human milk and cow's milk, Hesse demonstrates that if to 1 liter of 9.5% cream $1\frac{1}{2}$ liters of water are added, and to this 105 gm. of milk-sugar, and fresh egg-albumin (enough to represent 9.5 gm. dried albumin), a mixture is produced yielding 1.2% casein, 0.5% albumin, 3.8% fat, 6% sugar, and 0.3% ash. To insure sterilization, however, he has found better results can be obtained by drying and pulverizing the paste of albumin and sugar; and the similarity to human milk is more closely approached by adding to this in process of manufacture a certain amount of lacto-saccharate of iron. The resulting sterile powder is readily soluble in water, and when added to the diluted cream produces a mixture very closely resembling mother's milk in all its ingredients. In practice it was found that a reduction of the fat-percentage to 3, and of the sugar-percentage to 4.5, gave a more readily digested mixture. In a series of cases fed from birth for 1 to 5 months, the average monthly gain was 13 oz. [Not a very encouraging showing under conditions most satisfactory for testing a new process of feeding.]

Use and Limitation of Condensed Milk in Infant-feeding.—C. G. Kerley² recognizes the inadequacy of dilutions of condensed milk as an infant diet, and states that fully 95% of the many hundred marasmic and rachitic children observed had been fed on the meal foods or on condensed milk. At the same time he feels constrained to use condensed milk in many cases among the poor, the ignorant, and the careless, making up the deficiency in fat and proteids by the addition of cream or, in dispensary practice, of cod-liver oil. With the latter cases the dose of oil varies with the age of the baby, the ability to digest it, and the season of the year. Ten drops to a dessert-spoonful, 3 or 4 times daily after feeding, are usually prescribed. During very hot weather the dose must be reduced or suspended if there are evidences of gastrointestinal disturbance. The low proportion of proteids may be increased by adding a meat-broth prepared by boiling 1 pound of lean beef in a quart of water till the liquid is reduced to 1 pint. Such a broth contains 0.8% proteids, so that 1 part of condensed milk to 12 of broth will give 0.5% fat, 1.4% proteids, and 4% sugar, which with cod-liver oil will suffice till the age of 6

¹ Berlin. klin. Woch., July 27, 1896.

² Med. News, vol. lxx., No. 23, 1897.

months, when 1 part of condensed milk to 9 of broth may be used with the oil till the 8th or 9th month.

Sterilization.—Referring to the danger of scurvy from the use of sterilized milk J. K. Barton¹ states that comparatively or temporarily sterilized milk may be administered for any length of time without fear, but that sterilized milk that is put into hermetically sealed vessels, and which can thus keep fresh for several or many days, will produce scurvy unless some fresh food is administered daily. One meal of fresh whey daily will achieve this in younger infants than those who may have fresh vegetables, meat, or fruit.

Low-temperature Pasteurization.—R. G. Freeman's² later studies have led him to recommend a lower temperature for pasteurization than was previously considered necessary. From his previous studies he concluded that the tubercle-bacillus was the most resistant organism found in milk, and could not be certainly destroyed by a lower temperature than 75° C. More recent experiments, however, by various competent observers have given him strong reason to believe that a temperature of 65° C. for 15 minutes is amply sufficient to kill tubercle-bacilli. He has accordingly modified his pasteurizer in order to fit it for this lower temperature. If the milk introduced has a temperature of 10° C. (50° F.), the resultant temperature will be about 68° (155° F.); while if the milk has a temperature of 20° C. (68° F.), the resultant temperature will be about 69½° C. (157° F.). The improved apparatus is shown in the accompanying cuts (Figs. 48, 49).

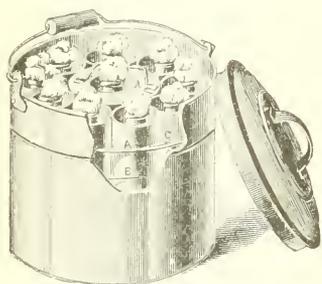

FIG. 48.—Showing the apparatus arranged for heating the milk before the pail is covered.

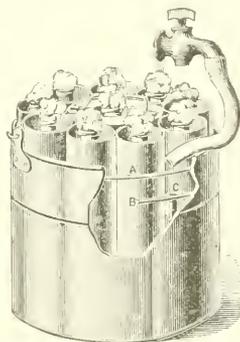

FIG. 49.—Showing the apparatus arranged for cooling the milk.

R. G. Freeman's pasteurizer.

Breast-milk Variations in Prematurity.—V. and J. S. Adriance³ present a clinical report of the chemical examination of milk from 200 mothers, which especially emphasizes the fact that in every case of prematurity the variations of the colostrum-period are present, but are exaggerated in the proteids. This increase in proteids extends over a longer interval than in ordinary colostrum-milk, and is not easily dispelled; it consequently taxes the delicate digestive organs of the untimely born infant for a longer period than usual in term-infants. In these cases it is difficult to say how long the disturbance will persist, and it is often wiser to give the child to a wetnurse whose milk has been demonstrated to be good by its effect upon her child and by analysis. In the meantime the mother's breast should be pumped and kept active for future use.

Analysis of Colostrum-milk.—George Woodward⁴ has made a series

¹ Brit. Med. Jour., Jan. 2, 1897.

³ Ibid., Feb., 1897.

² Arch. of Pediatrics, Aug., 1896.

⁴ Jour. Exper. Med., Mar., 1897.

of analyses of human colostrum-milk from 6 cases, which has been carried out with great care and accuracy. He concludes that colostrum-corpuscles are not always found in so-called colostrum-milk; but when they are present the percentage of proteids is higher, and as they disappear the percentage falls. The color of colostrum-milk is yellow, especially marked in negroes' milk; its reaction is alkaline, and its sp. gr. varies from 1024 to 1034, this variation being chiefly due to variation in the amount of fat. The fat varies from 2% to 5.3%, the proteids from 1.64% to 2.22%, and the ash from 0.14% to 0.42%. The total solids vary from 10.18% to 13.65%. An average colostrum-milk contains fat 4.00, proteids 1.9, lactose 6.5, ash 0.20, making the total solids 12.5. Two of the cases confirmed the observation of Townsend, that the infants of multipare do not lose as much weight in the colostrum-period of lactation as the children of primipare, and the 4 other cases showed results which agreed with those of the same observer—that the shorter the period of colostrum-milk the smaller is the so-called physiologic loss of weight in the newborn.

INFECTIOUS DISEASES.

Diphtheria.—Etiology.—In a discussion on "Diphtheria in Town and Country," before the British Medical Association,¹ interesting facts were mentioned, but nothing definitely established to account for epidemics of diphtheria. J. C. Thresh advanced the opinion that the proper field for investigation is the origin of sporadic cases, as their study will be more likely to lead to valuable etiologic conclusions than the investigations of extensive epidemics. He studied the statistics of the county of Essex, and found that the only positive point favoring the spread of cases was the overcrowding of population in the tenement-houses of towns. The quality of the water-supplies, presence or absence of drainage, the character of the soil and subsoil, seemed of trifling importance. The curve of the number of cases shows a depression in the early part of the year (February or March) and a marked rise in October. The time of the summer vacation seems to exclude the schools from playing any part in outbreaks, unless possibly a restraining influence.

For London, F. A. Dixey² showed that there is a decrease in the number of cases during the summer vacation for each year. He gave the figures for the case-mortality during the past 3½ years, and concluded that it is difficult to see what cause can have been at work to produce the marked diminution from 23.8 to 20.2 (representing the annual saving of some hundreds of lives), unless it be the treatment by antitoxin. Gordon Sharp³ gave the results of his studies as to the relation of soil to diphtheria and its organism. He was able to obtain from a peaty surface-soil (rich in organic matter) over a hard subsoil, an organism which in morphology and cultural peculiarities was indistinguishable from the diphtheria-bacillus. Diphtheria had been prevalent some years before in that district in a very fatal form, and still occurred up to recent times. His conclusions are: 1. Diphtheria would appear to be endemic in certain districts. Soils organically laden are dangerous, but much may depend on the nature of the subsoil. Where the subsoil is porous a neighborhood may be free. Where the subsoil is impervious the surface at certain seasons of the year may be a favorable breeding-ground. 2. Deep drainage renders soils innocuous which would be otherwise sources for spreading the disease. 3. A large amount of air in the surface-soil has a beneficial effect, and

¹ Brit. Med. Jour., Aug. 22, 1896.

² Ibid.

³ Ibid.

the contrary holds. This may be accidental. A moist rather than a water-laden soil seems to be the home of the organism of diphtheria.

DeBlasi and Russo-Travali¹ examined cultures from 234 cases of membranous angina, with the following results: 1. In 26 cases, with a mortality of 3.8%, the diphtheria-bacillus was absent. 2. Pure cultures of the diphtheria-bacillus were obtained from 102 cases; mortality, 27%. 3. The bacillus was associated with the staphylococcus pyogenes in 76 cases; mortality, 33%. 4. The bacillus was present with the streptococcus pyogenes and Fränkel's pneumococcus 7 times; mortality, 43%. 5. The bacillus was present with the streptococcus pyogenes 20 times; mortality, 30%. 6. In 3 cases the bacterium coli was associated with the bacillus, the mortality being 100%, which tends to show that the addition of the bacterium coli increases the severity of the disease. The virulence of the bacterium may be increased relatively by the action of the diphtheria-germ in lowering the vital resistance or directly as a result of the association of the two germs. [If the cultures in this last instance were taken shortly before death, it would of course be necessary to consider agonal infection as perhaps the cause for the appearance of the colon-bacillus.]

C. L. Wilbur² gives a statistic study of diphtheria and croup in Michigan with reference to age and sex incidence. He finds that the two forms of the disease are distinctly separated by their age and sex incidence, and also by their monthly and seasonal prevalence. Under 5 years of age males furnish a higher death-rate from diphtheria than females, while the reverse holds after 5 years of age, the reason for which is not clear. He suggests that it would be better to ascertain the death-rates for diphtheria and croup in terms of the susceptible population, under 15 for diphtheria, and under 5 for croup.

G. Homan³ has also studied the relations of diphtheria and croup as shown by the statistics of the city of St. Louis.

Pathology.—H. B. Biggs⁴ (in connection with the bacteriologic laboratory of the Health Department of New York City) investigated the virulence of the diphtheria-bacilli found in some cases of simple acute angina not presenting the clinical features of what is usually called diphtheria. In 48 such cases there were non-virulent bacilli in only 3. Out of 450 primary cultures made from April 1st–28th only 239 were true diphtheria. One hundred and seven cases reported as diphtheria to the department were excluded from that list by the bacteriologic examination, while during the same period only 80 cases considered to be false diphtheria or of doubtful nature were found to be due to the diphtheria-bacilli. [These rather important figures are the only ones which have come to notice tending to throw doubt on the oft-repeated claim that the bacteriologic diagnosis of diphtheria would in itself tend to lower the mortality of diphtheria by including a greater number of mild cases than it would exclude.] The author contends that the anatomic conception of diphtheria (an inflammation associated with the formation of a false membrane) is insufficient, and “that all inflammations of mucous membranes due wholly or in part to the Klebs-Löffler bacillus should be included under the name ‘diphtheria’ without reference to the site or extent or intensity of the inflammatory process or the character of the exudate.”

B. M. Bolton's⁵ observations in Philadelphia bear out Biggs with reference to the effect of bacteriology on the total number of diphtheria cases. Of 557 cases diagnosed as diphtheria, the bacilli were present in 507, or 90.2%. Of 148 cases which were not considered by the attending physician to be diph-

⁵ Med. and Surg. Reporter, June 16, 1896.

theria, bacilli were present in 40. The total number of true diphtheria cases, then, was reduced to 547.

Loos¹ experimented on animals with the blood-serum of healthy and diphtheric children, and found that in severe cases of diphtheria the blood can be shown to contain the toxin. Antitoxin is found in the blood not immediately, but some time after an attack. It is also found after a curative, but not after an immunizing dose of antitoxic serum.

Wassermann,² working on a similar line, found that the blood-serum of some individuals had strong antitoxic properties, while that of others had none, explaining the difference in the liability of individuals to diphtheria. It is of interest in this connection to refer to Fischl and Wunseheim's investigations on the blood of newborn infants (see *Year-Book* for 1897, p. 727).

J. Love³ also studied the blood-serum of healthy and diphtheric children with regard to the diphtheria toxins and antitoxins. In order to determine whether an injection of the healing serum would cause the serum of the individual to acquire antitoxic properties, a boy of 3 years was bled, and the serum found to have no antidiphtheric qualities. An injection of Behring's serum equal to 2000 units was then made, and 14 hours later the same blood not only delayed death in guinea-pigs, but actually prevented it. Five cases were next tested to determine whether a prophylactic injection could be recognized, 150 units being employed. The results were negative, and as a further proof of their slight utility 1 of the children under observation actually had an attack of diphtheria—a very mild one, however. By good fortune, a child, whose serum had been previously examined and found to contain no antitoxic qualities, suffered an attack of diphtheria. Fifteen days after recovery its serum manifestly delayed death in the guinea-pigs under experimentation, and at 60 days it had a distinct antitoxic influence. Love explains the lesser activity of the 15th day's serum by supposing that the reabsorbed toxins counteract, to a certain extent, the action of the antitoxins. In 2 cases where serum had not possessed any antitoxic properties during the course of the disease antitoxins appeared after recovery, at least in sufficient quantity to delay death. In 1 case strongly antitoxic serum was found during the course of the disease; but as in this instance cocci were found in the membrane and desquamation of the skin appeared, it was considered one of scarlet fever. In 2 instances virulent diphtheria-bacilli were found in the mouths of healthy children, and in both cases their serum was found to have strong antitoxic properties. On the other hand, toxins were found in the blood of a child suffering from a severe attack of diphtheria, that had failed to react to the serum-treatment. Love believes that this case indicates the limitation of the value of Behring's serum, as it shows that where patients are attacked in whom no antitoxin exists the poison can produce so much injury to the organs that recovery is impossible. Finally, investigation upon 2 children suffering from indifferent diseases showed that human blood-serum may retain its antitoxic properties unaltered for a long series of weeks.

G. S. Engel⁴ has made a number of observations on the blood in diphtheria, finding but one feature which seems to have value from a prognostic point. If the myelocytes (large, mononuclear, neutrophilic leucocytes) are present in 2% or more, the case will terminate fatally. The reverse of this does not always hold good, as 8 fatal cases were observed which showed no increase in these cells.

Symptoms.—O. Vierordt,¹ on the clinical features of diphtheria and diphtheroid anginas, remarks that it must always be the aim of clinical medicine to be able to establish a diagnosis in the simplest way possible and at the sick-bed. While methods of precision, examinations with the microscope and chemie reagents, may make the diagnosis of a disease clear, they are not sufficient for forming a judgment of an individual case, and individual patients are the objects of treatment rather than a "disease-form." He discusses then the clinical features of different forms of anginas and the bacteriologic investigations. He lays stress upon a point to which Koplik (*Year-Book* for 1897, p. 758) in this country has called attention, namely, that typical lacunar anginas may be of bacillary (Klebs-Löffler) origin. Such a tonsillitis may be follicular throughout its course, or it may develop after a few days into clinical diphtheria. On the other hand, there are anginas which resemble diphtheria in the formation of pseudomembrane, but differ from it in the absence of the specific bacillus. A feature of this group is its tendency to relapses. He recommends, to describe this class, the term suggested by Heubner—"diphtheroid" [which is much better than the term at present rather loosely used in this country to describe the same condition—"diphtheritic"]. For the other groups lacunar diphtheria and simple lacunar tonsillitis will be accurately descriptive. Unfortunately, these cannot always be separated clinically, and therefore bacteriologic investigation is greatly to be desired in each case. He describes 2 cases of necrotic angina, due to the staphylococcus pyogenes, setting up rodent ulceration.

Paralysis.—Goodall² has contributed a valuable paper analyzing the statistics of 1071 cases of diphtheria, occurring in preantitoxin days, with special reference to the occurrence of paralysis. The mortality-rate was 33.8%. Of the 709 survivors, 125, or 17.6%, became paralyzed, and 17 succumbed to the sequel. 22% were under 10 years of age, which is contrary to Gowers' statement that adults furnish the largest proportion of paralysis after diphtheria. The appearance of paralysis varied from the 7th to the 49th day, in the majority of cases not occurring until after the throat had cleared. The palate alone was first affected in 66% of the cases, and in combination with other muscles in 12% more. In a little over half of the cases the paralysis was limited, while it was generalized in about 12%. In no case did facial, glossal, vesical, or rectal paralysis occur. Sensory disturbances were common, manifested by tingling and numbness in the fingers and toes. The paralysis, which was not permanent in any case, varied from 1 to 15 weeks in duration. Contrary to Hensch and Gowers, Goodall, with de Gassicourt, found that the probability of paralysis increased with the severity of the attack of diphtheria. Goodall divides the modes of heart-failure into 3 groups, as follows: 1. That occurring when exudation is still present on the fauces, before other symptoms of paralysis have appeared, and being due to the direct action of the toxins on the nervous mechanism. 2. That occurring, after disappearance of the membrane, but during the other symptoms of paralysis, and being due to disturbed innervation or fatty changes of the heart-muscle, such as occur in fevers. 3. That occurring in convalescence, some time after the membrane has disappeared, and resulting from a degeneration either of the muscle or of the vagus. The symptoms usually present in the latter condition are: (a) alteration in the action of the heart; (b) paresis or paralysis of the intrinsic muscles of the larynx and alteration in the rhythm of respiration; (c) vomiting.

¹ Berlin. klin. Woch., No. 8, 1897.

² Brain, 1895; ref. in Buffalo Med. Jour., Oct., 1896, from Jour. of Nerv. and Ment. Dis., July, 1896.

Otto Katz¹ gives a valuable "contribution to the study of diphtheric paralysis." He has found the ganglion-cells always affected by one of two morbid processes, the more severe and uncommon of the two being necrosis or direct local death of the cell, which causes death of its processes, especially the axis-cylinder. The other process, less severe, is manifested by the appearance of fat-granules in the cell, and causes a degeneration of the nerve-fibres, not, like the first, an irreparable damage. That the neuron is only diseased and not destroyed, in this lighter affection, is seen in the greater difficulty in swallowing that patients experience, after a night's rest, than later on in the day, when the repeated attempts have, through irritation, made the reflexes more active. The same effect is seen when different substances are swallowed, a bland fluid like milk being harder to swallow than an alcoholic beverage. Katz believes that, aside from the true symptoms of paralysis, the other symptoms in convalescence, the weakness, loss of energy, anorexia, etc., are dependent upon central nervous disturbances. The cases under observation showed that the medulla oblongata was affected earlier and more severely, as a rule, than the rest of the cerebrospinal axis, but the greater prominence of symptoms depending on affection of the medulla is partly due to the importance of the nerves arising from it. The reason for the weaker resistance of the medulla to the action of the toxin is probably physiologic rather than anatomic, and depends upon the ceaseless activity of the centers of life with a consequent greater demand upon the circulation, and, therefore, a greater amount of toxin to resist.

A. Levi² reports a case of cerebral hemiplegia in the course of diphtheria, and reviews the literature of the subject. The causes, in the order of their frequency, are embolism, hemorrhage, and thrombosis. The complication is most frequent among older children, from 8 to 15 years, and the prognosis is grave, both for life and for restoration of function of the paralyzed limbs.

Diagnosis.—E. L. Vansant³ thinks that fewer cases of clinical diphtheria would give negative bacteriologic results if cultures were taken from the nasal cavities as well as from the pharynx, illustrating the statement by notes of 2 cases.

Koplik,⁴ in referring to the urgent need for a rapid method of bacteriologic diagnosis of diphtheria, states that if the culture be put in the incubator at a temperature of 37°–39° C. and examined in 2½ to 3 hours, the bacilli, if present, will be more easily detected than if the culture be not examined until several hours later.

Treatment.—E. M. Sutton⁵ recommends, as a useful adjunct to any other line of treatment, the use of a 1% or 2% solution of cocain atomized on the fauces and tonsils as often as seems necessary. One great advantage is that nourishment can be taken in greater amounts and more frequently because of the lessened discomfort in swallowing.

W. L. Pyle⁶ suggests the intravenous injection of mercuric chlorid, because of the safety of this method of administration and the increased efficiency of the drug when given in this way in other diseases in which its use is indicated.

Pinet⁷ uses a 0.5% solution of resorcin as a prophylactic against diphtheria, claiming that it is more powerfully antiseptic than boric acid.

H. Wickers⁸ applies to the pseudomembrane once or twice a day a mix-

ture of equal parts of glycerin and a saturated solution of sodium hyposulphit, finding that the membrane disappears after three or four applications, general treatment being, of course, used.

Antitoxin.—M. P. Haushalter,¹ in discussing the indications for the use of antitoxin, attaches importance to the morphology of the Löffler bacillus, considering the short bacillus to be nonvirulent (*cf.* Klein, *Year-Book* for 1897, p. 758), and its presence to be a coincidence without relation to the development of the pharyngeal inflammation. In case the pseudomembrane is white and bacteriologic examination shows strepto- or staphylococci with the short bacillus, the use of antitoxin may be deferred unless laryngeal symptoms arise. In a mild, localized angina without marked general symptoms, the result of the bacteriologic examination may be awaited, as these cases usually recover, even if due to the long bacillus, but a single injection will hasten the exfoliation of the deposit. Antitoxin should be given immediately, without waiting for the result of the bacteriologic examination, if the pharyngeal deposit is extensive, or if there are laryngeal symptoms, whether there is membrane elsewhere or not. If the bacillus is associated with the streptococcus, the antitoxin should be given in large and frequently repeated doses. In cases of croup it is recommended to inject 20 c.c. [number of units not stated], to be repeated every 12 hours until relief. Intubation or tracheotomy may be deferred as long as the pulse and color are good. Attacks of dyspnea warn against delay. With reference to immunization, Haushalter thinks that it is not wise, under ordinary circumstances, to submit a healthy organism to the possibilities of serotherapeutic accidents, however rare and slight they may be. The indication for preventive injections is a persistent fatal epidemic of diphtheria which cannot be controlled by ordinary hygienic measures.

The *Medical News* (Dec., 1896) investigated the different makes of antitoxin on the market with reference to the **strength in antitoxin-units**, the results being shown in the following tables:

TABLE I.—Shows the Results of the Examination of Nineteen Samples.

A. Monti¹ maintains that the **proper classification of diphtheria** is not merely into mild, severe, and grave forms, but into three groups on a pathologic-anatomic and bacteriologic basis, the terms mild, severe, and grave then being applied according to the clinical picture produced by the diphtheria-toxin. His three groups are: 1. A fibrinous form, in which the diphtheric products are only placed upon the mucous membrane. Virchow, Weigert, and Cohnheim call this the croupous form. 2. A mixed form, called also diphtheritic croup or the phlegmonous form, in which the fibrinous exudates lie deep in the tissues as well as upon the upper layers of the mucous membrane. 3. A septic, gangrenous form, in which a fibrinous pseudomembrane is formed in the deep tissues of the mucous membrane, the process really consisting of a necrosis of the tissues and a mingling of the dead particles with the diphtheric products. In the first form, death, when it occurs, is usually due only to the mechanical obstruction; in the second form both the obstruction and the action of the diphtheria-toxins may cause a fatal termination; while in the third form it results from the joint action of the diphtheria-toxins and pathogenic bacteria. According to Sidney Martin, there are two classes of diphtheria-toxins. The first is found in the diphtheric membrane, causing the local and general symptoms of diphtheria. When a sufficient amount of this toxin is taken up into the circulation it changes the albuminous bodies of the tissues into "tissue-poisons." There are two varieties of these, one belonging to the class of digested proteids—albumoses; the other, an organic acid belonging to the non-proteids.

The specific action of the albumoses is in small doses to produce fever, and, if the action is long continued, paralyzes; in large doses, they cause prostration, with fatty degeneration of the heart and kidneys. The antitoxin can neutralize only the toxin formed in the pseudomembrane, and cannot neutralize the "tissue-poisons," which explains why the sequels of diphtheria continue to appear after the use of antitoxin [and why an early injection of antitoxin is very desirable]. The pathology, then, of diphtheria necessarily

¹ Arch. f. Kinderh., Bd. xxi., II. 1-3, 1896.

conditions several clinical pictures of the disease, rendering it impossible to group all cases together in estimating the value of a therapeutic agent.

In 1895 Monti treated 104 cases of diphtheria with antitoxin, of which 72 belonged to the fibrinous form, 26 to the mixed form, and 6 to the gangrenous form. An exhaustive analysis is made, including classifications according to the location, extent, and duration of the membrane, ages of the children, and the degrees of severity.

In the *fibrinous form* there were 31 mild, 12 severe, and 29 grave cases. In all the grave cases the larynx was involved, there being a high degree of stenosis in 25, of which 3 died. "In none of the earlier methods of treating diphtheria have I been able to point in such severe diphtheric infections of the larynx to so favorable a result, and in this regard I must consider the results obtained by serum-therapy as brilliant." Of the 12 severe cases 3 died, all being artificially fed newborn infants. All of the 31 mild cases recovered, but it is to be taken into consideration that this result might not have occurred without serum-therapy, and that with other methods of treatment the diphtheric process would have shown a much greater tendency to involve other mucous membranes, or, through the formation of tissue-poisons, to produce sequels which might endanger life. The 72 fibrinous cases gave a general mortality of 6% to 8%. In one case there was a slight paralysis of accommodation and deglutition appearing 2 days after the injection, which, owing to its short duration, was attributed to the toxic working of the albumin-bodies in the horse-serum. In another case there was a light transitory albuminuria, also considered as due to the serum.

With regard to **dosage**, Monti recommends in tonsillar diphtheria with a thin pseudomembrane and mild constitutional symptoms a dose of 600 units as sufficient to limit the process and bring about rapid recovery. 1000 units are to be used if the general symptoms are more severe, or if the membrane is thicker or extends to the uvula, mouth, or post-pharyngeal wall. If at the end of 24 hours the symptoms are aggravated or stationary, the number of units was not enough to free the system from the toxin, and the dose should be repeated. Should the pseudomembrane, when first seen, extend over the tonsils, fauces, and pharynx, the initial dose must range from 1500 to 2000 units, depending upon the character of the membrane, the fever, and the duration of the disease before injection. A repetition of the dose is indicated if there is no improvement in 24 hours. If the pseudomembrane is situated both on the nasal and on the pharyngeal mucous membranes, 2000 to 3000 units should be given at once, and repeated as above. Laryngeal cases will need from 1000 to 1500 units if there is a slight degree of stenosis and a slight tonsillar deposit. This must, however, be repeated in 12 hours, if signs of improvement have not appeared. When the laryngeal obstruction is marked, large doses (2000 to 3000 units) should be given at once, and repeated in full or half doses, according to circumstances, every half hour. In the course of a single case it may be necessary to give as many as 5000 units. If the deposit on the tonsils and pharynx is extensive and thick, and the stenosis of high degree, the first dose should be not less than 2500 units. If the diphtheria is simultaneously nasal, pharyngeal, tonsillar, and laryngeal, even larger doses (3000 units) are to be used, with repetitions of 2000 units at intervals of 12 hours, until a bettering is noticed. Monti is of the firm opinion that other observers' more unfavorable results than his are due to too small amounts of antitoxin, and that in the fibrinous form of diphtheria serum-therapy causes a more rapid decline of the disease than any other method of treatment could bring about.

If sufficient antitoxin is used at the beginning of an attack, an improvement is always noticed within 24 to 36 hours, a constant criterion being a normal temperature.

Monti saw 26 cases of the phlegmonous form (also called diphtheric croup), of which 3 were relatively light, 9 were severe (*mittelschwer*), and 14 were very grave (*absolutschwer*), the local conditions in all being extensive and severe. 10 of this group died, a mortality of 37%, which "shows that the action of the heilserum in the phlegmonous form of diphtheria is uncertain." The reason why all of these cases are really grave is because the sudden development of the pseudomembrane on several mucous membranes leads to a rapid and abundant formation of toxins, which, on account of the changes in the deeper tissues, are quickly absorbed, and, as quickly, set up extreme intoxications and degenerative processes, which, of course, cannot be restored by an antidote to the causative poisons; therefore serum-therapy, in spite of the use of large doses, will be unable to save as many of these cases as of the fibrinous form. Further investigation is, accordingly, necessary to perfect serum-therapy for the phlegmonous form.

Six cases of the gangrenous, septic form [which probably corresponds to the malignant form of other writers] were observed, with 1 recovery—83% mortality. This series, although small in number would seem also to make further investigation necessary. With the failure of other methods of treatment, and with little to be hoped for from the antitoxin, it is, however, well to begin at once with large doses, and occasionally a case may be saved. In the 104 cases, one-third showed sequels due to the albumin-bodies of the serum, the frequency of their appearance being dependent upon the amount of serum used; therefore Monti urgently recommends the use of serum of high potency.

F. Ganghofner¹ has contributed an exhaustive article on **the serum-treatment of diphtheria**. Justice cannot be done to the pamphlet in a brief review, but perhaps the most interesting chapters are those on the nature, mode of action, and limitations of the antitoxin. Ganghofner has given the views of the different investigators very fully, with their reasons for their theories. He quotes Behring as considering the antitoxin a specific product of the immunized animal body. Buchner and others think that the toxin introduced in the process of immunization contains specific cell-substances of the bacteria, which are modified and rendered harmless in the animal organism. The blood of a healthy animal has been shown to have a bactericidal action (due to proteid bodies, alexins), a globulicidal action (dissolving blood-corpuscles of another species), and an antitoxic action, all of which processes Buchner looks on as similar in nature, and considers any antitoxic serum to act by increasing the normal capabilities of the blood in a specific direction, artificial immunization, therefore, being the combination of alexin and antitoxin-action. Emmerich thinks that the bacterial poisons unite with the globulin of the blood to form substances which he calls "immuntoxinproteins." Roux's vitalistic theory supposes that the poisons exert a stimulating influence upon certain cells, probably the phagocytes. Buttersack maintains that the cells of the body can only produce what they have always produced, and that the toxin acts through the nervous system, increasing the quantity of the products, but making no qualitative change.

While all of this is theory, it has been definitely shown by Brieger and Boer that the antitoxin is an albuminous body, capable of being separated

¹ First supplementary volume to the Handbook of Special Treatment of Internal Diseases. G. Fischer, Jena, 1897.

from the serum. However, speculation is still rife as to its mode of action. Behring thinks that a neutralization occurs of the toxin by the antitoxin, the artificial or passive immunity being more quickly obtained than the active, but being of more transitory duration. Buchner opposes the neutralization-theory because a mixture of the antitoxin and toxin of tetanus which gave no symptoms when injected into mice, produced tetanus in guinea-pigs. It has also been shown that some antitoxins will protect against other than their special toxin; thus, antitetanus-serum protects against snake-venom. Therefore, Buchner holds that the antitoxin acts, not on the toxin to neutralize it, but on the animal body to render it resistant to the action of the toxin. Max Gruber holds the same view, but emphasizes the share of the animal's own serum in reacting to the antitoxin. Gabritschewsky explains the healing of the local process in diphtheria by the local leukocytosis, sequestration of the necrotic mucous membrane, and the phagocytosis of the leukocytes. The necrotizing power of the diphtheria-virus paralyzes the phagocytic action of the leukocytes, while the antitoxin tends to maintain this action, by rendering the cells less susceptible to the poison, thus explaining the rapid disappearance of the pseudomembrane after antitoxin injections. Schlesinger found that the leukocytosis which accompanies diphtheria tends to disappear as the case approaches recovery, but persists in those cases that are to result fatally. Following the injection of antitoxin there is a marked diminution in the number of white cells, and then a slow increase, not, however, reaching the earlier height. This he considers to be a favorable action of the antitoxin, either directly upon the blood-cells or indirectly upon them through the blood-making organs. The general consensus of opinion seems to indicate the leukocytes as furnishing the ultimate protection through their products, nuclein and spermin.

After discussing other theories and also Smirnow's method of obtaining the antitoxin by electrolysis, and considering objections to the acceptance of the Klebs-Löffler bacillus as the cause of diphtheria, Ganghofner asserts that all these theories cannot change the fact that the diphtheria-antitoxin obtained by Behring's method is the best remedy by far for diphtheria that has been brought out up to the present time.

With regard to the limitations of the action of antitoxin, it is generally agreed that it is of great value if used before the third day, but that after that time the result is more uncertain. In the so-called septic cases its value is also lessened, and some discussion has arisen as to the nature of the septic diphtheria. Heubner and Ranke maintain that it is not always a mixed infection, as bacteriologic examination sometimes gives a pure culture. Ranke found, however, that even in septic cases the antitoxin gave good results when used early, and he, therefore, concludes that "either Behring's serum antagonizes streptococci also, or else the so-called septic diphtheria is not a true septic infection secondary to the diphtheria, but a high degree of general infection with the diphtheria process itself."

With regard to **local treatment**, Ganghofner advises it only in severe cases where the deposit is extensive, or the infection a mixed one. In early cases not far advanced he considers it unnecessary.

Lennox Browne¹ has become more strongly opposed to **the antitoxin treatment** than before. He gives a list of clinicians in different parts of the world who are "either definitely adverse to the treatment, or who deprecate the extravagant enthusiasm of some of its advocates." He makes an epitome of his objections (which are practically the same as those advanced by other

¹ Jour. Laryngol., Rhin., and Otol., Dec., 1896.

opponents of the treatment, and are therefore given *in extenso*) as follows: 1. Objections to the claims for antitoxin do not come from one or two writers, but from authorities in all parts of the world; 2. The basis of comparison of the new treatment with the old, as adopted by enthusiasts, is unfair; 3. Percentage-mortality is also misleading; 4. The gross mortality from diphtheria in this [London] and other large cities has not decreased; 5. To the increased attention given to the subject by the introduction of serum is the improved mortality mainly due, for the death-rate of cases treated with serum is out of all proportion greater than that of cases treated without it in the same hospitals. 6. This is especially true in the case of children attacked under 5 years of age, the period of life at which diphtheria is admittedly most fatal; 7. The value of immunizing-injections of antitoxin with a view to prevent diphtheria is but slight, and cannot outweigh the dangers of the procedure; 8. The scientific basis on which the treatment is founded cannot be sustained by any practical test, especially since internal medical and local treatment, as formerly adopted, is still continued; 9. The benefits, equally with the dangers, of the antitoxin are due to the albumin in the blood-serum, and not to any special antidotal element; 10. The assertion that the comparative failure of antitoxin in this country is due to insufficient dosage is not sustained by the figures now available. [In view of the publications of Biggs and others, objection 4 is scarcely tenable at present, and objection 8 is answered by the American Pediatric Society's investigations with regard to croup. If objection 9 is true, then the serums relatively high in antitoxin units are of less value than the more dilute.]

Sidney Martin¹ emphasizes the effect of the antitoxin in limiting the growth of the membrane, and urges that the initial dose should be large (4000 units in one injection) and given as early in the course of the case as possible.

The compilation showing the greatest **number of cases treated with antitoxin** has been made by Loddo,² who collected official statistics of 86 hospitals in Europe, America, Australia, and Japan. They include 10,000 cases, with an average mortality of 18%. Seven thousand of these cases, showing a mortality of 20%, were compared with preceding cases, which had a mortality of 44%. Guerard³ collected reports of 3760 cases treated in private practice, giving a mortality of 7.8%.

E. M. Goodall⁴ reports the use of antitoxin for diphtheria in 2 patients who were affected at the time with **post-scarlatinal nephritis**, the nephritis not being in any way unfavorably influenced. In a third case in which the nephritis had subsided, it relapsed 10 days after the diphtheria attack and 4 days after the appearance of an antitoxin-urticaria which was accompanied by fever. Recovery was prompt.

Fourrier⁵ has used the diphtheria-antitoxin with great success in a number of severe cases of **scarlet fever**. Dotti⁶ recommends it in pertussis, having seen the paroxysms in a case complicated by diphtheria cease after the injection of antitoxin.

Adamkiewicz⁷ attributes the **deaths following antitoxin-injections** to a disturbance of the self-regulating apparatus which protects the system against noxious influences within certain limits. This adaptive mechanism of the organism is disturbed first by a forcible injection, and secondly by the specificity of the substance injected.

⁷ Wien. med. Presse; ref. in Arch. of Pediatrics, Dec., 1896.

A. King¹ reports convulsions with disturbed respiration and a slow, weak pulse in an adult, after 2 separate injections of 1 c.c. each of antitoxic serum.

A. Possett² reports in detail on **59 cases of diphtheria** treated in the Innsbruck Hospital. It is interesting to note that cerebral embolism occurred in one of the fatal cases. The antitoxin was found to act very favorably in a great number of cases, but in some cases its use seemed to be without effect, the explanation for which, the author thinks, cannot be given until further researches are made on the antitoxin characteristics of human blood-serum.

P. Bernheim³ reviews his **statistics of diphtheria** for the past 20 years, seeing a fall in the death-rate of 12%, from 19.9% to 7.7%, which he attributes to an absolute diminution in the number and severity of cases. He has apparently used the antitoxin but little, seeing no specific action from it.

E. Rosenthal⁴ reports his own results in **intubation** before the introduction of antitoxin, and collects the reports of other observers, showing not only the lowered mortality, but the marked shortening in the time during which it was necessary to leave the tube in the larynx.

The Committee of the American Pediatric Society appointed to investigate the **value of antitoxin in laryngeal diphtheria** reports that 1704 cases were collected, giving a mortality of 21%. The mortality of 637 intubations was 26%; of 20 tracheotomies, 45%; of 11 tracheotomies subsequent to intubation, 63%; of 1036 nonoperated cases, 17%.

It is emphasized: first, that before the use of antitoxin it was estimated that 90% of laryngeal diphtheria cases required operation, whereas now, with the use of antitoxin, 39.21% require it; second, that the percentage-figures have been reversed, formerly 27% approximately representing the recoveries, while now, under antitoxin-treatment, 27% represents the mortality.

J. Herald⁵ reports 100 cases treated with antitoxin in the Kingston General Hospital (Ontario), without a death. In 12, intubation was necessary.

M. Tschlenow⁶ reports on the use of antitoxin in **102 cases** of diphtheria in his practice among the Cossacks of Southern Russia. The mortality of 15.6% is wonderfully good, considering the poverty of the people, who opposed the treatment at first, but were soon so impressed by its value that they brought cases over 25 miles for treatment. No other treatment was adopted.

M. Gornow⁷ also reports on **130 cases** treated only with antitoxin—mortality 13.8%. During 1 month when no antitoxin was obtainable the mortality rose to 52%. Of the 112 recovered cases, 2.8% were subsequently affected with palatal paralysis, 1 with paraplegia, and 1 with hemiplegia.

J. H. Moore⁸ reports a case of diphtheria in which **3 relapses** occurred in a few weeks, the membrane disappearing each time after the use of antitoxin. The bacilli persisted until all mercury by the mouth was stopped and 500 units of antitoxin injected night and morning for 5 days. During the 4 weeks of treatment 16,500 units were given without any untoward result.

The **insusceptibility of nurslings** to diphtheria makes interesting the report of a family epidemic by D. G. Sanor,⁹ one of the patients being an infant 9 days old. Injection of 750 units in two doses was followed by rapid recovery.

⁹ N. Y. Med. Jour., June 26, 1897.

A. J. Turner and L. N. Ashworth¹ report on the **use of antitoxin** in the Brisbane Children's Hospital. Their experience was so favorable, especially in laryngeal cases, where the mortality was reduced from 60% to 13%, that they believe that, with rare exceptions, no child ought to die of diphtheria, provided that a sufficiently large dose of antitoxin be given at the start.

H. M. Biggs and A. R. Guerard² report on the use of antitoxin by the N. Y. City Health Department, and include an exhaustive *résumé* of the published statistics from all quarters. The Health Department provided antitoxin free for the poor, and the cases treated were, therefore, as a rule, among the very poorest classes and in the most unfavorable surroundings. Over 1200 cases were injected, with a mortality of 15.8%, or, excluding moribund cases and those dying in 24 hours, 10%. In the same way the mortality of the laryngeal cases was 30.4% or 22%. Kossel is quoted extensively, in his collection of statistics, which show that there has been a decrease not only in the mortality-percentage, but also in the absolute number of deaths. [Without quoting figures further, those interested in seeing how decided a fall there has been in the number of deaths are referred to Biggs and Guerard's paper.]

W. H. Seibert³ gives a similar table for cities of the United States.

J. Lewis Smith⁴ reports favorably on 5 months' use of antitoxin in the N. Y. Foundling Asylum, attributing the unsatisfactory results obtained earlier to the quality of serum used.

I. M. Snow⁵ finds that Buffalo is an exception to the general rule for other cities in that the number of deaths from diphtheria has not been lessened, although the percentage of deaths has been lowered.

Glaser⁶ gives the **statistics** of the Hamburg General Hospital with reference to diphtheria for the 19 years from 1872-91. In the whole town there were 52,000 cases, with a mortality of 14%. Over 4000 cases were treated in the hospital, with a mortality of 36%. Of those admitted before the fourth day of the disease, 37% died; of those admitted later, 50% died. Of 1768 tracheotomies, 20% recovered.

Prophylaxis.—C. Fränkel's exhaustive address at the Kiel Congress on the prevention of diphtheria is reported thoroughly by G. Sobernheim.⁷ The importance of the subject is fully emphasized by the figures for the death-rate of the disease in Prussia for the 12 years from 1875 to 1886, which show that over half a million human beings died from diphtheria in that time, a rate of 165 deaths to 100,000 population. For the whole of the German Empire the figures were first obtained in 1892 and 1893, with a rate of 118 and 158 respectively. The almost incredible statement is made and verified that between the ages of 2 and 15 years 98% of deaths are due to diphtheria. Since the discovery of the diphtheria-bacillus the preventive measures do not have to be aimed in the dark, but can be directed with a purpose. After a discussion of the mode of propagation of the disease by individuals and contaminated objects (rarely by dust, as the bacilli do not survive desiccation for any length of time), the points are mentioned on which immunity and susceptibility rest: local conditions, especially of the mucous membranes of the upper air-passages, and general conditions, as the presence or absence of antitoxins, "those natural protecting substances of the body which are found in the blood in the majority of human beings, but are absent in many." One class of protective measures

has for its aim to put the individual in a condition to resist infection, the other class attempts to confine and destroy the infection. In the first class are all hygienic products, both of local antiseptics and of constitutional measures, such as cold bathing, which will tend to build up the individual and also to improve the resisting power of the mucous membranes; also other hygienic measures which tend to uplift the lower classes and to foster cleanliness. With regard to immunizing-injections, while Fränkel does not believe that the causal connection has been definitely proved in the 6 or 7 fatal cases collected by Gottstein,¹ yet he says that many physicians will hesitate before recommending a not absolutely harmless measure against a not absolutely certain infection. The concentrated serums are, however, rendering the risk so slight that it may be scarcely considered.

The second class of protective measures is covered by thorough isolation and disinfection. The former can only be obtained in a hospital, and should be continued as long as the bacilli remain on the affected mucous membranes.

Measles.—W. Moeller² studied the **statistics of epidemics of measles**, especially that of Munich in 1887, and arrived at the following conclusions: 1. There is no fixed periodicity in the recurrence of epidemics of measles. 2. For an epidemic of measles to arise it is necessary that there be the contagium acting on unprotected individuals. The intervals between epidemics is being continually shortened by the increase of commerce and of population. 3. There are certain factors still unknown, varying from time to time, which favor the spread of epidemics. Whether the warmer seasons exert their lessening influence upon the number of cases of measles directly because of the higher temperature, or indirectly through the dilution of the contagium by the better ventilation of rooms, cannot be determined. 4. An average for 20 years in Munich shows the mortality for measles to have two maximal periods, a slight one in December and a much greater one in May and June. 5. The mortality from measles in Munich for the first, and still more for the second, half of the 80's was nearly 3 times that for the decade from 1870 to 1880. The first half of the present decade shows a marked decline in the rate. 6. No age shows immunity to the infection, but nurslings are less susceptible than others. 7. Children under 5 years furnish almost all the fatal cases, and the majority of these are under 2 years of age. 8. In Munich the relative mortality for children under 1 year of age is 55 times, and for children between 2 and 5 years is 12 times that for children over 5 years. 9. Although the average number of cases is less, owing to the shorter intervals between epidemics, yet in Munich the average age of the fatal cases has not been lowered. 10. Both sexes, in Munich, show about an equal number both of cases and of deaths. 11. The absolute rate of mortality, like the relative, shows for the different divisions of Munich constant and important variations, and falls and rises with the birth-rate, the evident reason for this being imperfect care and nursing. 12. Primary thoracic rachitis increases threefold the disposition of a measles patient to catarrhal pneumonia and doubles the danger of this complication.

Diagnosis.—II. Koplik³ asserts that small, irregular spots of a bright-red color with a minute bluish-white speck in the center of each, appearing on the mucous membrane of the mouth and lips, provide a constant and pathognomonic sign of measles. He has always found them present in measles and never in any other disease. They occur at the beginning of the disease, when the diagnosis is doubtful, increasing in intensity to reach their height

¹ Therap. Monatsh., May, 1896.

² Arch. f. Kinderh., Bd. 21, H. 4.

³ Arch. of Pediatrics, Dec., 1896.

and to fade when the skin eruption appears. Robet¹ reports varieties of eruptions preceding the measles-rash, considering them to be due to streptococcus infection, with entrance through the inflamed mucous membranes. Bernard,² in a discussion on the prodromal and secondary exanthems (preceding or following other infections), thinks that they are not always due to the streptococcus, but sometimes depend on the virus of the infectious disease in the case.

Relapse.—Chauffard and Lemoine³ have observed 11 cases of relapse after measles, 8 of which occurred in one family. The relapses occurred from 11 to 14 days after the primary attack and none was serious. Eonnet⁴ reports 4 relapses after measles, all occurring within 20 days after the previous attack. In 1 case the child had had measles for the first time 3 years before. He also reports several attacks occurring in 122 of 300 cases which had been under his own observation, and insists upon the frequency of recurrence. Gottstein⁵ reports the case of a girl of 10 who had measles with marked eruption and slight respiratory symptoms. Two years later she had another attack, in which the catarrhal symptoms were pronounced, the eruption late and slight. He believes that the case supports Schleich's theory of acquired immunity, and that in the first attack the skin became immunized and was therefore but little affected in the subsequent attack.

G. J. Dudley⁶ notes the seeming occurrence of **measles during convalescence from scarlet fever**. The measles-eruption appeared 4 days after desquamation from scarlet fever began. The child had had no opportunity for infection by measles for 14 days, so that the incubation-period must have been at least that long. [The diagnosis of the measles is a matter of some doubt, owing to the possibility of a post-scarlatinal accidental rash.]

Complications and Sequels.—T. M. Allison⁷ records a case of **hyperpyrexia** in measles with bronchopneumonia, the axillary temperature reaching 109° at least twice. The issue was fatal. Wunder⁸ observed as a rare sequel to measles **gangrene of the soft parts** of the thoracic wall. Recovery ensued. W. A. Ellison⁹ saw **acute ascending myelitis** occur from the fifth to the seventh day of measles in a boy of 14 years, the postmortem temperature being 42.9° C. (109° F.). Ed. Mackey¹⁰ reports fatal **septic phlebitis** of the arm occurring during an attack of measles. There was no bacteriologic report. Rouger¹¹ describes 2 forms of **hemorrhagic measles**, 1 a true hemorrhagic form in which there are visceral as well as subcutaneous hemorrhages with a grave state, the other form including infectious purpuric erythemas, the infection being of buccal, pharyngeal, or bronchial origin, and occurring either in the course of measles or subsequently. The eruptions become hemorrhagic usually from the second to the fourth day, taking 10 to 15 days in which to fade. The prognosis is good unless there is marked dyspnea from laryngeal or pulmonary involvement. Méry and Lorrain¹² made a bacteriologic examination of **gangrene of the lung**, complicating measles, and found streptococci and bacilli resembling the Klebs-Löffler bacillus and some resembling streptothrix. M. Mosets¹³ reports 3 cases of **nephritis**, occurring in one instance with the appearance of the measles-rash, in

¹³ Vereinsbl. d. pflz. Aerzte, Sept., 1896.

the others several days later. Two other cases of nephritis were observed at the same time which were considered to be of measles origin, although there was no eruption. F. Bezold¹ found either mucopurulent or **purulent secretion in the temporal bone** in all cases dead of measles. The otitis media is not due to extension from the Eustachian tube, but to general systemic infection. Perforation of the drum-membrane rarely occurs, and the prognosis of the local condition even then is usually favorable.

Scarlet Fever.—**Myositis** as a complication of scarlet fever is reported by M. Bruck,² who has seen 3 cases. The muscles became tender from 2 to 3 weeks after the eruption had appeared, and the temperature rose to 38.5° C. (101° F.). The symptoms subsided in a few days with the use of the salicylates. Goodall,³ reports a case of scarlet fever dying in convulsions, the condition being found, postmortem, to be **thrombosis** of the veins of Galen. M. Alexieff⁴ reports 2 cases of **hemiplegia** in scarlet fever, 1 recovering completely, the other presenting postmortem a thrombus in the left middle cerebral artery. M. N. Ingerslen⁵ reports 3 cases of **surgical scarlet fever** in which the eruption started around a wound in the skin. The throat in each case was red, but there was no pseudomembrane except in one case, when it was slight. Amitrano⁶ reports a case of **typhoid fever** developing in convalescence a scarlatiniform eruption with fever, which was followed by desquamation. After this fever had subsided marked meningeal symptoms appeared for a few days. These disappeared, and after desquamation was complete a second intense erythema appeared, which was also followed by desquamation, after which recovery ensued. Weisbecker⁷ has treated cases of typhoid fever, scarlet fever, pneumonia, and the bronchopneumonia of measles with **blood-serum** from patients who had recovered from the corresponding disease, without any marked effect in shortening the course, but apparently making the patients more comfortable. **Warm baths** (35° C.) have been used by J. Schill and G. Schellenberg,⁸ in many cases of scarlet fever, all of the cases assuming a mild type in a short time. Varnali⁹ reports a case of scarlet fever complicated with **diphtheria**, running an afebrile course. The records¹⁰ of **2000 cases** of scarlet fever admitted to the Bagthorpe Fever Hospital showed that relapse, with sore throat, fever, and a rash lasting from 1 to 4 days, occurred in 14 cases. Accidental rashes were excluded. Depasse¹¹ reports a case of **hyperpyrexia** in scarlet fever. On the 12th day a temperature of 107.5° F. was reached and maintained for 70 hours following, in spite of antipyrin and cold baths. Decline of temperature and good recovery ensued. W. P. Northrup¹² among **details of the treatment** of scarlatina at the Willard Parker Hospital notes the use of douches of **hot saline solutions to the throat** to relieve the local symptoms and to prevent ear complications and cervical abscess. A wet-pack, Dover's powder, and nitroglycerin are relied upon for nephritis, while for hyperpyrexia tub-bathing is insisted upon as the most efficient means of reducing the temperature and of combating the attendant nervous symptoms. The temperature of the bath is to be regulated by the urgency of the case. Marsden¹³ has investigated the **joint-affections** occurring during or subsequent to the course of scarlet fever and divides them as fol-

lows: 1. Scarlatinal synovitis, which occurs in 7% of cases, nearly always appearing from the 4th to the 10th day; in 72% of cases affecting the wrists. It has no relation to the severity of the throat-symptoms or to rheumatism, and seems caused by the scarlatinal poison. 2. The septic form, occurring in 0.75%, often connected with fatal cases and closely related to severe throat-symptoms. This is probably due to mixed infection. 3. Rheumatic, less frequent and occurring usually in convalescence. 4. Tuberculous—occurs late, and the previous disease only affords the predisposition to the tuberculous; orchitis, a rarer complication, probably arises from a mixed infection from the throat.

Typhoid Fever.—J. O'Malley¹ records a **family epidemic** of typhoid fever. Both parents and three children became infected at about the same time, and in all the disease ran the typical course. J. P. Crozer Griffith² reports a positive **Widal reaction** with the blood of an infant 7 weeks old. The child was born when the mother was in the third week of typhoid fever, and it had been entirely well itself. He thinks it was probably a case of fetal typhoid, though admitting the possibility of the agglutinative principle having reached the child's blood through the placental circulation. The mother's milk had not been tested. Mossé³ reports that he obtained the Widal reaction from the blood of a newborn infant whose mother had passed through typhoid fever in her sixth month of gestation. The mother's milk and placental blood also gave the reaction. [While the Widal reaction will be of great value in deciding as to the nature of intestinal infection in infants, and will perhaps increase to a considerable extent the number of recognized cases of typhoid fever under 2 years of age, yet such cases as the above must be carefully investigated to determine how long the infant's blood will give the reaction after the breast-nourishment has been removed. This question and the full value of the Widal test will undoubtedly be settled in time.] S. S. Adams⁴ reports 4 cases of **temporary insanity** following typhoid fever in children. G. N. Acker⁵ reports a case of typhoid fever in a boy of 8 years, terminating fatally with **gangrene of the lungs**. The typhoidal lesions had begun to heal.

Varicella.—P. Bolognini,⁶ in an epidemic of 15 cases of varicella, found 12 complicated with a **staphylococcus and streptococcus infection**, which caused the vesicles to pustulate and form blebs. One case, resulting fatally from abscess of the kidney, gave a pure culture of streptococci. Von Stark⁷ observed a case of general **anasarca**, without other symptoms, in a boy of 2 years, just recovered from varicella. The edema disappeared in 10 days, and was attributed to the preceding infection. [This seems reasonable, until more light is thrown on the etiology of angioneurotic edema.] Löhr⁸ reports two cases of varicella terminating fatally, one from **miliary tuberculosis**, the other from septic infection. J. P. C. Griffith⁹ records a case of **varicella gangrænosæ**. Gangrenous ulcers ranging from the size of a split pea to that of a quarter-dollar developed from the vesicles. The distribution was universal, and death resulted. J. Comby¹⁰ observed in a case of varicella a **scarlatiniform rash** [probably streptococci].

Pertussis.—**Etiology.**—Kohn and Neumann¹¹ made bacteriologic studies without arriving at any definite conclusions, having found in 20 out of 25

cases a streptococcus, to which they did not attach any importance. Koplik¹ has isolated a **motile bacillus**, growing on hydrocele-fluid, and of very small dimensions, 0.8μ long and 0.3μ broad. It will not produce the symptoms of pertussis in the lower animals.

E. Czaplewski and R. Hensel² have worked out a method which has not failed, in every case of pertussis thus far examined, to show a **characteristic bacillus in the sputum**. The more severe and more advanced the case, the more numerous are the bacilli. The method consists in washing the sputum in a test-tube containing peptone water, putting it through at least three washings to free it from superficial contamination with other germs. The more solid lumps are then taken for the smear-preparation, which is fixed and stained with dilute carbol-fuchsin. The bacillus is oval, with rounded ends which sometimes stain deeper than the center, giving the appearance of a diplococcus. It resembles the influenza-bacillus but differs in its ability to grow on the ordinary media. It is polymorphous, the completely developed organism being only two or three times as long as it is broad.

Incubation.—Léon³ reports a case of pertussis in which the **period of incubation** could be exactly fixed at 11 days. The contagion was derived from a child in whom the diagnosis was only established 4 days later, showing that the disease is contagious in the early stages.

Symptoms.—Guérin,⁴ in a study of the temperature in pertussis, finds in many cases an irregular temperature, intermittent, sudden in onset and subsidence, and reaching as high as 40° C. He considers it to be due to the disease, and not to any complication. [We have observed in several cases a similar condition with nothing to account for the febrile paroxysm.]

J. Fröhlich⁵ found in all of 55 children with pertussis a marked **leukocytosis**, which kept pace proportionately with the number of kinks.

Bernhardt⁶ reported to the Society of Internal Medicine, Berlin, a case of pertussis in a child of 5 years, in which a **paraplegia** occurred, which he attributed to capillary hemorrhage in the spinal cord. In the discussion Furbringer upheld an infectious origin for the hemorrhages, while Leyden considered them mechanical. Baginsky thought the paralysis was hysteric.

At the Frankfort Congress Ritter⁷ gave the results of his observations in epidemics including **1163 cases** of whooping-cough. Seasonal influence could not be noted, but strong children seemed more disposed than weak ones. Five children had second attacks, and 37 who were exposed to the disease at one time without taking it, contracted it at a subsequent exposure. In the sputa of 147 patients Ritter's diplococcus *tussis convulsivæ* was found in every instance. For treatment he prefers bromoform, and has seen no bad results. Sonnenberger,⁸ with Kassowitz, prefers antipyrin, but thinks that extreme care should be used in giving it. Neumann⁹ has found Ritter's diplococcus in only 1 out of 18 cases.

Theodor¹⁰ notes 2 cases of **hemiplegia** occurring during pertussis. Both regained power completely. In 1 case chorea minor appeared 4 months after the hemiplegia, which he attributes to hemorrhage at the time of the hemiplegia—probably in the basal ganglia. The chorea disappeared after 4 months. He also notes a case of recurrence of pertussis.

¹⁰ Ibid.

Tuberculosis.—K. Szegö¹ discusses the present status of our knowledge on the **inheritance** of tuberculosis, and concludes “that the transmission of tuberculosis is either bacillary or predisposing (perhaps toxic). Transmission does not exclude contagion, but, on the contrary, the predisposed furnish the most receptive soil. It is difficult to say which form of transmission predominates. It may result from infection of the semen or of the ovum, or it may occur through the placenta. An affection of the respiratory passages or of the glands near the mouth and nose points to contagion, while tuberculosis of the brain, bones, joints, and abdominal viscera suggests a congenital origin. The inherited germ of tuberculosis can remain latent in the system for an indefinite period until the vital resistance is lowered, when it is then able to become pathogenic.”

Lymphatic Tuberculosis.—Starek² calls attention to the frequency of the occurrence of **enlargement of the cervical glands** in children that have carious teeth. In 113 children with enlarged cervical lymph-glands he found that 41% had carious teeth, and, in the absence of other apparent causes, he concludes that the swollen glands resulted from the defective teeth. The two conditions corresponded in situation and in time of development, the enlargement of the glands being upon the same side as the diseased teeth, and the anterior glands being enlarged when the incisor teeth were involved, the posterior when the molars were involved. He holds that the disease is tuberculous in quite a number of these cases, and reports 2 interesting examples. One, a boy of 18, who had always been healthy, had caries of the molar teeth on both sides, with enlargement of the cervical glands. The glands were excised and the teeth extracted. Tubercle-bacilli were found in cover-slip preparations from two of the teeth, while the glands were tuberculous. The second case was that of a girl aged 14, one of whose molar teeth on the left side was carious; there was an enlarged gland below the ramus of the jaw. Between the diseased molar and the adjacent tooth, and forming the floor of the cavity in the tooth, were characteristic nodules with typical giant cells. The gland was tuberculous. [These observations are of considerable interest; that tuberculous adenitis of the cervical group may occur with disease of the teeth and mouth seems well established. We cannot, however, refrain from calling attention to the unreliability of the statistical evidence which he adduces showing the frequency of carious teeth in children with enlarged cervical glands. The author fails to state the frequency of carious teeth without enlarged glands.]

Marfan and Apert³ note the case of a child which showed the **first signs of glandular tuberculosis** at 9 months; after death at 17 months extensive intestinal, mesenteric, bronchial, and cervical tuberculosis was found. The occurrence of cervical adenitis with ulcers of gums as the initial lesion, and the facts that the mother had healed glandular tuberculosis and that two other children had had tuberculosis, led the authors to think it probably a case of infection by the mother's milk, though cow's milk had been occasionally used.

Kossel⁴ found the **pulmonary lesions** and those of the adjacent glands most important in 22 cases which died of tuberculosis, and in 14 other children who presented tuberculous lesions after death from other causes. The digestive system was affected with a frequency next to the respiratory. The author considers that the absence of older foci in the liver in any of these cases speaks strongly against intrauterine infection.

¹ Arch. f. Kinderh., Bd. xxi., H. 5 and 6.

² Rev. de la Tuberculose, July, 1896.

³ Rev. mens. des Mal. de l'Enfance, June, 1896.

⁴ Der Kinder-Arzt, vii., 19, 1896.

L. E. Holt¹ records the presence of tuberculosis in 102 of **1045 post-mortems** at the New York Infant Asylum and the Babies' Hospital. The lungs were affected in 99%, the bronchial glands in 96%, the spleen in 75%, other organs less frequently. He thinks 3 cases were infected in utero. In one this probability seemed especially strong, since the 20-days-old child of a tuberculous mother had cheesy glands. The frequency of pulmonary lesions points to infection by the respiratory tract, and the comparative infrequency of lesions in the digestive tract leads him to remark that isolation and such sanitary measures will produce more good than milk and dairy inspection, although these also must be continued.

Maas² notes the rarity of **tuberculosis of the genital organs** in children, and adds another to the 7 cases recorded. There was tuberculous ulceration of the mucosa of the uterus and tubes, and nodules in the walls of his case. The probable exclusion of other sources and a line of old fibrous tubercles in adhesions extending inward from the umbilicus led him to consider the navel the avenue of infection.

Labbé³ adds 2 cases of **tuberculosis of the myocardium** to the 36 previously reported. The first occurred in a boy of 6 years, whose cardiac symptoms were increased area of dulness, pain, irregular pulse, and edema. At autopsy tubercles were found in numerous organs; the pleuræ were adherent to the pericardium, which was thickened and contained cheesy nodules. The hypertrophied heart-muscle was lardaceous and hard, especially at the apex. The second subject died with pulmonary tuberculosis in other organs as well, and in the myocardium was a cheesy tubercle which showed through the pericardium. Tubercle-bacilli were found in both specimens.

Syphilis.—E. Welander⁴ reports the case of a child with **congenital syphilis** in which the infection seemed to be post-conceptional, as the father developed chancre 8 weeks before the child was born and infected the mother at that time, both subsequently showing secondary symptoms. He believes placental disease, such as hemorrhagic necrosis of the endothelium, may result in infection of the child, which would not occur were the placenta healthy. Zappert⁵ relates a case of hereditary syphilis in which the only manifestations were **divergent squint** of the left eye, paralysis of the iris, and ptosis of the eyelid. Specific treatment brought about entire cure. He thinks the condition due to neuritis of the oculomotor. G. F. Harding⁶ records the case of a child who developed **secondary syphilis at 3 years** of age. Although both parents were infected shortly before the conception of the child, it showed no signs until 3 years old, and then a probable chancre appeared on the arm, followed by a secondary eruption. The author thinks that a short course of mercurial treatment taken by the mother early in the disease had prevented infection in utero, and that infection came from subsequent contact with the mother at a time well defined in the history, the child having lived apart from the mother for the first 3 years of life.

Glandular Fever.—J. P. West⁷ records an epidemic of 96 cases of what is now called glandular fever, occurring in a hamlet of 100 inhabitants and in the surrounding country. The ages of those affected varied from 7 months to 13 years, although both older and younger children were exposed. The duration averaged 16 days. But one death occurred, and there were no recurrences

¹ Med. News, Dec. 12, 1896.

² Arch. f. Gynäk., vol. xii., part 2, 1896.

⁷ Arch. of Pediatrics, Dec., 1896.

or sequelæ. The most marked symptom was the swelling of the carotid lymph-glands, which was nearly always double, though often beginning on one side. In three-fourths of the cases either the post-cervical, axillary, or inguinal glands were enlarged. In 37 cases the mesenteric glands could be felt; while enlargement of the liver was noted in 87 cases, and of the spleen in 57 cases. There was no ear-trouble nor coryza, and no abnormal pulmonary signs were discovered. All but one case occurred between Oct. 1 and June 1. There was no definite period of incubation, but 7 days after exposure was the average time of appearance of the attack. Convalescence began in the severe cases with a thin greenish mucous diarrhœa, and diarrhœa was present in almost all the mild cases. Treatment was of no influence in shortening the disease. No case of mumps occurred during the epidemic; 57 of the children had had or have since had mumps in the ordinary way. The cases sprang up in families isolated from each other, and there seemed to be no house-to-house infection. Dawson Williams¹ reports 3 cases of glandular fever in the same family. About a week elapsed between the development of the first and second cases, and the same interval between the second and third. In all the affection was unilateral. No acute disease of the throat was present, but there was chronic granular pharyngitis. T. E. Sandall² records a case of the same affection in an infant of 6 months. The glandular swelling was limited to one side. Alex. McPhedran³ reports a case in a boy of 4 years. The child passed through an attack of mumps a few weeks later. S. M. Hamill⁴ reviews the literature, in reporting several cases.

Pneumonia.—E. Schlesinger⁵ analyzes 173 cases of croupous pneumonia in children, occurring in the K. and K. Friedrich Children's Hospital. The monograph is an interesting and valuable one. J. P. C. Griffith⁶ discusses the varying features of pneumonia in children. Comba⁷ records the case of a child who died on the sixth day of life after presenting, clinically, aphonia, diffuse sclerema, and general weakness. The autopsy showed serous infiltration of the skin and of the muscles, and foci of bronchopneumonia in the lungs. There was general cloudy swelling of the liver and kidneys, and occasional areas of fatty degeneration were seen. Bacteriologic examination of the blood and lung-tissue showed a bacillus resembling in its characteristics the bacillus of Friedländer. The infection seems to have occurred from the foci in the lungs.

Peritonitis.—Brun,⁸ after observations on 3 new cases, reasserts his earlier claim that peritonitis from the pneumococcus may be distinguished from that of other forms. It begins as sub-umbilical peritonitis, and after the subsidence of the acute symptoms suprapubic tumefaction appears, which is sometimes distinctly fluctuating. This sign, together with pointing or fistulization of the umbilicus, he considers almost pathognomonic. The prognosis is less grave than in other forms of purulent peritonitis. Eleven cases out of 14 recovered. It is more frequent in girls, and since the pneumococcus has been found in the walls and cavity of the uterus it seems probable that the tubes and the uterine lymphatics are the sources of infection in some cases at least.

Mumps.—Michaelis and Bein⁹ have found in 7 cases of mumps a **diplococcus** 1μ in size and resembling the biscuit-shaped meningococcus in appearance. The microorganism was obtained in all cases in the fluid from Steno's

¹ Lancet, Jan. 16, 1897.

⁸ Presse méd., Feb. 27, 1897.

⁹ Deutsch. med. Woch., suppl. 1, page 93, May 13, 1897.

duct; in 1 case from the pus of an abscess. It stained with Löffler's methylen-blue, was decolorized by Gram's method, and grew on all the usual culture-media. They think it bears etiologic relation to the disease.

P. M. Meeray and J. J. Walsh¹ found a **micrococcus**, usually in the form of a diplococcus, in Steno's duct in all cases of mumps examined. The same microorganism was found in pure culture in the blood of 3 of 8 cases thus examined. In 3 other cases cultures from the blood gave this microorganism mixed with others. Two were sterile. In 5 healthy children the microorganism was never found. The diplococcus showed the same characteristics as that described by Laveran and Catrin.

F. L. Benham² records a case of **mumps with severe orchitis**, in which there was high temperature for about a week, sometimes reaching 104.8°, and part of this time accompanied by stupor and other severe cerebral symptoms. The rare cases of mumps exhibiting cerebral symptoms he divides into those showing (1) high fever and delirium, (2) insanity—both of these due to excessive poisoning of the disease, and (3) paralysis—probably due to thrombosis or embolism. These are conjectures, since pathologic records are wanting.

Other Infectious Diseases.—F. M. Crandall³ records epidemics of **influenza** in 3 families. In the first, 7 of a family of 9, including 3 children, developed the disease, the mother and a boy of 2 years escaping. Seven cases occurred in the second family, and of those, 3 were below puberty. In the third family, of the 10 members but 3 escaped; 4 children were among those affected. Follicular tonsillitis was noticed at the same time in many of the cases.

Haushalter⁴ records a case of **gonorrhœal rheumatism** in a newborn male child who had gonorrhœal ophthalmia. The left wrist and right knee became swollen in the 4th week of life, and cultures from the fluid removed from the joints showed gonococci, as did the examination of the pus from the conjunctivæ. As in the 10 similar cases reported, the duration of the joint-disease was short (1 week) and recovery ensued.

Griffon⁵ records the case of a newborn infant with double purulent ophthalmia, in which **purulent arthritis** of the right hip and wrist afterward developed. During life, in liquid from the hip-joint, staphylococci and probably gonococci were found; the vaginal secretion showed the same, and the conjunctival pus contained both these microorganisms and a bacillus. Examination of the blood was negative. Pus taken after death from the affected joints showed probable gonococci; all cultures showed only staphylococci and the bacillus mentioned.

G. A. Turner⁶ quotes from Arthur Mitchell the frightful previous mortality of 67.2% from **tetanus neonatorum** among all children born on the island of St. Kilda. The newborn were wrapped in blankets, with no dressing to the umbilicus. Turner had antiseptic dressings of iodoform applied and carefully changed daily, and no deaths from tetanus have occurred since among the children thus treated.

A thorough *résumé* of the European literature for 1896 on **vaccination** is given by L. Voigt.⁷

E. Kronenberg⁸ records a case of infection from **vaccinia**. A few days after washing his face with a sponge used by a child with vaccinia an 8-year-

¹ Med. Rec., Sept. 26, 1896.

⁷ Arch. f. Kinderh., Bd. 22, H. 3 and 6.

⁸ Deutsch. med. Zeit., xviii., 283, 1895.

old boy developed an eruption of vesicles on the cheeks, eyelids, and nose, and in the mouth. After inoculation from the contents of one of the pustules the father developed typical vaccinia.

Krasnobajew¹ exhibited a boy, 8 years old, with **actinomycosis of the intestine**. The diagnosis was made by finding the ray-fungus in the pus from one of the fistulae. Improvement was marked under persistent use of potassium iodid.

R. Abrahams² reports as **rheumatism of the newborn** the cases of 3 infants whose mothers had all had attacks of rheumatism in the later months of pregnancy. The father, also, of one child was rheumatic, and there was a history of rheumatism in the family of another. Two of the children were found within the first day of life to have swollen, red, and tender joints, and the third had the cardiac murmur of aortic insufficiency. In one child suppuration occurred later in some of the joints, while the second case which presented joint-trouble recovered under the use of salicylate of sodium, and an endocardial murmur which was at first present disappeared.

GENERAL NONINFECTIOUS DISEASES.

Rachitis.—J. P. West³ records rachitis in a breast-fed infant of 4 months, seemingly due to the demonstrated deficiency of fat in the mother's milk. J. L. Morse⁴ publishes the results of the examination of the blood of 20 rachitic infants, and concludes from these and other publications that most cases are accompanied by anemia of a severity generally proportionate to the severity of the process. The anemia may be of any form, but usually the hemoglobin is relatively and absolutely decreased. Leukoeytosis is more frequent when splenic tumor exists, and any of the forms of leukocytes may be increased. There is nothing distinctive of the disease in the condition of the blood. J. Thomson⁵ describes the case of a rachitic boy of 13 months, who had convulsions, laryngismus stridulus, facial irritability, and head-nodding. Changing the diet from a weak dilution of condensed milk to a milk-and-cream mixture was followed by distinct improvement, but the condition persisted in lessened intensity. About a year later, after a fit, he had convulsive laughter, and shortly afterward died in a general convulsion. No autopsy was allowed.

Scurvy.—D. Lichty⁶ records a case of infantile scorbutus with such marked tumefaction of the gums as almost to cover the incisor teeth. S. E. Leard⁷ records a case of the same disease. A. H. Bogart⁸ notes 2 cases in which the lesions were subperiosteal, with no mouth or skin symptoms. J. Leidy⁹ records 9 cases, 7 of which were seen in dispensary practice. Six of the infants had been fed upon one or other of the proprietary infant's foods and 3 upon sterilized milk. A. H. Burr¹⁰ records a case with marked swelling of the femur and scapula and suppuration of the hemorrhagic cutaneous lesions. C. W. Townsend¹¹ records 12 cases, in 1 of which there was hematuria. Three had moderate rickets. W. F. Cheney¹² saw 1 case associated with marked rickets.

Status Lymphaticus.—Galatti¹³ records a case in which death occurred

¹ Arch. f. Kinderh., Bd. 23, II. 1-3.

¹² Med. News, vol. lxxviii, No. 9, 1896.

¹³ Wien. med. Blätter, Dec. 10, 1896.

in a child with status lymphaticus 10 hours after an injection of diphtheric antitoxin, and in which the rapidly fatal issue seemed due to the lymphatic condition. He insists upon a guarded prognosis and treatment of these cases.

Biedert¹ found an **enlarged thymus** as the cause of death in a case which had presented, during life, the symptoms of croup, and for which intubation and then tracheotomy had been performed without benefit. Death was caused by pressure on the trachea and by obstruction to the venous circulation. The enlargement of the gland was due to round-cell infiltration and increased vascularity.

T. Escherich² emphasizes the danger of using certain procedures which are usually harmless, such as **hydrotherapy**, in children with status lymphaticus. As an instance of this danger, he relates the case of a 2-year-old boy who went into collapse while in a wet-pack of salicylic-acid solution used for prurigo, and death occurred the next day. He further considers the relation tetany and laryngospasm bear to the lymphatic constitution, and details a case with marked laryngospasm in which the other main symptoms of tetany were present, though latent, and in which case sudden death occurred during a laryngeal attack. Postmortem the thymus and numerous other glands were found enlarged. He suggests that here we may have an indication of the pathogeny of tetany and of laryngospasm, and mentions the possibility that the thymus may be related to these spasmodic attacks as is the thyroid to exophthalmic goiter.

Diabetes Mellitus.—Josias³ points out that we cannot use opiates in diabetes in children as in adults. Of medicinal remedies, he recommends Fowler's solution in full doses, and, to diminish the sugar, antipyrin in daily doses of 10 to 20 gr. The infrequency of diabetes mellitus **in infancy** makes it of interest to refer to a case in a child $2\frac{1}{2}$ years old, reported by L. Rosenberg.⁴

Arthritis Deformans.—W. Stowell⁵ reports a case of arthritis deformans in a girl of 9 years. The disease was of 3 years' duration, and the child was nearly helpless from ankylosis of the shoulders and elbows and extreme flexion of the head on the chest. Massage benefited her greatly.

F. G. Finley⁶ records the case of a girl of 11 years with **chronic polyarthritis**. Nearly 4 years before, the affection began in the right ankle, with swelling and stiffness, and was then considered tuberculous. Subsequently the right knee, the metacarpophalangeal articulations, the wrist, left knee and left ankle became affected, and the legs drawn up; the patient had been bed-ridden for 2 years. The swelling left the joints 2 years previous to the report, but they remained almost without motion and useless. There was some crepitation on movement. The soft parts of the joints were thickened, and the skin over them was tense and glossy. The bodily organs were normal. No Heberden's nodosities were present, and there was no history of rheumatism or tuberculous in the family. Tonic treatment and manipulation had resulted in marked improvement.

DISEASES OF THE ALIMENTARY TRACT.

F. Forchheimer⁷ contributes a suggestive paper on **elimination as an etiologic factor** of diseases of the alimentary canal, pointing out that as

¹ Berlin. klin. Woch., June 29, 1896.

² Ibid., July 20, 1896.

³ Jour. des Praticiens, Aug. 6, 1896.

⁴ Münch. med. Woch., May 18, 1897.

⁵ Arch. of Pediatrics, Oct., 1896.

⁶ Montreal Med. Jour., vol. xxv., No. 2, 1896.

⁷ Arch. of Pediatrics, Jan., 1897.

the absorptive function of any part of the tract lessens as compared with another, its eliminative capabilities probably increase. The value of lavage and purgatives in the different diseases is in part due to their removing not only the irritants, but also the toxalbumins and other substances that have been eliminated from the circulation into the canal.

Beco¹ describes as **diphtheroid stomatitis** an affection of infants which has often been confused with aphthous stomatitis. It occurs in the form of discrete plaques on the middle of the lower lip, dorsum and edges of the tongue, and, more rarely, on the gums. These are not preceded by vesicles, are adherent, and detachment leaves a bleeding ulcer. The affection is parasitic and due to several microorganisms, of which those most frequently found are the staphylococcus aureus and the streptococcus pyogenes. When plaques have formed the disease may be transmitted. Glika² describes a similar affection of staphylococcic origin, first vesicular and then becoming membranous.

F. Fede³ describes a **disease of the mouth** seen in Lower Italy, and affecting children shortly after the eruption of the lower incisors. The appearance is somewhat like that of an aphtha situated on the frenum and under surface of the tongue—a raised, gray swelling, which is at first papillomatous and later of the nature of a granuloma. There are 3 types of the disease: one in which the general health is good; a second, in which the local condition has lasted for some time and some intercurrent disease, like tuberculosis, sets in; and a third, a severe form, which may terminate fatally. The local treatment is excision and cauterization. [Of the terms suggested for the condition, Riga's disease and aphtha cachectica are the best.]

S. S. Adams⁴ records a case of **pharyngo-esophageal stenosis** in a child of 4 months. Until 2 weeks before admission it had been well, since which time, and until its death 2 weeks after admission, it had regurgitated all food which it attempted to swallow. A catheter and the examining-finger were arrested below the epiglottis. Postmortem the pharynx was found to end in a wide cul-de-sac, with only a pinhole-opening into the esophagus, and this perhaps artificial. There was no evidence of inflammation from any cause.

A. Clopatt⁵ considers that the cause of acute **retropharyngeal abscess** is usually to be found in affections of the skin, or of the mucous membranes of some of the cranial cavities, with infection through the lymphatics leading to the postpharyngeal glands. Sometimes enlargement of the cervical glands in the acute infectious diseases may lead to the condition. He records 6 cases, 3 of which were under a year of age, 2 under 2 years, and 1, 2 years old.

Diarrheal Diseases.—A. F. Plicque⁶ recognizes: 1. Simple diarrhea, for which he uses ordinary treatment; 2. Green bilious diarrhea, in which the green color is recognized as due to bile by the nitric-acid tests, and for which alkalies (sodium bicarbonate) are essential; 3. Green bacillary diarrhea, for which the most important medication is lactic acid; 4. Cholera infantum, in which he insists upon continued feeding in spite of vomiting, stimulation, and the use of lactic acid, hydrochloric acid, and laudanum.

A. Baginsky⁷ contributes a valuable monograph on the **pathology of the diarrheal diseases** of childhood, with the following conclusions: 1. The summer-diarrheas of children are in the beginning only functional dis-

⁷ Arch. f. Kinderh., Bd. xxii., H. 3-6.

turbances of motion and secretion with abnormal chemistry of digestion; later the intestinal wall undergoes severe anatomic changes. 2. These changes may range from catarrh to necrosis of the mucous membrane. 3. The follicular changes are peculiar and independent of the catarrhal, although if they are of long duration the two coexist; the follicular changes often lead to ulceration. 4. The causes of the inflammation are not specific germs, but the ordinary saprophytic bacteria which inhabit the intestinal canal and take on a special virulence. 5. Under some circumstances, other bacteria, not ordinarily present, may gain access to the intestinal tract and cause disease with severe anatomic changes. 6. These bacteria may penetrate into other organs, especially the kidney, and set up inflammation even to suppuration; the metastasis rarely occurs through the blood-vessels. 7. The most severe disturbances are caused by the products of bacterial metabolism, which are either of the nature of acids or products of albumin-decomposition, which may have proceeded as far as ammonia or its compounds; these act as powerful irritants in the intestine and so injure the wall as to gain access through the circulation (blood and lymph) to more remote organs, and throw such a strain upon the eliminative organs as to destroy them. 8. Through the influence of this intoxication the whole organism loses its power of resisting the many forms of hostile microbes, and disposition to disease is shown in the occurrence of many complications.

O. Reinach¹ reports the use of **sterilized cow's serum for gastro-enteritis**. Of 15 infants, 11 showed marked improvement of circulation, digestion, and general appearance. The 4 other cases died—2 of lobar pneumonia, 2 of severe follicular disease of the intestine. The favorable action of the injections is attributed to the fluid added to the blood, the stimulating action on metabolism of the salts of the serum, and to the nutriment in the albumin of the serum. No unfavorable effects were noted, except slight fever in 2 cases and an eruption like measles which appeared in 1 case 2 weeks after the injection. From 10 to 26 c.c. were used in one injection.

Lesage² has treated 52 children with grave diarrheas with **serum obtained from asses** after injecting colon-bacilli from virulent milk or stools. 26 children had no marked symptoms after 48 hours, 14 were improved, 12 unimproved. In all cases where the stools were green the color disappeared after the injections. The serum obtained after treating asses with the colon-bacilli normally present in stools did not give these results.

Watu³ advocates the treatment of infantile diarrhea with **cooled boiled water** given in small portions, while food is excluded for from 8 to 24 hours. This is said to promote recovery by diluting and flushing out the intestinal contents, and by carrying out with them the dissolved toxins.

K. Szegö⁴ made a **bacteriologic study of the intestinal discharges in infants**, some of whom were healthy, while others had "dyspepsia," which term was not used to include the diarrheas, but to cover those cases in which there were sour-smelling acid stools, containing mucus and curds. Many bacteria were found, the bacillus coli communis being the predominant form. There was no bacterial distinction between the two groups of cases, so the dyspepsias were considered to be merely changes in the chemistry of digestion.

W. Soltau Fenwick,⁵ in a report on the **pathology of infantile marasmus**, drawn from observations on 16 cases, shows that the failure of nutrition is due to organic and often incurable changes in the mucous membrane of the

¹ Münch. med. Woch., xliii., 42, 1896.

² Rev. de Thérap. Med.-Chir., No. 24, 1896.

³ Thèse de Paris, No. 40, ii., 1896-97.

⁴ Arch. f. Kinderh., Bd. xxii., H. 1 and 2.

⁵ Brit. Med. Jour., Sept. 26, 1896.

stomach and intestines (see Plate 2). By means of test-meals and lavage the condition of gastric digestion may be ascertained and the prognosis made.

L. E. Holt¹ reports a case of **appendicitis in a child** 2½ years old. There was persistent vomiting, with moderate constipation and considerable fever. Examination under chloroform failed to reveal anything in the abdomen suggestive of intussusception or appendicitis. Signs of peritonitis were marked on the following day, and death occurred 5 days after the initial attack of vomiting. At the autopsy the appendix was found to contain a hard concretion just above a perforation, which was an inch from the distal end.

The maximum length of time at which it is justifiable to continue enemata to reduce an **intussusception** is not yet clearly defined; but those who favor the medical rather than the surgical treatment will find encouragement in the reports of W. P. Northrup² and M. H. Brown,³ the former reporting 1 and the latter 2 cases in which the persistent use of enemata accomplished reduction. In one of Brown's cases 2 days had elapsed after the onset, and in the other fecal vomiting had set in. Fifteen injections in all were required in the latter case.

Th. Hecker⁴ records a case of **congenital intestinal occlusion**. Vomiting began soon after birth, and continued uninterruptedly. There were jaundice and distended abdomen. A catheter passed only 6 cm. into the rectum. The stricture could not be reached per rectum, however, so an artificial anus was made in the groin. A feculent fluid flowed from the opening. The child died on the 6th day of life. Postmortem there was found old and recent fetal peritonitis, and two separate tracts of intestine were discovered. The lower began blindly above at the cecum and continued as a collapsed, cord-like body extending to the anus. The other began at the pylorus, and ended at the pelvic brim. The separation seemed due to torsion, and this to either fetal peritonitis or volvulus. The mother had suffered from slight abdominal trauma at the 4th month of pregnancy, but this scarcely bore any relation to the condition.

DISEASES OF THE CIRCULATORY SYSTEM AND BLOOD.

Congenital Defects.—J. P. C. Griffith⁵ calls attention to the difficulty and sometimes impossibility of diagnosing **congenital cardiac defects** *intra vitam*. He reports a case of perforate septum ventriculorum in a child of 4 years, in which the diagnosis was reasonably well established during life, and was confirmed at the autopsy. A. Caillé⁶ reports **transposition of the great arteries of the heart** in an infant of 6 weeks. The aorta arose from the thick-walled right ventricle and the pulmonary artery was given off from the left ventricle, the walls of which were of moderate thickness. T. M. Rotch⁷ records an unusual congenital **malformation of the heart** of an infant which seemed perfectly well and had normal heart-sounds until 16 days old, when it became cyanosed, dyspneic, and cold, and died next day. Post-mortem the heart was found hypertrophied, and the foramen ovale open; the interventricular septum was incomplete, and the aorta arose from the right ventricle, the pulmonary artery from the left ventricle. The latter vessel was dilated into a pouch, from which were given off the right and left pulmonary and a third vessel which seemed to be the ductus arteriosus, and which took the place of the arch and descending aorta and supplied the trunk and lower extremities. The aorta supplied the head and arms.

PLATE 2.

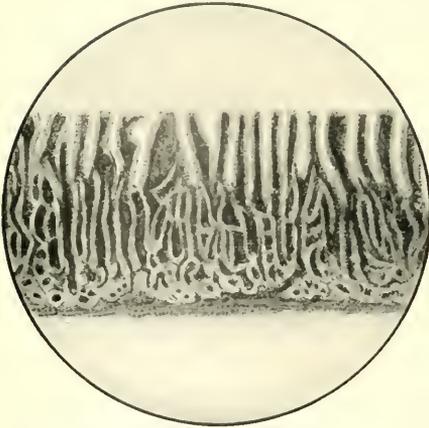

FIG. 1.—Drawing of the mucous membrane of the stomach of a healthy infant ($\times 65$).

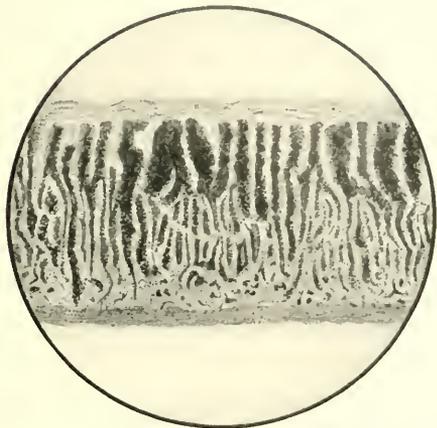

FIG. 2.—Drawing of the mucous membrane of the stomach in the first stage of chronic catarrh, showing the exudation of round cells between the gastric glands ($\times 65$).

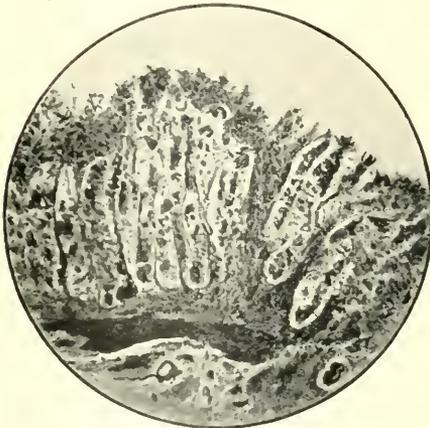

FIG. 3.—Photomicrograph of the stomach in a case of marasmus, showing the formation of fibrous tissue between the glands—second stage of interstitial gastritis ($\times 65$).

FIG. 4.—Photomicrograph of the stomach in a case of marasmus, showing complete cirrhosis of the mucous membrane, with obliteration of the glands—third stage of interstitial gastritis ($\times 65$).

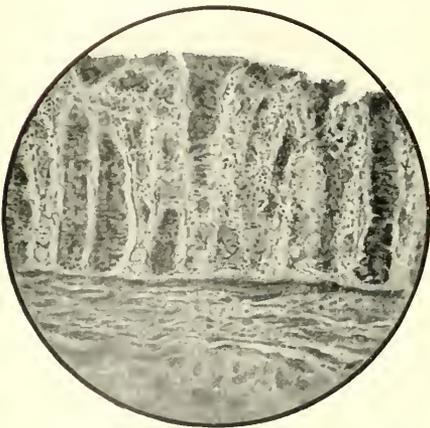

FIG. 5.—Photomicrograph of the cecum, showing the effects of chronic inflammation upon the glands of the mucous membrane ($\times 65$).

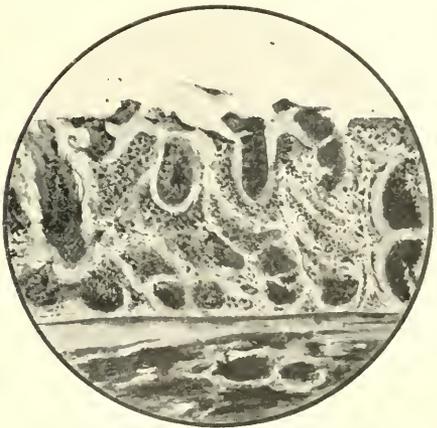

FIG. 6.—Photomicrograph of the descending colon from a case of chronic marasmus, showing partial obliteration of the glands of the mucous membrane ($\times 65$).

Myocarditis.—Weill and Barjon¹ decide from their examination of the hearts from 4 children who died with endocarditis that parenchymatous myocarditis occurs in childhood, especially in the course of a chronic endocarditis. These hearts showed an excessive development of the protoplasm of the muscle-cells, while the contractile substance suffered. The elementary fibrils were thinned and separated, the nuclei proliferated and enlarged, and the muscular striæ were diminished, while vascular and interstitial changes were absent. Three of the cases died during or soon after recurrent attacks of rheumatism, with evidences of a general febrile infection, and from this they conclude that the myocarditis seems to come from infection due to rheumatism. Erysipelas and probably other contagious diseases are also active. The condition manifests itself by asystole, lasting some days to several months, without change in the cardiac rhythm.

Adhesive Pericarditis.—L. E. Holt² records the case of a child of 16 months in which adhesive pericarditis with complete obliteration of the pericardial sac was found after death. The family history bore no relation to the condition and it had not been suspected during life. There was acute pneumonia and extensive pleural adhesions were present on both sides. G. M. Swift³ reports 4 cases at the ages of 4, 6, 10, and 14 years.

Endocarditis.—A. J. Wood⁴ records the case of a girl who had rheumatic endocarditis at 12 years of age. Compensation was established, but this broke down at puberty and the child died. He considers puberty an especially trying time for children with damaged hearts.

Malignant Endocarditis.—J. H. Fruitnight⁵ reports a case and discusses the etiology, pathology, symptoms, and treatment. Its infrequency in children is mentioned, a point also emphasized in the discussion by W. P. Northrup, L. E. Holt, and Wm. Osler. Wood⁶ records a case of malignant endocarditis in a girl of 5. Severe paroxysms of pain in the head, fever, cough, and weakness of the right side were the early manifestations. Right-sided complete hemiplegia also existed. The heart was somewhat enlarged, and there was a loud systolic murmur. The spleen was enlarged, the urine albuminous, and petechiæ appeared. Optic neuritis and retinal hemorrhages were present. The temperature reached 104° F. and a convulsion preceded death in coma. A history of rheumatism was not obtainable. At the autopsy the anterior mitral valve was much thickened and infiltrated, and a large antemortem clot hung from the valve. There were infarcts in the spleen, kidney, and brain, and petechial hemorrhages throughout the body. No primary cause was discovered, except possibly old pleurisy. The records of the Children's Hospital at Melbourne furnish but 1 other case in 10 years.

Hematoma of Valve.—V. Kahlden⁷ reports a hematoma of the posterior leaflet of the mitral valve, with a diameter of 12 to 14 mm., in the heart of a child 1 year of age which had apparently presented no cardiac symptoms during life. It caused a spherical, hollow tumor projecting mainly from the upper surface of the valve and bounded by the upper and end surfaces of the leaflet. The vessels of the valves were thickened and the lumen narrowed. The hollow portion of the tumor contained some fibrin. The commonly favorable course of hematoma of the valves seemed interfered with in this case by the large size of the tumor. Death was caused by miliary tuberculosis secondary to infected bronchial glands.

⁴ Intercol. Med. Jour. of Australasia, Jan. 20, 1897.

⁵ Ibid., Sept., 1896.

⁶ Intercol. Med. Jour. of Australasia, July 20, 1896.

⁷ Ziegler's Beiträge, Bd. xxi., H. 2, 1897.

Arteriosclerosis.—Seitz¹ reports 3 cases of arteriosclerosis in children, with hypertrophy of the left ventricle. Preceding infectious diseases seemed to be the only causes.

Anemias.—A. Baginsky² reports 2 cases of **pernicious anemia** in children aged 3½ and 10 years. The bacterium coli was found in the blood, and may have been of etiologic significance. F. Theodor³ tabulates 45 cases of acute **leukemia**, 6 of which occurred in children under 10 years. He reports a case in a boy of 4 years, ending fatally in 6 weeks. The proportion of white to red cells approximated 1 to 3. Cultures from the blood on different media remained sterile. A family history pointing to syphilis was considered to have some etiologic bearing.

Purpura.—E. A. T. Steele⁴ records a fatal case of **purpura hæmorrhagica** probably due to "scurvy rickets," and with the rare complication of pemphigus. The disease began with epistaxis and bleeding gums. Later purpuric spots appeared on the face and limbs, and in the center of many of these were large bullæ filled with dark serum. The wrists and ankles were swollen and the child cried if moved. Death occurred the day after admission, in hyperpyrexia and coma. Autopsy showed many small hemorrhages in the lungs, a decolorized clot in the superior longitudinal sinus, soft and porous bones, and enlarged ends of the ribs. Claude⁵ notes a case of **infectious purpura** occurring as the eruption of measles was disappearing and while the child was in a second attack of bronchopneumonia. The issue was fatal. Another case was apparently toxic, as it came on during violent poisoning from tainted meat and bacteriologic examination was negative.

Melæna Neonatorum.—The literature of this disease is reviewed by J. W. Smuck,⁶ who reports 2 cases, one of them recovering. F. M. Crandall⁷ reports an unusual case, the hemorrhages appearing first on the 15th day after birth. Recovery ensued under rest, small doses of paregoric, and abstinence from food for a short time. J. L. Morse⁸ also records a case remarkable for the severity of the symptoms and for the recovery. A fatal case is reported by R. H. Shaw.⁹ J. v. Chrzanowski¹⁰ reports 2 fatal cases in which cultures of the blood during life were negative. He discusses at length the different theories with regard to the etiology.

Hemophilia.—E. Berggruen¹¹ reports a case of hemophilia in a girl of 9, developing cerebral apoplexy, hematuria, and pernicious anemia, but recovering under the use of tablets of bone-marrow. Cultures of the blood were taken, with negative results. Comby¹² records the case of a girl, aged 11 months, in whom from the third week of life there had been continuous and spontaneous hemorrhages from the nose, mouth, and rectum, and into the substance of the skin, without, however, impairing in any manifest way the child's development. There was a history on the father's side of hemophilia, but not on the maternal side. The patient was the only living one of their children; there had been two other girls, who had died in infancy, but had not shown any signs of hemophilia.

DISEASES OF THE LIVER, SPLEEN, AND GENITO-URINARY SYSTEM.

Lewin¹ discusses briefly simple **hypertrophy of the spleen**, describing 2 cases not depending on rachitis or syphilis, one of the patients being cured by arsenic, the other by electricity. S. M. Hamill² exhibited a boy of 6 years with an enlarged spleen reaching several inches below the costal border, syphilis being suspected as the cause.

Lancereaux³ protests against allowing children **alcoholic beverages**. He details the condition of a child of 13, whose father died of alcoholic cirrhosis of the liver, while the mother was living, but intemperate, and had allowed the little girl since her third year about half a liter of wine every day. The child was extremely small, pale, and had an enormous liver and spleen, and the urine contained considerable amounts of albumin. A second child had taken from half a liter to a full liter of wine each day since its second year, and at 14 years of age had had for several years severe night-terrors and symptoms of neuritis. This child also was very ill-developed, and had enlargement of the liver and spleen, albuminous urine, muscular atrophy, weakness and some loss of sensation in the limbs. Both cases had uremic attacks.

J. A. C. Kynoch⁴ records the case of a child that had **jaundice**, vomiting, distended abdomen, and white stools from birth, with progressive emaciation. After death at the age of 3 months the **liver** was found enlarged, while the common duct was narrowed a little below its commencement, and toward its lower end it was so small as to appear like a small cord. No orifice could be readily found in the papilla, but bile flowed through the entire duct, though slowly and with some difficulty. The case resembled congenital obliteration of the bile-ducts. There was no family history of syphilis, and the child exhibited none of the signs of specific disease. **Acute yellow atrophy of the liver** has been observed by F. Lanz⁵ in a boy 4 years old, and by Aufrecht⁶ in an infant 6 days old.

Schön⁷ found **cyclic albuminuria** in 2 sisters, both the subjects of **chlorosis**. Since fatty degeneration of blood-vessels and consequent edema by transudation occur in chlorosis, the author suggests that cyclic albuminuria may have the same cause.

Thomas⁸ remarks upon the frequency of **hematuria or albuminuria in infantile scurvy**, and records a case in which these conditions were the earliest and most marked symptoms. He considers the cause an irritant in the blood, and thinks the diagnosis might be early secured in suspected cases by examining the urine. Hematuria may be sometimes the only symptom of the disease.

Simmonds⁹ examined the kidneys in 60 athreptic infants who had presented no digestive or respiratory disturbances. All showed **parenchymatous nephritis**. After excluding other causes, he attributes the nephritis to purulent otitis media, which was present in all of these cases and in 128 of 133 cases dead of athrepsia. Many bacteria were found in cultures of the exudate from the middle-ear and the same microorganisms were found in the kidneys.

E. Cacace¹⁰ reviews the literature of **renal sarcoma** in children, reporting

¹⁰ La Pediatria, Feb., 1897.

a case in a girl of 7 years. Durante¹ reports a similar case in a girl of 2 years.

Steinmetz² reports a case of **primary sarcoma of the urinary bladder** in a child 2 $\frac{3}{4}$ years of age. But 31 other cases of primary tumor of the bladder are recorded, most of which were sarcomatous, and 23 occurred within the first 5 years of life. Hematuria is an infrequent symptom, while symptoms of stone are common. Prognosis is fatal—only 1 of 15 operated cases lived. Death usually occurs in from 10 weeks to 3 months.

Trumpp³ describes a primary and a secondary form of **cystitis** due to the colon-bacillus, both occurring more frequently in girls than in boys. In the primary form the bacilli gain entrance, either directly through the walls of the rectum and bladder, or through the urethra, and this form may be mild or of severe type with grave complications. The secondary form is usually consequent to follicular enteritis. Of 17 cases of intestinal disease, 14 showed colon-bacilli in the urine. Treatment consisted of lysol irrigations and salol internally.

Various pathologic conditions of the **kidneys** are described by A. Baginsky,⁴ including pyelonephritis, lymphomatosis, and sarcoma. He has also⁵ studied the metabolism of a child with diabetes mellitus.

P. Sommerfeld⁶ examined the urine from 70 cases of **scarlet fever** and 30 cases of diphtheria, testing for albumoses, but with negative results. The cases included all types of the diseases, and Sommerfeld concludes that, if albumoses occur in the urine in these diseases, no prognostic significance can be attached to them.

H. Hellendall⁷ reports 2 interesting cases of **hereditary contracted kidney** occurring in sisters, one 12 years old, the other 6 months. There was no family history of syphilis, but the mother had been under treatment for chronic nephritis, which, from the history, evidently began when she was pregnant with the first of the 2 children. Both children died with bronchopneumonia and enteritis, and the kidneys were found very atrophic and granular, and in the younger child the cortex of the kidney showed areas of cartilage.

DISEASES OF THE NERVOUS SYSTEM.

J. Zappert⁸ gives a thorough discussion of the **etiology of nervous diseases in childhood**. He groups the causes in 4 main divisions—traumatic, infectious or toxic, hereditary or family, and psychic—and considers them in order in their relations to diseases of the peripheral nerves, cord, and brain, and to diseases with no discoverable anatomic basis.

F. A. Packard⁹ records a case of **endothelioma of the cerebral membranes**, with the interesting symptom of wasting of the paralyzed muscles which has been noted in but 7 previous cases, which are reviewed. The patient, a 14-year-old girl, had had mental disturbance and headache for a year, and 5 months before death a left-sided convulsion. Subsequently blindness, at first temporary, but afterward permanent, appeared with choked disk. Paralysis of the left arm and leg with atrophy of these members came on, and she had numerous attacks of Jacksonian epilepsy affecting the paralyzed limbs. There was a conical, sessile, hard tumor, an inch in diameter, which was firmly

attached to the calvarium, just back of the vertex. Postmortem there was found a growth continuous with this external growth, lying on the cerebral surface of the parietal and posterior portions of the frontal region, not extending to the lateral aspect, but running down into the great longitudinal fissure. It involved the upper portion of the Rolandic fissure and the ascending parietal and frontal convolutions, while the supramarginal and angular gyri escaped. Microscopically it was found to be an endothelioma. There was no descending degeneration of the pons, medulla, or upper cord.

H. D. Chapin¹ details a case of **multiple tuberculous brain-tumor**. There were symptoms of tumor during life, and lumbar puncture had been performed and the fluid examined for tubercle-bacilli, without result. Autopsy showed 3 tumors about the size of walnuts, one on the basal surface of the left cerebellar lobe, one at the head of the right caudate nucleus, and one in the substance of the anterior and posterior quadrigeminal bodies. The author has had fluid obtained by lumbar puncture in several cases of tuberculous meningitis examined, and tubercle-bacilli were never found. S. S. Adams² also reports a case of tuberculous abscess of the brain, with firm, cheesy masses in the right hemisphere.

M. P. Jacobi³ records the interesting clinical history of a girl of 11, who had had, about 6 months before coming under observation, an attack of what was probably **cerebrospinal meningitis**. Following this there was a varied complex of symptoms, chief among them being ataxia, absence of knee-jerks, vomiting in the nature of gastric crises, and disturbances of tactile and heat sensibility. After a thorough discussion of the case the author concludes that the most probable lesions were those of a disseminated meningitis affecting especially the meninges of the cerebellum.

Wentworth⁴ draws the following conclusions from the use of **lumbar puncture** in 29 cases: 1. The normal cerebrospinal fluid contains neither cells nor fibrin, and is perfectly clear. 2. In cases of meningitis the cerebrospinal fluid is invariably cloudy when withdrawn. The degree of cloudiness is to some extent proportionate to the amount and character of the exudation in the meninges. 3. The cloudiness is caused by cells. The character of the cells differs with the variety of meningitis. After withdrawal more or less fibrin is formed in the fluid. The presence of these cells and fibrin is pathognomonic of inflammation in the meninges. 4. The cloudiness is oftentimes so slight that close observation is necessary to detect it. 5. The operation is not difficult to perform on infants and children. It is not dangerous, if strict cleanliness is observed. 6. The differential diagnosis between the various kinds of meningitis can be made by microscopic examination of the sediment, by cultures taken from the fluid, and by inoculation-experiments. 7. Inoculation-experiments afford the surest means of determining tuberculous meningitis. They are of value to distinguish between the varieties of meningitis in order to determine if tuberculous meningitis is recovered from. 8. In the normal fluid a faint trace of albumin is usually present, about 0.02%, or less, by quantitative analysis. In meningitis the amount of albumin is increased, and has varied from 0.03% to 0.1%. 9. In one case a diagnosis of general infection with the staphylococcus pyogenes aureus was made from cultures taken from the cerebrospinal fluid. A. Caillé⁵ reports 21 cases of lumbar puncture in which the fluid was examined for sugar, albumin, and bacteria. Tubercle-bacilli were found in 5 of 7 cases of tuberculous meningitis; 1 case of cerebrospinal meningitis showed

¹ Arch. of Pediatrics, Feb., 1897.

⁴ Boston M. and S. Jour., Aug. 6, 1896.

⁵ Arch. of Pediatrics, Aug., 1896.

pneumococci; 2 cases of acute hydrocephalus showed sterile fluid with a trace of albumin; 1 case of brain-tumor, sterile fluid with 0.2% of sugar. In 2 cases he attempted the local treatment of tuberculous meningitis by means of lumbar puncture, injecting in one case a solution of sodium salicylate, and in another iodoform in water. The autopsies showed extensive lesions, and the author suggests a more radical and thorough irrigation by combining with the lumbar puncture a trephine-opening in the skull.

M. Nicoll¹ gives the clinical notes and postmortem findings in a case of acute **ependymitis**, the choroid and pia being unchanged.

J. Grósz² reports on the clinical features and postmortem findings in a case of **congenital cerebral diplegia**. The child was the product of ectopic gestation, delivered by Cæsarean section, and lived 4 months. At first only the right arm and leg were spastic, showing some improvement, but during the second month the left side began to stiffen and athetosis was present in both hands. The child died of inanition, and the brain was found to be compressed, the pressure on the right hemisphere having been prenatal and due to the position of the fetus; the membranes over the left hemisphere were the seat of an internal chronic hemorrhagic pachymeningitis.

Romme³ reviews the claims of various authors as to the **etiology of tetany**, and concludes that the views of Kassowitz and his school (that it is a manifestation of rickets) and those of others who would ascribe the condition to any especial primary disease, are incorrect, as there are no constant post-mortem findings in tetany, and it occurs with various diseases. Clinical and pathologic studies tell us only that the main symptoms are evidences of mechanical or reflex hyperexcitability of the cord and peripheral nerves due to a diversity of causes.

At the Frankfort Congress (1896) there was an interesting discussion⁴ on **laryngismus stridulus**, with papers by Loos and Lange. The former has seen 164 cases, 14 of them ending fatally, and most of them being complicated by tetany. Lange's paper was on the relation of laryngeal spasm to rickets, especially to craniotabes, and the connection between the two was shown to be very slight. With reference to the etiology of spasm of the glottis and tetany, Fischl thinks that we have still much to learn, the infectious or epidemic origin being difficult of proof, and digestive disturbances occurring in greater amount in summer-time, when tetany and laryngismus are rare. Biedert⁵ thought that this might be explained by the difference in the nature of the digestive disturbances, the acute carrying off the toxic materials, while the chronic, which occur in cooler weather, allow a greater chance for the absorption of toxic substances. Lewin⁶ reports a case of laryngismus stridulus which depended upon indigestion set up by the use of a certain infant's food. The attacks ceased with a change of diet, to return again when the "kindermilch" was used, and to disappear when it was discontinued. J. Abercrombie⁷ states that in his experience facial irritability is always present in tetany, but he has changed his belief that it is to be found only in tetany, as he has never failed to find it present in a case of laryngismus stridulus. He has also seen it in about 20 cases of rickets, none of which presented signs of laryngismus or tetany.

Among the nervous symptoms of **rachitis A. Jacobi**⁸ classes insomnia, night-terrors, hyperidrosis of the head, Chvostek's facial phenomenon, laryn-

⁸ Ibid.

gismus stridulus, general convulsions, hydrocephalus, Trousseau's symptom, tetany, nystagmus, and spasmus nutans. He explains the ability of some rachitic children to sleep when held erect in the arms as due to the lessened hyperemia of the brain, and their arousing when laid down as due to the increase in cerebral congestion. He thinks that the coexistence in a rachitic child of Chvostek's and Trousseau's signs is not a sufficient basis for the diagnosis of "latent tetany."

L. Braun¹ advances the view that **pavor nocturnus** is not a disease *sui generis*, but a neurasthenic symptom due to inflammatory, parasitic, and other affections of the gastrointestinal tract and of the external genitalia, to insufficient sleep, and other causes. The prognosis is favorable if these causes be sought for and removed.

A. Stengel² reports a case of **arsenical neuritis** in a boy of 5, to whom Fowler's solution had been given in increasing doses until a maximum dose of 10 drops 3 times a day was reached. The physiologic action was then noticed, and the drug discontinued. Three weeks later it was seen that he did not use the right foot properly, and 2 weeks after this the gait suggested poliomyelitis or neuritis. The paralysis increased for a time, and the diagnosis of neuritis was made by the almost completely symmetric character of the paralysis, the absence of decided wasting, the preservation of reflexes, the distinctly tottering and ataxic gait, and the disturbance of station. Recovery ensued. As elimination does not keep pace with administration even when moderate doses are given, the author advises that the remedy be discontinued from time to time for periods of a week or two.

L. S. Somers³ reports a case of **rumination** in a boy of 5 years. The child had had convulsions when 3 months old, and seemed intelligent as an infant. When 3 years old he had measles and lost his hearing, after which he could not speak intelligibly, and 6 months before the rumination began it had been noted that his head was hydrocephalic. The rumination occurred usually 15 to 20 minutes after meals, sometimes at other periods, when he would regurgitate, remasticate, and again swallow his food. Treatment and training brought about decided improvement. A maternal uncle and cousin had been unable to speak until 6 years old.

Epstein⁴ reports 8 cases of **catalepsy in rachitic children**, all of whom presented evidence of imperfect or arrested development of the intellect, which with their general weakness recalled the condition of patients exhibiting catalepsy after grave diseases like typhoid fever. In the cases he reports a limb that was raised or otherwise moved kept the new position for 15 minutes or longer. There was no tremor during this time, and the reflexes of the cataleptic member were diminished.

C. W. Townsend⁵ reports 5 cases of **thigh-friction**, a form of masturbation, in infants under 1 year of age, all of whom were females.

Collignon⁶ gives as the diagnostic points of **migraine** in children of 4 or 5 years, recurring attacks of vomiting lasting 3 or 4 days, attended not with marked headache, but with considerable prostration, contracted pupils, pallor, slight fever, rapid respiration, and sensibility to light and sound. The individual attack may begin suddenly with palpitation or epistaxis, and may also end suddenly.

W. Osler⁷ gives the French classification of the tic or **habit-move-**

¹ Jahrb. f. Kinderh., Jan., 1897.

² Arch. of Pediatrics, Mar., 1897.

³ Med. Rec., Apr. 17, 1897.

⁴ Rev. mens. des Mal. de l'Enfance, Jan., 1897.

⁵ Arch. of Pediatrics, Nov., 1896.

⁶ Ibid., Aug., 1896.

⁷ Ibid., Jan., 1897.

ments, as follows: 1. Simple tic or habit-spasm, including mainly the common cases of spasmodic movement, chiefly of the facial muscles, which are, to a certain extent, under the control of the will. 2. Tics with superadded psychic phenomena, *maladie de la tic convulsif*, or Gilles de la Tourette's disease, in which, in addition to the simple tic, there are explosive utterances and imperative ideas. 3. Complex, coördinated tics, which include actions more extended and involved than simple tics, and also such conditions as head-nodding or swaying, and other bizarre movements. 4. Tic psychique, in which the imperative idea is the psychic equivalent of, and has an origin similar to, the motor tic.

W. Osler¹ describes a case of **head-swaying** in a girl of 5. At times there would be a rhythmic swaying of the head from side to side to the extent of a foot from the median line. The condition had existed from infancy, and the only point in the history that seemed to have any bearing was that other members of the family were nervous.

Osler² also reports 2 unusual types of night-terrors in boys aged 7 and 11 years. The attacks in the first case consisted in incoherent muttering, were more in the nature of night-mare than night-terrors, and ceased when the hypertrophied tonsils and adenoid growths were treated. A third case was related in which the attacks came on during waking-hours. Chloroform-inhalation seemed to control them.

John Thomson³ reports the case of a girl who, from the age of 7 until menstruation became established at 13, had a **sensory hallucination of worms** crawling beneath the skin and of dryness of the palms and soles.

TUMORS.

E. Neuhaus⁴ gives an extensive report of a case of **congenital sarcomatosis** of the skin, the child dying at the age of 2 months. The author reviews the literature of the subject.

A. Johannessen⁵ reports a case of **sarcoma of the pelvis** in a girl 11 months old.

I. M. Snow⁶ records the case of a boy of 13 months in whom **multiple laryngeal papillomata** developed after an attack of tracheobronchitis. The main symptoms were complete and persistent aphonia, stridulous breathing, recession of the chest, and attacks of dangerous dyspnea. Tracheotomy caused relief for 50 days, when a fatal attack of diphtheria occurred. At autopsy 3 cauliflower growths were found almost completely occluding the lumen of the larynx.

E. Berggruen⁷ reports a case of **neurofibromatosis** in a boy of 11 years, involving the cerebrospinal axis as well as the peripheral nerves. He gives an exhaustive report of the case, introducing it with a review of the literature on neurofibromatosis.

G. N. Acker⁸ records a **sarcoma of the thymus gland** and bronchial glands. The most conspicuous symptom during life was great edema of the left side of the face and of the left arm. A large growth of the thymus, involving part of the left lung and compressing the left subclavian vein, a large tumor in the left axillary space, and a smaller mass in the right axillary space, all sarcomatous, were found after death.

THERAPEUTICS.

M. Jewnin¹ used **warm baths** (30°–35° R.) in 5 cases of cerebrospinal meningitis, all of which ended in recovery. Renant² advocates the use of warm baths in bronchitis in infants. Three or four baths at 100° F., if the rectal temperature of the child reaches 102°, combined with cold to the head and stimulants, are said to cause rapid improvement and prevent extension to the fine bronchioles. C. J. Rix³ uses as a routine treatment for measles the full bath at 90° to 100° F., and continued for about 10 minutes. The first bath is given as soon as the disease is suspected, repeated every 12 hours, or oftener if necessary to bring out the rash, and continued twice daily until the temperature is normal. He claims that this treatment shortens the disease and almost entirely prevents renal and pulmonary complications and sequelæ.

L. Maestro⁴ concludes from the use of **ichthyol** in pills ($\frac{3}{4}$ to 3 gr. in 24 hours, rapidly increasing the dose to 10 to 15 gr. in the day) that it is one of our most valuable remedies in whooping-cough. No untoward action was noticed, and the attacks decreased rapidly in number and severity, while the duration of the disease was shortened.

Vargas⁵ has found his best results from the use of **phenocoll hydrochlorate** in a daily dose of from 0.07 gm. to 2 gm. It seems to act as a sedative rather than a germicide.

Maisend⁶ uses nasal **insufflation in pertussis** of a powder of equal parts benzoin and salicylate of bismuth with $\frac{1}{2}$ part of quinin sulfate. The attacks were said to become less severe and more infrequent, and the cure was rapid.

Ferreira⁷ ascribes to **bromoform** both a sedative action on the nervous system and a direct action on the pathogenic microorganisms when used in pertussis. In doses of 3–6 drops at 1 year of age and in corresponding quantity to older children he claims that a cure usually ensues in 6–12 days.

Lable and Ondin⁸ report 22 cases of whooping-cough treated exclusively by **ozone**. This seemed to act through its antiseptic properties, and, they consider, reduced with rapidity the violence and frequency of the attacks, the dyspnea and cyanosis, and shortened the duration of the disease.

Staas⁹ especially recommends **antispasmin** for whooping-cough in infants under a year, in whom bromoform may cause serious symptoms. It is also recommended in the spasmodic cough of measles. The dose, under a year of age, is $\frac{1}{6}$ to $\frac{1}{4}$ gr.

Moncorvo¹⁰ used **analgen** in doses of 0.25 to 1 gm. in 24 hours in 33 cases of malaria in children, and considers it a useful adjuvant to quinin, and a substitute when the latter cannot be administered, as analgen is tasteless and not depressing. It also seemed of use in other diseases, especially in acute and subacute tuberculosis for the fever and cough.

Oppenheimer¹¹ thinks that the value of **oxygen-inhalation** in pneumonia is due to its being a very powerful heart-stimulant.

M. Goriatchkine¹² strongly opposes the use of **alcohol** by prescription in all cases except in acute diseases with heart-failure, and combats any tendency of parents to give it to children, lest the habit be formed. He states that of

1671 children from 1 to 12 years of age, seen at Saint Olga's Hospital in Moscow, 506 took alcohol either as the result of environment or by advice of a physician. He cites the case of a child with night-terrors and restless sleep, and with enlarged liver and spleen, whose habit it was to take 2 glasses of port and a teaspoonful of cognac daily.

M. L. Brown¹ has used **potassium bromid** with great satisfaction in cholera infantum, considering it to be a specific, or physiologic antidote to the toxins which cause the disease.

A. Salter² reports rapid cure of ringworm of the scalp by 4 applications (daily or every second day) of a 40% solution of **formaldehyd**.

Senft³ uses **lactophenin** as an antipyretic in children, claiming that it does not disturb the stomach nor depress the heart.

A. Dobrowsky⁴ used **desiccated thyroids** in cases of parenchymatous goiter, obesity, prurigo, and idiocy, with improvement in all except the last condition. Thyroid-feeding is of great value, in his opinion, in those patients who, through idiosyncrasy, cannot tolerate the iodine preparations. To a child with chorea, who was passing about 300 c.c. of urine daily, and who was receiving no apparent benefit from large doses of arsenic, D. I. Wolfstein⁵ gave thyroid-extract, with the result that the flow of urine immediately increased to normal and the choreic movements disappeared, so that the child was perfectly well in a month's time.

J. F. Hartop⁶ recommends **phosphorus** for the chronic headaches of children, whether dependent upon rachitis or not.

TOXICOLOGY.

Anthony⁷ records a case of **creolin-poisoning**. Inhalation of the drug had been ordered for pertussis, and 5j was given internally to the 5-year-old boy by mistake. The symptoms most marked were coma, contracted pupils, muscular relaxation, weak and irregular pulse and respiration. Atropin $\frac{1}{100}$ gr., followed by $\frac{1}{50}$ gr. hypodermically, caused rapid improvement, and after large doses of magnesium sulfate recovery ensued.

L. Fischer⁸ saw grave **bromoform-poisoning** in a child of 2½ years. Forty drops of the drug were ordered in a mixture, and, being heavy, it probably sank to the bottom, and the child received the whole amount in one dose. The author therefore advises against the use of the drug in mixtures. W. F. Cheyney⁹ records a case of bromoform-poisoning in a child of 3 years. The drug had been prescribed in a mixture with alcohol, syrup, and water, and the symptoms of poisoning—laughing intoxication, followed by vomiting and coma—came on after the last dose, so that the bromoform had probably been swallowed nearly or entirely in one portion. An emetic and strychnin hypodermically brought recovery. Czygan¹⁰ saw a child of 2½ years accidentally poisoned by 5 to 7 gm. of bromoform. Coma ensued quickly, and the symptoms persisted, though somewhat lessened in intensity after hypodermics of ether, excitation of the skin, and artificial respiration. Injections of 1.5 gm. of tincture of nux vomica within an hour restored the reflexes, and complete recovery after 5 hours' coma ensued upon the application of the faradic current.

H. Conrads¹ reports a case of **petroleum-poisoning** in a child of 1½ years. An unknown quantity had been swallowed, immediately after which the gait became ataxic. The child became semi-unconscious, as if thoroughly drunk, the pulse rapid and irregular, the respirations very rapid, and the temperature subnormal. The symptoms improved rapidly after lavage. Next day there were signs of bronchitis, and the respirations were 120 to the minute, but these symptoms soon subsided. Five other cases have been reported, in all of which consciousness was befogged and the pulse weak and rapid. The respirations were in several cases very rapid, due, he thinks, to hyperemia of the lungs. The pupils were very variable, as was the temperature. The diversity of some of the symptoms he attributes to the various kinds of petroleum which caused the poisoning.

MISCELLANEOUS.

Precocious Maturity.—J. L. Morse² reports a case of precocious maturity in a girl infant, menstruation beginning at 9 months. He reviews the literature of the subject, arriving at the following conclusions: Precocious maturity is a physiologic congenital anomaly of development. Menstruation is never the first symptom, but is always preceded and accompanied by others. Menstruation most often appears in the first two years; it is accompanied by ovulation. The attributes of maturity are not all acquired before the age of 7 or 8 years. Sexual desire is soon developed. Pregnancy may occur early. Menstruation may continue as long as when it begins at the normal time. The etiology of precocious maturity is unknown. The relation to precocious menstruation is obscure. There is no medical treatment. As the mental development of the unfortunates afflicted with this condition is usually far less than the sexual and physical, they must be carefully guarded against voluntary or involuntary intercourse. Wladimiroff³ records a case of precocious adolescence in a rachitic girl of 6½ years.

Superficial Gangrene.—B. K. Rachford⁴ details a case of superficial gangrene in an infant of 7 months. A spot of dry gangrene of the skin of the left buttock, 3 by 3½ in. in size, appeared suddenly, accompanied by pain but no fever, and preceded by no indisposition. The gangrenous skin separated after 17 days, and the remaining ulcer healed after about 3 months, during which time there were none but the local symptoms. The baby had suffered no injury and had been in good health, and there was no family history bearing on the case except the fact that the father had probably had syphilis. M. Cailland⁵ discusses at length a similar condition under the term "infectious disseminated gangrene of the skin."

Transposition of the Viscera.—Reefschlager⁶ reports a case of transposition of the viscera in a child who died at 23 months. The position of the stomach, intestines, liver, and spleen was the reverse of the normal, as was that of the heart, lungs, and great vessels. There was but one cardiac ventricle which communicated by the usual orifice with the right auricle, but was closed to the left auricle. The blood-current was from the venæ cavæ into the left auricle, thence through several interauricular foraminæ into the right auricle, thence to the ventricle, and finally into the aorta and pulmonary

⁶ Berlin. klin. Woch., Jan. 25, 1897.

artery. Emaeciation, some cyanosis, and clubbing of the fingers and toes were the only signs during life. Death was caused by tuberculous meningitis.

Insolation.—H. A. Lafleur¹ records a case of insolation in an infant of 13 months. The temperature reached 108° F., but was controlled by cold full baths, and the child recovered completely. In the discussion, Fruitnight, Seibert, Griffith, and Adams spoke of cases of insolation in infants seen by them. In one mentioned by Griffith the temperature reached 110° F.

Hospitalism.—O. Heubner² has noted that the same infants did better outside of institutions than within them, even when cared for in like manner. He examined bacteriologically the cleansed nipples and the nurses' hands, and found quantities of living colon-bacilli. To prevent infection from child to child from the sources mentioned and many others, he recommends that children in institutions be put in wards containing not more than 8 beds, and that separate nurses have charge of the feeding and of the bodily care of the children in those wards.

H. D. Chapin³ refers to hospitalism as most likely to affect infants under one year of age, and says that admission should therefore be made only for acute illnesses, discharge not being delayed for more than two weeks after convalescence has begun. The hospitalism is first manifested by the child's weight remaining stationary; then a loss in weight occurs, associated with hydremia, dryness of the skin, and wearing off of hair from the occiput. There is also a tendency for latent, hypostatic pneumonia to set in. Female children are apt to develop vaginitis. As soon as signs of hospitalism appear the child should be promptly discharged, because, if the atrophic tendency becomes well started, recovery will be impossible even under new and favorable hygienic surroundings.

PATHOLOGY.

BY JOHN GUITÉRAS, M. D., AND DAVID RIESMAN, M. D.,

OF PHILADELPHIA.

Resume of the Year's Progress.—Among the problems in general pathology the etiology of tumors is still *facile princeps*. The researches of the year in this field have not brought a definitive solution, although the investigations of the Italian school seem strongly to point to blastomycetes as the cause of cancer. Pathologists, however, have been made cautious by the collapse of the erstwhile much-acclaimed "protozoan theory," and there now exists a conservatism that demands indisputable proof before acquiescing in a new doctrine. Another interesting question is that raised by Rosenfeld, namely, as to the existence of fatty degeneration as a morbid process. His experiments are on the surface very convincing; whatever fallacy, if any, there may be in them, will no doubt be soon brought to light. In bacteriology the subject of agglutination is absorbing a great deal of attention. The phenomenon is now viewed, especially by Widal, as not related to immunity; its true significance is not yet established, nor is its specificity definitely proved. Of importance are also the cumulative observations on the virulence of the gonococcus, which is shown to be capable of producing grave secondary lesions—endocarditis, pleurisy, pyemia, peritonitis—as well as diverse morbid processes in the female pelvic cavity. The various fundamental problems connected with the subject of antitoxins still await solution; there is as yet no union of the opposing schools. In pathologic technic the growing popularity of formalin as a preserving and fixing agent, and of thionin as a nuclear and bacterial stain, is to be noted. In the domain of special pathology, the nature of Graves' disease is one of the most interesting problems; considerable space is given to it in this section. Reference is also made to certain important researches in pneumokoniosis, a subject that in American literature has not received much attention. In the pathology of the nervous system the interesting observations of Marinesco on the effects of infectious diseases merit special mention. The experiments of Goldscheider and Flatau on the influence of the toxins and antitoxins of tetanus are important, both in themselves and in their bearing on the problems of acquired immunity. Cirrhosis of the liver receives considerable attention in this present section—the theory of Aufrecht is briefly given; we are constrained to withhold our opinion on it for the present. Under the subject of "the urinary organs" some reference is made to the alloxur-bodies; space forbade us entering at greater length into the questions connected with the origin of those interesting nitrogenous compounds. In this same section Councilman's excellent article on nephritis is also abstracted. Various interesting subjects, such as the study on terminal infections by Flexner, the experiments of Abbott on the effect of alcohol on resistance to infectious diseases, Virchow's latest views on inflammation, as well as numerous other matters, will be found treated in the final section entitled "miscellaneous."

THE BLOOD AND BLOOD-MAKING ORGANS.

The Properties of the Extravascular Blood.—M. Hahn¹ finds that the diastatic ferment in blood and blood-serum (discovered by Majendie) is, unlike the globulicidal and bactericidal agents, not destroyed at 55° C., but only at between 65° and 70° C. Light, which causes the globulicidal and bactericidal agent quickly to disappear, has but little effect on the diastatic ferment. The bactericidal agent and the ferment were also proved to be entirely independent. The lipolytic property of serum is destroyed at 60° C. (Harriot, Camus). Hahn was also able to confirm the earlier observation of Röden, that the contact of blood inhibits the action of the labferment, pepsin, and trypsin. The action is not a simple chemie one, for by heating the serum to 65° C. the inhibitory property is destroyed, and the serum is promptly digested by trypsin. These facts are suggestive in connection with the old problem why the stomach or the pancreas does not digest itself. Some studies were made on the glycolytic property of the blood, which is not connected, as some have claimed, with the coagulation of the blood, being in this respect analogous to the bactericidal agent. Like the latter, it is destroyed by a temperature of 55° C., and, like it, is augmented in hyperleukoeytosis. Nevertheless, the two are not identical, for the serum is bactericidal but not glycolytic. The observations, however, show that there is an intimate relation, though not an identity, among the globulicidal, the bactericidal, and the glycolytic properties of the blood, and that these are connected with the active albumins in the sense of Buchner, as is especially shown by their slight resistance to trifling physical influences. On the other hand, the ferment-destroying substance, the diastatic and the lipolytic ferments do not seem to be united to such labile bodies. [These researches, though in a sense physiologic, are of great interest to the pathologist, and suggest experimental studies in diabetes, obesity, and other diseases, as well as offering pegs on which to hang new theories.]

A New Morphologic Constituent of Blood.—Wernicke² has made some observations on the blood that are of interest in relation to Müller's subsequently published discovery of the hemakonia (see *Year-Book*, 1897, p. 671). In addition to the well-known morphologic elements, the blood contains yet another constant constituent, in the form of minute spheric bodies, the number of which increases in preparations not fresh. Diverse studies have shown that these small motile bodies are nothing more than dispersed granulations of the neutrophiles or myelocytes, which become free when these cells disintegrate. For this reason it is not permissible to attribute any pathologic or diagnostic significance to such bodies. Larger motile granules (1–2 μ) may be: (1) eosinophile granulations (most frequently); (2) γ -granulations (very rare, except in leukemia); (3) Laveran's "corps sphériques"—*i. e.*, young, unpigmented malarial parasites; or (4) very small, pale microcytes and poikilocytes. For purposes of differentiation staining is indispensable. The author employs the following solutions: (a) Saturated watery solution of methylen-blue, 100; eosin (French, soluble in water), 1.5; absolute alcohol, 132; distilled water, 168; 20% NaOH solution, 16 drops. After standing 10 days and then filtering, the solution is used warm (heating on cover-glass). (b) Distilled water, 100; glacial acetic acid, 2 drops; $\frac{1}{2}$ % eosin solution, 1.0; concentrated solution of orange, 3 drops. This is used for decolorization (a few seconds only); the

¹ Berlin. klin. Woch., June 7, 1897.

² Przegląd Lekarski, Mar. 7, 14, 21, 1896; ref. in Centralbl. f. allgem. Path. u. pathol. Anat., Mar. 1, 1897.

cover-glass is then washed in water, dried, and mounted in balsam. Normal red corpuscles will be rose-colored, poikilocytes poor in hemoglobin a bluish-red, small lymphocytes uniformly dark blue, eosinophile granulations bright red, δ -granulations dark blue, and γ - (basophile) granulations dark bluish-red. Plasmodia become steel-gray-bluish. The protoplasm of the neutrophiles and blood-plaques remains unstained.

The Action of Drugs on the Leukocytes of the Blood.—George Wilkinson¹ injected various drugs—potassium iodid, pilocarpin nitrate, camphor, antipyrin, quinin hydrochlorate, salicin, and sodium salicylate—into animals, and studied the changes in number and structure of the leukocytes in the blood. The general results of the experiments may be stated thus: the first effect of the drug-injection was to cause a diminution in the number of leukocytes per c.mm. The degree and duration of the diminution varied with the drug employed, but with all those mentioned above, unless the dose was very small, its occurrence was recognized when the blood was examined sufficiently early. As a rule, it was not of long duration; but a notable exception occurred in the case of one of the experiments with quinin hydrochlorate. A large dose (0.7 gm.) of this drug caused the death of the animal 2 days after the injection; the blood was examined frequently between the time of injection and its death, and on every occasion the scantiness of the leukocytes was very striking. Coincidentally with the diminution in the total number of leukocytes there was a distinct increase in the proportion of the uninuclear to the multinuclear varieties. Following the diminution there was observed in the case of all the drugs employed an increase in the number of leukocytes per c.mm. This change did not occur in the above-mentioned experiment, in which a very large dose of quinin was administered; but with smaller doses of this drug its occurrence was noted, although, as with salicin and salicylate of sodium also, the degree of increase was slight in comparison with that which followed the injection of the other drugs. With nearly all of them the increase was a much more evident phenomenon than the preceding diminution, and was of much longer duration. It was further constantly distinguished by the fact that the multinuclear leukocytes were relatively more increased in number than the uninuclear forms. Regarding structural changes, it was found that repeated doses of pilocarpin caused a disappearance of the granules in the small oxyphile leukocytes. Neither the large oxyphile cells with coarse granules (Ehrlich's eosinophile cells) nor the red corpuscles showed any change.

The Effects of Repeated Hemorrhages on the Blood.—A. H. Hill² tabulates the results obtained by bleeding dogs. From a study of his table we learn that repeated venesection produces a steady reduction in the specific gravity and a reduction in the solids, and an increase in the amount of fibrin. There is a diminution in the amount of ash, of hemoglobin, and of red corpuscles, and an increase in the number of leukocytes. This increase affects chiefly, if not altogether, the multinuclear elements.

Post-phlebotomic and Post-revulsive Hyperleukocytosis.—Maurel³ found on the day following a venesection a genuine hyperleukocytosis which continued for several days. Such an augmentation of leukocytes may be of value in infectious diseases. Regarding the effects of revulsants (cauterization, punctures, mustard, cantharides, and ammonia), Maurel found that during the first few hours following their application there is a hyperleukocytosis, but it is only apparent, and depends on a transportation of the leukocytes along the vessel-walls into the circulatory stream. After about the 4th day of the application a true leukocytosis dependent on newly formed leu-

¹ Brit. Med. Jour., Sept. 26, 1896.

² Ibid.

³ Gaz. des Hôpitaux, Aug. 13, 1896.

kocytes is observed, and it is possible that this leucocytosis is useful to the organism in bacterial infections. We may see in this a justification of the popular use of revulsives in these diseases.

The Influence of Baths on the Alkalinity of the Blood.—A. Strasser¹ found that cold baths increased and warm baths decreased the alkalinity of the blood; likewise of the urine.

The Changes in the Blood in Jaundice.—v. Limbeck² states that icteric blood is deficient in sodium chlorid. This depends on a lack of NaCl and a reduction in the volume of the serum. The latter is produced by an increase in the volume of the red corpuscles, which in turn is due to the presence of bile-salts in the plasma.

Blood-coagulability and Serous Hemorrhages.—A. E. Wright,³ whose researches on blood-coagulability are well known, in the present paper takes the stand that certain conditions of serous transudation are to be considered as depending on deficient blood-coagulability. *E. g.*, he names: 1. *Serous hemorrhages into the skin*—*i. e.*, urticaria—particularly those following (a) the injection of diphtheria-antitoxin; (b) the eating of acid fruits; (c) the eating of crabs or shellfish; probably also the urticaria following the ingestion of rhubarb and the administration of soap-enemata is due to the same cause, both producing an abstraction of lime-salts. (2) *Serous hemorrhages into the subcutaneous and muscular tissues*, the best example of which is the serous hematoma seen in hemophilia; chilblains may also belong here. 3. *Serous hemorrhage into the tubules of the kidney*—cyclic albuminuria. 4. *Serous hemorrhage into joints and serous cavities*. Joint-effusions are a prominent symptom of hemophilia, but some pleural and pericardial effusions are also probably due to diminished blood-coagulability, a belief which the author thinks is substantiated by the association of mucous-membrane hemorrhages and signs of defective clotting of the blood in the large vessels often seen post-mortem. 5. *Serous hemorrhages into the intestinal canal*. The diarrheas of hemophiles and those seen in purpura hemorrhagica, also the diarrhea occurring after croupous pneumonia at a time when peptone (albumose) is being excreted in the urine, are referable to diminished blood-coagulability. The author also thinks that the non-irritant hydragogue cathartics owe some part of their efficacy to their power of diminishing blood-coagulability, while the constipating action of lime-salts is due to the opposite effect. In like manner, the notoriously constipating effect of a milk-diet may be in part due to the large percentage of calcium-salts contained in cow's milk. This last inference is to some extent confirmed by the fact that obstinate infantile constipation will often disappear when the child is put upon a diet of citrated milk; *i. e.*, milk which has been deprived of its excess of lime-salts by an addition of $\frac{1}{400}$ th of citrate of sodium. The general conclusion is then postulated that a defect of blood-coagulability tends to manifest itself, not only in "actual hemorrhages," but also (according to the particular idiosyncrasy of the patient) in some one or more of the forms of "serous hemorrhage" which have been described.

Although the question of treatment does not belong to this part of the *Year-Book*, we shall, for completeness' sake, append the author's words on that topic: methods of treatment which augment blood-coagulability will be methods of treatment that will be appropriate, not only to the prevention and treatment of "actual hemorrhage," but also to the prevention and treatment of "serous hemorrhage." The more important of these therapeutic measures

¹ Wien. med. Presse, Nos. 22 and 23, 1896. ² Centralbl. f. innere Med., No. 33, 1896.

³ Lancet, Sept. 19, 1896.

appear to be the following: (*a*) the exhibition of calcium chlorid (or other soluble lime-salt) in suitable quantities; (*b*) the avoidance of such vegetable acids as citric, malic, tartaric, and oxalic, which form insoluble salts with lime; (*c*) the concentration of the blood either by diaphoretics or by such purgatives as do not owe their efficacy to a power of reducing blood-coagulability; (*d*) the restriction of the amount of fluid ingested; (*e*) the increase of the amount of carbonic acid in the blood, either by direct inhalation of the gas or by other methods; and (*f*) the avoidance of alcohol. Some experiments are then cited illustrating the effect of treatment on local edema. [The author's reasoning appears to us somewhat theoretic. He leaves out of consideration the influence of the vessel-wall on transudation, an influence that is not passive, but probably active—"lymphagogue." The fact that the serous hemorrhages are localized, points to a local factor, and if a general one like lessened coagulability does exist, it can probably only play the part of a predisposing factor.]

The Blood in Pernicious Anemia.—Cabot,¹ from a study of 50 cases of pernicious anemia, concludes that the points most typical in the blood of this disease are: 1. A reduction of the number of red cells to about 1,000,000; 2. The absence of leukocytosis; 3. Possibly a relatively high percentage of hemoglobin in some cases; 4. Increase in average diameter of the red cells; 5. The presence of large numbers of polychromophilic red cells; 6. The presence of nucleated red cells, a minority being normoblasts; 7. The presence of myelocytes; 8. A relatively high percentage of small lymphocytes at the expense of the polymorphonuclear cells. Postmortem examination in 8 cases brought out nothing not already well known. Fatty degeneration and pallor of all organs were noted in all; the "tiger-lily" heart in 6; and pericardial and peritoneal ecchymoses in 4. The spleen was slightly enlarged in 2; no enlargement of lymphatic glands was observed. The marrow was examined in 5 cases, showing in all a notably red color in the shaft of the long bones. No microscopic appearances were recorded.

Peculiar Blood-changes in Purpura Hæmorrhagica.—Bensaude² confirms Hayem's observation of the absence of retraction of the blood-clot and of the formation of serum in 16 cases affected with various forms of purpura hæmorrhagica, all of which presented large cutaneous ecchymoses and hemorrhages from the mucous membrane. Purpuras in which the hemorrhages were small did not present the blood-anomaly. The author has succeeded, though the researches are not yet completed, in producing the blood-lesion and hemorrhages in animals by the injection of the blood of a purpuric patient. [We may add that Müller and Denis have observed absence of blood-plaques in cases of Werlhof's disease.]

The Relation between Leukemia and Pseudoleukemia.—Martin and Mathewson³ point out the close relation between these two diseases, and quote examples in which, together with well-marked lymphatic hyperplasia, a variable blood-picture as regards the leukocytes existed, and are of opinion that leukemias in their various manifestations, acute and chronic, lymphatic, splenic, and myelogenous, the similar varieties of Hodgkin's disease, and all such like affections characterized by a hyperplasia of the lymph-gland structures, when no primary focus can be found, are for the present to be classed in one group.

The Leukocytes in Splenic Leukemia.—Maurel⁴ in 4 cases of splenic leukemia noted that the leukocytes were more voluminous than the normal; that their activity was less; and that they were less resistant to extreme temperatures. They died at 44° C., and lost their movements at 32°

¹ Boston M. and S. Jour., Aug. 6, 1896.

³ Brit. Med. Jour., Dec., 1896.

² Sem. méd., Jan. 20, 1897.

⁴ Sem. méd., July 28, 1897.

C., whilst normal leukocytes die only at 46° C., and lose their movements only toward 25° C.

Apparent Crystallization of Eosinophile Granulations.—A. J. Patek,¹ in some cover-glass preparations of blood from a case of suppurative axillary adenitis, found peculiar eosinophilous sheaf-like crystals, which he believes originated from the eosinophile granulations of the leukocytes.

Acute Leukemia.—Benda² describes the anatomic lesions observed in 7 cases of acute leukemia. The hemorrhages into the tissues and the regional adenopathies were characteristic. The splenic tumor differed from that of acute infectious diseases in being less soft and not so large. A peculiar lesion of the veins was also constantly observed—the walls were permeated by numerous lymphomatous nodules, which, however, did not seem to lead to thrombosis. The chief blood-change was the increase of uninnuclear elements.

Differential Count of the Leukocytes.—Jolly³ writes as follows: 1. In estimating the variations in the proportion of the different forms of white corpuscles accurate results can be obtained only when preparations of dried blood are examined which have been fixed with care and always by the same process. 2. It is not possible to conclude with certainty concerning the increase or diminution of a given variety of leukocytes by a simple examination without counting; this is particularly the case when a variety which is normally present in small numbers is under consideration. 3. If the leukocytes are divided into two classes, a total of at least 300 should be counted; if the leukocytes are divided into three classes, a total of at least 400 should be counted; this method will yield results which are nearly accurate, with a maximum error of about 4 in each 100; this classification allows for large and small uninnuclear elements and for multinuclear elements, but excludes eosinophiles. 4. It is also necessary to allow for the possible unequal distribution of the different forms on the cover-glass as the count is made.

A New Method of Determining the Alkalinity of the Blood.—

Berend⁴ recommends the following method: After cleansing the pulp of the finger a prick is made with a stick or needle. The blood is drawn into the mixer up to the mark 0.1, and the latter then emptied into a centrifuge-tube (see Fig. 50) containing 5 c.c. of a 1% neutral NaCl solution, and washed out by repeatedly sucking up this solution. The latter is then at once centrifuged, and the clear serum-solution poured into a glass vessel. To the corpuscular mass remaining 10 c.c. of water (neutral) are added, and the mixture placed aside. The serum-solution is mixed with litmus so that it is not too highly colored, and titrated with an acid solution, and back with sodium hydrate. The mean of the two figures is taken as the result. The corpuscle-mass is then poured into a porcelain dish, the tube rinsed with 5 c.c. of water, and litmus added until the red color is completely obscured. To the bluish-green, opaque mixture the acid solution is added in excess; after stirring, the mixture is titrated with sodium-hydrate solution, drop by drop. Sufficient has been added when the solution loses its red color and is again opaque. The last drop (0.05 c.c.) is deducted, and the difference between the acid and the alkali used determined. The sum

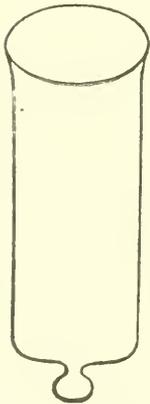

FIG. 50.—Centrifuge-tube. The spheric projection ought not to have a capacity of more than 0.20 c.c.

¹ N. Y. Med. Jour., Oct. 17, 1896.

² Centralbl. f. innere Med., June 26, 1897.

³ Arch. de Méd. expér. et d'Anat. path., July, 1896.

⁴ Zeit. f. Heilk., xvii., H. 4, p. 351; Univ. Med. Mag., Mar., 1897.

of the estimations of the serum and the corpuscles represents the total alkalinity. The double titration referred to above is performed by first titrating with a centinormal sulphuric-acid solution; an excess of acid is then added, and the solution titrated back to the blue color with a $\frac{1}{50}$ normal sodium-hydrate solution.

The Pathology of the Lymphadenoid Structures.—W. G. Spencer¹ deals in an admirable manner with this subject, particularly as far as the physiologic aspects are concerned. The papers scarcely admit of abstracting; we would only refer to his treatment of lymphadenoma, a term which applies to a growth of lymphadenoid tissue closely resembling in structure that of a lymphatic gland. He classifies the lymphadenomata as follows: 1. Local lymphadenoma: (a) simple or benign, and (b) malignant. 2. Generalized lymphadenoma or lymphadenomatosis: (a) benign, and (b) malignant. The terms in common use—leukocythemia or leukemia, pseudoleukemia, Hodgkin's disease, and lymphosarcoma—are greatly confused and employed differently by different authors. The only rational way at present of grouping the various cases of lymphadenoma is by taking the point of origin in each case. The various localities in which lymphadenomatous growths may occur are then considered.

THE CIRCULATORY SYSTEM.

Tuberculosis of the Intima of the Aorta.—Victor Hanot and Levy² report the case of a man, aged 61, in whom there was a distinct tubercle on the upper portion of the intima of the thoracic aorta. The tubercle was about the size of the head of a pin, and its nature was proved by the finding of the tubercle-bacillus.

Perforation of the Vena Cava.—S. Flexner³ reports 2 instances of perforation of the inferior cava in amebic abscesses of the liver.

The Sequelæ of Pericardial Obliteration.—Heidemann⁴ finds that in certain cases presenting ascites and hydrothorax, without edema of the legs, there is a general chronic inflammation of all the serous membranes. The pericardial adhesions lead to myodegeneration of the heart, and the stasis resulting from this to ascites, because the peritoneal vessels are more pervious on account of the chronic peritonitis. The cirrhotic processes observed in the liver are produced by extension inward of the inflammatory irritant from the capsule of the liver and by the chronic hyperemia of the organ. Through hyperplasia and contraction of the fibrous tissue upon and in the liver the stasis and ascites are increased.

Myocardial Changes in Diphtheria.—Scagliosi⁵ describes the results found by him in the hearts of cases of diphtheria that had died in from 3 to 10 days after the onset of the disease. The sequence of phenomena is as follows: 1. The poison first acts on the vessel-walls, especially on the small arteries; 2. It diffuses into the tissues, being aided in this by the changes in the vessel-walls, and causes degenerative changes in the muscles; 3. Around the altered vessels and muscle-fibers small-cell infiltration may occur, but this is never a primary phenomenon. Regarding the vascular changes, the intima may be swollen, the endothelial cells bulging into the vessel-lumen and often showing some loss of staining-power. The middle coat may undergo hyaline changes, and some leukocytic infiltration may be found in the adventitia. All these changes occur early, preceding the degeneration of the muscle-fibers.

¹ Lancet, Mar. 6, 13, 20, 1897. ² Arch. de Méd. expér. et d'Anat. path., Nov., 1896.

³ Am. Jour. Med. Sci., May, 1897. ⁴ Berlin. klin. Woch., Feb. 1 and 8, 1897.

⁵ Virchow's Archiv, Oct., 1896.

Capillary congestion is usually well marked, and there may be small hemorrhages. In the muscle the earliest change is a loss of striation and a granular degeneration, the latter affecting groups of fibers irregularly in patches or portions of individual fibers. A further stage, seen in those fibers in which the change is advanced, is the fusing together of the granular matter into a hyaline and highly refractive substance. The changes in the muscles occur first in the columnæ carneæ and beneath the endocardium. In the later stages fatty degeneration also occurs. From these observations the author concludes that the primary effect of the diphtheria-toxin is to produce a parenchymatous inflammation which corresponds in the mode of its production with the changes described by him and Perence in the central nervous system in diphtheria—first, alteration in the vessel-walls, and then degenerative changes in the nearby nerve-cells.

Pulmonary Complications of Aortic Aneurysm.—A. Fränkel¹ refers to the pulmonary complications of aortic aneurysm, among which he names fibroid pneumonia, croupous pneumonia, and pulmonary tuberculosis. All of these are contingent on a narrowing of the trachea or bronchus, special factors operating to bring about now one and now another process. Among the causes of aneurysm syphilis plays, in his opinion, a very important part; it had existed in 11 out of 30 cases (over 36%).

Infectious Endocarditis in Typhoid Fever.—W. T. Connell² reports a case of this rare complication of typhoid fever; vegetations were found on the mitral and tricuspid valves. Microscopic examination of the vegetations showed the staphylococcus.

Calcareous Degeneration of the Heart.—J. J. Hanley³ found at the autopsy on a tuberculous subject a calcified plate 8 cm. long, from 3 to 5 cm. wide, and 5 mm. thick, situated mainly on and in the posterior wall of the left ventricle of the heart.

THE NERVOUS SYSTEM.

Ascending Degeneration, and the Changes in Nerve-cells Consequent Thereon.—Rob. A. Fleming⁴ has made a large series of nerve-sections, and from examination of the central ends concludes—1. That in process of time a slow atrophy of “motor” fibers occurs. 2. That certain “sensory” fibers degenerate centrally, possibly because severed from their peripheral trophic centers. 3. That the minute fibers found in a normal nerve undergo very marked change. 4. That distinctive connective-tissue increase occurs. The fine fibers mentioned in 3, as Gaskell has pointed out, are probably designed for the supply of vessels, and they mostly leave the cerebrospinal axis in certain regions alone, pass to the sympathetic ganglia, and from them return to peripheral nerves. These fibers, scattered all through the funiculi in which they occur, seem to find their way to the periphery of a fasciculus at different levels, and probably do so near their points of distribution. The bulk of these vasomotor nerves is medullated. The author is at present engaged in determining how far these fine fibers degenerate after division of a nerve. The changes occurring in the nerve-cells—in those of the ganglia on the posterior roots and those of the anterior horns—are summarized as follows: 1. The cells of the ganglia on the posterior nerve-roots undergo definite changes as the result of nerve-section or ligature, and do so at a much earlier period than the multipolar cells in the cord—beginning probably as early as the 4th

¹ Deutsch. med. Woch., Nos. 6 and 7, 1897.

² Montreal Med. Jour., Aug., 1896.

³ Medical Council, Aug., 1896.

⁴ Brit. Med. Jour., Oct. 3, 1896.

day and certainly by the 7th day. 2. That one of the very first changes observed in the cells of the ganglia and anterior cornu is a diminution in the size of the nucleus—in proportion to the size of the cell, and that sometimes, but not in all cases, nucleoli also become smaller, and very frequently the nuclei take up an eccentric position, sometimes even bulging the cell-wall. 3. That in both sets of cells the chromatic granules are either smaller in size, fewer in number, and scattered through the cell-body, tending to be most numerous around the nucleus, or else they are grouped together in large masses round the nucleus, leaving the periphery of the cell quite clear. 4. That pericellular lymph-spaces may become enlarged, especially in the ganglia-cells, and where the enlargement is very marked the cells become proportionately smaller in size—although actual atrophy may also occur. In several specimens the author found large vacuoles—not the vacuoles described by many writers as occurring in the cells of the cord and cerebral cortex, which are probably to some extent artificial—but big vacuoles, more resembling distended pericellular lymph-spaces. They differ, however, inasmuch as they are surrounded by the remains of cell-protoplasm containing chromatic granules. 5. That in the multipolar cells not merely are there these changes in position and size of nuclei, and arrangements and number of chromatic granules, but there is, as a later phenomenon, marked disintegration of cell-protoplasm. This disintegration has been described by Marinesco as occurring in certain cord-lesions in man. It consists of patches, which with toluidin-blue and eosin are whitish in color and surrounded by masses of chromatic granules. In conclusion, the author points out that after a lesion of axis-cylinder processes those trophic cells suffer first the processes of which conduct stimuli toward the cell.

Changes of the Central Nervous System in the Course of Infections.—Marinesco¹ has examined the spinal cords and brains of a number of individuals that had succumbed to infectious diseases, such as pneumonia, bronchopneumonia, typhoid fever, smallpox, erysipelas, miliary tuberculosis, etc., and found lesions in the majority of cases. The changes in the cells varied greatly in intensity, and showed gradations from partial chromatolysis to degeneration of the cytoplasm. The same variability existed in the interstitial and vascular changes. In some cases (pneumonia, bronchopneumonia, etc.) he noted a genuine meningitis, with extensions along the pial trabeculae and the presence of diplococci. Besides a well-marked leukocytic infiltration he also observed instances in which interstitial nodules of neuroglia-cells were situated at times in the gray, at times in the white matter. Although there was great variability, it seemed as if diseases attended with leukocytosis provoked especially vascular changes. [The author, to our surprise, includes miliary tuberculosis among the diseases characterized by leukocytosis.] Other infections, by reason of their toxins, exert a harmful influence on the nerve-cell. The age of the patient, the duration of the disease, the height of the temperature, are other important factors. But whatever the factors may be, it is evident that the more intense the nervous phenomena, the greater the interstitial and parenchymatous lesions in the nervous system.

Action of the Influenza-bacillus on the Central Nervous System.—A. Cantani,² Jr., was able to produce striking nervous phenomena in rabbits by injecting cultures of the influenza-bacillus directly into the brain. It seems that the latter is a *locus minoris resistentie*. The bacilli produce an intracellular poison, the first action of which is on the central nervous system.

Brain-lesions in Acute Yellow Atrophy of the Liver.—C. W.

¹ Sem. méd., July 28, 1897.

² Zeit. f. Hyg. u. Infektionskrank., xxii., H. 2, Oct., 1896.

Burr and A. O. J. Kelley¹ describe the brain-lesions in a case of acute yellow atrophy of the liver in a man aged 40. In sections stained by Lenhossek's method changes were found in the nucleolus, nucleus, and cell-body. The nucleolus was situated variably, as in normal cells, but was of somewhat irregular contour, though but slightly, if at all, increased in size. The nucleus was distorted in shape. Owing to the excessive staining-tendency of the finer chromophilic granules, the two or three chromophilic bodies normally seen were not visible. The karyoplasm also evinced an abnormally great affinity for the stain. The cell-body was most intensely affected, the changes varying from slight implication to almost complete destruction. In some cells only a few chromophilic granules had disappeared; in others the cell-body was almost devoid of these granules, a few perhaps remaining at the periphery of the cell. In some instances the nucleus and cell-contents had been entirely destroyed, or the nucleus had dropped out of the cell. In many of the cells not so excessively affected there was an appearance suggestive of fat-globules and detritus. The protoplasmic processes, as a rule, showed no deviation from the normal. In sections stained by Berkeley's method swelling and atrophy of the processes, probably stages of one process, were observed. The lesions described by the authors were parenchymatous, affecting the nerve-cells primarily, and were not secondary to vascular changes. In all probability they were the result, as suggested by the writers, of the action of a poison.

Lesions Induced by the Action of Certain Poisons on the Nerve-cell.—H. J. Berkley² has studied the brains of three guinea-pigs that died after injections of diphtheria-toxin. In all, moniliform swellings were found on the dendrites, with denudation of the gemmules. Some of the psychic cells showed alterations in their outlines, while the neuroglia presented advanced swelling. The axons and collaterals appeared well stained. The cerebellar cells showed less change than those of the cerebrum. From studies conducted on the cerebra of hydrophobic and diphtheric guinea-pigs it would appear that all severe infections are followed by brain-cell degeneration of an order not dissimilar to that found in the cells of the abdominal viscera under similar conditions—a degenerative process unaccompanied by inflammatory reaction and a tendency to atrophy and necrosis.

Degenerative Changes in the Spinal Roots, and their Intra-spinal Prolongations in Consequence of Cerebral Disease.—A. Pick³ reports a case of tumor of the left hemisphere, one of softening, one of osteosarcoma with compression of the brain, one of glioma, and one of cerebral hypertrophy, in all of which he found a more or less marked degeneration of the posterior roots, at times also of the anterior roots. In view of the case of cerebral hypertrophy, the author thinks the degeneration is probably an effect of cerebral pressure.

Effect of Tetanus-toxin on the Ganglion-cells.—Goldscheider and Flatau⁴ found, by using Nissl's stain, that disintegration of Nissl's chromophilic elements took place within a short time after the intoxication. Tetanus-antitoxin given at the proper time after the toxin prevented the changes; when injected after the production of the latter it was capable of causing restitution of the ganglion-cells to the normal. [The antidotal effects of antitoxin could not be more clearly shown, and the discoveries seem to strengthen the view of the Behring school, that toxin and antitoxin neutralize each other. Another subject to which Goldscheider also referred in a discussion on the aims of

¹ Jour. Nerv. and Ment. Dis., Nov., 1896. ² Bull. Johns Hopkins Hosp., Feb., 1897.

³ Prag. med. Woch., 36 and 37, 1896.

⁴ Centralbl. f. allg. Path. u. path. Anat., July 15, 1897.

modern therapeutics is suggested by these observations—namely, that there is really no antagonism between the humoral and the cellular theories—toxins and antitoxins act on the cell.]

The Pathology of Epilepsy.—Joseph Collins¹ reports the findings in the portion of cortex excised from the brains of 2 epileptics, one a youth of 20, the other, a married woman of 30. In the first case the area for the right hand was cut out; on microscopic examination the excised piece showed: (1) meningo-encephalitis; (2) marked obliteration of the blood-vessels of the pia and cortex; (3) slow degenerative changes in the ganglion-cells; (4) softened areas at junction of gray and white matter; (5) replacement of the softened area by true neuroglial tissue. In the second case the area in which the left leg-center is situated was removed and examined by Nissl's method. The ganglion-cells were found much altered, staining more deeply than normal cells, and presenting shrunken and attenuated protoplasmic processes. In addition there was a great scarcity of cells.

Pathologic Changes in Dementia Paralytica.—Boedecker and Juliusburger² report the clinical histories and anatomic findings in 3 cases of paralytic dementia. We reproduce, in condensed form, the pathologic changes discovered. In the first case, a man of 45, without history of syphilis, alcoholism, or trauma, the pia was turbid, but easily peeled off, except in the region of the right posterior central convolution, where it was adherent, and carried bits of the brain with it on removal. The cortex in this region had a grayish-red color, and was marked by a granular striation. The ependyma was distinctly granulated. Macroscopically, the spinal cord showed no changes. In microscopic examination of brain-sections the pia was found adherent and thickened over the right central gyrus; blood-vessels were abundant, but showed no thickening; pigment-masses were present, especially about the vessels of the pial trabeculae. Compared with the corresponding region of the left side, the right showed a great excess of blood-vessels. The stratification of the cells of the cortex was no longer visible; instead, a dense cell-accumulation was noted. The pyramidal cells were smaller and shrunken; many were devoid of processes and stained intensely. Evidently, the changes consisted of an extraordinary increase of the interstitial tissue, with diminution in number and degenerative changes of the ganglion-cells. In addition, a degeneration of the pyramidal tract was, by means of Marchi's method, found extending from the right central convolutions down into the lumbar region of the spinal cord. The second patient, a painter, had had syphilis and lead-poisoning, and had also suffered a trauma. At the autopsy chronic leptomeningitis and granular ependymitis were found. The cortex of the right posterocentral convolution and its transition into the paracentral lobule were diminished in comparison with the left side. In the third patient, a bookkeeper, aged 54, the macroscopic lesions consisted in a granular ependymitis and atheroma of the basilar vessels. In both the second and the third cases stained alcoholic preparations of the brain-cortex from the right motor area showed hyperplasia of the neuroglia and diminution of the ganglion-cells; but neither the vessels nor the pigment seemed to be increased. The pyramidal tracts in both cases were the seat of degeneration, rendered visible by Marchi's stain. The interesting features in these 3 cases are, first, the involvement of a localized cortical area; secondly, the degeneration of the pyramidal tracts, showing, as has already been noted by others, that there are cases of paralytic dementia in which the primary cortical disease leads to secondary degeneration in the spinal cord. Finally, the coexistence of sensory and motor disturbances in the

¹ Jour. Nerv. and Ment. Dis., Oct., 1896.

² Neurol. Centralbl., Sept. 1, 1897.

limbs tributary to the affected brain-areas seems to corroborate Wernicke's view that every cortical region constitutes the central projection-field for the entire sensibility and motility of the corresponding part of the body. The old contention as to which is the primary process, the vascular changes or those in the nervous elements, is passed over by the authors. They think that the two are practically inseparable.

Typhoid Meningitis.—L. Kamen¹ reports another case of typhoid fever complicated with fibrinopurulent meningitis due to the typhoid bacillus, and points out the fact that he was the first to call attention to the occurrence of typhoid meningitis.

Serous Meningitis.—For the best and the first exhaustive exposition of this subject we are indebted to Quinke.² The pathology of the condition is still in dispute, although the general belief is that it is an inflammation, a meningitis or ependymitis of serous character, analogous to serous pleuritis, synovitis, or pericarditis. Three cases, with autopsies in two, are reported by Morton Prince.³ The disease occurs at all ages, usually causes an internal hydrocephalus, and may be acute or chronic. The etiologic factors are trauma, mental strain, alcoholism, otitis media, and acute infectious diseases. Microscopic examination of the ependyma in one of Prince's cases showed only a slight increase in the neuroglia lying beneath the ependyma, and no evidence of any inflammatory change.

Serous Meningitis due to the Pneumococcus.—Levi⁴ reports 2 cases of serous meningitis which were due to the action of the pneumococcus, and in which that organism was found in the exudate. The first case was in an infant aged 3 months and 3 days. At autopsy there was a double bronchopneumonia and a thick serofibrinous exudate beneath the arachnoid. The cerebrospinal fluid and the pneumonic areas in the lungs contained pneumococci. The second case occurred in a child, aged 6½ months. At autopsy there was a double bronchopneumonia, ventricular hydrocephalus, and a serous exudate beneath the arachnoid. The pneumonic areas in the lungs and the hydrocephalic fluid contained pneumococci. The author concludes as follows: 1. The pneumococcus is capable of producing a meningitis which is characterized by a serous exudate between the meninges and a marked vascular congestion. These lesions, of an infectious origin, are usually due to the microbial toxins (pseudomeningitis); but they frequently result from the presence of the microorganism itself, and, from this point of view, the pneumococcus acts like the bacillus typhosus, the microorganism of grippe, the streptococcus, and probably also the bacillus coli communis. 2. These cases of meningitis, as toxic lesions, may have a tendency to recover. They indicate, as a rule, an attenuated infection which the phagocytes are able to conquer; whilst purulent exudates indicate the victory of the microorganisms over the phagocytes, which are degenerated into pus-corpuscles. It is probable that certain cases of meningeal accidents (pneumonic meningitis) are lesions of this nature. 3. It is not proper to say that a given cerebrospinal fluid is sterile when cultures have been made on the ordinary media only. A pneumococcus of weak vitality may not grow, but the inoculation of a mouse may demonstrate its existence. In case this inoculation is negative it will, perhaps, be possible to prove that the trouble was due to toxins by a certain immunization which the injection will convey to the mouse in respect to virulent inoculations.

4. These lesions may leave permanent trouble behind them, and may probably be the cause of persistent hydrocephalus or of cerebral sclerosis.

On Certain Toxic Lesions of the Posterior Columns of the Spinal Cord.—Redlich¹ presents a critical digest of the spinal lesions in various intoxications. In cases of *ergot-poisoning*, in which psychoses of different kinds, epileptiform attacks, and phenomena resembling those of tabes are the chief symptoms, the principal lesion found was sclerosis of the posterior roots and posterior columns. In *pellagra*, a disease produced by the ingestion of spoiled maize, the lesions found by Tuzek resembled those of a combined sclerosis, and were most intense in the upper part of the cord, gradually diminishing lower down. Neither the posterior roots nor the gray matter was involved. The symptoms, if we might allude to them here, were chiefly of a paralytic and spastic nature; disturbances of sensation, ataxia, and myosis were absent. Regarding lesions of the posterior columns in *infectious diseases*, the observations are surprisingly few, but they suffice to show that, as in the other cases, the posterior system-tracts have a special vulnerability to the influence of toxic agents. So far, such lesions have been found positively only in diphtheria. This is important and interesting, since it has been customary to ascribe all the nervous complications of that disease to multiple neuritis. Lesions of the posterior columns are also met with in *chronic intoxications* and in *polymyositis*, and the author cites cases of the latter affection (some dependent on alcohol, others on lead) in which sclerosis of the posterior columns was found. The question as to the relation of the spinal lesion to the affection of the peripheral nerves cannot be answered positively. Some maintain that the former is secondary, either by direct extension of the process along the sensory nerves through the spinal ganglia into the cord, or in other ways. Redlich, however, believes that the two lesions are co-ordinate; in other words, that the same noxious agent acts on the peripheral nerves and on the posterior root-system of the cord; that there is, in short, a lesion of the entire sensory neuron. The author next considers the changes in the posterior columns in *pernicious anemia, leukemia*, etc. Since Liehtheim first called attention to these changes quite a large number of cases have been reported, and a study of these leads to the conclusion that grave anemias of different etiology may produce similar cord-lesions. These lesions are focal degenerations in the posterior columns, which may coalesce and lead to ascending degeneration; the posterior roots and the fibers in the gray matter escape. The process is not strictly symmetric, involves the cervical cord more than the other parts, and presents histologically acute degeneration of the nervous tissue with secondary hyperplasia of the neuroglia. The anemia is not directly the cause of these changes; the latter are probably due to toxic substances circulating in the blood. The last subject dealt with is the lesions of the posterior columns in *diseases of metabolism and constitutional diseases*. Sandmeyer, Leyden, and Williamson describe cord-changes in diabetes mellitus; Lubarsch, in 6 cases of gastric cancer, found changes in the posterior columns, once also small foci in the lateral tracts, and is inclined to attribute them to the absorption of decomposed gastro-intestinal contents. Fleiner describes macroscopic changes of a doubtful nature in the posterior columns in 2 cases of Addison's disease. From the foregoing facts we can draw the conclusion that there are poisons of exogenous and of endogenous origin that are capable of producing a primary degeneration of the nervous structures, especially of the posterior columns. From the point of view of the localization two groups are recognizable—one, exemplified by the lesions in

¹ Centralbl. f. allg. Path. u. path. Anat., Dec. 15, 1896; Univ. Med. Mag., Mar., 1897.

pernicious anemia, presents disseminated foci of degeneration; in the other, as, *e.g.*, in ergot-tabes, the degeneration is systemic, affecting the posterior roots and their tracts. But it is to be noted that in no case was any reference made to diseases of the spinal ganglia which could explain the involvement of the posterior roots. In concluding, Redlich points out that these facts may have an important bearing on our conception of tabes, and implies that in them we may perhaps find support for the theory of the toxic origin of that disease.

The Spinal Cord in Pernicious Anemia.—C. Eugene Riggs¹ reports a case of pernicious anemia with marked spinal changes. Patches of sclerosis were present in nearly all the columns, but none, except possibly the left direct cerebellar and the right direct pyramidal, had all their fibers involved. The scleroses were, the author thinks, probably vascular in origin. (See Plates 5, 6).

J. Mitchell Clarke² describes the cord-changes in 2 cases of pernicious anemia. In the first, a woman of 46, the changes consisted in fairly complete degeneration of the posterior columns, extending the whole length of the cord and the lower dorsal and upper lumbar regions, and a small area of degeneration in the posterior part of the left lateral column. The internal posterior root-zone escaped, and this explained the preservation of the knee-jerk. With Golgi's stain a marked hyperplasia of the neuroglia in the degenerated areas was demonstrated. In the second case, a laborer, aged 38, the gray matter of the cord was particularly affected—the vessels were intensely injected and there were numerous microscopic hemorrhages distributed chiefly about the central parts of the gray matter. Small areas of sclerosis were also noticed. Some of the nerve-cells of the anterior horns showed degenerative changes. The walls of the small vessels appeared thickened; the central canal was blocked. All the changes were most marked in the upper dorsal region.

The Spinal Cord in Tetanus.—Walter K. Hunter³ reports studies in 3 cases. In the cord of the first, a lad of 12, he found dilatation of the vessels, especially in the gray matter, and minute hemorrhages. There were no signs of round-cell infiltration. Regarding the ganglion-cells, the only change noticed (on comparing with normal cords) was that the plasma stained more diffusely, and showed none of the normal differentiation of its substance. The second had been successfully treated with antitoxin, but developed exfoliative dermatitis, to which he succumbed in 5 days, 15 days after the onset of the tetanic convulsions. No hemorrhages were found, and the hyperemia was scarcely more marked than in a normal cord. The ganglion-cells presented an appearance similar to that of the first case. The third case was a child of 4, which died in spite of an injection of antitoxin. The *bacillus tetani* was cultivated from the wound. The cord, including the ganglion-cells, was normal. From these cases the author concludes that the hyperemia (noted in Cases I. and II.) is probably the same as that seen in the other organs, and results from the spasm of the muscles of respiration. Its absence in the third case is difficult to explain; possibly the child died from syncope rather than from asphyxia. The changes in the ganglion-cells in two of the cases the author brings in line with those experimentally produced by Marinesco in guinea-pigs, and looks upon them as early signs of degeneration, the result of the toxins, though it is possible that the toxin is a powerful stimulant, and that the degeneration is the consequence of overuse.

The Pathology of Bulbospinal Atrophospastic Paralysis.—Hoche⁴ used Marchi's method for the study of the nervous system of a typical

¹ Internat. Med. Mag., Sept., 1896.

² Brit. Med. Jour., Aug. 7, 1897.

³ Ibid.

⁴ Neurol. Centralbl., Mar. 15, 1897; Univ. Med. Mag., May, 1897.

case of amyotrophic lateral sclerosis with progressive bulbar palsy in a man, aged 52, who died with symptoms of vagus-paralysis a year and a half after the beginning of the disease. The designation in the title is employed in accordance with the suggestion of Senator.¹ The patient had presented spasticity of the upper and lower limbs, with exaggerated reflexes, some atrophy of the interossei of the hands, fibrillary twitching, *main-en-griffe* of the left hand; the pupils and external ocular muscles were normal; the tongue showed no anomaly; sensory or sphincter disturbances were absent; mimic movements were normal; there was progressive impairment of swallowing and of speech, and toward the end persistent acceleration of the pulse. The gross morbid findings were unimportant. In Marchi's (and Weigert's) preparations the following was noted: a degeneration of the entire motor pathway and slight changes in the ganglion-cells; in addition, extensive degeneration of the fiber-systems that unite the motor nuclei, both of the cranial and of the spinal nerves—viz., the posterior longitudinal bundle and the short tracts of the anterolateral columns. It was apparent from a combined study of Marchi's and Weigert's sections that the degeneration in the pyramidal tracts had progressed from below upward; it could be traced through the corona radiata to the central convolutions. In the nuclei of the cranial nerves but little degeneration of the ganglion-cells was noted; in the cord the number of cells was reduced in the cervical portion, apparently not at all in the dorsal, while in the lumbar region the fibrillar network of the anterior horns plainly showed degenerative changes. In marked contrast with these rather insignificant cell-changes were the degenerations of the root-fibers of the ocnomotor, pathetic, abducens, facial, glossopharyngeal, vagus, hypoglossus, and spinal accessory nerves. The involvement of the ocular nerves was interesting in view of the absence of clinical symptoms referable to the eyes, while those in the facial, hypoglossus, and spinal accessory were more marked than had been expected. The chief interest of the case lies, however, in the involvement of the two commissural tracts. Marie was the first to call attention to this degeneration in the anterolateral tracts, and Brissaud went so far as to consider amyotrophic lateral sclerosis a primary disease of the supplemental or commissural fibers. While withholding his full approval of this theory, the author believes that the changes demonstrated in the posterior longitudinal bundle in his case accord very well with it, for this bundle is for the motor cranial nerves what the short tracts of the cord are for the nuclei of the different spinal segments. The pathologic anatomy of amyotrophic lateral sclerosis (bulbospinal atrophospastic palsy) may be summed up as follows: 1. Destruction of the motor cortical neurons—degeneration of the pyramidal tracts to their terminations. 2. Destruction of the peripheral motor neurons—motor pathway from the nuclei of the cranial and spinal nerves to their terminations—the muscles. 3. Destruction of the commissural cells and fibers in the cortex, the posterior longitudinal bundle, and the anterolateral tracts of the cord. Of the clinical phenomena which correspond to the disappearance of the commissural tracts we know practically nothing.

THE DIGESTIVE TRACT.

Tuberculous Occlusion of the Esophagus with Partial Cancerous Infiltration.—W. Pepper and D. L. Edsall² report a case of tuberculous occlusion of the esophagus, with partial cancerous infiltration of the strictured portion of the gullet. This rare case forms the text for an ex-

¹ Deutsch. med. Woch., 1894.

² Am. Jour. Med. Sci., July, 1897.

haustive paper on tuberculous occlusion of the esophagus and on the association of tuberculosis and cancer. The authors consider that in their case the tuberculous lesion preceded the development of the cancer.

The Infectious Origin of Certain Perforating Round Ulcers of the Stomach.—Widal and Meslay,¹ in the body of a patient dead of staphylococcic pyemia secondary to a suppurating corn of the sole of the right foot, found a liter of pus in the pericardium, and abscesses in the kidney, the epididymis, and the lung. Gastric pain, vomiting, and hematemesis had been absent. On opening the stomach a punched-out ulcer was found, the base being formed by the subperitoneal tissue; about the ulcer the mucosa and submucosa were considerably edematous and vascularized. Staphylococci were, however, not found in the sections. But despite their absence the acute ulcer should be attributed, Widal and Meslay believe, to the infection. They hold that a small abscess or erosion was produced by the staphylococci, and that the gastric juice rapidly transformed a small loss of substance into a large ulcer. Primarily microbial, the ulcer later became peptic, the bacteria disappearing with the spread of the lesion. The first stage of ulceration is sometimes found in cases dead of septicemia, as, *e. g.*, in women that have perished of puerperal infection. In animals dead of experimental infections these early stages of ulceration are frequently encountered, and even true ulcers, though more rarely, may be seen. In endeavoring to settle the infectious origin of ulcers we cannot depend on the finding of the pathogenic microorganism, for the latter is only discoverable in the beginning stages, in the region of the specific ulceration; when the round ulcer has once been formed the organisms are no longer found—the ulcer has lost all signs of its specific etiology. [Nauwerck² has reported 2 cases of such mycotopeptic ulcers, one in connection with endocarditis of rheumatic origin, the other in a case of scarlet fever. The edges of the first showed masses of streptococci and diplococci; those of the second, streptococci. He believes that many gastric ulcers begin as hemorrhagic erosions, and that some of these were microbial in origin.]

Congenital Hypertrophy and Stenosis of the Pylorus.—F. Schwyzer³ reports a case of this kind in a female child 3 months old, that had died with symptoms of chronic gastritis. The pylorus formed a distinct tumor, 2.4 cm. in length, and 2.1 cm. in width. On microscopic examination the hypertrophy was found to depend chiefly on a hyperplasia of the circular layer of muscle-fibers.

Cancer of the Stomach with Unusual Metastasis.—Israel⁴ reports a case of gastric cancer in a man 57 years old, in which the stomach was no larger than a small fist, the lesser curvature being greatly shortened and occupied by a deep gangrenous ulcer. The metastasis had spared the organs usually involved in cancer of the stomach—namely, the liver, lung, spleen, and kidney. Secondary nodules were, however, found in many other localities—the retrogastric, mediastinal, and retroperitoneal lymph-glands; both suprarenals, the tail of the pancreas, the left testicle, and both tonsils; also the mucous membrane of the jejunum and colon, and the rectum, in which the lowest metastasis was situated 2 cm. above the anus. The mesenteric glands were but slightly affected. During life a left-sided recurrent paralysis had existed. At the autopsy it was found that one of the mediastinal glands at the side of the trachea had become as large as a hazelnut on account of cancerous infiltration. A cancerous periadenitis had fixed the left recurrent larynx.

¹ Sem. méd., Mar. 17, 1897.

² Münch. med. Woch., Sept. 17, 1895; Year-Book, 1897, p. 692.

³ N. Y. Med. Jour., Nov. 21, 1896.

⁴ Berlin. klin. Woch., Jan. 25, 1897.

geal between the gland and the trachea; the nerve, for a distance of a little less than 1 cm., was infiltrated. The distribution of the secondary growths indicates that metastasis took place both along the lymph-paths and the arterial system.

A Case of Myosarcoma of the Small Intestine.—Babes and Nanu¹ report a case of myosarcoma of the small intestine. The specimen was obtained, by operation, from a man aged 30, and was as big as two fists. Microscopic examination showed that the growth took its origin from the muscularis, and was produced, the authors believe, by a sarcomatous transformation of the muscle-cells. Diagnostically important is the fact that this form of tumor in the present case and in 3 others recorded occurred in the fourth decennium, cancer being more frequent later in life. Metastasis usually takes place early in sarcoma of the small intestine.

Cirrhosis of the Liver.—H. D. Rolleston and W. J. Fenton² publish a study of 114 cases of cirrhosis of the liver abstracted from the autopsy-records of St. George's Hospital, London. We give their more important conclusions: 1. There is a high rate of mortality from tuberculosis in cases of cirrhosis, and in fatal cases of cirrhosis pulmonary tubercle, often obsolete, is found in 21.2%; while in latent cases of cirrhosis, death occurring from other causes, pulmonary tubercle was less frequent, being present in 14%. 2. Taking all the cases, cirrhosis is commoner in males, 5:2, but it is more often latent than in females. 3. Cirrhosis is fatal to women earlier in life (3 years 8 months, or at the age of 46.6 years) than in males (50.3 years). 4. There is little or no difference between the average ages of persons dying from cirrhosis and those dying from other causes but with cirrhotic livers. 5. Alcoholic cirrhosis is fatal earlier (3 years 4 months on the average) than non-alcoholic cirrhosis; this is more especially so in females. 6. Cirrhotic livers are, on the average, considerably increased in weight (65.49 oz.). 7. The livers of cases dying from nonalcoholic cirrhosis are very much lighter (weighing 41 oz.) than the livers of cases dying from alcoholic cirrhosis (67.7 oz.). 8. Alcoholic cirrhosis is commoner than nonalcoholic cirrhosis. 9. There is a marked difference (20 oz.) between the weight of the nonalcoholic livers in cases fatal from cirrhosis and in cases with cirrhotic livers dying from other diseases. 10. In cases fatal from cirrhosis the heavier livers are found at an earlier age than the lighter ones. 11. Malt-liquors and spirits may both give rise to enlarged cirrhotic livers. The author's figures, though scanty, are opposed to the view that beer necessarily or usually gives rise to an enlarged and spirits to a contracted cirrhotic liver. Fatty change was more marked, contrary to expectation, in spirit-drinkers' livers. 12. Fatty change occurs equally in large and small cirrhotic livers; half of the large livers (weighing over 60 oz.) did not show any fatty change. 13. In cases fatal from cirrhosis the liver weighs less than normal in 23% of the cases. 14. Of cases fatal from cirrhosis, 80% were alcoholic, 12.7% nonalcoholic, and in the remainder there was no evidence either way. 15. In women dying from the effects of cirrhosis a large liver associated with head-symptoms and with little or no ascites is more frequent earlier in life, while later a small liver and ascites are more often met with. 16. Ascites and hemorrhages were commoner in males than in females dying from cirrhosis. 17. In both sexes the decade between 50 and 60 years of age is the one in which most deaths result from cirrhosis. 18. In patients with latent cirrhosis the liver was generally much enlarged, weighing on an average 67.19 oz. In only one group—cases fatal from granular kidney—was this not so. The weight of the liver in fatal granular

¹ Berlin. klin. Woch., Feb. 15, 1897.

² Birmingham Med. Rev., Oct., 1896.

kidney approaches the normal weight. 19. Taking the average weight of the normal spleen as 7 oz., it is increased in the cases fatal from cirrhosis; whereas it appears that latent cirrhosis does not, apart from complications, lead to splenic enlargement. 20. The average weight of the spleen is heavier in alcoholic than in nonalcoholic cases of cirrhosis. 21. In cases fatal from cirrhosis there is no constant relation between the weight of the liver and that of the spleen. This appears to be true also of all cases of cirrhosis.

T. N. Kelynaek¹ has collected 121 cases of common cirrhosis of the liver from the postmortem records of the Manchester Royal Infirmary. Those secondary to cardiac and other chronic affections have been omitted; likewise syphilitic, biliary, and hypertrophic cirrhosis. From a study of the 121 undoubted cases the author draws the following conclusions: 1. Common cirrhosis cannot conveniently be divided into alcoholic and nonalcoholic varieties. Most examples met with in hospital occur in alcoholic subjects. 2. Nearly 50% of the cases die directly from the effects of the hepatic cirrhosis. 3. Over 12% die from active tuberculosis. Tubercle of the peritoneum occurs in a little over 9%. Either active, latent, or obsolete tubercle is met with in nearly 24% of all cases. 4. Cirrhosis appears commonest in males, the proportion being about 2 to 1. 5. The average age at death is—for males, 45½, and females, 42 years; that is to say, cirrhosis is fatal to women earlier than to men by 3½ years. 6. Ascites occurs in 56% of all cases. It is usually less extensive in females than males. 7. Ascites constantly occurs in association with hematemesis, and they are not to be considered as mutually exclusive. 8. The weight of the liver averages—in males, a little over 53 ounces; in females, nearly 54 ounces. 9. The liver is increased in size in nearly 33% of all cases, diminished in about 61½%, and normal in size in about 5½%. 10. The liver varies in size between its antemortem and postmortem conditions. 11. Typical "hobnailed" livers are not common at the present day, although evidence of alcoholism is constantly being met with. 12. The spleen in hepatic cirrhosis weighs on the average in males 14¼ ounces, in females a little over 11½ ounces. 13. The spleen is enlarged in 83%, normal in size in nearly 9½%, diminished in 7¼%. 14. The "cyanotic" spleen of hepatic cirrhosis is larger and heavier than that met with in "cardiac" cases. 15. Renal "cirrhosis" only occurs in association with hepatic cirrhosis in a little over 18½% of all cases.

Experimental Cirrhosis of the Liver from Phosphorus.—Aufrecht² has administered phosphorus hypodermically to rabbits and has studied the changes produced in the liver, employing Biondi-Heidenhain's stain. He was able to produce a typical cirrhosis, but is of the opinion that this was never the result of an interstitial inflammation, but was due to an inflammation of the liver-cells at the periphery of the acini; the apparently newly formed tissue is nothing more than the morbidly altered peripheral cells of the hepatic acini. This is, he maintains, also true of human cirrhosis, to which the experimental is completely analogous.

The Condition of the Gall-bladder in Persistent Obstruction of the Ductus Choledochus.—Ecklin³ finds that in cases of stone the gall-bladder is usually atrophied (in 110 out of 172 cases); in other cases of obstruction (121 out of 139) it is generally dilated. The contraction may be brought about by inflammation of the gall-bladder or the bile-ducts.

Primary Sarcoma of the Liver.—Bramwell and Leith⁴ report an

¹ Birmingham Med. Rev., Feb., 1897.

² Deutsch. Arch. f. klin. Med., Bd. lviii., H. 2 and 3, 1897.

³ Centralbl. f. innere Med., No. 5, 1897.

⁴ Edinb. Med. Jour., Oct., 1896.

enormous primary sarcoma involving nearly the whole of the right lobe and part of the left lobe of the liver in a married woman of 25 years. A large blood-cyst developed in the tumor and simulated hepatic abscess. The tumor was a spindle-cell sarcoma, probably arising from the cells lining the perivascular lymphatics of the intralobular capillaries of the liver. On account of its numerous blood-vessels, the growth deserved the name of angiosarcoma. [It is interesting that there was no metastasis whatever.]

Cancer of the Pancreas with Dilatation of the Stomach.—V. H. Taliaferro¹ records a case of cancer of the head of the pancreas, with infiltration entirely around the duodenum close to the pylorus, causing constriction at this point and dilatation of the stomach.

Primary Sarcoma of the Tail of the Pancreas.—F. J. E. Ehrmann² reports a primary round-cell sarcoma of the tail of the pancreas in a woman 56 years of age. The growth had given metastasis to the liver.

"Fremdkörpertuberculosis" of the Peritoneum.—De Quervain³ describes a case of what the Germans call "Fremdkörpertuberkulose" of the peritoneum, the result of rupture of an echinococcus-cyst. At the operation, a few weeks after the rupture, a piece of the omentum containing small nodules closely resembling tubercles was removed. The nodules consisted of giant cells, epithelioid cells, and small round cells, and contained in their center a distinct piece of echinococcus-membrane. Some of the larger nodules showed caseation. Quervain considers the condition a benign process analogous to that developing about every aseptic foreign body.

The Etiology of Dysentery.—W. Janowski⁴ gives an exhaustive *résumé* of the literature of the etiology of dysentery, summing up his conclusions in the following words: Dysentery is etiologically not a single disease, and is probably never caused by a single parasite, but by the conjoined action of several varieties. The data of literature permit us to say that the ordinary dysentery is caused by a bacterial association; tropical dysentery, however, is probably produced by the association of "definite species of ameba with bacteria."

THE RESPIRATORY TRACT.

Fibrinous Bronchitis.—Klein⁵ examined the coagula chemically and microchemically, and found that they were composed of mucin, not of fibrin, and suggests as a better name for the disease *bronchitis pseudofibrinosa vel mucinosa*.

Experimental Researches on Pneumoconiosis.—Claisse and Josué⁶ have made a study of this subject under the following heads: simple anthracosis, influence of anthracosis on morbid states, and influence of morbid conditions on anthracosis. They conclude: 1. That experimental anthracosis, even after inhalations of long duration (280 administrations), produces neither true anatomic lesions nor functional disturbance of the respiratory apparatus. It may, therefore, be affirmed that the different acute or chronic inflammatory, sclerotic, or ulcerous lesions described in human pathology, in the chapter on pneumoconiosis, are not due to the direct action of the dust, but rather to the infectious processes which are superadded. Any of the microorganisms which habitually infect the bronchi may become the pathogenic agents of these secondary infections. This is particularly true of the tubercle-bacillus. It

¹ Med. Brief, Dec., 1896.

² Jour. Am. Med. Assoc., Dec. 12, 1896.

³ Centralbl. f. Chir., p. 1, 1897.

⁴ Centralbl. f. Bakteriol., Parasiten. u. Infektionsk., Jan. 30, Feb. 6 and 15, Mar. 5, 1897.

⁵ Wien. klin. Woch., No. 31, 1896. ⁶ Arch. de Méd. expér. et d'Anat. path., Mar., 1897.

will be useful to revise the pathologic anatomy of human pneumoconiosis, employing modern histobacteriologic methods. The experiments show that bronchitis, phthisis, and sclerosis of an anthracotic, siderotic, or like origin do not exist in the strict sense; but that lesions due to the streptococcus or to the tubercle-bacillus, etc., occur in patients who are subjects of anthracosis, siderosis, etc. 2. That the influence of pneumoconiosis upon the evolution of morbid states may be neglected when the inhaled dust-particles are very small in size. The migration of such dust across the alveolar wall and through the pulmonary tissue is made without incident. On the other hand, voluminous dust-particles having angular surfaces may become lodged in the bronchioles; they act under such circumstances as foreign bodies in the air-passages. The local traumatism produced by the presence of these bodies prepares a soil upon which inhaled microorganisms may develop, and thus excite acute or chronic secondary affections which must have considerable influence upon the evolution of a preexisting morbid state. 3. That morbid states have no appreciable influence on the evolution of pneumoconiosis if they are of short duration, but favor its development if they are prolonged. This increase of anthracosis is thus explicable in certain of the author's experiments in which lesions of the lymph-nodes or of the pneumogastric nerves were present. The lesions of the lymph-nodes increase pneumoconiosis by impeding the circulation and the elimination of particles of dust by the lymphatics. Pneumogastric lesions act by destroying the defence of the upper bronchial passages, thus permitting the penetration of an abnormal quantity of dust even into the alveoli. Pneumogastric lesions also act, possibly, by the vasomotor troubles which they produce. The marked increase of anthracosis produced by vagotomy renders directly appreciable the role of the pneumogastric nerve in the protection of the air-passages, not only from inert and insoluble dust, dangerous simply by its accumulation, but also from living, microbic, infecting dust.

Primary Carcinoma of the Pleura.—Benda¹ reports a massive primary tumor of the left pleura in a man of 54. Nearly the entire pleura was affected; microscopically, the growth consisted of epithelioid cells and stroma. The author looks upon the tumor as a carcinoma, taking the view that the cells lining the pleural cavity are epithelial. [As the majority of pathologists adopt Thiersch and Waldeyer's theories of the origin of tumors, they cannot agree with Benda in classing his tumor as carcinoma, and would probably designate it as endothelioma, meaning thereby a peculiar connective-tissue tumor belonging to the sarcomas. But it seems to us that the best basis of classifying tumors, as long as the causal one is not available, is the morphology; and according to that, any tumor that presents the histologic features of a carcinoma, no matter what its "Provenienz," is a carcinoma. Hausmann, in his recently published book,² is of the same opinion.]

Charcot-Leyden and Calcium-oxalate Crystals in Sputum.—D. Riesman,³ in the sputum of an asthmatic patient, found, in addition to Charcot-Leyden crystals, crystals that appeared to be calcium oxalate. He refers to a similar observation made by Ungar, and calls attention to Cohn's studies,⁴ by which it seems to be established that Charcot-Leyden crystals are not octahedra, but hexahedra.

Albuminous or Serous Expectoration.—West⁵ reports the occurrence of albuminous or serous expectoration following paracentesis thoracis.

¹ *Centrallbl. f. innere Med.*, No. 10, 1897.

² "The Mikroskopische Diagnose der bösartigen Geschwülste."

³ *Phila. Polyclinic*, Sept. 12, 1896.

⁴ *Arch. f. klin. Med.*, 54, p. 515, 1895.

⁵ *Clinical Society Trans.*, xxix., p. 169, 1896.

After 40 ounces of fluid had been withdrawn with a siphon the patient began to cough; expectoration commenced in 10 minutes, and in 3 hours the patient brought up a pint of frothy fluid. The fluid divided into 3 layers on standing; it was rich in mucin and poor in albumin. Its production is ascribed to edema of the lungs.

THE THYROID AND THYMUS GLANDS.

The Physiology and Pathology of the Thyroid Gland.—Victor Horsley¹ reviews the work of the last few years on these subjects. He believes, with Gley, that the parathyroid is a gland *sui generis*, and has a specific function related to that of the thyroid; and holds further, with the majority of writers, that while myxedema and cretinism result from simple loss of the function of the thyroid gland, exophthalmic goiter depends on a perversion of that function.

Hemorrhagic Cysts of the Thyroid Gland.—W. I. Bradley² points out that there is a form of cystic enlargement of the thyroid gland not generalized, but localized, in which the enlargement is not due to multiple retention-cysts, but to the development of large isolated cystic swellings, either solitary or not exceeding 3 or 4 in number. These cysts appear to be essentially of hemorrhagic origin, and are probably due to rupture, traumatic or otherwise, of some of the vessels of the organ.

The Pathology of Exophthalmic Goiter.—An interesting discussion on this subject took place at the Carlisle meeting of the British Medical

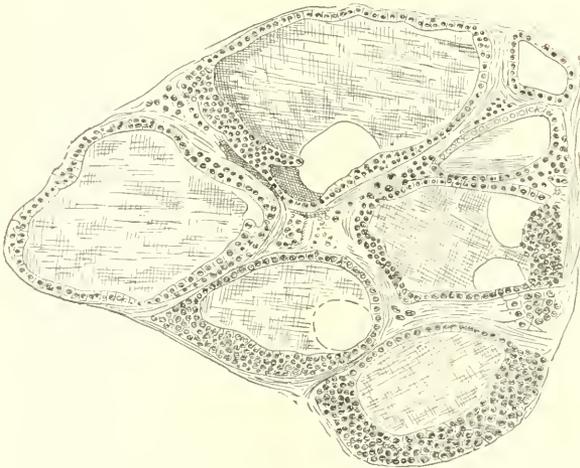

FIG. 51.—Normal thyroid gland (Brit. Med. Jour., Oct. 3, 1896).

Association.³ G. R. Murray, basing his views on the paucity of lesions in Graves' disease apart from those of the thyroid gland, the similarity of the histologic changes between compensatory hypertrophy and exophthalmic goiter, the apparent antagonism between myxedema and this disease, the transformation of cases of exophthalmic goiter into myxedema by the development of fibrosis in the thyroid, and, finally, the effects of overdoses of thyroid extract, adopts the theory that in exophthalmic goiter there is an excessive formation and

¹ Brit. Med. Jour., Dec. 5, 1896.

² Jour. Exper. Med., July, 1896.

³ Brit. Med. Jour., Oct. 3, 1896.

absorption of thyroid secretion, which may or may not be normal in character, and that the symptoms of the disease are due to the presence of this excess of

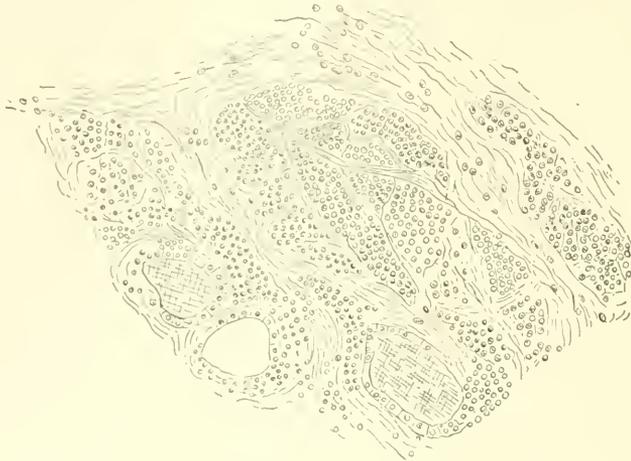

FIG. 52.—Fibrosis of thyroid gland from case of myxedema (Brit. Med. Jour., Oct. 3, 1896).

secretion in the blood, and to its action upon the tissues and especially upon the nerve-centres in the medulla. The practical conclusion from this is that

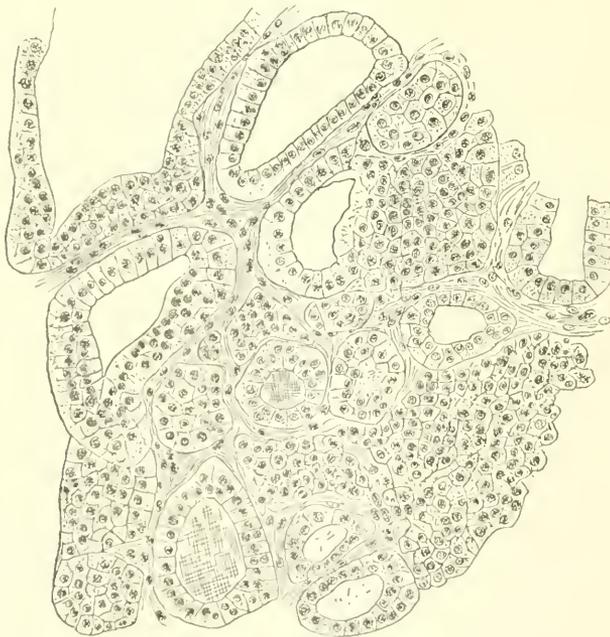

FIG. 53.—Compensatory hypertrophy of thyroid gland of monkey (Brit. Med. Jour., Oct. 3, 1896).

we should endeavor to improve our methods of treating the diseased thyroid gland. We want to be able to induce a moderate degree of fibrosis, and so imitate the natural process of recovery. Removal of a portion of the gland,

though most successful in some cases, has proved to be a dangerous operation in others. Possibly injections of iodine, electrolysis, or some similar means of starting a limited fibrosis, may help us to attain the object we have in view without danger. Victor Horsley was also of the opinion that the functional disturbance appeared to be a perversion of the secretion of the thyroid.

The objections to the thyroid theory of Graves' disease were stated by Walter Edmunds, and they were presented so clearly that we reproduce them almost in full. The changes in the thyroid are practically identical with those found in an hypertrophied portion of the gland; in an animal after excision of a portion of the thyroid the remaining part hypertrophies; these changes in animals, then, are due to compensating hypertrophy. In Graves' disease, too, the changes in the thyroid are due to compensating hypertrophy; in other words, the change in the thyroid is not the primary lesion. This, too, tells against the view that the disease is due to an excessive secretion of normal thyroid juice, because if it were, there would be no occasion for a com-

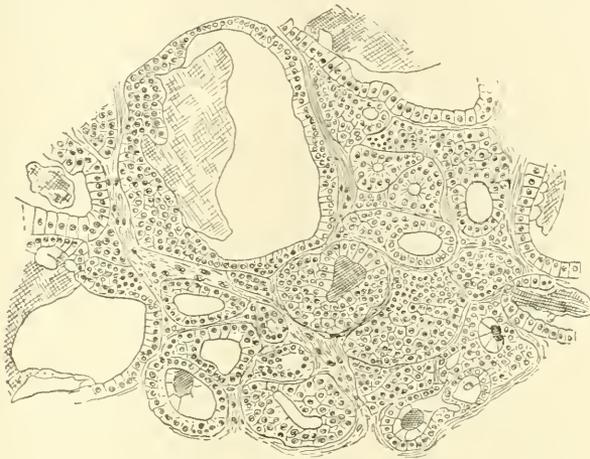

FIG. 54.—Thyroid gland, exophthalmic goiter (*Brit. Med. Jour.*, Oct. 3, 1896).

pensating hypertrophy. It is certainly very natural to conjecture that, as myxedema is due to a decrease of thyroid secretion, Graves' disease is due to an excess; but there are objections to this theory. First, although the contrast between the symptoms of Graves' disease and those of myxedema is well marked in the chronic forms, in the acute form (as seen in dogs) it is not at all marked—indeed, the two affections resemble one another. In both there are well-marked tremors and occasional attacks of dyspnea. Secondly, the theory of excessive secretion will not explain the exophthalmos; the injection, subcutaneously, of thyroid extract in large quantities into monkeys does not produce exophthalmos in these animals, although the condition can be readily enough produced in them by the injection of cocaine. Thirdly, the theory will not explain why in many recorded cases the exophthalmos was on one side, or mainly on one side, and the enlargement of the thyroid more marked on that side. Fourthly, the not uncommon occurrence of myxedema following Graves' disease seems to support the secretion-view; but the theory would require an interval of good health in the transitional stage. One finds mention of cases in which the two diseases appeared to coexist. Edmunds recently saw a case in which this condition possibly existed and which improved while taking thyroid extract. Finally, against the secretion-theory is the effect of

thyroid-feeding; different results have been obtained, and the majority of observations seem to show that the treatment does no good, but it does not seem to do harm with the certainty that might be expected were the symptoms due to an excess of thyroid-secretion. The secretion of the enlarged thyroid of Graves' disease is probably abnormal, but its physiologic effect has not been recorded; it would certainly be desirable when the opportunity presents to determine this point by experiment. Besides the thyroid being enlarged, the thymus is also enlarged; if this condition occurs in a considerable number of cases, it has some important bearing on the pathology. Microscopically the enlarged thymus contains—(1) a large number of lymphocytes; (2) the concentric corpuscles of Hassell seem to be enlarged and in an active condition, somewhat inconsistent with the view that they are fetal remains with no part to play in the organism; (3) here and there numerous eosinophile corpuscles are found. The pathology of the disease must be partly nervous and partly humoral; the exophthalmos must be produced in some way through the nervous system, and, on the other hand, it is difficult to see how removal of a portion of the enlarged thyroid gland can act directly on the nervous system. It is possible that the primary lesion is a derangement of the metabolism of the body. J. G. Adami and J. Hill Abram, on the whole, agreed with Murray.

The thyroid-theory was also strongly opposed by Robert Hutchison, who maintained that two of the arguments in favor of the thyroid theory, (1) the contrast between the symptoms of myxedema and those of exophthalmic goiter, and (2) the alleged fact that cases of exophthalmic goiter are aggravated by thyroid-feeding, were entirely fallacious. Any disease characterized by an exaggerated rate of metabolism would present a similar contrast to a disease such as myxedema, in which general metabolism was abnormally slow. It would be found on consideration that the general symptoms of fever were just the opposite of most of the symptoms of myxedema. It had been proved by experiment that thyroid-feeding caused an increased metabolism in the tissues, and it was not to be wondered at if it should exaggerate the symptoms of such a disease as exophthalmic goiter, in which metabolism was already too rapid. No one would expect fever to be benefited by thyroid-feeding. Hutchison was inclined to regard the disease exophthalmic goiter as consisting essentially in a specific change in tissue-metabolism, probably due to a functional alteration in the central nervous system, the relationship of the enlargement of the thyroid to these changes being as yet undetermined, but not to be regarded as their primary cause. [The question of the pathology of Graves' disease is still unsettled, but it seems that Möbius' view of the thyroid origin of the symptoms is the most satisfactory. That, however, there must be a cause for the thyroid-changes no one can deny; and to discover that ultimate cause is a task of the future.]

Eulenburg¹ is of the opinion that the assumption merely of an increased secretory activity of the thyroid gland does not explain Graves' disease, but that we must assume also a qualitative change, the latter depending on primary modifications in the blood supplied to the gland. The toxic action of the altered secretion is expended chiefly in the nervous system, on the higher psychic centers especially, and thus gives rise to the hysteroneurasthenic nature of the disease.

John Hill Abram,² from an examination of the thyroid gland in 4 cases of exophthalmic goiter, is led to reiterate an earlier statement made by him,³

¹ *Centralbl. f. innere Med.*, June 26, 1897.

² *Liverpool Med.-Chir. Jour.*, July, 1896.

³ *Lancet*, Nov. 16, 1895.

that the goiter in Graves' disease is not a vascular one. The microscopic changes are summed up as follows: absence of colloid; duct-like character of the alveoli; hypertrophy of the epithelium.

Metabolism in Exophthalmic Goiter.—Matthes¹ was able to confirm the fact that there is in Graves' disease an increased destruction of albumins. After strumectomy this destruction gradually suffered a diminution, which was coincident with an increase in body-weight.

The Pathology of the Thymus Gland.—Ernst Siegel² reports a most interesting case that seemingly settles affirmatively the question as to the existence of the so-called *asthma thymicum*. In a boy 2½ years old, suffering from dyspnea, in whom tracheotomy gave no relief, the thymus was elevated and stitched to the fascia over the sternum, with the result that the threatening dyspnea disappeared; the child eventually made a good recovery. The author also has reviewed the literature, and finds a considerable number of cases recorded in which dyspnea, generally fatal, was caused by an enlarged thymus. The manner in which the thymus hyperplasia produces dyspnea is still *sub judice*. Direct pressure on the trachea alone seems hardly sufficient, for Scheele has shown that in dead children a weight of 1000 gr. is necessary to compress the trachea so that air cannot pass. For the purpose of demonstrating compression of the trachea it is best to remove the latter together with the thymus, and then to divide both by transverse section. [The pathology of the thymus as a whole, and that of hyperplasia in infancy in particular, demand careful attention. Friedleben maintained that the thymus could not cause laryngismus, and that there was no *asthma thymicum*, a view also adopted by Robert H. Harvey,³ in a paper dealing with the literature on the *constitutio lymphatica*. Arnold Paltauf explained the sudden deaths in which the thymus was found enlarged (most of them recurring during swimming) as connected with a pathologic state that he designated the *constitutio lymphatica*, characterized by hyperplasia of the entire lymphatic system, including the thymus gland, and often by a hypoplasia of the vascular system, and in females of the generative organs. The relief given in Siegel's case by operation points, it seems to us, to some influence exercised by the thymus. The whole question, however, still requires answer. We have ourselves seen a case from the Maternity of the Hospital of the University of Pennsylvania in which an enlarged thymus was apparently the cause of death.]

Primary Epithelioma of the Thymus.—Paviot and Gerest⁴ report a case of primary epithelioma of the thymus in a woman aged 52. Histologic examination of the growth showed masses of cells which were so arranged that they formed little spheres, the so-called concentric bodies of Hahn and Thomas. These bodies are the essential element in the histologic diagnosis of epithelial tumors of the thymus. These bodies are more easily seen if sections are cut from the periphery of the fresh tissue.

THE URINARY TRACT.

Uric-acid Excretion in Croupous Pneumonia.—Dunn and Nowaczek⁵ report 5 cases of croupous pneumonia in which they estimated the uric-acid elimination throughout the course. In all the cases the amount of acid began to increase the day before the crisis set in, and after the crisis suddenly increased so markedly that the quantity eliminated was threefold

¹ Centralbl. f. innere Med., June 26, 1897.

² Berlin. klin. Woch., Oct. 5, 1896.

³ Chicago Med. Rec., Dec., 1896.

⁴ Arch. de Méd. expér. et d'Anat. path., Sept., 1896.

⁵ Zeit. f. klin. Med., Bd. xxxiii., II. 1 and 2, 1897.

that excreted during the febrile stage. This "uric-acid crisis" lasted 3 or 4 days. Dunin and Nowaczek did not count the number of leukocytes, and as the leukocytes usually fall to normal at the time of or near the crisis, it cannot be said that there was actually an association in their cases between the uric-acid eliminated and the number of leukocytes. But the authors believe that their results substantiate Horbaczewski's view that the uric-acid elimination is dependent on the nuclein derived from the destruction of leukocytes.

The Urine in Myxedema.—Hertoghe and Masoin¹ found the urine feebly toxic in myxedema.

The Urine in Hypertrophic Osteoarthropathy.—Guérin and Étienne² report a case in which the urine of the patient contained, on an average, 0.328 gm. of lime, 0.140 gm. of magnesium, 20.831 gm. of urea, and 1.737 gm. of phosphoric acid, every 24 hours. This hypophosphaturia clearly shows that the decalcification of the osseous system is effected only at the expense of the carbonate of lime, and this decalcification, which occurs only in the initial stage of the disease, explains the accompanying deformities.

The Alloxur-bodies in Gout and Granular Kidney.—Kolisch has announced the opinion that there is in gout an increased elimination of alloxur-bodies, and that the quantity of uric acid is lessened in proportion to the extent of involvement of the kidneys; for in nephritis the alloxur-bases are increased. Rommel³ found only average quantities of alloxur-bodies eliminated in a case of chronic gout following lead-poisoning, and despite advanced granular kidney the uric-acid elimination was normal. In a non-gouty case of granular kidney, on a diet free from large quantities of nuclein, and in the absence of leukocytosis, Rommel found an elimination of alloxur-bodies above the normal. These high values of uric acid in advanced Bright's disease go to show that the theory making the kidneys the only source of uric acid cannot be true.

Alloxur-bodies and their Relation to Gout.—Malfatti,⁴ in a case of gout, found an increase of alloxur-bodies above the quantity eliminated before the attack, but the amount did not exceed normal limits. This would disprove Kolisch's theory that gout is a disturbance of metabolism in which the nuclein-content is increased beyond the normal. The author adopts the view that gout is a process in which the normal metabolism is altered in such a way that the nitrogen-equilibrium is destroyed, and that periodically nitrogen is either eliminated in excess or retained in the body.

Influence of Ingestion of Albumin on Alloxur-bodies.—Hess and Schmoll⁵ found that the ingestion of albumin and parannuclein (egg-albumin and yolk of egg) had no influence upon the excretion of alloxur-bodies in the urine. The quantity of those bodies in the urine seems entirely to depend, first, on the quantity of nuclein (food or body-nuclein) broken up, and, second, on the degree of further oxidation.

Elimination of Methylen-blue in Renal Disease.—Achard and Castaigne⁶ have found that in cases of renal disease the elimination of methylen-blue injected under the skin is retarded as compared with the elimination in a normal subject. If a healthy man receives a hypodermic injection of 0.25 gm. of methylen-blue, the urine will become feebly tinged in half an hour; in an hour the blue color is distinct, and increases up to the 4th or 5th hour. After remaining at its maximum several hours, it diminishes, and disappears between the 35th and 50th hour. In an individual with improperly functioning kidneys the blue color appears in the urine much later—not until 1, 2, 3, or even

¹ Rev. Neurol., Aug. 30, 1896.

² Arch. de Méd. expér. et d'Anat. path., July, 1896.

³ Zeit. f. klin. Med., Bd. xxx., H. 1 and 2.

⁴ Wien. klin. Woch., No. 32, 1896.

⁵ Arch. f. exper. Path. u. Pharmacol., Bd. xxvii., p. 242.

⁶ Sem. méd., May 5, 1897.

more hours have elapsed; the duration of elimination may be diminished or prolonged; in these persons nearly all of the methylen-blue is retained in the organism. If the urine contains very little methylen-blue, it may be shaken in a tube with a little chloroform, which takes up the coloring-matter. Voisin and Hauser,¹ in connection with this subject, point out that the methylen-blue is eliminated really in two forms—as a colored substance and in the form of a colorless compound. Sometimes, when the urine is not colored by the methylen-blue, boiling will cause the blue tint to appear, showing that the substance is present in the form of a colorless compound.

Fibrinuria.—Klein² reports a case of fibrinuria in which the autopsy revealed atrophy and amyloid degeneration of the kidneys. What relation, if any, existed between the amyloid disease and the fibrinuria remains unrevealed. Klein also observed coagula in the urine of a case of cystitis; chemie examination showed them to be composed of nucleo-albumin surrounded by an envelope of mucin.

Formation of Urobilin.—Joffé, in 1868, first noted the occurrence of urobilin in the urine of febrile patients; 10 years later Gerhardt described a urobilin-icterus in which the skin, instead of having the greenish-yellow color of ordinary jaundice, has a dirty yellow color, and the urine gives no reaction with Gmelin's test, but shows a marked increase in urobilin. Vaughan Harley³ reviews the various theories propounded for the explanation of the origin of urobilin; we shall merely name them, not having space for a detailed account: hepatogenous, hematogenous, nephrogenous, histogenic, and enterogenous. Harley adopts the last, which was first advanced by Maly, but does not deny the possibility that under certain pathologic conditions urobilin may be formed in the tissues or the blood.

According to the enterogenous theory, urobilin is formed in the intestines out of bile-pigment, probably by the action of bacteria. Its place of formation is chiefly the large intestine. The author has also investigated the visible color-changes in the feces in various parts of the intestinal tract, and has endeavored to determine the nature of the staining of the intestinal walls seen postmortem. The general conclusions are as follows: 1. Bile-pigment present in the upper part of the small intestine during its passage along the alimentary canal is converted into some colorless chromogen, to be again converted in the lower part of the small intestine into pigment. 2. Urobilin is, as a rule, formed in the large intestine below the ileocecal valve, and only rarely in the small intestine; that is to say, only in those parts where intestinal putrefaction is most active. 3. The staining of the wall of the cecum and large intestine with urobilin is due to postmortem diffusion, and is not any indication of the absorption of urobilin in the living animal. Why in some cases it is most marked in the cecum and just below the cecum, and not in the rectum, can only be explained by the fact that those parts are generally found in the postmortem room more decomposed than the rectum. 4. The increase of urobilin in the urine, as well as having pathologic significance—as has been already recognized in cases of internal hemorrhages, such as cerebral, peritoneal, or hemorrhagic infarctions, and extrauterine pregnancy, and probably when red blood-corpuscles are being destroyed, as in infectious fevers, scurvy, and pernicious anemia—points also in favor of increased intestinal putrefaction, and may be a useful chemie test for such purpose.

W. B. Ransom⁴ enumerates the following conclusions: 1. "Pathologic" urobilin is "normal" urobilin present in increased amount. Some of its supposed properties are (as Hopkins has shown) due to admixture with hematoporphyrin.

¹ Gaz. hebdom. de Méd. et de Chir., May 27, 1897.

² Wien. klin. Woch., No. 31, 1896.

³ Brit. Med. Jour., Oct. 3, 1896.

⁴ Ibid.

Urobilin in the urine is probably always derived from the bile, being absent when all the bile escapes from the body. It was found especially abundant in cases of hepatic congestion or cirrhosis, in some cases of jaundice without white stools, in some cases of typhoid fever, even after subsidence of the temperature to normal, and in a case of Graves' disease with severe diarrhea but no fever. It was not found increased in pernicious anemia, nor in a case of hemophilia with extravasations. 2. The pigment of the feces (apart from that of food) consists of various and varying reduction-products of bile, some of which give no bands in the spectrum. One, stereobilin, is identical with a concentrated solution of urobilin and is usually present. In one case of pernicious anemia hydrobilirubin, with two bands (λ 480 to λ 510, and λ 590 to λ 610), was found in its stead. 3. Urobilin in urine is probably mainly derived from stereobilin absorbed from the intestines. The fact that it was found in ascitic fluid in cases of portal obstruction, but was not found in the fluid of pleural effusions, supports this view. In cases of hepatic disorder and of slight jaundice without white stools it is possible that the urobilin of the urine may have its source in bile which has not reached the intestine, but has been reduced in the liver. In the discussion Harley agreed that there were as many if not more cases of pernicious anemia with pale urine, but he thought that even in these the urobilin was increased.

Nephritis.—In a scholarly paper, W. T. Councilman¹ describes his researches into the subject of the forms of nephritis, their anatomic characters, and bacteriology. He proposes the following classification: 1. *Acute Diffuse Nephritis.*—(a) Acute degenerative nephritis; (b) acute glomerular nephritis; (c) acute hemorrhagic nephritis; (d) acute interstitial nephritis. 2. *Subacute Glomerular Nephritis.* 3. *Chronic Diffuse Nephritis.*—(a) Chronic glomerular nephritis; (b) chronic arteriosclerotic nephritis; (c) chronic degenerative and interstitial nephritis. 4. *Senile Nephritis.* 5. *Amyloid Nephritis.*

Nephritis due to the Diplococcus Lanceolatus.—Michelle² reports the occurrence in children of parenchymatous nephritis due to the diplococcus lanceolatus. In 18 out of 19 cases of nephritis he found the organism in the kidneys. Not rarely the nephritis is a primary lesion, the organisms probably reaching the kidney through the blood.

Interstitial Nephritis in Children.—Bernhardt³ reports 2 cases of chronic interstitial nephritis in children, one a boy suffering from pulmonary phthisis, the other a case in which the nephritis was an accidental discovery. One of the kidneys of the latter case was filled with calculi.

Congenital Cystic Degeneration of both Kidneys.—Burekhardt⁴ reports the case of a male infant, born after a tedious labor and dying 25 minutes after birth. On opening the abdomen 2 large tumors were found, $6\frac{1}{2} \times 3\frac{1}{2} \times 3\frac{1}{2}$ in., which were the cystically degenerated kidneys.

Colon-bacillus and Infection of Urinary Tract.—Max Melchior⁵ concludes a literary study with the statement that the colon-bacillus is the most frequent cause of cystitis and purulent affections of the urinary organs.

TUMORS.

The Origin of Tumors.—Ribbert,⁶ in further elucidation of his theory

⁶ Deutsch. med., Woch., No. 30, 1896.

of the origin of tumors (see *Year-Book*, 1897, p. 706), points out that a study of the margin of a tumor can give no proper clue as to the mode of the original development; especially can no reliable conclusions be drawn from an examination of the growing edges of a gastric or intestinal cancer. The proofs so far offered in favor of the view that cancer spreads by a direct downward growth of the epithelium are entirely inadequate. Regarding the question whether, in addition to the separation of the cells from their physiologic connections, an increased proliferative tendency is necessary, the author is of the opinion that the proliferation consequent on the separation is sufficient, and that an augmented power of growth or a diminished resistance of the surrounding tissues need not be assumed.

Malignant Growths.—E. Klebs¹ does not believe in the parasitic origin of malignant growths; neither coccidia nor blastomyces have anything to do with the propagation of tumors. The only characteristic of malignancy is metastasis, and this is brought about by the transport of cells from the original growth: he would employ the term implantation. We frequently see a dissemination of normal epithelium, as in the multiple adenomas; but here it does not produce carcinoma. The malignancy of tumors, the faculty of spreading by its elements, is due to a modification of the tumor-cells. The embryonic condition of any part of the body can only be regarded as one of the causes of tumor-formation, but not of the malignancy of the tumors. As to the origin of the modification of cell-life giving rise to cancerous growth, the author, as already stated, refuses to accept the microbial theory, and holds that one of the strongest arguments against it is the fact that cancer nearly always originates as a secondary metamorphosis of proliferating tissue. He then refers to the well-known instances of the development of cancer in lupous or tuberculous ulcerations of the skin, in adenomatous, papillomatous, and polypoid vegetations of the neck of the uterus, etc. Regarding the true features of cancerous proliferation, it is found by the author in a *hypermitosis* of the cells, a feature to which Hansemann so strongly called attention. This hypermitosis is associated with the penetration of leukocytes into the epithelial cells; the leukocytes feed the epithelial cells. The author finally sums up the phases of carcinomatous metamorphosis as follows: The first stage is that of chronic irritation or inflammation, originated by microbes or by mechanic, or probably also by chemic influences producing a chronic state of hyperplasia, the so-called benign growths composed of all normal tissues constituting the part. This development can lead to diffuse hyperplasia or tumor-formation. The second stage commences with new emigration of leukocytes and progressive development of certain cells, losing through the hypermitotic production the faculty of normal tissue-formation. The excessive proliferation and the possibility of living in a strange medium promote the formation of metastasis, the true feature of carcinoma.

The Role of "Rests" in the Origin of Tumors.—W. Roger Williams² is an ardent advocate of Cohnheim's theory of the origin of some, but not of all, tumors. He, however, widens the concept of rests as originally laid down by Cohnheim, who thought they consisted solely of embryonic tissue, which, after sequestration, lay dormant in the body without undergoing further developmental changes. The "rests," as we now know them, always present indications of having undergone more or less development. The author limits himself to a consideration of mammary and uterine neoplasms springing from rests. The former may arise from embryonal or postembryonal glandular sequestrations, or from heterotopic rests. Many cases in illus-

¹ Jour. Am. Med. Assoc., Mar. 27, 1897.

² Brit. Med. Jour., Oct. 10, 1896.

tration are cited from the literature. In the case of the uterus it has been shown that islets of cylindric epithelium or embryonic remnants often persist in the portio, and it is from such residual elements that, the author believes with Ruge and Veit, the great majority of the primary cancers of this part originate. If the current views as to the origin of the deciduoma malignum are correct, the part played by rests in its origin would be very interesting. The author also thinks that the proneness of uterine fibroids to calcification probably depends on the inclusion of osteogenic elements sequestered from adjacent parts during early embryonic life. Besides arising from rests, malignant and nonmalignant tumors may originate wherever undifferentiated cells are present, and they are most prone to arise where such cells most abound.

On the Presence of Nerves in Tumors and of other Structures in them as Revealed by a Modification of Ehrlich's Method of "Vital Staining" with Methylen-blue.—H. H. Young¹ was able to demonstrate by means of a modification of Ehrlich's method of vital staining by methylen-blue the existence of definite nerve-fibers in 5 out of 10 tumors, none of them developing from nerves nor being true neuromata. In the case of the sarcomas he believes that the nerves are integral parts of the growth as much as are the sarcomatous blood-vessels. As to their function, no definite statement can be made; a part at least may be connected with the vasomotor system. Regarding the nerves found in carcinoma, the author is of the opinion that they represent normal structures that have been surrounded by the invading cancer-cells; but it would not be surprising if subsequent investigations should prove the presence, at least in the stroma of cancers, of nerves which may properly be considered actual parts of the new growth. Many *mastzellen* were found in the tumors by the methylen-blue method, the cells evidently possessing a special affinity for the dye. They were observed in both sarcomata and carcinomata. Numerous blue-staining cell-inclusions were found in two of the tumors, both sarcomas of bone; their nature was doubtful. In the sections of sarcoma and carcinoma treated by the modified Ehrlich method a considerable number of fibrils having a special affinity for the blue dyes were encountered. They bear no resemblance to nerve-fibers, are often very long, and as a rule straight; their significance is undetermined. [These researches are interesting and suggestive, and open a profitable field in oncology.]

Deciduoma Malignum.—Julia Cook² reports a case of deciduoma malignum in a woman aged 30, who had been confined 3 weeks before admission to hospital. Death occurred about 5 weeks later, and at the autopsy an oval mass, 2 in. by 1 in., was found growing from the posterior wall of the uterus, projecting forward and filling the cavity. It had an irregular, pinkish, somewhat granular appearance. Secondary nodules were found in the lung and ovary. Microscopically, the growth showed: 1. Large irregular spaces filled with blood, fibrin, and leukocytes. 2. Protoplasmic masses, the so-called syncytia, in which were imbedded nuclei of varying shapes and sizes, staining irregularly and containing one or more nucleoli. In some parts the syncytial masses were vacuolated or split into elongated cavities, which gave the appearance of a coarse network. Where new tissue was being invaded the syncytium appeared to advance by means of narrow, finger-like processes. 3. Epithelioid cells, occurring singly or in groups of two or three or in larger masses adhering together. Some of these cell-masses were free in the blood-spaces; in parts they adhered to the syncytia, or blocked off one blood-space from another. No blood-vessels were seen, and no intercellular substance was detected in the

¹ Jour. Exper. Med., Jan., 1897.

² Brit. Med. Jour., Dec., 1896.

growth. Without expressing an opinion as to the true nature of the deciduoma, whether it is sarcoma or cancer, the author adopts the view that it is a distinct pathologic entity, a disease arising from the products of conception.

The Nature of Chloroma.—Paviot and Gallois¹ believe that chloroma (*cancer vert* of Aran) is constituted by enlarged lymphatic glands of the temporal, orbital, and occipital regions, which are due to leukemia.

Pathology of Rodent Ulcer.—H. Muir Evans² thinks that rodent ulcer arises in abortive lacrimal glands upon the face, corresponding with the sites in which these glands exist in many of the higher mammalia.

Teratoma of the Tunica Vaginalis.—Koslowski³ reports an interesting teratoma of the tunica vaginalis removed from a boy 1 year and 9 months old. The tumor had no connection with the testicle, was surrounded by a fibrous capsule, and had attained the size of a plum. Microscopic examination showed the presence of cysts and tubules lined by columnar epithelium and resembling the tubules of the rectum; cysts with ciliated epithelium; and cyst-like spaces, the walls of which had the structure of the skin, showing epiderm, hair and hair-follicles, sebaceous and sweat-glands. Parts were also found resembling more complicated organs, as, *e. g.*, a chambered structure suggesting the heart. Cartilage and nerve-cells arranged in the form of ganglia were likewise present. The tumor represents an embryo, the parts of which have, so to say, been mixed and have remained in the earliest developmental stage. [This tumor is well explained on the "parthenogenetic" theory of Wilms.]

Leydenia Gemmipara Schaudinn, a New Rhizopod found in Ascitic Fluid.—Von Leyden and Schaudinn⁴ found in the ascitic fluid of a patient suffering from ascites, edema, aortic insufficiency, and multiple abdominal tumors (detected after abdominal puncture) a large number of round cellular elements, filled with fat-like drops and yellowish pigment-granules, and occurring in nest-like groups. In a number of cells the formation of pseudopods was observed. In a second case, one of cancer of the stomach, these same cells, with the formation of bristles or bead-like projections from the periphery, could be noted. Some of the cells seemed to present a formation suggesting budding. Schaudinn, a competent zoologist, pronounced the bodies a species of rhizopods, and gave them the name of *Leydenia gemmipara*, the latter term expressive of the mode of reproduction by budding. A connection between the amebæ and the carcinoma is considered possible, and it is striking that the small buds projecting from some of the amebæ bore a close resemblance to the parasitic enclosures in cancer-cells described by Sawtschenko.

THE BLASTOMYCETES.

F. Sanfelice,⁵ in a further communication, gives the results of inoculations of *saccharomyces neoformans* into animals. 1. *Mus musculus*.—Ten mice inoculated in the peritoneal cavity died in 8 days. Miliary nodules were found in the omentum and, not always, small gray spots in the spleen and kidney. *Saccharomyces* were found in the organs and several times in the blood. 2. *White rats*.—Of 2 inoculated under the skin 1 died in 1½ the other in 2 months. At the point of inoculation both showed a growth the size of a hazelnut; miliary nodules were found in the omentum; there was swelling of the

⁴ Centralbl. f. innere Med., Nov. 14, 1896.

⁵ Ann. d'Igiene Sperimentale, vol. vi., nuova serie, Fasc. iii., p. 265, 1896; Centralbl. f. Bakteriöl., Parasitenk. u. Infektionskrank., Feb. 6, 1897.

spleen and mesentery, and small gray specks were found on the kidney. Saccharomycetes were observed in the organs, but not as numerous as in mice. 3. *Rabbits*.—Subcutaneous inoculation in 4 was unsuccessful. Of 8 animals inoculated in the peritoneal cavity, 2 died in from 1 to 1½ months, with swelling of the inguinal and axillary glands and nodules in the spleen and kidney. In the organs blastomycetes were not as numerous, but the new formation of cells was more abundant than in mice and rats. 4. *Dogs*.—Of 30 dogs inoculated in various ways, only 2 inoculated in the mammary gland showed tumors at the point of injection and in various organs (the one dog was killed in 2 months, the other died after 10 months), of the slut that died in 10 months, Sanfelice calls the tumors epithelioma. 5. *Chickens*.—Of 8 chickens only 3 presented new formations of saccharomycetes neoformans.

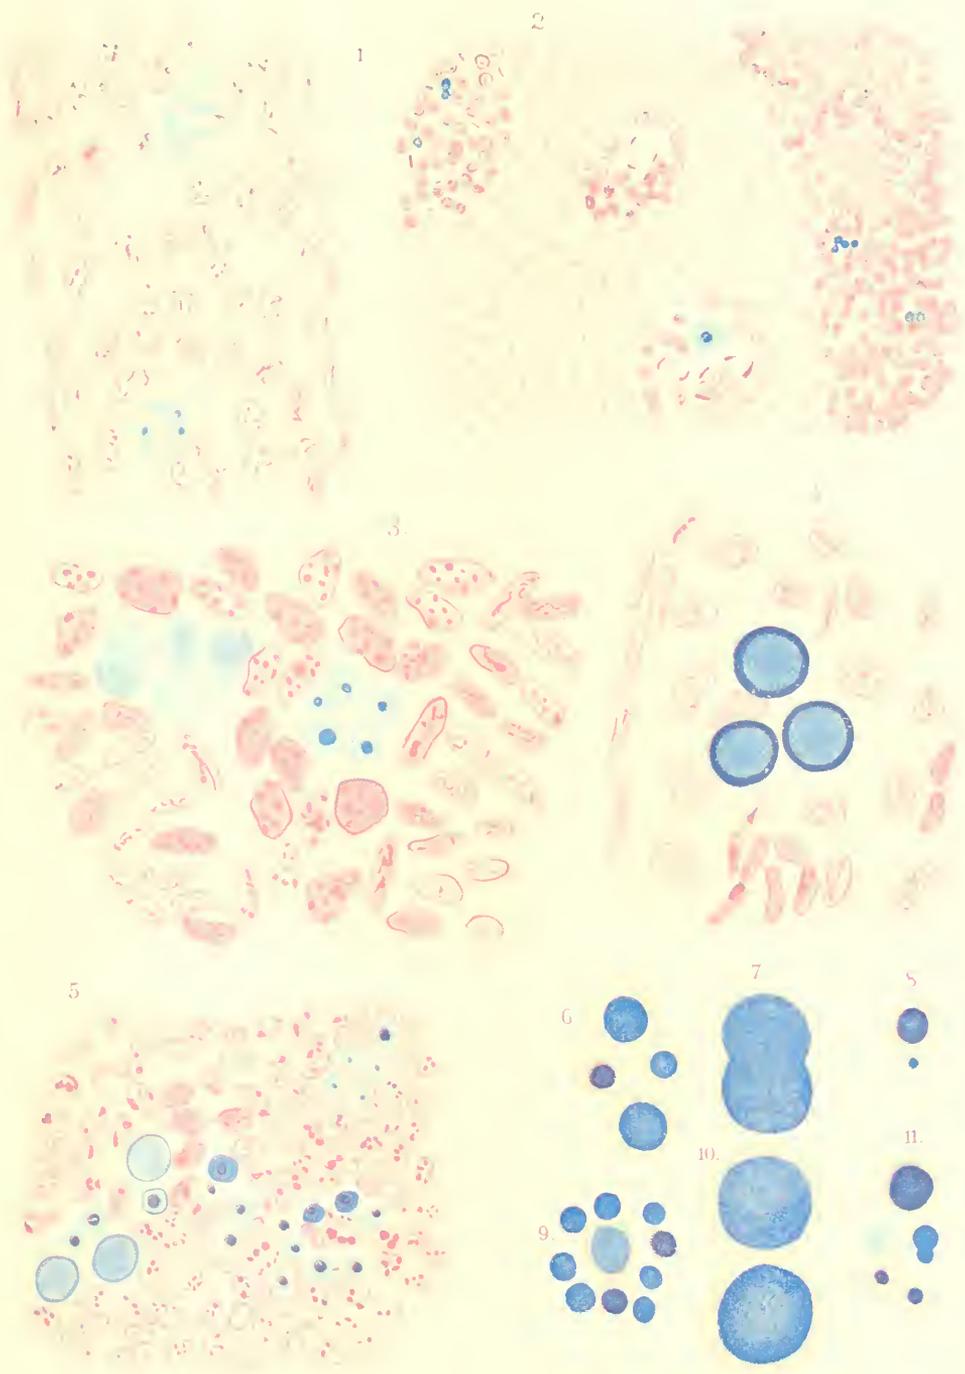

Blastomycetes and Cancer.—R. Binaghi,¹ a pupil of Sanfelice's, in an enthusiastic and well-written article, maintains both the parasitic nature of carcinoma and the theory that blastomycetes are the etiologic agents of these growths. In 40 out of 53 carcinomas he was able to demonstrate the presence of these parasites (see *Year-Book*, 1897, p. 708). The exceptions he attributed to faulty fixation and to the fact that it is not always possible to find the parasites by examining a few sections only, and it is probable that another part of the tumor might show them. The method of preparing and staining sections is as follows: the tissue is fixed in absolute alcohol or in Müller's fluid, being, when the latter is used, hardened in alcohol up to absolute. From absolute alcohol it is transferred, for purposes of clearing, to xylol, and then is imbedded in paraffin. After the sections have been mounted with albumin, and freed from paraffin by means of xylol, they are placed in a dish of absolute alcohol. The sections are then stained for from 5 to 15 minutes in Ehrlich's solution, washed in distilled water, and treated for from 2 to 5 minutes with Gram's solution; again washed in water, and then dipped for from 2 to 3 minutes in a 1% watery solution of safranin, and washed in water. They are then carried through three dishes of absolute alcohol, until clouds of color cease to be given off. After clearing in xylol, they are mounted in balsam. The parasites are violet or of a shining blue, the tissues red. The parasites appear both free and enclosed in the neoplastic cells; they are also found among the cells of the round-cell infiltration. In answer to the contention that the so-called parasites may be the result of degeneration, the author offers the testimony of the "chemic reaction." When sections containing the parasites are treated with sulphuric acid the cell-elements are gradually dissolved, while the parasites remain and become more highly refractive. When alkalis are employed instead of the acid the results are even more striking—the tissue-cells disappear entirely, but the parasites remain. These reactions the author seems to consider as proof of the cellulose character of the bodies. The final conclusions are as follows: 1. In cancer there occur constantly parasitic forms which differ from the elements of the tissues and from other accidental elements. 2. The parasites are, as far as their morphologic properties, their specific behavior toward stains, and their reactions with chemic agents are concerned, identical with the blastomycetes. 3. They are not found in other pathologic nor in normal tissues. 4. In view of their relation to the cells of the neoplasm and their regular and definite distribution, the assumption that they are accidental may be excluded, and the conclusion that they are the real cause of carcinoma is justified.

D. B. Roncali² believes that the etiologic relation of blastomycetes to can-

¹ *Zeit. f. Hygiene*, xxiii., II. 3, p. 283.

² *Centralbl. f. Bakteriol., Parasitenk. u. Infektionskrank.*, Nos. 9 and 10, 1897.

PLATE 3.

cer is established, (1) because of the morphologic proofs, from a study of the histology of the tumors; (2) because of the successful isolation of the products (ferments) of malignant neoplasms in man; (3) because of the production of malignant new growths in animals by the inoculation of the isolated blastomycetes. The blastomycetes are morphologically identical with the so-called coccidia; they resist concentrated acids and alkalis, and are rarely found in other pathologic conditions [not at all (Binaghi)]; they are found in tumors at the points of active growth, not in the center, where degeneration is in progress. They are found either in the cell-protoplasm, rarely in the nucleus, or between the bundles of fibrous tissue; they react to specific stains and give the cellulose-reaction with iodine. The lesions produced by inoculation in lower animals are variable; the higher mammals (dog) are less susceptible than the lower (guinea-pig, mouse, rabbit, rat, etc.). Some of the blastomycetes produce lesions of a neoplastic and not of an inflammatory character. In dogs new growths may be produced which spread along the lymphatics to various organs, and kill the animals by cachexia. Some parasites, inoculated into the milk-glands of sluts, produce new growths of an epithelial nature. [This is apparently a very strong array of facts which almost compels acquiescence in the theories of the Italian school, but the failure of the protozoan theory, which was so enthusiastically received, to maintain itself, has made nearly all men cautious in the acceptance of new doctrines.]

The Protective Means of the Organism against Blastomycetes.

—G. Jona,¹ using *saccharomyces opiculatus*, found that injected in large numbers into the blood, the peritoneal cavity, or the subcutaneous tissue of rabbits, the organisms were always promptly destroyed, chiefly through the action of the fluids, and always in the region inoculated—*i. e.*, in the blood, the peritoneal cavity, or the subcutaneous tissue.

TUBERCULOSIS.

Concerning New Preparations of Tuberculin.—Robert Koch,² in the introductory part of this important article, dwells on the subject of immunity, and contrasts the two distinct forms—*i. e.*, the one against the bacterial toxins (*e. g.*, tetanus) and that against the microorganisms (typhoid fever, cholera). The ideal type of immunity is that against both these noxious agencies. In the case of tuberculosis, on account of its prolonged course, one is disinclined to believe in the existence of an immunity, and persons who have recovered from an attack of the disease are not immune; indeed, they seem more liable to a new invasion. But there are facts which seem to indicate that tuberculosis can carry with it a certain degree of immunity. This is observed in miliary tuberculosis in man and in the experimental tuberculosis of the guinea-pig. There is a period in those affections when the bacilli, which previously propagated actively, become very scarce. Unfortunately this condition supervenes too late to be of use. In miliary tuberculosis of man and in experimental tuberculosis of the guinea-pig there is a rapid general invasion of the organism with bacilli, and it appears that we must look to this phenomenon for the explanation of the period of immunity accompanying the disease. In the ordinary form of human tuberculosis the bacilli present are too few and their absorption too restricted for the production of immunity, which seems to be contingent on the dissemination of the bacilli through the entire system, as in miliary tuberculosis. Efforts to obtain an artificial immunity with living

¹ Centralbl. f. Bakteriol., Parasitenk. u. Infektionskrankh., Feb. 6, 1897.

² Sem. méd., Apr. 7, 1897; Univ. Med. Mag., June, 1897.

or dead bacilli failed; abscesses were invariably the result; if bacilli were injected into the circulation of rabbits, they set up nodules in the lung, in which they were found unabsorbed and unaltered. Unmodified bacilli proving thus inefficacious, Koch endeavored to render them absorbable by chemie means. Treatment with dilute mineral acids or alkalis facilitated absorption; but, evidently through destruction of the active agent, immunity was not produced. The next attempt was to secure immunity with extracts prepared from the bacilli themselves, and resulted in the discovery of tuberculin, which has the property of evoking a reaction in individuals affected with tuberculosis, a property that renders it a useful diagnostic agent, particularly in pearl-disease of cattle. In referring to this subject, Koch takes occasion to deny emphatically that a mobilization of bacilli occurs during the use of tuberculin. The continued injection of tuberculin is capable of inducing an immunity, but this extends only to the bacillary toxin, not against the bacillus itself. Another unfortunate circumstance is the loss of reaction to tuberculin before a complete cure has been attained; relapses occur during which the reaction returns. The necessity of finding an antibacterial substance thus remained. By treating the bacilli with a 10% sodium-hydrate solution Koch obtained an alkaline extract (T A) which produced reactions very similar to those of tuberculin, except that they were briefer in duration, while the reactive power of the organism persisted longer; the results, too, were more constant. But the preparation possessed the disadvantage, dependent on the presence of the bodies of dead bacilli, of producing abscesses. On removing the bacilli by filtration the substance approached tuberculin in its action, but being less staple was inferior to the latter.

Koch next conceived the idea of mechanically reducing the bacilli to a detritus capable of absorption by the tissues. He had found that the bacilli contained two fatty acids which constituted a protective envelope and prevented absorption. The first essential was the destruction of this fatty substance. This was secured by triturating the bacillary mass in an agate mortar with an agate pestle; it was then taken up with distilled water and submitted to centrifugation. In this way an upper opalescent but transparent layer (T O) and a muddy residue were obtained. The latter was dried, triturated, and centrifuged; the residue from this was similarly treated. By this process a series of clear fluids, which from the second onward presented no difference, was obtained. These fluids were collectively termed T R (residual tuberculin). Both preparations are readily absorbable, and neither produces abscesses. Further researches demonstrated that T O contains the substances soluble in glycerin, T R those insoluble, whence the former resembles tuberculin, and especially T A, but is only feebly immunizing, while T R possesses marked immunizing power. In employing it, it is not necessary, as in the case of tuberculin, T A, or T O, to produce a reaction, but it is important cautiously to render the patient rapidly insensible to progressively larger doses. T R contains all the immunizing factors of cultures of the tubercle-bacillus, the proof being that the subject immunized with it no longer responds to large doses of tuberculin or T O. For the preparation of T R it is necessary to use young, highly virulent cultures. The immunizing substances are conserved by the addition of 20% glycerin. Administration and dosage are simple. The injections, as in tuberculin, are given beneath the skin of the back. The fluid contains 10 mgm. of solids per c.c., and before using is diluted with saline solution; the inaugural dose is $\frac{1}{500}$ mgm. The injections are repeated every second day, and the dosage is gradually increased. Koch has generally pushed it to 20 mgm. He succeeded in rendering guinea-pigs so completely immune that they were able to withstand

inoculations of virulent bacilli. The point of inoculation presented no changes; the neighboring lymph-glands were generally normal, and even when slightly swollen were free from bacilli. Immunization required from 2 to 3 weeks. In infected animals treated with T R regressive changes were always observable in the tuberculous foci. In the case of human tuberculosis the remedy is of little use in advanced stages or in those in which secondary infection has occurred.

In lupus, Koch has always seen a more marked improvement than that yielded by ordinary tuberculin or by T A. It is too early, however, to speak of "cure." Violence in reaction, infiltrations in the region of the pulmonary lesions—common phenomena under the use of tuberculin—were not observed. The only local alteration consisted in a transitory increase of crepitant rales; a very favorable influence was exercised on the fever. In conclusion, Koch states his belief that everything that is possible of attainment with cultures of the tubercle-bacillus can be attained with these preparations. It is possible, however, that combinations of T R with T O, or serums derived from T O or T R, in the preparation of which he is at present engaged, may give better and more rapid results. [The therapeutic results obtained so far seem to have been unsatisfactory.]

The Earliest Stages of Experimental Tuberculosis in the Rabbit's Cornea.—F. Schieck¹ has endeavored to settle the dispute still existing between the school of Metschnikoff and that of Baumgarten relative to the part taken by the fixed cells in the formation of the tubercle. The former, as is known, refers all cellular elements of the tubercle to the leukocytes, while the latter holds that they originate chiefly from the fixed cells, a leukocytic infiltration occurring as a later and secondary feature. Schieck confirms Baumgarten's theory of the participation of the fixed cells, but shows that the number of leukocytes depends on the character of the region of inoculation, and the quantity and quality of the bacilli. As in Baumgarten's experiments the eyes were kept constantly under the influence of atropin, which retards leukocytic immigration, that observer necessarily obtained different results regarding the participation of the white cells from those of Schieck.

Histologic Alterations of the Liver and of the Kidneys produced by the Tuberculous Toxins (Tuberculin).—Carrière² injected large doses of tuberculin into animals, and found the following lesions in the liver and in the kidneys:—

Liver: 1. Tumefaction of the cells of the periphery of the lobule, particularly in those cases in which the doses of tuberculin were very large. 2. A special necrosis of the centrolobular cells, characterized by fragmentation and by a reticular condition, vacuolization of the protoplasm, and fragmentary and granular degeneration of the nuclei. 3. Endothelial lesions of the portal vein in cases in which large doses of tuberculin were injected into the veins. 4. Vasodilatation of the centrolobular capillaries and areas of interstitial hemorrhage. 5. Endarteritis in the cases in which tuberculin was injected in large doses; slight periarteritis in the opposite cases. 6. Absence of fatty or amyloid infiltration.

Kidney: 1. Glomerular hyperemia or glomerulitis, more pronounced when the experiments were continued for a long time. 2. Tumefaction and necrosis of the epithelial cells of the convoluted tubules and of the ascending limbs of Henle's loops. This necrosis, as that of the hepatic cells,

¹ Ziegler's Beiträge zur path. Anat. u. allg. Path., xx., H. 2, 1896; Centralbl. f. Bakteriol., Parasitenk. u. Infektionskrank., Jan. 20, 1897.

² Arch. de Méd. expér. et d'Anat. path., Jan., 1897.

was characterized by the fragmentary degeneration and vacuolation of the protoplasm and the fragmentary disintegration of the nuclei. 3. Simple tumefaction of the lining epithelium of the other portions of the uriniferous tubules, which were often obstructed by granular casts. 4. Slight endarteritis, hyperemia, and interstitial hemorrhages in animals that had received large doses; slight periarteritis in those that had received small doses during long periods of time. 5. Neither fatty degeneration nor amyloid infiltration was found.

Tuberculin, therefore, contains substances which are capable of producing profound modifications in the structure of the liver and the kidney.

Tuberculosis of the Tonsils in Children.—E. Schlesinger,¹ as the result of the examination of the tonsils in 17 cases of tuberculosis, concludes that pulmonary phthisis is almost always accompanied by tonsillar tuberculosis, and, conversely, in tuberculosis of the tonsils pulmonary phthisis is never absent. In trivial tuberculous lesions of the lungs the tonsils are free from tuberculous changes.

G. Gottstein² describes primary tuberculosis of the adenoid vegetations of the nasopharynx and the pharyngeal tonsils.

Miliary Tuberculosis secondary to Tuberculosis of a Mesenteric Gland.—D. Riesman³ reports a case of acute miliary tuberculosis, affecting especially the liver and lungs, originating from a single large caseous mesenteric gland.

Tuberculosis of Small Animals.—Cadiot,⁴ supported by the results of numerous careful autopsies, opposes the prevalent opinion that tuberculosis is rare in dogs. Within a few years he dissected no less than 205 that had the disease. [Tuberculosis in a St. Bernard dog is also reported by U. G. Houck.⁵] Of 9 tuberculous cats, one had a cervical fistula, another ulcerations about the nose. Such external forms of tuberculosis he found to be very frequent in parrots. Of special significance is the fact that the tuberculosis of the latter animals is transmissible to mammals. While mammalian tuberculosis is harmless for chickens, it can be inoculated into parrots; human tuberculosis is also transferable to these birds. These facts show that the tuberculosis of our domestic animals is justly to be feared as a source of human tuberculosis.

Tubercle-bacilli in Feces from a Nontuberculous Intestine.—R. B. Shaw⁶ reports the case of an old tuberculous patient who had suffered from diarrhea for 6 months. In the feces a moderate number of tubercle-bacilli were found. At the autopsy no intestinal tuberculosis was discovered. The source of the bacilli was evidently the sputum. The case was interesting in other ways—the blood showed 400,000 red corpuscles and 8% hemoglobin. There were also found at the autopsy meningeal hemorrhage and a prominence in front of the verians cerebelli.

DIPHThERIA.

Cultivation of the Diphtheria-bacillus on Nonalbuminous Media.—N. Ushinsky⁷ has succeeded in growing the diphtheria-bacillus on his albumin-free medium (containing iron). The unfiltered culture is almost as toxic as bouillon-culture, the filtrate from 6 to 10 times weaker. He was unable to precipitate the toxin by Brieger and Boër's method.

Glycerin-media for Diphtheria-bacillus.—A. M. Gossage⁸ recom-

¹ Berlin. Klinik, II. 99, 1896.

⁸ Lancet, Aug. 15, 1896.

mends the use of a medium containing a large percentage of glycerin for the cultivation of the diphtheria-bacillus. He prefers glycerin-serum containing 9% of glycerin. By means of this medium he claims that it is possible positively to distinguish, in stained specimens, the diphtheria from the pseudodiphtheria bacillus, the former showing, when stained with methylen-blue, metachromatism, the latter not. [It seems to us that in view of the slender dividing-line between the diphtheria-bacillus and forms resembling it, such a fundamental difference as that pointed out by the author, which is "so characteristic that the merest tyro could recognize it," cannot exist. Kanthack¹ also strongly opposes Gossage's statements.]

The Influence of Carbon Dioxid on the Growth and Toxin-production of the Diphtheria-bacillus.—N. P. Schierbeck² found that a weakly acid medium through which CO₂ is passed (air containing 8% CO₂) constitutes the best medium for the production of the diphtheria-toxin.

The Differences between the Xerosis-bacillus and the Diphtheria-bacillus.—J. Eyre³ sums up the differences between these two organisms as follows: 1. After inoculation of the secretion upon the blood-serum colonies of the xerosis-bacillus do not appear within 36 hours; those of the diphtheria-bacillus appear in from 16 to 18 hours. 2. When grown in neutral bouillon or milk, the xerosis-bacillus never gives rise to an acid reaction; the diphtheria-bacillus invariably does. 3. When grown upon potato the xerosis-bacillus rapidly degenerates and dies; the diphtheria-bacillus grows with more vigor and to a greater size than on any other medium. 4. When grown upon 10% gelatin colonies of the xerosis-bacilli are not visible to the naked eye within 48 hours; the colonies of diphtheria-bacilli can be recognized in from 12 to 24 hours. 5. The invariably innocuous nature of the bouillon-cultures of the xerosis-bacillus when inoculated into the subcutaneous tissues of animals susceptible to the bacillus of diphtheria. As to the exact nature of the xerosis-bacillus—whether it be a nonvirulent and slightly altered species of the bacillus diphtheriæ, or a totally separate and distinct bacillus—it is impossible at present to decide.

Diphtheria-bacillus in Normal Throats.—H. W. Gross⁴ examined 314 normal throats and noses for the Klebs-Löffler bacillus, and found it present in 7.9% of the cases examined.

The Production of Antitoxin by the Passage of Electricity through Diphtheria-cultures.—B. M. Bolton and H. D. Pease,⁵ continuing the researches of Smirnow and others, were able to produce antitoxin by electrolysis of diphtheria-cultures. The antitoxin was produced over the positive pole, and the strongest obtained was such that 2 c.c. neutralized 10 times the minimal fatal dose for guinea-pigs.

The Production of Potent Diphtheria-antitoxins.—G. E. Cartwright Wood⁶ secured very potent diphtheria-antitoxin (in the case of one horse the serum contained 1000 immunity-units in 1 c.c.) by injecting the horses with Martin's diphtheria-albumose. After a fortnight the animals could tolerate large quantities of ordinary toxin, and a high degree of immunity was rapidly developed.

Antitoxin in the Blood of Normal Horses.—B. M. Bolton⁷ found antitoxin in the blood of 3 out of 12 horses tested previous to the injection of diphtheria-toxin.

TYPHOID FEVER.

Atypical Forms of Typhoid Fever.—Chiari¹ believes that there are forms of typhoid fever without intestinal and mesenteric lesions, such cases deserving the name typhoid septicemia. In the cases seen by him Widal's test had been obtained, yet at autopsy the characteristic lesions were absent, but the typhoid-bacillus was shown to be present by bacteriologic examination. Such cases must be distinguished from those in which, in the absence of lesions in the intestines, a diagnosis can be based on the characteristic changes in the mesenteric glands, and in which the finding of the bacillus confirms the diagnosis. [The existence of typhoid septicemia was pointed out some years ago by Italian writers. The knowledge of the occurrence of this form of typhoid infection ought to help pathologists in clearing up certain obscure cases that clinically present themselves as typhoid fever.]

THE GONOCOCCUS.

II. Heiman² publishes further studies on the **biology of the gonococcus** (see *Year-Book*, 1896, p. 1001). The organisms were obtained for cultivation by centrifugalizing the urine. It was found that the purulent sediment was acid, while the pus, which was obtained by means of a platinum-loop from the urethra, was neutral or alkaline. The author's more important conclusions are as follows: 1. In the examination of secretions from urethritis the employment of the centrifuge not only is the most convenient method, but also gives the best and most reliable results. 2. The medium employed by Hammer, consisting of albuminous urine plus glycerin-agar, does not give so good results as chest-serum agar. 3. Fractional sterilization of serum should be continued longer than 6 days, and after an interval of 2 or 3 days it should be sterilized again on 3 consecutive days. 4. Fermentation-broth (Theobald Smith's) plus liquid chest-serum, Dunham's peptone-solution plus liquid chest-serum, nutrient broth plus liquid chest-serum, are recommended as liquid media for the gonococcus. 5. Gonorrhœal pus submitted to centrifugalization and kept moist at room-temperature contained living gonococci after 48 hours, as proved by culture. 6. In gonorrhœal pus which had been smeared on linen the gonococcus was demonstrated morphologically by Gram's method after 49 days on cover-glass. 7. The gonococcus was demonstrated after 29 days in cover-glass preparation made from pus which had been dried on glass. 8. In chronic urethritis, culture-media alone are to be recommended for the detection of the gonococcus. 9. In 34 examinations of gonorrhœal threads with cover-glass alone, by Gram's method, 7 cases showed the gonococcus. 10. Of 61 cases of gonorrhœal threads examined with cover-glass and culture-media, 13 gave positive results with cover-glass and 14 with culture-media. 11. For the collection of the secretions and threads for planting at least 2 specimens of urine must be obtained; first, that which washes out the urethra; second, that which contains threads of the posterior urethra and secretion expressed from the prostate. 12. A urethra may contain gonococci which lie dormant and may be innocuous in that person for years, but which may at any time excite an acute gonorrhœa in another person.

Culture of the Gonococcus.—Wassermann³ employs the following medium: 15 c.c. of hog-serum, 30–35 c.c. of water, 2–3 c.c. of glycerin, and 0.80 gm. of Salkowski's nutrose (sodium phosphate and casein). The mixture is

¹ *Centralbl. f. allg. Path. u. path. Anat.*, Oct. 15, 1897. ² *Med. Rec.*, Dec. 19, 1896.

³ *Sem. méd.*, July 28, 1897; *Berlin. klin. Woch.*, Aug. 9, 1897.

sterilized by boiling from 20 to 30 minutes over an alcohol-flame. At the moment of using an equal part of liquefied 2% peptonized agar is added and the whole poured into a Petri dish. Wassermann found in the cultures of the gonococcus an active toxin which produced an inflammation at the point of injection, as well as fever and muscular and articular pains. The toxin is contained in the bodies of the bacteria, and not in the filtrate of the cultures. All efforts to produce immunization failed.

Internal Localization of the Gonococcus.—D. N. Eisendrath¹ reviews the literature on the subject of the internal localization of the gonococcus from the time of the discovery of the bacterium.

Fatal Systemic Infection from Gonorrhoea.—J. M. Robinson² reports the case of a hotel-clerk, aged 32, who presented signs of septicemia, complicated shortly before death with swelling of numerous joints, for which no cause could be discovered. At the autopsy an old urethral stricture was found; the urethral pus contained gonococci. The author thinks the posterior urethritis was the source of the pyemia. [This is probably correct, although we should be inclined to think that the ordinary pyogenic organisms were to blame, and not the gonococcus itself.]

THE STREPTOCOCCUS.

The Specificity of the Erysipelas-streptococcus.—Petruschky³ discusses this question, and comes to the conclusion, which, of course, is not new, and has been accepted by most recent writers, that there is no specific erysipelas-streptococcus. The particular morbid condition produced by streptococcus-infection depends on—1. *The seat of infection.* Dermal erysipelas, *e. g.*, arises only when the infection is in the lymph-spaces of the skin or mucous membranes. 2. *The virulence of streptococcus for man.* This is by no means equal to the virulence of the same streptococcus for mice or rabbits. 3. *The individual resistance of the infected person.* 4. *The influence of existing diseases* which modify the resistance of the individual. In tuberculosis, diphtheria, scarlet fever, small-pox, typhoid fever, and influenza the resistance is lessened; in carcinoma and sarcoma it is not lessened, but perhaps increased.

Nonidentity of the Streptococcus of Marmorek and the Streptococcus of Erysipelas.—J. Courmont⁴ maintains that the streptococcus of erysipelas and the streptococcus of Marmorek are two different species. [The reasons given are not cogent.]

The Question of the Homology of the Streptococci.—C. Zenoni⁵ found a very large streptococcus in the false membranes of a case of peritonitis secondary to an old gonorrhoea. The question arose as to the identity or non-identity of the organism with the ordinary streptococcus. As the bacterium after successive cultures and on various media changed its form to that of the other, and as immunity could be produced against it with Marmorek's serum, it must be considered identical with the other forms of streptococcus.

The Value of Chrysoidin in the Diagnosis of Cholera.—Blachstein⁶ claims that chrysoidin is of diagnostic value with respect to cholera-cultures, producing in the turbid bouillon a flocculent precipitate with clearing of the medium. Walter Engels⁷ shows that other vibrios respond in the

⁴ Sem. méd., July 28, 1897.

same manner, whence it follows that chrysoidin has but little diagnostic value and cannot be used as a substitute for the serum-reaction.

The Cause of Rabies.—E. Marx¹ doubts the fact that Bruschetti found the cause of rabies, believing that the latter has probably cultivated a contaminating organism. Furthermore, paralytic rabies is not so clearly characterized that it might not be simulated by another infection attended with paralysis. He himself has examined nearly 60 cases of rabies, and only once found a bacterium resembling Bruschetti's rabies-bacillus. He does not believe that bacteria have anything to do with the etiology of the disease.

The Influence of the Röntgen Ray on the Poison of Rabies.—E. Frantzius² found that the x-ray acting for not less than an hour on the spinal marrow of rabbits dead of rabies influenced the poison in such a manner that in animals inoculated with it a distinct prolongation of the incubation-period was noticeable, but death was not prevented. The hope that the Röntgen ray would prevent a fatal termination of the disease must, therefore, be abandoned.

A Pathogenic Streptothrix.—Scheele and Petruschky³ presented at the Fifteenth Congress of Internal Medicine at Berlin cultures of a streptothrix variety which they had found in the sputum of a man who, after an attack of influenza, developed pleuropneumonia, cystitis, pyelitis, and multiple cutaneous abscesses. The bacteria were also cultivated from the abscesses. This is the first time that a pathogenic streptothrix has been found *intra vitam*.

Virulent Pneumococci in Dust.—Netter⁴ demonstrated, after the manner of Cornet, the presence of virulent pneumococci in the dust of a hospital-ward.

The Smegma-bacillus.—A. S. Grünbaum⁵ examined 50 specimens of urine from 47 individuals for the smegma-bacillus, by centrifugalizing the urine, spreading the sediment on cover-glasses, and staining in the usual way with Ziehl-Neelsen's and Gabett's solutions. In no case was the bacillus found in the urines of men, but it was present in 59% of the urines from women. It was never found in urine obtained by catheter from either women or men. The author succeeded in growing on milk a bacillus from the smegma which stained red with carbol-fuchsin, and was not decolorized in 2 minutes by Gabett's solution.

Pertussis.—Julius Ritter⁶ found in all cases of pertussis examined the diplococcus described by him in 1892, and in 3 fatal cases was able to demonstrate its presence on the inflamed bronchial mucous membrane.

The Cause of Mumps.—At a session of the Verein für innere Medizin of Berlin, held on March 29, 1897, Michaelis⁷ described the microorganism found last year by von Leyden in the parotid-saliva, obtained by catheterization of Stenon's duct, and reported researches carried on by him (Michaelis) and Bein. The organism is morphologically and culturally characteristic; it is a motile diplococcus, resembling in form, position in cells, and staining-properties the gonococcus. It grows on ordinary media, also on aseptic fluid and milk, which last is curdled by it. Inoculation of animals, even direct injections into the parotid and testicle, was unsuccessful. The coccus possesses a very slight virulence.

⁷ Ibid., Apr. 12, 1897; Univ. Med. Mag., June, 1897.

The Bubonic Plague.—M. Ogata¹ made careful studies during the pest-epidemic in Formosa, from which he has drawn the following conclusions: 1. In the tumefied lymph-glands of pest-sufferers and in the organs and blood of cadavers a pathogenic bacillus is found that in experimental animals produces a disease resembling the plague. 2. The plague-bacillus is not found constantly in the blood of patients suffering from the disease; not even in grave cases. 3. The bacillus may be found in the bile and the urine. 4. The bacillus is transported from wounds by insects, such as fleas and mosquitoes. 5. In the lymph-glands, blood, and internal organs of rats falling ill spontaneously or after artificial inoculation, the same bacillus as that of human plague is found. 6. The fleas found on rats suffering with the plague likewise contain virulent plague-bacilli and are capable of spreading the disease after the death of the rats. 7. In the blood, lymph-glands, and internal organs of pest-sufferers or cadavers other bacteria in addition to the plague-bacillus may be found. 8. The plague-bacillus is but feebly resistant against antiseptics. 9. In the floors of the pest-houses the bacillus was not found. [To these conclusions the author, whose scientific method speaks volumes for the thoroughness of the Japanese, appends some valuable suggestions regarding the prophylaxis of plague-epidemics. Of interest to us in the United States is his advice thoroughly to disinfect rags, wools, etc., coming from plague-stricken countries; ships from such regions should be inspected and quarantined.]

The Bacillus of Yellow Fever.—J. Sanarelli² describes a bacillus that he found in cases of yellow fever studied by him as director of the hygienic laboratory at Montevideo. The organism is a small rod with rounded ends, 2 to 4 μ long, occurring in pairs in culture and in groups in the tissues. It was never found in pure culture in the cadaver, and its isolation was possible in only 58% of cases. Strange as it may appear, it is not found in the gastrointestinal tract, but in the blood and tissues. It is facultative anaerobic, stains by Gram's method, and is very resistant to drying. Pathogenic for nearly all animals, its chief properties are: (a) steatogenic [causing fatty degeneration]; (b) congestive and "hemorrhagiparous;" and (c) emetic. The filtered toxin produces analogous consequences. Injections of filtered cultures in man give rise to typical yellow fever. [It would seem as if Sternberg's bacillus X and Sanarelli's bacillus were identical; nevertheless the latter's discovery, which he has followed up with efforts toward the preparation of immunizing and curative substances, deserves attention. The studies and experiments should be repeated; unfortunately, the opportunity for the work has been very good in the United States.]

Hospital-gangrene.—Vincent³ obtained in 47 cases of hospital-gangrene from the membranous pulp covering the ulcers a bacillus of from 4 to 8 μ long, 1 μ broad, not coloring by Gram's method, but staining well with thionin, and displaying a great resisting-power to antiseptics. In 40 out of the 47 cases a spirillum was also found, usually in small numbers and most abundant just beneath the pseudomembrane. Vincent considers this spirillum the true cause of hospital-gangrene. It produces a necrotic and hemorrhagic process, but its action is mainly local. Cultivation of neither organism succeeded. Inoculation of the pus into artificial wounds of animals gave no results, except in a rabbit suffering from general tuberculosis—in which an unhealthy wound was produced; similar results were obtained by injecting the bacillus with cultures of streptococci, colon-bacilli, etc. Two factors seem necessary to the production of hospital-gangrene: a condition of inanition in the patient and an association of the specific agent with other microorganisms.

¹ Centralbl. f. Bakteriol., Parasitenk. u. Infektionskrank., June 24, 1897.

² Sem. méd., July 7, 1897.

³ Ann. de l'Inst. Pasteur, Sept. 25, 1896.

Chronic Glanders in Man.—Buschke¹ describes a case of chronic glanders localized to one extremity. It is the fifth recorded case, and, like the others, was characterized by a remarkably chronic course, the presence of intramuscular, subcutaneous, and subperiosteal abscesses, and a localization at the nares. The diagnosis can only be made after bacteriologic examination and by getting Straus's reaction (see *Year-Book*, 1897, p. 716), which is to be supplemented by cultures from the testicular pus. Mallein may perhaps be of use in the diagnosis.

The Thrush-fungus.—Max Steiner² finds that rabbits inoculated with pure cultures of the thrush-fungus (*Soorpilz*) die in from 5 to 10 days, a considerable number presenting paresis, chiefly of the hind limbs. In the microscopic sections (nearly all organs were affected) he noted well-marked round-cell infiltration about the fungus-colonies.

Pathogenic Spirillum in Schuylkill Water.—A. C. Abbott³ describes a pathogenic spirillum isolated from the Schuylkill River water at Philadelphia. The organism (*Vibrio schuylkilliensis*) is pathogenic to pigeons, guinea-pigs, and mice, and is closely allied to the *Vibrio Metschnikovi*. Pigeons rendered immune to *Vibrio schuylkilliensis* were also immune to *V. Metschnikovi*.

Influence of Sunlight on the Bacteria of Street-dust.—Wittlin⁴ found that sunlight had a distinctly bactericidal action on the bacteria of street-dust, but that sprinkling of the dust favored the growth of bacteria.

PROTECTION AND IMMUNITY.

The Bacteriologic Contamination and the Preservation of Vaccine-lymph.—G. H. Weaver,⁵ in a study of this subject, arrives at the following conclusions: 1. Vaccine-lymph in a fresh, pure state almost always contains bacteria, and often pathogenic forms. 2. Pure vaccine-lymph after being kept in a fluid state, or dried upon ivory points as now prepared, is unfit for use and often dangerous. 3. Vaccine-lymph diluted with pure glycerin or equal parts of glycerin and distilled water, becomes sterile in about 2 weeks, and should not be used sooner. 4. All animals used for propagating vaccine-lymph should be tested with tuberculin before being used. 5. All vaccine establishments should be regularly inspected by properly qualified officials, and samples of virus from each lot of vaccine examined bacteriologically by a competent person, and the result certified before it is placed upon the market. 6. Each package of vaccine-lymph should be so marked that the date on which it is taken, and, if fluid, what has been added, shall be shown.

Self-protection of the Organism against Bacterial Infection.—A. J. Kondratieff⁶ has prepared from the adrenals and spleen of the horse (which is susceptible to tetanus) a substance (*atovogen*) which protects white mice against an otherwise positively mortal dose of tetanus-toxin, so that 50% of the animals survive. The protective substance resembles the enzymes, and is chemically allied to the antitoxins and toxins, which, as Brieger has shown, are nonalbuminous bodies. The author then expounds this theory of tetanus-immunity (based on Courmont and Doyon's), which briefly is as follows: after its entrance into the organism the tetanus-poison forms a nontoxic combination

¹ Arch. f. Dermat. u. Syph., Bd. xxxvi., H. 3; Centralbl. f. Bakteriol., Parasitenk. u. Infektionskrank., May 10, 1897.

² Centralbl. f. Bakteriol., Parasitenk. u. Infektionskrank., Mar. 30, 1897.

³ Jour. Exper. Med., July, 1896.

⁴ Wien. klin. Woch., No. 52, 1896.

⁵ Jour. Am. Med. Assoc., Dec. 26, 1896.

⁶ Centralbl. f. Bakteriol., Parasitenk. u. Infektionskrank., Mar. 30, 1897.

with the proteids of the cell-protoplasm, which combination at the end of the incubation-period decomposes in one of two ways: either the toxin is split off from the albumin and poisons the nervous system, or harmless products are split off—in susceptible animals antitoxin, in naturally immune animals other nontoxic compounds. Similar combinations can be formed by antitoxin and atoxogen, and it is the presence of atoxogen (always found in the normal body) and of antitoxin that promotes the reaction whereby the poison is transformed into antitoxin (or other nonpoisonous products). The active immunity remaining after recovery from tetanus can be explained by the existence of specific changes of the proteids which result after combination with the toxins.

The Mechanism of Reaction to Peritoneal Infection.—Durham¹ has undertaken a study of the factors concerned in the reaction of the peritoneum to infection. For the inoculation young agar-cultures of various bacteria were employed, the dose being regulated by a standardized loop. Within a variable period peritoneal fluid was withdrawn, and examined in hanging-drop and fixed preparations on cover-slips. At the autopsy on the animal the various membranes and organs involved were also examined. The different cells concerned in peritoneal inflammation are the following: (a) *Hyaline cells*. (b) *Coarsely granular oxyphile cells*—the *a*-granulation-cell of Ehrlich, for which the author proposes the not very euphonious term megoxyphile cell or megoxyeyte. Contrary to the usual belief, Durham holds that this cell can be phagocytic, though it is much less so than the hyaline and other cells. (c) *Finely granular oxyphile cells* (microxyphile cell or microxyeyte)—cells containing fine oxyphile granules and a more or less pigmented nucleus. They do not occur in the normal peritoneal fluid of man or the guinea-pig, and probably not in that of the rabbit. (d) *Macrophage*. This appears within 20 hours after an easily recoverable inoculation. Its nucleus is pale, large, and oval or round, and the protoplasm stains with basic dyes. The cell has an extraordinary capacity for ingesting microxyphile cells, bacteria, etc., and is apparently derived from the endothelial cells of the omentum and the peritoneal covering of the various organs. (e) *Basophile cell*. This was not observed in the peritoneal fluid, but was found adherent to the mesentery, omentum, parietal peritoneum, etc.

The changes following peritoneal infection are divided by the author into five stages: 1. Stage before leukopenia; 2. Leukopenic stage; 3. Microxyphile stage; 4. Macrophage stage; 5. Recovery to normal.

1. Among the changes occurring in this stage are the “balling” together of the cells, apparently due to increased stickiness of their surfaces. This increased surface-stickiness also facilitates phagocytosis. When the bacteria are extremely virulent they swim about and hit all forms of cells with perfect impunity, none remaining adherent. If many nonvirulent individuals are present, some become adherent to the hyaline cells, producing at times a “hedgehog” appearance of these cells. A preliminary attack of the megoxyphile cells, and a subsequent phagocytosis by the hyaline cells, as described by Kanthack and Hardy, were never observed. Microbes adhering to the hyaline cells immediately lose their motility, but contact with the megoxyphile (eosinophile) cells is not harmful to them. 2. The leukopenic stage is due to the combination of several factors: (1) attachment of the cells to the membranes lining the peritoneal cavity, especially the omentum; (2) removal of cells by the lymph-paths; (3) entanglement in clots; (4) actual destruction of cells; (5) in sexually mature female animals removal by the Fallopian tubes. Of these the first is the most important. Bacteria also become adherent to the

¹ Jour. of Path. and Bacteriol., Mar., 1897.

omentum, and in cases in which the peritoneal fluid is entirely sterile cultures from the omentum may show abundant bacterial growth. This is most readily demonstrated after Pfeiffer's reaction. This proves that microorganisms continue living among multitudes of phagocytic cells upon the omentum and on pseudomembranes, while the peritoneal fluid becomes absolutely sterile. In regard to chemotaxis, the author is very sceptical, and considers the phenomena ascribed to it as largely physicochemic in nature. 3 and 4. *The Microxyphile and Macrophage Stages or Stages of Leukocytosis.* The microxyphile cells appear in all cases whether virulent or nonvirulent microorganisms or solutions are used, the number depending on the virulence and quantity introduced. If the infection is highly virulent or toxic, only a few cells appear; if mild, they are found in increasing numbers. In the former case the cells disintegrate rapidly and phagocytosis is slight. By acting upon the microorganisms with bactericidal serum a good deal of phagocytosis may be observed. As to the source of the microxyocytes, the author holds that they emigrate from the blood-vessels. Regarding the macrophages, which are actively phagocytic, their origin is probably not hemal, but local. In all animals that recover from peritoneal infections there is constantly a very considerable microxyocyte leukocytosis, followed by the appearance of macrophages. These phenomena appear essential to recovery. As to the nature of the resistance, the author believes that intracellular (phagocytosis) and extracellular processes run hand in hand, and that probably neither alone is sufficient.

Changes in the Microorganisms after Inoculation.—The bacteria assume a coccus-like or spheric condition; the more virulent the infection, the more difficult it is to discern these extracellular degeneration-forms. These bodies, which are formed without direct interference on the part of the cells, are ingested by phagocytes.

Conclusions and Summary.—1. By means of cellular changes which occur after peritoneal infections in guinea-pigs the following stages may be recognized: (a) preliminary stage; (b) leukopenic stage; (c) microxyphile stage; (d) macrophage stage; (e) return to normal. 2. The peritoneal fluid, membranes, and lymph-paths must be examined in order to obtain complete and accurate notions of the processes. 3. The nomenclature megoxyphile cells, or megoxyocytes, for coarsely granular eosinophile cells, and microxyphile cells, or microxyocytes, for finely granular eosinophile cells, is suggested. 4. The megoxyocytes take a minimal share in the processes of bacterial destruction. They may be very scanty during the leukocytic period. 5. Important changes are to be observed upon the peritoneal membranes; of these the omentum is especially to be noticed. 6. Pure cellular and pure humoral theories fail to account for many of the phenomena of bacterial destruction in the peritoneal cavity. Both are of importance. A compromise between the two seems the most satisfactory for the explanation of the facts. Alexocyte theories of secretion, etc., are at present not entirely satisfactory, as all the other possible factors have not yet been eliminated or defined. 7. Extracellular degeneration of microbes can always be detected in normal animals, even in the face of the most virulent and toxic infections. It is especially well seen in actively and passively immunized animals and in animals to which temporary resisting power has been given. 8. The observations of Issaëff on the period of general increased resistance are worthy of careful notice in discussing the theory of immunity. Issaëff's period of resistance promises to be useful clinically as an aid to the surgery of the peritoneum. 9. The general phenomena of reaction of the peritoneal infection resemble those occurring in the blood after intravascular and in connective tissue after subcutaneous infection. 10. The

general phenomena after peritoneal infection in rabbits and guinea-pigs are not widely dissimilar from those occurring in man.

Concerning the Augmentation of the Natural Resistance by the Production of Hyperleukocytosis.—Hahn¹ refers to the fact that Buchner more than two years ago discovered that pleural exudates rich in leukocytes, obtained by the injection of sterilized aleuronat-emulsion into the pleural cavity of animals, were more bactericidal than the blood or blood-serum of the same animals. The greater power was proved to depend on the leukocytes or on some secretory product furnished by them. The thought then suggested itself that it might be possible by increasing the number of leukocytes in the blood to augment the natural resistance of the individual. Two courses lay open for the accomplishment of this purpose: either the quantity of bactericidal substances could be increased by the introduction of fluids rich in leukocytes obtained from other animals, or a hyperleukocytosis could be produced by artificial means. The first course seemed unproductive, since Buchner had shown that the alexins of different animal species are mutually destructive. The second gave better results. Hyperleukocytosis was secured by the injection of nuclein or nucleinic acid. When dogs were used it was found that the blood obtained during the stage of hyperleukocytosis was decidedly more bactericidal than the normal blood of the same animal. But the author points out that the favorable effect of hyperleukocytosis cannot be expected in cases in which the bacteria are localized and do injury by their poisons, but only in those in which they are actually circulating in the blood. For the purpose of studying the effects of hyperleukocytosis in man the blood of a patient receiving tuberculin-injections was employed. It was found that leukocytosis followed the injections, but only when the number of white cells reached 13,000 or 14,000 was any increase in bactericidal power observed. This indicates, however, that the bactericidal properties of human blood depend in the main on the number of leukocytes. Yet it is not likely, as already indicated, that hyperleukocytosis will exert a favorable influence on all bacterial infections. We know, for example, that in diphtheria progressive increase in the leukocytes is not a favorable symptom. This will probably be found true of all infections in which the bacteria remain localized and act by virtue of poisons which they elaborate. In such cases the point is not so much the destruction of the bacteria as the neutralization of their toxins, and the antitoxin-treatment will be of chief use.

Alkalinity of the Blood and Infection.—Fodor and Rigler² have continued their researches on this subject, and in their present essay deal among other things with the *influence of protective inoculations* on the blood-alkalinity, finding that the injection of anthrax and schweinerotlauf vaccine causes an increase in the alkalinity. Rabic virus produces a rapid fall of alkalinity, but when an animal inoculated with such virus is treated antirabically there is only a very slight diminution of alkalinity. The *influence of toxin and antitoxin-injections* was also tested. The injection of diphtheria-toxin is followed by a rapid fall of alkalinity, after which there is a slight rise, and then a gradual decline until death. Between the quantity of toxin on the one hand, and the depression of the alkalinity, the rapidity of this depression, and the period from the injection to the death of the animal, on the other, there is a noticeable, though not rigid, parallelism. Antitoxin-injections increase the alkalinity, but, differing from that following vaccination, the increase is only transient, lasting scarcely 48 hours. When antitoxin and toxin are simultaneously injected at

¹ Berlin. klin. Woch., Sept. 28, 1896.

² Centrabl. f. Bakteriol., Parasitenk. u. Infektionskrank., Feb. 6 and 15, 1897.

opposite points the alkalinity-depressing action of the latter is neutralized; there is even a slight increase. The resistance of the animals runs parallel with the increase in alkalinity. When antitoxin was injected first and toxin afterward, there was just as great a reduction of alkalinity as if the antitoxin had not been injected, and the animals died. This result differs markedly from that observed in the case of vaccines—an injection of virulent anthrax after an antecedent immunizing injection of anthrax-vaccine caused no diminution in alkalinity. Maragliano's tubercle-antitoxin produced a rise in alkalinity, likewise transient as that from diphtheria-antitoxin. Laborious investigations were made to determine the cause of the changes in alkalinity. It seems that the increase in alkalinity is brought about chiefly through organic substances, which are increased in the blood during immunization and antitoxin-treatment, and diminished in consequence of infection or the introduction of toxins. The organic substance raising the alkalinity is not furnished by the injected fluid, nor is it produced by any chemie transformation of the latter, for the degree of alkalinity bears no regular relation to the quantity of fluid introduced. Everything seems to point to the theory that the injections act as *specific excitants* of a vital reaction in the body, in response to which the body—*i. e.*, the leukocytes—produces specific substances with bactericidal and antitoxic properties. This reaction of the body Fodor terms *cytochemism*. The variations in alkalinity after injections, etc., are a sign and even a measure of this vital reaction. Whether the alkaline substance found in the animal after immunization and antitoxin treatment is identical with that which protects an infected animal against infection or toxin, and, if so, how the substance is formed, are questions that must be solved in the future. [The careful researches of Fodor and Rigler must impress every one as deserving weighty consideration; they serve to confirm the observations of Calabrese (*Year-Book*, 1897, p. 727). The authors do not distinctly state that the organic substance upon the presence of which the variations in alkalinity are said to depend is also the protective substance, though it seems to us as if their leanings were in that direction. Whatever the outcome of future investigations may be, they have shown by their experiments that the alkalinity is an index of the state of the battle of the organism against infection. Perhaps this fact may in time be utilized by the clinician.]

The Role of Iron in the Phenomena of Motion and Degeneration in Cells and in the Bactericidal Action of Immune Serum.

—In a somewhat obscure and highly theoretic preliminary communication N. Sacharoff¹ propounds the hypothesis that the bactericidal action of the serum of immunized animals is conditioned on a combination of the substance of the microorganisms with an iron-containing body, which by transmitting oxygen kills the bacteria. This hypothesis he bases (1) on the fact discovered by Metschnikoff and Bordet, that the formation of the bactericidal substance takes place in the protoplasm of the neutrophile leukocytes; (2) on the transformation of bacteria englobed by leukocytes into an eosinophile substance before their destruction, this substance containing iron which serves as a mordant for eosin; and (3) the fact, discovered by him, that the granulations of the neutrophile leukocytes contain iron. An attempt to prove this hypothesis by chemie means failed, so the author had recourse to histologic studies. The basis of these was an artificial vacuolization by which important facts in cellular biology have revealed themselves to the author. To produce vacuolization in the cells of the blood he employs a concentrated solution of picric acid in absolute alcohol. Under the influence of this reagent the red corpuscles become

¹ Centralbl. f. Bakteriol., Parasitenk. u. Infektionskrank., Mar. 5, 1897.

vacuolated, and bodies resembling blood-plates appear in the vacuoles. In thick parts of the blood-film dark or black bodies are seen that gradually assume a crystalline form. The bodies and crystals are the pierate of hematin or of a hematin-like body. As the nuclei of erythrocytes and hematoblasts and the eosinophile granulations also become vacuolated under the same conditions as the red cells, the author infers that this is likewise produced by the splitting off of hematin contained in these cells. The same thing is true of the neutrophile granulations. The hematin in all these cells is united with a larger or smaller quantity of proteid bodies. The molecule of nuclein in the granulations has, it may be inferred, the property of splitting up in various ways, a fact of great significance for the theory of immunity. As proteids are not capable of direct oxidation, chemists have assumed the existence of a living proteid. This latter, the author believes, is identical with the iron-containing paranuclein-substance of the blood and the tissue-cells. Upon the molecular attraction of the iron-containing granulations for oxygen depends the motility of leukocytes, as probably also that of muscles, spermatozoa, bacterial cilia, pulsating infusorial vacuoles, centrosomes, etc. Degeneration of bacteria (as of other cells) is due to the too rapid transformation of the nuclein of the microorganisms into the iron-containing paranuclein-granules, and the further oxidation and destruction of the latter. The author has shown that the nucleoli (metachromatic bodies) of bacteria contain iron. The degeneration of cholera-vibrios in the bodies of leukocytes is explained on the theory that the iron in the cells unites with the nuclein of the bacteria. In the decomposition of the paranuclein of the leukocytes a simpler substance is formed which resembles the bactericidal substance. The author considers the iron-containing body split off from the paranuclein and acting on the microorganisms the bactericidal substance. In the mode of formation of this substance, which must be different for each species of bacteria, he sees the cause of the specific action of immune serums. Many facts show that the bactericidal substance passes out of the leukocytes into the serum, where it collects in the immunizing process. It probably consists of two parts: an iron-containing and an iron-free body; the former undergoes destruction in the union of the bactericidal substance with the microorganisms. The presence of dissolved paranuclein in very fresh serum proves that this substance can also be formed outside of the leukocytes. This fact serves to reconcile the views of Metschnikoff and his opponents. The action of fresh cholera-serum on cholera-vibrios (in Pfeiffer's phenomenon) is brought about by the same iron-containing substance as that which destroys the intracellular vibrios. The specificity of action of the agglutinating substance is explained by the meeting of two substances which only have the ability to unite and agglutinate when their chemie composition is similar. One of these substances is the bacterial protoplasm (formed by the paranuclein-bodies of the bacteria), the other is the agglutinin, which is the iron-free element of the bactericidal substance. The agglutinin itself is incapable of destroying the bacteria; for that purpose it must be conjoined with the iron-containing part of the paranuclein.

The Presence of Bactericidal Substances in Leukocytes.—Schattenfroh¹ has made some experiments with the purpose of proving Buchner's theory that the alexins are products of the leukocytes. By means of the injection first of aleuronat-suspension and then of physiologic salt-solution he obtained an exudate very rich in leukocytes. The repeatedly frozen and thawed exudate possessed an extraordinary bactericidal power, which greatly

¹ Münch. med. Woch., No. 1, 1897; Centralbl. f. Bakteriol., Parasitenk. u. Infektionskrank., Mar. 30, 1897.

surpassed that of the unfrozen exudate. The bactericidal substances obtained had almost no influence on cholera-vibrios, but acted energetically on staphylococcus pyogenes aureus and bacterium coli. If coagulation occurred in the exudate, it was less active than that free from cells. The author believes in that case more nutritive and less bactericidal substances are extracted.

The Action of Antitoxins.—Ehrlich,¹ by means of an interesting experiment, shows that a toxalbumin can be neutralized by its antitoxin, without any participation of cell-activity. Ricin, it has been shown, produces in the extravascular blood as well as in the living animal a peculiar coagulation, in which the red corpuscles agglomerate and are thrown down. Ehrlich filled 6 test-tubes with 10 c.c. of a mixture of 95 c.c. normal saline solution, to which 0.5% sodium citrate and 5 c.c. of rabbit's blood had been added. One c.c. of a 2% ricin solution promptly precipitated the corpuscles from this mixture. Ehrlich now treated 1 c.c. of the ricin solution with 0.3, 0.5, 0.75, 1.0, and 1.25 c.c. of antiricin-serum diluted one-half. Test I. behaved like the control-tube; with 0.5 and 0.75 c.c. of serum the coagulation was retarded, and was incomplete with 0.75 c.c. With 1.0 c.c. only a trace of coagulation showed itself. The same ricin and antiricin mixtures were now used for animal-experiments. Six mice were inoculated with 0.4, 0.5, 0.6, 0.7, and 0.8 c.c., respectively, of the 6 mixtures. Mouse I. died in 18 hours; mouse II. in 30 hours; mouse III. showed moderate infiltration; the others remained healthy. The animal-experiment thus confirmed the conclusions drawn from the test-tube experiment—namely, that, as far as ricin is concerned, toxin and antitoxin influence each other by direct chemie action.

Influence of Nerve-section on Local Resistance.—Charrin and Nittis² found that when they cut the sciatic nerve of a rabbit on one side, and immunized the animal with antiproteus-serum, and then inoculated the same quantity of a proteus-culture into each hind foot, the abscess attained a larger size in the foot deprived of nervous influence than in the other, or, if the immunity was high, developed only in the former foot.

The Influence of Acute Alcoholism on the Normal Vital Resistance of Rabbits to Infection.—A. C. Abbott³ was entrusted by the Committee of Fifty to Investigate the Alcohol Question with the investigation of the influence of acute and chronic alcoholism on resistance. His conclusions as to the influence of acute alcoholism are as follows: The normal vital resistance of rabbits to infection by streptococcus pyogenes (erysipelas) is markedly diminished through the influence of alcohol when given daily to the stage of acute intoxication. A similar, though by no means so conspicuous, diminution of resistance to infection and intoxication by the bacillus coli communis also occurs in rabbits subjected to the same influences. While in alcoholized rabbits inoculated in various ways with staphylococcus pyogenes aureus individual instances of lowered resistance were observed, still it is impossible to say from these experiments that in general a marked difference is noticed between alcoholized and nonalcoholized animals as regards infection by this particular organism. It is interesting to note that the results of inoculation of alcoholized rabbits with the erysipelas-coccus corresponded in a way with clinical observations on human beings addicted to the excessive use of alcohol when infected by this organism. In the course of the work an effort was made to determine if, through the oxidation of alcohol in the tissues to acids of the corresponding chemie group, the increase of susceptibility could be referred

¹ Fortschr. d. Med., xv., No. 21, 1897; Centrabl. f. Bakteriol., Parasitenk. u. Infektionskrankh., Mar. 30, 1897.

² Sem. méd., Jan. 13, 1897.

³ Jour. Exper. Med., July, 1896.

to the diminution in the alkalinity of the blood as a result of the presence of such acids. The number of experiments thus far made on this point is too small to justify dogmatic statements, but from what has been gathered there is but little evidence in support of this view. Throughout these experiments, with few exceptions, it was seen that the alcoholized animals not only showed the effects of the inoculations earlier than did the nonalcoholized rabbits, but in the case of the streptococcus-inoculations the lesions produced (formation of miliary abscesses) were much more pronounced than are those that usually follow inoculation with this organism. With regard to the predisposing influence of the alcohol, one is constrained to believe that it is in most cases the result of structural alterations consequent upon its direct action on the tissues, though in a number of the animals no such alteration could be made out by macroscopic examination. The author believes, however, that closer study of the lesions of the animals would have revealed important structural changes. [An interesting result of these experiments is the fact that rabbits bear really enormous quantities of pure ethylic alcohol—7.5 to 10 c.c.; equivalent doses for a man of 150 pounds would be represented by from $\frac{2}{3}$ to $\frac{5}{6}$ of a pint of absolute alcohol.]

Immunization against Typhoid Fever.—Pfeiffer and Kolle¹ injected typhoid-culture, sterilized at 56° C. (1 dose agar-culture in 1 c.c. bouillon) under the skin of the back of persons that never had had typhoid fever. Within 2 or 3 hours chilliness, vertigo, malaise, and pain at the point of inoculation set in, and the temperature rose by evening to 38.5° C. All phenomena subsided on the following day. The blood obtained by cups on the 11th day showed features which it did not possess before the inoculation. The serum presented the same degree of bactericidal properties as that of typhoid convalescents. The authors hope that their method may be made applicable in typhoid epidemics, especially among armies in the field.

Immunity to Hog-cholera.—E. A. de Schweinitz² has succeeded in conferring immunity against hog-cholera upon guinea-pigs by injecting them with serum from an immune hog. He also noted the fact observed in some other diseases that an animal may remain immune to hog-cholera while its serum has lost the power of conferring immunity upon other animals. The author also found that swine-plague serum had no protective power against hog-cholera, nor hog-cholera serum against swine-plague infection.

Toxins and Electricity.—Marmier³ has repeated the experiments of Smirnow and of d'Arsonval and Charrin of producing antitoxins from toxins by means of the electric current, but failed entirely to confirm them. Smirnow's method of electrolysis with weak currents does produce a destruction of toxin, but the formation of antitoxin is only apparent, for during electrolysis hypochloric salts are formed which, as Martin's not yet published results show, have a certain degree of curative action in diphtheria.

Antistreptococcic Serum.—Merieux and Miemann⁴ tested three specimens of antistreptococcic serum and found "Lyon-Vaise" the strongest. Bornemann⁵ likewise made experiments with various brands of antistreptococcic serum, including one of his own. The results were not at all satisfactory, and Petruschky,⁶ in reviewing both of these papers, remarks that they do not offer any grounds for applying the serum in the treatment of disease in man.

⁶ Centralbl. f. Bakteriol., Parasitenk. u. Infektionskrank., Mar. 30, 1896.

He thinks that there is as yet no positive proof of the production of a specific transmissible immunity to streptococic infection.

The Production of Streptococcus-antitoxin by means of Electricity.—Bonome and Viola¹ have succeeded in converting virulent streptococic toxin into antitoxin by means of the alternating electric current.

Cholera Immunity.—Kolle² has immunized 3 persons by Haffkine's method: first, $\frac{1}{12}$ of a 24-hour agar-culture killed with chloroform, in 5 days the same quantity of living culture, and 5 days later $\frac{1}{8}$ culture, injected into the back. Eleven persons received only $\frac{1}{10}$ dead agar-culture; finally, he inoculated 3 persons with $\frac{1}{10}$ dead culture that had been preserved four weeks. In all cases a painful infiltration and fever ensued.

The results were confirmatory of Haffkine's experiences that immunity sets in about the 5th day after the injection, reaches its height on the 20th, and then diminishes, although it is still demonstrable for a year afterward. He, furthermore, corroborated his own previous assertion that the blood of immune persons contains bactericidal but not antitoxic substances. An important fact brought out by Kolle is that dead cultures give just as good results as living cultures, and are, of course, considerably safer.

Antibodies in Milk.—Rudolf Kraus³ found that the milk of goats immunized to typhoid, cholera, or colon-bacillus, produced Pfeiffer's phenomenon when injected into the peritoneum of guinea-pigs, together with the typhoid, cholera, or colon-bacillus, and also caused agglutination of the organisms on the concave slide or in the test-tube. In regard to the cholera-goat the relation of the strength of the serum to that of the milk was as 10:1, and resembled that found by Ehrlich and Wassermann for the antitoxins of serum and milk. It appears then that the excretion of antibodies in milk is analogous to the excretion of antitoxins.

Antivenomous Serum.—A. Calmette⁴ showed before the Conjoint Board of the Royal College of Physicians (London) and Surgeons (England) the efficacy of antivenomous serum in protecting animals against venom, and curing them when injected in time after the administration of the venom.

Limitations of Antitoxins.—T. R. Fraser⁵ calls attention to the limitations to the antidotal power of antitoxins, in particular of antivenene, believing that an estimation of this power by experiments *in vitro* will lead to fallacious conceptions. He also reiterates his theories of the mode of action (chemic antidote) and the origin of antivenene (from the venom itself, in part, at least, being normally one of its constituents). Calmette⁶ takes issue with Fraser, and is of the opinion that antivenene is a physiologic antidote rendering the body-cells immune, and that it is not produced from venom.

Death from Antitoxin.—The sudden and sad death of Prof. Langerhans' son after an injection of antitoxin has given rise to considerable polemic literature. Prof. Strassmann, who, at the request of the State, made the autopsy, came to the conclusion⁷ that death probably took place from inspiration of food during an act of vomiting. Prof. Langerhans⁸ vehemently opposes this view, and contends that death was due to poisonous effects produced by the antitoxin, which, as Bischoff, Ehrlich, and Strassmann have shown, was normal.

Cause of Death from Serum-injections.—Chas. T. McClintock⁹

does not believe that the injection of air in hypodermic medication, as in serum-injections, is responsible for some of the sudden deaths recorded, but would class the phenomena observed, varying from slight faintness to death, as shock.

Contribution to the Theory of Agglutination.—E. Levy and H. Bruns¹ have studied bacterial agglutination, comparing the observations of Gruber, Durham, Pfeiffer, and Kolle, and others. They noted the phenomenon in connection with the cholera, typhoid, colon, and pyocyaneus bacillus, and also with proteus. In all these cases the animals yielding the serum had been treated with dead cultures of the bacteria. The authors now hit upon the thought that it might be possible to endow the serum with agglutinating properties by injecting the soluble metabolic products of the bacteria, although Gruber, the discoverer of the *agglutinins*, had held that these, the agglutinins, were formed from the constituents of the bacterial bodies. Levy and Bruns injected filtered cultures of typhoid and cholera into rabbits, and, indeed, found that the serum developed typical agglutinating power. It was also observed that this did not occur immediately, but that several days ($3\frac{1}{2}$ –5) were required. Then, however, it seemed as if the reaction appeared all at once.

Widal² is of the opinion that the agglutinating property of blood-serum is not a protective phenomenon of the organism.

Transmission of the Agglutinating Substance by the Breast-milk.—Widal and Sicard³ found that mice, the serum of which they had endowed with the agglutinating property, transmitted it to their young, while guinea-pigs and cats did not. The ingestion of strongly agglutinating goat's milk by man does not transmit the reaction to the blood. These differences in the transmissibility of the agglutinating substance by way of the digestive tract is at present not explicable. The authors are not prepared to discuss the hypothesis of the digestive chemism, but recall the fact that agglutinating milk coagulated naturally or by the action of an acid, such as acetic or hydrochloric acid, loses only a small part of its agglutinating power.

Serum-diagnosis by Means of Dried Blood-samples in (experimental) Cholera.—Wyatt Johnson and E. W. Hammond⁴ obtained Pfeiffer's reaction with the dried blood of animals $3\frac{1}{2}$ days after infection with virulent cholera-culture.

The Agglutinating Property of the Blood-Plasma.—Achard and Bensaude⁵ have undertaken a series of experiments which are designed to show whether the agglutinating property of the blood is dependent upon the blood-corpuscles, or whether it is a characteristic of the blood-plasma. They have shown that blood-plasma which has been deprived of all formed elements possesses the agglutinating power perfectly. They have also shown that the presence of very large numbers of white and red corpuscles does not increase the agglutinating power of the plasma to an appreciable degree. They have concluded that living leukocytes which have been separated from the primitive plasma do not retain the agglutinating property. They think that the differences in the agglutinating property of the different fluids of the body are not to be accounted for by the presence of white corpuscles; but rather are dependent upon the elective action of the living membranes—glandular epithelia in particular—which are concerned in the transudation of the agglutinating substances. Their experiments have also shown that the blood always contains the largest quantity of the agglutinating substances, and that the agglutinating substances are preserved for the longest time in the blood.

⁴ N. Y. Med. Jour., Nov. 28, 1896. ⁵ Arch. de Méd. expér. et d'Anat. path., Nov., 1896.

Distribution of the Agglutinating Substance in the Body of Typhoid-fever Patients.—Courmont¹ has examined the comparative agglutinating power of the blood of the general circulation and of that from various organs in 7 autopsies on cases of typhoid fever. In 3 cases an exact quantitative estimation was made. While the blood of the heart, of the lung, of the kidney, of the thyroid gland, and of the ovary exhibited a very marked agglutinating action, like that of the blood during life, the blood of the liver and spleen, the bile, and the juice of the mesenteric glands gave a reaction, on an average, ten times less intense; in some cases it was entirely absent. The liquid of serous cavities produced an intense reaction, most frequently when there was an acute effusion due to the presence of another micro-organism. This is not true of pleural effusions due to the typhoid-bacillus (Ménétrier).

TECHNIC.

Preservation of Museum-specimens.—T. L. Webb² recommends the following method of preserving gross specimens for museum-purposes:

1. Soak the object in Jores' fluid for from 1 to 3 days, the fluid being changed once or twice. 2. Wash specimen in 95% alcohol; Webb places it in methylated spirit for half an hour. 3. Place in alcohol and leave there until the normal color returns, but no longer. Here, too, he uses methylated alcohol. 4. Preserve in glycerin and water, equal parts. It is well to change this fluid once after about a week's immersion. Jores' fluid is prepared by Webb as follows: sodium chlorid, 5ss; sodium sulfate, ʒij; magnesium sulfate, ʒij; water, ʒl. These are mixed, and from ʒij to ʒv of formalin added.

Conservation of Gross Morbid Specimens in their Natural Colors.—C. Kaiserling³ places the organ in an abundant quantity of a solution of: formalin, 750 c.c., distilled water, 1000 c.c., potassium nitrate, 10 gm., and potassium acetate, 30 gm. In 24 or 48 hours the specimen is transferred, after allowing the solution to drip off, to 80% alcohol, when the original color will reappear. After 12 hours it is placed for 2 hours in 95% alcohol, and finally conserved in a mixture of equal parts of water and glycerin, with the addition of 30 parts of potassium acetate. Delicate objects, as intestine, remain in this only 1 or 2 days, and are then transferred to equal parts of glycerin and water plus absolute alcohol (1:10).

The Preparation of Anatomic Specimens by the Formalin-alcohol-glycerin-potassium-acetate Method.—Melnikow-Raswedenkow⁴ gives the details of a method, already published in abstract, by which anatomic preparations can be preserved in their natural color. The specimens are treated first with formalin, then with alcohol, and finally with glycerin and potassium acetate. The author has devised the following schema of his method:

STEP I.—*Fixation of Specimen; Change of Color.*—(1) *Dry Method.*—Cotton saturated with undiluted formalin.

(2) *Moist Method.*—Cotton soaked in 10% formalin with the addition of—
(a) Gases: (1) H₂O₂; (2) H₂S. (b) Reducing-substances: (1) hydrochinon; (2) hydroxylamin; (3) pyrocatechin. (c) Reagents rich in oxygen—*e. g.*, potassium chlorate. (d) Acetates: (1) potassium acetate; (2) sodium acetate; (3) aluminum acetate; (4) ammonium acetate; (5) calcium acetate; (6) magnesium acetate; (7) strontium acetate; (8) nickel acetate; (9) barium acetate; (10) manganese acetate. (e) Various combinations of reagents of groups b and c

¹ Sem. méd., Feb. 24, 1897.

² Berlin. klin. Woch., Aug. 31, 1896.

³ Centralbl. f. allg. Path. u. path. Anat., Feb. 10, 1897.

⁴ Birmingham Med. Rev., June, 1897.

with those of group *d*; the best is—sodium acetate, 4% ; potassium chlorate, 0.5%.

STEP II.—Restoration of color by means of alcohol, 50%, 75%, and 95%.

STEP III.—Preservation of color in glycerin containing an acetate. Small organs or pieces of organs are immersed in the fixing-solution and then into alcohol; in the case of large organs injection first of a fixing-solution, then of alcohol, is recommended.

Explanation of the Schema.—The organ, without previous washing in water, is laid on cotton saturated with pure formalin. This method is especially valuable when it is desired to preserve mineral or mineral-like deposits,—*e. g.*, uric-acid infarcts of the kidney. The specimens preserve an almost natural color for more than a year. In the moist method cotton is saturated with 10% formalin containing any one of the reagents under *a*, *b*, *c*, or *d*, and is then wrapped completely around the specimen. When 10% formalin, with 3% sodium acetate and 0.5% potassium chlorate, is employed, about 48 hours are required for fixation. In the second step the cotton already used is squeezed out, and then weak alcohol, 60%, poured on. After 3 or 4 days alcohol of about 80% is substituted, and at the end of a week the strength is raised to 95%. Afterward the specimen is transferred to a conserving solution (glycerin, 20; potassium acetate, 15; distilled water, 100), in which it can remain perpetually. All the fluids employed in this method can be used a second time.

At the conclusion of his paper the author offers an explanation of the mode of action of his method, which, however, it is not necessary to reproduce here.

Preparation of Frozen Sections by Means of Methyl and Ethyl Chlorid.—H. W. Cattell¹ recommends a very simple method of preparing frozen sections. The tissue, prepared by Hamilton's,² Orth's,³ or Plenge's⁴ method, is placed with some formol and gum acacia fluid upon the specimen-holder of the microtome, and a small stream of ethyl chlorid, methyl chlorid, or anesthetic (a mixture of these two agents), is played from above directly upon the specimen. The tube containing the ethyl chlorid is held about a foot from the specimen, and moved from place to place until the specimen is firmly attached to its base of support, and the upper portion is coated with a few crystals of ice. These crystals are extremely small and delicate, and, therefore, do not injure the tissue so markedly as in some other of the freezing-methods. The specimen is readily frozen in from thirty seconds to a minute. Sections are then cut and placed in water or 50% alcohol, and mounted in the usual way. Excellent stained preparations may be prepared in 15 minutes or less from the time that the tissue is removed from the body.

A Rapid Method of Preparing Permanent Sections for Microscopic Diagnosis.—L. Pick⁵ recommends the following method: the excised or everted material is freed from blood and coagula by dipping in water and then brought directly on to the freezing-plate of the microtome and frozen. In order that the freezing should be rapid and not too severe it is important that the mass be laid flat, and be not thicker than 2 or 3 mm. The breadth is immaterial up to 1 cm. square, or even greater. The ice block so obtained in a few seconds must be merely firm, not stone-hard; the knife must cut through lightly and without grating. Particles from curettage may be laid on the plate, a half dozen or more at once, and sections obtained from all at one time. The sections as they are cut are wiped from the knife-blade by the finger-tip, floated onto a 4% aqueous formalin-solution, and left there

¹ Internat. Med. Mag., Dec., 1896.

² Text-Book of Pathology, vol. i., p. 58.

³ Berlin. klin. Woch., No. 13, 1896.

⁴ Virchow's Archiv, cxliv., p. 409.

⁵ Brit. Med. Jour., Jan. 16, 1897.

4 minutes to harden and fix the cell-plasma and intercellular substance. The use of the finger in place of a brush is to allow the warmth of the former to thaw the section before it reaches the solution, avoiding in this way the formation of air-bubbles in the tissue, which are often very annoying. From the formalin-solution the section is carried directly into a 4% alum-carmin solution (4 gm. carmin boiled three-quarters of an hour in 100 gm. 5% aqueous alum-solution, cooled, filtered), and left from 3 to 5 minutes, staining a deep red. For transporting the sections from one liquid to another up to absolute alcohol a glass rod is used, about which the section is rolled, obtaining a flat and even specimen much more quickly and conveniently than with a spatula. The section taken from the carmin-solution is rinsed in pure water to remove the superfluous stain, using the glass rod as before, and then dehydrated by bringing it for 15 seconds each into 80% alcohol and absolute alcohol. Finally it is placed in xylol-carbol to clarify, and mounted and conserved in Canada balsam. The microtome employed is the Jung-Heidelberg Hobel (carpenter's plane).

The Preparation of Blood for Microscopic Examination.—Henry G. Piffard¹ lays down a number of rules dealing with some important points in technic for the guidance of hematologists. He prefers the Zeiss glass slide 76x26 mm.; in cover-glasses he condemns emphatically the square variety, by means of which, he thinks, good smears cannot be obtained. Cover-glasses should be tested as to thickness, and only those approaching 0.17 mm. should be employed. He advises battery-fluid (water, 9 oz.; potassium bichromate, 1 oz.; sulphuric acid, 1 oz.) for purposes of cleansing. The cover-glasses are left in this 24 hours, then rinsed in water, then placed in distilled water, and from this transferred to pure methylic alcohol, where they are kept until needed. A straight surgical needle (the author uses one made of an alloy of iridium and platinum) should be employed for making the puncture. The cover-glasses are held in forceps; one of these should be of the self-closing variety, the other any sort that will hold the cover nicely. Heating is preferred as a method of fixation, the author employing an electric heater controlled by a rheostat. The ordinary staining-methods are recommended, especially eosin and methylen-blue. The author prefers to examine the cover-glasses mounted dry, and prepares his permanent preparation, not with balsam, which he cannot condemn strongly enough, but by placing the covers in a ring of cement. A few words as to choice of condenser conclude the paper. [We are glad that there is a medical man in the United States who is not averse to dealing with the difficult mechanical problems of optics, but cannot follow him in all the innovations he suggests. For routine-work mounting with cement and by means of a turning-table is too time-consuming, and it is not likely that the convenient balsam-method will be abandoned.]

In another communication, Piffard² gives some valuable suggestions as to stains and technic. In the first place, he recommends oil of cinnamon (cassia) as superior to balsam; still better is his naphthalin-amber (see *Year-Book*, 1896, p. 973). He also points out a common error, viz., the use of the word methyl-blue when methylen-blue is intended; the former is an acid, the latter a basic stain. He is partial to thionin as a nuclear stain; in this we fully agree with him. As to eosin, only that soluble in alcohol should be used. He also recommends Grübler's neutral red as a beautiful basic and nuclear stain. [We have found a combination of eosin and thionin to give the most beautiful results. Thionin is especially useful for staining Ehrlich's mastzellen. The best effects are obtained when the section is first stained in a strong solution of eosin, and then, after washing in water, is placed in thionin.]

¹ Med. Rec., Oct. 17, 1896.

² Med. Rec., Feb. 13, 1897.

A Method of Fixing and Staining Blood.—G. Lovell Gulland¹ recommends a new method of fixing and staining blood-films. In its most rapid form the process is as follows: a small drop of blood, drawn in the usual way, is taken up on the center of a cover-glass held with forceps, and distributed evenly between that and another cover. The utmost care must be taken to avoid all pressure, as the after-appearance of the red corpuscles depends almost entirely upon the way in which this maneuver is carried out. The covers are then gently and rapidly slid off one another, and dropped with the wet side downward into the fixing-solution. This is made up of: absolute alcohol saturated with eosin, 25 c.c.; pure ether, 25 c.c.; sublimate in absolute alcohol (2 gm. to 10 c.c.), 5 drops (more or less). The quantity required for use at one time, which may be 5 to 10 c.c. for 4 cover-glasses, should be poured into a wide-mouthed bottle or flat dish, and may be used several times over if it be preserved from evaporation. The fixation of the elements is practically instantaneous, but the cover-glasses should be allowed to remain in the solution for at least 3 or 4 minutes, to fix the film to the cover. They are then taken from the solution with forceps (steel forceps will do), and washed rapidly but thoroughly by waving them to and fro in a small basin of water. They are then stained for 1 minute (not longer) in a saturated watery solution of methylen-blue, and again rapidly washed in water. Next they are quickly dehydrated in absolute alcohol, which at the same time removes the excess of methylen-blue, cleared in xylol, and mounted in xylol-balsam on a slide. The method is no less useful for fixing pus, sputum, and anything else which can be spread in a film; only with these it is generally advisable to prolong the fixation.

Yolk of Egg as an Addition to Culture-media.—A. Capaldi² finds the addition of yolk of egg to culture-media of great value. A fresh egg is broken, the white allowed to escape, and the yolk with the adherent white placed in a sterile Petri dish. In order to get rid of any bacteria on the outside of the yolk (the yolk itself is always sterile), it is burnt at one point with a glass rod. With a platinum needle the charred part is removed and 3 or 4 drops of the yolk are added to the agar, which has previously been melted and allowed to cool to 45° or 47° C. Plates are then prepared, or the agar is allowed to solidify in the tubes. The medium may be used for diphtheria-bacilli, which grow upon it as rapidly and as well as on blood-serum; and the tubercle-bacillus does this also. The yolk may be added to bouillon; in such yolk-bouillon the diphtheria-bacillus produces a stronger toxin than in ordinary bouillon.

A New Method of Staining Bacteria, especially the Gonococcus.—L. Pick and J. Jacobson³ recommend the use of a mixture of two basic dyes. The combinations that can be employed are numerous. For the gonococcus they suggest the following method: 1. Spread pus on cover-glass or slide, and dry. 2. Pass thrice through flame. 3. Stain at the most for from 8 to 10 seconds with distilled water 20 drops, carbol-fuchsin 15 drops, concentrated alcoholic solution of methylen-blue 8 drops. 4. Rinse in water; dry. 5. Mount in Canada balsam.

Culture of Amebæ.—O. Casagrandi and P. Barbagallo⁴ were unable to obtain pure cultures in liquid media. Of solid media, egg-albumin, well sterilized by Tyndal's method, mixed with peptone, and alkalized with

¹ Brit. Med. Jour., Mar. 13, 1897.

² Centralbl. f. Bakteriöl., Parasitenk. u. Infektionskrank., xx., Nos. 22 and 23, 1896.

³ Berlin. klin. Woch., Sept. 7, 1896.

⁴ Centralbl. f. Bakteriöl., Parasitenk. u. Infektionskrank., May 10, 1897.

sodium carbonate, is a very efficient medium. Agar is not reliable; much better is *Fuscus crispus* (5%) of Celli and Fioca (see *Year-Book*, 1897, p. 738). With respect to the reaction of the medium, amebæ can live in an alkaline as well as in a neutral medium, but they can also adapt themselves to an acid reaction. Of interest are the authors' observations on the presence of organized substances. They find (*a*) that protozoa are not necessary for the propagation of amebæ; the two can live side by side in cultures without the one swallowing the other, although parasitic amebæ have the habit of ingesting trichomonads, etc. (*b*) Bacteria are also not necessary, though by some authors a symbiosis of the two has been assumed. The authors hold that the ameba coli is only a commensal in the human bowel, and has nothing to do with the production of catarrhal affections, the latter being caused by bacteria. (*c*) Fungi and (*d*) blastomycetes are likewise contaminations, and are not essential to the growth of amebæ in culture-media. The authors divide amebæ into cultivatable and noncultivatable forms. Those living free—*i. e.*, nonparasitic—are cultivatable; all parasitic amebæ found in feces and all those not possessing a contractile vacuole or a multinuclear cyst are noncultivatable.

MISCELLANEOUS.

The Role of the Vessels and the Parenchyma in Inflammation.

—In a masterly address delivered at the Twelfth International Congress, at Moscow, on the "Role of the Vessels and the Parenchyma in Inflammation," Virchow¹ sums up as follows: 1. Inflammation, as at present definable, is not a uniform process with constant characteristics. 2. According to their nature, four varieties of inflammation are distinguishable: the exudative, the infiltrative, the parenchymatous, and the proliferative. Each of these furnishes different products. 3. The necessity to group these under one name is less a scientific than a practical and diagnostic one. It is the desire to distinguish the inflammatory infiltrates, exudates, metamorphoses, and new formations, from the noninflammatory. 4. The diagnostic interest is heightened by therapeutics, inasmuch as the different varieties of inflammation demand a certain uniformity of treatment. 5. The condition of the vessels and of the local circulation presents not inconsiderable differences in the various forms of inflammation. While the inflammatory hyperemia appears as a prime factor in exudative and infiltrative inflammations, it occupies only a secondary part in the metamorphosing and proliferating forms. 6. The conditions of the parenchyma are no less varied. The exudative inflammations produce the least, the proliferative and metamorphosing the greatest alterations. The infiltrations are similar to the exudations. There is, however, no inflammation in which the parenchyma is entirely unaffected. In some cases the participation is chiefly passive; as an example may be mentioned the greater friability of the lung-tissue in exudative pneumonia (hepatization) and the destructive action of many infiltrations. In other cases, as in the secretion of mucus, the parenchyma furnishes the chief part of the exudate. 7. The common character, in the narrower sense, of inflammatory changes in the vessels and in the parenchyma consists in that the cause of the changes in each case is to be found in an irritation which evokes certain activities (actions, reactions). The primary consideration in diagnosis, therefore, is whether the process is really irritative. 8. The irritation involves both the nerves and the vessels, and the specific as well as the nonspecific parenchyma. It varies with the constitution of the irritated parts and the nature of the acting irritant. The irritants are at times

¹ *Centralbl. f. allg. Path. u. path. Anat.*, Oct. 15, 1897.

mechanic, more often chemie in nature. The irritative action of many bacteria depends likewise on chemie products. 9. The not improper comparison of inflammations with fever, which is based on the temperature-rise in the external parts, is not valid for inflammation as a whole, but only for the increased fluxion to the inflamed part, in as far as such a comparison is possible. Indeed, it can be said that the modern opposition against the essentiality of fever is in line with that, as yet poorly developed, against the unity of inflammation. There are febrile diseases and inflammatory diseases, but neither fever nor inflammation has a separate existence. [Despite the stupendous labors expended on the investigation of the process of inflammation, it is evident, and is clearly pointed out by the Nestor of pathologists, that no comprehensive definition can be framed. It is particularly the so-called parenchymatous inflammations that are stumbling-blocks, for it is often next to impossible to say to what extent the parenchyma-changes are part of the inflammatory process, and to what extent they are purely degenerative. In the kidney, especially, does this question confront us often.]

Inflammation.—Paul Grawitz,¹ whose views as to the origin of the cells in inflammation have not met with general acceptance, endeavors in the present essay to answer his opponents by an appeal to biologic data. He denies, in the first place, *in toto*, the leukocytic nature of the cells—*i. e.*, their derivation from the blood—claiming that there is no observation on record sustaining the Cohnheimian view. As for the proliferation-theory of Virchow, he is willing to let it stand, but cannot consider it the only source of the cell-accumulation. His own view, “the Schlummerzellen-theory,” is that the cells originate from cell-particles and from the intercellular substance. He combats the teachings of Senftleben and Leber, who interpreted the cells found in supposedly dead cornea introduced into the tissues as immigrated cells. In the first place, he shows that the corneal tissue employed was not dead, for (a) the removal of the cornea from an animal dead for several days, or (b) the heating to 80° C. for $\frac{1}{4}$ hour, or (c) the drying of the tissue, is not sufficient to kill it, so that under favorable conditions it is incapable of manifesting certain signs of life. If such pieces of cornea are introduced, *e. g.*, into the lymph-sac of a frog, they will become pervaded by wandering-cells, which, however, are not immigrated cells, but are derived from the still-living corneal tissue. This is proved by the fact that in absolutely dead cornea (killed by heating to 52° or 55° C. or by immersion in sublimate solution) no wandering-cells are found when it has been kept in a frog’s lymph-sac. The corneal wandering-cells are readily distinguished from the adhering lymph-cells of the frog by the fact that the former take the gold stain, the latter not. Pieces of cornea from a hare, removed 10 or 12 days after death, and kept 1 day in the lymph-sac, still showed gold-staining wandering-cells, although mould had already formed on the corneal surface. All wandering-cells found in a transplanted recuperable cornea originate from the living tissue itself; their formation is intimately connected with the preservation of vitality, and ceases at a degree of temperature which by no means corresponds to the coagulating-point of albumin, and also disappears under the influence of sublimate and similar noxious agents which kill the protoplasm. Arguments are also brought forth to show that the usual evidence relied upon to prove that the intercellular substance is dead, is fallacious. Whether the newly formed cells arise solely from cell-particles or from the matrix, must be left to the future to decide. [Grawitz’s experiments admit, it seems to us, of other interpretations than those he has given.]

Is there a Fatty Degeneration?—Rosenfeld² has tried to solve in an

¹ Wien. med. Woch., Jan. 23, 1897.

² Centralbl. f. innere Med., June 26, 1897.

interesting manner the question whether there is such a thing as fatty degeneration, and has arrived at the conclusion that there is no such process. The differentiation of fatty processes into two—infiltration and degeneration—was based on the hypothesis of the origin of fat from albumin, which hypothesis, the author tells us, has been disproved by Pflüger. He (Rosenfeld) has investigated many of the conditions in which fat is apparently formed from albumin, as the fatty liver of phloridzin- and phosphorus-poisoning, and the formation of milk. In fasting animals receiving phloridzin fat to the amount of 75% is stored in the liver. But this fat cannot be derived from the albumins of the hepatic cells, for the quantity of albumin in the liver is not materially diminished. The fat has been carried from the “fat-depots” to the liver, as may be observed in dogs that, having through long starvation become devoid of fat, are then fed with a foreign fat—*e. g.*, sheep-tallow. When such sheep-tallow dogs are given phloridzin the sheep-fat is carried from the subcutaneous tissue to the liver, in which nearly 50% of such fat may then be found. In phosphorus-poisoning the fat is also only infiltrated, for in totally fat-free animals phosphorus-poisoning is not able to produce fatty liver, because the fat-depots are empty. If the fat originated from albumin, it is difficult to understand why it is not formed from the abundant albumins present. If the sheep-tallow dog is poisoned with phosphorus, the fat is carried from the depots to the liver, which may store as much as 40% sheep-tallow. That the fat in the milk is not derived from albumins was shown by the following experiment: a sheep-tallow slut was allowed to become pregnant; and then received only the leanest meat. The fat in the milk was sheep-fat, and hence it cannot have been formed in the body of the animal, for then it would have been dog-fat, but must have been conveyed to the mammary glands from the fat-depots. The theory of a fatty degeneration, the author insists, must be entirely relinquished; in its stead is to be placed that of an albuminous degeneration of the cell; this injury to the cell is followed by the infiltration of fat as a reparative attempt. The fat of the organism consists of the fat of the food and that formed from the carbohydrates.

Terminal Infections.—It is a common experience to see patients that have suffered from chronic diseases succumb to some form of acute infection. Simon Flexner¹ has undertaken a study of this subject, based on a large series of carefully investigated autopsies made at the Johns Hopkins Hospital. He found 255 cases of chronic heart- or kidney-disease, or of both combined, in which bacteriologic examination had been sufficiently complete to make them of use for this study. Of these 255 cases, 213 gave positive and 42 negative results. Negative results, as the author clearly states, do not afford positive proof of the absence of microorganisms—a number of factors may prevent development of cultures.

Bacteriologic study of cases of chronic Bright's disease showed in 32 cases unassociated with cardiac or other chronic disease 29 positive and 3 negative results. Similarly, of 112 cases of combined chronic renal and chronic cardiac disease, 85 yielded positive and 27 negative results. In a considerable number of cases of chronic Bright's disease other chronic diseases were present. These consisted of tumors, such as carcinomata, sarcomata, and myomata, of cirrhosis of the liver and lungs, chronic proliferative peritonitis, etc. Of 54 cases of combined chronic Bright's disease, bacteriologic examination gave 51 positive and 3 negative results.

A similar study of the cases of chronic heart-disease yielded the following: the number of cases of heart-disease alone in which bacteriologic examinations

¹ Jour. Exper. Med., July, 1896.

were made was 41, of which 32 were positive and 9 negative. The number of cases of chronic heart-disease associated with other chronic diseases than chronic Bright's disease was 22, of which 16 gave positive and 6 negative results. The cases of combined chronic heart- and kidney-diseases are the same as are given with the summary relating to the latter organ.

The infections may be local or general, the former being much more common. In the general infections, in contradistinction to the local infections, no special group of bacteria is present. At times the point of entrance of the microorganism cannot be made out at the autopsy. In the series of chronic kidney-diseases 38 cases of general infection are included. The microorganisms causing these infections were the streptococcus pyogenes, 16 cases; staphylococcus pyogenes aureus, 4 cases; micrococcus lanceolatus, 6 cases; gas-bacillus, three times alone and twice combined with the bacillus coli communis; the gonococcus, anthrax-bacillus, bacillus proteus, the last combined with the bacillus coli, the bacillus coli alone, a peculiar capsulated bacillus, and an unidentified coccus, each in one instance. What is striking in this list is the preponderance of the usual pyogenic cocci. These may occur without association with abscess-formation. In a large proportion of the cases of septicemia visible focal lesions within the organs were not present at the autopsy. The usual conditions found were acute splenic tumor and more or less severe parenchymatous degeneration of the viscera, with sometimes microscopic necroses of tissue-cells as well.

Of the 16 instances of streptococcus-infection the infection-atria into the general circulation were believed to be as follows: cellulitis, erysipelas, leg-uleer, bed-sore, 7; phthical cavity, 1; laparotomy, 2; tapping abdomen, 1; acute pleurisy, peritonitis, or pericarditis, 3; sloughing angiosarcoma, 1; necrosis of placental attachment in uterus, 1. Of the 4 cases of staphylococcus aureus septicemia there were: acute pericarditis following diphtheria, 1; operation upon the perineum and cervix uteri, 2; undetermined (generalized melanotic sarcoma), 1. Of the 6 cases of micrococcus lanceolatus infection, acute pneumonia claimed 4; acute endocarditis and acute pericarditis, and pleuritis, 1 each. The 5 gas-bacillus cases gave aneurysm of the aorta opening externally, amputation of arm, each 1 case, and intestine 3 cases. The 2 proteus cases took their origin, one in a sloughing bed-sore and the other from a chronic diphtheric colitis. The capsulated bacillus gained entrance from an ascending pyelonephritis; the anthrax-bacillus from an anthrax-edema of the face.

The number of local infections was much larger—127 among the cases of chronic Bright's disease, of combined heart- and kidney-disease, and of kidney and other chronic diseases. The bacteria were for the most part the same as those met with in the general infections. Certain bacteria appeared with such frequency in certain organs that these may be inferred to offer better opportunities for their growth. Thus the colon-bacillus was commonly found in the kidneys and lungs, and the streptococcus in congested and edematous lungs.

Regarding the infection-atria in the local infections, the intestine was found to be the portal of entry not only of many of the bacteria found in the inflamed peritoneum, but also of some of those present in the pleura, upon the heart-valves, and within the organs.

In cases of heart-disease uncomplicated with kidney-disease terminal infections were often encountered. Of 41 cases of arteriosclerosis and chronic valvular disease cultures showed in 32 the presence of bacterial infection, while in 22 cases of cardiovascular disease, associated with some other chronic condition than Bright's disease, positive results were obtained in 16. In these 48

positive cases the distribution of the bacteria was general in 14 instances. The microorganisms associated with these septicemias were streptococcus pyogenes, 9 cases; micrococcus lanceolatus, 2 cases; staphylococcus pyogenes aureus, 1 case; staphylococcus albus and streptococcus, 1 case; bacillus coli communis, 1 case.

An interesting point brought out by the author's studies is the fact that the bacillus pyocyaneus is, like the more common pyogenic organisms, capable of producing distinct and widespread lesions. He has met with several instances in which extensive necrosis, associated at times with ulceration, had been caused by it in the gastrointestinal tract.

It being evident from all these observations that chronic diseases predispose to infection, it becomes important to determine whether there is a demonstrable difference in the bactericidal power possessed by the body-fluids and cells. Some experiments were made by the author in this line, primarily to estimate the relative bactericidal power of normal blood-serum and that from individuals suffering from chronic diseases. Normal serum was in 2 out of 3 cases (the author is in doubt whether the exceptional case should be included) found to be strongly bactericidal to the staphylococcus aureus, while of 9 samples of blood taken from persons suffering with some form of chronic disease, no appreciable effect was exerted upon this microorganism in six.

The author recognizes the importance of the antitoxic substances as an additional factor in establishing and preserving immunity, and expects to deal with that phase of the question in a future communication. [The studies which the author has begun deserve to be extended to a wider field, for the question of terminal infections is not so very different from that of infections in apparently healthy subjects. We find that the same diseases which carry off the cardiac and renal sufferer attack other persons.]

Histologic Changes Produced by Ricin and Abrin Intoxications.—Simon Flexner¹ has made a careful histologic study of the changes produced in animals by repeated doses of ricin and abrin. We have not space to describe these in detail, but a comparison with the changes found in many forms of bacterial infection and toxemias discloses their essential similarity. The chief and characteristic lesions are degenerative and focal in character—are especially focal necroses. The toxins exert their influence upon individual cells, but not all the cells of the body show the same susceptibility to their action, lymphoid cells suffering to a greater degree than epithelial cells. Furthermore, the various organs do not suffer to an equal extent; thus, the liver-cells are more affected than those of the kidney and adrenals. Finally, in highly differentiated cells, not all parts of the protoplasm need be equally affected by the poison.

There is evidence to prove that the extent of cell-injury in any particular organ is in a measure proportionate to the functional activities exerted in dealing with the particular poison. It is not easy to account for the focal character of the lesions in the organs, assuming the action to be due to a soluble substance contained within the circulating blood and fluids of the body. The author would elucidate it by reference to the part played by the circulation of the blood in the affected organs. The action of the poison has been shown to be exerted in part upon the capillary walls, causing necrosis and fragmentation of the endothelium, and nowhere is the injury to the capillary parietes greater than in the areas in which the necrosis is found. This fact suggests the possibility that in certain capillaries in which the circulation was much diminished or was temporarily at a standstill at the time when the irritant acted with the

¹ Jour. Exper. Med., Mar., 1897.

PLATE 4.

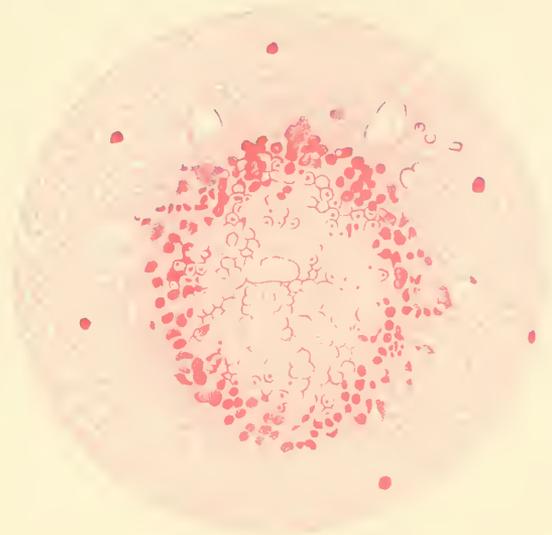

FIG. 1.—Focal area of necrosis of liver-cells and single cell-necroses. Karyolysis to be seen in the center and pyknosis and karyorrhexis in the periphery of the nodule. A few fragments of nuclei are also present in the central portion. Methylene-blue and eosin staining. (Objective No. 3; eye-piece No. 3.)

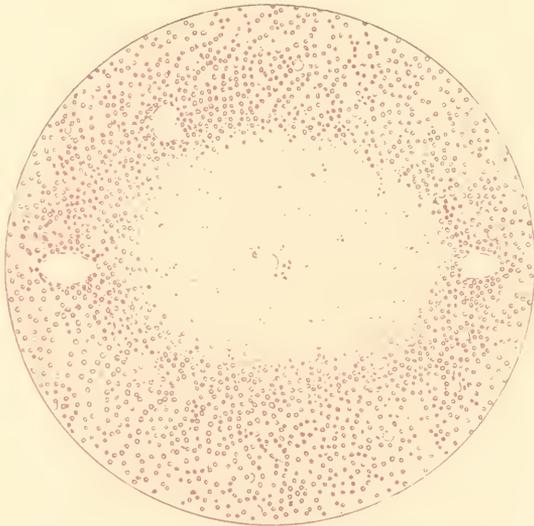

FIG. 2.—A focal area of necrosis similar to Fig. 1. Magenta staining to show the alterations in nuclei and protoplasm. Karyorrhexis is more marked than in preceding figure. (Same magnification as Fig. 1.)

(*Jour. of Exp. Med.*, March, 1897.)

greatest intensity, so much damage was done to the vessel-wall that a freer transudation than occurred elsewhere took place into the tissues in the neighborhood, resulting in the destruction of cell-groups. Reference is also made to intracapillary thrombosis as a possible factor in the local necrosis. [The great significance of these observations appears to lie in the light they shed on focal necrosis in various organs in man. In animals that survived a long time the author was able to note reparative changes, and the replacement of the necrotic areas by new tissue—by a scar; in other words, a form of cirrhosis developed. It is especially the chronic changes that will prove of interest in the study and interpretation of fibroid changes in man. We append an illustration (Plate 4) showing focal necrosis of the liver.]

Echinococcus-cyst of Rectovesical Space.—Nuyens¹ describes an echinococcus-cyst between the bladder and the rectum, and collects 32 cases from the literature with the view of establishing a general symptomatology of the condition.

Multiple Echinococcus-cysts.—W. C. Keyes and F. C. Busch² report the case of a German, aged 53, in whose body at the autopsy were found a large hydatid cyst of the right kidney, a cavity at the base of the right lung, and two cavities below the diaphragm, one of which communicated with that in the lung. All these cavities had a calcareous lining. Neither hooklets nor scolices were found in the 3 cavities, so that their nature remained in doubt. The authors refer to 2 other cases of echinococcus-disease that have occurred in Buffalo, in the practice of Roswell Park, which have not yet been reported. [Echinococcus-disease appears to be more frequent in the United States, possibly only because the cases observed are published more often than was the custom formerly. We have ourselves observed a case of echinococcus-cyst of the liver and possibly of the lung in a negro from Delaware.]

Sarcosporidia.—Plumbe³ has studied the action of the sarcosporidium on the tissues of its host, and concludes: 1. These organisms are usually inoffensive parasites. 2. Exceptionally they become the cause of more or less extensive inflammatory lesions, with destruction of the muscular tissue, and may cause death if the organ attacked is essential to life (heart or diaphragm). 3. The inflammatory lesions appear only after the complete development of the parasite and after the rupture of the capsule which contains it. 4. The inflammation always terminates by the organization of the infiltrating tissue.

The Relation of the Specific Gravity and the Amount of Albumin in Pathologic Fluids.—Ott⁴ has estimated the amount of albumin in pathologic fluids (by means of Kjeldahl's method, and multiplying the percentage of N by the factor 6.25) for the purpose of determining (1) the amount of albumin in the various diseases; (2) the relation of these amounts to the specific gravity. In the first table, containing 25 examinations, 11 appertain to the fluid in cancer of the peritoneum—the albumin was about 4% on an average. The amounts differed in the same case at different punctures. In peritoneal tuberculosis it was 6.558%; in hepatic cirrhosis from 2.006% to 6.887%; in echinococcus-cyst of the liver 0.360%; in ovarian cysts from 1.818% to 5.435%; in pyopneumothorax from 8.281% to 8.928%; in hydrocele the amount was usually high, but varied greatly, from 0.737% to 7.851%. The general conclusion from these figures is that there is no definite amount of albumin for any one disease. A study of the specific gravity in the light of the albumin-content of the fluids showed further that the former—*i. e.*, the spe-

¹ Centrbl. f. Bakteriolog., Parasitenk. u. Infektionskrank., Feb. 15, 1897.

² Buffalo Med. Jour., Aug., 1896.

³ Arch. de Méd. expér. et d'Anat. path., Nov., 1896.

⁴ Zeit. f. Heilk., xvii., H. 4, p. 283.

cific gravity—does not permit any conclusion as to the quantity of albumin in pathologic fluids, and that it is of no diagnostic value. For example, the fluid from a case of cancer of the peritoneum and that from an echinococcus-cyst had the same specific gravity, 1009, yet the former contained 2.6% albumin and the latter only 0.36%.

The Significance of the Leukocytes in Exudates and Transudates.—Winiarski¹ confirms the assertion of Korczynski and Wernicki that in serous exudates which neither show a tendency to pass into suppuration nor are due to malignant disease the lymphocytes, especially the small ones, numerically preponderate. When the neutrophiles are in the majority the case is either one of neoplasm (carcinoma) or suppuration is going to take place. The presence of eosinophiles and of red corpuscles is without significance. The author found in all pleural and peritoneal transudates almost exclusively lymphocytes; in the purulent pleural exudates only neutrophiles; in all serous inflammatory effusions, where new growths were not present, lymphocytes were practically found alone. None of the last group ever passed into suppuration, although the number of lymphocytes rose at times as high as 6230 per cb. mm. In a case of metapneumonic serous pleurisy in which the number of leukocytes was small, but in which neutrophiles were chiefly present, suppuration developed later. All this is true of peritoneal exudates. In the serous pleural exudates the number of leukocytes varies from 270 to 9270 per cb. mm., in the transudates from 60 to 300. In peritoneal effusions the numbers are smaller. During the absorption of exudates and transudates the number of leukocytes increases; during the formation of fibrinous deposits it diminishes.

Pigmentation from Injection of Suprarenal Gland Extract.—Charrin² produced pigmentation in dogs by the injection of aqueous glycerin-extracts of suprarenal glands from guinea-pigs.

Toxicity of Human Sweat.—Arloing³ found the human sweat toxic for animals. If the intravenous injections did not produce a fatal termination in from 1 to 3 days, the animals died later in a cachectic state. The toxicity varies with the circumstances that accompany or precede sweating, with the individual, the mode of preparing the extract, and the susceptibility of the experimental animals.

NERVOUS AND MENTAL DISEASES.

BY ARCHIBALD CHURCH, M. D.,

OF CHICAGO.

Introductory Epitome.—In the department of nervous diseases the past year has seen considerable activity. A great deal has been written about meningitis, and there is a very general belief that a form of acute serous meningitis may now be differentiated. This matter, however, is still under consideration, as it is recognized that meningitis is a disease of heterogenetic origin. The subject of cerebritis is a growing one. Cases of acute primary hemorrhagic cerebritis are being reported from all parts of the world, and it is likely that the clinical differentiation of the disease will be made possible by the accumulation of abundant material. Operative interference in hydrocephalus under new methods promises better results, and puncture of the lateral ventricles, when puncture of the lumbar cord is not productive of relief in cerebral pressure, is gaining adherents. The do-nothing attitude in the face of cerebral hemorrhage is likely to give way to more active interference when the differential diagnosis is sharply made between the condition of hemorrhage and thrombosis. Attention may also be called to the treatment of the hemiplegic state, so commonly neglected. A number of very important and interesting cases of cerebellar tumor, with and without operation, leads to the belief that surgical invasion of the posterior fossa has a larger field than had been supposed. The relation of the anterior gray matter of the spinal cord to peripheral neuritis is more and more well established by recent investigations. The subject of neuralgia has received important contributions, and the disorder apparently is a common one. The literature of syringomyelia is rapidly growing. The condition is now recognized as very far from rare, and cases are being reported on every hand. Cord-changes following the pernicious anemias, including leukemia and the like, are well represented in the literature of the year. It is now evident that such changes are not confined to the white matter, as was at first supposed, but that they are heterogeneous in distribution and multiform in character. Material and experiments are bringing forward the fact that myelitis is usually the result of arterial disease or of infection reaching the cord by the arterial route; in other words, that it is a softening rather than an inflammation. The frequency of spinal and cerebral hemorrhages in the newborn has received additional importance from the investigations of Schäffer. An important contribution is made to the joint-changes in locomotor ataxia, independent of so-called arthropathies. The anesthetics of tabes have been well worked out, and the important group of symptoms dependent thereupon has become general property. In the treatment of the disease a new method of stretching, which actually stretches the cord, is described, and the exercise-treatment to restore muscular control, as devised by Fränkel, which is herein outlined, has received decided support.

In the treatment of tetanus, antitoxin has been frequently tried during the past year, but the results are about the same as quoted in the *Year-Book* for

1897. Material is rapidly accumulating to show the relation of tetany to infection, especially infection arising from the gastrointestinal tract. The post-mortem findings in acromegaly almost uniformly include a pituitary tumor. Such cases now number nearly a score. A great deal of work has been done on the subject of exophthalmic goiter, and the value of the thymus treatment has been pretty well established as being slight. Treatment by ablation of the cervical sympathetic is gaining adherents, especially in France. The intimate, if not identical, relations of myxedema, cretinism, and goiter have developed during the past year. Some valuable contributions have been made to the literature of epilepsy from the Craig Colony in New York. Nothing particularly new in regard to the treatment of this neurosis has been forthcoming. Less value than formerly is attached to operative treatment in partial epilepsies.

In mental diseases importance attaches to the views regarding the bed-treatment of acute cases, and to the further elaboration of the subject of toxins and insanity. A number of notable papers on senile mental disturbance have appeared. Among the most interesting contributions to the subject of parietic dementia are the findings of Piccinino, who, in several instances, claims to have discovered Lustgarten's bacillus of syphilis in fluid drawn from within the cranium. Studies on the subject of idiocy have been unusually numerous.

DISEASES OF THE CEREBRAL MENINGES AND CRANIAL NERVES.

Non-tuberculous Posterior Basic Meningitis in Infants.—J. W. Carr¹ calls attention to what he considers a special variety of meningitis; 11 cases were observed in Victoria Hospital, Chelsea, all of them occurring in previously healthy infants under 1 year of age. The onset was gradual in some, sudden in others; but in all the most characteristic symptoms were severe vomiting, extreme head-retraction, and stupor passing into coma of several weeks' duration or more, with retracted head to the last. The cases all terminated fatally in from 5 weeks to 3 months; 10 necropsies were had, demonstrating inflammation of the pia-arachnoid in a very definite area at the base of the brain, with hydrocephalus and in some cases closure of the openings between the fourth ventricle and subarachnoid space. No tubercular disease was discovered in the cranial cavity or elsewhere. In two of the cases tapping of the lateral ventricles was done, in one with distinct improvement. In two other cases trephining proved rapidly fatal, apparently from too rapid escape of fluid. The nature of the infection was not determined, though it was supposed to have some relation to the epidemic cerebrospinal form.

Pachymeningitis Hæmorrhagica Interna.—Adolf Meyer² gives the findings in 21 cases showing hemorrhagic laminated membranes, 4 being in senile dementia, 7 in general paralysis, 1 in chronic mania, 1 in acute mania, 6 in terminal dementia, and 2 in epilepsy. In cases in which the membrane was single and the condition simple the deposit was found to be due to hemorrhage arising from the surface of the dura, and in a number of other cases membrane arising at this point secondarily involved the pia, and was even associated with pial hemorrhage in one instance. All of the cases, according to the writer, may be denominated vascular dural exudation. [This is at variance with some recent dogmatic statements to the effect that pachymeningitis is a misnomer, and that the condition arises from the soft membranes, and would better be called meningeal hemorrhage.]

¹ Brit. Med. Jour., Apr. 17, 1897.

² Path. Report III. East. Hosp. for the Insane, 1896.

Acute Serous Meningitis.—G. Boeninghaus, in a critical monograph¹ upon this subject, bases his conclusions upon 27 recorded cases, with an additional case under his personal care and treatment. The author divides acute serous meningitis into external and internal or ventricular, and acknowledges that the internal form may be secondary to the external. The ventricular form is the less serious, and death usually occurs at a much later period than in the external variety. In the majority of cases recorded the cause of the meningitis was middle-ear disease. This of itself throws some doubt on the diagnosis, especially in those cases that were not sectioned. The 5 cases operated on with recovery are interesting, but the evidence is not conclusive that the disease was serous meningitis; 3 of these were also secondary to ear-disease. In one of the remaining cases spinal puncture was done, and in the other trephining and puncture. [It must be admitted that the acute serous meningitis is extremely infrequent, although many good observers believe in its existence. A suppurative focus as a primary source of infection cannot be excluded without the most systematic and rigid examination of every portion of the body, and those who are doing the largest amount of postmortem work rarely fail to find some such primary origin for what appears to be a serous meningitis.]

Epidemic of Cerebrospinal Meningitis.—F. H. Williams and W. T. Councilman² reported an epidemic of cerebrospinal meningitis in a paper read before the American Medical Association, June, 1897. By lumbar puncture fluid was withdrawn from a little below the spinous process of the second lumbar vertebra and then studied by Dr. Councilman, who found organisms in 77 cases, including staphylococci, streptococci, and diplococci. The spleen was enlarged in some cases. Similar organisms were found in the nasal sinuses and once in an abscess of the tonsil. The most common bacterium found was the diplococcus intracellularis meningitidis (Jäger).

An Early Symptom of Meningitis.—Simon³ states that tubercular meningitis always presents during the early period a disharmony in the respiratory movements of the diaphragm and thorax.

Atrophy of the Optic Nerve from Inflammatory Causes.—Wilder⁴ gives the report of a case of optic atrophy, due perhaps to cerebral meningitis, in which the ocular fields were greatly reduced and vision was much obscured, but in which notable improvement was obtained, as shown by perimeter charts, after the subconjunctival injection of mercuric chlorid, and vision raised from $\frac{20}{120}$ to $\frac{20}{40}$ after 4 injections practised within a month. References to this method of procedure, especially as carried out by Derier, will be found in the same article.

Sallard⁵ calls attention to the claim of Valude for the use of antipyrin in the treatment of optic atrophy by subcutaneous injections. Jeffrois had also tried the method in 10 cases, injecting the antipyrin deeply under the muscles of the back. Injections were continued daily for 5 months, with amelioration in 3 cases, but no modification of the visual field in any. The author gives preference to strychnin.

Congenital External Ophthalmoplegia.—Gourfein⁶ reports 6 cases of this condition in the members of one family, the father and 5 sons. The mother of the first patient was also said to have suffered from the same condition, and a half-sister, daughter of this mother, had a convergent squint; 2 daughters were free from defect. There was no trace or evidence of syphilis.

¹ Published by J. F. Bergman, 1897.

⁶ Rev. méd. de la Suisse Romande, No. 12, 1896.

In these cases ptosis was marked, the supereiliary arches were flattened, and there was rotary nystagmus, but no protrusion of the eyeball. There was more or less amblyopia, but no false projection. He believes that the condition consisted in a congenital defect of the muscles, and that it was not of nuclear origin.

W. M. Leyzinski¹ reports a patient 4 years of age, of German parentage, born at full term after normal labor, without asphyxiation. Primary dentition commenced at 8 months, but owing to large size and great weight the child did not walk until he was 14 months old. There were no convulsions, the health being especially good—even the infectious diseases were escaped. No injuries. The child had always been bright and talkative, slept well, and was free from nocturnal disturbances. At the end of the first year he began to draw his head backward, and it was then noticed that the eyes turned inward. Upon examination there was found a convergent strabismus, more pronounced in the left eye. Neither eye could be turned beyond the middle line. Pupils normal. The author quotes the literature of the subject, and reports cases to show that associated malformations are frequently found. In the few postmortem examinations there has been found complete absence of the muscles in question, or they have been present but ill-developed or attached to the eyeball in abnormal position. Whether the nuclear condition is primary or secondary to the muscular loss is not yet determined.

Treatment of Trifacial Neuralgia.—William M. Leyzinski,² after defining what he means by trigeminal neuralgia, says of the treatment that the most efficient therapeutic measure is rest of the organs of mastication and articulation, and quite often complete bodily rest in bed. Conversation and solid food are forbidden. Nourishment, which is important, is maintained by semi-fluid or fluid food, sometimes introduced through the nasal tube. He also finds morphin, opium, aconitin, the coal-tar derivatives, cocain, nitroglycerin, and the fluid extract of ergot useful. The only form of aconitin that has proved valuable in his hands is the crystallized aconitin of Duquesnel, and this often succeeds when other aconite preparations fail. In conclusion, he says, "As there is a possibility—nay, even great probability—of relief in most cases of tic douloureux or chronic trigeminal neuralgia without surgical operations, the latter should be seriously considered only as a *dernier ressort*, or after all available resources have been exhausted.

C. L. Dana³ makes an additional contribution to this subject, adding 5 cases that have been treated by large doses of strychnin hypodermically, to the 8 cases formerly reported and mentioned in the *Year-Book* for 1897. Of the first 8 cases 6 were relieved and 2 were not relieved. In the last 5 cases 4 have been successfully managed by this method. Dana discourages surgical operations, and believes that this line of treatment, which, it will be recalled, embraces rest in bed, should be persistently tried.

Tiffany⁴ gives an analysis of 108 cases of facial neuralgia treated by intracranial operation. Of these cases 24 were fatal. In the discussion of the cases the author states that intracranial resection of the branches of the fifth nerve relieves pain for the time and perhaps permanently, but pain may recur in the same or neighboring territory. Recurrence of pain after known **removal of the Gasserian ganglion** is not recorded, but he doubts the expediency of removal of the entire ganglion. Marchant and Herbert⁵ report 2 cases of extirpation of the Gasserian ganglion for the relief of rebellious facial neuralgia.

⁵ Rev. de Chir., Apr. 10, 1897.

They analyze 93 additional cases collected from the literature. In these there were 17 deaths.

Sewill¹ relates 2 cases of trigeminal neuralgia which he considered **due to the loss of the teeth**. He found that, all teeth being gone, the approximation of the jaws put the maxillary articulations in an abnormal position, and perhaps served to make traction upon the lower branch of the fifth. In both cases the neuralgia was confined to this portion of the trifacial. Relief was given by introducing proper dental plates, and the condition could be reproduced by having them removed for a few days.

Facial Hemiatrophy.—Schlesinger² reports a man of 23, who complained of pain on the right side of the neck, difficulty of swallowing, and disturbance of vision of the right eye. Later there were paralysis and atrophy, with fibrillary contractions of the right side of the tongue and difficulty in pronunciation; still later, complete paralysis of the vocal cord, wasting of the right side of the face, disturbance of gait, vertigo, and anxiety. The previous history of the patient was free from notable incident. The facial atrophy was very pronounced, involving the bones of the head. A tumor could be felt on the right side of the pharynx, and it was supposed to be the cause of the cerebral symptoms, and that the facial atrophy was a basal affection connected with this tumor. [Additional cases tend to show that facial atrophy is due to disease of the fifth nerve, and it is to be hoped that this case will eventually come to autopsy and that others may be added, to make the matter plain.]

E. S. Yonge³ reports a case following intense facial neuralgia of 6 months' duration and publishes a photograph.

Paralysis of the 5th Nerve.—Sidney Phillips⁴ presented a woman before the Clinical Society of London with paralysis of the left 5th nerve. The following symptoms were present: anesthesia and analgesia of the left side of the cheek and of the hard and soft palate; insensibility of the teeth to pressure and loosening of several of them; loss of sensation on the left side of the tongue, and loss of sense of taste over the posterior third, as well as the anterior two-thirds, strychnin, sugar, and salt being unrecognized; anosmia of the left nostril, with a constant sanious, ichorous discharge and frequent epistaxis; a left conjunctival injection with an area of cloudiness of the surface of the cornea unless the eye was kept constantly protected by a watch-glass, and even with this protection a tendency to growth of loops of vessels over the cornea, which was kept in check by atropin; sight on the left side was defective, nothing smaller than 14 Snellen being read; there was no optic neuritis, but there was pallor of the disk.

Facial Paralysis.—F. Schultze⁵ asserts that in peripheral facial paralysis the base of the tongue on the affected side occupies a lower level than on the sound side when the organ is lying in the floor of the mouth, and that this may be noticed also upon protrusion. He thinks it is due to the fact that paralysis of the facial nerve also involves the stylohyoid muscles and the posterior belly of the digastric.

Solitary Tubercle of the 7th and 8th Cranial Nuclei.—Manasse⁶ exhibited a specimen of this sort removed from a tuberculous patient, 43 years of age, who had become deaf in the left ear and presented left facial palsy with reaction of degeneration. The autopsy revealed in the posterior part of the pons, on the left side, a tumor the size of a hazelnut, containing a cavity filled with friable cheesy material. Both the 7th and 8th nerves were im-

⁶ Arch. f. Ohrenh., vol. xli., p. 62.

bedded in the mass. The vagus, glossopharyngeal, and accessory nerves were firmly adherent to a tumor of the same sort, and other tubercles were found in the cerebellum and right occipital lobe.

Anton¹ reports a fibrosarcoma of the auditory nerve. The patient was seized with headaches and blindness of the right eye and three hours later with blindness of the left eye. There were vomiting, and ringing, hissing sounds in his ears and difficulty of hearing. Bilateral optic neuritis and right facial paralysis appeared. Death occurred 8 months later. The autopsy revealed a tumor the size of a hen's egg situated between the pons and cerebellum. [Both of these cases show the vulnerability of the auditory group, which, of all the cranial nerves, is the most commonly affected by new growths.]

Spasmodic Torticollis.—Richardson and Walton² make a further contribution to the study and treatment of spasmodic torticollis, and report upon some of the cases appearing in a former paper by them, giving three additional ones. They properly look upon the disease as often based upon a neurotic foundation and as constituting a tic, in some instances a mental tic. They point out that all operations in such instances may be followed by improvement through the effect of the operation *per se*, and also find that the same influence may be accomplished by massage, electricity, gymnastics, and hypnotism. They would reserve surgical measures until everything else has been tried or unless the case was too well established and severe to justify delay. De Quervain³ strongly advocates Kocher's method, which consists in division of the sterno-cleido-mastoid and of the cervical muscles at the back of the neck, including the splenius and the greater and small rhomboids, and subsequently the inferior oblique, avoiding the great occipital nerves that pass near this point. The author believes that the operation produces not only palliation, but sometimes a cure.

J. S. Risien Russell⁴ reports an experimental investigation of the cervical and thoracic nerve-roots in relation to the subject of wry-neck that is of great surgical importance. The experiments were carried out upon monkeys, and the cervical roots were stimulated by electricity. The movements of the head resulting on extension of the anterior spinal nerve-roots were as follows: *First Cervical Root.*—The movement characteristic of an excitation of this root is a well-marked lateral inclination of the head onto the shoulder of the side excited. *Second Cervical Root.*—Excitation of this root produces a movement of the head closely resembling that which resulted on excitation of the first root—*i. e.*, a lateral inclination of the head to the side stimulated, by which means the side of the head and face are approximated to the shoulder. *Third Cervical Root.*—The movement which predominates is distinctly one in which the head is drawn backward, and the occiput being drawn to the side excited, the chin is directed upward and to the opposite side. *Fourth Cervical Root.*—There is still less of the lateral inclination of the head so characteristic of the first and second roots, while the backward movement of the head, in which the occiput is drawn to the side stimulated, is still more pronounced than in the third root. *Fifth Cervical Root.*—The little movement that results consists in a slight drawing of the occiput backward and to the side stimulated. *Sixth Cervical Root.*—The movement corresponds in all respects to that represented in the fifth. *Seventh Cervical Root.*—The movement which results on excitation of this root is decidedly more pronounced than that observed in connection with the fifth and sixth roots. *Eighth Cervical Root.*—As in the case of the seventh, movement of the head appeared to be entirely one indi-

² Am. Jour. Med. Sci., July, 1896.

⁴ Brain, 1897.

rectly induced by the vigorous drawing down of the scapula by the latissimus dorsi. *First Thoracic Root.*—The movement of the head obtained by excitation of this root depends largely on whether the latissimus dorsi is represented in it or not; when it is so the representation is only slight, so that the resulting movement of the head, while resembling that produced by excitation of the seventh and eighth cervical roots, is very much smaller in amount. *Second Thoracic Root.*—The movement is a lateral curving of the spine by the action of the erector spinæ, and the head is slightly tilted laterally toward the opposite side.

Angina Pectoris.—Osler¹ in a number of able lectures gives a very full consideration of this neuralgic disorder, and in the final lecture² advises, in its *general management*, an investigation of the exciting causes of the attacks. The use of exercise within the limits of the individual's abilities is to be systematically adopted, and the diet regulated strictly to the requirements of the patient and his personal peculiarities. As to general medical treatment, he directs attention to underlying conditions, such as gout and syphilis, against which vigorous measures should be adopted. The persistent and intelligent use of the iodids, colchicum, and the nitrites is insisted upon. He cordially indorses the use of nitroglycerin, and urges that its dosage be pushed to the requirements of the case, preferring nitrite of amyl to meet the paroxysms. Commencing with doses of nitroglycerin of $\frac{1}{100}$ gr. three times a day, he increases until the patient takes four or five or even more times as much three times a day—care being taken to select an active preparation, and being guided by the flushing of the face and throbbing of the head as to its activity. Arsenic also comes in for a share of praise.

In regard to the *treatment of the attack*, he urges that gastrointestinal disturbance should be particularly guarded against, and the moment the patient feels any difficulty in the stomach Hoffman's anodyne, spirits of camphor, peppermint-water, or hot whiskey should be taken with a carminative draught to remove the difficulty. For the paroxysm itself he lists three remedies: nitrite of amyl to be inhaled, morphin hypodermically, and chloroform by inhalation if the first two do not succeed. He states that he has never seen any dangerous effects from the careful use of chloroform, even in persons with very weak hearts, and that the vigorous and continued use of the nitrites—in the form of trinitrin—never gives rise to any disturbance.

DISEASES OF THE BRAIN PROPER.

Acute Nonsuppurative Encephalitis.—Data regarding this recently differentiated disease is accumulating in all quarters. J. J. Putnam³ reviews this subject, adds a case, and gives a synopsis of Oppenheim's reported 6 cases.⁴ The case reported by Putnam followed several weeks after the mumps. Most other cases that have been of record have followed influenza, though Brie's case was in a dement, without known antecedent acute infection. Putnam's case was a healthy boy 13 years of age, who had passed through an attack of mumps with apparent recovery for 10 days, when he woke up feeling badly, and complained of a squint in his eye, but followed his usual occupations. Next morning he had a partial ptosis of both lids, but more on the right side, and impairment of motion of the right eye, which turned inward. He also became slightly hard of hearing, complained of pain in the forehead, which developed into intense, persistent headache, and he manifested dulness and drowsiness,

¹ N. Y. Med. Jour., Nov.-Dec., 1896.

² Ibid., Dec. 19.

³ Jour. Nerv. and Ment. Dis., Jan., 1897.

⁴ Deutsch. Zeit. f. Nervenheilk. for 1895.

passing into lethargy, from which he could not be aroused. Two days later his temperature was 100°, the paralysis of the eyes and deafness had increased, and he grew steadily worse with delirium; but generally his consciousness was good when he was fairly roused. Sensations of numbness referred to the left arm and leg were complained of, and these limbs were weaker than on the right side, though there was no paralysis. The temperature ranged from 99° to 100°, and pulse from 70 to 90. Ophthalmoscopic examination showed double optic neuritis. He would not respond to questions. The knee-jerks and wrist-jerks were absent on both sides. As far as could be judged, in the comatose condition of the patient, the sensibility of the skin of the entire left side of the body, and the left extremities, was less than on the right. Under expectant treatment, with rather large quantities of nourishment and full doses of strychnin, the case made a gradual recovery. The fever disappeared in about 10 days, but the hearing and sight continued as before. He continued to improve gradually, and 3 months later sight was still defective, with double vision. The boy then had epileptiform attacks, which at first occurred many times during the day, lasting 5 to 15 seconds, with twitching of the right arm and right side of the face. These attacks grew less frequent. About a year after the attack his hearing was practically normal, but the diplopia was still present. The epileptiform seizures had ceased, but there seemed to be some loss of mental vigor. [It will be seen that the symptoms often closely resemble those of meningitis, for which it has no doubt been frequently mistaken. The treatment would be practically the same in either case.]

W. W. Murawjew¹ reported a case to the Neurological Society of Moscow. J. Feinberg² reports a case following influenza and terminating favorably, but with persisting slight paresis of the right upper extremity.

Hydrocephalus.—Henle³ calls attention to a surgical plan introduced by Mikulicz in cases of hydrocephalus, the purpose of which is to secure continuous drainage, at the same time preventing infection. The first case was a child of 6½ months, who had a purulent periostitis of the upper portion of the thigh-bone, from which an acute hydrocephalus developed. In the absence of persistent communication between the ventricles and the subdural spaces Mikulicz introduced a gold tube into one lateral ventricle communicating with the scalp. The purulent cerebrospinal fluid was readily drained, and after 50 c.c. had been withdrawn the scalp was closed over the end of the gold tube, which had been furnished with a plate to prevent its slipping within the cranium. Owing to the suppuration of the stitch-hole the small tube was discharged 25 days later. After 12 days the tube was again introduced in the opposite lateral ventricle, and the fluid evacuated was clear and free from infectious microbes. The child died 6 days later. At the autopsy 2 large abscesses were found in the lower portion of the left hemisphere, one the size of a billiard-ball, the other as large as a walnut. Henle also calls attention to the case of Troje, reported at the German Surgical Congress of 1893, in which Mikulicz's glass-wool drainage had been similarly introduced into the lateral ventricle. Two years after this operation the drainage remained in place and the child had improved in speech and in gait. The hydrocephalus was trifling in amount and showed no tendency to increase.

[Previous to Mikulicz's first suggestion, as carried out by Troje, a similar operation was devised by L. L. McArthur, of Chicago. A child of 6 months, with subacute hydrocephalus, was operated on in such a manner as to introduce a metallic tube into the descending horn of the lateral ventricle, the tube being

¹ Neurolog. Centralbl., June 1, 1897.

² Ibid., July 15, 1897.

³ Centralbl. f. Chir., Sept. 5, 1896.

fitted with a collar which rested upon the surface of the skull at the margin of the drill-hole which had been used to penetrate the cranium. Improvement in all symptoms promptly appeared. Six months later the corresponding side of the head was reduced in size, but the hydrocephalic condition increased and persisted on the opposite side of the head, apparently from obliteration of Monro's foramen. A second case, in a child of about 4 years, in whom the hydrocephalic condition had reached an extreme degree and the head measured 25 in. in circumference, was similarly operated. This operation was also followed by benefit and disappearance of the convulsions and of the comatose attacks. A third case of subacute hydrocephalus was operated on by Christian Fenger, of Chicago. Within 3 hours the temperature suddenly ran up to 107° and the child died the same day. The purpose of the operation is to place the ventricular cavities in permanent communication with tissue-spaces from which absorption can readily take place, and avoid a fistulous tract along which infection would be propagated.]

Puncture of the Lateral Ventricle.—Von Beck¹ reports 3 cases of puncture of the lateral ventricle. He maintains that puncture of the ventricle will often be preferable to Quincke's spinal puncture, as in many instances the fluid cannot be withdrawn by the spinal route, while puncture of the ventricle through a small trephine-opening, the needle being introduced into the ventricle through the lateral portion of the cortex, is easily accomplished and presents no greater dangers than spinal puncture.

Large Brain-tumor Successfully Removed from the Left Frontal Region.—Thomas and Keen² report the case of a boy 17 years old, well developed, who presented no symptoms until a few months before the operation, which was done March 27, 1896. He was seen by Drs. Osler and Starr, the latter of whom made the following report:

“The general symptoms and course of the case make it evident that Mr. de B. is suffering from a tumor of the brain. The existence of a right facial paralysis, a thickening of speech, a protrusion of the left eyeball, with greater degree of optic neuritis in the left eye, and very marked change in mental characteristics and mental activity, the hebetude and indisposition to move about, with some decided instability in motion, point to the left frontal lobe as the seat of this tumor. The slowly progressive character of the symptoms, with lack of great variability in their character, and the absence of headache and tenderness on percussion, make it seem probable that the tumor is of a hard, sarcomatous character rather than a vascular glioma, and make it open to operation. Such an operation is necessarily exploratory, and it seems likely that the best point for exploration will be over the second frontal convolution about its middle, the probable situation of the tumor being subcortical within the white matter of the frontal lobe, pressing backward upon the motor tract and upward toward the cortex of the posterior part of the second frontal convolution. It is the absence of epileptic attacks which leads specially to the idea of the tumor being subcortical. If exploratory operation is undertaken, I suggest that the method employed be that of a large bony flap, in order that the surface exposed may be as large as possible. If, after the opening of the dura, nothing is found at the spot indicated, and palpation at the bottom of the deepest fissure accessible fails to reveal any growth, I suggest that the base of the frontal lobe over the orbit be investigated, if possible, by lifting the entire lobe and exploring with the finger beneath. From the fact that destructive lesions of the forward tip of the frontal lobe appear to give rise to few symptoms, I think it would be justifiable to make an incision into the frontal lobe

¹ La Tribune méd., No. 13, 1896.

² Am. Jour. Med. Sci., Nov., 1896.

for the purpose of exploring the white matter in case the tumor is not found at either of these two positions."

Finally, after a thorough trial of mercury and iodid had been made without effect, an operation was done and a large tumor removed. Its position corresponded accurately to the expectations, being subcortical, located in the frontal lobe, and protruding through the cortex at a point corresponding to the second frontal convolution. The tumor was $7\frac{1}{2}$ cm. long, $5\frac{1}{2}$ cm. broad, and 4 cm. deep, weighed $2\frac{1}{2}$ oz., and is among the largest that have been removed. It was shelled out without much difficulty, but its lower portion invaded the lateral ventricle, which was widely opened. Subsequently the cavity left by the enucleation of the tumor was packed with gauze which extended into the lateral ventricle. An uneventful recovery occurred, and in view of the fact that the tumor was of a noninfiltrating character, being a firm sarcomatous mass, there is a fair probability of the result being permanently good. [The opening and packing of the lateral ventricle are novel and instructive, showing that even these spaces may be invaded.]

Intracranial Aneurysm.—Macleren¹ reports a case of a domestic servant aged 40, who had been suddenly seized with pain in the left side of the head and left eye, at the same time becoming aware of a rushing noise in the left side of the head. Shortly afterward the eye felt weak and watery and the eyelid swelled. Upon examination the eyeball was found pushed forward, both lids on the left side swollen and edematous, with congestion of the conjunctival vessels and almost complete paralysis of the external rectus, but the pupil was active and vision normal; the fundus and disk were normal. On auscultation a loud systolic bruit was heard over the cranium, extending a short distance down the back of the neck, being loudest over the left temporal region. Upon pressure of the left common carotid the murmur disappeared, and was not influenced by pressure on the right side. Everywhere the arteries were atheromatous, the heart large, and the apex-beat two inches to the left of the middle line. There was considerable albumin in the urine. The common carotid was tied, and improvement began at once; the swelling disappeared slowly, the bruit instantly. Patient was discharged from the hospital seven weeks after the operation, the condition of the eye being then perfect.

Disease of the Anterior Lobe of the Brain.—Durante² reports the case of a man who had suffered for some time with pains in the head, which at first were improved by anti-syphilitic treatment. Later, prominence of the left parietal region, exophthalmus, and amblyopia appeared, memory was diminished, and the patient became melancholy and unsocial and had hallucinations. Three hard syphilitic gummata were removed from the frontal lobe. The next day vision and memory returned, and eight days later the man's intellectual and moral faculties recovered their normal condition. Six months later he had an attack of Jacksonian epilepsy. The second case was a woman who had loss of memory for words and things, altered moral sense, etc. On operating an adherent fibrous body was found and removed from the frontal lobe. The patient changed as if by magic, and speedily recovered her intellect and moral faculties. [These cases, while reported too briefly to be very valuable, emphasize the importance of moral and mental disturbance as symptoms of lesions of the frontal lobe.]

The Treatment of Cerebral Hemorrhage.—Byron Bramwell³ points out that at the commencement of the attack of cerebral hemorrhage the first

¹ Brit. Med. Jour., Jan. 2, 1897.

² Sup. al Policlinico, Oct. 31, 1896; Brit. Med. Jour., Jan. 2, 1897.

³ Treatment, July, 1897.

indication is to arrest the bleeding and limit the extravasation. To this end he raises the head and shoulders, places an icebag to the head, warmth to the feet, leeches behind the ears, and gives a drop or two of croton oil to produce a brisk watery evacuation and determine the blood to the intestines. Venesection, bleeding from the temporal artery, compression of the common carotid artery, and ligating the carotid artery on the side of the hemorrhage, are other measures which may be recommended. Bleeding is contraindicated in those cases in which the pulse is feeble, rapid, or weak, the heart dilated or weak, and the patient very old or debilitated. If there is retention of urine, the bladder should be emptied by catheter, and the patient must be kept dry in case of incontinence. The author is doubtful whether any internal remedies have influence in arresting the bleeding. Ergot has been recommended, but it is of no utility. The nitrites, including nitrite of amyl, may be useful in some cases in which the pulse is hard and tense, but venesection is better. Aconite has also been recommended in cases of full, bounding pulse. In cases in which the coma gradually becomes deeper, the pulse slower and slower, the respiration more and more affected, and evidence of progressive hemorrhage is marked, trephining and tapping the hemorrhagic cavity to prevent rupture into the lateral ventricles should be considered. Fortunately, such cases are rarely met with. The second indication is to attend to the condition of the bladder and take means to prevent, if possible, the formation of a bed-sore. The third indication is to sustain the vital powers by appropriate feeding, and, if necessary, by the administration of cardiac tonics and stimulants. If the patient recovers from the state of coma, the next effort is to allay the secondary cerebritis. At this stage the author commences the administration of potassium iodid 5 gr. 3 times a day. If symptoms of secondary cerebritis, consisting in a rise of temperature, headache, muscular twitching, delirium, return of coma, develop, a brisk purge is again administered, an ice-bag applied to the head, and potassium bromid or bromid and chloral added to the iodid. When the secondary cerebritis subsides the bromid and chloral are discontinued, and complete rest is enjoined until the acute changes around the clot have subsided. The author postpones attention to the paralyzed limbs, except such as is necessary for the comfort of the patient, until he has reason to suppose that acute changes have subsided in the neighborhood of the clot—namely, 6 weeks or 2 months. In the recovery of motor control he lays great stress upon the value of frequently repeated systematic voluntary efforts by the patient to use the paralyzed limbs. In the prevention of subsequent attacks a great deal can sometimes be done by removing exciting causes; blood-pressure should be kept down, sudden efforts, mental excitement, exposures, straining at stool, must be avoided, and a quiet, routine life must be led. The diet should be light and nutritious, and gouty or kidney conditions must be under constant surveillance.

Treatment of the Hemiplegic State.—Archibald Church¹ discusses the treatment of this common condition, urging that in the treatment of a case of hemiplegia, from whatever source arising, the paralytic members should be carefully massaged from the first, and all joints put through their full range of motion, even during the period of coma following the stroke. This is essential to prevent the tendency to joint-changes and the rigidity and limitation of joint-motion which sometimes develop very early, and to maintain the functional sensitiveness of the muscles to any slight cerebral impulses which may reach them. After a week or ten days very decided massage and electric treatment should be used and applied to the muscles which ordinarily are overbalanced in the hemiplegic attitudes. These measures consist principally, in

¹ Chicago Med. Recorder, June, 1897.

the majority of cases, in faradizing and massaging the extensors of the shoulder, arm, wrist, and fingers, while in the lower extremity attention must be given to prevent foot-drop; the anterior leg-muscles require the most treatment. After the first week or ten days the patient should be encouraged to attempt motion in the paralyzed members, and his courage maintained in the face of apparent helplessness. At this time advantage may be taken of the phenomena of associated movements, and the patient urged and repeatedly encouraged to make double-sided movements, firmly fixing his attention upon the paralyzed side. As movements return in the limbs from above downward, first appearing in shoulders and hips, then in elbows and knees, and last of all in hands and feet, this order should be followed in directing voluntary movements. The erect position and attempts at walking may be advised much earlier than is ordinarily done. It is important to insist early upon the step being taken in a proper manner, and to this end elevation of the toe with light orthopedic apparatus or an elastic band is strongly advised. As soon as secondary rigidity sets in, which takes place in from a few weeks to 3 months after the stroke, the difficulties are greatly increased and progress is much retarded. It is important to secure all possible advantage before this appears, and to delay its appearance as far as possible by the judicious use of massage and electricity. As long as the limbs can be kept supple there is room for hope.

S. Erben¹ teaches the patient the proper position of the feet at each step; then insists upon his duplicating them, instead of merely swinging the paralyzed limb in advance of the sound one and then bringing up the sound foot to or a little in front of the affected one.

Cerebral Syphilis.—Kuh,² in a very capable article, discusses the subject of cerebral syphilis. He gives preference to the use of mercury, but believes that the iodid should not be omitted, and prefers inunctions as a means of administering the metal. After a month's use of inunctions the mercury is stopped and iodid substituted, and the inunctions again resumed after another month, with or without the iodid, according to the gravity of the case.

Sunstroke.—Alexander Lambert,³ in a very admirable article, gives a history of numerous cases of sunstroke, and statistics regarding insolation in New York. Of the utmost importance are the findings of Ira Van Gieson as to changes in the nervous system in 3 of the cases. A fuller report is expected to follow later. Sections were examined from the spinal cord, cerebellum, and various portions of the cerebrum, and all showed more or less pronounced changes in the chromophile plaques of the ganglion-cells. These were sometimes changed in shape and reduced in number, at other times they were broken into fine dust, and in others had entirely disappeared. The nucleus is stained more deeply with methylen-blue than normal, and abnormal spheric granules appear. It is supposed by Van Gieson that these conditions show an acute auto-intoxication, and that this may be considered the basis of insolation.

Later Results of Fractures of the Skull.—W. N. Bullard⁴ reports 70 cases of cranial fracture passing through the Boston City Hospital, the diagnosis depending upon the case-records and evidences in the patient. The fractures occupied the base, frontal, parietal, temporal, and occipital regions, and embraced both sexes and all ages. The time elapsing between the injury and investigation varied from 9 months to 47 years. In 15 of the cases trephining had been done. His conclusions are as follows: 1. Out of 70 persons with fractures of the skull, 37 presented no symptoms when examined some

¹ Neurolog. Centralbl., Feb. 1, 1897.

² Am. Jour. Insan., Jan., 1897.

³ Med. News, July 24, 1897.

⁴ Boston M. and S. Jour., Apr. 29, 1897.

time later. 2. Seven persons only presented serious symptoms, and in at least 4 of these it is doubtful whether the symptoms were due to the injury. 3. The most frequent consequences found were headache, deafness, dizziness, and inability to resist the action of alcohol on the brain. 4. Out of the 15 cases in which operation (trephining, etc.) was performed, 12 had no symptoms; in 1 it was doubtful whether the symptoms present were due to the injury; in another the symptoms were slight (headache rare, tension over wound while lying in bed); the other was deaf, but had no other trouble. We are justified, therefore, in concluding, so far as our statistics lead, that those cases in which trephining was performed have shown much better results, as far as the symptoms discussed were concerned, than those in which no operation was performed.

Tumor of the Cerebellum.—Thomas, Barker, and Flexner¹ had a patient, a school-teacher of 30, who complained of difficulty in walking, deafness, and difficulty in seeing. The symptoms extended over 3 years, commencing with fainting, and severe headaches brought on by excitement, especially by laughing. The pain was very severe, but was momentary, and there were momentary losses of vision, especially in the left eye and sometimes in both. Difficulty in walking then appeared; at times she staggered as if she were drunk, and finally walking became impossible. There was a tendency to fall to the left and there was some tremor in the legs. She also complained of tingling in the feet and numbness in the nose and mouth; deafness occurred in the left ear, and was subsequently followed by right-sided deafness. There was some slight jerking of the eyeballs, which later became a well-marked nystagmus, increased toward the left. Fields of vision were at first contracted; the colors were seen in their normal order; then vision was lost in the left eye and afterward in the right eye, the neuroretinitis being followed by atrophy. Sensation objectively was undisturbed, and there was no parietic condition aside from that in the eyes. The deep reflexes were active, and as long as she could stand she had a tendency to fall to the left if unsupported. There were also some pain and drawing at the back of the neck, and at times vomiting. A diagnosis was made of tumor involving the corpora quadrigemina. At the autopsy, made by Flexner, the tumor was found occupying the left lobe of the cerebellum, measuring 6x4x4 cm., attached to the periosteum in the floor of the cerebellar fossa. It had exerted lateral pressure on the left corpora quadrigemina, but there was no growth directly into these bodies. The left half of the pons was also flattened almost to the median line, the left crus was pressed upon, and the left superior peduncle of the cerebellum completely flattened. The middle and right lobes of the cerebellum were free from tumor and the effects of direct pressure. Upon microscopic examination the neoplasm was found to be an alveolar sarcoma.

Joseph Collins and G. E. Brewer² report a case of subcortical cerebellar tumor, in part removed, with death 2½ months later. The patient was 26 years old, an unmarried laborer, without notable family history or personal antecedents of any significance. On Oct. 20, 1896, headache suddenly developed, the pain being principally in the back part of the head, of a boring, agonizing character, and soon after dizziness occurred, aggravated by movement. In a few weeks the gait was uncertain and staggering. Later on, vomiting occurred repeatedly, and the headaches then became generalized and often were located in the frontal region. When seen he was apathetic, remained in bed, and was disinclined to talk. At that time the special senses were not altered, nor was there any cranial nerve disturbance. The right

¹ Bull. Johns Hopkins Hosp., Nov., 1896.

² Med. Record, May 15, 1897.

knee-jerk was lively, the left diminished, and the patient did not hear as acutely in the right ear as in the left; no difference in strength on the two sides of the body, and sensation of touch and position showed no disturbance. There was a moderate degree of choked disk in both eyes, but more marked on the left side. The condition remained unchanged for a month, with the exception that sleeplessness was added. On Feb. 10, 1897, the knee-jerks were very much diminished on both sides, and the gait was simply asthenic. There was some loss of hearing on the right side. A diagnosis, or rather a guess, was made that there was a cerebellar tumor, probably situated subcortically on the right side close to the middle lobe. The patient eagerly accepted operation, and after the dura was opened the cerebellum appeared normal. The finger, however, introduced into the substance of the right lobe a distance of $1\frac{1}{2}$ in. detected a nodule $\frac{3}{4}$ in. in diameter. The position of the tumor was quite close to the 4th ventricle and necessitated great care. It was removed by the finger and Volkmann's spoon. The patient's condition became critical, but he rallied, with immediate improvement in all his symptoms. He did not vomit after the operation nor complain of headache. Two months later his eyesight was nearly normal, and he had gained 30 pounds. During this time he presented two peculiar symptoms: a continuous salty taste in the mouth and a notable increase in the secretion of the urine. During the first month he ordinarily passed 100 ounces of urine in 24 hours, and one day passed 196 ounces. He then presented a pleural effusion with slight temperature only. A clear fluid was withdrawn, which upon examination was found negative as to microorganisms. He suddenly failed and became stuporous with fixed pupils. The vomiting recurred and he was *in extremis*. The symptoms pointed to rapidly increasing intracranial pressure. Under restoratives, but without an anesthetic, the wound was opened and showed a comparatively healthy condition. The finger carried into the substance of the cerebellum impinged upon a large hard mass, irregular in outline and firmly fixed. A gentle effort was made to get the finger beneath it, when instantly the patient stopped breathing and was dead. Upon postmortem examination 24 hours later the right cerebellar hemisphere was found about one-fourth smaller than the left and in its substance, in close proximity to the ventral surface, in the neighborhood of the vermis, there was a hard, irregular mass, the same that had been felt on the operating-table. It measured when removed 4.5 cm. in length, this diameter lying transversely in the brain; 3.5 cm. in width, anteroposteriorly; 2.5 cm. in thickness. It was irregular in form and almost fibroid in hardness. When laid open it was a pale yellowish caseous-looking mass, and was in every respect, as well as by subsequent proving, a tubercle. The ventricles of the cerebral hemispheres were distended and enlarged, containing a corresponding amount of fluid, due apparently to the pressure of the tumor upon the lower exit of the ventricular passages. [This case is interesting as showing the ability of surgery to invade the cerebellum and actually remove a tumor, or a portion of a tumor, as it is not clear whether the mass removed was a part of the larger growth subsequently found or an independent mass. The immediate improvement after the removal of the tumor was also of the most satisfying nature, and life might have been continued for an indefinite time, as far as the intracranial condition was concerned. It is possible that the active interference served to rapidly increase the tuberculoma and led to internal hydrocephalus and death. At the postmortem extensive tubercular changes in the pleural cavity and in the lungs were also detected. This case, with perhaps the exception of that reported by Stewart and Anandale, is the only one in which a cerebellar tumor has been removed without

early fatal termination, though a number of cerebellar cysts have been evacuated with immediate and permanent benefit.]

Agusto Murri,¹ in a report to the Medico-Chirurgica Society of Bologna, describes the clinical history of a youth of 17 who presented the majority of symptoms of cerebellar tumor. An operation was done by Dr. G. Bendani, who extracted from the left half of the cerebellum a part of the tumor, which the microscope showed to be fibrosarcomatous. Total removal was impossible. One month later the boy was still alive and rather better than worse.

Cerebellar Hemorrhage.—Robert E. Peck² gives an account of 4 cases of this rather rare accident, and tabulates the symptoms in these 4 cases and in 20 others published in the literature. The most constant symptoms occurring in this outline were: vomiting, 55% ; paralysis, 45% ; headache, 30% ; vertigo, 35%. The headache was usually occipital, sometimes severe, generally preceding the onset of the more serious symptoms by a longer or shorter period varying from a few days to several weeks, and in one instance there was severe headache for 2 months prior to the attack. Paralysis occurred in 9 out of 20 cases. In 4 cases it was confined to the left side, in 2 cases to the right side, opposite the lesion. In one instance the upper extremities were free and the lower limbs paralyzed. Unconsciousness is an inconstant condition which developed in all but 4 cases at some time before death ; in 3 cases the patients were semicomatose, and in 1 instance the patient remained conscious to the end.

Huntington's Chorea.—J. Mitchell Clarke³ gives the history of an instance of this family affection, and reports postmortem examinations upon 2 cases. He sums up the morbid changes as consisting "in a widespread but partial degeneration of the cells of the cerebral cortex, especially the cells of the second and third layers, most marked in the frontal and motor convolutions, together with an increased amount of interstitial tissue and number of neuroglia-cells."

DISEASES OF THE SPINAL MENINGES AND SPINAL NERVES.

Ascending Degeneration of the Nerves and the Changes in the Nerve-cells Consequent Thereon.—Fleming⁴ first goes over the contributions to this subject. The differences of opinion which have been expressed he attributes some to the manner of operating upon the peripheral nerves and others to the technic employed. In his own series of experiments he used boiled water only, rejecting all antiseptics. He rejects all cases in which union was not by first intention, thus avoiding infection-cases and the changes of the nerve dependent upon it. He also calls attention to the differentiation of nerve inflammation and the Wallerian degeneration. His results were, briefly, that in the process set up by division or ligation of a nerve there was a slight atrophy of motor fibres, with certain sensory fibres degenerating centrally, possibly because separated from their peripheral trophic cells ; that the minute fibres found in a normal nerve undergo very marked change ; that a distinctive connective-tissue increase occurs. By comparing the normal with the operated side he was able to check up his findings, many of which he was thus able to distinguish as mainly artificial.

In the cells he noted the following changes : "1. The cells of the ganglia on the posterior nerve-roots undergo definite changes as the result of nerve section or ligation, and do so at a much earlier period than the multipolar cells

¹ Lancet, Jan. 30, 1897.

³ Brain, 1897.

² Yale Med. Jour., June, 1897.

⁴ Brit. Med. Jour., Oct. 3, 1896.

in the cord—beginning probably as early as the fourth day, and certainly by the seventh day. 2. That one of the very first changes observed in the cells of the ganglia and the anterior cornu is a diminution in the size of the nucleus, in proportion to the size of the cell, and that sometimes, but not in all cases, nucleoli also become smaller, and very frequently the nuclei take up an eccentric position, sometimes even bulging the cell-wall. 3. That in both sets of cells Nissl's granules, otherwise known as the chromatic granules, are either smaller in size, fewer in number, and scattered through the cell-body, tending to be most numerous round the nucleus; or else they are grouped together in large masses round the nucleus, leaving the periphery of the cell quite clear. 4. That pericellular lymph-spaces may become enlarged, especially in the ganglion-cells; and where the enlargement is very marked the cells become proportionately smaller in size, although an actual atrophy may also occur. In several of my specimens I found large vacuoles; not the vacuoles described by many writers as occurring in the cells of the cord and cerebral cortex, which are probably to some extent artificial, but big vacuoles, more resembling distended pericellular lymph-spaces. They differ, however, inasmuch as they are surrounded by the remains of cell-protoplasm containing chromatic granules. 5. That in the multipolar cells not merely are there changes in position and size of nuclei, and in arrangements and number of chromatic granules, but there is, as a later phenomenon, marked disintegration of cell-protoplasm, well seen in some of my specimens. This disintegration has been described by Marinesco as occurring in certain cord-lesions in man. It consists of patches, which with toluidin-blue and eosin are whitish in color and surrounded by masses of chromatic granules.

“In no case did I find any evidence of degeneration in the anterior roots, and I wish to hold over the description of the posterior roots till the full details of my experiments are published, as it would add greatly to the length of this paper. The abdominal sympathetic ganglia show also changes similar in certain respects, but of them I cannot yet speak with confidence. The diminution in size of the nuclei is a point not previously recorded, and yet it is a result upon which it is possible to count with considerable certainty. If, however, there is any inflammation, pus, etc., at the site of lesion, the nuclei may swell up, becoming greatly distended. This appearance is by no means common in my experiments. When examining the cord of a case of peripheral neuritis in which the one arm was much more paralyzed than the other, the nerve-cells in the anterior cornu on the affected side showed diminished size of nucleus and cells as compared with those on the less affected side, and the whole nucleus had a crenated appearance. It is extremely interesting to find the same changes in the multipolar cells in at least one case of peripheral neuritis as after experimental ligation or section. [The importance of this line of investigation and its bearing on the cord-changes in peripheral neuritides, so called, and in the genesis of posterior scleroses of the cord, cannot be overestimated.]

The same author¹ gives a detailed report of 2 cases of peripheral neuritis terminating fatally, in which he found the following spinal changes: “The tracts of white matter show practically nothing. The nerve-cells in the cord, although fixed in Müller's fluid, and therefore not so capable of showing nuclear changes, still demonstrate certain interesting facts, because the multipolar cells on the two sides of the cord show distinct differences. On the left side the cells are practically the nerve-cells of a normal specimen hardened in Müller's fluid. On the right side we find great shrinking of the cells as a

¹ Brain, 1897.

whole. The nuclei are much smaller, and in place of having a distinctly rounded contour their outline is jagged and totally irregular. On the left side the cells show a clear, distinct nucleolus and endonucleolus, and a rich, refractile chromatin network. On the right side the nucleus stains more deeply and homogeneously, the nucleolus is with difficulty made out, and it is sometimes impossible to distinguish the endonucleolus. There are one or two healthy cells in each cell-group of the right anterior horn; there are rather larger numbers of degenerated cells on one side, and the apparently normal cells on the other are quite characteristic. Anilin blue-black reveals further that the affected cells possess fewer processes."

Brauer¹ discusses a case of fatal multiple neuritis occurring in a syphilitic patient treated by mercury. The only cause for the neuritis was the syphilis and the mercurial poisoning. The author is inclined to attribute it mainly to the mercury, in spite of the rarity of such action, but thinks the specific poisoning contributed to the wide involvement of nerves. [We have seen a case of multiple neuritis caused by quarter-grain doses of the green iodid given t. i. d. for several months immediately get well upon the discontinuance of the mercury.]

Erythromelalgia.—Contrary to the views of Nonne, Dehio² considers that erythromelalgia is a special disease with a special pathology of its own. He believes that the hand- and foot-symptoms in his case were due to lesion of the lumbar and cervical portions of the spinal cord, but limits it to the posterior horn of the gray matter. Headache, dizziness, vomiting, and facial symptoms he attributes to intracranial lesion. He thinks the disease is central rather than peripheral, and may be gliomatous in nature.

Henry L. Elsner³ reports a case of this disease in which Raynaud's condition was clearly present, and resulted in amputation of the thumb by dry gangrene. The author calls attention to the rarity of the association of these two conditions, and to the fact that despite the absolute independence of them, as asserted by Mitchell and others, they may be combined and the differential diagnosis rendered difficult or impossible. T. W. Prentice⁴ reports 2 cases in women, in both of which the hands were affected, and in one of which the thumb was at one time so cyanotic as to lead to the fear of gangrene. Both patients were of a neurotic temperament, and other evidences of general nervous instability were present. [The majority of writers are inclined to follow Mitchell in his later expressions that in this condition we are dealing with one of the many phases of polyneuritis.]

Paralysis following Anesthesia.—An editorial⁵ calls attention to the palsies that follow anesthesia, and to the article of Vautrin read at the meeting of the French Medical Congress of 1896, in which he related 3 cases of post-anesthetic palsy, one involving the deltoid, biceps, and brachialis anticus; another involving the deltoid and the long supinator, and a third affecting the face. It is usually the right brachial plexus that seems to be affected, but the face and tongue may be affected, accompanied by ocular troubles, such as dilatation of the pupil, amaurosis, etc. The palsy is sometimes noticed immediately after waking from the anesthesia, or it may be several hours or days afterward. These palsies come on irrespective of the anesthetic employed. Two forms are recognized—one peripheral, the other central in origin; the first being the more frequent and the arm the part usually affected. They are to be attributed to pressure on the brachial plexus, especially when the arm is elevated to facilitate operations on the breast and abdomen. Traction on the shoulder in arti-

¹ Berlin. klin. Woch., Mar. 29, 1897.

³ Med. News, June 19, 1897.

² Ibid., No. 37, 1896.

⁴ Med. Rec., July 10, 1897.

⁵ Ibid., Oct. 17, 1896.

ficial respiration may have the same effect. Vautrin also suggests that other cases may be due to the toxic conditions provoked by long anesthesia. The palsies of central origin are due to cerebral accidents, especially hemorrhages, which are favored by the struggles of the patient during the period of excitement. Garrigues¹ reports 5 cases of paralysis following anesthetics, in his service, adds 9 cases from the paper of Buedinger,² and refers to Vautrin's paper. [The writer has recently seen a case of sciatica due to the lithotomy position employed for two hours in a hysterectomy operation, with weakness in the leg and some loss of sensation about the toes, and a large amount of pain. The most sensitive point was at the sciatic notch and behind the neck of the femur.]

Intradural Section of the Spinal Nerves for Neuralgia.—Abbe³ collected 7 cases of this operation, 3 of which were by himself, and from these cases he draws the following conclusions: a comparatively new and interesting field of work is opened by these few cases. Thus far, even in weak patients, the operation has been devoid of risk. It is sound in theory, and has yielded enough results to show that it may become a meritorious operation. It should be resorted to early in cases of ascending neuritis, which have heretofore been subjected to successive nerve-stretching and resection and finally amputation, uniformly without benefit. The experimental and practical evidence shows that two additional roots higher up than the apparent origin of pain should be included. There ought to be no risk in severing the posterior roots of the third and fourth cervical, as well as those to the brachial plexus, simply because they supply the phrenic, inasmuch as that needs motor supply only, and at best it has the opposite phrenic in reserve.

Meralgia, or Paresthesia of the External Femoral Region.—John C. Shaw⁴ reports 3 cases, giving diagrams of the paresthetic areas. These cases conform closely to those of Roth and Bernhardt. He points out that advanced age, or at least middle life, has some relation to the condition. As a rule, one leg only is affected; but it may be both. Bernhardt considered the symptoms due to degenerative neuritis of the external cutaneous, and was inclined to attribute it to infection and toxic states. It has been suggested by others that it might be due to compression of the nerve by the fascia as it emerges from the pelvis. For this claim there is no foundation. It is increased by awkward positions during the attacks of tingling, but not otherwise. Roth attributes it to disorders of the venous circulation of the nerve, but this does not explain the selection of this particular nerve. The author is inclined to attribute it to toxic infectious causes, in spite of the fact that, as a rule, it has a unilateral distribution. Osler⁵ proposes the term paresthesia meralgia. T. H. Benda⁶ reports a case that complained of this disturbance in the distribution of the external cutaneous nerve for over 30 years. C. Dopfer⁷ reports a case. He thinks that in some cases, at least, neuralgia and neuritis may both be excluded, and attributes the condition to congestion of the veins in and about the nerve, as was first suggested by Roth.

DISEASES OF THE CORD PROPER.

Syringomyelia.—Hinsdale⁸ furnishes an essay on this subject which re-

¹ Am. Jour. Med. Sci., Jan., 1897.

⁸ Neurolog. Centralbl., Mar. 15, 1897.

ceived the Alvarenga Prize for 1895. It contains a bibliography of 514 references, and is the most complete *résumé* of the subject available to the English reader. It is also published as a monograph.

Dereum and Spiller¹ report a case of syringomyelia limited to one posterior horn in the cervical region, with arthropathy of the shoulder-joint and ascending degeneration of the pyramidal tracts. This is a case reported upon several times, and appears as an illustration in a number of books. The confirmation of the diagnosis by autopsy, with exact lesions, makes it a valuable one.

Astic² calls attention to the **boat-shaped deformity of the thorax** which has been met with in some cases of syringomyelia. It consists in a characteristic depression of the central portion of the anterior wall of the chest above the lower margins of the pectoral muscles, on either side of which the chest-wall rises, so that the shoulders appear to be brought forward. This depression has no resemblance to any hitherto-described deformity, and is not a consequence of atrophy of the pectoral muscles nor of scoliosis, but seems to be a trophic lesion analogous to those in other parts of the skeleton. It does not cause any functional trouble. He gives 4 cases, illustrated by photographs.

G. Marinesco³ calls attention to the vasomotor disturbance of syringomyelia, with especial emphasis upon edema of the hands, for which he uses the somewhat fantastic designation of *main succulente*.

At a *séance* of the Société médicale des Hôpitaux de Paris, Feb. 12, 1897,⁴ Marinesco and Jeanselme presented a report on 3 cases of Morvan's disease, with autopsies. Marinesco's report was on a case frequently used by Charcot in illustration of his lectures. Jeanselme reported the necropsies of 2 cases in Bretagne, where Morvan first recognized the disease. In all 3 cases cavities occupying the region of the gray matter of the cord were found, while careful examinations for the bacillus of leprosy and other forms of bacterial life, both in the cord and in the peripheral lesions, were negative.

Progressive Muscular Atrophy of the Duchenne Aran Type.—

J. B. Charcot, son of the late Professor J. M. Charcot, in a brochure entitled *A Contribution to the Study of Progressive Muscular Atrophy of the Duchenne-Aran Type*, Paris, 1895, takes up the controversy between those who discard the autonomy of this type and the classical teaching of his father on the subject. He is enabled by searching the literature and by bringing forward the material at his disposal in La Salpêtrière to produce two or three cases only in which the lesion was confined with practical completeness to the anterior horn. [It must be evident to one who is not wedded to special names for diseases that the contention is one of words and not of conditions. The progressive atrophies showing spinal lesions take on the pure atrophic atonic wasting, or the spastic tonic atrophy, as the anterior gray is primarily affected or is affected secondarily, in point of time, to the pyramidal tracts. The process practically is one and the same, usually reaching from the motor cortex to the muscular terminals, and it is conceivable that in some cases it may be limited to the lower motor neuron, producing the so-called Duchenne-Aran type. Involvement of the pyramidal tract, if occurring early enough to produce symptoms through the lower motor neuron, gives rise to the amyotrophic lateral sclerosis variety.]

Treatment of Progressive Muscular Dystrophy by Physical Exercise.—Alfred Wiener⁵ reports a case that appears to be one of the myopathic dystrophies, in which great benefit followed persistent exercises calcu-

⁵ Am. Jour. Med. Sci., Oct., 1896.

lated to develop the muscles which had wasted and were greatly weakened. After two years of exercise-treatment the man was able to execute readily every possible muscular motion, but still showed weakness in some of the groups, and the wasting, while it had improved, had not entirely disappeared. The muscles of the face had not improved, and these were the only ones that had not been exercised. The lordosis was lessened and the scapulae projected less, the patient being able to put on his coat, collar, and shirt without assistance, which he formerly was unable to do. He could turn about in bed and walk great distances without exertion, and was able to ride 40 miles on a bicycle in one day. The gait, formerly waddling, had become normal. The author urges others to try this line of treatment, and expresses the hope that some of these cases are not inherently beyond improvement.

Epidemic of Acute Poliomyelitis.—Altmann¹ gives an account of 14 cases occurring within 2 months, only 1 isolated case having appeared in the community 8 years previously. In 2 instances 2 members of the same family were attacked in rapid succession. Pasteur² reported an epidemic of poliomyelitis in 7 children in one family. [The reader is also referred to the Vermont epidemic reported by Caverly, and outlined in the *Year-Book* for 1897.]

Pernicious Anemia and the Spinal Cord.—In special literature during the last two or three years a great deal has appeared regarding the spinal cord in cases of pernicious anemia. Lichtheim was the first contributor. Nonne examined 17 cases, in 7 of which the findings in the spinal cord were negative, in 3 lesions were clearly defined in the neighborhood of vessels, and in 7 there were spinal cord lesions of pronounced character. These he attributed to vascular disturbance, either hemorrhagic or by diffusion, similar to the changes which appear in the retina in some cases of pernicious forms of anemia. C. Eugene Riggs³ reports a case at some length, and furnishes illustrations of cross-sections of the cord at every segmental level from the first cervical to the fifth lumbar (Plates 5, 6). The clinical history of the case is rather meager, but indicates a pronounced anemia. Unfortunately, there is no statement of the condition of the brain aside from the fact that the arteries of the circle of Willis showed thickening of the middle coat. In the spinal cord he noted degenerations in the anterior pyramidal tract, the direct cerebellar tract, the crossed pyramidal tract, the column of Lissauer, the column of Burdach, the posterior external field of the posterior column, and the column of Goll. All other columns were normal throughout their entire extent. The gray matter appeared normal throughout. The arteries wherever present showed thickening of the endothelium, and here and there an inward projecting growth of new connective tissue. [Clinically these cases sometimes present symptoms which lead to their being mistaken for locomotor ataxia or multiple neuritis. A close examination should enable the physician to exclude both of these conditions, and if he is aware of the association of cord-lesions of the indiscriminate vascular type with the pernicious anemias, it will not be difficult to clear the diagnosis.]

K. Petran⁴ in 9 cases of pernicious anemia found changes in the nervous apparatus in all. Teichmueller⁵ reports a case of pernicious anemia with arteriosclerosis, paresthesia, chronic enteritis, and increased knee-jerk. Post-mortem, small hemorrhages were found in the corpora striata and corpora quadrigemina. Microscopic examination revealed such changes as have been described by others, especially by Nonne, in the posterior columns, and

hemorrhages in the anterior and lateral columns as well as in the gray matter. The author does not believe that these changes constitute a combined-system disease, but attaches much importance to the lesion of the gray matter. Bastianelli¹ reports a case marked by clinical evidences of disturbance in the lateral columns, especially by increased reflexes and some loss of power, in which changes were found in the posterior lateral columns, but none in the gray substance. In a second case spinal symptoms antedated the recognition of the pernicious anemia. A third case presented changes in the gray substance of the cord in addition to the posterolateral variations.

M. Nonne² investigated the changes in the nervous system, especially in the cord, consecutive to splenic **leukocythemia**. From the literature he finds that 2 cases have been reported in which there were changes in the cranial nerves. These were reported by Eis-enlohr and Müller, who found multiple hemorrhages in the sheath and substance of the nerves, with lymphoid elements similar to those found in other organs in this disease. Kast and Alt have also reported 2 cases in which paralysis on the part of the cranial nerves was due to changes in their nuclei in the medulla. Aside from the 2 cases reported by Nonne in this connection, Müller has reported a case in which there was a slight sclerosis of Goll's and Burdach's columns in the upper portion of the cord in a case of splenic leukocythemia. Nonne's first case was a man 59 years old, who presented an enormous splenic tumor and great enlargement of the liver, with the usual blood-count and all the clinical features of splenic leukocythemia. He showed no symptoms on the part of the nervous system, but at the autopsy, and subsequently, Nonne found in the dorsal and cervical cord, and also in the lumbar cord, small spots of acute myelitic changes in the nerve-substance, confined to the white portion of the cord, the gray substance being entirely spared. The roots, ganglia, and meninges were normal. In the cervical cord there was a clearly marked sclerosis of Goll's columns. In the second case, a male of 31, with well-marked clinical evidence of splenic leukocythemia but who presented no objective symptoms on the part of the nervous system, similar spots of myelitic softening were found, particularly in the direct and crossed motor tracts. In this case there was no sclerosis of Goll's or Burdach's columns. Nonne suggests that the changes in leukemia are considerably like those in pernicious anemia, to which subject he has already made notable contributions, and he expects similar changes in other fatal anemias. He believes it likely that the majority of cases of splenic leukocythemia will present these changes, just as is the case in pernicious anemia, with or without clinical symptoms of involvement of the nervous apparatus. A plate showing the areas of the cord involved and the microscopic character of the myelitic spots, as well as the sclerotic portions of the cord, accompanies the article.

Dr. Abrams³ had a patient who had Hodgkin's disease and locomotor ataxic symptoms. [The ataxic symptoms were probably due to the cord-changes secondary to the leukemia.] J. Michell Clarke⁴ reports two cases, in one of which the changes in the cord were confined to the white matter, especially the posterior columns with a small tract of degeneration in one lateral column. In the other case the gray matter was notably involved.

Toxic Lesions of the Posterior Column of the Spinal Cord.—Redlich⁵ gives a *résumé* of the spinal lesions in various intoxications associated with psychoses of different sorts, epileptiform attacks, and phenomena

¹ Bull. del R. Accad. Med. di Roma, xxii., 1895-96.

² Deutsch. Zeit. f. Nervenheil., H. 3, Bd. 10.

³ Med. Rec., Aug. 7, 1897.

⁴ Brit. Med. Jour., Aug. 7, 1897.

⁵ Centralbl. f. Allg. Path., Dec. 15, 1896.

resembling those of tabes. In ergotism the principal lesions found were sclerosis of the posterior roots and posterior columns. In pellagra, due to the eating of spoiled maize, the lesions were those of combined sclerosis of the posterior and lateral portions of the cord, or practically the posterior half of the cord, and were most intense at the upper levels, gradually diminishing below. Neither the posterior roots nor gray matter was involved. The symptoms are paralytic and spastic, with disturbance of sensation, ataxia, and contracted pupils. In chronic intoxications, polyneuritis and lesions of the posterior columns of the cord are also met with, and the author gives a number of instances of the latter affection dependent upon alcohol, etc., in which sclerosis of the posterior columns was found. The relation of the spinal lesion to the peripheral affection in the nerves, according to Redlich, is a coördinate one, some agents acting on the peripheral nerves and the posterior root-system of the cord at the same time. The changes in the cord due to pernicious anemia present a number of lesions, from which Redlich draws the conclusion that grave anemias of different origin may produce cord-lesions. These are focal degenerations in the posterior columns, which may lead to descending degeneration of the posterior roots, and the fibres of gray matter may escape. The process is indiscriminate, and inclined to affect the cervical cord more than the other portions. The anemia is the indirect cause of the change, which is due, apparently, to toxic substances circulating in the blood. [It thus appears that from a variety of poisons arising from within the body or absorbed from extraneous sources, and from a number of blood-states, sclerotic processes of systemic or indiscriminate distribution may be set up in the cord.]

Myelopathia due to Acute Endarteritis.—E. Biernacki¹ gives the full history and complete anatomic investigations in 3 cases that presented the clinical appearance of acute transverse myelitis. In all 3, under a proper technique, acute softening was found variously distributed in white portions of the cord, in most instances in the shape of triangular infarcts with the base toward the pia, and, most important of all, in all cases in anatomic association with such foci there was found an obliterating pial endarteritis the starting-point of the cord-lesion, in two instances apparently attributable to syphilis, in one, without known cause unless due to exposure to cold. [That acute myelitis is frequently due to endarteritis, and is in effect a thrombotic softening, there can be no doubt. Even embolism may act in this way, as shown by the following:] Prof. Singer² found, through the injection of embolic substances into the vertebral arteries, that he could produce in the cervical and upper cord a cross-myelitis corresponding in all particulars to the clinical type.

Lumbar Puncture.—Furbringer³ notes a case in which lumbar puncture several times repeated secured no fluid, although there was every evidence of intracranial distention. The autopsy showed tuberculous at the base of the brain, with great ventricular dilatation. The base of the brain was converted into a gelatinous and very edematous mass, which extended into the spinal canal, filling the dura and completely plugging the passages. [It is not unlikely that this condition will be found with considerable frequency in tubercular meningitis of the base, the usual location. It is also well recognized that disease of this character may obstruct the passage from the ventricles into the subarachnoid spaces, and consequently lumbar puncture will fail to secure fluid from the intracerebral chambers. The importance of lumbar puncture, from a diagnostic standpoint, must be limited to the cases in which positive evidences are obtained. In such instances the value and practicability of ventricular puncture

¹ Deutsch. Zeit. f. Nervenh., H. 3, Bd. 10.

² Deutsch. Zeit. f. Heilk., Bd. 17, 1897.

³ Deutsch. med. Woch., No. 45, 1895.

should be kept in mind. Ventricular puncture in one case at St. Luke's Hospital, under the writer's care, furnished tubercle-bacilli, where no fluid could be obtained by the spinal method.]

Tumors of the Spinal Cord.—L. Bruns¹ records 2 cases of spinal tumors, with operation. The first case was a woman of 24, of good heredity. She first complained of pains in the region of the sacrum, radiating into the lower members and into the hypogastrium. Paraplegic symptoms followed, corresponding to a lesion appearing to be located at the junction of the dorsal and lumbar cord, and later the lumbar enlargement seemed to be invaded, the bladder and rectum being paralyzed. A diagnosis was made of fibrosarcoma of the spinal cord beginning in the pia mater and the arches of the right side of the lumbar enlargement, finally compressing the cord from the fifth lumbar pair to the last dorsal segment. Operation followed. No tumor was found. Fourteen months later the patient died, and at autopsy multiple sarcomas of the meninges and of the spinal roots were discovered, especially in the lumbar cord. The tumors penetrated the pia mater along the roots and invaded the cord-substance. The entire lumbar cord was transformed into a compact sarcomatous tumor as large as a small apple and the sarcomatous degeneration extended along the pia mater and the roots as high as the middle of the dorsal cord.

The second case was a man of 18, without heredity, who had already undergone several operations for tumors, teratoma of the abdominal cavity, sarcomas of the subclavicular glands and of the testicle. Cutting-pains developed near the left nipple, and total motor and sensory paraplegia followed, extending to this level. A metastatic tumor of the meninges, located between the 3d and 4th dorsal roots, with extension to the 2d dorsal pair, was the diagnosis made. Operation discovered a tumor outside the dura mater, surrounding the posterior portion of the cord, involving the roots of the 2d to 5th pairs. Partial extirpation was accomplished. Much blood was lost, and the patient died the same day. Upon examination postmortem the tumor was found to extend to the 5th and 6th dorsal roots, and at the point where it exerted most pressure extended around the cord to the posterior surface of the vertebral bodies. The anterior surface of the dura mater was not invaded. The tumor was found to be a metastatic sarcoma located in the extradural fat, the internal surface of the dura mater, the pia mater, and the cord being intact as far as tumor-infiltration was concerned. The spinal cord was completely softened and practically divided for the length of $1\frac{1}{2}$ cm. at the point of greatest compression, and was much diseased between the 2d and 7th dorsal segments. The lumbar cord was normal except for descending degenerations in the pyramidal tracts.

Joseph Collins and G. W. Blanchard² describe a case of tumor of the spinal pia at the first cervical segment, which during life was considered a case of cervical pachymeningitis. The symptoms, briefly recapitulated, were as follows: 1. Pain, at the onset, in the back of the neck, later extending into the side of the face and into the upper extremities, and later into the lower extremities. 2. In the beginning the pain was continuous, and of a dull, irritating character; later it occurred paroxysmally, and was of a lancinating nature. 3. A feeling of tension and spasticity in the cephalic extremity, and, to a less degree, in the upper extremities, more particularly in the left arm. 4. Progressive loss of strength in the left upper extremity, and, to a less degree, in the left lower extremity. 5. Exaggeration of the deep reflexes. In the beginning this exaggeration was of the left side alone, but later increased myotatic irritability was universal. 6. Progressive flaccidity of the parts

¹ Arch. f. Psychiat., Bd. 28, II. 1, 1896.

² Med. News, July 10, 1897.

which had previously shown a state of tension or spasticity. 7. Progressive and uncontrollable diarrhea. 8. Symptoms referable to deranged intracranial circulation, pressure, and delirium. During the delirium the patient died, apparently of exhaustion, and the autopsy was held within a few hours. On opening the spinal canal nothing noteworthy was encountered until the pia was reached. This was found to be distended, and upon puncture in the dorsal region a considerable quantity of clear fluid escaped. The distention subsided. Some small white calcareous flakes were found in the dorsal and lumbar regions. On opening the skull and upper portion of the spinal canal a tumor of the pia was found lying upon the cord from the upper margin of the foramen magnum downward 2.1 cm. It was about 2 cm. in its widest measurement. The tumor had the appearance of a sarcoma, was dark reddish in color, and very firm to the touch. Upon microscopic examination it showed the structure of a spindle-celled sarcoma with very large blood-vessels and evidence of small hemorrhages from the degenerated vessels. Foci of cheesy degeneration were also found. The cervical cord at the point which had been subjected to pressure showed degeneration in the crossed pyramidal tracts and the posterior columns.

W. E. Cladek¹ reports a case in which the symptoms were for a long time misleading and obscure. Rather suddenly, he lost power in the lower extremities, with rectal and vesical incontinence, sensation was dulled, and he gradually sank and died 6 months after the original injury, having lost sensation and motion from the waist down. A bedsore had formed. On opening the spinal canal the arches of the vertebrae were found softened, and a growth covering the dura, from which it seemed to spring, completely filled the spinal canal and crowded out through the spinal openings. The growth extended from the second lumbar to the ninth dorsal vertebra, and the cord was not directly involved except by pressure, no adhesions being present. The growth proved to be a spindle-celled sarcoma.

Spinal Hemorrhages in the Newborn.—Schäffer² makes report upon cases observed in the Heidelberg clinic. In 100 autopsies of newborn infants he found that 1 in every 10 had blood extravasated in the vertebral canal, while cerebral extravasations were twice as frequent. In 17 cases the vertebral hemorrhage followed the use of forceps or extraction by the breech. Some of the children perished at birth, others at varying periods subsequent to birth; 64 of the children died of birth-injury. He observed that premature children most often sustained birth-injury, while those born at term developed the postpartum diseases. The most frequent location for the bleeding was in the cervical and dorsal regions, less frequently in the neighborhood of the medulla and in the lumbar cord. He believes that Schultze's manipulations in asphyxiated children may cause spinal hemorrhage. [The etiologic relation of such hemorrhages to spastic paralysis and to syringomyelia has been affirmed by many writers.]

Caisson-disease.—A. Hoche³ describes 2 cases of spastic paraplegia following exposure in caisson-work in the building of the Rhine bridge at Kehl. He then proceeds to the discussion of the disease, with a review of the literature on the subject, and accepts the gas-theory as set up by Catsaras, and experimentally proved by him, as well as by P. Vert. He speaks of the congestion-theory, ordinarily emphasized by American and English writers only to condemn it. When a large amount of gas occurs in the aorta the passage of such gaseous collection into the pulmonary circulation may terminate in

Unusual range of motion in tabes hypotonus (Nouv. Icon. de la Salp., July and Aug., 1896).

sudden death, and this occasionally occurs in the history of caisson-disease. In the same way it may produce fatal cerebral conditions. The tendency of the gas-emboli to absorption explains the temporary manifestations in lighter cases. The gas that is produced by the removal of increased pressure in the blood is mainly nitrogen, but oxygen and carbox dioxid are also thus liberated, and may separately or in combination act as emboli. He accounts for the usual gradual onset of symptoms by the progressive liberation of the gases. Incidentally he speaks of the liability of employers for injuries of this character arising through neglect to take sufficient time in passing the men through the locks, as it has been very fairly proved that time proportionate to the numbers of atmospheres of difference will protect against accidents arising from the change in air-pressure. Snell¹ also adopts the gas-theory, but thinks carbon dioxid is probably the pernicious agent, and lays much stress on the ventilation of such works.

Joint-changes in Locomotor Ataxia without Arthropathies.—

Frenkel and Maurice Faure,² in a beautifully illustrated article, give the results of their investigations into the range of joint-motion in locomotor ataxia, and find that, as a rule, all joints have an increased range of extension and flexion, more especially of extension. They selected 33 cases of tabes, and afterward compared with them a number of cases of hysteria and neurasthenia. For purposes of investigation they selected the position secured by hyperflexion of the lower extremity upon the chest, as shown in Plate 7, Fig. 1, and noted the angle formed by the two extremities. In this number of tabetics the angle thus obtained averaged about 110°, sometimes reaching the extraordinary angle of 150°. This was obtained without the slightest pain to the patient, and was maintained for a considerable length of time without difficulty. Among normal individuals, often embracing children and females, an angle of 65° to 70° was ordinarily obtained, and only exceptionally did it exceed 80°, but this was accomplished with considerable pain in the posterior portion of the flexed thigh. The observation was also checked by similar examination of hysterics and neurasthenics, in whom muscular tone is comparatively reduced, and here an average of about 85° was noted. The same condition was also observed in other joints, as in the ankle-joint, where the range of movements in inversion, shown in Plate 7, Fig. 2, largely exceeds that which could be secured in a normal foot. They explain this over-range of motion by the lowered tonus in the muscles, and call attention to the fact that this lack of tone had been formerly pointed out by Debove.

Bailey³ takes up the subject of the **effect of early optic atrophy upon the progress of tabes**, and gives a history of 12 cases which he examined. From them he draws the following conclusions: 1. In about 75% of the cases of tabes in which optic atrophy is an early symptom some of the other tabetic symptoms may be late in appearing, or may not develop at all. This is especially the case in respect to the lightning-pains and the incoördination of movement. The loss of knee-jerk in such cases is very constant. 2. The most distressing symptoms may develop simultaneously with or immediately succeed the blindness. 3. The association with the optic atrophy of oculomotor palsies is without prognostic significance. 4. The subject will receive its best elucidation by the observation over long periods of time of patients with "primary optic atrophy." [In this article, which is prepared with great attention to detail, there is no mention made of the occasional recession of ataxia after the appearance of optic atrophy, a fact insisted upon by Benedict.

¹ Compressed-air Illness, London, 1896. ² *Nouv. Icon. de la S. Impét.*, July and Aug., 1896.

³ *Med. Rec.*, Nov. 14, 1896.

and which does undoubtedly occur as in a case now under observation in which there were extreme ataxia and the characteristic gait, which completely disappeared when vision was reduced to counting fingers at three feet. At present the man can walk with eyes closed with as much precision if not more than the ordinary individual.]

H. T. Patrick,¹ after calling attention to the early investigations of trunkal anesthesia in locomotor ataxia described by Lachr, publishes a number of cases of **tabetic anesthesia**, with diagrams showing in almost every instance a close relation in the distribution of the anesthesia to the segmental areas that have been mapped out by Thorburn, Starr, Head, and others. Often there is an area of hyperesthesia above the anesthetic band, and the anesthesia is not complete, but is more pronounced for tactile impressions than for painful stimulation. The usual location affected is a band about the body, level with the nipple, sometimes being confined to a patch over the pectoral muscles, from which it is likely to spread in a girdle about the entire trunk. This anesthesia may appear early, but is usually only found when the ataxia is well marked.

A. B. Bonar² gives as the result of an investigation of **the anesthetic areas** in 21 cases of locomotor ataxia a confirmation of the evidence of Laehr and Patrick.

Bettman³ gives his observations of **Fraenkel's exercise-treatment** of ataxia and the rules Fraenkel lays down for the employment of this means. "There are two classes of exercises, those performed in bed and those performed out of bed. In bed, the patient is called upon to flex, extend, abduct, and adduct each leg separately, and then both simultaneously. The knees and hips are likewise exercised. The patient is asked to place the heel of one foot on the big toe of the other foot. Place the heel upon knee of the other leg and then slowly travel from the ridge of the tibia toward the ankle. Exercises are made alternately, first with one leg, then with the other one, with open and with closed eyes. These exercises are attempted over and over again, every morning a half-hour, with frequent rests between times. The patient is encouraged to persevere until he succeeds. The exercises are repeated twice a day, a half-hour in the morning and again a half-hour in the afternoon. 1. Patient is placed with his back to a chair, heels together; then seats himself slowly in the chair, and is then made to rise in the same careful manner. No cane is used. If patient cannot stand, an attendant is placed at either side of him to support him if necessary. 2. One leg is placed at an ordinary walking-step in front of the other, and then placed with great exactness back into its original position. Same exercise is then performed with other leg. The patient, if necessary, supports himself with a cane or otherwise. 3. Walks three paces slowly and with precision. 4. Rest in standing position, one foot before the other; with hands placed akimbo he flexes his knees and slowly raises himself again. 5. Patient, as in exercise No. 2, advances one foot, then returns it to its original position, and then puts it one step behind the other one. This exercise is usually a very difficult one, requiring as it does a great deal of balancing power. 6. Walk twenty steps as in exercise No. 3. 7. No. 2, performed without a cane. 8. Stand without a cane, with feet placed together and hands on hips. 9. Stand without a cane, feet separated; various movements with the arms, grasping objects, forcing back outstretched hand of physician, etc. 10. Maintain same position as in No. 9, flexing trunk forward, backward, to the right and to the left. 11. Exercise No. 9, with feet

¹ N. Y. Med. Jour., Feb. 6, 1897.

² Med. Rec., May 22, 1897.

³ Jour. Am. Med. Assoc., Jan. 2, 1897.

together. 12. Exercise No. 10, with feet together. 13. Walk along a painted line on the floor, patient supported by a cane. 14. Same without a cane. Exercises for the fingers and arms are also employed, based on the above-mentioned principles." [This method of treating ataxia is extremely valuable, and will often serve to keep patients on their feet, perhaps for years, when otherwise they might become bedridden, and it will sometimes succeed in getting patients on their feet who have not walked for a long period of time.]

Tourette and Chipault¹ have investigated, and during the past 4 years put into operation, a **plan of stretching the spinal cord**. They first determined by suspending a cadaver in a Sayr apparatus, without the arm-pieces, that the cord was not influenced mechanically by the procedure; on the contrary, by seating the cadaver upon a table with the lower limbs extended and forcibly bending the trunk forward, the result in 5 bodies was that the cord was actually elongated, as was proved by measurements, the vertebral arches and dura having been removed. The greatest stretching of the cord took place below the middorsal region, and was about equally divided between the cord and the cauda, amounting all together to from 1.1 cm. to 2. cm., the stretching of the cord proper being tolerably uniform, the variation occurring in the cauda. This finding was then applied to the treatment of cases of locomotor ataxia, for which purpose a small low table with a slight headboard was provided. By a waistband the patient is secured to the headboard, and by a circling about the shoulders to which are attached cord and pulleys playing through a sheave, placed between the thighs close to the body, the trunk is forcibly flexed anteriorly. The method was used in 47 cases selected with some care, the early and practically stationary cases of mild degree not being included, and the late cachectic cases also being excluded as well as the cases of acute and very rapidly progressing form; 22 of these 47 patients showed improvement in all their symptoms; especially was there amelioration of the pains and the various visceral crises, as well as improvement of the sensibility. Renal troubles, particularly retention, were improved. Impotence was favorably affected. Twelve of these 22 cases were markedly incoördinate, and in 10 the gait presented some improvement. Ocular and palpebral symptoms were not modified, which the authors rather incline to attribute to the fact that the stretching of the cord only affects the lower portion of it. Fifteen other of the 47 cases received some slight benefit; 10 secured no benefit whatever. The patients received from 15 to 20 *séances*, usually every second day, lasting from 8 to 12 minutes; and the authors advise that the method should be used from 3 to 4 months consecutively, say for 40 or 50 *séances*, when an interval of a month or two should follow. In conclusion, they state that, based upon their experiments, extending over 4 years, and their experience they consider spinal flexion as the only means of attaining elongation of the cord exempt from the dangers of suspension, and obtaining twice as much benefit as by the earlier method.

Friedreich's Ataxia.—Zabludowski² presents a case which was considerably improved by massage.

William G. Spiller³ reports a case of **cerebellar hereditary ataxia, with autopsy**. Death occurred from tuberculosis.

Hodge⁴ reports 4 cases of **family ataxia** in one family. They correspond closely to the cerebral type of Marie. Pauly and Bonne⁵ describe three

¹ Nouv. Incon. de la Salpêtr., May-June, 1897.

² Brit. Med. Jour., Oct. 24, 1896.

³ Brain, 1896.

⁴ Brit. Med. Jour., June 5, 1897.

⁵ Rev. de Méd., Mar. 10, 1897.

brothers of 26, 23, and 12 years, who between the ages of 5 and 15 developed rigidity in the lower extremities, nystagmus, difficulties of speech, increased knee-jerks, ankle-clonus, and other evidence of lack of development in the motor tracts or in the cerebellar control. The cases closely conform to those of the hereditary cerebellar type.

Little's Disease.—The French are inclined, following Brissaud, to regard as cases of Little's disease only the congenital spastic forms of diplegia which are due to lack of development of the pyramidal tracts of the cord. This condition is commonly the result of premature birth or the birth of a child of very small dimensions, at term. Embryologically it has been shown that the lateral motor tracts in the cord are the last to develop, and the fibres only become myelinated at the 9th month and not fully developed until several months after birth. Joseph Collins, in an editorial,¹ quotes Van Gehuchten and others to the same effect, and states that this author contends that absence of the myelin-sheaths of the corticospinal fibers constituting the pyramidal tract is attended by the same clinical phenomena as the degeneration of the fibers. In both conditions there is an absence of the inhibitory action of these fibres upon the ganglion-cells of the anterior horns.

Family Spastic Paraplegia.—C. Achard and H. Fresson² report a family presenting 2 cases of this disease. It seemed stationary, and consisted of a pure spastic paraplegia. The first symptoms were noticed under 16 months of age—that is, as soon as the children commenced to walk, which is rather younger than in most of the reported cases, in some of which it appeared as late as 20 years, and at 56 years in Strümpel's case. As in most other reported cases, the disease seems to have been incited by an acute infection, the exact nature of which, however, in the present instance, is not clear. The family history contains nothing notable from a neuropathic standpoint except an epilepsy in a sister of one of the patients. Syphilis is excluded. Newmark³ gives a description of two families in which the children were afflicted with a spastic condition of the lower extremities. Jendrassik⁴ throws doubt upon the degeneration of the pyramidal tracts as beginning primarily in the cord-fibers in cases of spastic paraplegia. He believes the process may commence at the cells of origin, either in the brain, in the bulb, or in the spinal cord, and would speak of diplegia cerebri, bulbaris, or spinalis, according to the location of the commencing cellular lesion. The author does not believe in the explanation that the pyramidal tracts fail to develop normally in prematurely born children, and thereby cause the typical form of Little's disease, in which he is at variance with the authors already quoted.

Multiple Spinal Sclerosis.—Eichhorst⁵ records a case of multiple sclerosis in a child. The disease was congenital and inherited. The boy was born two years after symptoms of multiple sclerosis had appeared in the mother. Slight tremor on voluntary movement was the only symptom noticed until the boy reached 8 years, when tremor on voluntary movement, nystagmus, optic atrophy, scanning speech, and exaggerated tendon-reflexes appeared. He died shortly afterward. Microscopic examination showed sclerotic islets in all parts of the cord, but none in the pons or brain. In the mother, who died a few years later, the sclerosis had the same limited distribution.

NEUROSES FOLLOWING INFECTION.

Chorea.—The vexed question of the **relationship between rheumatism and chorea** that has had warm advocates on both sides since its early conception by Kirks, is illuminated by the examination of 552 cases of rheumatic fever and 157 cases of chorea, made by T. Churton, and summarized in the *Brit. Med. Jour.* of Sept. 19, 1896. From these cases and a study of the current literature on the subject he adduced the following conclusions: 1. The postulated toxin (x) being accepted as an essential element in the causation of rheumatism, depressing conditions (y) determine the first position or locus of the disorder—that is, what cells or tissues (z) the toxin shall strike. (There is probably a quite separate and independent causation for (x)). In 91 cases of rheumatism in which the incidence of the chill, strain, etc., was recorded with precision, and also the joints or parts first affected, it was seen in every case—or with very few, and doubtful, exceptions—that the part receiving the impact of the conditioning cause was the first to become disordered by the toxin—for example, wetting of feet always caused arthritis first in the lower extremities; of shoulders, in the upper extremities. 2. If (x) and (y) are given, the position of (z) can be stated within certain limits. 3. If (y) is a fright, shock, or intense excitement, (z) will be the nervous system; in the developing brain of a child the result is usually chorea; in adults it may be delirium or coma, perhaps hyperpyrexia. 4. Arthritis or endocarditis may follow the nervous disorder, since the symptoms themselves may become causes of depression of tissues, and thence of multiplication of microorganisms and toxins. 5. Similarly, chorea may follow arthritis; but, 6, arthritis is never the first result of fright; and 7. Chorea is never the first result of chill, unless fear or brain excitement accompanies the chill. 8. A man who, being rheumatic, and having no other known disease, is accidentally subjected to strong excitement—a quarrel—and in a few hours develops chorea, is an “experiment devised by Nature” to prove that the essential cause of the two disorders is the same, and that only the conditioning (localizing) causes are different. In non-rheumatic persons, even young children, brain-disturbance does not cause chorea.

H. L. K. Shaw¹ has been observing the **knee-jerk in chorea**, and with certain London observers believes in the “choreic knee-jerk,” the characteristic feature of which is its irregularity. On striking the patellar tendon the reflex is manifested in several ways: the foot may be jerked upward a slight distance, stop a moment, then complete its course and return, or it may be stopped several times in its upward excursion. More commonly these stops occur in the descent of the foot, the ascent being normal, or the foot may remain stationary at the height of the upper excursion for a second or more, and then descend normally or in an irregular manner, as above described. These jerky movements may occur in both the ascent and descent of the foot. The reflex itself is not exaggerated, and is often slightly diminished. It is sometimes necessary to use Jendrassik’s method of reinforcement to bring out the choreic knee-jerk. Its intensity bears no relation to the severity of the chorea.

Habit-chorea.—Wharton Sinkler² discusses the subject of habit-chorea, basing his paper upon 141 cases that have passed through the Philadelphia Infirmary for Nervous Diseases. The author is disposed to follow in the footsteps of Weir Mitchell, and considers habit-chorea as identical with or closely allied to Sydenham’s chorea, and believes that similar lines of treat-

¹ Albany Med. Ann., May, 1897.

² Am. Jour. Med. Sci., May, 1897.

ment are of advantage in both. [There can be no question that in some instances habit-chorea partakes closely of the nature of Sydenham's chorea, but the majority of cases which can be properly called habit-chorea are, as insisted by Gowers and as reiterated and confirmed by French observers, a form of tic. It is a mental habit, and the mental factor is the important one in it. Arsenic without the addition of moral suasion—in other words, mental treatment and constant suggestion and encouragement—is practically of no value whatever. Aside from its tonic qualities it is doubtful that it ever accomplishes any good in true habit-chorea. It would be advisable that the term habit-chorea be entirely dropped, and the term habit-spasm, or, better, spasmodic tic, be employed.]

Chorea in the Aged.—Riesman¹ reports a case of chorea in a man of 75, affecting the limbs on the left side, especially the hand; he concludes that: 1. True Sydenham's chorea may occur in advanced life and may run a short course, terminating in recovery. 2. The majority of cases of chorea occurring late in life run a chronic and progressive course. 3. At the commencement of the disease it is, as a rule, impossible to say whether it will terminate favorably or become chronic. 4. The movements are generally most marked in the arms; they may begin in the lower extremities, and rarely may remain confined thereto. In 20% of the cases in the table they were unilateral. 5. The mind is normal in three-fifths of the cases in which no hereditary element exists. 6. Rheumatism holds a very subordinate relation to the chorea of late adult life. 7. Endocarditis is comparatively rare, having occurred in only 12.3% of the cases collected in the table. 8. The anatomic lesions in the fatal cases are not characteristic. [While it is certain that Sydenham's chorea in extremely rare instances appears after the age of 40, a close scrutiny of the cases in the above, coupled with the fact that rheumatism is usually absent, cardiac lesions wanting, the onset gradual, recovery exceptional, and the movements of an athetoid character, there is much ground to doubt that many of these cases are those of true chorea. In view of the advanced age, the existence of senile arterial changes, the variations in the postmortem findings, and the hemiplegic distribution, it is much more than likely that they are due to organic changes in the cerebrum, usually of vascular origin.]

Tetanus and its Treatment.—Alexander Lambert² makes a careful study of this subject, in which he gives special emphasis to the localization of tetanus in the body, principally at the point of infection, a fact having important bearing upon the treatment. Under this head he discusses the local and the general measures. Locally, reliance must be placed upon disinfection and antitoxic measures; that is, those calculated to destroy or arrest the toxic products. Against the spores it is practically impossible sufficiently to saturate the tissues with antiseptics, as they are resistant to the action of such agents; but by the addition of a little hydrochloric acid, especially with carbolic acid, they may be readily killed. Silver nitrate and the iodine preparations, as, for instance Gram's solution and Lugol's solution, are also of advantage. He therefore advises that the tetanus-wound be thoroughly cleansed, the most active antiseptics used, and in addition the iodine preparations. Regarding amputation he speaks guardedly, but rather favors it. General treatment consists in, first, speedy elimination of the poisons; second, administration of physiologic antidotes; and, third, the use of chemie antidotes, which change the poison by destroying it or rendering it inert. The elimination of tetanus-poisons is managed through the kidneys, and to this end the author advises active diuresis and the ingestion of large quantities of fluids. Physiological

¹ Am. Jour. Med. Sci., Aug., 1897.

² N. Y. Med. Jour., June 5, 1897.

antidotes of the most value are chloral, bromids, physostigmin, and perhaps also antimony, suggested by Bross, who employed it successfully in 5 acute cases, giving it in doses of $\frac{1}{5}$ to $\frac{1}{6}$ gr., with an equal amount of morphin, every two hours. Chemic antidotes in the form of hypodermic injections of corrosive sublimate and carbolic acid, as by Baccelli, have been recommended; but there is doubt of their being efficacious, as the toxin is operative in the presence of a $\frac{1}{2}$ % solution of carbolic acid, which indeed (as is used in the laboratory for the purpose of preserving it. Antitoxic serum seems to be of value. This, the author believes with Tizzoni, does not act by neutralizing the active principles of the infection, but by immunizing those parts of the body not already tetanized, thus limiting the tetanus locally. In estimating the value of the antitoxin the author accepts 80 % as a fair statement of the fatality usual in tetanus. He analyzes a total of 114 cases, which presented a mortality of 46 % under the antitoxin treatment, and recognizes (as has been pointed out in previous issues of the *Year-Book*) that cases which appear after prolonged incubation, or appear after a short period of incubation but in a mild form, usually get well without any treatment, and so eliminates a large number of these cases. He found that in acute cases developed within 8 days of the injury 31 recovered under antitoxin, or 38.71 %, as compared with 80 % shown by former statistics, and calls attention to the fact that there are certain cases of tetanus of such short incubation and such rapidity of onset that in spite of all treatment they die within 24 to 36 hours after the first symptoms appear. These cases he still considers hopeless, as at least 24 hours are required to secure full saturation of the system with the antitoxin. With Bazy, Nocar, and others he is inclined to advise preventive inoculations of antitoxin in animals and men presenting grimy and dirt-laden wounds, such as sometimes are followed by tetanus. This recommendation is especially based upon Roux's statement, amply proved by experiment, that the toxin can be readily neutralized at the time of infection, but that a very short time afterward it requires doses thousands, and even hundreds of thousands, of times larger to accomplish the same purpose.

Hendley¹ reports a case of tetanus treated with corrosive sublimate, with recovery. Poli² reports the case of a boy of 16 who was kicked on the foot by a horse, and 5 days later developed symptoms of tetanus. Bromid and chloroform were given internally and injections of a 1 % carbolic solution every 2 hours. In 12 days the patient was practically well, but the injections were continued every 2 hours for another 2 weeks; 500 in all were given, with no bad results. Hoefling³ relates the case of a lad of 17 who developed tetanus about a week after a crushing injury to the little finger; 5 days after the onset he was unable to open his mouth; 8 days after the onset 5 gm. of dry antitoxin, dissolved in 45 c.c. of sterilized water, were injected, without much improvement; 2 days later there was difficulty in breathing, and a second injection produced immediate improvement, from which point the patient steadily got well.

Tetany.—Gustav Singer,⁴ in a paper taking up the subject of **autointoxication**, refers to a case of tetany in a man 41 years of age, who was attacked with diarrhea and weakness after eating roast pork. Three days before admission to the hospital constipation set in, and this was followed within 24 hours by typical tetany. The urine contained no albumin, but indican, diacetic acid, acetone, and aromatic sulfates were present. Under treatment with calomel and purges, followed by iodoform internally, the tetany entirely disappeared

¹ Brit. Med. Jour., Jan. 16, 1897.

² Gaz. degli Ospedali, Mar. 14, 1897.

³ Deutsch. med. Woch., Apr. 1, 1897.

⁴ Wien. med. Presse, No. 12, 1897.

and the urine became normal. [The case seems to be a very conclusive one regarding the source of tetany, at least in some instances, from intestinal intoxication.] Oldo¹ rejects the view that in childhood tetany is merely a manifestation of **rickets**, although admitting the frequency of rickets. He accepts the view that the essential cause of the nervous symptoms is a toxemia due to the absorption of poisonous bodies produced in the gastrointestinal canal. This is usually attended by dilatation of the stomach and long retention of food in that viscus. He believes that tetany in the adult is essentially the same, and the result of gastric indigestion marked by hypersecretion of gastric juices containing an excess of hydrochloric acid. The changes in the anterior gray matter of the spinal cord noted by Weiss and others he considers are due to a toxin circulating in the blood. In the treatment of tetany the two indications are the expulsion of toxic substances and the prevention of their formation. Both are met by calomel, which he recommends to be given in doses of $\frac{3}{4}$ gr. every other day, or in larger doses, depending upon the age of the patient. The stomach is to be washed out, a measure to be used with discrimination, however, owing to the risk of exciting laryngeal spasm. The diet must be carefully supervised, and a deficiency of acids in the gastric contents supplied to check decomposition in the intestines. He also recommends in some instances to wash out the large intestine with a boric-acid solution, and the use of vermifuges where there is a suspicion of worms. For the immediate relief of the spasms warm baths are the most effective agents, and of drugs, chloral, which may be given by enema. As a sedative in the continuance of the tetanic state he prefers bromid of strontium, and in some cases has resorted to inhalations of chloroform. A sponge soaked in very hot water applied to the front of the neck often relieves laryngeal spasm, and it may be necessary to follow it by the inhalation of chloroform carefully administered in very small quantities, as at first it may have a tendency to aggravate the spasm.

Cassel² has made an analytical study of 6822 cases, with special attention to determining the nature of tetany and its **relationship to rickets and laryngeal spasm**. There were 60 cases of tetany. The nutrition was good in 14, moderately good in 13, poor in 23, and bad in 10. All presented spontaneous intermittent spasm, which could be induced by pressure upon the large nerves and vessels of the affected parts. In all but three the facial phenomenon was present. Only two had laryngeal spasm, and both of these presented craniotabes in addition to other symptoms of rickets. Without exception the children were nervous and slept badly. Fourteen presented temperature, in 9 the result of complicating conditions, and in the remainder without apparent cause. In 21 cases digestive disturbance preceded or accompanied the tetany, in 5 there was chronic dyspepsia, in 43 digestive disorder, in 6 obstinate constipation, in 4 habitual vomiting. Rickets was present in 52 of the 60 cases; in only 8 was there no trace of rickets. Tetany was seen throughout the entire year, although the largest number appeared to occur in the spring and late autumn. There was no suggestion of an epidemic occurrence of the disease, nor was there any relation as to frequency between tetany, rickets, laryngeal spasm, and craniotabes. He concludes that tetany is neither a complication of rickets nor of digestive disturbance, but is dependent upon unfavorable conditions of living, improper nutrition, and bad air. Kassowitz³ reports a case of latent tetany and rickets, recovery from the tetany following the administration of phosphorus. He discards the gastrointestinal origin of tetany,

¹ Rev. de Méd., June-Sept., 1896.

² Deutsch. med. Woch., Jan. 28, 1897.

³ Neurol. Centralbl., Mar., 1897.

and insists upon the association with rickets, having never seen tetany occur with gastrointestinal catarrh in the absence of rickets, and points to the seasonal variation of tetany, which is opposed to that of gastrointestinal disorders. J. B. McConnell¹ reports a case in which well-marked tetany came on during convalescence from scarlet fever. The condition improved under the use of sodium bromid and potassium salicylate and disappeared within a week.

Tetany and Mental Disease.—F. Schultze² reports a case of a girl of 16, presenting a classical type of tetany, in whom, after a week of disease, during which time she was given doses of iodothylin, mental disturbance appeared in the form of mild mania, during which she was uneasy, restless, and more or less destructive. He refers to the case recorded by Fränkl-Hochwart in 1891, and a subsequent case by Hochhaus, in which there were epileptic attacks in addition to the mental disturbance. [Osler is inclined to believe that mental features in tetany are not purely accidental, but may be considered, perhaps, as a part of the manifestation of the disease.]

Endemic Paralytic Vertigo of Japan, or Kubisgari.—Miura³ gives a report of this disease, which prevails in Northern Japan. It occurs from May to October among laborers of both sexes and all ages, coming on in paroxysms, with ptosis, diminished vision, double vision, optic hyperemia, motor disturbance of the tongue, lips, and muscles of mastication, and paresis of the muscles of the neck, body, and extremities. The involvement of the neck-muscles and the ocular symptoms are the most common. There may be increased reflexes, lachrymation, increase of saliva, and nasal secretion. In the intervals the patients are free from the symptoms, or after severe attacks may retain a mild degree of ptosis. The attacks seem to be brought on, in patients subject to the disease, by the stooping posture. They also present some weakness of the neck-muscles during the intervals between the paroxysms. There are likewise weakness and depression, loss of appetite, and headache. Miura calls attention to the resemblance of this disease to Erb's asthenic bulbar paralysis [a sketch of which was given in the *Year-Book* for 1897], but points out that it most resembles the paralyzing vertigo described by Gerlier, which is epidemic in certain parts of Switzerland. The disease seems to be due to an infection, and is associated with the habits of life, hard work, and close quarters with cattle that obtain in both Japan and Switzerland. P. Lucas-Championnière⁴ gives a similar description of this paralytic vertigo and indicates its infectious character.

TROPHONEUROSES.

Acromegaly.—Vinke⁵ reports a case of acromegaly, photographs of which appear in the *Year-Book* for 1897. He collects from the literature 12 recorded autopsies in which the pituitary gland was found enlarged or disorganized. [A number of other autopsies showing pituitary tumors are noted in the following paragraphs.] Rathmell⁶ gives the clinical history and postmortem findings in a case of acromegaly showing some peculiarities. For a period of months previous to the patient's death there was projectile vomiting of everything introduced into the stomach, necessitating rectal alimentation. He was also troubled with attacks of dyspnea, in which the respiration was of the marked Cheyne-Stokes character, and finally died from apnea. On postmortem the

⁴ Jour. de Méd., May 25, 1897.

⁵ Med. Rec., Nov. 28, 1896.

⁶ Jour. Am. Med. Assoc., Mar. 20, 1897.

costal cartilages were found ossified, the lungs speckled with calcareous particles, all the bones of the skeleton characteristically enlarged. A number of sharp-pointed spinous projections, on the inner surface of the skull, pressed on the dura. There was a tumor of the pituitary, weighing 476 gr. after it had been immersed in alcohol for a number of weeks, and about the size of a hen's egg, and a very tortuous posterior cerebral artery on the left side, resembling a string of beads. Harlow Brooks¹ reports a typical case of acromegaly, with full autopsy. The pituitary fossa was enlarged and contained an ovoid, red mass measuring 1.5 cm. by 0.7 cm., attached to the lower portion of the pituitary body. It pressed on the left optic tract posterior to the chiasm. The hypophysis was also enlarged to about five times its ordinary dimensions. The thyroid gland was symmetrically enlarged. The thymus was found persistent and symmetrical in form. The sympathetic ganglia were large and distinct. Microscopic examination of the enlarged pituitary demonstrated an apparently simple hyperplasia of the lymphadenoid portion of the body. R. Roxburgh and A. J. Collis² report a case of acromegaly in a woman of 35, in whom symptoms had occurred several years before. At the necropsy, 43 hours after death, a large thymus gland, measuring 3.5 in. long and 1.5 in. wide, was found. The thyroid gland appeared normal. The skull presented enormously dilated frontal sinuses, some signs of meningitis were detected, and the pituitary body was the size of an English walnut, very soft and vascular. The microscopic characteristics of the growth were midway between those of glioma and round-celled sarcoma, but from their description and the drawing it is not unlikely that it was a disintegrated adenoma. Hansemann³ describes a case of acromegaly, recognized postmortem, with the usual pituitary tumor. In reviewing the literature of the subject he finds records of 15 cases going to section, 12 of which presented enlargement of the pituitary gland. The 3 not showing this condition embraced at least 2 cases that properly could not be called acromegaly and the third case was doubtful. E. Comini⁴ report 3 cases, in one of which postmortem was obtained. In this the hypophysis was also enlarged. Von Schwoner⁵ reports a case of acromegaly in a woman of 50 whose mother had also presented the disease at about the same age. T. A. Tamburini⁶ reports a case; postmortem discovered a tumor of the hypophysis with enlargement of the sella turcica.

Prof. W. Uhthoff⁷ reports 3 cases, in 2 of which the full picture of acromegaly was established, and in 1 of these a sarcomatous enlargement of the hypophysis was found after death.

Acromegaly and Gigantism.—Walker⁸ reports, with a number of photographs, a case of acromegaly of the giant type in a boy of 16, admitted to Cook County Hospital. At that age he presented a weight of 245 pounds and a stature of 6 ft. 5½ in. The hands and feet were enormously enlarged and of the typical pattern. The superciliary ridges were hypertrophic, but the lower jaw was proportionate to the head. He was noticed to commence to grow very rapidly at the age of 6, but at birth weighed 13 pounds, his brothers and sisters averaging 9 and 10 pounds. Marinesco⁹ secured skiagraphs in 3 cases of acromegaly of the common massive type and in 1 of the giant variety. In all the cases of acromegaly the lateral aspect of the last phalanges appeared to be

¹ N. Y. Med. Jour., Mar. 27, 1897.

⁸ Jour. Am. Med. Assoc., Jan. 23, 1897.

excavated, probably as the result of the very considerable enlargement of the epiphyses of these bones. The case of gigantism showed an increase in the direction of length.

George R. Murray¹ reports, with plates and skiagraphs, 2 cases of acromegaly, the first of which also presented exophthalmic **goiter**, and the second cystic goiter. The association of acromegaly with exophthalmic goiter is, therefore, including this case, on record 5 times. The presence of goiter in acromegaly has been more frequently noted. Rolleston² reported to the Medical Society of London a case of acromegaly in which the disease had been present over 2 years. For 4 or 5 months the patient had been under treatment by pituitary and thyroid extracts, and had shown great improvement, which had been maintained after she left the hospital.

Exophthalmic Goiter.—Gerhardt³ calls attention to the distended condition of the arteries of the body generally in this disease, especially the aortic branches, but finds similar conditions in the arteries of the extremities, as in the palmar arches and the crurals. He also notes capillary pulsation, and pulsation of the spleen, of the liver, and even of the kidneys. [This calls attention prominently to the fact that vasomotor disturbances of the disease are not limited to any particular part.] Tricomi⁴ reports 3 cases of Graves's disease, with marked improvement after partial resection of the lateral lobes of the thyroid.

James A. Spalding⁵ reports a case of goiter in which the protrusion of the eyeballs successively required their **enucleation** because of the purulent choroiditis and hypopyon which had destroyed sight. In a search of the literature he can find but one other case in which the exophthalmus was of this grade. This was reported in Mooren's "Fuent' Lustren."

H. C. Wood⁶ advocates the use of **splenic extract** in the treatment of this disease, and reports a case with satisfactory result. The remedy is rather disagreeable, causing dyspepsia, pain, and vomiting. Used hypodermically it causes great local irritation and even suppuration.

Thymus-feeding in Exophthalmic Goiter.—Owen⁷ has collected the reports of Mikulicz, Cunningham, Eads, Solis Cohen, McKie, Maude, Todd, and Williams who have all had more or less good results in this disease from the therapeutic use of the thymus gland given in a manner similar to that used in thyroid-feeding, and in somewhat similar doses. He says: "Some facts also suggest the possibility of an antagonism between the thymus and thyroid in their relationship to the nervous system." Mackenzie⁸ gives the details of 15 cases of exophthalmic goiter treated with thymus gland, as reported by others. He then adds 20 cases in which he himself had employed the thymus. Of these 20 cases, 1 died, in 6 no improvement was observed, and in 13 there was some improvement. In none did he observe any such decided effects on the symptoms or progress of the disease as would justify him in concluding that the thymus has any great therapeutic activity. As a matter of comparison, he then adds 20 similar cases treated on general principles and by other methods, and in final conclusion states that he finds "the thymus gland has no specific action in Graves's disease. In most cases it had no effect on the heart, or on the goiter, or on the exophthalmus, but at the same time did seem to have some value in improving the general condition." He would rank it with cod-liver oil. The dose varied from a few grains to several

⁸ Am. Jour. Med. Sci., Feb., 1897.

ounces 3 times a day. He would place the usual dose at 1 to 2 drams a day of the fresh gland or its equivalent in the extracts and powders.

Resection of the Cervical Sympathetic for Exophthalmic Goiter and Epilepsy.—Jonnesco¹ has performed complete and bilateral resection of the cervical sympathetic nerve in Basedow's disease. In both cases the operation was followed by the disappearance of prominence of the eyes and lessening in the size of the goiter. The tachycardia was relieved in one case, but persisted in the other. Jaboulay² reports 3 new cases in which he has followed Jonnesco's plan. The first patient was reported cured in a few days; the second case presented immediate relief as to the goiter, rapid heart, and tremor; the third patient was better from the time of operation, and ultimately much improved. The author would also apply the operation to ordinary cases of large goiter, as it seems invariably to diminish the size of the gland, removing the danger from extirpation or pressure. Valençon³ refers to the cases of Jonnesco, Jaboulay, and Marchant. In the case operated upon by himself the sympathetic was divided upon both sides, and the patient left the hospital 9 days later cured of her exophthalmia. Reclus and Faure⁴ have reported a case. Medical treatment had been without benefit and electricity brought only passing amelioration. The cervical sympathetic was readily resected on either side through an incision along the posterior border of the sternomastoid muscle, and improvement speedily ensued. By the 7th day the exophthalmos had almost entirely disappeared, and the ulceration of the cornea had cicatrized; the swelling of the neck had diminished; the pulse was reduced to 90; the trembling was less marked; and the general condition was greatly improved.

Myxedema.—Notkin⁵ divides the symptoms following the removal of the thyroid into two marked groups, those of tetany and those of myxedema. Myxedema he considers the resultant of an albuminous substance, probably "thyreoprotein," whereas tetany depends upon auto-intoxication of the thyroidectomized animal with products of metabolism which are not of a proteid nature. While thyroidless men and animals are restored to perfect health by the administration of thyroid substance, and the albuminous poisons causing myxedema are neutralized by Baumann's iodothylin, this preparation has no antitoxic property in respect to the poison inducing tetany. In a number of experiments on dogs he found that thyroids controlled the tremor and cachexia, but that iodothylin was powerless. Robert Hutchinson⁶ refers to former articles in which he showed that the chemistry of the thyroid furnishes two proteids, a nucleo-albumin and colloid matter. The extractives include creatin, xanthin, etc., and resemble those of other organs, but include, according to Fränkel, amido-bodies, to which an important part in the activity of the gland is to be ascribed. Separating these three varieties of products, Hutchinson experimented with each, and reached the conclusion that the pure colloid matter was the essential constituent of the gland, a position which is confirmed by the statements of Horsley and others, that the athyroidal state is proportionate to the absence of the colloid material in the gland. Hutchinson advises the use of the colloid material, which has a uniformity of activity and is capable of scientifically adjusted doses.

A correspondent of the *Boston Medical and Surgical Journal*, June 24, 1897, gives Kocher's views on **goiter and cretinism**, the results of his investigations as chairman of the Committee of Twenty-five Physicians. More than

¹ Centralbl. f. Chir., Jan. 16, 1897.

⁴ Gaz. hebdom. de Méd. et de Chir., p. 592, June 24, 1897.

⁵ Wien. klin. Woch., Oct. 22, 1896.

⁶ Brit. Med. Jour., Jan. 23, 1897.

76,000 school children between the ages of 7 and 16 were reviewed, with their parentage and antecedents. The investigations were principally made in the Canton of Berne, Switzerland. The formulated results may be briefly stated as follows: the female is more frequently the victim of goiter than the male. In children between the ages of 9 and 14 years goiter reaches its highest degree of frequency, and rarely appears before they are sent to school, where the position of the head in reading and writing gives a tendency to the ailment. There is, therefore, a school-goiter. The secondary changes in the thyroid are proportionate to the advanced age of the individual. Congenital goiter is extremely rare. A still greater exception is congenital atrophy of the thyroid. Kocher noted that the districts supplied with water from the fresh-water sandstone showed a prevalence of goiter, while in the districts in which the water originated from salt-water sandstone goiter was infrequent. He concluded, however, that the prevalence of goiter depended upon the abundance of organic elements in the water rather than upon its source, and that neither deficient nourishment, unhealthy dwellings, nor wretchedness and poverty are a direct causation. Often the districts rich in goiter are separated by narrow limits from those free from the disease, and he discovered in goiter-laden localities oases free from goiter. He also found that there were actual goiter-fountains, the water of which almost invariably produced goiter in the children that drank it. On the other hand, in localities where goiter was prevalent families who had a private water-supply were sometimes free from the infection. Brooks and rivers and long, open conductors of water were unfavorable.

As to cretinism, Kocher, referring to heredity, finds that strong, healthy parents who in regions free from cretinism had begotten normal children, moving into a cretinoid district produced cretins. In these cases, however, the parents, one or both, had previous to the birth of the cretinoid children developed goiter. Such parents upon returning to their former place of residence have again had healthy children. In Kocher's opinion, whenever goiter or cretinism appears in children one of the parents will be found to have goiter; that cretinism arises only and solely when by degeneration of the thyroid gland, due to goiter or some other injury to the gland, its function is impaired or destroyed. Goiter is, therefore, the first stage of cretinism either occurring in the individual or through the parentage. He goes further, and declares that congenital inherited cretinism is derived from the mother alone, while inherited cretinism that appears after the lapse of a few months or years is derived from the father alone. This is explained by the fact that the fetus is supplied with normal thyroid conditions if the mother be not in an athyroidal state, and the inherited tendency from the father may be corrected during intrauterine life and even during lactation by the mother's condition, and only appears when the maternal source of thyroid products is cut off. The reports closes with the injunction to boil the drinking-water, thereby destroying the organic matter, the source of goiter in parents and of cretinism in the offspring.

Grünfeld¹ tried **thyroantitoxin** in 3 cases of exophthalmic goiter, 4 of obesity, 2 of bronchocele, and 1 of simple psoriasis. The drug induced loss of body-weight in 7 of the cases within a few days, subsequent loss of weight being very gradual. In one case of exophthalmic goiter the body-weight rapidly increased, in another it remained stationary. In one case of exophthalmic goiter there was rapid improvement at first, followed by relapse; the other two improved markedly, but were improving when the drug was commenced. In all cases the thyroid tumor softened without diminishing in size. In two cases the perspiration was decreased. In one there was decrease of

¹ Wien. med. Bl., Nos. 49 and 50, 1896.

pigmentation. Doses of 2 gr. a day were administered in some cases, though usually less. Grünfeld considers the preparation to have a certain therapeutic importance and one distinct from Baumann's iodothylin.

Hyperostosis Cranii.—Putnam¹ writes on the subject of hyperostosis cranii, for which Starr proposed the term megaloccephalie, and adds a number of cases (see Plate 8). The disease appears to develop early in life, often as the result of injury or of local inflammatory processes, and consists in an osteitis with deformities. Frequently there are osteophytic outgrowths on the exterior and the interior of the skull, giving rise to symptoms of cerebral tumor in the latter locality. Involvement of the cranial nerves at their exits is a common feature, and the patients usually perish as a result of the encroachment upon the cerebral structures. Dr. Edes² adds an additional case of this disease. Several of the cases mentioned by Putnam and the one by Edes, as well as the one reported by Starr³ some months previously, were treated, without advantage, by the administration of thyroids. The suggestion that the disease is analogous to acromagaly does not seem to be borne out by the facts, as this disease is confined to the bones of the skull, especially the anterior portion, and the upper part of the face, and in most instances does not involve the extremities. Hinsdale⁴ reports a case that occurred under the observation of Dr. Herwirsch, of Philadelphia.

Raynaud's Disease.—Aitken⁵ reports a case of Raynaud's disease associated with uremic symptoms, marked by vascular spasm. The uremia reached the point of producing convulsions, which occurred sometimes in rapid succession, and during these periods the patient passed an extraordinarily small amount of urine with a gradually diminished output of urea. Death finally followed from uremic coma. This case, taken in connection with the numerous cases of Raynaud's disease marked by hemoglobinuria and the cases showing cerebral symptoms from vascular spasm, indicates the widespread nature of the vascular disturbance and the secondary symptoms which might arise from derangement of parenchymatous organs. Osler⁶ reports three cases of Raynaud's disease in which there were notable **mental symptoms**, and refers to other instances in the literature in which it has been noted in asylum cases or under other conditions. There seems to be nothing uniform in the mental features associated with Raynaud's disease; sometimes there are maniacal disturbances, at others depression.

PSYCHONEUROSES.

Neurasthenia.—Knapp⁷ discusses the mental symptoms in 150 cases of neurasthenia, 100 of which were observed in hospital and the remaining 50 in private practice. The commonest mental symptom he finds to be a simple depression, which existed in 27 cases to a degree sufficient to warrant complaint. He finds this more common in private patients than in those entering general hospitals. In some cases the depression passes beyond physiologic bounds and enters the realm of melancholia, the line of division being an indefinite one. Ideas of suicide occasionally result from the depression, and usually occur under conditions of more or less pain, the sight of lethal weapons, or opportunities for self-destruction. These impulses are usually fully described by the patient, unlike those which occur in melancholia and which often show the result of prolonged premeditation. He considers them analo-

Hyperostosis cranii (Am. Jour. Med. Sci., July, 1896).

gous to the vague suicidal impulses that are common in mental health, in which people think of jumping in front of a train or from a height, or shooting themselves, or taking poison, but which impulses are controlled promptly and with readiness. Aside from simple depressions, the largest mental manifestation of neurasthenia may be classed under the head of imperative ideas and morbid fears. These he finds, as might be expected, more common among his private patients than in the hospital cases, mental disturbance being in some relative proportion to the mental development, education, and experience of the patient. He noted such morbid ideas in 21 cases out of his 50 private patients, 15 times in the form of fear, and 6 times in the form of imperative ideas. In the severe forms of neurasthenia, in which the chronic character of the trouble and the failure of various forms of treatment lead to despondency, these fears may persist, and out of them grow delusions which carry the patient into the field of insanity. This is either in the direction of melancholia, or these patients will discuss their morbid fears with the greatest readiness and dwell minutely upon all the circumstances, without a corresponding amount of dejection. The ideas becoming fixed, the condition approaches paranoia, into which it may eventually pass.

Epilepsy.—II. Higier¹ reports a case of **epileptic paroxysmal paralysis** which is closely related to the Jacksonian variety of epilepsy. A boy 6 years of age, of sound parentage, like his sister had convulsions in infancy, which were attributed to the teeth, and was rachitic from the age of 2 years until brought under observation. From the age of 3 he had grown well and developed both physically and mentally. At about the age of 5½ he had experienced a convulsion with loss of consciousness and other evidences of an epileptic character, including the tonic and clonic phases. A week and a half later he complained of prickling, tickling sensations below the right knee, and at the same moment felt such a complete weakness of the limbs that he scarcely had time to seek the bed. Since that time, nearly every day, sometimes 15 or 20 times a day, he has experienced similar attacks. Under personal observation the paresthesia and loss of power seemed to affect the lower extremities without subjective feeling of cramp or contracture. There was no alteration of the patellar reflexes or sensibility.

Clark² makes a study of **mental automatism in epilepsy**, either following an epileptic attack or taking its place, and recites several cases in which the automatism lasted several hours and even several days, during which time the patients acted in a practically normal way, and their automatism was only determined by comparison with their more natural moods. In one case a female patient had a severe attack the night before admission to the Craig Colony. After three weeks of automatism the patient became conscious of where she was, and partially conscious of what had occurred since her admission. In another case a first attack was followed by maniacal disturbance lasting for some days. Three years after this first attack the patient, on his way home from work as a railroad engineer, stopped in the way-station, threw out both operators, and sent a message by telegraph to the central station and received the reply. After doing so he locked the door of the station and went on his way home. He only became aware of what he had done by finding the key of the station in his pocket the next morning. In both these cases the return to consciousness was rather sudden. In another instance the patient, in an automatic state, carried packages about the colony and conversed rationally upon any subject suggested. During the day he made but one mistake in carrying messages and packages, and the same day received letters and

¹ Neurol. Centralbl., Feb. 15, 1897.

² Boston M. and S. Jour., Jan. 14, 1897.

papers from his friends. The following morning he was entirely oblivious of their receipt and of all the occurrences of the previous day. The same author¹ tabulates 9545 epileptic seizures arranged to show the number of attacks occurring in each hour during the day. He finds that they were about evenly divided, the greatest number, 537, occurring between 4 and 5 A. M., and the least number, 224, between 7 and 8 P. M. The author points out that these particular patients being under bromid and chloral, the early morning hours would be the furthest removed from the last bromid dose, and the low tone of the nervous system in the early morning hours may in addition predispose to the frequency of the fits at that hour. Clark² also gives a brief account of 3 cases of epilepsy presenting psychical attacks substituting the fits. Regarding the prognosis in these cases, he considers it unfavorable as to recovery, but of better prognosis as to life than is usual in the cases showing more pronounced motor storms.

A. M. Bleile³ reports on **examinations of urine** carried out at the Epileptic Colony at Gallipolis, Ohio, the purpose of which was to seek for poisonous bodies, ptomaines or toxalbumins, and variations in the ordinary constituents of the urine. The examination covered a period of 30 days, embracing 12 patients. Consideration was given to the specific gravity and amount, urea, uric acid and its relation to urea, phosphates, sulfates, and indol. As to specific gravity and quantity, the epileptic attacks cause, according to this series, no definite variation in either direction. It was found that very generally there was a diminution of the total phosphates, and that there was usually an increase of alkaline phosphates in the ratio existing between the alkaline and earthy forms. This variation, however, is supposed to be no greater than would be occasioned by muscular exercise of equal violence and duration to that produced in the motor phenomena of the fit. Sulphuric acid was investigated as total sulfates, both in the form of ethereal and preformed. The ethereal sulfates embraced the aromatic series, phenol, indol, skatol, etc. The greatest importance was attached to the ethereal, as showing the amount of putrefaction going on in the organism, and its increase, absolute or relative to the preformed sulfates, was considered an index of putrefactive activity, though it is admitted that forms of putrefaction or fermentation may occur without the formation of these bodies, as is claimed by Herter and Smith. For the whole period it was found that in all cases the total amount of sulfates remained below the average normal, this, with other similar findings, being attributed to the diminished quantity of meat in the dietary of these patients. As a general result, it was noted that the putrefactive sulfates were absolutely and relatively decreased below the quantities found in ordinary health and upon an ordinary diet. The author, however, inclines to the view that putrefaction in the economy might go on in certain directions without increasing the ethereal sulfates, but would be indicated perhaps by the production of different bodies, still to be discovered. The search for indol or indican shows practically the same thing as the investigation for the ethereal sulfates in general. In regard to urea, nothing in particular was found, the sum total being usually below 30 gm. of the normal amount, owing to the restricted diet. The same was true of uric acid; but as to the ratio between uric acid and urea the writer finds, contrary to the assertion of Haig and in agreement with Herter and Smith, that the proper proportions were not overpassed at any time by their epileptic patients. In a general way, Bleile anticipates that some toxic substance will be discovered in epilepsy, probably in the uric-acid

¹ Med. Rec., July 31, 1897.

² Ibid., Feb. 20, 1897.

³ N. Y. Med. Jour., May 8, 1897.

group similar to the paraxanthin found by Rachford in migraine. The toxicity of the urine was determined by injections of the ethereal putrefactives into frogs and rabbits, and showed that in epilepsy it was increased.

Medical Treatment of Epilepsy.—Mairel and Bose¹ have reported their experiments with pituitary extract in 21 epileptics. Its administration was followed by a slight elevation of temperature and increase in pulse, but no effect upon the epilepsy was produced. In some instances a slight delirium was occasioned.

Féré² gives a *résumé* of a number of cases treated by **borax**, showing that very little importance is to be attached to the remedy.

Spratling, Superintendent of the Craig Colony for Epileptics, in his third annual report to the State Board of Charities of New York, October 13, 1896, states regarding the treatment of epileptics under his care that **the Flechsigs treatment** was tried in 12 carefully selected cases. In 3 the opium produced great stupor and had to be withdrawn, bromid being at once substituted. The others had the full course of opium, and then bromid was administered. The results were at the time of the report: 1 had had no attacks, 2 were greatly improved, in 3 the attacks were reduced to one-third of their former frequency and severity, and 6 showed no improvement. *Thyroids* were administered in 5 cases, and resulted in benefit in 2 cases; 2 others were slightly benefited, and 1 derived no benefit. The changes induced related to the physical and mental state of the patients, and no modification of the epilepsy was observed. A great majority of the cases were treated by *bromid and chloral*, in addition to which importance is attached to the *dietetic management*, the purpose being to reduce the overconsumption of meat so characteristic of the neurosis, and to furnish outdoor labor, with resulting good physical conditions. He observed that 131 out of 145 cases admitted showed the various *stigmata of degeneracy* in the ear, palate, face, and cranium. Valuable tables showing the character of the aura, the character of the attack, the time of its occurrence, and the assigned causes, with other data related to the disease, are appended.

Henry P. Frost³ reports upon the use of **sulfonal and trional** in the management of these cases. The patients invariably felt well under the influence of the medicine, and disturbances among them in the way of assaults and altercations were less frequent. The dose varied from 5 gr. twice daily to 10 gr. three times a day, the object being to obtain a slight effect only, and the larger dose was rarely continued more than a few days in any case. In one case the heart was seriously depressed even by a very moderate dose of sulfonal.

Flechsigs⁴ reviews the unfavorable results of the **Flechsigs treatment** with the combination of opium and bromids, as reported by several recent writers. He believes that the fatal cases on record have no relation to the treatment, pointing out that a fatal result is common enough in status without any treatment or under any treatment. In his own experience, in treatment by increasing doses of opium, 6 cases out of 50 have had no recurrence. All of the cases treated were severe, of many years' duration, and had resisted all previous treatment. When the opium is used the patient must be treated as one who is seriously ill, and kept under skilful medical attendance and observation.

Operative Treatment of Partial Epilepsy.—[The question of operation in epilepsy is one that has called for very much attention during the last few years. The optimistic outlook of 6 or 8 years ago has unfortunately not

¹ Arch. de Physiol., No. 3, 1896.

² Nouv. Icon. de la Salpêtr., July and Aug., 1896.

³ State Hospitals Bull., Oct., 1896.

⁴ Neurol. Centralbl., Jan., 1897.

been substantiated by results, and there is a tendency to go to the opposite extreme.] A conservative estimate of operation in epilepsy is furnished in an article by Sachs and Gerster,¹ of New York, in which the following conclusions are reached: 1. Those cases of partial epilepsy are suitable for operation in which at most 1 to 3 years have elapsed since the trauma or the onset of the disease. 2. In depression of the skull or in other injuries to the skull operative interference is indicated even after years. The prognosis, however, is less good the longer the elapsed time since the original injury. 3. Simple trephining may suffice in many cases; this is especially true if one is concerned with skull-injury, or with cyst-formation. 4. Excision of the cortical lesion is advisable, if the epilepsy is of short duration and referable to an exactly localizable portion of the brain. 5. Since such lesions are often only visible microscopically, excision should be undertaken even if the diseased part macroscopically appears normal. Still one should, however, use the greatest caution, in order that the proper portion be excised. 6. Surgical interference in epilepsy occurring in connection with infantile cerebral paralysis is permissible, if it occurs not too long after the onset of the paralysis. 7. In old cases of partial epilepsy, in which very probably an extended degeneration of association-fibers has taken place, surgical interference is entirely useless.

Braun² has reported a successful case, the patient remaining free from recurrence during a period of 6 years since the operation. In addition, an analysis is given of 22 cases treated by removal of the motor center from which the epileptic attack had started. In 14 of these cases treatment had been completely successful, but in only 5 had the interval between the operation and report exceeded a year. [Braun is inclined to be more hopeful regarding the advantages of operation in traumatic Jacksonian epilepsy than in any other form, which corresponds with the experience of competent writers the world over.]

Beach³ calls attention to his early use of **gold foil placed within the dura** to prevent adhesions between the meninges and the cortex. The operation was done in 1892, with favorable results regarding the epileptic attacks, which had returned subsequent to a previous operation done in the ordinary manner. He refers to a case seen by Oliver, of Cincinnati, who had the opportunity of making a post-mortem examination, and found that adhesions had been prevented. Sachs and Gerster, in an article already referred to, make the same recommendation. [This measure has everything to commend it.]

Hysteria.—Kattwinkel,⁴ in a careful examination of 104 cases of hysteria, found that in 100 there was abolition of the pharyngeal reflex, and concludes that the disappearance of this reflex is a very satisfactory stigma of hysteria, and must be so recognized.

Prince⁵ relates several cases in which sensory impairment on one side was associated with **monocular blindness**. His cases prove that a high degree of binocular vision is absolutely consistent with hysterical monocular blindness.

P. Ricker and A. Songues⁶ give the history of a case of **male hysteria** in which the principal symptom was contracture of the anterior and posterior muscles of the trunk, producing a rigid, semiflexed position of the body, which could not voluntarily be extended dorsally nor further flexed anteriorly (see Fig.

¹ Deutsch. med. Woch., Aug. 27, 1896; also Am. Jour. Med. Sci., Oct., 1896.

² Centralbl. f. Chir., No. 44.

³ Boston M. and S. Jour., Mar. 25, 1897.

⁴ Deutsch. Arch. f. klin. Med., Bd. 57, Sept. 5 and 6, 1896.

⁵ Am. Jour. Med. Sci., Feb., 1897.

⁶ Nouv. Icon. de la Salpêtr., Mar. and Apr., 1897.

55). Over one shoulder-blade and about a portion of the chest there was a zone of hyperesthesia containing a hysterogenetic spot that made the diagnosis certain. This hysterical spasm was the result of traumatism, and, as in other cases, such as those of P. Janet, referred to in the *Year-Book* for 1897, and the cases published by Duret and by Vieh, was solely dependent upon the fixed idea of dorsal injury. [It is not unlikely that many cases of so-called traumatic lumbago and of rigidities of the spine after traumatic conditions may be of this same nature.]

Karplus¹ reports a case of hysteria in which there was **absence of the pupil-reflex**. The diagnosis was confirmed by Krafft-Ebing, and the symptom was also recognized by Bernheim, the ophthalmologist. An observation by Féré constitutes with this the only two in the literature in which hysteria served to paralyze the pupil. To these we now add the following: V. Jez² reports a case of hysteria in a male who presented the full clinical features of Charcot's grande hystérie; but in addition there was paralysis of the facial, of the hypoglossus, and of the third cranial pairs, causing complete ophthalmoplegia, etc., with loss of hearing, all of which passed away under general treatment of the neurosis.

Arthur Van Harlingen³ takes up a consideration of **hysterical neuroses of the skin**, and gives an extensive bibliography. The different affections of the skin which have been described as occurring in the course of hysteria he lists as follows: erythema, dermatitis, urticaria (including dermographism), hyperidrosis, edema, urticaria bullosum, pemphigus, herpes zoster, eczema, gangrene, pigmentation, vitiligo, lichen, chromidrosis, ecchymosis, hematidrosis. He then describes them in detail. These, the author states, belong to one category marked by erythema, which may go on to urticaria and edema. In a further stage there are vesicular and bullar formations, and finally gangrene. Side by side with these are noted alterations in pigmentary deposit and disturbances of sweat-secretion. They make up a group of vasomotor neuroses. Other disturbances of the skin, such as those found in erythromelalgia, Raynaud's disease, Morvan's disease, disturbances of the hair and nails, are probably more commonly coincidences than due to the hysteria.

FIG. 55.—Contraction of trunk-muscles in traumatic hysteria (Nouv. leon. de la salp., Mar. and Apr., 1897).

MENTAL DISEASES.

Pathologic Studies in Insanity.—Adolf Meyer⁴ reports on 192 autopsies in the two years, 1893 to 1895. In a large number of senile dementes he finds that the fundamental cause consisted in atheromatous

¹ Wien. klin. Woch., No. 52, 1896.

² Ibid., Aug. 1, 1896.

³ Am. Jour. Med. Sci., July, 1897.

⁴ Path. Report, Ill. East. Hosp. for the Insane, 1896.

degeneration of the cerebral blood-vessels and in the frequently resulting atrophy of the brain. These anatomical changes stand as the basis of senile dementia. In 25 cases of epilepsy a large variety of organic lesions are recorded; 15 of the 25 showed some lesion of the nervous system, and the author is at a loss often to decide whether the lesion was primary or secondary. In one case only does he note sclerosis of the cornu ammonis. Among the other conditions found were a small foci of softening, hemorrhagic pachymeningitis, tubercle, cerebral hemiatrophy, diffuse cortical sclerosis, etc. In general paralysis the pia in all cases presented more or less edema and opacity which almost invariably involved the ependyma of the ventricles. Regarding the syphilitic etiology of the disease, the detailed histories are not competent. It is noted only 8 times in 41 cases. The groups of cases denominated acute mania or acute delirious mania will be found interesting to those who are inclined to look upon acute psychoses as of toxic or septic origin. Lesions of the body-organs, usually of an infectious character, were commonly present.

Anatomic Changes in the Brain in Paranoiac Insanity.—Feist,¹ as the result of an examination of the brains and nervous systems of four paranoiacs, reports one case showing peculiar punctate, mesh-like growths in the neuroglia of the posterior columns of the cord, apparently due to degenerated axis-cylinders. There was also a neuroma on one of the dorsal nerves. In another case there was an ascending degeneration of the posterior 6th cervical root, with hyperplasia of the neuroglia of the posterior columns. A third case presented a disappearance of fibres in the gray matter of the cord and a small spot of softening in one anterior horn, due to vascular sclerosis, degeneration of the white matter, and atrophy of the cerebral cortex. A fourth case gave hyaline areas in the gray matter of the cord and some degeneration of the posterior columns. The most constant change was in the posterior columns, in the form of degeneration of the nerve-fibres and diffuse hyperplasia of the neuroglia. The relation of these changes to paranoia is as yet unexplained. They may have something to do with the anesthesia and indifference to traumatism, inflammation, etc., so common in such cases. [The indifference to cutaneous sensibility is not confined to paranoiacs, but reaches its highest degree in the demented, and is a very common finding in paresis. The changes in the cord cited above are not sufficiently marked or widely distributed to account for these particular symptoms. Their value consists in showing the tendency of the nervous system to break down, though the four cases mentioned were all advanced in years, and some of these changes may be of senile origin merely.]

Intestinal Autotoxis and Insanity.—A. McL. Hamilton,² after discussing the possible relation of intestinal autointoxication to mental disturbance, reaches the following conclusions, which are based largely upon his investigations of evidence of putrefaction, as shown by the condition of the urine, and particularly by the presence of the ethereal sulfates in that excretion, as they are taken as an evidence, and to some extent as an indication, of the amount of putrefaction occurring within the economy: 1. Urines rich in indican contain very little or no preformed sulphuric acid, and are toxic. 2. When the sulfate ratio is materially changed, it is likely to indicate autotoxis in connection with an increase in the amount of combined or ethereal sulfates. 3. Such indications are generally found with acute insanities, in which rapidly developing symptoms occur. 4. Fugacious and changing illusions and hallucinations, unsystematized delusions, confusion, and verbigeration in connection

¹ Virchow's Archiv, Bd. 138, p. 443.

² N. Y. Med. Jour., Nov. 14, 1896.

with insomnia, pallor, intestinal indigestion, constipation, and rapid exhaustion, are due to autotoxis. 5. Paranoiac states, or those in which concepts are the features, chronic stuporous conditions and certain forms of dementia have little to do with the formation of intestinal products of putrefaction. 6. Various postfebrile, traumatic, alcoholic, or drug insanities are those in which autotoxis is most constant. 7. The variations in the excretion of combined sulfates keep pace with the changes in the progress of an established insanity, aenes and epileptoid attacks being directly connected with the putrefactive processes. 8. The most successful treatment consists in lavage, intestinal douches, gastric and intestinal antiseptics by means of hydrochloric acid; borax, sodium salicylate, charcoal, guaiacol, or naphthalin in small, repeated doses, and the administration of a combination of the red marrow from the small bones, blood, and glycerin.

W. von Jauregg,¹ basing his statements upon clinical and chemical facts, supposes that many acute psychoses are dependent upon autointoxication from gastrointestinal derangements. These are shown by acetone, diacetone, and butyric acid in the urine, and he corroborates von Jaksch's observations of acute mental trouble, such as amnesia and postepileptic and postalcoholic deliriums following upon acetonuria. His treatment is based upon calomel and iodoform to empty and disinfect the gastrointestinal canal.

Masturbation and Insanity.—Goodner² reports 4 cases of young males in whom insanity, which caused them to be brought to the Illinois Southern Hospital for the Insane, was attributed to masturbation. In 3 there was the stuporous form of melancholia. In the fourth a diagnosis of acute melancholia was given. Although the author is inclined to believe that hereditary tendency is a much stronger factor than masturbation itself, in these 4 cases no such element existed, and he thinks that onanism acted as the sole exciting cause of the insanity. [The cases are not reported with sufficient fulness, and the history is not sufficiently complete to enable the reader to decide for himself whether masturbation played any part or not.]

Mania following Orchotomy; Successful Treatment with Testiculin.—Cabot³ reports a case in which during a crushing-operation for stone the surgeon removed both testicles, in a well-preserved man of 75. He had, however, showed some slight mental disturbance previous to the operation. Following recovery from the anesthetic there was confusional mental disturbance with exacerbations of a maniacal sort. The wound healed kindly and the prostate became considerably reduced, so that a month after the operation the patient passed some urine voluntarily. With care to prevent suggestion and without informing the patient or his friends, testiculin was employed for about two weeks, under which a practically complete improvement of the mental symptoms appeared. [This is perhaps the first case in which the substitution of an organic extract for these removed organs has been tried. We hope to have later accounts of the case and of other cases of a similar nature which now are falling into the hands of surgeons who do orchotomy for enlarged prostate. The possibility of the increased mental disturbance being due to the anesthetic, and not to the orchotomy, must be kept in view.]

Typhoid Fever in Insanity.—R. A. Goodner⁴ discusses the influence of typhoid fever in the production of insanity, and its effect upon insanity when occurring during mental disease. He reaches the following conclusions: Typhoid does not cause insanity nearly so often as is believed and

¹ Wien. klin. Woch., No. 19, 1896.

² Med. News, Feb. 27, 1897.

³ Ann. of Surg., Sept., 1896.

⁴ Medicine, Feb., 1897.

taught. If typhoid causes insanity, it is usually indirectly the result of the great general physical enfeeblement. Typhoid often results in mental recovery, by renovating and improving the condition and functions of the intestines. The melancholias are most likely to be benefited by or to recover after typhoid, as they commonly originate in derangement of the gastrointestinal tract. A valuable lesson to be drawn from a study of the effects of typhoid on the insane is that in treating the insane or those predisposed to mental trouble we should give special attention to the intestinal tract. [Taking into account the relation of acute infections and confusional mania there is little reason to doubt the causative relation of typhoid to many cases of acute mania. It is also true that it is often the inciting cause, a predisposition existing. With the author's conclusions as to the effect of typhoid when occurring in the insane we can agree, but as to the mechanism the case is not proved.]

Insanity in Women.—Rohe¹ takes up this subject again, and continues his plea for gynecological work among insane women. He is inclined to discredit the number of cases showing mental disturbance after gynecological operations, and believes that the mental disturbances following pelvic operations are analogous to those of climacteric insanity, except where they come on within a few days of the operation, when they are usually in the nature of septic delirium.

Endemic Insanity.—Laffan² describes an area of four square miles in County Meath, Ireland, with a population of about 300 persons. One-half of the families have one or more insane, suicidal, idiotic, or goitrous members. This he attributes to consanguinity and heredity, as the conditions under which the people live and their agricultural employment neither account for the endemic nor serve to limit it.

Influence of Tobacco on Nervous and Mental Disorders.—Buccelli,³ after some experiments with tobacco and observations upon its use, reaches the following conclusions: 1. Tobacco is a poison, which, perhaps more than any other, though having little effect in health, has, on the other hand, the most pronounced action in diseased conditions. 2. Tobacco is especially a poison to the subcortical and bulbar nerve-centers, as is demonstrated by the phenomena developed in individuals affected with serious morbid processes of the cortical centers. 3. Being thus capable of producing disastrous effects in convalescent cases who were given to its use before their disorder, and had then suffered no disadvantages, we should be very cautious as to permitting the resumption of its use in such cases, especially in asylums.

Morphinism.—Erlenmeyer⁴ advocates the chemical treatment of morphinism. He has abandoned the method of simply rapidly cutting off the morphin, which method he formerly most vigorously advocated, and now finds superior results in what he calls the chemical treatment. He noticed that the sudden withdrawal of the drug was associated with symptoms of hyperacid dyspepsia, and upon investigation found that the suffering caused by the discontinuance of morphin was attended by the presence of an excess of hydrochloric acid in the stomach. This accords with the fact that morphin is eliminated through the stomach after having been absorbed, and one habituated to the drug, being deprived of the regular sedative effect of the morphin upon the glandular apparatus of the stomach, is placed in a condition of over-gastric activity, excess of acid is poured out, with symptoms of gastric dis-

order and reflex disturbance. To counteract this, Hitzig washed out the stomach and introduced a solution of Carlsbad salts. Erlenmeyer, on the other hand, aims at the neutralization of the acid by means of Fachingen water, which contains a considerable portion of sodium bicarbonate. Thirty cases have been treated in this manner with an entire absence of gastric or nervous symptoms, but the craving for morphin remains unappeased, and it must be gradually withdrawn.

Magnan's Sign in Chronic Cocainism.—Ribakoff¹ has observed Magnan's sign as a predominant symptom of cocain-addiction in 2 cases. This sign consists in an hallucination of cutaneous sensibility characterized by a sensation of foreign bodies under the skin, which are described as inert and spherical, varying in size from a grain to a nut, or as living organisms, worms, bugs, etc. It seems peculiar to intoxication by cocain, and is of considerable differential value. [In the case of a physician, falling under the writer's notice, this hallucination was attributed to "little bugs" that dug deeply into the tissues. He was a mass of scars and wounds where he had proceeded with a scalpel to eject the invaders. In this case there was also hallucination of sight, as he claimed to be able to see the bugs, and asserted that he had watched them boring through the marble top of the washstand. Another physician addicted to cocain had precisely the same ideas.]

Bed-treatment and Isolation in Acute Insanity.—Heilbronner² draws the following conclusions on this subject: 1. In institutions that receive a large number of excited patients the association of the same in large observation-halls is accompanied with serious disadvantages. 2. These disadvantages can be relieved: *a.* By a separate observation-room for the extremely disturbed cases, and, eventually, a third for quiet and orderly patients, separate from the receiving-ward properly so-called; *b.* By a subdivision of the observation-ward, and, finally, by removing the most affected patients into single rooms of a homelike appearance. 3. By suitable architectural arrangements permitting this separation into single rooms, together with thorough watching and care, and the use of the treatment in bed; isolation in this form is to be considered as a valuable therapeutic method. 4. Isolation for other than therapeutic reasons can in this way be reduced to a minimum, but cannot as yet be altogether dispensed with. For certain cases rooms of a stronger construction should be provided.

A. Bernstein³ reports the results of this method for the acutely insane, as shown in a year's experience in the psychiatric clinic at Moscow. He finds it practicable beyond expectation, and that under this method of treatment the manifestations of the mental disorder become less intense, the motor excitement is reduced to a minimum, the intellectual excitations diminished, and the delirium is milder and monotonous. He deduces from this no general conclusions, and leaves the future to decide whether the contraction, so to speak, of the intellectual horizon, tends to repose of the brain or to mental decadence. The experience of the Moscow clinic proves only one thing, viz., the negative finding that recovery is not more prompt and frequent than under the former methods with all their disadvantages. In this he admits that he is in disagreement with some others who have reported on the results of this treatment elsewhere, but he appeals, apparently with reason, to their own statistics in support of his opinion. He deprecates the zeal for this new method which would make it a routine treatment, disregarding the individual needs of every patient, but believes it an advance, as aiding to do away with

¹ *Gaz. degli Ospedali e delle Clin.*, Aug. 4, 1896.

² *Am. Jour. Insan.*, Apr., 1897.

³ *Ann. Médico-Psychologiques*, iv., No. 1, Jan., 1897.

seclusion, untidiness, and destructiveness, and the costly and objectionable appliances hitherto employed to meet these requirements.

Clark Gapen,¹ describing this method at Kankakee, speaks very highly of the results obtained by bed-treatment. According to him, "nearly every new case is given bed-treatment under nursing-care for a month, more or less, according to circumstances." He seems to precede the treatment with massage and flushing of the colon, and a steam or vapor bath, after all which "the patient is both weary and thirsty." Then he is put to bed under the care of the female nurse and food administered. The patient usually goes to sleep as soon as he has partaken of the food, and generally awakes quieter. This is described as the routine treatment, and is applied as well to irritable epileptics as to violent maniacs. Gapen is enthusiastic in favor of female nurses, and says that in no case has there been any indignity offered them, though it was feared this might happen. He finds this class of patients are much more quiet in the hands of women than men. His system requires a specially fitted ward, in which are four trained female nurses and three orderlies, who have charge of never more than 11 cases. It is spoken of, nevertheless, as "taking all the troublesome cases off the other wards."

Senile Insanities.—Ralph Lyman Parsons² treats this very important subject in a careful article. Perhaps senile insanity falls as often under the immediate care of the general practitioner as any other form of mental aberration, and very many of these cases can be properly cared for at home if their circumstances are such as to enable them to have the proper liberty and supervision. The author considers the causation of senile insanities as those so remote as to have been beyond control; those in action in earlier periods of life; and those in action when senility is impending. Under the second class, which are within the range of medical direction, are principally the causes of vascular change and premature senility of the arteries. These are chronic alcoholism, syphilis, gout, rheumatism, venereal excesses, great and prolonged physical strain, intense and long-continued mental application, with anxiety or worry and lack of self-control, as indulgence in the passions of grief or anger. Causes in operation at a more advanced period of life are some of those above enumerated; others are due to advanced physical feebleness and the associated mental decay. At this time many men attempt to maintain a youthful habit which their powers does not justify. This pride may lead them to physical or mental excesses. On the other hand, cases are encountered in which the patient is inclined to yield too readily to the feeling of feebleness, and here needs encouragement. A lack of sufficient food and of digestive ability is one of the prominent causes of the invasion of mental disturbance late in life. This is usually associated with insomnia or with disturbed and inadequate sleep, which is often pieced out by a nap during the day. The indications are clearly for full attention to the digestive apparatus and the securing of a proper amount of sleep at suitable intervals. The prophylactic management of these various items will at once suggest itself. In case of actual insanity the question at once arises whether the patient shall be treated at home or in a sanitarium, hospital, or asylum. This must be determined by the individual circumstances of each case and the character of the mental disturbance. The manias usually require institution-management. The depressed features and the demented forms can be readily cared for at home. The author points out very forcibly, in case lay attendants or kind neighbors assume charge of the patient, that they must be individually instructed by the physician most thor-

¹ N. Am. Pract., Feb., 1897.

² Med. Rec., Oct. 10, 1896.

oughly in all the details of watchfulness and nursing, and that it is never safe to trust anything to their appearance of intelligence.

Shäfer¹ calls attention to **the mental state of the aged**, opening with the statement that old age is the period of normal decline, an intermittent stage between growth and death. It is a physiological process presenting a special aspect, which is the consequence of complicated atrophic processes, and may be considered as a particular phenomenon of cellular life. From a mental point of view the evolution of old age may be divided into three periods, with numerous variations. The first period is characterized especially by a change of temperament, and of instinctive manifestations, sometimes badly controlled. In this stage the old man remains the master of his faculties, but with difficulty acquires new ideas. The second period is prefatory to dementia, and is characterized, first, by the gradual disappearance of mental faculties; second, by the gradual disappearance of affective faculties and the sentiments; third, by the return of instinct. Disappearance of faculties and sentiments occurs in inverse order to their acquisition, the most complex and most elevated first subsiding. The weakness of intellect and of sentimental life always creates a disharmony in their ideas and judgment eminently likely to produce erroneous interpretations and the perpetration of reprehensible acts or leading to action under sudden impulse. In this way the author explains the frequency of suicide among the aged, acts of immodesty and exhibitionism. The artistic acquisitions do not follow the law of recession laid down by Herbert Spencer, often remaining to the last. The third period is the period of senile dementia. The aged reach it gradually, or sometimes suddenly after a period of physical or intellectual overactivity. In certain of the aged, physical decay is not accompanied by intellectual degradation. Regarding responsibility, the author states that it is practically complete in the first period of senility, partial or limited in the second, and *nil* in the third. Certain of the aged grow old with great suddenness—they are precociously senile. This seems to be due to heredity or acquired diathetic influences, such as infections or intoxications. Melancholia is the psychosis most frequently observed in the aged, and all the psychoses are usually manifest in exaltation of the sentiment of personal preservation and preservation of property, frequently with erotic tendencies.

Paretic Dementia.—Piccinnino,² an assistant of Prof. Bianchi, reports five examinations of paretic brains in the laboratory of the Institute Psichiatrico of the University of Naples. These cases of paresis had clear syphilitic histories in some instances, in others it was suspected or denied. With the greatest precautions portions of the meninges and brain were removed through small trephine-openings, to prevent contamination by the removal of the calvarium, and culture-experiments gave absolutely negative results. Slightly modified staining-methods of Lustgarten for his syphilis-bacillus, on the other hand, revealed a great abundance of this bacterium in all the tissues, especially in the perivascular spaces. The same method employed in a number of brains of other varieties of insanity met with a negative result. [It is to be hoped that these findings will be at once confirmed or refuted, as in case they are true it definitely fixes the syphilitic etiology of paretic dementia.]

Gross³ discusses **the early diagnosis of paretic dementia**, and maintains that the differential diagnosis in the early stage of general paresis mainly concerns neurasthenia, and he further points out the important consideration that the ordinary hydrotherapeutic treatment of neurasthenia is very likely to aggravate general paresis. He bases his statements upon the

¹ Lyon Thesis for 1896, abstracted in Arch. de Neurol., June, 1897. ² Ann. di Neurologia.

³ Heidelberg Allg. Zeit. f. Psych., H. 3, Bd. 2.

observation of 189 cases. In only 10 of these was a very acute onset noted; in all the rest neurasthenic or pseudoneurasthenic conditions marked the early stage. He would base the differential diagnosis, even before motor symptoms and intellectual enfeeblement appear, upon the modifications of character, certain expansive phenomena, cerebral excitement, and spasmodic activity. He calls especial attention to the modifications of character which show themselves in a tendency to brutishness, with the occasional appearance of mental confusion, shown by tardiness of conception and enfeeblement of thought, with a diminution of memory. The abnormal acts of general paretics are traceable to the loss of elevated sentiments and an impairment of judgment. These acts, often considered as the cause of neurasthenia, are really the symptoms of the general paresis, and embrace heedless speculation, absurd conduct, and all sorts of excesses. He admits, however, that there is a considerable series of cases in which the differential diagnosis is impossible. Here he considers the age to furnish certain useful indications, stating that neurasthenia is a constitutional affection that nearly always shows itself during youth, while, on the contrary, parietic dementia is a disease of adult life. In his 189 cases only 3 appeared before the age of 30. He believes that when neurasthenia shows itself between 30 and 50 years of age, in a man up to that time of normal health and not neuropathic, that very fact should weigh for something in raising a suspicion of general paresis. In the same way, the appearance of psychical trouble for the first time in adult age has some significance, and apparent recovery is not sufficient to upset the diagnosis. In regard to remissions, he cites a number of interesting and important cases in which the periods of depression, with ideas of persecution and the hypochondriacal delirium, have, even after many months or years, during which there was apparent health, recurred with the full train of somatic conditions common to paresis. He has noted remissions of from 2 to 10 years between the first and second manifestations of the disease, and in many of these cases the first attack was not at the time recognized as belonging to the malady.

August Hoch¹ reports **general paresis** in sisters aged 16 and 19 years respectively, with the autopsy in one case. He makes the following summary, in which especial attention may be called to the luetic history of the father: "It is evident that the two sisters, who were in apparently good health previous to the onset of their disease, gradually developed the symptoms of general paralysis, the one beginning at the age of 10, the other at the age of 15 years. There is a neuropathic heredity, inasmuch as the father was prematurely senile, the mother very nervous. Besides, it is probable that the father has had lues, and we have seen that a luetic heredity is very common in such cases. [It may be said to be invariable.] The clinical course in both sisters was that of a simple progressive dementia, lasting in one case for 6 years, in the other, so far, 4 years. We see from the literature that this simple demented form is the most common in these juvenile cases. The autopsy in the younger sister proved the diagnosis. The lesions in the cerebral cortex were those commonly seen in general paralysis. Similar changes were found in the basal ganglia. In the cerebellar cortex was seen a more or less pronounced degeneration of many Purkinje cells, with great increase in the neuroglia of the cortex and marked diminution in the thickness of the cortex. In the cord the anterior and lateral pyramids were affected. This degeneration could be followed into the pons, but was apparently lost in the crura. From the upper dorsal cord upward there was a degeneration in Gowers' tract, the field of degeneration becoming best marked in the high cervical region and at the be-

¹ Jour. Ment. and Nerv. Dis., Feb., 1897.

ginning of the medulla oblongata. This degeneration is probably due to changes in the gray matter of the cord, which we find in the upper portions in the center of the gray matter on either side. We have finally concluded that while we have every reason to regard the cases which Honien described as differing in their essential disease-process from general paralysis, it may be impossible to differentiate the two diseases clinically." Alzheimer¹ has collected the recorded cases of general paralysis of the insane occurring in children and young persons; 38 cases have been reported, and to these the writer adds 3 cases observed by himself, 1 beginning at the age of 9 years. Unlike the disease in adults, it occurs with equal frequency in the two sexes. The onset in 8 cases was in the 13th or 14th year, in 11 cases it was in the 15th or 16th year, while other cases began a little later. In 28 out of 34 cases hereditary syphilis was certain or probable, and in more than half the cases there was some neurotic heredity. The symptoms and pathology were the same as in adults, and the duration of the disease was about 4½ years in most of the cases, but in some was more than 7 years.

Kleptomania.—A. Lacassagne² calls attention to this variety of mental disturbance, and endeavors to classify the subjects of the tendency to steal when this tendency is due to some mental disturbance rather than a manifestation of vice. He points out that kleptomaniacs have usually been considered as individuals who steal absolutely for the sake of stealing, but he does not take that view of it. In his estimation kleptomania has a special place, and is a morbid manifestation that may appear in a number of neuroses and manias, and is also in all these forms a manifestation of vicious and feeble natures. Kleptomaniacs are criminals by opportunity, and merit some consideration, for often there is no premeditation, but an absence of all desire and a struggle against the inclination to steal, which in them is rarely a result of morbid impulse. He pertinently remarks that the majority of kleptomaniacs of late have been arrested in the large department stores, and that they are inclined to confine their operations to these exciting and fashionable places of business, and that therefore kleptomania at present is most common in the large cities. The author states that in London the police and the proprietors of these places have a list of kleptomaniacs which numbers over 800, with only about a dozen men on the list. When a merchant misses some article, if he can recall the recent presence in his shop of any of the kleptomaniacs on the list, their friends are notified. In some cases the price of the article is returned from as many as a dozen different sources, as often the kleptomaniacs can give no account of themselves and cannot deny the implied charge. In the large bazaars of Lyons and Paris the proprietors state that there are more losses from kleptomaniacs than from thieves. The author points out that thieves usually attempt to sell or dispose of their plunder, while the kleptomaniac secretes and preserves it, and usually, in an individual case, the kleptomaniac confines herself to a certain sort or list of articles, which are taken in great number, but without any possibility of usefulness. Kleptomaniacs frequently become so habituated that they appear at regular hours, and in some places are regularly expected.

Lacassagne would divide them into three categories: First the collectors, who gather articles, apparently for the pleasure of possession. The author likens them to the bibliomaniacs, who, although they buy their books, derive a certain morbid pleasure in merely having them at hand. In the kleptomaniac the formality of the buying is dispensed with, and perhaps there is an additional excitement in executing the theft. In this group he recognizes certain elements

¹ Allg. Zeit. f. Psychiat., lii., fasc. 3.

² Jour. de Méd. de Paris, Oct. 25, 1896.

of dementia and feebleness of will, and believes that a modified punishment usually serves as a salutary lesson for the future with them.

His second class contains those of unstable makeup, who are unable to resist the temptation to steal, and who usually have behind their thefts some motive, such as vanity or coquetry. In certain instances they degenerate into regular thieves, greatly enjoying the excitement and anxiety of the acts of theft.

In the third class he places those actually diseased, such as maniacs, imbeciles, and paralytics, who steal without knowing what they do, their thefts representing internal evidence of their mental disturbance.

In regard to prophylaxis, he points out that these stores present a temptation truly diabolical, and that the plan of supervision now secretly maintained should be superseded by a system of uniformed inspectors, so that the prospect of being apprehended would constantly serve to restrain the kleptomaniac, who is too often inclined to steal under the impression that it may be done without detection. Further, that when kleptomania has once become established such people should be compelled to stay away from places in which their inclination is likely to overcome their self-control.

Walter Channing¹ makes a study of **palatal deformities in idiots**, reviewing the subject and adding many observations of his own. He disagrees with the statements of Clouston and discredits his observations. In his own studies he follows the plan of Talbot, and reaches the following conclusions: 1. Two-fifths of the palates of idiots are of fairly good shape. 2. Palates of normal individuals may be deformed. 3. In the idiot it is a difference in degree, and not in kind. 4. In either case it shows irregular development anatomically. 5. Palates of average children and idiots under 8 years of age probably do not in the majority of cases markedly differ. 6. There is no form of palate peculiar to idiocy. 7. The statement that a V-shaped or other variety of palate is a "stigma of degeneracy" remains to be proved.

W. L. Andriezen,² in a paper entitled "**The Pathogenesis of Epileptic Idiocy and Epileptic Imbecility**," takes up the subject of the fine anatomic changes in these conditions. The observations extended over 14 cases of epileptic idiots or imbeciles and several cases of epilepsy, 1 being a case of typical epilepsy in a child, operated on by Horsley. After giving the changes found in the nerve-cells and the neuroglia in detail, he says that the morbid process in the brain underlying epileptic idiocy and imbecility may be briefly stated, as follows: "There is a sclerotic overgrowth of the neuroglia fibre-cells (diffuse or focal, and in the latter case often corresponding to a particular vascular territory), with corresponding slow irritation, destruction, and final atrophy of the nerve-cells and fibres in the same area." Then taking a bird's eye view of all the cases reported and examined, he says "the type of lesion present in the before-mentioned cases was as follows: "(a) A diffuse sclerosis or overgrowth of the neuroglia fibre-cells in the brain-substance. (b) A coextensive change in the nerve-cells. This change was of two kinds—namely, negative and positive. The negative changes consisted in a defective development (fewness and slenderness) of protoplasmic processes—imbecile type of nerve-cell; while the positive changes consisted of an increase in amount and diffusion of pigment throughout the cell-body, especially its basal part, and a displacement of the nucleus toward the apex of the cell. Later changes were a gradual destruction and atrophy of the nerve-cell processes consequent upon or coextensive with the further outgrowth of the glia (sclerosis) until whole groups or islands of cells might be so destroyed.

¹ Jour. Ment. Sci., Jan., 1897.

² Brit. Med. Jour., May 1, 1897.

“There is thus a common pathogenic basis for epileptic idiocy and imbecility, and for focal epilepsy occurring in the child—namely, anomalies of growth and nutrition impressed upon the growing nerve-cell as well as the neuroglia-cell, and affecting predominantly this or that area of the brain, frequently in territories corresponding to a particular vascular distribution.

“In cases of epilepsy supervening in adult life, after the brain-cells had attained complete development, the changes found were (as regards the nerve-cells) only of the positive kind just mentioned. But, in addition, these very frequently exhibited intranuclear vacuolation of the cortical cells also, an observation of Bevan Lewis which I can fully confirm.

“In the brains of nonepileptic imbeciles, sclerosis and myerogyrria are both conspicuous by their absence. When the epileptic neurosis is present, however, this process is also present. The positive or negative changes in the nerve-elements themselves are present in varying degrees. It is in the combination of these two classes of pathologic lesions that we find the surest indication, the seal as it were, of epileptic idiocy or epileptic imbecility in the brain.”

D. Telford Smith¹ calls attention to the **misshapen hands** found in the Mongol type of idiots, which he deems as significant as the cranial formation and the markings of the tongue that are described by Shuttleworth. In one of these instances he had a skiagraph made of the hand, showing defective development of the middle and terminal phalanges of the little finger, with deviation of the finger outward, giving it a convex line on the ulnar aspect of the hand. Casts and photographs from the hands of these idiots also show thickened, spade-like extremities, suggestive of those sometimes seen in cretins.

Infantile Cerebral Degeneration, with Changes of the Macula.

—Kingdon and Risien Russell² report what they consider a peculiar disease occurring in 4 children. They look upon the disease as a family affection without reference to sex, consanguinity, syphilis, or any of the usual hereditary diseases, but common in the Jewish race. In the first stage the fully developed child, born at full term, shows symptoms toward the end of the third month in the way of muscular enfeeblement and impairment of sight. Definite changes in the macula are detected about the 4th or 5th month; the child becomes so helpless that it cannot sit up, and vision is almost or entirely lost. Muscular atrophy ensues; the deep reflexes are exaggerated; later there are rigidities. Convulsions do not usually occur, and the temperature is normal. Such children generally die within 2 years. Symmetrical degeneration of the pyramidal cells of the cortex and the fibers of the pyramidal tracts throughout their course is found upon microscopic examination. The 5th nerve and the superior cerebellar peduncle and the fillet may also show degeneration. The retina is usually much thickened and the optic nerve is atrophied. [The cases are identical with those reported by Sachs as cases of “family amaurotic idiocy,” already noted in the *Year-Book* for 1897.]

ORTHOPEDIC SURGERY.

BY V. P. GIBNEY, M. D., AND H. W. GIBNEY, M. D.,

OF NEW YORK.

Prefatory Remarks.—The advances in orthopedic surgery have kept pace with those in other departments. The correction of spinal deformities dependent upon Pott's disease promises to be a most marked advance. M. Calot, a French surgeon, has held out hope to the hunchback in some wonderful results, obtained by means which have heretofore appeared hazardous. The medical journals and daily press have been so full of Calot's work that it has been deemed unnecessary to devote space in these pages to more than a recapitulation. Management of the cold abscess is still *sub judice*. The narration of cases and the presentation of statistics and individual opinions are still as impotent as ever. The best work in orthopedic surgery is done, as a rule, by men who are fortunate enough to get cases in the early stages. The prevention of deformity is as important as the correction. Very little progress has been made in the appliances for correction. The greatest advances have been made in operative procedures. The recognition of the value of the specialty by the different medical colleges throughout the country adds fresh impetus, and it is believed that the education of students in early diagnosis will do more than anything else to enhance the value of orthopedic surgery.

DISEASES OF THE SPINE AND THORAX.

Some Apparatus for the Treatment of Pott's Disease.—J. C. Schapps¹ has devised a very convenient wheel-couch, which makes recumbent posture in the treatment of Pott's disease less distressing to the anxious mother and enables the little patient to lead an out-of-door life. The couch is so constructed that the patient can lie upon canvas, while the frame on which the canvas is stretched corresponds very closely with the Bradford frame already in use. [One chief objection to this couch is the absence of springs. So long as the patient is thus recumbent it is good to diminish jar as much as possible. For very young patients, too young for the use of plastic apparatus, or for steel braces, this seems to be an admirable device.]

Control of the Spine by a New Method.—E. A. Tracy² has devised apparently a very simple method of securing control of the spine, and at the same time of making traction, in efforts to *reduce deformity*. Considering the impetus given to reduction of deformity by Calot, this method of Tracy's is timely. It is illustrated in the accompanying figure, which speaks for itself. While he does not advocate the administration of an anesthetic, this can be easily done, and much more accurate traction made by means of screws at the ends of the frame. [At the International Congress in Moscow, 1897, one or two surgeons advocated mechanical means for making traction,

¹ N. Y. Med. Jour., Aug. 1, 1896.

² Boston M. and S. Jour., Oct. 1, 1896.

rather than manual force, in crowding the bosse down with the patient lying prone. The results certainly showed that this is a preferable way.]

Successful Laminectomy in Pott's Paraplegia.—J. Punton¹ records a case of great interest in a patient aged 27, who, in the spring of 1894, developed the disease. The most prominent spinous process was that of the sixth dorsal. The loss of power appeared shortly after the bosse was discovered, and within a month he was compelled to take to bed. Shortly thereafter paraplegia came on. Seven months later the bosse was larger, there was

general anesthesia of the limbs, deep reflexes were exaggerated, ankle-clonus present in both limbs, and motor paralysis of spastic type was complete. Bladder and rectum were never involved. Nov. 23, 1895, laminectomy of the fifth and sixth dorsal vertebræ. Ten days later there was full use of the limbs, and the paralysis seemed to have disappeared. Four weeks later there was a tendency of the deformity to return. Muscular weakness followed and the spastic paralysis returned. Jan. 28th a second operation on the seventh and eighth dorsal vertebræ, when a large abscess was discovered and its contents evacuated. A sinus remained at the date of report, but the paralysis had disappeared and the outlook was good.

¹ Jour. Nerv. and Ment. Dis., Dec., 1896.

Operative Treatment of Pott's Disease.—Diakonoff¹ reports 3 cases in which resection of the vertebral ends of the ribs was resorted to, in order to reach the seat of disease. Two of the cases died shortly after operation. In the third case, that of a child, the deformity involved the seventh cervical and first and second dorsal vertebrae, with complete paralysis of the lower extremities. The incision exposed the transverse processes of the second and third dorsal. The heads of the second and third ribs were removed, when a pus-cavity was discovered, connecting with the spinal canal. Carious bits of bone were removed by a sharp spoon, and the cavity drained; the dura was found intact. The wound was sewed up and iodoform emulsion injected through the drainage-tubes, which were removed two weeks later. Twenty-three days after operation mobility was established in the limbs, and at the end of another month the patient was walking without the use of apparatus.

Compression-paraplegia in Pott's Disease of the Spine.²—In December, 1896, an important discussion on this subject was held at a meeting of the New York Neurological Society. The papers for discussion were 3 in number: V. P. Gibney, 74 cases analyzed; N. M. Shaffer, 40 cases; and De Forest Willard, giving the result of operative procedures in a large number collected. In the first paper there were cured 45, improved 12, unimproved 8, died 9, in a total of 74. In the second paper there were 32 recovered, 8 still under treatment, in a total of 40. All of the cases tabulated in the first two papers were treated by mechanical appliances, and were not subjected to operation. Willard's conclusions from the operative side of the discussion were as follows: 1. Prognosis in pressure-paraplegia is hopeful unless the cord has been actually destroyed. 2. Laminectomy for Pott's paraplegia should never be undertaken until at least 1 year of persistent treatment by rest, fixation, and extension (together with alteratives, etc.) has been most patiently tested. 3. The dangers from the operation are shown by statistics to be great; 24% dying from the immediate shock, 36% within 1 month, and 46% within 1 year. At least 65% either died or were not improved by operation. 4. The dangers are hemorrhage, prolongation of the operation, and manipulation of the cord. 5. In spite of these risks the operation is justified in selected cases when persistent and carefully applied measures have failed. R. Abbe, in the discussion, was reluctant to operate because of the danger of disseminating tuberculosis by operation. Under a careful technic he believed the operation could be made without disturbing the spinal cord, and that the removal of the laminae could be done without impairing the strength of the column. M. A. Starr, C. A. Herter, E. D. Fisher, B. Sachs, and J. Collins all expressed themselves as unwilling to advocate operative procedures, except in desperate cases.

Spinal Cord from a Case of Pott's Disease.—H. D. Boyer³ reports on a cord taken from a case without angular deformity, but paraplegic and without control of both bladder and rectum. The laminae of the dorsal vertebrae from the fifth down were carious. The bodies were carious and filled with cheesy matter. In the dorsal region the dura was greatly thickened, and here the cord was completely surrounded by thickened tissue, in some places to the extent of half an inch. The cord had been greatly pressed upon and nearly destroyed by both mechanical and inflammatory processes. There was no distinct line of demarcation between the cord and white matter, both being almost totally destroyed; cells were few in number; the central canal was filled by new epithelial cells. [Microscopic examination was very

¹ *Centrabl. f. Kinderh.*, i., 309, 1896.

² *Jour. Nerv. and Ment. Dis.*, Apr., 1897.

³ *Ibid.*, Nov., 1896.

thorough, and those interested are referred to the paper for details. The case would seem to be one of osteomyelitis of the spinal column, and emphasized the hopelessness of any operative procedures so long after the invasion of the paralysis, which was six or eight months.]

Dana and Frankel¹ have also reported a case, of which the following is a summary: the patient was a male, aged 60, of nontubercular history. He had very severe spinal pains for 6 months, followed by rapid paraplegia. There was no kyphosis. Death followed 1 year later. The autopsy showed necrosis of vertebrae, tubercular pachymeningitis, and transverse myelitis.

Posture in Diagnosis.—R. Sayre² has illustrated very accurately the different positions assumed in Pott's disease of the spine, and has very properly dwelt upon the assistance one gets in a diagnosis from noting carefully these different attitudes. [The paper is copiously illustrated, and while it makes no effort at presenting anything new, is certainly worthy of record in the *Year-Book*.]

Forcible Reduction of Deformity.—Perhaps the most interesting paper that has appeared in many years, and one that has elicited more discussion, is that of M. Calot, presented to the Paris Academy of Medicine.³ He stated that he had done forcible correction of the *bosse* 37 times, without an accident and with the happiest results. The procedure was regarded both in this country and abroad as so radical that surgeons have been slow to adopt it. The discussion in the journals, and at foreign societies, has developed a certain distrust in the author's claims. Certain accidents have occurred. [The final results are, in some instances, not satisfactory, and the evidence furnished has not been such as to make one feel that assurance in the method that the author himself proclaims. The field is limited, but after all there are enough cases to justify a careful resort to this measure. In the more recent invasions of the column the deformity ought to be overcome and the good position maintained. In these recent cases the treatment will certainly confer a boon upon humanity. It is not a new thing to get recession of deformity. Ambroise Paré, in 1650, published a book, *De Gibborum Corrigeuda Deformitatum* recommending an apparatus for forcible correction.]

Diagnosis and Treatment of Pott's Disease in the Adult.—V. P. Gibney⁴ reports a variety of diseases simulating Pott's disease of the spine, and calls attention to the difficulty of diagnosis, as well as to the results obtained by appropriate treatment. The subjects are: 1st, neuroses of the spine; 2d, rheumatic spondylitis; 3d, fracture of the spine; 4th, multiple osteomyelitis, involving some portion of the vertebrae; 5th, malignant disease of the vertebrae; 6th, Pott's disease proper. All are illustrated by cases, and the protection of the spine in Pott's disease of the adult is shown to yield good results. Indeed, there is no reason why one should not get as good a result in the adult as in the child.

Lateral Curvature, Resection of the Ribs.—Hoffa⁵ puts on record a case of severe scoliosis, in which he performed a section of portions of the ribs. The operation suggested by Volkmann in 1889 was carried out by Hoffa, with an improvement in the condition of the patient. He repeated the operation in a second patient, a boy of 10, presenting curvature from rhabdomyosarcoma. The ribs were sharply bent and made a marked projection. The incision was made from the upper border of the deformity of the ribs to the lower border downward. He made a subperiosteal resection at the ninth rib,

¹ Post-Graduate, July, 1896.

² Trans. N. Y. State Med. Soc., 1897.

³ Ann. de Chir. et d'Orthopédie, Dec., 1896.

⁴ Med. News, Feb., 1897.

⁵ Zeit. f. orthopäd. Chir., p. 401, 1896.

which was the sharpest portion of the deformity. He divided the seventh and eighth ribs the same way, while the third, fourth, fifth, and sixth were twisted out of their vertebral articulations. Although the pleura was perforated, there was no serious disturbance. After the operation the thorax was fixed by adhesive plaster. At the end of eight days the patient was allowed to go about. It is claimed that there was not only great improvement in appearance, but that considerable relief was later effected by means of gymnastic treatment supplemented by a corset. The operator recommends in scoliosis not only resection of a portion of the ribs on the convex side, but on the concave a linear osteotomy. He thinks this would enable one to correct the twist of the spine. [That this operation is radical no one will question, and it is doubtful whether any but a bold surgeon like Hoffa would attempt it. It is difficult to see how any correction of the twist can be accomplished by resection of the ribs on the convex and osteotomy on the concave side. Whether one could correct this twist if he had command of the vertebral ends of the ribs on the concave side, is a question. What should be done with the projecting ends of the ribs after correcting the twist, is a question quite as important. The damage that is likely to be done the pleura, as he himself did, must have due weight, and it is doubtful whether one would get off so well as he. The photographs published certainly show an improvement.]

Forcible Correction without Cutting.—Delore¹ advocates the forcible correction of scoliosis under an anesthetic. A cushion is placed under the axilla and under the pelvis. The patient lies upon the side, and strong force is used in pressing upon the projecting ribs. During this procedure the adhesions are broken down between the ribs and spinal column, the author claims, and a correct position is secured. In some instances the correction is easily made, while in others much force is employed. After all, no evil results have thus far been met with by the author. A fixed bandage is employed, and later, twice a day, manual force is used to secure still further correction. He follows this with the corset to maintain the good result. The patient lies upon the right, or the projecting, side at night. [While this method is radical, it is what is often done by orthopedic surgeons, viz., forcible correction in suspension. It is not uncommon, in highly deformed cases of lateral curvature, to partially suspend the patient, and have an assistant secure the pelvis while the operator presses forcibly on the ribs of the projecting side, crowding the column into a position of over-correction, so far as it is possible. The plaster bandage is immediately applied, and the parts are held in good position until the plaster sets. The idea, therefore, is not new, except in that an anesthetic is employed.]

For Lateral Curvature, the Bicycle.—O. G. Kiliani² recommends a modification of the seats and handle-bars, in the ordinary bicycle, in the treatment of milder cases of lateral curvature. He takes advantage of the old-fashioned chair-seat, with one side raised, and makes the seat of the bicycle correspond. The height of one or the other side of the handle-bar contributes to an elevation or depression of the shoulder, and thus one gets practically the same position of the spine as is obtained in one of Roth's movements, known as the key-note.

DISEASES OF THE HEAD AND NECK.

A Wry-necked Family.—J. H. Thompson³ presents, in a brief com-

¹ Zeit. f. orthopäd. Chir., p. 416, 1896.

² Med. Rec., Oct. 31, 1896.

³ Lancet, July 4, 1896.

munication, the photographs of four members of a family, all of whom have this deformity. The family history is absolutely negative. In only one case did the deformity develop in childhood, and this was the most severe of the four. The spasm was choreiform in character and the patient had great difficulty in speaking and swallowing. The limbs were likewise affected, but not to so great an extent as the head. The second patient developed wry-neck at the age of 32. There are no convulsive movements, no paralysis, and no loss of sensation. The third patient developed the deformity in adult life; the fourth when she was about 18 years of age.

Spasmodic Wry-neck.—Pattee¹ publishes a very interesting paper on the expectant treatment of 8 cases, with cure. There is no definite line of treatment carried out in any case reported, but the author seems to have studied carefully the causation, and after futile attempts at different methods succeeded in finding a method which yielded good results. The paper is well worthy of a careful study, inasmuch as this form of torticollis is usually very rebellious to treatment of any kind.

DISEASES OF THE HIP.

A Modified Splint.—Ap. M. Vance² presents a leather splint which he gave to the profession a few years ago, supplemented by the lower portion of the ordinary Thomas knee-splint. The foot-piece differs from the foot-piece of the knee-splint in that it has a leather splint-shoe, with means for securing traction. [There is really nothing new in principle about this apparatus, but, as the author claims, it is a simple method of fixing a hip and securing a certain amount of traction. It is shown in the accompanying figure.]

Osteotomy as a Treatment for the Disease in the Early Stage.—R. F. Tobin³ advocates a most extraordinary method of treating the disease in its early stage: that of an osteotomy on a level with the lesser trochanter. [The case he figures in a photograph, however, is not hip-disease in the first stage. One is, to say the least, surprised that a surgeon of any standing should advocate so radical a measure in the early stage. Fortunately, however, Howard Marsh⁴ writes a very just criticism. The orthopedic surgeon in this country who is fortunate enough to get a case in the early stage does not need to resort to operative measures, because the average splint, with attention to details, enables him to secure an excellent result. We are prepared to admit that in dispen-

² Med. News, Aug. 29, 1896.

⁴ Ibid., May 8, 1897.

sary practice the splint is often abused, and the disease sometimes advances to the second and third stages, but even this is exceptional. In the more advanced stages, say, where deformity has become fixed, then osteotomy is an excellent routine treatment.]

Death after Osteotomy.—W. R. Townsend,¹ at a meeting of the Orthopedic Section of the New York Academy of Medicine, presented a specimen of the hip-joint from a boy who died within 36 hours after a simple subcutaneous osteotomy. The patient reacted well from the operation, and it was not until the following day, toward the close of the first 24 hours that vomiting appeared, accompanied by a weak, rapid pulse, speedy collapse, and death. The autopsy failed to reveal any cause of death. It was the opinion of the members taking part in the discussion that an embolism had occurred, though there was no positive proof of this. [In view of the large number of patients submitted to this simple operation, the case is extraordinary.]

Muscular Atrophy; Contraction of the Arteries of the Limb as a Probable Cause.—A. G. Miller² claims that diminution of the blood-supply from contraction of the artery, or main arteries, is probably the cause of the atrophy which takes place so early in tuberculous disease of the hip-joint. He has frequently seen contraction of the arteries in limbs amputated for disease. He advances other arguments in favor of this theory, and closes a very interesting paper with the following conclusions: "1. Muscle-atrophy is a common symptom in tubercular joint-disease. 2. No explanation of this atrophy has been suggested hitherto, except a mysterious reflex influence. 3. Contraction of arteries has been seen and proved to exist. 4. The muscle-atrophy is likely to be caused by a diminished blood-supply rather than by nerve-influence. I assume therefore that arterial contraction and consequent diminished blood-supply are the cause of muscle-atrophy in tubercular joint-disease." [We are free to admit that the argument induced by the author is weighty, because we have always felt that there was something vague about this "mysterious reflex influence." The theory which seeks to establish reflex centers and reflex nerves has been nothing more than a suggestion accompanied by little or no proof.]

Double Excision, with Cure.—Prewit³ reports a case in a boy whose disease developed on the left side when he was 2½ years of age. Three years later there were indications of disease in the right hip, as an abscess had already formed. Later there were sinuses, and the disease was progressing from bad to worse, when, after unsuccessful attempts at curetting to relieve the patient, he excised the left hip, which healed without suppuration. Nearly a year later he excised the right hip, finding both head and acetabulum extensively diseased. The patient made a good recovery. When presented to a society the sinuses were healed and the boy walked without crutches. There was likewise a small range of motion. [Such instances are not new, but exceedingly rare. It not unfrequently happens in double hip-disease that a surgeon is so pleased with the result of resection on one side that he is tempted to perform it on the other. The results, are, as a rule, unsatisfactory, and the author of this report is to be congratulated.]

The Non-bloody Reduction of Congenital Dislocations.—G. R. Elliot,⁴ after a visit to Lorenz, presents a very complete record of the work done by the Vienna surgeon, and demonstrates his new method with the record of a case or two. To Sept. 25, 1897, 83 cases have been operated upon by Lorenz, and the results were thought to have surpassed those obtained by the

PLATE 9.

Apparatus for the gradual reduction of flexion and subluxation of the knee (from photographs furnished by E. B. Young .

open method. [Our own experience in this direction is at least satisfactory, though the results thus far secured have not been perfect. The procedure appeals to the general practitioner and to laymen with more force than ever did the bloody method—a method still on trial. As for ourselves, we believe that the cases suitable for bloody reduction are few, and that the technic of the operation, the after-treatment, and the subsequent use of splints are not fully comprehended. In Hoffa's private hospital at Würzburg great attention is given to massage and muscle-pedagogy. It may be, therefore, that the good results which the European surgeons claim to have established are largely due to the after-treatment. Lorenz has published a volume of 372 pages, with 54 figures, and the work has been translated by J. Cottet, into French, with a preface by Dr. Brun. The publishers are Geo. Carre et Aenaud.]

DISEASES OF THE KNEE.

Gradual Reduction of Deformity.—E. B. Young¹ describes and illustrates a means of gradually reducing flexion and sublucation of the knee on the principle of the genuclast. The apparatus consists of the ordinary frame for holding the patient in bed, and an arched strip of scantling supported by an upright at each end. The uprights are fastened firmly to the bed, while small galvanized iron pulleys may be fastened at any point along this arch. By means of the weights and pulleys the thigh is held in position while traction is made in the line of deformity of the leg. At the same time force is employed by means of the weights against the posterior aspect of the upper third of the leg. Indeed, the pads and straps are so applied that direct force is brought to bear against the salient points in the deformity. The author has had an opportunity of using the apparatus in the Children's Hospital, and he claims that the deformity is reduced in a remarkably short period of time—from two to three days in rather severe cases. Plate 9 represents the apparatus in use. The first step in the treatment is the reduction of the sublucation of the head of the tibia. The counterextension strap *A* prevents the lower end of the femur from moving forward, and the whole force of extension, *B*, applied to the lower limb tends to separate the tibia from the femur. The traction at *C* pulls forward the head of the tibia. As much weight may be applied as the patient can stand with comfort; but the amount attached to *B* should be sufficient to prevent the pull on *C* from disturbing the position of the leg while the tibia is being brought into place. After the backward displacement is fully overcome, all that is necessary is to keep the tibia in position and slowly pull out the flexion after the manner shown in the illustration. The weight at *C* is reduced until just sufficient to keep the head of the bone forward, while that at *B* is increased as much as possible. The traction at *A* is carried downward through a pulley attached to a frame on which the child lies, and upward over another pulley, so that the downward pull at the lower end of the femur counteracts the tendency at *C* to flex the knee-joint. [The method is certainly deserving of credit so far as one can judge from the study of a report, because there is nothing quite so intractable as these minor deformities of the knee, accompanied by flexion and sublucation.]

Non-calcifying Plastic Ostitis.—Pitts and Shattock,² at the London Pathologic Society, presented a specimen removed by amputation from a woman, aged 39, who had received an injury to her knee when she was 31. The limb was removed on account of pain and discomfort and failure to get

¹ Boston M. and S. Jour., Oct. 8, 1896.

² Brit. Med. Jour., Jan. 23, 1897.

relief in various hospitals. The upper half of the tibia had undergone a uniform transformation into cancellous bone-like substance so void of earthy salts that the bone itself was as pliable as India-rubber; a like tissue filled the medullary cavity. It was easy to make specimens for microscopic purposes without artificial decalcification. After appropriate staining the trabeculae were found surrounded with osteoblasts. The spaces between the trabeculae were everywhere occupied by highly cellular connective tissue. Quite a full description followed, and its relationship to other conditions of bone was fully discussed.

Conservative Operation in a Case of Tubercular Goneitis.—H. Lilienthal¹ reports a very rebellious case. The account given of the condition is such as to lead one to class it among the most desperate of these tubercular lesions of the bones involving the knee. The operation performed was that advised by Mayo, of Minnesota. "After applying the Esmarch constrictor, the knee was opened by a transverse incision through the ligamentum patellae, taking in, in this case, more than two-thirds of the circumference of the limb. All the structures were divided as in resection of the knee, and so far as possible cut away. The patella was removed. The quadriceps bursa was laid open by an incision at right angles to the first one, and this last cut had to be extended nearly to the fold of the groin. All diseased surfaces were thoroughly scraped. Other extensive incisions were made longitudinally over the fibula, and also over the inner aspect of the knee. Every recess was laid open in so thorough a fashion that drainage-tubes were dispensed with, the wounds being stuffed with weak iodoformized gauze, which was, at subsequent dressings, replaced by nosophen gauze, because I feared iodoform-poisoning from the vast extent of the wounded surface. The leg was now flexed on the thigh *beyond* a right angle. The gaping knee-joint was also thoroughly packed, and the patient sent to bed with the limb in this flexed position." Under chloroform three weeks afterward the parts were flushed and an attempt made to straighten the limb. Contractures of the soft parts had resulted from this long-flexed position, and it was necessary to take a thick shaving from the femoral condyles before the limb came into a suitable position. Healing went on rapidly. Three months from the date of the first step in the Mayo operation the child was discharged cured.

Displaced Semilunar Cartilages.—Douglas Graham² reports several cases reduced by massage and certain movements. He makes a very fair argument for this method of treatment, and gives this rule for its replacement: "Flex the leg, then extend suddenly, rotating the leg internally if it be the internal cartilage, outwardly if it be the external cartilage, and exert pressure over the offending region." He feels that it can be held in place by a figure-of-8 bandage and a few folds of bandage as a pad. This bandage and pad, he thinks, affords a safe limit to the motion, and a dislocation is not apt to occur. [It has long been claimed by masseurs that much could be done for these displacements about the knee, but the results are not always satisfactory. Graham's paper, however, is very clear on the subject, and is worthy of record.]

DISEASES OF THE FOOT.

Metatarsalgia.—R. Jones,³ after a lengthy discussion on the literature of the subject, recommends the following treatment: 1. Abstain from continuing any action which produces the pain; 2. Increase the depth of the inner aspect

¹ Pediatrics, May 15, 1897.

² Am. Jour. Med. Sci., Nov., 1896.

³ Liverpool Med.-Chir. Jour., Jan., 1897.

of the heel in order to produce slight inversion of foot; 3. Wear thick soles with well-fitting insteps and roomy around the heads of the metatarsals; 4. Insist that the sole be at least one-quarter of an inch thicker behind the bases of the metatarsals. This putting of an extra heel just back of the ball of the foot is a device originating with the late Hugh Owen Thomas. The objection to it is that it makes the shoe very awkward and clumsy, and does not seem to be necessary in a large proportion of cases. Jones has not found the measures just enumerated sufficient to give relief in all cases, and he prefers exsection of the metatarsal head to incision or amputation.

W. S. Halsted,¹ of Johns Hopkins University, after a careful examination of 20 cadavers, fails to find the anatomic conditions which have been described so frequently by Morton. In no single instance did he find the head of the fifth metatarsal more than a quarter of an inch posterior to that of the fourth. As a rule, it was not more than one-eighth of an inch. He found also that the digital nerves passed below the inferior transverse ligaments, and did not appear in the normal foot between the heads of the metatarsals, or between the head of the fifth and the neck of the fourth. He found no evidence to support Morton's theory of the causation, but believed that Lorenz had given a more satisfactory explanation, which was that of the flatfoot. This giving way of the arches produces inflammatory thickening of the sheaths of the nerves, and sometimes fibroneuromata. Microscopic examination convinced him that these conditions were present, and that the nerves should be excised. Most of his cases, he believed, could be cured by the usual treatment for beginning flatfoot.

Anatomy of Congenital Clubfoot.—Nichols² presents a dissection of two specimens from the feet of a child stillborn. The description is supplemented by reference to other anatomic papers and goes into detail quite thoroughly. The author arrives at a conclusion which a careful study of the anatomy of clubfoot usually warrants—viz., that the deformity is due to alterations in the shape of all of the bones of the foot, and is formed by the contraction of certain tendons and ligaments. The chief deformity is at the midtarsal joint, and is due to an inequality of facets of the os calcis and astragalus. He believes that if one fails to correct this obliquity the deformity is not corrected. He also believes that in resistant cases this obliquity should be corrected by an osteotomy of the neck of the astragalus, followed by forcible reposition of the foot. [While there is nothing specially new in his work, we welcome every paper bearing upon the anatomy of clubfoot, and bespeak for it a careful study. The subject should be frequently brought before the members of the profession, and hence is referred to in these pages.]

Compression of the Front of the Foot.—E. H. Bradford³ has made quite a study of prehistoric footprints and the foot of Art. From this study he constructs an argument against universal compression of the foot in civilized life. The article in question is a very interesting study. He concludes with the following: "It is well to remember that it is not the tail which separates man from anthropoid apes, but the shape and strength of the foot, especially of the first metatarsal and its accompanying phalanges. It is that which gives to man the erect gait, and it is a mutilation not to preserve this given strength."

Flatfoot, its Causes and Treatment.—N. M. Shaffer⁴ presents in a more complete form views, which he is known to have held for many years, of the causation of flatfoot. It is due, he believes, to a shortened gastrocn-

¹ *Medicine*, II., No. 8, p. 631.

² *Ibid.*, Oct. 29, 1896.

³ *Boston M. and S. Jour.*, Feb., 1897.

⁴ *N. Y. Med. Jour.*, May 29, 1897.

mius in the majority of cases. He makes this statement: "Among the hundreds of cases that I have examined during the past 8 or 10 years, I do not recall over three or four instances where I could not satisfy myself that the tendo-Achillis was tense and unyielding when flexion was attempted beyond 90°." His treatment, therefore, is to elongate this tendon, and the well-known shoe which bears his name is employed as a means of treatment.

Hallux Valgus, the Operative Treatment of.—R. F. Weir¹ has an excellent article on this subject, and recommends a curved incision, which enables one to more readily extirpate the bursa and remove any sesamoid bones. One is further enabled to dissect out the dorsal extensor tendon, cut it near its attachment, and secure it to the periosteum at the inner side of the base of the first phalanx. A further advantage claimed for the incision is that it leaves a cicatrix that is not rendered sensitive by shoes. [The paper is well illustrated, and from our own experience we can heartily recommend this procedure.]

Automatic Hammer-toe Springs.—From the *Lancet*, Nov. 21, 1896, we reproduce drawings of two springs for hammer-toe (Figs. 58 and 59).

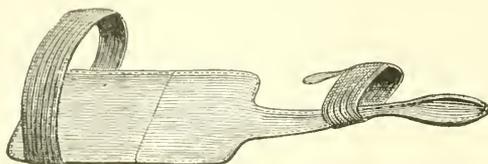

FIG. 58.—Spring for use in hammer-toe (*Lancet*, Nov. 21, 1896).

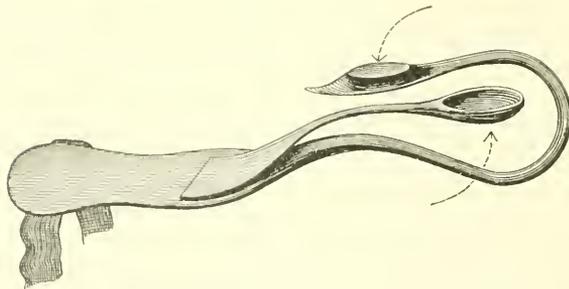

FIG. 59.—Spring for use in hammer-toe (*Lancet*, Nov. 21, 1896).

One of these (Fig. 58) is made to be worn within an easy-fitting boot, while the other (Fig. 59) is put on at night. A reference to the illustration is all that is necessary, as one can easily understand how the springs should be constructed.

Achillo-bursitis, Anterior.—S. Lloyd² presented a paper to the Orthopedic Section of the New York Academy of Medicine, and in an abstract we find this disease is the result of traumatism from tight shoes. It sometimes comes from bicycle-riding, or may be the result of septic, tubercular, gonorrhoeal, or rheumatic infection. The most prominent symptom is pain under the tendo-Achillis when standing. The pain is also found in the plantar region. There are swelling on either side of the tendon and extensive inflammation of the surrounding tissues. The paper is replete with interest, and it inclines us to classify still further the numerous affections in the

¹ *Ann. of Surg.*, Apr., 1897.

² *St. Louis Med. Rev.*, May 15, 1897.

region of the heel. The treatment naturally suggested is rest, warm baths, and in some instances counter-irritation. [We are reminded now that in many instances we have diagnosed this condition rheumatic, and without any special evidence therefor.]

Dislocation of Peronei Tendons Treated by Operation.—G. M. Smith¹ offers a cure, in suturing the tendon to the fascia behind the sheath, having excised an oblong piece of periosteum from the malleolus, and brought this over the tendon already secured to the fascia. The result was excellent, but the time elapsed had not been sufficiently great to enable him to speak with confidence of the permanency of the cure. Kousmine² makes a half-moon incision to the bone, behind and below the external malleolus, and a trapeze-shaped space on the periosteum is cut around so that the base of the trapeze corresponds to the lower edge of the malleolus. After doing this he cuts out a small flat piece of bone and raises it perpendicular to the malleolus. This piece of bone is not completely removed, and the tendon is placed behind it. A couple of nails are inserted to hold the bone in place and keep the tendons in position. The bone acts as a kind of trap-door. It is claimed that in 17 days the plaster-of-Paris can be removed and the nails withdrawn, when the tendons are found in normal position. It is further claimed that the operation has proved curative and brilliant.

SHOULDER.

The Treatment of Old Dislocations.—F. B. Lund³ discusses very fully the old dislocations one encounters in the shoulder. He claims that the method of Kocher, for the reduction of old dislocations as well as recent ones, is fraught with danger. It is easy, he claims, to fracture the humerus. He quotes from Monks, who has met with this accident, and also from Morton. In recent dislocations the scapula is held by voluntary muscular spasm, while in ancient dislocations this element does not prevail; hence it is necessary to secure pretty firmly the scapula in all attempts at reduction. Failing to reduce, he advocates arthrotomy. That is, he thinks this would be an ideal operation if the glenoid cavity could be opened so as to receive the head with a fair probability of its remaining in place. As this is very improbable, he advocates resection. The literature of the subject shows that many of the arthrotomies were done with the idea of completing the operation by resection. While the mortality after resection is a little greater than that of arthrotomy, he was led to believe from his investigation that it was not less dangerous, but that even any open operation should be postponed until all reasonable attempts at reduction by the employment of manual force could be made. He cautions against misapplied force, and the danger of rupturing vessels by such procedures. In the discussion which followed his paper, presented at the Surgical Section of the Suffolk District Medical Society, it was evident that many old cases had been reduced after months had elapsed. Porter reported that he had records of a case in which reduction was accomplished 4 years after the injury. [Personally, we incline to a free resection rather than an arthrotomy. We have been led to prefer this in the management of congenital dislocations of the shoulder where the structures are more or less shortened, and where it is difficult to secure a glenoid cavity. Referring also to the good functional results obtained after resection for disease and for gunshot-injuries, we recall a number of very useful shoulders.]

² Rev. de Chir., Sept., 1896.

³ Boston M. and S. Jour., Apr. 29, 1897.

DISEASES OF THE HAND.

Cleft Hand ; Operation for the Use of Periosteal Flaps.—C. M. Dowd¹ reports a very instructive case of cleft hand, the cleft extending down to the middle, apparently, of the palm, between the middle and ring fingers. In this case the fourth and fifth metacarpal bones were fused into one and separated from the third. The ring and little fingers were widely separated from the other fingers, and resembled the claws of a crab or lobster. The adduction was remedied by removing a wedge-shaped piece from the distal end of the fused fourth metacarpal bone, and forcibly adducting the fingers. The closure of the cleft was made by approximating the metacarpal bones, turning back the lateral flap and the periosteum from each at the place of divergence, and sewing these together with catgut. Firm apposition by a chromicized gut ligature around the shaft of the third metacarpal bone and through that of the fused fourth and fifth was made. An excellent result was obtained. In summing up, he makes the following pertinent statement: "The bones, the joints, the tendons, and the soft parts present peculiarities which must be met in each case. The device of raising the periosteal flaps, and thus joining the bones together by newly formed deposit, has been neglected, so far as I know; but it is so manifest a thing to do, that it must have been done where suitable conditions existed." [The good result obtained we certainly commend. It has many advantages over such devices as wire, pegs, nails, etc. This union gave a most satisfactory firmness to the hand and it caused no practical inconvenience from lack of pliability. We are pleased to give place to an abstract of this case, because it is evident that much can be done by special surgery in these congenital deformities. The removal of bone to correct deformity is certainly commendable. A careful dissection is always required. Good asepsis must be secured, and the results are generally satisfactory.]

SPASTIC PARALYSIS.

S. Ketch² presents a very fair *résumé* of the **orthopedic treatment of spastic paralysis in children**. He very properly condemns the use of apparatus—such apparatus as is generally employed. The indications for simple mechanical procedures are usually clear enough to enable the surgeon to correct certain deformities and to maintain the foot or the knee in good position. The education of muscles by manual exercise is commended. What pleases us best is the prominence he gives tenotomy and myotomy, supplemented by overcorrection. In his experience at Randall's Island Hospital, where there are a number of idiots with spastic paralysis, he noted their mental condition before and after operative procedures. He was inclined to commend Rupperts' views. He was convinced that many of these cases after tenotomy not only showed cure of the deformities, but also a great improvement in the mental condition. We do not think he dwells with sufficient emphasis upon the importance of maintaining the position sufficiently long after tenotomy, although he makes this statement: "The danger of relapse after tenotomy is, I think, much greater in this class of cases than in either the congenital or acquired clubfoot." [What we have found in our experience is a tendency to overcorrection. For instance, if a foot is operated on for equinus, it requires a long and patient course of after-treatment to prevent calcaneus.]

H. L. Taylor³ presented the subject in a different aspect. His treatment

¹ Ann. of Surg., Aug., 1896.

² Med. News, Mar. 27, 1897.

³ Am. Medico-Surg. Bull., Nov. 21, 1896.

was such a management of the case as would promote coordination and self-helpfulness of the child. He insisted upon memo-muscular training by methods analogous to those of the kindergarten and manual-training school. [This treatment was successful many years ago in the hands of the elder Seguin, so that the author very properly calls attention to this method in conjunction with orthopedic measures. It is interesting to note that no orthopedic surgeon recommends electric treatment, or at least, if it is employed, it is of secondary importance.]

J. Collins¹ has a very interesting editorial on congenital spastic rigidity from a historic standpoint. [It is pleasing to note that the subject was first scientifically treated by the late Dr. Little, whose memory orthopedic surgeons love to honor. Indeed, this affection was known as Little's disease. The author of the editorial discusses likewise the clinical as well as the pathologic side of the question. It is, on a whole, a very masterly review of the subject, and well worthy of perusal.]

MISCELLANEOUS.

Sacro-iliac Disease.—F. B. Judge-Baldwin² gives a brief review of the literature of this disease and reports a case that is of much interest, in that it presents some unusual features, and especially a cure by operation. A woman 26 years of age, 5 months after confinement, in September, 1893, had the first train of symptoms referable to the sacrum. These were: aching at the bottom of the back, pains in the left limb as she walked, and a feeling as if she "had a broken bone." The symptoms lasted a few weeks; but 6 months later they recurred, and early in January, 1895, a swelling in the left groin appeared. The reporter saw her first in April, 1895, finding a large psoas abscess, without spinal angularity. There was no pain in the lumbar region, and no abnormality about the hip-joint. She responded to the test for sacro-iliac disease, and, although her general health was dangerously impaired, she was operated upon May 1, 1896. "The line of incision was determined by drawing a line 3 in. from the anterior superior iliac spine to the posterior inferior spine. One and a half inches from the posterior inferior spine was a point for insertion of the scalpel," and he showed a horseshoe-shaped incision about 2 in. wide downward, the muscles being divided to the periosteum and held well away. This incision gave a good view of the sacroiliac joint, which looked spotty and grayish. On introducing a chisel into this area it passed readily into the joint, and the parts immediately thereabout were scraped away, leaving a perforated pelvis. Care was taken to remove all broken-down bone. Drainage was employed; the dressing was changed 3 or 4 times during the next 18 hours, on account of impending collapse. The healing was rapid; by July 24th the patient was on a spinal carriage, and on August 13th on a Thomas splint with crutches. The sinus closed on March 17, 1896. October 1, 1896, patient was reported as "perfectly well. She has had no ill-health since the operation, and walked so well that it would be difficult to detect that she had had any disease of the joint." [The reporter is to be congratulated on this brilliant result. The difficulty of removing the bone in the neighborhood of the sacroiliac junction is recognized by all surgeons, and it is seldom that a thorough operation can be made. The details of the operation and of the subsequent history have been omitted in our abstract.]

Fragilitas Ossium in Childhood.—Griffith³ contributes an interesting

¹ Med. News, Feb. 6, 1897.

² Brit. Med. Jour., Dec. 19, 1896.

³ Am. Jour. Med. Sci., 1897.

paper on idiopathic osteopsathyrosis, which is supplemented by a case in a child born June, 1893, who in March, 1894, sustained a fracture of the right femur, near the hip; Sept. 11, 1894, another fracture; and up to the time of his report of the case other fractures had occurred. The final result of the case is not given, but the presumption is that the limbs grew stronger and in time the brittleness of the bones disappeared. This case closely corresponds with cases under our observation. In 57 collected cases Griffith drew conclusions as to etiology, which was that of inheritance in 11 cases; in 7 there was a family predisposition without direct inheritance; in 24 cases there was no family predisposition recorded; the remaining 15 were classed as doubtful. The disease affected males more than females, in the ratio of 47 to 19. It began in early life—sometimes before birth; syphilis and rickets seem not to have had any direct influence in the production of the fragility. It was noted that in this affection the union of the fractures was prompt. The treatment which seemed to give the best results was alternatives, the maintenance of the general health, and protection of the limbs. Muscles must not be allowed to waste for want of use, and fractures should be set as early as possible.

Congenital Defects in Long Bones.—B. E. McKenzie¹ publishes a paper detailing a number of congenital deformities of the legs, wrists, and hands, which may be found in most any large collection. In one case a dissection was made, which gave a very clear idea of the anatomy of the parts. After operating on some of these cases and securing results that were far from satisfactory, he concludes as follows: "All things considered, if one is to judge from the 5 cases of this kind here reported" (the kind referred to is where the tibia is absent), "I think it must be placed beyond controversy that the most convenient support to be secured for the patient is found in the artificial limb, which may be applied to a good stump." [We agree with the author in the conclusion to which he has come. It is seldom that a good walking limb can be secured where the tibia is absent.]

Congenital Absence of Both Patellæ.—A. T. Bristow² adds to the list of cases already published a case in which the radiograph showed clearly the absence of the patellæ. The paper itself is valuable on this account, but in addition a list of cases in literature has been collected.

W. B. Hopkins³ reports a case in which both patellæ were absent. Fifteen cases are briefly reported in connection with this one. [In looking over this report one finds several where the patellæ were rudimentary. In our experience it is not so uncommon. In a large orthopedic clinic a certain number of rudimentary patellæ are seen every year. We find that the bones develop to a very useful size in the course of a few years, enabling the patients to walk with comparative ease. In many instances the patellæ are reported as absent, when in reality they are simply rudimentary. In the case reported by Bristow the radiograph confirmed the truth of his statement.]

OPHTHALMOLOGY.

BY

HOWARD FORDE HANSELL, M. D., AND WENDELL REBER, M. D.,
OF PHILADELPHIA.

General Epitome.—Advances in ophthalmology since the publication of the 1897 *Year-Book* have not been few or unimportant. The tendency seems to have been to seek the elevated standard of original research, and while many authors content themselves with the recital of a case or two and venture to draw conclusions from them as bases for universal laws, others have enriched literature with thorough investigations of disease, and, by shedding light into places hitherto dark, have helped both student and practitioner. For example, the utilization of the *x*-rays, foreshadowed in our epitome of last year, has become general, and its use in the localization of foreign bodies in the interior of the eye and orbit almost universal. No up-to-date ophthalmic surgeon would attempt to decide as to the presence of a piece of metal in a doubtful case without employing this method. Perfection in apparatus and better understanding of the properties of the rays will lead to a more intelligent use of them, and will mean much for future medicine and surgery. In the choice as to the operation—simple or compound—for cataract we are to-day in about the same position as in 1897. The caprice of the operator, rather than the peculiar indications of the case, decides the question. Americans of large operative opportunities are in favor of the simple operation. Europeans of equal authority and experience are about divided. Our own suggestion (conveyed in part in the text) is that the large majority of oculists whose cataract-extractions number perhaps 25 in a year should continue to practise the method they have pursued from the beginning. The risk of an unsuccessful termination to a single case because of nervousness or other causes originating in a novel procedure, when by following the usual method a good result would have been obtained, is not justifiable. Discission or extraction of the lens in high myopia for the retardation of pathologic changes in the choroid and the improvement of vision has proved its superiority to the correction of the optical defect by lenses, and has steadily advanced in favor, until its general adoption seems to us to be merely a question of a short time. The operation recently brought prominently before the profession by Fukala was introduced many years ago, but was abandoned later because of its risks. Asepsis and antiseptics, however, have made its revival possible. Diseases of the retina and choroid, congenital or acquired, from constitutional or local causes, are practically on their old footing. When potassium iodid fails our only resource is empiricism. Electrolysis, that promised so much when heralded as a cure for retinal detachment, has met the same fate that awaited further experience with Schöler's injections of iodine, substitution of rabbit's vitreous, and other novel procedures. Puncture, galvanocautery, rest in bed, and bandaging are still recommended and practised as the least unsatisfactory of the methods proposed. Investigation into the intimate nature of

interstitial keratitis has changed our old-time conception that this disease is always congenitally syphilitic in its nature. It is now frequently ascribed to other diatheses, such as acquired syphilis, influenza, rheumatism, and tuberculosis. While the general signs and symptoms are the same, irrespective of the cause, that form due to acquired syphilis has its own distinctive features. The subconjunctival treatment of this and other diseases of the cornea and of the uveal tract has been this year (as last) the subject of extended discussion. The general consensus of opinion, outside of France, relegates this form of therapy to a second or third place among the methods employed, and it seems to us is reserved for those cases in which the surgeon, having tried other means and failing to effect a cure, does not blame injections much because they fail also. The preference is given to mercuric cyanid over the sublimate or normal salt-solution. There is manifest a disposition to defer acceptance of the etiologic classification of the different forms of conjunctivitis until the responsibility of the various microorganisms can be more sharply defined. Studies of climatic environment, supposed to be an active factor in the origin and spread of granular lids and trachoma, show that altitude is a less potent factor than racial and individual peculiarities. We regret to have to record each year that, in spite of the recommendations of the value of certain medicaments, no one remedy has yet been brought forward that will replace the roller-forceps of Knapp, and subsequent treatment by copper and other astringents. Retinoscopy is slowly but surely installing itself as a reliable objective method in the daily work of many careful refractionists. The trend in refraction-methods is toward objectivity, and any objective method that offers precision of result and ease of application may be sure of just such a gracious reception as is being accorded to retinoscopy.

ANATOMY AND PHYSIOLOGY.

The Brain and Vision.—Sharkey¹ devotes the clinical and pathologic data of 3 unusually interesting cases to the solution of the problem, that, although each angular region seems to be able to subserve vision in both eyes, it cannot make up for hemianopsic defect produced by disease of the occipital lobe. To him, the only tenable explanation is that the occipital lobe is a lower center through which the visual impulses must pass on their way to the higher centers in the region of the angular gyrus, and that disease of the lower center, or of the fibers in connection with it, intercepts the visual impulses on their way to the higher centers; but each higher center being connected with the whole of both occipital lower centers, destruction of one higher center does not interfere permanently with vision in either eye. His cases would seem to indicate that the convolutions surrounding the posterior extremity of the fissure of Sylvius are especially concerned with the vision of the opposite eye, and in such a direct manner that destruction of them in one hemisphere produces transitory blindness of the opposite eye, while bilateral destruction of them causes permanent blindness in both eyes. Parinaud² divides vision into binocular, monocular, and simultaneous. The last is distinguished from the second by identical projection of the same object by each eye. Each form has motor, sensory, and connecting fibers. In squint, binocular vision is present, but simultaneous binocular vision is absent. The image of the squinting eye, falling on a part of the retina disassociated in function from that of the other, is suppressed. The motor apparatus is represented by convergence and the connecting fibers by a reflex established by two images that

¹ *Lancet*, May 22, 1897.

² *Ann. d'Ocul.*, June, 1896.

at the first moment of vision are not on corresponding points of the retina, but when vision is established become so.

Photometry.—Snellen¹ states that, owing to the variation in illumination, reliable figures recording vision can be obtained only by the use of a photometer that shall give vision under known conditions of light. The acuity is modified according to the size of the object, the illumination, the size of the pupil, and the adaptation of the retina.

Aqueous Humor.—The labors of E. Niesmamoff² substantiate the conclusions formulated by Greeff two years ago (see *Year-Book*, 1896) as to the secretion of the aqueous humor and its origin. The author states that the amount of aqueous secreted is in proportion to the difference in pressure in the vessels of the ciliary body and the intraocular pressure.

Parallax Test.—A simple method of locating opacities in the cornea, lens, and vitreous is detailed by E. Jackson.³ It is known as the "parallax test," used with the plane mirror at 10 to 12 inches. A body situated anterior to the plane of the pupil will move in the direction taken by the eye, while one posterior to the plane of the lens will move against the direction taken by the eye. Bodies lying about the same plane as the pupil will show little, if any, movement. There are many practical applications of the method.

Orbit.—L. Koenigstein⁴ contributes an elaborate study of the anatomy and physiology of the orbit and its contents. It constitutes a valuable enrichment of our knowledge of this little-studied side of ophthalmology.

Color.—P. Hilbert⁵ claims that abnormal color-perceptions are always subjective; that they arise centrally as conditions of irritation of the color-vision centre; and that although they cannot be originated by external conditions, they may be intensified by them. He further holds that these facts are explainable only on the hypothesis of a color-vision center distinct from the light-perceptive center. Gorty's method of color-examination,⁶ priority for which is claimed by H. Adler,⁷ is to lay before the candidate a number of colored pencils, the wood of each of which corresponds to that of the crayon. The pencils are taken up one by one and the candidate is to write upon a sheet of white paper the name of the color of the pencil in hand; *e. g.*, with a red pencil the word "red" is written, with a green one, "green," etc. The paper on which this writing is done is signed by the writer, and this paper filed away for future reference in case of complaint by the candidate of unfair dealing.

REFRACTION.

Accommodation.—Tscherning's theory of accommodation has been materially strengthened by the observations of Hess,⁸ Stadfeldt,⁹ and especially by Czsellitzer,¹⁰ who by elaborate experimental researches have shown that during accommodation the middle portion of the lens is more highly refractive than the periphery, and that traction on the zonule produces central increase of curvature and peripheral decrease, giving a hyperbolic shape to the lens. Tscherning contends that the total change of shape which the lens will have to undergo to effect a given increase of curvature in the pupillary area would be considerably less according to his theory than according to that of Helmholtz. Hess,¹¹ by experiments on his own eyes, determined that

¹¹ Ibid., May, 1897.

during accommodation the lens sinks downward about $\frac{1}{3}$ mm., and that when the head is displaced toward either shoulder there is corresponding displacement of the lens. These, he says, are passive movements, due solely to the weight of the lens.

Ocular Hygiene.—The plain truths of prophylaxis are pointed out by S. D. Riskey's¹ *résumé* of the results of the examinations of many thousands of school children, truths that ought to be put into practical execution in our public-school system. Sanitary science can have no more important or fruitful field of application. W. F. Southard² compares the attention given by intelligent parents to their children's teeth with that bestowed upon their eyes, much to the disadvantage of the latter, and emphasizes the greater importance of good vision and ability to read without asthenopia to the development of the child's faculties. A. C. Simonton³ objects to the glaze of the paper on which the *Jour. of the Am. Med. Assoc.* is printed. [This is a subject well worth agitating. Paper of dead finish is the only paper that should be used for literature, and if the publishers of medical journals were but properly approached in the matter, we believe that they would not be slow to make an improvement, in which they would soon be followed by publishers everywhere.] W. B. Carhart⁴ submits that while the eyes of the children of the present generation are not intrinsically any weaker or more diseased than those of their forefathers, the demands of the school-life of to-day have compelled the necessity of aiding their eyes with glasses.

Statistics.—Among 53,333 pupils in the public schools of Baltimore, Harlan and Woods,⁵ found vision equal to $\frac{2}{20}$ in 43%, $\frac{2}{30}$ in the better eye in an additional 39%, between $\frac{2}{30}$ and $\frac{2}{200}$ in 15%, and less than $\frac{2}{200}$ in the better eye in $\frac{1}{2}$ % of the cases.

Criminology.—In an investigation of the eyes of 362 criminals, with a view to determine whether their defects might be held responsible for their criminal lives, or might be classed among hereditary characteristics of degeneracy, H. True, J. Gaudibett, and Rouveyrols,⁶ determined that the ocular and visual defects were of no more value than other anatomico-physiologic defects in determining abnormal mental deviations.

Refraction and Body-weight.—G. M. Gould⁷ suggests that increase of body-weight is attended by decrease of refraction, and that decrease of body-weight is attended by increase in refraction, owing to the influence on the form of the eyeball of the varying amount of fat in the orbit. Illustrative cases are submitted.

Eyesight and Veils.—C. A. Wood⁸ voices the general sentiment of the profession when he condemns the wearing of veils. By testing the vision of an individual with normal sight while wearing the different varieties (lace, chiffon, single-thread, dotted, etc.), he found vision seriously interfered with in every case, and concludes that all veils are pernicious in their effect, the dotted kind in particular.

Visual Tests.—Brown⁹ calls attention to the mistake made in prescribing plus for minus lenses by reason of the assumption that 20 feet is equal to infinity. Distances less than 20 feet would give correspondingly greater errors. J. Ramos¹⁰ offers a new series of test-types based on a novel applica-

tion of the laws of retinal perception. He favors the decimal system in expressing visual acuity. Proceeding on physiologic principles, G. M. Gould has revived the idea of a black test-card on which are lithographed white letters.¹ The great advantage to be derived from its use is the restfulness felt by the patient, to which testimony is often spontaneously given. [For 8 months we have been using one of these cards with the greatest satisfaction. Absence of retinal tire during the subjective examination has been especially noticed.]

Objective Refraction.—The principles underlying the application of this latest method in objective refraction are clearly set forth by J. Thorington,² in his monograph. J. W. Ellis³ observes that one ought to test his ophthalmometer at regular intervals with a convex mirror made for the purpose, in order that the instrument may not by its faulty indications lead the worker into error. G. J. Bull⁴ considers the information given by the ophthalmometer is often more trustworthy and useful than that given by skiascopy or any other objective method of refraction. [The relative merits of skiascopy and ophthalmometry are too well appreciated in this country to permit of much growth of this doctrine.]

Asthenopia.—In treating of asthenopia as a forerunner of neurasthenia St. J. Roosa says,⁵ “Unless corneal astigmatism reaches a dioptré with the rule, or a quarter of a dioptré against the rule, it does not of itself produce asthenopia. Given normal refraction in both eyes, there can be no such thing as want of muscular equilibrium, except in cases of paresis. When a patient comes having normal vision, a low degree of hypermetropia (1 to 3 D.), and either no astigmatism or a half dioptré with the rule, there must be something besides the eye which is at fault in the production of the asthenopia [!].” “Repeatedly I have found this condition of things to be the premonition of neurasthenia or general nervous breakdown. To give such patients” (that is, patients with 0.5 D. astigmatism or 1 to 3 D. hypermetropia) “glasses, is at best a placebo” [*sic!*]. “In my judgment, no one is ever the better for glasses unless they see better with them or are much more comfortable with them. Even when vision for distance is perfect with the glasses, I do not urge such patients to wear glasses except for the near. The point I make is that when in a case of asthenopia the refractive conditions do not justify the ordering of glasses, thorough investigation of the whole train of symptoms should be instituted.” [To this last proposition we are sure every sane ophthalmologist will assent, but if 0.5 D. of astigmatism or 3 D. of hypermetropia is not a factor in neurasthenia, what degree of ametropia does Dr. Roosa feel will “justify in ordering glasses?” This is retrogression pure and simple. It amounts to retraction of those truths which the ophthalmic world has enunciated for 20 years. Such statements proceeding from one high in authority are fraught with exceeding danger. We believe, with Dr. Roosa, that the eye is only one factor in neurasthenia, but it may easily prove the one additional factor necessary to insure nervous breakdown.] There is a much larger grain of truth in the statement of S. D. Reynolds,⁶ whose study of the records of 2000 astigmatics convinced him that correction of the ametropia relieves asthenopia only in persons otherwise in good health. Recovery in all other cases is contingent upon other means of relief. P. W. Maxwell⁷ traces a connection between accommodative asthenopia and nasal

¹ Ann. Ophth. and Otol., Jan., 1897.

⁵ Retinoscopy, Phila., 1897.

⁶ Ophth. Rev., June, 1897.

⁷ Brit. Med. Jour., Sept. 22, 1896.

obstruction, claiming that many patients will lay aside their glasses after the nasal functions have been rectified. Especially did he find his idea applicable in cases presenting pharyngeal adenoids as a complication. [Maxwell's conclusions would be much more readily accepted if he had shown in the histories he cites that the refractive error had been painstakingly measured and persistently worn before proceeding to nasal treatment. Judging from his case-histories, the estimations were of the manifest refraction, or were made with the ophthalmoscope, either of which methods may lead even the most careful observer far astray.] The 4 cases of epilepsy affirmed by J. S. Kirkendall¹ to have been cured by correction of ametropia and graduated tenotomy are strikingly similar to the generality of such cases detailed by A. L. Ranney in his recent monograph.² [There ought to be greater reason offered for tenotomy of both interni (Kirkendall), than esophoria of 1°, even though the abduction be but 3°.] Causes for asthenopia, other than errors of refraction, are said by H. Gradle³ to be found in inherited nervous instability, enfeebling infectious diseases, anemia, impaired digestion, faulty habits, chronic blepharitis and conjunctivitis, disturbance of the retinal pigment, muscular anomalies, nasal affections, hysteria, and insomnia. He advises absolute rest of the eyes and dark glasses. The ocular expressions of eye-strain (Clarke)⁴ are blepharitis, phlyctenular keratoconjunctivitis, scleritis, recurrent iritis, and, under certain conditions, cataract and glaucoma.

Mydriatics.—Homatropin, in E. Jackson's hands,⁵ has proved an efficient, reliable cycloplegic capable of producing complete ciliary paralysis, and possessing the therapeutic influences for which a mydriatic is indicated in cases of eye-strain. As compared with other drugs of the class, it is least likely to cause general poisoning or local harm by glaucoma or conjunctival irritation, and it entails upon the patient the shortest period of disability. F. Mayo⁶ secures as complete cycloplegia from 6 instillations of a 2% solution of homatropin at 5-minute intervals as from a 1% solution of atropin used 3 times daily for 2 days. On the other hand, Hansell⁷ states that homatropin is not a reliable cycloplegic in young individuals. T. E. Murrell's further trial of scopolamin hydrobromate as a cycloplegic in 150 more cases (making 200 in all) only emphasizes the commendations he bestowed on the drug last year (see *Year-Book* for 1896).⁸ In his hands it has proved the ideal cycloplegic, in which opinion he is joined by C. A. Oliver.⁹ An undoubted instance of poisoning following the instillation of 1 drop of a 0.2% solution of this drug is reported by C. P. Pinckard.¹⁰ The patient, a 48-year-old woman, had experienced no unpleasant symptoms from the use of homatropin a year previously. The case further shows that scopolamin distinctly increases the intraocular tension.

Presbyopia.—G. M. Gould¹¹ calls attention to a mistake that may be made by opticians of inverting the presbyopic segment frequently cemented to the distance-correction. To avoid this he recommends that the upper edge of the segment have a sharper curve than its lower edge, which is ground of the same curve as the lower edge of the distance-correction. Anent this same topic, W. F. Southard¹² claims that much comfort can be given to many presbyopes who wear bifocals, by having the reading-segments made small and

almost square in shape. The inability of hyperopes and presbyopes to see clearly through their glasses at night is said by E. Jackson¹ to be due to the dilated pupil. The cornea near its periphery is less hyperopic than in the pupillary region, and therefore the glasses are too strong. He also found² that when the difference in the refraction of the two eyes exceeds 2 D. that the lens of the stronger eye may be decentered to save the prismatic effect and the annoyance of looking through the periphery of the lens. An examination of 300 individuals by J. Barrett³ showed the interpupillary distance to be on an average 2 mm. greater than the distance between the visual axes.

Myopia—In a discussion before the Section on Ophthalmology of the British Medical Association (1896), Drs. J. B. Lawford, F. R. Cross, Argyll-Robertson, P. W. Maxwell, Henry Juler, and David Little were of one accord in endorsing the operative treatment of high myopia in those cases in which no contraindications presented. A. Mooren's experience with this class of cases has now reached a total of 149 without a failure [!],⁴ and only serves to confirm him in his opinion of some years ago, that the procedure is markedly beneficial in the large majority of properly selected cases. Speaking elsewhere of the dangers lurking in progressive high myopia, he says: "Full myopic corrections for near-work are pernicious, as they induce exaggerated accommodative effort and ciliary spasm, and thus intensify the refractive error, causing progressive myopia. Furthermore, retinal detachment and slow inflammatory changes are much more likely to supervene." [Our own experience has been that in myopes under 25 years of age full corrections are not only tolerated, but are really welcomed for near-work after the accommodation has been temporarily assisted with pilocarpin and the convergence properly trained with prisms.] V. Fukala, in his monograph⁵ and elsewhere,⁶ reviews his practice of this method in high myopia for a number of years, and enunciates views that are largely held by most of the disciples of the operation. He offers as advantages after the operation: enlargement of the retinal images, better illumination of the images, simplification of the optical apparatus, and increase of the retinal functional activity. Th. Gelpke and W. Bilher,⁷ basing their faith on an experience with 59 cases, are enthusiastic advocates of the surgical treatment of high myopia. Vacher's conclusions⁸ are judicial and safe. He says extraction of the transparent lens is a grave operation that should only be performed with great prudence and under the most rigorous antiseptic precautions. Myopia progressing rapidly between the ages of 12 and 16 may be operated upon after the age of 12, if there be a large staphyloma and if the number of the diopters of myopia exceed the number of years of the patient. Only one eye should be operated on, and that the more seriously affected. Operation on the second eye should not be undertaken until later, and then only at the express request of the patient if the myopia continue to progress. After the 30th year myopia of more than 15 diopters, predisposing to retinal detachment, justifies extraction of the transparent lens when the visual acuity permits. Panas⁹ and Ascher¹⁰ are both advocates of discission or extraction of the lens in myopia of 16 D. or higher.

In progressive myopia of from 9 D. to 29 D., representing vision equal to $\frac{1}{3}$ or less, Drouart¹¹ has done iridectomy and sclerotomy 248 times, arresting

the myopia, stopping fundus-changes, and greatly improving vision. There was never retinal detachment following the operation. He prefers iridectomy to sclerotomy. Along with the removal of the lens, says M. Salzmann,¹ we probably remove a source of considerable irregularity of refraction, and vision is improved for the reasons advanced by Fukala. A residual myopia of 3 D. is the ideal post-operative condition. Persons whose vocation demands continued work at the near-point will derive but little benefit from the operation, the indications for which should never be based solely on a certain degree of refraction. F. Otto's² conception of an ideal after-result is 4 D. of myopia. He also points out the possibility of divergent strabismus following upon the destruction of binocular vision, which, if it should happen to affect the operated eye, would vitiate the result of the operation. He believes that ancestral impress counts for more than consanguinity in the production of congenital myopia. Martin³ says the latter condition is never axial, but depends upon the increased refraction of the ocular media. It must not be forgotten that myopia may occur in persons who have never had but one eye, as shown in Duane's⁴ patient. In Philadelphia the removal of the lens for the cure of high myopia has been limited to a very few cases.⁵ In the large majority of cases correction by means of a well-adapted and accurately made glass confers vision good enough to render operation unjustifiable. While Chauvel⁶ grants that removal of the crystalline lens may be useful in some cases of high myopia, he maintains that our experience is still too limited to judge definitely of the modifications to which the eye may subsequently be subjected. J. Hirschberg,⁷ too, thinks that reduction of progressive myopia by discission of the lens is a procedure that calls for the most judicial consideration. For high myopia F. C. Hotz⁸ advocates a bifocal that is exactly the reverse of the ordinary bifocal in that the main lens constitutes the correction for near-work, while the distance-correction is secured by cementing a segment to the upper margin of the main lens. The lower edge of this segment must be at least 3 mm. above the center of the main lens.

Astigmatism.—Hess,⁹ by an elaborate series of experiments on himself with cylindrical lenses, disproves the hypothesis of partial correction of corneal astigmatism by a secondary action on the part of the lens, claiming that the pupillary state and the palpebral fissure must be reckoned with in such cases. H. Gradle fails utterly in his attempt to negate the above findings of Hess as to the impossibility of unequal lenticular contraction in the correction by the patient of his own astigmatism. The 2 cases selected by Gradle¹⁰ for the support of his hypothesis were most unfortunate in their evidence, one of them being a young astigmatic whose best corrected vision was but $\frac{1}{5}$; the other, a young woman whose best corrected vision was not only a scant $\frac{1}{4}$, but presented also congenital oculomotor palsies of some of the muscles of her left eye. Hess,¹¹ in responding, reaffirms his position of a year ago (see *Year-Book*, 1897, p. 325), that the whole phenomenon is explained by lid-pressure so exerted by the patient as to correct his own astigmatism. In C. Williams'¹² study (in 100 office-cases) of the discrepancy between the astigmatism indicated by Javal's ophthalmometer and the total

astigmatism by trial-lenses, Javal's instruments gave the position of the axis of the cylindrical glass in about 50% of the cases, and the astigmatism to within 0.5 D. of the accepted glass in 54% of the cases. His chief use of the Javal is as a rapid approximate indicator of the axis and degree of astigmatism. [This, we think, fairly reflects the views of most careful refractionists who are skilled in the use of Javal's instrument, namely, that its best service is as an indicator in refraction.] To determine accurately the meridian in astigmatism, F. W. Coleman¹ uses a cylinder from 0.5 to 1.5 diopters stronger than the accepted cylinder, and finds the preferred axis, which will be the angle for the accepted cylinder. He resorts to this method only when the accepted cylinder is of 0.5 D. strength or less. [A useful suggestion.] It is well known that the astigmatism following cataract-operation gradually diminishes for some months, until only 1 or 2 D. remain. Luciola² says that a small corneoscleral incision that does not allow the aqueous humor to escape will generally increase the corneal curvature of that meridian in which the incision is made. This is contrary to the effect of the incision for cataract, which decreases the corneal curve in that meridian, and Luciola therefore suggests this measure as a radical cure for astigmatism. A naval officer who was the subject of acquired astigmatism, had presented 5 years before the time of report an emmetropic left eye; 5 years later F. L. Henderson³ found a regular myopic astigmatism of 1.75 D., induced, as Henderson believes, by the pressure of the orbicularis on the left eye while using the right eye on a surveyor's sextant. H. Aschheim,⁴ too, speaks of an instance of acquired astigmatism of 32 D. occurring in a young woman with scrofulous cornea. The pupil was so involved by anterior synechiæ as to assume a slit shape. In the correction of irregular astigmatism Th. Lohnstein⁵ employs a hydro-diascope, his own device, fashioned on Thomas Young's theory. He has worn the apparatus himself (high M+Am.), an aggregate of 7 hours in one day, without discomfort.

Tinted Glasses.—Risley's⁶ examination of a large number of coquilles showed that not one in a dozen was free from some cylindric or prismatic defect or other irregularity which could only add to any existing strain in an ametropic eye. To correct this evil and secure uniformity in smoked glasses, E. Pergens⁷ proposes that a smoked glass of 1 mm. thickness should absorb $\frac{1}{10}$ of the light from a Hefner amyliacetate light one meter distant.

MUSCLE-AFFECTIONS.

Paralyses.—A careful study of the oculomotor nuclear conditions secondary to long-standing isolated paralysis of some one of the ocular muscles will be of more definite value⁸ to ophthalmic science than a whole array of physiologic and anatomic experiments. By combining the results obtained in a few selected and well-studied cases the relative positions of the separate nuclei can be fixed with scientific accuracy. Among the **causes** of paralyses in infants Dujardin⁹ mentions traumatism from forceps during delivery. He asserts that this cause is frequently overlooked, and that when the child becomes older the squint is ascribed to hyperopia. C. A. Wood¹⁰ observed a patient with optic-nerve atrophy accompanied by oculomotor paralysis

from plumbism. W. M. Leszynsky¹ refers congenital absence of outward movement of both eyes to arrested development affecting the external recti, or to a faulty insertion of those muscles. H. Spicer² suggests as a cause of squint the secondary contraction of the internus following paralysis of the externus in childhood from whooping-cough, fits, etc., and after recovery the squint is maintained by habit. A. Duane³ lays particular stress on the **frequency of paralysis** of the inferior and superior recti, and asserts that it escapes attention because our visual line is ordinarily directed below the horizontal plane of the eyes. The part that these vertical paralyses play in convergence-insufficiency is worthy of consideration. C. Kunn⁴ has studied 8 peculiar cases of acquired ocular palsy of some one of the ocular muscles, in which fixation was performed by the palsied eye, and that too, in several instances in spite of the fact that the **vision** of the palsied eye was much lower than that of its fellow. The 13th published case is reported by de Schweinitz⁵ of **recurrent abducens paralysis** in a 6-year-old girl. M. Straub⁶ adds 3 classic cases of paralysis of divergence, in all of whom lateral conjugation was perfectly performed. The patients were aged 53, 29, and 20. **The prognosis** of true nuclear traumatic paralysis of the ocular muscles, says P. Simon⁷ is quite favorable. The therapy of these conditions is largely symptomatic; iodids to promote absorption and electricity to stimulate nerve-action. In a case of long-standing paralysis of the external rectus J. E. Giles⁸ remedied the condition by excising a portion of the internal rectus of the paralytic eye. [This operation has been frequently performed, and is the only one that should be considered. The result, however, is improvement in appearance only, since the function of the muscle is not in the least restored.]

Nystagmus.—Nystagmus is acquired in other occupations than that of coal-mining. Thus Snell⁹ found it among artists and painters, composers, metal-rollers, platemakers, plankcutters, sawmakers, fitters, ironfounders, etc., in all of whom the nystagmus may be ascribed to the necessity of elevating the corneas above the horizontal line. D. Gourfein's¹⁰ observations on 6 cases of congenital ophthalmoplegia and nystagmus, with preservation of the functions of the iris and ciliary muscles, in a father and 5 sons, convince him that the congenital variety of external ophthalmoplegia is not of nuclear origin, but is clearly a hereditary affection consisting entirely in defects of the muscles. Schwarz,¹¹ in speaking of Königshofer's case of voluntary movements of one eye while the other eye was held in the primary position (Heidelberg Congress, 1896) remarks that such anomalies of ocular movements are not uncommon among hysterics, and states further that it is a faculty that is acquired with comparative ease. By finding the position of rest in nystagmus and then tenotomizing the contracted muscles so that the visual lines would be brought from deviated and abnormal directions, J. E. Coburn¹² has been able to relieve the oscillation and improve vision in nystagmic patients.

Relation of Shape of Orbits to Visual Planes.—G. T. Stevens'¹³ study of the normal directions of the planes of vision in relation to certain cranial characteristics shows that in the dolichocephalic (long skull) the orbit is horizontally long and low, inducing kataphoria or restriction of upward

rotation; in the mesocephalic (medium high head) the orbit is strongly arched above, inducing anophoria or restriction of the downward rotation; in the brachycephalic (broad skull) the orbit is not only long and low, but is also directed down and out, inducing restriction of both upward and downward rotation. Stevens fixes the average upward rotation at 30° to 35° and the downward at 50° .

Relation of Accommodation and Convergence.—G. A. Berry¹ claims that the close theoretic relation between accommodation and convergence is maintained only in those individuals who are emmetropic, or nearly so; that it is seldom correct to measure the meter-angles of convergence by the number of diopters of accommodation in use for certain distances, this relation depending upon the refraction and the power of fusion. In testing for operation the deviation for the far and not for the near should be the guide. It must be remembered that limitation of external rotation is not caused by structural weakness of the muscles, but is due to an increase of innervation to the interni, and limitation of internal rotation to insufficiency of convergence. Atropinization or bandaging of the good eye is seldom of benefit. The surgical treatment is tenotomy for the former and advancement for the latter. Apropos of bandaging, F. W. Martin² has observed that wearing a bandage a few days after tenotomy will make manifest a squint that was supposed to have been perfectly corrected. He recommends this as a means of determining heterophoria.

Center of Rotation.—E. Landolt³ insists that the center of rotation of the eye is not a fixed point in the vitreous [as stated in his own and others' text-books], but that its location is the resultant of all the forces that hold the globe in position and which move it.

Strabismus.—C. Kimm⁴ says that the existence of concomitant squint demands that the mobility of the eyes shall be normal, and that the strabismic eye shall be able to follow all movements of its neighbor fixing in any distance. In sleep and in ether-narcosis, while the squint has changed from its previous condition, it is not lost; but the eyes present an irregular strabismus, the cortical impulse acting to produce a symmetrical displacement. This fact proves that the associated movements of the eyes are the result of experience, and not an inherent faculty. Defects of motility are always congenital, and while the eyes may be freely movable the central field of locomotion or the center governing locomotion may be defective (here locomotion differs from rotation). Factors contributing to squint are the orbit, globes, muscles, and innervation (orientation). Amblyopia is not a consequence, but often, when the mechanical conditions are not favorable to parallelism of the axes, is a cause of squint.

Malposition of the macula is held by G. M. Black⁵ to be responsible for that variety of heterophoria in which there is esophoria with the phorometer in the presence of apparent divergence, or exophoria with the phorometer with apparent convergence. This condition is to be diagnosed by means of the perimeter, when the angle α will be found to be larger than normal in esophoria and smaller in exophoria; while M. Sachs⁶ rejects the idea of a vicarious macula (or secondary macula) in strabismus, contending that the squinter is a person who sees single with each eye, and that there can be no binocular vision because the visual fields do not overlap each other. W. B. Meany⁷ assumes that binocular fixation is a faculty that

exists from birth [this is untenable ground. As presumed evidence], he quotes an instance of convergent squint in a 19-year-old male that was completely corrected by tenotomy of the internus and advancement of the externus of the squinting eye, combined with subsequent orthoptic exercise. Savage¹ believes that the true cause of typical antipathy to binocular single vision resides in the fact that the macula of one eye is connected with the right side of the brain, while the macula of the other eye is connected with the left side of the brain [on this assumption all symmetrical motions of the limbs should be anatomical anomalies]; while C. M. Hobby² is convinced that accuracy of coordination when one eye is covered, as with the Maddox rod, is not essential to ease of vision, but admits the frequent coincidence of asthenopia and difficult or imperfect coordination. He further holds that a difference in size of retinal images equal to 10% is compatible with mental association.

A. Duane³ reiterates that squint and insufficiency, or heterophoria, differ only in degree, and must be treated on the same principles based on etiology. The several causes that may induce insufficiency are each to be given proper weight in deciding treatment.

To test the degree of rotation of the cornea and, to a certain extent, the strength of the individual muscles, Wood⁴ has suggested the simple method of using strips of paper on which are printed letters and numbers, to be adjusted to the perimeter. The letters that can be read nearest to the periphery indicate the degree of turning of the cornea. [The objection to this device is that patients with considerable optic defect are forced to read through the edges of their glasses, and thereby lose acuity of vision proportionately to the strength of the glasses, in addition to having the apparent position of the letters altered by the prismatic effect of the lenses.]

If in concomitant strabismus there is the slightest limitation of individual movement of either eye, says C. Kunn,⁵ the case is one of congenital defect of movement of the eyes, provided other complications are absent.

G. T. Stevens⁶ claims that the tropometer, his instrument designed to measure rotations of the cornea, confirms his views frequently expressed, that lateral deviations will often be found in cases in which the tension of the vertical muscles is unequal, and that the former depends upon the latter.

Heterophoria from Nasal Reflex.—H. B. Chandler⁷ urges caution in approaching heterophoria from the surgical side, offering in support of his contention several histories of instances of muscular anomalies induced by enlarged turbinated bodies. [There is food for thought in his article.]

Asthenopia.—Walter⁸ suggests an analogy between accommodative and muscular asthenopia and the professional neuroses, such as writer's cramp, and divides asthenopia or oculo-dyscinesia into the spastic and parietic, and believes that the best results would accrue from their treatment on this basis, rather than by surgical alterations in the tensions.

Treatment.—Marked improvement in the oculoneural reflexes resulting from paresis of the superior oblique muscle, in a youth, was afforded by division of the superior rectus of the same eye by D. Webster.⁹ W. R. Parker¹⁰ details an interesting history of a 33-year-old woman, the subject of a suppressed upward squint of 7 degrees, on whom he performed **tenotomy** of the right superior rectus, bringing the deviation down to 2 degrees, which gradu-

ally increased, however, to 7 degrees, necessitating tenotomy of the inferior rectus when balance was secured. Four months later, deviation of 7 degrees was again manifested, and in a second division of the right superior rectus overcorrection occurred, which was controlled by a stitch. Several hours later the stitch gave way, and diplopia appeared, when a deeper stitch was inserted, apparently overcorrecting the new deviation. After a few weeks, however, perfect muscle-balance was found, and the patient used her eyes freely with complete relief.

In a discussion before the Section of Ophthalmology in the British Medical Association,¹ on the question of precision in squint-operations, P. W. Maxwell stated that in only about 5% of cases was perfect binocular vision obtained. His review of 179 cases, comprising his own experience, showed that **tenotomy with advancement** was equal in effect to double tenotomy. He pleaded for the angular measurement of all cases of squint. Landolt favored advancement in each eye as a measure designed to aid weak muscles, in the place of tenotomy, which at best could but weaken strong ones; moreover, the latter procedure allows the globe to come forward in the orbit and to slip partly out of the grasp of the recti muscles. Berry thought it unnecessary to attempt precise adjustment, believing it best to leave a little convergence. Bickerton resorted to advancement with great confidence, stating that personal observation of Stevens's technic had convinced him of the value of advancement, dividing the effect between the two eyes. Vignes² adds his testimony to the value of advancement of the externi in the treatment of internal squint. C. B. Taylor³ expects a great deal more from advancement of the internus than from advancement of the externus. In convergent squint he believes in thorough tenotomy of the internus, with subsequent shortening of the externus if necessary. He does not hope for the establishment of binocular fixation. Repeated operations are discouraging to the patient, and he, therefore, accomplishes all he can at the primary operation. [There is a large grain of truth in this last sentence. The operator can at best but approximate the visual lines to parallelism, while the final accurate adjustment must be made by means of prisms.] After the 9th year, H. Parinaud⁴ says, squint cannot be straightened without operation. The center for coordination is immature at birth, and is developed by use. Therefore, ametropic eyes in which vision is bad are infinitely more subject to strabismus than those of normal acuity. He defines concomitant strabismus as a vice of development of the apparatus of binocular vision, of which the principal symptom is the defect of convergence of the two eyes upon a fixed object. A. G. Bennett⁵ is enthusiastic over the results obtained by **prism-exercise** in 46 cases of low exophoria; 30 were apparently cured, 9 were benefited, 4 showed no improvement, and in the remaining 3 the result was unknown.

Valk's operation for shortening the muscles is essentially that of Savage,⁶ modified by the use of catgut instead of silk sutures. Deschamps⁷ has devised a pair of strong forceps, blunt and curved, for grasping and holding the muscles before the tendon is cut in the operation for advancement (Fig. 60).

W. Rider⁸ argues from 2 cases of muscular asthenopia unsuccessfully treated by **graduated tenotomies** that that operation is, as a rule, irrational and dangerous. [There is very little doubt that a reaction against operative treatment has set in, and that many cases are now treated on strictly medicinal

White.¹ The eye finally healed, and parallel axes with good binocular vision were eventually secured.

THE EYE IN GENERAL DISEASE.

Autoinfection.—That the eye may be the seat of expression of an auto-intoxication is plainly shown by Panas.² The condition may be induced by germs or their toxins, brought by the circulation either from external sources or from the absorption of waste-products not eliminated by the natural excretories (endo-infection), giving rise to disturbance of the nervous system, and thus so influencing the growth of the cells upon which the body-health depends as to produce a condition of “tendency to infection,” or “latent microbism.” This influence of the nervous system is seen in the bilaterality and symmetry of the infection. The sources of the intoxication are eruptive fevers, and dyscrasie, diabetes, albuminuria, uremia, oxaluria, phosphaturia, gout, chronic rheumatism, leukemia, scurvy, syphilis, tuberculosis, leprosy, hemorrhagia, puerperal and traumatic fevers, typhus, cerebrospinal meningitis, influenza, diphtheria, erysipelas, pernicious anemia, malarial fevers, and the nasopharyngeal tract; in women, the utero-ovarian apparatus. As chemie poisons, may be enumerated alcohol, nicotin, carbon disulphid, lead, santomin, and quinin. No ocular tissue is immune. Panas pronounces sympathetic ophthalmia an endoinfection. “The vasomotors of the sympathizing eye are influenced by reflex action, which creates in them a condition of *minoris resistentie*. In this case, as in others, it is a question whether the endoinfection of the sympathizing eye proceeds from toxins or from attenuated microbes charged with blood. One thing is certain—that in a traumatic eye (especially when previously irritated chemically) microbial activity is effected with the greatest facility.” The necessity for local and general antiseptics in a case of traumatic

¹ Va. Med. Semi-monthly, Nov. 27, 1896.

² La Clin. ophtal., May 10, 1897.

eye is obvious. Trousson,¹ Vacher,² and Boucheron³ are among Panas's supporters, while DeWecker⁴ and Meyer⁵ accept only in part the theory of autoinfection as the cause of many of the diseases named. D. M. Campbell⁶ likewise remarks the relation between certain diathetic conditions and the correlated inflammations of the iris and ciliary body, believing that they are autoinfections, and that treatment looking to the digestive tract and all the emunctories will be vastly helpful to the local treatment of many ocular disorders. P. D. Keyser⁷ also suggests regulation of the diet in all cases of subjective visual sensations. For those instances in which ocular and hepatic disorders are not simply coincident, Streminski⁸ offers two hypotheses, ascribing them either to the circulation of biliary elements in the blood, or to the alteration in the blood caused by the absence of bile in the intestines. The resultant ocular disorders are sudden or gradual hemeralopia, due either to an insufficient production of visual purple or to alteration of the optic-nerve tissues, amblyopia, limitations of the fields, imperfect color-sense, xanthopsia, dilated or contracted pupils, asthenopia, moderate papillitis, altered caliber of the retinal vessels or retinal hemorrhages, and pigmentary retinal degeneration, with atrophy and proliferation of the pigment of the choroid. The anatomic changes consist in interstitial sclerosis of the retinal and choroidal elements. According to A. Wagenmann,⁹ the choroid and sclera are the tissues that suffer most in gout, although this diathesis also frequently underlies eczema of the lids, painful hemorrhagic iritis, migraine with visual disturbances, and especially presenile glaucoma. The effect of antiarthritic treatment upon the latter class of cases is striking—indeed, they will often yield only when general treatment is systematically resorted to. Secondary arthritis following autoinfected gonorrhoeal ophthalmia, in a male nurse aged 28, is reported by L. Weiss and W. Klingelhoffer.¹⁰ The association of the gouty diathesis with cataract is clearly demonstrated by S. D. Risley.¹¹ "The excess of uric-acid salts in the blood-serum of gouty and rheumatic subjects may be and doubtless is sufficient to disturb the nutritive equilibrium in all the organic cells, but falls with especially disastrous results on the unstable transparent cells of the lens and vitreous body. It is a significant fact that the ectodermic structures of which the lens is one, and the avascular connective tissue in and about the joints another, are precisely the localities which suffer earliest and most constantly in the evolution of gout."

Relation to Kidney-disease.—H. F. Hansell¹² speaks of a patient exhibiting a central color-scotoma, who died 6 weeks after examination, from interstitial nephritis. Hansell says, "If this observation is confirmed in a number of cases, the discovery of central color-scotomata will afford an important indication of the speedy approach of a fatal termination." Unilateral neuroretinitis of albuminuric origin is, according to de Schweinitz,¹³ not very common. It has been found by subsequent observation of some of these cases that the second eye becomes affected before death. In a nephritic, Higgins¹⁴ notes acute edema of the conjunctiva so extensive that the cornea was covered by its folds. The choroid also showed signs of edema. This relation of deficient urinary excretion to certain obscure ocular disorders is also forcibly illustrated by E. E. Wright's array of cases.¹⁵

Diabetes.—Marked rapid change in the refraction of 2 glycosurics, varying with the amount of sugar in the urine, is recorded by S. D. Risley.¹ In each case, as the general condition improved, there was decided abatement in the accommodation, calling for the addition of from 1 to 4 D. spherical to the original correction; but when the sugar reappeared in the urine in any amount return to the original glasses became necessary. Risley assumes a change in the density of the tissue-fluids as the explanation of the phenomenon. [Compare with Appenzeller's case,² in which a transitory myopia of 1 D. disappeared along with the glycosuria.] Cataracts in diabetics are not always dependent upon the diabetes. The age, acuity of vision before the cataract appeared, and its variation with the amount of sugar in the urine are to be considered. Sous³ finds iritis a not infrequent complication. The lens is usually soft. In a polyuric, showing neither albumin, sugar, nor casts in the urine, H. F. Hansell⁴ observed mild optic neuritis and retinitis similar in all respects to the albuminuric variety, save that the star-shaped figure, instead of affecting the foveal region, had selected the retina to the nasal side of the disk. The man died 8 months later. Contracted kidneys were found.

Tuberculosis.—A. Stiel⁵ treated a patient for what he took to be iridocyclitis, and later chronic serous choroiditis, until the development of an anal fistula aroused his suspicions and led to an investigation, which revealed the tuberculous nature of the disorder. The incident teaches that tuberculosis of the uveal tract may simulate iridochoroiditis or cyclitis, chronic serous or plastic choroiditis, etc., and that exhaustive search into all the body-functions is necessary in all chronic affections of the uvea. DeWecker⁶ agrees with Leber that ocular tuberculosis is not primary, and that enucleation is not advisable. He removed completely an area of tuberculous material from an iris in a 5-year-old boy whose health was good; 7 years later vision in the operated eye was normal.

Syphilis.—J. Hirschberg⁷ contends that when, with a mydriatic pupil, small blood-vessels or their remains can be revealed in the cornea, careful search should be instituted for other evidences of acquired and especially hereditary syphilis.

Marasmus.—C. Koller⁸ records the 18th and 19th published cases of a fatal disease of infancy, presenting symmetrical changes in the macula. The disks and retinae atrophy, and the foveal region is occupied by a dark-red mass, circular in outline and surrounded by a clear white patch of atrophic choroid. The disease occurs often in 2 children of the same family; all die before their fourth year, of marasmus. There is no muscular paralysis, but the child is never well developed or strong enough to hold up its head or to walk. Koller attributes the malady to progressive degeneration in the cortex of the brain and the retina.

Malaria.—Guarnieri⁹ enumerates the following retinal lesions found in the graver forms of malarial poisoning: swollen arteries and veins, perivascular edema, sometimes swelling of the papilla itself. In the blood of the retinal vessels were found the well-known changes in the red blood-corpuscles characteristic of malaria, thus explaining most of the visual disturbances complained of by victims of malarial fever. Basseres¹⁰ considers retinal hemorrhage a

more frequent complication of malaria than is generally supposed. The lesion is due to thrombi of parasitic origin, alterations in the blood, or weakening in the coats of the vessels through the irritating action of the malarial germs. Litten's¹ case of leukemia presented a peculiar affection of the eyelids, which at first had the aspect of edema, but on closer examination proved to be small lymphatic tumors which were not adherent to the skin. Köbner² looked upon the case as remarkable because of the rarity of skin-lesions in leukemia.

Goiter.—The course of exophthalmic goiter is pretty well illustrated by R. T. Williamson's study of 24 cases that were followed for some years; most of the cases were very little influenced by treatment.³ Six terminated fatally, 7 recovered completely, 7 others were much benefited, and 4 remained unchanged by treatment. The above therapy did not include any of the animal extracts. [It would be interesting to have contrasted 3 series of cases: the first dealing with cases treated according to the usual therapy, the second being an animal-extract series, and the third a surgical series.]

In a discussion on the pathogeny of exophthalmic goiter Murray⁴ stated that the cause of the disease must be sought in the thyroid gland. He knew of no case in which it was found normal after death. Edmunds and Robert Hutchinson,⁵ dissenting from Murray, were of like mind in considering Graves' disease essentially a specific change in tissue-metabolism, due probably to a functional alteration in the central nervous system. The cardinal symptoms of Graves' disease are put down by W. C. Krauss⁶ as tachycardia, exophthalmos, tremor, and goiter. Sängner⁷ inveighs against meddling surgery in exophthalmic goiter, and challenges surgeons to show lasting benefit following extirpation of the gland. [The results in such cases reported from thyroid-feeding in the last year relegate surgery (at least temporarily) to a secondary place in the treatment of this disorder.] Grocco⁸ refers to certain atypical instances of Graves' disease described in literature that were accompanied by paresis of the extrinsic ocular muscles, weakness of the extremities, and variable ability to speak, masticate, and swallow. These, he suspects, are really examples of Erb-Goldflam disease, and he suggests that when there is associated with a transient or variable ophthalmoplegia easily induced fatigue of other muscles of the body and exophthalmos, with no decided evidences of organic lesion, a suspicion of the presence of the Erb-Goldflam symptom-complex is justifiable.

Diphtheria.—Schirmer⁹ states positively that postdiphtheric ocular palsies are not directly due to the presence of virulent microbes. The fact that these paralyzes have been so frequently noted since the application of serum-therapy to diphtheria would rather indicate that the antitoxic serum does not destroy the toxins. In summarizing the results of serum-treatment in 16 cases of conjunctival diphtheria, R. Greeff¹⁰ observes that the severe forms of the disorder prove a test for the value of serum-treatment, as formerly the most careful treatment was unavailing. Serum-treatment is without effect in pseudodiphtheria of the conjunctiva, nor is it prophylactic against postdiphtheric ocular paralyzes. H. Bruns saw 3 cases presenting so little membrane on the conjunctiva and such slight symptoms in the first case that diphtheria was not suspected until a bacteriologist verified the diagnosis of

diphtheria of the conjunctiva. The author¹ comments fittingly on how such mild cases of so deadly a disease may become particularly dangerous as sources of infection, remarking that they have probably caused many cases the etiology of which was shrouded in mystery. The conclusion is obvious that during the prevalence of diphtheria-epidemics or -endemics children with sore eyes are to be viewed with wholesome suspicion, and should be quarantined until the exact nature of their malady shall have been shown by bacteriologic examination. In the case observed by C. D. Westcott² membranous conjunctivitis occurring in a 3-year-old boy was traced postmortem to the streptococcus pyogenes in the blood and the eye, although the antemortem conditions led to the diagnosis of diphtheric conjunctivitis. [All of which goes to prove that we are yet far from possessing all the truth about membranous conjunctivitis.]

Chlorosis.—As a complication of chlorosis, Dieballo³ mentions optic neuritis and aggravated headaches, suggesting brain-tumor. When treatment had restored the hemoglobin and corpuscular elements of the blood the optic neuritis faded away.

Typhoid.—Spontaneous orbital and intraocular hemorrhages, one of the rarest complications of typhoid fever, were seen by C. E. Finlay⁴ in a 10-year-old boy, presenting also subcutaneous ecchymoses and epistaxis. Vision in both eyes was completely abolished, secondary metastatic choroiditis supervening in the left one.

Menstruation.—A young woman who applied to A. E. Davis⁵ because of sudden blindness in her left eye was found to be the subject of vicarious hemorrhage from the choroidal vessels into that eye. Friedenwald⁶ also speaks of cases of punctate keratitis, recurrent conjunctivitis, iritis, and hemorrhages into the vitreous that appeared during the menstrual periods only, although that function was normally performed.

Hysteria.—F. S. Millbury⁷ cured 3 cases of confirmed hysterical amblyopia by suggestion.

Puerperium.—Puerperal infection of both eyes was observed in 2 instances by Janerskierwicz.⁸ The first woman became blind 10 days after parturition; in the other, aged 36, both eyes became swollen and blind a few weeks after her 7th normal pregnancy.

Epilepsy.—After correction of the refraction, a neurotic patient of Marlow's⁹ gained 20 pounds, and at the end of 5 years continued free from an intense nervousness and occasional epilepsy that had baffled many physicians for some years prior to the correction of the refraction.

Whooping-cough and Tonsillitis.—G. Fatterer¹⁰ speaks of paresis of the muscles of both eyes associated with tonsillitis, and Craig¹¹ of palsy of the 6th and 7th nerves occurring during whooping-cough, probably induced by a small venous hemorrhage into the 4th ventricle.

Vaccination.—A. F. Rutherford¹² reports an instance of accidental vaccination of both eyelids and the conjunctiva of the left eye, in a 28-year-old woman who had inoculated herself from her child's arm.

The Eye as a Help in Diagnosis.—Ocular symptoms are often found

¹² Quart. Med. Jour., July, 1896.

helpful by H. Gradle¹ in establishing a diagnosis, for instance: edema of the lids suggests arsenic-poisoning or Bright's disease; blood in the lids, scurvy; pallid conjunctiva is associated with anemia; a suspicion of accident, whooping-cough, or general vascular disease is aroused by hemorrhages under the conjunctiva; deep infiltration of the cornea may mean inherited syphilis, while superficial streaks of opacity are sometimes found in malaria; plastic iritis points to syphilis or rheumatism; the Argyll-Robertson pupil is an early indication of tabes; contracted pupil is associated with the acute stage of cerebrospinal diseases, and with opium- or chloroform-narcosis, while a dilated pupil may mean any one of several cerebrospinal affections, asphyxia, diphtheric paralysis of accommodation, intraocular hemorrhages, leukocythemia, hysteria, muscular paralyses, and cerebral syphilis.

Miscellaneous.—K. Goh² says that septic retinitis and metastatic chorioretinitis are not inflammatory processes in the sense that they are the only parts affected by the microorganisms, but that they are secondary to somatic changes in the blood which induce degeneration of the tunica intima, and thus predispose to hemorrhage.

C. S. Bull³ refers to panophthalmitis and orbital cellulitis, with subsequent diaphragmatic abscess, the latter probably metastatic. Among miners Bourguet⁴ found nystagmus, and choroidal and optic atrophy to be the prevailing ocular lesions, and attributes them principally to the poison-laden atmosphere, for in well-ventilated mines the men were found to be comparatively free from ocular lesions. A case of chloroma is fully described by S. C. Ayres and A. Alt.⁵

Cerebrospinal Diseases.—H. de Gouvea⁶ reports a case of transitory blindness, followed by loss of the lower field of vision of one eye that continued four weeks, in an epileptic. The ophthalmoscope showed marked edema of the upper halves of the retinae. The ocular manifestations of epilepsy, in the order of their frequency, are: affections (spasm) of the ciliary muscle, of the muscular tunics of the retinal arteries, and of the extrinsic muscles. As the literature of tumors of the pons increases, it is becoming evident that the ocular symptoms play no little part in making up the symptom-complex. Disturbances of function of the 3d, 4th, and 6th nerves seem to be the most frequent symptoms (Hoffman⁷ and Bisehoff⁸). To the above symptom-complex H. Upson⁹ adds orbicular paralysis and bilateral optic neuritis. H. F. Hansell's¹⁰ case illustrates how closely all the symptoms of brain-tumor may be simulated by cyst of the brain. The cyst involved the right frontal lobe, producing high-grade bilateral choked disk, concentric narrowing of the visual field terminating in blindness, and intense headaches, with general convulsions shortly before death. Syphilitic growths at the sphenoidal window involving the optic foramen also simulate brain-tumors; *e. g.*, Rochon-Duvigneau¹¹ reports several such cases, with a characteristic array of ocular palsies and amblyopia, always of grave prognosis. Some cases recover under mixed treatment. The symptoms referable to tumor of the pituitary body noted by Stirling¹² were bilateral optic atrophy, giddiness, iris-paralysis, frequent flushings and perspiration of the head and neck, sleepiness, increase of body-fat, and photopsiæ. In 2 cases of polyencephalitis

superior acuta¹ the main symptoms were extra- and intraocular palsies. G. Hinsdale,² in his monograph on syringomyelia, classifies the ocular symptoms of this recently much-studied disorder into symptoms referable to the pupil, the oculomuscular apparatus, the fundus, and the visual field. Franke³ saw akromegaly unfold its features in a 31-year-old woman previously healthy, producing in time typical bilateral temporal hemianopsia. There was some improvement in her condition following the use of powdered extract of hypophysis taken from an ox. There is much added to the knowledge of this subject by Streminski's⁴ study.

J. Soury⁵ investigates comprehensively the relations of the retina, the optic path, and the occipital lobe to the completed visual act, and confirms Munk in his view that the region of the calcarine fissure is especially concerned in central visual acuity. A 74-year-old patient of B. Schirmer's⁶ experienced fiery photopsia at the time of rupture of the deep cerebral artery into the occipital lobes in the region of both calcarine fissures. Schirmer claims that this is the first instance of well-proved subjective sensation excited by the pressure-stimulus communicated to the occipital cortex. A wonderfully interesting instance of word-blindness is recorded by W. P. Morgan,⁷ occurring in a bright, well-grown 14-year-old son of intelligent parents. The only words he read at all were "the," "and," "that," "of," while other words meant absolutely nothing to him. He conversed well, read figures quickly and correctly, and was fond of arithmetic and algebra. The case is unique in that it was congenital and secondary to some lack of development in the region of the left angular gyrus. J. M. Rattray,⁸ alludes to an instance of word-blindness accompanying degeneration of the cerebral blood-vessels in a 75-year-old man who had been a teacher of no little ability up to within a few months of his illness. P. Steffan⁹ says sensory anopsia (soul-blindness) may be subcortical, cortical, or transecortical, in which latter case the association-fibres are involved. Sensory anopsia may be either physiologic or pathologic, and mixed forms may also appear. According to F. Peterson,¹⁰ between 7% and 8% of idiots are congenitally blind. Many present certain visual and ocular defects, such as hyperopia, defective color-sense, strabismus, nystagmus, congenital cataract, inequality of the pupils, and microphthalmos, and good binocular vision is uncommon. He states that the normal child takes pleasure in the sight of objects as early as the 11th day; the eyes are coordinated by the end of the second month, and he begins to distinguish colors correctly about the age of 2 years. In a child 12 years old there appeared myosis, retraction of the globe, narrowing of the palpebral fissure, and paralysis of the vasa motores of the same side secondary to caries of the first dorsal vertebra, which Cousoy¹¹ adduces as additional evidence that nerve-filaments to the iris proceed from the ciliospinal center in the cord between the 7th cervical and 1st dorsal. The most frequent eye-symptom in Friedreich's ataxia is nystagmus of the ataxic variety, says C. W. Burr.¹² Marked optic atrophy never occurs, while strabismus, diplopia, and ptosis are met with as complications rather than a part of the disease. To the eye-symptoms of a kindred disease to the foregoing (multiple sclerosis), C. Kunn¹³

adds 3 that he claims are new, namely—nystagmus when a near object is fixed upon, dissociation of the normal ocular movements (developed strabismus), and a sort of nystagmus of the ciliary muscle evidenced by rapid variation in the accommodation.

CONGENITAL AFFECTIONS.

Of the Cornea.—Congenital opacities of the cornea in an infant the subject of purulent conjunctivitis were observed by Barbacheff.¹ Their origin has been demonstrated by Kölliker to be a retardation or cessation in the process of the mesoderm that differentiates the cornea from the sclera. In W. Reber's case² the opacity was central, $5 \times 5\frac{1}{2}$ mm., and unilateral, and within 2 years shrank fully 2 mm. without treatment. He does not commit himself either to the inflammatory or the arrest-of-development theory, but says that "when embryologists tell us whether the cornea clears from periphery to center, or from center to periphery, we will have taken a long step toward a better understanding of the etiology of this affection." Peltesohn³ describes a defect in the stroma of the anterior layer of the iris, situated in the outer lower quadrant, that at first produced the impression of an iridodialysis. Patient was a 52-year-old laborer.

Of the Anterior Chamber.—Hartridge⁴ speaks of an instance of a cyst moving freely in the anterior chamber both in a mother and her son. It was dark in color and about the size of a large shot.

Of the Vitreous.—J. A. White⁵ refers to bilateral persistent hyaloid artery, which he discovered in a highly myopic woman whose refraction he was estimating.

Of the Choroid.—Dunn⁶ says that in coloboma of the choroid the scotoma is not necessarily the size of the coloboma, and indeed it may be absent. Its presence and size depend upon the amount of damage done to the overlying retinal tissue by the processes, whatever they may be, that determine the choroidal coloboma.

In treating of the pathology of this affection Ginsberg⁷ says it has no relation to the ocular fissure, and that it is probably due to some disturbance in the mesodermic layer.

Of the Optic Nerve.—Fournier and Sauvinau⁸ attribute the cause of congenital optic-nerve atrophy, absorption of choroidal and degeneration of retinal pigment, paralysis of external rectus, and immobile pupil coexisting in the left eye, while the right eye was normal, to inherited syphilis, in spite of a nonsyphilitic history. Two cases of coloboma of the optic nerve and one of medullated nerve-fibers associated with myopia are reported by Moll.⁹

Anophthalmos.—Complete anophthalmos in a 7-year-old Chinese girl was observed by L. Steiner.¹⁰

DISEASES OF THE LIDS.

Association-movements.—[Association of lid-movements with jaw-movements is not uncommon, but association of movements of the upper lid with the movements of the external ocular muscles other than the superior

¹⁰ Ibid., Sept. 26, 1896.

rectus is rare.] J. Brixa¹ details fully 2 such cases in which, in addition to Graefo's sign, there was elevation of the upper lid associated with action on the part of the internal recti, while any attempt at abduction brought the upper lid down quickly. H. Friedenwald² saw 2 cases of this kind, one peculiar by its late appearance (at the 14th year), the other unique in showing association of the levator with the pterygoid of the opposite side.

Itching of the lids, as a result of nasal stenosis, and cured by opening of the nasal passages, is recorded by Prince.³

Molluscum Contagiosum.—The 3 cases detailed by H. Muetze⁴ indicate that molluscum of the lids or lid-margins is frequently the cause of conjunctival catarrh, and that it is undoubtedly contagious.

Tuberculosis.—Bacteriologic examination was required to determine to Armignac's⁵ satisfaction the tuberculous nature of a lid-affection that was followed some weeks later by involvement of the larynx and lungs, leading to death.

Vaccine-pustule.—J. H. Egbert⁶ tells of a 11-year-old girl who, while sleeping with her sister, who had been recently vaccinated on the arm, acquired a vaccine-pustule on her eyelid.

S. Reiner⁷ puts on record the 17th case of syphilitic tarsitis in medical literature, classic in all its features except that the conjunctiva bulbi was rather extensively involved. Gallaemarts⁸ considers extragenital chanere not more predisposed to produce constitutional syphilis than chanere on the genitals. He reports an instance of lid-chanere caused by the application of the tongue of a syphilitic. Chanere of unknown origin, found on the eyelid of a 5-year-old negro boy is recorded by J. H. Egbert.⁹

Ptoxis.—Ed. Pergens¹⁰ refers recurrent unilateral ptoxis, after operation for its relief, to astigmatism, because the patient is inclined to close partially the palpebral fissure in his efforts to see. Advancement of the levator palpebra superior for traumatic ptoxis occurring in a child was done by C. A. Oliver¹¹ with marked success. In view of the failure of many operations practised for the cure of ptoxis, Motaïs¹² proposes to remove a tongue of muscle and tendon, 3 mm. wide and 10 mm. long, from the middle of the superior rectus and suture this into the cartilage of the lid. Parinaud¹³ suggests suturing the entire superior rectus to the lid by passing the thread under the muscle through the adjoining conjunctiva into the posterior extremity of the lid, bringing the two ends of the suture out from the lid at its ciliary margin and tying them. Both writers claim good results and no interference with the movements of the ball. Harold Wilson¹⁴ prefers pedicellate flaps for the repair of lid-malposition, except in those cases in which the cecatrix, involving not only the lids but also the surrounding parts, has not the necessary qualities for plastic purposes. In this class of cases Thiersch's method promises the best results.

C. H. Beard claims that the chief ends to be gained in operations for ectropion and trichiasis following conjunctival cicatrization are to replace the atrophied tissues and to relieve the lid-tension. For the first he transplants mucous membrane from the mouth, and for the second he does a free cantho-

plasty, including a division of the external canthal ligament. F. C. Hotz¹ splits the margin of the lid back of the hair-bulbs in correcting the deformities after trachoma, and speaks highly of the efficiency of Thiersch's skin-transplantations in repairing the disfigurements of ectropion. Argyll-Robertson² employs the device of cutting out of a piece of paper an exact pattern of the surface that has been bared and placing this pattern upon the skin at the part whence the graft is to be taken, allowing about a fifth or sixth of the width of the flap all around the pattern for shrinkage. He also employs what he terms the "tether"-stitch to keep the transplanted flap in position (Fig. 61).

Tumors.—An unusual form of growth proceeding from the inner canthal portion of the lower lid is reported by A. A. Hubbell.³ The tumor, globular in form and about 1 in. in diameter, was successfully removed. A young Egyptian woman, under the observation of Kenneth Scott,⁴ submitted to operation for a tumor of the upper lid that displaced the globe 24 mm. downward. Microscopic examination of the tumor revealed small-celled sarcoma, although 10 months after operation there was no indication of recurrence. Trouseau⁵ finds that epithelioma of the lids and conjunctiva, after removal, is less frequent and longer in recurring than epithelioma in other parts of the body, and Fage⁶ states that sarcoma of the lids, having its origin in the conjunctiva or neighboring parts, is frequently observed, but that only 7 or 8 authentic cases of true primary sarcoma of the lids have been reported.

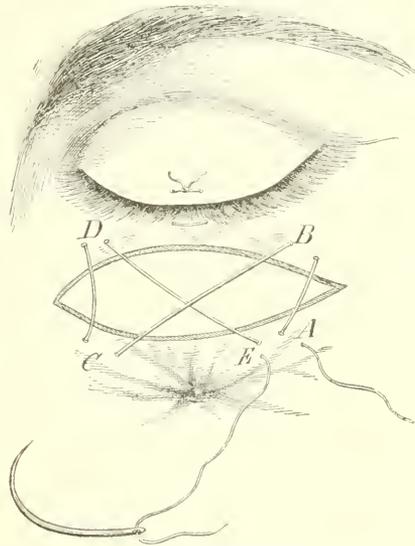

FIG. 61.—Argyll-Robertson's "tether"-stitch for holding the skin-graft in position by lacing the thread over it (Practitioner, Aug., 1896).

DISEASES OF THE CONJUNCTIVA.

Bacteriology of the Normal Conjunctiva.—R. Randolph's bacteriologic investigations of 100 perfectly healthy eyes⁷ demonstrate that the normal conjunctiva always contains bacteria, among which the staphylococcus epidermis albus is found with such frequency that it must be regarded as a regular inhabitant of the conjunctival cul-de-sac. This coccus, though but slightly pathogenic ordinarily, may under certain conditions become harmful. Neither irrigation with distilled water nor instillation of a 1 : 5000 solution produces sterility of the conjunctiva, all of which facts induce Randolph to conclude that in operating upon the normal conjunctiva or cornea, as in cataract-operations, the surgeon would do well, in the present state of our knowledge, to direct his asepsis and antisepsis chiefly, if not solely, to the hands, instruments, cocain, and atropin. Our knowledge of the microorganisms of the normal and abnormal conjunctiva and lacrimal sac is also much enriched

¹ Ann. Ophth. and Otol., July, 1896.

⁷ Arch. of Ophth., July, 1897.

by the contribution of J. McFarland and S. S. Kneass.¹ The form of mucopurulent conjunctivitis, described by Morax² and T. Axenfeld,³ is another addition to the comparatively small list of microbial eye-diseases in which there seems little doubt that the microorganism has been identified.

Epidemic Conjunctivitis.—S. Stephenson⁴ believes, with Morax, Weeks, and Beech, in a specific microorganism which is accountable for epidemic acute catarrhal conjunctivitis, and he considers the diagnosis in such cases incomplete without a microscopic examination of the secretion. The bacilli are to be found at some stage in every instance of the disorder, and their numbers stand in direct relation to the severity of the inflammation. They are readily killed by antiseptics or by drying. 2% silver solution is his main reliance in the treatment of this affection. He further details⁵ the incidents of an epidemic of catarrhal ophthalmia affecting 23 out of 25 male infants in one of the wards of the London Central District School, although, by rigorous prophylaxis and quarantine, the epidemic was confined to this one ward. All the affected cases made a good recovery. In an epidemic of acute conjunctivitis that swept through 2 schools near Karlsruhe Gelpke⁶ saw 22% of the children fall victims to it, although within 8 weeks all had recovered. Fränkel's pneumococcus is held responsible by H. Clifford⁷ for most cases of catarrhal conjunctivitis. To all these contagion-theories of catarrhal ophthalmia A. H. Jacob⁸ demurs, holding overcrowding, dark and ill-ventilated rooms, damp soil, and insufficient diet accountable for the affection. He bases his contention on many years' experience with the disorder among the paupers of Ireland.

Purulent Conjunctivitis.—L. Howe⁹ draws a striking picture of the results that would follow compulsory observation of Credé's method in the prophylaxis of conjunctivitis of the newborn. He says there is a direct proportion between ease of transportation and a low rate of blindness, while a higher ratio is to be expected where travel is poor and inconvenient. He pleads for renewed activity in promoting legal measures looking to the prevention of ophthalmia neonatorum, in which plea he is joined by Zimmerman¹⁰ and Ferguson.¹¹

The latter writer urges the Canadian government to pass laws regulating its treatment, as has been done in many of the United States, mainly through the instrumentality of Howe, of Buffalo. Knies¹² holds that subsequent infection is as often responsible for purulent conjunctivitis as immediate infection occurring during delivery, while A. E. Adams¹³ condemns the obstetrician who neglects to adopt Credé's method when there is the least suspicion that the conjunctiva may be infected. Walter, on the other hand, lays stress¹⁴ on attention to general nutrition and the necessity of promoting active circulation in the subjects of this condition. K. Hoor¹⁵ does not favor Kalt's irrigation-method for purulent conjunctivitis, although he himself has employed a somewhat similar method for 12 years. He objects to Kalt's tube or any other hard instrument that may abrade the cornea. In pediatrics A. Pukalow¹⁶ is

credited with having made use of calomel in 57 cases of purulent conjunctivitis, with results superior to those secured from any other remedy.

Gonorrheal Conjunctivitis.—Chartres¹ asserts that the serious ophthalmias are those produced by streptococci or by an association of streptococci and gonococci, or by the combination of these 2 with others. The gonococci when alone are comparatively harmless [?] and yield to treatment, which should be prompt and vigorous, consisting of copious irrigations with potassium permanganate, boric acid, and cauterization with silver nitrate. This combination acts on all the various species of microbes which may be producing the ophthalmia. He concludes by insisting on the necessity of bacteriologic investigation. Hansell² has seen gonorrheal conjunctivitis secondary to a gonorrhea induced by intercourse during menstruation. Formalin has proved effective in his hands in this affection. Aqueous extract of suprarenal capsule produces great bleaching of the conjunctiva, but after the astringent action has passed away the inflammation returns in greater force than before. Hansell favors exclusion of the sound eye, providing that the dressing is changed and the eye sealed often enough. [In a case of postoperative congestion of the anterior ocular segment, occurring in our own experience, the extract of suprarenal capsules induced marked ischemia of the eye in 10 minutes, but the patient returned the following day suffering excruciating pain from the terrific engorgement of the anterior ocular circulation. It will require some study to determine just what may be the most effective sphere of action of the aqueous extract of suprarenal capsules.] In the gonorrheal conjunctivitis of adults, Knies³ uses fluorescin to map out for cauterization any denuded or desquamating corneal areas. Wandless⁴ from an experience of 1 case, advocates the application of 8% silver solution in gonorrhea of the conjunctiva.

Phlyctenular Conjunctivitis.—The treatment of phlyctenular conjunctivitis by subconjunctival injections of sublimate 1:3000, advocated by Evans,⁵ is mentioned only that it may be condemned. [The well-known simple and effective remedies, attention to the nares and intestinal tract, and alteratives are greatly to be preferred.]

Membranous Conjunctivitis.—Until the etiologic classification of the different forms of conjunctivitis assumes more definite outlines, H. Coppez,⁶ prefers to retain the old anatomic classification, though he looks forward to the day when treatment will have reference to etiology rather than to symptoms only. A. Pileher is convinced that the Löffler bacillus bears a causative relation to ordinary membranous conjunctivitis, and argues for the retention of the generic term "membranous conjunctivitis" for all of the varieties until the etiology of the different forms can be sharply defined. Ewetzky⁷ and H. Woods⁸ associate themselves with the above views, while C. H. Sproneck⁹ contends that Behring's serum can be used to differentiate between nonmalignant and true diphtheria of the conjunctiva. In a false membrane removed from the neighborhood of the caruncle in a case of membranous conjunctivitis J. Ehre¹⁰ found numerous bacilli of Friedländer. Cultures were injected into the tail of a mouse, and 48 hours later the heart-blood of the mouse was filled with encapsulated Friedländer bacilli.

Granular Conjunctivitis.—In granular conjunctivitis, Kalt¹¹ recom-

mends free application of 1 : 5000 to 1 : 300 potassium permanganate in addition to the usual remedies, and Dubat¹ speaks well of the effect of raw petroleum applied twice daily with a brush.

Vernal Catarrh.—Darier² differentiates graphically between trachoma and the palpebral form of vernal catarrh. Trachoma attacks by preference the fornix of the conjunctiva, while vernal catarrh limits its invasion to the tarsal portion of that membrane; again, the semicartilaginous character of the papillae in spring catarrh is almost pathognomonic. For the latter condition, Wechsler³ finds antipyrin and sulfate of quinin quite effective. In some cases the disposition is to become chronic, in which case the disease persists without regard to season. Infectious conjunctivitis originating in animals is characterized by two main symptoms,⁴ distinct voluminous granulations resembling trachoma-cells and a subacute adenitis attacking the preauricular and cervical glands. The affection is benign and usually monocular. It has also been studied by Despagnet⁵ among workmen in slaughter-houses, and the main symptoms put down by him as glandular swelling of the conjunctiva with pus containing granulations on the lid. M. Villard,⁶ during his studies of the normal conjunctiva of rabbits, found granulations much resembling trachoma in man, and he demonstrated lymphatic vessels directly connected with the granulations. The verification of these findings is important, as it brings into close relation the granulations and the lymphatic glandular tissues. Villard infers by analogy that the same condition exists in man.

Trachoma.—According to T. Federow,⁷ there is no anatomic identity between trachoma foci and granules of the conjunctiva. The greatest evils following in the wake of trachoma, says M. Kirsch,⁸ are the limitation to education, susceptibility to inheritance, influence upon the capability of armies, the latter in itself a calamity to the home and a danger to the monarchy. J. W. Heustis⁹ points out the danger that lurks in the slightest corneal abrasion when complicated with granular lids. The dissemination of trachoma can be diminished, it is claimed by Probsting,¹⁰ by state supervision of school hygiene. Chibret,¹¹ reporting on the geographic distribution of trachoma, says: "In Cuba the three great branches of the human family are represented by the negroes, the whites, and the Chinese. The Chinese are affected twice as often as the whites and 8 times as often as the negroes. Santos Fernandez (quoted by Chibret) found 16 cases of trachoma among the negroes to 67 among the whites and 111 among the Chinese. The freedom from trachoma of the eye of the negro is shown by J. M. Ray.¹² Chibret further states that occupation plays an insignificant part in immunity from trachoma, while hygienic conditions are of great importance. Lymphatic temperament and malarial infection favor its inroads. Irritation from dust is considered by S. M. Burnett¹³ an important causative factor in trachoma, especially in those predisposed to conjunctival irritation. An altitude of 3000 meters furnishes the ideal climate. It is in part due to this latter advantage that Ole Bull¹⁴ ascribes the immunity of the Norwegians from trachoma. G. Hirsch,¹⁵ however, opposes Bull's view that trachoma is largely a matter of race, disposition, and approach

to the sea-level, claiming that trachoma has been brought into his district (eastern Germany) by miners and artisans, who poured into the region spreading trachoma through the province notwithstanding that the altitude was fair and trachoma had been previously quite rare in that locality. D. Reynolds¹ is satisfied that trachoma is, *per se*, the local manifestation of a constitutional infection just as urgently demanding mercury and quinin as though it were some other form of that miasmatic infection which begets remittent and intermittent fevers. [The facts do not lend probability to this theory.]

E. Nesnamoff² finds unusually rapid good results wait on the treatment of trachoma with the following: pure iodine, 1 to 2 pts.; liquid white vaselin, 100 pts.; sulphuric ether q. s. to make thorough solution. To be applied once daily, taking care to protect the cornea from contact with the solution. Burchardt's³ treatment consists in touching all the granules (even to 400) with the point of a narrow galvanocautery. In the intervals between the cauterizations he uses tannate of quinin, which has proved quite effective. Unusual results in the handling of trachoma are spoken of by T. Proskauer⁴ from the application of a 1% solution of formalin, which must necessarily be preceded by 8% cocain solution. If the application is quickly and lightly made, there will be little or no reaction. The large gray granules will be the first to disappear, then the follicles, while the smaller whitish follicular bodies will often resist treatment for a long time. J. S. Fernandez⁵ claims the credit of introducing jequirity in the treatment of trachoma. For small discrete trachomatous granules R. H. Elliott⁶ prefers the actual cautery, because of its painlessness, even in children. For trachoma with pannus, Trousseau⁷ considers iodized glycerin (equal parts of glycerin and tinct. iodine) the best treatment. J. W. Bullard, on the other hand, relies on silver and copper; surgery is his last resort. J. H. Claiborne⁸ discountenances the continued use of atropin in granular conjunctivitis, as it may cause the formation of granulations, which cannot be distinguished from true trachoma.

H. Armaignac⁹ reports a case of undoubted primitive tuberculosis of the palpebral conjunctiva, verified by the finding of a few Koch's bacilli. The eye in other respects remained uninvolved. The palpebral ulceration was treated and cured by frequent application of silver nitrate, bathing with saturated solution of potassium chlorate, and curettage. The patient died, 2 years later, from laryngeal and pulmonary phthisis. E. Valude¹⁰ describes another case similar in all respects to that of de Wecker.

Syphilis.—Another instance of primary lesion occurring on the conjunctiva is reported by R. Hitchman.¹¹

Urticaria.—Urticaria of the conjunctiva following the ingestion of veal and strawberries is noted by S. M. Stoeker.¹² The analogy between the conjunctival condition and the cutaneous lesion which coexisted was complete.

Ophthalmia Nodosa.—G. Knapp¹³ believes that many cases of so-called ophthalmia nodosa, in which the history is vague and uncertain, are caused by the confinement in the conjunctiva of caterpillar hairs that have escaped casual examination, and can be found only by the use of a strong magnifying lens.

Phlebolith.—A perfectly smooth oval body, 4 by 6 mm., which S. Bur-

nett¹ removed from one of the conjunctival veins of a 30-year-old woman proved to be a typical phlebolith.

Pterygium and Plastic Operations.—In 3 different instances C. H. Baker² repaired large denudations of the bulbar conjunctiva with Thiersch's skin-grafts, with the most gratifying results. K. Hoor³ employed with equally good results the membrana testæ from boiled eggs in restoring 2 conjunctivæ buttonholed during the operation for symblepharon. In dealing with large pterygia, F. C. Hotz⁴ dissects the growth, allows it to retract toward the inner canthus, and then places parallel with the cornea a narrow Thiersch skin-graft, about 2 by 10 mm., which, when it becomes attached, forms a smooth white barrier, over which the pterygium never advances. Trousseau⁵ removes the head of the pterygium, and cauterizes the union of the head and body a little behind the limbus.

Tumors.—True papilloma of the conjunctiva occurring in a 47-year-old healthy man came under O. Stuelp's⁶ observation. The microscope fixed the diagnosis. S. Bomboletti⁷ refers serous cysts of the conjunctiva to an enlargement of an emissary duct of one of Krause's glands of the lower fornix of the conjunctiva. Injury may originate the condition.

An unusual sequel to exenteration is mentioned by W. A. Wagemann,⁸ who saw carcinoma develop in the conjunctival cicatrix left by the operation. The patient was 70 years old. Small-celled sarcoma of the upper lid, probably the result of inoculation during an operation for removal of a melanosarcoma at the limbus, is reported by A. Szulislawski.⁹ The patient was a 55-year-old farmer.

AFFECTIONS OF THE LACRIMAL APPARATUS.

Physiology.—The part that the facial nerve plays in lacrimal secretion is well shown by Tribondeau's experiment on a dog¹⁰ that developed a perfectly dry eye 3 weeks after deep section of the facial nerve, thus confirming Goldschneider's and refuting Tepliaschin's theory.

Congenital Anomalies.—In a patient showing double harelip and coloboma of both eyelids van Dnyse and Rutten¹¹ traced the tear-duct from the coloboma of the lower lid all the way down to the left half of the upper lip. J. H. Eyre¹² observed a case of congenital supernumerary caruncle in a 38-year-old man that was strikingly similar to the one described by Stephenson last year (see *Year-Book*, 1897).

Sarcoma.—C. A. Veasey¹³ and S. Snell¹⁴ add two more to the few reported cases of sarcoma of the lacrimal caruncle. Both were nonpigmented and contained large and small round cells.

Inflammation.—R. Randolph¹⁵ has met with an instance of bilateral nonsuppurative inflammation of the lacrimal gland, the so-called "mumps of the lacrimal gland."

Obliteration of the Duct.—For impassable bony stricture Scott¹⁶ passes an ordinary small pointed drill attached to a dental machine along the pre-

vously slit lower canaliculus, directing it exactly in the way in which a lacrimal probe is introduced, tilting it and then drilling through the bony tissue into the unobstructed portion of the duct. Three other burrs, respectively 2, 3 and 4.5 mm. in diameter, are made to pass through the opening, and the advantage thus gained is maintained by the introduction of a leaden style. He claims uniformly good results from this method. R. S. Miller¹ finds styles much the most satisfactory way of treating lacrimal obstructions, especially those following abscess.

Anesthesia.—A. E. Davis² has used hypnotism in a number of cases to pass lacrimal probes, and even for slitting up the canaliculus without pain. Its quieting influence was a source of much comfort to nervous patients, for by suggestion alone he prevented these patients from worrying about their eyes and from dreading the next visit, with its attendant pain. [It is a matter of surprise that hypnotism, highly extolled by some writers as the most desirable means of preventing pain, has not had more general application.]

AFFECTIONS OF THE CORNEA.

Ulceration.—Evidence collected by J. E. Weeks³ is sufficient to establish the fact that the pneumococcus of Friedländer is capable of producing grave ulcerative conditions in the eye, and that the pneumococcus of Fränkel has been observed as the pathogenic microorganism in case of tenonitis, panophthalmitis, hypopion keratitis, conjunctivitis, and probably in some cases of dacryocystitis. Nuel⁴ says that punctate keratitis and analogous forms that are characterized by the presence of spiral microbes, of which he found many in a case studied, are diseases of special microbes that are absolutely typical. Antonelli and Giglio⁵ have shown that many of the asthenic ulcers are really tuberculous lesions. Cultures of the detritus from the floor of the ulcer should be made in every instance to determine its character.

Burnett,⁶ de Schweinitz,⁷ and O. Belt⁸ endorse formol as an efficient remedy in 1% solution in arresting ulceration and in lessening opacities. C. Mayet⁹ has tried with success, in chronic indolent ulcers that refused to be cured by other means, transplantation of a flap of conjunctiva to the ulcer. H. Sureau¹⁰ substitutes for hot compresses and hot bathing (universally recommended and of the greatest service in relieving pain and stimulating healing) "cataplasms of linseed meal" [a dangerous substitution.] W. Bruner¹¹ recommends the actual cautery when simpler methods have been tried unsuccessfully or "occasionally in severe cases in which it is evident from the first that something radical will be necessary." The remedies found most useful by Kalt¹² are the galvanocautery, tinct. iodine, iodine-glycerol, phenique and methyl-blue, preferably the first named. The proneness of the eye of the negro to diseases of the cornea and uveal tract is pointed out by J. M. Ray.¹³

Interstitial Keratitis.—The causes mentioned by different writers are: hemorrhagic urticaria, E. Stern;¹⁴ the menstrual epoch, König and Meyer;¹⁵ in the order of their frequency, hereditary syphilis, tuberculosis, acquired syphilis, influenza, malaria, rheumatism, R. Greef,¹⁶ and

Achenbach;¹ beginning phthisis, O. Schirmer.² E. Valude³ says that the interstitial keratitis of syphilis is characterized by its unilateral character, slight tendency to vascularization, and beneficent results of treatment. The prognosis is more favorable than in the hereditary form. C. D. Marshall⁴ differentiates the two forms thus: the anterior part of the eye is most commonly affected in tertiary or congenital, while the choroid is peculiarly susceptible to inflammation during the course of acquired syphilis. K. Moulton⁵ observed in a man, 67 years old, a true nonsyphilitic **annular interstitial keratitis** that surrounded the central two-thirds of the cornea; recovery ensued. W. Reber⁶ and H. Moulton⁷ report cases of **congenital corneal clouding**, in neither of which were there any signs of inflammatory or syphilitic origin. Reber inclines to the arrested-development theory as a cause for the phenomenon.

Treatment.—Greef's theory⁸ of this disorder is German in its adherence to innervation as the elect method in specific cases. This, in connection with a "sweat cure," accomplished by the liberal use internally of sodium salicylate, has proved highly efficient in his hands. He utterly discountenances the subconjunctival injections of "homeopathic" amounts of mercury to hasten the absorption of post-inflammatory cloudings of the cornea. During the recent epidemic of small-pox in Havana C. E. Finlay⁹ saw 24 cases of **variolous pustule of the cornea**, although for some unknown reason the lesions appear at a later period than in other tissues. A translucent facet, eccentrically situated, slow in progress, and interminable in healing, developed in the third week. Treatment has little or no influence on the duration of the affection.

The Electric Light.—J. Ogneff,¹⁰ after exposing the eyes of rabbits, frogs, and pigeons to a powerful arc light, found that the cornea and conjunctiva were the parts to suffer most, while the retina (contrary to the usual findings) was least affected.

Neuroparalytic Keratitis.—I. Lusch¹¹ saw this condition in a married woman 42 years of age, who was otherwise perfectly healthy.

Lead-deposits.—H. Derby¹² describes a peculiar incrustation of the cornea secondary to ulcer that presented all the characteristics of deposit after using a lead collyrium, although chemical examination of the scale failed to reveal lead.

Herpes.—The treatment advised by Galezowski¹³ consists in weak duboisin and eserin, insufflation of powdered iodoform and cocain, and the same in ointment once daily, occlusion, galvanocautery if necessary, and in infecting progressive ulcer, injections under the conjunctiva of antitoxin.

Blood-staining.—De Schweinitz¹⁴ refers to a case of this kind in a 4-year-old girl, in whose right eye there occurred several hemorrhages secondary to abscission of a prolapsed iris.

Tumors.—Thomas¹⁵ reports the removal of a dermoid cyst attached to a linear base extending from the cornea to the inner canthus. The major part of the tumor was covered with skin and hung out between the lids. C. D. Westcott¹⁶ describes keloid of the cornea encountered by him in a 3-year-old

child as secondary to ophthalmia neonatorum. The microscope confirmed the diagnosis.

Congenital defects of the cornea are classified by Barabacheff¹ thus: glaucomatous, adherent leucoma, sclerosis—all of which are the result of intrauterine inflammation. He cites a case of undoubted interstitial keratitis of syphilitic origin occurring in the second generation. C. A. Woodruff's² case of binocular and monocular diplopia is unusual and interesting, as presenting varying vision and refraction dependent upon the relation of the pupil to the corneal cicatrices [and unless carefully studied would suggest intracranial complications]. A. Tepljaschin³ enjoyed the unusual opportunity of examining microscopically the eyes of a child born with opacity of both corneæ. There were no other congenital anomalies, and the infant died on the third day. Tepljaschin concludes that the opacities originated in an intrauterine inflammation.

Leukoma.—Associated with conjunctivitis of the newborn J. S. Fernandez⁴ saw 2 instances of complete corneal clouding that slowly disappeared without treatment. In 3 cases of nebulous cornea in which iridectomy had improved vision, Stern⁵ added to the vision in each case by tattooing the cloudy corneal area.

E. Stephenson⁶ lauds **electrolysis** for the dissipation of corneal opacities. He employs a current of from $\frac{1}{4}$ to $\frac{1}{2}$ ma. under a pressure of $1\frac{1}{2}$ to 3 volts. Any excess of these amounts will defeat the purpose of the treatment by its over-effect. The current should be accurately controlled by a rheostat and milliampèremeter, the galvanometer being placed near the patient's head, so that variations of the current may be closely followed. The indifferent electrode is held in the patient's hand, while the active pole is attached to a bulb-pointed silver probe, which is gently, but rather rapidly, passed over the opacity. The cornea must be kept moist. Slight frothing will be noticed during the manipulations, which ought to be continued for about a minute. In the list of cases published the average improvement in vision was from 50% to 66%. After 15 to 20 daily applications it is well to suspend treatment for a month. [We are glad to note that Stephenson insists upon the use of a milliampèremeter in the work. To our minds, no intelligent and accurate electrolysis can be applied without one which graduates the amount administered as accurately as does a medicine-glass the dose of a remedy at the bedside.]

ANOMALIES AND DISEASES OF THE LENS.

Congenital displacement of the lens occurring in 7 members of a family of 10 is recorded by E. S. Miles.⁷ Cramer⁸ speaks of meeting with an instance of lenticonus posterior in a 9-year-old girl. The refraction of the peripheral portions of the lens was plus 4 D., while the central portion was minus 11 D. A well-authenticated case of retention of transparency of a lens in which a foreign body had lain quiescent for 16 years is reported by T. B. Archer.⁹ At the expiration of that time, when the man was 30 years old, the lens became opaque without assignable cause.

Moon-blindness.—Ole Bull¹⁰ believes that moon-blindness is due to a

¹⁰ Ann. d'Oculist., July, 1896.

partial change in the lens, leading to a collection of opaque spots on the surface and radiating opaque fibers in the center of the lens.

"Second Sight."—St. J. Roosa¹ attributes so-called second sight to lenticular myopia—a swelling of the lens-nucleus that may or may not be the forerunner of cataract. [This opinion is recorded, not because of its novelty, but because the explanation of the condition is not generally known.]

A. Duane² corroborates E. Jackson's³ explanation of the method of determining the **position of an opacity** in the lens by means of the corneal reflex of the ophthalmoscopic mirror, namely, the real corneal reflex is always seen in the direction of the center of curvature of the cornea, but as the eye is rotated the reflex appears to move across the pupil exactly as would an opacity situated just behind the posterior pole of the lens. The comparison of the relative rate of movement of opacities with the movement of the reflex across the pupil determines the depth of such opacities.

The claim made by Wolff that **regeneration of the lens** is possible, is substantiated by Erick Müller.⁴ The lens was removed from larvæ 3 to 6 cm. in length. Within one day changes were noted in the posterior layer of cells of the iris that in 2 months resulted in the formation of a new lens that had every appearance of a normal one [!].

Causes of Cataract.—The presence of a cilium in the anterior chamber produced capsular cataract in a patient of E. Schwartz.⁵ Hennecke⁶ ascribed unilateral cataract, observed in a 14-year-old boy, to intestinal worms. That cataract may follow a blow that in no wise compromises the other ocular structures is demonstrated by the case reported by Lenz,⁷ which occurred in a young farmer. Wettendorfer⁸ includes attacks of epilepsy among the causes.

Diabetes.—Boucheron, in speaking of the proneness of diabetics to suppuration, referred incidentally to the prophylactic use of the antistreptococcic serum previous to operation, and related the case of a 66-year-old diabetic, in whom, about the time that the injections of the streptococci had become most attenuated, cataract-extraction was done, followed by normal healing and perfect ultimate result.⁹ The author claims this to be the first case of its kind published.

At what Age should Cataract-extraction be Performed?—A. Elschsig¹⁰ says "those cataracts which show intensely white nuclei and transparent, bluish-white anterior cortices are least suitable for operation. All other cataracts in persons over 50 years of age may be safely extracted as soon as the vision is so reduced that the patient cannot perform his usual duties." De Schweinitz¹¹ prefers to wait for maturity, or for that time of life when the lens, even though immature in the ordinary sense of the term, will cleanly leave its capsule. According to C. B. Taylor,¹² there is no limit to the age for cataract-extraction, even if the patient's physical condition is only fair. In his experience he has operated on a number of people over 80 and 3 over 90, one of these being 96 years of age.

Artificial Ripening.—D. Little¹³ gives his adherence to Förster's method, basing his conclusions on his experience with 40 cases. The final extraction then resolves itself into a normal operation for thoroughly mature

cataract. De Schweinitz¹ prefers extraction of immature cataract by the combined method to the performance of an operation for ripening. Del Toro² prefers early extraction to artificial ripening. On the other hand, W. F. Coleman,³ B. F. Fryer,⁴ and Stevenson⁵ argue for preliminary iridectomy, especially in the practice of young ophthalmic surgeons, as conferring the greatest safety to the patient. [While much is to be said in favor of preliminary iridectomy, and while Coleman has enumerated the advantages and disadvantages attending two operations instead of one, he has not reckoned with the nervous shock incident to every ophthalmic operation, no matter how slight, a factor that demands recognition in all surgery.] The point is well made by J. Widmark⁶ that surgeons who will operate only upon naturally ripe cataracts will at times be beset with many difficulties. From 1882 to 1892 he has dealt with 79 immature cataracts; those occurring after 55 years of age were extracted as immature cataracts; those between 40 and 55 were subjected to Förster's operation, and those under 40 were treated by discission. In 89% the visual result was good, in 9% relatively good, and in 2% unfavorable. He would operate on any unripe, slowly progressing cataract in a person over 55 as soon as the vision sinks below $\frac{1}{16}$. He has performed Förster's operation 10 times in private practice, and 16 times in his hospital work, without a failure.

Simple or Combined Operation?—A review of the facts deducible from the statistics⁷ of 11,250 cataract-extractions reported by F. M. Wilson⁸ (see *Year-Book*, 1897), J. B. Story,⁹ D. Webster,¹⁰ J. E. Weeks,¹¹ O. Hallauer,¹² W. Albrand,¹³ W. Berger,¹⁴ indicates what we have before stated (see epitome, *Year-Book*, 1898), that the choice as to simple or combined operation will be largely according to the caprice of the operator, each surgeon offering statistics that support his own method. Two of the Germans adhere to Graefe's operation, while Story and the Americans are all advocates of simple extraction. G. A. Berry¹⁵ will find many supporters of his claim that no fixed rule can be observed in determining whether the simple or combined operation shall be done in a given case. The utmost discrimination is called for. His experience would indicate that vision is perhaps better after combined than after simple extraction.

Plettinick-Bauchau¹⁶ extracts cataract according to Galezowski's method as follows: with the Graefe knife the puncture is made exactly at the junction of the opaque border of the cornea 3 mm. below the horizontal diameter. If the pupil is large enough (atropin is used if necessary), the point of the knife divides the capsule in all directions. Counterpuncture is made directly opposite, and the cutting edge of the knife is so directed that it emerges in the cornea 2 mm. from its superior border. Iridectomy he seldom practises on account of its immediate disadvantages, namely, hemorrhage from the iris and choroid, prolapse of vitreous, and escape of the lens into the anterior chamber instead of out through the cut. He considers its antiphlogistic effect exaggerated. The author says, "In the interest of suffering humanity and of ophthalmic science we hope that the better procedure of simple extraction

¹⁶ Rec. d'Ophtal., Aug., 1896.

made by the elliptical incision of Galezowski will be adopted throughout the entire world."

Complications.—Infiltration of the cornea near the cut and slow recovery after extraction are explained by Abadie.¹ He found that because of the slanting incision the cut edge of the iris becomes adherent to the posterior surface of the corneal wound. This hitherto unsuspected accident can be avoided by making the puncture as normally and as peripherally as possible, so as to penetrate into the anterior chamber through the minimum corneal thickness, and the same manœver and precaution should be observed for the counterpuncture. The section must be continued and finished exactly in the periphery.

Bourgeois² calls attention to a cause for retardation of the cicatrization of the wound after cataract-extraction, namely, entropion of the lower lid, caused and maintained by the dressings applied to the eye.

Darier,³ in a case of cataract with obliteration of the anterior chamber, introduced two lance-shaped knives inversely to each other in the corneoscleral border, one at the right, the other at the left, a little above the horizontal diameter of the cornea. As soon as the points had perforated the cornea they were withdrawn and a cataract-knife, curved and sharp on its convex edge, *with a button at its end*, was entered through one of the incisions, brought out through the other, and the cornea incised, the incision measuring about one-third the circumference of the cornea.

Sanford's⁴ experience in extraction of cataracts **in albinos** has taught him to avoid iridectomy because of prolonged hemorrhage from the cut edge of the iris.

Complete atrophy of the iris followed the third discission of a cataract in a 24-year-old man in a case of F. H. Edsall.⁵

Dislocation of the Lens.—Slight partial dislocation of the lens, Dunn⁶ asserts, can be cured by the continued use of atropin, which gives the zonula a chance to repair, or by eserin if vision is improved by its instillation and where the tests show atropin produces a still further tilting of the lens. Higgins⁷ removed a lens dislocated into the vitreous without iridectomy while the patient was lying prone on an operating-table. K. Hoor⁸ saw a case in which a lens dislocated into the vitreous during a cataract-operation set up so much sympathetic disturbance 6 months later that enucleation was necessary. [This is not an infrequent eventuality. Since the cortical portion of the lens becomes absorbed while lying in the vitreous extraction of the nucleus is not always a difficult feat.]

Discission in Secondary Cataract.—Da Gama Pinto⁹ is enthusiastic over the operation for secondary cataract, and feels that even Knapp does not speak highly enough of the blessings of a successful secondary operation. Pinto performed discission in 61% of 529 cases, giving the preference to what he terms posterior discission, in which the narrow Graefe knife is introduced 7 mm. back of the limbus and the capsule divided from behind; 70% of such discissions were successful. A modified cataract-knife is preferred by A. Elschmig¹⁰ to the needle for discission of either primary or secondary cataract.

Jocqs¹¹ believes that in cases of occlusion of the pupil following iritis and in circumscribed and stationary lenticular opacities, discission and extraction

will give far more acute, hence useful, vision than the traditional optical iridectomy.

DISEASES OF THE IRIS.

Congenital Anomalies.—In recording instances of partial aniridia and corectopia (slit-shaped pupil), W. C. Posey¹ assumes that these anomalies represent non-development of the arteries which, springing out into the anterior chamber from the major circle of the iris, collect about them the tissue that makes up the iris-stroma. He believes that this theory is applicable to all congenital malformations of the iris. In K. Hook's case the aniridia was bilateral.² W. Goldzieher³ found glaucoma and ectopia lentis associated with bilateral congenital absence of the iris in a 14-year-old girl, and congenital eversion of the posterior pigment-surface of the iris (ectropium uvæ congenitum) is recorded by G. Spiro.⁴

Functional Diseases.—A strong, healthy young lady whose hair, previously dark, turned gray when she was 18 years old, was observed by J. C. Clemensha⁵ to have irides that varied in color, ranging from black to bluish-gray through the various shades of brown, brownish-yellow, and yellowish-green. Mental emotion seemed to be a factor in the causation of the changes. A case of voluntary dilatation of the pupil in a woman is held by Bechterew⁶ to be due to the existence of an established relation between the upper psychical center (center for voluntary impulse) and the center which innervates the dilator muscle of the pupil. Two facts argue for this hypothesis: 1. At the same moment when the pupil became dilated the patient felt a sensation of protrusion of the eyeball; 2. When the pupil became dilated it remained in this condition for some time, and the dilatation did not disappear until after repeated closure of the lids. The faculty of voluntary dilatation had been acquired 5 years before Bechterew saw the patient.

Paralyses of the Iris.—F. W. Marlowe⁷ holds a hemorrhage into the 3d nerve-centers responsible for incomplete sudden paralysis of both 3d nerves observed in a young man. Complete recovery ensued without treatment. T. K. Monro⁸ asserts that the Argyll-Robertson pupil has for its cause a lesion of the center in the 4th ventricle, is not due to a degeneration of the spinal center in the lower cervical region, and therefore ought to be grouped with the other varieties of ophthalmoplegia. Speaking of unilateral iris-paralysis occurring in connection with an affection of the sympathetic in a 37-year-old syphilitic, W. H. Wilder⁹ says: "this condition is supposed to depend on a nuclear lesion, but here we have the rare example of a one-sided reflex iridoplegia with involvement of the sympathetic. I am, therefore, strongly inclined to locate the lesion in or about the ciliary or ophthalmic ganglion which lies in the orbit about $\frac{3}{4}$ of an inch behind the globe." [This is in accord with the theory of Mendel (see *Year-Book*, 1897).] Recurrent oculomotor paralysis with anesthesia of any or all of the branches of the 5th nerve is attributed by W. H. Haynes¹⁰ to a vascular change, excitation, or edema affecting the root of the 3d nerve and spreading to the 5th.

Myotics.—H. Snellen, Jr.,¹¹ pronounces pilocarpin the best myotic known

because of the permanence of its solution and the absence of conjunctival irritation and other complications or general disturbances following its use.

Iritis.—Iritis giving rise to deposits on the posterior surface of the cornea in the manner described by Friedenwald (see *Year-Book*, 1897) is alluded to by J. Dunn.¹ Two full histories of **gonorrhœal iritis** occurring in young men are given by R. del Castillo.² While anointing the upper lid with the milky juice of a plant belonging to the euphorbia family, for the removal of warts from the eyelid, some of the juice got into the eye, and when R. Hilbert³ saw the case there was violent iritis with hypopyon, which, however, yielded quickly to treatment. W. Cheatham⁴ is persuaded that **serous iritis** never exists without coincident cyclitis and choroiditis, and sometimes hyalitis, and he therefore argues for the use of Noyes' term, "serous uveitis," as a better description of the true pathologic condition. Gertrude Walker⁵ well says that painless iritis, easily mistaken for less serious diseases, and readily diagnosed by the instillation of a mydriatic, is an insidious and dangerous affection, because not brought to the notice of the oculist until late in the disease, when synechiæ have formed. Under the title "uveitis iridis," Grandelement⁶ describes an inflammation of the posterior wall of the iris which he claims is a continuation of the ciliary part of the retina. It is distinct from iritis, is essentially chronic, and attacks women, occurring preeminently during menstruation and recurring during the menstrual periods for many years. It is not caused by syphilis, rheumatism, or gout, and, although of unknown origin, is favorably affected by iridectomy.

A nice point in the pathogeny of **rheumatic iritis** comes out in the report of the Calcutta Ophthalmic Hospital⁷ of the work done from 1890 to 1895. Of the 670 cases of iritis seen, but one was rheumatic in nature, which fact Col. Sanders (the reporter) ascribes to the almost exclusively vegetable diet of the East Indians.⁸

Tuberculosis.—Tubercle of the iris was studied by E. Ammann⁹ in a 3-year-old boy and also in a 50-year-old man. In both cases enucleation became necessary.

Gumma of the Iris and Ciliary Body.—True gumma of the ciliary body that finally yielded to specific treatment was seen by H. C. Hight¹⁰ in a 31-year-old Malay, 2½ years after the primary infection. He says that, in addition to the signs of syphilitic iritis, there was bulging forward of the iris adjacent to the tumor, producing different depths in the anterior chamber, gummatus growths in the iris, circumscribed discoloration and distention of the sclera (ciliary staphyloma), and almost total loss of vision from exudation into the vitreous and the pupillary area. [This is described as a rare disease by the author. It is, we believe, very common, but escapes notice because attention is usually confined to the iris, which by its great similarity to the tissue of the ciliary body is seldom affected without coincident involvement of the ciliary body.]

Uveal Cysts.—M. W. Zimmermann¹¹ advised iridectomy for 2 brownish tumors protruding from behind the outer lower quadrant of both irides. Operative interference was declined, and now these melanotic tumors, probably benign, are very little larger than they were 4 years ago. Zimmermann ven-

tures the opinion that these are uveal cysts, not secondary to malignant neoplasms, and perhaps arising from the anterior border of the ciliary body. A. L. Whitehead¹ has also seen an instance of cyst of the iris, the result of the introduction into the anterior chamber of a 29-year-old man of a particle of corneal tissue during the performance of an iridectomy for rheumatic iritis 2 years before.

Tumors.—J. Hirschberg and A. Birnbacher² claim to have found a carcinoma spongiosum proceeding from the posterior surface of the iris in a 26-year-old man, and in a young woman of about the same age F. H. Edsall³ discovered primary sarcoma of the iris.

AFFECTIONS OF THE CHOROID.

Inflammation.—C. A. Oliver⁴ records the changes in the field, and the daily alterations in the form, of the scotomata in 2 cases of acute double retinochoroiditis following a flash of lightning and a flash from burning lycopodium. Galezowski⁵ protests against the common supposition that such diseases as atrophic choroiditis, interstitial disseminated choroiditis, with either pigmented or white patches, and herpetic choroiditis, are serofulous, and declares that they should be regarded as syphilitic and treated with mercury.

R. S. Randolph⁶ met with metastatic iridochoroiditis ending in panophthalmitis in a 9-months-old infant. Rupture of the globe finally ensued. No rational origin could be made out.

Detachment.—A case of spontaneous detachment of large sections of the choroid, the space intervening between the sclera and choroid filled with greenish exudation that was partly purulent, but without special microbes, and probably originating from a small malignant tumor of the ciliary body, is recorded by Dor.⁷ Contrary to the experience of previous writers, Dor's patient had severe pain and increased intraocular tension.

Sarcoma.—J. Hirschberg⁸ speaks of sarcoma of the choroid with retinal detachment, in which he punctured the globe far back with a cataract-knife, and the next day the outlines of the tumor were plainly visible. Enucleation became necessary later. Neese⁹ does not agree with Fuchs that carcinomatous sarcoma or mixed sarcoma of the choroid occurs twice as frequently in the posterior half as in the anterior half of the eyeball, contending that an analysis of the literature shows the liability to invasion of either half is about the same.

SYMPATHETIC OPHTHALMIA.

Under the title of "A New Form of Sympathetic Ophthalmia," Nuel¹⁰ describes what are only the manifestations of a tardy sympathetic ophthalmia leading to secondary optic atrophy. Donaldson¹¹ enucleated the right eye of a young woman for cyclitis following traumatic rupture of the sclerotic. Four weeks later there developed sympathetic inflammation in the left eye, relapsing with more or less irregularity for 5 years. At the end of this time the eye became injected and painful during an attack of acute catarrhal conjunctivitis, and eventually vision was almost entirely lost. K. Hoor¹² relates an

instance in which a bit of copper entered the ciliary region of one eye, and was finally discharged from a small abscess 3 months later, when the sympathetic signs in the other eye immediately disappeared. In 2 cases of sympathetic ophthalmia L. Dor¹ saw great improvement in the condition of the remaining eye a long time after enucleation of the primarily diseased one, brought about by the instillation of the extract of the ciliary body of an ox into the conjunctival sac every 2 hours. In one case withdrawal of the treatment caused immediate return of the inflammation. This case had been previously treated by all the usual remedies without success. In the management of this disorder A. Trousseau² does not approve of the application of the galvanocautery to an inflamed eye that is causing sympathetic inflammation.

GLAUCOMA.

Classification.—L. Connor³ believes that the foundation of glaucoma is a constitutional dyscrasia which should be sought out in every case and removed as far as possible. S. O. Richey⁴ reaffirms his position of two years ago (see *Year-Book* for 1896) that glaucoma is nothing more than a chronic interstitial ophthalmitis or gout of the eye. He believes⁵ more in the causative possibilities of the vortex veins in glaucoma than in a vicious anterior filtration angle. Schoen⁶ asserts that it is caused by accommodative strain, and that it can be prevented by early correction of errors of refraction. Of 140 cases 48% were hyperopic and 33% astigmatic, and none of these patients possessed a lens correcting the refraction for distance. Schoen does not speak of glaucoma in myopia, but R. Randolph⁷ had a case in a high myope 61 years old that presented typical attacks daily, with complete subsidence of the symptoms in the intervals. Sulzer⁸ draws the following conclusions from his researches: 1. Glaucoma may be divided into 3 classes—the circulatory, vascular, and nervous; 2. They have in common vascular degeneration, primary in the second class, secondary in the first, and tertiary when it depends on a disturbance of arterial circulation produced in the first class by an inequality between the intraocular and arterial tension, and in the third by direct nervous influence; 3. The degenerative and nervous circulatory troubles are mutually interdependent and reinforce each other; 4. Circulatory disturbances play the principal role in all glaucomas; 5. The excavation of the optic disk is not a mechanical effect of plus tension, but is dependent upon degeneration of peripheral fibers of the retina and nerve and loss of nutrition from insufficient circulation.

Malignant glaucoma is defined by H. Friedenwald⁹ as an intense acute increase of tension of an eye on which iridectomy for simple glaucoma has been recently performed and the anterior chamber has failed to become reestablished. It is followed in nearly all cases by incurable blindness. He considers that it arises from structural alterations in the lymph-vessels of the posterior portion of the eye rather than dislocation forward of the edge of the lens into the angle of the anterior chamber, or to irritation of the ciliary body, or to sudden exudation after iridectomy from the choroidal veins into the vitreous, altering the character of the latter. Recovery followed in one case after the hourly exhibition of strong solutions of eserine, and in another from internal

administration of sodium salicylate. Where malignant glaucoma has developed after iridectomy in one eye, that operation should not be employed as a means of cure of glaucoma in the second.

Valois¹ warns against accepting the **diagnosis** of glaucoma in cases that seem to have all the symptoms, including cupping of the nerve-head, without careful examination to determine whether other causes are not acting, and whether the excavation is a true cupping, the vessels bent on the edge, and their continuity lost, or a shallow depression that may be only physiologic. He calls such cases "pseudoglaucoma." Randall² emphasizes the importance of testing for knee-jerk and other reflexes, and of carefully measuring the field for white and colors in the differential diagnosis between simple glaucoma and atrophy of the optic nerve. Reisse³ diagnosed by exclusion an absolute glaucoma occurring in an eye injured 18 years previously by a blow from a ball.

Treatment.—In the irritative or prodromic stage myotics may ward off active disease for 4 or 5 years. Rochon-Duvignaud⁴ and Trousseau⁵ find no benefit from iridectomy in simple glaucoma, and Hausell⁶ opposes iridectomy because it may precipitate an acute attack and produce astigmatism of the cornea and irregular refraction through the enlarged pupil, perhaps malignant glaucoma following nonclosure of the wound (see above), and finally because eserine will retard for some years the progress of the disease. Chavellereau⁷ relies upon medical treatment alone. After total loss of vision, including light-perception, had existed for 3 weeks after an acute onset of glaucoma, Taylor⁸ iridectomized and restored useful vision. The curative action of iridectomy is believed by Abadie⁹ to be due to the section of vasodilator veins which course circularly in the diaphragm of the iris and which incision interrupts. Chavellereau¹⁰ speaks highly of De Vincenti's operation of incision of the tissue of the iris in the angle of the anterior chamber. Pflüger¹¹ proposes to excise the iris, leaving the pupillary border intact, thus permitting contraction of the pupil to myotics, which may subsequently be employed. Connor¹² advises that such attention should be given to the bowels, skin, and kidneys as will secure the most prompt elimination of effete tissue. The diet should be regulated to such articles and in such quantities as can be perfectly digested. The liberal use of water internally and externally greatly assists in restoring the fluids of the body to a state of reasonable purity. To all this S. O. Richey¹³ agrees, and suggests therapeutically a mixture of sodium salicylate, ammonia, and taraxacum, taxis, and weak eserine solution. He says that cases under his observation for 10 years with persistent halo-symptom, increasing refraction, and progressive excavation of the disk, have shown but little, if any, loss of vision and no persistent contraction of the field.

Glaucoma with Ocular Tumors.—A. S. Martin's comments¹⁴ on C. D. Marshall's paper on "Tension in Intraocular Tumors"¹⁵ are important. He says: "There is nearly a constant relation between closure of the angle of the anterior chamber and increased tension; many eyes with normal tension have been known to contain tumors. Tension is more often raised in the presence of a choroidal than a ciliary tumor. The plus tension is due to the glaucoma and only secondarily to the tumor." For the differentiation of primary and secondary glaucoma he offers the following working rule: "When

an eye has gradually become blind, and develops an attack of acute glaucoma without involving the second eye, a tumor is probably present in the affected eye; if, however, the eye has lost its sight, and glaucomatous signs appear in the fellow eye, tumor will hardly be found in the offending eye.³

The subject of glaucoma is thoroughly reviewed by A. W. Stirling¹ in a series of articles.

AFFECTIONS OF THE RETINA.

Congenital Anomalies.—We note records of the following anatomic curiosities: coloboma of the retina without fissure of the choroid, by Fr. Hoesch²—the 19th published case; unusual tortuosities of the retinal arteries, by S. E. Cook;³ angioid striae in the fundus, by J. Dunn;⁴ medullated nerve-fibers continued far out onto the retina along some of the vessels, associated with posterior polar cataract and fine vitreous opacities, by de Schweinitz;⁵ anomalous oval bodies in the retina, by Tiffany.⁶ [These were probably choroidal and not retinal. Such opaque ganglionic cells in the vesicular layer would certainly interfere with the acuity of vision, which in this case was normal. Congenital anomalies are for clinicians merely curiosities. Few opportunities present themselves for examination after death from which the study of embryology and the origin of disease might be enriched.]

The restoration of vision to an eye that had been blind as the result of traumatism, iritis, and cataract for 17 years, by D. Webster,⁷ is another instance of the **retention of function of the retina** after having been for a long time in abeyance.

Glioma.—S. E. Cook⁸ says that if the tumor be not too far advanced and is still intraocular, and the vessels be not too numerous, the living cells are arranged in a cylinder or zone around each vessel. A proper regard for the embryonic origin of the tissues from which it springs and the character it assumes would, he thinks, place this tumor in closer relationship with the carcinomata than with the sarcomata.

E. Wintersteiner⁹ has found glioma to be binocular in 24% of all cases reported, and he states plainly that the seed of the trouble is sown in utero, no matter how late in life it may make its appearance, and that it is curable in its earliest stages. Nieden¹⁰ used cancer-serum unsuccessfully on a child. Six weeks later he injected a 2% formol solution, which caused sloughing of the parts and seemed to limit the progress of the tumor. He thinks that the formol treatment may prolong the life of such patients. Grand,¹¹ on the contrary, thinks that the contraction in size and improvement in appearance claimed by Nieden are to be attributed to the lowered vitality of the patient, since death followed in some of the patients 2 months after use of formol.

Embolism.—Nuel¹² is convinced from anatomic investigation that the cherry spot seen in the macula in embolism of the central artery is due to engorgement of the macular arteries. All other vessels in his case, excepting those around the papilla which anastomose with the vessels of the nerve-entrance, were atrophic. C. F. Clark¹³ considers from a review of the litera-

ture and a study of his own cases that the time-honored theory that in "embolism of the central artery" a so-called "cilioretinal" vessel serves to preserve the integrity of the papillomacular area," is not proved; but Wadsworth¹ reports his second case, in which central vision was preserved and the foveal region nourished by large cilioretinal vessels (Fig. 62). Embolism of a

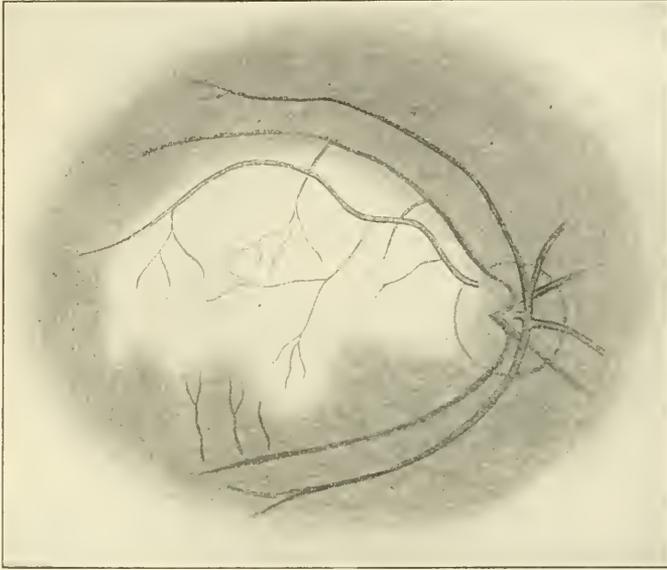

FIG. 62.—Embolism of central artery; macula supplied by a cilioretinal artery. Retention of central vision (Boston M. and S. Jour., Dec. 24, 1896).

branch of the central artery occurring 8 weeks after a normal childbirth in a perfectly sound woman is fully described by O. Stuelp.²

Thrombosis.—T. A. Woodruff³ encountered a thrombosis of the central retinal vein with tremendous choked disk. The patient was 48 years old, and presented no especial lesion that could be held to account for the condition. A full histologic description of the pathologic changes is recorded by S. Tuerk⁴ as seen in a 67-year-old tavern-keeper, the subject of emphysema.

Hemorrhage.—De Schweinitz⁵ describes an unusual form of macular change after iritis, consisting in an oval reddish area at the macula, giving the impression of a disintegrating hemorrhage and containing in its center 2 white dots. This spot was surrounded by a greenish ring somewhat raised, so that the reddish ring portion appeared as if at the bottom of a small pit, the sides of which were composed of the greenish border described. The macular reflex was unusually distinct and the nerve-head and the retinal vessels were normal. In explanation of the greenish ring he thought it was likely that in such instances of macular lesion, in addition to the change visible to the ophthalmoscope in the center, there must occur some thickening of the extra layer of ganglionic elements in the circummacular region. As a symptom of vascular degeneration in a 60-year-old woman, the subject of aortic stenosis and asthma, F. Pincus observed hemorrhages between the

⁵ Phila. Polyclinic, July 18, 1896.

vitreous and retina produced by a coughing-fit.¹ Postmortem examination of a case of retinal hemorrhage by J. H. Fisher² showed that the blood was effused between the hyaloid membrane of the vitreous and the internal limiting membrane of the retina, and was contained between these membranes. It had not perforated the latter, nor was it found in the true retinal tissue. R. Simon³ reports another instance of retinal hemorrhage secondary to retinal vascular changes similar to the cases mentioned by Friedenwald (see *Year-Book* for 1897, p. 926). C. A. Oliver⁴ observed rupture of the inferior retinal vein in the eye of a young man who was struck in that eye by a flying missile, not otherwise compromising the structure of the globe.

Central Retinitis.—C. S. Bull⁵ calls attention to the patches of yellowish exudation in the retina near its center and inflammation of the optic nerves consecutive to angiosclerosis of the walls of the vessels, dependent upon gouty conditions of the blood. Marked impairment of vision from excessive use of the eyes in close and very fine work, followed by perfect recovery, is reported by S. M. Theobald.⁶ The defect consisted of an exudative central retinitis with corresponding scotoma for white.

Commotio retinae with retinal edema, as the result of contrecoup, was seen by M. Linde⁷ in 17 cases.

Retinitis Pigmentosa.—A 30-year-old woman applied to W. Goldzieher⁸ for failing vision, which he found to be due to glaucoma complicating retinitis pigmentosa. Though the patient's parents were not blood-relations, 6 of her 8 brothers and sisters were the victims of nyctalopia that had incapacitated 3 of them for work. Gould⁹ reports 2 cases, a brother and sister, whose only subjective symptoms of retinitis pigmentosa were a partial night-blindness, shown by stumbling, etc. The fields showed considerable limitation for white and colors, and in 1 case extreme irregularity with limitation. There was not a particle of abnormal pigmentation, except at the extreme periphery a minute brown stippling. The patients' paternal grandfather was night-blind all his life, and became wholly blind at 70, but his eyes were never examined by an oculist. In a review of the literature there are found only 5 cases that may be relied on as similar to Gould's cases. In the French reports no fields are given, and records of the refraction and other details are omitted. For the closer study of this subject Gould suggests interrogation of every office-patient as to his vision after dark, and as to whether they bow their heads at night (to see the floor or ground in darkness); that careful account be taken of the form- and color-fields and of the refraction. The important facts to determine are: (a) Is the disease progressive? (b) If so, is it the incipient stage of what later becomes typical retinitis pigmentosa? (c) What is the pathology of the abnormal color-fields? and What is the etiology of the disease?

A decidedly unique pigment-anomaly of the retina, occurring in both eyes and supposed to be congenital, was studied and is pictured by H. Pretori.¹⁰ (See Plate 10, Fig. 1.) The patient was a glassblower 52 years old, with normal vision in right eye and $\frac{1}{10}$ of normal in left eye. The changes were practically identical in both eye-grounds.

“**Hemeralopia.**”—Krienes¹¹ ascribes this symptom to a disturbance or

destruction of the relation between waste and repair of the visual substance. He claims that it is not a functional disease, for it always originates in some form of chorioretinitis. [The term hemeralopia, from the doubtfulness of its meaning, should not be used.] Wilbrand¹ concludes that in the neurotic eye there is relatively slower restoration of the visual purple after light-stimulation than that which occurs in the normal eye. While fundus-changes in hemeralopia are sometimes not visible with the ophthalmoscope, there must be some lesion in the nerve, retina, or choroid following chorioretinitis syphilitica, choroiditis disseminata, or retinitis pigmentosa. The association of night-blindness with xerosis of the conjunctiva and cornea was noted by C. Kollock² in negro children of tuberculous, scrofulous, or syphilitic diathesis living on the South Carolina coast. The ocular media, other than the cornea, are clear, and the nerve-head is slightly swollen and of a dirty white color.

Retinitis proliferans was the final outcome of two instances of laceration of the optic nerve and central blood-vessels recorded by C. Zimmerman.³

Albuminuric Retinitis.—J. Hinshelwood⁴ contributes a notable exception to the ordinary gloomy prognosis of albuminuric retinitis in the case of a 62-year-old woman, who was alive and in good health 3 years after an attack that had reduced her vision to $\frac{1}{60}$ in each eye.

Detachment.—As causes H. O. Reik⁵ mentions granular kidney, albuminuria of pregnancy, diabetic retinitis, tumors, and pregnancy, in addition to the most frequent factor—namely, high myopia. Nuel⁶ adds disease of the macula and exudation into the posterior layers of the retina of albuminous material, as in albuminuric retinitis; disease of the walls of the retinal vessels, which leads to changes in their level and length; retraction of the vitreous and alterations in the rods and cones, producing a relaxation of their adherence to the choroid.

R. L. Randolph⁷ found the microscopic changes in the vitreous body of eyes exhibiting detached retina to consist in fibrillary alterations in the vitreous, sustaining the position of Nordenson and Nuel. I. Casper's 4 cases of striae in the fundus showed the course of development so plainly that he does not hesitate to assert that all retinal striations represent the residue of cured detachments.⁸

B. L. Millikin⁹ comments on the finding of progressive retinal detachment in 3 brothers, none of whom had suffered from any marked constitutional disorders. They were of a large family, characterized in an unusual degree by long life and general good health.

Detachment of the superior temporal vein, occurring as the terminal stage of a previous hemorrhage, is fully detailed by J. Dunn.¹⁰

Indications of Choroidal Disease.—Elschnig's¹¹ theory that idiopathic detachment is primarily caused by localized retinochoroidal disease received confirmation from two cases studied by T. Collins. A circumscribed, extending detachment is one of the earliest symptoms, and may be for a long time the only one, of choroidal tumor, according to Rockliffe.¹²

Treatment of Detachment.—Electrolysis, according to the method of Terson (see *Year-Book*, 1897), was employed by Montgomery¹³ in 4 cases un-

successfully. In one of them it undoubtedly caused glaucoma. It is painful, valueless as a curative agent, and may excite glaucoma. Chavellereau,¹ Fromaget, and Lagrange² have rejected it because, they say, it increases the area of separation. Eye³ evacuated the fluid by means of a cannula, through which he introduced a small bundle of horsehairs. This was removed in a few days on account of conjunctival inflammation. After recovery the field was normal. [We think Eye's surprise was as great as it was agreeable.]

C. A. Wood⁴ sums up the whole subject when he says "that we have as yet discovered no better device than that reported by some of the older ophthalmologists with occasional success—namely, rest in bed, bandages, atropin, and the internal use of some absorbent." He reminds the profession that spontaneous cure often occurs, in which case the measures employed are wrongly given the credit.

DISEASES OF THE OPTIC NERVE.

Anatomy.—Partial crossing of the optic nerves at the chiasm is now reaffirmed by Gruetzner.⁵ This theory was temporarily abandoned when Kölliker, as a result of the study of microscopic sections, reported at the Anatomic Congress in Berlin that the nerves crossed entirely. [There is little reason to believe that Kölliker's position can be maintained.] E. Berger⁶ proposes a division of the fibers of the distal portion of the optic nerve into 3 groups—namely, central, supplying the anterior retina; intermediate, supplying the equatorial region; and peripheric or subpial, supplying the peripapillary zone. Lesions of the central group are characterized by peripheral contractions of the visual field, lesions of the intermediate group produce a zone of amblyopia around the blind-spot, and lesions of the peripheral group increase the size of the blind-spot.

Functional Diseases of the Nerve.—As the result of an application of a 5% solution of cocain to the posterior nares, J. H. Shastid⁷ witnessed complete amblyopia lasting 4 days. Beauvais⁸ speaks of a patient who, after watching vivid lightning, claimed to be blind. The man directed his gaze downward and held the lids closed, the exact reverse of the usual position of the sightless globes of an amblyopic. The pupils reacted normally and the fundi were healthy, showing plainly that the blindness was simulated.

Perimetry.—Willetts⁹ continues to insist that our present method of perimetry is faulty, inasmuch as it fails to take account of the fact that the retina is histologically the same throughout its whole expanse. He offers as the practical corollary of this fact his own demonstration that the true visual field is round, extending 70° in all directions from the fixation-point, and contends that any method that shows the usual nasal limitation of the normal field of vision for form or color is wrong, for no such contraction exists. [This is an advanced position which will require abundant anatomic and clinical evidence to render it tenable.] H. Wilbrand¹⁰ emphasizes the point that perimetry can only be of diagnostic value when considered in connection with the central visual acuity and the fundus conditions. [The real clinical worth of perimetry, as set forth in the publication mentioned, can be

unhesitatingly pronounced the most comprehensive and authoritative work on this subject that has appeared in the English language.] Wilbrand¹ shows elsewhere that the absolute extent of the visual field can be determined only by the smallest and least luminous object which can be perceived by the most peripheral cones of the retina. To meet this proposition he has devised what he calls his "Dunkel-perimeter," of the usual hemispheric form, to be used in a thoroughly darkened room, in connection with pin-head-sized test-objects made of phosphorescent material. The normal retina will recover itself in the dark room, and show a normal field a few minutes after entering the room, and each half-hour in excess of this time will be the measure of the pathologic condition. He claims for the method an exactness not obtainable by ordinary perimetry.

Hemianopsia.—In the case of binasal hemianopsia reported by C. A. Veasey,² there were associated nausea and vomiting, tremor, numbness, and heaviness of the left leg, vertigo terminating in coma, which after 20 hours ushered in death. Coggin's 7 cases of homonymous hemianopsia,³ loosely and inaccurately described and without report of autopsies, are of no particular interest. W. A. Holden⁴ says that hemiachromatopsia, accompanied by a hemiopic light-sense disturbance, must be due to an affection of the fibers of the visual path, and not of the ganglion-cells of the cortex.

Optic Neuritis.—G. E. de Schweinitz⁵ reports 5 cases of unilateral optic neuritis assigned severally to rheumatism, syphilis, chlorosis, albuminuria of pregnancy, and degenerative changes in the vessels of the optic nerve, or endo-vasculitis. In the optic neuritis or amblyopia accompanying purulent disease of the sphenoidal cavities Holmes⁶ urges immediate and effective drainage by drilling through the anterior wall, removing if necessary the middle turbinated bone. Partial retention of the placental membranes and menorrhagia following miscarriage were found by Minor⁷ to give rise to acute optic neuritis and considerable loss of vision, a condition of things which was soon righted when the uterine functions had been restored. In specific neuritis P. Webster⁸ found contracted fields and scotoma for red. When optic neuritis coexists with otitis media purulenta Ostman⁹ thinks that the ocular condition is the expression of a meningitis secondary to the otitic process.

"Choked Disk."—The origin of choked disk is still unsettled. In a discussion at the March meeting of the Berlin Neurologic and Psychiatric Society,¹⁰ Jacobson, in reporting a case, committed himself to the mechanico-inflammatory theory, stating that the primary agent was the irritant toxins, the stagnation being a secondary, yet powerful, factor. Bruns,¹¹ attacking the inflammatory theory, observed that the toxins would never find their way down the optic-nerve sheaths to the nerve-head were it not for the increased intracranial pressure; and that even if the cerebral fluid were rich in toxins, it could avail nothing save in the presence of increased intracranial pressure. Jacobson¹² replied that as yet no one has succeeded in producing choked disk experimentally, and that therefore Bruns' position, along with that of Schmidt and Manz (see *Year-Book* for 1897, p. 933), is untenable. E. von Grosz's division of choked disk into inflammatory and edematous¹³ is based on the microscopic examination of the optic nerves of 3 sufferers from brain-tumor, and a consid-

¹² *Ibid.*

¹³ *Neurolog. Centralbl.*, Apr. and May, 1897.

¹⁴ *Centralbl. f. prakt. Augenh.*, May, 1897.

eration of the literature of the subject. To his mind, edematous choked disk is the accompaniment of true brain-tumor, while tubercle and gumma give rise to the inflammatory form, although these differences can be made out only in the early stages of the disorder. Vision will obviously be better with the first form. Unfortunately, we are not yet able to localize the cerebral process by means of any special characteristics on the part of the neuritis. He thinks that, even if the tumor cannot be removed, the effect of trephining is not injurious to the patient, and is markedly beneficial to the optic nerves. Eperon¹ is an adherent of the mechanical hypothesis.

Optic Atrophy.—Treacher Collins² report of permanent scotoma with partial atrophy of the optic nerve, due to 5 minutes' exposure of the retina to direct sunlight, by a young man, clinically illustrates the result arrived at experimentally by Usher and Dean,³ that wounds of the retina in animals can set up nerve-degeneration corresponding to the part of the retina that has been injured. O. J. Short⁴ says that mercurial inunctions in conjunction with hot baths are always beneficial in partial optic atrophy; that unless the origin is specific or from some blood or mineral poison, potassium iodid is oftener harmful than helpful. When vision is $\frac{2}{200}$ or more, benefit may be expected; when it is less we can only hope to arrest the progress of the disease; while in those cases showing light-perception only, treatment is unavailing. Strychnin is serviceable only in spinal atrophies. Rapid acute atrophy associated with tabes dorsalis in a 40-year-old farm laborer was ascribed by W. Reber⁵ to syphilis. M. Benedikt⁶ inveighs against too heroic treatment in the optic-nerve degenerations of tabes [but just why, we cannot imagine]. L. R. Culbertson's suggestion,⁷ that ovariectomy in women and castration in animals are a cause of optic atrophy, cannot be viewed as more than a coincidence in the 2 cases he reports—a woman and a colt. [A deduction from 2 cases when hundreds of such operations are done daily is absurd.] C. W. Kolloek⁸ records permanent improvement in a patient with optic-nerve atrophy from $\frac{2}{200}$ to $\frac{2}{50}$, following systematic inhalations of amyl nitrite, after persistent medication with potassium iodid and strychnin had failed.

Toxic Amblyopia.—Nuel⁹ controverts the accepted idea that the central scotoma of toxic amblyopia is due to interstitial neuritis of the macular fibers of the optic nerve, and finds that the earliest changes take place in the macular cells themselves, and that the atrophy of the macular bundle is secondary and consecutive to the atrophy of the retinal cells from which they arise. C. A. Wood¹⁰ believes that secondary alterations in the nerve in chronic plumbism are the result of fatty metamorphosis consequent upon peri- and endarteritis, and that the ocular lesions are peripheral and distinct from those changes which coincidentally occur as results of renal or cerebral complications arising in the course of long-standing intoxication. Higgins agrees with other writers,¹¹ that tobacco-amblyopia is more common among the poor, because they smoke the cheaper tobaccos, which are richer in nicotin. In Belt's case,¹² alcohol-tobacco amblyopia and multiple neuritis were encountered in the same patient. F. van Fleet¹³ speaks of what may be a true amblyopia potatorum occurring in an artist addicted to rum. The blindness followed a debauch, and despite strychnin carried to $\frac{2}{3}$ gr. hypodermically per day, the amblyopia

became permanent and the nerves thoroughly atrophic. Ellis'¹ patient, a tobacco-, alcohol-, and morphin-slave, was given 120 gr. of quinin in 24 hours for an acute malaria. He became perfectly blind, but in 2 weeks recovered a part of his former vision. Ellis queries whether this was toxic amblyopia, and, if so, was it from the tobacco, alcohol, morphin, or quinin? [It was plainly induced by the quinin in a subject whose optic nerves had long since been prepared for the easy engrafting of such a condition.] Toxic amblyopia following the prolonged internal use of iodoform has been twice seen by J. W. Russell,² who treats his cases of phthisis systematically with iodoform, sometimes working the dose up to 10 gr. 3 times a day. Both of his cases were pronounced upon by Wood White, who said of them, "this amblyopia differs from that of tobacco in that there is no color-scotoma." [This is a strange assertion on the part of White. Priestly Smith³ distinctly states in the history of his case that there was not only central color-scotoma, but that it was absolute at a point below the fixation-point.] A. G. Thomson⁴ ascribes the amblyopia in a case observed by him to drinking large quantities of Jamaica ginger. The ophthalmoscope showed the classic changes of alcohol- and tobacco-amblyopia. In the treatment of toxic amblyopia de Wecker⁵ advocates the injection of artificial serum, 60 to 100 gm. (Cheron's serum). Parinaud, Darier, and others,⁶ consider the method inferior to milk-diet, purgatives, and pilocarpin.

Cyst of the Optic Nerve.—S. D. Risley⁷ furnishes a beautiful drawing of a cyst of the optic nerve accompanying bilateral chorioretinitis, which he observed in a 38-year-old Polish woman (see Plate 10, Fig. 2).

INJURIES TO THE GLOBE.

The first two recorded instances of the **diagnosis of the presence of pieces of metal in the eyeball by means of the Röntgen process** were that of C. F. Clark and that of C. H. Williams.⁸ Both were eminently successful. Since then G. O. Ring,⁹ H. F. Hansell,¹⁰ and G. E. de Schweinitz¹¹ have published details of cases confirmatory of the value of this means of diagnosis. Experiments and the practical application of the methods found most useful in determining the location of the foreign body have been successfully made by Lewkowitch,¹² who claims that his calculations, based on double images, have never been more than 1 mm. wrong; by Sweet,¹³ who has had equally successful results by the use of an especially devised apparatus (see Figs. 63, 64), and by Oliver and Leonard.¹⁴ J. Hirschberg¹⁵ holds that skiagraphy can be of no use in assisting the determination of the location and the extraction of bits of copper that have entered the eye. [Copper cannot be extracted by the magnet, but can be diagnosed and located by the x-rays.] He related 2 histories of copper-injuries to the eye, both successfully operated.

Ardoin¹⁶ substantiates Leber's observations on the extreme danger to the eye and the susceptibility to sympathetic inflammation from wounds made by copper, and advises immediate removal if possible, and, when impracticable,

the enucleation of the ball. Another instrument, less practical than the Röntgen apparatus, is the "sideroscope," invented by Asmus. It consists essentially of two magnetic needles so suspended in appropriate tubes that their slightest turnings can be observed and registered. A. Barkan¹ used it in connection with either Haab's or Hirschberg's magnets with success.

Instances of **extraction of pieces of steel and iron** from the vitreous, with preservation of the globe, and in some cases of the sight, are recorded

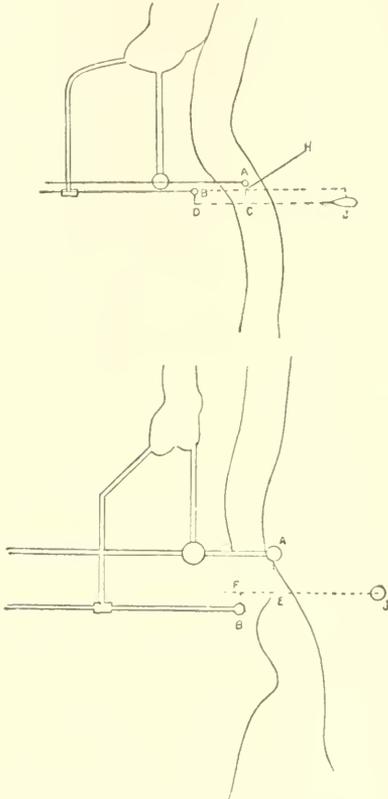

FIG. 63.—Outlines of negative taken by Sweet's method.

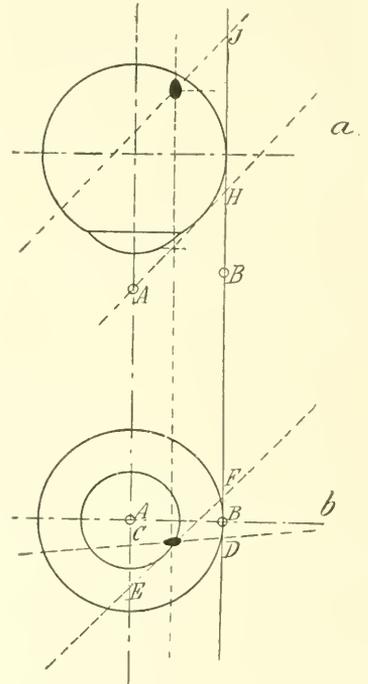

FIG. 64.—Sweet's projection-lines for locating foreign bodies in the eye: *a*, transverse section; *b*, vertical section.

by F. Buller² [6 cases, 1 unsuccessful], H. F. Hansell,³ J. E. Weeks,⁴ who used Haab's magnet, and G. O. Ring,⁵ and in some of the cases in which the *x*-rays were used, mentioned above.

Traumatism.—Buckner⁶ reports a case of rupture of the choroid from traumatism to the forehead, and de Wecker⁷ mentions instances of emptying the orbit, paralysis of an external rectus, ptosis and keratitis, in each instance produced by compression on the parts of the mother or by the forceps in instrumental delivery. He calls attention to the fact that the eyes of the

infant in the process of birth are exposed to other dangers than infection. Penetration of all the tunics of the eyeball by a piece of window-glass is reported by Marie Haydon.¹ The conjunctiva was drawn over the wound and sutured; recovery was uninterrupted. C. A. Oliver² does not recommend suturing the edges of the rupture in the sclera made by the escape of the lens when dislocated by traumatism, or of the cut in the conjunctiva through which the lens has been removed.

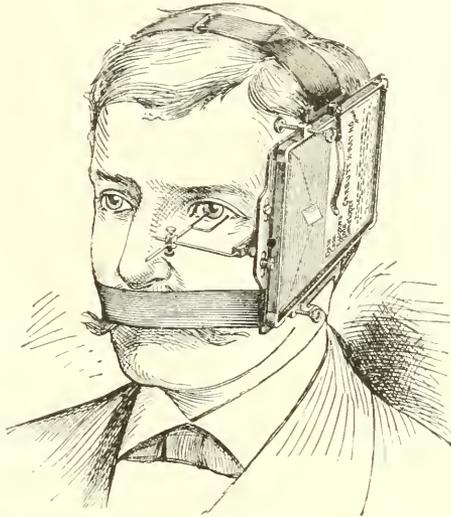

Fig. 65.—W. M. Sweet's x-ray apparatus for locating foreign bodies in the eye, applied.

Meningitis after Operation.—G. E. de Schweinitz³ prefers evisceration to enucleation when acute panophthalmitis is present, feeling that the chances of secondary infectious meningitis are thus lessened. Lapersonne⁴ enucleated an eye on account of an injury received. Ten days later fatal meningitis developed. Pneumococci were abundant in the pus found at the base of the brain. The most active antiseptic, he says, is hypochlorite of calcium purified in sterile water.

DISEASES OF THE ORBIT.

Functional Diseases.—J. Terson⁵ affirms the existence of an orbital affection of spontaneous or traumatic origin, which is characterized by alternation of the two opposite conditions, enophthalmos and exophthalmos, the former succeeding transient attacks of the latter until the exophthalmos becomes permanent. The exophthalmos originates in voluntary and involuntary efforts, and in compression of the jugular veins. The connective tissue and fat of the orbit are absorbed, the veins become dilated and varicose from atrophy of their muscular fibers, and there is atrophy of the muscular fibers of Müller. The disease is a trophic neurosis depending on lesions of the sympathetic nervous system. Treatment consists in electrization, tonics, and the local application of hamamelis virginica. This disease should not be confounded with the stabile exophthalmos due to orbital tumors or goiter.

¹ Phila. Polyclinic, Oct. 24, 1896.

³ Phila. Polyclinic, Sept. 6, 1896.

² Ophth. Rev., June, 1897.

⁴ Rec. d'Ophthal., June, 1897.

⁵ De l'Enophthalmie et de l'Exophthalmie Alterans, 1897.

A. B. Kibbe's¹ case of pulsating exophthalmos, exhibiting an unusually complete picture of cavernous sinus thrombosis, belongs to that rare class of cases (*e. g.*, Churchman's, *Year-Book*, 1897, p. 912) in which all the symptoms are dissipated by ligation of the common carotid.

Periostitis.—W. Reber² refers to an instance of bilateral tertiary orbital periostitis and cellulitis encountered in a married woman aged 41. Despite the most active treatment from the start, one optic nerve atrophied completely as the result of long-continued stretching attending the accompanying exophthalmos, while the other nerve escaped injury.

Pseudoplasmes.—S. Snell³ counsels caution in approaching surgically certain apparently organic tumors of the orbit. His 3 case-histories, showing disappearance of the tumor in each case under potassium iodid, teach plainly that medical treatment should be resorted to before operation. Snell concurs with Panas in believing that there is a class of orbital tumors amenable to drugs, and that they are neither specific nor malignant. [These tumors would likely fall into the class "pseudoplasmes" proposed by Panas (*see Year-Book for 1897, p. 911*).] Ayres⁴ met with an orbital condition in a 7-year-old boy that might also be styled a "pseudoplasm" because of its indeterminate character. The exophthalmos became so great as finally to usher in death from conjunctival hemorrhage [a rare occurrence]. The patient was the subject of leukocytosis, or "chloroma," as Ayres prefers to style it.

Tumors.—An orbital tumor, ill defined in character, affecting a 2-year-old child, was removed because of threatened destruction of the left eye. Fifteen months later, when the growth had recurred, the patient's parents refused F. H. Knagge⁵ permission to operate again, and the child died soon afterward. C. S. Bull⁶ concludes, from a study of 36 cases, that the prognosis of malignant tumors of the orbit is highly unfavorable; that surgical interference is almost invariably followed by a return of the tumor; and that repeated operations shorten the life of the patient, in which opinion he is joined by R. Sattle,⁷ who feels that in such cases surgery ought only to be exploratory. The same author says elsewhere⁸ that epithelioma of the soft tissues of the orbit is more amenable to surgery than the other forms of malign neoplasms. Of 3 cases detailed, one was alive 2 years and another 5 years after operation. The third one died a week after removal of the tumor. The ocular disturbances observed in epithelioma of the sphenoidal sinus by Morax⁹ were continuous headache, progressive failure of vision, with sudden blindness later, although there was no lesion of either fundus; finally, optic atrophy, oculomotor palsy, exophthalmos, and death from intercurrent bronchopneumonia. H. Knapp¹⁰ removed a congenital cavernous angioma, 27 by 24 mm., from an orbit, restoring the displaced eye to the normal position and to the full exercise of its functions.

Hydatid Cyst.—Two cases of hydatid cyst of the orbit have been reported during the year, one by P. Varese,¹¹ who saw the condition in a 15-year-old girl, in whom the disease induced optic neuritis, and the other by L. von Iseckutz,¹² who successfully removed the parasite.

OPERATIONS.

P. Fridenberg¹ employs 2 radiographs in **locating foreign bodies with the x-rays.** He cuts a plate so that it will fit into the anterior orbital margin, protects the cornea with cotton, and bandages the plate against the eye. The Crookes tube is held 14 in. back of the head, and the rays are passed through the opposite temple. In this way he located 5 bird-shot that had gone entirely through an eye and lodged in the orbit. [Fridenberg's method is practically that employed by Dahlefeld and Pohrt² and in the laboratories of Philadelphia.]

Asepsis and Antisepsis.—Absolute alcohol, while a valuable disinfectant for instruments infected under the conditions which ordinarily surround us in everyday life, has been proved by R. Randolph³ to be unreliable for the sterilization of instruments infected with a pure culture of septic micrococci. His contention is supported by an extensive array of bacteriologic experiments. A sterile conjunctival sac will most likely be secured by combining asepsis and antisepsis, and E. Franke,⁴ therefore, cleanses the sac thoroughly by simple irrigation, and then instils the antiseptic, preferably sublimate in 1:5000 to 1:10,000 solution. In this way, although all the bacteria may not be destroyed, they will at least be rendered inert. Bach⁵ considers that asepsis is all that is necessary in ophthalmic surgery. Antiseptic treatment not only does not destroy all the germs, but it also irritates the conjunctiva, inducing a catarrhal condition highly unfavorable to operations. The open-wound treatment of all operations on the eye is lauded by J. Hjort,⁶ who supports his contention with statistics covering 112 operations, including 52 cataracts and numerous iridectomies, dissections, and sclerotomies. His preparation of the eye is essentially aseptic, while the after-treatment practically resolves itself into the use of cold compresses and the injunction of quiet. Viewing the cilia as the most likely source of infection, he frequently epilates both lid-margins before operation. He does not hesitate to apply the open method to cataract-extraction in the presence of dacryocystitis. His series of 112 cases treated after this method does not include one failure.

For Epithelioma.—F. T. Smith⁷ tells of a case in which he proposed to remove the inner half of an upper lid for epithelioma. While preparing for operation the patient fell into the hands of an empiric, who cauterized the growth thoroughly, and, to Smith's surprise, there was perfect healing. [By means of glacial acetic acid we have succeeded in removing repeatedly just such growths, but they have invariably recurred, until there was no remedy other than the knife.]

For Ectropion.—Terson⁸ excises redundant conjunctiva and sutures the edges; he then removes a triangular piece of skin and the underlying orbicularis muscle from the neighborhood of the external canthus. He has operated 4 times, with excellent result.

Pterygium.—Boeckman⁹ dissects the apex from the cornea and the body from the underlying connective tissue, cleaning up the sclera from all connective tissue to which the pterygium had been attached and replacing the pterygium in the space thus cleared. It adheres to the sclera and remains fixed for all time.

Iridectomy.—Lawford¹⁰ prefers Schöler's method of performing iridot-

omy—so-called extraocular—to iridectomy for artificial pupil made for optical purposes. A small incision is made through the cornea near, but not at, the limbus; the iris is carefully withdrawn and divided perpendicular to its pupillary margin. He claims that this method avoids the disturbing refraction of the lens-periphery. Prolapse of the retina through the corneal wound made during iridectomy for glaucoma, and occurring the day of the operation, is recorded by D. Webster,¹ who ascribes the unusual complication to choroidal hemorrhage.

Hemorrhage after Enucleation.—Sattler's experience² teaches that removal of the eye in bleeders sometimes involves serious consequences. Once in a young hereditary hemophilic, and once in an elderly arteriosclerotic, he rescued his patient from fatal syncope only after the most vigorous treatment continued 24 to 36 hours. G. F. Saker³ employs a spray of hot sterilized water in arresting hemorrhage after enucleation.

Enucleation, or Mules' Operation.—The question of the choice of these 2 operations has been freely discussed. The weight of authority seems to be in favor of the latter if care is exercised in the selection of the case, but most writers agree with Kalt⁴ that it is not preventative of sympathetic inflammation. In panophthalmitis it is said to be the safer procedure, and Hughes⁵ claims it does not provoke postocular inflammation or meningitis; but Stocker and Pflüger⁶ have both enucleated and eviscerated in many cases of panophthalmitis without ill-results. James Barrett's case⁷ of death following excision of an eye would indicate that the excision had determined the fatal result, had not the autopsy shown the existence of previous meningitis. F. Allport,⁸ H. Schmidt,⁹ F. W. Coleman,¹⁰ and H. Bickerton¹¹ are strongly in favor of evisceration. The last is enthusiastic over the results obtained in 40 cases. Communications from Brudenell Carter and H. Juler, warmly commending the method, appear in his article. R. del Costello¹² states that the operation is preferable only in leucomatous eyes, and surgeons should be slow to abandon the safer and oftener indicated enucleation. H. Claiborne,¹³ has substituted glass-wool and asbestos for the glass ball of Mules, without success. Where removal of the ball and its contents is indicated he considers enucleation to be the better operation, although Belt¹⁴ has had fair success with the substitution of a fine, soft sponge, which, he says, fills with new tissue, the sponge-fibers being apparently absorbed. A. Bourgeois¹⁵ condemns Mules' operation because of the danger of sympathetic inflammation from the resistless glass ball, and has substituted for it with success in 2 cases the employment, after a modified enucleation, of a ball of black silk. The center or nucleus of the ball is made from a wad of catgut. Finally, E. Pflüger¹⁶ believes that enucleation is the only operation that will insure against sympathetic ophthalmia.

Tattooing.—L. de Wecker¹⁷ performs the operation of tattooing for 2 purposes—optical and cosmetic. Improvement of vision has been decidedly greater after iridectomy and tattooing than after iridectomy alone, because the total exclusion of the rays of light by a dense black patch prevents the irreg-

Subconjunctival injections: showing penetration of injected material about the globe
(Knapp's Arch. of Oph., July, 1897).

ular and imperfect refraction through a semitransparent spot. Care must be taken to accurately outline the spot and thoroughly saturate it with the ink.

THERAPEUTICS.

Subconjunctival injections of mercuric cyanid have been employed in checking panophthalmitis by Lagrange and Fromaget,¹ in vitreous opacities as well as in many diseases of the choroid and retina by Chavellereau,² and in hypopyon keratitis by J. Dunn.³ Healing was wonderfully rapid in Dunn's case. [In one instance of ulcer cornea serpens one of the editors of this department had an absolutely parallel experience.] In a case of paralysis of the superior oblique followed by interstitial keratitis S. M. Payne⁴ records the development of corneal inflammation while the patient was taking 75 gr. of potassium iodid daily for the muscular paralysis. After 4 injections of sublimate, aimed at the keratitis, the muscle completely regained its power. In those affections amenable to mercury internally, namely, iritis, iridocyclitis, iridochoroiditis, specific hyalitis, and optic neuritis, W. Wilder⁵ claims the subconjunctival treatment is particularly serviceable. The case of a 9-year-old boy with optic atrophy, whose vision Wilder improved from $\frac{20}{120}$ to $\frac{20}{40}$, is interesting. In the discussion before the Section on Ophthalmology of the American Medical Association of the value of subconjunctival injections of mercury E. H. Bernstein advocated the use of mercuric cyanid rather than bichlorid,⁶ claiming for it quicker and more complete absorption. He finds this treatment to be of considerable use in infectious diseases of the anterior ocular segment and in specific iritis. DeSchweinitz, Baker, and Roy join him in this opinion, while Stirling, Savage, and Reynolds have had unfavorable experiences with this method. Impelled by the controversy over the rationale of subconjunctival injections C. Mellinger and D. Bossalino⁷ introduced sterilized India ink beneath the conjunctivæ of rabbits, and demonstrated beyond cavil that fluids so introduced follow the greater lymph-spaces and surround the entire globe, the amount of ink actually entering the eyeball (see Plate 11) being small in comparison with the total amount injected. They believe that the fluids not only surround the eye and the optic nerve, but also communicate with the suprachoroidal and intravaginal spaces of the optic nerve. After having produced an ulcer in the center of the cornea in rabbits by injecting cultures of staphylococci, von Sicherer⁸ treated one eye with subconjunctival injections of the various medicaments used for the purpose, leaving the other eye untouched. He found that the injections produced in fact a slight salutary effect, by causing a considerable leukocytosis around the infected focus. The simple 2% salt-solution is as effective as the more irritating salts, and deserves preference over these injections; but there is no necessity for the injections at all, as the same effect is produced by the simple application of a salve of the yellow oxid of mercury, followed by an occlusive dressing. The leukocytosis thus produced is equal in extent to that caused by any other method, and the ulcer heals as promptly. Wilder⁹ says it is impossible to obtain as good results from salt as from bichlorid solutions. Abadie¹⁰ repeats his injections against bichlorid solutions, and especially when iodoform is used

contemporaneously in purulent ophthalmia, on account of their evil effects on the cornea. He insists that boric acid and potassium permanganate 1:1000 are equally useful and not injurious. Galezowski¹ has abandoned mercurial injections in the treatment of syphilitic eye-affections, because he believes them inefficacious, dangerous, and likely to cause thrombi and erysipelas. D. Roy² feels that we cannot depend exclusively upon this treatment in ulcerative or interstitial keratitis, iritis, and lesions of the uvea, but as an adjuvant it is most useful.

Intravenous Injections.—Notwithstanding the urgent claims of Bacelli, who introduced the method of treatment of grave ocular syphilitic lesions by intravenous injections of mercury, that it is absolutely free from danger, Galezowski³ urges against its adoption. He reasons that the insertion of the needle into the vein will cause erysipelas, the incorporation into the blood thrombi and embolism, and the absorption of mercury pytalism of serious nature.

Yellow Oxid.—W. D. Babcock⁴ has yellow ointment made according to the following formula: English graphite, 10 gr.; yellow oxid, 20 to 40 gr.; theobroma oil, $\frac{1}{2}$ oz.; antimony butter, 2 gtt. This prevents precipitation of the mercury and its decomposition by light. W. M. Sweet⁵ finds that Jamieson's salve, consisting of 3 parts of lanolin, $\frac{1}{2}$ part of oil of sweet almond, $\frac{1}{2}$ part of distilled water, is not only a bland and soothing application in itself, but is a useful base for other eye-ointments. Coleman⁶ prefers the red to the yellow oxid. While chemically the same, the latter commonly contains free sublimate. He states that experiments upon animals show that the yellow is more irritating than the red oxide.

Formol.—Compresses soaked in formol in increasing strength from 2% to 10% were effective in reducing the volume and cicatrizing the ulceration in an inoperable tumor of the face after failure of the cancer-serum of Emmerich-Scholl in a patient of Nieden.⁷

Serum.—The same writer has essayed the cure of recurring melanosarcoma of the eye and recurring glioma by injections of the cancer-serum, with negative results. Despagnet⁸ treated 10 cases of diphtheric ophthalmia by means of serotherapy. He reports cure in 9 and loss of the cornea in 1.

Electrotherapy.—D. A. von Reuss⁹ method of electrotherapy is novel enough to merit description. In using the constant current he employs a small platinum disk slightly concave on one side, isolated entirely, except on the concave surface, with a coat of varnish. This plate is applied directly to the eyeball after it has been thoroughly cocaineized. The positive or negative pole is used according as it is desired to obtain a greater or less degree of irritation. Treatment should be from 60 to 80 seconds of 1 to $1\frac{1}{2}$ ma. every other day. This method has proved in his hands very beneficial to episcleritis. His use of the faradic current is also unique in that he has the patient take one of the electrodes in his hand while the operator takes the other, and then with the free hand gently presses upon or strokes the closed lids. In this manner great relief from pain was afforded in recent iritis and in iridocyclitis. In a case of inflammatory glaucoma two applications dispelled all the symptoms. In a case of episcleritis periodica fugax (Fuchs) that had resisted all recognized treatment less than a dozen faradizations were necessary to dissipate the symptoms. These results are unusual, and ought

⁸ Ibid., Dec., 1896. ⁹ Beitr. z. Augenh., July, 1896.

to prompt investigators to renew their efforts in the electrotherapy of the eye.

Heat and Cold.—W. C. Posey¹ lays down the following rules for the application of cold and heat in ocular disorders: cold in the form of compresses in hyperemia of the conjunctiva, in the early stage of purulent ophthalmia (unless there is corneal involvement), after penetrating wounds of the eye, especially when the iris and lens have been injured. Moist heat is to be used in the later stages of purulent ophthalmia and pannus, in all forms of keratitis, in suppurative ophthalmitis, in muscular asthenopia, and in secondary iritis; while the primary form of iritis will be found more amenable to dry heat. Hot applications are to be avoided when there is any tendency to disease of the deeper structures, for fear of adding to the congestion of these delicate membranes. With healthy eyes it matters little whether cold or warm water be used to bathe the eyes.

Curettage.—T. H. Pleasants² endorses Santarnecki's method³ of hydraulic curettage in the treatment of corneal ulcers.

Antipyrin.—A. Sallard⁴ does not agree with Valude as to the good results of hypodermic injections of antipyrin in optic-nerve atrophy, and prefers injections of strychnin sulfate.

Homatropin.—The use of homatropin, 2-5%, as a cycloplegic is preferred to that of the other mydriatics by Jackson,⁵ when instilled by the surgeon himself, by dropping 1 to 2 drops on the upper corneal border every 5 minutes until 6 applications are made. He finds it entirely reliable, and its brevity of action is a great advantage. On the other hand, H. F. Hansell⁶ says that it cannot be relied upon to paralyze accommodation completely in young persons.

Scopolamin.—For quick pupillary dilatation in incipient iritis C. A. Oliver⁷ prefers scopolamin hydrobromate to atropin. Where prolonged use of such drugs is necessary the alternate use of scopolamin and atropin seems the best method. The duration of the healing and soothing powers is not so lasting with the former as with the latter.

Ichthyol.—In 3% solution or ointment ichthyol has been found serviceable in Panas' clinic in catarrhal conjunctivitis, phlyctenular and follicular conjunctivitis, and in blepharitis. Its action is astringent and antiseptic.⁸ G. D. Jacovides⁹ recommends it in 50% solution or in ointment, 2.5 to 5 gr. in 100 gr. vaselin, in the treatment of the various forms of conjunctivitis.

NEW REMEDIES.

Holocain.—This new aspirant for anesthetic honors is, like phenacetin and lactophenin, a synthetic derivative of phenetidin. According to Tauber,¹⁰ it is feebly soluble in water, is neutral in reaction, and should be warmed in porcelain vessels. 1% solutions remain clear for 2 months. R. Kuthe¹¹ has used it in 45 eyes for removal of foreign bodies, and Gutmann,¹² in tenotomies, dissections, tattooing of the cornea, and galvanocautery work, with great satisfaction. R. Heinz¹³ pronounces it a protoplasmic poison, stating that it arrests amoeboid movements, and that it is also inimical to bacterial growth in the

¹³ Centralbl. f. prakt. Augenh., Mar., 1897.

strength of $\frac{1}{10}\%$ solution. 1% solution will arrest putrefaction or fermentation completely, thus rendering unnecessary any preliminary sterilization in operations. [If these last two statements are verified, we have been presented with an ideal local anesthetic.] A large number of experiments with 5% solution caused no intoxicating symptoms. Anesthesia supervenes 1 to 3 minutes after the use of a 1% solution, and lasts 10 minutes. Gutmann¹ remarks that the pupil, ocular tension, and accommodation are unchanged. The advantages over cocain are its inherent antiseptic qualities, its rapid action, the preservation of the corneal epithelium, and no after-effects. These statements are substantiated by the labors of Hirschfeld² and Lowenstamm.³ It must not be forgotten that subcutaneously the drug is an active poison, though this does not lessen its efficiency and safety in ocular practice. Brudenell Carter⁴ used holocain once for cataract-extraction and once for slitting the canaliculus, securing complete anesthesia in each instance in 4 minutes. There was no particular effect on the conjunctival blood-vessels, the pupil, or the accommodation.

Eucain.—This other claimant for the position now occupied by cocain is endorsed by J. E. Jennings⁵ as superior to the latter because it does not decompose when kept in solution, is rendered aseptic by boiling, is less poisonous, dilates the pupil but slightly, and does not paralyze the accommodation or denude the cornea of its epithelium. The only point in which it is inferior is that it causes smarting and conjunctival injection. Vollert,⁶ on the other hand, tested eucain in Leber's clinic, and found that it produces a considerable mydriasis, is similar to cocain in its action, and affects the corneal epithelium much more than cocain. He thinks that eucain will hardly find a place in ophthalmology, and quotes Hirschberg, who for a while used it for removing foreign bodies, but has discarded it. These views of Vollert and Hirschberg are shared by J. E. Willetts,⁷ F. Wustfeld,⁸ and Best.⁹

Mydrol.—Mydrol, or iodohylate of phenylpyrazolin, is offered as a new mydriatic by Cattaneo.¹⁰ It dilates the pupil slightly, anesthetizes the conjunctiva but not the cornea, partially paralyzes the ciliary muscle, diminishes tension in strong solution, and enlarges the palpebral fissure, the effects disappearing entirely in 20 to 36 hours. He recommends it for ophthalmoscopy.

Scopolamin.—C. A. Oliver¹¹ recommends scopolamin hydrobromate in 1% solution as the best mydriatic in plastic iritis and the best cycloplegic for refraction. C. S. Hawkes¹² noticed sleepiness and delirium with hallucinations of sight and hearing in a young person after the absorption by the conjunctiva of 2 tablets of scopolamin hydrobromate, each containing $\frac{1}{100}$ gr.

Argentamin.—According to K. Hoor,¹³ argentamin, in 3% to 5% watery solution once or twice a day, or oftener if required, seems, by reason of its alkalinity, to possess all the advantages of silver nitrate without any of its disadvantages.

Formalin.—E. O. Belt¹⁴ and S. Burnett¹⁵ both add their testimony to the efficiency of formalin in from 1:1500 to 1:3000 solution in arresting corneal ulceration.

NEW INSTRUMENTS.

Colored Glasses.—S. B. Allen's studies¹ lead him to believe that not the light- but the heat-rays do most harm to the eye. Redness of the disk and of the retina to the nasal side of the disk are the resulting changes. He hopes to compass the difficulty by having constructed 2 thin surfaces of lightly smoked glass containing a solution of alum between them, as he has found that this solution has the property of cutting off the heat-rays. [If alum has this effect, it occurs to us that lenses ground from glass into which ammonioferic alum enters as a constituent would fulfil the purpose.]

Axonometer.—Williams² has devised an apparatus for the rapid and accurate determination of the axis of a cylinder worn in glasses or spectacles. [The objection to the instrument is that since a large proportion of corrections are compound, and since the spherical must be determined in the usual way with lenses from the test-case, it has little value.]

Bifocals.—Bourgeois³ commends superimposed double spectacles for patients requiring two corrections, in which the near correction shall be a single lens and the distance-correction equal to the combined strength of both lenses. Thus, in a cataract-patient who accepts +10 D. for distance and +16 D. for near work, he places the near correction in a permanent frame and -6 D. in the movable portion that is joined by a pair of hinges to the upper rim of the frame and can be raised and lowered at will. [This cannot compare with the lenticular bifocal (cemented bifocal) in any of its features.]

Binocular Lens.—E. Jackson⁴ offers a binocular lens, to be used with oblique illumination, which consists of 2 segments of planoconvex lenses of from 20 D. to 40 D. joined at an angle of 20 to 30 degrees. It gives a magnification of from 8 to 15 diameters, but its chief advantage is the impression it conveys of the depth of the object surveyed. [In furnishing the third dimension, this instrument adds not a little to the accuracy ordinarily obtainable in inspection of the anterior section of the eye.]

Ophthalmoscopic Mirror.—The same author also suggests that to obviate the annoying reflex from the sight-hole of the ophthalmoscopic mirror a thin piece of glass should be cemented to the glass of the sight-hole, and that its edges should extend beyond the margin of the opening in the silvering.⁵

Skiascopy.—Instruments to facilitate skiascopy are offered by Mitchell⁶ and by J. E. Jennings.⁷ The former is light and cheap, the latter cumbersome and expensive.

Accommodation-stick.—A. E. Prince⁸ adds to our armamentarium a combined age- and refraction-scale for the rapid determination of accommodation (see Fig. 66).

Combination Spectacle and Hand Reading-glass.—C. Koller⁹ describes a combination of a spectacle and hand reading-glass, which he devised to facilitate reading with defective vision. It is based on the observation that vision of at least $\frac{6}{24}$ is necessary to the discernment of ordinary type. He accomplished his object by mounting a very strong convex lens, 15 to 30 D., in a 2-inch tube fitted into the eye of an ordinary spectacle-frame (see Fig. 67).

Clinoscope.—The clinoscope recently devised by G. T. Stevens¹⁰ meas-

ures the torsion of the eyes when gazing at a fixed object with the axes of vision presumably parallel. The instrument is practically useful in examining for functional anomalies, or for paralysis or paresis of one or more of the ocular muscles.

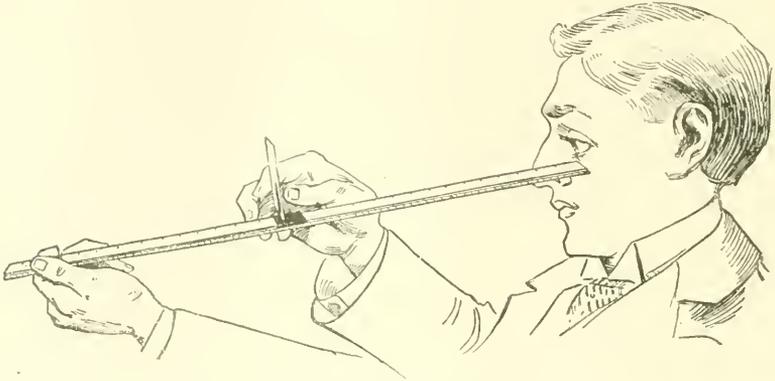

FIG. 66.—Prince's combined age- and refraction-scale (*Arch. of Ophth.*, Jan., 1897).

Advancement.—Valk¹ likes a double hook for elevating and stretching the muscle to be advanced. He uses catgut instead of silk sutures, and one needle in taking the tuck in the muscle.

Speculum.—R. Murdoch² adds to his speculum a small fixation-forceps, which he can attach to the speculum for steadying the eyeball during iridectomy for cataract.

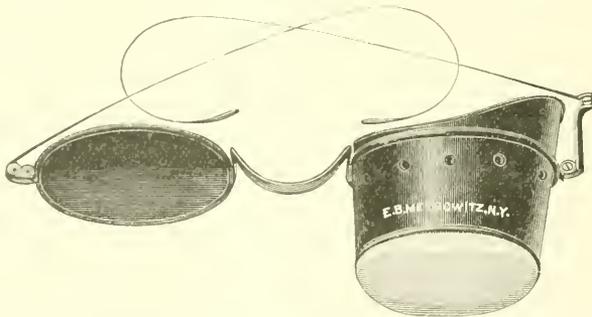

FIG. 67.—Keller's combination spectacle and hand-glass (*Ann. Ophth. and Otol.*, Oct., 1896).

Photography.—Th. Guilloz³ has completed an apparatus for instantaneous photography of the fundus oculi. The photographs show a reversed image, from which the author has succeeded in eliminating the reflection from the cornea and the optic disk.

OTOLOGY.

BY CHARLES H. BURNETT, M. D.,

OF PHILADELPHIA.

During the past year many valuable articles have been written upon diseases of the external ear, the most important of them pertaining to foreign bodies in the auditory canal, malignant diseases of all parts of the external ear, and myringodermatitis. The last-named disease may be easily overlooked. It is likely to occur in measles, and in this disease, therefore, myringodermatitis should be looked for. The most important of all diseases, acute otitis media, has received widespread attention. Since upon the prevention, or upon the proper treatment, of this disease depend the hearing, and in some instances the life of the patient, the importance of this malady cannot be overestimated. The secondary results in many of the cases reported do not seem to have been necessary. They tend to show that too much caution cannot be observed in the avoidance of all forms of irritant treatment, nor too close an adherence to conservative, aseptic measures in acute otitis media. It is a regrettable fact that much of the secondary infection of an acutely inflamed ear is due to the domestic treatment, always septic, the patient receives before the physician is called in. The latter must bear in mind, therefore, that usually in such cases he has to combat at the outset of his services artificial lesions of an inflamed organ.

The great advantages of intratympanic surgery in chronic purulent and in some forms of chronic catarrhal otitis media continue to be shown by numerous reports of the results obtained by reliable operators, to which reference is made in the following pages. The brilliant results of surgical interference in otitic lesions of the cranial cavity are also demonstrated by a review of the writings of both general and special surgeons in Europe and America. In fact, the literature of otology for the past year shows that important advances have been made in every department of this specialty.

DISEASES OF THE EXTERNAL EAR.

Malformation of the Auricle.—J. F. Binnie¹ has reported a case of microtia on both sides in an adult man, without much evidence of the presence of an osseous auditory canal on either side; also a case of malposed auricle (below the normal position) associated with harelip. Max² reports rectification of malformation of the auricle by operation, under cocaine-anesthesia. An **acquired circular defect** in the auricle near the bifurcation of the anti-helix, the consequence of an ulcer, is reported by the same writer.³

Othematoma, cured by incision of the sac and packing, is reported by G. A. Webster.⁴ A. D. McConachie⁵ reports the occurrence of 3 cases of

⁴ Boston M. and S. Jour., Oct. 8, 1896.

⁵ Jour. Eye, Ear, and Throat Dis., vol. i., No. 3.

hematoma auris in the sane. In the first case the blood-tumor was considered to be an idiopathic one. The sac was opened 3 times, refilling twice; but the third time injections of carbolic acid solution (strength not given) were followed by agglutination of the perichondrium to the cartilage, and healing with considerable deformity. No history of traumatism could be found in this case. In the second case, traumatism being the cause of the formation of the blood-tumor, prompt incision without injections was not followed by healing. Finally, after several incisions, recovery followed an injection of a carbolic acid solution and tight bandaging. There was considerable deformity of the auricle subsequently. In the third case, also caused by violence, prompt incision, evacuation, and firm bandaging were followed by quick recovery with the usual puckering of the auricle. L. P. Clark¹ regards the occurrence of hematoma arising in the insane as justifying a very grave prognosis. W. F. Robertson² has demonstrated that degenerative areas in the cartilage of the auricles occur in the insane, and that hematoma may occur easily without the aid of anything that could be fairly termed traumatism. An ordinary slight touch on the auricle of the insane may produce traumatism.

Degenerate Auricle.—Scientists and neurologists, however, are forced to lay little stress upon the occurrence of any one or two stigmata. It is only the combination of several that is indicative of a corresponding degeneration of the cerebral tract.³

Angioma of the Auricle.—J. Gruber⁴ reports the occurrence of an angioma, mistaken at first for a sebaceous tumor, in the concha of a man. The growth was attacked by incisions through the skin as for removal of a sebaceous cyst, the profuse hemorrhage revealing its true nature. The contents were scraped away, little blood was lost, and under iodoform-compresses recovery took place quickly.

Keloids of the Auricle.—W. Scheppegegrell⁵ reports 2 cases of keloid tumor of the auricle, the result of piercing the lobule for earrings. The tumors were removed after local injections of a 4% solution of cocaine muriate. There were no recurrences after 6 and 14 months respectively.

Lupus of the Auricle.—Ciarrocchi⁶ reports a case of lupus pernio of the left auricle in a man of 35. It was relieved by the use of ignipuncture with the thermocautery of Paquelin and cataplasms of rice-water.

Hemorrhagic Ecthyma of the Auricle.—Two cases of partial necrosis of the auricle, the so-called "ecthyma térébrant" of infancy, are reported by O. Barnick⁷ as occurring in the clinic of Habermann, in Gratz. The patients were 3 and 4 years old respectively, and died shortly after the aural condition was noted, of chronic tuberculosis of the glands and bones. In each instance the disease began on the front surface of the helix, and extended from this point, gradually spreading until it reached and implicated the hairy scalp above and the skin below the auricle. In the pus from these latter ulcers tubercle-bacilli were found.

Epithelioma of the Auricle.—Compaired⁸ reports 2 cases of epithelioma of the auricle and auditory canal, cured by amputation, followed by treatment with potassium chlorate. Roncali⁹ reports a case of melanotic sarcoma

of the auricle, which spread from the zygomatic region to this part of the ear, and thence to the middle ear, notwithstanding an operation on the auricle early in the disease.

Artificial Diseases of the Lobule.—According to Vior-Travieso,¹ gangrene, noma, septic phlegmons, chronic exudative erysipelas, and eczema, both humid and impetiginous, are caused by the ordinary septic method of piercing the lobule of the ear.

Congenital Aural Fistula.—A case of congenital aural fistula or sinus, with recurring inflammation, is reported by A. H. Cheatele.² Under a general anesthetic this sinus was laid open, all suspicious-looking membrane cut away, the cavity thoroughly mopped with pure carbolic acid, and the whole wound packed with double cyanid gauze and allowed to heal from the bottom. In 1 month recovery had taken place.

Reflex Effect of Cerumen Plugs.—R. W. Merrick³ reports the occurrence of ear-cough, deafness, vertigo, and nausea from the presence of hard cerumen in the ear. He thinks that in nervous patients a melancholic form of dysthymia may be produced by mechanical irritation in the external ear.

Epidermis-plugs in the Ear.—H. Hessler⁴ reports 35 cases of epidermis-plugs in the external ear observed in his own practice within the last 17 years. These foreign bodies of endogenous origin are best removed with a hooked instrument; not by syringing, as fluids cause them to swell. Their instrumental removal, however, should not be attempted by any one but an expert, as improper force in such an operation may cause fatal irritation.

Herpes of the Meatus.—Herpes at the orifice of the external auditory canal is reported by L. S. Somers.⁵ This was cured by tonics and the local application of yellow oxid of mercury.

Foreign Bodies in the Ear.—Preobraschensky⁶ presents safe conclusions regarding extraction of foreign bodies from the ear that can be summed up by saying that no inexpert hand should attempt instrumental extraction, and that syringing will usually remove a foreign body if it has not been previously impacted by unskilful efforts at removal with instruments. Letting alone foreign substances in the ear is far better than inexperienced efforts to get them out. Yearsley⁷ observed severe ear-pain resulting from the entrance of a pellet of wool through a perforation in the membrana tympani in a case of chronic purulent otitis media. The wool had been inserted into the meatus for protection, but slipped into the canal and thence into the drum-cavity. Upon removal of the foreign substance all acute inflammation disappeared. Lalatta,⁸ in an article on foreign bodies, demonstrates by 3 cases how innocuous an inanimate foreign body in the ear is, so long as it is not touched by an unskilful hand. No endeavor at removal is better than rough and unskilful ones.

Hummel,⁹ in a lecture on foreign bodies in the ear, delivered to military surgeons, formulates these conclusions: 1. There is no reaction between the normal auditory canal and the foreign body placed in it; as such, the foreign substance is unattended with danger. 2. Therefore, every hasty endeavor at removal is not only unnecessary, but may be injurious. 3. In all cases in which no rough endeavors at removal are made, syringing with warm water is

sufficient to remove the foreign body. 4. The general physician should never employ anything but the syringe to remove foreign bodies from the ear. 5. An instrumental removal should never be attempted by any one but a specialist skilled in the use of ear-specula and the technic necessary in such cases.

Fracture of the External Auditory Canal.—Galletti¹ has contributed an account of 5 cases of indirect fracture of the external auditory canal. The prognosis is generally favorable; there is, however, danger in some instances, of injury to the cerebral meninges. Denker² observed a fracture of the anterior lower wall of the auditory canal, caused by the force of a fall upon the lower jaw. The blood was removed by syringing with an antiseptic solution (bichlorid 1:1000), and the ear gently tamponed with iodoform-gauze. Recovery soon took place. [This is a rare form of accident to the ear.] Ostmann³ has treated successfully connective-tissue **strictures of the auditory canal** by means of electrolysis with a current of 4-5 ma. in four or five sittings at intervals of 8-10 days.

Hyperostosis of the external auditory meatus, according to A. Hartmann,⁴ is simply an anomaly of development, and has nothing to do with inflammatory or morbid processes. J. Dunn⁵ has operated successfully by way of the mastoid upon hyperostosis of the auditory canal, caused by chronic purulence of the middle ear.

Respiratory Movements in the Membrana Tympani.—V. Hammerschlag⁶ has demonstrated that there are normally motions in the membrana tympani synchronous with the respirations and pulsations of the heart. E. Donaldson⁷ describes a flaccid cicatrix in the membrana tympani, movable with respiration, observed by him in a woman of 25. This condition was a variable one, and whenever observed was attended with autophony. B. Gomperz⁸ draws attention to the fact that subjects of valvular occlusion of the Eustachian tubes suffer at times from modified tensions (bulging) of the upper posterior quadrant of the membrana, accompanied by sensations of tension or compression in the ears and tinnitus. Masini⁹ reports the occurrence of **aural myoclonus** in 3 men, all the subjects of marked dyspepsia and neurasthenia. L. S. Somers¹⁰ reports a case of autotraumatic **rupture of the membrana tympani**. The deafness was finally relieved some weeks after the accident by drawing the impacted membrana into proper isolation by the pneumatic speculum. [No secondary infection had occurred in this case, as nothing was dropped or put into the ear after the traumatic perforation ensued.] C. J. Colles¹¹ reports 2 cases of traumatic rupture of the drum-head from the concussion caused by a discharge of artillery. [Both of these cases would have done much better if the ears had not been syringed immediately after the rupture of the membrane before they were seen by Colles. Simple stopping the meatus with antiseptic cotton or gauze is sufficient in such cases.]

Syphilitic Exudation in the Membrana.—J. Dunn¹² reports the occurrence of syphilitic exudation into the folds of mucous membrane about the head of the malleus. The patient was a man with syphilitic history and chronic catarrhal deafness in the affected ear. The exudation was confined to the region of the membrana flaccida and malleus. It was attended with pain in the ear and mastoid tenderness. Pricking the exudation-sac and the ad-

ministration of potassium iodid were followed by recovery. Courtade¹ has observed in hereditary syphilis, in a woman of 21, intense injection in Shrapnell's membrane and of the handle of the malleus.

B. Gomperz² succeeded in bringing about the **closure of chronic perforations** in the membrana in 4 cases out of 10 in which the effort was made by touching their edges with trichloroacetic acid preceded by local anesthesia with 10% solution of cocain. [As no advantage is to be gained by the closure of such perforations, we wonder at the time wasted on such experiments.]

Myringodermatitis.—J. E. Sheppard³ calls attention to the important fact that a form of inflammation in the outer layer of the drum-membrane may exist with the formation of blebs either behind or below the malleus. [We have found such conditions of not uncommon occurrence, and suggest for them the name of myringodermatitis. They occur in measles and from exposure to cold winds or cold-water baths. In cases we have treated, dry heat has controlled the pain, while spontaneous rupture of the blebs has been awaited. Paracentesis has not been found necessary in our cases. If, in performing paracentesis of the blebs, the perforation should be carried into the drum-cavity, a secondary inflammation of this cavity would certainly follow. Spontaneous rupture of the blebs is likely to occur within 24 hours.]

DISEASES OF THE MIDDLE EAR.

Etiology of Acute Otitis Media.—J. Holinger⁴ claims that in all cases acute otitis media is largely due to adenoids in the nasopharynx. These are primarily the seat of acute inflammation in coryza, and even in the infectious diseases of childhood, the sepsis spreading from them to the middle ear. In all instances treatment and cure of the ear-disease must therefore be preceded by treatment and cure of the nasopharyngeal adenoid inflammation. [This is true to some extent, but we often see perfectly healthy ears, with normal functions, become the seat of acute inflammation as the result of the treatment of nasopharyngeal catarrh, adenoids, etc.] Lannois⁵ has shown we cannot establish any pathologic differences between acute catarrhal and acute purulent otitis; the same microbes determine both conditions, and it is merely a question of resistance of the organism. A case of acute otitis media caused by the nasal douche, with distinct secondary infection of the middle ear and mastoid cavities by improper treatment of the inflamed ear, necessitating mastoid trepanation finally after 4 months of pain, is reported by C. H. Burnett.⁶ Acute otitis media followed by mastoiditis and an epidural abscess, entirely relieved by operation, is reported by J. E. H. Nichols.⁷ A case of acute purulent otitis media complicated by a retropharyngeal abscess, which apparently had formed by burrowing along the tract of the tensor tympani muscle, was observed by F. L. Stillman.⁸ The abscess was discharged into the pharynx, and entire recovery of the patient in all particulars ensued in the course of 2 months after the initial inflammation in the ear.

Acute otitis media, followed by mastoiditis in the course of 2 months, unrelieved by operation, is reported by Grunert and Leutert.⁹ Ten days after the mastoid-operation the patient died with symptoms of meningitis. The autopsy revealed chronic leptomeningitis, with edema of the pia mater. [It

would be interesting to know what treatment was applied to the ear in the acute stage of inflammation. We have never observed mastoiditis succeed acute otitis, except as the artificial result of improper treatment of the primary otitis.]

Middle Ear in Diphtheria.—In 25 autopsies upon children who had died of true diphtheria E. Lommel¹ found only 1 case in which the middle ear was unaffected. He concluded, therefore, that otitis forms part of the clinical picture of diphtheritic inflammation of the respiratory tract.

Diagnosis of Acute Otitis Media.—The importance of early diagnosis and treatment of inflammation of the middle ear, especially in children, is pointed out by J. H. Fruitnight.²

Richard Frothingham³ shows that "on account of the anatomic relations of the middle ear and the gravity of some of the results of middle-ear disease, as regards not only permanent loss of hearing, but also danger to life, no part of the body is of more importance to all practitioners; and still there is no branch of medicine about which the majority of physicians know so little." He then gives a most significant list of incorrect diagnoses of ear-diseases he has known to be made within a short time, viz., "unrecognized acute middle-ear suppuration followed by meningitis;" acute mastoid disease diagnosed as "cellulitis;" furuncle of the canal diagnosed as "mastoid-disease;" "acute middle-ear suppuration" diagnosed and treated as "neuralgia;" otalgia dentalis diagnosed as "a gathering in the ear;" acute middle-ear suppuration diagnosed on the right, but the same disease on the left overlooked; polypus from Shrapnell's membrane the unrecognized cause of head-symptoms; polypus of the ear diagnosed as "chronic catarrhal disease;" acute middle-ear disease with a bulla of the membrane diagnosed as a "malignant growth;" and dried white desquamated epithelium in the canal diagnosed as "the ossicles coming out."

Treatment of Acute Otitis Media.—N. H. Pierce,⁴ in an article on the modern pathology and treatment of acute otitis media, presents a valuable reiteration of the rational treatment of acute otitis media as set forth by Gradenigo and Pes and Lermoyez and Helme (see *Year-Book* for 1896, pp. 836-841), by which secondary infection and chronicity are avoided. Briefly, this means apply no local anodyne-treatment to the ear, as it is useless and harmful: employ dry heat. If pain continues without spontaneous rupture in 12 hours, puncture the drum-membrane at the lower posterior border; then do nothing but place a thin strip of antiseptic gauze in the canal, a tuft of the same in the concha, and let the ear alone till the dressings are moist with secretions; then remove and renew them. Avoid all forms of inflation of the tympana, as well as all forms of aspiration, swabbings, etc. Timely remarks in the same direction upon the modern and rational (nonirritative) treatment of acute otitis media are also made by R. Otto.⁵ Karminski⁶ enjoins upon aurists the greatest care in avoiding infection of the acutely inflamed ear. He shows that the staphylococcus is often conveyed to the ear by the finger of the surgeon, by instruments, and by medications. R. W. Seiss⁷ makes an earnest plea for conservative treatment in acute otitis media, maintaining justly that lavage of and syringing the inflamed ear can be done properly only by the aurist. D. M. Campbell⁸ demonstrates the value of cautious aseptic treatment in acute and chronic catarrhal diseases of the nose and ear in children.

Acute Otitis Media in Acute Polyarthritic Rheumatism.—O. Wolf¹ claims that acute otitis media is often a prodrome of acute articular rheumatism, and suggests that the bacteriologist in searching for the microbe of polyarthrititis should examine the secretions taken from the drum-cavity immediately after paracentesis of the membrane has been performed in a case of acute rheumatic otitis media.

Complications of Acute Otitis Media.—J. E. Sheppard² has given an instructive "analysis of 114 cases of mastoid involvement complicating acute middle-ear suppuration . . . of less than 6 weeks' duration;" 51 were operated upon by Sheppard, 3 were operated upon by others, 1 died without operation, 34 recovered without operation, while the result in 25 is unknown. Sheppard makes the following summary based on the above very large number of cases of what may be termed acute mastoiditis: 1. For opening the mastoid the gouge or the chisel has invariably been used, excepting when the cortex was so much softened as to make the sharp curet more applicable; 2. For clearing out the mastoid sharp curets were used for the outer, the blunt curet for the deep portions; 3. Grippe, outside of the acute affections of the nose and nasopharynx due to cold, etc., has played the most important role in the etiology. Of those operated upon, 4 died; 2 from meningitis about 3 days after operation, 1 from erysipelas and then meningitis 2-3 weeks after operation, and 1 from erysipelas 2 weeks after operation. 4. The symptoms are important in about the following order: (*a*) pain in the mastoid, or in some part of the affected half of the head; (*b*) tenderness, either of the whole or of some part of the mastoid (oftenest of the apex); (*c*) drooping or bulging of the posterior superior canal wall, especially if close to the membrane; (*d*) posterior superior perforation of the membrane, especially if pointing or teat-like; (*e*) pulsating tinnitus, when it continues as a marked symptom after the time it should have ceased were the case a simple middle-ear suppuration; (*f*) the external symptoms are redness and edema of the mastoid, and pushing outward of the auricle; 5. Abortive measures should be employed in a majority of cases for from 2 to 5 days, and will be successful in curing a fair proportion of all cases. If these fail, then the conclusions are that "we must time and again operate on the strength of one or two symptoms, and often with these only slightly marked. If a patient is seen before the external manifestations of mastoiditis have developed, we should not wait for their appearance (symptoms of empyema being present), because by so doing we give the pus the same opportunity to break through the internal as through the external mastoid cortex, and while awaiting the latter event we leave the patient exposed to the former danger. The operation, if performed with due care, is relatively free from danger. Danger to the patient arises, not from the operation, but from delay in performing it."

Pyemia in Acute Otitis Media.—Röpke³ reports a case of well-marked pyemia fully established in the third week of the aural disease. The secondary infection in this case was evidently due to the improper treatment of the ear in the acute stage of inflammation by syringing with chamomile-tea and poulticing, as ordered by the family physician. The local mastoid symptoms were largely negative. There was nearly constant pain in the left temple. The eye-ground was not examined. Chills, rapid rise and fall of temperature, the permanently rapid pulse, even in intervals of normal temperature, tumor of the spleen, and the dry, cracked, thickly coated tongue, were relied upon in establishing the diagnosis of otic pyemia from osteophle-

¹ Arch. f. Ohrenh., Dec., 1896.

² Trans. Am. Otol. Soc., July, 1896.

³ Arch. of Otol., Oct., 1896.

bitis. Suppuration of the mastoid cells and probably acute necrosis of the bone-tissue of this cavity were evidenced by the profuse discharge from the ear and the tenderness of the mastoid to pressure. No external symptoms of sinus-phlebitis were present. There was no edema, neither at the region of the temple nor at the posterior boundary of the mastoid. The mastoid cavity and antrum, when opened, were found filled with pus and granulations, and were completely cleared out. The vertical portion of the lateral sinus was then found to be exposed from necrosis of its bony covering. The sinus-wall was free from disease, but it did not pulsate. It was punctured, but neither blood nor pus was aspirated. It was evident that the thrombus thus shown to be present was solid, and *further interference with it was deemed inadvisable*. The wound was tamponed and bandaged. The temperature fell immediately, but rose the next day to 39.8° C. after a chill. The spleen could not be felt. From the 5th day after the operation the temperature remained normal. On the 10th day the patient left her bed, and in one month she was dismissed from the hospital entirely well, with very good hearing in the previously diseased ear. [But the secondary infection of the middle ear, from the improper treatment of the ear in the acute stage of inflammation jeopardized the life of the patient.]

Cerebral Abscess from Acute Otitis Media.—Gorham Bacon¹ reports the occurrence of abscess in the temporosphenoidal lobe, in connection with acute otitis media. The first symptom, loss of memory, occurred in about the fifth week of the disease, and in the eighth week there ensued sensory but no motor aphasia, severe headache, and subnormal pulse. The temperature and pulse remained normal, but the mastoid was somewhat swollen and tender. The latter was chiselled open with difficulty, as eburnation had taken place, and the antrum freed from granulations and pus. In 10 days the patient complained of general headache and became delirious at times. Slight optic neuritis with faint edema was detected. An abscess was sought for, found, and emptied, but the patient died, apparently from shock, about 10 hours after the operation. A communication was found to have formed between the suppurating attic and the cranial cavity. W. Milligan² reports a case of abscess of the same region of the brain, following acute otitis media. The symptoms were similar to those in the case reported by Bacon, having, however, motor, in addition to sensory aphasia. There was dilatation of the left pupil—*i. e.*, on the affected side—a symptom frequently noted of late, *viz.*, the wider pupil on the side corresponding to that of the brain affected with abscess. The cerebral abscess was evacuated by operation. The patient did well for nearly two months after the operation, when hernia cerebri occurred and the patient died with symptoms of basal meningitis. The postmortem examination revealed no erosion of the roof of the parietes of the middle ear and no symptoms in the mastoid cells. “Apparently the pathogenic organisms had been carried directly from the middle ear to the interior of the temporosphenoidal lobe by way of the lymphatics or small venous arteries, no bone-lesion intervening.” [In reflecting upon the notes of this case we feel that the secondary infection of the ear, which passed to the brain at last, was due to the three months of “various forms of local treatment which were tried” before Milligan was consulted. Three months’ trial of “various forms of local treatment of an acutely inflamed ear could not fail to convey sepsis to the ear and result in secondary infection, chronicity, and final infection of the cranial cavity.]

¹ Trans. Am. Otol. Soc., July, 1896; Arch. of Otol., July, 1896.

² Arch. of Otol., July, 1896.

Meningitis in Acute Otitis Media.—H. Knapp¹ reports "a case of acute purulent otitis media in which marked symptoms of meningitis developed," and in which the opening of the mastoid and cranial cavities was followed by prompt improvement and subsequent recovery. No pus was found in this case, but the extensive area of "destructive osteitis in which suppuration might occur any day," discovered in the mastoid, antral, and sigmoid regions, seems to have justified the operation.

Meningismus in Acute Otitis Media.—Cozzolino² calls attention to the fact that very frequently pseudomeningeal symptoms, or meningismus, in young children are due to acute inflammation of the middle ear. In many of these cases perforation of the membrana tympani and discharge from the ear are wanting. It is claimed that this is due to the fact that the disease is produced by the Talamon-Fränkell microbe, which, possessing very feeble destructive power, the membrana is left intact, but the disease is perhaps all the more likely to travel to the internal ear and brain. [A paracentesis of the membrana in such cases would save the ear and the life of the patient.]

Facial Paralysis in Acute Otitis Media.—In a case of acute suppuration of the middle ear, followed by caries of the Fallopian tube and paralysis in five weeks, in which there had been most of that time intense pain but no fever, F. L. Jack³ opened the mastoid cells, but found no pus, nor carious bone in the thick outer walls. Continuing the chiselling a quarter of an inch farther inward and forward a small pus-cavity was discovered in the Fallopian region. Under antiseptic irrigations and dressings the pain was entirely and promptly relieved, the temperature became normal, and the paralysis disappeared.

Cozzolino,⁴ in an article on the "surgery of the Fallopian canal in cases of otitic facial paralysis," shows that in removing septic and phlogistic matter from the tympanic and mastoid zones of this canal the paralysis may be relieved. His method he terms "radical mastoidotomy," by which he frees the nerve from diseased bone surrounding it. It is worthy of note that Politzer⁵ records two instances in which facial palsy due to chronic purulency in the middle ear was entirely cured by surgical exposure and thorough curetting of the suppurating ear-cavities. Geronzi⁶ reports a case of facial paralysis of otitic origin followed in three years by labio-glosso-laryngeal paralysis from ascending degeneration of the seventh nerve on the same side, in a man of 45, of intemperate habits. O. Barnick⁷ observed facial paralysis supervene after curetting the drum-cavity in a man of 40, in whose case the mastoid cavity was found to be the seat of a cholesteatoma metamorphosed into a blood-cyst. This case was finally cured after operation upon the middle-ear cavities and the mastoid process, clearing the spaces of a sanious fluid, and the formation of a permanent opening behind the ear. Eitelberg⁸ reports the occurrence of facial paralysis, without aural suppuration, associated with Ménière-symptoms. These phenomena appeared in a man of 35, after a fall from a horse, but recovery ensued after months of treatment. It was thought that the facial paralysis might have been rheumatic, as it appeared shortly after a painful swelling of the cheek from a carious tooth.

Simulated Deafness.—Ostmann⁹ demonstrates that minute acquaintance with otologic diagnosis ranks above all other means for the detection of aural malingering.

⁹ Monats. f. Ohrenh., Sept., 1896.

Impaired Auditory Center.—Functional impairment of the auditory center as the result of catarrhal deafness is pointed out by J. A. Mullen.¹ [This is analogous to atrophy of the auditory center, supposed by some to occur in deaf-mutes.] F. Alt² reports **deafness from mumps** cured by potassium iodid, pilocarpin injections, and acoustic exercises. Gruber claims that bilateral deafness after mumps is incurable. J. L. Minor³ has reported 8 cases of deafness following mumps. The left ear was affected in 5 of these; when the middle ear alone is attacked there is some hope of recovery of hearing, but there is none when the internal ear is the seat of the lesion. Trifiletti⁴ describes a case of **deafness due to atheroma** of the arteries, and ascribes to the same cause the pathogenesis of senile deafness.

The Ear in Bright's Disease.—Haug⁵ has reported a case of nasal and aural hemorrhage in Bright's disease from alcoholism. There first occurred very severe pain in both ears, together with tinnitus and some deafness, and then hemorrhages as above stated, especially in the drum-cavities.

A. H. Buck⁶ in an elaborate paper presents the relations of goutiness to diseases of the ear, showing that this diathesis may induce disease in different portions of the organ of hearing.

Middle Ear in Malignant Disease of the Nasopharynx.—A case of fibrosarcoma of the nasopharynx and middle cerebral fossa, with associated ethmoiditis, empyema of the sphenoid cells, otitis media, and pachymeningitis, is reported by T. Hubbard.⁷

Gellé⁸ claims that **ankylosis of the stapes** enfeebles but does not abolish hearing. Therefore, when deafness has become chronic, the stapes being ankylosed, the aurist is confronted with a lesion of the labyrinth or even of the brain causative of deafness. In his opinion this should call for hesitation before mobilization or removal of the stapes is effected, with a view to relieve the deafness. [Retraction and impaction of the stapes in the oval window are more important considerations than simple ankylosis of this bonelet.]

Treatment of Catarrhal and Sclerotic Diseases of the Middle Ear.—R. H. Fridenberg⁹ suggests some hygienic principles in the prevention of ear-disease, consisting in maintaining an aseptic condition of the nasopharynx by treatment with gargles and sprays and the removal of any possible nidus for pathogenic germs, such as diseased tonsils, decayed teeth, etc. H. Jackson¹⁰ calls attention to the great importance of carefully examining the nose, throat, and ear during the course of **scarlet fever**. There are pseudomembranous lesions of the palate, and these processes may spread to the postpharyngeal wall and, after invasion of the pharyngeal vault, to the nose. Such a process is usually found on the third or fourth day of the disease, and is the direct cause of the most alarming and fatal complications of scarlet fever, namely, septicemia, purulent otitis media, and infection of the cervical glands, besides serious kidney-lesions. He advises sprays of Dobell's solution for the mouth and nose. The nasal douche is condemned. In order to prevent infection of the mucous membrane of the middle ear, by forcing nasal mucus through the Eustachian catheter, A. Lucac¹¹ proposes to pass a

¹⁰ Arch. of Otol., Apr., 1897.

constant stream of air through the catheter during the introduction of the latter through the nose, thus keeping nasal secretions from the beak. [This current of air ceases, of course, as soon as the beak of the catheter reaches the nasopharynx and is about to be inserted into the mouth of the Eustachian tube, when a renewed air-current is demanded.] E. Morpurgo,¹ as a result of careful observation of cases in the Marine Hospital at Trieste, concludes that sea-baths exercise a beneficial effect upon ear-diseases in the **scrofulous**. B. A. Randall² deems it of the first importance in the treatment of chronic catarrhal deafness to place the nasopharynx in the best possible condition before treatment of the Eustachian tube and middle ear can relieve the hardness of hearing. "Only a small proportion of cases will present deformities or hypertrophies which compel operative intervention to free the air-passages."

Massage of the membrana and ossicula by means of the pneumatic speculum is also advocated, while the Politzer form of inflation of the tympana is not employed in such cases. The foregoing form of treatment may have to be carried out a year before any improvement is seen, though usually good results have been obtained sooner. Even pneumomassage must be applied to the ear with caution, or pain and permanent injury to the already weakened ear may occur. A. Lucae³ therefore places a small slit in the air-conducting tube near the ear-piece, thus forming a "safety valve," for the escape of excessive inward pressure upon the membrana tympani. Unusual dryness of the nose and throat, with increased deafness, in chronic aural catarrh is said by T. H. Shastid⁴ to follow doses of **belladonna**.

W. Vulpius⁵ draws attention to the fact that Kinnicut and M. A. Starr, while employing **thyroid extracts** in cases of myxedema with which hardness of hearing was associated, observed that with improvement of other symptoms the hearing was also greatly improved.

Gradenigo,⁶ recognizing the infective origin of ozena, probably from a diphtheritic bacillus (Belfanti), has found that ozena and concomitant chronic otitis in some cases are greatly benefited, at least for a long time, by hypodermic injections of **diphtheritic serum**. Bayer⁷ regards ozena as a tropho-neurosis, and proposes to treat it with **interstitial cupric electrolysis**; but this treatment is always painful, and in 7 cases thus treated by Bayer 2 suffered from acute otitis media, 1 of which succumbed apparently from an intracranial abscess. [The method is highly censurable.] Nonfétid ozena, first described by Abel,⁸ has been observed in two cases, and reported by C. H. Burnett⁹ in connection with chronic aural catarrh, which it had produced. The nasal and aural lesions were improved by the use of sprays of Dobell's solution and Boulton's solution of iodine and carbolic acid.

Botey¹⁰ claims that **puncture of the membrane of the round window** and aspiration of the endolymph will relieve vertigo, tinnitus, and some of the affections of the labyrinth, due to excessive intralabyrinthine pressure. Cozzolino¹¹ claims to have suggested puncture of the round window for the relief of tinnitus and vertigo, in 1888, at the International Congress of Otolaryngology held at Brussels. A similar suggestion, puncture of the outer labyrinth wall, to relieve increased labyrinth tension, is made by A. H.

¹¹ Ibid., Feb., 1897.

Cheate.¹ Forns² has demonstrated that the operation of puncture of the round window, as suggested by Botey, is almost impracticable in any case, but especially so when the plane of the round window is turned backward, instead of outward toward the membrana tympani. In any case Forns justly claims that puncture of this window is very likely to permanently injure the soft tissues of the labyrinth.

Cohen-Kysper³ makes the general statement that deafness due to the sequels of catarrhal and suppurative inflammations of the tympanum may be successfully treated by injections of **digestive ferments**, especially of dog's pepsin, into the drum-cavity, so as to bathe the stapes and oval window, allowing the injected fluid to lie in such position one hour. Such treatment, however, he does not employ in sclerosis of the drum-cavity. [No statistics are given.]

Vibration or massage of the nasal mucous membrane is highly recommended by T. H. Shastid⁴ for improving the hearing in chronic aural catarrh. The same writer⁵ has found that Lucae's vibrating sound applied to the membrana tympani in chronic catarrhal deafness has better effect after tenotomy of the tensor tympani than before it. Wegener⁶ claims to have produced good results in sclerosis of the mucous membrane of the drum-cavity by means of gentle pneumatic massage, the tinnitus especially being relieved. [This instrument acts like the well-known Siegle pneumatic speculum.]

A. Iljisch⁷ draws attention to a form of "**double massage**" for the treatment of chronic catarrhal otitis media, consisting of inflation of air into the drum-cavity, by a catheter, at the same moment that the membrana tympani is drawn outward by rarefaction of the air in the external auditory canal, by means of a simple arrangement of rubber ball and tubing worked by the hand. Instead of the hand, an electric motor may be arranged to effect the pumping for the rarefaction. [Pneumomassage may be of the greatest value in the treatment of chronic catarrhal otitis media, but phonomassage, or massage with a pressure-sound, is not only irrational, but usually injurious.]

Stapedectomy.—C. De Rossi⁸ reports his observation of stapedectomy in 4 four cases of hyperplastic catarrh of the middle ear with ankylosis of the ossicula. [While no good results seem to have been obtained by the operation in the above-named cases, no harm occurred to the patients.] The operations were performed in the ear clinic of the University of Rome. According to the observations and data accumulated by C. Grunert,⁹ there is little to hope for the betterment of the hearing in the removal of the stapes in cases of ankylosis between the stapes-foot-plate and the vestibule (oval window). E. B. Gleason¹⁰ reports benefits to hearing from tenotomy of the stapedius, section of the incudostapedial joint, and mobilization of the stapes. The operations are performed under local anesthesia of the membrana by cocaine.

Removal of the Incus.—Chronic tympanic vertigo (Ménière's symptoms), a paroxysmal condition of impaction of the stapes in the oval niche and compression of the labyrinth-fluid, the compensatory yielding of the round window membrane being inhibited by its rigidity, induced by the catarrhal state of the mucous lining of the tympanic cavity, can be entirely re-

lieved by the surgical removal of the incus, and the consequent liberation of the stapes, as shown by C. H. Burnett¹ in a report of 26 cases operated upon by him.

CHRONIC PURULENT OTITIS MEDIA.

Tuberculous otitis media is said by H. Monscourt² to occur in 3 different forms: 1, the subacute; 2, the chronic; and, 3, the acute form. The latter is rare. Heuss³ recommends **xeroform** as an insufflation-powder in otorrhea. W. Cheatham⁴ has found the instillation of 10 drops, 2 to 3 times daily, of a mixture of dilute **hydrochloric acid**, 10 drops, with 1 fluidounce of **pyrozone**, to effect a cure of chronic suppuration of the middle ear, even in attic complication, in a short time. **Camphorated salol** is employed with advantage in purulent otorrhea of children, by Campo and Compaired.⁵ W. H. Fritts⁶ reports a case of chronic otitis media with great tissue-destruction in both ears, in which excellent results were finally obtained by a careful, judicious **local antiseptic method** combined with tonics, after the removal of the malleus and sequestra from the right ear. Zeroni⁷ discovered in a polypus which he removed from the chronically suppurating ear of a girl of 16, true **cholesteatoma**. He says that though such an occurrence has been observed before, it is a rarity. After the removal of the polypus and treatment of the ear the suppuration soon ceased. R. E. Moss⁸ demonstrates by notes of 3 cases the advantages of free exposure of the middle-ear cavities in chronic purulent otitis media, and in 1 case the advantage of simpler methods, like instillations of strong solutions of nitrate of silver.

Rueda,⁹ in an article on the conservative treatment of **attic suppuration**, admits that after months of unsuccessful conservative treatment by means of the curet, injections with the tympanic syringe, etc., surgical removal of diseased bonelets is the only hopeful method of cure. He also thinks prompt operation by removal of diseased bonelets will obviate the necessity of the more heroic operations of Stacke, Zaufal, and others upon the attic by way of the mastoid. [This corresponds entirely with our experience in attic suppuration.]

Excision of Necrotic Ossicula.—J. H. McCassy¹⁰ demonstrates the importance and advantages of treatment in both acute and chronic suppuration of the middle ear. In 1 case he reports prompt and entire cure of chronic purulency by excision of the remnants of the chronically inflamed membrana, malleus, and incus. Bing¹¹ reports cure of chronic suppuration after removal of the malleus in a case which defied all other treatment. The hearing became very good. C. Grunert and E. Leutert,¹² in a report on excision of the diseased ossicula in chronic purulency of the ear, as observed in the clinic of Halle, state that such operation, if it did not result in a cure in a few months, was succeeded by the Stacke operation for exposure and evacuation of the attic and antrum. [This is very surprising to us, as we have waited patiently as long as a year before rewarded by seeing entire cure of the purulency by excision of necrotic tissue in the drum, by way of the auditory canal.]

¹¹ Aust. Otol. Soc.; Jour. Laryn., Rhin. and Otol., Oct., 1896.

¹² Arch. f. Ohrenh., June, 1897.

J. A. Stuckey¹ reports the good effect of excision of the diseased ossicles and membrana in chronic suppuration of the middle ear. E. J. Moure² demonstrates the advantages of generous surgical exposure of the middle-ear cavities and removal of ossicles in 59 cases of chronic suppurative otitis media.

H. Schwartze³ presents the following conclusions respecting caries of the ossicula and the operations indicated: 1. When isolated caries of the ossicula is diagnosed, extraction of the diseased ossicula by the external auditory canal is indicated; 2. When the existence of isolated caries of the ossicula is doubtful, extraction of the diseased ossicula through the external meatus should be performed, as it is a minor and less destructive operation than that through the mastoid, and in any event, even if it does not effect a cure, the removal of the diseased ossicles lessens the danger of retention of pus in the epitympanic cavity; 3. When caries in the antrum or cholesteatoma is present in addition to caries of the ossicles, the extraction of the ossicles through the external meatus should not be relied upon, but a radical operation for the exposure of all middle-ear cavities should be performed immediately.

Ferri⁴ has contributed an excellent article on the extraction of the malleus and incus in chronic suppuration of the middle ear, and in lesions the result of chronic suppuration of the middle ear; 45 cases were operated upon with the following results: chronic suppuration: 24 cured; 5 improved; 1 unchanged. In the lesions following chronic suppuration, 15 cured.

Urbantschitsch⁵ has demonstrated that in 8 cases of the radical or Stacke operation on chronically suppurating middle-ear cavities good results were obtained notwithstanding the closing of the retroauricular opening. Again, Urbantschitsch⁶ reports his results and experiences based on the surgical exposure of the middle-ear cavities in 12 cases. "Operative exposure of the middle-ear cavities—the so-called radical operation of the middle ear—consists in the formation of a wide communication between the auditory canal and the drum-cavity on the one side, and the mastoid antrum and varying areas of the mastoid process on the other, so that all these parts are thrown into a common cavity. At the same time the malleus, incus, and the remnant of the membrana tympani are removed and the posterior wall of the cartilaginous auditory canal is split and thrown back, so that from the entrance to the ear the tegmen tympani and mastoid antrum are brought into view and rendered easily accessible to necessary treatment."

This author observed among his cases 6 in which necrotic disease had exposed the dura mater of the cerebellum, and 3 in which it had exposed the dura mater of the temporal lobe over the tegmen tympani. In all of the latter cases the disease penetrated the dura, and portions of the brain-tissue escaped into the middle ear and were syringed out at the meatus in one case. This case got entirely well after surgical exposure of all diseased parts. In another case the cerebellar dura was penetrated by the necrotic disease and portions of cerebellar tissue escaped through the middle ear. In this case, too, entire recovery ensued after surgical exposure and cleansing of the diseased middle ear and cranial tissues.

"Operative exposure of the middle-ear spaces affords us the important information that frequent grave and far-reaching destruction induced by various middle-ear affections may penetrate to the brain and the sinus, not only with-

⁶ Wien. klin. Woch., July 16, 1896.

out striking symptoms, but even in the midst of those of perfect health, so that it is only when the diseased nidus is exposed by operation that the real danger in which the patient stands is fully shown. The more cases of chronic purulent inflammation of the middle ear, and also cholesteatoma of the middle ear, that are subjected to this radical operation, the more plainly is the great worth of the operation shown. Furthermore, as experience teaches that the operation is usually well borne and is followed by the best effects in the most varied conditions, we may conclude that the operative exposure of the middle-ear cavities is one of the most valuable of otiatric interferences."

A. Politzer,¹ in 53 cases of chronic suppuration of the middle ear, has exposed the middle-ear cavities by surgical operation. In 17 instances the suppuration stopped at once; 6 patients died, 3 from pyemia existing before the operation, 2 from chronic tuberculosis, and 1 from cerebral abscess existing before the operation on the ear. The rest of the 53 cases remained under observation. [To say the least, these measures in cases of chronic otitic suppuration are plainly indicated as prophylaxis of deeper cranio-otic lesions.] Mongardi² reports the good effects of exposure of the middle-ear cavities by the Stacke-Küster method. The chronic purulency was cured and the hearing restored. A case of chronic purulency of the middle ear of 3½ years' duration after scarlatina, in a child 7 years old, which yielded only to complete surgical exposure of the middle-ear cavities, is reported by Gomperz.³ The tympanic antrum was found full of cholesteatomatous material, granulations, and pus.

A. Politzer⁴ reports a reduction of otorrhea, existing from birth, in a woman of 30, after surgical exposure of the middle-ear cavities, and the removal of granulations, pus, and sequestra, one of which was the modiolus and the lamina spiralis ossea of the cochlea. O. Barnick⁵ reports 20 cases of surgical exposure of the middle-ear cavities in Habermann's clinic, in Gratz. In one-half of these cases simple caries of the bone was present, while in the rest of the cases cholesteatomatous masses were found in addition to the carious process. The retroauricular opening is maintained only when the bone has been largely destroyed by the cholesteatoma, and the opening shows no marked tendency to close by granulations. As a rule, these operators endeavor to bring about a closure of the tympanic mouth of the Eustachian tube by cauterizations during the after-treatment in order to prevent the subsequent passage of septic matter from the nasopharynx to the middle ear. Max Toeplitz⁶ reports 5 Stacke operations in 2 years for the relief of chronic purulency of the middle ear; 2 have recovered entirely and 3 are greatly improved and bid fair to be soon entirely cured. E. J. Moure⁷ admits the advantages of intratympanic surgery in chronic purulent otitis media, but cannot admit that ossiculectomy is of benefit in the progressive deafness of sclerosis or dry chronic otitis with arthritis or ankylosis of the stapes. H. A. Alderton⁸ has devised an antrotome for the accurate performance of mastoid antrotomy in chronic purulent otitis media. [An ingenious instrument, but only to be used with safety in an antrum and mastoid cavity in which the lateral sinus lies far behind. The position of the latter cannot be positively known until the mastoid is opened by a chisel or a hand drill carefully managed.] J. Habermann⁹ points out the important fact and illustrates it by 5 cases,

¹ Aust. Otol. Soc., June, 1896; Ann. des Mal. de l'Oreille, Jan., 1897.

⁹ Arch. f. Ohrenh., Apr., 1897.

that purulent disease of the middle ear may pass directly from the tympanic cavity by a carious process directly into the labyrinth and the petrous pyramid. 4 of the cases referred to proved fatal, 1 from meningitis and thrombophlebitis, and 3 from pyemia; the fifth was successfully operated upon for an abscess 1 cm. in diameter which lay in the *petrous part of the temporal bone*, over the bulb of the jugular.

MASTOIDITIS.

Acute Mastoiditis.¹—A. H. Cheate² claims that “on examining the formation of the ‘mastoid’ antrum in fetal life it can be clearly seen that it is a definite and regular part of the middle ear.” A. Broca³ draws attention to the fact that furuncle near the ear, accompanied by lymphangitis, may be mistaken for mastoiditis. Primary inflammation and abscess of the mastoid are reported by Dunbar Roy.⁴

Chronic Mastoiditis.—Latent otitic mastoiditis presenting the appearance of trigeminal neuralgia has been reported by R. Spira,⁵ and “latent” mastoid disease in which the external symptoms are slight in comparison to the deep underlying mastoid lesions, is described and illustrated by 3 cases by E. Fridenberg.⁶ Chincini⁷ regards the wholesale condemnation of the so-called Wilde’s incision, as expressed by Duplay, and later by Chipault and Demoulin (see *Year-Book* for 1896), as unjustifiable, since it is not sustained by facts, and is too theoretical. [Wilde’s incision is useless unless there is periostitis of the outer mastoid table or pus beneath the soft tissues over the mastoid.] “When the symptomatology of mastoid disease is obscure the indication is to operate, not to delay. The mastoid operation is harmless; delay may be fatal.”⁸

A. Bronner⁹ delineates the indications for **surgical treatment** of diseases of attic and mastoid as set forth by Schwartz: 1. In acute primary or secondary inflammation of the mastoid process, if under antiphlogistic treatment the symptoms of pain, tenderness, and fever do not improve in a few days; 2. Chronic inflammation of the mastoid process, with recurrent attacks of swelling; 3. Fistula over or near the mastoid process; 4. Chronic inflammation (purulent) of the middle ear without apparent affection of the mastoid process if there are any symptoms of retention of pus, or of diseased bone (pain, fever, etc.), or if there is a cholesteatoma; 5. Persistent pain over the mastoid process; 6. Chronic otorrhea without any symptoms of retention of pus or swelling of the mastoid process, as soon as we have reason to think that the inflammation has spread beyond the middle ear.

Purulent inflammation of the middle ear with surgical perforation of the mastoid cells, followed by erysipelas and recovery, has been reported by Kipp.¹⁰ O. Barnick¹¹ reports 18 cases of simple perforation (Schwartz’s method) of the mastoid in Habermann’s clinic, in Gratz, 14 of which recovered. One of the cases died of intercurrent pneumonia and one died of scarlatinous nephritis. Barnick¹² also reports a case of extensive destruction of the temporal bones after scarlatina, in a child. The mastoid cavities were opened freely on both sides, and granulations, sequestra, and the diseased tissues, extending even into the

¹² Ibid.

internal ears, removed. The patient recovered her health, but the hearing was irrevocably destroyed by the extensive necrosis.

M. D. Lederman¹ reports extensive necrosis of the petromastoid bone following chronic suppurative otitis media on the right side in a deaf-mute woman of 62. After the disease had lasted 9 months facial paralysis occurred suddenly on the right side. A mastoid operation was indicated, and performed at the end of a year of chronic aural suppuration. At this operation, in "clearing out the upper and posterior portion of the antrum and cells, the finger encountered the dura mater." After the operation exposing the middle-car cavities there was improvement for a month, when sudden hemorrhages from the ear, nose, and mouth, preceded by paralysis of the left leg and arm, ended the patient's life. It seemed plain in this case that long and extensive disease had existed within the ear and cranium without much external manifestation. Softening of the lower portion of the right temporosphenoidal lobe of the brain was found postmortem, accounting for the paralysis in the leg and arm of the left side.

Lake² proposes in Stacke operations on the mastoid to pave the floor of the artificial opening between the external ear and the antrum with skin of the meatus only, the cartilage being dissected off at the time of the operation. A. C. Smith³ reports uniform success in 13 mastoid operations, and Dunbar Roy⁴ reports a case of primary inflammation and abscess of the mastoid, occurring in a negro girl 10 months old. B. Gomperz⁵ reports a successful radical operation with Koerner's autoplasty, upon a case of mastoid caries in a young girl. Grunert and Leuter⁶ report 87 cases of mastoid operation in Schwartz's clinic, in Halle, for the year ending April, 1897. Of these, 46 recovered, in 21 the result is unknown, 7 were still under treatment, 8 were not cured, and 5 died of intracranial complications. H. L. Swain⁷ reports two instances of purulent inflammation of the mastoid cells, followed by epidural abscess and relieved by trepanation. Stern⁸ opened the mastoid in a case presenting nervous phenomena. The sinus appeared healthy, but later the jugular vein became painful and the region infiltrated. Finally an incision into this tumefaction liberated pus, and recovery ensued without further operation. Hemorrhage from the carotid sinus during an operation on the mastoid was observed by Bloch.⁹ This patient died 14 months later of hemorrhage from the carotid.

Sheibe¹⁰ has operated successfully on the mastoid under local anesthesia by chlorid of ethyl. The antrum and an extradural abscess in the posterior cerebral fossa were exposed without causing any pain. In 6 other cases of mastoid disease chlorid of ethyl was used successfully as a local anesthetic in 5, general anesthesia being necessary in 1. Abscess of the mastoid extending along the course of the lateral sinus, with pus resting on the dura, but without any local or general symptoms beyond fulness in the head, and entirely relieved by operative exposure of the mastoid cells and sinus region, is reported by W. G. E. Flanders.¹¹ C. J. Blake¹² obviates the objections to a drill in mastoid operations by the "use of a long, broad-bladed drill, cutting at an obtuse and not at an acute angle, rotated with one hand and held firmly with the other at a point so near the blade that a very slight deviation of the operative end is represented by a wide and easily appreciable movement of the

handle." The preliminary opening in the cortex made with this drill is to be enlarged with a chisel.

Lichtwitz¹ reports a case of **Bezold's mastoiditis** (burrowing of pus from the mastoid into the neck) successfully operated upon. The cervical abscess was opened first, then the antrum and mastoid cells. H. du Fougerey² has observed that abscesses of the neck, consecutive to acute and chronic inflammations in the middle ear, form in 3 ways: 1. Abscess by direct irruption of pus into the tissues of the neck; 2. Abscess by way of the veins; 3. Abscess by way of the lymphatics. Luc³ reports a case of Bezold's mastoiditis (perforation of the medial plate into the cervical region) terminating fatally with symptoms of encephalic abscess. An operation was not permitted and there was no postmortem. H. L. Swain⁴ observed a trapezius abscess the result of spontaneous perforation of the inner and posterior wall of the tip of the mastoid, that had become diseased from chronic purulent otitis media. Entire recovery followed complete trepanation of the mastoid and drainage of the abscess by counter-openings.

CHOLESTEATOMA OF THE TEMPORAL BONE.

H. Schwartze⁵ discovered at a postmortem a true **cholesteatoma of the squama** in a man of 41, who had died of pulmonary phthisis. There was no trace of cholesteatoma in any portion of the middle ear. The origin of the growth in this case was probably from an embryonal offshoot of laminated epithelium. During an operation by A. Kuhn⁶ on the mastoid for the removal of a cholesteatoma death occurred by the entrance of air into the injured sigmoid sinus, as shown by finding air in the right ventricle at the autopsy. He suggests that keeping fluid over the opening in the sinus would tend to prevent the entrance of air into the circulation. R. Sattler⁷ observed a case of secondary cholesteatoma of the mastoid in a girl of 17, relieved by trepanation and evacuation of the growth. The opening behind the auricle was maintained.

Spontaneous recovery of true cholesteatoma and cholesteatomatous retention-cysts, without retroauricular openings, is pointed out by K. Redmer.⁸ Four illustrative cases are given, and the author concludes that all such masses of whatsoever nature ought to be removed by Zaufal's method, if operation is resorted to, without a permanent retroauricular orifice. He also thinks that surgical closure of the Eustachian tubes, according to Hang's suggestion, is not necessary for the permanent cure of cholesteatomatous cavities, as shown by one of Redmer's cases, in which a cure had persisted for 10 years, with entirely patulous Eustachian tubes. Koerner,⁹ too, reports spontaneous recovery of cholesteatoma without permanent opening, as after Zaufal's operation. A. Politzer¹⁰ reports a case of cholesteatoma of the middle ear, with pyemic symptoms, cured by operative opening of the cavities of the middle ear. He is in favor of maintaining a permanent opening behind the auricle, in order to be able to remove any recurrent cholesteatomatous flakes which may form. J. Gruber,¹¹ however, is of the opinion that in the case of small cholesteatomatous collections in the tympanum, and even in the antrum, all desired

results can be obtained in the majority of cases by removal of the pars eptympanica. In the case of large ones in the mastoid there would be absolute necessity for free opening of the mastoid process and the maintenance of the aperture.

Guranowski¹ observed, in a man who had suffered from childhood with chronic purulency of the ear, cholesteatoma filling the drum-cavity, the attic, and the antrum, which were found to have been converted into one cavity by natural processes. This circumstance had acted as a prophylactic against encroachment of disease upon the cranial cavity. P. Bolewski² detected cholesteatoma in the middle-ear cavities of a child of 7. Thorough surgical exposure of these cavities and evacuation of the nonsuppurating cholesteatomatous masses were followed by entire recovery, without a permanent opening behind the ear.

INTRACRANIAL COMPLICATIONS OF OTITIS.

A quotation from A. Broca³ will form a proper introduction to this subject: "When an otitis improperly treated passes into a chronic state it frequently leads to the death of the patient by an intracranial complication. This complication will be, according to the nature of the ear-disease, an acute meningitis, a thrombosis of the dural sinuses, an abscess situate between the petrous bone and the dura, or an abscess in the cerebrum or in the cerebellum. Frequently several of these lesions are associated, constituting a malady beyond the reach of art. At the onset this complexity is not present, and the diagnosis of the solitary or predominant lesion is often possible and some of the lesions are surgically curable."

T. R. Pooley⁴ claims that the condition of the fundus of the eye often confirms a diagnosis of otic intracranial disease arrived at from other symptoms, and sometimes is the only symptom. If optic neuritis is found, the diagnosis of extension of ear-disease to the brain is certain, no matter whether other evidence exists or not. Unfortunately, optic neuritis does not explain the nature of the intracranial lesion. Marked optic neuritis alone occurring in chronic otorrhea is sufficient indication for opening the mastoid, even when only a slight optic edema exists. Optic neuritis as an indication for exploratory opening into the cranium, in otitic lesions, can be considered only in connection with other symptoms. It seems, however, to make the presence of other intracranial disease more certain.

Lumbar Puncture in Otic Intracranial Lesions.—E. Leutert⁵ contributes a most interesting article on the "Importance of Puncture of the Lumbar Spinal Cavity in the Diagnosis of Intracranial Complications of Otitis," based on 11 cases in which the method was employed in the differential diagnosis between diffuse meningitis and abscess of the brain, apparently with considerable advantage. [The operation of puncturing the lumbar rhachitic space seems to be attended with no disadvantage.]

Sinus-thrombosis.—Fever extending over several days in an acute otitis media, after cessation of the first acute stage, free discharge of pus from the drum-cavity continuing, and also especially in the course of a chronic purulent otitis media without an acute process and without great retention of pus in the drum-cavity, continuous high fever is practically an unmistakable evidence of the existence of a sinus-affection, according to the observations of

¹ Arch. f. Ohrenh., June, 1897.

² Ibid.

³ Ann. des Mal. d'Oreille, Nov., 1896.

⁴ Med. Rec., Aug. 15, 1896.

⁵ Münch. med. Woch., Feb. 23, 1897.

Leutert.¹ The same eminent observer has formulated the following conclusions:² "1. An otogenous pyemia without sinus-thrombosis has never yet been observed. 2. The occurrence of such a disease is so improbable as not to enter into diagnostic consideration. 3. The variety of metastases occurring in sinus-thrombosis, both in acute and in chronic aural suppuration, is explained by the different quality of the thromboses, especially whether tubular or solid. 4. Therefore, immediate surgical exposure of the sinus is advised in every case of empyema of the mastoid process occurring after acute otitis media, if, after the acute stage has passed and the escape of pus from the drum-cavity is ample, fever of 30° C. (102.3° F.) and over sets in. 5. In recent cases the result of this must be awaited. If the fever does not abate by the 3d day, or if after abatement of the fever for a short time the temperature again goes up, either with or without a chill, the sinus should be immediately opened. 6. If the case has become subacute and high fever has been present for some time, especially, however, if to a chronic suppuration without marked mastoid implication continued high fever for several days occurs, and diffuse meningitis can be excluded by lumbar puncture, then too must the sinus already exposed by operation be laid open. (Exception: When there is perisinuous suppuration confined under high pressure, which condition can sometimes cause fever, even if not as high as that caused by thrombosis.) 7. In young children the diagnostic value of high fever is not so great, but the possible presence of sinus-thrombosis must be kept in view. 8. Isolated thrombosis of the bulb of the jugular vein generally occurs indirectly through the agency of microorganisms which have passed from the diseased sinus-wall and have found in the jugular bulb favorable conditions for lodgement and the formation of a thrombus on the intima. 9. Exploratory puncture of the sinus is of value only when the result is positive."

E. B. Dench³ reports a successful exposure and removal of a thrombosis of the lateral sinus, on the fifth day after the acute inflammation in the middle ear. A. Broca⁴ observed an acute otitis followed by mastoiditis and a collection of pus surrounding the lateral sinus in a child of eight. Evacuation of the pus-cavity, by surgical exposure, through the mastoid, and packing with iodoform-gauze were followed by prompt recovery. J. L. Adams⁵ reports a successful operation in a similar affection of the lateral sinus, the result of *septic* treatment of an acutely inflamed ear. Prompt recognition of the disease and operative relief of the thrombosis resulted in entire recovery. Wall⁶ reports a case of lateral sinus-thrombosis, with operation and recovery. The patient was diabetic. A case of septic otitic sinus-thrombosis cured by operation is reported by Zaufal.⁷ Ligation of the jugular was performed in this case. Denker⁸ reports a case of otitic sinus-phlebitis and metastatic purulent pleurisy cured by operation first on the mastoid and the sinus, though the firm, cheesy clot found in the latter was let alone, and then in three days on the chest by resection of the sixth rib in the anterior axillary line, with the evacuation of a liter of fetid pus. A. J. Horsey⁹ reports a case of chronic suppuration of the middle ear, mastoid infection, sigmoid sinus-thrombosis, septic pneumonia, and death. A mastoid operation, and five days later trepanation over the temporosphenoidal lobe, failed to save life. [It seems to us, from perusal of the notes of this

⁹ Canada Lancet, Apr., 1897.

case, that the only hope of success in operation lay in prompt and thorough exposure of the lateral sinus at the time of the mastoid operation, or perhaps before that time.]

A. Broca¹ observed thrombosis of the lateral sinus without cervical swelling as the result of chronic otorrhea in a boy of 12. An operation upon the apophysis and sinus failed to relieve, as general pyemia induced a fatal gangrenous pneumothorax, surgical intervention having been delayed too long. The same observer² successfully operated in a case of lateral sinus-thrombosis, with phlebitis of the jugular, by simple disinfection of the sinus and vein, the latter being ligated. The sinus-disease was the result of chronic purulent otitis media. Necrosis of the petromastoid portion of the temporal bone, producing perforation into the middle and posterior cranial fossæ, with softening of the temporosphenoidal lobe of the brain and ulceration of the sinus, with fatal hemorrhage, is reported by M. D. Lederman.³ Mayo Robson and Herbert Keighley⁴ report a case of mastoid suppuration followed by lateral sinus pyemia, successfully treated by partial excision of the sinus and ligation of the internal jugular vein in the neck.

Extensive, noninfected thrombosis of the several sinuses of the brain, and of the jugular vein, due to operative injury of the lateral sinus, followed by recovery, is reported by R. Hoffman.⁵ There was also in this case crossed facial paralysis supposed to be due to cerebral congestion, as there were on the right side opposite the affected ear and sinus optic papillitis and edema of the lids. [We venture to suggest that the optic and facial symptoms on the right side may have been due to stasis induced by the thrombosis of the left lateral sinus and extending through the torcular around to the right lateral and ophthalmic sinuses.] K. Weissgerber⁶ reports a case of sinus-thrombosis, following acute otitis media, cured by exposure of the diseased sigmoid sinus, and then four days later by ligation of the nonthrombotic internal jugular vein. Two cases of sinus-thrombosis with marked involvement of the internal jugular vein, the result of chronic suppuration of the middle ear, are reported by the same writer as unrelieved by operation, death occurring from embolic abscesses in the lungs. [These cases show that in the acute form prompt surgical interference offers great hope of saving the patient, while delay in operating in any case, permitting the disease to extend beyond the diseased sinus, is fatal to the patient.]

In a boy of 14 chronic purulency of both ears resulted fatally, notwithstanding free surgical exposure of the middle-ear cavities on both sides and of the sinus on the right side. The autopsy revealed cholesteatoma of the left antrum, inflammatory thrombosis of the right transverse, the right inferior petrosal, and basilar sinuses, and of the jugular vein. There were also purulent infiltration of the muscles of the neck, lung abscesses, and purulent infarction of the lungs. Grunert and Leutert,⁷ who report this case, say that the diagnosis of sinus-thrombosis was made very late in this case, as the fever was not very high at first. They also claim that meningitis could have been excluded, and the diagnosis of sinus-thrombosis differentiated by lumbar puncture. Chronic purulent otitis media in a tuberculous child of 7, resulting in fatal thrombosis of the right transverse sinus, is reported by Grunert and Leutert.⁸ In this case both ears and mastoids were affected, and the middle-

ear cavities on both sides were exposed by a Stacke-operation. A cysticercus was found in the pia mater at the base of the brain.

Otogenous Pyemia.—O. Brieger¹ has contributed a most valuable article on otogenous pyemia. He shows that this disease may occur under three different forms: 1. Without sinus-phlebitis; 2. With thrombophlebitis of the lateral sinus; 3. With thrombosis of the cavernous sinus. The first-named form is rare, and usually appears as a dermatomyositis, without muscle-abscesses. It may also appear as an osteophlebitis without involvement of the lateral sinus (Körner). In the latter form the metastases are rarely located in the lung, while arterial emboli are observed much more frequently than in sinus-phlebitis. H. Hessler's² recent article substantiates Körner's statement that a large group of cases of otogenous pyemia, which differ clinically by the absence of all local symptoms of sinus-thrombosis, by the greater benignity of the entire disease-picture, by the unity of pulmonary metastases and relatively frequent metastatic joint- and muscle-involvement, indicate a special classification.

This classification is not impaired by the occasional occurrence of pulmonary abscesses, as is shown by a case reported by Brieger, and also by one reported by C. H. Burnett.³ Brieger states that "in operation on the mastoid undertaken during the early days of the disease the subjective mastoid symptoms were lessened, but the general condition was not only repeatedly uninfluenced, but increased fever and chills were observed. The local course was also more unfavorable and more tedious than usual in cases operated upon before the inflammation had reached its height and pus was demonstrable."

In speaking of pyemia with thrombophlebitis of the lateral sinus, the second class named above, Brieger says that while the treatment of sinus-phlebitis has improved, no great advance has been made in its diagnosis. "The most weighty indication of its existence, according to our present knowledge, has been the general evidence of pyemia." The temperature-curve, however, in sinus-phlebitis does not always follow the pyemic type. This form of pyemia is often confounded with typhoid fever, malaria, and tuberculosis. Peptone has been found in the urine in this form of pyemia, disappearing after successful operation on the sinus. "Among the most important symptoms of sinus-phlebitis are changes in the background of the eye." Griesinger's symptom—circumscribed, hard infiltration extending backward from the posterior border of the mastoid—is not considered by Brieger pathognomonic of sinus-thrombosis. Extension of the thrombosis to the jugular vein is occasionally directly perceptible, but swelling and sensitiveness along this jugular tract must be taken with caution, as Schwartz has observed these symptoms without coexisting inflammatory change in the vein, the sensitiveness in this region being due to changes in the lymph-plexus near it. The diagnosis of sinus-thrombosis is still obscure. Brieger, in common with H. Hessler, J. O. Green, E. A. Crockett, and others, deem prompt exploratory exposure of the sinus in suspected sinus-phlebitis as entirely justifiable and much more advantageous to the patient than waiting for positive symptoms of the presence of sinus-thrombosis, when it is generally too late to operate with any hope of relief. An exploratory incision may be more advantageous than an exploratory puncture and aspiration of the sinus. Sinus-thrombosis may be cured by clearing out the primary pus-collection and evacuating the pus which bathes the sinus. Mere pulsation of the exposed sinus does not preclude the presence of a thrombus within, as this pulsation

¹ Arch. of Otol., Oct., 1896.

² Arch. f. Ohrenh., Bd. xxxviii.

³ Trans. Am. Otol. Soc., 1883.

is due to the impression made upon its walls by the general pulsation of the cranial sinuses.

Ligation of the jugular is unquestionably justified only when it is locally indicated. . . . The systematic application of ligation as an integral part of the operative therapy of sinus-phlebitis is not justified. It is an error in pyemia without sinus-phlebitis. . . . The principal point, in Brieger's opinion, in deciding as to whether or not the vein should be ligated, is dependent upon the local findings in the vein itself, or at least at the cranial end of the thrombus. The sole contraindication for the operation, aside from the conditions of the heart, Brieger believes to be purulent leptomeningitis, the presence of which is to be demonstrated not only by diffuse meningeal symptoms, which under certain circumstances accompany sinus-thrombosis, but most certainly by spinal (lumbar) puncture.

The third form of otitic pyemia characterized by thrombosis of the cavernous sinus requires, according to Brieger, a special classification in contradistinction to lesions of other cranial sinuses. Körner has shown that this form of thrombosis is due frequently to the passage of infection from the middle ear, by way of the carotid canal, to the cavernous sinus. While no one symptom may be considered positively pathognomonic of its existence, the occurrence of edema about the brow and orbit, exophthalmos, paralysis of the ocular muscles, immobility of the eyeball, edema of the lids, chemosis of the conjunctiva, and often choked disk on the side of the chronic aural suppuration, justify the surgeon in concluding that he is confronted with thrombosis of the cavernous sinus.

The only treatment so far successful is prompt exposure of the middle-ear cavities, opening freely the *lateral* sinus, and permitting judicious hemorrhage in the hope that the normally forcible blood-current in the sinuses will eject the thrombus either at the artificial opening in the lateral sinus or throw it into the general circulation, when, if not infectious, it may be dissolved without metastases. Brieger reports one case, a man of 22, in which recovery ensued rapidly after generous opening of the *lateral* sinus, though all the above-named serious symptoms were present before the operation. Isolated otitic thrombophlebitis of the cavernous sinus has not been successfully treated by the Krause method of exposing it as for intracranial resection of the trigeminus. The sinus has been repeatedly reached and injured by Krause, Finney, and Czerny in trigeminus resection.

E. Rimini¹ observed a case of pyohemia consecutive to an acute purulent otitis media, following diphtheria, in a child of 3. One injection of serum No. 1, of Behring, had caused the disappearance of the false membranes in the fauces, in 3 days. Ten days later, symptoms of scarlatina ensued, with aural pains and suppuration, and in six days later death supervened after general pyemic symptoms. A. Politzer² reports recovery after otitic pyemia. First, there was an operative exposure of the mastoid cavity and the lateral sinus; later, there was thrombosis of the jugular vein, with phlegmonous inflammation about it. On the 22d day purulent metastasis occurred in the elbow-joint, when all rigors ceased and recovery set in. J. H. Clayton³ reports a case of peripetrous suppuration resulting from chronic purulent otitis, mastoid caries, and involvement of the lateral sinus on the left side. A small abscess in the temporal lobe near the sinus was found after death, and pus had found its way from the mastoid over both surfaces of the petrous

¹ Berlin. klin. Woch., July 6, 1896.

² Aust. Otol. Soc., 1896; Jour. Laryn., Rhin. and Otol., Oct., 1896.

³ Birmingham Med. Rev., Aug., 1896.

bone and into the left orbit. F. W. Maekenzie¹ reports a fatal case of otitic pyemia in a man of 39. An operation on the mastoid and lateral sinus was suggested promptly, but rejected by the patient, who succumbed in three weeks after the initial pyemic symptoms. Well-marked otitic pyemia, terminating apparently in embolic abscess of the liver, is reported by M. D. Lederman.²

A case of otitic pyemia cured by excision of the thrombosed internal jugular vein is reported by H. Eulenstein.³ This operation was performed 3 days after surgical exposure of the middle-ear cavities, the lateral sinus, the posterior cerebral fossa, and the evacuation of a large pus-cavity near the jugular bulb. Chills and fever continuing after this operation, the ligation was considered as the last resort, though there were no external symptoms pointing to its thrombosed condition. F. P. Hover⁴ reports the case of a man of 47, who suffered with great pain and tumefaction of the left side of the head. Incision into this region gave vent to a quantity of pus, and finally dead bone and granulations were removed; but the temperature of the patient rose to 105° F., coma supervened, and the man died 10 days after the above operation. The autopsy revealed a purulent thrombus in the left lateral sinus extending back as far as the torcular and forward into the superior petrosal sinus, the inferior petrosal being normal. E. Rimini⁵ reports a case of pyemia following acute otitis media of a benign form. The patient was a child of 7. The mastoid was opened, but showed no disease. The sinus was then opened and pus escaped. Thrombi were found and removed, but the sinus was free from pus. Recovery finally took place in three months. A case of septic otitic thrombosis of the sigmoid sinus cured by ligation of the jugular and laying bare the sinus is described by Zaufal.⁶ Notwithstanding metastatic abscesses in the glutei muscles of the left side and purulent pleurisy entire recovery ensued in six weeks. W. Ridley⁷ has reported "middle-ear" pyemia cured by ligation of the internal jugular vein, and removal of a fetid clot from it. An epidural abscess was also opened, and the lateral sinus, blocked only in its mastoid portion, was cleaned out, and recovery ensued. W. R. H. Stewart⁸ reports a case of pyemia following middle-ear suppuration in a boy of 11. With vomiting, rigors, and a temperature of 97°, the antrum was laid open, with temporary relief. The lateral sinus was then explored and found to contain a healthy clot. The dura was incised, letting out a large quantity of serous fluid. Rigors still continuing, the lateral sinus was slit, the healthy clot removed, and then recovery took place.

Otitic Meningitis.—E. B. Dench⁹ reports a case of otitic meningitis occurring as a result of chronic suppuration in the left ear of a man of 60. For 3 weeks the patient suffered from dizziness and pain in the left ear and corresponding side of the head, without elevation of temperature. Suddenly at the end of this time the temperature rose, the other symptoms continuing. Dench then etherized the patient and opened the cranial cavity so as to expose that part of it immediately above the drum-cavity. The tympanic roof was found roughened and bloody serum escaped from the epidural space; a dural flap was turned down, and the aspirator thrust into the brain-substance, but no pus was found. The dural flap was then replaced and the lateral sinus was explored in both directions, but was found to contain fluid blood. The evacuation of the bloody serum from the epidural space and the antiseptic

⁸ Ibid., Nov. 7, 1896.

⁹ Trans. Am. Otol. Soc., July, 1896.

treatment of this region and of the entire wound-cavity were followed by rapid recovery. The case was regarded as one of infective meningitis. [The latter was due probably to osteitis of infectious origin from the suppurating drum-cavity.]

Acute, diffuse, suppurative meningitis of otitic origin A. Broca¹ regards as beyond the reach of surgical art, but as often in the presence of meningitic symptoms the chief lesion is really a cerebral (epidural) abscess, he believes that an exploratory operation is demanded. He reports² 2 cases of acute otitic meningitis unsuccessfully operated upon, in one of which diffuse osteitis of the temporal bone was marked. Both patients were children of 5.

Riehl³ observed an otogenous meningitis with thrombosis of the sigmoid sinus, the tympanic cavity, antrum, and mastoid cells being filled with a dark-red jelly-like mass, but the membrana atrophic and imperforate. The origin of the disease was considered hematogenous after influenza.

Otitic Cerebral Abscess.—Luc⁴ presents an excellent review of the generally accepted laws of diagnosis and treatment of cerebral abscess consecutive to cranial suppurations—*i. e.*, in the frontal sinuses and middle ear. Lannois and Jaboulay⁵ observed in a man who had been affected with chronic otorrhea for 25 years sudden symptoms of cerebral abscess: vertigo, staggering, nausea, dysphasia, violent headaches, and hemiparesis of the right side, without rise of temperature. Sensory aphasia and homonymous hemianopsia, with preservation of pupillary reaction, pointed to the temporal lobe as the seat of the abscess. Amnesic aphasia, a symptom suggesting an abscess in the left temporal lobe, and leading to an operation, is reported by A. Kuhn.⁶ But the autopsy revealed diffuse suppurative meningitis and the sac of the spinal dura filled with pus. [Lumbar puncture would have aided in a differential diagnosis in this case.] T. R. Pooley⁷ observed a case of chronic purulent otitis media in a boy of 12, followed by mastoid periostitis, mastoiditis interna, abscess of the cerebrum, thrombosis of the lateral sinus, meningitis, optic neuritis, and death. Mastoid chiselling, removal of pus, and curetting of the cells and the antrum revealed carious destruction of the lateral sinus and exposure of the dura at that point. [As within three days of that time the choked disk in the eye on the side of the affected ear was marked and the headache increased for a month until the patient died, it seems that a deeper penetration into the cranial cavity in the tract of the sinus at the time of the mastoid operation might have been attended with the happiest results.] C. Grunert⁸ reports the occurrence of an otitic abscess of the temporal lobe, the result of chronic purulency of the ear, relieved by thorough exposure of the middle-ear cavities first, and then, a month later, by trepanation of the cranium through the squama. G. Bacon⁹ reports the successful operative treatment of an abscess in the temporosphenoid lobe on the left side, the result of chronic otitic suppuration. [The case presented an instance of the exceptional occurrence of chills, high temperature, rapid pulse, and convulsions—symptoms of thrombosis of the lateral sinus rather than brain-abscess, in which we expect subnormal pulse and temperature. There were, however, aphasic symptoms in Bacon's case, which led to the suspicion of the presence of a temporosphenoidal abscess, in spite of the apparently contradictory ones of chills, fever, and convulsions.] R. C. Myles¹⁰ reports a

¹⁰ Ibid.

case of brain-abscess, the result of chronic suppuration in the middle ear of a child 7 years old. After removal of the mastoid cortex a flexible curet was passed into the attic, and while euretting the tegmen the instrument passed without force and resistance, into the cranial cavity. This was followed by a gush of pus—more than a wineglassful. After two abscesses in the connective tissue about the mastoid, in the course of 3 months after relief of the brain-abscess, entire recovery ensued. D. Kaufmann¹ reports a case of chronic suppurative otitis media in which pyemic symptoms led to radical operative exposure of the middle-ear cavities and opening of an extradural abscess. 15 days later symptoms of cerebral compression led to opening of an abscess in the right temporal lobe, but this was followed by thrombophlebitis, meningitis, and death. Gilbert Barling² reports the occurrence of an abscess in the temporal lobe, resulting from purulent otitis, successfully operated upon, with speedy recovery of the patient. Before the operation there were unconsciousness, and paralysis of the left arm, opposite the diseased ear, as guiding symptoms of abscess in the temporal lobe. These phenomena disappeared immediately after the evacuation of pus from the brain by operation. [We are not informed that the middle-ear cavities, from which the infection of the brain originates in such cases, were cleansed and the infectious nidus destroyed. Unless this is done, if the patient survives the first attack of otitic brain-disease, he still remains exposed to the liability of further infection from the diseased ear.]

Gradenigo,³ in an article on the operative treatment of otitic cerebral abscess, shows, first, that local treatment of the ear in chronic purulency, if not based on rational surgical laws, will lead to the development of endocranial complications; whereas a rational local treatment of purulent inflammation of the middle ear will be a benefit to the patient, both in preventing the formation of endocranial complications, or leading to their spontaneous resolution if only in their initial stage, "as, for example, circumscribed foci of pachymeningitis above the tegmen tympani." In doubtful cases it is more of a risk to wait for decided symptoms of intracranial complications than to perform an exploratory operation on the cranium. The best way of approach to exposure and evacuation of an otitic abscess of the temporosphenoidal lobe is through the mastoid and then the tegmen of the antrum and tegmen tympani. If the condition of the patient makes the operation directly upon the brain imperative, the mastoid and tympanic openings may be deferred to a second intervention. When the symptoms of the patient are equally grave, but when the diagnosis of meningitis has the greater probability, the suspected region of the brain must be approached through an opening just above and in front of the osseous auditory canal.

As to whether the aural surgeon or the general surgeon should operate in cases of otitic endocranial lesions, Gradenigo says "the operator ought to possess, by frequent operations on the temporal bone, the best anatomic and pathologic knowledge of these parts, and that we cannot conceive of a modern otologist who would not be a surgeon before he became an otologist." Two cases of otitic cerebral abscess are reported by Gradenigo.⁴ In the first, a child of 6, the subject of chronic otorrhea, was attacked with symptoms of pyemia and cerebritis. Though in a comatose state, the child was etherized, the mastoid and middle-ear cavities opened, and relief given to coma and some other symptoms. Two days later an epidural abscess was opened into the middle ear by puncture of the denuded dura over the tegmen tympani. In the

¹ Aust. Otol. Soc., Oct. 27, 1896.

² Brit. Med. Jour., June 12, 1897.

³ Arch. Ital. di Otol., Jan., 1897.

⁴ Ann. des Mal. de l'Oreille, Apr., 1897.

second case, a man of 20, surgical exposure of the middle-ear cavities revealed a cerebral abscess directly over the tegmen tympani. This was punctured and evacuated through the drum-cavity. Trepanation of the squama was also performed, but no further abscess was found in the brain, and the man recovered. Urbantschitsch¹ reports what might be termed a spontaneous evacuation of an epidural abscess through the tympanic cavity after surgical exposure of the middle-ear cavities. The pus-cavity was entirely healed under the instillation of a 10% emulsion of glycerin and iodoform every other day for 3 weeks. B. A. Randall² reports the occurrence of an extradural (epidural) abscess from mastoid empyema, and states that in ten instances within a year after trephining a suppurating mastoid the earies of its inner plate was so great as to necessitate exposure of the dura and liberation of pus between it and the bone. P. Avoleo³ reports his results with craniotomy in 4 cases of otitic purulent processes within the cranium. Recovery ensued after operative relief in 1 case of cerebral abscess and 2 instances of circumscribed purulent inflammations of the dura. The operation failed to relieve in a case of diffuse purulent meningitis.

A temporosphenoid abscess, the result of chronic purulent otitis of 28 years' duration, was successfully operated upon by J. M. Cotterell.⁴ The pulse and temperature became subnormal in this case, and the cerebation very dull, symptoms indicating the operation on the brain, three days after the mastoid had been opened. N. S. Roberts⁵ reports 4 successful operations on the mastoid in children: one in a child of a year and a half, involving the middle cerebral fossa, in the form of an epidural collection of pus. An otitic brain-abscess, the sequel of chronic purulent otitis media, in a boy of 13, entirely relieved by trephining the squama, and, after the escape of an epidural collection of pus, freely incising through the healthy dura into the anterior convolutions of the temporosphenoidal lobe, is reported by J. E. H. Nichols.⁶ In this case, before entire recovery ensued, erysipelas occurred, which was greatly benefited by the local application of a saturated solution of aceto-tartrate of aluminum.

Cerebellar Abscess.—H. Schwartze⁷ observed a case of otogenous cerebellar abscess, from chronic purulent otitis, in a woman of 22. The prominent symptoms for seven weeks were intense, though intermittent, pain in the occiput, nausea and vomiting, subnormal temperature, but very rapid pulse, 100–150 (accounted for postmortem by the discovery of chronic endocarditis deformans), and varying width of pupils, the *right* being generally the wider. After death an abscess the size of a walnut was found in the *right* cerebellar hemisphere, with circumscribed lepto- and pachymeningitis interna. The rapid pulse was considered incompatible with the presence of brain-abscess, and an operation therefore contraindicated.

Macewen⁸ says "when you have a cerebellar abscess caused by a focus in the middle ear, we find that that abscess is in immediate contiguity with the lateral sinus; we do not find it occurring in other parts. If, therefore, after opening the middle ear, we find that the erosive process has taken a backward direction, and that it comes in contact with this sinus, and if the symptoms of an abscess have already been noted, then be assured that you can get at that abscess by going around this large blood-channel to its posterior surface: . . . in every case of cerebellar abscess which I have had, arising from middle-ear disease, this has been the course that it has taken."

⁸ Occidental Med. Times, Nov., 1896.

A cerebellar abscess following otitis media of four months' duration, successfully treated by operation, is reported by H. S. Walker.¹ The only symptom which may be called characteristic of cerebellar abscess was increased knee-jerk on the side of the diseased ear and abscess in the cerebellum. Acland and Ballance call attention to this symptom, as well as muscular weakness, chiefly of the arm, and conjugate deviation toward the unaffected side from weakness of the ocular muscles, as characteristic of the presence of a cerebellar abscess. Gilbert Barling² reports two cerebellar abscesses the result of purulent otitis media. In one instance there was also an extradural suppuration and in the other a second abscess in the cerebellum not reached by the operation. Both cases proved fatal. There were horizontal nystagmus in both of these cases, and paralysis of the sixth nerve in one, on the side of the diseased ear. T. Heiman³ has observed his 7th case of cerebellar abscess of otitic origin. The patient was 21 years old, had fever with morning remissions and marked cerebral symptoms. When first seen by Heiman the temperature was 37° C. and the pulse 54-48, with intense headache, especially in the region of the right occiput, the side of the more diseased ear, increased by percussion. The right pupil was the wider, there was choked disk, and the right eyelid could not be closed. There was also inconsiderable paresis of the lower facial branches. The tongue turned toward the left, there were thirst and apathy, and the speech was slow and indistinct. In a sitting posture the head fell forward, then turned toward the left and continued to move with pendulum-like oscillations. The vertigo was intense in the sitting posture and with the least movement of the head. There were paresis of the upper and weakness of the lower extremity on the left side. Foot- and patellar-reflex were increased. Vomiting was frequent and persistent. The temporal bone was trephined in three places, the dura did not pulsate, and at two points the temporal lobe was punctured, but no pus was found. After this operation the headache and paresis were lessened and the speech improved. Two weeks later all the symptoms grew worse, and there was added twitching of the left arm and of the right side of the face. The middle-ear cavities and the dura over the tegmen were exposed by operation, and pus escaped, but relief did not ensue, and two weeks later the right occiput was trephined and the right cerebellar lobe explored, but no pus was found. Slight improvement for a few days, and then all the symptoms of central pressure returned, and the patient died with symptoms of general tubercular marasmus. The autopsy revealed an abscess of the right lobe of the cerebellum and the processus vermicularis, superficial cysts in the right cerebral hemisphere, caries of the right tympanum, and chronic purulency of both ears. There were also cavities in the lungs, pyopneumothorax, and general marasmus.

Carcinoma of the Temporal Bone.—Danziger⁴ reports 2 cases of this rare malady. One occurred in an unmarried woman of 54, who suffered from chronic otorrhea, the result of scarlatina in her 10th year. The ear-disease had never received any treatment. The second case was that of a man of 53, syphilitic, but not before affected with ear-disease. Both cases proved fatal.

Alveolar sarcoma of the cerebellum, giving rise to disturbances in gait, hearing, and vision, is reported by H. M. Thomas.⁵ W. Milligan⁶ reports 2 cases of malignant growth—one angiosarcoma, the other myxosarcoma—in

¹ Brit. Med. Jour., Mar. 6, 1897.

⁶ Arch. of Otol., July, 1896.

ears for a long time the seat of chronic suppuration. The first-named growth occurred in a woman of 63; the other in a woman of 18. In the latter a very radical removal of diseased tissue was effected, but repullulation of the morbid growth soon ensued. Hoggr¹ observed a case of sarcoma of the base of the skull involving the middle ear.

Tuberculous Disease of the Temporal Bone.—O. Barnick² reports 3 cases of tuberculous inflammation of the temporal bone, 1 terminating in extensive destruction of the mastoid, the lower part of the squama, the petrous pyramid, and partial thrombosis of the superior petrosal and sigmoid sinuses, with tuberculous disease of the sphenoid and occipital bones. Manasse³ discovered a solitary tubercle on the eighth nerve, in a consumptive. The growth was situated to the left of the pons. The facial and auditory nerves were imbedded in the cheesy mass and could not be isolated. Tubercular caries of the middle ear, perforating the fenestræ, and invading the internal ear, in a child 3 months old, is reported by W. Haenel.⁴ The pathologic process, as shown by section of the decalcified bone, had begun near the tympanic mouth of the Eustachian tube and passed backward as far as the antrum. The infection apparently had reached the middle ear through the Eustachian tube. The infection of the dura mater, which had taken place through the petrosquamous suture, had remained localized. Poli⁵ reports a case of purulent otitis media in a child 18 months old. Endocranial symptoms led to exploratory craniotomy and the discovery of tubercle of the left cerebral peduncle. Death occurred 3 months after the operation. H. L. Swain⁶ observed a purulent collection in the lateral ventricle as a result of chronic purulent otitis media, with caries of the roof of the tympanum. Death occurred with a temperature of 107° F.

The relation of the aurist to the surgery rendered necessary by chronic purulent otitis media is well summed up by C. J. Blake.⁷ "The surgery of a suppurative process within the temporal bone which, beginning in the middle ear, has implicated the mastoid process and threatens contiguous structures, has to take into consideration, not merely the effort to save life, but also to conserve, as far as possible, the hearing power, and to leave undisturbed the equilibrating function of the ear; it has also to take into consideration the possibility of injury to important structures lying in minutely close relationship to the necessary operative field. Under these circumstances it is a tenable proposition that no aural surgeon should undertake an operation upon the mastoid in a case of suppurative implication of that cavity without being prepared by his mental and material equipment to enlarge his operative field to any extent demanded, or without having, if he does not possess it himself, the necessary surgical assistance and counsel at hand.

"The fact that it is easier for the aurist to learn to open the cranial cavity and to operate upon the lateral sinus in the brain, than for the general surgeon to acquaint himself with the technical procedures of operation within the temporal bone and middle ear, is an argument in favor of leaving the subject of the intracranial complications of suppurative middle-ear disease where it now largely stands—in the hands of the special practitioner."

DISEASES OF THE INTERNAL EAR.

Syphilis of the Internal Ear.—E. A. Crockett¹ describes a form of acute syphilitic affection of the ear, probably due to an effusion into the labyrinth in a previously normal ear, characterized by sudden deafness, tinnitus, and vertigo, coming on in the late secondary or early tertiary stage of systemic syphilis. The difference between this form of sudden deafness, tinnitus, and vertigo, and that due to nonsyphilitic causes, is that the deafness is not so profound in the specific form. The syphilitic aural affection yields promptly to a few doses given hypodermically of pilocarpin ($\frac{1}{6}$ gr.), whereas nonsyphilitic labyrinth-diseases are entirely unaffected by pilocarpin. According to an article on disease of the internal ear, by Thomas J. Harris,² pilocarpin gives the best results in syphilitic diseases of the internal ear.

Caries of the Internal Ear.—Extensive caries of the petrous bone, the result of purulent otitis media after scarlet fever in a child $2\frac{1}{2}$ years old, terminating in sequestration of the osseous semicircular canals and the posterior part of the vestibule, has been reported by Guranowski.³ H. S. Walker⁴ removed a sequestrum consisting of the cochlea, semicircular canals, the internal auditory meatus, and parts of the mastoid cells, following scarlet fever. A large cavity was left, the posterior and upper walls of which were formed by the dura mater of the middle and posterior fosse.

Internal Ear in Submarine Workers.—F. Alt⁵ reports apoplectic affections of the labyrinth in 3 men employed in submerged caissons. When the Eustachian tube is permeable the ear endures the increased atmospheric pressure in submarine caissons; when it is not permeable, the inward pressure of the membrana produces congestion of the drum-cavity and finally of the internal ear, as Alt has shown by experiments on animals.

Anemia of the Labyrinth.—Lermoyez⁶ claims that deafness, tinnitus, and vertigo may be caused by either congestion or anemia of the labyrinth. The inhalation of a few drops of nitrite of amyl will temporarily relieve these symptoms if they be due to ischemia, but will increase them if they be due to congestion. This differentiation in etiology will enable the physician to properly treat the disease. In a case of anemia of the labyrinth Lermoyez found that trinitrin in doses of $\frac{1}{100}$ gr. three times daily permanently relieved the deafness, tinnitus, and vertigo. In cases of congestion of the labyrinth an alterative or absorbent treatment would be indicated.

Internal Ear in Leukemia.—A case of so-called Ménière's disease, caused by leukemic disease of the auditory nerve, in a man of 66, is reported by F. Alt and F. Pineles.⁷

Internal Ear in Diphtheria.—Sudden, bilateral, total deafness in true diphtheria in a woman of 33, with previous good hearing and no history of syphilis, is reported by J. C. Wilson.⁸ The middle ears seemed in no way affected. The tinnitus and vertigo were marked at first, but gradually in six months the tinnitus greatly diminished and the vertigo ceased. [The onset of the ear-disease in this case resembled that of the internal ear affection occurring in syphilis and mumps.]

Traumatism of the Internal Ear.—Ménière's group of symptoms

⁸ Trans. Cong. Am. Phys. and Surg., May, 1897.

following traumatic lesion of the labyrinth have been noted by Politzer,¹ in a case of fracture of both temporal bones (from a blow on the head) involving the labyrinth. Death occurred in about six weeks from meningitis; the day before death albuminuria appeared. New growth of connective tissue in both labyrinths was detected by microscope after death. Politzer draws attention to this rapidity of formation of connective tissue, and believes that the rapid and incurable deafness which occurs in various kinds of panotitis can be explained by the development of new growth of connective tissue in the labyrinth. It also shows why prompt and energetic absorptive treatment fails entirely in such cases. Whether the fatal meningitis resulted from the fracture, or from purulency of the sphenoid sinus or the middle ear, could not be determined, as there was no demonstrable connection between these foci of suppuration and the cranial cavity. D. Kaufman² reports a case of complete ambilateral deafness three days after a fall upon the occiput. This result was supposed to be due to traumatic apoplexy in the labyrinth terminating in degeneration, necrosis, and secondary hemorrhages in the internal ear. J. Gruber³ observed a fracture of the temporal bone, caused by a fall upon the head. The case proved fatal in four days from widely diffused meningitis. T. A. Kenefick⁴ reports a case of the apoplectic form of Ménière's disease, in which, as the author thinks, spontaneous recovery of the tinnitus, dizziness, and deafness, ensued in about two weeks from the time of sudden onset at night. [So far as we know, the deafness resulting from an intense extravasation within the labyrinth, such as occurs in Ménière's disease, never disappears and is usually bilateral. Therefore, we think this was a case of vertigo, nausea, etc., of tympanic origin.]

Thos. Barr⁵ points out that many cases of drowning from "sudden cramps" are in reality cases of fatal ear-giddiness, induced by the sudden entrance of cold water into the drum-cavity in persons with perforated membrane.

Psychic Deafness.—Psychic deafness is often confounded with deaf-muteness. The former is rather an inability to learn to talk in one who can hear, rather than muteness in one who cannot hear, and has therefore never learned to talk, as in cases reported by S. Heller⁶ and V. Urbantschitsch. In Heller's⁷ case, a boy of 3½ years, there was great nervous excitability, evinced as paroxysms of rage. The hearing was good, but the power to speak remained latent. By combating this excitability and awakening and cultivating the faculty of concentration and perception, the power of speech was gained. In Urbantschitsch's case⁸ a teacher, a woman of 22, grew dull of hearing without apparent cause, and, as a result of the impaired function, became melancholic and subject to delusions with suicidal intentions. Under careful acoustic exercises—words spoken slowly and near the ear, fair hearing was slowly regained. [Many cases of psychic deafness seem to possess what is termed "latent hearing," by some observers.]

Deaf-mutes.—Ottolenghi⁹ advises education of deaf-mutes with the idea of giving them full use of what powers they have, and to restore them to civil and penal responsibility if possible. V. Pendred¹⁰ reports two cases of associated goiter and deaf-mutism in the same family. Mingazzini¹¹ offers a clinical observation of a case of so-called hysterie deaf-muteness in a man with a neurotic history. Recovery took place after both intra- and extra-

¹¹ Arch. Ital. di Otol., Jan., 1897.

laryngeal application of faradic and galvanic currents. G. Alvarez¹ claims to have cured deaf-muteness in a girl of 15, by treatment of the nasopharynx and the removal of the nonabsorbed gelatinous matter of infancy which had remained in the drum-cavity. Barbera² maintains that deaf-muteness is a stigma of degeneration, while Verdos³ claims that many cases can be cured, especially those resulting from rhinitides that have passed into the middle ears. Forns⁴ claims that this is the only class of curable mutes, while those resulting from nonabsorption of the connective-tissue jelly present in the middle ears at birth, and those caused by disease of the internal ear and auditory nerve-center, are incurable. J. Sendziak⁵ maintains that an early operation on adenoid vegetations, even in infancy, will prevent the development of deaf-dumbness.

Hallucinations of Hearing.—Kaufman⁶ claims that the ear in those affected with hallucinations of hearing generally presents organic changes, and also that a vicious interpretation of subjective noises in the ear causes hallucinations. Scéglas,⁷ too, states that all hallucinations of hearing are not due to purely neuro- or psychopathic causes, but that alterations in the peripheral sensorial apparatus will be found to have a large share in their production.

Tinnitus.—G. W. McCaskey⁸ writes on the diagnostic significance of subjective head- and ear-sounds, chiefly in neurotic cases without ear-disease. In all cases coming before the neurologist the ear should be examined at the outset, in order to find out whether or not local ear-disease is present. The diagnosis of tinnitus can be made in obscure cases (those not caused or aggravated by local ear-disease) only "after the broadest and most searching clinical investigation that rational, scientific medicine can give." Auditory allochiria and extracranial noises were observed by Verdos⁹ in a man of 50. At the time of writing no remedy had given any relief, and no explanation of the causes of the disease was offered. Tinnitus, when a warning of epileptic fits must be regarded according to W. R. Gowers¹⁰ as originating in the auditory center in the cortex, not in the nerve.

Fibrosarcoma of the Acoustic Nerve.—W. Anton¹¹ reports the occurrence of fibrosarcoma of the acoustic nerve in a man of 55. The man was seized with headache and blindness of the right eye, and three days later with blindness of the left eye. At times he vomited, and he suffered from roaring and hissing-sounds in the ears, and hardness of hearing. Optic neuritis occurred on both sides and facial paralysis on the right. Death occurred 8 months after the first symptoms. The autopsy revealed a tumor the size of a hen's-egg, rather soft, with rough surface, situated between the pons and the cerebellum. The origin of the nerves on the left was normal; on the right side the 5th, 7th, and 8th nerves ran on the under surface of the tumor, and then over the latter. The 7th and 8th nerves were imbedded in the tumor, and were accompanied by the morbid tissue as far as the internal porus acusticus.

The same author reports the accidental discovery of a similar kind of tumor at the autopsy of an old man. The growth was the size of a nut, and rough, connected with the left acoustic nerve and extending as far as the internal porus acusticus. The acoustic and the facial nerves were separated by the tumor, but connected by a bridge of partly degenerated medullary fiber. In both these cases the fibrosarcoma originated from the sheath of the acoustic and partly from that of the facial nerve.

DISEASES OF THE NOSE AND LARYNX.

BY E. FLETCHER INGALS, M. D., AND H. G. OHLS, M. D.,

OF CHICAGO.

Review of the Year's Work.—While no brilliant discoveries have illumined the field, a vast amount of faithful clinical work has led to improved methods and apparatus in various lines. Hypertrophic rhinitis, as usual in late years, has been a fruitful subject for study. Turbinotomy, as practised by Carmalt Jones, has its enthusiastic supporters; but equally competent operators raise a note of warning which will doubtless be generally heeded by the profession. D. Bryson Delavan suggests a plan of incision that is certainly simple. John Edwin Rhodes outlines a plan of treatment of atrophic rhinitis for which he does not make extravagant claims, but which certainly enables patients to live in comfort. E. B. Gleason and Arthur W. Watson offer operations for the relief of deflection of the septum. Thomas Fillebrown made a study of the anatomy of the frontal sinus and the antrum, throwing new light upon the relation of suppuration in these cavities. Much study has been devoted to the subject of laryngeal tuberculosis, and the experience of Solomon Solis-Cohen with formic aldehyd and that of W. Scheppegrell with cataphoresis with copper electrodes promise relief of much suffering. Electrolysis has been applied by Arthur B. Duel to the dilatation of the Eustachian tubes for the relief of throat-deafness.

Anesthesia.—Barelay J. Baron¹ reports a case of severe strangulation following an operation on adenoids under nitrous oxid gas, according to the method advocated by W. G. Holloway.² As a local anesthetic, J. E. Newcomb³ recommends guaiacol as a substitute when cocain is contraindicated. [We have been disappointed in the results in attempting to get local anesthesia by the application of guaiacol. After cocain has been applied guaiacol has appeared to cause more smarting than when no cocain had been used, and it has frequently utterly failed to secure anesthesia.] He has used it 36 times in the nose, pharynx, and larynx, and on the average obtains anesthesia in 10 minutes. He proposes a solution as follows: to olive oil add 10% of dry zinc sulfate; heat over a water-bath one hour and add 12½% absolute alcohol; shake several times during 24 hours; decant and add 5% guaiacol. M. Broeckhaert⁴ had a patient, an army officer, whose skin was blistered by solutions of cocain. C. W. Ingraham⁵ believes that a 2% solution of cocain applied thoroughly to the olfactory region will immediately relieve nausea in 9 out of 10 cases.

Eucain.—The earlier reports of eucain indicated that it caused hyperemia of the mucous membrane, and Lewis A. Somers⁶ said that property militates greatly against the use of the drug in active inflammatory conditions. A 4% solution applied on a cotton swab caused anesthesia in from 8 to 10 minutes,

⁶ Therap. Gaz., Jan. 15, 1897.

lasting about 20 minutes. A 10% solution in sterilized water will keep indefinitely, and may be boiled without impairing its efficiency. W. Jobson Horne and Macleod Yeardsley¹ found that eucain causes no hyperemia, but, on the contrary, slight ischemia, not to be compared to that caused by cocain. The only ill effect noted was the unpleasant taste, lasting half an hour. One patient in whom cocain had previously caused alarming syncope was, later, under the influence of eucain 3 times without ill effect. Joseph Gibb² concludes: 1. Eucain is equal to cocain in its anesthetic effects; 2. Eucain is nearly as effective as cocain in reducing engorged turbinates; 3. Eucain is superior to cocain in being less likely to produce toxic symptoms; 4. Eucain is superior to cocain in producing far less unpleasant subjective symptoms, especially in the larynx. Vinci³ finds that the toxic dose of eucain for the rabbit is 15 to 20 cgm.; of cocain, 10 to 20 cgm. The only alarming report on eucain available is that by T. H. Shastid.⁴ In his patient, a man of 32, the application of a 5% solution to the turbinate caused slight intoxication, with amblyopia lasting several hours.

Bacteria in the Nares.—W. H. Park and Jonathan Wright⁵ have recently examined the mucus of 36 healthy nares, and conclude, contrary to their investigations of 10 years ago, that the bactericidal properties of the mucus are poor or absent, though it does not form a good culture-medium. E. L. Vansant⁶ examined the mucus from 100 cases of chronic nasal disease. Although none of the cases were febrile or showed other clinical signs of diphtheria, 30 cultures from 26 cases showed diphtheria-bacilli. The diseases in which they were found included: 11 of 25 cases of atrophic rhinitis; 3 of 16 cases of chronic purulent rhinitis; 5 of 14 cases of rhinitis; 3 of 7 cases of nasal syphilis; 3 of 31 cases of hypertrophic rhinitis; none in 2 cases of diseased accessory sinuses; none in 1 case of fibrinous rhinitis; in 58 cultures staphylococci were found. He emphasizes the importance of disinfection of the nares. The patients with diphtheria-bacilli were pale and listless, showing apparently a slow chronic toxemia.

Nasal Malformation.—W. R. H. Stewart⁷ operated on a man with a bifid nose, due probably to imperfect fetal development, caused by a dermoid cyst that was removed in infancy. The removal of excessive bone and cartilage from the septum and a flap-operation restored the normal shape. Robt. C. Myles⁸ notes the liability to stenosis following operations involving the vestibule. To relieve the contracted band he passes a trophine along the floor and inserts a long tube, to be worn several months. Later the bridge may be removed by a Graefe knife and a Berens' cork or Asch's tube worn for a week. In that form of nasal occlusion caused by enlargement of the anterior edge of the triangular cartilage the excess of cartilage is removed by subperichondrial dissection. Geo. C. Stout⁹ reports a case of atresia in an infant of 3 months, whose respirations were habitually 105 per minute. Dilatation of the nares by bongs reduced the respirations in a few weeks to 45, and stopped the attacks of laryngismus stridulus to which it had been subject.

Physiology of the Nose.—J. L. Goodale¹⁰ studied experimentally the action of the nasal mucous membrane upon the air inhaled; the normal alterations in intranasal air-pressure, and the route taken by respired air within the nose. He finds the relative humidity of the air after passing the nasal

chambers is near the saturation-point with reference to its own temperature, but falls considerably below the saturation-point for the temperature which it subsequently attains. The nose is also, in an atmosphere not excessively dust-laden, a nearly complete filter for the inspired air.

Acute Rhinitis.—H. J. Mulford¹ offers a protest against the classic treatment. He attributes acute rhinitis to the accumulation within the blood of the products of tissue-waste, urea, uric acid, etc. The indication is to restore the activity of the excretories and to neutralize the foreign matter in the blood. Calomel or podophyllin stimulates the liver; lithia or soda overcomes the condition of the blood, and a free supply of water opens the kidneys. Pilocarpin would seem an ideal remedy, but it is unreliable. By this method the cold is cured in from 24 to 48 hours. M. Courtade² recommends saline douches at 122° F. to abort coryza. The heat is the important factor, and either sodium chlorid or bicarbonate may be used with good effect.

Phenacetin in Nasal Catarrh.—J. S. Woodruff³ found that phenacetin applied locally gives satisfactory results in nasal catarrh. He mentions two cases, one in which a profuse nasal discharge following scarlet fever had lasted four years, and another in which there were itching and dryness of the nasal passages, with frontal headache. In the first, phenacetin was administered in the form of snuff; in the second, dissolved in glycerin, with success. The author does not mention to what the above symptoms were due.

Nasal Hydrorrhea.—D. Braden Kyle⁴ relates a case and reviews the literature of 26 others. The profuse discharge of clear alkaline, irritating fluid was preceded by headache and sneezing. The mucous membrane presented the appearance of chronic congestion, as if the venous return were obstructed. Examination of the blood showed the plasmodium malariae, and the patient improved on quinin-bromid and arsenic sulphid.

Fibrinous Rhinitis.—Lewis S. Somers⁵ describes a case of membranous rhinitis, in which repeated bacteriologic examinations were made before the Klebs-Löffler bacillus was discovered. The disease pursued a mild course. Of two children infected by exposure to this case one developed a laryngeal diphtheria and died; the other had a membrane on both tonsils without severe constitutional disturbance. He thinks the first was originally a case of fibrinous rhinitis, becoming infected later with Klebs-Löffler bacillus. Glover⁶ gives the autopsy of a woman of 67, in whom a false membrane extended throughout the respiratory tract, serum-cultures from which developed only pure staphylococci.

Turbinotomy for Hypertrophic Rhinitis.—Peter Abererombie⁷ gives an analysis of 66 cases of turbinotomy by Carmalt Jones with his spokeshave. Relief from obstruction was obtained in 62. Patients varied in age from 6 to 71 years. In 49 cases both sides were operated on. As to anesthetics, nitrous oxid gas was given to 5 patients, who felt no pain at all. In 31 cases in which a 10% solution of cocain was applied more or less pain was felt, in some cases severe. Hemorrhage, free at first, was controlled by cotton-wool plugs. In no cases has atrophic rhinitis resulted. On the contrary, a reproduction of normal mucous membrane takes place, becoming in a few cases excessive. Finally, he recommends the operation as both successful and highly desirable in many instances. Henry B. Hitz,⁸ from an experience in many cases, in-

⁸ Laryngoscope, Nov., 1896.

dorses the spokeshave, and meets the objection that the function of the turbinate is thereby destroyed, with the question whether the function is not already destroyed when hypertrophy is sufficient to cause obstruction. Fayette C. Ewing,¹ although formerly an assistant in Mr. Jones' clinic, voices the sentiment felt by all those whose motto is to "restore as nearly as possible the relationship of the parts," when he says, "reason knows no rationalism that will justify the spokeshave." The Laryngologic Society of London² discussed turbinotomy, Dundas Grant exhibiting 18 cases out of 35 operated on by himself. Half of this number remained completely free from their primary symptoms, and the rest were relieved. Notable regeneration of the turbinate took place in 6. Hemorrhage was serious in 1, free in 5, moderate in 7. In 8 cases of anterior partial turbinotomy the nasal symptoms were cured in 5 and relieved in 2. He considers the partial resection advisable if only as a preliminary to posterior operation. Crosswell Baber recommended the operation, especially when the removal of septal obstruction does not give free breathing-space. Lambert Lack maintained that the cases must be very exceptional in which complete relief could not be obtained by other and milder measures. [We agree with Lack, but have seen a few cases in which turbinotomy became necessary. In most of these a nasal scissors was the only instrument needed; bleeding was checked by packing with a long strip of antiseptic surgeons' lint.] Semon reported the case of a theologic student in whom turbinotomy was followed by typical atrophic rhinitis, and an increase of the laryngitis to which he had been subject. Scames Spicer never noticed pharyngitis sicca following the operation, but, on the contrary, found that the temporary dryness of the throat that sometimes followed was far less annoying than the dry mouth and throat before. Watson Williams condemned the operation as unnecessary, dangerous, not under perfect control, and liable to be followed by unfortunate complication.

Transfixion.—Blondian³ passes a lance-shaped cautery at dull-red heat beneath the mucous membrane of the inferior internal angle of the turbinate for a distance of 7 or 8 cm. A single operation is usually sufficient; the mucous surface is uninjured and synechiæ are never produced. [We have tried this frequently, but have been disappointed in the results.] Marked polypoid degeneration of the posterior end usually shrivels up after one transfixion. The Eustachian tube should be avoided. D. Bryson Delavan,⁴ noting the inefficiency of snare and caustics, though they are not conservative, for the reduction of hypertrophies, described a method of incision with a small ophthalmic knife. The point of the knife is carried obliquely as far as possible into the turbinate, and with a slight sweeping motion is brought out of the same opening. The parts are kept contracted with cocain for some hours after the operation, which causes little irritation. Arthur W. Watson,⁵ after trying the cautery to reduce the granulation-tissue following removal of the spur of the septum without permanent relief, obtained rapid reduction of the mass by friction, as advocated by C. C. Rice.

Nasal Reflexes.—Chas. N. Cox⁶ reports a case of redness of the tip and alæ of the nose due to swelling of the turbinate, and relieved by cauterization of the latter. Touching the inferior turbinate with a probe caused swelling, and at the same time the tip and alæ suddenly became red. Max Thorner⁷ had a case of amaurosis of the right eye following the

⁵ Phila. Polyclinic, Nov. 7, 1896.

⁶ Brooklyn Med. Jour., Oct., 1896.

⁷ Jour. Am. Med. Assoc., Sept. 26, 1896.

removal of polypi on that side with the cautery. Rethi¹ relates 2 cases of chlorosis due to hyperesthesia of the olfactory nerve, and relieved by light cauterization of the olfactory area. Horace Clark² thinks that hyperesthesia of the pharynx is the most common reflex disturbance of intranasal disease, and that the nasal disease most often causing a reflex is posterior polypoid degeneration. Arthur J. Hobbs³ inadvertently relieved 2 cases of priapism by a spray of cocain applied to the nares to relieve the congestion of the erectile tissue there. He also mentions several cases of sneezing due to erotic emotions accompanied by the same turgescence of the turbinate.

Rhinitis Sicca.—U. Ribary⁴ says rhinitis sicca anterior may be regarded as atrophic rhinitis confined to the septum. In this condition the ciliated is converted into pavement epithelium. It precedes erosions and exposes the subject to various infections. Acute cases are susceptible to treatment by ointments containing zinc oxid and bismuth subnitrate. When chronic, a return to the normal is not to be expected [but ointments to prevent drying of the mucus upon the surface give much relief, and mild cauterizations with nitrate of silver sometimes give permanent benefit].

Atrophic Rhinitis.—W. Peyre Porcher⁵ says atrophic rhinitis is not a disease *per se*, but is the result of any inflammation, acute or chronic, specific or non-specific, which ends in a purulent discharge sufficiently prolonged to wash away the epithelia and destroy the nasal mucosa, turbinates, etc. [The belief that atrophic rhinitis is the result of varying degrees of inflammation excited by various causes appears to be strengthened by the reports of many observers; but the etiologic relation of the purulent discharge cannot be accepted by most pathologists.] Ralph W. Seiss⁶ extols massage with a cotton swab for 3 to 6 minutes at a sitting. The swab may be dipped in ointment with 5% or 10% of europhen to advantage, or in solution of thymol in albolene. The europhen is less painful than thymol, and may be used as a dusting-powder with stearate of zinc. He claims arrest of the disease and great comfort from treatment extending over several months. The need is for an agent to control fibrosis. W. Peyre Porcher⁷ gets the best results by packing the vault of the nares daily with cotton tampons carrying a strong solution of iodine, glycerin, and potassium iodid. Capart and Cheval⁸ still use the bipolar method of electrolysis, and claim cures in 90% of cases so treated. [This claim is so remarkable that we are led to suspect that their cases were not all fully developed, or else that the word "cures" was used in the Latin sense.] John Edwin Rhodes⁹ gives a thorough review of the literature, and notes cases in which hypertrophy preceded the atrophic process and others which presented atrophy in one part of the nares and hypertrophy in another. As a cleansing douche he recommends the following tablet, dissolved in 4 ounces of tepid water: potassii chloratis, gr. iiss; sodii bicarbonatis, gr. x; sodii chloridi, C. P., gr. x; sodii salicylatis, gr. v; sodii biboratis, gr. v; thymol., gr. $\frac{1}{8}$; eucalyptol., $\mathfrak{M}\frac{1}{4}$. After cleansing the nares with the douche $1\frac{1}{2}$ gr. of the following powder should be blown into the nares two or three times a day: sodii biborat., gr. ij; hydrarg. oxid. flav., gr. ij-v; iodol., gr. j; cocain. hydrochlorat., gr. iiss; magnes. carb., gr. ij; sacch. lactis, q. s. ad gr. 100.

Animal Parasites in the Nares.—H. M. Folkes¹⁰ removed from the

nares of a negro in Guatemala 131 screw-worms, none of which were under 10 mm. in length. A spray of an alcoholic solution of chloroform followed by irrigation assisted in the process of removal.

Rhinolith.—P. McBride¹ removed from the naris of a woman of 32 a rhinolith measuring $1\frac{1}{2}$ by 1 by 1 in., but found no ulceration and no evident loss of substance or cicatrization.

Etiology of Hay-fever.—Chas. P. Grayson² thinks that the digestive system rather than the nervous system is at fault in the development of hay-fever. [We have observed pronounced and peculiar symptoms referable to the digestive system in this disorder, but they have appeared to us rather a result than a cause, and could not be taken as an evidence that the nervous system was not primarily at fault.]

Deflection of the Septum.—John O. Roe³ concludes: 1. That devia-

FIG. 68.—Vertical, transverse section through the anterior portion of the nose; angular deviation of the septum, with hypertrophy of the tissues at the angle of the deviation. The dotted line indicates the direction of the saw-cut for the removal of the obstruction (Gleason).

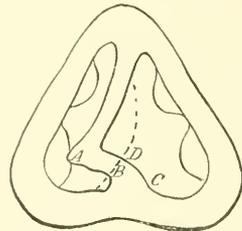

FIG. 69.—Vertical, transverse section through the anterior part of the nose; angular deviation of the septum without hypertrophy of the tissues at the angle of the deviation. The dotted line indicates the direction of the saw-cut for forming the tongue-shaped flap covering the button-hole in the septum; *A B* and *D C*, portions of the septum to be denuded (Gleason).

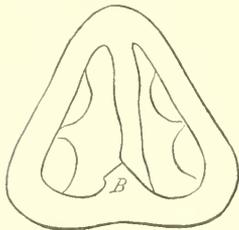

FIG. 70.—Vertical, transverse section through the anterior portion of the nose, showing position of the septum after the tongue-shaped flap has been thrust through the button-hole in the septum. After healing has occurred, the parts at *B* are sometimes abnormally thick; but redundant tissue can readily be removed with the saw (Gleason).

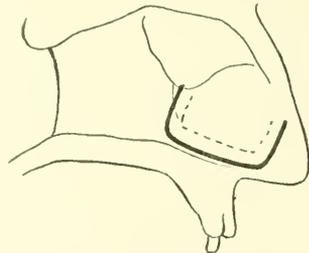

FIG. 71.—Sagittal section through the nose to the right of the septum. Convex surface of deviated area of the septum. The dark line shows position of U-shaped saw-cut through the septum about the deviated area on the convex side, and the dotted line the position of the same saw-cut on the side of the septum. In some instances the mucous membrane on the concave side of the septum apparently rides over the saw teeth and is not cut to the extent shown in the diagram (Gleason).

tions of the septum are produced by a variety of causes operating upon different persons; and that upon the same person several different influences may be operating at the same time. 2. That heredity plays a very important part as a predisposing cause, not only by the dyscrasias which may be transmitted, but by the blending of different races in the composite type, which brings

¹ Jour. Laryn., Rhinol. and Otol., Feb., 1897.

² Univ. Med. Mag., July, 1896.

³ N. Y. Med. Jour., Oct. 10, 1896.

about an infinite variation in the conformation of the osseous and cartilaginous structures. 3. That the three local causes most frequently producing deviation, spurs, and ridges of the septum are trauma, nasal obstruction, and unequal growth of the different component parts of the vomer. The last-mentioned cause is itself produced mainly by local malnutrition or diseased conditions of the structures of the nasal passages, inducing an unequal development of the two sides of the septum, which causes a bulging or bending to the side of greatest development. The fact that the vomer is composed of two laminae, separated by a plate of fibrocartilage, which is continued forward to form the triangular cartilage of the nose, readily explains how the unequal development takes place. E. B. Gleason,¹ instead of overcoming the resiliency of the deflected septum, makes it a factor in holding it in the proper position (see Figs. 68-71). He saws a U-shaped incision through the base of the septum so as to surround, except above, the whole deflected area. After paring the convex edge of the flap and the concave edge of the base of the septum he forces the flap through the incision and lets the resiliency "do the rest." Arthur W. Watson² takes advantage of resiliency by a similar operation, but uses a knife and makes the incision along the crest of the deviation.

E. J. Moure³ says these are due to luxations of the cartilaginous septum from the shallow groove in the superior maxilla, complicated by thickening. The septum may be forcibly replaced or gradually brought into position by the redresseurs of Delstanche.

Abscess of Septum.—W. E. Casselberry's⁴ patient, a boy of 16, was supposed to have asthma owing to dyspnea caused by the abscess. Early incision at the lower edge of the abscess and daily opening with a probe until the cavity is effaced are essential to prevent the destruction of the cartilage and deformity. H. G. Ohls had an unreported case in which moderate depression of the bridge of the nose had already occurred. Suppuration had ceased, leaving a separation of the plates of cartilage. Tubes of dental rubber with a packing of gauze above the tubes, worn for about 5 weeks, restored the patency of the nares and corrected the deformity. Gouguenheim⁵ believes that the cause of abscess is always trauma, though traumatic hematoma does not always lead to abscess.

Acute Purulent Perichondritis.—Gottlieb Kicer⁶ describes a rare affection of the septum as primary acute perichondritis, with phlegmonous symptoms occurring in otherwise healthy persons. Tumors form on both sides of the quadrangular cartilage, often communicating by a necrosis or perforation of the septum.

Tubercular Ulceration of Septum.—Hill,⁷ in the discussion of Symonds' case of rapid ulceration of the septum in spite of scraping and applications of lactic acid, suggested trichloroacetic acid, 25%, in these cases, as lactic acid is not strong enough.

Nasal Syphilis.—Albert Kohn⁸ removed a large granulating mass which developed in connection with a chancre of the nares. This was twice reproduced at intervals of 2 days, following removal. The disease was checked by inunctions, but the naris was occluded except a small passage through the lower meatus. J. Dionisio⁹ describes 31 cases of tertiary syphilis charac-

terized by simple tumefaction of the mucous membrane, running its course without any signs of ulceration or purulent secretion. Chas. H. Knight¹ cautions

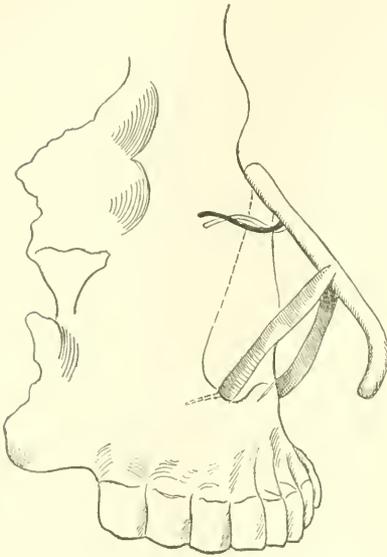

FIG. 72.—The Martin bridge (N. Y. Med. Jour., Sept. 19, 1896).

against the use of destructive agents in treating syphilitic disease of the nose, but says that necrosed bone may be removed before it is completely detached after the active symptoms have been controlled by treatment. This is especially important before inserting the Martin bridge (Fig. 72) to correct the deformity. If the disease is active, the pressure of a bridge is very liable to cause extensive ulceration. At least 3 years should have elapsed after active symptoms cease before the bridge is inserted. [Two years more should elapse before the case is reported as improved or cured.]

Sarcoma of the Nares.—Wm. Thomson² saw a round-celled sarcoma of the antrum extending into the nose and recurring after two operations. Within a month following the last operation the tumor protruded through the incision in the cheek. It was blue, tense, lobulated, and had almost closed the eye. Further operation was declared useless. Three months

later the tumor had disappeared, with unbroken covering and with no other treatment than poultices of comfrey root. G. Melville Black³ reports removing with the cold snare and ennetting the attachment of an alveolar sarcoma involving the middle turbinated region, in a woman aged 38 years, in April, 1894. In 2 years it had not recurred. H. Lambert Lack⁴ exhibited before the Laryngologic Society of London a man aged 65, from whom in Feb., 1895, he had removed with polypus-forceps a sarcoma of the middle turbinate, and scraped away a large portion of the lateral mass of the ethmoid with Meyer's ring-knife. No recurrence has taken place.

Anosmia.—M. Joal⁵ recommends inhalations of carbonic acid gas, from an inverted siphon-bottle with a nasal tip, both to restore the sense of smell and to arrest acute coryza and vasomotor attacks.

Nasal Dermoid Cyst.—Albert Kohn⁶ removed from a woman 65 years old several dermoid cysts attached to the middle turbinate. The cysts contained cheesy material. They had not recurred within 6 months.

Epistaxis.—C. G. Cowie⁷ plugged the anterior naris of a woman aged 65, to control a moderate epistaxis. A few hours later blood escaped from the lacrymal canal and filled the conjunctival sac. He then made 2 attempts to plug the posterior nares, but on both occasions the patient retched so violently when the plug touched the enlarged tonsils that she sustained a double dislocation of the jaw. Swoboda⁸ quotes 4 cases of death from epistaxis. One was a case of hemophilia due to septicemia in an infant with gonorrheal

conjunctivitis and rhinitis. In another case purulent rhinitis was accompanied by epistaxis. In 2 other deaths from epistaxis the patients had diphtheria.

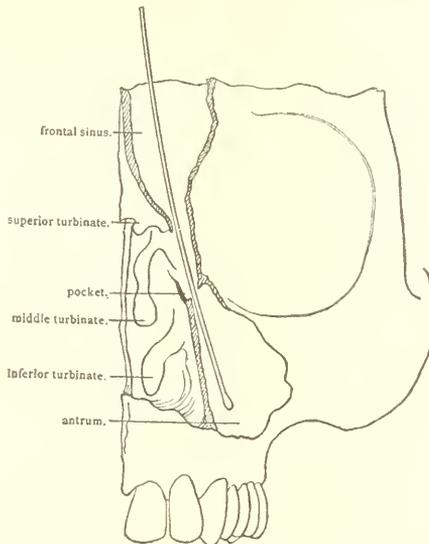

FIG. 73.—Infundibulum terminating in foramen of maxillary sinus (Dental Cosmos, Nov., 1896.)

Anatomy of Frontal Sinus and Antrum.—Thomas Fillebrown¹ found that in 8 specimens the infundibulum, instead of terminating in the middle meatus, continued as a half tube, terminating directly in the foramen

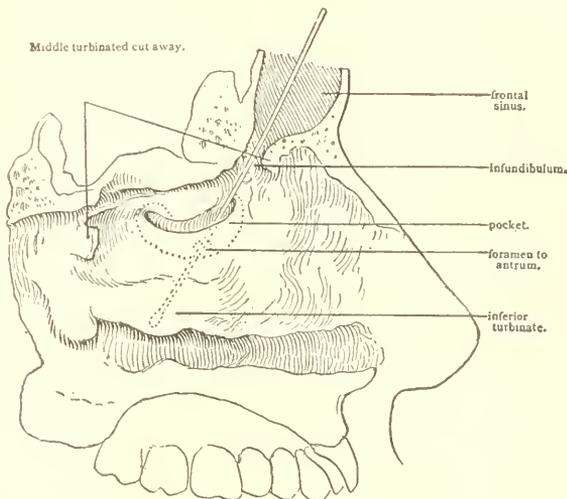

FIG. 74.—Infundibulum terminating in foramen of maxillary sinus (Dental Cosmos, Nov., 1896.)

of the maxillary sinus (see Figs. 73, 74). In 7 of these there was a fold of mucous membrane covering the foramen and forming a pocket, which pre-

¹ Dental Cosmos, Nov., 1896.

vented any secretion from the frontal sinus getting into the meatus until the antrum and pocket were full.

Sinusitis.—W. E. Casselberry¹ thinks that 9 out of 10 cases of acute empyema recover spontaneously. Henry L. Wagner² described a case of seropurulent sinusitis of 3 years' duration, with severe neuralgic pains, in a painter. All the upper teeth had been removed, and the supraorbital nerve had been resected, without relief of the neuralgia. The writer opened the antrum freely and noted a bluish-gray hypertrophy of the mucous membrane, which gave the lead-reaction with sodium sulphid. Iodids internally relieved the pain in a few days and caused the discharge to cease. Frank C. Todd³ had a case of frontal sinus disease in which paroxysms of pain in the frontal region were followed by epileptic convulsions. Reducing the swelling of the ethmoid by cocain solution allowed pus to escape from the sinus, and as the inflammation subsided the convulsions ceased.

The Accessory Sinuses in Zymotics.—M. Wolff⁴ examined the accessory sinuses in 22 cases of diphtheria, in 12 of which the diphtheria-bacillus was found in the antra, with inflammatory edema. Various cocci were also present. One frontal sinus and 6 out of 7 sphenoidal sinuses examined contained diphtheria-bacilli. The sphenoidal sinuses were not developed in 15 cases. Five cases of measles and 2 of scarlatina showed various bacteria, with severe inflammatory changes.

Transillumination.—F. E. Sampson⁵ says of the indications obtained

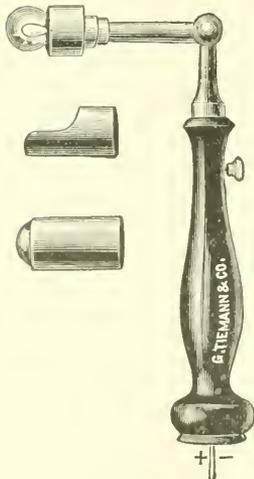

FIG. 75.—Heryng's antrum-illuminator.

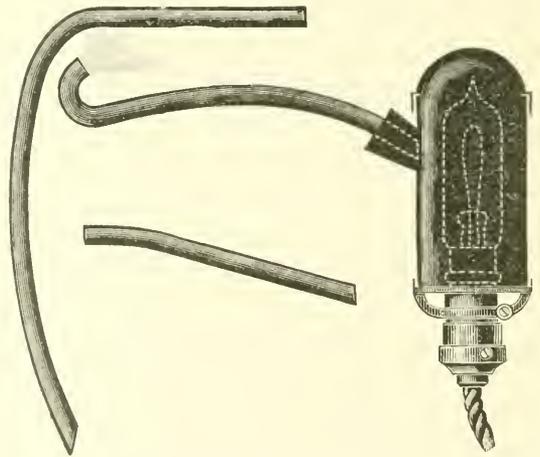

FIG. 76.—Chevalier Jackson's lamp for transillumination.

by transillumination: "Ordinarily, when the sinus shows dark, we will find pus, or at least a greatly thickened mucosa; but let us run briefly over the possibilities: if the sinus shows clear, it means one of two things—it is either healthy or contains a mucocoele; if clearer than its fellow, it does contain a mucocoele, unless the other sinus be diseased, absent, or contains a solid neoplasm. If it shows dark, the sinus contains pus or has a thickened mucosa—unless it be a solid neoplasm or the sinus is absent." W. Scheppegrell⁶ reviews

¹ *Medicine*, Oct., 1896.

³ *Laryngoscope*, Oct., 1896.

⁵ *Laryngoscope*, Aug., 1897.

² *N. Y. Med. Jour.*, Aug. 15, 1896.

⁴ *Medicine*, Sept., 1896; *Zeit. f. Hyg. u. Infectiouskrank.*

⁶ *Ann. Otol., Rhinol. and Larynx*, May, 1897.

the various methods of transillumination and gives a comprehensive analysis of the indications obtained by this method of diagnosis. He recommends Heryng's lamp (Fig. 75) as the most useful. He has adapted a more powerful light to it, and removed the interrupter from the handle, and uses a foot-switch for completing the circuit. He commends also the ingenious lamp of Chevalier Jackson (Fig. 76). The glass rods, *A, B, C*, are silvered on the sides and covered with enamel, so that the light of the 50-candle-power lamp issues from the end of the rod with undiminished intensity. The different shapes of the rods facilitate their use in every procedure to which the method is adapted. He classifies the different methods of examination of the antrum as follows: 1. Opacity of the cheek of the affected sides, or the method of Voltolini-Heryng. 2. Opacity of the pupil of the affected side, or the method of Davidsohn. 3. Absence of the luminous sensation of the diseased side, or the method of Garel. 4. A modification of the above methods by placing the lamp directly under the maxillary sinus, not under the nasal fossæ, or the method of Ruault. 5. Opacity of the nasal wall of the sinus observed by rhinoscopy, or the method of Robertson. In conclusion, he finds transillumination a valuable addition to our means of diagnosis, but believes that it must be corroborated by other signs.

Congenital Stenosis of the Nasopharynx.—St. Clair Thomson¹ quotes Escat on stenosis of the nasopharynx simulating adenoids. Fig. 77 shows the average anteroposterior section of the healthy nasopharynx of a child of 10. Fig. 78 represents the same space of a child of 11½ years with congenital stenosis. Fig. 79 represents a man of 45 who had congenital sten-

osis and emphysema for 10 years, necessitating constant mouth-breathing. This individual was not insane, but was a marked degenerate.

Etiology of Acute Nasopharyngitis.—J. Lewis Smith² states that a large proportion of cases are due to microbic infection, especially to influenza in this country. He recommends having the air of the nursery moist and impregnated with the vapor of eucalyptus, carbolic acid, and turpentine.

Medication of the Nasopharynx.—John H. Hollister³ describes Liebreich's method of medicating the nasopharynx as follows: 30 to 40 drops

¹ Practitioner, Jan., 1897.

² Med. News, Aug. 12, 1896.

³ N. Am. Pract., Feb., 1897.

of the medicament are dropped upon a cotton-wool tampon large enough to fill the nasal vestibule. With the mouth open the ala nasi is compressed and the fluid passes into the nasopharynx.

Ultimate Prognosis of Adenoids.—D. Bryson Delavan¹ notes a variety of pathologic conditions in the adult following adenoids in youth, and concludes that adenoid hypertrophy does not tend to spontaneous cure; that when present in any marked degree it demands thorough treatment; and, finally, that if left to itself the prognosis is far from satisfactory.

Adenoids in Adults.—Edward F. Parker² notes the frequency with which spurs of the septum are found in adults with adenoids persisting, and he believes that the spurs are an important factor in preventing the atrophy of the hypertrophied lymph-tissue at puberty, by keeping up the irritation and vascularity which were the original causes of the growth.

Unusual Symptoms of Adenoids.—John A. James³ was asked to tracheotomize a 3-year-old child for croup, with respiration 45 per minute and extreme dyspnea. Learning that the child was a mouth-breather and had enlarged tonsils and adenoids, he removed them, with immediate relief of the dyspnea. Boulay⁴ noted the case of a boy of 12 who had adenoids and enlarged tonsils, and who for two years suffered with epileptiform crisis between 4 and 6 A. M. The attacks ceased after removal of the adenoids and tonsils. Grondoch⁵ noted enuresis in 13% of children with adenoids, operation giving relief in half the cases and improvement in a third more. Upon recurrence in 4 cases, enuresis followed in all. John Sendziak⁶ operated on a congenital deaf-mute, 5 years old, removing adenoids, and thereby restoring the hearing so that the child soon began to talk and made rapid intellectual advancement.

Lymphotome.—Jacob E. Schadle⁷ has devised an instrument on the

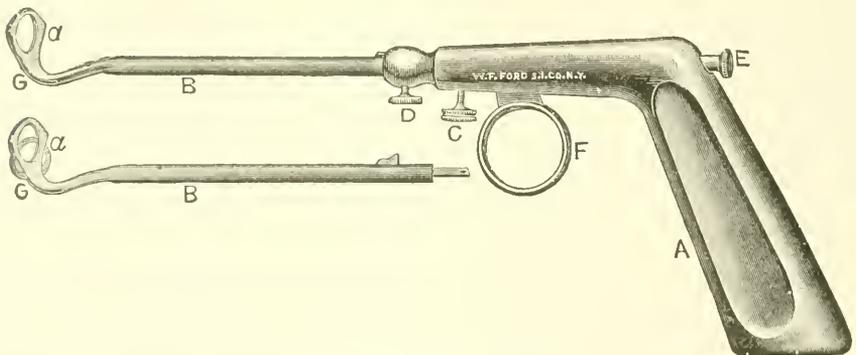

Fig. 80.—Schadle's lymphotome: A, aluminum handle; a, cutting blade; B, cannula; C and D, thumb-screws; E, push-button; F, ring trigger; G, Gottstein's curve.

principle of the tonsillotome, with a flexible cutting-blade for the removal of adenoids (Fig. 80).

Forceps for Adenoid Operation.—James J. Concanon⁸ recommends the removal of adenoids without anesthesia by means of a cutting-forceps (Fig. 81) of his design, with a guard that acts as a palate-retractor and pro-

teets the septum. When the adenoids extend low in the pharynx he supplements the use of the forceps by one sweep with the Gottstein curet.

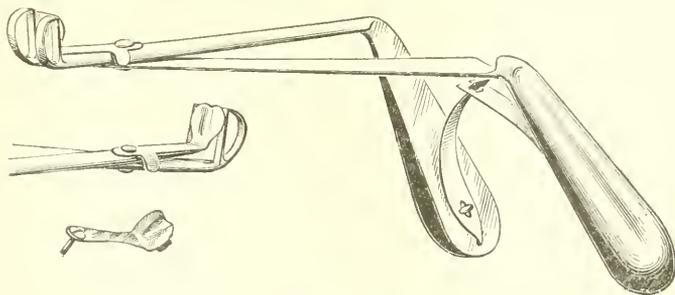

FIG. 81.—Concanon's cutting-forceps.

Primary Tuberculosis of the Pharyngeal Tonsil.—F. Pluder and W. Fischer¹ found latent tubercles in the mucosa of 5 out of 32 hypertrophied pharyngeal tonsils examined; bacilli were only scantily present in the diseased part, never in the epithelium or healthy lymph-follicles. The disease was sometimes confined to a small part of the tonsil, but distinct caseation was found in half the cases. The following list includes the microscopic observations recorded:

Lermoyez	in 32 cases found tuberculosis 2 times
Gottstein	in 33 " " " 4 "
Brindel	in 64 " " " 8 "
Pluder and Fischer	in 32 " " " 5 "

Nasopharyngeal Fibromata.—E. Fletcher Ingals² reported a large fibroma removed by electrocautery snare in 1894, and the base cauterized several times until the growth in the nares and nasopharynx was destroyed. Part of the tumor passing behind the palate-bone and beneath the zygomatic arch caused a swelling in the cheek. After injecting a 4% solution of cocain, 15 minims of an aqueous solution containing 25% of lactic acid and 15% of carbolic acid were injected into the mass through the mucous membrane of the cheek. This caused severe pain and reaction. Several subsequent injections of lactic acid, 25%, and carbolic acid, 5%, with glycerin, 12%, preceded by the cocain solution, produced little pain or reaction, and caused the growth to almost entirely disappear. [A year after this report the growth had not recurred. He recommends the lactic acid especially in all inoperable tumors, the carbolic acid and cocain being used to minimize pain.]

Alcohol Injections for Cancer.—Edwin J. Kuh³ reports that he removed from a man of 36, with atrophic rhinitis, a tumor that appeared to be an enlarged pharyngeal tonsil, in July, 1896. Sections of the tumor showed it to be epithelial cancer, and it recurred so rapidly that the nasopharynx was nearly filled by a soft bleeding mass within a month. The diagnosis of carcinoma being confirmed by Nicholas Senn and operation being considered hopeless, Kuh made daily injections of erysipelas prodigious toxins. After 10 injections two-thirds of the growth disappeared, but growth began in spite of subsequent injections. In October injections of alcohol, after the method of C. Schwalbe and O. Hasse, were begun with 3 minims, and increased to 30 minims. After the seventh injection reduction in the size

¹ Arch. f. Laryn. u. Rhinol., in Jour. Laryn., Rhinol. and Otol., June, 1897.

² N. Y. Med. Jour., Sept. 18, 1896.

³ Chicago Med. Recorder, Apr., 1897.

began, and after the eleventh little of the growth remained. At the time of writing the nasopharynx was free from growth. The principle of treatment is to surround the periphery of the neoplasm with the alcohol to induce sclerous contraction in the connective tissue, and thus reduce the blood-supply. The tumor itself is supposed to undergo sclerotic contraction in its interstices and a fatty regressive metamorphosis in its parenchyma. [If it is true that a few injections of alcohol will produce sclerosis of any tissue, it would seem to resemble the effects on the liver of chronic alcoholic irritation. Many observations will be necessary before such an assumption can be considered proved.]

Electrolysis for Stricture of the Eustachian Tube.—Arthur B. Duell¹ reports brilliant results in the rapid dilatation of the Eustachian tube by electrolysis. After a few treatments patients have remained free from tinnitus and vertigo, and the hearing has been greatly improved for several months or until the report was made. He uses copper bougies from No. 3 to No. 6, French, mounted on No. 5 piano-wire. These are carried through insulated silver catheters (Fig. 82). The bougie is connected with the negative

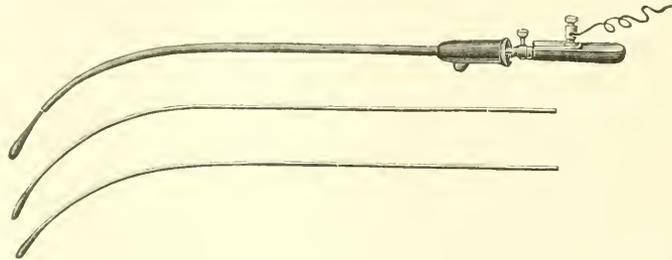

FIG. 82.—Duell's electrodes.

pole of the galvanic battery, the positive pole being applied to the patient's hand by the ordinary sponge electrode. The current should be accurately regulated and never exceed 5 ma.

Epithelioma of the Soft Palate.—Thomas Hubbard² injected liquor potasse into an epithelioma developing in the soft palate and anterior pillar of the fauces, causing the growth to slough. There was no return of the tumor, and the patient gained 40 pounds within a few months. The growth was due to irritation by a tooth-plate. The patient had previously acquired the cocain-habit from Birney's catarrh-snuff.

Glossitis.—J. L. Goodale³ reviews the literature of "wandering rash of the tongue" and "Moeller's superficial glossitis," and cites cases to show the probable identity of these affections, for which he proposes the name glossitis superficialis migrans.

Foreign Body in the Tongue.—A. V. Anderson⁴ removed from a man's tongue an amber mouth-piece of a pipe one inch long which had been forced into the tongue a month before from contact with a hawser when jumping off a pier to rescue a man from drowning. In the excitement the man forgot his pipe.

Actinomycosis of the Tongue.—Clai  ⁵ describes a case in which aspiration of a gumma-like tumor of the tongue revealed the ray-fungus and potassium iodid effected a cure.

⁵ Jour. of Larynx, May, 1897; Presse m  d., Mar. 31, 1897.

Lingual Tonsil.—J. F. Barnhill¹ accounts for the great difference in the disturbance caused in different people by the presence of lingual tonsils or other growths in the glosso-epiglottic spaces in two ways: first, in persons of highly sensitive nervous systems the slightest touch of a foreign body against the hypersensitive epiglottis will excite the reflex centers of the air-tract in a degree that would not be possible in one whose nervous tone is normal; second, the conformation of the epiglottis in many cases is such that, instead of standing up and away from the base of the tongue, as it normally should, it curls unduly forward, projecting its crest directly against the base of the tongue and over the glosso-epiglottic spaces, thus unduly infringing upon the smallest nodule of lymphoid tissue, and giving rise to symptoms equal in severity to those found in cases in which the spaces are filled with tumors many times larger, but with normal epiglottis. Functional heart-disease is often much aggravated, and he believes sometimes wholly caused, by disease of these spaces. Globus hystericus usually accompanied such cases, together with other symptoms commonly classed hysteric. He believes some of these cases are cured by proper attention to the upper air-tract, and particularly the spaces under consideration. Other symptoms are sore throat, the nature of which can only be determined by laryngoscopic examination, when there may be found to exist any one of the varieties of tonsillar affections which are better known in connection with the diseases of the faucial tonsil, such as acute lingual tonsillitis, acute follicular lingual tonsillitis, etc.

Malignant Disease of the Tonsil.—David Newman² quotes five cases in which cancerous growths of the tonsil were completely removed by five different surgeons through the mouth without external incision, and reports two cases of his own operated on in 1890 and 1891. He then describes fully two cases requiring external operation. In one the tumor was small and strictly limited to the tonsil. After splitting the cheek to the ramus of the

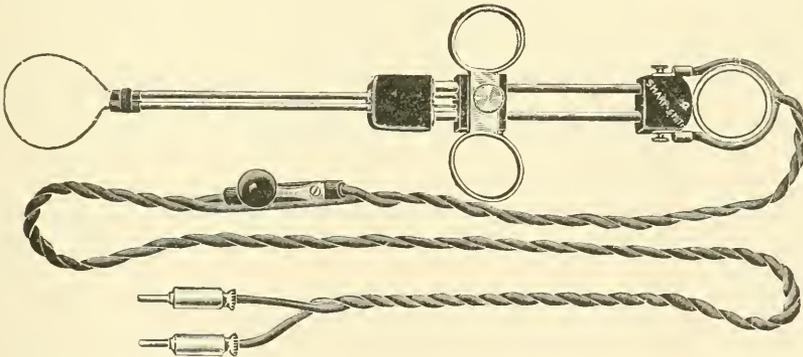

FIG. 83.—Gradle's snare.

jaw, he dissected out the tonsil with blunt scissors. In the other case the growth involved the tonsil and edge of the posterior pillar, without affecting the lymphatics. He removed it by lateral pharyngotomy, with division of the jaw at the angle. These cases were reported 5 and 8 months respectively after operation. The diagnosis must be made early by microscopic examination of the new tissue, not the glandular tissue surrounding it. He prefers the knife to the cautery, on account of the greater ease in distinguishing healthy from diseased tissue.

¹ Laryngoscope, Aug., 1897.

² Brit. Med. Jour., Jan. 2, 1897.

Hypertrophy of the Tonsils.—Lacoanet¹ noted a case of great enlargement of the tonsils following diphtheria, which was treated by serum. Under astringents, diet, and sulphur baths the tonsil atrophied. He ascribes the enlargement to either the poison of Löffler's bacillus or the serum, and advises against surgical intervention.

Tonsil-punch.—W. Hill² recommends the punch devised by Kretschman for the removal of tonsils, when the guillotine is not practicable.

The Hot Snare.—Henry Gradle³ devised a hot snare (Fig. 83) for using either platinum, or preferably steel wire. The current-closer is placed in the cable a foot from the handle and is operated by the hand that holds the tenaculum. [The galvanocautery is especially valuable in removing tonsils when there is danger of hemorrhage, but it is followed by much greater reaction than the tonsillotome, and in some cases by a large amount of cicatricial tissue; therefore, usually it is an unsatisfactory instrument in tonsillotomy.]

Bone-growths in the Tonsil.—Alex. W. Sterling⁴ exhibited 3 patients with bony growths projecting into the tonsillar region. The first case was a young lady of good personal history. Her tonsils had been cauterized, and when tired she often complained of pain originating in the right tonsil and radiating through the right side of head and right shoulder. On palpation an immovable hard mass was detected below the tonsil and projecting to the level of its anterior surface. By exclusion, he determined that it was the styloid process of the temporal bone. The two other cases were a brother and sister, aged 65 and 64. In each both styloids could be detected, but neither patient had suffered in any way from the anomaly. Deichert,⁵ in tonsils removed from 3 persons, found connective tissue with cartilage and bone-cells, which he attributed to aberration of fetal cartilage.

Calcium Sulphid in Tonsillitis.—W. Bayard Shields⁶ recommends calcium sulphid in 1 gr. doses to abort tonsillar inflammation and prevent abscess-formation (quinsy). He gives 4 doses at hourly intervals, 6 doses at intervals of 2 hours, and then every 3 hours till inflammation subsides. In 150 cases this treatment gave relief in from 2 to 6 days. If this dose causes depression, heart-stimulants are given. [This does not appear a very rapid result of treatment; indeed, there may be some question whether many of the cases would not have recovered in the same time if left entirely to themselves. The application of a spray of guaiacol, 50%, in oil of sweet almonds, in most cases cuts short the inflammation in from 12 to 36 hours.]

Scarlatinal Sore Throat.—Lape⁷ recommends **resorcin**, 5% to 10% in glycerin, applied on a brush or swab two to four times a day, after gargling with boric acid solution.

Reflex Cough.—Furet⁸ says reflex cough may be due to any pathologic alteration of the tonsil owing to the involvement of the tonsillar plexus of nerves. Emil Mayer⁹ says cough is reflex in its origin: 1. When it is spasmodic, practically constant, without expectoration and temperature; 2. When the physical signs of pulmonary disease are absent; 3. When it persistently resists all medication; 4. When the general health remains comparatively undisturbed; and, 5. When upon removal of the cause it promptly ceases.

⁹ Laryngoscope, Mar., 1897.

Enlarged Pharyngeal Arteries.—P. McBride¹ traced a pulsating artery across the pharynx of a woman of 67. In a second case a pulsating tumor in the region of the tonsil simulated an aneurism, but proved to be a cyst. In a woman of 61, not only the pharyngeal, but a number of arteries in different parts of the body pulsated visibly. E. Harrison Griffin² noted a pulsating tumor with old syphilitic scars in the pharynx of a woman of 49; the swelling was about the size and shape of a lead-pencil. In another woman of 45 he saw a similar artery traversing the visible length of the pharyngeal wall.

The Bucco-pharyngeal Zona.—Lermoyez and Barozzi³ described a case of bilateral zona of the mouth and pharynx occurring in a man of 78. The vesicles were arranged with geometric symmetry over the palate, uvula, and inner surface of the lips, the successive crops of vesicles lasting several weeks. The differential diagnosis follows:

HERPETIFORM ANGINA.	PHARYNGEAL ZONA.	RECURRENT PHARYNGEAL HERPES.
Sudden onset, with headache, rigor, and intense general disturbance.	Insidious onset; very little general disturbance.	General disturbance often absent.
Pain in the throat increases. It is slight at first, but becomes intense at the time of eruption, and lasts to the end of the attack.	Less pain in the throat. It is most marked at the onset, and then decreases. It has disappeared almost as soon as the eruption appears.	Very little pain. Burning sensation often unnoticeable.
Eruption bilateral.	Eruption unilateral.	Eruption very intense. Often localized to the same area during each relapse.
Attacks the tonsil particularly; but also affects simultaneously the pharynx, larynx, and lips.	Limited to the area supplied by a nerve, usually the second division of the 5th. It affects the palate, uvula, gums, and cheeks, leaving the tonsils and pharynx intact.	A particular spot; often in the neighborhood of the anterior pillar.
Short duration—four to six days.	Longer duration—fifteen to twenty days.	Eight to ten days' duration.
Acute course.	Subacute course.	
Frequently recurs.	Never recurs.	Always, recurs, often with periodicity.

Primary Tuberculosis of the Pharynx.—Walter. F. Chappell⁴ noted tubercular infection following the removal of the pharyngeal tonsil from a girl of 19. The cervical glands soon become enlarged and tender, and the lateral pharyngeal folds resembled collections of granules—hard, tender, and blue. Frequent examination of the lungs revealed no pulmonary involvement for 4 months. Then rapid development of miliary tuberculosis caused her death in 3 months.

Thyroid Extract in Myxedema.—J. Woodman⁵ reports the case of a woman of 38, who had developed myxedema 8 years before. Her weight had increased from 120 to 240 pounds; sweating ceased with the onset of the disease, and the skin became hard, dry, and deeply pigmented; the hair was coarse and brittle. Nothing was lacking of the typical symptoms of a severe case. Four months' treatment with thyroids reduced her weight 60 pounds, and in all

¹ Edinb. Med. Jour., Dec., 1896.

⁴ N. Y. Med. Jour., Sept. 19, 1896.

⁵ Med. Rec., Oct. 31, 1896.

other respects the patient returned to her normal condition. John W. Farlow¹ reports a localized myxedema lasting 2 years, in a woman of 46. The face was slightly involved, but general symptoms were not marked. Under thyroid extract the patient made slight gain.

Iodin in the Thyroid Extract.—Bammann and Goldmann² found that thyro-iodin, 3 to 6 gr. a day, prevents tetanic symptoms in thyroidless dogs. The same remedy cures the tetany, but is all excreted by the kidneys. Hennig³ says iodin is combined in the gland with albumin and globulin. The physiologic effect of thyro-iodin is to increase the excretion of phosphoric acid, nitrogen, chlorine, and sodium chlorid.

Pharyngeal Teratoma.—A. W. de Roaldes⁴ removed from a male infant of 6 weeks a sessile dermoid tumor attached to the posterior pillar of the fauces, and large enough to cause dyspnea when falling into the larynx. It had much the shape of an auricle. Section showed fibrocartilage, fat, loose connective tissue, and skin. Achard classifies it as a simple form of the very rare epignath monsters.

Apomorphin in Acute Laryngitis.—Thos. Hubbard⁵ recommends apomorphin, gr. $\frac{1}{30}$, in freshly compounded acidulated mixture, as a most efficient relaxing expectorant. Given every 2 or 3 hours, it causes a free seromucous flow in from 12 to 36 hours.

Edema of the Larynx.—W. P. Meyjes⁶ reports a case of acute idiopathic edema of the epiglottis in a man of 41. A spray of ichthyol, $\frac{1}{3}$ % in ice-water every 15 minutes, with ice externally, gave rapid relief. Dunbar Roy⁷ describes a case of suddenly appearing and disappearing swelling of all the tissues of the neck in a man of 36. By measurement the neck was found to be actually greater in circumference during the attacks, which occurred about 10 A. M. at frequent intervals, lasting only a short time. The swelling of the neck was firm, and did not pit on pressure. The attacks were accompanied by palpitation of the heart and some dizziness. The thyroid was not enlarged. The interarytenoid space was obliterated by swelling without congestion. The vocal cords were normal. No organic disease except myopia was discoverable. Max Thorner⁸ intubated a man of 18 who had suffered with dyspnea for 8 years, from a stenosis of the larynx of unknown origin; 15 hours later the tube was removed at the request of the patient. A few moments of comfortable breathing were followed by a rapid edema of the larynx and death. This case emphasizes the necessity of watching carefully, and for some time after removing the tube, cases of chronic stenosis.

Varicella of the Larynx.—M. Marfan and J. Halle⁹ describe 2 cases of varicella in which dyspnea necessitated intubation. Antitoxin was given in both cases before the vesicular eruption, on the supposition that it was diphtheria. One of these cases is said to be the only recovery on record.

Urticaria of the Larynx.—Delbril¹⁰ says the symptoms may simulate edema of the larynx when the respiratory trouble precedes the skin eruption. On examination red, raised erythematous patches may be seen in the pharynx, even when a view of the larynx and trachea is impossible. For acute cases with severe pulmonary symptoms and no cutaneous eruption, he recommends brisk friction to induce its appearance.

¹⁰ Jour. de Méd., July 25, 1896; Brit. Med. Jour., Oct. 3, 1896.

Fracture of the Larynx.—A. W. de Roaldes¹ describes a fracture of the left cornu of the thyroid cartilage caused by forcible manipulation of the larynx by a man who was partly suffocated by an olive-pit. The sensation of a foreign body persisted several months.

Foreign Bodies in the Larynx.—Guy Hinsdale² made an autopsy on a boy 4 years and 9 months old who died suddenly, and found a pencil $2\frac{1}{4}$ in. long impacted in the larynx and trachea (Fig. 84). Cyanosis just before death was supposed to indicate heart-disease.

E. W. Davis³ describes the case of a child of 15 months, who choked on a piece of peanut-shell. A man introduced his finger forcibly into the larynx, which relieved the dyspnea partly. The following day tracheotomy was performed, and 52 days later the child expectorated the shell, the tube being worn for 75 days. He thinks that the injury done by introducing the finger violently caused an edema that prevented the shell being discovered. Max Thorner,⁴ by means of Kirstein's autoscope and Krause's straight tube-forceps, removed a chicken-rib, $1\frac{1}{2}$ in. long, lodged in the right ventricle, extending across the cavity. N. Palazzolo⁵ removed a large leech that had been in one of the ventricles for 10 days. J. Walker Downie⁶ located a pin in the larynx by means of x-ray photographs, and removed it by median thyrotomy. Ten days after using the x-ray pricking and heat were felt over the back of the head and neck; vesication and sloughing of the skin followed, and the hair over a large area came out.

Papillomata in the Larynx.—G. Hunter Mackenzie⁷ shows the success that may follow simple tracheotomy for papillomata. A child with congenital papillomata wore a tracheotomy-tube for 7 months, during which time a number of papillomatous particles were detached and expectorated. The dyspnea following final removal gradually improved, and the voice became normal for the first time. He believes that the rest from coughing and phonation causes atrophy of the growth. F. Lohrstorfer⁸ intubated a child three times for papillomata, with relief of dyspnea each time. Later a tracheotomy preparatory to a radical removal of the growth was followed by death, owing to some obstruction in the cannula. H. Heryng⁹ recommends sulphuric acid of phenol, 30%, applied thoroughly, to cause absorption of papillomata. On the aryepiglottic folds and cartilages of Santorini the application will cause them to disappear. In other parts they should be operated on before applying the remedy. [There is reason to believe that the neglected *thuya occidentalis*, applied in the form of fluid extract or tincture, and at the same time administered internally, will cause the destruction of papillomata.]

Acute Perichondritis of the Thyroid Cartilage.—C. W. Richardson¹⁰ reported a case of acute suppurative perichondritis in a man of 24 with-

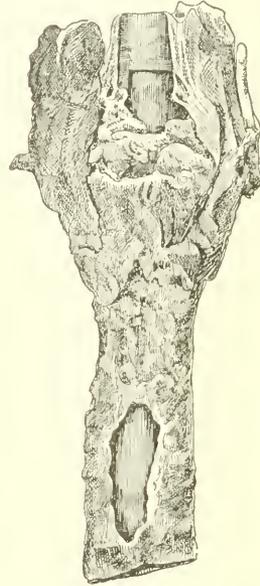

FIG. 84.—Pencil in the larynx (Internat. Med. Mag., Feb., 1897).

⁸ Med. Rec., Oct. 10, 1896.

¹⁰ Ann. of Otol., Rhinol. and Laryn., May, 1897.

out discoverable cause. Swallowing became extremely painful, and edema of the larynx caused such dyspnea that incisions into the edematous tissues became necessary. Finally, evacuation of a large abscess just above the sternal notch gave relief to the acute symptoms, and was followed by rapid gain of strength and weight, though the voice gained strength very slowly, and after 9 months was easily fatigued.

Gonorrhœal Perichondritis.—H. S. Birkett¹ relates an interesting case of inflammation of the left crico-arytenoid joint, with edema of the mucous membrane covering it and tenderness on external pressure, occurring during an attack of gonorrhœal rheumatism. Application of Leiter's ice-coil gave marked relief. Within a week the swelling disappeared and the voice became normal.

Feeding in Paralysis of the Larynx.—Frank Savery² had a case of malignant stricture of the esophagus, involving and causing paralysis of both recurrent laryngeal nerves, with aphonia, dyspnea, and dysphagia. To avoid the latter symptom, he recommends giving liquid food from a feeding-cup introduced into the lower angle of the mouth, the patient lying on his side with the head well over the side of the bed. In this position the fluid passes not over, but by the side of the larynx, through the hyoid fossa, and enters the esophagus without coming in contact with the posterior commissure of the larynx.

Laryngeal Vertigo.—Albert C. Getchell,³ from a study of 77 cases, including 2 of his own, concludes that laryngeal vertigo occurs in persons in whom there is evidence of unstable equilibrium of the central nervous system. There is some abnormal condition of the air-passages, likely to produce laryngeal irritation, with cough and glottic spasm. The spasmodic closing of the glottis may, and in many cases does, act directly and immediately upon the inhibitory centers of the brain and cause syncope. A severe paroxysm of coughing, which produces congestion of the cerebral vessels, may also cause syncope; but it will not cause it unless there be an existing disorder of the central nervous organ.

Laryngeal Tuberculosis.—S. Oakley Vander Poel⁴ calls attention to the appearance of the larynx in early tubercular disease. In the case described there was no evidence of ulceration or of tumefaction of the posterior laryngeal wall, but merely a slight thickening of the mucous membrane, with a white, milky, somewhat purulent mucus containing no tubercle-bacilli, but which he considers almost pathognomonic. In his case this condition occurred in a patient with a healed tubercular cavity of long standing, and it was followed by a rapid development of typical ulceration and death in a few months. F. Brannsfeld⁵ finds that inhalations of from 10% to 30% solutions of **lignosulphite** cause increased expectoration, with easier respiration and improved appetite. In laryngeal cases cough becomes easier, dysphagia diminishes, and ulcers clean up to a certain extent. However, no specific influence on the bacilli or on the tubercular process is claimed for this inhalation. J. Lardner Green⁶ strongly recommends the inhalation of 1 or 2 drops of **formalin** from a Jeffery's respirator in the early stage of phthisis. Both the micrococcus pneumoniae and the bacillus tuberculosis rapidly decrease in number under the treatment. For acute cases the formalin should be diluted with water. Solomon Solis Cohen⁷ has had good results in infiltrative, ulcerative, and vegetative cases from the use of **formic aldehyd** in $\frac{1}{2}$ % to 4% solutions.

¹ N. Y. Med. Jour., Sept. 19, 1896.

² Lancet, Sept. 18, 1896.

³ Boston M. and S. Jour., Nov. 5, 1896.

⁴ N. Y. Med. Jour., July 18, 1896.

⁵ Deutsch. med. Woch., Apr. 1, 1897.

⁶ Brit. Med. Jour., Jan. 23, 1897.

⁷ N. Y. Med. Jour., Oct. 24, 1896.

The intense burning and strangling sensation can be prevented to a large extent by the previous application of cocain solution of proportionate strength, from 4% to 20%. He begins with $\frac{1}{2}$ % solution of formic aldehyd and gradually increases to 4%, equivalent to 10% of the commercial preparation, rubbing the remedy into the tissues thoroughly twice a week. He attributes to the formic compounds iodoform, chloroform, bromoform, and formaldehyd, a specific antitubercular influence. **Bromoform** is recommended as a local analgesic for painful tubercular ulceration. In several early lesions the application of bromoform followed by insufflations of iodoform has been followed by healing. W. Scheppegrell¹ recommends **cataphoresis with a copper laryngeal electrode**, as preferable to curetting or the cautery in laryngeal tuberculosis. With the Kirstein autoscope a slightly curved electrode may be used to better advantage. The advantages which he found in the method of applying cupric electrolysis in the treatment of laryngeal tuberculosis are as follows: 1. There is no real destruction of the tissues, and there are no lacerations of the surfaces which might form a point of entrance for new pathogenic germs for reinfection, as in the case with the method of curettage, and, to a certain extent, also with the galvanocautery and simple electrolysis. The cure is effected by the healthy reaction of the tissues in the same manner in which we often see specific lesions heal when the system is under the influence of mercurials. 2. In the cases which he treated by this method there was absolutely no reaction or hemorrhage following the application—a point of great importance with tuberculous patients. 3. This method does not demand the high degree of manipulative skill required for curettage, or for the manipulation of the electrocautery in the larynx, and is especially simple when direct laryngoscopy can be used. 4. This method is applicable in all cases of laryngeal tuberculosis.

Tuberculosis and Syphilis of the Larynx.—E. Harrison Griffin² claims that a constitution that is prone to tuberculosis renders the patient more susceptible to its development if the syphilis is not quickly and properly treated. He quotes cases to prove: 1. Tubercular and syphilitic ulcerations are found side by side in the larynx. 2. That the presence of a syphilitic ulcer by the side of a tubercular ulcer in the anatomy exercises a moderating influence upon the tubercular deposit, if the syphilis be treated, and prolongs the life of the patient. 3. Do not rely upon the report of the microscope in all these cases, as the tubercle-bacilli will be found if there be phthisis, but the syphilitic element, if present, is overlooked. 4. In the case of a mixed sore the syphilitic ulcer will generally progress quicker than the tubercular, but can be easily controlled if the right diagnosis is rendered. [The diagnosis of mixed infection of this kind is extremely difficult, and cases bearing out this position are very rare in the practice of the most experienced laryngologists.] Leopold Glück³ treated a series of 30 cases of syphilis of the larynx with intermuscular injections of **corrosive sublimate**. Mucous patches were present in many cases. Of 14 ulcers, 10 were located on the vocal cords. None of them left a cicatrix, thus indicating that they all belonged to the secondary stage. The strength of the solutions used varied from 3% to 5%, beginning with the weakest. The treatment averaged from 15 to 18 days, and the total amount injected in each case varied from 9 cgm. to 2.53 gm. The results obtained were gratifying, and the author recommends the method as best adapted for lesions in the larynx. Irsai,⁴ from 4 years' ex-

¹ Med. Rec., May 29, 1897.

⁴ Rev. hebdom. de Laryn., in Am. Medico-Surg. Bull., Aug. 15, 1896.

perience with the injections, recommends them highly for speedy relief when the lesions cause dyspnea. He injects a 5% solution once a week into the gluteal muscles.

Chorditis Tuberosa.—Johnson Elliott¹ notes that improper or excessive use of the voice is the cause of chorditis tuberosa in adults subject to chronic nasal catarrh. Sopranos are not subject to it, though the Italian method of singing is said to induce it in some cases. [We have not found sopranos exempt.]

Changes in the Voice.—Cartex² found only 1 case of injury to the voice in 6 oöphorectomies. In some cases the voice gained both in tone and compass. C. Biaggi³ describes the voice due to arrest of development of the larynx during puberty. In 2 cases complete cure followed removal of nasal obstructions. [This defect in the voice is seldom, if ever, due to want of development of the larynx. It may be speedily cured in most, if not in all, cases by the method recommended by Mulhall, of St. Louis, in the *Transactions of the American Laryngological Association*. In a number of cases that have come under our observation the cure has been effected in from 2 to 10 days.] Felix Semon⁴ applied the galvanocautery to a singer's nodule, and thereby changed the high falsetto voice of a clergyman to a deep basso.

Stammering and Stuttering.—Geo. A. Lewis⁵ defines stammering as the inability, under certain conditions, to articulate or control the organs of speech, which are usually, under such circumstances, tightly held together, accompanied in many cases by the substitution of one sound for another. Stuttering is a defect in respiration and vocalization, oftentimes causing spasmodic action or the rapid repetition of one word or syllable before the following can be uttered. He indicates by a graphic representation the relative influence of the physical and mental types of defective speech. Stammerers of the former class are troubled continually about the same. Mental emotions and impaired health do not much increase the severity of their affliction. When the mental type predominates they can speak well when free from excitement, but stammer violently under a variety of emotions when tired or ill.

Stammering and Hypnotism.—Thos. B. Keyes⁶ reports 2 cures of stammering by hypnotic suggestion. One patient, a man of 22, had stammered 16 years, and was cured by 3 treatments. The other case required 11 treatments. From these cases he believes that hypnotic suggestion offers a reliable method of treatment.

Surgical Treatment of Stammering.—G. Hudson Makuen,⁷ in the case of a youth of 19, who had never been able to speak intelligibly, found that the tip of the tongue was too short. Dividing the genio-hyo-glossi muscles freely, following by tractions on the tongue and vocal exercises, gave him almost perfect articulation, and was followed by rapid mental development. Another boy of 8 years was cured of stammering within 2 months by the removal of adenoids and the amputation of the tip of the uvula.

Intubator.—Louis Fischer⁸ describes a new aseptic intubator which grasps the head of the tube without obstructing the lumen, thus allowing more time for the operation. He also devised a corrugated rubber tube, which is not as easily coughed up as the smooth tubes, nor do secretions adhere to it as to the metal tubes.

CUTANEOUS DISEASES AND SYPHILIS.

BY LOUIS A. DUHRING, M. D.,

OF PHILADELPHIA.

INFLAMMATIONS.

Two Cases of Urticaria Treated by the Administration of Calcium Chlorid.—According to A. E. Wright,¹ “serous hemorrhage” (an increased transudation of the fluids of the blood into the tissues) may be due to a diminished blood-coagulability, and, therefore, we may hope to control the transudation by correcting this defect. To this end he recommends that large doses of calcium chlorid (30 gr. t. i. d.) be administered at the outset to supply the deficiency of lime and to bring the patient rapidly under the influence of the drug; afterward reducing the dose (to 5 gr. t. i. d.), so that excessive quantities of lime shall not accumulate in the system. One of the cases reported had followed the injection of 25 c.c. of antitoxin.

Urticaria following an Enema.—J. E. Moorhouse² reports the case of a woman of 38, who suffered from an attack of dysenteric diarrhea followed by constipation. An enema of soap and water was followed by urticaria, which lasted 4 days. The itching and discomfort were slight. The author believes that the eruption was the direct result of a toxemia due to the absorption of fecal matter liquefied by the warm water. All other causes were excluded in considering the case. [The case bears points of resemblance to that reported by Hale in the *Brit. Med. Jour.*, vol. i., p. 474, 1895.]

Case of Ritter's Dermatitis Exfoliativa Neonatorum.—W. A. Newman Dorland³ describes a case of this rare disease (termed by Ballantyne keratolysis neonatorum), which is characterized by an acute cutaneous hyperemia, followed by an excessive exfoliation of the epidermis, and accompanied at times by a vesicular or bullous formation and by a high mortality. It is more common in male than in female infants, and generally appears in the second week, and rarely after the fourth or fifth week. At first apparently healthy, an erythematous hyperemia or superficial dermatitis appears on the face or the buttocks, which soon becomes generalized. There is no elevation of temperature nor gastric disturbance. Exfoliation of the epidermis soon sets in, large flakes coming off. The entire process occupies a week or two, and may be unaccompanied by systemic disturbances; but in many cases there will develop complications, as diarrhea, pneumonia, or marasmus, the infant ultimately dying from exhaustion or from loss of body-heat due to the extensive exfoliation. The author's case was of a mild type, and recovered.

Notes on Dermatitis Venenata.—James C. White⁴ calls attention to some cases of dermatitis due to poisons not commonly recognized. One was that of a young woman with hands and wrists greatly swollen, and the dorsal

¹ Brit. Jour. Dermatol., viii., No. 3, 1896.

⁴ Boston M. and S. Jour., Jan. 28, 1897.

surfaces of her hands thickly occupied by a papulo-vesicular efflorescence in process of development, with much heat and itching. Two days previously she had washed five bushels of recently dug parsnips (*pastinaca sativa*). Another case was that of an inflammation of the skin of the hands excited by oil of cassia, the girl having been engaged in dipping wooden tooth-picks in oil of cassia for the purpose of giving them an agreeable perfume. Reference is also made to the stinging properties of the hairs which grow at the base of the point of the hop hornbeam, and a case is mentioned in which an irritation was caused which did not disappear for several hours. A case of a fireman is given whose skin was poisoned by wearing a shirt dyed in anilin-black. It caused an infiltrated erythema of a brilliant red color, decidedly elevated above the general surface, occurring either in uniform areas of considerable extent or in smaller, discrete, circular patches, varying in size from a pea to a dime. [Dr. White is an authority on this subject, having published valuable articles and a book on dermatitis venenata. The cases referred to are new in the literature of affections of this kind.]

The Relation of Dermatitis Herpetiformis to Erythema Multiforme and to Pemphigus.—Louis A. Duhring¹ discusses this subject, stating that some cases of dermatitis herpetiformis possess similar features to those characteristic of erythema multiforme, especially to the erythematous and bullous varieties of that disease. In dermatitis herpetiformis, however, the cutaneous manifestations are in most instances more intense, more persistent, and more chronic. The formation of pustules, especially miliary and acuminata, so common in dermatitis herpetiformis, is a symptom that is lacking in erythema multiforme. The other well-known disease to which dermatitis herpetiformis bullosa bears likeness is pemphigus, but from which it differs in important particulars. As characteristic of dermatitis herpetiformis may be mentioned irregularity or even capriciousness in the production of the lesions; polymorphism, more notable even than in erythema multiforme or eczema; the tendency to relapses and to recurrences; the irregularity in the evolution of the lesions, especially a tendency to radical and abrupt changes in the kind of lesions; and, finally, the presence of herpetiformity, without which dermatitis herpetiformis cannot exist. All these features are peculiar to the disease and are wanting in pemphigus. The conclusions reached are: 1. That dermatitis herpetiformis is in most instances a disease with well-defined, tolerably constant clinical features; 2. That it is more closely allied to erythema multiforme than to any other generally recognized disease; 3. That the bullous variety resembles pemphigus, but differs from it in the peculiar inflammatory and herpetiform character of the lesions, as well as in the tendency to polymorphism, the irregular and peculiar evolution of the lesions, and in its cause.

Case of Dermatitis Herpetiformis involving the Alimentary Canal and Ending Fatally.—J. Kenneth Watson² reports the case of a woman of 52, who was admitted into the hospital with the following history: after family bereavement, which had brought about serious mental depression, she began to complain of an eruption which commenced at the back of the shoulders, and had continued to spread rapidly up to the time of admission. The skin was covered with an eruption consisting chiefly of large bullæ, irregular in shape and size, situated on an erythematous base. In addition to the bullæ there were scales and pustules. The temperature was not raised, nor were there any signs of acute illness. There was a general feeling of "soreness" rather than of great irritation, accompanied by constitutional depression.

¹ Am. Jour. Med. Sci., Feb., 1897.

² Lancet, July 11, 1896.

She was a year past the menopause. A mixture containing potassium iodid, perchlorid of mercury, and liquor arsenicalis, was ordered, and an ointment containing zinc oxid and ammoniated mercury. Under this treatment the skin improved very rapidly, the contents of the bullæ drying up and the lesions being replaced by raised pigmented and discolored patches. On the fourth day two bullæ were noticed, one on each side of the hard palate posteriorly, and at this time diarrhœa set in, which became very intractable, although it was partially held in check by copper sulphate and opium in pill-form. Mercurial treatment was now stopped, and on the eleventh day opium in larger quantities had to be administered. From this time the patient rapidly became weaker, and for two days before death the diarrhœa was accompanied by vomiting, which could only be partially controlled. She died on the fourteenth day. The points of interest in this case are: 1. The universal distribution, almost no part of the trunk or limbs being free; 2. The apparent lack of any cause beyond the mental condition; 3. The coincidence of the rapid healing of the skin-lesions with the commencement of the diarrhœa, indicating the involvement of the alimentary canal by the disease; 4. The rarity of death from this disease.

Herpes Zoster following Extraction of Teeth.—George Pernet¹ reports the case of a woman aged 25, from whom six teeth were extracted under gas (four lower incisors, right lower canine, and a left molar). Six days afterward a marked herpes zoster appeared in the right axillary region and over the right mamma. A year before, twelve teeth were removed under ether, when she suffered much from shock, loss of blood, and from the anæsthetic.

Counterirritation in the Treatment of Herpes.—Theodore Wilkins² states that in nearly all cases of herpes zoster a tender spot may be found higher up over the nerve-trunk. At this point he recommends the application of a counterirritant in the form usually of fly-blisters or turpentine. The pain in most cases is speedily relieved, and the eruption dries up much sooner than would be the case in the natural evolution of the disease.

Case of Duhring's Impetigo Simplex.—N. J. Kaufman³ reports an example of the impetigo simplex of Duhring, some authors inclining to doubt the existence of the disease. The subject was a child 4 days old. There was no history of impetigo contagiosa in the family or neighborhood. There existed about 12 straw-yellow, firm, discrete, elevated, thick-walled, semiglobular pustules, about the size of a finger-nail, surrounded by a pronounced dark-red areola, disseminated over the chest, abdomen, and legs. There was no depression nor umbilication, nor did the lesions coalesce. After 7 or 8 days some of the pustules became slightly bloody, and then dried to yellowish or brownish crusts, fell off, and left no scar, but a slightly reddish spot which faded in a few days. The disease lasted four weeks. The general health was good. The microscopic examination showed many agglutinated pus-corpuscles, a few red corpuscles, pus-cocci, and broken-down epithelial cells.

Blood-erythema.—Harrison⁴ calls attention to a peculiar state of the skin in which arterial blood sprinkled upon it causes irritation and sets up an erythema (first described by Shield). The case of a surgeon, who for a great many years was annoyed by the irritation resulting from arterial blood coming in contact with his skin, making him uncomfortable, is cited. It was not

¹ Brit. Med. Jour., Jan. 30, 1897.

³ Jour. Cutan. and Genito-Urin. Dis., June, 1897.

⁴ Brit. Jour. Dermatol., p. 42, June, 1897.

² Med. Rec., Sept. 26, 1896.

altogether a subjective sensation, for after washing off the blood a pink stain was left on the skin, which lasted for 15 minutes or longer. He was also very susceptible to the smell of blood. Mr. Chappell Fowler was acquainted with a surgeon who suffered from the same irritation. He was asthmatic and of very neurotic temperament, and the smell of blood was loathsome to him. After a case of postpartum hemorrhage he had seen an erythematous rash on the arm where the blood had been projected some hours after carefully washing the part, and there was irritation.

A Puzzling Eruption following Sunburn.—Erythema—edema—purpura—ulceration.—What was it?—The patient-physician¹ reports the case as follows: in apparently perfect health the physician drove in an open-case carriage, bare-handed, starting, on a very hot summer day, at 7 A. M. At 10 A. M. the neck, backs of hands, and thumbs began to burn. At 11 A. M. the burning was so intolerable that he stopped at a druggist's and applied watery extract of hamamelis. By noon, when he returned home, the burning was unbearable, lead-and-opium wash affording no relief. At 4 P. M. he left by train for Boston. About midnight the parts began to swell, and by the next morning edema was very pronounced, the face and hands resembling erysipelas. Next day petechial spots appeared, the burning and itching continuing. On the third day extravasation of blood began, and after the ninth day ulceration and sloughing set in. Though in good health, the patient had been addicted for fifteen years to the daily use of morphia, but had been cured of this habit two years before. For two months before the attack he had used 3 or 4 ounces daily of fluid extract of coca. During the first five weeks of the cutaneous disease a condition of nervous erethism existed constantly. Appetite was "extra good" until the end of the third week, then fair. The bowels were regular until the fourth week, then constipated for ten days; afterward they were all right. The temperature was normal throughout attack.

Dermatitis, etc., due to the X-rays.—T. C. Gilchrist² records the case of a man of 32, who, after he had exposed his right hand, wrist, and lower portion of the forearm for three weeks for four hours daily to the x-rays, noticed that the skin turned red and swollen, without pain. The swelling first occurred on the back of the hand, then active inflammation set in. Three weeks later there were aching, darting pain up the forearm, and throbbing pain, preventing sleep. Under the use of hot-water applications and the internal administration of bromids the swelling and the other signs of acute inflammation subsided. Three weeks from the beginning the dorsal aspect of the hand was pigmented a dark-brown color, and the epidermis was exfoliating, the skin beneath being dry and of a dull reddish color. Ten days later the skin was stretched and glossy, and there was a distinctly thickened state of the first and second phalanges of all the fingers. All movements of the hand were painful. Sensation was much impaired before exfoliation of epidermis took place. An excised portion of the skin examined histologically showed the vessels of the corium to be dilated, and the pigment-cells of the papillæ to be almost as numerous as are usually found in a section of negro skin. Photographs were at this stage taken of the sound as well as of the affected hand, and revealed a distinct osteoplastic periostitis and probably an osteitis.

E. E. King³ reports a case in which, after six weeks' exposure of from two to six hours daily of the right side, the right hand began to swell, the feet became stiff, and large blisters appeared on the dorsal aspect, which produced great pain. The demonstrations were discontinued, and the hand recovered. Two

months later the patient was again exposed to the rays, this time the left side being placed toward the instrument. In about six weeks swelling of the lips and left cheek occurred, and a few days later the left hand swelled with blebs, ached like a severe sunburn, and the skin was discolored. The finger-nails showed signs of shedding; the eyelids were edematous and there was conjunctivitis on both sides. About two-thirds of the side of the face exposed to the rays was affected. Subsequent notes state that the skin of the hands was congested, infiltrated, and unusually smooth, the left being almost entirely devoid of hair. All the nails were in a state of exfoliation. The hair on the left side of the face was to a great extent lost, the eyebrows, moustache, and whiskers being almost gone, the skin in these regions being very smooth and different from that of the other side.

H. R. Crocker¹ reports (with portrait in color, Plate 13) the case of a boy aged 16, upon whom the experiment of radiographing the spine was made. A Crookes tube was placed about 5 inches from the epigastrium, a flannel shirt intervening between the tube and the skin. The next day the skin felt irritated, and was of a deep red color in the area subjected to the rays from the tube. Six days after the experiment the skin felt stiff when he bent his body, and a few days later vesicles formed. Subsequently the patch was the size of a hand, very sharply defined, and raised. The lower border was sharply outlined; the upper much less so. The color was a dark or purplish red. Numerous flat vesicles occupied the surface of the skin. The skin felt sore, but was not very tender. There was only moderate itching. A week later the epidermis became detached, leaving a raw surface which healed very slowly.

Hypertrophic Lichen Planus.—J. A. Fordyce² records the following case: the subject was a man, aged 54, the skin-disease having appeared two and a half years before. The anterior surface of the right leg was the seat of numerous, closely aggregated, flat-topped, warty elevations, of a purplish-red to a brownish-red color, and of irregular outlines. These lesions were moderately firm, and covered by a thickened stratum corneum, which could be seen as minute horny plugs dipping below the cutaneous surface. Surrounding the warty lesions were a great number of brownish-red papules situated around and independent of the hair-follicles. These papules corresponded in their main features with lichen planus papules, having flat, shiny tops, angular outlines, and some showing the central dell. The lesions varied in size from a pin's head to a pea, or even larger. Intermingled with and about the smaller papules were individual and grouped sepia-brown to black pigment-spots, which evidently represented the involution-stage of the papules that had not developed into the larger tumors. This pigmented area extended upward and outward over the leg until it became continuous with a similar group of lesions in the right popliteal space. Here the same general condition existed of warty growths, small papules, and pigmented spots, as seen on the anterior surface of the leg. The warty growths in this locality were softer, pinkish to bluish-red in color, and formed the most prominent feature of the clinical picture (see Plate 12). They were elevated from a quarter to half an inch above the skin-level, and formed a band-like group extending across the popliteal space for a distance of three inches or more. At right angles to this band another group of lesions extended upward. The left popliteal space and the sacral region on either side of the gluteal fold were affected in a similar, though less pronounced, manner. The genital region was implicated in a most curious and striking manner by the new growths, which occurred as isolated, dome-shaped, hard, purplish-red papules in the hair over the pubes. The skin of the penis, with

¹ Brit. Med. Jour., Jan. 2, 1897.

² Jour. Cutan. and Genito-Urin. Dis., Feb., 1897.

the exception of a narrow ring about the prepuce, was almost completely surrounded by the papillomata, which had coalesced in a diffuse infiltration made up of elevations and depressions. The growth here was distinctly pinkish in color, quite firm, painless to pressure, perfectly dry, and not marked by evident desquamation. The skin which was not attacked was the seat of a deep patchy pigmentation, and spots of leukoderma. On elevating the organ its under surface was seen to be the seat of similar warty tumors, which were arranged in the form of bands on either side of the raphe, and extended in a continuous, beadlike line of nodules along the raphe of the scrotum, suggesting an antioinculation from contact with the apposed surface. The scrotum was deeply pigmented; the inguinal nodes somewhat enlarged, but painless. The posterior surfaces of the forearms were a trifle pigmented, rough, and showed a papular development not unlike that seen in prurigo mitis.

Prurigo.—James C. White¹ gives a critical review of our knowledge of this disease, and finds that the views of dermatologists in all countries are discordant. He says: "We find wide differences of opinion held by accomplished dermatologists concerning the primary manifestations and their mutual relations upon the anatomic character of the so-called characteristic lesion or lesions and upon their pathologic significance; deviations from the Hebra standard in point of the parts affected and course of the disease; marked variations in type and prevalence in different countries and nationalities." He sums up his views of the situation by stating that he can go no farther than to "accept the existence of a condition of early childhood allied to pruritus and urticaria in its visible manifestations, and not to be positively distinguished from them in its first stages, often becoming in certain parts of the world a chronic affection due to some inexplicable national cutaneous traits, or inherent customs of living—a condition which certainly lacks many of the essential elements of individuality."

E. Besnier,² of Paris, discusses this disease in its totality, but especially its position among other allied diseases of the skin, and concludes that it begins in early childhood as a cutaneous disturbance manifesting symptoms closely related to pruritus and to urticaria, from which disease it is indistinguishable in the beginning; that it occurs in certain parts of the world in consequence of inexplicable national peculiarities of the skin or of heredity, taking on a chronic form characterized by certain well-defined clinical features. [The paper thus succinctly abstracted is an elaborate, lengthy, and valuable contribution to the pathology of this much-discussed disease, which in some large centers of population in the United States is practically unknown (as in Philadelphia), and in others (as Chicago) is only rarely met with. It occurs in its most pronounced form in Austria.]

On the Restriction of Meat in the Treatment of Psoriasis.—L. Duncan Bulkley³ states that there are few who will contend that this disease is wholly local in its origin, either in the line of idiopathic cell-derangement or external causation. All who are familiar with the disease know only too well how temporary and relatively unsatisfactory local treatment proves to be. Observation and study, with a large amount of material, extending over many years have led the author to the conclusion that the disease is dependent upon a blood-state closely allied to that belonging to gout and rheumatism, which is perhaps best expressed by the term "uricacidemia." The chief point in the article is that free indulgence in meat is very likely greatly to aggravate the eruption of psoriasis, whereas its restriction (especially

¹ Jour. Cutan. and Genito-Urin. Dis., Jan., 1897.

² Monatsh. f. prakt. Dermatol., Sept. 15, 1896.

³ Med. Rec., Jan. 9, 1897.

the avoidance of beef and mutton, including meat-extracts and strong soups) will materially aid in its removal. The author does not wish to be understood as saying that the eating of strong meat alone will produce the eruption, or that its avoidance will surely cure the eruption, but that the element under consideration is of great importance in the management of psoriasis.

Local Treatment of Variola.—F. S. Purman,¹ stimulated by Bryan's success, treated 2 cases of variola antiseptically by a somewhat different method. As soon as the papules developed into vesicles the surface was scrubbed with soap and water, followed by solution of hydrogen dioxid. The vesicles were then opened, the fluid permitted to escape, and the cavity touched with pure carbolic acid, and the surface again washed with solution of hydrogen dioxid, oiled to relieve the smarting, and finally covered with cloths wrung out of carbolized water. No pitting of the skin resulted in either case.

Arrest of Variola in its Vesicular Stage.—Alonzo Bryan² thinks that the eruption can be arrested in its vesicular stage, and that the pustular stage is due to infection of the vesicles by pyogenic organisms. A case is narrated in which the hands and forearms, the seat of a papular eruption, were disinfected by means of soap and water, alcohol and corrosive sublimate (1 : 500), and a solution of hydrogen dioxid. The parts were then wrapped in borated cotton. On the parts thus treated most of the vesicles dried up into adherent dry scales, without any suppuration, only a small number forming pustules. When vesicles only had formed there was no scarring or pitting. On the rest of the body the disease ran its usual course.

Treatment of Acne.—G. T. Elliot,³ after discussing the general treatment of the disease, says: There are innumerable local remedies employed in the treatment of acne, but all those which are of any benefit are to a certain degree antiseptic in action. They are in the forms of lotions, salves, and powders. When the process is acute, and the inflammatory symptoms are active, then soothing applications are at first preferable, such as a 2% salicylic acid ointment, or a lotion of magnesiae carbonat., zinc. oxid., $\bar{a}\bar{a}$ \bar{z} j; hydrarg. bichlorid., gr. j to ij; aq. rosae, \bar{z} iv. M. In place of this, a dilute lead wash, or the lotion of lead water and opium can be used, or any other mild application. The remedy used should be kept as long as possible in contact with the surface, and not simply dabbed on once or twice daily.

When the acute symptoms have subsided, or when the inflammatory reaction is more of a chronic type, and this is the rule, then more stimulating applications are necessary. The majority of those which offer good results contain sulphur, either in powder form, or in an ointment or a lotion. The sulphur mixed with starch in the proportion of 1 to 8 or 1 to 4 may be used, or it may be incorporated in Bassorin paste. When used as an ointment, its strength should be at least 10%, and even 20% or more. \mathcal{R} . Sulph. sublim., \bar{z} ij; aetheris, spts. vini, glycerin., $\bar{a}\bar{a}$ \bar{z} ij; aq. calcis, aq. rosae, $\bar{a}\bar{a}$ \bar{z} iv. M. or, \mathcal{R} . Sulph. lactis, \bar{z} iv; tinct. saponis viridis, \bar{z} x; glycerin., \bar{z} vj; spts. vini, \bar{z} j. M. Both are good lotions in chronic cases. One of the most useful is potass. sulphuret., zinc. sulphat., $\bar{a}\bar{a}$ \bar{z} j; aq. rosae, \bar{z} iv. M. All of these are applied at night after a preliminary soap-and-water washing, and allowed to remain over night. They produce a certain amount of reaction, a more or less marked temporary shrivelling and scaling of the skin, but are not to be dispensed with for that reason. If their effects are severe, they can be weakened in strength or used less frequently. Vlemineckx's solution is also at times of benefit, as is also a paste: \mathcal{R} . Sulph. sublim., \bar{z} iss; glycerin., \bar{z} j; spts. vini camphorat., \bar{z} x; aq. rosae, q.s. M. (Besnier).

¹ Med. Rec., Sept. 5, 1896.² Ibid., July 10, 1896.³ Post-Graduate, Oct., 1896.

The mercurial preparations are much esteemed, but care should be taken not to use them when any sulphur preparation is being or has been applied. A favorite lotion is: *R.* Hydrarg. bichlor., gr. xv; ammon. chlor., gr. 30-70; spts. vini, $\bar{\text{v}}$ iv; aq. rosæ, ad $\bar{\text{O}}$ j. *M.* or, the corrosive sublimate can be used in any other combination desired.

Ointments are extensively prescribed, though in Elliot's experience they are of value only in particular cases, when uncomplicated by a seborrhœa oleosa, and when there is a natural dryness of the skin. The ointment may be a sulphur one, or of beta-naphthol, 5% to 15%; or of ichthyol, 10% to 25%, or more; or of resorcin, 5% to 20%; or of some of the mercurials—the white precipitate, the ungt. hyd. oxid. rub., 5%, or the ungt. hyd. nitratis, $\bar{\text{v}}$ j to $\bar{\text{v}}$ ij, ad. $\bar{\text{v}}$ j. A very useful combination when much pustulation exists is: *R.* Ungt. hyd. oxid. rub., $\bar{\text{v}}$ ij; ungt. sulphuris, $\bar{\text{v}}$ vj; ungt. zinc. oxid. ad. $\bar{\text{v}}$ ij. *M.*

Care in the local treatment of acne should be taken that too severe measures are not employed, so as to avoid secondary injuries to the tissues, which may be of more moment than the skin-disease itself, and in consequence the effects of the remedies should always be carefully watched, and the amount of reaction should be controlled. Success in the treatment of acne depends particularly upon the proper conception of both the etiologic factors existing in each case presenting itself, and also in a knowledge of the pathology of the disease. Every example of acne should be regarded as distinct and whatever remedy or mode of treatment is instituted should be prescribed after careful investigation into the indications furnished by the patient's history. Routine treatment cannot but furnish more failures than successes.

Etiology of Acne.—Lomry,¹ from a bacteriologic examination of comedo and pustular acne, concludes that the staphylococcus pyogenes albus is constantly present in the pustule of acne, but that it possesses a very weak virulence. By passing it through the animal body it can be made as virulent as the yellow staphylococcus, becoming at the same time yellow and acquiring the faculty of liquefying gelatin. Besides the staphylococcus albus, there are present also occasionally a yeast-fungus and a bacillus, always in small numbers. In noninflamed comedo there is an abundant development of microbes, the staphylococcus albus always being present, but not in such numbers as in the acne-pustules. In comedo one observes at the beginning of the inflammatory process a microbial development intermediate between that of the pustule and that of the noninflamed comedo. When inflammation sets in in comedo there occurs a considerable diminution in the number of kinds of microbes. The skin of those not affected by acne is as rich in microbes as that of the acne-subject. In the comedones and pustules which sometimes occur on those not affected by acne the same microbes are found as in those who have acne. The presence of certain microbes is not sufficient to explain the occurrence of the malady. There must be a peculiar soil. We cannot accept the theory of a specific cause in acne. The staphylococcus albus is seen in many other diseases of the skin. The clinical features which Unna brings forward to contrast acne with other staphylococcic infections of the skin may be explained by the difference in the virulence of the microbes. The special bacillus of Unna is only a variety of the bacterium coli with attenuated virulence.

Case of Folliculitis Decalvans.—George Thomas Jackson² reports, with photographs, a case of this rare disease. The subject was a woman 35 years old, nervous and worried over family matters. Her appearance showed that she was harassed. She was very thin and her face was drawn. The hair turned gray prematurely. She suffered with intense headache. The disease had

¹ Dermatol. Zeit., Bd. iii., H. 4.

² Jour. Cutan. and Genito-Urin. Dis., July, 1896.

begun 6 years before, on the vertex. Since then new patches had formed from time to time, especially since she was injured in a railroad accident one year ago. None of the old patches have got well, but, on the contrary, have spread slowly into the surrounding parts. There are now some ten patches scattered over the scalp. They are irregular in shape, cicatrized in their centers, and push out into the surrounding parts, so that the full extent of the ravages of the disease can be seen only by raising the hair about them. They vary in size from a marrowfat pea up to a patch 2 in. or more in diameter. They seem to begin by the appearance of a small red spot with stumps of hair in it. This slowly invades the surrounding parts, the oldest part becomes crusted, and when the crust falls the scalp is found to be cicatrized and reddened. The disease is attended by no discomfort. Ever since the beginning the patient has been treated by various physicians, but without any benefit. In the diagnosis tinea tonsurans was excluded. Alopecia areata is another possible diagnosis, and one that probably would have been made before we knew of the existence of folliculitis decalvans. It differs from alopecia areata in the chronicity of the patches, in the redness of the scalp, in the crusting that is seen in one part of their course, in the irregular shape of the patches, in their peculiar invasion of the surrounding parts, and in the cicatrization of the center of the patches. The course of the disease is inflammatory, and it spreads as if from local infection. We are ignorant as to its cause. The cases observed have been refractory to treatment.

Chronic Equinia of the Skin.—Buschke,¹ as the result of his study of the literature of the subject and the examination of a case of his own, concludes that there is a form of chronic equinia localized upon the extremities, the ulcers of which have nothing characteristic in their appearance, being almost the same as syphilitic ulcers. The diagnosis is to be made by bacteriologic examination and intraperitoneal inoculation according to the method of Straus, supplemented by the identification of the bacilli by staining and culture. Mallein is possibly available for diagnostic purposes in human equinia. The treatment is extirpation when possible, or cauterization with the Paquelin.

Case of Bucco-facial Actinomycosis Cured.—M. Duguet² reports a case (with portraits taken before and after treatment) of this rare disease which was radically cured. The subject was a young man, and the disease recent, the fungus having very probably penetrated a carious tooth. Cure was obtained after 4 months by treatment with potassium iodid taken internally and injections of tincture of iodine into the fistules and diseased structures. The lesions bore more resemblance to syphilis than to either cancer or lupus.

Some Glycosuric Dermatoses.—C. W. Allen³ observes that if there were sufficient marked characteristics to distinguish the diabetic eruptions from those of similar nature, but of distinct non-diabetic causation, we might be warranted in making of them a class apart, as the syphilides, leprides, etc. The writer's objection to this is that many of the cutaneous manifestations due to the presence of sugar in the system occur in glycosuria (which is not to be confounded with the disease diabetes). Instances of dermatoses disappearing with a transient glycosuria are quoted, and the possibility of glycosuria following funicular and suppurative processes is referred to. Both symptoms might depend upon a common cause. An instance of true diabetes following carbuncle, or at least not being detected until some time afterward, was mentioned. A series of eruptions which the writer had not found mentioned in the literature of *dermatoses diabeticæ* are recorded. The first of these is an eruption involving

¹ Arch. f. Dermatol. u. Syph., Bd. xxxvi., H. 3.

² Presse méd., No. 39, 1897.

³ Jour. Cutan. and Genito-Urin. Dis., Dec., 1896.

the scalp, extensor surfaces of the arms, backs of the hands, thighs, legs, and backs of the feet. It consists of rounded lesions, either with a "scooped-out" center or covered with crusts which had a central depression somewhat like those seen in *acne varioliformis* of Hebra. Other lesions have the appearance of superficial erosions, rather oblong than rounded, presenting a glazed surface. They are irritable rather than itchy. The picture as a whole is more suggestive of *acne cachecticorum* than of the *acne necrotica* above mentioned, which is usually limited to the forehead and a few hairy regions, and has smaller lesions with a crust "mortised-in" at the summit. The lesions, too, are much more obstinate than those of *acne varioliformis*.

Another form of lesions which occurred in the presence of a high percentage of sugar is described as acute multiple gangrene of the skin, of very superficial nature, the ulcerations extending at the periphery until some reach the size of a quarter-dollar; the base grayish-yellow, with the red points of papillæ showing through. [The patient was confined to bed for a fortnight.] Pigmented areas remained where many of the lesions had existed, and some of them became covered with a strong growth of hair. Bronzing of the skin as a condition *per se* is spoken of, and the fact that Mossé demonstrated pigmentations on mucous membranes in diabetics, contrary to the generally accepted view. Erysipelas in diabetics is then taken up, and an instance of death related in which the patient was syphilitic, very obese, and affected with extensive sloughing and undermining of the skin about the trunk. Erythema, dermatitis, and eczema about the genitals, possibly leading to gangrene, receive passing notice, and xanthoma diabeticorum, which some observers maintain is not a xanthoma at all, but more properly called *lichen diabeticus*, is touched upon. The latter is not thought by the author to bear a close clinical relationship to the xanthoma usually seen about the eyelids. The peculiar vulnerability of the skin in diabetics is referred to, and the slight tendency to heal which lesions from injury or disease manifest. [The article is interesting and instructive.]

Balsam of Peru in Scabies.—Jullien¹ states that he has used balsam of Peru, according to the method of Peters and Tanturri, in about 300 cases of this disease. Balsam of Peru contains an essential oil, the vapor of which is extremely toxic to the itch-mite. The patient is rubbed in the evening for fifteen or twenty minutes with the balsam. The vapor itself is sufficient to kill the parasite. The patient sleeps afterward in a night-shirt impregnated with balsam of Peru, and the next morning he is well soaped and has a bath. This treatment is particularly useful in patients affected with secondary eczematoid and other inflammatory lesions, and in weakly persons, in the subjects of heart-disease, in pregnant women, and in nurslings.

Tinea Versicolor on the Soles of the Feet.—E. D. Smith² reports the case of a man addicted to drink the soles of whose feet gave him much uneasiness. The soles of both feet were the seat of patches of a considerable size and of pale-red color, their peripheries being darker than their centers, which were nearly of the color of the normal skin. There was slight itching especially annoying after going to bed. The patches were easily distinguishable by daylight, but with difficulty by lamplight. The microscope revealed the fungus peculiar to *tinea versicolor*. A few applications of tincture of iodine effected a cure. [Such cases are very rare, and the importance of employing the microscope as an aid to diagnosis in cutaneous diseases is admirably illustrated.]

Bald Ringworm.—Dubreuilh and Frèche³ call attention to a form of

¹ Sem. méd., Apr. 15, 1896.

² N. Y. Med. Jour., Oct. 31, 1896.

³ Brit. Jour. of Dermatol., Nov., 1896.

ringworm, under this title, which resembles alopecia areata so closely as to be distinguished from it with difficulty. They report two cases, one certainly, the other probably, of animal origin, due to the ectothrix variety of the trichophyton. The transformation from the ordinary form of ringworm to that resembling alopecia areata was sudden. These cases, the authors think, give a positive foundation for the belief in a relationship between ringworm and alopecia areata.

A Study of the Trichophyton Fungi.—As the result of his investigations Krösing¹ concludes in part that Sabouraud's division of the trichophyton fungi into large-spored and small-spored (megalosporon and microsporon) is unwarranted. The size of the spores varies in the same fungus and in the same culture. Classification of the human trichophytoses therefore, according to their localization (trichophytosis of the scalp, of the beard, of the non-hairy parts), based upon the size of the fungus, cannot prove satisfactory.

Deep and superficial affections (sycosis and trichophytia circinata) may be caused by the same fungus. There are forms of suppuration produced by the trichophyton alone. It is thus far impossible to draw conclusions concerning the fungus at the bottom of it from the clinical picture presented by any trichophytosis.

The Anatomy of Trichophytosis.—Waelsch² finds that the trichophyton tonsurans grows through the cortex of the hair, upward and downward, for a variable distance, but spares the hair-bulb. It develops in the lower corneous layers, as well as in the cells of the hair-follicle in process of cornification. By its growth in the skin the fungus produces inflammation of the skin, causing exudation on the surface, proliferative processes in the epithelial layers, folliculitis, perifolliculitis, and ultimately destruction of the follicle.

The degree of the inflammation, and especially the depth to which it penetrates, are dependent upon the anatomic structure of the parts affected. When the follicles are superficial the inflammation will be less than when they are deep-seated. The presence of the fungus alone is sufficient to cause severe inflammation. To ascribe severe inflammation to a mixed infection with staphylococci, the author thinks, is not justifiable. From a pathologico-anatomic point of view all the morbid processes in the various forms of trichophytosis are the same, varying only according to the anatomic structure of the affected parts, the susceptibility of the individual, and the virulence of the fungus.

Tinea Tonsurans in an Adult.—J. Abbott Cantrell³ reports the following rare case: the subject was a man aged 25, who was employed as salesman in a hat-store, it being his custom to place on his head every hat that had been handled by him, and in doing so it was supposed he contracted the disease. Immediately upon its being discovered by him he presented himself for diagnosis. The scales examined microscopically showed that the trichophyton tonsurans was present. The lesion was situated upon the vertex; it was circular, with the edges sharply defined, the center being somewhat scurfy or nutmeg-grater-like, the hairs being dry, brittle, and broken off. After 4 months' treatment the condition resolved itself into a kerion and got well in a short time. [Tinea tonsurans is a rare condition in adults, being very seldom met with in countries where dermatology is cultivated.]

Formic Aldehyd in the Treatment of Ringworm of the Scalp.
—Alfred Salter⁴ treated 40 cases of ringworm of the scalp in the outpatient

¹ Arch. f. Dermat. u. Syph., Bd. xxxv., H. 1 u. 2.

² Ibid., Bd. xxxv., H. 1.

³ Phila. Polyclinic, Aug. 22, 1896.

⁴ Brit. Med. Jour., Sept. 12, 1896.

department at Guy's Hospital with this remedy. The preparation most used was Schering's "formalin" in full (40%) strength. The fluid was rubbed in with a brush or mop for ten minutes, the hair having been shaved round the margin of the patches. The application was repeated every other day on four occasions and then discontinued. In some patients the head was painted every day for four successive days. Of the 40 cases only 5 required repainting from nonradiation of the disease, and in these the fault lay not with the remedy, but in the fact that, owing to the struggles of the children, no proper application could be made. The ages of the children treated ranged from 4 to 12, and the extent of the disease varied from a small, strictly localized patch to areas which were practically coextensive with the whole scalp. Microscopic examination was always made before commencing the treatment, and the actual presence of the trichophyton verified, whilst before pronouncing any case cured microscopic examination was again made. In 38 of the cases the fungus presented the characters of trichophyton microsporon. Formalin thus applied induces discomfort and irritation of very brief duration rather than actual pain, and does not vesiculate the scalp as it does the skin elsewhere. Only 3 cases showed any suppuration after its use, and in these the process was slight and did not destroy any of the follicles. It produces, however, a thick crust, and the subsequent application of some emollient is advisable. Growth of healthy hair commences immediately, and in three or four weeks the denuded patch is covered with hairs $\frac{1}{8}$ in. long. Allusion must be made to a remarkable occasional complication of the treatment. In 6 cases edema of the face was noted some hours after the painting. In one case this was so extensive as to completely prevent vision from swelling of the eyelids, and the forehead pitted $\frac{1}{2}$ in. on pressure. The skin, however, was neither hot nor red, and there was no pain nor constitutional disturbance. The edema only occurred when the area treated was very large, and the condition is probably analogous to that produced by a nettle-sting. It is interesting in this connection to remember that the active toxic agent in the nettle is formic acid, and that it is thus closely related to the substance now under discussion. The occurrence of this edema renders it advisable to deal with limited areas at a time.

Treatment of Chronic Tinea Tonsurans.—Herman B. Sheffield¹ treated in an institution 369 cases of tinea tonsurans, most of which had previously resisted varied forms of treatment. The diagnosis in all cases was confirmed by the microscope. Chrysarobin had been freely used during a period of four months, with the result of setting up a suppurative inflammation of the scalp and face in about 20% of the cases, and acute conjunctivitis in more than half of them. After some experimentation the following combination of drugs was found to constitute "the most reliable formula, curing all cases in about four weeks:" *R. Acidi carbonici, ol. petrolei crudi, āā ʒij; tinct. iodini, ol. ricini, āā ʒiiss; ol. rusci, q. s. ad Oj. M.* Sig. Apply over entire scalp once a day for four successive days; wash off thoroughly with green soap on the sixth day; then clip the hair close and wash again as before. Repeat this course of treatment regularly for three successive weeks. After this plan had been followed for the period stated the microscope failed to reveal the trichophyton fungus in the majority of the cases. To relieve the slight eczematous eruption which was still present the following was ordered: *R. Resorcin., acid. salicylic., āā ʒiv; alcoholis, ʒiv; ol. ricini, q. s. ad Oj.* This was well rubbed into the scalp. After about two weeks the hair in the bald spots began to grow, and no relapse of the disease has since occurred. The advantages are that the cure is speedy, and attended with but little inflammation. It can be

¹ *Am. Medico-Surg. Bull.*, Sept. 5, 1896.

easily and rapidly applied. The mixture being thickly applied excludes the air, thus retarding the growth of the fungus, while by keeping the scales and broken-down hair closely adherent to the primarily affected spots the liability of autoinfection is lessened.

The author also praises highly glacial acetic acid as a destroyer of the trichophyton fungus. In 8 acute sporadic cases of tinea tonsurans it was tested with excellent results. It was applied in the following manner: after clipping the hair close to the scalp the affected areas were touched with the acid by means of a cotton swab once every third day, making in all three applications. Care was exercised to prevent the acid reaching the healthy scalp. Two days after the third application the scalp was washed with soft soap and covered with a sulphur ointment (5j ad 5j), after the hair had been clipped again. The resorcin-salicylic oil referred to is useful as a preventive, and should be used toward the end of the treatment with stronger remedies.

Henry A. Pulsford¹ gives his **experience in the treatment of ring-worm of the scalp in the New York Skin and Cancer Hospital**, the material upon which his paper was based being the clinical records of 75 cases treated during the ten years ending in 1892. All the cases were inmates of this hospital during the entire course of their treatment. All the circumstances were favorable, not only for cure of the cases, but for the accumulation of data as to the value of the various methods of treatment employed. From the author's analysis we may conclude that, of all the remedies used upon these 75 cases, the preparations of mercury proved the most efficient. Of the others, iodine, naphthalin, salicylic acid, and chrysophanic acid seem worthy of further trial, while croton oil, properly used, was as valuable as electrolysis in eradicating the last traces of the disease. The results obtained in the treatment of ringworm of the scalp, finally, give full corroboration to the recent dictum of Wickham, of Paris, that "No matter what methods are employed, the duration of treatment necessary to the thorough cure of ringworm of the scalp cannot practically be reduced to less than eight months."

ATROPHIES AND HYPERTROPHIES.

Alopecia Areata as a Result of Exposure to the Röntgen Rays.—Frederick S. Kollé² reports the following case (with photograph): the subject was a boy, 12 to 13 years of age, who had sat for some pictures before. A radiogram of his skull was made. The exposure was one of forty minutes, made in the usual way, with a Thompson double-focus or standard vacuum-tube. The distance between the tube and skull was a little over eighteen inches. As the time of sitting was long for him, he was advised to close his eyes and so overcome the monotony of watching the minutes pass by on a clock hanging directly in front of him. He did so, fell asleep, and slept throughout the sitting. This was the only radiogram made that day. Radiograms of his body were subsequently completed in the four sections necessary, and the boy disappeared until three weeks later, when he reappeared, showing a large area of hair missing upon that side of the head exposed to the vacuum-tube, as shown by the photograph. There had been no premonitory symptoms of itching or inflammation; all the patient knew was that on the night previous the hair had suddenly fallen out. The integument, or scalp, appeared bald and somewhat elevated, and slightly edematous. There was no redness, sensibility was not impaired, the patch was regular, and scaling was absent. The area was perfectly bald, not even lanugo-hairs being present.

² Brooklyn Med. Jour., Dec., 1896.

Common Alopecia: its Nature, Cause, and Mechanism.—R. Sabouraud,¹ who has studied ringworm so thoroughly, summarizes his conclusions on common alopecia as follows: I. The specific microbacillus of oily seborrhea introduced into the pilosebaceous follicle causes there four constant results—namely, (a) sebaceous hypersecretion; (b) hypertrophy of the sebaceous glands; (c) progressive papillary atrophy; (d) death of the hair. II. On the scalp, this infection has the vertex for its usual site, oily seborrhea giving rise to the baldness. *Common alopecia is only oily seborrhea of the vertex in a chronic state.* The follicular seborrheic infection is indispensable to the baldness. The infection remains intense, pure, and permanent until the alopecia is fully constituted and the ultimate sclerosis of the follicles occurs. III. Common alopecia is then a microbial, specific, well-characterized disease. A remarkable statement of the author in this paper relates to the action of the seborrheic toxin on the hair-papilla. The cocoon (described elsewhere) remains circumscribed in the upper third of the hair-follicle, consequently the bacilli themselves do not reach the papilla. Death must then be produced by toxins generated in the neighborhood of the cocoon of the hair. Cultures of the microbe on artificial media furnished a toxin which, when injected into sheep, rabbits, and guinea-pigs, produced loss of hair without any other symptom. These inoculations, done under all conditions, would seem to preclude errors in the results obtained. The author points out certain errors of observation as to these facts, which have led such observers as Unna and others astray. They are: (1) examination of seborrhea by surface-scraping, instead of section through the integument; (2) the misconception that the pathology and physiology of the follicle are the same as those of the epidermis, than which nothing is more erroneous; (3) the presence of pityriasis accompanying alopecia. When the two occur coincidentally the baldness is due to a subjacent seborrheic infection, but they may be commingled. [This work by the distinguished dermatologist, microscopist, and pathologist, is experimental and novel. The conclusions should be received cautiously. They require to be verified by other observers before being accepted as final.]

Pitting about the Hair-cups.—Browning² describes a trophic change of the skin in certain nervous disorders of central origin. It consists in a faint depression, frequently oval, in the direction of the lines of the skin, about the exit of each hair. It is slightly paler than the surrounding skin, like a minute cicatrix, but soft to the touch, and is usually found upon the extremities, most markedly upon the lower. On the upper it is seen best on the outer side of the forearms; on the lower, chiefly on the front and outer side of the leg below the knee. In chronic anterior myelitis associated with progressive muscular atrophy the author has never found this pitting absent. It has been noted also in paralysis due to lead-poisoning, spastic tabes of syphilitic origin, and grave hysteria. It would seem that this pitting is indicative of disease of the spinal cord, especially of the anterior horns, and is useful in differentiating central from peripheral disease. Its occurrence indicates a grave disorder.

Too Much and Too Little Hair.—G. T. Jackson³ concludes, from a study of the first hundred cases of hirsuties in his case-book, that hypertrichosis in women is very largely a matter of heredity, especially on the maternal side. It has comparatively little to do with disorders of the reproductive organs. Brunets are more prone to it than blondes. A woman with hirsuties is a little less apt to bear children than one without hirsuties. The

¹ Ann. de Dermatol. et de Syph., t. viii., No. 3, 1897.

² Jour. Nerv. and Ment. Dis., Sept., 1896.

³ Med. News, July 11, 1896.

most frequent age for the appearance of the affection is between the sixteenth and thirtieth years. There is but one treatment—by electrolysis, which the author recommends under certain conditions. With regard to premature alopecia, he states that in men seborrhea and heredity are the main causes. In women anemia, chlorosis, and neurasthenia are contributory factors. The chances of improvement and restoration are much greater in women than in men. Massage is highly esteemed in the treatment. [The operation of electrolysis for the removal of superfluous hair from the face of women in marked cases should never be undertaken without due consideration of the ability of the subject to carry out the treatment to the end. A face operated on here and there, and left "half-finished," is more disfigured than if nothing had been done. The operation is tedious and expensive, and is generally followed by obvious, often disfiguring, scarring.]

A Rare Case of Acquired Hypertrichosis.—Valentine Zarubin, of Charkoff, Russia,¹ gives the notes of this case: the subject was a woman of 38. She married at 23, and bore a child after a year. Two years later a pregnancy was interrupted at the eighth month, the child dying. She was in bed for 6 weeks, and had much pain in the sexual region. She first remarked an abundant growth of hair on the breast. A little later the whole body was covered, and finally, after 3 months, the face. From this time, her head began to grow bald; 6 weeks after childbirth her abdomen began to enlarge enormously, but pregnancy was not recognized by the accoucheurs consulted. For three years the patient consulted physician after physician, and tried every means to rid herself of beard and moustache (shaving, pulling the hair out, epilation by electrolysis), but without avail; 6 months after, the abdominal swelling was reduced, but the pain continued. Having exhausted her money, she exhibited herself to the public. The family history showed no such anomaly. The woman was tall, strong, and well nourished; a brunet. The whole surface was abundantly covered with hair, especially the face, where it was nut-brown in color. The hair of the beard was soft and fine. The same was true of the body, except that the growth was shorter. The head was so bald that a wig was worn to cover it. The genital and axillary hair was normal. No peculiarities were remarked in the teeth. The breasts were well developed, the carriage was masculine, and the voice coarse. Menstruation appeared at 16. After the first year the periods were abundant, regular, and lasted 7 days. After the premature labor the menses did not appear for 11 years. Sexual sense was normal. Gynecologic examination showed hypertrophy of the clitoris, with a well-developed glans and prepuce. The other organs were normally feminine. There was a left-sided salpingo-oöphoritis. As to the etiology of the case, one sees that heredity has no place. The anomalies in the sexual sphere pointed out by various authors were present in this instance (amenorrhœa). In the cases of De Creccio,² E. Hoffmann,³ Durval,⁴ and others, beard and moustache existed in pseudohermaphrodites of feminine sex. In this case a false feminine external hermaphroditism (*pseudo-hermaphroditismus femininus externus*) existed. The etiologic factor was, very possibly, a severe psychic disturbance.

Lesser⁵ has reported a similar case in a girl of 6, in whom the growth began at the age of 4. Besides the hair on face, pubes, axillæ, and the body in general, the child exhibited signs of precocious development, menstruating first when 3 years of age.

Ichthyol in Ichthyosis.—Max Klonk¹ reports a severe case of ichthyosis treated by him in a boy 15 years of age. The disease first manifested itself in infancy, and had resisted all previous treatment. The patient first received a warm bath of 20 minutes' duration, containing 10 oz. of pure ichthyol, and was then rubbed down with a bland soap and water, a rough towel being used for drying. The skin was now rubbed with pure ichthyol, the patient wrapped in woollen blankets, and given repeated doses of extract of jaborandi to stimulate diaphoresis. The next day the patient was rubbed down with soap and water, and in the evening a warm bath containing sea-salt was given. On the third day the treatment of the first day was repeated. Thus, the patient received, in the course of 1 week, 3 ichthyol baths and inunctions, 3 warm soap-baths (in the morning), and 3 sea-salt baths (in the evening). Three 2-gr. capsules of ichthyol were taken daily for the first week, 6 daily the second week, and 8 daily the sixth week, this latter quantity being continued for some time. Under this treatment the patient gained rapidly in weight, and the horny masses were cast off. After 4 weeks' treatment the greater portion of the surface was free from disease, the skin being smooth, soft, and moist. During the day the body was kept moist with glycerin and water (1 : 3); occasionally an ointment of sulphur, resorcin, zinc, and benzoated lard was substituted. Another case is cited in which the most remarkable results were obtained in the short period of 18 days. The unusually favorable results achieved by this treatment have convinced the author that ichthyol is a remedy possessing specific virtue in ichthyosis. [It is not stated how long the cases remained free from disease.]

Streaked Skin Affections of the Lower Extremity.—Julius Heller² believes that the striated distribution of the disease over a part or the whole of the lower extremity is dependent upon anatomic conditions, and is common to the whole class of such affections. The cases depicted and described were observed by Unna, Shearer, Philippon-Unna, and Neumann. Some were of an inflammatory nature, others possessed the general characters of nevi, for the most part unilateral. Heller concludes that all attempts to explain by any one system the streaked or striated affections of the lower extremity fail. In one case involvement of the larger lymphatics can without doubt be considered the cause of the streaked character of the eruption, but in other cases this factor can be with certainty excluded. The anatomic basis of every case must be separately determined.

Case of Symmetric Morphea attended with the Formation of Bullæ and Extensive Ulceration.—Prince A. Morrow,³ after referring to the statistic frequency of morphea and scleroderma in this country, reports a case of morphea which was remarkable for the number and size of the plaques, their symmetric distribution, the occurrence of bullæ, and the extensive breaking down and ulceration of some of the patches. The patient was a man 66 years of age, who had always enjoyed excellent health with the exception of attacks of inflammatory rheumatism. One year before, the first patch appeared upon the anterior surface of the right thigh. Similar patches were soon observed upon both right and left thighs and over the tibial regions. Three months later, broad, bandlike patches appeared upon the lower abdomen, the sides of the trunk, on the back between the shoulders, and along the spine. These patches were symmetric in form and disposition. Over the right thigh they had become confluent and formed a continuous sheet, completely investing the limb in its upper and middle thirds. On the left limb they were for the

¹ Ohio Med. Jour., vii., 1896. ² Internat. Atlas of Rare Skin Diseases, part xii., 1895.

³ Jour. Cutan. and Genito-Urin. Dis., Nov., 1896.

most part discrete. They presented a white, lardaceous appearance, were slightly elevated and surrounded by a well-defined lilac border. To the feel they were hard, rigid, and unyielding. The integument could not be pinched up. The white surfaces were stippled over with numerous punctiform indentations corresponding to the follicles of the skin. There was complete absence of hairs on the affected surfaces, with suppression of the sudoral and sebaceous secretions. Sensation was but slightly impaired. The affected surfaces below the knees soon became ulcerated. Cicatrization of those surfaces did not take place until six months later. A noticeable feature was the formation of numerous bullæ of the size of a marrowfat pea or larger, which upon rupturing later discharged an amber-colored fluid, leaving superficial excoriations which healed in a few days. These blebs occurred here and there upon the cicatricial area without assignable cause. Their occurrence was a constant feature for 2 or 3 months. Under large doses of potassium iodid and the thyroid extract there occurred a notable and steady improvement. Later sodium salicylate was substituted for the iodid. The skin lost its boardlike hardness and many of the patches underwent involution.

Porokeratosis.—M. B. Hutchins¹ describes a case of this new and rare disease of the skin, to which Mibelli, of Italy, first directed attention in the *International Atlas of Rare Skin Diseases*, in 1893. The case occurred in a man of 32, the disease having first appeared in early childhood on the border of the left palm as a "seedwart"-like growth, spreading gradually until the age of 15 years. The patch involved the palm and dorsum of the hand, the boundary of the described area being irregular, wavy, about one line in width and height, and formed of horny epidermis. "The border is like the outside of a seam, with a longitudinal thread-like line dividing its lateral halves. Here and there in this line are round, millet-seed-sized or smaller, blackish epidermic concretions, which can be picked out." The "seam" can be snipped off without causing pain or injury to the papillæ. On the dorsum of the first phalanx, external to this "seam," the hairs are broken in their follicles, and the latter show dirty, horny plugs. There existed several other similar areas of disease on the palm, fingers, and dorsum of the hand, and one on the face, the size of small coins. Some of the "seams" or ridges were tortuous in outline, like a burrow. The area of the patch included in the border showed the skin to be smoother than normal (slightly atrophic). All the epithelial structures were involved in the process. A photograph is given. [Mibelli called the disease, based on its histology, "porokeratosis," or keratosis of the sudoriparous ducts. Respighi designated it "hyperkeratosis eccentrica." It is allied to *ichthyosis hystrix linearis*.]

Nævus Acneiformis Unilateralis.—S. B. Selhorst² reports a case of this rare disease, to which he thinks the name given is suitable. The subject was a woman of 24, in good health. The condition existed from birth; it was limited to the left side of the body, occupying the thorax, neck, abdomen, and arm to the second phalanges, the point at which the sebaceous glands cease. It followed the course of the cutaneous nerves. The lesions consisted of oval spots, which coalesced to form one large patch, on which were numerous flat scars bounded by raised patches of skin. The diseased area was dotted over with large, single and double comedones. Occasional small ulcers were met with, resulting from the destruction of tissue following folliculitis and perifolliculitis round the comedones. The microscope verified the clinical picture, so that the term *nævus acneiformis* of this strange disease is not inappropriate. Photographs accompany the description.

¹ Jour. Cutan. and Genito-Urin. Dis., Oct., 1896.

² Brit. Jour. Dermatol., Nov., 1896.

Hypertrophic Rosacea (Pachydermatosis).—Isadore Dyer¹ reports the case of a man, aged 60, a native of Germany, and a farmer by occupation. The disease of the skin of the face had been gradually developing for many years. The skin was thickened in rugæ, running chiefly in parallel lines, crossed at many points, thus giving the skin a tessellated appearance. There was extensive scaling, with excoriations here and there, due to scratching, itching being almost constant. The color of the skin was a dull red, but in no-wise brownish, bronzed, or dusky, as one would expect to note in leprosy. There were no tubercles nor telangiectases. The backs of the hands were similarly affected. The condition seemed to warrant designating the disease pachydermatosis. After one month's use of thyroid extract great amelioration of all the symptoms occurred, and later the case was regarded as cured. [The case is interesting because of the resemblance of the lesions to those of lepra. A similar case is reported with the title "Hypertrophic Rosacea" in the *Pictorial Atlas of Skin Diseases* of the models of the Hôpital St. Louis, Paris.]

NEW FORMATIONS.

Treatment of Keloid with Thiosinamine.—R. C. Newton,² from his experience in 2 cases, thinks favorably of this mode of treatment. It has a distinct action on scar-tissue [as H. Hebra pointed out in connection with lupus vulgaris and corneal opacities in *Internat. klin. Rundschau*, 1892]. Tousey³ first called attention to its value in keloid. Newton used a 10% solution in absolute alcohol, 18 minims being injected into the deltoid muscle, and subsequently every 4 or 5 days. There were nausea and vomiting, and the injections were painful. The cicatricial tissue (in one case) and keloid (in the other case) became softer and smaller under the treatment. One case received 29 injections in all. [The treatment seems to have been followed by moderately satisfactory results; but it cannot be regarded as of great value.]

Myoma Multiplex of the Skin.—H. R. Crocker⁴ reports a case of this rare skin disease. Babes divides it into 4 varieties, namely: 1. Myomata springing from the vessel-walls; 2. Hyperplasias of the arrectores pili; 3. Neoplasms from the deep muscular layer of the skin; 4. Myomata from embryonic "remnants." Crocker's case was in a man aged 43. Eighteen years before, there appeared on the left side of the lower jaw a small tumor, which was at first regarded as a fibroma. Slowly a number of similar tumors formed around the primary one, until a patch of closely aggregated, painless, brownish-red tumors formed, each tumor occupying a space $1\frac{1}{2}$ by 1 in. in area. The tumors were excised. A short account of 12 cases observed in various countries is given.

Xanthoma Diabeticorum.—A. R. Robinson⁵ describes the case of a woman who had never been jaundiced herself and had never had a relative thus affected. During the past 10 years, however, she had suffered from gall-stones. The eruption first showed itself in 1891, especially upon the anterior surfaces of the forearms and about the elbows, with a few scattered spots upon the knees. With the exception of those about the elbows, they all disappeared. In the second attack about 150 lesions made their appearance upon the right arm, and about the same number upon the left; but in the latter there was none over the fingers or joints. About 50 lesions were present upon each leg, from the calf to the middle-thigh region. The face and eyelids were free. The

¹ New Orl. M. and S. Jour., Jan., 1897.

² N. Y. Med. Jour., Mar. 20, 1897.

³ *Ibid.*, May 2, 1896.

⁴ Brit. Jour. Dermatol., Jan., 1897.

⁵ Jour. Cutan. and Genito-Urin. Dis., Dec., 1896.

size ranged from that of a pin's point to a pin's head. The color was yellowish, with a tinge of red. On pressure the yellowish color was intensified. The urine showed no sugar, but the report of the examiner was that it appeared "glycosuric." It contained 20% by bulk of albumin and a few granular casts. The interesting features of the case were the absence of sugar in a person who had the physical appearances of a diabetic, the presence of a parenchymatous nephritis, the desquamative hidradenitis, and the condition of the gall-bladder.

The Treatment of Lupus Vulgaris with Salicylic Acid and Creosote Plaster.—W. Dubreuilh and Bernard¹ observe that Unna's salicylic-acid-and-creosote plaster has the advantage of attacking the diseased parts alone, the tubercles being thoroughly destroyed by the salicylic acid, and the healthy tissue remaining unaffected; the creosote subdues the pain of the application. The plaster contains equal parts of salicylic acid and creosote, or a larger quantity of creosote. It should be large enough to include some of the healthy skin, and should be renewed once daily. The application is painless at first; burning pain is experienced when the lupus begins to ulcerate. According to Unna, the pain lasts from 5 to 15 minutes, but the authors say it seldom exceeded 1 minute in their experience. After the plaster is removed the surface is cleansed with moist cotton, and the application renewed. After 3 or 4 applications the lupus-nodules begin to ulcerate separately, and after 8 to 10 applications the entire diseased area is either ulcerated evenly or is covered with deep, cup-like ulcerations. The healthy skin and cicatrices are never attacked by the salicylic acid. The authors have treated 10 cases according to this method. They prefer the stronger plasters for the treatment of the deeper foci of disease, and use about 20 plasters on an average in every case. In the treatment of sclerosed lupus the plaster did not answer well; the authors are of the opinion that in this form of lupus surgical treatment, especially scarification, is more useful.

Like other methods of treatment, the plaster does not bring about a complete cure. Relapses may occur. Patients who object to surgical treatment may be treated advantageously with the salicylic-acid-and-creosote plaster. It is less severe than by mercuric chlorid and caustic potassa, and less painful and dangerous than arsenical paste. The treatment of lupus superficialis with the plaster promises the best results. Suspicious points can be cauterized with silver nitrate, or destroyed with galvanocautery or with other local remedies, like pyrogallie acid, during cicatrization.

Treatment of Lupus Vulgaris by Means of Electrolysis.—A. Ravogli² states that electrolysis acts very gently, destroying the tubercle by the combination of scarification with its histochemic action. In cases of lupus in which small tubercles are scattered, especially on the face, it is a good method. It leaves a small and scarcely perceptible scar. A salve consisting of salicylic acid, 20 gr., creosote, 30 drops in 1 oz. of vaselin, is first employed; with this application the crusts fall off and the tubercles show plainly as whitish points. Each of the tubercles is then treated with electrolysis, the application of the salve being continued. When the necrosed tissue has sloughed off and granulation commences, the sites of the tubercles are touched every alternate day with a 5% solution of nitrate of silver, covering the surface with a salve of zinc or boric acid until recovery. With this method perfect success was obtained in 5 weeks in 1 case. Two more cases are at present under treatment with similar results, showing that electrolysis is to be considered as a valuable agent in the treatment of this disease.

¹ *Monatsh. f. prakt. Dermatol.*, xxii., Feb., 1896.

² *Jour. Am. Med. Assoc.*, Dec. 5, 1896.

Thyroid Extract in Lupus.—J. Barclay¹ reviews the use of this drug in lupus vulgaris, quoting the favorable experience with it of P. Abraham, B. Bramwell, and Lake. He records three cases with favorable results after the drug had been administered for a long period. The reaction in one case was very severe, the burning pain being very distressing, and similar (though less violent, both locally and constitutionally) to that observed after the use of tuberculin injections. Two of the cases he believes to have been permanently cured in one year. The dose of the drug required is larger than for myx-
edema.

F. G. Proudfoot² has also had good results with the same drug in two cases of lupus. By degrees one case took as much as 75 gr., the other 90 gr. daily, but later about 15 gr. daily was the dose administered. The treatment was continued over a period of eight months, both cases, it is said, having departed from the hospital absolutely well.

An Oidium in the Skin of a Case of Pseudo-lupus Vulgaris.—T. C. Gilchrist and W. R. Stokes³ report the results of microscopic investigation in a case of disease of the skin which resembled lupus vulgaris more than any other well-known disease. Miliary abscesses were found in the epidermis and in the upper portion of the corium, in all of which were numbers of doubly contoured, refractive, round, and ovoid bodies, many of them with buds, others with vacuoles. They were arranged singly or in groups, contained granular protoplasm, and resembled closely blastomycetes. No tubercle-bacilli could be found in any of the sections. The writers were of opinion that this extensive cutaneous disease was caused by the species of oidium described, and that this is the only example in literature of a pure disease of the skin which has been shown to be caused by a species of oidium, and the third example in which lesions of the human skin have been produced by organisms allied to the yeast-fungi, Busse's case and Gilchrist's case being the other two. [The case is of much interest, especially in connection with Wernicke's, Busse's, and Gilchrist's investigations in other similar cases recently reported.]

Case of Erythematous Lupus Cured by Injections of Lamb-serum.—Legrain⁴ reports a case of erythematous lupus of the face cured by injections of serum obtained from a lamb. The disease had been treated for more than a year with the local applications and internal remedies usually employed in such cases, without success. Linear scarifications, while producing a slight improvement, had not been of more than transient benefit. Two months after cessation of all treatment two injections of lamb-serum, of 10 c.c. each, were given at intervals of five days. Three days after the first injection the patches were paler, and ten days after the second they had disappeared without leaving any signs of disease.

Importance of Early Treatment in Cutaneous Malignant Epitheliomata.—A. R. Robinson⁵ states that in all cases of malignant epitheliomata there are: 1. An abnormal and excessive proliferation of epithelium; 2. The proliferation is atypical, and is associated with the production of a poison which injures the surrounding tissues; 3. Changes, usually of an inflammatory character, occur in the surrounding connective tissue, lessening the resisting power of the skin; 4. Invasion of the connective tissues by the new epithelial elements by way of the lymph-channels, tending to secondary infection of lymphatic structures. The author further says that "it seems that carcinomata contain a poison, a toxin—as shown by experimental injections

¹ Brit. Med. Jour., Oct. 24, 1896.

² Ibid., Jan. 2, 1897.

³ Bull. Johns Hopkins Hosp., July, 1896.

⁴ Ann. de Dermatol. et de Syph., No. 1, 1896.

⁵ Med. News, Apr. 10, 1897.

and implantations of cancerous material—which injures connective tissues, differing in this respect from the benign epitheliomata.” Injury to the connective tissue of the part favors a more rapid extension of the disease, and should always be borne in mind in locating a case of this kind. Thus mild caustics, which can only destroy the growth to a limited extent, act injuriously on the surrounding connective tissue, and thus favor the extension of the epithelial proliferation. Nothing is worse than meddling treatment in epithelial cancers. Whatever the method employed for their removal or cure, it should be effective. [The article contains much that is of value to the practitioner and is replete with sound teaching.]

Dermatitis Papillaris Maligna (or Paget's Disease).—A. M. Sheild¹ reports a case in which the lesion, occupying the breast of a woman aged 47, measured 11 in. vertically and 10½ in. from before backward. It was dusky-red, glazed, and possessed a slightly thickened, quite definite margin. The nipple was destroyed by ulceration. The gland was not enlarged. The disease began six years before, after an abscess of the breast. [The case is interesting on account of the large size of the lesion.]

Lymphendothelioma Cutis Multiplex.—Gustav Riehl² reports the case of a rare disease occurring in a woman aged 75, a native of Hungary, characterized by numerous, circumscribed, firm and hard, uneven, nodular, symmetrically distributed tumors, varying in size from a pea to a small hen's egg, occupying the skin and subcutaneous tissue, and also the mucous membrane of the mouth. They had begun to form on the face three years before. The clinical diagnosis was that of a peculiar form of sarcoma cutis. Later the lymph-glands began to swell; fever set in; a few of the tumors ulcerated, especially on the face, followed by erysipelas; and the woman died from bronchitis six days after the erysipelas began. The principal structure of the tumors was alveolar. Microscopic sections showed in numerous places that the lymph-vessels were enlarged and in direct relation to the neoplasm, and that the tumors began to form in the endothelium of the lymph-spaces. The diseased lymph-glands showed the same alveolar structure as the cutaneous tumors, the same arrangement and order of cells, and an absence of any relation with the blood-vessels.

Concerning differential diagnosis, it may be said that carcinoma, except in the case of the lenticular variety, never occurs so markedly multiple and over so large a surface. Sarcomata, with or without pigment, as a rule are less hard and ulcerate more rapidly. For the same reasons granuloma fungoides would be excluded. The clinical picture of the case was regarded as unique.

A Case of Sarcoma of the Skin successfully Treated by Arsenic.—Pospelow³ reports a case of sarcoma in which the use of arsenic in increasing doses was followed by the complete disappearance of the tumor, which was situated upon the nose, and had been excised, but returned after six weeks. New lesions beginning to appear upon other parts of the face, further surgical treatment was deemed useless, and recourse was had to the internal use of arsenic. The drug was prescribed in the form of Asiatic pills, each containing one-twelfth grain, and of these at first one, finally nine, were taken daily. One month after beginning this treatment the tumor was decidedly smaller, the secondary lesions much flatter and apparently undergoing retrogression. These large doses of arsenic were well borne, and occasioned no disturbance of the digestive tract. At the end of ten months the cure was apparently complete.

¹ Brit. Jour. Dermatol., p. 443, Nov., 1896.

² Wien. klin. Woch., Nov. 12, 1896.

³ Arch. f. Dermatol. u. Syph., Bd. xxxiv., H. 2.

The author emphasizes the necessity for perseverance in the treatment, since the good effects of the arsenic only appear slowly.

An Unnamed Granuloma.—Tenneson, Leredde, and Martinet¹ endeavor to show that the affection which has been described by Brocq, Barthélemy, and others, under the names "symmetrical disseminated folliculitis of smooth parts," "acnitis," "follicelitis," "acne varioliformis, hidradenitis destruens suppurativa," "disseminated suppurative idrosadenitis," "disseminated suppurative spiradenitis," does not originate in the hair-follicles, the sebaceous nor the sweat-glands, but that it is a granuloma which can invade the glands secondarily, but does not begin in them. The authors believe that the discrete form is more common than is supposed; that it develops upon a scrofulous soil; and that it is of microbic origin.

Congenital Sarcomatosis of the Skin.—Neuhaus² states that of all the neoplasms of childhood sarcoma is the most frequent; of congenital sarcomata the commonest occur in the kidneys. Metastasis of internal sarcomata to the skin is not rare, but primary sarcoma of the skin is extremely rare. The case of a child two months old, of healthy parents free from syphilis and tuberculosis, is cited. The infant appeared normal at birth, but when bathed on the fifth day by the mother the left leg was noticed to be thicker than the right. At the age of five weeks an incision was made into the leg and a gelatinous mass as large as a hen's egg was removed. The bones were apparently healthy and not connected with the growth. At about this time the mother noticed on the external aspect of the right ankle a bluish nodule as large as a pea. Similar nodules appeared upon other portions of the body, some undergoing ulceration. The child was large and apparently well nourished. The nodules varied in size from a lentil to a small apple, were elastic, and presented pseudofluctuation. They were sharply circumscribed and movable upon the subjacent tissues. They were seated in the skin and in the subcutaneous connective tissue. The lymphatic glands were slightly enlarged. There was no evidence of involvement of any internal organ. Examination of the growths disclosed round-cell sarcoma. The child died in ten days. Postmortem examination disclosed widespread metastasis, the evidence pointing to the cutaneous covering of the left leg as the seat of the original growth, which must have been congenital.

Nonidentity of Yaws and Syphilis.—C. W. Daniels,³ of British Guiana, concludes that yaws has no resemblance to primary or to secondary syphilis, and shows none of the associated lesions, and that if it be considered as a tertiary manifestation there are neither primary nor secondary stages.

THERAPEUTICS.

Gelanthum in Skin-diseases.—P. G. Unna,⁴ of Hamburg, after two years' experience with this vehicle, recommends it very strongly. The difficulty with the soluble varnishes used heretofore has been that insoluble substances like zinc oxid, sulphur, and chrysarobin, cannot be suspended in them, but collect in lumps or fall to the bottom, but in gelanthum they are evenly divided and remain suspended. Hygroscopic substances, like ichthyol, easily form a dry coating in this vehicle, and large quantities of the necessary medicaments can be added, as of ichthyol 30%; of salicylic acid, resorcin, and pyrogallol 4%; and of carbolic acid 5%, without destroying its varnish-like properties. Two incompatible bodies, such as salicylic acid and zinc oxid,

¹ Ann. de Dermatol. et de Syph., No. 7, 1896.

² Arch. f. Kinderh., Bd. xxi., H. v., vi.

³ Brit. Jour. Dermatol., Nov., 1896.

⁴ Therap. Woch., Sept. 13, 1896.

which in watery solutions undergo chemical reaction, can be used together in gelanthum. Fats can be fixed with it to the amount of 10%, and glycerin 20%, to prevent its drying too quickly.

Gelanthum—named from its principal constituents—consists of equal parts of gelatin and tragacanth (about 2½% of each). Each substance is macerated slowly in cold water, then subjected to steam and filtered. By this means the gelatin is deprived of a part of its gelatinous property. The two substances are then mixed and subjected to steam for two days, and then pressed through gauze. Glycerin 5%, some rose-water, and 2% of thymol are added. The medicament to be added, if not soluble in water, must be rubbed into a soft paste with water, and fats must first be emulsified by gums and water. As compared with the old soluble varnishes, it presents the following advantages: it spreads easier, dries more quickly, and with a smoother surface; it holds the solid substances evenly suspended and finely divided upon the skin; it tolerates all substances singly and together; hygroscopic substances are made to dry; it bears an addition of fat to prevent drying too quickly. Finally, it is a cheap vehicle. [The preparation is difficult to make on account of the apparatus required. It may be obtained from New York importing-houses.]

Use and Abuse of Arsenic in Dermatologic Affections.—Albert E. Carrier,¹ a number of years ago, read a paper before a society, in which he took the ground that arsenic was too freely used in the treatment of cutaneous diseases. A larger experience convinced him more fully of the truths of the statements made in that paper, and he does not prescribe arsenic now in one-quarter of the cases that he then thought demanded it. In getting the previous history of patients that have been referred to him for treatment he usually finds that arsenic has been used, and he concludes from this that the remedy is still very freely used by the general practitioner in the treatment of skin diseases.

The diseases in which arsenic has been used with benefit are: pemphigus, herpes zoster, lichen ruber, lichen planus, psoriasis, chronic urticaria, dermatitis herpetiformis, and some forms of erythema multiforme; yet even in these cases, prescribed by those skilled in its use, it often fails to benefit. To illustrate some of its unfavorable effects, a case of psoriasis was cited, in which arsenic in small doses had been given for some time, when without any apparent cause the whole body became pigmented. Previous to this the palms and soles became the seat of small, warty growths, which completely covered their surfaces and required frequent paring in order to make walking possible, or to enable the patient to follow his occupation of a carpenter.

The abuse of the remedy consists, first, in its administration indiscriminately, in giving it for acne, or for eczema, or even for scabies, etc. Another abuse consists in the lack of care in the selection of the preparation to be used. The aqueous solutions of pure arsenious acid are the most convenient to give, and if freshly prepared are the best for use; but these solutions deteriorate with age, losing some of the arsenic, and no case should be held as not yielding to arsenic until arsenious acid has been given. Good results are slow in following its use, and we should be content to wait even months for a cure; in order to prevent relapses it should be continued for a considerable length of time after all evidences of the disease have disappeared.

In conclusion, arsenic is useful in only a very limited number of skin-diseases. Second, its use in apparently selected cases is often disappointing. Third, it must be given for a long time before deciding that no good will result from its use. Fourth, we should be careful in the selection of the prop-

¹ Physician and Surgeon, July, 1896.

aration to be used, and a verdict should not be rendered against the value of the drug unless arsenious acid has been used. Fifth, its use in cases that are liable to return must be continued for some months after apparent cure is obtained; lastly, it must be borne in mind that when it is given in properly selected cases it may be followed by untoward effects that are not amenable to treatment.

[This subject is one of great importance to the profession, and the sooner physicians unfamiliar with the treatment of cutaneous diseases become impressed with the observation that arsenic may be harmful as well as beneficial, the better for all concerned. There is a vast amount of mischief made by the indiscriminate and reckless administration of this potent drug.]

Uses of Resorcin in Dermatology.—M. B. Hartzell¹ states that this drug in many of the milder forms of eczema often proves extremely serviceable in allaying itching and diminishing hyperemia; and even in the oozing stage, when the inflammation is not too acute, it often acts most happily in diminishing the discharge and favoring the speedy formation of cornified epithelium. Many cases of erythematous eczema will recover under the judicious use of this remedy alone. It is best used in aqueous solutions, 10 to 15 gr. to the ounce; ointments are more likely to prove irritating. The addition of $\frac{1}{2}\%$ sodium chlorid to aqueous solutions has seemed to increase the sedative action, possibly by favoring the absorption of the drug. The following formulæ are given: \mathcal{R} . Resorcin., gr. x-xv; glycerin., ℥x; liq. calcis, ʒj. When there is oozing a half dram of bismuth subgallate to the ounce may be added. In other cases the following paste is useful: \mathcal{R} . Resorcin., gr. xv; amyli, zinc. oxidī, āā ʒij; petrolati, ʒiv. The drug is also useful in painful ulcers of the leg, which so frequently complicate varicose veins and eczema. In these cases it is especially useful in ointment-form, 5 to 20 gr. to the ounce. In seborrhea of the scalp it is one of the most valuable remedies, in the strength of about 20 gr. to the ounce. In blondes it causes a slight brownish tinge of the hair. Resorcin is also valuable in epithelial cancer, acting in a remarkable way in promoting cicatrization. In this disease it is best used as a plaster, about 70 gr. to 3 drams of the plaster-mass. It is also useful as a parasiticide, especially in ringworm in its several forms.

Pilmogen (liquor adhæsivus).—E. Schiff,² of Vienna, recommends this as a vehicle for the application of drugs upon the skin. It is "a solution of nitrated (*nitric*) cellulose in acetone," which is painted on the epidermis in the form of a thin film. It resembles elastic collodion mixed with a corresponding amount of oil, such as castor oil. It forms an adhesive, impermeable coating on the skin, and on account of the oil it contains follows the movements of the skin without breaking or cracking. The solution is clear, of a pale yellow color, and through the evaporation of the acetone is cooling, but burns on abraded epidermis or on wounds. Most of the drugs in everyday use in dermatology may be applied successfully with it, either in solution or suspension. It is insoluble in water. The preparation is highly recommended by the author as an elegant method of applying drugs to the skin, possessing fewer objectionable features than most similar varnishes before the profession.

Notes on Some of the Newer Remedies used in Diseases of the Skin.—L. Duncan Bulkley³ calls special attention to the value of resorcin in seborrheic eczema, used in the strength of about 6% in zinc ointment or as a lotion with a little alcohol and glycerin. The solution is particularly applicable to the scalp. The same remedy used stronger, even up to 25%,

¹ Therap. Gaz., June, 1896.

² Wien. med. Woch., No. 46, 1896.

³ Jour. Am. Med. Assoc., Nov. 28, 1896.

will sometimes give excellent results in *acne rosacea*. The application is kept on for several days, and causes some little inflammation, after which the previous redness and pustular condition will be found to have largely disappeared. Resorcin is also valuable in certain ulcerative conditions, notably those of a tuberculous nature, used as a 10% ointment. The author speaks highly of the value of ichthyol. As an antipruritic remedy it is often of great service. As an ointment, 6% to 10% strength, it is often very valuable in *eczema*, and may be used in quite acute conditions. In *dermatitis herpetiformis* a watery solution, 5%, 10%, or even 20%, will often give more relief than any other local remedy. Taken internally, it is useful in hemorrhoids, 5 to 15 drops after each meal. It relieves the congested vessels of the rectum and anus.

A New Traumaticin.—Ducommun's¹ method of preparation consists of mixing an aqueous solution of soap with a solution of alum. A magma is formed, from which the excess of water is squeezed out with the hands, and the residue, while still moist, is dissolved in ether. It is much used in the clinic in Berne.

Nitrate of Silver in Diseases of the Skin.—R. Abrahams² speaks of the value of this drug in warts, every variety of "wart" being amenable to it. The silver stick should be worked down to the bottom of the wart and around its interior. In some cases the lesion should first be scraped. In corns, after maceration, a 30% solution is valuable. The solid stick is useful in *lupus vulgaris*; the nodules should be bored into, as F. Hebra first pointed out many years ago. The author also refers to its use in suitable cases of epithelioma, to be used as in *lupus*. Reference is also made to its value in leg-ulcers and in chancroids and phagedenic ulcers. The application of a saturated solution in neglected or maltreated venereal ulcers will quickly change their aspect and bring about healthy granulating tissue. In *erysipelas*, as well as in *eczema*, it is useful. It is especially useful in *eczema intertrigo*, the result of friction and sweating. It abates the itching and the discharge, and cures the disease of the skin. It should be used in solution, from 3% to 10% or even 20%. In *marginate eczema* complicated with a fungus it is particularly useful in 20% or 50% strength.

Absorption of Methyl Salicylate by the Healthy Skin.—Linosier and Lannois³ find that the healthy skin is capable of absorbing certain substances in larger amounts than are generally used therapeutically. In persons upon whose skin *guaiaecol* had been applied, upward of 3 gm. were recovered in the urine passed in twenty-four hours. Methyl salicylate is readily absorbed by the skin; after an application of 4 gm. to the thigh as much as 1.3 gm. of salicylic acid may be found in the urine passed during the following twenty-four hours, and at the same time an analysis of the evacuations from the bowel shows that a large quantity is eliminated in this way. The method of applying methyl salicylate to the skin is the same as that employed for *guaiaecol*. The liquid is spread out on the skin (usually on the thigh) by means of a dropper or brush; the part is then covered with water-proof and cotton-wool (to keep the temperature up), the whole being left in place for twenty-four hours; 4 gm. of methyl salicylate are usually employed each time. Mixing the drug with lard or other oils interferes with its absorption.

Local Treatment of *Seborrhœa Capitis*.—Herbert Skinner⁴ advocates the following formula for cleansing the scalp in *seborrhea*: *sapo cast.*

¹ Rev. internat. de Méd. et de Chir., Sept. 25, 1896.

² Jour. Am. Med. Assoc., Jan. 30, 1897.

³ Med. Weekly, Mar., 1896.

⁴ Brit. Jour. Dermatol., p. 70, 1897.

alb., ʒj; alcohol., ʒj; æther. methyl., ʒij; aq., ʒij. Dissolve the soap in the water, add the spirit, clarify by filtration through kaolin, and then add the ether. Various ingredients can be added to this, even mercuric chlorid. One of the best methods to cleanse the scalp is with the following shampoo-liquid: ammonii carbonat., ʒss; boracis, ʒj; aq. Oj. Dissolve and add glycerin, ʒiv; bay rum, Oj.

Quillaia-washes, consisting, for example, of two parts of a perfumed spirit or lavender-water and one part of fluid extract of quillaia, are soothing, but possess doubtful cleansing properties. The following is a new formula made with saponin, and is an improvement on most of the preparations of this kind: saponin., ʒj; tinct. benzoin. simpl., ʒj; aq., ʒss; glycerini, ʒj; acid. carbolici, ʒj; aq. cologniensis, ad ʒj. Dissolve the saponin in the water and add the other ingredients. An antiseptic and stimulating "hair-tonic," containing no alkali, and therefore having no tendency to bleach the hair, may be compounded as follows: acid. salicylic., gr. xv; resorcinol, ʒss; tinct. cantharidis, ʒss; tinct. capsici, ʒj; saponin., ʒj; lanolin., ʒj; aq. rosæ, ad ʒx. Melt the lanolin, dissolve the saponin in the same quantity of water, and incorporate the two. Dissolve the acid and resorcinol in the tinctures and rose-water respectively. It should be brushed into the scalp once daily.

The following "tonic for the hair" is recommended, having several points to commend it, not the least being the combination of a small percentage of oil with alcohol: tinct. cantharidis, ʒxiv; tinct. cinchonæ. ʒij; tinct. benzoin. simpl., ʒvj; spirit. lavandulæ, ʒss; ol. ricini, ʒij; alcohol, ad ʒx. Dissolve the castor oil in the alcohol, mix with the tinctures and spirit, and filter through kaolin. For a natural grease for the scalp the following, the liquid lanolin preparation, will be found useful: lanolin., ʒss; saponin., gr. iv; aq., ʒss; alcohol., ʒj. Dissolve the saponin in the water, stir in with the lanolin, which has been previously melted, and when cooling add the spirit. This makes a thick cream, devoid of stickiness or greasiness, which can be poured out of a bottle.

The Pathology of Itching, and Its Treatment by Large Doses of Calcium Chlorid, with Illustrative Cases.—Thomas D. Savill¹ states that he has had success in the use of calcium chlorid in the treatment of this affection. It has been shown that this drug has a marked effect on the blood—namely, increasing its coagulability. The author believes that the irritated state of the nerve-endings and fibrils which exists in this complaint, manifested by itching and tingling, is due to some change in the quality and composition of the blood. The paper is accompanied by an elaborate table of cases thus successfully treated, with the remedies previously used without effect. In each case either a cure was made or great benefit obtained. The doses must be not less than 20 gr. three times a day, and should be gradually increased; 30 or even 40 gr. have often succeeded where less have failed. As thirst frequently follows the administration of the drug, it is best to cover the salt taste with a dram of tincture of orange-peel and one ounce of chloroform-water, in which form it is an acceptable medicine. The diet during its use should be restricted, especially as to sugar. The bowels should be kept freely active. Improvement may be noted after the first dose, but recovery sometimes does not take place until the blood has become saturated with the drug. Upon recovery the dose should be gradually, not suddenly, reduced.

Picric, or Carbazotic, Acid as a Therapeutic Agent, especially in the Treatment of Certain Inflammatory Skin-affections.—William Maclellan² states that picric, or carbazotic, acid, in watery and alco-

¹ Lancet, Aug. 1, 1896.

² Brit. Med. Jour., Dec. 26, 1896.

holic solutions, has for long been recognized, especially in France, as a useful application for superficial burns. The admirable results which the author has seen follow the free application of picric acid in solution to painful and extensive burns led him to try its effect in the treatment of certain skin-affections. In 1877 L. L. Grangé drew attention to the healing-power of this remedy in some varieties of eczematous eruption. Acute eczema, associated as it usually is with burning, severe itching, and profuse discharge, is rapidly relieved and cured under the influence of picric acid. Owing to the powerful astringent properties which this chemical possesses, it forms, when applied over a discharging or denuded surface, a protective layer of coagulated albumin and epithelial debris, under which healing rapidly proceeds; and as a potent antiseptic, by inhibiting the action of, or destroying, the microbes on which the formation of pus depends, it completely prevents suppuration.

Applied as a pigment with a brush or piece of absorbent wool, even to an extensive surface, it is quite free from danger, and causes not the slightest pain, however vascular the surface may be. Almost immediately itching and smarting abate, and in a few days, when the protective crust is removed or separates, the underlying skin is found to be comparatively dry, free from redness, and covered with a new epidermis.

In acute eczema occurring in children (*eczema capitis et faciale*), which is usually so intractable to the ordinary methods of treatment, the author has had most encouraging results from its use. If the hair on the child's head happens to be long, it should be cropped short and all adherent crusts removed by means of poulticing. The raw surface should then be freely painted over, morning and evening, for three or four days in succession with a saturated watery solution. During this treatment the scalp, and the face when it is involved, should be protected by means of a calico mask. After the lapse of a few days the pellicle which has been formed by the action of the picric acid can be removed by some emollient if it has not previously separated, and if any undue redness or moisture remain a fresh application may be made. The cessation of irritation permits the child to sleep, and its general health soon improves.

Although picric acid is so specially valuable in acute discharging eczemas, it will be found an efficient remedy in almost any superficial inflammatory affection. Thus in 3 cases of erysipelas the author found a saturated solution of picric acid superior to any local remedy he had hitherto tried. It arrested the inflammation and prevented the disease from spreading, and much more rapidly diminished local discomfort than carbolic acid, dusting-powder, or ichthyol. Carbazotic acid is a harmless topical agent. Although so nearly akin to carbolic acid, no apprehension need be entertained as to its absorption, even when applied to extensive surfaces. Like nitric acid it limits its own action by coagulating the albumin of the tissues to which it is applied. As heat readily decomposes the acid, accidental stains may be removed from the underclothing by boiling.

The Action of Salicylic Acid on the Sound Skin.—Menahem Hodara¹ has studied its action histologically, in order to better understand its effects clinically. The action of the acid is confined to the horny layer; an oozing surface is never seen. The experiments were made by applying salicylic acid in varying strengths, and in the form of ointments and collodion, to the skin of man and of rabbits. When applied to the human skin for 2 or 3 days in the form of plaster it produced a swelling of the horny layer and moderate intercellular edema of the prickle and granular layers. When the

¹ Monatsh. f. prakt. Dermatol., Aug. 1, 1896.

salicylic plaster was allowed to remain for from 8 to 10 days the prickle layer was found necrotic to various depths. After the skin has become necrotic the process of casting off and of new formation begins at once. Active proliferation begins in the deeper layers and in the adjacent epithelium, a new prickle-cell layer appears beneath the necrotic mass, and a new granular and horny layer is produced. Salicylic acid (30%) in collodion acts more energetically. Salicylic acid in man causes no emigration of polynuclear leukocytes. Its action is rather that of causing in the corium a slight inflammation. In the rabbit a concentrated salicylic acid plaster causes a complete necrosis of the whole epidermis, with suppuration. Briefly, it may be stated, salicylic acid in small amount on the healthy skin causes an exfoliation of the horny layer. Employed in larger quantity and for a longer time, it produces a desquamation, derived partly from the corneous layer, partly from the mucous layer, which has become necrotic in places.

SYPHILIS.

Treatment of Syphilis by Intravenous Injections of Mercury.

—According to J. Ernest Lane,¹ the plan of treating syphilis by intravenous injections of mercurial solutions was originally suggested by Baccelli in 1893, and has since been carried out by many Continental surgeons: in Italy by Jemma, Colombini, Nieddu, Campana, and Bruni; in Germany by Görl, Neumann, and Lewin; in France by Abadie; and in Russia by Stoukovenkoff and Kusel. Lane, having charge of all the male wards in the London Lock Hospital, had unusual opportunities of giving a fair and impartial trial to this novel method of treatment. He systematically adopted it in every case of syphilis that came under his care in the hospital during 9 months, and states with conviction that he has formed a very favorable opinion as to its merits, and believes that, with certain reservations, it compares favorably with other methods of treatment, whether it be by inunction, by intramuscular injection, or by internal medication, its special feature being the rapidity with which patients can be brought under the influence of mercury.

The preparation he has utilized throughout has been cyanid of mercury in 1% solution, and the amount used at each injection was usually 20 minims, or about $1\frac{1}{4}$ gm., though in some of the more severe cases he commenced with double this dose for the first 1 or 2 injections. At first the injections were employed every other day, but after a short time he introduced them daily. A loop of bandage was first tightly applied round the upper arm, and selection was made of the most prominent vein in the neighborhood of the elbow-joint; the skin in that region was rendered aseptic in the customary manner, and the needle was thrust into the vein, the syringe filled with the solution being attached to it; the bandage was then removed, and the syringe was emptied into the vein and then rapidly withdrawn; the finger was placed on the puncture for a few seconds, and the operation was complete.

The advantages may be summarized as follows: the injections are absolutely painless, in which respect they are in direct contrast with intramuscular injections; the functions of the digestive tract are not interfered with; the doses of the mercurial salt are small, are certain of absorption, and can be easily regulated to the varying susceptibilities of different individuals; with ordinary precautions the treatment is perfectly safe, and, even if the vein is missed, little or no inconvenience is caused thereby; the resulting improvement is certain and rapid, and consequently it would seem to be indicated in cases of cerebral

¹ Brit. Med. Jour., Dec. 12, 1896.

syphilis; the author's experience does not warrant him in offering an opinion as to whether this treatment is followed by relapses, but so far he has not met with any. The only real objection he can see to the method is the difficulty experienced in some instances of bringing the veins into sufficient prominence, and in a certain proportion of cases, especially amongst women, this is an insuperable obstacle. In conclusion, he is of opinion that in intravenous injections we have a valuable addition to our antisyphilitic therapeutic agents, though the plan is one which obviously cannot be recommended as a routine practice.

Injections of Calomel for Syphilis.—Louis Jullien¹ remarks that the subcutaneous method possesses the two advantages that the liver and the alimentary mucous membranes are spared. The vehicle used is liquid vaselin. The dose varies from 1 to 2 gr., according to the size of the individual. The locality is preferably the supra- and infraspinous fossæ of the scapular region. Strict asepsis must be enforced. The interval between the injections varies according to circumstances; it may be from 8 to 20 or more days. Among the advantages can be cited the promptitude of its effects, the intensity of its action, and the persistence and positive character of its cures.

Sixteen Years' Experience in the Treatment of Syphilis by the Hypodermic Injection of Mercuric Chlorid.—T. S. Dabney² states that the hypodermic method of treating syphilis possesses many advantages over other methods when used by physicians bold enough to disregard the dosage recommended by most writers on therapeutics. The only test in giving medicines is the effect, and the dose should be increased until that is obtained. The author reports seven cases taken from his case-book in which the treatment advocated was employed successfully. The following objections raised against the treatment by subcutaneous injections are considered. They are (1) unnecessary pain; (2) subcutaneous infiltration; (3) large indurated and painful swelling; (4) inflammation; (5) abscesses; (6) stomatitis; (7) pyalism; (8) disturbances of circulation and respiration. Pain does occur in some cases. In hyperæsthetic cases the treatment is hardly admissible and cannot be recommended. The injection of morphin with the mercury is condemned. The author sees no objection to subcutaneous infiltration. When the needle is not thrust in deep enough an area of inflammation may in some instances be set up. Pyalism and stomatitis have never been observed by the author in cases treated in this way, whereas he has rarely seen a case treated by other methods without them.

The advantages claimed for this method are (1) accuracy of dose; (2) exactness in intervals between doses; (3) rapidity of action of the medicine; (4) small amount of mercury and the short time needed to effect a cure; (5) the constant effect of the drug, day and night, and the personal supervision of the physician; (6) the certainty of the patient getting the right medicine, and of its being properly administered at regular, stated intervals; (7) absence of gastrointestinal disturbance; (8) quick diagnosis in questionable cases.

The needle should be plunged quickly through the skin and well into the subcutaneous tissue, care being taken to avoid adipose or muscular tissue. The injection should be made very slowly. As soon as the bichlorid solution comes in contact with the albuminous serum, the soluble mercuric chlorid immediately becomes the albuminate, which is not very soluble, and herein lie the efficacy and safety of these large doses of this highly corrosive poison. The solution usually employed is 8 grains to the ounce, from 5 to 15 minims being used for each injection, every second, third, or fifth day, until, say, ten or more injections have been given. The dosage should be gradually increased.

² New Orl. M. and S. Jour., Apr., 1897.

Serum-therapy in Syphilis.—Mueller-Kannberg¹ reports 12 cases treated with serum. He calls attention to Kollmann's negative results obtained in 1890; and to the favorable results of Tommasoli's six experiments with serum taken from lambs, in which all the symptoms rapidly disappeared after the injection of from 2 to 8 c.c. In seven other cases the symptoms disappeared so rapidly that it was not found necessary to use more than 50 c.c. in each case, and none of these showed any recurrent symptoms. Fournier and Feulard, however, after using this serum, were unable to corroborate the above results. Lewin used serum obtained from horses prepared by Aronsohn. The first two cases treated were girls, aged 17 years, neither of whom had received any previous antisyphilitic treatment; they received 5 c.c. of the serum by injection in the gluteal region; after the fifth injection one was attacked by persistent urticaria, when corrosive sublimate treatment had to be substituted. There had been no change in the syphilitic symptoms. The third case was an 18-year-old girl, with initial chancre on the upper lip and enlargement of the glands; after the first injection her general condition became so serious that it was necessary to discontinue the treatment. The fifth patient showed urticaria eleven days after the first injection. The sixth patient was treated for five consecutive days with 5 c.c. of the serum, with some rise of temperature after the last injection. This case was also followed by erythema and urticaria.

In all other subsequent cases the treatment, for like reasons, has to be discontinued. As a result of these experiments, Mueller-Kannberg says he cannot see that the treatment with serum has any decided influence upon the course of syphilis.

Treatment of Malignant Syphilis.—Albert Neisser² defines "malignant syphilis" to be a severe form of the disease characterized by certain symptoms differing rather in their nature than in mere severity from the usual forms of the malady. Every case of severe syphilis must not be included under the designation of "malignant." For example, when syphilis is rendered a dangerous disease on account of the relation of the organs invaded the term "malignant" is inappropriate, the term "grave" being more suitable. Subjects suffering from malignant syphilis do not bear mercurial treatment well. No successful result is to be looked for from "forced cures." In former times the rule was laid down that mercury should never be prescribed in malignant forms of the disease; but Neisser thinks this is an extreme view. The insoluble salts, in the form of subcutaneous injections (valuable as they are in Neisser's opinion), should never be employed in malignant syphilis. A certain degree of success follows the use of potassium iodid, especially if it is administered when fever is present. In cases in which antisyphilitic treatment, even when persevered in, is ineffective, the only possibility of benefiting the patient is by the use of tonics (arsenic, strychnin, iron, quinin, baths, especially sea-baths) and the external use of sulphur in the form of sulphur ointment or the sulphur-bath. The latter often proves successful. The early employment of mercury and its administration in large doses have nothing to do with the development of the malignant form of the disease. Neisser agrees with Fournier in insisting that the individuality of each case must be borne in mind, and that the pauses between the courses of treatment should be properly observed. "Antisyphilitic serum" is not regarded as a valuable remedy, either in malignant or in any other form of syphilis.

Value of Potassium Iodid in the Hypertrophic Lesions of Syphilis.—T. Baer³ calls attention to this subject, especially as such lesions

¹ Arch. f. Dermatol. u. Syph., vol. xxxv., II. 2.

² Brit. Jour. Dermatol., Jan., 1897.

³ Med. Week., 1896.

are met with in women. Granulating papules, tubercles, etc., do not improve readily under mercury; but they yield rapidly to the iodine salts. The doses should begin with 15 and increase to 300 gr. daily.

How Long is Syphilis Contagious?—C. T. Drennen¹ would assert dogmatically that treatment does remove, not only the manifestations of this disease, but the disease itself, and with it its contagiousness. Syphilis loses its virulence as time progresses, and by the end of the sixth year it has practically lost its contagiousness, with here and there an exception. Patients who have been well treated may marry in three or four years after the primary lesion.

Syphilitic Reinfection.—H. Fitzgibbon² gives a valuable article on this subject, with some personal cases, and also discusses the nature of syphilis and its place in classification. The conclusions of the lengthy and interesting paper may be given as follows: 1. Syphilis is a specific fever of the same class as the other major exanthemata. 2. That if uncomplicated by pre-existing constitutional cachexia or coexisting septic influence, it runs a definite course, by which it exhausts in the system of its recipient the elements upon which its virus can feed. Thus, like variola, vaccinia, etc., the first attack is followed by a period during which the same individual is insusceptible of reinfection. 3. That the effects of syphilitic infection are no more necessarily lifelong than the effect of any other zymotic eruptive fever, although slower in its course. 4. Too much importance has been attached to the question of the possibility of second infection with syphilis as the only reliable proof of complete recovery from the disease. 5. From reported cases it would appear that when second infection with syphilis occurs the disease is more likely to be of an aggravated type than in first attacks. This the author is inclined to regard as due to contact with septic infection rather than to pure syphilitic virus. [The large experience of the author with syphilis entitles his views to respect.]

H. P. Collings³ also reports a case of syphilitic reinfection. The second chancre occurred 9 years after the first chancre and 28 days after exposure. [The history is clear, and there seems every reason to accept this case as an authentic instance of reinfection.]

J. D. Thomas⁴ likewise reports a case of syphilitic reinfection, in this instance the second chancre occurring five years after the first chancre. The first lesion was a characteristic Hunterian chancre; the second manifested itself 2 weeks after exposure as an indurated and characteristic abraded sore in the right sulcus. There was no question as to the disease on both occasions.

The Pigmentary Syphiloderm and its Diagnostic Value.—G. Lewin⁵ regards this manifestation as of importance, but states that it is not an absolutely certain diagnostic sign of syphilis, for he has observed it upon a large number of men who never had syphilis. Since it may exist upon nonsyphilitics, its presence is no indication for syphilitic treatment. Anti-syphilitic remedies possess no influence over the disease. Syphilitic women who become pregnant do not show the leukoderma more pronouncedly than those who are not pregnant. It may appear upon parts of the skin that before had been the seat of some syphiloderm. It is not established that there exists any connection between the two affections. It is necessary, perhaps, to seek the cause of the leukoderma in a paralysis of certain centers which govern the movements of pigment—paralyses which have been caused by a toxin of syphilis.

MATERIA MEDICA, EXPERIMENTAL THERAPEUTICS, AND PHARMACOLOGY.

BY HENRY A. GRIFFIN, M. D., AND J. R. TILLINGHAST, JR., M. D.,

OF NEW YORK.

The progress of the past year in pharmacology has been marked rather by that development of former knowledge which is of lasting value than by brilliant achievements which so often are ultimately but disappointments. Animal therapy has received considerable attention, and much good work has been done in its study, notably by Oliver, Mairet, and Bose. It must be confessed, however, that little of therapeutic value has been added to our knowledge of this subject, although it is equally clear that its limitations are as yet unreached. The usual number of pharmacologic novelties has been forthcoming, and of them the most important, so far as can now be judged, are considered in the body of this report. Among all these it is presumable that some may demonstrate a practical value, although the experience of previous years would prognosticate for the majority a brief tenure of life. In dulcin a distinct advantage would seem to have been attained as compared with saccharin, and the combined actions of disinfection and astringency represented in tannoform, especially in its internal employment, would suggest for this remedy a future of considerable usefulness. In view of the hopes placed upon antistreptococcic serum and the urgent necessity for a remedy which may be relied upon in septic infection, it is unfortunate that the later reports of its use are far from encouraging. Recalling the successes obtained by other protectant and curative serums, it would appear reasonable to hope that streptococcic infection might be similarly combated. Certainly the results so far obtained are not to be considered as final, since faulty technic may be the explanation of present disappointment. The mesal button has attracted considerable attention during the last twelve months, and a further understanding of its activities has been gained. From this it would appear that the drug, though interesting in no small degree, and useful no doubt in some of the conditions it is expected to combat, is scarcely to be rated of greater therapeutic reliance than cannabis indica, whose activities indeed its own in many respects resemble. Formaldehyd has received abundant attention, and much testimony is forthcoming as to its value. Indeed, so unanimous is the opinion as to its usefulness that it seems quite within the bounds of reason to hope that we have at last found an ideal disinfectant.

Acetanilid continues to be largely used both in its topical application and in the popular "headache powders," of which there are so many. That its reckless administration is by no means without danger, however, is indicated by the frequent reports of toxic effects produced (see *Year-Book* for 1897, p. 1101). A. E. Brindley,¹ of Manchester, England, reports the case of a woman who had

¹ Brit. Med. Jour., Sept. 12, 1896.

taken "kaputine" powders for neuralgic pain without the advice of a physician. The number of powders taken is not stated, but the patient had taken one just before her admission to the hospital, where she came under Brindley's observation. One of these powders, on chemic examination, proved to consist mainly of acetanilid. On admission the skin of the entire body was of a bluish-gray color, and the same appearance extended to the lips and tongue. The skin was warm and moist, and the patient complained of no distress. There was no dyspnea even on movement, and examination of the heart and lungs gave a negative result. There was no sensory disturbance, and the reflexes were normal. The conjunctivæ were yellowish and the urine contained a good deal of bile. There was bile also in the feces. Spectroscopic examination of both blood and urine was made, and was negative, as was the microscopic examination of the blood. From these symptoms it was believed that the acetanilid had caused a sufficient destruction of the coloring-matter of the blood to give rise to the symptoms of a nonobstructive jaundice. The patient was put on a milk-diet and salines were administered. Under this treatment the skin regained its normal appearance and the symptoms gradually disappeared.

Acetylene.—Considerable interest has recently been taken in the poisonous effects of acetylene. Experiments have been conducted by Grehaut, Berthelot, and Moissan,¹ upon dogs, with a view to determining its poisonous properties as compared with carbonic oxid. The acetylene used was prepared carefully from calcium carbid, as Moissan found that the gas thus made, and purified subsequently by being liquefied, had a very pleasant ethereal odor, and when inhaled in not too large quantity produced no ill effects. If, however, it contained calcium sulphid and phosphid, as may be the case when the calcium carbid is made from coal and impure lime, the odor is most unpleasant. From the experiments of these observers it would appear that, while acetylene in proportions as high as 40% by volume may be fatally poisonous, yet it is much less poisonous than ordinary coal-gas. The toxic effects of acetylene, therefore, as it was formerly prepared, were, it is now thought, due to the presence of carbonic oxid or hydrogen cyanid. The researches of Mosso and Ottolenghi,² working with dogs, guinea-pigs, and other animals, seem to lead to similar conclusions. They found that if the gas was rapidly administered the animals were much more apt to recover when placed in the air than when it was given more slowly. Large doses seemed to cause death chiefly by respiratory paralysis, and, indeed, the paralytic phenomena seemed to preponderate throughout.

Ammonol, also called ammoniated phenyl-acetamid, is a substance whose formula and preparation have not been made public. R. G. Eccles,³ however, has examined the substance chemically, and reports great variation in its composition, even to the degree that "no two samples were alike." He states that ammonol is composed of acetanilid, sodium bicarbonate, and ammonium bicarbonate. The drug is said to be antipyretic and analgesic, but recent publication upon the subject are few in number.

Analgene is the name given to a new antipyretic and analgesic remedy derived from coal-tar. The drug is soluble in slightly acidulated water, and, having no taste, is especially applicable to the treatment of children's disorders. Mongorvo⁴ has employed it in 59 cases of children sick with various ailments, of whom 33 were suffering from malarial poisoning. The 33 cases ranged

¹ Boston M. and S. Jour., July 30, 1896.

² Brit. Med. Jour., Apr. 17, 1897, from Riforma Med., Jan. 23, 1897.

³ N. Y. Polyclinic, Aug. 15, 1896, from Charlotte Med. Jour., vol. viii., No. 6.

⁴ Univ. Med. Mag., May, 1897, from Bull. de l'Acad. de Méd. de Paris, Nov. 10, 1896.

from 20 days to 13 years in age, and the dose of the remedy varied from 25 cgm. to 3 gm. in 24 hours. No injurious influence was observed upon the respiration or circulation, and though large and long-continued doses produced a more deeply colored urine, neither albumin nor sugar was ever found in it. In all malarial cases the action was favorable and rapid, the temperature being lowered and the duration of the disease apparently being made shorter. The other cases treated (26) by Mongorvo included "tuberculosis, lymphangitis, arthrosynovitis, parotiditis, Pott's disease, hip-disease, epilepsy, hysteria, chorea, otalgia, herpes zoster, urticaria, and painful tumor of the liver." In these, too, the action of the remedy was excellent, fever being reduced and pain made less. In hysteria, chorea, and epilepsy the nervous symptoms were benefited.

Anhalonium Lewinii, mescal button, has been made the subject of considerable study of late, and, if we may judge by the reports, we are in a fair way to have another "habit" on our hands in mescal intoxication. The very complete review of our present knowledge of the subject by Prentiss and Morgan¹ has led to personal experiments by S. Weir Mitchell² and Havelock Ellis.³ We have, therefore, a very complete picture of the phenomena of mescal-poisoning, for the drug interferes but little with clear mental action.

Anhalonium Lewinii is a plant belonging to the genus *Anhalonium*, of the natural order Cactaceæ or Cacti (see Pellotín, p. 947). The exact place of this species in the genus is as yet a matter of discussion among botanists. It grows in rocky and barren soil, often in places almost inaccessible, in the valleys of the Rio Grande and Pecos Rivers in Texas and New Mexico. The mescal buttons, the commercial form of *Anhalonium Lewinii*, consist of the dried tops of the plant, and are of brown color, $\frac{1}{2}$ – $1\frac{1}{2}$ in. in diameter by about $\frac{1}{4}$ in. thick, with curled-up edges. The average weight is about 4 gm. They are rather hard, but brittle, and can with difficulty be pulverized in a mortar. In the mouth the button swells, becoming soft under the influence of the saliva, and has a persistent, nauseous, and very bitter taste, with a marked sensation of tingling in the fauces. The powdered drug acquires a nauseous odor when moistened.

Physiologic Action.—Prentiss and Morgan⁴ reported the results of some experiments upon man to determine the physiologic action of this drug (see *Year-Book* for 1897, p. 1103). The most remarkable effect was in the production of visions of color in rapidly changing and very varied forms. These could, as a rule, be seen only when the eyes were closed, and were distinctly heightened by rhythmic noise. The sensation accompanying these visions was one of pleasure, and the memory was also agreeable. They were rarely under the control of the will, and were about as often subject to the suggestion of others. At times there was occipital headache, as in the case of Mitchell, which persisted for some days, but that this is not an invariable sequel is shown by the experience of Ellis. The effect upon the mind seems to be comparatively slight. In some cases the reason and will are said to be entirely unaffected; in some, slowness of thought and loss of the power of expression or of attention are mentioned. All observers seem to agree that a dilatation of the pupil, which is well marked and persists for from 12 to 24 hours, is one of the phenomena following the administration of the drug. Accommodation seems to be but little affected, however. Depression of the muscular system in greater or less degree is apparently always present, and in some cases partial anesthesia of the skin was noticed as the effects of the drug began to pass away. The respiration was rarely affected, and the heart-action,

¹ Med. Rec., Aug. 22, 1896.

³ Lancet, June 5, 1897.

² Brit. Med. Jour., Dec. 5, 1896.

⁴ Therap. Gaz., Sept., 1895.

which at first becomes slower and stronger, returns to the normal during the period of greatest activity of the drug. The effect upon the stomach seems to vary with the individual, from a sense of occasional fulness and uneasiness to actual nausea and vomiting. Insomnia, persisting for a number of hours, appears to be a uniform effect.

Several alkaloids have been obtained. Lewin, in 1888, separated a substance which he called anhalonin. This alkaloid, which has since been obtained in a pure state by Ewell, is described as "a white, strongly alkaline substance. It crystallizes from aqueous solution in prismatic, sometimes tabular crystals of the rhombic system. It is soluble in a large quantity of water, and is very soluble in alcohol, ether, chloroform, benzin, and petroleum-ether. Its melting-point is 77.5° C., and it can be sublimed without decomposition. It forms salts with the ordinary acids." Anhalonin hydrochlorate, a white, odorless substance forming needle-like crystals, has also been obtained. It is soluble in 50 parts of water, in which solution it is very bitter, and to some extent also in alcohol. It melts, with decomposition, at 254° - 255° C., and rotates the plane of polarized light to the left. A sulfate of somewhat similar appearance and properties is described by Lewin. It is almost insoluble in alcohol. A second alkaloid, for which the name "mescaline" is proposed, is now being studied by Ewell. It forms a salt with hydrochloric acid which is much more soluble in water and in alcohol than is the similar salt of anhalonin. A third alkaloid has been separated by Ewell from the mother-liquor left after the separation of anhalonin and mescaline. It also forms a hydrochlorate, crystalline and of a slightly yellow color, neutral in reaction, and readily soluble in water and alcohol. The taste is acid and slightly bitter, with persistent after-taste. Experiments upon animals with these three alkaloids seem to show that they differ materially in their effects. The results are not sufficiently definite, however, to justify a detailed account at the present time. The buttons also contain a resinous substance, apparently of complex nature, one or more wax-like bodies, etc.

The probable **therapeutic uses** of anhalonin are said by Prentiss to be as follows: "In general 'nervousness,' nervous headache, nervous irritative cough, abdominal pain due to colic or griping of the intestines, hysteric manifestations, and in other similar affections in which an antispasmodic is indicated; as a cerebral stimulant in neurasthenia and in depressed conditions of the mind—hypochondriasis, melancholia, and allied conditions; as a substitute for opium and chloral in conditions of great nervous irritability or restlessness, in active delirium and mania, and in insomnia caused by pain. In the last condition it acts to produce sleep not as a hypnotic, but by relieving the cause of the insomnia. In full physiologic doses it produces insomnia, but in therapeutic doses it does not have this effect." Several cases of its use in neuralgia and general neurasthenic conditions are already on record, but its use as a therapeutic agent must still be considered experimental.

Animal-extracts.—The therapeutic value of extracts of the various so-called ductless glands has received its share of the attention of investigators (see *Year-Book* for 1897, p. 1104), with the contradictory results that are common to all remedies during the experimental period. George Oliver¹ gives the result of his work with these extracts, especially as regards their effect on the circulatory system. From his report it would appear that the blood is supplied by the ductless glands with materials which powerfully affect the circulation, especially by their action on the vasomotor muscles. This effect seems to be produced both when the extract is injected so that it reaches the blood

¹ Indian Med. Rec., Oct. 16, 1896.

directly and when it is exhibited by the mouth. These are both important facts if further research shall establish them.

In detail: the **thyroid extract** seemed to cause a fall in blood-pressure. Apparently this action was due to the effect on the vasomotor system, causing an increase in the caliber of the arteries, as the force and frequency of the heart appeared to be unaffected. An extract of the spleen also produced a fall in blood-pressure, but this was followed later by a rise, the meaning of which has not been explained. On the other hand, the extracts prepared from the **pituitary body** (see p. 949) and from the **suprarenal capsules** (see p. 954) seemed to exert a contrary effect. A powerful contraction of the arteries was noted, with a corresponding rise in blood-pressure. At the same time the force of the heart's action was increased, but these extracts appeared to affect the frequency of the beats in different ways. The extract obtained from the pituitary body, while it did not inhibit the heart's action, diminished the frequency of the beats. That from the suprarenal capsules, however, increased the number of beats until the contractions were almost continuous, dilatation being incomplete, and the heart eventually stopped in systole.

The activity of both these extracts is destroyed by long boiling. The active principle of the suprarenal capsule is said to be found in the medullary portion. It is a dialyzable, organic principle soluble in water, and its activity is destroyed by alkalis as well as by boiling. It is unaffected, however, by acids, and its action is not interfered with by stomach-digestion. It is active in very minute doses, and the maximal effect may be produced when not more than fourteen millionths of a gram of active adrenal material to the kilogram of body-weight is given. Muret¹ reports some clinical results from the use of an **ovarian extract**. He was led to try this remedy from a consideration of these facts: 1. Without ovaries there is no uterine development of menstruation; 2. Ablation of ovaries in young children causes them to grow up without any feminine attributes; 3. After puberty loss of ovaries entails cessation of menstruation and atrophy of the genital organs; 4. Osteomalacia is believed to have been cured by oöphorectomy. He argues from these facts that there exists an internal ovarian secretion the absence of which would explain the first, second, and third conditions, while if it were excessive or altered osteomalacia might occur. He publishes 21 cases treated since 1893. A glycerin-extract of the ovaries of young cows, known as "liquid ovarin," which contained 1 gm. of ovarian tissue in 0.5 gm. of glycerin, was used at first. This was injected into the buttocks daily in doses of 0.5 to 1. gm. Later it was found that compressed tabloids, each containing 25 to 30 gm. of dried gland, were quite as efficacious as the injections, and this method of administration was therefore adopted. Two or three tabloids were given daily, and were well borne, even when the treatment was continued for a month or more.

The cases on which the report is based were: 9 patients who sought relief from nervous disorders accompanying the physiologic menopause, 3 whose symptoms were due to premature menopause following removal of the ovaries, and 4 cases of chlorosis. In the remainder menstruation was irregular from various local causes. In all these cases it is claimed that improvement followed the use of the ovarian extract, and that in some a cure was effected. The chlorotic patients were treated for two weeks by rest in bed alone, and then ovarin was given for two weeks. A more marked improvement is said to have occurred during the second than during the first fortnight.

Antipyrin.—That antipyrin still has an extended use is shown by the very

¹ N. Am. Pract., Dec., 1896, from Rev. méd. de la Suisse Romande, July 20, 1896.

considerable number of articles which have appeared in regard to it during the past year. These articles are very largely in reference to the toxicology of the drug.

Edwin Webster¹ reports a case of poisoning (see also p. 931) in a girl of 19, in which the recovery was rapid and complete, but which presents interesting features. The patient was anemic, and was being treated with Blaud's pills. One morning, as she complained of headache, the following draught was prescribed: antipyrin, gr. v; potass. bromid., gr. vij; spts. ammon. camp., ʒj; aq., q.s. ad. ʒj. About 10 minutes later the physician was hurriedly summoned and found the following condition: there were "cold shivers, severe and gasping dyspnea; the face was swollen, especially about the eyes, and so much so as to prevent any possibility of opening them or of seeing, except with great difficulty, the pupil; and the body was covered with a bright-red rash like scarlet fever and resembling that of urticaria, in that it presented wheals which were of different sizes, from that of a small papule to some as large as a five-shilling piece. The temperature in the axilla was 97° F., and the pulse, which was very intermittent, was only 50. She complained of no pain. The tongue was very dry. The lips and general aspect were decidedly cyanotic." The patient was immediately put to bed and external heat applied. Whiskey, strychnin, and digitalis were administered, and at the end of 3 hours the shivering ceased. The other symptoms, however, continued, and the breathing was at one time so bad that artificial respiration was considered. At the end of 8 hours, however, the breathing began to improve, and after 4 hours more the only symptoms remaining were a faint rash and slight puffiness about the eyes. The rash did not completely disappear for 30 hours, but on the next evening, though suffering somewhat from weakness, she was up and on the following day went about her work as usual.

Of the reports on *idiosyncrasy*, among the most interesting are that of Steinhardt² regarding the effects of the drug on himself, and that of Briquet³ of a case of acquired idiosyncrasy. Steinhardt suffered from migraine and habitually took 15 gr. of antipyrin during the attacks. He was greatly annoyed by the occurrence of small aphthous ulcers on the mucous membrane of the lips, cheeks, and tongue, which were slow to heal, but which he did not think of connecting with the antipyrin. In April, 1888, however, he noticed that the under lip became swollen and edematous immediately after taking a dose of the usual size, and 2 hours later an ulcer appeared on the tongue, followed shortly by several on the cheeks and lips. These healed only after a fortnight. He then stopped taking the drug for 2 years. On repeating the dose at the expiration of this time the same symptoms again occurred, and were not only more severe, but were accompanied by a dermatitis of the genital region. Four years later another dose of the drug brought about a repetition of the symptoms. A similar intolerance developed in him to all drugs of this kind which he used for the headache, but in the case of antipyrin alone was it so pronounced. He reports a similar idiosyncrasy in one of his patients.

Briquet's case was that of a young man who, previous to an attack of typhoid fever, from which he fully recovered, had no intolerance of antipyrin. Since his recovery, however, the most minute doses have caused an erythematous eruption, accompanied by bullæ, about the genital organs and on the mucous membrane of the mouth. A somewhat larger dose (1½ gr.) caused ulceration

¹ Lancet, Jan. 30, 1897.

² Edinb. Med. Jour., Jan., 1897, from Therap. Monatsh., Nov., 1896.

³ Am. Medico-Surg. Bull., Apr. 10, 1897, from Méd. moderne.

of the bullæ, the ulcers healing with difficulty after about 2 weeks. He was steadily becoming more susceptible to the drug. [The similarity between these cases is noteworthy and interesting.]

Incompatibility with Calomel.—H. Werner¹ has made a study of the reaction that occurs on mixing antipyrin with calomel outside the body, testing both qualitatively for the presence of mercuric chlorid, and quantitatively to ascertain the relative amount of this poison produced. The results of his investigation lead us to think that the utmost care should be taken to prevent these two drugs from coming together in the human stomach. Should they be thus combined the reaction, which, according to Werner, may be roughly expressed thus:

would probably give rise to a sufficient amount of mercuric chlorid to seriously endanger the patient's life. A table is given in which the results of Werner's experiments are compared with the maximum doses of mercuric chlorid at a given age, according to Biedert, as follows:

Age.	Calomel and Antipyrin given	Mercuric Chlorid formed.	Max. Doses acct. to BIEDERT.
2 years	0.2 gm.	0.00468 gm.	0.002 gm.
4 "	0.3 "	0.00596 "	0.004 "
8 "	0.4 "	0.00928 "	0.008 "
20 "	1.0 "	0.0232 "	0.020 "

The experimenter did not acidify his solutions; but if we accept the theory that the action of calomel is due to the formation, in the presence of the acid gastric juice, of corrosive sublimate, it will be readily seen that the quantity of the latter would be even greater than that shown by the tests.

New Compounds.—G. Patein and E. Dufan² have given us a description of two new compounds of antipyrin. Antipyrin para-oxybenzoate is a crystalline solid, which may be recrystallized from its solution in boiling water or alcohol. With ferric chlorid it gives the antipyrin reaction. It melts between 78° and 82° C.; is soluble in 130 parts of cold and much more freely in boiling water; is very readily soluble in alcohol, and but slightly so in ether. It is obtained as follows: to an aqueous solution of 8 gm. of antipyrin is added a concentrated alcoholic solution of 5.5 gm. of para-oxybenzoic acid. There ensues a union of a molecule of each of these substances without the elimination of water, and the result is an oily liquid which slowly crystallizes. Antipyrin meta-oxybenzoate is obtained in a similar way and by a similar molecular union, but remains a liquid under ordinary conditions.

The reports on the *therapeutics* of antipyrin show that its use by itself is relatively decreasing. It is being employed rather as a corrective and adjuvant to other preparations, and as such is largely used. By such combinations the toxic effects appear to be diminished, while the antipyretic, analgesic, and hypnotic effects remain. Leprevost³ reports from France 47 cases of measles in which antipyrin was used to reduce the temperature. He sums up his conclusions thus: "1. Antipyrin is well tolerated by children. 2. It pro-

¹ Am. Medico-Surg. Bull., Aug. 29, 1896, from Pharm. Zeit., xli., p. 395, 1896.

² Am. Medico-Surg. Bull., July 25, 1897, from Journ. Soc. Chem. Indust., xv.

³ N. Y. Med. Journ., vol. lxiii., p. 192.

duces prompt lowering of the temperature, not always to a very great extent, but with certainty in the immense majority of cases. 3. The maximum of the fall of temperature is obtained at the end of two hours in most cases. 4. Antipyrin seems to act in cases in which simple baths, or those to which mustard has been added, and moist applications have failed; in all cases, if the immediate antithermic effects were not more intense, they were more lasting. 5. It has no action on the classic thermic cycle of measles, or on any of its complications. 6. The most varied complications have no influence at all on the results obtained with antipyrin, and the failure of the drug should not be imputed to them. 7. No antithermic reaction, or a very feeble one, is often an unfavorable element in the prognosis; this rule is not absolute, and, as recovery may supervene in a case in which there has been no reaction, so may death occur with an abnormally high or an abnormally low temperature in patients who previously showed a notable lowering of the temperature. 8. Antipyrin has no action at all on the rapidity of the pulse. 9. It seems to ameliorate dyspnea in a slight degree. This action does not often begin until two hours after the ingestion of the drug."

Rousseau,¹ of Bordeaux, reports most favorably upon 500 of his hospital cases in which he used antipyrin in very small doses in infantile diarrheas and colic, especially when they occurred during teething.

Frederick Graves,² of Birmingham, England, reports the successful use of antipyrin in a case of diabetes mellitus with sudden onset, fever, epileptoid attacks of a nature resembling those of uremia, maniacal raving, and the presence of acetone; 10 gr. were given t. i. d. for three days, and from this time the improvement was steady and rapid under appropriate diet and treatment.

Several reports³ have appeared regarding the use of antipyrin as an anesthetic locally applied in the surgery of the genito-urinary tract and in obstetrics. Much is claimed for its efficiency, and no toxic effects are noted, but a more extended observation of clinical data is desirable.

Antistreptococcic Serum.—As is often the case, the later reports of experiments with this remedy are less promising than were those first published. Petruschky⁴ reports his experiments with cultures of streptococci and an antistreptococcic serum which he obtained from Marmorek. He found, on giving a dose which Marmorek had stated to be absolutely fatal, that his rabbits were killed only in exceptional instances. He then used two of his own cultures of streptococci which he had grown for two years, and found them to be much more virulent. The action of these cultures was not checked by the antistreptococcic serum even when the latter was injected during the first twenty-four hours after infection. In consideration of these facts Petruschky thinks the following conclusions are justifiable: "That the therapeutic action of the serum is not yet to be recommended in man; and that up to the present time there is no certain proof of the possibility of serum-therapy in streptococcic infection."

Calomel and Potassium Bromid Incompatible.—In an article by W. J. Robinson⁵ on the incompatibility of antipyrin and calomel the assertion was made that potassium bromid formed a very poisonous compound with calomel. This having caused some surprise and comment, the author has further set forth this subject in a letter⁶ to the editor of the *New York Medical Journal*, which, because of the importance of the subject, we quote all but entire:

¹ *Ephemeris*, p. 1786, Jan., 1897. ² *Ibid.*, from *Brit. Med. Journ.*, vol. i., p. 970, 1896.

³ *Ibid.*, p. 1787.

⁴ *Med. News*, Jan. 9, 1897, from *Presse méd.*, Nov. 11, 1896.

⁵ *N. Y. Med. Jour.*, Feb. 13, 1897.

⁶ *Ibid.*, Apr. 17, 1897.

“In many minds there seems to be the impression that when a mercurial salt is combined with another salt there is only a liability of the acid radical being changed, but not of the base—*i. e.*, mercurous chlorid, for instance, may become converted into a mercurous bromid, but not into mercuric bromid. This is, of course, wrong. Any mercurous salt may, by some of the mercury being precipitated in the metallic state, become converted into a mercuric salt. This is exactly what takes place when calomel and potassium bromid are triturated together; mercury is separated, and mercuric bromid—a highly poisonous compound—is formed.

“The reaction is plainly expressed by the following equation :

“The presence of water or moisture seems to be necessary for the reaction to take place, because if the potassium bromid is dried, so that all interstitial moisture is driven off, no change occurs in the mixture; but the reaction occurs immediately on the addition of water.

“The bromid and calomel should therefore never be prescribed together, whether in powder-form or in a mixture; and when they are administered separately the interval should not be too short—say, one or two hours.”

Chloralose appears to have given considerable satisfaction as a hypnotic, but reports are not wanting as to unfortunate manifestations produced by it, generally, however, as a result of doses unnecessarily large. James Tyson¹ gives us a valuable contribution upon the subject, reporting his experiences with the drug. In one case of obstinate insomnia 10 gr. of chloralose were given at bedtime each night. For three nights nothing but sound and refreshing sleep was the result. During the fourth and fifth nights, however, the patient arose and entirely disrobed himself, remaining naked until morning, but awakening quite unconscious of what had taken place in the night. In the second case, one of habitual insomnia, 5-gr. doses of chloralose had for two nights afforded refreshing sleep. On the third night, the usual dose failing to cause sleep, a part of another 5-gr. cachet was taken after several hours, and later the remaining part. In the morning the patient was found sleeping heavily and breathing stertorously, and could not be aroused. Later, however, he awoke feeling well and unconscious of anything unusual. In a third case a 10-gr. dose of the drug having failed to affect an habitual insomniac, the dose was repeated in an hour, with the result of causing at first restlessness with sleep, but later excessive violence, which required forcible restraint. At the same time there was involuntary evacuation of the bladder and bowels. A quiet sleep finally occurred, from which the patient awoke in his usual state. Tyson believes that in these cases the untoward results were caused by doses too large, and recommends that the dose employed should be between 3 and 5 gr. for adults. He thinks highly of the remedy when thus used, but insists upon certain precautions of administration. It should always be given in solution, in either hot water or hot milk. If its bitterness is objected to, then it may be given in cachet, but the objection to giving in cachet or powder is the danger of its being unabsorbed in the stomach and so causing failure, while if repetition is practised the conjoint action of these doses may cause unfortunate results. The cases most benefited by chloralose appear to be the simple insomnias, for it is little if at all analgesic. It may also be used in insanity, in cardiac disease, and in Bright's disease. In tuberculosis,

¹ Univ. Med. Mag., Dec., 1896.

however, the dangerous effects of the drug seem most likely to occur, and therefore, especially if debility is present, it should be withheld. The advantages of chloralose as properly given are its rapidity of action and freedom from dulness, sleepiness, and other ill results on the following day (see *Year-Book* for 1896, p. 1032).

Coal-tar Antipyretics.—J. A. Martin¹ gives a brief review of the results of his study of the coal-tar derivatives—antipyrin, acetanilid, phenacetin, and lactophenin. He undertakes to show the relation existing between these drugs from a chemie, physiologic, and therapeutic standpoint. *Chemically*, all these preparations are obtained from carbolic acid through some of its derivatives, and contain also the radical of some organic acid. Thus antipyrin is obtained by the action of heat on phenyl-hydrazin and diacetic ether; acetanilid, by boiling pure aniline (phenyl-anim) with glacial acetic acid, equal parts by weight, for a day or two, when acetanilid and water result. Phenacetin again is para-phenetid in which an atom of hydrogen has been replaced by the acetic acid radical, acetyl; and similarly in lactophenin an atom of hydrogen in para-phenetid in is replaced by lactyl, the lactic acid radical. It will be noticed that in the first three compounds the hydrogen is replaced by acetyl, while in lactophenin lactyl is substituted. This fact is said to have an important bearing on the relative action of the drugs.

As to the *physiologic action*, it must be borne in mind that the aim has been to retain the antipyretic effect of carbolic acid, while doing away with its caustic and poisonous properties. Carbolic acid diminishes heat-production while at the same time it increases the dissipation of heat. But, unfortunately, aside from its caustic action, which was readily got rid of in its derivatives, it reduces arterial pressure by paralysis of the vasomotor centers and by markedly depressing the heart. Furthermore, death is generally due to respiratory paralysis.

Antipyrin meets the requirements only to a limited degree. It is, to be sure, noncaustic and freely soluble in water, and it reduces febrile temperature to a marked degree. But it is decomposed in the body, the products of its decomposition acting on the hemoglobin of the blood to form methemoglobin. Thus, it is said, it gives rise to the symptoms of poisoning—ataxia, paraplegia, convulsions with general rigidity, stupor and coma, with dilated pupils, sweating, cyanosis, and marked depression of both heart and respiration. In addition, there often exists a personal idiosyncrasy against antipyrin which makes its promiscuous administration very dangerous. A most alarming condition of the patient has more than once been produced by a very small dose (see p. 927).

Acetanilid has a similar action when given in large doses or to patients having an idiosyncrasy against it. The action on the blood is the same, and while the sweating, when it occurs, is less severe, the cyanosis is said to be more marked than that which follows the administration of antipyrin (see p. 927; also *Year-Book* for 1897, p. 1101). The pulse-rate falls markedly, and its character becomes thready. The fall in temperature seems to be due to a diminished heat-production.

Phenacetin, on the other hand, while it lessens heat-production, does so by an influence on the nervous system, while the blood-pressure, according to Martin, remains unaltered. But, again, we find among the unpleasant symptoms the profuse sweating and the cyanosis. This cyanosis, Martin believes, is due to the action of the acetic acid on the hemoglobin, as in the case of antipyrin and acetanilid (see *Year-Book* for 1897, p. 1131).

¹ Atlanta M. and S. Jour., July, 1896.

Lactophenin, like phenacetin, lessens the production of heat by an action on the nervous system, without affecting the blood-pressure. It is said that this antipyretic action, though rapid, is not abrupt, and lasts from four to six hours. Martin has not found that the subsequent rise of temperature was accompanied by shivering or other unpleasant effects, and he has never known cyanosis to follow its administration. The reason for this he believes to be that none of its decomposition-products affects the hemoglobin. He considers the analgesic and hypnotic effects to be decidedly more pronounced than those that are produced by either of its three predecessors, while the heart and respiration seem to be entirely unaffected (see *Year-Book* for 1896, p. 1064; also see p. 942).

In regard to the *therapeutics* Martin makes the following statement: "In my opinion, the day is not far off when antipyrin will be almost wholly discarded on account of the uncertainty of the degree of its action, and on account of its incompatibility with a large number of drugs in common use; acetanilid will find a home with the surgeon as an antiseptic dressing; and phenacetin, which has done a noble work as a forerunner, will give way to its younger and more worthy brother, *lactophenin*."

Codein.—Although we much doubt how widespread is the failure to appreciate this valuable remedy, for our observation has led us to believe that it is in very general employment, still it may be that some have failed to realize its advantages. For this reason the attention called to codein by a recent writer¹ is a matter which should be widely published, for the facts he points out are true beyond question and valuable to the utmost. Although codein suffers from its relationship with morphin, and is overshadowed by a comparison with it, in many respects it has the advantage of the comparison, for it seldom disturbs digestion and is less likely than morphin to constipate. Furthermore, it is not so dangerous a remedy as is morphin used habitually, for it has not the enslaving and therefore dangerous tendencies of that drug. Among the conditions most benefited by codein are irritating coughs. In these, especially that of pulmonary tuberculosis, from $\frac{1}{2}$ to 1 gr., in pill, taken at bedtime will do much to promote quiet and rest. In pneumonia $\frac{1}{4}$ gr. is an excellent sedative addition to a cough-mixture when cough is causing suffering and exhaustion. In pelvic discomfort and pains of varying kind the remedy is remarkable in its power to relieve. In nausea due to nervous causes its action is often good. In the abdominal distress and post-prandial diarrhea of some varieties of dyspepsia codein has unique power to benefit, the method of administration recommended in such cases as these being $\frac{1}{2}$ gr. in pill taken 10 minutes before meals. In the cure of the opium-habit, too, codein may be employed as a sedative substitute for temporary and diminishing employment. The writer emphasizes what is a matter of vast importance, namely, that if good results are expected, a reliable drug should be employed. [This is of rather more importance in the case of codein than in the case of most drugs.] He furthermore thinks that codein pills should be gelatin-coated, made as ordered, and compounded with the addition of a sufficient quantity of aromatic sulphuric acid. Codein sulfate is preferable to the alkaloid itself. [As supplementary to what is here said of the usefulness of codein in irritating and exhausting cough, the formula of a cough-mixture much employed in the hospitals of New York is given: R. Codeinæ, gr. $\frac{1}{4}$; ac. hydrocyanic. dil., ℥ij; ammon. chlorid., gr. iij; syp. prun. virg., ad ʒj. Sig.: Dose ʒj.]²

Commelina (*Yerba del Pollo*) is the name under which several plants

¹ Therap. Gaz., Aug. 15, 1896, from Maryland Med. Jour., Apr. 18, 1896.

² Formulary of the Roosevelt Hospital, New York City.

of the family *Commelinaceæ* are known in Mexico. Alfonso Herrera¹ has recently contributed a very interesting article upon this subject. Although the chief activity of commelina is as a hemostatic, of old the remedy had extensive employment by the Aztecs in the treatment of fevers, headaches, neoplasms, and hemorrhages, as well as in certain conditions associated with parturition. The remedy was neglected for a long time, and in fact, until the experiments conducted with it in 1863 by Hernandez and Alzate, it was little esteemed. Since that time, however, it has been largely employed as a hemostatic. What may be the active principles of yerba del pollo it is difficult to say, though acetic acid may be found in the juice, and in the extract obtained from the plants ammonium acetate, potassium chlorid, albuminoids, vegetable albumin, chlorophyll, extractive, and cellulose.

It would appear that the most frequent hemostatic use of commelina in Mexico is in metrorrhagia and hemoptysis, the extract being employed in injections for the former condition and in pills in the latter. The pills may contain 1 or 2 gr. of the extract, and from 24 to 48 pills even may be given in a day. For injection from a dram to an ounce of the extract may be added to a pint of water. Commelina, in the form of the extract, has also some employment in leucorrhœa and as a hemostatic in capillary hemorrhage. For wounds a strong solution of the extract may be applied upon lint, or a poultice made from the powdered plant. [Although commelina cannot but interest us, and while no doubt it may be in many cases a remedy of value, it is unnecessary to more than call attention to the very limited employment which styptic drugs now have and the very manifest dangers associated with their local application.]

Condurango, it will no doubt be remembered, enjoyed a brief notoriety some few years ago as a remedy for gastric cancer. That its curative power against this condition does not exist is generally conceded, but many observers have called attention to its undoubted stomachic influence, an action which has, no doubt, made the remedy at times productive of relief from many of the dyspeptic symptoms of gastric carcinoma, and has even led to the error crediting it with curative power. In this connection the report of G. Bardet² is of interest. He regards condurango as sedative, and valuable therefore in nerve-irritability. The sedative influence, he thinks, is especially manifested in gastric pain, and at the same time stomach digestion is improved. Not only is condurango a stimulant to gastric digestion, but, according to Tcheisow, it promotes biliary and pancreatic digestion as well. Bardet suggests that when prescribing condurango it is wise to specify the bark of the white variety, this being the variety which has received most study. Of a 20% tincture the dose is from 2 to 4 teaspoonfuls; and of the extract 7 to 15 gr. may be given.

Creolin.—Results are not wanting to show that this substance is not as innocuous as has been believed, and in this connection the investigations of Hobday,³ of the Royal Veterinary College, are both interesting and instructive. A solution containing about two ounces of creolin to the quart of water was applied to a couple of valuable ferrets to eradicate lice and mange, with the result that within half an hour both animals were dead. This called the attention of Hobday to the possible toxic effects of the preparation, and he undertook a series of experiments upon dogs and cats, the results of which he thus states: "That creolin is an irritant and narcotic poison to the dog and cat; that it is especially toxic when spread in emulsions of a certain strength

¹ N. Y. Med. Jour., June 19, 1897, from Am. Jour. Pharm., June, 1897.

² Am. Jour. Med. Sci., May, 1897, from Nouveaux Remèdes, No. 3, p. 65, 1897.

³ Ephemeris, p. 1817, Jan., 1897, from Lancet, vol. i., p. 1733, 1896.

over a large area of the body; that its effect is more rapid and violent when mixed with water than when applied pure or in an ointment; that applied externally in certain proportions it will act as a violent irritant; that the pure creolin is more toxic than the less refined preparations; and that it is less readily absorbed from the stomach, from small wounds, and from the subcutaneous tissue than from a large area of skin-surface."

Digitoxin.—The confusion which has long existed in connection with the digitalis glucosids is a matter of as much practical importance as theoretic, and all efforts made to solve the problems which pertain to foxglove are to be encouraged. Actuated by a desire to bring order out of the present chaos M. L. Adrian¹ advances several propositions which we quote entire: "1. The digitoxin studied in 1888 by Lafont and Bardet is not identical with the more active commercial article of 1893-'94. 2. This difference leads us to believe that digitalis, besides the digitalin already isolated in purity, contains a very active glucosid of the strophanthin type. 3. This digitoxin is not in every case a pure drug, for its variations have been demonstrated, and for this reason it should be omitted from the pharmacopœia for fear of accidents. 4. The digitalin of Nativelle is a pure, crystallized product of constant composition and of constant pharmacologic action, and for these reasons should be the only one admitted to the pharmacopœias. Recently Kiliani² has presented a glucosidal body of the chemical formula $C_{36}H_{50}O_6$, or exactly that established by Arnaud for crystallized digitalin. This substance, designated as digitoxin, is none other than the crystallized digitalin of Nativelle." [It need not be said that such statements, if confirmed, are important; but until pharmacy shall provide us with more reliable and constant digitalis principles, and ones which, however pure, are not variable with their manufacture, we must confess a preference for the preparations of digitalis itself, howsoever objectionable these may be as compared with idealized glucosids.]

A New Disinfectant Derived from Petroleum.—Although the substance described is not as yet obtainable commercially, and therefore its medical importance is rather more theoretical than real, yet the researches of Bartochewitch,³ of Kharkow, with a substance he obtained from petroleum are full of interest. To petroleum-refuse he added 20 parts by volume of strong sulphuric acid, and, mixing thoroughly, he allowed a precipitate to form during 24 hours and in the cold. This precipitate was a mass resembling tar, and above it was an opalescent black fluid. This fluid having been decanted, there was added a 10% solution of caustic potash somewhat less in amount than the original volume. By shaking there was developed a smooth, soapy, yellowish-brown mass, from which emulsions could be prepared. The emulsion which Bartochewitch employed in his experiments contained 200 parts of the disinfecting substance shaken for 15 or 20 minutes with 800 parts of water at 75° C., and subsequently filtered through cotton-wool. The result of this treatment was a dirty, milky liquid containing fatty particles and an aqueous solution of the disinfectant, free from every sort of microorganism. Separation took place in this emulsion after standing for 2 or 3 days, but slight shaking restored its former condition. Investigation showed that the alkalinity of the fluid was equivalent to 1% of caustic potash. For purposes of investigation he employed spores of bacillus anthracis on silk threads, cultivations of the same organism in broth, and similar cultivations of bacillus prodigiosus, bacillus typhi abdominalis, bacillus cholerae asiaticæ, staphylococcus pyogenes, and

¹ Am. Jour. Med. Sci., May, 1897, from Nouveaux Remèdes, No. 3, p. 78, 1897.

² Compare Year-Book for 1896, p. 1035, and for 1897, p. 1116.

³ Medicine, Sept., 1896, from Med. Week., Feb. 14, 1896.

streptococcus erysipelatis. He also applied his testing to the disinfection of fecal matter. As an index of the strength and power which the disinfectant showed, it may be said that the anthrax bacillus was killed by it in 24 minutes, and the same bacillus with its spores in 48 minutes.

The conclusions which Bartochewitch¹ reached from these experiments are : 1. Being without any odor of its own, the disinfectant destroys evil smells, developing only at the beginning of its action a slight ammoniacal smell ; 2. Its oily particles, resulting from the decomposition of the soapy, disinfecting mass, gradually rising to the surface of the liquid to be disinfected, prevent the access of oxygen from the air to the putrefying products, and thus hinder their further decomposition ; 3. The liquid being disinfected gradually separates out of the disinfectant the active constituents, whereby the continuance of its action is insured ; 4. The disinfectant need only be added to the contents of cesspools, etc., in the proportion of 1% or 2% of the refuse, feces, etc. ; thus, calculating the normal amount for each person at 1500 c.c. of urine and 400 gm. of feces, it is necessary to pour into a privy or cesspool from 20 to 40 gm. of the disinfecting substance, an average of 30 gm., instead of about 2000 gm. ; 5. The cheapness of this mode of disinfection is beyond doubt, for to render innocuous the excretions of one man costs from $\frac{3}{4}$ to 1 kopek—*i. e.*, one farthing—a day. Thus, with the exception of tar and its products, this is the cheapest disinfecting-substance known.

Dulcin² is the name given to a substance obtainable from Berlin-blue, and said to be 250 times sweeter than cane-sugar. It is a white, crystalline powder, which is soluble in 800 parts of water at 15° C., in 50 parts of boiling water, and in 15 parts of 90% alcohol. The long-continued use of dulcin by diabetics is said to be unproductive of injury or disagreeable effect, and as compared with saccharin it is advantageous from having a taste more nearly resembling that of sugar. Dulcin has been employed in pastils, which contain 25 mgm., the equivalent of 5 gm. of sugar. [See *Year-Book* for 1896, p. 1037.]

Eosote is a commercial name given to the valerianate of creosote, a fluid distilling at 240° C. It is to be had in gelatine capsules, each of which, it is said, contains about 3 gr. The drug is said by E. Grawitz³ not to be caustic or poisonous. Its therapeutic applications are those of creosote. The beginning dose is a capsule 3 times a day, given with milk in plenty ; later 2 or even 3 capsules may be given at a dose.

Grawitz⁴ has employed eosote in 35 cases of tuberculosis, and as an intestinal antiseptic, in many cases of gastrointestinal disturbance. In most of these the treatment was very successful, and it was rarely necessary to withhold the drug because of digestive disturbance, even after administration for many weeks. Grawitz is warm in his recommendation of eosote because of its cheapness, its palatability, the comfort with which large doses are taken, and the freedom from toxic effect.

Euchinin is a recently introduced preparation of quinin which is asserted to have the curative power of the latter without to the same degree its property of causing noises in the ears, heaviness, and gastric disorder, and also without its disagreeable taste. The drug is produced by the action of ethyl-chloro-carbonate upon quinin, and occurs in needle-shaped crystals which are soluble in alcohol, chloroform, and ether, but little soluble in water. We owe our infor-

¹ N. Am. Pract., Aug., 1896, from Med. Week., Feb. 14, 1896.

² Med. Rec., June 19, 1897, from Jour. de Méd. de Paris, Feb. 7, 1897.

³ N. Y. Med. Jour., Aug., 15, 1896, from Therap. Monatsh., 1896, No. 7 ; Therap. Woch., July 19, 1896.

⁴ Brit. Med. Jour., Oct., 1896, from Therap. Monatsh., July, 1896.

mation upon this subject mainly to O. Van Noorden.¹ Euchinin has basic properties, and uniting with certain acids it forms crystallizable salts. Of these the chlorid is freely soluble in water, the sulfate is somewhat soluble, and the tannate is less soluble. This euchinin tannate is highly to be recommended, and is advantageous in that it is without taste. The chlorid or hydrochlorid, on the other hand, has an exceedingly disagreeable taste, while euchinin itself is without taste unless left long upon the tongue, in which case it is somewhat bitter, but if given in milk or sherry or cocoa no unpleasant taste is noticed. The usual dose of euchinin is between 1 and 2 gm., and it is said that this dose may be given daily for a considerable time without ill effect. A single large dose (2 gm.) in one case produced sensations of heaviness in the head. The drug is advantageously administered in tablet or enclosed in cachet, and to children it may be given in milk, soup, or cocoa, its tastelessness rendering it peculiarly fitted for pediatric practice.

It is to be regretted that Van Noorden was unable, owing to the absence of cases, to test the action of euchinin upon malarial disease. He has reported upon the action of the drug in whooping-cough (15 cases), hectic fever in tuberculosis (14 cases), sepsis from various causes (5 cases), as well as in pneumonia, typhoid fever, and neuralgia. In pertussis and in febrile states Van Noorden states that from $1\frac{1}{2}$ to 2 gm. of euchinin are required to accomplish the work of 1 gm. of quinin. As to the result accomplished, it is stated that 12 cases of whooping-cough were rapidly benefited, and in the febrile cases the temperature was lower within a few days. In neuralgia the effect was also good, and especially brilliant in one case in which the pain was supraorbital, a dose of 0.6 gm. of quinin or 1 gm. of euchinin acting when other remedies had failed, the favorable influence being witnessed in several later attacks.

Ferrostyptin is a substance of recent introduction, said to be antiseptic and styptic and valuable as a substitute for ferric chlorid. Its composition² is unpublished as yet, but it is thought to contain about 20% of iron together with ammonium chlorid and, perhaps, acetanilid. It occurs as a yellow, crystalline powder of sharp and saline taste and an odor which resembles that of carbolic acid. It is freely soluble in water, but is insoluble in alcohol and ether. The watery solution if heated to boiling undergoes coagulation, and a gelatinous precipitate is formed in it by the addition of acids. This, however, is dissolved if the acid is added in excess. If alkalis are added, ferric hydroxid is precipitated. Ferrostyptin melts at 112° C. The clinical value of ferrostyptin is undetermined, but it has been regarded as likely to be of value in dentistry and gynecology. Among the advantages³ claimed for it are freedom from caustic properties, the pulverulent condition, and its action as an antiseptic. The remedy was introduced by Eichengrün.

Formaldehyd, formyl or formol (see *Year-Book* for 1896, p. 1039, and for 1897, p. 1120), is a colorless gas of pungent odor, very irritating to the mucous membrane of the nose and throat if inhaled for more than a few seconds. Chemically it is formic aldehyd, and has the formula CH_2O . It combines with hydrogen sulphid and with volatile compounds derived from ammonia, acting thus as a deodorant. With water it forms a stable, colorless solution, somewhat volatile and having the odor of the gas, not inflammable and practically nontoxic. The 40% (saturated) solution is the commercial formaldehyd, or formalin. It also forms an effective combination with gelatin, known as glutol (see p. 939).

¹ Jour. Am. Med. Assoc., Mar. 10, 1897, from *Centralbl. f. innere Med.*, Nov. 28, 1896.

² *Ephemeris*, p. 1838, 1897.

³ *Am. Medico-Surg. Bull.*, Sept. 5, 1896, from *Apoth. Ztg.*, xi., p. 440, 1896.

Preparation.—Formaldehyd is usually prepared by incomplete combustion of methyl alcohol. Thus far, the most effective and economical method has seemed to be to pass a current of air saturated with methyl alcohol over a heated spiral coil of platinum. On condensation the product is a solution of formaldehyd in methyl alcohol. A. Brochet¹ points out an element of danger in this method, for he has found that the gas when made in this way is mixed with not inconsiderable amounts of carbon monoxid. He recommends a method by which hot air is made to pass over finely divided para-formaldehyd. The gas thus prepared is so dilute that no polymerization takes place on cooling.

Uses.—As an anti-septic, germicide, and disinfectant, formaldehyd has been the subject of many reports, and while we must not lose sight of the tendency to favorable reports on new preparations, the fact that it has some value in this direction would seem to be pretty well established so far. Nearly all observers appear to unite in emphasizing its freedom from taste and odor in weak solutions, together with its ready volatility and the absence of poisonous effects. F. C. J. Bird² thus summarizes the effects produced by the various solutions: "1 : 125,000 kills anthrax-bacilli; 1 : 50,000 prevents the development of typhus-bacillus; 1 : 25,000 forms a useful injection in leucorrhœa; 1 : 2500 destroys the more resistant microorganisms in one hour; 1 : 500 is useful for the irrigation of catheters and as a mouth-wash; 1 : 200 or 1 : 250 is a general disinfectant solution for washing hands and instruments, spraying in sick-rooms, and as a deodorant; 1 : 100 is used for lupus, psoriasis, and other diseases of the skin." Aronsohn and Burkhardt, as quoted by H. C. Wood,³ conclude from their experiments that formaldehyd is not only germicidal, but that it also deprives the toxins of diphtheria and of tetanus at least of their poisonous power. Should further observation confirm this belief its importance is evident. The general opinion seems to have been that as a germicide formaldehyd is as powerful as the bichlorid of mercury. Later reports do not appear to establish this fact altogether. Walter,⁴ after an exhaustive series of experiments, states his conclusions thus: "1. Formalin in the strength of 1 : 10,000 arrests the growth of the germs of anthrax, cholera, typhoid fever, diphtheria, and staphylococcus pyogenes aureus. 2. In the gaseous form it arrests growth, even when greatly diluted. 3. In 1% solutions it kills pure cultures of pathogenic germs in an hour. In diluted alcoholic solutions the effect is more intense. 4. In 3% solutions, especially with the addition of alcohol, the hands may be freed from all germs. More extended investigations are necessary to show the degree to which the skin is affected. 5. By spraying artificially infected matter with formalin solution, and afterward enclosing it in air-tight vessels, such matter may be sterilized. 6. By means of formalin (or, in other words, formaldehyd) leather articles, uniforms, etc., may be thoroughly disinfected in large quantities, and without in any way injuring these articles; 24 hours' exposure is requisite for such disinfection. The possibility of disinfecting rooms may be considered as demonstrated by other experts. 7. Fœces are almost instantly deodorized by a 1% solution, and are disinfected (germ-free) in 10 minutes by a 10% solution. 8. Formalin acts well as a caustic. 9. It is an excellent preservative."

To the surgeon this substance presents many possible improvements in methods of sterilization. It is said not to affect instruments, leaving the edges of knives undulled, while the hands may be rendered aseptic by a 3% solu-

² Am. Jour. Med. Sci., Jan., 1897, from Am. Jour. Pharm., No. 11, 1897.

³ Univ. Med. Mag., June, 1897.

⁴ Ibid., May, 1897, from Zeit. f. Hyg., vol. xxi., 1896.

tion, especially if subsequently rinsed in alcohol. It is also said to be a very efficient aid in sterilizing catgut, and several methods have been recommended. It acts by so hardening the gut that it is not damaged by subsequent boiling. As a local application, also, it is said to offer many advantages, though in too concentrated solution it is irritating to the sound tissues. No case of poisoning is reported. H. C. Wood¹ refers to its use in Philadelphia, both in hospital and private practice, for all sorts of wounds, carbuncles, and infected sores. For cleansing infected wounds a 2% solution was used, and for continuous application $\frac{1}{4}$ %. In strong solution a mild caustic action results. Von Winckel, in Berlin, found that irrigation with a solution containing 1 part in 10,000 was effective in diseases of an infectious nature in the female genital organs. O. Hasencamp,² of Toledo, Ohio, also reports favorably on the use of a 5% solution in gonorrhoea in the male.

Much is said in favor of formaldehyd in ophthalmologic practice. Its value in this connection was noted by Valude in 1893, but recently it has come into more extended use. J. M. Davidson,³ of Aberdeen, Scotland, gives a very conservative and, therefore, valuable account of his use of this agent. He finds the most serviceable solution to be 1 part of formalin to 2000 or 3000 of water. This he has found to be of very great value when used freely in infected abrasions of the cornea and in hypopyon ulcers. Hasencamp⁴ also finds it of use in conjunctivitis.

Salter⁵ reports good results from the use of the 40% solution painted on in ringworm of the scalp; 40 cases were thus treated, and microscopic examinations made both before and after the application showed the trichophyton to have disappeared in each case. A temporary irritation and the production of a thick crust rendered the subsequent application of an emollient advisable. Edema of the face, unaccompanied by pain or constitutional disturbance, was a remarkable complication in 6 of the cases, but was only noticed when the area painted was large.

By far the most important fact in regard to this substance appears to be that it will act as a germicide in the gaseous state, owing to its power to permeate almost all organic substances. In this way, by the use of one of the many formaldehyd-generators now for sale in this country, it seems possible to completely disinfect a room with the contained furniture in about six hours. The experiments of Roux, Trillat, and Bosc⁶ gave remarkable results in this connection. The only resistant germs that were found were bacillus subtilis (of hay) and bacillus mesentericus, neither of which is of pathologic importance. The process was found to be more certainly effective the more perfect the contact of the infected material with the gas, although many remarkable instances of its power of penetration are reported by these and other authors. At the conclusion of the process of disinfection the windows were opened and allowed to remain so for two days, when the room was found to be odorless and habitable. No injury to any object in the rooms followed the use of this method. F. C. Robinson,⁷ of Bowdoin College, has devised a lamp, which is automatic, to produce the vapor of formaldehyd.

E. G. Horton⁸ has conducted experiments at the University of Pennsylvania to test the value of this agent in disinfecting books. He finds that:

⁷ Jour. Am. Med. Assoc., vol. xxvii., p. 675.

⁸ Ephemeris, Jan., 1897, from Med. News, vol. lxxx., p. 152.

"1. Books can be disinfected in a closed space simply by vapor of commercial formalin, by using 1 c.c. of formalin to 300 c.c., or less, of air. 2. The effect produced in the first 15 minutes is practically equivalent to that observed after 24 hours. 3. An increase in the amount of air to each c.c. of formalin is not counterbalanced by an increase in the length of time of exposure. 4. In case the disinfection has been incomplete, the vitality of the organisms has been so weakened that they survive only if transferred in a few hours to media suitable for their development. 5. The use of the vapor of formalin is not detrimental, as far as observed, in any manner to the books, nor is it objectionable to the operator beyond a temporary irritation of the nose and eyes."

H. C. Wood¹ states that the action of the drug upon the higher animals is comparatively feeble. In sufficient doses it acts as a violent irritant. It is worthy of note that the poisonous effects are much more marked after exhibition by the stomach than after hypodermic injection. Free inhalation, as noted by Mosso and Paoletti, is liable to cause a pulmonary inflammation which may be severe enough to cause death.

The purely medicinal uses of formaldehyd have so far been few, though Rosenberg² has given it internally in a solution of milk-sugar, which he calls sterisol. Examination of the urine, shows that it is eliminated very slowly by the kidneys. Hamaide³ describes an inhaler devised for the treatment of pulmonary tuberculosis by this agent, which produces a vapor of 2% to 10% strength. The odor may be disguised by Austrian Pine. The coughing-spells are said to become less troublesome and the quantity of fetid expectoration is diminished.

In preserving and hardening pathologic and anatomic specimens formaldehyd is most useful. The specimens are rendered hard without shrinking, and retain the original colors to a much greater degree than when other agents are used. The penetrating and preservative powers are also said to be good. Lester⁴ has found it very efficient as a preservative for ointments in proportion of about 2 drams to the pound. He found it useful also in mucilages and pastes.⁵

Formopyrin is the name which Marcourt⁶ has given to a combination of antipyrin and formaldehyd. It is prepared by dissolving equal molecular weights of the two components in water and mixing the solutions. The mixture having stood for eight or ten days, there is formed a crystalline substance, which is formopyrin. The next step in the process is the drying of the precipitate upon a porous slab, by which the excess of formaldehyd is absorbed, and its purification by recrystallization from alcohol. Formopyrin is insoluble in cold water, somewhat soluble in boiling water, insoluble in ether and benzine, but freely soluble in alcohol and chloroform. It melts at 142° C., and is decomposed at a temperature higher than this. At the present time the value of formopyrin is purely one of inference, for it has had no reported clinical use to justify the supposition that it will act as an anodyne, antipyretic, and antiseptic.

Glutol is a combination of formalin (see page 936) with gelatin which promises to be of considerable value, if we may judge from the early reports.⁷

⁴ *Ephemeris*, p. 1839, Jan., 1897.

⁵ Those who wish to look up the literature of this agent will find a very complete bibliography in a "Résumé of the Uses of Formalin," by Geo. C. Freeborn in *N. Y. Med. Journ.*, vol. lxiii., p. 770.

⁶ *Ann. Medico-Surg. Bull.*, July 25, 1896, from *Report de Pharm.*, vii., p. 214, 1896.

⁷ *Ephemeris*, p. 1848, Jan., 1897.

To make it, 2% of formalin is added to a warm aqueous solution of gelatin. On stirring there results a combination in the form of a clear, transparent mass having a glassy lustre. This may be powdered, and is usually presented in this form. The advantage claimed is that in contact with animal tissues the compound is decomposed, setting free the formalin, which acts as a continuous antiseptic. The many uses to which such a compound might be put will be readily seen.

Grindelia Robusta.—The following is an abstract¹ representing the result of laboratory investigation which Dott. Luigi d'Amore has conducted with this drug: "He finds that in frogs it produces first a paralysis of the higher nerve-centers, then of the lower. The nerves and muscles preserve their excitability only through direct action upon them, so they at last lose their irritability. With dogs it is found that large doses depress and weaken the nerve-centers after having markedly excited them. With frogs, when the drug is applied to the heart, there is a slow and progressive diminution of the beat and a lengthening of the systole; sometimes the action is so energetic that there is a rapid diminution of the number of beats and arrest of the heart in systole and with an inexcitable myocardium. With warm-blooded animals the phenomena which it produces may be ascribed to an exciting action upon the bulbar center of the pneumogastric, which, when a large dose is introduced at one time into the circulation, appears to be paralyzant. The effects upon blood-pressure are that with small doses there is a slight raising, which is more evident with medium doses; but as the amount is increased the pressure gradually and continually falls during the same time that the oscillations are shorter. In its action upon the respiratory system we have the most interest, for here we find the most extensive use of the drug. Experiments show that when its effects on the pneumogastric are considered, and also its power of contracting bronchial muscles and its action on the heart, that it is likely, in proper doses, to be of value as a remedy for the symptoms of asthma. When in addition we bear in mind that the drug contains an active principle, likely a terpene, which benefits the associated catarrh, the clinical use of the drug has a scientific foundation. So far as its effect on bodily temperature exists, it apparently possesses a paralyzing action on the thermogenic center. The secretions are changed as follows: the urine is increased by small, and diminished by large doses, partly from changes in blood-pressure and partly from direct action on the renal epithelium. The saliva and bile are increased. Both urine and saliva are of greenish tinge."

Hemol.—From the application of this remedy in 30 instances J. Bartelt² has reached the following conclusions: "1. There is no doubt that this remedy is capable of absorption, and in very debilitated individuals is useful for the building up anew of the red blood-corpuscles. 2. The relatively small content of iron frequently, even after three weeks' use, does not present any clinical results; therefore the favorable action of hemol must be due to the entire constitution of the remedy, which may be designated as a blood-corpuscle extract. 3. Its administration is very simple, for, with the exception of gastric ulcer, which it may irritate, there are no untoward symptoms arising from its use. It does not give rise to constipation, the appetite remains unchanged or improved, and the teeth do not become blackened nor carious. 4. There is especially to be commended for the use of neurologists and dermatologists a combination with as much arsenous acid as may be necessary, of a hundred times as much of the

¹ Am. Jour. Med. Sci., Apr., 1897, from *Giornale della Associazione Napoletana di Medici e Naturalisti*, *Puntata 5a e 6a*, p. 331, 1896.

² Am. Jour. Med. Sci., Jan., 1897, from *Therap. Monatsh.*, H. 10, S. 533., 1896.

drug, which should then be given in pill-form. In this way the unpleasant gastric symptoms to which arsenic may give rise are obviated. Doubtless the arsenous acid combines with the drug, forming an arseno-hemol analogous to the copper-, zinc-, or mercury-hemol, and it is probable that there is a rapid absorption."

Holzinol.—Oppermann has used formaldehyd (see p. 936) in a 60% solution in methyl alcohol, which he called *holzin*. Rosenberg,¹ in order to do away with the irritating effects of this solution, combined it with a small quantity of menthol, giving to the combination the name of *holzinol*. He says that by allowing this fluid to evaporate slowly in a room, from a small apparatus, the room and its contents, even including food, may be rendered sterile without injury. He used it also in whooping-cough, and found its influence favorable in all stages. In solution of a strength of only 1 part in 100,000 he states that the development of bacteria is prevented, and 1 part in 75,000 is germicidal.

Improved Mercurial Ointment.—L. A. Harding² has devised a new method for making mercurial ointment, the advantages claimed for it being rapidity of making and a product which keeps well. The ingredients and proportions are as follows: mercury, 12 oz.; expressed oil of almond, 1 oz.; ether, 2 dr.; gum benzoin, 2 dr.; lard and suet, mixed in the proportions of the U. S. P., 10½ oz. The benzoin is powdered, placed in a bottle, and shaken with the ether. The mercury and the oil of almond are then added, and the mixture is shaken with a rotary motion until it gathers into a mass. This is placed in a mortar and rubbed up with a part of the mixed lard and suet; the remainder is finally added, and trituration is continued until the mercury disappears and a perfect mixture is obtained.

Intestinal Capsules and Pills.—The use of keratin and of shellac for coating pills designed for intestinal action only is well known. Several new methods of coating pills intended for this purpose have been devised, and Weyland³ cites that of C. F. Hausmann among others. This process consists of placing gelatin capsules, which have been filled with the medicament, in an 0.8% solution of formaldehyd and allowing them to remain for 18 minutes. They are then removed, washed with water, and dried at 50° C. By this treatment the capsules are rendered insoluble in the stomach, but are dissolved with ease by the pancreatic juice. According to Weyland, the essentials in the process are the strength of the formaldehyd solution and the duration of maceration. Properly treated these capsules are insoluble in water at 38° C., though soluble if long exposed to the action of boiling water. If placed in artificial gastric juice, they are soluble, it is true, but only after an exposure of 10 or 12 hours, a duration of exposure which will seldom be encountered therapeutically. The action of artificial pancreatic juice is quite the opposite, for, whether the capsules have previously been exposed to the action of gastric juice or not, a solution is effected in one or two hours. [It is much to be hoped that this process may demonstrate its value clinically, for in many instances the keratin process has been a disappointment, apart from the very tedious and troublesome manipulations which it involves. We have had, however, no personal experience with the new coating.] (See *Glutol*, p. 939.)

Iodol continues to be extensively employed, though recent literature upon the subject is not rich. From its use in 558 cases, of which 187 were chancre

¹ Med. News, Feb. 27, 1897, from *Deutsch. med. Woch.*, Nos. 39 and 40, 1896.

² *Am. Medico-Surg. Bull.*, Aug. 15, 1896, from *Am. Druggist*, xxviii., p. 297, 1896.

³ *Am. Medico-Surg. Bull.*, Sept. 5, 1896, from *Pharm. Rev.*, iv., p. 164, 1896.

or chancroid, Dominico Majacchi¹ finds reason to praise it most highly. It is advantageous for several reasons: 1. Its freedom from odor renders it more acceptable to patients than iodoform; 2. It is nontoxic even when used very freely; 3. It hastens healing; 4. The preparations employed are stable and nonirritant. A number of formulæ for preparations of iodol have recently been published and are here presented:²

"*Iodol-ether*.—A 10-to-20% ethereal solution for injection into fistulous tracts and for sprays. By spraying it upon the gauze with which a wound has been bandaged an excellent iodol gauze is had.

"*Iodol-ether-collodion*: iodol, 1 part; ether, 5 parts; collodion, 10 parts. For applying to open or sewed wounds.

"*Iodol-alcohol-glycerin*: iodol, 1 part; alcohol, 16 parts; glycerin, 14 to 34 parts.

"*Iodol-lanolin*, containing 5% to 10%, for inunction in glandular tumors.

"*Iodol-vaselin*: iodol, 1 to 2 parts; vaselin, 10 to 15 parts. For internal as well as external abscesses.

"*Iodol Paste*.—Iodol triturated with a few drops of alcohol and sufficient glycerin to yield the desired consistency, for vaginal tampons.

"*Iodol gauze and cotton*.

"Iodol is also used in powder in ophthalmic practice, and as a substitute for potassium iodid internally (up to 1 gm. per day). In the last case its action is said to be of greater persistence than that of potassium iodid, for its presence in the urine can be shown even after six days, whereas potassium iodid disappears in 1½ to 2 days."

Lactophenin.—Hermann Strauss, of Giessen, Germany, and F. Kolbl,³ of Vienna, after using lactophenin for considerable periods of time in large doses in the treatment of neuralgia and muscular pains, have concluded that it is far from harmless. Strauss reports three cases in which jaundice and dyspeptic disturbances were produced, owing to retention of bile, as was shown by the colorless condition of the feces. Kolbl reports two cases of a similar character.

Loretin, though still in use, it would seem, has not been the subject of much report during the past year. E. Wyllys Andrews,⁴ however, has pursued its study, and speaks highly of it. According to him, the substance is somewhat irritant to new wounds, and, therefore, is not desirable save in cases of sepsis. The mixture of loretin in the proportion of about 1 to 10 of boric acid, magnesia, or starch, is also recommended as an application to ulcerated surfaces, and the effect produced upon sluggish and varicose ulcers is said to be stimulant and beneficial, while even phagedenic ulceration is favorably influenced. To small chaneroids it may be applied pure, with the result of stimulating their rapid cicatrization. Andrews is emphatic in his preference for loretin over iodoform, so far as its freedom from toxic properties is concerned, for in several hundred cases of its employment he failed to discover any evidence of poisonous effect. In the disinfection of old fistulae this writer thinks that loretin is of unusual value, and was favorably impressed with its influence upon carbuncle. To the report of Andrews is appended a bacteriologic report upon loretin by S. P. Black, which leads to the conclusion that the real antiseptic power of the drug is slight.

Herbert Snow,⁵ surgeon to the Cancer Hospital, London, in the course of a

¹ Ephemeric, p. 1866, Jan., 1897.

⁴ Chicago Med. Rec., July, 1896.

⁵ Ephemeric, Jan., 1897, from Brit. Med. Jour., vol. ii., pp. 1549 and 1637, 1895.

report upon loretin, says: "My own experience is confined to the powder, which I have never found occasion to mix with any other substance. Dashed on the skin, or over a granulated wound, this causes not the slightest irritation or unpleasant sensation. It immediately destroys the malodor of the most fetid cancerous sore, controlling this in a manner which no other agent I have yet tried will do. Copiously puffed with an insufflator into the deep cavity formed by evacuating the axilla of carcinomatous glands, it efficiently precludes suppuration, even when free hemorrhage has taken place after closing the wound, an occurrence almost inseparable from anesthetic vomiting when the patient has been removed from the operating-table. Not the slightest bad symptom from its employment in this way has so far been detected. When there is no deep cavity a wound dusted with loretin heals rapidly by first intention. I have had recourse to loretin in some 60 cases, mainly operations on the breast and axilla, notoriously a test-region for antiseptics. In my hands it has proved an ideal antiseptic and deodorant, with no single drawback; and I am sure that no surgeon who has once tried it will ever again resort to the noisome and toxic iodoform, from the free use of which I have seen more than one death. Though whenever old-established agents answer sufficiently the purpose I have a strong prejudice against novelties, yet this substance—non-poisonous, devoid of smell, and absolutely preventative of suppuration—seemed to me so marked an advance upon anything previously brought forward, that I felt constrained to direct thereto the notice of the section." Somewhat later Snow adds to the above: "by pointing out a peculiar quality which the 6 months' experience gained since the July meeting has shown me it possesses. While taking first rank as a nonpoisonous, nonirritating, odorless antiseptic and deodorant, I find that when dusted on a raw surface it relaxes the blood-vessels. Hence the wound is prone to become subsequently filled by a clot, which, however, does not suppurate, as would be the case under almost any other circumstance, but is eventually reabsorbed. The incident is not desirable, and I now apply loretin only to the skin-surface, never dusting it into a cavity unless there be special risk of suppuration, and then only very sparingly. I would take leave to add that long experience has shown me the ideal condition in which to leave any operation-wound to be the utmost attainable maximum of dryness, avoiding all swabbing with fluids, however antiseptic. It is probably that the efficacy of iodoform, loretin, and the like is very largely due to their capacity for absorbing moisture, without which microbe proliferation does not occur." [The value of a report such as this is necessarily very great, but of all its wisdom the wisest is contained in the concluding sentences, a truth which too many are unaccountably apt to disregard.]

Magnesium Sulfate.—Few cases of poisoning by Epsom salts have been noted, but the importance of knowing that such symptoms may occur is evident. J. H. Neale,¹ of Leicester, England, observed such a case in a boy of 15. The day before he was seen by the physician he had taken an ounce of magnesium sulfate, proved by subsequent analysis to be pure, and which caused only three slight movements from the bowels. Soon after he began to feel sick, and continued growing worse until the following evening. When seen then he was conscious, but apathetic, markedly cyanosed, the trunk covered with a roseolous eruption, pulse too feeble to be counted, and temperature 105°. The stomach and bladder were dilated and there was an occasional tetanic spasm of the right side of the face and of the right arm. There was some vomiting of greenish fluid. The only treatment employed was directed to the relief of symptoms and stimulation. The patient made a good recovery. [Although of exceed-

¹ Lancet, Aug. 15, 1896.

ingly uncommon occurrence, poisoning by magnesium sulfate is not unknown. A case reported by Christison in some respects resembles that reported by Neale. In Christison's case a fatal result in a boy of 10 was attributed to 2 oz. of the salt, and that without purgation. Absorption sufficient to cause poisoning is, in truth, very rare, but the experiments of Recke, Hay, and Curci show that the injection of magnesium sulfate within the veins is productive of circulatory disturbance and death from respiratory or circulatory failure.^{1]}

Malarin is the name given to a new patented compound said to be² "the citrate of a condensation-product of aceto-phenon and para-phenetidid" or³ "acetophenonphenetidid." The name "malarin" is copyrighted. The preparation of the substance is by heating acetophene and paraphenetidin in molecular proportions, alone or with dehydrating substances, in a vessel having a return-condenser. The drug occurs in needle-shaped crystals, which are lemon-yellow in color and of slightly acid taste. It is insoluble in water, but is readily soluble in hot alcohol and in ether. It is said that malarin is free from injurious properties to man, and that doses of 30 gm. for every 75 kilos of body-weight cause neither sugar nor acetone to appear in the urine. Furthermore, no injurious effect is noted upon the urinary apparatus. The application of the compound medicinally is as an antipyretic and antineuralgic, and thus employed in doses of 0.5 gm. is said to be prompt in action and harmless. Thus have been treated fevers, toothache, neuralgic headache, and nervous excitement. [Although the reports which have reached us of "malarin" are in its favor, it is far too early to express opinions as to its worth, for as yet it has had little employment other than in Germany, and, so far as we are aware, no observations have been made upon it in this country. It is possible that we shall find it a preparation of value, but it is difficult to see how it can be superior to others of its class which are now in general use, apart from the very decided prejudice which prevails in this country against drugs of the patented order.]

Mercuro-iodo-hemol (see *Year-Book* for 1897, p. 1127), according to Kobert,⁴ contains mercury, 13%; iodin, 28%; and hemoglobin. It has received commendation from a number of sources, and is held advantageous not only for its antisyphilitic powers, but because of its freedom from irritant properties and its action as a bloodmaker. It is especially of value, therefore, in the presence of debility and anemia, and may be administered for a long period without ill result. The preparation is ordinarily given in pills, for whose preparation the following formula is employed: mercuro-iodo-hemol, 10.0 gm.; opium, 1.0 gm.; glycerin ointment, enough to make 100 pills. To be given three times a day; at first one, then two, three, and later four pills.

Metallic Mercury for Hypodermic Injection.—The following formulæ are given in a recent publication⁵ as the most important ones in which mercury and fatty substances are combined, constituting the so-called gray oil (*huile grise*), for the purpose of subcutaneous introduction. The dose is not more than $\frac{3}{4}$ gr., and should be given not oftener than once a week.

1. (Lang.) R \bar{y} : mercury, lanolin, each 3 parts; olive oil, 4 parts.—M.
2. (Gay.) R \bar{y} : mercury, 20 parts; lanolin, 5 parts; liquid vaselin, 35 parts.—M.

Nitroglycerin.—It has been the experience of all observers that the dose of nitroglycerin is a very variable matter, and latterly there has been a growing tendency to disregard all arbitrary measurements in its continued use, and to grade the doses employed solely with regard to the physiologic effects produced. Acting under this plan many have succeeded in giving doses of nitroglycerin far in excess of the text-books— $\frac{1}{100}$ or $\frac{1}{50}$ gr.—and with most beneficial results. W. L. Armstrong,¹ writing upon this subject, speaks of the variability in response to nitroglycerin, and quotes the cases reported by H. C. Wood, in one of which one drop of a 1% alcoholic solution caused insensibility, and in two of which two drops caused abolition of consciousness and the radial pulse ; these as examples of smallness of active dose. As showing the other extreme of therapeutic doses there is cited the case of Whittaker, in which $1\frac{1}{10}$ gr. was given every 3 hours, a matter of $8\frac{1}{2}$ gr. in 24 hours. The writer goes on to say that he is unable to find in literature a suggestion that arterial contraction affords a toleration of the drug, as compared with arteries in their normal condition, and argues that toxic symptoms from nitroglycerin are present only after “the drug has relaxed the arterial walls beyond their normal tonicity.”

The experiments reported by Armstrong, as tending to prove his belief, are full of interest. In six cases with normal circulation nitroglycerin was given in doses of $\frac{1}{100}$ gr. every hour. In all of these headache was the result observed within 24 hours—*i. e.*, a dose of $\frac{1}{5}$ gr. in 24 hours caused poisoning. In the next instance it was observed that a patient with atheromatous arteries, but no increase of tension, and who previously had taken none of the drug, upon taking $2\frac{1}{2}$ gr. of nitroglycerin at a single dose, suffered no inconvenience whatever. From this it is argued that the atheroma prevented the relaxation of the arteries supposedly necessary for toxic manifestations. In the third set of cases patients were employed whose arterial tensions were high, but whose arterial walls were free from atheroma. Of these cases there were two. The first patient received gradually increasing doses of nitroglycerin during a period of 25 days, at the end of which time the daily amount taken was 76 gr. The clinical result of this was the loss of arterial tension and the disappearance of the symptoms previously experienced, but at no time was headache complained of or other manifestation of toxicity. The abrupt cessation of the remedy then resulted in a rapid return of the arterial tension as well as of the subjective symptoms. In the second case the nitroglycerin was given in increasing amounts during a period of four weeks, at the end of which time the dose amounted to 125 gr. in 24 hours, the only result of this enormous dose being beneficial, the arterial tension having disappeared. The dose of 8 gr. every hour while awake was finally increased to 9 gr., when slight headache resulted and no further increase was made. In both these cases it is emphasized that the relaxation of the radial arteries was observed some time before the largest doses were reached, and increase was practised further simply that the limit

¹ Med. News, Oct. 31, 1896.

of toleration might be observed. The author's conclusions seem well warranted, and indeed the study which he reports is one of much interest and importance. He sums up as follows: "1. It is only when dealing with arteries in which there is no more than the normal tonicity of the walls that the drug is liable to produce disagreeable effects. Under this condition it should be administered with caution and in small doses. 2. In cases of arterial tension the drug can be used more freely than has been customary among practitioners, the dose being proportioned to the degree of tension. 3. In cases of arterial tension tolerance of the drug is rapidly acquired, and by a slight increase day by day very large doses can soon be taken with safety, the constant guide being the degree of tension in the arterial wall."

Orphol is the name employed to designate betanaphtol-bismuth, a substance partaking of the actions of betanaphtol and bismuth, and therefore employed as an intestinal antiseptic and astringent. It is said to contain about 20% of betanaphtol and about 80% of bismuth oxide chemically combined. The doses recommended are from 2 to 5 gm. for children and from 5 to 10 gm. for adults.¹ Orphol occurs as a powder light brown in color, of agreeable odor and aromatic taste. Golmier,² of Erfurt, speaks highly of this remedy in diarrhea due to tuberculous inflammation of the intestinal canal. This observer calls attention to what is already well known, namely, the disadvantages which tamin and opium have in such cases, and declares that the remedy needed in these diarrheas is a reliable intestinal antiseptic which at the same time is astringent. This combination he finds ably represented in orphol. Among the cases which Golmier reports there is one whose record is most interesting and instructive. The patient was 52 years of age and phthisical, suffering much from thin, watery movements, flatus, and abdominal pain. He received opium with no benefit, and then orphol was given in doses of 15 gr. every two hours and continued for several days. As a result of this, diarrhea ceased and the movements lost their previously foul odor. The appetite at the same time improved, together with the general appearance. The remedy was continued in the same doses and with the same frequency, with the result, however, of producing constipation. Upon lessening the amount given, however, and increasing the length of the intervals this over-astringent effect disappeared, the bowels moving daily and the feces being of a gruel-like consistency. Golmier believes that the action of orphol depends upon its being decomposed in the intestines into its components the naphtol manifesting antiseptic effect and the bismuth astringency. It is said that a little naphtol may be found in the urine. (See *Year-Book* for 1896, p. 1027.)

Parthenium Hysterophorus is a plant growing in some of the Southern States, as well as in Cuba and Jamaica. Its medical introduction is due to José R. Tovar, who in 1885 proclaimed its advantages in neuralgia and in certain fevers. H. V. Arny,³ writing upon this subject, calls attention to the confusion which has surrounded the discussion of its active principles, some speaking of an alkaloid called partheninin and others of a parthenicin. From a thorough and prolonged study of the subject Arny has isolated, besides the usual plant-constituents, a volatile oil which has the heavy odor of the plant, and yields a stearopten of camphoraceous taste; as well as a principle to whose presence is due the intense bitterness of the plant. This principle appears to be neither an alkaloid nor a glucoside, and the author places it as a proximate principle similar to santonin. The name given to this sub-

¹ *Ephemeris*, p. 882, Jan., 1897.

² *Am. Medico-Surg. Bull.*, Feb. 25, 1897, from *Allg. Med. Central-zeit.*, No. 96, 1896.

³ *New Orl. M. and S. Jour.*, May, 1897.

stance is parthenin, and since Army obtained no other principles from the plant he is disposed to regard the so-called partheninin and parthenicin as impure forms of parthenin.

As to the therapeutics of parthenin there has been some discussion, and Army reports that in Jamaica the drug is thought remedial in certain skin-diseases, especially those which are herpetic and pustular, as well as in ulcers. Tovar speaks of his parthenin as beneficial in facial neuralgia, as well as in a case of fever and anorexia in which quinin had failed. Its antineuralgic character was confirmed by Guyet, though he failed to obtain antipyretic action from it. The dose of either partheninin or parthenicin is placed at 0.05 gm. every hour in neuralgia and at 1 gm. in intermittent fever, and parthenin can, therefore, be given on this basis, according to Army. This investigator proposes to prepare a sufficient amount of parthenin to enable thorough clinical trial to be made, and we may therefore expect further reports upon this subject, which at present has reached no very practical status.

Pellotin, a hypnotic of recent introduction, is a crystalline substance of bitter taste. Its solubility in water is slight, but alcohol, ether, and chloroform readily dissolve it. Crystalline salts are produced by the combination of pellotin with acids, and of these the hydrochlorid has had some therapeutic employment, being exceedingly soluble in water. The medical introduction of pellotin is due to F. Jolly, of Berlin. The chemical formula of the substance is said to be $C_{13}H_{19}NO_3$.

From experiments which A. Heftner¹ has conducted with pellotin we gather the following information: injected into frogs it produces slight narcosis in 10 or 15 minutes, the reflexes being diminished and responsive only to strong irritation. Later, however (after 20 or 30 minutes), reflex irritability becomes much accentuated, even to the production of tetanic movements. It is noted, too, that the condition of great nerve irritability may remain pronounced for a considerable time, even for several days. Finally, however, and after prolonged tetanus, the motor irritability is lost. The channel by which pellotin is eliminated is renal, at least in part, the drug having been recovered in the urine. The action of the drug upon man in many respects resembles that of morphin, for following its administration by mouth there occur drowsiness and lassitude, followed presumably by sleep. It is noticeable that during the sleep so caused the pulse-rate may be lowered. Headache and nausea have been attributed to the use of pellotin. [Pellotin is as yet little known in this country, and our information upon the subject is therefore obtained chiefly from European sources. The following, though doubly a quotation, has appeared to us the best brief which we have encountered in our search of the literature of the subject and worthy of verbatim repetition.]

From this source² we learn that pellotin "is an alkaloid discovered in a species of Mexican cactus called anhalonium." (See Anhalonium Lewinii, p. 924. See also *Year-Book* for 1897, p. 1103.) "The natives of Mexico are reported to swallow slices of this plant, to which they give the name of 'pellote,' and Heftner, of Leipsig, has now succeeded in isolating its soporific alkaloid. Pellotin itself is not soluble in water, but its hydrochlorate is extremely soluble. Its physiologic action was first tried on frogs, and then on mammals, which very soon became unable to stand or perform spontaneous movements, and shortly afterward an increase of the reflexes was observed, followed by tetanic convulsions. This action of the drug on animals was not identical with that which Heftner observed in himself, for after taking 5 cgm.

¹ Am. Jour. Med. Sci., Nov., 1896, from Therap. Monatsh., H. 6, S. 327, 1896.

² Ephemeris, Jan., 1897, from Lancet, vol. i., p. 1760, 1896.

($\frac{3}{4}$ gr.) he became very drowsy and ultimately fell asleep. The drug was then given by Jolly to a number of patients in the neurologic wards of the Charité Hospital in Berlin. The first case was that of a man suffering from alcoholic neuritis who, after an injection of 4 cgm. became very drowsy, and one hour afterward he fell into a sleep which lasted for four hours. Heftner had observed in himself a diminished pulse-rate, and the same symptom was perceptible in this patient, during the first hour of whose sleep the pulse fell to 56 per minute, rising again to 76 before the man awoke. Another patient with multiple sclerosis took 5 cgm. during the afternoon, and after half an hour he also slept soundly for several hours. Similar results were obtained in a series of other cases. In patients suffering from tabes the soporific action was equally satisfactory, but the pains returned after they woke. In delirium tremens the effect was less prompt; in one instance 12 cgm. (equal to $1\frac{3}{4}$ gr.) were needed only to tranquillize an excited patient, and no sleep ensued. In 20 cases of different kinds the remedy was given as a hypnotic in the evening; 2 cgm. had no effect, but from 4 to 6 cgm. were efficacious in producing sleep, and no injurious consequences of any kind were observed. Some patients complained of giddiness, and declined to take the medicine, but the greater number did not suffer in this way. Jolly says that 6 cgm. (equal to about 1 gr.) of pelletin are equal to 1 gm. (equal to $15\frac{1}{2}$ gr.) of trioval, or 2 gm. (equal to 31 gr.) of hydrate of chloral. The number of cases is yet too small to justify the formation of a definite opinion as to the new remedy, but it undoubtedly deserves further trial."

Although it is true that 58 cases are too few to afford the drawing of conclusive deductions as to the value of a remedy, yet in reporting his experience with pelletin in the treatment of insomnia Pilez¹ has given us much valuable information. His patients were inmates of insane asylums in Vienna. Of the entire number (58) treated with pelletin there was produced a most excellent result in 29 cases, sleep appearing within an hour and a half and continuing through the night. In 17 cases the result was less pronounced, but still beneficial, while absolute failure of hypnotic effect was experienced in but 12 cases, and of these Pilez regards 4 as inappropriate subjects for the test. The smallest dose which Pilez employed was $\frac{1}{3}$ gr., given subcutaneously, and 19 of the cases treated responded to this amount. In no case was more than 1 gr. administered, and though Jolly has taught that 2 gr. of pelletin hydrochlorid may be given hypodermically without ill-effect, Pilez places the range of dose between $\frac{1}{3}$ and $\frac{2}{3}$ gr., repeated 3 times if required. In one of the cases reported by this writer $\frac{1}{3}$ gr. of pelletin was productive of sleep in a patient in whom 60 gr. of paraldehyd had failed to affect, and in another to whom 75 gr. of the same drug had been given without success. In none of his cases did Pilez observe the slowing of the pulse already mentioned, but in 2 cases there occurred coma and dizziness, although one of these patients was suffering from paranoia with sensory hallucinations. The author thinks highly of pelletin, and rates it as often successful where other drugs have failed.

Picrocarmine solution, of a stability sufficient to remain good for 5 years, is said to be prepared as follows:² a solution is made of pure carmine in a mixture of 1 part (by volume) of ammonia-water and 4 of water, the carmine being in slight excess. The solution is allowed to stand for 2 days, and is then filtered. Following this it is exposed (though protected from dust) until a precipitate commences to form, when it is filtered again, and to it is added a concentrated solution of picric acid. The mixture is then stirred

¹ Brit. Med. Jour., June 5, 1897, from Wien. klin. Woch., No. 48, 1896.

² Am. Medico-Surg. Bull., Sept. 12, 1896, from Pharm. Jour., No. 1357, p. 505, 1896.

and allowed to stand for a day, when it is filtered, and to it is added 1 part of chloral hydrate for each 1000 parts. After standing for one week a final filtration is done and the product is bottled in small glass-stoppered vials.

The pituitary gland remains an enigma in spite of attempts to solve its function. The recent investigation of the subject by Mairé¹ and Bosc² is interesting, although the result of their experimentation is negative. As subjects of experimentation they have employed rabbits, dogs, healthy men, and epileptics. The pituitary gland of the ox repeatedly fed to dogs apparently produced no effect whatever. A solution of the gland made by pounding it up in water was administered to dogs hypodermically, but no sequelæ were observed, save for the slight and temporary elevation of temperature and slight wasting. The intravenous introduction of this solution caused death from thrombosis, a result not unnatural, and certainly not peculiar to the substance employed.

The internal administration of the gland to man in health was productive of no result whatever, and its subcutaneous introduction caused slight fever with malaise, which continued for about one day. The administration of the gland, both by mouth and by hypodermic injection, was practised upon 21 patients the subjects of epilepsy. So far as the convulsive attacks are concerned, their number was certainly not diminished by the treatment, but rather they seemed to be made more frequent. In many of these cases the ingestion of the gland seemed to be the cause of mental exaltation or delirium, which appeared 3 or 4 days after the administration of the gland. These delirious attacks in some cases resembled those sometimes seen in epileptics, and, therefore, the element of coincidence must be entertained. In other cases, however, the attacks were of an aberration different from that which had previously been observed in these cases.

Poisonous Honey.—Lyman F. Kebler³ has made an exhaustive study of this subject from a historic standpoint in connection with a case which came under his observation. He is of the opinion that the toxic properties of the honey are determined by the character of the flowers on which the bees feed. At times examination reveals poisonous alkaloids, but this is by no means always the case. At times also the poisonous character can be detected by the color and taste of the honey.

Purity of Drugs.—Several articles bearing on this question have appeared during the past year, and all show a desire on the part of both physicians and pharmacists for some means by which drugs and galenical preparations of a definite and uniform strength may be obtained.

G. F. Hanson,⁴ of San Francisco, gives many examples of the adulteration of drugs. Among the gums, gum arabic and gum tragacanth have long been subject to substitution by cheaper gums. In America apple and mesquite gums are used. The gummy exudate of the almond and palm is added to the inferior grades of tragacanth, and even the dark caramania or mosul gum is said to be similarly used after being brought to the proper color with white lead, while the untaught native of Nubia or Abyssinia, scorning such scientific mendacity, simply adds anything he can get in the way of sticks, dirt, pebbles, and bark, and thus makes up the additional weight.

An investigation of some specimens of powdered licorice of late has shown that the drug had been exhausted for the preparation of the solid extract and

¹ Brit. Med. Jour., Oct. 3, 1896, from Arch. de Physiol., No. 3, p. 600, 1896.

² Am. Jour. Med. Sci., Nov., 1896, from Arch. de Physiol., No. 3, p. 600, 1896.

³ Medicine, Jan., 1897, from Med. and Surg. Reporter, Sept. 12, 1896.

⁴ Pacific Med. Journ., Sept., 1896.

ammoniated glycyrrhizin, the residue being the "powder." Digitalis-leaf is said to be often adulterated by the addition of the leaves of mullein and elecampane. Ergot also often contains substitutes, such as the fungus of wheat. These, however, as a rule do no harm, and some are said to be even more active than the pharmacopœial preparation. At the worst, we shall get only a less active drug.

A mixture of resin with oil of turpentine is very frequently substituted for Venice turpentine; and one of resin and fat, with a little water to make it turbid, often takes the place of Burgundy pitch.

It is an interesting fact that the consumption of copaiba balsam yearly exceeds the importation by something like 40,000 pounds, if the figures for 1893 and 1894 can be taken as a criterion. The most frequent addition is of Gurgin balsam, or East India wood-oil. It may be easily recognized by the greenish-violet tinge that it gives when examined in strong sunlight to a specimen of copaiba to which it has been added. Paraffin or vaselin oil is also used. Once in a while some Para copaiba is said to be found on the market from which the oil has been distilled.

The fact that aconite root often lacks proper alkaloidal strength is rather due to ignorance on the part of those who gather it regarding its condition, the season in which it should be taken, and the proper method of preservation. Gamboge is sometimes found in the market filled with sand, powdered bark, and rice-flour.

Flaxseed-meal is an article that suffers frequently from adulteration. It contains at times traces of rape or mustard seed; but as these have a higher commercial value than the flaxseed itself, it is only fair to suppose that the addition is accidental. For intentional adulteration the simplest material is ground "oil-cake," the residue left after the linseed oil has been pressed out from the seeds. But crushed wheat, bran, cornmeal, middling, etc., are also often used for this purpose.

Of the various wood-chips imported for use both as drugs and as dyes, there is often an adulteration by mixing in the chips of inert woods. Thus to the resinous heartwood of guaiacum is added not infrequently the useless sapwood; quassia-chips are adulterated with other bitter woods or simply with oak; and logwood with Brazil-wood chips.

The leaves of buchu are occasionally mixed with those of an inferior species of Barosma or with the leaves of altogether different plants. Senna often contains a large amount of argel leaves, which considerably increase the griping without adding at all to the purgative power of the drug. *Hyoscyamus alba*, which grows along the northern coast of the Mediterranean Sea, is sometimes sold for *hyoscyamus niger*. The leaves of the bearberry are sometimes mixed with those of the red whortleberry, probably through ignorance on the part of those by whom they are gathered.

The oils, especially the more expensive of the essential oils, are largely adulterated, for the temptation is great. For instance, in the oil of rose there is often a goodly quantity of Indian grass or of geranium oil. Attar of rose crystallizes at 12.5° C., and to the resulting stearopten spermacti or some form of paraffin is added to increase the bulk. The ingenuity displayed in the adulteration of the oils of peppermint, spearmint, eajuput, lemon, etc., is almost beyond belief. Olive and cod-liver oils bear the greatest part of the attacks upon the fixed oils, both because the price is high and because the consumption is large. To olive oil are added generally the cheaper nut- and seed-oils, such as cottonseed, walnut, peanut, poppy, rape, and benne oils. Cod-liver oil often contains a large proportion of porpoise and other fish-oils, the favorite

being that obtained from shark liver, as this gives the tests for cod-liver oil. It is, however, of less specific gravity.

As a rule, the adulterants used, as may be seen from the foregoing examples, are not actively harmful. They are used rather to increase the bulk with a cheaper article and thereby to add to the profits.

Pyramidon, a drug proposed as a substitute for antipyrin, is of an introduction so recent that little is known either of its properties or of its usefulness. Huchard¹ has prescribed it in maximum daily doses of 15 gr., and has never observed from it any influence upon arterial tension, though the opposite has been asserted by German observers. He reports that Deguy, as a result of his experimentation with it, rates it as exceedingly poisonous, and warns that its use must be attended with much care. [We are not aware of any other than meager reports upon pyramidon, and, in fact, the statements of Huchard were made verbally at a meeting of the Société de Thérapeutique.]

Pyrantin, or para-eth-oxyl-phenyl-succinamic acid, the recently introduced antipyretic, is derived from the reaction taking place between succinic acid (obtained by the distillation of amber) and phenacetin. These are melted together and boiled with alcohol, when pyrantin will crystallize out in prismatic, colorless needles. These crystals are but slightly soluble in cold water (1 in 1317), though more soluble in boiling water (1 in 86.6).² The action of pyrantin is said to resemble that of phenacetin, but A. Piretti, its introducer, claims that it is devoid of the objectionable features of phenacetin's action as well as superior to other similar antipyretics. It is said that the drug is without injurious effect upon the digestion, circulation, and respiration, and Renzi and Di Giovanni have reported it as a remedy of value in acute rheumatism, having administered it in doses of 1 to 3 gm. per diem.³ Caution should be observed that pyrantin is not confused with the antipyretic and analgesic mixture known as "pyretine." [It is too early as yet to assign to pyrantin its proper pharmacologic place, for reports as to its clinical employment are scanty.] (See *Year-Book* for 1897, p. 1135.)

Quinin sulphovinate has been highly recommended by Alex. K. Finlay⁴ as suitable for hypodermic administration, since it possesses marked solubility in water (1 in 3) and freedom from irritant after-effects. Its quinin-value is about equal to that of quinin sulfate. The use of the remedy in the form of tablets for the preparation of solutions is objectionable, it is said, because in tablet-form it is but slowly dissolved. The preparation of a solution from the crystals, however, is easily accomplished, and is rendered possible within a few seconds if gentle heat be employed. The solution of quinin sulphovinate is said to keep for a long time, and especially is preservation secured by the addition of a little alcohol. [It is much to be hoped that further use will establish the value of this salt for subcutaneous administration, for though the need for thus giving quinin is often urgent, it cannot be said that the salts previously used thus are always free from objection.]

Salacetol is a compound of salicylic acid and acetol. In some respects it resembles salol in action, though far more rapid in effect. Unlike salol, however, its separation into its component parts is not productive of poisonous substances. According to Riechetti, salacetol is superior to other salicylates as an intestinal antiseptic, and is non-poisonous even in large doses. It is said to be inactive against the soluble ferments, and to antagonize the bacillus coli

¹ N. Y. Med. Jour., June 5, 1897, from *Indépendance méd.*, May 12, 1897.

² Med. Bull., Dec., 1896.

³ *Ephemeris*, Jan., 1897.

⁴ Am. Medico-Surg. Bull., June 10, 1897, from *Med. and Surg. Jour.*, xlix., p. 200, 1896.

communis and the organisms of cholera and typhoid fever. Mosso¹ reports his results from its external application in powder or salve and with glycerin. He says that in external use the body-heat and the presence of a liquid somewhat alkaline promote its decomposition, and its antiseptic action follows without irritation. (See *Year-Book* for 1896, p. 1067.)

Sanoform is still another substitute for iodoform, though as yet we know it only by report from abroad, and we cannot arouse ourselves to great enthusiasm over a remedy thus described when we remember the many drugs which have claimed the same substitution, and recall the fact that iodoform survives and thrives, while the larger number of its substitutes are forgotten. Perhaps we have at last found the ideal substitute for iodoform; certainly the reports upon sanoform thus far received are in its favor. The name sanoform has been applied to what is, chemically speaking, di-iodo-methyl salicylate, a substance brought forward by A. Arnheim, of Berlin. It is prepared by the action of iodine upon oil of gaultheria (methyl salicylate). It appears as a colorless, crystalline powder which has neither odor nor taste. It is unaffected by light and air, and may be heated to 200° C. without undergoing decomposition. It is insoluble in water and in glycerin, but is readily soluble in ether, chloroform, and benzol, and soluble in 200 parts of cold alcohol and in 10 parts of hot alcohol. It contains 62.7% of iodine.

As to the clinical value of sanoform, Schlesinger² is convinced of its superiority over iodoform, quoting Arnheim's report. According to these observers, healing would appear more rapid and certain from the application of sanoform than from iodoform; irritation, too, was unnoticed, and not the least of its valuable qualities are nontoxicity and freedom from odor. Of the cases which Arnheim reported, 22 were chaneroid, 20 chanere, 6 bubo, 16 phimosis, and 3 surgical wounds. From his experience with these he concludes that the application of sanoform in powder produces dryness in a secreting ulcer practically within two days, the powder and the secretion uniting to form a protective beneath which suppuration soon stops. The iodine of sanoform seems in strong combination, and not to be released by cell-action, for after the hypodermic injection of a fine emulsion of sanoform potassium iodid was not discoverable in the urine, and iodine only by careful search. It would seem, too, that absorption of sanoform is exceedingly slow, and after injection it is discoverable in the urine only after 24 hours, and being eliminated with much slowness may be found in the urine for about two weeks. As to the method of applying the drug, Schlesinger commends a 10% gauze, and it is certainly advantageous that this can be sterilized without the decomposition of the sanoform. In addition to this gauze a 10% ointment of sanoform may be employed, a 1% collodion solution, or the substance may be applied in powder. It is to be noted as an additional advantage of sanoform that it is free from staining-properties (see *Year-Book* for 1897, p. 1137).

Sodium Chlorid as an Iodin Solvent.—As regards the employment of sodium chlorid to effect the solution of iodine in water, Müller³ thinks it more desirable when the solution is intended for internal employment. For example, to produce a local effect on the pharynx he adds to the water used $\frac{1}{2}$ % to 1% of sodium chlorid. The following is suggested as a suitable prescription: tincture of iodine, 1 to 2 gm.; sodium chlorid, 2 gm.; distilled water, 200 gm. The tincture of iodine is that of the "Codex Medicamentarius," and is made by dissolving 10 gm. of iodine in 120 gm. of alcohol.

Soluble bismuth phosphate is said to be prepared by the fusion of bismuthic oxid, soda, and phosphoric acid. Of the first-named ingredient it contains about 20%. The chief value of the salt lies in its ready solubility in water, a solubility so great that a 33% solution may be prepared. To solutions so strong, however, there is the objection that they soon become clouded; a 5% solution will, on the other hand, remain unaffected for a day or more. If bases or acids be added to a solution of this salt, it rapidly becomes cloudy, and boiling is said to produce a similar result. The reaction of these solutions is almost neutral and their taste saline and bitter. Dörffler¹ has employed the preparation with success in the acute intestinal catarrhs of early years. Gastric sedation is said to be a prompt result of this treatment, and so soon as the presence of bismuth in the stools is indicated by their black color their disagreeable character also disappears and the movements become fewer in number. A persistence in the treatment is usually productive of recovery within a few days, and it is recommended that the remedy be not discontinued until the diarrhea has been absent for some days. The dose of the remedy employed is, unfortunately, not stated.

Sphygmogenin is the name given to the substance which Fränkel² has obtained from the suprarenal body (see p. 954). The substance has not as yet been isolated in a pure state, though sufficiently for obtaining characteristic reactions. Among the various substances which have been found in the adrenals sphygmogenin is thought to be the one which increases arterial tension.

Strophanthus was first brought to the notice of the French Academy of Medicine in 1865, but the practical demonstration of its use as a valuable remedy in cardiac disease did not occur until 20 years later, when the result of the careful and patient researches of Frazer was reported. Of late, there has been an endeavor on the part of clinicians and therapeutists to discover the exact therapeutic value of this remedy, and to obtain reliable and uniform preparations of it. With this end in view H. C. Wood and W. S. Carter³ have directed their studies to the effects of strophanthin, in order to determine whether the action of this active principle represents that of the crude drug. A series of experiments on mammals was made, and seemed to show that the strophanthin put upon the market by first-class manufacturers is exceedingly active. The arterial pressure was found to be somewhat increased, but rather by an action on the heart and vessel-walls than by any effect upon the vasomotor centres. Experiments were also made with an extract of strophanthus, from which it would appear that this preparation is also active. Its effect upon the blood-pressure is, however, less marked than that of strophanthin.

A series of clinical experiments is also being conducted by Reynold W. Wilcox with preparations of strophanthus from various sources, by which he hopes to establish a practical working-basis for the tincture from a particular drug-source. The first report on these researches, giving the results of the use of strophanthus in 12 cases, has already appeared.⁴ The preparation employed was a tincture made especially for the purpose from the *strophanthus hispidus* (variety *Kombé*) of the U. S. Pharmacopeia. It was, therefore, a uniform preparation from a reliable source. Its use led Wilcox to the conclusion that this so-called variety (*Kombé*) of strophanthus was rather one of several absolutely distinct species of strophanthus. Should this opinion prove to be correct, it will doubtless have an important bearing on the therapeutic

² Am. Medico-Surg. Bull., June 6, 1896, from Pharm. Ztg., xli., p. 195, 1896.

³ Therap. Gaz., Oct. 15, 1896, from Am. Jour. Pharm., July, 1896.

⁴ Am. Jour. Med. Sci., May, 1897.

value of preparations of the drug. To record the effect of the remedy upon the circulatory system Dudgeon's sphygmograph was used. The object of the study was to ascertain the dose more exactly, to find out the real effects of the administration of the remedy, and what, if any, were its advantages over other drugs when properly employed. The 12 patients who were the subject of this report all showed marked cardiac symptoms. In some there were evidences of a valvular lesion; in some there was dilatation of one of the chambers of the heart, and in some the heart-action was enfeebled by a weak heart-muscle. In most, two or more of these conditions were combined. In all, the blood-pressure was low, as shown by the tracings of the sphygmograph. In all there is said to have been an improvement both in symptoms and physical signs. The author concludes that the proper dose of the preparation used is about 5 drops in water, three or four times a day. He considers that the advantages that have heretofore been claimed for *strophanthus* over *digitalis* are borne out by this series of experiments. These advantages he sums up as follows: 1. Greater rapidity of action; 2. Absence of vasoconstrictor effects; 3. Greater diuretic power; 4. The absence of digestive disturbance following its use; 5. No emulative action; 6. Its greater value in childhood and safety in old age. The contraindications to the use of *strophanthus* are also summarized, namely: when compensating hypertrophy is sufficient or excessive, and when the heart presents an advanced state of muscular degeneration or a high degree of mechanical defect. With these limitations, and provided a reliable preparation is used in doses not too large nor too frequently repeated, Wilcox prefers *strophanthus* in: 1. All cases in which we wish to establish compensation; 2. All cases of arterial degeneration in which a remedy that causes more energetic cardiac contractions is required; 3. All cases of cardiac disease in which diuresis is necessary; 4. All cases of weak or irritable heart; 5. All cases of cardiac disease in childhood or old age.

The observations of Balfour¹ have led him to a rather different conclusion, for he decidedly prefers *digitalis* to *strophanthus*. He believes that the unfortunate symptoms which at times follow the administration of *digitalis* are due to a misconception of the true action of the remedy, and a consequent abuse of it. *Digitalis* acts, he says, by improving the general nutrition of the organism and by improving the metabolism of all the tissues, this action being particularly marked in the case of the cardiac muscular fiber. Thus the cardiac muscle is strengthened and its elasticity increased, the irritability of the heart being thereby relieved. The good results obtained are, therefore, permanent. *Strophanthus*, on the other hand, has proved in his hands an uncertain and dangerous drug. It acts as a heart-poison rather than as a heart-tonic. It stimulates the heart to increased action, it is true, but in so doing it calls upon the reserve of cardiac energy without improving the metabolism. Thus the more feeble the heart, the greater is the danger attending the use of this remedy. It acts only by helping the patient through an emergency until rest, warmth, and nutritious food shall have accomplished what the drug has failed to do.

Suprarenal capsules, it would appear from the report of Gourfein,² are by no means altogether benign in their influence. He tells us that in the glycerin extract of these bodies there are proteid substances which are precipitated by alcohol and are devoid of poisonous influence, but that the extract also contains materials which are not precipitated by alcohol and are exceed-

¹ Boston M. and S. Jour., Oct. 8, 1896.

² Buffalo Med. Jour., Aug., 1896, from Compt. rend. de la Soc. de Biol., 1895; Jour. Chem. Soc., 1896.

ingly toxic in action. These poisonous substances, being uninfluenced by heat, may be obtained by extracting the adrenals with hot water, precipitating with alcohol, and evaporating the remaining clear liquid over a water-bath. The substance thus obtained, if injected hypodermically, appears to violently attack the central nervous system and promptly causes death. The amount of this poison which the suprarenal bodies contain is said to vary considerably, and it is asserted that extracts of muscle and spleen obtained in precisely the same manner manifest no such influences.

Tannoform is a condensation-product of nutgall tannin and formic aldehyd. It is an odorless and tasteless powder of light, yellowish-gray color. It is insoluble in water, but is soluble in alcohol. It is also soluble in dilute alkaline solutions, but is precipitated from this solution if an acid is added. Although formaldehyd uncombined has a pronounced action upon the tissues, its combination with tannin is devoid of injurious properties, though the antiseptic and drying powers of the formaldehyd are said to remain. The remedy, in addition to its antiseptic power, is useful as an astringent, and has the great advantages of tastelessness, absence of irritant effect upon the stomach, and finally, since it is not dissolved by the gastric secretions, a power to reach the intestine unchanged. Zuntz¹ thus reports the results of his experimentation with this agent. A small quantity placed upon the healthy skin much diminishes the secretion of sweat; moreover, it deodorizes this and indirectly prevents the cutaneous irritation which may follow excessive sweating. For chafing and certain cases of eczema thus caused he rates tannoform as superior to any agent now employed. In such ailments the combined properties of the remedy render it unique, and it is as pleasant in action as it is effective. Zuntz has also used the remedy upon wounds, a crust forming from it which serves as a protectant; he is as yet, however, undetermined as to its value in such cases as compared with other applications. The field of usefulness of tannoform, according to D. de Buck and L. de Moor,² is a little more extended, and they value it as an application to wounds, ulcers, and bed-sores, and in bromidrosis as well as in inflammations of mucous membranes, such as ozena, balanitis, and vaginitis. They report upon 2 cases so treated, and regard it as an efficient remedy in both acute and chronic intestinal catarrhs. A dose so large as 15 gr. may be given without causing irritation, and since it is both astringent and antiseptic its action is explained, for we have already said that the drug is not dissolved in the stomach, and therefore cannot exhaust its astringent properties upon the stomach and its contents. The same observers³ have employed tannoform in combination with starch or tale in the proportion of 1 to 5, and have applied it pure as well. They have also used it in ointment with vaselin or lanolin in a variety of skin-diseases in which astringent and antiseptic action is required, and in the cases both of children and adults.

Traumatol (iodokresin) is described by W. Schatlenmann⁴ as a fine, amorphous powder, which is without odor and in color is violet-red. It is a compound of cresylic acid and iodine, and is said to contain 54% of the latter. It is not soluble in water or alcohol, and it is not dissolved by acids. It is readily soluble, however, in chloroform and alkaline solutions, if strong. Clinically the drug may be applied for antiseptic effect, the form of application being in powder, gauze, collodion, vaselin, glycerin, or plaster. Crayons of

¹ Am. Medico-Surg. Bull., Sept. 5, 1896.

² Am. Jour. Med. Sci., Jan., 1897, from Rev. de Thérap. Medico-Chir., No. 19, p. 579, 1896.

³ Am. Medico-Surg. Bull., No. 7, 1896, from Belg. méd. ii., No. 33, 1896.

⁴ Am. Jour. Med. Sci., May, 1897, from Thérap. Monatsh., H. 2, S. 89, 1897.

traumatol are also employed. Among the preparations whose appropriate strength is mentioned are a 5% to 10% traumatol-zinc paste, a 10% traumatol lanolin vaselin, and a 10% to 50% chloroformic solution. The powder is advantageously applied in many conditions of genito-urinary surgery as in bubo, phimosis, and the removal of papillomata, and it is recommended that collodion be afterward applied as a covering. In powder, too, as well as in solution in chloroform, its action upon syphilitic disease of mucous membranes is said to be good, and the crayons are valuable as stimulants to the healing of fistulae. In addition to the antiseptic action of the drug it is thought to have a drying effect; and since it is not irritant, a number of cutaneous disorders are appropriately treated with it. Schatlenmann thinks highly of this substance, and cites in its favor the very excellent action which it manifested in 75 cases in which it was employed to the exclusion of other agents.

Traumatol appears to have certain advantages over iodoform, especially as a surgical application; but when we recall the many drugs which have appeared as contestants for iodoform's field of usefulness, and note how few have survived, a certain amount of skepticism in the case of each new aspirant would seem not without justification. Traumatol has been thoroughly tested by Ladevie,¹ however, and his report of cases treated by himself and others is highly in favor of the drug. Its employment was in essentially the same cases as are so often treated with iodoform, and much benefit has followed the application. The antiseptic power of traumatol has been demonstrated bacteriologically, and it is said that the drug is neither irritating nor poisonous. It is claimed, also, that by internal administration traumatol is productive of antiseptic action upon the bronchi, and that its effect upon tuberculous diarrhea is most excellent.

Trional must be held to have established itself firmly as an excellent and reliable hypnotic. Indeed, many go so far as to pronounce it ideal, and call special attention to its value in childhood and its harmlessness. That serious results seldom follow its use is true, but that it is harmless is an error which cannot be too promptly corrected. It is in its prolonged employment that trional is likely to cause toxic symptoms, and, therefore, during such a course there should occur intervals of several days in which no trional is given; the possible necessity for hypnotic action during these periods being met by the administration of another drug. In this way the cumulative tendency of trional may be avoided, for the danger of toxic action from occasional or interrupted use is slight. This poisoning from the long-continued use of trional is well illustrated by a case reported by Gierlich.² The patient was addicted to the use of morphin, and in order to produce sleep (presumably because insomnia resulted when morphin was withdrawn) took about 45 gr. of trional per diem for a period of two months. As a result there occurred pronounced ataxia, tremor throughout the body, and great mental depression, together with weakening of memory and some disturbances of speech. The withdrawal of trional was followed by the improvement of the patient (the morphin being given in the customary amount), but the nerve-disorders did not altogether disappear until five weeks later.

Another element of danger in the prolonged employment of trional is the necessity for increase of dose. We think that this is a matter which is too little appreciated; necessarily, however, as the power of the drug appears rapidly to diminish with habit, there is demanded the use of larger amounts, and from this the danger of accumulation is apparent.

¹ Brit. Med. Jour., Oct. 17, 1896, from Allg. Wien. med. zeit., Sept. 1 and 8, 1896.

² Univ. Med. Mag., Apr., 1897, from Centrallbl. f. innere Med., No. 51, 1896.

Among those who have recently studied the subject and reported upon the uses of trional is Ruhemann.¹ He belittles its harmful properties, it is true, and rates the occurrence of poisoning as rare. He has given the remedy with much freedom, and in one case indeed he gave almost 3500 gr. within 6 months. Ruhemann thinks highly of trional as a hypnotic for children, and gives the following information as to the appropriate doses: for infants of from 1 month to 1 year, 3 to 5 gr.; 1 to 2 years, 6 to 12 gr.; 2 to 6 years, 12 to 20 gr.; 6 to 10 years, 20 to 25 gr. These doses will doubtless impress those familiar with the subject as large. They certainly are excessive, and to us would seem scarcely prudent; but Ruhemann is in conflict with many observers not only upon this, but upon other views of trional as well. The adult maximum dose of the remedy he places at 30 gr., but in the presence of dyspepsia he recommends the rectal injection of 20 gr. in milk, and says that the action of trional when so given is remarkably prompt, sleep appearing in from a quarter to a half hour, and lasting from 6 to 9 hours. As to the cumulative action of trional, Ruhemann is more than skeptical, and takes issue with some who think that cardiac disease is a contraindication. The cases in which he finds trional of value are severe chorea and cerebral excitement in childhood, but he denies that it is a specific against insomnia, though crediting it with favorable influence in the sleeplessness of neuroses and neurasthenia, in that of phthisical night-sweats, and that which follows acute disease. In insomnia due to pain or to cough he thinks little of it, save when in combination. In contrast with these views in many respects are those of Scognamiglio,² who, while praising the remedy highly for its influence in mania, melancholia, and other nervous disorders, is also of the opinion that it is valuable in pulmonary diseases as well as in pain from various causes, neuralgia, and even pains of tabes. This observer is of the opinion that trional has no ill effect upon the digestion, circulation, or respiration, but his observation upon the real influence of the drug, in view of the opinion of many that it is the cause of hematorporphyrinuria, is full of interest. In the urine of men taking this drug he failed in every case to detect hematorporphyrin, and similarly in the urine of dogs and of rabbits to which moderate doses (7 to 15 gr. a day to dogs, 1 to 7 gr. to rabbits) were given. It was only when the dose was much increased (45 gr. a day) that hematorporphyrin was detected in the urine upon the third day. As a result, therefore, of his observations, both clinical and experimental, Scognamiglio rates trional as powerfully hypnotic, and safe as well, providing its daily dose is from 15 to 30 gr. He ranks it the superior of sulphonal, morphin, and chloral hydrate, and thinks that the danger of hematorporphyrinuria is very remote. Another report upon the use and action of trional is that of von Mering,³ and, representing as it does the deductions afforded by almost a thousand cases, it is of great value. In view of the doses prescribed by others it is interesting to note that von Mering found it rarely necessary to give more than 15 gr. of the remedy, or at most 20 gr. in cases of insomnia pure and simple, and that he regards drowsiness occurring upon the following day as indicative that the dose was excessive. What we have already said as regards the continued use of trional is corroborated by von Mering, who advises, if a daily hypnotic is required for a long time, that the trional be occasionally substituted by another remedy, such as chloralamid, chloral hydrate, or amyl hydrate. In this connection, too, it may be said that although in a number of von Mering's cases the remedy was continued for 3 or 4 months, and with no ill effect, the

¹ Therap. Gaz., Dec. 15, 1896, from Jour. des Praticiens, July 25, 1896.

² Therap. Gaz., Aug. 15, 1896; Rivista clinica e Terapeutica, No. 11, 1895.

³ Med. News, Nov. 7, 1896, from Therap. Monatsh., Aug., 1896.

administration was on every second or third day only, and the doses from 15 to 25 gr. As to the power of trional, von Mering, in common with most observers, rates it as superior to sulfonal, and less likely than that remedy to cause disagreeable results. He evidently does not value the remedy as a reliable anodyne or analgesic, as does Scognamiglio, for in cases of insomnia caused by pain he recommends its combination with $\frac{1}{10}$ gr. of morphin. Much that is recommended by von Mering is also advised by a writer in the *Journal de Neurologie*,¹ who places the maximum adult dose at 15 or 20 gr., amounts in excess of this being permitted only in the insane, and for children of 10 about 12 gr. He, too, regards the drug as harmless even if given for long periods of time, but wisely recommends that it be given on alternate days and in a large quantity of hot water. (Compare *Year-Book* for 1897, p. 1144.)

Unguentum durum is a recently introduced ointment-base which has the following composition: paraffin (solid), 4 parts; wool-fat, 1 part; liquid paraffin, 5 parts. F. Miehle² says that it resembles white-wax ointment, and therefore that it is a desirable substance for protectant applications, while at the same time it has a considerable power of penetration. It will absorb over 10% of water, and is useful in the preparation of lead ointment, carbolic ointment, and ointments which contain liquid antiseptics.

Unguentum molle is a new ointment-base which has the following composition: paraffin (solid), 11 parts; wool-fat, 5 parts; liquid paraffin, 34 parts. This resembles white vaselin. It is easy to make, is not expensive, and is said to be absolutely permanent. It is superior to petroleum in some respects, being more active in penetrating ability and of superior consistence. The ointment is said to absorb a weight of water equal to its own, and with an equal weight of glycerin to make an exceedingly smooth ointment. The subject has been fully presented by F. Miehle.³

Urea, according to Klemperer and Friedreich, is actively diuretic. The cause of this action, according to Friedreich,⁴ is a stimulation of the renal epithelium similar to that brought about by caffeine. In support of his belief, Friedreich has conducted experiments upon the subject, and has also employed the agent clinically with success. Among the cases which he treated thus in 1892-93 was one of hepatic cirrhosis without renal lesion, and to this patient urea was given and gradually increased in amount until 12 gm. were taken in a day. By this the amount of urine voided was increased sevenfold. A second and similar case showed a like result, and in a third the urine was increased from 400 c.c. to 750 c.c. Of these patients the first took in all 157 gm. of urea without untoward effect, and the second 200 gm. In the third, treatment by urea was suspended because of the occurrence of pneumonia. Had the doses in the first two cases been larger from the beginning (in Klemperer's case 10 gm. were given from the outset), it is possible that the resultant diuresis would have been even more pronounced (see *Year-Book* for 1897, p. 1144). [Although the results of this experimentation are both interesting and valuable, the excrementitious nature of urea and practically complete ignorance as to its toxic possibilities would suggest great caution in its use. In the absence of renal lesion its use would seem permissible in view of the report of Klemperer, but renal impairment would seem to considerably curtail its field of usefulness.]

Viburnum Prunifolium.—A very thorough experimental research has recently been conducted by Theodore Sherman⁵ upon the action of black haw,

¹ Am. Medico-Surg. Bull., Dec. 26, 1896, from Jour. de Neurol., No. 14, 1896.

² Am. Medico-Surg. Bull., Sept. 5, 1896, from Pharm. Ztg., xli., p. 403, 1896.

³ Ibid.

⁴ Am. Medico-Surg. Bull., Oct. 10, 1896, from Brit. Med. Jour.

⁵ Edinb. Med. Jour., Nov., 1896.

and forms the basis of an admirable report. The subject, as obtainable from medical literature, is graphically presented, and botanic and clinical matters discussed. The chief part of the report, however, concerns the experiments which the author conducted upon both warm-blooded and cold-blooded animals, and his conclusions thus based are as follows: "In mammals, warm-blooded animals, owing to the difficulty of giving a large enough dose hypodermically, there is no marked effect except drowsiness and some lessening of motor power. If the substance be introduced into the heart directly, there is rapid lowering of blood-pressure to about one-half the normal, with slow return to near the normal as the drug is eliminated. Although too much reliance must not be placed on experimental results in cold-blooded animals as applicable to warm-blooded animals, including man, we may be allowed to take something from these results and use them as *probably* applicable. Thus, there is *probably* some diminution of reflex irritability, a quieting effect on involuntary muscle, possibly some lowering of blood-pressure, which, even though small, might afford relief in congested conditions. Then, and very important, there is the effect of the valerianic or viburnic acid in neurotic and hysterical conditions. In the pharmacopœia there are many drugs capable of bringing about all these desired effects. Why, then, use *Viburnum prunifolium*? Opium is one of our sheet-anchors, but then there are dangers and inconveniences attending its use. The patient may acquire the opium-habit; the constipation caused by it is very troublesome, and it is very toxic. *Viburnum* has similar good effects, though not so strong. It is a good form in which to administer valerianic acid. Its effect upon unstriped muscle, though not so strong as that of opium, gives the relief necessary. It has scarcely any effect in causing constipation. Toxic effects have only been noticed with very considerable doses. Herrick has seen disturbance of vision, dryness of mouth, and headaches; and Wilson has observed similar conditions, but these were with doses larger than are usually administered to man." The article is concluded by a list of *viburnum* preparations which, though varied, includes little that requires submitting to the American reader.

Since *viburnum* is a drug of American medical introduction, and furthermore is extensively employed among us, the familiarity of readers of the *Year-Book* with the subject may to a certain extent be assumed, but the indications for its employment as set down by Sherman are none the less useful. They are: In *habitual abortion*, where this is not caused by syphilitic infection or by fatty placenta, there seem, undoubtedly, good results to follow the use of *Viburnum prunifolium*. In *threatening abortion*, however caused, and at any period of gestation, if the case is seen soon enough, it seems to be very successful. In *dysmenorrhœa*, if functional, spasmodic, or ovarian, or attended with menorrhagia, it often cures. If there is flexion or stenosis, it gives great relief, though, of course, it cannot cure. In the menorrhagias and metrorrhagia of the *menopause* and in the nervous disorders of that time it is very beneficial. *After-pains* are so readily relieved by it that some (*e. g.*, Auvar) consider that its use is dangerous unless all clots are cleared out of the uterus previously. It may be used in the diagnosis of *false pains*, speedily relieving them. It is also used with success in *colicky diarrhœa* and in *dysentery*. Some even claim that it has a curative effect on cramps of voluntary muscles.

Wine of Iron and Quassia.—The following is a recently published¹ formula: R: tincture of quassia, 30 parts; pyrophosphate of iron and sodium, 5 parts; Malaga wine, 1000 parts. M. S.: a tablespoonful before each of the two principal meals.

ANATOMY.

By C. A. HAMANN, M. D.,

OF CLEVELAND, OHIO.

OSTEOLOGY.

Sesamoid Bones of the Hand.—Edward Fawcett¹ has studied these bones in 38 persons by means of skiagraphy. His results confirm Pfitzner's observations, which were made on a very large number of hands. The two metacarpophalangeal sesamoids of the thumb were found in every case examined; considerable variation in size was noted. A single sesamoid was present in 68½% of the cases in the interphalangeal joint of the thumb. A single radial sesamoid was found in the metacarpophalangeal joint of the index finger in 55.2% of the cases; it is oval in shape and its long axis is placed in the long axis of the finger. In the metacarpophalangeal joint of the little finger a sesamoid bone was present in 71% of the cases. In the middle and ring fingers no sesamoids were met with. Fawcett did not find that the age or the muscular development of the individuals had any bearing on the number or size of these bones.

Ossification of the Third Trochanter in Man.—A. F. Dixon² found in the femur of a young subject a small epiphysis for the gluteal ridge of the third trochanter; it was 25 mm. in length and 12 mm. in width. In examining a large number of human femora this epiphysis was found in two other bones, and a number of mammals, among them the rabbit, tapir, and horse, also show it. "The fact that the third trochanter of man thus closely resembles in its mode of development that of lower mammals adds to it an interest, especially as the presence of this trochanter is stated to be a characteristic of the femora of higher rather than of lower races, and of man rather than of apes."

Metopic Suture.—G. Papillault,³ in an investigation on this suture carried on in the Anthropologic Laboratory in Paris, arrived at the conclusion that metopism is due to a greater development of the brain, the pressure of the cranial contents being greater in such cases than in others. The cause of a persistent frontal suture is thus to be sought for in the brain itself. Of 807 male crania, 9.91% were metopic; of 329 female crania, 11.85%.

Asymmetry of the Sternum.—A. Birmingham,⁴ upon examining 54 sterna, found that 87% were asymmetrical and 13% were approximately symmetrical. He found that the most marked irregularity was a depression of the clavicular facet, which was associated with a corresponding diminution of the vertical depth of the sternum on the same side; this was found on the right side in 50% of the specimens, and on the left side in 37%. The line of

¹ Jour. Anat. and Physiol., vol. xi., part i. p. 157.

² Ibid., vol. x., part iv., p. 502.

³ Mém. de la Soc. d'Anthropol. de Paris, t. ii. (iii e serie) 1er Fasc., and Jour. Anat. and Physiol., vol. x., part iv., p. 584.

⁴ Dublin Jour. Med. Sci., Jan., 1897.

junction between the manubrium and gladiolus is oblique, and slopes downward on the right side oftener than on the left. In about 59% of sterna there is a longitudinal curve occupying the entire bone; this curve is more often directed to the right than to the left.

Congenital Absence of both Patellæ.—A. T. Bristow¹ describes a case in which both patellæ were absent, the fifth on record. The patient, a child of 2½ years, was the subject of pes varus on both sides. In all the recorded cases there were additional developmental errors. [The writer has the limbs of a peromelic monster in which both patellæ are absent; there is also absence of both tibiæ and of certain of the tarsal bones. In connection with Bristow's case, it is to be remembered that at the age of 2½ years the patella is still cartilaginous, and would therefore give no indication of its presence in a Röntgen photograph.]

THE HEART AND BLOODVESSELS.

Moderator Band in Left Ventricle.—Sir William Turner² describes a second case in which he found the so-called moderator band in the left ventricle. It was 38 mm. in length, 9 mm. in its greatest diameter, and ½ mm. in its narrowest part. It consisted of muscular fibers covered with endocardium, and passed from the anterior to the posterior wall of the ventricle, thus enabling it to exert a moderating influence on the dilatation of the cavity. The septal wall presented a large smooth surface—*i. e.*, the columnæ carneæ were absent over it. [Though such bands in the left ventricle are but rarely met with, still it would seem that their occurrence would be nothing very strange or inexplicable when we consider the mode of development of the musculature of the heart; the columnæ carneæ, as is well known, represent the enlarged and thickened remains of the trabeculæ which in early embryonic life unite the endothelial heart-tube with the outer fibromuscular tube. Such trabeculæ might remain attached to opposite walls of the ventricle by their extremities, and being free in the rest of their extent, just as certain of the columnæ are normally, would appear as moderator bands.] Such moderator bands have also been seen in the left auricle.³

Structure of the Larger Arteries at different Times of Life.—N. Grünstein⁴ has made some investigations on the structure of the arterial wall which are of practical interest. The intima and media increase in thickness as age advances; in the carotid, subclavian, and aorta the intima increases relatively more in thickness than the media, whereas in the common iliac the media increases more than the intima. In the larger vessels, as Unna has shown, part of the elastic tissue becomes changed into elacin, and thus the elasticity of the vessel-walls is diminished. Upon staining with methyl-blue Grünstein found localized patches in the aorta, and in the carotid and subclavian vessels, which stained more deeply than the rest of the arterial wall; this would indicate a change in the tissue the nature of which is not known.

Elastic Tissue in the Walls of the Cerebral Arteries.—Triepel⁵ has studied the structure of the internal carotid, anterior, middle, and posterior cerebral, basilar, and vertebral arteries, with reference to the amount and arrangement of the elastic tissue. The sections were stained with orexin. It was found that the coats of these arteries contain but little elastic tissue. The elastica interna is present; a few circular fibers are found in the middle coat, and

¹ Med. News, p. 15, Jan. 2, 1897.

² Jour. Anat. and Physiol., vol. x., part iv., p. 569.

³ Ibid., Apr. and July, 1896.

⁴ Arch. f. mikroskop. Anat., xlvii., p. 583, 1896.

⁵ Deutsch. med. Woch., Feb. 4, 1897; Vereins Beil., No. 5, p. 31.

rather more circular fibers in the external coat, together with a few longitudinal fibers. The *elastica externa* and marked longitudinal elastic fibers in the outer coat are thus practically absent. Where the vertebral artery passes through the foramen magnum it contains numerous and well-marked longitudinal and circular fibers in the outer coat, and also elastic fibers among the circular muscular fibers. The changes in the structure of the vessel here are to be attributed to the elongation to which it is subjected in the movements of the head. In the neck the media of the vertebral contains elastic plates; this vessel shows distinctly how mechanical influences modify the structure and arrangement of the elastic tissue in the arterial coats.

Vasa Vasorum and Lymph-paths of the Vessel-walls.—Schiefferdecker¹ gives a summary of the main facts concerning the mode of distribution of the vasa vasorum. The main deductions that can be made from the work of previous investigators are as follows: 1. The muscular coat of the vessels is the chief tissue requiring nutrition; the muscular tissue is nourished either by capillary vessels in the adjacent adventitia, or by capillaries which enter the muscularis itself. 2. It seems that the presence of capillaries in the muscularis is dependent upon the thickness of the intima and upon whether the vessel is an artery or a vein. 3. The vessel-wall is nourished both from without (*i. e.*, by the vasa vasorum) and from within (*i. e.*, by the blood traversing the interior of the vessel). 4. When thickening of the intima occurs the blood contained in the lumen of the vessel can no longer nourish properly the tissues of the wall that it formerly did; then the vasa vasorum multiply and enter the muscularis and even the intima, which are ordinarily devoid of vasa vasorum. Thus the thickening of the intima is primary and the proliferation of the vasa vasorum is secondary. Schiefferdecker then describes subendothelial lymph-plexuses which he found in the pig's aorta by means of staining with lactate of silver; stomata were not present. These subendothelial lymph-spaces have been described by Hoggan in the veins.

THE DIGESTIVE SYSTEM.

Secretion of Saliva.—Erik Müller² has examined the salivary glands of man, the cat, dog, and rabbit, and the results of his works agree in the main with the views of Altmann, that the saliva is formed from typical intracellular granules; these granules undergo changes in size as assimilative processes go on. Some of the results of the investigation are as follows: 1. The saliva is a product of granules which undergo characteristic transformations. 2. The secretion is present in the gland-cells in the form of small round vacuoles, which are separated from the surrounding protoplasm by a wall which can be stained. These vacuoles were first demonstrated by Retzius in Golgi preparations and by the author in ordinary preparations. 3. These vacuoles are formed in granules in the cells. 4. The cells have a different appearance, depending upon their richness in granules; some of them have large clear granules, separated from one another by a reticulum containing very small granules that take the stain; other cells have large granules that can be stained. 5. During very active secretion the granules which can be stained become changed into secretory vacuoles. 6. The secretory capillaries of albuminous glands are all intercellular.

Topographic Anatomy of the Spleen, Pancreas, Duodenum, Kidneys, etc.—A. Birmingham³ gives the results of his examination of the

¹ Deutsch. med. Woch., Sept. 16, 1897; Vereins Beil., p. 185.

² Arch. f. Anat. u. Entwicklungsgesch., H. 5 u. 6, p. 305, 1896.

³ Jour. Anat. and Physiol., vol. xi., p. 95.

viscera in three subjects hardened with chromic acid solution. Among them are the following: "1. The lobus Spigelii of the liver has an anterior free surface as well as a posterior, and it lies in a special 'recessus Spigelii' on the posterior abdominal wall. 2. The empty stomach is in shape that of an attenuated and modified pear, with its wide end directed backward and to the left; the greater part of the long axis runs forward and a little inward in the horizontal plane, and turns to the right and downward a few inches from the pylorus. Its great curvature looks forward and to the left, its lesser to the right and backward. Special attention is called to the 'stomach-bed,' which forms the floor of a chamber in which the stomach lies. [The "stomach-bed" is a shelf-like arrangement supporting that organ. It is formed by that portion of the pancreas situated to the left of the median line; this part of the pancreas is quite thick anteroposteriorly, and its upper surface (anterior surface of His) forms a large part of the shelf. The pancreas is in such relation with the left kidney that the top of that organ forms part of the shelf. The tail of the pancreas extends to the spleen, so that the plane of its superior surface runs upward and backward into the gastric surface of the spleen, and thus the bed is completed behind and to the left. The transverse mesocolon, supported by coils of the small intestine, extends the bed anteriorly.] 3. The duodenum does not lie in the coronal plane, as usually represented; the first half of the first stage and all beyond the middle of the transverse stage lie approximately in the coronal plane; the intermediate part is moulded backward by the side of the cava, and lies almost in the sagittal plane. The cava does not lie behind the descending duodenum, but to its left. The duodenum is also connected behind to the right ureter and psoas. 4. The body of the pancreas projects forward as a distinct ridge into the abdominal cavity and is not flattened against the posterior wall. It is prismatic, but the three sides of the prism are nearly equal. Two forms of tail are described—one, which is long and slender and curves back beneath the basal surface of the spleen, the other, short and stout, which abuts against the lower part of the gastric surface of the spleen. 5. The suprarenal bodies lie not very far from the sagittal plane, and the right is nearly posterior to the vena cava. 6. The names 'anterior' and 'posterior' are suggested, instead of superior and inferior pancreaticoduodenal, as probably being more correct."

Innervation of the Dentine.—Michael Morgenstern¹ has investigated the nerves of the dentine by means of the modified Golgi method. He finds that there are nerve-fibrillæ, between the elementary cells of which the odontoblasts are formed. The nerves of the dentine are found in the dentinal canals (intratubular fibers) and also outside of the canals (intertubular fibers), the latter being more numerous. In the crown of the tooth most of the nerve-fibers are parallel with the dentinal tubules, whereas in the neck of the tooth and in the fang they in part follow the tubules and in part lie in the long axis of the tooth. By the formation of anastomoses a plexus is formed. The nerve-fibers of the dentine pursue a wavy course, divide dichotomously, and give off numerous branches. Most of the ramifications end free. Intertubular fibers frequently enter the tubules. At the border of the dentine and enamel is a more or less separate system of nerve-fibrillæ, which, however, anastomose in many places with the intradentinal fibers.

The Duodenum and Pylorus.—Thomas Dwight,² in the examination of 70 adult bodies, finds that the V-shaped duodenum is more frequently met with in women than in men; the irregular forms of the duodenum preponder-

¹ Arch. f. Anat. u. Physiol. (Anat. Abth.), p. 378, 1896.

² Jour. Anat. and Physiol., vol. xi., part iv., p. 516.

ate in males. In the majority of adults of both sexes the lowest point of the duodenum is opposite the fourth lumbar vertebra, or the disks above and below it; in about one-fourth of 54 bodies examined it was opposite the third, and in about half a dozen opposite the fifth lumbar vertebra. "In the 54 cases already mentioned, the duodenum was on the right of the aorta till just before the terminal flexure 26 times; it was wholly on the right 6 times. The fourth part lay in front of the aorta 11 times, and the third part actually crossed the aorta 11 times." In many of the cases a fold of peritoneum intervened between the aorta and the gut. The fourth part of the duodenum is preŕenal in exceptional cases only. The pyloric opening in 30 cases was found to be practically always oval, though the long axis of the opening may lie in any direction. The average size of the orifice was 14×11 mm., the extremes being 7×4 mm. and 20×18 mm.

THE NERVOUS SYSTEM.

Course of the Taste-fibers.—A. F. Dixon¹ discusses the unsettled question of the course taken by the taste-fibers. He opposes the belief of Gowers and others, "that the path of taste from all parts in which this sense exists reaches the brain by the root of the fifth nerve," which belief is chiefly based on clinic and pathologic evidence. Dixon refers to the fact that both the facial and glossopharyngeal nerves, "which are denied the possibility of carrying taste-impulses," are anatomically, in part at least, nerves of sensation, for the facial possesses a ganglion (geniculate) which is as much a homologue of the spinal ganglia as the Gasserian ganglion is; the chorda tympani, the nerve of taste for the anterior portion of the tongue, is connected with the seventh. Furthermore, the pars intermedia of Wrisberg is in part continuous with the chorda tympani, and seems to "represent the continuation of the chorda tympani fibers, through the ganglion-cells to the brain;" if we do not regard the chorda tympani as a nerve of sensation, then it is difficult to see what are the sensory branches of the geniculate ganglion that correspond to the fibers passing from the ganglion to the brain in the pars intermedia. The ganglia of the glossopharyngeal resemble the ganglia of the posterior spinal nerve-roots structurally, and in all likelihood "as many fibers leave the ganglion as enter it." When we consider this, it is difficult to see how the small nerve of Jacobson can contain all the fibers of the glossopharyngeal nerve which convey taste-impulses, as the adherents of the view of Gowers would have us believe. The point is also made that if "the taste-impulses passing in the facial and glossopharyngeal nerves leave them by the great superficial petrosal and Jacobson's nerve to join the trigeminal, as has been maintained, then these impulses in their course to the brain pass not only through ganglionic nerve-cells of spinal ganglion type twice in each case (namely, of the seventh and fifth nerves and of the ninth and fifth nerves), but they also pass through the otic or Meckel's ganglion. If they have this complicated course, they are the only special sense-impulses which pass through multipolar sympathetic nerve-cells on their way to the brain." He then brings evidence that seems to show that the chorda tympani and the great superficial petrosal are to be regarded as afferent branches of the seventh nerve, and that Jacobson's nerve is a branch of the ninth.

Change of Brain-weight after Preservation in Formalin Solutions.—Edw. F. Latan² finds that the weight of the human brain when preserved in 10% formalin solutions increases during 1 month from 2% to 3%;

¹ Edinb. Med. Jour., p. 395, Apr., 1897.

² *Antom. Anz.*, vol. xiii., p. 323.

after conservation for 5 months and over the increase amounts to 1%. In 5% solution the weight increases 9% in the first 4 days; after 1 month, 10%; after 5 months, 7%; and after immersion for 1½ years the increase is 6%. In 1% solution the weight increases during the first 2 days 14%; after 1 month, 23%; and after 1½ years, 19%. The spinal cord placed in a 10% solution increases 10% during the first 3 days; after 50 days, 14%. In 1% solutions the cord during the first 3 days increases 11%; after 50 days, 13%. Thus it appears that the lower the percentage of formalin in the solution the greater is the increase in weight of the brain; the spinal cord increases in weight considerably more than the brain.

Position and Dimensions of the Optic Chiasm.—Zander¹ has studied the gross relations of the chiasma opticum in connection with the subject of acromegaly and enlargements of the pituitary body. He found in the examination of 23 specimens that the pituitary body had a sagittal diameter of 8 mm. on the average, the extremes being 6 mm. and 10.5 mm. The average transverse diameter was 11.9 mm., the extremes being 10 mm. and 14.5 mm. The average vertical diameter was found to be 6.55 mm. Enlargement of the pituitary body has been found to cause certain visual disturbances, and these have usually been ascribed to pressure upon the posterior surface of the chiasm and upon the optic tracts. Zander states that this is not the case, for the position of the chiasm is such that the enlarged hypophysis would not press in that direction. He examined 55 preparations in which the optic tracts, chiasm, and nerves were exposed from above. In none of the preparations did he find the chiasm occupying the optic groove, as is stated in most anatomic text-books; in fact, the optic groove was found to be present in only 34 out of 100 skulls, while in 44 this surface was plane and in 22 it was convex. The anterior border of the chiasm never reaches the optic groove, being distant from it 10.34 mm. on the average, the extremes being 4.75 mm. and 17 mm. The intracranial portion of the optic nerve was found to vary in length from 6 mm. to 21 mm. This portion of the nerve would necessarily be very short if the chiasm lay in the groove; furthermore, the angle of divergence is less than a right angle, whereas if the chiasm had the position it is usually said to occupy the angle would have to be very much larger. Again, the groove is too small for the chiasm. The posterior border of the commissure extended behind the upper edge of the dorsum sellæ for a distance of 1.58 mm. on the average, and only in a few cases was it found in front of it, so that the hypophysis cannot lie behind the chiasm; it lies in front of it and when the diaphragma sellæ is removed the chiasm can be seen to lie in the angle of divergence of the two optic nerves. The sagittal diameter of the chiasm was found to vary from 4 mm. to 13 mm.; the transverse from 9.75 mm. to 19.75 mm.; the vertical diameter is greatest at its anterior border, where it averages 3.1 mm. It is interesting to note that in 60% of the cases the commissure was placed to one or other side, so that it did not lie symmetrically; this would cause variations in the length of the intracranial portion of the optic nerves. Tumors of the hypophysis would not be likely to grow upward, behind the chiasm, but would bulge between the two optic nerves into the cisterna chiasmatis, a small recess of the subarachnoid space situated between the chiasm, olivary eminence, and diaphragma sellæ; in some cases the inferior surface of the commissure would be subjected to pressure. The enlargement in a vertical direction would have to amount to at least 0.5 cm. before the optic paths could be compressed by the tumor.

The Eye of the Newborn.—E. v. Hippel² finds that hardening in

¹ Deutsch. med. Woch., Jahrg. xxiii., No. 3; Vereins Beil., No. 3, p. 13, 1897.

² Deutsch. med. Woch., Aug. 26, 1897; Vereins Beil., p. 162.

Müller's fluid changes most markedly the lens; less markedly the cornea. The retinal fold at the ora serrata, described by Lange, he considers an artefact. v. Hippel found the thickness of the fresh lens to be 3.76 mm.; its posterior surface is more curved than the anterior. He finds that the ora serrata are well developed, contrary to the opinion of Schoen (see *Year-Book* for 1896, p. 1086), and distinguished ora serrata of the pigment-epithelium and of the retina proper. The physiologic cup is present, and has the same appearances as in the adult. The optic-nerve fibers are nonmedullated. The fovea centralis is quite flat, and the bodies of the cones in its deepest portions are but imperfectly developed. Retinal hemorrhages are frequently encountered.

The Glands of the Ciliary Body.—Leslie Buchanan¹ finds that the pigmented cubical cells of the pars ciliaris retinae have small processes or outgrowths, which lie adjacent to the hyaloid membrane and are structurally to be regarded as glands. They are always deeply pigmented. In cases of increased intraocular pressure these processes are in a condition of increased activity, whereas when the intraocular pressure is diminished they are less active. He therefore believes that they have to do with the secretion of intraocular fluids. The structures were first described by Treacher Collins.

Histology of the Ciliary Nerves.—G. Gutmann² finds that a transverse section of the ciliary nerves is elliptical in man as well as in animals. The fibers are small and medullated, though nonmedullated fibers also occur; a fine endoneurium is present. The sheath contains a small amount of pigment. The interfibrillar tissue is small in amount and finely granular. In a transverse section of the ciliary nerve 10 μ in diameter 314 medullated fibers were counted.

On the Presence of Ganglion-cells in the Iris.—Authors differ in regard to the question as to whether ganglion-cells are found in the iris. N. Andogsky³ finds bipolar and multipolar cells only in the superficial nerve-networks of the ciliary processes, and none in the iris.

THE GENITO-URINARY ORGANS.

Elastic Tissue in the Fallopian Tubes.—A. Buchstap⁴ has made an examination of the oviducts of 102 individuals of different ages to determine the amount and arrangement of the elastic tissue. Some of his results are as follows: up to the end of the first year elastic fibers are found only in the peritoneum and subserous tissue, especially about the bloodvessels. From the age of 3 to 7 years the elastic tissue increases in amount, the previously existing fibers becoming larger. Fine fibers are also met with in the deep circular muscular layer. In the tubes of girls of 14 to 17 years elastic fibers are met with in the mucous membrane. In women of 21 to 45 years the elastic network is fully developed. Climacteric changes begin at about the 45th year; the elastic tissue has entirely disappeared from the mucosa by the 55th year, and to a large extent from the other layers of the tube. In senile tubes elastic tissue is found only in the serosa. Apparently the amount of elastic tissue is the same in the uterine, outer, and intermediate portions of the tube.

Anatomy of the Ureters.—Schwalbe⁵ describes the ureter as consisting of an abdominal and a pelvic portion. In the abdominal portion there is always a spindle-shaped dilatation, situated just above the brim of the pelvis,

¹ Jour. Anat. and Physiol., vol. xi., N. S., part ii., p. 262, 1897.

² Arch. f. Anat. u. Entwicklungsgesch., xlix., 1, p. 1, 1897.

³ Arch. f. Augenh., p. 86, Feb., 1897.

⁴ Centralbl. f. Gynäk., xxi., 28, 1897.

⁵ Centralbl. f. die med. Wissenschaft., Nov. 21, 1896.

and known as the greater dilatation; this is more marked on the right side. The narrowest part of the ureter is about 70 mm. from the kidney; this is the "superior isthmus." The "inferior isthmus" is the junction of the pelvic and abdominal portions. The pelvic portion of the tube also has fusiform enlargements. These characteristics are more marked in the female. As the above-mentioned dilatations are not present in quadruplets, the conclusion is drawn that the upper dilatation is to be looked upon as caused by the obstruction to the flow of the urine by the angle at the brim of the pelvis. Schwabel and Solger,¹ as well, found these dilatations in the fetus. They had been described previously by Luschka and others.

Pyramids of Malpighi.—Rudolph Maresch² reaches the following conclusions concerning the number and arrangement of the renal pyramids: 1. The kidney of man is made up of many more reniculi than has previously been believed. In addition to the complete and distinct furrows seen in lobulated kidneys, there are numerous incomplete ones, so that there are in reality two or three times as many as the number (8–18) usually given. 2. For every incompletely circumscribed reniculus of a lobulated kidney there is a single pyramid. 3. For each completely circumscribed reniculus there are usually at least two or more pyramids. 4. The Malpighian pyramids coalesce extensively as the papille are approached, so that scarcely ever one papilla corresponds to one pyramid; usually two to four pyramids combine to form one papilla, and sometimes as many as nine. 5. A papilla which corresponds to several pyramids need not necessarily be unusually wide or show traces of subdivision.

Intraepithelial Glands in the Urethral Mucosa.—G. Klein and K. Groschuff³ describe intraepithelial "glands" in the mucous membrane of female infants from 1 to 3 years of age. They exist in the form of cup-shaped cavities within the epithelium, looking very much like a single alveolus of a gland; they are quite numerous, sometimes 30 to 40 being found in a single section. Many of them resemble the taste-buds in that they have a narrow, tapering porus, and are apparently devoid of a distinct lumen; others are in wide, open communication with the surface, and their cavities are filled with a secretion. Their diameter varies from 20μ to 50μ . That they are not pathologic formations is evident from the fact of their being found within the intact epithelium, and from the regular arrangement of their cells. Whether they are to be looked upon as glandular in character or as nervous organs cannot be positively stated as yet. These structures were not found in adult females or in children under one year of age.

Lymphatic Vessels of the Urinary Bladder.—D. Gerota⁴ corrects a previous assertion made by himself, that lymphatic vessels are to be found in the mucous membrane of the bladder. In the examination of more than 60 bladders he could not demonstrate, either macroscopically or microscopically, the presence of lymphatic vessels belonging to the mucous membrane. None are found in the trigonum. The few vessels found in the submucosa of the vesical neck are lymphatics of the urethra, which extend for a short distance into the neck of the bladder, but soon enter the muscular coat.

Membrana Propria of the Uriniferous Tubules.—It was shown in 1891 by Mall that the membrana propria of the uriniferous tubules consists of fine fibers of reticulated tissue. George Rühle⁵ has also investigated the subject, and his results confirm in the main those of Mall. He finds that the membrana propria consists of fine, circular and longitudinal fibers, which are

¹ *Anatom. Anz.*, Bd. xii., p. 347.

² *Ibid.*, p. 299.

³ *Ibid.*, p. 197.

⁴ *Ibid.*, Bd. xiii., Nos. 21 and 22, p. 605.

⁵ *Arch. Anat.*, p. 153, 1897.

only a somewhat thicker and more regularly arranged layer of the interstitial reticulated tissue of the kidney. The layers of fibers vary in thickness in the different portions of the tubules; they are very thin around Bowman's capsule and around the tubuli contorti; around the excretory ducts they form thick, concentric layers. The fibers are not connected with the spindle-shaped cells of the connective tissue, no processes of the cells being continued into the fibers. The cells lie in more or less intimate contact with the fibers. In the kidney of the newly born infant there is no organic connection between the connective-tissue cells and the fibers of the reticulated tissue. By boiling the reticulated tissue gelatin can be obtained.

THE MUSCULAR SYSTEM.

Innervation of Muscles.—K. V. Bardeleben,¹ with Dr. Frohse, has made some important observations on the innervation of muscles, the description of the details of which are to be published in the *Handbuch* edited by Bardeleben. The authors find that the point of entrance and the branching of the nerve do not have a definite relation to the form of the muscle. Every nerve divides dichotomously, or the main trunk gives off but a single branch at any one place. Every motor nerve, prior to entering the muscle, gives off one or more nerves to vessels (vasomotor nerves). The nerve either enters with the vessels, thus forming a sort of hilus, or it enters the muscle independently of the vessels. As soon as the nerve approaches the muscle it gives off at least one recurrent branch to the proximal portion of the muscle. The points of entrance may be upon the deep surface of the muscle, at the margin, or on the surface. The nerve may enter the proximal portion of the muscle, as, for instance, in the semitendinosus—this is rare; at the junction of the upper and middle thirds; or at the middle of the muscle. It never enters the extreme distal portion. The point of entrance is assumed by the authors to be where a nerve-fiber about 0.03 mm. in thickness (just visible macroscopically) enters a muscle-bundle about 1 mm. in diameter. Intramuscular plexuses, which have not previously been described in higher vertebrates, were found in all the muscles examined, as the deltoid, biceps brachii, brachialis anticus, supinator longus, long muscles of forearm, sartorius, gracilis, etc. Frohse has found an anastomosis of the deep branch of the ulnar nerve and the branch of the median nerve supplying the flexor brevis pollicis.

Variations of the Facial Muscles and their Relation to Expression.—That a number of the muscles of expression are derived from the platysma myoïdes was first pointed out by Gegenbaur and Ruge; the platysma itself is to be regarded as an unused portion of the common muscular mass, which in its facial portion has become divided and differentiated into the muscles of expression. The occasional connection of the platysma with the orbicularis palpebrarum, zygomaticus minor, and other muscles of the face, is one of the evidences of the common origin of these muscles. The facial muscles in the lower mammals and in the anthropoids do not present the complexity and degree of development that they do in man, nor are they so independent of the platysma; the greater development of the cerebral functions of man, and the consequently more marked expression of the emotions, have led to the specialization of the facial muscles. These muscles, phylogenetically speaking, are younger than others, and are to be regarded as "progressive muscles" in the sense of Wiedersheim. They are, furthermore, quite variable,

¹ Deutsch. med. Woch., No. 23, p. 115, June 3, 1897.

and often are not alike on the two sides. In the lower races the more primitive condition of these muscles is apparent.

J. Popowsky¹ describes the facial muscles in a native of Ashantee. The platysma, besides being continuous with the zygomaticus minor, was also united to the retrahens aurem; an orbito-auricularis was also present. The levator labii superioris, zygomaticus major and minor, and levator labii superioris alaeque nasi were united to one another; this reminds one of the condition found in the anthropoids. It can readily be surmised that the facial expressions in such an individual would be modified considerably from the lack of differentiation of these muscles. Popowsky concludes from the examination of numerous dissections that the muscles first appearing in man, viz., the zygomaticus minor, corrugator supercilii, and transversus glabellæ, are the most variable. Particularly is this the case with the first-named, and this muscle may be looked upon as passing through an intermediate phase of its development, and as not yet having reached its highest degree of specialization. The corrugator supercilii is a derivative of the orbicularis palpebrarum, and in the adult presents varying degrees of union with that muscle; in the fetus these two muscles cannot be separated from each other. Vertical fibers of the corrugator are met with, sometimes well developed and independent; at other times existing rather as parts of the frontalis. The existence of these vertical fibers is to be regarded as a higher degree of development of the muscle; when they contract they produce short transverse wrinkles above the root of the nose, as seen in the expression of grief and sorrow. In some works of art these transverse furrows, which are intended to express the emotion of grief, are represented as extending entirely across the forehead; such furrows are, of course, produced by the contraction of the frontalis, and are not correct anatomically. The occasional occurrence of the transversus glabellæ indicates a progressive development of the muscles of the forehead, these muscles being the ones concerned in the expression of some of the higher intellectual functions. When this muscle is present the upper portion of the orbicularis palpebrarum is more highly developed; the orbicularis is, according to Duchenne, the muscle of reflection ("le muscle orbiculaire palpébral supérieur est le muscle de la réflexion, de la méditation)."² It is to be assumed that the appearance of the transversus glabellæ in man as a variation is due to the greater development of the upper part of the orbicularis, and that this in turn is due to the higher development of the psychological functions. It is possible that the two vertical furrows between the eyebrows seen in the portraits of some gifted persons, as Hippocrates, Blumenbach, Franklin, Beethoven, Johannes Müller, Gladstone, v. Bismarck, and others, are due to the contraction of the transversus glabellæ. In the future, it is possible that this small muscle, now occurring only as an anomaly, may be constantly present, just as the other muscles of expression now are.

A Method of Injecting the Bony Labyrinth.—Gustav Brühl³ suggests the following method for preparing the labyrinth: macerated temporal bones are washed for several days in running water, and then decalcified, using for this purpose 2% to 5% hydrochloric acid solutions for the bones of the newborn, and 5% to 10% solutions for those of adults. After washing the decalcified bone for 24 hours in running water it is dehydrated with alcohol in gradually increasing strength; to the alcohol is later added cupric sulfate. The fenestra rotunda and internal auditory meatus are closed with collodion,

¹ Internat. Monatsh. f. Anat. u. Physiol., Bd. xiv., p. 149, 1897.

³ Anatom. Anz., Bd. xiii., p. 93.

celloidin, cork, or, best of all, sponge; then the needle of a hypodermic syringe, surrounded by a piece of sponge, is inserted into the oval window, and mercury to which has been added a small quantity of glycerin is injected under low pressure. The injection is continued until the mercury flows out of the aqueducts; the aqueducts are then occluded with sponge or cement. The preparation is then placed in carbol-xylol to remove any remaining water, and is then suspended in xylol. In this way preparations are secured which show plainly the topography of the internal ear; the variations in the structure of the cochlea and semicircular canals in different animals can be shown. If the bones are weighed before and after injection, the volume of the bony labyrinth can be determined. Brühl found this to be about 120 c.mm. in the newborn and 210 c.mm. in the adult.

Method for Studying Macroscopically the Development of the Bones in the Fetus.—O. Schultze¹ describes a simple and effective method for clearing the soft tissues so that the bones can be plainly seen through them. [Th. Kölliker made use of an analogous procedure in his studies on the intermaxillary bone some years ago.] The fetus, which has been preserved in alcohol, is placed in an aqueous solution of caustic potash (3% to 5%), where it remains until the bones become plainly visible; the length of time varies with the size of the fetus, the time that it has previously been in alcohol, and the degree of concentration of the potash solution. In large fetuses it is necessary to remove the brain and viscera. The preparations can be preserved in a 2% solution of formalin, to which 30% of glycerin is added.

MISCELLANEOUS.

Development of the Mammary Gland.—E. Kallius² has described a human embryo about 15 mm. in length, in which the "milk-line," first observed in pig embryos by O. Schultze, was present. Extending from just below the upper extremity, along each side of the trunk in the midaxillary line, for a distance of 1.5 to 2 mm., was a ridge-like elevation of the epidermis; it was about $\frac{1}{3}$ mm. in width and $\frac{1}{5}$ mm. in height. No local enlargement of the ridge was present. Microscopically it is seen that the entire ridge is due to a thickening of the epithelium; this thickening of the epithelium is most marked in the situation of the future mammary gland, and here the cells extend downward into the mesodermic tissue. As the caudal extremity of the embryo is approached the ridge gradually becomes less conspicuous. Kallius regards this ridge as the earliest, or, at any rate, a very early stage, of the developing mammary gland. Whether it is present in all embryos will have to be determined by future observations. The subject is an interesting one in connection with supernumerary mammae and nipples. Hugo Schmidt³ has observed similar elevations in two embryos of about the same age as those of Kallius; the ridges were asymmetrical. It is probable that the "Milchleiste" of man is a suddenly appearing and rapidly disappearing structure, as Kallius expresses it.

Placenta.—Th. W. Eden,⁴ from his studies of the placenta in the early and in the late stages of pregnancy, concludes that this organ toward the end of pregnancy shows degenerative and senile changes, just as the organs present in old age. Degenerative changes in the vessels—*i. e.*, endarteritis—and infarcts are met with. Atrophy and degeneration of epithelial structures occur.

¹ Grundriss d. Entwicklungsgesch. d. Menschen.

² Merkel u. Bonnet's Anatom. Hefte, Bd. viii., H. i., p. 155, 1897.

³ Anatom. Anz., Bd. xi., p. 702.

⁴ Jour. Pathol. and Bacteriol., p. 265, 1896.

These changes in the "senile" placenta are responsible for intrauterine death of the fetus in some cases.

Histology of Adenoid Tissue.—Erwin Hoehl¹ reaches the following conclusions in his investigations of the adenoid tissue in various organs: 1. The connective-tissue framework of the organs belonging to the lymphatic apparatus consists, after it has reached complete development, partly of collagen-containing fibers and partly of a reticulum destitute of cells. 2. The trabeculæ of this reticulum are composed of very many fine fibers of equal size; some of these are united into bundles, others spread out like a fan; they are imbedded in a homogeneous ground-substance. 3. The finer trabeculæ are surrounded by elastic fibers which wind spirally about them, while in the larger trabeculæ the bundles of elastic fibers can be seen in the interior. 4. In many places, for instance in the lymph-sinuses, the trabeculæ are covered with cells which are morphologically and physiologically related to endothelium; in other places the trabeculæ are not covered with cells. The trabeculæ form the supporting framework of the organ. 5. Essential differences in different species of animals (man, ox, dog, cat) are not found. The author concludes that the artificial digestion of histologic specimens with trypsin does not produce artefacts if the process is carefully carried out.

The Mammary Gland in its Active and in its Resting Condition.—Josef Szabo² distinguishes three states of the secreting cells of the mamma: 1st, that of absolute inactivity or rest; 2d, that of activity; and, 3d, that of relative inactivity, in which the gland is prepared for secretion. The active gland-cells can be distinguished from those in a state of relative inactivity by a characteristic peripheral grouping of the chromatin. He finds that the epithelium of the gland is always in a single layer, and believes that the cells in the exercise of their function do not perish, but remain capable of secreting during the entire period of lactation. Mitotic changes were found only in the glands of pregnant animals and in those examined in the first few days of secretory activity; no mitoses were seen after the gland had been active for several days.

Form of the Follicles of the Thyroid Gland.—J. J. Streif³ finds that along with the rounded, oval, and polyhedral follicles of the gland there are also forms which closely resemble the tubules of a tubular gland, though the tubules are closed at each end. Some of the vesicles have secondary out-growths, and at times two vesicles of equal size are in open communication with each other. A system of canals or ducts, however, is not found. The author conceives that the gland originates as a branched tubular gland. The secreting parts are not connected by ducts as in a gland, however, for the secretion has to escape through the walls of the vesicles, and thus finds its way into the lymph-spaces of the connective-tissue septa.

Prepatellar Bursæ.—Bize⁴ describes the bursæ and connective-tissue spaces in front of the patella. He states that the connective-tissue spaces are subcutaneous, subaponeurotic, and subtendinous. A superficial mucous bursa, lying in the superficial fascia over the lower extremity of the patella, is found in 88% of cases; it is usually single. A subaponeurotic bursa lying between the fascia lata and the tendon of the quadriceps is found in 95% of cases; it lies most often over the lower and inner portions of the patella. A subtendinous bursa, lying between the two portions of the tendon of the quadriceps,

⁴ Jour. de l'Anat. et de la Physiol., xxxii., p. 85, 1896.

over the inner portion of the patella, is found in 80% of cases. These bursæ, or the spaces from which they originate, are formed in the latter half of intrauterine life. Hygromata of these bursæ are due to an accumulation of fluid in them. [Gruber, Linhart, and Luschka long ago described multilocular and superimposed prepatellar bursæ; their presence would account for the recurrence of bursal swellings after excision.]

Congenital Anonychia.—Paul Jacob¹ records a case of this kind, which, on account of its great rarity, is deserving of being mentioned. The patient, a boy, 14 years of age, had no nails on either the fingers or the toes. In place of them there was delicate skin. No other congenital anomalies existed, though the teeth were defective. Two sisters of the boy had the same defect of the nails, but the parents had normally formed nails. Anatomically and embryologically it was impossible to explain satisfactorily the anomaly.

PHYSIOLOGY.

By G. N. STEWART, M. D.,

OF CLEVELAND, OHIO.

THE BLOOD, THE LYMPH, AND THE CIRCULATION.

Coagulation of the Blood.—[This subject has been further illuminated by a vast amount of painstaking research during the past year.] The mechanism of the anticoagulant action of albumose has been to a certain extent elucidated by C. Delezenne,¹ who finds that when a solution of this substance is caused to circulate through the liver a body is formed which is capable of suspending the coagulation of the blood *in vitro*, a property which [as is well known] albumose itself does not possess. A similar, or perhaps identical, body is produced when the serum of the snake is made to pass through the liver.² He accordingly supposes that this anticoagulant substance is the product of a secretive reaction of the organism, and particularly of the hepatic cells [a view originally brought forward by Gley and Pachon]. Incidentally he confirms the result of Starling (*Year-Book* for 1897, p. 1162), that ligation of the lymphatics of the liver does not prevent the anticoagulant action of "peptone," and rejects the counterstatement of Gley and Pachon,³ who, however, reaffirm their view [but without bringing forward anything materially new]. On the other hand, Athanasiu and Carvallo⁴ lay stress on the fact that "peptone blood" will always ultimately coagulate if time enough be given, and interpret this [too hastily, we think] as a proof that it is not the presence of an anticoagulant substance which hinders coagulation, but something else. This "something else" they find in the lack of fibrin-ferment, due to the profound modification in the formed elements of the blood, and particularly in the increased mobility of the leukocytes, in virtue of which they wander out of the vessels into the tissue-spaces. They deny that the leukocytes are destroyed [as Löwit, Wright, and others had stated]. Fano,⁵ however, defends his position that there is no want of fibrin-ferment in "peptone blood," and Dastre and Floresco⁶ bring forward evidence to the same effect, and assert that it is the over-alkalinity of the "peptone plasma" which prevents it from coagulating. Athanasiu and Carvallo⁷ reply that peptone plasma is certainly not more alkaline than normal plasma, and accuse Dastre and Floresco of inaccuracy in comparing the alkalinity of peptone plasma with that of normal serum, which is less alkaline than normal plasma; and they clinch the matter by showing that no fibrin-ferment can be obtained by Schmidt's method from peptone plasma [thus bringing us round once more, after so much work and so much controversy, to the already ancient view of Wooldridge. It is evident that much remains to be cleared up before the last word shall have been spoken on this question. In the meantime, it seems

⁷ Ibid., p. 375, Apr., 1897.

to us that no theory can be complete which does not take account of the facts, that injection of albumose may under certain conditions, some of which are known and others as yet undiscovered, produce not retardation, but hastening of coagulation, and that if a first injection fails to be followed by the ordinary anticoagulant effect, a second, repeated under conditions which would usually insure success, is equally ineffective. It might be plausibly suggested that if the immediate and most common effect of the presence of albumose in the blood be to stimulate the hepatic, or other, cells to the secretion of a substance that hinders coagulation, the organism in its turn reacts against the presence of this substance, and makes an effort to protect itself by the production of a second body with fibrinoplastic powers. In this case the final result of an injection of albumose would be determined, in any given case, by the relative intensity of two antagonistic processes.]

[The old statement of Claude Bernard and others that the blood of the hepatic vein coagulates more slowly than the venous blood in general, which might seem to indicate that even under normal circumstances, and in the absence of any artificial stimulus, the liver produces an anticoagulant substance, is put in doubt] by the experiments of N. Paulesco,¹ who failed to detect any such difference in the blood of fasting dogs.

Arthus and Huber² show that the primary cleavage-products of the digestion of gelatin and casein have the same effect as the fibrin proteoses in preventing coagulation.

Pickering,³ working with Norway hares, some specimens of which are albino in summer and pigmented in winter, has found that intravascular clotting is caused by the injection of nucleoproteids or certain synthesized colloids during the pigmented, but not during the albino condition. [This is an observation of great interest, because it brings the previously observed difference between albino and pigmented rabbits in regard to intravascular coagulation into relation with a periodically recurring metabolic change. Not less curious, although strangely overlooked till this late day] are the facts reported by C. Delezenne,⁴ that the blood of birds, when drawn without coming into contact with the tissues, coagulates with marked slowness, and that coagulation is greatly hastened by the addition of extracts of the muscles or other organs.

Blood-pigment.—A. Gamgee⁵ has reinvestigated, by the aid of photography, and greatly extended Soret's discovery of the absorption-band in the extreme violet, which, according to him, is much more characteristic of hemoglobin and several of its derivatives than any of the bands in the less refrangible portions of the spectrum. [It is of considerable theoretic interest that] turacin, the copper-containing pigment first investigated by Church, shows a precisely similar band (Gamgee);⁶ while of some practical importance is the announcement by A. Jolles⁷ of a method adapted both to the scientific and the clinical estimation of the iron in small quantities of blood. The method depends on a comparison of the color of a solution of ammonium sulphocyanid, to which a known amount of iron has been added, with that of a similar solution after addition of the ash of a known quantity of blood.

Hemopoiesis.—To the vexed question of the part played by the spleen in the formation of the blood, J. Laudenbach⁸ makes an elaborate series of contributions. He supports the orthodox conclusion that the spleen takes a

share in the synthesis of the hemoglobin and the development of the red corpuscles, although after its removal compensation is to a certain extent established, particularly by the increased hemopoietic activity of the bone-marrow. W. S. Hall and M. D. Eubank¹ state, among other interesting results, that regeneration of the blood after hemorrhage takes place more rapidly if the hemorrhage has been followed by **transfusion of an artificial serum**. [It is, indeed, well known that injections of this kind bring about, in addition to local effects within the vascular system, general metabolic changes. Thus] A. Charrin and A. Desgrez² assert that even solutions of the mineral constituents of serum cause when injected into the veins of rabbits a slight elevation in the quantity of urea excreted, while entire serum causes a marked increase; and they suppose that some of the common effects of the new serum-therapy may be due to the mineral substances, since these are practically the same in all artificial serums. [But the composition of the diet does not seem to have been sufficiently controlled; and it is hardly permissible in observations of this kind to be content with a mere estimation of urea.]

The effects of the introduction into the blood of large quantities of solutions of NaCl and Na₂CO₃ have been studied by Bosc and Vedel³ in normal animals and in dogs affected by intravenous injections of bacillus coli.⁴ They conclude that the 0.7% NaCl solution has the minimum harmful and the maximum physiologic effect, although much stronger solutions can be borne. [The writer of this abstract has found no harmful results in dogs after the injection of solutions of NaCl of the strength of 2% to 5% into the blood, and these strong solutions would seem to have the advantage of attracting water from the lymph-spaces, and thus for a considerable time of automatically increasing the volume of the circulating fluid.]

Otto Weiss⁵ has made the remarkable observation that when the serum of a male rabbit was injected into the veins of a female rabbit albuminuria followed, while this was not the case when the serum was injected into a male animal. He believes that a true sexual difference is at the bottom of this phenomenon, and that it was not merely an accidental result. [The similar observation of Favoret, who saw albuminuria when the serum of a bitch was injected into a dog, certainly speaks in favor of this interpretation, but the number of experiments is too small to establish a definite conclusion.]

Permeability of the Corpuscles.—The relations between the corpuscles and the plasma have been illustrated by numerous researches since our last report. H. J. Hamburger⁶ states that in the blood of the jugular vein the volume of the corpuscles, both colored and colorless, is greater than in the blood of the carotid artery, so that in the living body a rhythmic variation in the volume of the corpuscles takes place; they swell in the systemic and shrink in the pulmonary capillaries. He explains the phenomenon by the assumption that under the influence of CO₂ the substances which attract water increase to a greater degree in the corpuscles than in the serum, so that there is a disturbance of osmotic equilibrium. This can only be restored by the passage of water into the corpuscles. He attributes to these changes a certain significance in nutrition [which it is difficult to deny, if the variations in volume be admitted. And, indeed, there is no doubt that such variations can be produced outside the body by the alternate action of CO₂ and O, as v. Limbeck and Gürber had previously shown], and as G. N. Stewart⁷ has incidentally

⁶ Zeit. f. Biol., Bd. xxxv., pp. 252 and 289, 1897.

⁷ Jour. Boston Soc. of Med. Sci., June 3, 1897; Centralbl. f. Physiol., p. 332, Aug. 7, 1897.

demonstrated by a perfectly different method in the course of a research on the electric conductivity of blood. He finds that the conductivity of blood that has been reduced is somewhat less than that of the same blood when saturated with oxygen, and further that the conductivity of one and the same sample of defibrinated blood increases as the relative volume of the corpuscles in it decreases. The explanation of this is that, in comparison with the serum, the corpuscles are nonconductors. The electrical conductivity and, therefore, the molecular concentration (as regards the inorganic salts) of serum do not vary much in different animals of the same species, nor even in the different mammalian species investigated. On these facts Stewart has founded a method for rapidly estimating the relative volume of plasma and corpuscles in blood. His results have been confirmed by the independent investigations of W. Roth¹ and by those of St. Bugarsky and F. Tangl.² The fact that the red blood-corpuscles are nonconductors so long as they are intact, raises the question whether or not they are permeable to such ions as exist in serum. An answer to this question is attempted in the experiments of H. Koeppe,³ S. G. Hedin,⁴ and C. Eykman;⁵ and while they are all agreed that the ions Na, K, and SO₄ cannot pass through the corpuscles, there is still some dispute in regard to others.

Osmosis and Lymph-formation.—[There is apparently some slackening in the activity of research on this subject, and most of the papers that have appeared during the current year have been devoted to the discussion of facts already known or theories already formulated.] H. J. Hamburger⁶ again takes up his parable in favor of the secretion-theory of Heidenhain. W. Cohnstein⁷ endeavors to repel the assaults of Hamburger, Mendel, and others on the filtration-theory of Ludwig, while S. J. Meltzer and I. Adler,⁸ on the cognate topic of absorption from the peritoneal cavity, assume a position midway between that of Heidenhain and that of Cohnstein (*Year-Book* for 1897, p. 1166). They insist on the importance of the part played by the tissue-spaces, which they look upon as a system of reservoirs anatomically independent of both blood-capillaries and lymph-capillaries, although capable of interchange with both. [We doubt, however, whether there is any good histologic basis for this view.] Lazarus-Barlow⁹ continues his work on the "initial rate of osmosis," which, however, Hamburger¹⁰ criticises on the ground that in this "initial-rate of osmosis," as determined by Barlow, both the permeability of the membrane and the rate of diffusion are mixed up with the true power of attraction of water by the solution.

The Beat of the Heart.—[The proofs of the myogenic origin of the cardiac beat seem to be speedily accumulating.] Engelmann,¹¹ in a series of papers, accompanied by a colossal bibliography, works out in great detail the line of investigation so brilliantly begun, now more than a dozen years ago, by Gaskell, and concludes in favor of the muscular origin of the heart-beat both in the adult and in the embryo. W. T. Porter¹² makes the weighty observation that a portion of the apex of the ventricle (of the cat), presumably ganglion-free, connected with the rest of the heart only by its blood-vessels, continues to beat with a rhythm of its own for a considerable time. O. Lau-

gendorff,¹ proceeding with his investigations on the action of the isolated mammalian heart, comes to the conclusion [an important one, if correct] that in fever the increase in the temperature of the blood is an influential factor in the acceleration of the heart. No removable heart-standstill, such as is readily induced in the frog's heart, can be caused in the heart of a warm-blooded animal. P. Botazzi² puts forward the ingenious theory [for which, however, we do not think he produces any real evidence] that the oscillations of tonus [previously described by others] in the auricles of the frog's heart are simply due to contractions and expansions of the sarcoplasmic part of the muscular tissue, independent of the contractions of the fibrillæ [which almost everybody else believes to be the only contractile portions of the fiber].

Heart-sounds.—Sir Richard Quain³ is responsible for the novel view that the first sound of the heart is due, not to vibrations of the auriculoventricular valves, nor to the muscle-sound of the contracting ventricles, but to the impact of the blood on the semilunar valves at the moment of the systole, and the resistance to its onward movement which it experiences there. [While great weight must be given to an authority so distinguished, and while some of the facts which he cites seem to favor such a theory, yet it appears to us that before it can be accepted it must be sufficiently elaborated to explain, among other things: 1. How it is that of two sounds produced (by hypothesis) in the same situation, one should be heard best over the position of the cardiac impulse and the other in the aortic area. 2. How it is that, since the auriculoventricular valves are during the ventricular systole exposed to the same conditions (high pressure on the ventricular, and low pressure on the auricular surface) as the semilunar valves are exposed to during the ventricular relaxation (high pressure on the arterial and low pressure on the ventricular surface), and since their structure is similar, and since both offer resistance to the effort of a stream of blood to regurgitate, a sound should arise only in the vicinity of one of the sets of valves. 3. How it is that the first sound is not *always* altered in aortic incompetence unaccompanied by aortic stenosis.] Possibly some light may be thrown upon such questions by the photographic method of recording the heart-sounds, which has been further elaborated by A. de Holowinski.⁴

Output of the Heart.—G. N. Stewart⁵ has measured, by a new electric method, the output of the heart in more than 20 dogs, ranging in weight from less than 5 to about 35 kilos. He arrives at the conclusion that the older estimates of Vierordt, Volkmann, and others are too high, while the more modern estimates of Tigerstedt and Stolnikow are too low. He calculates that the average output of the left ventricle of a man weighing 70 kilos would, under the conditions of his experiments, not exceed 80 c.c. per beat. This agrees fairly well with the results of Zuntz and Schumburg,⁶ who, comparing, by the aid of the *x*-rays, the size of the heart at rest and during severe muscular work, and using the data obtained by Zuntz on the horse, estimate that during work twice as much blood (120 c.c.) may be ejected from the left ventricle at each beat as during rest (60 c.c.).

The Cardiac Nerves.—[The common belief, founded on the experiments of Baxt, that there is no antagonism between the inhibitory and augmentor nerves of the heart must, so far as warm-blooded animals are concerned, be modified in the light of experiments of R. Hunt,⁷ who states that

⁷ Jour. Exper. Med., p. 151, Mar., 1897.

in all cases the result of simultaneous stimulation of the two nerves is approximately the algebraic sum of the effects of stimulating them separately. [This result certainly does not hold in all its generality for an animal like the frog, for the author of this abstract¹ could only detect such an antagonism under special conditions, and then chiefly in the action of the nerves on the ventricle.] L. J. J. Muskens² believes he has proved the existence of **reflexes set up in the ventricle** of the frog's heart [as Knoll had previously done for the rabbit].

The voluntary acceleration of the heart is the theme of a paper by H. Van de Velde,³ who asserts that the power is present, in rudiment at least, in a very large number of persons, and that it can be cultivated, although it is a dangerous acquisition.

Vasomotor Nerves.—Ch. A. François-Franck and L. Hallion⁴ have made a beautiful series of experiments on the vasomotor innervation of the liver. They enclosed the organ in a plethysmograph, and recorded the blood-pressure at the same time in the portal vein and the hepatic artery. They find, among other results, that excitation of ordinary sensory nerves causes almost constantly, and excitation of the visceral sensory fibres in the vagus occasionally, a reflex constriction of the branches of the portal vein. A similar reflex regulation of the circulation in the pancreas has been demonstrated by the same observers;⁵ while A. Biedl⁶ announces the discovery in the splanchnics not only of vasodilator, but also of secretory fibers for the suprarenal capsules. [But we must say that the evidence he presents for the existence of this latter group is of the scantiest.]

METABOLISM, NUTRITION, AND DIETETICS.

Internal Secretion.—[No striking discovery in this subject has marked the past year, but our knowledge has been widened in various directions.]

Thyroid and Parathyroid.—[While it must be admitted, as Blumreich and Jacoby⁷ assert, that there is a marked difference in histologic structure between the parathyroids and the thyroids, and while it has certainly not been proved that this difference diminishes when the thyroids proper are removed, yet we must characterize as too absolute the statement of these observers, that excision of the parathyroids in the rabbit has no influence on the result of thyroidectomy. For the experiments of Gley,⁸ Moussu,⁹ Vasalle and Generali,¹⁰ and Rouxeau,¹¹ have shown [conclusively, in our opinion] that in the dog, cat, and rabbit the presence of the parathyroids is sufficient to prevent the appearance of the symptoms characteristic of complete thyroidectomy, while this is not the result if the parathyroids be removed and the thyroids proper retained. W. Edmunds¹² also finds that the presence of a single parathyroid in the dog is sufficient to prevent death, while in the absence of both parathyroids at least 40% of the thyroid tissue must be left if life is to be maintained. [But he appears to speak only of the external parathyroids, and if he left 40% of the thyroid, in all probability one or other of Köhn's "internal parathyroid bodies" would, sometimes at any rate, be included in this remnant.]

It is still uncertain what the active constituent of the thyroid secretion really is, although, for the moment, Baumann's thyriodin¹ has advanced to the place of honor among the artificial products. E. Wormser,² however, denies that it has any effect in preserving the life of dogs after thyroidectomy. He goes so far as to say that none of the substances as yet isolated from the thyroid is alone able to replace the gland itself, but that they must be all given together in order to do this. That thyriodin has a smaller effect on the general metabolism, as measured by the increased production of CO₂, than the fresh gland has, was shown by Magnus-Levy, and has been confirmed by F. Voit.³ The excretion of nitrogen is markedly increased by both, but, according to B. Schöndorff,⁴ only after a certain amount of the body-fat has first been used up. Hutchison⁵ finds that the "colloid" can be split up by gastric digestion into a body consisting of a proteid in union with iodine, and another substance containing iodine but no proteid. The latter is less active than the former.

I. Ott⁶ confirms the observation of Oliver and Schäfer that thyroid extract diminishes the rate of the heart and lowers the blood-pressure. It also produces a rise of temperature. A. Exner⁷ has made the statement that after extirpation of one thyroid lobe (in the cat) division of the superior and inferior laryngeal nerves on the opposite side caused the tetany which is so characteristic a consequence of complete thyroidectomy. [This would be an important observation, if confirmed, as it would indicate the existence of a nervous control of the internal secretion of the thyroid, or at least the possibility of a loss of its function when its vasomotor nerves were paralyzed. But we confess that the experiments do not wear a very convincing aspect, even when taken in conjunction with] Katzenstein's discovery⁸ that histologic changes are caused in the gland by section of these nerves.

Suprarenal Capsules.—N. de Dominicis⁹ [with nearly the whole physiologic world against him] still defends the theory that the fatal result of extirpation of the suprarenals is due to what he calls a "neurotic cause," and not to any chemie action of poisons produced in the organism and normally neutralized or destroyed by the secretion of the glands. [It must be said, however, that the present trend of research is more and more in favor of the "chemie" theory. Thus] Szymonowicz¹⁰ confirms in most essential particulars, in an independent research, the statements of Oliver and Schäfer,¹¹ and extends their work by showing that the blood coming from the veins of the capsules causes, when injected into the circulation, the same phenomena as the extracts of the organ, although [as was to be expected] in a less degree. It is true that Szymonowicz, like Cybulski, believes that the main action of the substance which causes a rise of blood-pressure is on the vasomotor center, and that Gottlieb¹² sees in the ganglion-cells of the heart its chief point of attack, while Oliver and Schäfer have demonstrated a vasoconstriction of peripheral origin, which has been confirmed by the observation of Bates¹³ that long-continued pallor of the conjunctiva can be caused by dropping a small quantity of the extract into the eye. But in regard to the production of some active substance or substances by the capsules there is substantial agreement, and a certain degree of progress has even been made in their isolation and

recognition by chemie tests. J. J. Abel and A. C. Crawford, *e. g.*,¹ have shown, by separating the constituent which raises the blood-pressure in the form of a benzoyl compound, that it is a substance with basic properties, and must probably be classed with the pyrrol compounds or with the pyridin bases or alkaloids. B. Moore² also suggests that the active substance is a pyridin derivative. It seems certain that it is not a pyrocatechin compound, as Mühlmann³ supposed, although it is possible that some pyrocatechin is present in the gland, but, in any case, according to P. Langlois,⁴ not enough to produce the physiologic results observed.

The possible existence in the capsule of other substances capable of producing toxic effects is illustrated by the experiments of S. Vincent,⁵ who finds that sufficiently large doses of the extract, injected subcutaneously, produce first slowness, then paresis, and finally paralysis of voluntary movement. [But it is hazardous to assume, without special proof, that such toxic effects are specific to the capsules. Bouchard and others, *e. g.*, have shown that extracts of the liver have toxic properties, and although it may be, as Vincent says, that this is not the case with the filtrate from the boiled extracts, yet the results of Mairet and Vires,⁶ who found that hepatic extracts lose their power of inducing intravascular coagulation, but not their general toxic properties, by being heated to 60° C., emphasize the necessity for caution.] That the capsules, in addition to toxic, possess also, under certain circumstances, antitoxic properties, is suggested by the observation of Ed. Boinet,⁷ that animals deprived of their capsules succumb to a smaller dose of a poison like strophanthin than normal animals. [But this might have been due merely to the general condition of the animals, and not to the removal of a specific antitoxic mechanism.]

Thymus.—Abeles and Billard⁸ state that total ablation of the thymus in the frog [in which animal the organ persists in the adult condition] causes death, due, they believe, to a true autointoxication. The chief symptoms are muscular weakness, going on to paralysis, trophic disturbances including discoloration of the skin, and certain alterations in the blood. Subcutaneous implantation of the thymus does not sensibly prolong life.

Pituitary.—[It cannot be said that any real advance has been made in our knowledge of the function of this organ.] Mairet and Bose⁹ find that although ingestion or subcutaneous injection of pituitary extracts produces hardly any effect in healthy men and animals, intravenous injection (in animals) is followed by severe and even fatal symptoms. In epileptics ingestion of the gland causes delirious attacks 3 or 4 days after administration. [But we doubt whether they have succeeded in showing that these are at all different from the attacks commonly seen in persons suffering from epilepsy.]

General sketches of the present position of the doctrine of internal secretion will be found in papers by W. D. Halliburton,¹⁰ J. W. Warren,¹¹ R. W. Chittenden,¹² W. H. Howell,¹³ and J. G. Adams.¹⁴ The last-named author deals particularly with the relations of internal secretion to pathologic anatomy.

The Energy of Muscular Contraction.—[A crowd of writers have again attacked this ever-interesting problem, and while much yet remains obscure, we think that the tendency, noted by us in the *Year-Book* for 1897, to look upon the muscle as a machine which can and does make use of various kinds of food-substances, according as the supply of this or that material is plentiful or scanty, is becoming more and more pronounced.] Thus, J. Frenzel¹ shows [very clearly, we think] that both with a diet of pure fat and in hunger the energy corresponding to the work done by a dog could not possibly have come altogether from the combustion of proteids; some of it must have been due to the oxidation of fat. That fat can be burnt as such in the contracting muscle without undergoing a previous conversion into glycogen or glucose, as Chauveau and Seegen have contended, seems to follow from the experiments of Zuntz,² who finds that, had this conversion first to take place, about 30% more energy would be necessary to yield a given amount of work on a fatty than on a carbohydrate diet; and this is not the case. He concludes [and we think the conclusion not only just but inevitable] that all food-substances are alike capable of yielding the energy of muscular work without first being changed into sugar. This conclusion cannot be considered as in any way shaken by the observation of F. Laulanié,³ that in animals on a diet free, or nearly free, from carbohydrates the respiratory quotient, after an increase during work which carries it nearly to unity, falls during the subsequent period of repose to less than its original value—an observation which he interprets [on insufficient grounds] as indicating the replacement of the glucose used up during work by glucose formed during the interval of rest by an incomplete oxidation of fat. [Nor does a second research by the same author,⁴ on the changes that take place in the respiratory quotient during the digestion of a carbohydrate meal, lead to any more definite decision as to the immediate destiny of the carbohydrates absorbed from the alimentary canal, since its results can be harmonized either with the theory that some of the absorbed glucose is burnt as such without undergoing transformation, or with the counter-theory that it is first changed into fat, which is then partially oxidized to form glucose.] The mere fact that sugar, as Schumburg⁵ and others have shown, even in small quantities (30 gm. for a man), causes rapid restoration of exhausted muscles tells in reality neither for nor against the assumption that sugar plays the leading part in muscular metabolism.

Seegen⁶ sees no contradiction [nor can we] between his view that the energy of muscular contraction comes mainly from carbohydrates, and the contention of Pflüger that the carbohydrate is united with proteid before it is oxidized in the muscle; for Seegen regards the ultimate, and Pflüger the proximate, source of the energy. That an increased amount of proteid is broken down during severe muscular exertion has long been known, and fresh evidence of it is afforded by the experiments of J. C. Dunlop, Noël Paton, R. Stockman, and I. Macadam,⁷ who add the important observation that it is muscle-proteid which is broken down, because the increased excretion of nitrogen and sulphur is not accompanied by an increase in the uric acid, nitrogenous extractives, and phosphorus. Now these waste-products arise from nuclea proteids, in which muscle is poor. That the chemie change in contraction is essentially an oxidation is once more illustrated, and in a striking fashion,

by the researches of A. Broca and Ch. Richet,¹ who find that when the muscles of a warm-blooded animal are caused to contract in the absence of oxygen (during asphyxia) they rapidly lose their contractility, and those of W. Kühne,² who shows that when all oxygen has been removed the protoplasmic movements of the staminal hairs of *Trodeseantia* completely cease, and cannot be excited by electric stimulation when proper precautions are taken against the production of oxygen by electrolysis. But that even now much remains undetermined as to the precise seats of the oxidative processes in the body is emphasized by the results of Ch. Bohr and Henriques,³ who [contrary to the prevailing opinion] appear to have demonstrated a considerable production of CO₂ and consumption of O within the pulmonary circulation, thus reviving [of course with quantitative modifications] the old theory of pulmonary combustion first put forward by Lavoisier.

As to the **quantitative relations between energy expended and work done** by a contracting muscle N. Zuntz⁴ makes the important generalization that all mammals hitherto investigated use in normal work approximately the same quantity of chemie energy per unit of work. A little more than one-third of the energy expended can be transformed into mechanical work. A. Chauveau⁵ and his pupil, J. Tissot,⁶ have contributed an elaborate series of papers on the same subject, which, however, have been severely criticised by Zuntz⁷ and by I. Munk,⁸ and do not, at this stage of the controversy, call for further remark here.

Glycogenesis.—On the vexed question of the postmortem production of sugar in the liver Pavy⁹ maintains his original view that it is due to the action of an unorganized ferment, while Noël Paton¹⁰ believes that all the evidence shows that the conversion of the glycogen into glucose is a process bound up with katabolic changes in the "surviving" hepatic cells. [We think the truth is that both factors are concerned. It is certain that unaltered glycogen may sometimes be found in the liver many hours after the death of the animal even when the temperature has been artificially kept up. But we cannot follow Seegen¹¹ in his refusal to admit that the hepatic glycogen is the source of the hepatic glucose.]

Animal Heat.—J. Lefèvre¹² cites the results of experiments made on himself and on animals to determine the amount of heat lost under various conditions. The body was immersed in a bath of such dimensions that the quantity of water needed to cover it was a minimum. He finds that far from resisting cold by following a law the inverse of Newton's law of cooling, as Richet and others have asserted, the body loses more and more heat as the temperature of the bath is lowered. [If it should turn out that this statement is correct, the explanation will probably be found in such vasomotor changes in the skin as favor increased loss of heat, combined, at least in the case of the lower animals, with that reflex increase in the metabolism with which they confront a fall of external temperature. Lefèvre's final result, that the amount of heat lost depends only on the initial temperature of the bath, and is the same when that temperature is kept constant and when it is allowed to rise, is so

novel and unexpected that we hesitate to accept it without confirmation.] The existence of a chemic regulation of the heat-production in man has been investigated by Eykman¹ for inhabitants of the tropics (Dutch East Indies), as had previously been done by Loewy for inhabitants of the north temperate zone (Berlin), and with a like negative result. [While we are thus justified in concluding that at the top of the animal scale the chemic regulation of temperature so characteristic of the smaller animals is either altogether wanting or very feebly developed, it has been shown by H. M. Vernon² that even in such poikilothermal animals as the frog, newt, and earthworm the gaseous metabolism is to a certain extent independent of the external temperature and under the control of the nervous system.]

Among the numerous other researches in this department of physiology which the exigencies of space prevent us from referring to in detail, may be mentioned those of J. Rosenthal³ on calorimetric technic; that of M. S. Pembrey⁴ on the deep and surface-temperature in a case of traumatic section of the spinal cord; a paper by C. F. Hoover and T. Sollmann⁵ on the temperature, pulse-rate, and nitrogenous metabolism during fasting in the hypnotic sleep; and one by J. Fawcett and W. Hale White⁶ on the marked rise of temperature caused by β -hydronaphthylamin. [The statement in this last paper "that the rise of temperature cannot be due to diminution of the heat-loss, since the respiration is increased, and animals which, like rabbits do not perspire must lose most of the heat they part with by the lungs," has a medieval sound, and ought not to appear in a modern research.]

RESPIRATION.

Regulation of Respiratory Movements.—Boruttau⁷ puts forward the theory that the variability in the effects of stimulation of the vagus on the respiratory movements [which has impressed everybody who has studied the subject] is due not to the existence in the nerve of two sets of fibers, but to a difference in the results of excitation of the same fibers according to the nature of the stimulus and the condition of the animal. All momentary stimuli, according to him, are inspiratory while all long-lasting stimuli are expiratory. M. Lewandowsky,⁸ while agreeing with Boruttau, that only one set of respiratory fibers exists in the vagus, entertains a different view in regard to the manner in which they produce their effect. After section of both vagi the respiration is no longer permanently influenced by any reflex mechanism, but solely by the respiratory center. [This dominant role of the vagi was extended by Filehne and Kionka (*Year-Book* for 1897, p. 1178), even to that increase in the respiratory activity which is so constant an accompaniment of muscular exercise, the vagus-endings in the lungs, according to these observers, being stimulated by the excess of CO₂ in the blood.] C. Speck,⁹ however, takes exception to these experiments, and concludes that the excitation is set up in the capillaries of the contracting muscles. [But Filehne and Kionka still saw increased respiratory activity on tetanizing a limb connected with the trunk only by its blood-vessels, and it seems to us to savor of special pleading to suggest, as Speck does, that the *nerri vasorum* might run for a

sufficiently great distance in the vascular walls to establish a nervous connection. At any rate, this has never been proved.]

[As to the direct action of the blood on the respiratory center, it is generally acknowledged that it may be stimulated both by deficiency of O and by excess of CO₂, but it has been a subject of long-continued discussion which of these factors is the more potent under normal conditions.] N. Zuntz and A. Loewy¹ now bring forward evidence that comparatively small alterations in the amount of CO₂ in the inspired air cause a relatively great increase in the respiration, while the deficiency of O must be much more decided to bring about any notable effect. It is, of course not at all out of harmony with this, that when very large quantities of CO₂ are inhaled (30% and upward in rabbits) a condition of narcosis comes on without any dyspnea (A. Benedicenti).²

The **influence of alterations in the atmospheric pressure** has been studied by Lewinstein,³ who makes the remarkable observation that rabbits exposed continuously to a pressure of 300–400 mm. Hg die in 2 or at most 3 days, with widespread fatty degeneration (of heart, liver, kidneys, diaphragm, etc.). A. Loewy, J. Loewy, and L. Zuntz,⁴ comparing their observations on men exposed to various pressures in the pneumatic cabinet with the effects of a mountain climate on the same individuals, have brought out the interesting [though not entirely novel] fact that the action of mountain air does not depend merely on its degree of rarefaction, but on other complex stimuli. They deny that any increase in the specific gravity of the blood takes place at high levels. [This is opposed to the experience of other observers, who have found an increase in the number of the red corpuscles.] Possibly the discrepancy is accounted for by the method (Hammerschlag's) which they used for determining the specific gravity, and which, despite the precautions adopted (L. Zuntz)⁵ [the necessity for these we can vouch for from personal experience] would hardly reveal small differences of concentration. The effect of **rapid variations in atmospheric pressure**, such as workmen are exposed to in the air-lock of a caisson, has been investigated experimentally by R. Heller, W. Mager, and H. v. Schrötter,⁶ with the result that all the serious permanent disturbances of the nervous and circulatory systems are believed to be due to the liberation of gas in the vessels when the pressure is suddenly reduced. The symptoms can in part be relieved by again raising the pressure. This is especially true of the circulatory troubles, and is of some therapeutic interest.

Types of Respiration.—An exhaustive study of the influence of sex, age, and race on the type of the respiratory movements has been made by G. W. Fitz.⁷ [His work deals a final blow at the long-tottering theory that sexual differences in respiratory type exist. When women breathe differently from men this, according to Fitz, is due far more to peculiarities of dress than to peculiarities of organization.]

Oxygen-tension of Arterial Blood.—J. Haldane and J. L. Smith⁸ have determined by means of a new method, first described by Haldane,⁹ the oxygen-tension of human arterial blood as it leaves the lungs. Since it exceeds the partial pressure of the oxygen in the external air, and, *a fortiori*, that of the oxygen in the air of the alveoli, the gaseous exchange in the lungs cannot be explained by diffusion alone.

Experimental Pneumothorax.—Rodet and Nicolas¹ show that a gas, such as CO₂, introduced into the pleural cavity is very soon replaced by a mixture of CO₂, N, and O, by exchange with the blood circulating in the pleural membrane.

DIGESTION AND ABSORPTION.

The influence of intractestinal pressure on the **absorption of substances from the alimentary canal** has formed the subject of an investigation by H. J. Hamburger,² who asserts that a rise of pressure favors absorption, which completely ceases when the pressure falls to zero. This latter fact he considers a telling argument against the theory of "vital" absorption, which is further invalidated by his observation that an increase of intraabdominal pressure also hastens the disappearance of liquid from the peritoneal cavity, when it is not sufficiently great to obstruct the blood-flow by compressing the veins.³ [We do not think, however, that Hamburger's conclusions necessarily follow from his premises, nor is it certain even that his premises are correct.] For Waymouth Reid⁴ has demonstrated by careful experiments that the water, organic and inorganic solids of the serum of an animal are absorbed from a loop of its intestine when the hydrostatic pressure in the capillaries of the intestinal wall is considerably greater than that in the cavity of the intestine. Ligation of the lacteals does not affect the result. [It is difficult to harmonize this with any purely physical theory of absorption.] Reid,⁵ however, sees no reason to suppose that the mesenteric nerves affect the absorption of such substances as peptone and water in any other way than by their influence on the caliber of the blood-vessels. The defensive function of the mucous membrane of the intestine against certain bacterial poisons (toxins of cholera, diphtheria, and pyogenic bacilli), which seems to be indicated by the researches of Charrin and Cassin,⁶ is also, so far as it goes, in favor of the "vital" hypothesis of absorption. So, too, is the selection of the path of the lacteals by the fat in preference to the path of the blood-vessels, particularly if we accept the somewhat heretic doctrine put forward by B. Moore and D. P. Rockwood⁷ that most, if not all, of the fat is absorbed in a soluble form (as soap or fatty acid) by the epithelial cells. That **fat-splitting** goes on energetically in the alimentary canal, even in the absence of the pancreas, has been shown by Abelman, and this is confirmed by E. Hedon and J. Ville;⁸ while S. Rosenberg⁹ has found that after ligation and section of its ducts and blood-vessels, followed by almost complete degeneration of the pancreas, a large amount of fat was still absorbed. No sugar appeared in the urine; the animal lived for 10½ months, and then died from a pneumonic affection. Even in the total absence of both bile and pancreatic juice Hedon and Ville saw absorption of the fat of milk to the extent of more than 20%. This explains the possibility of the absorption of fat from nemata, which has been carefully studied by P. Deucher.¹⁰ To attain the best results the fat should be given in the form of an emulsion, heated to body-temperature, after previous evacuation of the bowel. The researches of

Harriot¹ and of Cohnstein and Michaelis² render it probable that we must even extend the role of the fat-splitting ferments beyond the limits of the alimentary canal, for they bring forward evidence that fat-splitting goes on in the blood itself.

Cholagogue Action of Bile.—In a valuable investigation of the action of bile in a case of biliary fistula Pfaff and Balch³ reinstate this medieval remedy as the only real cholagogue at present positively known. Doyon and Dufourt⁴ confirm this conclusion. Salicylate of sodium may to a certain extent act as a cholagogue; calomel not at all.

With the view of elucidating the **mechanism of obstructive jaundice**, Wertheimer and Lepage⁵ established a fistula of the thoracic duct in a dog, and then injected into the branch of bile-duct serving one lobe of the liver a quantity of sheep or ox-bile, which has a characteristic spectrum owing to the presence of cholehematin. They collected the bile secreted by another lobe, and found that it assumed the color and showed the spectrum of the foreign bile. They convinced themselves by postmortem injection that there was no direct communication between the two branches of bile-duct, and therefore concluded that the injected bile must have been absorbed into the blood in the one lobe and excreted by the other. [Should these experiments be confirmed, they would show that the importance of the lymphatics in the absorption of the bile in obstructive jaundice has been singularly exaggerated. It seems very possible, however, that in the injection the pressure was raised in the bile-ducts to a greater height than can ever be the case when they are simply ligated. And that actual injury was inflicted on the hepatic tissue is indicated by the fact that the lymph collected from the fistule was always deeply tinged with blood-pigment.]

Feces.—[It is well known that the feces represent not only the unabsorbed constituents of the food, but also, to an appreciable extent, the secretions of the alimentary canal.] An investigation by a quartette of observers, H. Hammerl,⁶ F. Kernmanner, J. Moeller and W. Prausnitz,⁷ shows that the latter element is even more important than has been supposed. Indeed, it would appear more correct to speak of food-substances as causing the *formation* of a smaller or a greater amount of feces than of their being more or less completely absorbed. [Contrary to popular belief] there seems to be no essential difference in the completeness with which animal and vegetable food is taken up from the alimentary canal, nor does the number or kind of the intestinal bacteria appear to vary with the nature of the food.

Digestive Ferments.—R. Pfeleiderer⁸ finds, in confirmation of previous observers, that of all acids HCl is the best helpmate both of pepsin and of rennin. W. D. Halliburton and T. G. Brodie⁹ state that a milk-curdling ferment, differing in certain respects from rennin, exists not only in extracts of pancreas, but in fresh pancreatic juice [a point on which there was some doubt]; and J. W. Warren,¹⁰ bringing together the results of several of his pupils, shows that the zymogen of a milk-curdling ferment exists in the gastric mucous membrane of a very large number of vertebrates, although not in all that were examined.

Movements of the Stomach.—S. J. Meltzer¹¹ has continued his inter-

esting researches on the movements of the stomach, and reports that stimulation of the peripheral end of either vagus in the dog causes contraction, which is always confined to the pyloric end and lesser curvature.

Innervation of Swallowing.—F. Lüscher¹ asserts that the recurrent laryngeal (in the rabbit), in addition to its motor fibres for the laryngeal muscles and the upper portion of the esophagus, contains afferent fibres, stimulation of which causes reflex swallowing movements. [These experiments support the older statements of Burkert and Krause, in opposition to those of Horsley and Semon, Hooper, etc.]

THE NERVOUS SYSTEM.

Nerve-cells.—Vitzou,² whose preliminary communication we noticed in the *Year-Book* for 1897, has now published his complete paper on the regeneration of nerve-cells. He concludes [and his work appears to be sound] that the brain in young monkeys possesses the power of reproducing the substance lost by operation. He removed completely the occipital lobes in a macaque monkey, and saw that the power of vision, lost for a time, was gradually regained. Histologic examination proved that new nerve-cells and nerve-fibers had made good the deficiency.

F. C. Eve³ has reinvestigated the question whether functional activity produces any histologic change in lymphatic nerve-cells, and, unlike previous observers, comes to a negative conclusion. He thinks that the shrinking of the cell and nucleus which has been described is probably due to the reagents used in fixing the tissue. The only change of any kind he could detect was the occurrence of a slight, diffuse blue stain (with methylen-blue) in the cell-substance. [It is evident that such a conclusion, reached by a competent observer, renders a repetition of the well-known work of Hodge and others a desideratum. But evidence is gathering every year that the histologic structure of nerve-cells is actually affected by various circumstances] and Berkley⁴ has even detected marked differences in the dendrites of the pyramidal cells of a man who, after a long course of addiction to alcohol and opium, died in an insane asylum, and those of a typical healthy brain.

A. Hill⁵ has published an elaborate study of the conditions under which the chrome-silver (Golgi) method succeeds, with a criticism of its results, and announces the discovery in the granule-layer of the cerebellum of small "granule-cells" with *centripetal* axis-cylinder processes.

Spinal Paths.—E. Wertheimer and L. Lepage⁶ state [although this is not new] that the integrity of the anterior pyramid is not essential for the conduction of impulses from the cerebral cortex to the muscles of the opposite side. According to them, the path by which the motor impulses pass from the cortex to the muscles of the same side ("homolateral" path) is direct, and not crossed. [This is a view which has been steadily growing in favor of late years, but the novel suggestion of M. Rothman,⁷ that the pressure of degenerating on sound fibers at the decussation may cause the latter to degenerate, if it should prove to be correct, would again place the whole question in doubt, for the fibers that degenerate in the lateral pyramidal tract on the same side after removal of one Rolandic area might possibly belong to the motor cortex of the opposite side. The subject certainly requires renewed investigation.]

Sherrington¹ makes a further contribution to our knowledge of the peripheral distribution of the fibers of the posterior roots and their cerebral homologues. One of his most interesting conclusions is that the sense of taste as well as of touch is destroyed in the monkey in the anterior two-thirds of the tongue after intracranial section of the fifth nerve. He definitely establishes the rule that the sensory nerves of a skeletal muscle are in all cases derived from the spinal ganglion corresponding to the segment of the cord containing its motor cells. The question whether any of the fibers of the posterior root are of intraspinal origin, he² also attacks, and comes to the conclusion, as Singer and Münzer had previously done, that in mammals the original negative result of Waller is correct. For the frog the same conclusion is reached by R. J. Horton-Smith.³ [In the chick, however, it is generally admitted that a few of the posterior root-fibers do arise in intraspinal nerve-cells.]

Reflex Action.—F. Gotch⁴ makes a noteworthy contribution to the long-standing controversy on the nature of the **knee-jerk**. He reaches the catholic conclusion that the tendon-tap causes two distinct effects, a direct stimulation of the vastus internus muscle on the same side and a reflex stimulation of this muscle, confined in the rabbit to the opposite side, but, possibly, in certain animals and under certain conditions, involving the same side also. P. Stewart⁵ also furnishes evidence of the existence of a true crossed reflex knee-jerk, the average time elapsing between the tendon-tap and the appearance of the jerk on the opposite side being about 0.126 second.

Max Verworn⁶ states that pressure or friction on the flanks of a frog whose cerebral hemispheres have been removed causes a tonic reflex contraction of muscles in all parts of the body, which outlasts the stimulus sometimes for as long as an hour. The reflex center is in the ventral portion of the mid-brain (optic lobes). [The author of this abstract has observed long-continued and general spasmodic contractions in frogs and also in *Menobrachius* after excision of the cerebral hemispheres, when the mucous membrane of the mouth was scratched with a pair of forceps. These phenomena are perhaps related to the reflex contractions noticed by Sherrington⁷ in "brainless" monkeys and termed by him from their long duration "cataleptoid."]

Sherrington, in conjunction with H. E. Herring,⁸ has continued his brilliant researches on the cortical inhibition of antagonistic muscles during the performance of coördinated movements, and brings forward numerous additional illustrations of such inhibition.

Cortical Localization.—Wesley Mills⁹ concludes from his studies on the effects of stimulation of the cortex in a large number of animal groups that areas of the same name in different animals are not on the same functional plane [*i. e.*, have not attained the same level of organization]. In birds he finds no evidence of the existence of any "motor centers." Pitres¹⁰ also raises his voice against the conventional view that the motor and sensory areas are separated from the rest of the cortex by hard-and-fast functional lines. In particular he sees no reason for supposing that any definite region is especially associated with the intellectual powers.

S. J. Sharkey¹ adds three interesting and well-studied cases to the precious, but as yet all too scanty, stock of evidence on the cortical localization in man. They corroborate the view, derived from experimental physiology, that the angular gyrus and occipital lobe are both concerned in vision, the former as a higher, the latter as an intermediate or lower center.

The Sympathetic System.—Langley and Anderson² complete their work on the innervation of the pelvic viscera by a paper dealing with the anatomy of the lumbar and sacral sympathetic nerves; while Langley³ asserts, in opposition to the results of Schäfer and Moore [and the evidence he brings forward is undoubtedly strong], that the fibers which cause contraction of the spleen, like all or nearly all the fibers of the splanchnic nerves, make junction with the ganglion-cells in the solar plexus. And he takes the opportunity to reiterate his generalization that there is but one sympathetic cell on the course of each sympathetic fiber. A lucid account of our present knowledge of the constitution of the sympathetic system has been published by G. C. Huber.⁴

D. Courtade and J. F. Guyon⁵ endeavor to rehabilitate the doctrine of v. Basch that the same nerve supplies the longitudinal muscular coat of such organs as the bladder and the intestines with inhibitory and the circular coat with motor fibers, and *vice versa*. [It is an extraordinary circumstance that no reference is made by these writers to the well-known work of Langley, who has conclusively shown that there is no foundation for v. Basch's idea.]

SPECIAL SENSES.

Th. Beer,⁶ in continuation of his remarkable investigations on the mechanism of accommodation in the lower animals, makes the further announcement that the cephalopod eye, like the eye of fishes, possesses a negative accommodation—*i. e.*, an accommodation for distance. From this he draws the general conclusion that all animals living in the water, when they possess the power of accommodation at all, have a negative and not a positive accommodation. The explanation he believes to be [and it is a very plausible one] that under water the greatest possible distance of distinct vision must be very much less than in air, and that, since water offers a relatively great resistance to locomotion, it is more important for the water-living animal to discern its prey or its enemy when it is near than when it is remote.

ELECTROPHYSIOLOGY.

A series of important contributions to the theory of **galvanotropism** has been made by J. Loeb,⁷ among which is included⁸ an examination of the question whether electromagnetic vibrations (Hertzian oscillations) have the power of stimulating such excitable tissues as the nerves of the frog. [So far as we can see at present, we think that more confidence is to be placed in the negative answer of Loeb than in the positive results of B. Danilewsky.⁹]

F. Gotch and G. J. Burch¹⁰ have added largely to our knowledge of the electromotive properties of the *Malapteruus electricus*; and F. S. Locke¹¹ has examined in detail the action of ether on contracture and on the so-called positive cathodic polarization.

LEGAL MEDICINE.

By WYATT JOHNSTON, M. D.,

OF MONTREAL, CANADA.

Epitome.—The discovery by Florence of a characteristic chemical test for semen is a most important addition to medicolegal technic. The Röntgen photography has been quietly accepted by most courts as part of the regular medicolegal repertoire, perhaps with too little regard to the possible sources of error involved. Agitation in favor of a better system of appointing experts has been vigorously carried on in America during the year, but so far “much cry and little wool” appears to be the result. Even in France, where a much more satisfactory system exists, there has been a noteworthy amount of friction between the experts and the courts in recent years. Between the primitive state of affairs in which the dictum of the ordinary general practitioner is accepted as gospel, and the highly organized ones in which the decision of medical matters is left in the hands of medical men, the transition-stages are bound to be unsatisfactory, though the end is worth striving for. In the Luetgert *cause célèbre* the objectionable features of the present expert system were well shown. The Medicolegal Congress at Brussels and the Medicolegal Section of the Moscow International Congress brought out little that was novel. It is singular that neither in the American nor in the British Medical Association has legal medicine been allotted an independent section.

1. Literature.¹—The admirable series of lectures by P. Brouardel² forms the most notable addition to the literature of the year on this subject. The very full reports of numerous cases, mostly personal, make these lectures of special value. The late E. v. Hofmann’s parting gift to science was an excellent hand-atlas of legal medicine.³ In America Witthaus’s completing volume of the *System of Medical Jurisprudence and Toxicology*, edited by himself and Becker, gives the best statistical information available regarding toxicology. The deaths of E. v. Hofmann, G. Tarde, and A. Wernich have occurred during the year.

2. Criminology.—The increasing frequency of homicide in the United States is commented on by P. Bartholow,⁴ who estimates the number of reported homicides as increasing from 1808 per annum in 1885 to 4292 in 1890, and to 10,500 in 1895. This latter rate of 15 per 100,000 population is said to be 25% higher than in Italy, double that in Spain, 5 times that of Austria, 9 times that of France, and 20 times that of England, Scotland, or

¹ The subject-matter has been divided as follows; 1, general medicolegal literature; 2, criminology; 3, medical jurisprudence; 4, medicolegal pathology, violent death and injuries; 5, medicolegal tests; 6, toxicology; 7, sexual; 8, mental. The abridgment needed to keep within the limits of space allowed was made at the expense of Nos. 2, 6, 7, and 8.

⁴ Jour. Am. Med. Assoc., Nov. 14, 1897.

Germany. [Some better system of collecting criminal statistics similar to those followed in Europe is needed in order to decide matters of such importance.]

Judicial castration as a punishment for rape is being regarded with increasing favor in districts where this crime is prevalent. In Kansas a bill to legalize it has been introduced. [It might advantageously be tried as a substitute for lynching in certain localities.]

3. Medical Jurisprudence.—[Judging by the titles of recent medico-legal text-books and of courses of lectures in the medical colleges, it is not yet generally understood that this term implies, strictly speaking, medical law and not legal medicine.]

Medical Secrecy.—The Playfair case, in which a distinguished physician took advantage of evidences of pregnancy gained during an operation upon a patient who happened also to be a family connection, to indulge in acts of persecution toward the lady, did not really open up any debatable points in reference to the relations of physician and patient. The opinions of the English Bench which were incidentally expressed during the trial shows that the absence of definite and fixed rules in the matter of secrecy is a decided source of danger to the physician. Although the award of \$60,000 damages is large, there can be little doubt that the physician acted improperly. In France the secrecy enjoined by law is so great that even the public hospital records showing the dates of admission of patients cannot be used as evidence against criminals who have been treated in the institutions. W. Lefuel¹ deals very clearly with this phase of the subject.

Responsibility of Medical Men.—That this has become a very serious matter in France recent events have shown. In a recent case experts who had failed to recognize a typical case of coal-gas poisoning (and had given evidence whereby an innocent woman was sentenced to penal servitude for life and remained in prison till other similar deaths in the same dwelling led to an investigation) were ordered to pay jointly 40,000 fr. damages.² A more recent instance was that in which an expert directed to examine a woman charged with infanticide declared that she had recently been delivered. She was confined to prison, where 2 weeks later she gave birth to a child. The learned judge pronounced the expert's error to be inexcusable, "as he could have established the fact of pregnancy simply by examining the blood, which according to all standard authorities shows peculiar and characteristic alterations during pregnancy" (!). The decision of this modern Dogberry has led to a formal protest from the Société méd.-légale de France,³ as it happens that no leading medicolegal work refers to the matter at all and the statements existing in medical literature are contradictory.

These occurrences have led A. Lacassagne to classify categorically the causes of experts' errors as follows:⁴ 1. Of omission—forgetting a scientific rule, as in neglecting to open an important cavity, to note an important observation, or to make a necessary control. 2. Of commission—acting contrary to medicolegal practice, as in doing the docimasia-test wrongly; misinterpreting appearances, as in taking lividity for ecchymosis. Errors he considers excusable if they arise from want of scientific training or practice in medicolegal work, but inexcusable if they arise from presumption, exuberant imagination, or haste in drawing conclusions. The fact that in France any physician when ordered by a judge to make an *expertise* has no power to refuse, makes the matter a very serious one. A penalty of 3 months' imprisonment was meted out to Laporte⁵ by a Paris court for having unskil-

¹ Ann. d'Hyg. pub., Jan., 1897.

² Druaux case, Rev. de Méd. légale, 1897.

³ Ibid., July, 1897. ⁴ Arch. d'Anthrop. crim., Jan., 1897. ⁵ Sem. méd., Oct. 23, 1897.

fully caused the death of a woman through a bungling attempt to perform craniotomy with a large mattress-needle, after trying to use a cold chisel and mallet. As he rejected the offer of the family to obtain other medical aid, and as the case occurred in the heart of Paris under circumstances not specially urgent and not calling for improvised methods, he was certainly imprudent. The autopsy showed perforations of the bladder and peritonitis, but it was not clearly shown that these were caused by the instrument employed, and the exceptional severity of the sentence has been severely criticised. The case is mentioned as showing that a more uniform understanding on both sides should be had as to when a physician oversteps the limits of scientific practice. In America no cases having very important bearings in this direction have arisen during the year.

4. **Medicolegal Pathology: Violent Death: Injuries.—Death.**

—A. Martin¹ considers that **cadaveric spasm** is totally distinct from post-mortem rigidity, and is due to the last vital act of the nervous system. The essential feature is an absolutely instantaneous death—too rapid even for a few minutes' agonal struggle. Precocious rigidity, on the other hand, depends for its causation on a special condition of the muscle-fiber. [It is not easy to see how the distinction could be so sharply made.]

F. Strassmann² has estimated quantitatively (by measuring the shortening which takes place in pins driven into the hearts of dogs 1 hour after death, and again examined 24 hours later) the extent of the alteration in the volume of the chambers due to **rigor mortis of the heart**, to which he was the first, in 1889, to direct attention.

A. Lacassagne³ reports a case of a body found within a trunk, in which the symmetric distribution of ecchymoses about the shoulders, elbows, and knees led him to conclude that the **strangulation** which was the cause of death had actually taken place after the body had been placed in the trunk. P. Brouardel⁴ reports the case of a boy who shut himself in a trunk to hide, and died from suffocation. When found the body was so much swollen that after removal it could not be replaced, giving rise to the wrong impression that it had been placed there originally by force.

R. Schultz⁵ considers that in doubtful cases of strangulation microscopic examination of the skin for flattening of the papillæ and capillary hemorrhages may be necessary. The classic description of **suggillation** about the line of compression by a cord is never met with in practice. Any suffusion of the bridge of skin between two furrows is specially important, as this cannot be affected by hypostasis. Teard⁶ discusses the Cauvin case, in which a young man received a life-sentence because certain experts had declared that fracture of the larynx could not be produced in the case of a woman of 82 by a young girl, using her hands alone. A new trial, ending in acquittal, was granted, when it was learned that a parallel lesion had without doubt been produced in another case by a young girl.

P. Dittrich⁷ reports a case of **self-strangulation** done by an insane old man partly paralyzed in both legs and the right arm. An unsuccessful attempt to hang himself to the bedpost had immediately preceded the strangulation, which was by means of a cord.

Autoextirpation of the Larynx.—S. Szigeti⁸ reports a suicide so

¹ Arch. d'Anthrop. crim., July, 1897.

⁸ Ibid.

remarkable that its possibility would hardly have been entertained had not the circumstances excluded homicide, in a woman of 42. The appearance of the injury is shown in Fig. 85. A table-knife was used, the first cut being made downward with the head thrown back, and the larynx being then probably grasped by the hand and excised by a series of sawing cuts. Death followed in 8 hours. The carotids, jugulars, and vagi were intact. One similar case is on record (by Jameson), in which the victim removed half one side of his larynx and brought it himself to the hospital where he sought relief.

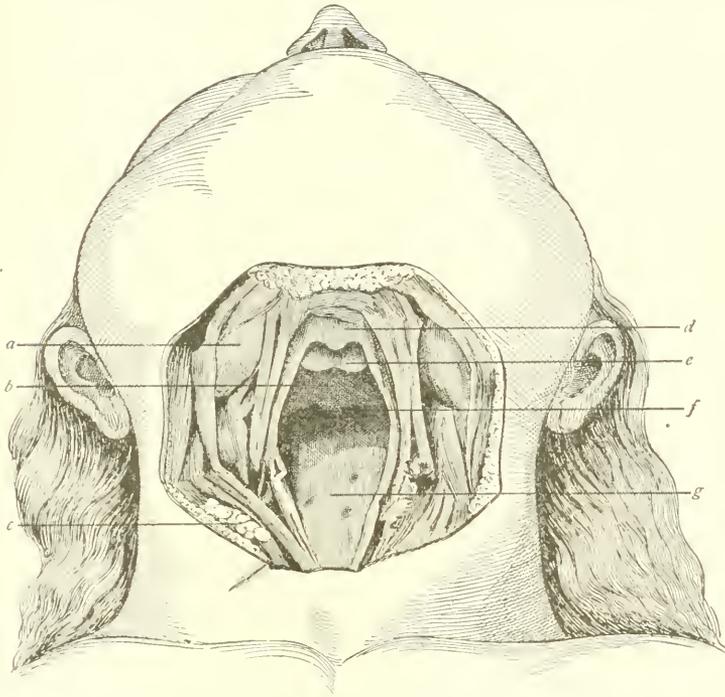

FIG. 85.—A case of suicide by excision of the larynx: *a*, submaxillary gland; *b*, soft palate; *c*, sternocleidomastoid muscle; *d*, hyoid bone; *e*, epiglottis; *f*, pharynx; *g*, esophagus, posterior wall (Szigeti, Vierteljahr. f. ger. Med., II. 2, 1896).

Electricity.—J. Kratter¹ has written a very complete monograph on this subject, with a very full bibliography.

Diagnosis of Vital from Postmortem Injuries.—R. Schultz² gives a lengthy review of the subject. The absence of ecchymosis and hemorrhage, where other extensive lesions exist and cause lowering of the general blood-pressure, is emphasized. Marked anemia of the organs is considered one of the most reliable signs of injuries having existed antemortem, as is also the occurrence of very profuse hemorrhages into the internal cavities, which cannot occur postmortem, and any appreciable suffusion about a large, gaping wound. Absence of signs of vital reaction by no means indicates that the lesions have been produced after death, and a knowledge of the conditions under which the body has remained since death may exclude the possibility of postmortem lesions, and so remove all doubt in the absence of positive signs of vital action. A. Lesser³ has been able by interposing soft pads, when inflicting experimental injuries after death, to produce edema without ecchymosis.

¹ Deutke, Leipzig, 1896. ² Viertelj. ger. med. Supplement, 1896. ³ Ibid., Jan., 1897.

Visceral changes in superficial burns have been studied experimentally by C. R. Bardeen,¹ who does not substantiate the statement that the essential cause of the lesions is capillary thrombosis, but finds them to be of the nature of focal necroses, similar to those occurring in infectious diseases, though cultures from the organs remain sterile. These focal necroses he was able to produce experimentally in animals.

Fat-embolism.—G. Puppe² finds that fat-emboli occur in subacute cases of phosphorus-poisoning, though absent in peracute cases, which die before the degenerative changes have time to develop fully.

Air-embolism.—J. Perkins³ reports 2 cases of so-called uterine air-embolism, and also a doubtful case.¹ A review of the cases already recorded is given, and one is struck by two circumstances—that the patients died suddenly in the office of physicians or others who, rightly or wrongly, had acquired the name of being abortionists, and that where the instrument employed was known, it was a hollow one (syringe or catheter). He was able experimentally to admit sufficient air to kill a dog by simply opening the jugular and raising the head. [The pathologic proof of uterine air-embolism appears to be very defective in most of the cases. Although men of first-class scientific standing have reported cases, no one has yet taken the trouble to test the gas found and see what it really is. There is no evidence proving experimentally that uterine air-embolism is possible unless a hollow instrument is used.] Welch and Flexner⁵ consider that many of the cases reported as air-embolism are really due to infection by the gas-bacillus (*b. aërogenes capsulatus*). This is the more likely to lead to confusion when the body is examined early, before decomposition has developed. [In the absence of the facilities or technical training necessary to make a complete bacteriologic examination there are two simple tests which any one can carry out—keeping the organs to see if gas-formation occurs, and keeping a drop or two of the blood dried for microscopic examination for bacilli. We have found it easy, by doing an autopsy carelessly, to enable small quantities of air to enter either the right or left heart from the cut vessels of the neck, if the blood be fluid and the shoulders slightly raised.]

Hiller, Meyer, and Schrotter⁶ state that in **arterial air-embolism** (air in left circulation) death is not due to accumulation of air in the heart-cavities, but to obstruction of the coronary or cerebral arteries. The condition is rare, and chiefly occurs when gases expand in the blood from a lowering of the surrounding air-pressure (caisson-disease). Attention is also called to the possibility of its occurring through the coincidence of ordinary air-embolism and an abnormal communication between the two sides of the heart. The characteristic appearance of small air-bubbles is most distinctly seen in the coronary or mesenteric arteries.

Infanticide.—An unusual case is reported by F. Strassmann.⁷ The mother endeavored to tear off the lower jaw and larynx of the child. The lower jaw was fractured in two places and a tear from each angle of the mouth extended down the neck, below the larynx. Death followed in two days, the autopsy showing that much blood had been aspirated and swallowed. H. Mitzenzweig⁸ reports a similar lesion as being caused by self-help during labor, though the child was strangled immediately after birth.

Accidental Death in Serum-therapy.—In the Langerhans child whose death occurred suddenly after a dose of diphtheria antitoxin, and

⁶ New England Med. Monthly, June, 1897.

⁷ Zeit. f. klin. Med., Bd. 32, 1897.

⁸ Ibid., 1897.

attracted much attention, F. Strassmann, after making an autopsy, found that death was due to inspiration of vomited matters into the air-passages. There was marked edema of the glottis and the suffocative attack commenced by a fit of coughing.

Destruction of Dead Body.—In the Luetgert trial at Chicago in Oct., 1897, it was alleged that a woman's body had been dissolved in a soap-vat into which 378 pounds of crude potash had been put and the solution heated with steam. Afterward cold water was run through the vat. The finding of fragments of bone, declared by one set of experts to be human, and to be parts of a femur, humerus, rib, phalanx, and temporal bone, as well as finding some corset-stays, false teeth, and some articles of jewelry recognized as belonging to the deceased, aroused suspicions. It was shown by the State that, under parallel conditions, solution of the body was possible in a few hours. [A really scientific and impartial study of this novel problem has not yet been made. From a scientific standpoint the verdict of the jury is immaterial, as the enduring triumphs of legal medicine are won in the laboratory and not in the court-room.]

Wounds and Injuries.—The zeal with which the medicolegal aspects of injuries are studied in Germany is shown by the publication of two special periodicals, a *Monatschrift* and an *Archiv für Unfallheilkunde*. In our own medical literature the work in this direction is scanty and singularly barren of scientific interest, largely no doubt because it is regarded from a business rather than a scientific standpoint. The duties and responsibilities of the official physicians of corporations are commercial and executive, rather than medical. While our railway surgery has advanced rapidly in the matter of organization, its contributions to science have been by comparison, disappointing.

Altman¹ concludes, in regard to **injuries of the lung** that, if the immediate effect is survived, the chances of recovery are relatively good. Punctured wounds are practically as serious as lacerated ones, the lesion of the pleura being the main consideration. Pneumonia and tuberculosis can often be traced to the result of trauma. Prolonged observation of a case is necessary before giving a prognosis, and this should always leave a wide margin for possibilities.

Important monographs on injuries of the **brain and nervous system** have been published by Crocq² and by C. Phelps,³ the latter dealing especially with pistol-shot wounds.

Injuries of the diaphragm are considered medicolegally by L. Israel.⁴ Lacerations usually occur on the left side, and affect middle-aged men. Diaphragmatic hernia is likely to happen, and is best diagnosed by Litten's sign.⁵ The most serious results from this lesion are those which arise from constriction of the stomach and intestine.

A full discussion on **contusions of the abdomen** took place before the Eleventh French Congress of Surgery at Paris.⁶

A. Wegener⁷ considers that in **injuries of the intestine** perforation must be regarded legally as a naturally fatal injury. In subcutaneous rupture of the intestine the abdominal walls are usually free from all marks of injury. Perforation, apart from other causes of shock, does not cause instant death. Omission to perform a laparotomy should not constitute malpractice:

Castex⁸ deals with the legal bearing of **diseases and injuries of the**

⁷ Ibid.

⁸ Ann. d'Hyg. pub., June, 1897.

ear, nose, and throat; J. W. Park¹ with the eye and ear; F. Colley² with injuries of the tongue, especially with reference to the extent to which the functions of swallowing, taste, and speech remain after injury or removal. W. Ambrosius³ considers very carefully the injuries of the male urinary tract, giving a very full bibliography and citing in particular a large number of cases of rupture of the bladder.

Trauma and carcinoma are studied by W. Berger,⁴ who supports the usual view that repeated or continued slight injuries are most important in this respect. B. Schuchardt⁵ gives a lengthy report of a case in which an affirmative report and superarbitrium were given in support of a **traumatic origin for tuberculosis** in a case in which a blow on the lumbar region was followed by neurasthenia and later by pulmonary tuberculosis.

Vaccination and Tuberculosis.—The following are the conclusions of a Prussian government report by Gerhardt and v. Leyden:⁶ "Apart from the possibility that faulty technic leading to erysipelas, sepsis, or syphilis may produce a predisposition, through general weakening of the system, favorable to invasion of tubercle-bacilli; also the possibility that in children who have tuberculous glands, very exceptional cases with high fever might lead to generalization of the process, there is no ground for assuming that tuberculosis can occur through vaccination."

Interval before Death after Stab-wounds of the Heart.—M. Richter⁷ reports that out of 27 cases periods of 5 minutes to 5 days elapsed in 10; in 10 others, owing to the bodies being found dead, the interval remained uncertain; 4 were able to walk into or from rooms to give alarm; 1 (suicide) closed the knife and put it in his pocket; in only 2 was death known to be instantaneous. Death from heart-wounds is thus less rapid than from those of large vascular trunks. The shape, size, situation, and direction of the wound are stated to have made little difference. [None of them, however, happened to involve the auricle, which we have found always to cause very rapid death.]

Accidental Gunshot-wounds.—J. N. Hall⁸ gives a useful citation of the circumstances under which these occur, with especial reference to cases in which homicide was made to simulate accident. G. Corin⁹ was able with small shot to produce experimentally fracture of the ulna at 12 meters distance.

5. Medicolegal Tests.—[The subjects comprised under this category become every year more varied. Bacteriology and photography have been the branches in which development has been most active during the year.]

X-rays in Legal Medicine.—The first recorded appearance of Röntgen photography in court was at Nottingham, England, in February, 1896, before Mr. Justice Hawkins, Miss Gladys Froliot, an actress, promptly obtaining damages for an accident to her foot when the skiagraph was produced in court. Very few judges have objected to this form of evidence, though one court in New Jersey, finding that no precedent existed in that State, declined to establish one.¹⁰ Doubtless, judging from the present tendency to give scientific demonstrations of all kinds before jurors, the fluoroscope will appear in evidence. That the skiagraph is not yet entitled to the same unhesitating credence granted to ordinary photographs is pointed out, amongst others, by E. A. Tracy,¹¹ who gives two photographs of the same hand (reproduced in

Figs. 86 and 87), showing well how pathologic changes may be accidentally simulated (not to mention intentionally) simulated. The chief cause of error is due to the rays diverging from one point and not being refrangible.

Bordas and Ogier¹ utilized the process to detect the contents of "inferdas machines" sent by mail, also to show ossific points in the fetus. Bordas

FIGS. 86 and 87.—Showing how pathologic changes may be accidentally simulated by a skiagraph (Jour. Am. Med. Assoc., Nov. 5, 1897).

claims that lungs of stillborn children appear opaque and expanded lungs transparent in skiagraphs.

Photography.—H. J. Gosse² emphasizes the importance of making the eyes of dead bodies look more lifelike before photographing. When this is not accomplished by a simple wet compress, moistening the conjunctiva (but not the cornea) with a weak alum solution or instilling a 25% glycerin solution will often succeed. Where the globe is very flaccid, injection of glycerin into the posterior chamber with a hypodermic syringe is advised. Sir H. D. Littlejohn³ insists on the importance of photographing the principal lesions found at each stage of medicolegal autopsies. [This is rendered specially necessary by the very thorough dissection-methods considered necessary in forensic cases, which make it almost impossible to preserve satisfactory specimens for future study without a feeling that one is neglecting some incision which may later on prove to have been essential.]

Blood-stains.—S. Szigeti⁴ advises the use of hot concentrated carbolic acid as a solvent for old blood-stains in substances liable to be acted on by alkalis. It gives the acid hematin spectrum, and by diluting with alcohol it can be made to give that for reduced hematin. By adding concentrated H_2SO_4 hematoporphyrin can be obtained.

Iodin-test for Seminal Stains.—Florence's reaction,⁵ obtained by bringing a drop of solution of iodine trichlorid (iodine, 2.5; potass. iodid, 1.65; water, 30) into contact with a moistened filament or a drop expressed

¹ Ann. d'Hyg. pub., May and Aug., 1896. ² Ibid., Dec., 1896. ³ Lancet, Jan. 2, 1897.

⁴ Viertelj. ger. Med., Supplement, 1896.

⁵ See Arch. d'Anthrop. crim., 1895.

from a stain is recognized by prompt and abundant appearance of brown acicular and rhomboidal crystals, strongly resembling those of hemin in size, color, and appearance. The fixed alkalis and heat dissolve them, but they reappear on cooling, and are insoluble in weak ammonia. They are produced by contact of the solution with certain alkaloids, but not by any of the secretions or fluids of the body and not typically by the semen of animals. The test has been confirmed by a number of observers, who all agree as to its simplicity and usefulness as a preliminary test to see at once whether it is worth while examining for spermatozoa (for which Florence recommends employing a solution of crocein, producing double staining of the heads, best studied with a $\frac{1}{2}$ immersion-lens). We have found¹ that the prostatic and vesicular components of the semen tested separately do not give the reaction, and found it absent in 2 cases (advanced chronic vesiculitis and carcinoma of prostate), although spermatozoa were abundant. Lecoq and Richter² have obtained the reaction from cholin. E. Posner³ obtained it in a case of azoospermia, and thinks the prostatic element the essential one. E. di Mattei⁴ had negative results with purely prostatic secretions. W. Florence⁵ confirms Richter's statement that cholin gives the reaction, and has obtained it from putrefied alkaloidal bodies in egg yolks. W. F. Whitney⁶ tested for the crystals, with negative results, in material containing Chareot-Leyden crystals (supposed to be identical with spermatic crystals). He recommends staining the film (obtained by pressing the moistened and disassociated filaments on a cover-glass and allowing it to dry) first with aqueous eosin and then with strong aqueous methyl-green, to obtain double staining of spermatozoa-heads. Mount in balsam.

American Observations on Entomology in Legal Medicine.—

Results corresponding with those of Ménézier were obtained by G. Hough in Massachusetts, with bodies freely exposed to the air. He gives new points for the more ready classification of diptera.⁷ M. G. Motter, in studying 150 buried bodies at Washington, D. C., found a much more varied and numerous fauna than that noted by Ménézier.⁸ [We have personally⁹ found that during the warm weather the results at Montreal are nearly, but not quite, in accord with Ménézier's statements. Montreal air- and soil-temperatures happen to correspond with those of Paris during the summer. Ménézier's publications chiefly refer to exposed and not to buried bodies.]

Glycogen-function of the Liver.—A. Lacassagne and E. Martin¹⁰ have confirmed and extended some valuable forgotten observations of C. Bernard, showing that the livers of people meeting sudden or violent deaths contain 1% to 2% glucose—readily recognized by rubbing up the liver in water, boiling the emulsion, and testing the filtrate by Fehling's solution. An opalescent filtrate indicates unconverted glycogen. Two hundred bodies were examined. The test is negative in death from exhausting diseases and fevers, and hence, if positive, it implies that injuries to a sick person have been the immediate cause of death. Positive reactions are given in diabetes and deaths from apoplexy, hemoptysis, and hemorrhage. Stillborn children give positive reactions; but if syphilitic, negative ones. [We have tested the results and find them on the whole to be as stated.]

Bacteriology in Legal Medicine.

—Bordas and Descoust¹¹ found that

¹ Boston M. and S. Jour., Apr. 8, 1897.

² Wien. klin. Woch., No. 24, 1897.

³ Berlin. klin. Woch., No. 28, 1897.

⁴ Cristalle del Florence, Naples, 1897.

⁵ Arch. d'Anthrop. crim., Nov., 1897.

⁶ Boston M. and S. Jour., Apr. 8, 1897.

⁷ Brit. Med. Assoc., annual meeting, Sept. 2, 1897.

¹¹ Rev. de Méd. légale, Mar., 1897.

gaseous decomposition did not occur in stillborn lungs exposed to spontaneous decomposition, and that when decomposing fluids were injected into the bronchi no gas was found unless air was injected at the same time. Malvoz¹ found absence of microorganisms in the tissues of healthy persons dying suddenly, and after the onset of putrefaction the deeper tissues remained free from bacteria for some time. In death from disease, the bacteria of terminal infections were present uniformly. [Our personal experience has been the same, the organs of healthy persons being often sterile some days after a violent death.] Wilman² considers the presence of the water-bacteria in the lung-alveoli and the stomach and intestines a valuable sign of drowning. Predominance of liquefying colonies is the distinguishing feature. [We presume the test would only be practicable during the early periods of immersion, when it is least needed. Further observations by bacteriologists are necessary to decide its practical value.]

G. Pouchet³ reports an outbreak of sausage-poisoning in 1895; 11 cases, 1 death. No toxic substances could be isolated chemically, but virulent bacilli of the hog-cholera group were obtained in culture. [Pouchet's claim that this was the first successful application of bacteriology to legal medicine is too absurd to be seriously discussed. In any case his failure to obtain the bacilli from the dejecta leaves the chain of proof incomplete.]

Cicatrices as an Index of Right- and Left-handedness.—J. N. Hall⁴ found that cicatrices from whittling, etc., average from 4 to 12 on the opposite hand to that used habitually to hold the knife, as compared with 1 to 4 on the knife-hand. In women needle-pricks on the forefinger are equally significant. Of 100 persons examined, the results confirmed this in 91; in 8 the scars were too scanty to justify an opinion, and only 1 led to an error. Equal distribution of scars on both hands is suggestive of ambidexterity (left-handedness overcome). The test is more available than that of writing, as children naturally left-handed are taught to use the right hand for that purpose, though a weapon would still be held in the left.

Examination of Hairs.—P. Mimakow⁵ found that dry heat below 150° C. produces no macro- or microscopic changes in hairs. At from 180° to 200° hairs are discolored red or black in 15 to 20 minutes. Hairs of normal appearance may show microscopically splitting and swelling at the tip and gas-bubbles in the shaft. This microscopic change was noticed after pistol-shots at a distance of 25 cm., where no change could be detected by the naked eye. Washing in water, then in alcohol, and mounting in balsam, are advised. F. Ringberg⁶ found that changes may occur in the color of the hair many years after death from the effects of decomposition.

6. Toxicology.—E. Michel⁷ found that **carbon monoxid** may persist in blood-extravasations for from 2 to 5 days after it has disappeared from the circulating blood. Daniel⁸ describes a simple modification of Haldane's quantitative colorimetry test for CO. A 1% solution of normal blood in water is mixed with sufficient of a 1% solution of blood previously saturated with CO from illuminating-gas to give the same tint as a 1% solution of the blood to be tested. [A very full discussion of the whole subject of carbon monoxid took place at this congress, but the statements on many important points still remain irreconcilable.] I. Brouardel⁹ has published a valuable monograph on arsenic-poisoning.

⁷ Ibid., Oct., 1897. ⁸ Ibid., July, 1897.

⁹ Etude sur l'Arsenicisme, Paris, 1897.

7. The establishment of the special journal, *Annales de l'Unisexualité* (Leipzig), would serve a useful purpose if it relieves the scientific press from the necessity of publishing the endless supply of prurient detail having little novelty or scientific interest, which forms the bulk of the literature on sexual aberration.

There has been an increasing tendency to regard trauma as the cause of nervous and mental disturbances. More exact knowledge as to the anatomical and chemical conditions of the nervous and secretory organs has had a marked influence in the direction of transferring medicolegal problems in connection with this class of cases from the realms of hypothesis and metaphysics to those of tangible fact.

Absorption of Poisons.—J. S. Metzler¹ found that by ligating the stomachs of rabbits and dogs at cardia and pylorus strychnin could be retained for even 15 hours without producing any effect. Prussic acid under the same conditions was promptly toxic, ecchymoses of the mucosa leading to the inference that the difference was due to its direct absorption through lesions produced in the blood-vessels by contact.

The distribution of poisons in the body has been studied by A. Lesser² on a large scale (231 cases), his paper, however, not yet being completed. G. Miller³ found that after a few days burial strychnin became diffused through all parts of the bodies of rabbits when injected after death into any of the body-cavities.

Effect of Bacteria on the Toxicity of Alkaloids.—S. Holenghi⁴ found that the potency of weak atropin solutions in bouillon was progressively weakened by growth of *B. coli* and other putrefactive bacteria. Strychnin solutions at first showed an increase to double or treble the original toxicity (estimated by observing the degree of dilution in which a distinct physiologic effect was still obtainable), followed by a gradual diminution after the end of the first week.

PUBLIC HYGIENE AND PREVENTIVE MEDICINE.

BY SAMUEL W. ABBOTT, M. D.,

OF BOSTON, MASS.

Introductory.—Progress in public hygiene in the United States has steadily advanced in the past thirty years or more. During that time nearly every State has established its Board of Health, and all the cities and many large towns now have local Boards of Health. Medical men have always constituted the most important factor in such boards, and will undoubtedly continue to fill such places in the future. The most important department of public hygiene is the management and control of infectious diseases, and one of the principal objects of preventive medicine is the limitation of the spread of those diseases which are preventable and are mostly of the infectious class. The subjects of isolation, quarantine, disinfection, notification of disease, hospital provisions, the supervision of water-supplies and systems of sewerage, plumbing-inspection, burial or disposal and transportation of the dead, and school-inspection, all are related more or less intimately with the general subject of disease-prevention. To these may be added such groupings or general topics as municipal hygiene, which embraces many of the foregoing subjects, the hygiene of occupations (industrial hygiene), food- and drug-inspection, the sale of poisons, and finally, as a basis of fixed and definite information as to the value of many of the foregoing measures, vital statistics.

THE MANAGEMENT AND CONTROL OF INFECTIOUS DISEASES.

Susceptibility to Infection in Relation to Age.—In his *Fourteenth Report for the City of Providence, R. I.* (1896), Chapin continues his researches on scarlet fever and diphtheria. These are directed to ascertaining the percentage of persons of different ages exposed to each of the above diseases who either contract them or fail to do so. The results are embodied in statistical tables, which possess a high etiologic value. It is obvious that the value of such tables depends on the care with which the data are obtained and the certainty that a uniform system of inquiry is pursued throughout. The headings of Chapin's returns are too copious to reproduce in their entirety; but the following will indicate the scope of the inquiries: number of families in which there was more than one susceptible child; number of families in which there was a second case; number of susceptible children in all the above families; number of these children who were attacked, etc., etc.

A separate table gives the ratio of cases to number of presumably susceptible persons exposed to infection. During the last ten years, for scarlet fever the ratio was as follows: for infants under one year, 26.3%; for the second year of life, 47.6; third year, 58.0; fourth year, 62.6; fifth year,

66.3; sixth year, 63.5; seventh year, 66.2; eighth year, 62.3; ninth year, 55.0; for adults over 20 years, 6.0. The percentage for scarlet fever at all ages was 38.4; that for diphtheria 30.6; the highest susceptibility for diphtheria (62.7%) was at 4-5 years, and corresponded with the age at which the susceptibility was highest for scarlet fever.

The Value of Health-resorts for Consumptives.—The German Society of Public Health voted to recommend the collection of statistics of persons who have been treated at such homes or resorts, the inquiry to include a period of five years after leaving them.¹ The following conclusions were also presented for discussion at the same meeting: 1. Since neither the destruction of the specific cause of the disease nor the treatment of the sick by tuberculin has produced a demonstrable lessening of consumption, the health authorities turn to the hygienic and dietetic treatment, which can be conducted in sanitary homes or resorts. [This statement is altogether too dogmatic and exclusive. Lessening of the death-rate from phthisis is continually going on, and is due to a much greater number of factors than is admitted in the foregoing paragraph.] 2. Such resorts can only limit the spread of consumption, and that gradually, when they are erected in large numbers and are accessible to the poor. 3. The duty (of providing such resorts) rests upon those insurance companies which provide against disability from sickness and old age. These companies have the right to treat their insured before the period of breaking-down, in order to avoid that condition. In the effort to make use of this right, these societies should place the tuberculous patient as soon as possible in a health-resort, since it is only in the first stages of illness that the disease may be arrested and the working-powers of the sick man restored or preserved. Hence these organizations should aid in providing such resorts. 4. Sanitary homes for consumptives should be arranged and conducted on correct hygienic principles. They may be plainly furnished, but must contain everything that, according to experience, is necessary to increase the resistance of the human body against the development of tuberculosis. 5. These resorts should be provided with all the necessary apparatus for destroying the specific germs of tuberculosis, and making them innocuous to the neighborhood. 6. Without the constant services of a wise superintending physician the success of such treatment will be questionable. It is his duty to maintain the courage of the patient by the influence of his own personality, and to accustom him to that mode of life which is essential to his recovery, so that, after his dismissal, he will continue to practise the same mode of life at home.

The Imperial Board of Health of the German Empire, in a recent circular² upon the same subject, first calls attention to the prevalence of **tuberculosis** in the German Empire and **its incidence upon the wage-earning period of life**. (Out of a total of 268,500 deaths of persons between the ages of 15 and 60 years, 88,654, or almost one-third, were from tuberculosis.) It also calls attention to the proofs of the curability of the disease existing in the frequent occurrence of autopsies in which the evidence of cure is found. Furthermore, the circular cites the experience of the German Sanitaria, Görbersdorf and Falkenstein, and that of the large insurance companies which provide against disability from disease. The **value to the Empire of the added length of life** in persons who have been cured or whose health is improved is estimated at $7\frac{1}{2}$ million marks, or a little less than 2 million dol-

¹ Deutsch. Vierteljahr. f. öff. Ges. und Gesundheitspflege, 28, 1, 104, 1896.

² Ein Beitrag zur Beurtheilung des Nutzens von Heilstätten für Lungenkranke, Bearbeitet im Kaiserlichen Gesundheitsamte, Berlin, 1896.

lars annually. Hence the circular commends the establishment of homes for consumptives as a "blessing to mankind."¹

Report of the Metropolitan Asylums Board (London) upon Antitoxin in Diphtheria.—The prominent point brought out in this report, as in nearly all recent reports upon the subject, is the necessity of beginning the antitoxin treatment as early in the course of the disease as possible. Comparing the results obtained under this treatment in 1896 with those of the non-antitoxin year 1894, the following figures are presented: Cases treated in 1894, 3042—fatality, 29.6 %; in 1896, 4175—fatality, 20.8 %.

Fatality according to Day on which Treatment was Begun.

Day of first treatment.	Fatality (per cent.)		
	London.		Massachusetts.
	Antitoxin, 1896.	No antitoxin, 1894.	Antitoxin in 1895 and 1896.
First	4.7	22.5	1.5
Second	12.8	27.0	8.1
Third	17.7	29.4	9.5
Fourth	22.5	31.6	18.1
Fifth	24.6	30.8	16.0
All cases	20.8	29.6	11.8

The lowered rate of mortality represents 365 lives saved. The report concludes as follows: "We have only to add that we still hold to the opinion that in the antitoxic serum we possess a remedy of distinctly—greater value in the treatment of diphtheria than any other with which we are acquainted." The figures for Massachusetts are added to the foregoing table.

The following statement is made in the *Twenty-eighth Annual Report of the State Board of Health of Massachusetts* (1896): "The most important lesson which is taught by these returns is the necessity of prompt administration of antitoxin in each and every case."

Conveyance of Typhoid-fever Infection by Means of the Air.

—E. Gennano,² in a paper on the aerial convection of disease-germs, details the results of a series of experiments in which sterilized floor-dust, sand, peat, and loam were inoculated with a culture of the typhoid bacillus. Equal portions were dried, in some cases quickly, in others slowly, and in others but very little, and the length of time in which cultures might be obtained from them was compared. He concludes from these experiments that the typhoid-bacillus cannot live in the dried state, and hence dry dust cannot convey it. Moreover, it retains great vitality in moist places, and can exist in an *apparently* dried condition, such as is presented when it is surrounded by materials such as linen, articles of clothing, wood, and lumps of earth containing feces, which have moisture of their own, but as they become dry the bacilli perish. The danger is not that the bacilli pass into the air from them, but that particles of the materials containing bacilli are conveyed directly or indirectly to the mouth by the hand and by food and dishes. This character of the bacillus of retaining its vitality in a partially dried state must be considered as the chief source of infection. In his opinion, air-infection, especially from a dis-

¹ See also on the same subject, *Recueil des Travaux de Comité Consultatif d'Hygiène publique de France*, 25, p. 72, Melun, 1896. Also, *Ueber Volkshelstätten für Lungenkranke*, Georg Liebe, Breslau, 1896.

² *Zeit. f. Hyg.*, xxiv., 3, p. 423.

tance of several hundred meters, as maintained by Froid-boise,¹ must be absolutely impossible, and in this respect the typhoid-bacillus is like the cholera-germ. Air-infection by typhoid fever presupposes a mechanical attrition of material so fine that it becomes dry and consequently dies. [The chief method of transmission of typhoid fever infection is through the medium of water and milk, the latter being only a disguised form of the former. In a review of forty years' work of the Health Department of Glasgow, the author, J. B. Russell, says: "If we consider the history of enteric fever in detail, we observe that everything like an epidemic prevalence has been caused by the distribution of infected milk."²]

Unusual Sources of Typhoid Fever.—In addition to the recent attacks of illness due to the eating of oysters which had been gathered in waters polluted with sewage, reported in the special report of the Local Government Board,³ another similar source is mentioned by Ramaroni,⁴ of Bastia, Corsica. The author names five different kinds of shell-fish (mostly gasteropod mollusks, snails, limpets, etc.) which are usually eaten raw. These are collected near the mouths of sewers of the city and the public abattoir chiefly during the months of December to April, and in these months there has been during the past few years a decided increase in the prevalence of typhoid fever, contrary to the usual habit of prevalence in the autumn. The use of oysters as food increases largely in September, in accordance with a popular impression that they are not as healthful in the summer months. A writer in the *Boston Medical and Surgical Journal*, under the head of "Oysters and Typhoid Fever," calls attention to the fact that many cases of typhoid fever occurring in cities having good water-supplies are unexplained, and that their occurrence may be due to the increased consumption of oysters from bays and harbors largely polluted by sewage.⁵ Geschwind⁶ states that the kitchen gardeners of Bayonne are accustomed to sprinkle the foliage of certain leguminous plants with the contents of privy vaults diluted with water, and that the products are eaten raw as a salad. Several cases of typhoid fever among the officers of the garrison were traced to this source, and an expert found upon these plants the bacilli of typhoid fever, the coli communis, streptococci, staphylococci, the bacillus tuberculosis, and the joints of tenia.

The Notification of Measles.—With reference to the propriety of considering *measles* as a notifiable disease, English authorities appear to be divided in opinion.⁷

Transmission of Anthrax-infection by Hides and Leather.—G. Giuglio,⁸ of Palermo, has demonstrated by experiment on guinea-pigs the possibility of transmission of anthrax-infection by hides and leather after they have been submitted to the ordinary processes of tanning.

Disinfection by Formaldehyd.—Recent valuable articles upon the efficiency of formaldehyd have been contributed by Walter,⁹ Pfuhl,¹⁰ Strüver,¹¹ and Kinyonn.¹²

¹¹ Ibid., vol. xxv., p. 386.

¹² Weekly Reports of Marine-Hospital Service, Jan. 29, 1897.

Walter's conclusions, from his investigations, are as follows: 1. Formalin in the strength of 1:10,000 arrests the growth of the germs of anthrax, cholera, typhoid fever, diphtheria, and staphylococcus pyogenes aureus. 2. In the gaseous form it arrests growth, even when greatly diluted. 3. In 1% solutions it kills pure cultures of pathogenic germs in an hour. In diluted alcoholic solutions the effect is more intense. 4. In 3% solutions, especially with the addition of alcohol, the hands may be freed from all germs. More extended investigations are necessary to show the degree to which the skin is affected. 5. By spraying artificially infected matter with formalin solution, and afterward enclosing it in air-tight vessels, such matter may be sterilized. 6. By means of formalin (or in other words formaldehyd) leather articles, uniforms, etc., may be thoroughly disinfected in large quantities, and without in any way injuring these articles; 24 hours' exposure are requisite for such disinfection. The possibility of disinfecting rooms may be considered as demonstrated by other experts. 7. Feces are almost instantly deodorized by a 1% solution, and are disinfected (germ-free) in ten minutes by a 10% solution. 8. Formalin acts well as a caustic. 9. It is an excellent preservative.

The Relation of Infectious Diseases to the Milk-supply.—W. T. Sedgwick¹ presents in a very clear manner the sanitary requirements of a good milk-supply.²

The Effect of Cemeteries upon Health.—Experiments conducted by Lösener for the Imperial Board of Health of Germany³ showed that little harm need be feared in consequence of any escape of disease-germs from properly constructed graves to the surrounding soil or to neighboring water-supplies.

WATER AND WATER-SUPPLIES—SEWERAGE AND SEWAGE-AND REFUSE-DISPOSAL.

Treatment of Water Containing Lead.—The health officer of Pudsey, England, presents the results of experiments intended to remove the lead from the public water-supply of that town.⁴ The method adopted was simply the addition of 3 gr. of chalk to each gallon of water. The water was drawn the first thing in the morning from a lead service-pipe 180 ft. in length. Lead-poisoning had been prevalent in that town. The following results were secured by the adoption of this treatment. The two years 1892 and 1896 are selected because in the former year no treatment was employed, while in 1896 it was employed throughout the year.

Months.	Monthly average grains of lead per gallon.

⁴ Annual Report for 1896 of Medical Officer of Health, Pudsey, England.

The Softening of Hard Water.—The subject of softening hard water in those parts of the country which rest upon a stratum of limestone has not received in the United States the attention which it demands. The following statement,¹ however, shows that the question has decided economic value: "The hardness of the metropolitan water-supply is due almost entirely to the presence of the bicarbonate of lime in solution, which can readily be removed by treating the water with lime, as is successfully done by the Colne Valley Company. By this treatment with lime its hardness is reduced to about one-fourth of its original amount. This mode of softening water would appear to be the most economic, unless it can be shown that less than one-eightieth of the total supply is used for washing, for it entails only about one-eightieth of the expense incurred by the private consumers in the shape of additional soap."²

Sewer-gas and Sewer-ventilation.—Edward Walford³ concludes, after a careful investigation of the subject of sewer-ventilation, "that there is very little reliable evidence to show that the ordinary specific infectious diseases are caused by inhaling sewer-gas, and that usually, where sewage is responsible for their causation, the mischief has arisen through swallowing either water or food which has become contaminated with sewage-matters."

FOOD- AND DRUG-INSPECTION.

The Practical Advantages of Food- and Drug-inspection.—The Food and Drug Statute of England was enacted in 1875, and the first full report of the Local Government Board upon its operations was for the year 1877, so that the people have had the protection which it affords for about 20 years. The following figures represent the improvement which has actually taken place, comparing the figures of the first report (1877) with those of the last published report (1895). They are as follows (condensed):

Percentage of Samples Adulterated, as found by the Government Analysts.⁴

	1877.	1895.
Milk	24.1	11.1
Flour	6.0	..
Coffee	17.5	10.0
Mustard	18.8	6.0
Butter	10.8	8.2
Bread	7.4	1.7
Wine	32.2	8.3
All articles	19.2	9.3

This very satisfactory result, a reduction of the actual ratio of adulteration by more than one-half, represents a very great gain to the general consumer in the quality of many of the ordinary articles of food which are subject to adulteration. The results obtained by a similar inspection in the continental cities, especially in Paris and the cities of the Swiss cantons, are very much of the same character. In Massachusetts a similar law has been in operation

¹ E. Frankland's Report on the Examination of the Water supplied by the Metropolitan Water Companies; Twenty-fifth Annual Report of Local Government Board, 1895-96, p. 279.

² For further valuable information upon this point, reference may be made to the two following treatises on water: Water and Water-supplies, by John C. Thresh, London, 1896; Chapter on water-softening. Water and its Purification, by S. Rideal, London, 1897.

³ Sanitary Rec., p. 119, July 30, 1897.

⁴ Reports of Local Government Board, England, for 1877 and 1895.

14 years, and the results of the examination of about 80,000 samples of food and drugs, with about 1200 prosecutions of offenders, have shown a marked reduction in adulteration and a consequent improvement in the food-supply. The following extract from the *Twenty-seventh Annual Report of the State Board of Health of Massachusetts*, p. 647, serves to illustrate the foregoing statement: "In 1884, soon after the enactment of the law and before an adequate appropriation had been provided for its enforcement, an examination of spices and cream of tartar, and other articles of food, as sold in open market in Massachusetts, gave the following results [examinations of similar articles made in 1896 showed a marked improvement in each instance]: Samples of spices collected in 1884, 431; number adulterated, 216, or 50.1%. Samples of spices collected in July, 1896, 78; number adulterated, 2, or 2.6%. Samples of cream of tartar collected in 1884, 232; number adulterated, 77, or 33.2%. Samples of cream of tartar collected in July, 1896, 25, of which 1 was adulterated, or 4%. Out of 123 samples of butter, cheese, tea, coffee, and confectionery collected in 1884, 15, or 12.2%, were adulterated. Out of 82 samples of the same articles collected under similar conditions in July, 1896, all proved to be genuine.

INDUSTRIAL HYGIENE.

The Health of Zinc-workers.—The results of observations made upon the health of 1300 zinc-workmen by Seiffert¹ show that the blue line, the atrophy of parts about the mouth, the mucous membrane, adipose tissue, and muscular system, with changes in the tissues of the nervous and vascular systems and kidneys, point directly to lead-poisoning, and the actual use of 1% to 2% of lead as an alloy is sufficient to explain the trouble.

Prevention.—The author suggests the following remedies: 1. Among the young, only well-developed persons in perfect health and over 18 years of age should be employed. 2. The chief cause of the trouble is the dust of the workshops. Copious sprinkling of material, floors, and passage-ways should be done. 3. Gases and smoke should be carried away from the workmen. 4. Fresh water should be supplied in quantity sufficient for drinking-purposes. Drinking from open vessels exposed to the action of heat and dust should be forbidden. Water should be drawn from faucets and the mouth should be rinsed. Spittoons should be furnished for tuberculous workmen. Eating in the shops and the storage of food in them should be forbidden. Eating in rooms separate from the workshops should be encouraged. Other essential requirements are the provision of soap in abundance, the removal of sweat and poisonous dust from the body immediately after working-hours, changing of clothing after work, and the prevention of indulgence in drink. [Thus far very little has been accomplished in the way of investigations in industrial hygiene in America. There is here a wide and useful field for inquiry among the operatives in our manufacturing cities and mining districts.]²

In treating of the frequency of **consumption among workmen** Sommerfeld³ presents several tables. The following shows the mortality of such workmen from consumption as compared with the general mortality: the figures on the right show the deaths from consumption in each 1000 deaths

¹ Deutsch. Vierteljahrs. f. öff. Gesundheitspflege, 29, 3, 419, 1897.

² See also upon the same subject Hartmann's statement (Jahresber. d. preuss. Gewerbe-räthe, p. 187) that out of 2452 workmen in the zinc-works of Silesia (members of sick-benefit societies) there were 1382 cases of illness in 1893, or 56.3%, of which 11.9% were from diseases of the digestive organs, 1.6% from lead-poisoning, and 8.3% from rheumatism.

The Ventilation of Railway Cars.—In a lecture before the Franklin Institute of Philadelphia C. B. Dudley,² Chemist of the Pennsylvania Railroad Company, admits “that it is not possible at the present time properly to ventilate a passenger-car on a railway.” He states the problem as follows: “An ordinary passenger-coach contains about 4000 cubic feet of space. It is proposed to take into this small space at least sixty persons: to keep them in this space continuously, without allowing them a chance to get out, for four hours or longer; to keep them warm enough for their comfort in winter; and to supply them with enough fresh air to ventilate the car properly and at the same time exclude, throughout the year, smoke and cinders, and in the summer season dust. No problem has ever been committed to the experimental and mechanical engineering departments of the railroad so difficult of solution as this problem of ventilation.” By experiments with improved ventilators, plans of which were shown in the paper quoted, Dudley found that it was possible to take into the car 90,000 feet of fresh air in an hour; but this air could only be warmed about 40° above the temperature of the outer air. Hence, with an outdoor temperature of 0° such a car would be uncomfortably cold. Experiments are still in progress to secure better results. As a result of the experiments already made, Dudley says: “It is possible to get much more air into a car than any system now takes in. If we could content ourselves with 20,000 to 40,000 feet of air per hour in severe weather, it is possible to have such a system put on the cars to-day. In milder weather this amount could be increased to the full capacity of the system.”

VITAL STATISTICS.

Vital Statistics of the German Empire in 1894.—Rahts³ statement of the causes of death in the year 1894 in the German Empire, recently published, is a model report, and contains in a condensed form very full statistics of the mortality of the empire. It is illustrated with four excellent maps, representing the distribution of mortality from tuberculosis, acute lung dis-

¹ See also the reports of the Parliamentary Committee upon Dangerous Trades (London, 1896 and 1897), upon the dangers incident to the following occupations: bronzing, paper-staining and -coloring, the use of locomotives in factories, India-rubber manufacture, inflammable paint, dry-cleaning, the bottling of aerated waters, electric generating works, and wool-sorting and kindred industries.

² Jour. Franklin Institute, p. 3, July, 1897.

³ Ergebnisse der Todesursachenstatistik. Medicinal-statistische Mittheilungen aus dem Kaiserlichen Gesundheitsamte, 3, pp. 129-181.

eases, and the diseases incident to childbirth, with the mortality of infants under one year. The results of the summary are stated as follows :

1. The deaths in 1894 were less in number than those of 1892 or 1893. The difference between the mortality of 1893 and that of 1894 amounted to 2000 per million inhabitants. 2. The greatest decrease in the death-rate was among adults beyond the age of 60 years, and the principal decrease was in the deaths from acute lung diseases and influenza. The general death-rate was 22.4 per 1000. 3. There was a decrease in infant mortality (deaths under one year) which was coincident with a lessened birth-rate—the infant mortality amounted to 211 deaths (under 1 year) in 1000 births. About one-third of these deaths were due to intestinal catarrh. 4. The death-rate of childhood (1–15 years) has diminished more noticeably than the general death-rate. The mortality from diphtheria was less than that of the two previous years. Out of each 11 deaths at this time of life (1–15 years) 3 were from diphtheria. 5. More than one-third of the deaths of adults (15–60 years) were deaths from tuberculosis. 6. The lowest death-rate of adults (15–60 years) from tuberculosis occurred in three districts where the infant-mortality was high. Tuberculosis destroys the greatest relative number of adults in those districts where newborn infants survive in greatest numbers. 7. The increase of population in the course of one year was, therefore, more marked in districts having a high than among those having a low infantile death-rate.

The Decline in the Death-rate from Infectious or Preventable Diseases.—Kruse¹ shows very conclusively the decline in the death-rate from typhoid fever, diarrhea, small-pox, deaths in hospitals after surgical operations, etc., during 20 years in Germany. The ratio in successive five-year periods for typhoid fever per 10,000 living were as follows for 1875 to 1894: 6.17, 4.99, 2.78, and 1.86. Diarrhea, 1.63, 1.59, 0.45, and 0.3. Scarlet fever, erysipelas, consumption, and deaths after surgical operations also showed a similar decline—that of consumption being from 52 to 36.

The saving of human life in consequence of the reduction in the mortality from infectious diseases in Prussia is estimated by him at 70,000 persons in one year.

In Massachusetts the decline in the principal infectious diseases in the forty years 1856–95 was as follows—by five-year periods, including also the deaths from consumption and childbirth :

*Death-rates from Certain Causes and Groups of Causes by Five-year Periods (1856–95).*²

² Twenty-eighth Report of State Board of Health of Mass., p. 816, 1896.

The Extent of the Losses due to Ill-health.—The great object and end of sanitary work are the diminution of disease and the consequent prolongation of human life. The actual magnitude of the losses due to impaired health is stated as follows, by the Imperial Board of Health of Germany.¹ The estimate is made from the statistical returns of the workingmen's clubs. In 1891, out of a total membership of 6½ millions, there were more than 2,000,000 cases of sickness, each of which lasted about 17 days, on an average. These clubs paid out for medical attendance nearly 22 million dollars. Since it is safe to assume that among the remainder of the German population 24 millions of whom are old enough to work, the cases of illness are quite as numerous and protracted as among the insured members of clubs, the expenses of sickness in Germany in one year is not reckoned too high at 120 million dollars. In this sum the loss due to the stoppage of wages is not included.

¹ Gesundheitsbüchlein, p. 1, 1896. Introductory remarks.

PHYSIOLOGIC CHEMISTRY.

By JOHN J. ABEL, M. D.,

OF BALTIMORE, MD.

During the Year.—Among the more valuable papers that have appeared are those of Mörner, on the proteids and proteid-precipitating substances of the normal urine; of Blumenthal and others, on animal substances which yield on decomposition one of the sugars; of Nencki and his pupils, and of Kaufmann and Schöndorff, on the distribution of ammonia and urea, and on the seat of formation of urea; of Siegfried, Witmaek, and Müller, on the occurrence of phosphosarcic acid, or nucleon, in human milk, etc.; of Schlossmann, on the separation of the proteids of milk; of Jaffé and Hirschl, on phenylhydrazin precipitates in the urine. Many papers describing methods, more or less useful to the physician, for the detection of albumin, albumoses, peptones, urea, etc. in the urine, have also been summarized or referred to. Some of the recent and most valuable investigations in physiologic chemistry are described in such voluminous and technical papers that it is impossible to incorporate their results in the space at our disposal.

Acetylene.—C. O. Southard¹ gives a short account of the properties of this hydrocarbon, C_2H_2 , and of the methods for its manufacture, and thinks it ought to be of value as an illuminant for throat-work, etc., for physicians living in places where gas is not obtainable. Its explosive power is greater than that of gas, but it is no more dangerous when the proper precautions are taken. Brass should be avoided in pipes and burners intended for use with acetylene, as it unites with copper to form solid copper acetylene, which explodes violently on percussion or on heating to $200^\circ C$. The danger from poisoning is also pointed out, and it is asserted that the gas acts on blood similarly to carbonic oxid, only less energetically. This is, however, disproved by the recent excellent researches of Rosemann,² who finds, contrary to the older statements of Liebreich and Bistrow, that acetylene does not combine with hemoglobin, thus substantiating the experiments of Hermann and the more recent work of Ogier. Spectroscopic examination reveals no compound with hemoglobin. If such is formed, it is probably unstable and very different from carboxyhemoglobin. Conflicting statements as to the toxicity of acetylene having been made by previous investigators, Rosemann has made a considerable number of experiments, and finds that this gas is considerably less poisonous than pure carbonic oxid and also less poisonous than illuminating-gas. It should be borne in mind that Rosemann assumes that illuminating-gas contains only 8.88% of carbonic oxid, whereas most of the gas now used in our cities contains as much as 30%. Attention is also called to the toxicity of the products which may contaminate acetylene, such as sulphuretted and phosphoretted hydrogen. The recent experiments of the French authors, Gréhan, Berthelot, Moissan, and Brocinet,³ also show that the poisonous action of acetylene has

¹ Pacific Med. Jour., Sept., 1896.

² On the toxicity of acetylene, Arch. f. exper. Path. u. Pharmacol., vol. xxxi, p. 179.

³ Reviewed in Boston M. and S. Jour., July 30, 1896.

been greatly exaggerated, and when such was attributed to it, it was probably due to impure gas, CO or HCN.

Albumin-testing.—Tanret's Reagent.—A. R. Elliott¹ sets forth the delicacy and practicability of Tanret's method of detecting albumin, and points out to the practitioner how Tanret's reagent, which precipitates all modifications of albumin, as well as mucin, oleoresins, and alkaloids, may be made useful in a routine method for detecting and distinguishing different urinary proteids. Elliot, however, takes no note of the precipitation of bile-acids by Tanret's reagent, as was pointed out by Brasse² some years ago. Should such a precipitate be met with, it will be found to dissolve in ether; nor is mention made of the fact, to which attention is called in the treatise of Neubauer and Vogel, that uric acid may be precipitated by this reagent as above prepared.³ This precipitate, which is perhaps rarely met with in actual urine-testing, is soluble on boiling and is easily distinguished from proteids. It may also be avoided by diluting before testing.

Jolles⁴ announces a corrosive sublimate solution as a most delicate and practicable reagent for the detection of albumin in the urine. Glas,⁵ Fürbringer,⁶ and Spiegler,⁷ have all preceded Jolles in setting forth the claims of corrosive sublimate as a proteid precipitant, but Spiegler's work in this field is alone referred to. Jolles's solution has the following composition: hydrarg. bichlor. corros., 10; natrium chloratum, 10; acidum succinic., 20; aqua distill., 500. This reagent has the great advantage of being colorless; it may be applied to any urine, no matter what its composition may be, and when the result is negative one may rest assured that no traces of proteid, or at least none such as have a pathologic significance, are present. The test is made as follows: to 4 or 5 c.c. of filtered urine 1 c.c. of acetic acid (30%) and 4 c.c. of the reagent are added, and the whole is then shaken. To a second test-tube containing 4 or 5 c.c. of the same urine and 1 c.c. of acetic acid about 4 c.c. of distilled water are added and also shaken. This control-test is made to eliminate the disturbing action of mucin. A greater turbidity in the test-tube containing the reagent and urine indicates that albumin is present. The delicacy of the test is such that it still detects albumin when present in the proportion of 1:120,000. If iodids are present, a precipitate of mercuric iodid is formed, which is soluble in alcohol. The reagent has a specific gravity of 1.040, and may be used in the "contact-method," a method which is especially serviceable when the urine is loaded with bacteria, as no attempt to clarify the urine need first be made if the test be applied in this way.

Asaprol.—Aseptol.—Refractometer Method.—E. Riegler⁸ announces that asaprol in 10% solutions is a very delicate reagent for albumin. To 4 or 5 c.c. of urine 1 or 2 drops of hydrochloric acid and 10 drops of a 10% solution of asaprol are added. A precipitate indicates that albumins, albumoses, or peptones are present. Albumin is present if the contents of the test-tube remain cloudy on boiling. Aseptol, or orthophenolsulfonic acid, is, according to Riegler,⁹ also well adapted to detect albumin when present in the proportion of 1:20,000. Like asaprol, this agent precipitates albumins and peptones, and the precipitates in this instance also clear up on heating. To 5 c.c. of urine 15 or 20 drops of the commercial solution of aseptol (33 $\frac{1}{3}$ %) are added; the reagent is also serviceable in removing pro-

⁹ Wien. klin. Woch., No. 2, 1892.

teids preparatory to making tests for sugar. Riegler prefers asaprol to asaptol because its solutions are less decomposable. In a later paper the author describes a quantitative method of estimating albumin, which is based on the examination of the precipitate obtained with asaprol. This precipitate is dissolved in $\frac{1}{10}$ normal alkali solution, and then tested with Pulfrich's refractometer. The index of refraction of the alkaline solution of the urinary albumin varies with the concentration of the solution, and hence when constants and standards are given it becomes a simple method to calculate the amount of proteid present.¹

The Sulphosalicylic Acid Test.—R. Stein² sets forth the claims of the "sulpho-test" of Reoch and MacWilliams. Stein's method of employing this test is to add some crystals of sulphosalicylic acid to a small quantity of filtered urine in a test-tube. On shaking the tube a white homogeneous precipitate falls out instantly if considerable albumin is present, while with only very small quantities a cloudiness appears. Peptones and albumoses, which are also precipitated, are detected on boiling, when their precipitates will dissolve. The sulpho-test is thought by Stern to be of great value in cases with the small contracted kidney, when urine of low specific gravity is voided and when only very small quantities of albumin are present. Stein attributes to this test a very superior delicacy.

Ammonium Molybdate.—Yavorovsky³ describes the following test. He "adds an excess of sodium carbonate to the urine, filters it, evaporates it to one-third of its volume, and then filters it again. To 4 c.c. of the filtrate is added one drop of a solution of 1 part of ammonium molybdate and 4 parts of citric acid in 40 parts of water. If albumin or peptone is present, cloudiness results either immediately or after a certain time. If this is due to peptone, it dissolves on warming and reappears on cooling." A. G. R. Foulerton⁴ gives a study, for clinical purposes, of many of the methods in use for the detection of albumin and allied substances which occur in the urine in disease. The paper contains a table giving the reactions of albumin, albumoses, and peptones when nitric acid, Spiegler's solution, potassic ferrocyanid, metaphosphoric acid, picric acid, the biuret reaction, and the xanthoproteic reaction are used. It is also called to mind that the differentiation of proteoses and the separation of albumoses and peptones are by no means so simple a process as a tabular account of reactions might lead the physician to suppose. Foulerton also gives a list of many of the diseases in which proteosuria or peptonuria has been met with.

Albumosuria.—The recent investigations on albumosuria by Huppert,⁵ Zeehuisen,⁶ Haack,⁷ and on the connection between circulating albumoses and febrile states, by Krehl and Matthes,⁸ and Schultess,⁹ and others all demonstrate the practical importance that attaches to a knowledge of methods for separating proteoses. Leick¹⁰ has found that albumosuria occurs in fibrinous pneumonia at all stages of the disease.

Proteids and Proteid-like Substances in Normal Urine.—Many urinologists hold that the employment of exceedingly sensitive tests for albumin in the urine is to be criticised, not alone on the grounds that a mere trace of albumin is too readily accepted as the sign of a pathologic condition, but also because the sensitive tests so frequently require the exercise of a nice

chemic discrimination to decide whether the precipitate obtained is a normal constituent of the urine, albumin, a drug, or what not. The wide employment, however, of these sensitive tests gives new interest to the minute study of the urine. The distinguished physiologic chemist K. A. H. Mörner¹ has recently contributed an exhaustive study of the nature of the proteids and proteid-precipitating substances present in normal urine, and he concludes from his work that every so-called normal urine from adults of both sexes contains albumin, and also, as a rule, certain substances, chiefly chondroitin-sulphuric acid, which, when present in relatively large amount, may conceal the ordinary properties of the proteid, altering its coagulability and precipitability. Large quantities of urine, often as high as 250 liters, were required. The proteid-like material, always present in the form of a mucous cloud or nebeula, he collects as a sediment from urine preserved with chloroform, and finds that it consists of a *urine-mucoid* precipitated by acetic acid and a water-soluble mucin, which differs probably only in a minor way from the former. Both probably originate from the mucous membranes of the urinary passages. Boiling with mineral acids develops a strongly reducing-substance. The urine-mucoid is described as levo-rotatory (62° to 67°), has the percentage-composition C 49.4, N 12.74, S 2.3, and gives the proteid color-reactions. The results of certain experiments, such as boiling with hydrochloric acid, led Mörner to class this mucoid with the keratomucoids. The proteid matter which is held in solution in normal urine, hitherto described as "dissolved mucin," "mucin-like substance," or "nucleoalbumin," is found to consist chiefly of serum-albumin. The method employed to precipitate this serum-albumin was to shake dialyzed urine with chloroform, having previously added acetic acid. The proteid thus precipitated with acetic acid and chloroform consisted of serum-albumin in combination with nucleinic acid, chondroitin-sulphuric acid, and possibly other substances. In pathologic cases taurocholic acid may also acquire significance as entering into combination with serum-albumin to form with it a precipitable compound like those just referred to. The serum-albumin present is referred to the blood for its origin.

On the Uric-acid Zone in Heller's Test for Albumin.—T. Husche² has taken up the old question as to the composition of the white zone or cloud which more or less frequently interferes with the use of Heller's test. He finds that the uric-acid ring occurs only when highly concentrated urines are used, and that it agrees in appearance with Heller's description. It begins at a point a little above the line of contact of the acid and urine, has a sharply defined lower border, extending all throughout the supernatant layer of urine, and is completely dissolved by cautious heating. Sometimes the urates are thrown out in thick, flocculent streaks, gradually expanding as they extend upward; but more frequently, in place of these cloud-like streaks, a diffuse cloudiness is met with. According to Husche, most urines to which the test is applied show above the line of contact between acid and urine a fairly homogeneous cloudy layer, sharply outlined as to its lower surface, but extending upward in the form of a cloud. Previous dilution of the urine makes no change in the appearance of this zone, and heating does not cause it to disappear entirely, while on cooling it is often more marked than before and lies at a higher level. The genuine uric-acid zone never appears after previous dilution. The spurious zone just referred to is supposed to be caused by nucleo-albumins. Further communications are promised on this point. When

¹ Maly's Jahresh., vol. 25, p. 263; Skandinav. Arch. f. Physiol., vol. 6, pp. 332-437.

² Wien. med. Woch., June 19, 1897.

the urine contains albumin and is concentrated and rich in urates one may observe, first, the albumin-zone, more or less dense at the line of union between acid and urine, above this again the turbidity due to uric acid, and in this turbid space a cloudy disk which Husehe supposes to be caused by a nucleo-albumin.

Soluble Urates.—F. W. Tunnicliffe¹ publishes a preliminary note on the solubility of piperidin urate and hexamethylenamin urate in distilled water, but states that the physical conditions obtaining in blood and other physiologic and pathologic fluids differ sufficiently from those in distilled water to render further research necessary before any statements can be made as to the usefulness of the above bases in the treatment of lithemia in the human subject. Piperidin urate is soluble in distilled water at 36° C. or 98° F. to the extent of 9.1% ; hexamethylenamin urate at the same temperature is soluble to the extent of 3.3%. At 17° C. the former salt is soluble to the extent of 5.3% ; the latter to the extent of 0.7%. For purposes of comparison the solubility of the following known urates is given: piperazin urate at 17° C. 2% ; lithium urate, 20° C. 0.3% ; at 39° C. 0.9% ; potassium urate (acid salt), 20° C. 0.7%–0.8%. Further investigations are promised.

On the Danger of Filtering Urine with Talc.—Brandeth Symonds² finds by experiment that the use of purified talc for the purpose of clarifying urine and removing mucin and coloring-matters is to be avoided, since considerable albumin is also retained by the talc.

Ureometers.—Several ureometers have been described during the past few years, for each of which some special claim is made in the way of convenience, rapidity of manipulation, etc. G. A. Barbiera³ describes a new mercury ureometer of simple design for use in the hypobromite method. G. Cavallero,⁴ M. G. Mercier,⁵ and Th. Lohnstein,⁶ also describe forms devised by them. Linossier⁷ describes a very simple apparatus which can be put together at trifling expense. The calculation of the amount of urea corresponding to the observed volume of nitrogen is made after data furnished by Yvon, "allowance having been made for incomplete decomposition of the urea and of other nitrogenous substances, for temperature and pressure, etc."

Estimation of Urea.—E. Riegler⁸ describes a rapid and easy method of estimating urea based on the employment of Millon's reagent, which decomposes urea into equal volumes of carbon dioxid and nitrogen. The apparatus employed is simple. The results actually obtained vary from those required by theory by 0.01% to 0.52%. A. Kössel and H. Schmiel⁹ have compared the methods of estimating urea, which have been published by Gumlich, Mörner-Sjöqvist and Cazeneuve-Hugouenq, with a new method proposed by them. According to this method, 10 c.c. of urine to which a sufficient amount of barium carbonate has been added are put into a glass tube (sodium glass), which is then sealed and kept at 180 C. for one hour. The contents are then washed into a distilling-flask, barium hydrate is added, and the liberated ammonia is distilled into a $\frac{1}{10}$ normal hydrochloric acid solution, and thus estimated according to a well-known procedure. The new method was used in estimating the urea of normal and various pathologic urines, and was found to be satisfactory. The

results agreed with those obtained by the method of Gumlich; those obtained by the method of Cazeneuve-Hugoumenq were somewhat lower, and those by the Mörner-Sjöqvist method were slightly higher. A point which may have to be borne in mind is that kreatin and kreatinin can be made to yield ammonia when treated by Kossel's method.

Bernhard Schöndorff's Method.¹—This method, which requires considerable time, involves the precipitation and separation of compounds of the uric-acid series with the help of phosphotungstic acid, and determines the urea by decomposing it with phosphoric acid. From the ammonia obtained the amount of urea present is readily calculated. A second portion of the solution to be analyzed for urea is treated with an alkaline solution of barium chlorid and heated in sealed tubes to 150° C. The carbonic acid thus obtained as a decomposition-product of the urea is determined in the gasometric way according to Pflüger's directions. A control-analysis is also made to determine the amount of preformed carbonic acid present in the solution, and the amount thus found is deducted from that obtained (as above) by decomposition of the urea with barium chlorid. It will thus be seen that Schöndorff estimates the urea present in animal fluids and tissues by decomposing it and estimating not only the obtained ammonia, but also the carbonic acid; one serving as a control upon the other. The details of the method, the points to be borne in mind when kreatin and amido-compounds are present, cannot be given here, but must be looked up in the original. Further observations must determine the applicability of this method to the detection of very small quantities of urea.

Gréhant's Method.—M. Kaufmann² has examined the value of Gréhant's method for determining urea in blood and tissues. Gréhant's method dates from 1870, and makes use of a solution of mercury, 1 gm. in 10 c.c. of pure nitric acid, for decomposing the urea, the CO₂ and N liberated enabling one to estimate the urea. The method is well adapted to the estimation of urea in the blood, but in estimating urea in the tissues there is found to be a discrepancy in the amounts of CO₂ and N, other nitrogenous compounds being to some extent decomposed, yet even here the deviations from a standard estimation are not greater than when Schröder's method is used.

Urea in Animal Organs.—Making use of his method as just described, Schöndorff³ has studied the distribution of urea in the blood, in the muscles, heart, kidneys, and other organs of dogs fed on large quantities of meat, and concludes that the muscle-tissue contains urea, the identity of the urea being made to rest on the melting-point and the nitrogen-determinations. Urea was also found to be present in the red corpuscles, which contained as much as an equal amount of blood-serum. With the exception of the muscles, heart, and kidneys, all the organs were found to contain urea in about the proportion in which it is present in blood. M. Nencki and A. Kowarski,⁴ on the other hand, making use of v. Schöndorff's method, were unable to isolate any urea from 2.5 kgrm. of dog's muscle. These investigators compare all past statements as to the normal occurrence of urea in muscle to accounts of the sea-serpent. Their own method (stated in a few words) involves the use of phosphotungstic acid. The filtrate from the precipitate thus induced is freed from phosphotungstic acid, an alcoholic solution of organic substances supposed to con-

⁴ Arch. f. exper. Path. u. Pharmakol., vol. xxxvi., p. 395.

tain the urea is obtained, and after evaporating this with an alcoholic solution of *ortho*-nitrobenzaldehyd, urea, if present, will be thrown out as a white crystalline compound, melting at 200° C. and having all the properties of

This method, as the writer can testify, is exceedingly delicate, and, using it, the authors in question were unable to detect urea in the aqueous extract from 850 gm. of dog's muscle, or in 450 gm. of Liebig's extract. On the other hand, using only 100 gm. of dog's blood, they could easily detect urea in the form of its compound with *ortho*-nitrobenzaldehyd. Inasmuch as urea can be separated by several methods from the muscles of the ray and shark, and only negative results are obtained when the same methods are applied to mammalian muscle, they conclude that the latter contains no urea.

Seat of Formation of Urea in the Body.—M. Nencki, I. Pawlow, and I. Zaleski,¹ continuing the splendid work of Nencki and his pupils, have made careful estimations of the ammonia-content of the blood and various tissues, and their results are such as to strengthen the view that the liver is the chief urea-forming organ of the body. Every 100 gm. of blood from the portal vein contain on the average 3.4 times as much as NH_3 as an equal amount of arterial blood, and 3.5 times as much as the blood of the hepatic veins. The amount of NH_3 in both the blood and the organs is dependent on the nature of the diet, being much increased, especially in the liver, spleen, mucous membranes of the stomach and intestines, and muscles, when the dogs are fed on an exclusive meat-diet. The ammonia-content of the gastric mucous membrane is twice as high as that of the gastric contents, and is the result of a series of changes effected in proteids when the mucous membranes are in a state of glandular activity. The decomposable ammonia-compounds thus formed (carbarnates) are carried to the liver and there converted into urea. Directing the current of the portal vein into the inferior vena cava induces fatal ammonia-intoxication, on account of the accumulation of carbonic acid in the blood. Calculating from Cybulski's measurements of the velocity of the blood-flow in the portal vein and his own ammonia-estimations, Nencki concludes that the liver of the dog is able to hold back and convert into urea in the course of 10 hours as much as 4.72 gm. of ammonia, forming out of it 8.3 gm. of urea. It is admitted that the liver is not the only organ in which the formation of urea takes place; all the other organs of the body together, however, cannot compensate for the loss of the liver in regard to this function. The research in question is an exhaustive one, and note is taken of the objections that have been made by Pick, Lieblein, and Munzer to the view that the liver is the chief seat of urea-formation and to other points in the carbonic-acid theory of urea-function. M. Kaufmann² has also made, by means of Gréban's and v. Schröder's methods, extensive experiments on the question as to where urea is mainly formed. He tied the aorta and vena cava in the thorax and kept the animals alive for from 30 to 105 minutes after the operation by means of artificial respiration. The blood after this operation sometimes contained considerably more urea than before, pointing to the formation of urea in other organs than the liver, this organ having been cut off from all connection with the blood by the above-explained operation. The urea-con-

¹ Arch. des Sci. biolog. de St. Petersburg, vol. iv., p. 197.

² Arch. de physiol., vol. xxvi., p. 531.

tent of the blood of a starving dog was also compared with that of the liver, brain, muscles, and spleen. The blood contained 32 mgm. urea in 100 gm., the brain 86 mgm., the spleen 62 mgm., the muscles 64 mgm., the liver 109 mgm. in every 100 gm. of substance. Kaufmann concludes that while the liver is the chief seat of the formation of urea, the other organs named also all take a part in this function. W. H. Thompson¹ concludes from a series of experiments on the nature of the work of the kidney as shown by the influence of atropin and morphin upon the secretion of the urine, that the kidney is a glandular organ, comparable to the true elaborating glands, and that it elaborates a part of the urea excreted by it out of other substances.

Urea in the Portal Blood.—E. Cavazzani and L. Salvatore² have determined the urea in aqueous extracts of fetal blood by means of the hypobromite method, previously removing the proteids. They found that the average amount of urea in the fetal blood in 32 determinations was 0.215%. The amount thus found does not tally with that found in the maternal blood, and the authors think it probable that the fetus itself produces urea.

Nitrogenous Compounds of the Urine.—At the second international congress for applied chemistry held in Paris from the 27th of July to the 5th of August, the section devoted to medical chemistry and pharmacy adopted the following statements with regard to the nitrogenous compounds of the urine: 1. In the present state of our knowledge, provided that the proper experimental precautions be observed, the hypobromite method of estimating urea is to be considered as sufficiently accurate for the purpose of clinical research. 2. The total nitrogen of the urine is to be estimated by Kjeldhal's method. The calculated difference between the total nitrogen found and the amount of nitrogen in urea represents nitrogen in the form of "incompletely oxidized substances." 3. When a rigorous estimation of the amount of uric acid present is required, the Salkowski-Ludwig method is adopted by most authors. For practical purposes the method of Deniges, possessing, as it does, sufficient exactitude and quickness of execution, deserves to be adopted.³

Clinical Significance of Casts.—G. Barrie⁴ examined the urine of 50 inmates of a United States jail for albumin and casts, all the subjects being apparently in perfect health and varying from 15 to 65 years of age. In 40% of the cases casts of the hyaline and granular varieties were found, while in 1 case a few casts of the epithelial variety were found. The work of Gray, Shattuck, Brewer, Senator, Johnson, and others is commented on, and the general conclusion is arrived at that when apparently healthy persons exhibit both albumin and casts in their urine this state cannot safely be regarded as a truly physiologic condition, but in most such instances there is thought to be no doubt that the casts will disappear, the chances toward a serious result being about equal to those presented in a mild bronchitis. A few cases of renal insufficiency with all the symptoms of Bright's disease are also described, the outcome being sometimes fatal and again favorable, illustrating the fact that other things besides the mere urinary examination must be taken into account.

Preservation of Urinary Sediments.—Gumprecht⁵ points out the value of a method of preserving urinary sediments for teachers of clinical medicine and for medical experts. He collects the sediment by centrifugation, using tubes with a constricted neck terminating in a small globular enlargement at the lower end, as these allow the supernatant fluid to be poured off without disturbing the sediment. When enough sediment has been gathered

¹ Jour. of Physiol., vol. xv., p. 433.

⁴ Med. Rec., Jan. 23, 1897.

⁵ Centralbl. f. innere Med., No. 30, 1896.

a quantity of a $\frac{2}{10}\%$ solution of formalin is poured on it; the tube is shaken vigorously and then set aside. All constituents of the sediment retain their form and appearance. A series of sediments kept for a year were found to be unaltered, casts, epithelial cells, leucocytes, etc., retaining their original appearance. In order to avoid granular precipitations sediments from urines containing much albumin are washed once with physiologic salt-solution by the centrifugal method. Excess of urates may be removed by washing with warm water or concentrated solution of borax. In case red corpuscles or morphotie elements derived from erythrocytes are present in the sediment an aqueous solution of corrosive sublimate (1:20) is used for hardening. This solution is poured on the sediment prepared by centrifugation, the whole is shaken for five minutes, again precipitated, and washed six times by centrifugation with water or alcohol until all the sublimate has been removed, and then the formalin solution is added as already described.

Sugar in Urine.—Mark McDonald¹ points out the difficulties in deciding whether the urine contains a little sugar or whether it is simply that its normal reducing-substances are present in excessive quantity. The use of charcoal for removing the normal reducing-substances, as proposed by Sir William Roberts and by Seegen, is made the subject of a series of experiments. McDonald's results agree with those published by Seegen—namely, that filtration through animal charcoal leads to the loss of some sugar, the charcoal retaining it so firmly that even thorough washing will not remove all of it. The phenylhydrazin-test is also upheld by McDonald, who advises that small isolated crystals should be neglected in studying the precipitate produced by this reagent. The test may be rendered still more certain by treating a second portion of the urine with active yeast for from 12 to 24 hours, when on applying the test the result should be negative. J. Geyer² and others have attempted to show that the phenylhydrazin is poorly adapted to the determination of very small quantities of sugar. It must be admitted that the identity of the glycosazon-crystals can only be established with absolute certainty when melting-point determinations and analytical data are offered. J. A. Hirschl,³ in a valuable paper, replies to previous attacks on this method, and shows how the observance of a number of precautions may give to this well-known test a high degree of certainty. The characteristic needle-shaped crystals of glycosazon can always be secured when the fermentation-test gives positive results. The crystalline compound which is often thrown out in normal urines during the first fifteen minutes of heating, and which may be mistaken for a glycosazon, probably consists only of the glyeuromic acid compound of phenylhydrazin. In the course of further heating this disturbing precipitate turns into an amorphous brownish-yellow precipitate, which cannot be mistaken for the characteristic phenylglycosazon crystals.

Phenylhydrazin and Urea.—No one has yet determined in a satisfactory manner just what is the composition of the crystalline precipitate of needles, plates, burs, etc., which can be found in a large proportion of the urines of healthy people when this test is applied. M. Jaffé,⁴ in a very recent paper, has attempted the analysis of this precipitate, but thus far without a satisfactory result. He has, however, isolated from a precipitate similarly obtained from the urine of the dog a crystalline compound of urea and phenylhydrazin, known as phenylsemicarbazid, $C_6H_5NHCONH_2$. This compound crystallizes in plates, is soluble in hot water and hot alcohol, reduces Fehling's solution on boiling, and melts at $172^\circ C$. Jaffé has found that this

¹ Lancet, Sept. 19, 1896.

³ Zeit. f. physiol. Chemie, vol. 14, p. 377.

² Wien. med. Presse, vol. 30.

⁴ Ibid., vol. 22, p. 532.

compound is readily thrown out of dog's urine when the animals are fed on meat, not when they are fed on bread or milk. He has not found it in the urine of human beings on a mixed diet.

On Substances in the Animal Body from which Sugar is Split Off.—Blumenthal¹ gives a succinct statement of the properties of glycoproteids, and shows how their study is destined to throw light on the origin of sugar in the body in pathologic conditions. The list of substances at present known to contain a carbohydrate group in their molecule includes the mucins, chondrosin, protagon, jecorin, phospho-sarcic acid, adenylic acid, nucleohiston, and the nucleoproteids found by Hammersten to be present in the pancreas. From all of these substances it is possible to split off by chemical methods either a pentose or hexose, a galactose, etc., though in some instances the resulting carbohydrate has not been identified with certainty. In a broad way, therefore, all of these substances may be spoken of as compounds from which a sugar could be derived in the course of the metabolic processes taking place in the body. And of all the substances above named the nucleoproteid of the pancreas must be considered the most important from a clinical point of view, both because it occurs in relatively large quantity and because it yields much sugar (a pentose) on being decomposed. Blumenthal has discovered that certain nucleoproteids previously described by others as present in the liver, thymus, muscles, and pancreas, all yield a pentose when suitably treated, the osazone of which was isolated and found to melt at 153°–158° C. He has also isolated a new nuclealbumin from the thyroid, from the spleen, and from brain-substance, which also yields a pentose. It is apparent, therefore, that such compounds are widely distributed in the animal organism. They are constituents of the cell-nucleus, and it is therefore possible that in the breaking down of cell-nuclei in the body sugar appears. The fact that the sugar which is split off in the laboratory from these compounds is a pentose acquires significance when the modern instances of pentosuria described by Salkowski, Külz and Vogel, and others, are borne in mind. How we can square the above laboratory achievement with the fact that the pathologic sugar-production seen in diabetes leads to a hexose, and only in a minor degree, or not at all, to a pentose, is at present not clear. Blumenthal thinks it is possible that the body splits up these nuclealbumins in a different way, and that even if a pentose is first formed it might be changed either in a direct or in a more roundabout way into a hexose. He concludes, too, that it is not the proteid part of the nuclealbumin, but the nucleic acid contained in it from which the sugar is derived. He also does not think that Pavy has established the glucosidal nature of albumin, although he has rendered it probable, having obtained from egg-albumin a reducing-body whose osazone melts at 189°–190° C. That sugar can be formed in every cell of the body out of the nuclealbumins contained in its nucleus is the author's final conclusion.

Mucin of White Fibrous Connective Tissue.—To the above may be added that R. H. Chittenden and W. J. Gies² have studied the cleavage-products of the mucin of white fibrous connective tissue, and have separated from these products a carbohydrate body which forms a well-defined and crystallized osazone which melts at 158°–160° C. They are at present unable to make definite statements as to the exact nature of this carbohydrate.

Chemistry of Colostrum Milk.—G. Woodward³ reports analyses of 6 cases, and concludes that colostrum-corpuseles are not always found in so-called colostrum-milk; when they are present the percentage of proteids is

¹ Berlin. klin. Woch., Mar. 22, 1897.

² Jour. Exper. Med., vol. i., p. 186.

³ Ibid., Mar., 1897.

higher, and as they disappear the proteid percentage falls. The yellow color of colostrum-milk is especially marked in negro's milk; the specific gravity varies from 1024 to 1034, and this variation is chiefly due to the variation in the amount of fat present. The fat varies from 2% to 5.3%, the proteids from 1.64% to 2.22%, and the ash from 0.14% to 0.42%; total solids, from 10.18% to 13.65%; lactose from 5.6% to 7.4%. An average colostrum-milk contains 4% of fat, 1.9% of proteids, 6.5% of lactose, and 0.2% of ash, making the total solids 12.5% and water 87.5%.

Proteids of Milk.—A. Schlossmann¹ writes on the significance of the several proteids of milk and on the methods hitherto employed for separating them, and proposes a new method for effecting this separation. The new method precipitates the casein at 40° C. with a concentrated solution of potash-alum, albumin and globulin not being precipitated by this reagent; globulin is precipitated with magnesium sulfate; the rest of the proteid is considered to be albumin. The precipitates after being properly treated are estimated by the Kjeldahl method. For practical purposes it is not necessary to separate albumin and globulin; the two are estimated together as "water-soluble proteid." Schlossmann protests vigorously against the view that the casein and albumin of milk have an equal nutritive value. The unequal value of nourishment at the mother's breast and by means of the flask is due to the fact, so Schlossmann thinks, that the child in drinking, say, 1105 gm. of mother's milk, avails itself of more than 5 gm. of very soluble and readily absorbable albumin, while in taking as a substitute for the above amount of mother's milk the usual equivalent, say, 600 gm. of cow's milk, it would get only 1.8 gm. of soluble albumin. That albumin is the chief proteid of colostrum, coupled with the fact that the newborn child has but little capacity for peptonizing casein, is also adduced as an argument in support of the view that the albumin of milk has a special value as compared with the casein.

The Nucleon of Milk.—M. Siegfried² has made the important observation that cow's milk contains a nucleon which is closely related to the nucleon or phosphosarcic acid of muscles. Further observations have been published by his pupil, Karl Witmaack,³ showing that this substance is also present in human milk and in that of goats. Human milk contains more than twice as much of this physiologically important substance as cow's milk, and goat's milk about twice as much as cow's milk. The amount of nucleon in a liter of human milk varies from 1.1 gm. to 1.3 gm. M. Siegfried also comments in a recent paper on the very great physiologic importance which attaches to the new compound. Nucleon contains more phosphorus in organic combination than any other compound in milk. Cow's milk contains 0.6 gm. of this substance, while human milk contains 1.3 gm. Of the total phosphorus in cow's milk only 6% is present in nucleon, while in human milk 41.5% of the total phosphorus is present in the form of nucleon—indeed, almost all of the phosphorus contained in human milk is present as organically combined phosphorus in casein and nucleon. Although the total content of phosphorus is higher than in cow's milk, the preponderance of organically bound phosphorus in the latter is thought to be of great significance for bone-formation in the infant. Martin Müller⁴ has shown that the muscles of the newborn child contain at best only 0.057% of nucleon, as compared with the 0.11–0.22% found in the muscles of adults. This fact is also adduced to show the great significance of the new compound. Long-continued sterilization will decompose some of the nucleon contained in milk.

- Acromegaly**, 743; and exophthalmic goiter, 745; and gigantism, 744.
- Actinomycosis**, 75; buccofacial, 899; esophageal, 173; intestinal, 632; potassium iodid in, 233; of the tongue, 882.
- Action of drugs on leukocytes**, 651.
- Actol** in gonorrhoeal vaginitis, 525.
- Acute alcoholism**, 696; bronchitis, 158; diabetes mellitus, 97; endocarditis, 131; endarteritis, myelopathia due to, 732; ependymitis, 642; infectious diseases and leukemia, 120; laryngitis, 886; leukemia, 117, 654; malaria in Cameroon, 79; mastoiditis, 852; metritis, 553; nasopharyngitis, 879; non-suppurative encephalitis, 717; otitis media, 841; pancreatitis, 203; pericarditis, 125; perichondritis of the thyroid cartilage, 887; phthisis, 61; poliomyelitis, 87; polymyositis, 87; purulent perichondritis, 875; rhinitis, 871; serous meningitis, 713; vegetative endocarditis, 132; yellow atrophy of the liver, 197; brain-lesions in, 657; in children, 639.
- Adam (J.)** on puerperal sepsis, 513.
- Adami (J. G.)** on exophthalmic goiter, 672; on internal secretion, 980; on peritoneal lipoma, 195.
- Adamkiewicz** on antitoxin, 620.
- Adam-Stokes' syndrome**, 149.
- Adams (A. E.)** on purulent conjunctivitis, 802.
- Adams (J. L.)** on sinus-thrombosis, 856.
- Adams (S. S.)** on brain-abscess, 641; on pharyngo-esophageal stenosis, 634; on typhoid fever, 626.
- Addison's disease**, 123.
- Adenoid operation**, forceps for, 880; tissue, histology of, 971; vegetations of the pharynx, 880.
- Adenoma cervicis malignum cysticum**, 578; destruens, 578; malignant, 578.
- Adenomyoma of the round ligament**, 568.
- Adenosarcoma of the pylorus**, 186.
- Adherent pericardium**, 126.
- Adhesions**, intraperitoneal, 195.

- Adhesive pericarditis in children, 637.
- Adler (H.) on color-perception, 781.
- Adolescence, albuminuria of, 210.
- Adolphi on pelvic disease, 583.
- Adrian (L.) on digitoxin, 934.
- Adriance (V. and J. S.) on breast-milk, 609.
- Adults, adenoids in, 880; tinea tonsurans in, 901.
- Advancement, 791, 836.
- Aeria on impaction of gallstones, 189.
- Ailleck (J. O.) on chlorosis, 110.
- After-coming head, perforation of, 506; effects of anesthesia, 260, 266.
- Agalactia, 517.
- Age and susceptibility to infection, 1001.
- Aged, chorea in, 740; endocarditis in, 132; ovariectomy in, 588.
- Agglutinating property of blood-plasma, 699; substance in breast-milk, 699; in typhoid fever, 700.
- Agglutination in the milk in typhoid fever, 17; in the plague, 44; theory of, 699.
- Ague spleen, 357.
- Ahlfeld on placental delivery, 487.
- Ainhum and leprosy, 74.
- Air-embolism, 994; -passages, wounds of, 366.
- Airol, 228.
- Aitken (C. C.) on nephritis, 212; on Raynaud's disease, 748.
- Albarran on intermittent hydronephrosis, 429; on renal operations, 428.
- Albers-Schönberg on fetal syphilis, 518.
- Albinoes, cataract in, 812.
- Albrand (W.) on cataract, 811.
- Albu on albuminuria, 211.
- Albumin and the alloxur-bodies, 674; in pathologic fluids, 709; -testing, 1012.
- Albuminous expectoration, 668.
- Albuminuria of adolescence, 210; cantharides in, 214; cicatricial, 210; cyclic, 210, 639; in diabetes mellitus, 97; in infantile scurvy, 639; intermittent, 210; methylen-blue in, 214; partial, 210; in pregnancy, 461; pretubercular, 71; prognosis, 211; renipuncture in, 434; residual, 210.
- Albuminuric neuroretinitis, 793; retinitis, 821.
- Albumosuria, 210, 1013.
- Aleptonuria, 207.
- Alcohol in amputations, 250; for children, 645; and hepatic cirrhosis, 196; injections for cancer, 881.
- Alcoholic beverages, 639.
- Alcoholism, acute, 696.
- Alderton (H. A.) on otorrhea, 851.
- Alexander (L. S.) on snakebite, 440.
- Alexander (S.) on prostatectomy, 425.
- Alexander's operation, 567; labor after, 497.
- Alexandroff on coxalgia, 398.
- Alexeieff (M.) on scarlatina, 625.
- Alimentary canal, absorption of, 985.
- Alkalinity of the blood, 101, 106, 652, 654; and infection, 693.
- Alkaloids, toxicity of, 1000.
- Allbutt (T. C.) on albuminuria of pregnancy, 464.
- Allen (C. W.) on glycosuric dermatoses, 899.
- Allen (D. P.) on anesthesia, 261; on tuberculosis, 66.
- Allen (F. H.) on cyclopia, 459.
- Allen (S. B.) on colored glasses, 835.
- Allina on pancreatitis, 203.
- Allis (O. C.) on fracture of the femur, 391.
- Allison (T. M.) on measles, 624.
- Alloxins and gout, 92.
- Alloxur-bodies in anemia, 108; effect of albumin, 674; in gout and granular kidney, 654; and uric acid, 208.
- Allport (F.) on enucleation of the eye, 830.
- Alopecia areata, 903; common, 904.
- Alpago-Nevello on ascites, 193.
- Alt (F.) on deafness from mumps, 846; on the internal ear, 866; and Pineles (F.) on Ménière's disease, 866.
- Altemann on injuries of the lung, 995; on acute poliomyelitis, 730.
- Altuchoff and Sengiroff on abdominal hysterectomy, 575.
- Alumol in endometritis, 559.
- Alvarez (G.) on deaf-mutes, 868.
- Alzheimer on general paresis, 761.
- Amann on endothelioma of the cervix, 533.
- Amblyopia, hysteric, 796; potato-rot, 824; toxic, 824.
- Ambrosius (W.) on injuries of the bladder, 996.
- Ambulatory treatment of fractures, 389.
- Ameba, culture of, 703; in the intestines, 220.
- Amebic abscess of the liver, 198; dysentery, 193.
- Ameburia, 220.
- Amenorrhœa, 549; apiolin in, 550; bicycling in, 542; etiology, 550; during lactation, 489.
- Amidon (R. W.) on pneumonia, 165.
- Amitrano on scarlatina, 625.
- Ammann (E.) on tuberculosis of the iris, 814.
- Ammonia in the blood, 107; in the urine, 207.
- Ammonium molybdate, 1013.
- Ammonol, 923.
- Amnion, 458.
- Amniotic sac, supplementary, 458.
- Ampullar pregnancy, 479.
- Amputation, alcohol in, 250; of the foot, 252; at the hip-joint in tuberculosis, 250; intrauterine, 459; of the penis, 415; statistics of, 250; in tetanus, 740.
- Amyl nitrite in angina pectoris, 717; in optic atrophy, 824.
- Amyloform, 229.
- Anal pruritus, 358.
- Analgene, 923; in malaria, 645.
- Analysis of colostrum-milk, 609.
- Anasarca in varicella, 626.
- Anastomosis, intestinal, 293, 296; uretero-ureteral, 431, 539.
- Anatomy, 960; of congenital clubfoot, 773; of the eye, 780; of the optic nerve, 822; of the ureters, 966.

- Andrews (E. W.) on loletin, 942.
- Audriczen (W. L.) on epileptic idiocy, 762.
- Anemia, 107; alloxur-bodies in, 108; in anchylostomiasis, 222; blood in, 108; in children, 638; in heart-disease, 131; hemoglobin in, 108; of the labyrinth, 866; pernicious, 111; in rheumatoid arthritis, 88; specific gravity of the blood in, 108; splenic, 120.
- Anencephalus, 459; cystic, 459.
- Anesthesia, 255; after-effects of, 260; blood-pressure in, 261; cocaine, 269; hypnotic, 259; in labor, 483; local, 269; in nose-diseases, 869; paralysis, 262, 727; pneumonia after, 261; spartein sulfate in, 262; tabetic, 736; temperature in, 261.
- Anesthetics, 255.
- Aneurysm, 156; of the abdominal aorta, 368; aortic, 156; femoral, 368; galvanism in, 370; of the heart, 142; inguinal, 368; of the innominate artery, 370; intracranial, 720; thoracic, 156; wire in, 370.
- Angina, 172; diphtheroid, 613; necrotic, 613; pectoris, 149, 717; in influenza, 37.
- Angiodystrophia ovarii, 603.
- Angioma of the auricle, 838; of the orbit, 828.
- Angor animi, 149.
- Anhalonin, 925.

- Anhalonium lewinii, 924.
 Animal-extracts, 925; -heat, 982; organs, urea in, 1016; parasites, 220; in the nose, 873.
 Aniridia, 813.
 Ankylosis of the stapes, 841.
 Anomalies of the lens, 809; of the uterus, 552.
 Anonychia, congenital, 972.
 Anophthalmos, 799.
 Anosmia, 876.
 Anteflexion of the uterus, 561.
 Antepartum hemorrhage, 471.
 Anterior achillo-bursitis, 774; kolpotomy, 565; lobe of the brain, disease of, 720.
 Anthony on creolin-poisoning, 646.
 Anthracosis, experimental, 667.
 Anthrax-infection, transmission of, 1001; methylen-blue for, 233.
 Antibodies in milk, 698.
 Antimony in tetanus, 711.
 Antinoshin, 231.
 Antiphthisin in tuberculosis, 66; in tuberculous lymph-glands, 374.
 Antiplague serum, 45.
 Antipneumococcal serum, 163.
 Antipyretics, coal-tar, 931.
 Antipyrin, 926, 931; in atrophy of the optic nerve, 713; in diabetes mellitus, 633; in dysmenorrhœa, 551; in labor, 483; in optic-nerve atrophy, 833; para-oxybenzoate, 928; in pertussis, 627; in the plague, 45; in pruritus vulvæ, 528; in vernal catarrh, 801.
 Antisepsis, 225; in the eye, 829; intestinal, in cholera, 39; in the plague, 40.
 Antiseptic properties of saliva, 232; value of iodoform, 229.
 Antispasmin in pertussis, 645.
 Antistreptococcal serum, 697, 929; in blood-poisoning, 235; in malignant endocarditis, 133; in septic peritonitis, 304; in spreading gangrene, 231.
 Antitoxic treatment of typhoid fever, 33.
 Antitoxin, 685; death after, 629, 698; in diphtheria, 612, 615, 1003; in pertussis, 620; in scarlet fever, 620; in tetanus, 741.
 Antitoxins, action of, 696; limitation of, 698.
 Antitubercle-serum of horses in tuberculosis, 66.
 Antituberculous serum, 64.
 Antivenene in snakebite, 440.
 Antivenomous serum, 698.
 Anton (W.) on fibrosarcoma of the auditory nerve, 716, 868.
 Antonelli and Giglio on corneal ulcer, 807.
 Antrotomy, mastoid, 851.
 Antrum, 877.
 Anuria, 216.
 Anus, diseases of, 357; vulvo-vaginal, 531.
 Aorta, abdominal, aneurysm of, 368; thrombosis of, 155; congenital stricture of, 141.
 Aortic aneurysm, lung-complications in, 656; rupture of, 156; insufficiency, 138; intima, tuberculosis of, 655.
 Apert (E.) on purpura, 123.
 Apfelstedt on perineorrhaphy, 533.
 Aphtha cachectica, 631.
 Aphthous stomatitis, 172.
 Apollin in amenorrhœa, 550.
 Apomorphin in acute laryngitis, 886.
 Aponeurosis, rupture of, 381.
 Apoplexy, treatment of, 720.
 Apparatus for Pott's disease, 764.
 Appel (A. H.) and Thornbury (F. J.) on Widal's reaction, 24.
 Appendages, fetal, pathology of, 457.
 Appendectomy, 310.
 Appendicitis, 191, 303, 310; camphor in, 323; in children, 636; diagnosis of, 332; digitalis in, 323; drainage in, 327; morphin in, 317; operation in, 310, 330; pain in, 325; purgation in, 333; relapsing, 333; saline solution in, 323; treatment, 317, 326; typhoidal, 289.
 Appendicular colic, 302.
 Appenzeller on the eye in diabetes, 791.
 Appleby on puerperal eclampsia, 496.
 Apyrexia in tuberculosis, 61.
 Aqueous humor, 784.
 Archer (T. B.) on the lens, 809.
 Ardoin on foreign bodies in the eye, 825.
 Argemintin in eye-diseases, 831; in gonorrhœal vaginitis, 525; in rectal gonorrhœa, 525.
 Argonin in gonorrhœa, 401; in gonorrhœal vaginitis, 525.
 Argyll-Robertson on trichiasis, 801.
 Aristol in tuberculous lymph-glands, 374.
 Arloing on sweat, 710.
 Armaiguac (H.) on trachoma, 805; on tuberculosis of the lids, 800.
 Armstrong (G. E.) on perforation in typhoid fever, 292; on typhoid fever, 35.
 Armstrong (W. L.) on the menopause, 515; on nitroglycerin, 945; on rheumatoid arthritis, 89.
 Arnold (J. P.) on tuberculosis, 61.
 Arnozen on cyclic albuminuria, 210.
 Arny (H. V.) on parthenium hysterophorus, 946.
 Arrhythmia in influenza, 37.
 Arsenic in anesthesia-paralysis, 264; in angina pectoris, 717; in gastralgia, 181; in malaria, 82; in pernicious anemia, 115; in sarcoma of the skin, 911; in skin-diseases 913; in tuberculous lymph-glands, 374; in typhoid fever, 16.
 Arsenical neuritis, 643.
 Arterial air-embolism, 994; blood, oxygen-tension of, 984; hypermyotrophy, idiopathic, 154; tension, high, 155.
 Arteries, calcareous infiltration in, 155; diseases of, 153; ossification of, 154.
 Arteriosclerosis in children, 638.
 Arteritis nodosa, 154.
 Arthritis deformans in children, 633; gonorrhœal, 402; in pneumonia, 162; rheumatoid, 88; suppurative, in typhoid fever, 19.
 Arthropoda, 224.
 Arthus and Huber on the blood, 974.
 Artificial baths in heart-disease, 146; diseases of the lobule, 830; ripening of cataract, 810; serum in uremia, 215.
 Asaprol, 1012.
 Ascending degeneration, 656, 725.
 Ascher on myopia, 785.
 Ascheim (H.) on astigmatism, 787.
 Aschoff on pleurisy, 167.
 Ascites, chylous, 169, 191; diagnosis of, 193; from hepatic cirrhosis, 345; malarial, 80; pericarditic, 126.
 Ascitic fluid, 679.
 Ascepsis, 225; in the eye, 829; in labor, 482.
 Ascepticon in tuberculous lymph-glands, 374.
 Aseptol, 1012.
 Ashby on sterility in women, 545.
 Ashhurst (J.) on amputations, 251.
 Ashmead (A. S.) on ainhum and leprosy, 71.
 Ashton (W. E.) on suture-abscess, 595; on trachelorrhaphy, 535.
 Asphyxia in chloroform-anesthesia, 266; neonatorum, 519.
 Aspiration of the gall-bladder, 352; in hepatic abscess, 315; in purulent pericarditis, 125.
 Association-movements, 799.
 Asthenopia, 783, 790.
 Asthma, 165; dyspeptic, 180; thymicum, 673.
 Astic on syringomyelia, 729.
 Astigmatism, 786.
 Asymmetry of the sternum, 960.
 Ataxia, cerebellar hereditary, 737; family, 737; Friedreich's, 737.
 Athanasiu and Carvallo on the blood, 973.
 Atheroma, deafness from, 846.
 Atkinson (T. R.) on puerperal thrombosis, 516.
 Atmospheric pressure, 984.
 Atoxogen, 690.

- Atresia narium, 870; retrohy-menalis, 530; vaginal, 529.
 Atrophic rhinitis, 873.
 Atrophy, acute yellow, of the liver, 197; lactation-, of the uterus, 517; muscular, in hip-disease, 770; of the optic nerve, 713, 821; congenital, 799; progressive muscular, 729; of the skin, 903; of the uterus after castration, 519.
 Atrypin sulfate in trachoma, 805; in tuberculosis, 70.
 At(hill) on puerperal hemorrhage, 515.
 Attic suppuration, 819.
 Auche and Carrière on hemorrhagic pleurisy, 168; on the urotoxic coefficient, 215.
 Audebert on puerperal eclampsia, 495.
 Auditory canal, external, fracture of, 840; stricture of, 840; center, impaired, 846; meatus, herpes of, 839; hyperostosis of, 840; nerve, fibrosarcoma of, 716.
 Aufrecht on atrophy of the liver, 639; on hepatic cirrhosis, 666.
 Aufrecht's sign, 157.
 Auld on pneumonia, 164.
 Aural fistula, congenital, 839; myoclonus, 840.
 Auricle, angiona of, 838; epithelioma of, 838; degenerate, 838; hemorrhagic ecchyma of, 838; keloid of, 838; lupus of, 838; malformation of, 837; sarcoma of, 838.
 Auscultation of the heart in chloroform-anesthesia, 262.
 Auscultatory percussion, 127.
 Autoextirpation of the larynx, 992.
 Autoinfection, 510; of the eye, 792.
 Autointoxication, 55.
 Automatic hammer-toe springs, 774.
 Automatism, mental, in epilepsy, 749.
 Ayoledo (P.) on otitic cerebral abscess, 863.
 Axenfeld (T.) on conjunctivitis, 802.
 Axis-traction forceps, 501.
 Axonometer, 835.
 Aymard's sterilizer, 607.
 Ayres on pseudoplasms, 828.
 Ayres (E. A.) on symphysiotomy, 507; on tuboabdominal pregnancy, 475.
 Ayres (S. C.) and Alt (A.) on the eye, 797.
- BARCOCK** (R. H.) on hemoptysis, 69; on pulmonary stenosis, 138.
Baier (C.) on turbinotomy, 872.
Babes and **Nanu** on myosarcoma of the small intestine, 665.
Baccelli on hemoglobinuria, 82.
Back on the eye, 829.
Bacillus coli communis and **Widal's** reaction, 24; and nephritis, 211; colon, 676; of diphtheria, 684; dysentericus, 193; of Eberth, 161; fluorescens liquefaciens, 192; of Friedländer, infection with, 52; icteroides, 50; of Kitasato, 40; Klebs-Löffler, 611; of pertussis, 627; pyocyaneus and **Widal's** method, 24; smegma-, 206, 688; typhoid-, 10; of xerosis, 685; of yellow fever, 49, 689; of Yersin, 40.
Bacon (C. S.) on extrauterine pregnancy, 479; on labor, 483.
Bacon (G.) on cerebral abscess in acute otitis media, 841; on otitic cerebral abscess, 861.
Bacon (J. B.) on stricture of the rectum, 358.
Bacteria and **endometritis**, 556; in the nares, 870; staining of, 703; and sunlight, 690; and the toxicity of alkaloids, 1000.
Bacterial treatment of malignant disease, 247.
Bactericidal substances in leukocytes, 695.
Bacteriology of cholera morbus, 192; in legal medicine, 998; of the normal conjunctiva, 801; of pneumonia, 160; of pyosalpinx, 586.
Bacteriuria, 205.
Baer on carcinoma of the uterus, 576; on fetus papyraceus, 459, 502.
Baer on rectal gonorrhœa in women, 525.
Baer (T.) on syphilis, 920.
Baginsky (A.) on anemia, 638; on the bladder, 640; on pertussis, 627; on summer diarrhœa, 631.
Bailey (A. L.) on superfetation, 452; on triplets, 501.
Bailey (E. S.) on tuboabdominal pregnancy, 474.
Bailey (G. H.) on ether, 264; on locomotor ataxia, 735.
Baker (C. H.) on pterygium, 806.
Baker (R.) on litholapaxy, 428.
Baker (W. H.) on ovarian cyst, 601.
Balantidium coli, 221.
Bald ringworm, 900.
Baldwin (L. G.) on amenorrhœa, 549; on infant-feeding, 606; on salpingitis, 585.

 Byrne (J.) on uterine excision by the galvanocautery, 581.
 Cabot (A. T.) on castration for enlarged prostate, 422; on mania after orchotomy, 755.
 Cabot (R. C.) on pernicious anemia, 111, 653.
 Caecæ (E.) on renal sarcoma in children, 639.
 Cachexia, malarial, 81.
 Cadaveric spasm, 992.
 Caddy (D. J.) on febrile diseases, 53.
 Cadell (G. R.) on dysmenorrhoea, 551.
 Cadiot on tuberculosis of small animals, 684.
 Caillaud (M.) on superficial gangrene, 647.
 Caillé (A.) on congenital heart-defects, 636; on lumbar puncture, 641.
 Caïsson disease, 734.
 Calcareous degeneration of the heart, 656; infiltration of arteries, 155.
 Calcium; excretion of, in diabetes mellitus, 97; carbid in uterine carcinoma, 581; chlorid in hemoglobinuria, 210; in itching, 916; in urticaria, 891; oxalate in sputum, 668; sulphid in tonsillitis, 884.
 Calculus, biliary, 201; renal, 216; salivary, 171; vesical, 427.
 Calliano on asphyxia neonatorum, 519.
 Calmann on Alexander's operation, 567.
 Calmette (A.) on antitoxins, 698; on antivenomous serum, 698.
 Calomel in heart-disease, 146; injections of, in syphilis, 919; in tetany, 742; in typhoid fever, 31.
 Calot (F.) on Pott's disease, 413, 767.
 Camero on cystitis, 538.
 Cameron (M.) on dysmenorrhoea, 551; on retroversion of the pregnant uterus, 468.
 Cameroon, acute malaria in, 79.
 Campbell (D. M.) on autoinfection of the eye, 793; on otitis media, 842.
 Campbell (J.) on the sacral route, 357.
 Campbor in appendicitis, 323; in hemorrhoids, 358; in the plague, 45.
 Camphorated salol in otorrhea, 849.
 Campo and Compaired on otorrhea, 849.
 Camus and Gley on the blood, 106.
 Cancer, 240.
 Cannabis indica in dysmenorrhoea, 551.
 Canova on gonorrhoeal vaginitis, 525.
 Cantani, Jr. (A.) on the influenza bacillus, 657.
 Cantharides in albuminuria, 211.
 Cantlie (J.) on the plague, 41, 45.
 Cantrell (J. A.) on tinea tonsurans, 901.
 Capaldi (A.) on culture-media, 703.
 Capart and Cheval on atrophic rhinitis, 873.
 Cappelan on wound of the heart, 370.
 Caprara on pneumonia, 160.
 Capsule, suprarenal, 954.
 Carbazotic acid in skin-diseases, 916.
 Carbolic acid in pruritus vulvæ, 528; in tetanus, 741; in variola, 897.
 Carbon dioxide and the diphtheria-bacillus, 685; monoxid poisoning, 999.
 Carbonic acid in gonorrhoeal vaginitis, 525.
 Carburetted calcium in uterine carcinoma, 581.
 Carcinoma, alcohol injections for, 881; and blastomycetes, 680; blood in, 100; cocain in, 240; Coley's fluid in, 247; and leukemia, 119; opium in, 240; and trauma, 996; and uterine fibroid, 576.
 Carcinoma of the cervix in pregnancy, 469.
 Carcinoma of the colon, 296.
 Carcinoma of the conjunctiva, 806.
 Carcinoma of the corpus uteri, 577.
 Carcinoma of the esophagus, 174.
 Carcinoma of the Fallopian tubes, 586.
 Carcinoma of the heart, 241; marrow-infection of, 242; oophorectomy for, 247.
 Carcinoma of the iris, 815.
 Carcinoma of the lung, 166.
 Carcinoma of the pancreas, 204, 667.
 Carcinoma of the pleura, 170, 668.
 Carcinoma of the pylorus, 186.
 Carcinoma of the rectum, 362; operation in, 359.
 Carcinoma of the splenic flexure of the colon, 293.
 Carcinoma of the stomach, diagnosis, 182; gastroenterostomy for, 275; hematemesis in, 184; metastasis in, 664; septic infection in, 186; stomach-washings in, 183; symptoms, 185.
 Carcinoma of the temporal bone, 864.
 Carcinoma of the tonsil, 883.
 Carcinoma of the urethra, 536.
 Carcinoma of the uterus, calcium carbid in, 581; diagnosis, 578; erysipelas-toxins in, 580; etiology, 576; and obesity, 578; operation in, 581; organotherapy in, 581; sodium chlorate in, 581; treatment, 580; vaginal hysterectomy in, 582; in the young, 578.
 Cardiac complications in influenza, 37; contraction, frequency of, 148; disease in pregnancy, 462; disease, treatment, 141; failure, 145; hydrothorax, 130; hypertrophy in malaria, 81; impulse, 129; nerves, 977; neuroses, 148; sounds, graphic representation of, 128; syphilis, 141; tuberculosis, 71; tumors, 143.
 Cardiopathies, uterine, 540.
 Care of pregnant women, 457.
 Carhart (W. B.) on ocular hygiene, 782.

- Caries of the internal ear, 866.
 Carless (A.) on Graves' disease, 152.
 Carlucci (F.) on antituberculous serum, 65.
 Carnochan on elephantiasis of the leg, 376.
 Caro on the blood, 107.
 Carpenter (G.) on ovariectomy in the young, 559; on rectal exploration in children, 584; on tuberculous salpingitis, 586.
 Carr (J. W.) on posterior basic meningitis, 712.
 Carrien on nephritis, 215.
 Carrier (A. E.) on arsenic, 913.
 Carrière on tuberculin, 683.
 Carter (B.) on holocain, 831.
 Carter on the voice, 890.
 Caruncle, supernumerary, 806.
 Casagrandi (O.) and Barbagallo (P.) on culture of amebæ, 703.
 Casassio and Ligalea on tuberculous peritonitis, 305.
 Casrelli on variola, 48.
 Cassaet on bronchitis, 158.
 Cassel on laryngeal spasm, 742.
 Casselberry (W. E.) on abscess of the nasal septum, 875; on sinusitis, 878.
 Castex on ear-diseases, 995.
 Castration, endometrium after, 554; judicial, 991; for prostatic enlargement, 419; uterine atrophy after, 549.
 Casts, urinary, 1018.
 Catalepsy in rachitis, 643.
 Cataract in albinos, 812; artificial ripening of, 810; etiology, 810; -extraction, 810.
 Catarrh, nasopharyngeal, 374; vernal, 804.
 Catarrhal conjunctivitis, 802.
 Catgut, sterilization of, 589.
 Catheterism of the ureter, 432.
 Catheterization, retrograde, 416.
 Catrin on typhoid fever, 18.
 Cattaneo on antituberculous serum, 65; on mydriol, 834.
 Cattell (H. W.) on frozen sections, 701.
 Cavazzani (E.) and Salvatore (L.) on urea, 1018.
 Cavity, pulmonary, treatment, 365.
 Cayley (W.) on acute pancreatitis, 203.
 Ceci on cocaine-anesthesia, 269.
 Cecum, tuberculous, 72.
 Celli on dysentery, 193; and Santoni on malarial fever, 82.
 Cemeteries, 1005.
 Center of rotation, 789.
 Central nervous system in infectious diseases, 657; and the influenza-bacillus, 657; perineal laceration, 496; retinitis, 820.
 Cerebellar abscess, otitic, 863; hemorrhage, 725; hereditary ataxia, 737.
 Cerebellum, alveolar carcinoma of, 864; tumor of, 723.
 Cerebral abscess in acute otitis media, 844, 861; arteries, elastic tissue in, 961; degeneration, infantile, 763; diplegia, congenital, 642; endothelioma, 640; hemiplegia in diphtheria, 614; hemorrhage, 720; meninges, diseases of, 712; syphilis, 722.
 Cerebrospinal fever, 51; meningitis, 641, 713; warm baths in, 645.
 Cerumen-plugs, reflex effects of, 839.
 Cervellini on Addison's disease, 124.
 Cervical carcinoma in pregnancy, 469; dystocia, 496; pregnancy, 458; sympathetic, resection of, 746.
 Cervix uteri, diseases of, 533; endothelioma of, 533; hypertrophy of, 534, 561; laceration of, 534; stenosis of, 534; syphilis of, 533.
 Cesarean section, 508; post-mortem, 499, 508; in puerperal eclampsia, 495; technique, 508; vaginal, 508.
 Chaillons and Desfosses on hemimelus, 459.
 Chaleix on puerperal sepsis, 513; on trauma of the vulva, 528; and Ficux (G.) on retroversion of the pregnant uterus, 468; and Vivie on abortion, 474.
 Chambréant on the effect of maternal pulmonary disease on the fetus, 467; and Chemin on twin pregnancy, 500.
 Champagne in gout, 95.
 Chanere, soft, 403.
 Chandler (H. B.) on heterophoria, 790.
 Changes in the voice, 890.
 Channing (W.) on palatal deformities in idiots, 762.
 Chantemesse on typhoid fever, 11, 17.
 Chanutin on phlegmonous gastritis, 177.
 Chapin (H. D.) on hospitalism, 648; on infection, 1001; on multiple tuberculous brain-tumor, 641.
 Chaplin (A.) and Tunnicliffe (F. W.) on tuberculosis, 69.
 Chapman (W. J.) on prolapse of the rectum, 359.
 Chappell (W. F.) on tuberculosis of the pharynx, 885.
 Chappins and Chaneul on x-rays, 445.
 Chaput on intestinovaginal fistula, 536.
 Charbonnier (P.) on quadruplets, 501.
 Charcot (J. B.) on progressive muscular atrophy, 729; -Leyden crystals in sputum, 668.
 Charles on puerperal eclampsia, 494.
 Charpentier (A.) on puerperal eclampsia, 494; on puerperal sepsis, 513.
 Charrier and Apert on typhoid fever, 21.
 Charrin (A.) on pigmentation, 710; on pyocyanus infection, 53; on typhoid fever, 21; and Cassin on digestion, 985; and Desgrez (A.) on hemoptoresis, 975; and Nittis on nerve-section, 696; and Richet on tuberculosis, 57.
 Charteris and McLennon on eucain, 271.
 Chartres on gonorrhœal conjunctivitis, 803.
 Chase (W. B.) on carcinoma of the uterus, 578; on tubal pregnancy, 474.
 Chafford on hydatid cyst of the liver, 200; on pneumothorax, 167; and Lemoine on measles, 624; and Ramond on rheumatoid arthritis, 88.
 Chauveau (A.) on muscular contraction, 982; on the stethoscope, 217.
 Chauvel on myopia, 786.
 Chauvin on cholera, 39.
 Chavannez on uterine anomalies, 552.
 Chavellereau on eye-diseases, 831; on glaucoma, 817; on retinal detachment, 822.
 Cheate (A. H.) on acute mastoiditis, 852; on aural fistula, 839; on intestinal anastomosis, 305; on labyrinth-tension, 848.
 Cheatham (W.) on iritis, 814; on otorrhea, 849; *Chelidonium majus* for warts, 240.
 Chemistry of colostrum, 1020; physiologic, 1011.
 Cheron on thyroid extract, 547; on uterine fibroids, 510.
 Cheron's serum, 825.
 Cheverau on mitral stenosis, 136.
 Cheynex (W. F.) on bromoform-poisoning, 646; on scurvy, 632.
 Chiari on ovarian cysts, 599; on pancreatic disease, 203; on typhoid fever, 686.
 Chiasm, optic, 965.
 Chibret on trachoma, 804.
 Chiene on appendicitis, 328; on ovariectomy in children, 589.
 Child (L. F.) on the plague, 44.
 Children, acute yellow atrophy of the liver in, 639; adhesive pericarditis in, 637; anemia in, 638; appendicitis in, 636; arteriosclerosis in, 638; arthritis deformans in, 633; croupous pneumonia in, 630; cystitis in, 640; diabetes mellitus in, 633; diarrheal diseases in, 634; diseases of the alimentary tract in, 633; diseases of the blood in, 636; diseases of the circulatory system in, 636; diseases of the genitourinary system in, 639; diseases of the liver in, 639; diseases of the nervous system in, 640; diseases of the spleen in, 639; endocur-

- ditis in, 637; fragilitas ossium in, 777; gastroenteritis in, 178; glandular tuberculosis in, 628; gonorrhoeal ophthalmia in, 631; gonorrhoeal rheumatism in, 631; headache of, 646; infectious diseases in, 610; influenza in, 631; interstitial nephritis in, 676; intussusception in, 298; jaundice in, 639; leukemia in, 638; lymphatic tuberculosis in, 628; malaria in, 645; myocarditis in, 637; nephritis in, 639; nontuberculous meningitis in, 712; ovariectomy in, 589; peritonitis in, 630; pernicious anemia in, 638; polyarthritides in, 633; purpura hemorrhagica in, 638; rectal exploration in, 584; renal sarcoma in, 639; sarcoma of the bladder in, 640; scurvy in, 632; spastic paralysis in, 776; splenic hypertrophy in, 639; tuberculosis in, 628, 629; tuberculosis of the tonsils in, 681; tumors of, 641; typhoid fever in, 25, 626; valvular hematoma in, 637; Widal reaction in, 626.
- Chicini on mastoiditis, 852.
- Chipault on osteomyelitis of the vertebrae, 412.
- Chittenden (R. H.) on infant foods, 606; on internal secretion, 980; and Gies (W. J.) on mucin, 1020.
- Chloral in puerperal eclampsia, 494; in tetanus, 711; in tetany, 742.
- Chloralose, 930.
- Chlorids, retention of, in the body, 212.
- Chlorin for the hands, 231.
- Chloroform-anesthesia, apnoea in, 266; death during, 267; tracheotomy in, 266; as an anesthetic, 257; in angina pectoris, 717; decomposition of, 266; in puerperal eclampsia, 491; syncope, 268; in tetany, 742.
- Chloroma, nature of, 679.
- Chlorosis, 109, 549; bone-marrow in, 110; and the conus arteriosus, 110; etiology, 109; eye in, 796; ovarian therapy in, 559; ovarium in, 111; oxygen-inhalations in, 111; pathology, 110; red corpuscles in, 111; and splanchnoptosis, 109; symptoms, 111; treatment, 111; venous murmur in, 111.
- Choked disk, 823.
- Chologogue action of bile, 986.
- Cholangitis, 349.
- Cholecystectomy, 348.
- Cholecystitis in typhoid fever, 44.
- Cholecystotomy, 252.
- Choledochotomy, 348.
- Cholelithiasis, 201, 352; operation in, 348; sodium phosphate in, 202.
- Cholera, 38; chrysoïdin in, 687; immunization against, 38, 698; infantum, potassium bromid in, 646; inoculations, 38; intestinal antiseptics in, 39; intestinal lesions in, 38; microbe and the Widal reaction, 30; morbus, 192; serum-diagnosis of, 699; transmission of, 38; treatment, 38.

 Collins (J.) on epilepsy, 659; on Little's disease, 738; on spastic paralysis, 777; and Blanchard (G. W.) on tumor of the cord, 733; and Brewer (G. E.) on tumor of the cerebellum, 723.
 Collins (T.) on optic atrophy, 824.
 Collins (W. J.) on amputations, 250.
 Collodion in hemorrhoids, 358.
 Colloplexie ligamentaire, 562.
 Colmer (P. A.) on uterine rupture, 499.
 Coloboma of the choroid, 799; of the retina, 818.
 Colon-bacillus, 676; carcinoma of 293, 296; fistula in, 186.
 Colored glasses, 835.
 Color-perception, 781.
 Color-reactions of diabetic urine, 98.
 Colostrum-milk, analysis, 609, 1020.
 Colquhoun on pernicious anemia, 115.
 Column, posterior spinal, toxic lesions of, 661.
 Comba on croupous pneumonia in children, 630.
 Combemale and Raviart on tuberculin, 61.
 Comby (J.) on hemophilia, 638; on typhoid fever, 12; on varicella, 626.
 Comini (E.) on acromegaly, 744.
 Commelina, 932.
 Common alopecia, 904.
 Commotio retinae, 820.
 Compaired on epithelioma of the auricle, 838.
 Complications in leukemia, 119; in rheumatism, 86; in tuberculosis, 60; in typhoid fever, 13.
 Compression of the front of the foot, 773; of the iliac artery, 253; -paraplegia in Pott's disease, 766.
 Compulsory vaccination, 47.
 Concanon (J. J.) on adenoids, 880.
 Conception, 451.
 Condamin on abdominal section, 590.
 Condensed milk in infant-feeding, 608.
 Condurango, 933.
 Cone (C.) on tuberculosis of the Fallopian tubes, 586.
 Congenital absence of the ovaries, 553; of the patellæ, 778, 961; of the uterus, 552; affections of the eye, 799; anomalies of the iris, 813; of the lacrimal apparatus, 806; of the retina, 818; anonychia, 972; aural fistula, 839; cardiac defects, 636; cerebral diplegia, 642; clubfoot, 773; corneal opacity, 808; cystic degeneration of the kidney, 676; defects of the cornea, 809; in lung bones, 778; of the uterus, 552; dislocations, 770; of the hip, 399; displacement of the lens, 809; external ophthalmoplegia, 713; goiter, 747; hypertrophy of the pylorus, 664; intestinal occlusion, 636; lesions of the heart, 139; multilocular cyst of the omentum, 236; opacity of the cornea, 799; optic-nerve atrophy, 799; pyloric stenosis, 187; sarcomatosis of the skin, 644, 912; stenosis of the nasopharynx, 879; stricture of the aorta, 141; syphilis, 629; umbilical hernia, 459.
 Conitzer (L.) on tuberculosis of the prostate, 417.
 Conjunctiva, bacteriology of, 801; carcinoma of, 806; cyst of, 806; diseases of, 801; papilloma of, 806; sarcoma of, 806; tumors of, 806; urticaria of, 805.
 Conjunctival diphtheria, 795.
 Conjunctivitis, catarrhal, 802; epidemic, 802; formaldehyd in, 938; gonorrhæal, 803; granular, 803; membranous, 803; phlyctenular, 803; purulent, 802; syphilitic, 805; in typhoid fever, 15.
 Connel (J.) on dysmenorrhæa, 551.
 Connell (W. T.) on infectious endocarditis, 656.
 Connolly on pneumonia, 160.
 Connor (L.) on glaucoma, 816, 817.
 Conrads (H.) on petroleum-poisoning, 647.
 Consolas on pregnancy in a double uterus, 499.
 Constipation, 188.
 Constitutio lymphatica, 673.
 Constitution of the blood, 104.
 Constitutional diseases, 85.
 Consumptives, health-resorts for, 1002; segregation of, 63.
 Contagion, direct, in typhoid fever, 11; in tuberculosis, 56.
 Contagiousness of leprosy, 73; of pulmonary tuberculosis, 58; of syphilis, 921.
 Contracted kidney, hereditary, 640; pelvis, forceps in, 505; labor in, 492; thyroidin in, 493.
 Contraction, cardiac, frequency of, 148; muscular, 981; pelvic, 490; -ring, 484; of the stomach, 181.
 Control of the spine, 764.
 Contusions of the abdomen, 995.
 Conus arteriosus and chlorosis, 110; pulmonalis, stenosis of, 139.
 Convergence and accommodation, 788.
 Convexance of typhoid-fever infection, 1003.
 Convulsions, puerperal, 493.
 Cook (A. B.) on rectal fistula, 359.
 Cook (A. H.) and Cook (A. R.) on blood-poisoning, 235.
 Cook (J.) on deciduoma malignum, 678.
 Cook (S. E.) on glioma, 818; on the retina, 818.
 Cooke (A.) on pneumonia, 163.
 Coombs (C.) on puerperal sepsis, 513.
 Cooper (P. R.) on typhoid fever, 33.
 Coppey (H.) on membranous conjunctivitis, 803.
 Corcoran (W. J.) on uterine excision by the galvanocautery, 581.
 Cord, umbilical, 458; velamentous insertion of, 458.
 Corectopia, 813.
 Corin (G.) on gunshot-wounds, 996.
 Corinado on malarial fever, 78.
 Corish (J. L.) on chlorosis, 111.
 Cornea, blood-staining of, 808; congenital defects of, 809; congenital opacity of, 799; dermoid cyst of, 808; diseases of, 807; herpes of, 808; keloid of, 808; lead-deposits in, 808; tumors of, 808; ulceration of, 807; variola of, 808.
 Corneal opacity, congenital, 808; electrolysis in, 809.

- Cornell on enuresis, 215.
 Cornil on salpingitis, 584.
 Cornillon on gout, 93.
 Corning (J. L.) on reunion of nerves, 405.
 Corneal pregnancy, 481.
 Coronillas (G.) on perineal laceration, 496.
 Corpus uteri, carcinoma of, 577.
 Corpuses, permeability of, 975.
 Corrigan pulse, 138.
 Corsica, malarial fever in, 79.
 Corson (E. R.) on x-rays, 442.
 Cortical localization, 988.
 Cryza, 871.
 Cosgrave (E. M.) on coincident scarlet and typhoid fevers, 42.
 Coste on variola, 47.
 Cottam (G. G.) on anesthesia, 262.
 Cotterell (J. M.) on otitic cerebral abscess, 863.
 Cough, reflex, 884; in tuberculosis, 69.
 Coulthard (W. J. C.) on anencephalus, 459.
 Councilman (W. T.) on fetal malformations, 461; on maternal impressions, 458; on nephritis, 676.
 Counter-irritation in herpes zoster, 893.
 Courmon (J.) on Elsner's method, 33; on Marmorek's streptococcus, 687; on typhoid fever, 21, 27, 700.
 Course of the taste-fibers, 964.
 Courtade (D.) and Guyon (J. F.) on the sympathetic system, 989.
 Courtade (M.) on coryza, 871; on syphilis of the membrana tympani, 841.
 Cousins (J. W.) on excision of the knee-joint, 397.
 Coutts on infantile syphilis, 518.
 Covallero (G.) on the areometer, 1015.
 Cowie (C. G.) on epistaxis, 876.
 Cowpox, 46.
 Cow's milk, humanizing, 607; and tuberculosis, 57; serum in gastroenteritis, 635.
 Cox (C. N.) on nasal reflexes, 872.
 Coxalgia, 398.
 Coxa vara, 385.
 Cozzolino on facial paralysis, 845; on meningismus, 845; on tinnitus, 847.
 Craig (J.) on the eye in pertussis, 796; on leukemia, 118.
 Craig (T. C.) on tuberculosis, 63.
 Cramer on Bardenheuer's operation, 383; on the lens, 809.
 Crandall (F. M.) on influenza in children, 631; on melena, 638.
 Crandall (R. P.) on venereal disease, 401.
 Cranial nerves, diseases of, 712; nuclei, solitary tubercle of, 715.
 Craniotomy, 506; in puerperal eclampsia, 495.
 Crawford (A.) on food-poisoning, 55.
 Cree (W. J.) on labor, 482.
 Creeping gonorrhoea, 521.
 Creolin, 933; -poisoning, 646.
 Cresote in tuberculosis, 69; in tuberculous lymph-glands, 374; in tuberculous peritonitis, 305.
 Creseinamo on antituberculous serum, 65.
 Cretin, pregnancy in, 471.
 Cretinism, 746.
 Criminology, 990; eye in, 782.
 Cripps (H.) on ovarian cyst, 600; on the rectum, 525.
 Crocker (H. R.) on lepra, 74; on myoma multiplex, 908; on x-ray dermatitis, 895; on x-rays, 447.
 Crockett (E. A.) on syphilis of the internal ear, 866.
 Crocq on injuries of the brain, 995.
 Crook (J. K.) on chronic valvular disease, 133; on tuberculosis, 69.
 Croon (J. H.) on hysterectomy in puerperal sepsis, 597; on vaginal hysterectomy, 582.
 Crosse on inversion of the uterus, 500.
 Crosti on abortion, 473.
 Croton oil in ringworm, 903; in uremia, 465.
 Croup, diphtheric, 618.
 Croupous pneumonia, 159; arthritis in, 162; bacteriology of, 160; in children, 630; cold-sponge baths in, 165; complications, 161; digitalin in, 164; digitalis in, 164; etiology, 160; fowl-serum in, 164; hiccup in, 162; icterus in, 162; nucleic acid in, 164; oxygen-inhalations in, 145; pleural effusion in, 161; prognosis, 162; serum-therapy in, 163; suppurative hygroma in, 162; symptoms, 161; treatment, 163; uric acid in, 161, 673; venesection in, 165.
 Crystallization of eosinophile granulations, 654.
 Crystals, Charcot-Leyden, in sputum, 668.
 Czellitzer on accommodation, 781.
 Cuff (A.) on intestinal obstruction, 297.
 Culbertson (L. R.) on optic atrophy, 824.
 Cullen (T. S.) on adenomyoma of the round-ligament, 568.
 Cullingworth (C. J.) on puerperal sepsis, 510; on rupture of the uterus, 499.
 Culture of amebae, 703; -media, yolk of egg in, 703.
 Cumston (C. G.) on amputation of the foot, 252; on epididymitis, 101; on pruritus vulvae, 528.
 Cupric electrolysis in ozena, 847.
 Curative influence of fever, 83.
 Curatulo on the secretion of the ovary, 598.
 Curettage after abortion, 474; in cystitis, 538; of the eye, 833; uterine, 559.
 Curtin (R. G.) on Graves' disease, 151; on mitral stenosis, 135.
 Curvature, lateral, 767.
 Cushing (H. W.) on excision of the knee-joint, 395.
 Cutaneous diseases, 891; epithelioma, 910.
 Cutler (E. G.) on puerperal polyneuritis, 517.
 Cut-throat, 363.
 Cyclic albuminuria, 210, 639.
 Cyclopia, 459.
 Cyst, 236; of the broad ligament, 599; of the conjunctiva, 806; dermoid, of the ovary, 602; celiococcus, of the rectovesical space, 709; -fluids, digestive activity of, 205; hemorrhagic, of the thyroid gland, 669; hydatid, of the liver, 200, 236; of the orbit, 828; intermittent, ovarian, 600; of the iris, 845; of the mesentery, 284; multilocular ovarian, 600; of the omentum, 236; of the optic nerve, 825; of the ovary, 599; of the pancreas, 203, 353; papillary ovarian, 600; uveal, 814; vaginal, 532.
 Cystic anencephalus, 459; degeneration of the kidney, congenital, 676.
 Cystinuria, 207.
 Cystitis in children, 640; curettage in, 538; etiology, 537; gangrenous, 538; infantile, 528; prophylaxis, 537; saline solution in, 538; silver nitrate in, 538; treatment, 537.
 Cystoscope, 429.
 Cystotomy, 538; suprapubic, 426.
 Cytochemism, 694.
 Czaplowski (E.) and Hensel (R.) on pertussis, 627.
 Czerny on carcinoma of the colon, 297; on the Murphy button, 294.
 Czzygan on bromoform-poisoning, 646; on gastric carcinoma, 182.
 DABNEY (T. S.) on syphilis, 919.
 DaCosta (J. M.) on acute yellow atrophy of the liver, 197.
 Dahlefeld and Pohrt on foreign body in the eye, 829.
 D'Amore (L.) on *Grindelia robusta*, 940.
 Dana (C. L.) on trifacial neuralgia, 714; and Frankel on Pott's disease, 767.
 Dandois on ovarian dermoid, 602.
 Dancel on tuberculous esophagitis, 173.

- Danger of bicycling, 141.
 Daniel on abortion, 472; on x-rays, 447.
 Daniel (J. W.) on argonin, 401; on carbon-monoxid poisoning, 999.
 Daniels (C. W.) on *Tenia madagascariensis*, 223; on yaws, 912.
 Danilewsky (B.) on electro-physiology, 989.
 Danzige on carcinoma of the temporal bone, 864.
 Darier on cataract, 812; on toxic amblyopia, 825; on vernal cataract, 804.
 D'Arsonval and Charrin on diabetes, 99.
 Dastre and Floresco on the blood, 973.
 Dauber on gastroscorrhœa mucosa, 179.
 Davaine on echinococcus of the Fallopian tubes, 587.
 Davidson (J. M.) on formaldehyd, 938.
 Davies (H. R.) on carcinoma, 217.
 Davis (A. E.) on the eye in menstruation, 796; on the lacrimal duct, 897.
 Davis (A. N.) on aneurysm of the heart, 142; on pneumonia, 161.
 Davis (E. P.) on labor, 483; on serum-therapy in puerperal sepsis, 512; on symphysiotomy, 597.
 Davis (E. W.) on foreign body in the larynx, 887.
 Davis (G. G.) on amputation of the penis, 415.
 Dawbarn on fracture of the humerus, 391; on hallux valgus, 384.
 Dead body, destruction of, 995.
 Deaf-mutes, 867.
 Deafness from atheroma, 846; from mumps, 846; psychic, 867; simulated, 845.
 Death from antitoxin, 620, 698; during chloroform-anæsthesia, 267; after osteotomy, 770; -rate from infectious diseases, 1009; of tuberculosis, 59; from serum-injections, 698, 991; violent, 992.
 De Bernardi on antituberculous serum, 65.
 De Besse on gastric carcinoma, 186.
 De Blasi and Russo-Travali on diphtheria, 611.
 Debove on tuberculosis, 58.
 De Brun on ainhua and leprosy, 74; on malarial ascites, 80.
 De Buck (D.) and De Moor (L.) on tannoforn, 955.
 De Carrasquilla (J.) on lepra, 73.
 Deciduoma, malignant, 457, 678.
 Decio on delivery in the moribund, 499.
 Decomposition of chloroform, 266.
 De Creccio on hypertrichosis, 905.
 De Domenicis (N.) on hypertrophy of the heart, 141; on the suprarenal capsules, 979.
 Deflection of the nasal septum, 874; of the pregnant and puerperal uterus, 484.
 Deformity, hour-glass, of the stomach, 181; of the knee, 771; in Pott's disease, 767; in rheumatoid arthritis, 88.
 De Garmo (W. B.) on Bassini's operation, 337.
 Degenerate auricle, 838.
 Degeneration, ascending, 656, 725; calcareous, of the heart, 656; fatty, 705; of the uterine in pregnancy, 481; infantile cerebral, 763; leukoætic, 103; of the spinal roots, 658.
 De Gouvea (H.) on the eye, 797.
 Deguy on salpingitis, 566.
 Dehio on erythromelalgia, 727.
 De Holowinski (A.) on the heart, 977.
 Deichert on bone-growths in the tonsil, 884.
 De la Jarrige on tuberculosis, 65.
 Delatonr (H. B.) on foreign body in the esophagus, 274; on x-rays, 445.
 Delavan (D. B.) on adenoids, 880; on transfusion, 872.
 Delbet on hallux valgus, 384.
 Delbril on articularia of the larynx, 886.
 Del Costello (R.) on enucleation of the eye, 830; on iritis, 814.
 De Lee (J. B.) on antepartum hemorrhage, 471; on Cesarean section, 508.
 Delert on carcinoma of the uterus, 578.
 Delezenne (C.) on the blood, 973, 974.
 Delius and Kolbe on influenza, 38.
 Delivery in the moribund, 499.
 Delmis on pernicious anemia, 115.
 Delore on scoliosis, 768; on thyroidectomy, 377.
 Delorme on Whitehead's operation, 358.
 Del Toro on cataract, 811.
 Del Vecchio on suture of the heart, 370.
 Demelin (L.) on cardiac disease in pregnancy, 462.
 Dementia paralytica, pathology of, 659; parietic, 759.
 Dench (E. B.) on otitic meningitis, 860; on sinus-thrombosis, 856.
 De Niet on gastric malpositions, 174.
 Denis on abdominal pregnancy, 475.
 Denissenko on warts, 240.
 Denker on fracture of the auditory canal, 840; on sinus-thrombosis, 856.
 Dennis on fractures, 391.
 Dent (C. F.) on gastric ulcer, 181.
 Dentine, innervation of, 963.
 Denys on pneumonia, 164.
 Depage on cancer of the rectum, 362.
 Depasse on scarlatina, 625.
 Depla on myoma of the uterus, 568.
 De Quervain on fremdkörper-tuberculosis of the peritoneum, 667; on torticollis, 716.
 Derby (H.) on the cornea, 898.
 Dereum (F. X.) on neurasthenia in women, 522; and Spiller on syringomyelia, 729.
 De Renzi on antituberculous serum, 65; on pneumonia, 163.
 Derivation of the hymen, 553.
 Dermatitis exfoliativa neonatorum, 520, 891; herpeticiformis, 892; papillaris maligna, 911; venenata, 891; x-ray, 417, 894.
 Dermatoses diabeticae, 899.
 Dermoid cyst of the cornea, 808; nasal, 876; of the ovary, 602.
 De Roaldes (A. W.) on fracture of the larynx, 887; on pharyngeal teratoma, 886.
 De Rossi (C.) on stapedectomy, 848.
 Descaner on quadruplets, 501.
 Deschamps on advancement, 791.
 De Schweinitz (E. A.) on hog-cholera, 697.
 De Schweinitz (G. E.) on albuminous neuroretinitis, 793; on blood-staining of the cornea, 808; on cataract-extraction, 810; on corneal ulcer, 807; on foreign body in the eye, 825; on meningitis after eye-operations, 827; on optic neuritis, 823; on recurrent abducens paralysis, 788; on the retina, 818; on retinal hemorrhage, 819; on ripening of cataract, 811.
 De Seigneux (R.) on head-presentations, 485.
 De Silva (G. F.) on craniotomy, 507.
 De Smet on gonorrhœal vaginitis, 525.
 Despagnet on diphtheric ophthalmia, 832; on vernal cataract, 801.
 Desquamation in typhoid fever, 12.
 Destruction of dead body, 995.
 Detachment of the choroid, 815; premature, of the placenta, 471; of the retina, 821.
 Deucher (P.) on digestion, 985.
 Development of the fetal bones, 970; of the mammary gland, 970.
 Devar (P. A.) on slow pulse, 118.
 De Wecker (L.) on autoinfection of the eye, 793; on ocular tuberculosis, 794; on tattooing of the eye, 830; on

- toxic amblyopia, 825; on trauma of the eye, 826.
- Dextrocardia, 140.
- Dextrose in the urine, 206.
- Diabetes, bronzed, 97.
- Diabetes mellitus, acute, 97; albuminuria in, 97; antipyrin in, 633, 929; blood in, 97; in children, 633; diagnosis, 97; diet in, 99; electricity in, 99; etiology, 96; excretion of calcium in, 97; eye in, 794; and the lens, 810; levulose in, 99; liver in, 97; in married couples, 96; pathology, 97; phloridzin in, 98; spinal cord in, 97; statistics, 97; symptoms, 97; treatment, 98; uranium nitrate in, 98.
- Diabetic urine, color-reactions of, 98.
- Diagnosis of pelvic disease, 5-83.
- Diakonaf on Pott's disease, 766.
- Diaphragm, injuries of, 995; -phenomena in tuberculosis, 61.
- Diaphragmatic hernia, 190; peritonitis, 309.
- Diarrhea, antipyrin in, 929; in Graves' disease, 151; orphol in, 946; summer, 631.
- Diarrheal diseases in children, 631.
- Diazo-reaction, Ehrlich's, 32.
- Dickinson (L.) on adherent pericardium, 126.
- Diebala on anemia, 108.
- Dieballeo on the eye in chlorosis, 796.
- Diet in arterial disease, 155; in cardiac disease, 146; in diabetes mellitus, 99; in gout, 93; in typhoid fever, 35; in ureteritis, 539.
- Dietetic glycosuria, 95.
- Dietetics, 978.
- Dietrich on malignant lymphoma, 375; on pseudoleukemia, 121.
- Dieulafoy on appendicitis, 319; on the peritonitis of typhoid fever, 288; on tuberculous lymph-glands, 374; on typhoid fever, 13, 17.
- Digestion, 895; gastric, 175; pancreatic, 205; pepsin, 175.
- Digestive activity of cyst-fluids, 205; ferments, 986; for deafness, 848; hyperleukocytosis, 102; tract, anatomy, 962; pathology of, 663.
- Digitalin in pneumonia, 161.
- Digitalis in appendicitis, 323; in menorrhagia, 551; in pneumonia, 161.
- Digitoxin, 931.
- Dilatation of the esophagus, 172; of the stomach, 176.
- Di Mattei (E.) on seminal stains, 998.
- Dinshaw (V.) on scorpion bite, 110.
- Dionisio (J.) on nasal syphilis, 875.
- Diphtheria, antitoxin in, 612, 615, 1003; blood in, 612; cerebral hemiplegia in, 614; classification of, 616; cocaine in, 614; diagnosis, 611; etiology, 610; eye in, 795; heart-failure in, 613; internal ear in, 866; intubation in, 621; laryngeal, 621; mercuric chlorid in, 614; middle ear in, 842; myocardium in, 655; nurslings and, 621; paralysis in, 613; pathology, 611, 684; prophylaxis, 622; relapses in, 621; resorcin in 614; and scarlatina, 625; serum-therapy of, 615; sodium hyposulphite in 615; statistics of, 621, 622; symptoms, 613; treatment, 611; urine in, 640.
- Diphtheria-bacillus, 684; action of carbon dioxide on, 685; in normal throats, 685.
- Diphtheric croup, 618; ophthalmia, 832.
- Diphtheroid angina, 613; stomatitis, 634.
- Diplegia, congenital cerebral, 612.
- Diplococcus lanceolatus, neopluritis due to, 676; in mumps, 630; of pertussis, 688.
- Diprosopus, 459.
- Diptera, 998.
- Direct contagion in typhoid fever, 11.
- Dirner on ovarian papilloma, 600.
- Dissection in secondary cataract, 812.
- Disease, Addison's, 123; of anterior lobe of brain, 720; Basedow's, 377; Breisky's, 526; Bright's, 211; caisson's, 734; choroidal, 821; chronic valvular, 133; cutaneous, 891; fish-slime, 53; foot-and-mouth, 51; Glénard's, 190; Graves', 150; hip-joint, 398; Hodgkin's, 121; Little's, 738; Marie's, 89; Morvan's, 729; parrot, 74; Pavy's, 210; pelvic, 583; placental transmission of, 455; Pott's, 412, 764; Raynaud's, 748; Reichmann's, 178; Ritter's, 520; sacro-iliac, 777; venereal, 401; Weil's, 52.
- Diseases of the alimentary tract in children, 633; of the anus, 357; of the arteries, 153; artificial, of the lobule, 839; of the biliary passages, 201; of the bladder, 417, 537; of the blood, 100; of the blood in children, 636; of bone, 383; of the brain, 405, 717; of the bronchi, 157; of the cerebral meninges, 712; of the cervix uteri, 533; of the choroid, 815; of the circulatory system in children, 636; of the conjunctiva, 801; constitutional, 85; of the cornea, 807; of the cranial nerves, 712; of the esophagus, 172; of the external ear, 837; of the foot, 772; functional, of the stomach, 178; of the gall-bladder, 342; of the genitourinary system in children, 639; of the hand, 776; of the head, 708; of the heart, 127; hemorrhagic, 122; of the hip, 769; infections, 10; of the internal ear, 866; of the intestinal tract, 187, 284; of the iris, 813; of the joints, 393; of the kidney, 205, 428, 538; of the knee, 771; of the lacrimal apparatus, 806; of the larynx, 869; of the lens, 809; of the lids, 799; of the liver, 196, 312; of the liver in children, 639; of the lungs, 159; of the lymphatic system, 372; of the mediastinum, 171; mental, 753; of the middle ear, 841; of the mouth, 171; of the muscles, 380; of the myocardium, 141; of the neck, 768; of the nerves, 405; of the nervous system in children, 640; of the newborn, 517; of the nose, 869; of the optic nerve, 822; of the orbit, 827; of the ovaries, 598; of the pancreas, 203, 342; of the pelvic viscera, 5-83; of the penis, 414; of the pericardium, 125; of the peritoneum, 193, 284; of the pharynx, 171; of the pleura, 167; of the prostate, 417; of the rectum, 357; of the respiratory organs, 157, 363; of the retina, 818; of the spinal column, 412, 764; of the spinal cord, 412, 728; of the spinal meninges, 725; of the spinal nerves, 725; of the spleen, 202, 342; of the spleen in children, 639; of the stomach, 174; of the tendons, 3-0; of the testicle, 414; of the thorax, 764; of the thyroid gland, 377; of the ureter, 128, 538; of the urethra, 414, 536; of the urinary organs, 536; of the urine, 205; of the vagina, 526; of the vascular system, 367; of the vulva, 526.
- Disen (C. F.) on the heart, 127.

 the urethra, 536.
 Epstein on carcinoma, 100; on
 catalepsy, 643.
 Equinia, chronic, of the skin,
 899.
 Erosion of the knee-joint, 395.
 Erben (S.) on hemiplegia, 722.
 Erdheim on Cesarean section,
 508.
 Ergot in hemoptysis, 70.
 Erlenmeyer on morphinism,
 756.
 Errich on glanders, 76.
 Eruption, secondary, in small-
 pox, 47; after sunburn, 894.
 Erysipelas and menstruation,
 544; recurrent, 52; -strepto-
 coccus, specificity of, 687;
 -toxins in carcinoma of the
 uterus, 580.
 Erythema, blood-, 893.
 Erythematous lupus, 910.
 Erythrocytes, 104.
 Erythrol-tetranitrate, 155.
 Erythromelalgia, 727.
 Escat on cystitis, 538.
 Escherich (T.) on status lym-
 phaticus, 633.
 Eserin in glaucoma, 817.
 Eshner (A. A.) on mitral steno-
 sis, 136.
 Esophageal actinomycosis, 173.
 Esophagitis, tuberculous, 173.
 Esophagoscope, 172.
 Esophagotomy, 272.
 Esophagus, carcinoma of, 174;
 diseases of, 172; foreign body
 in, 272; fusiform dilatation
 of, 172; stenosis of, 173; sur-
 gery of, 272; tuberculosis of,
 663.
 Estimation of urea, 1015.
 Ether, after-effects of, 266; as
 an anesthetic, 257; -bron-
 chitis, 266; in puerperal
 eclampsia, 496.
 Etherization, oxygen after, 266.
 Étienne on placental transmis-
 sion of disease, 456; on ty-
 phoid fever, 15.
 Eubank and Hall on blood, 106.
 Eucaïn, 271; in eye-diseases,
 831; in nose-diseases, 869.
 Euchinin, 935.
 Endoxin, 231.
 Eulenburg on exophthalmic
 goiter, 672.
 Eulenstein (H.) on otitic pye-
 mia, 860.
 Europhen in atrophic rhinitis,
 873.
 Eustachian tube, stricture of,
 882.
 Evans on bicycling for women,
 541.
 Evans (H. M.) on phlyctenular
 conjunctivitis, 803; on rodent
 ulcer, 679.
 Eve (F. C.) on nerve-cells, 987;
 on retinal detachment, 822.
 Ewart (W.) on pericardial effu-
 sion, 125; on pericarditis, 126.
 Ewetzky on membranous con-
 junctivitis, 803.
 Ewing (F. C.) on hypertrophic
 rhinitis, 872.
 Examination of blood, 100; of
 hairs, 999; of the heart, 127;
 of the stomach, 174.
 Excessive size of the fetus, 502.
 Excision of the breast, 243; of
 the Gasserian ganglion, 714;
 in Graves' disease, 152; of the
 hip for tuberculosis, 250; of
 the knee-joint, 395; of necro-
 tic ossicula, 849.
 Excretion of calcium in diabetes
 mellitus, 97; of mucus from
 the bowel, 188.
 Excretions of parturient women,
 489.
 Exencephalia, 459.
 Exercise in cardiac failure, 145.
 Exfoliation of the bladder-wall,
 538.
 Exner (A.) on thyroid extract,
 979.
 Exomphalos, 459.
 Exophthalmic goiter, 150, 377,
 745; and acromegaly, 745;
 diarrhea in, 151; enucleation
 in, 745; excision in, 152; eye
 in, 795; and marriage, 151;
 metabolism in, 673; nitrogen-
 balance in, 152; organo-
 therapy in, 151; pathology,
 669; and pregnancy, 151; re-
 section of the cervical sympa-
 thetic for, 746; sodium phos-
 phate in, 152; splenic extract
 in, 152, 745; strumectomy in,
 152; tachycardia in, 151; thy-
 mus-feeding in, 151, 745;
 thyroantitoxin in, 747; thy-
 roid extract in, 151, 377;
 treatment, 151.
 Exophthalmos, pulsating, 828.
 Exostosis in typhoid fever, 15.
 Expectoration, albuminous,
 668; serous, 668.
 Experimental anthracosis, 667;
 cirrhosis of the liver, 666;
 pneumothorax, 985; thera-
 peutics, 922; tuberculosis, 60,
 683.
 Experts, medical, 991.
 Expiratory murmur, prolonga-
 tion of, 159.
 Exploration of the brain, 407;
 hydrostatic, 583; rectal, in
 children, 584; of the tho-
 racic cavity, 366; vaginal,
 583.
 Exploratory incision in frac-
 tures, 391.
 Expression and the facial mus-
 cles, 968.
 External auditory canal, frac-
 ture of, 840; ear, diseases of,
 836; hemorrhoids, 358; oph-
 thalmoplegia, congenital, 713.
 Extirpation of the rectum
 through the vagina, 361.
 Extract of pulmonary tissue
 in bronchitis, 158.
 Extraperitoneal ectopic gesta-
 tion, 475.
 Extrauterine pregnancy, 474;
 diagnosis, 478; extraperito-
 neal, 475; in an inguinal
 hernia, 476; operation in,
 480; repeated, 475, 479; rup-
 ture in, 480; salt-solution in,
 480; strychnin in, 480; symp-
 toms, 478; treatment, 480;
 twin, 475; with typhoid
 fever, 13; vaginal section
 for, 481.
 Extravascular blood, properties
 of, 650.
 Extroversion of the bladder,
 425.
 Exudates, leukocytes in, 710.
 Eye, anatomy of, 780; antisepsis
 in, 829; asepsis in, 829; auto-
 infection of, 792; in cere-
 brospinal diseases, 797; in
 chlorosis, 796; in criminol-
 ogy, 782; congenital affec-
 tions of, 799; curettage of,
 833; in diabetes, 794; in
 diphtheria, 795; enucleation
 of, 830; in epilepsy, 796; in
 exophthalmic goiter, 795;
 foreign bodies in, 825; in
 gout, 793; in hysteria, 796;
 and kidney-disease, 793; in
 leukemia, 795; in malaria,
 794; in marasmus, 794; me-
 lanosarcoma of, 832; in men-
 struation, 796; muscle-affec-
 tions of, 787; in nephritis,
 793; of the newborn, 965;
 in pertussis, 796; photog-
 raphy of, 836; physiology of,
 780; in the procerium, 796;
 Röntgen rays and, 825; syph-
 ilis of, 794; tattooing of, 830;
 therapeutics of, 831; in ton-
 sillitis, 796; traumatism of,
 826; in tuberculosis, 794; in
 typhoid fever, 796; in vacci-
 nation, 796; x-rays and, 825.
 Eye-diseases, yellow ointment
 in, 832.
 Eye-globe, injuries of, 825.
 Eyesight and veils, 782.
 Eye-strain, 783.
 Eykman (C.) on animal heat,
 983; on the blood, 976.
 Eye (J. H.) on supernumerary
 caruncle, 806; on the xero-
 sis-bacillus, 685.
 FABRE on lepra, 73.
 Fabre (J.) on palpation of the
 shoulder, 486; on pernicious
 vomiting of pregnancy, 462.
 Fabrius (J.) on ovarian cysts,
 599.
 Facial erysipelas, meningitis
 after, 52; hemiatrophy, 715;
 muscles and expression, 968;
 neuralgia, 714; intracranial
 operation for, 408; paralysis,
 715; in acute otitis media,
 845.
 Face on sarcoma of the lid, 801.
 Faintness, 148.
 Fallopian tubes, carcinoma of,
 586; echinococcus of, 587;
 elastic tissue in, 966; papil-
 loma of, 587; sepsis of, 585;
 tuberculosis of, 586.

- Family ataxia, 737; spastic paraplegia, 738.
- Fanning (F. W. B.) on sewer-air poisoning, 51.
- Fano on the blood, 973.
- Farlow (J. W.) on myxedema, 886.
- Fat-embolism, 994.
- Fat-necrosis, 203.
- Fat-splitting, 985.
- Fatty degeneration, 705; of the uterus in pregnancy, 484.
- Faucial tonsils, hyperplasia of, 71.
- Fawcett (E.) on sesamoid bones of the hand, 960.
- Fawcett (J.) on gout, 94; and White (W. H.) on animal heat, 983.
- Febrile diseases of unknown nature, 53; gastritis, 178.
- Febris autointoxica, 36; undulans, 50.
- Fecal fistula, 297; impaction, 188; tumors 188.
- Feces, 986; tubercle-bacilli in, 72, 684.
- Fede (F.) on Riga's disease, 634.
- Federow (T.) on trachoma, 801.
- Feeding, infant, 606; in gastric ulcer, 182; in paralysis of the larynx, 888.
- Feet, tinea versicolor on, 900.
- Fehling on placental delivery, 187; on the vaginal incision, 598.
- Fehring (J.) on encephalitis, 718.
- Feist on paranoiac insanity, 751.
- Femoral aneurysm, 368; hernia, 336, 338.
- Femur, fracture of, 385.
- Fenger (C.) on stricture of the ureter, 432.
- Fenwick (E. H.) on the cystoscope, 429.
- Fenwick (W. S.) on infantile marasmus, 635.
- Féré on epilepsy, 751.
- Ferguson on purulent conjunctivitis, 802.
- Ferguson (E. D.) on autointoxication, 56.
- Ferments, digestive, 986; in carcinoma of the stomach, 182.
- Fernandez (J. S.) on leukemia, 809; on trachoma, 804, 805.

- Fürbringer on albuminuria, 1012; on lumbar puncture, 732; on meningitis, 52; on pertussis, 627; and Freyhan on disinfection of the hands, 230.
- Furet on reflex cough, 884.
- Furman (F. S.) on variola, 48.
- Fusiform dilatation of the esophagus, 172.
- Futcher on gout, 93.
- Futran on patulous foramen ovale, 140.
- Futterer (G.) on the eye in tonsillitis, 796; on salivary calculus, 171.
- GABAROFF (A. V.) on suture-material, 228.
- Gabritschewsky on diphtheria, 619; on relapsing fever, 49.
- Gaff (J. V.) on sterility, 450.
- Gage (H.) on tubal pregnancy, 175.
- Galatti on status lymphaticus, 632.
- Galletti on fracture of the auditory canal, 840.
- Galezowski on choroiditis, 815; on herpes of the cornea, 808; on syphilis of the eye, 832.
- Galgey on anchylostomiasis, 222.
- Galkemarti on syphilis of the lids, 800.
- Gallant (A. E.) on oversize of the fetus, 502.
- Gall-bladder, aspiration of, 362; diseases of, 342; massage of, 350; in obstruction of the ductus choledochus, 666; supuration of, 278.
- Galliard on carcinoma of the esophagus, 174; on pneumonia, 162.
- Gallie acid in hemoptysis, 70.
- Galli-Valerio on dysentery,

- 193; on pseudoactinomycosis, 76.
 Gall-stone, ball-valve, 201.
 Gall-stones, impacted, 189, 297, 351; surgery of, 348.
 Galton (J. H.) on ovariotomy in the aged, 588.
 Galvanism in aneurysm, 370.
 Galvanocautery, uterine excision by, 581.
 Galvanotropism, 989.
 Gange (A.) on blood-pigment, 974.
 Ganghofner (F.) on diphtheria, 618.
 Ganglion-cells, effect of tetanus-toxin on, 658; in the iris, 966.
 Gangrene, 232; hospital, 234, 689; of the lung, 165; in measles, 624; of the pharynx, 172; puerperal, 516; spreading, 234; superficial, 647; in typhoid fever, 626.
 Gangrenous cystitis, 538.
 Gape (C.) on insanity, 758.
 Garber (F. W.) on purulent pericarditis, 125.
 Garner (L.) on amenorrhea, 550.
 Garrard (W. A.) on carcinoma of the colon, 296.
 Garrigues (H. J.) on anesthesia-paralysis, 262, 728.
 Garrod (A. E.) on gout, 92.
 Gasserian ganglion, excision of, 714; resection of, 407.
 Gaston (J. M.) on exploration of the thoracic cavity, 266.
 Gastralgia, arsenic in, 181.
 Gastroctasia, 178.
 Gastroctomy, 275.
 Gastric digestion, saliva and, 175; disease, illumination in, 175; disturbances in tuberculosis, 61; flatulence, 179; lesions in malaria, 81; malpositions, 171; secretion, 179; ulcer, 181, 281; laparotomy in, 281; perforation of, 281; sequela, 283.
 Gastritis, 177; febrile, 178; phlegmonous, 177; polyposa, 113.
 Gastroanastomosis, 181.
 Gastrodiaphany, 174.
 Gastrodynia neuralgic, 181.
 Gastroenteritis, cow's serum in, 635; in children, 178.
 Gastroenterostomy, 275, 279.
 Gastrojejunostomy, 279.
 Gastroptosis, 174, 176.
 Gastrostomy, 275.
 Gastroscorrhica, chronic, 178; mucosa, 179.
 Gaulard on puerperal sepsis, 513.
 Gauze in postpartum hemorrhage, 515.
 Gelanthum in skin-diseases, 912.
 Gellé on ankylosis of the stapes, 846.
 Gelpke (T.) on conjunctivitis, 802; and Bilker (W.) on myopia, 785.
 Gemmel (J. F.) on hepatic abscess, 345.
 General paresis, 759.
 Genital tuberculosis in children, 629.
 Genitalia and the thyroid gland, 547.
 Genitourinary organs, 966.
 Gennano (E.) on typhoid fever, 1003.
 Geophragia, 223.
 Gerhardt on exophthalmic goiter, 745; on pulsus paradoxus, 153; and von Leyden on tuberculosis, 996.
 Germ of soft chancre, 403.
 German empire, vital statistics of, 1008.
 Geronzi on facial paralysis, 845; on malformation of the heart, 140.
 Gerota (D.) on the bladder, 967.
 Gerster (A. G.) on the kidney, 431.
 Gersuny on fecal tumors, 188.
 Geschwind on typhoid fever, 1004.
 Gessner on ovarian myoma, 602; on pulmonary embolism, 595; on uterine carcinoma, 579.
 Gestation, extrauterine, 474.
 Getchell (A. C.) on laryngeal vertigo, 888.
 Geyer (J.) on sugar in the urine, 1019.
 Ghika on diphtheroid stomatitis, 634.
 Giant fetus, 460.
 Gibb (J. S.) on curcain, 272, 870.
 Gibbs on pseudo-beri-beri, 54.
 Gibert on typhoid fever, 11.
 Gibney (V. P.) on Pott's disease, 766, 767; on stiff joints, 398.
 Gibson (W. M.) on endocarditis, 132.
 Gierlich on trional, 956.
 Gigantism and acromegaly, 744.
 Gilbert and Fournier and Oudin on gall-stones, 202; on psittacosis, 74; and Garnier on chlorosis, 111; and Grenet on hepatic cirrhosis, 196.
 Gilchrist (T. C.) on x-ray dermatitis, 894; and Stokes (W. R.) on pseudo-lupus vulgaris, 910.
 Giles (A. E.) on vaginal douching, 558.
 Giles (J. E.) on oculomotor paralysis, 788.
 Gill on appendicitis, 192.
 Gillespie on albumosuria, 210.
 Gilpin (G. E.) on maternal impressions, 458.
 Ginglio (G.) on anthrax-infection, 1004.
 Gingoet and Degui on pneumonia, 164.
 Ginsberg on choroidal coloboma, 799.
 Girls, prolapse of the urethra in, 536; vulvovaginitis of, 528.
 Glacial acetic acid in trichophytosis, 903.
 Gladmon (E.) on malignant endocarditis, 132.
 Gland, pituitary, 949.
 Glanders, 76; in man, 690; serum-test for, 76.
 Glands of the ciliary body, 966; intraepithelial, 967.
 Glandular fever, 629; tuberculosis in children, 628.
 Glas on albuminuria, 1012.
 Glaser on diphtheria, 622.
 Glasses, colored, 835.
 Glaucoma, classification, 816; diagnosis, 817; malignant, 816; with ocular tumors, 817; treatment, 817.
 Gleason (E. B.) on deflected septum, 875; on stapedectomy, 848.
 Gleet of syphilitic origin, 404.
 Glénard's disease, 190.
 Gley on the thyroid gland, 978; and Pachon on the blood, 973.
 Glioma, 818.
 Glonoin in puerperal eclampsia, 496; in uremia, 465.
 Glossitis, 852.
 Glover on fibrinous rhinitis, 871.
 Glück (L.) on syphilis of the larynx, 889; and Schmidt on resection of the lung, 365.
 Glutol, 936, 939.
 Glycerin for inducing labor, 503; in uterine fibroids, 570.
 Glycogenesis, 982.
 Glycogen-function of the liver, 998.
 Glycoproteids, 1020.
 Glycosuria, 95; dietetic, 95; with incarcerated inguinal hernia, 96; in pancreatic cyst, 203.
 Glycosurie dermatoses, 899.
 Godart on papilloma of the Fallopian tubes, 587.
 Godding (C. C.) on non-venereal bubo, 403.
 Godfrey (F. W. A.) on vaginismus, 529.
 Godinho on vaginofixation, 566.
 Godlee (H. G.) on pulmonary osteo-arthropathy, 89; on tuberculosis, 60.
 Godson (C.) on labor, 483.
 Goelet (A. H.) on abdominal section, 591; on Alexander's operation, 567; on senile vaginitis, 528; on trachelorrhaphy, 534; on vaginal ligation of the uterine arteries, 571; on ventrofixation, 568.
 Goh (K.) on the eye, 797.
 Goiter, 377, 746; congenital, 747; dyspnea in, 378; exophthalmic, 150, 377; thyroid-feeding in, 646.
 Goldberger on fetus papyraceus, 502.
 Golding on infant-feeding, 606.
 Goldscheider and Flatau on the ganglion-cells, 658.
 Goldthwait (J. E.) on achillobdymia, 385.
 Goldzieher (W.) on aniridia, 813; on retinitis pigmentosa, 820.
 Golnier on orphol, 946.

- Golouboff on appendicitis, 199, 323.
- Gomperz (B.) on mastoiditis, 853; on the membrana tympani, 840; on otorrhea, 851; on perforations of the membrana tympani, 841.
- Gonæitis, tuberculous, 772.

- Stocker (S. M.) on urticaria of the conjunctiva, 805; and Pflüger on enucleation of the eye, 830.
- Stockman (R.) on pernicious anemia, 112.
- Stoerk (K.) in cocaine-anesthesia, 269; on the esophagoscope, 172.

- Stoltz on sterility, 450.
 Stomach-bed, 963; carcinoma of, 182, 275; changes in form and position, 176; contraction of, 181; dilatation of, 176; diseases of, 174; examination of, 174; foreign bodies in, 279; functional diseases of, 178; hour-glass deformity of, 181; motor insufficiency of, 179; movements of, 986; neurosis of, 178; -sound, Rosenheim's, 181; surgery of, 275; -washings in carcinoma, 183.
 Stomatitis, aphthous, 172; diphtheroid, 634.
 Stone, impaction of, in the ureter, 432; in the bladder, 427.
 Stone (I. S.) on abdominal salpingo-oophorectomy, 594; on abdominal section, 589; on the vaginal incision, 598.
 Stone (R. M.) on carcinoma of the uterus, 580.
 Stools on angina, 172; on aphthous stomatitis, 172.
 Storck (H.) on carious teeth, 374; on formalin, 181.
 Storer (M.) on rupture of ovarian cysts, 601; on torsion of ovarian cysts, 602.
 Story (J. B.) on cataract, 811.
 Stout (G. C.) on atresia narium, 870.
 Stowell (W.) on arthritis deformans, 633.
 Strabismus, 789.
 Strangulated hernia, 335.
 Strangulation, 992.
 Strasser (A.) on the blood, 652.
 Strassmann on antitoxin, 698; on menstruation, 451.
 Strassmann (F.) on death in serum-therapy, 995; on infanticide, 994; on rigor mortis, 992.
 Straub (M.) on oculomotor paralysis, 788.
 Strauss on the blood, 106; on uric acid and the alloxur-bodies, 208.
 Streaked skin-affections, 906.
 Strehl on Cesarean section, 508.
 Streminski on acromegaly, 798; on autoinfection of the eye, 793.
 Streptococci, homology of, 687; in tuberculosis, 59; in ulcerative endocarditis, 132.
 Streptococcus, 687; -antitoxin, 698; -infection, 52; Mar-morc's, 687.
 Streptothrix, 688.
 Stretching the spinal cord, 737.
 Stricture of the aorta, congenital, 141; of the auditory canal, 840; of the bile-duct, 349; of the Eustachian tube, 882; of the lacrimal duct, 806; of the rectum, 358; of the ureter, 432; of the urethra, 415.
 Strief (J. J.) on the thyroid gland, 971.
 Strontiumbromid in tetany, 742.
 Strophanthus, 953.
 Structure of the larger arteries, 961.
 Strümpell on glycosuria, 95.
 Strüver on formaldehyd, 1004.
 Strumectomy in Graves' disease, 152.
 Strychnin in anesthesia-paralysis, 264; in extrauterine pregnancy, 480; in optic atrophy, 824; in peritonitis, 308; in snakebite, 440; in trifacial neuralgia, 714.
 Stuart (A. M.) on abortion, 474.
 Stuckey (J. A.) on necrotic ossicula, 850.
 Stulp (O.) on embolism of the retina, 819; on papilloma of the conjunctiva, 806.
 Stuttering and stammering, 890.
 Subdiaphragmatic peritonitis, 308.
 Subpleural pulmonary abscess, 165.
 Sudamina in typhoid fever, 12.
 Sugar in gout, 95; in urine, 1019.
 Suker (G. F.) on eye-enucleation, 830.
 Sulfonal in epilepsy, 751.
 Sulphosalicylic acid test, 1013.
 Sulpho-test, 1013.
 Sulphur in acne, 897.
 Sulzer on glaucoma, 816.
 Summer diarrhea, 634.
 Sunburn, eruption after, 894.
 Sunlight and bacteria, 690.
 Sunstroke, 722.
 Superfetation, 452.
 Superficial burns, visceral changes in, 994; gangrene, 647.
 Superheated air on stiff joints, 398.
 Superinvolution of the uterus, 488.
 Supernumerary caruncle, 806.
 Supplementary amniotic sac, 458.
 Suppuration, 232; attic, 849; of the gall-bladder, 278; of ovarian cysts, 601; pelvic, hysterectomy for, 596; of the posterior mediastinum, 235; of renal fat, 432; in typhoid fever, 14; of a uterine fibroid, 569; in a vaginal cyst, 533.
 Suppurative arthritis in typhoid fever, 19; hygroma in pneumonia, 162; tenonitis, 792.
 Suprapubic cystotomy, 426.
 Suprarenal capsules, 954, 979; gland, injection of, 710.
 Sureaw (H.) on corneal ulcer, 807.
 Surgery, 225; abdominal, drainage in, 304; of intrathoracic tuberculosis, 363; of the intestines, 284; of the larger intestine, 296; orthopedic, 764; of the peritoneum, 300.
 Surgical fever, 233; injuries of the ureter, 539; scarlet fever, 625.
 Surmount and Predhomme on tuberculosis, 59.
 Susceptibility to infection, 1001.
 Suspensio uteri, labor after, 497.
 Suspension of the uterus, 568.
 Sutcliff (E.) on dislocation of the forearm, 399.
 Sutherland on gastric flatulence, 179.
 Sutton (C. F.) on vaccination, 46.
 Sutton (E. M.) on diphtheria, 614.
 Sutton (J. B.) on myelomata, 239; on tubal abortion, 475; on uterine fibroid, 569; on wandering spleen, 202, 356.
 Sutton (S.) on operation during pregnancy, 470; and Gordon on conception, 452.
 Suture-abscess, 595; buried, 337, 591; of the heart, 369, 370; -material, 228; metopic, 960; of the pleura, 365.
 Suturing of nerves, 405.
 Swain (H. L.) on Bezdol's mastoiditis, 854; on mastoiditis, 853; on tuberculosis of the ear, 865.
 Swain (J.) on x-rays, 444.
 Swallowing, innervation of, 987.
 Sweat, toxicity of, 710.
 Sweat-glands in nephritis, 212.
 Sweet (G. B.) on hemoglobinuria, 210.
 Sweet (W. M.) on foreign body in the eye, 825; on Jamieson's salve, 832.
 Swift (G. M.) on pericarditis, 637.
 Swinburne (G. K.) on argonin, 401.
 Switalski on opening of the abdominal wound, 596.
 Swoboda on epistaxis, 876; on melæna neonatorum, 518.
 Symmetric edema in peritonitis, 307; morphea, 906.
 Symonds (B.) on urine, 1015.
 Sympathetic ophthalmia, 815; system, 989.
 Symphysiotomy, 507.
 Syms (R.) on actinomycosis, 233.
 Syncephalus, 459.
 Synclitism in labor, 185.
 Syncope, chloroform-, 268.
 Syndrome, Adam-Stokes', 149.
 Synovitis, scarlatinal, 626.
 Syphilis, 918; and abortion, 473; calomel-injections in, 919; cardiac, 141; cerebral, 722; of the cervix uteri, 533; congenital, 629; contagiousness of, 921; of the eye, 794; fetal, 518; infantile, 518; intraurerine infection in, 518; intravenous injections in, 832, 918; of the internal ear, 866; of the iris, 814; of the kidneys, 404; of the larynx, 889; malignant, 920; of the membrana tympani, 840; nasal, 875; placental transmission of, 518; potassium iodid in, 920; primary, 404; serum-therapy in, 920; treatment, 405; and yaws, 912.
 Syphilitic conjunctivitis, 805; epididymitis, 404; gleet, 404; myocarditis, 142; nephritis, 404; reinfection, 921; tarsitis, 800.
 Syphiloderm, pigmentary, 921.

- Syringes, sterilization of, 229.
 Syringomyelia, 728.
 System, sympathetic, 989.
 Systolic heart-murmurs, 134.
 Szabo (J.) on the mammary gland, 971.
 Szaszzy on partus serotinus, 456.
 Szegő (K.) on gastroenteritis, 635; on tuberculosis, 628.
 Szigei (S.) on autoextirpation of the larynx, 992; on blood-stains, 997.
 Szulislawski (A.) on sarcoma of the conjunctiva, 806.
 Szymonowicz on the suprarenal capsules, 979.
- TABES dorsalis, 735.
 Tabetic anesthesia, 736.
 Tachycardia, 148; in Graves' disease, 151; in influenza, 37.
 Tania echinococcus, 223; mad-agascariensis, 223.
 Taft (L.) on abdominal hysterectomy, 574.
 Taliaferro (V. H.) on cancer of the pancreas, 667.
 Talma on chlorosis, 110.
 Tamburini (T. A.) on acromegaly, 744.
 Tanniform, 955.
 Tannet's reagent, 1012.
 Tapeworm, 223.
 Taraxacum in glaucoma, 817.
 Tarchetti on the blood, 105.
 Tarnier on postpartum hemorrhage, 515; on puerperal eclampsia, 195.
 Tarsitis, syphilitic, 800.
 Taste-fibers, course of, 964.
 Tattooing of the eye, 830.
 Tauber on holocain, 833.
 Taular on ovarian papilloma, 600.
 Taylor (C. B.) on cataract-extraction, 810; on glaucoma, 817; on squint, 791.
 Taylor (E. C.) on gastric ulcer, 281.
 Taylor (E. H.) on cancer of the rectum, 359; on soft chancre, 403.
 Taylor (F.) on anemia, 107; on chlorosis, 109; on pernicious anemia, 111; on splenic anemia, 120.
 Taylor (H. L.) on spastic paralysis in children, 776.
 Tears and Widal's reaction, 21.
 Technique of Cesarean section, 508; histologic, 700; of the Widal reaction, 29.
 Teichmüller on pernicious anemia, 115, 730.
 Teleonyx, 449.
 Telesky on hypertrophic osteoarthropathy, 91.
 Témoin on uterine fibroids, 571.
 Temperature in anesthesia, 261; in leukemia, 117.
 Temporal bone, carcinoma of, 864; cholesteatoma of, 854; tuberculosis of, 865.
 Tendons, diseases of, 380; -grafting, 383; injuries of, 381.
 Tenneson, Leredde, and Martinon on granuloma, 912.
 Tenonitis, suppurative, 792.
 Tenotomy for asthenopia, 790.
 Tension, high arterial, 155.
 Tepfjaschin (A.) on corneal defects, 809.
 Teratoma pharyngeal, 886; of the tunica vaginalis, 679.
 Terminal infections, 706.
 Terrier and Auvray on trauma of the liver, 343.
 Terrier on ovariectomy in the aged, 588; on tuberculosis, 58.
 Terrile on experimental tuberculosis, 60; on splenic enlargement, 120.
 Terson (J.) on diseases of the orbit, 827; on ectropion, 829.
 Testicle, diseases of, 414.
 Test-types, 782.
 Tetanus, 740; neonatorum, 631; spinal cord in, 662; -toxin and the ganglion-cells, 658.
 Tetany, 642, 741; and mental disease, 743; and rickets, 712.
 Tenbaum on diabetes mellitus, 97.
 Theilhaber on bicycling for women, 542.
 Theobald (S. M.) on retinitis, 820.
 Theodor on pertussis, 627.
 Theory of agglutination, 699.
 Therapeutic value of mixed toxins, 249.
 Therapeutics, experimental, 922; of the eye, 831.
 Therapy, ovarian, 546.
 Thibault on tubal pregnancy, 474.
 Thiemich on gastroenteritis in children, 178.
 Thioreclin and Lenoble on typhoid fever, 21.
 Thigh-friction, 613.
 Thiosinamin in keloid, 908.
 Third trochanter, 960.
 Thiroloix on rheumatism, 85; on typhoid fever, 19.
 Thirst after abdominal section, 590, 594.
 Thistle (W. B.) on typhoid fever, 34.
 Thoimot and Cavasse on typhoid fever, 21.
 Thomas (H. M.) on carcinoma of the cerebellum, 864; Barker and Flexner on tumor of the cerebellum, 723; and Keen (W.W.) on brain-tumor, 410, 719.
 Thomas (J. B.) on typhoid fever, 26.
 Thomas (J. D.) on syphilis, 921.
 Thomas (J. J.) on infantile scurvy, 211, 639.
 Thomas (J. L.) on Colles' fracture, 385.
 Thomas (T.) on dermoid cyst of the cornea, 808; on sacral meningocele, 413.
 Thomman (C. A.) on placenta prævia, 472.
 Thompson (J. H.) on cholelithiasis, 202; on skiagraphy, 218; on tuberculosis, 69; on wry-neck, 768.
 Thompson (W. G.) on hysteric fever, 56.
 Thompson (W. H.) on urea, 1018.
 Thomson (A.) on gastric ulcer, 182.
 Thomson (A. G.) on toxic amblyopia, 825.
 Thomson (H. C.) on the heart, 127.
 Thomson (J.) on menstruation, 611; on rachitis, 632.
 Thomson (S. C.) on stenosis of the nasopharynx, 879.
 Thomson (W.) on sarcoma of the nose, 876.
 Thomson (W. H.) on gout, 94.
 Thoracentesis, 363.
 Thoracic aneurysm, 156; cavity, exploration of, 366; effusions, 169.
 Thoracotomy, 364.
 Thorax, diseases of, 764.
 Thorington (J.) on objective refraction, 783.
 Thorne (M.) on edema of the larynx, 886; on foreign body in the larynx, 887; on nasal reflexes, 872.
 Thornley on typhoid fever, 35.
 Thorpe on filaria, 221.
 Thorsch on leukemia, 120.
 Threatened abortion, thyroid extract in, 547.
 Thresh (J. C.) on diphtheria, 610.
 Thrombosis of the abdominal aorta, 155; in influenza, 37; puerperal, 516; of the retina, 819; in rheumatism, 86; in scarlatina, 625; in tuberculosis, 60; in typhoid fever, 15.
 Thrush-fungus, 690.
 Thudichum on albuminuria of pregnancy, 461.
 Thymol in anchylostomiasis, 222; in atrophic rhinitis, 873; iodid in tuberculous lymph-glands, 374.
 Thymus, enlarged, 633; epithelioma of, 673; -feeding in exophthalmic goiter, 745; gland, 980; in Graves' disease, 151; pathology of, 673; sarcoma of, 644.
 Thyroantitoxin in exophthalmic goiter, 747.
 Thyroid cartilage, acute perichondritis of, 887.
 Thyroid-extract, 926; contra-indication to, 548; in deafness, 847; effect of, on the blood, 103; in exophthalmic goiter, 151, 377; as a galactagogue, 548; iodin in, 886; in lepra, 74; in lupus, 910; in myxedema, 885; in osteomalacia, 99; in symmetric morphea, 907; in threatened abortion, 547; in uterine fibroids, 570.
 Thyroid-feeding in goiter, 646, 886.
 Thyroid gland, 978; diseases of,

- 377; follicles of, 971; and the genitalia, 547; hemorrhagic cyst of, 669; pathology of, 669; in pregnancy, 464.
- Thyroidectomy, 377.
- Thyroidin, 979; in contracted pelvis, 493.
- Thyroiditis, 379.
- Ticcin on relapsing fever, 48.
- Tier-suturing, 590.
- Tiffany (L. M.) on facial neuralgia, 408, 714; on the retina, 818.
- Tiger-lily heart, 653.
- Tillmanns on fracture of the femur, 385; on nerve-suturing, 406.
- Tillotson (H. T.) on tuberculosis, 63.
- Tinea tonsurans in an adult, 901; chronic, 902; vesicolor on the soles of the feet, 900.
- Tinnitus aurium, 868.
- Tinted glasses, 787.

 Von Bungner on gastroenterostomy, 279.
 Von Chrzanoski (J.) on melena, 638.
 Von Fernwold (R. B.) on labor, 983.
 Von Grosz (E.) on choked disk, 923.
 Von Happel (E.) on the eye of the newborn, 965.
 Von Hayek on leukemia, 117.
 Von Herff on extrauterine pregnancy, 480.
 Von Hofmann (E.) on legal medicine, 990.
 Von Issekutz (L.) on hydatid cyst of the orbit, 828.
 Von Jauregg (W.) on insanity, 755.
 Von Kahliden (C.) on hepatic sarcoma, 199; on valvular hematoma, 637.
 Von Leignek on catgut, 229.
 Von Leyden and Schaudinn on ascitic fluid, 679.
 Von Limbeck on jaundice, 652.
 Von Mering on trional, 957.
 Von Reïssner on leprosy, 73.
 Von Reuss (D. A.) on electrotherapy in eye-disease, 832.
 Von Schlen on gonorrhoea, 403.
 Von Schrötter (H.) on atmospheric pressure, 984.
 Von Schwoner on acromegaly, 744.
 Von Sicherer on the eye, 831.
 Von Stark on varicella, 626.
 Von Tiesenhansen on puerperal thrombosis, 516.
 Von Winckel on formaldehyd, 938.
 Vulpius (W.) on thyroid extract, 847.
 Vulva, diseases of, 526; kraurosis of, 526; papilloma of, 533; pruritus of, 527; trauma of, 528.
 Vulvar tumors, 532.
 Vulvitis, 528.
 Vulvovaginal anus, 531.
 Vulvovaginitis of little girls, 528.
 WADE (W.) on gout, 93.
 Wadsworth (L. C.) on embolism of the retina, 819; on glycosuria, 95.
 Waelsch on trichophytosis, 901.
 Wagenmann (W. A.) on carcinoma of the conjunctiva, 806; on the eye in gout, 793.
 Wagner on carcinoma of the Fallopian tubes, 587.
 Wagner (H. L.) on sinusitis, 878.
 Waecher position, 506.
 Waldeyer on the ovary, 598.
 Walford (E.) on sewer-gas, 1006.
 Walker (A. B.) on rectal examinations, 526.
 Walker (A. W.) on acromegaly, 744; on acute vegetative endocarditis, 132; on inversion of the uterus, 500.
 Walker (G.) on iritis, 814.
 Walker (H. S.) on caries of the internal ear, 866; on otitic cerebellar abscess, 864.
 Wall on sinus-thrombosis, 856.
 Wallace (J.) on uterine fibroids, 570.
 Walter on asthenopia, 790; on formaldehyd, 937, 1004; on purulent conjunctivitis, 802.
 Walton on obstetric paralysis, 519; on osteoarthropathy, 90.
 Wandering spleen, 202, 356.
 Wandless on gonorrhoeal conjunctivitis, 803.
 Warburg's tincture in malaria, 82.
 Ward (A. H.) on persistent priapism, 414; on syphilis, 401.
 Warm baths in bronchitis, 645; in cerebrospinal meningitis, 645.
 Warren (C.) on gangrenous cystitis, 538.
 Warren (J. C.) on cancer of the breast, 241.
 Warren (J. W.) on digestive ferments, 986; on internal secretion, 980.
 Warthin (A. S.) on tubal pregnancy, 471.
 Warts, 210.
 Washbourne (W. H.) on pneumonia, 161; on rheumatism, 86.
 Wasserman (M.) on carcinoma of the urethra, 536; on diphtheria, 642; on the gonococcus, 686; on the x-rays, 219.
 Water, 1005.
 Waterhouse and Gibbs on chloroform-anesthesia, 266.
 Waters on gastroenteritis, 635; on the plague, 43.
 Watkin (T. J.) on abdominal salpingo-oophorectomy, 593; on abdominal section, 589; on drainage, 594.
 Watson (A. W.) on deflected septum, 875; on transfixion, 872.
 Watson (F. S.) on fracture of the patella, 388.
 Watson (J. K.) on dermatitis herpetiformis, 892.
 Way (E.) on fish-slime disease, 53.
 Weaver (G. H.) on vaccine-lymph, 690.

- Webb (T. L.) on histologic technique, 700.
- Weber (W. C.) on carcinoma of the stomach, 183; on revaccination, 46; on variola, 47.
- Webster (C.) on corneal pregnancy, 481.
- Webster (D.) on asthenopia, 790; on cataract, 811; on iridectomy, 830; on the retina, 818.
- Webster (E.) on antipyrin, 927.
- Webster (G. A.) on ophthalmoma, 837.
- Webster (J. C.) on pessaries, 564.
- Webster (P.) on optic neuritis, 823.
- Wechsler on vernal catarrh, 804.
- Weeks (J. E.) on cataract, 811; on foreign body in the eye, 826; on ulcer of the cornea, 807.
- Wegener (A.) on injuries of the intestine, 995; on massage, 818.
- Weight of the newborn, 547.
- Weill and Barjon on myocarditis, 637.
- Weil's disease, 52.
- Weir (R. F.) on disinfection of the hands, 230; on fracture of the malar bone, 387; on hallux valgus, 774.
- Weissbecker on scarlatina, 625.
- Weismayr on pneumonia, 160.
- Weisspecker on typhoid fever, 34.
- Weiss (L.) and Klingelhoffer (W.) on gonorrhoeal ophthalmia, 793.
- Weiss (O.) on the blood, 975.
- Weissblatt on fracture of the penis, 415.
- Weissgerber (K.) on sinus-thrombosis, 857.
- Welandor (E.) on congenital syphilis, 629; on fetal syphilis, 518; on syphilitic nephritis, 404.
- Welch and Flexner on air-embolism, 994.
- Wells (A.) on snakebite, 410.
- Wells (W. H.) on puerperal polyneuritis, 517.
- Welsh (W. J.) on dislocation of the elbow, 399.
- Wendling (L.) on hydrorrhachis, 459.
- Wentworth on lumbar puncture, 611.
- Werler (O.) on itrol, 401.
- Werner, (H.) on antipyrin, 928.
- Wernicke on the blood, 650.
- Werth on suppuration of ovarian cysts, 691.
- Wertheim on cystitis, 537; and Mandl on vaginofixation, 566.
- Wertheimer (E.) and Lepage (L.) on jaundice, 986; on spinal paths, 987.
- West (J. P.) on glandular fever, 629; on rachitis, 632.
- West (S.) on albuminous expectoration, 668; on diabetes mellitus, 98; on pneumothorax, 170; on pulmonary tuberculosis, 61.
- West (S. D.) on trachelorrhaphy, 535.
- Westcott (C. D.) on conjunctival diphtheria, 796; on keloid of the cornea, 808.
- Westmacott (F. H.) on osteoarthropathy, 91.
- Wetherill (H. G.) on extraperitoneal ectopic gestation, 475.
- Wettendorfer on cataract, 810.
- Weyland on intestinal capsules, 941.
- Whitby (C. J.) on self-poisoning, 56.
- White (J. A.) on persistent hyaloid artery, 799; on suppurative tenonitis, 792.
- White (J. C.) on dermatitis venenata, 891; on prurigo, 896.
- White (J. W.) on foreign body in the esophagus, 273; on orchotomy, 419; on x-rays, 413, 445; and Wood (A. C.) on surgical effections of the kidney, 430.
- White (W. H.) on carcinoma of the pancreas, 204.
- Whitefoot (R. M.) on Graves' disease, 151.
- Whitehead (L.) on cyst of the iris, 815; on x-rays, 441.
- Whitehead's operation, 358.
- Whitney (W. F.) on seminal stains, 998.
- Whooping-cough, 626.
- Wickers (H.) on diphtheria, 614.
- Widal on agglutination, 699; on coli-infection, 17; on pneumonia, 162; reaction, 16; in children, 626; and the cholera microbe, 30; specificity of, 29; technique, 29; in tuberculosis, 26; on typhoid fever, 15, 16; on the Widal reaction, 28; and Meslay on round ulcer of the stomach, 664; and Sieard on breast-milk, 699; on rheumatism, 86; on typhoid fever, 17, 18, 21.
- Widal's method and the bacillus coli communis, 24; and the bacillus pyocyaneus, 24.
- Widmark (J.) on cataract, 811.
- Wieden on lactation, 490.
- Wiegheiu on acute endocarditis, 131.
- Wieland on bacteria, 309.
- Wiener (A.) on progressive muscular dystrophy, 729.

- Willets (J. E.) on encain, 834; on the optic nerve, 822.
- Williams (C.) on astigmatism, 786; on the axonometer, 835.
- Williams (D.) on glandular fever, 630.
- Williams (D. H.) on stab-wound of the heart, 369.
- Williams (F. H.) and Connelman (W. T.) on cerebrospinal meningitis, 713; on the heart, 127.
- Williams (F. P.) on strangulated hernia, 336.
- Williams (H. L.) on labor, 483; on typhoid fever, 36.
- Williams (J. D.) on dysmenorrhoea, 551; on puerperal sepsis, 513; on pelvic contraction, 491.
- Williams (M. H.) on encain, 272.
- Williams (P. W.) on auscultatory percussion, 128.
- Williams (W.) on turbinotomy, 872.
- Williams (W. R.) on ovarian dermoid, 602; on tumors, 677; on uterine carcinoma, 576, 579.
- Williamson (R. T.) on diabetes mellitus, 97; on the eye in exophthalmic goiter, 795.
- Willoughby (B. F.) on the plague, 40.
- Wilman on drowning, 999.
- Wilson (F. M.) on cataract, 811.
- Wilson (H.) on ptosis, 800.
- Wilson (J. C.) on the ear in diphtheria, 866.
- Wilson (T.) on intermittent ovarian cyst, 600; on vaginal hysterectomy, 574, 582.
- Wilson (W. R.) on Cesarean section, 598.
- Wine of iron and quassia, 959.
- Winiarski on exudates and transudates, 710.
- Winslow (K.) on malarial fever, 78.
- Winter on uterine prolapse, 561.
- Winterberg on the blood, 107.

- Wintersteiner (E.) on glioma, 818.
- Witmaack (K.) on the nucleon of milk, 1021.
- Wittlin on bacteria, 690.
- Wladmiroff on precocious maturity, 647.
- Wolf (O.) on otitis media in rheumatism, 843.
- Wolf (M.) on tuberculosis, 57; of the ovary, 603; on typhoid fever, 11; on zymotics, 878.
- Wolter on cervical syphilis, 533.
- Women, bicycling for, 541; cloaca in, 531; fistulae in, 535; gonorrhoea in, 523; insanity in, 756; neurasthenia in, 521; neuroses in, 521; pregnant, care of, 457; rectal gonorrhoea in, 525; sterility in, 545.
- Wood (A. C.) on foreign body in the esophagus, 274; on the mesocard, 458; on x-rays, 445.
- Wood (A. J.) on endocarditis, 637.
- Wood (C. A.) on eyesight, 782; on oculomotor paralysis, 787; on retinal detachment, 822; on strabismus, 790; on toxic amblyopia, 824.
- Wood (G. E. C.) on diphtheria-antitoxin, 685.
- Wood (H. C.) on formaldehyd, 230, 937, 939; on Graves' disease, 152; and Carter (W. S.) on strophanthus, 953.
- Wood (W. C.) on uterine fibroids, 569.
- Woodbridge (J. E.) on typhoid fever, 34; method, 34.
- Woodhead (R. S.) on the tonsils, 374.
- Woodman (J.) on myxedema, 885.
- Woodruff (C. A.) on corneal defects, 809; on retinal thrombosis, 819.
- Woodruff (J. S.) on nasal catarrh, 871.
- Woods (H.) on membranous conjunctivitis, 803.
- Woodson (R. S.) on febris auto-intoxica, 36.
- Woodward (G.) on colostrum, 609, 1020.
- Woolsey (G.) on fractures, 391.
- Wooten on nephritis, 212.
- Worcester (A.) on labor, 482; on tuberculosis, 66.
- Word-blindness, 798.
- Workmen, tuberculosis among, 1007.
- Wormser (E.) on thyroidin, 979.
- Worsley (R. C.) on suture of tendons, 383.
- Wounds, 438, 995; of the air-passages, 366; gunshot-, 996; of the heart, 438; of the kidney, 428.
- Wright (A. E.) on Malta fever, 51; on serous hemorrhages, 652; on urticaria, 891; and Semple (D.) on typhoid vaccine, 23; and Smith on Malta fever, 51.
- Wright (E. E.) on the eye in nephritis, 793.
- Wry-neck, 380, 716, 768; spasmodic, 769.
- Wunder on measles, 624.
- Wustfeld (F.) on eucain, 834.
- Wyeth (J. A.) on amputation of the hip, 254; on cocaine-anesthesia, 270.
- Wylie (W. G.) on tubal pregnancy, 475.
- Wyman (S. E.) on tubal pregnancy, 474.
- Wyman (W.) on the plague, 44.
- XANTHOMA diabeticorum, 908.
- Xeroform in otorrhea, 849.
- Xerosis-bacillus, 685.
- x-ray dermatitis, 446, 894; traumatism, 445.
- x-rays in diseases of the stomach, 175; and the esophagus, 273; and the eye, 825; and fractures, 391; and the heart, 145; in intrathoracic disease, 218; in legal medicine, 996; in lung-diseases, 219; in rabies, 688; in tuberculosis, 68, 441.
- YARROW (T. J.) on eucain, 272.
- Yavoroosky on ammonium molybdate, 1013.
- Yaws, 912.
- Yearsley (M.) on foreign body in the ear, 839.
- Yellow atrophy, acute, 197.
- Yellow fever, 49; bacillus of, 49, 689; bacteriology, 49; kidneys in, 49; liver in, 49; pathology, 49; spleen in, 49.
- Yellow ointment in eye-diseases, 832.
- Yersin on the plague, 44.
- Yersin's bacillus, 40.
- Yolk of egg in culture-media, 703.
- Yonge (E. S.) on facial neuralgia, 715.
- Young (E. B.) on deformity of the knee, 771.
- Young (H. H.) on nerves in tumors, 678.
- Young (J. E.) on stenosis of the conus pulmonalis, 139.
- ZABLUDOWSKI on Friedreich's ataxia, 737.
- Zaboltony on the plague, 44.
- Zagari on malignant intrathoracic tumors, 166.
- Zambaco-Pacha on ainbum and leprosy, 74.
- Zander on the optic chiasm, 965.
- Zappert (J.) on congenital syphilis, 629; on nervous diseases, 640.
- Zarubiu (V.) on hypertrichosis, 905.
- Zaufal on otitic pyemia, 860; on sinus-thrombosis, 856.
- Zedel on ovarian cysts, 599.
- Zeehuisen on albuminuria, 1013; on ameburia, 220; on digestive activity of cyst-fluids, 205.
- Zenoni (C.) on the streptococci, 687.
- Zeroni on otorrhea, 849.
- Ziegler on placental delivery, 487.
- Ziematzky on bone-tuberculosis, 384.
- Zieniec on the stethoscope, 217.
- Zimmerman (C.) on purulent conjunctivitis, 802; on retinitis proliferans, 821.
- Zimmermann (M. W.) on uveal cysts, 814.
- Zinc chlorid in bone-tuberculosis, 384; in tuberculous lymph-glands, 374; permanganate in gonorrhoea, 401; -workers, health of, 1007.
- Zinn and Jacoby on parasites, 222.
- Zinsstage on placental delivery, 487.
- Zona, buccopharyngeal, 885.
- Zone, uric-acid, 1014.
- Zuber on pneumonia, 161.
- Zuntz (L.) on atmospheric pressure, 984; on the blood, 100.
- Zuntz (N.) on muscular contraction, 981, 982; on tanniform, 955; and Loewy (A.) on respiration, 984.
- Zweifel on pancreatic cyst, 355; on puerperal eclampsia, 493; on puerperal thrombosis, 516.
- Zygoma, fracture of, 386.
- Zymotics, accessory sinuses in, 878.

CATALOGUE
OF THE
MEDICAL PUBLICATIONS
OF
W. B. SAUNDERS,
No. 925 WALNUT STREET, PHILADELPHIA.

Arranged Alphabetically and Classified under Subjects.

THE books advertised in this Catalogue as being sold by subscription are usually to be obtained from traveling solicitors, but they will be sent direct from the office of publication (charges of shipment prepaid) upon receipt of the prices given. All the other books advertised are commonly for sale by booksellers in all parts of the United States; but any book will be sent by the publisher to any address, carriage prepaid, on receipt of the published price.

Money may be sent at the risk of the publisher in either of the following ways: A post-office money order, an express money order, a bank check, and in a registered letter. Money sent in any other way is at the risk of the sender.

See pages 30, 31, for a List of Contents classified according to subjects.

SPECIAL ANNOUNCEMENT.

MR. SAUNDERS is pleased to announce that arrangements have been completed for the publication of an English edition of the world-famous

Lehmann medicinische Handatlanten.

For scientific accuracy, pictorial beauty, compactness, and cheapness these books surpass any similar volumes ever published. Each volume contains from

50 to 100 Colored Plates,

besides numerous other illustrations in the text. These colored plates have been executed by the most skilful German lithographers, in some cases twenty or more impressions being required to obtain the desired result. There is a full and appropriate description of each plate (printed, for convenience, opposite the plate), together with a condensed outline of the subject to which the book is devoted.

The same careful and competent editorial supervision will be secured in the English edition as in the originals. The translations will be directed and edited by the leading American specialists in the different subjects.

The great advantage of natural pictorial representation is indisputable. For lasting and practical knowledge, one accurate illustration is better than several pages of dry description.

These Atlases offer a ready and satisfactory substitute for clinical observation, available only to the residents of large medical centers; and with such persons the requisite variety is seen only after long years of routine hospital service.

By reason of their projected universal translation and reproduction, affording international distribution, the publishers have been enabled to secure for these Atlases the best artistic and professional talent, to produce them in the most elegant style, and yet to offer them at a price heretofore unapproached in cheapness. The success of the undertaking is demonstrated by the fact that volumes have already appeared in German, English, French, Italian, Russian, Spanish, Danish, Swedish, and Hungarian.

While appreciating the value of such colored plates, the profession has heretofore been practically debarred from purchasing similar works because of their extremely high price, made necessary by the limited sale and the enormous expense of production. The very low price of these Atlases will place them within the reach of even the novice in practice.

The following volumes are in active preparation and will be issued at an early date:

Atlas of Internal Medicine and Clinical Diagnosis. By DR. CHR. JAKOB, of Erlangen. Edited by AUGUSTUS A. ESHNER, M.D., Professor of Clinical Medicine in the Philadelphia Polyclinic; Attending Physician to the Philadelphia Hospital. 68 colored plates, and 64 illustrations in the text.

Atlas of Legal Medicine. By DR. E. R. VON HOFMANN, of Vienna. Edited by FREDERICK PETERSON, M.D., Clinical Professor of Mental Diseases, Woman's Medical College, New York; Chief of Clinic, Nervous Dept., College of Physicians and Surgeons, New York. With 120 colored figures on 56 plates, and 193 beautiful half-tone illustrations.

Atlas of Operative Surgery. By DR. O. ZUCKERKANDL, of Vienna. Edited by J. CHALMERS DACOSTA, M.D., Clinical Professor of Surgery, Jefferson Medical College, Philadelphia; Surgeon to the Philadelphia Hospital. With 24 colored plates, and 217 illustrations in the text.

Atlas of Laryngology. By DR. L. GRÜNWARD, of Munich. With 107 colored figures on 44 plates; 25 black-and-white illustrations.

Atlas of External Diseases of the Eye. By DR. O. HAAB, of Zurich. Edited by G. E. DE SCHWEINITZ, M.D., Professor of Ophthalmology, Jefferson Medical College, Philadelphia. With 100 colored illustrations.

Atlas of Venereal Diseases. By DR. KARL KOPP, of Munich. Edited by L. BOLTON BANGS, M.D., late Professor of Genito-Urinary and Venereal Diseases, New York Post-Graduate Medical School and Hospital. With 63 colored illustrations.

Atlas of Skin Diseases. By DR. KARL KOPP, of Munich. With 90 colored and 17 black-and-white illustrations.

AN AMERICAN TEXT-BOOK OF APPLIED THERAPEUTICS.

Edited by JAMES C. WILSON, M.D., Professor of the Practice of Medicine and of Clinical Medicine in the Jefferson Medical College, Philadelphia. One handsome imperial octavo volume of 1326 pages. Illustrated. Cloth, \$7.00 net; Sheep or Half Morocco, \$8.00 net. *Sold by Subscription.*

"As a work either for study or reference it will be of great value to the practitioner, as it is virtually an exposition of such clinical therapeutics as experience has taught to be of the most value. Taking it all in all, no recent publication on therapeutics can be compared with this one in practical value to the working physician."—*Chicago Clinical Review.*

"The whole field of medicine has been well covered. The work is thoroughly practical, and while it is intended for practitioners and students, it is a better book for the general practitioner than for the student. The young practitioner especially will find it extremely suggestive and helpful."—*The Indian Lancet.*

AN AMERICAN TEXT-BOOK OF THE DISEASES OF CHILDREN.

Edited by LOUIS STARR, M.D., Physician to the Children's Hospital, Philadelphia, etc.; assisted by THOMPSON S. WESTCOTT, M.D., Attending Physician to the Dispensary for Diseases of Children, Hospital of the University of Pennsylvania. In one handsome imperial octavo volume of 1190 pages, profusely illustrated. Cloth, \$7.00 net; Sheep or Half Morocco, \$8.00 net. *Sold by Subscription.*

"This is far and away the best text-book on children's diseases ever published in the English language, and is certainly the one which is best adapted to American readers. We congratulate the editor upon the result of his work, and heartily commend it to the attention of every student and practitioner."—*American Journal of the Medical Sciences.*

"A condensation between the lids of a single volume of an amount of information upon childhood and its diseases which will be eagerly sought after by the profession."—*New York Medical Times.*

AN AMERICAN TEXT-BOOK OF DISEASES OF THE EYE, EAR, NOSE, AND THROAT.

Edited by G. E. DE SCHWEINITZ, M.D., Professor of Ophthalmology in the Jefferson Medical College, Philadelphia; and B. ALEXANDER RANDALL, M.D., Professor of Diseases of the Ear in the University of Pennsylvania and in the Philadelphia Polyclinic. *In Preparation.*

AN AMERICAN TEXT-BOOK OF GENITO-URINARY AND SKIN DISEASES.

Edited by L. BOLTON BANGS, M.D., Late Professor of Genito-Urinary and Venereal Diseases, New York Post-Graduate Medical School and Hospital; and WILLIAM A. HARDAWAY, M.D., Professor of Diseases of the Skin, Missouri Medical College. *In Press. Ready soon.*

This latest addition to the series of "American Text-Books" it is confidently believed will meet the requirements of both students and practitioners, giving, as it does, a comprehensive and detailed presentation of the Diseases of the Genito-Urinary Organs, of the Venereal Diseases, and of the Affections of the Skin.

Having secured the collaboration of well-known authorities in the branches represented in the undertaking, the Editors have not restricted the Contributors in regard to the particular views set forth, but have offered every facility for the free expression of their individual opinions. The work will therefore be found to be original, yet homogeneous and fully representative of the several departments of medical science with which it is concerned.

Illustrated Catalogue of the "American Text-Books" sent free upon application.

AN AMERICAN TEXT-BOOK OF GYNECOLOGY, MEDICAL AND SURGICAL.

Edited by J. M. BALDY, M.D., Professor of Gynecology in the Philadelphia Polyclinic, etc. Handsome imperial octavo volume of over 700 pages, with 360 illustrations in text, and 37 colored and half-tone plates. Cloth, \$6.00 net; Sheep or Half Morocco, \$7.00 net. *Sold by Subscription.*

"The nature of the text may be judged from its authorship; the distinguished American authorities who have compiled this publication have done their work well. It is well indexed,—an important feature in a work essentially intended for reference. . . . The work is very fully illustrated, and the wood-cuts and plates are of high excellence. . . . This addition to medical literature deserves favorable comment."—*British Medical Journal.*

"It is practical from beginning to end. Its descriptions of conditions, its recommendations for treatment, and above all the necessary technique of different operations, are clearly and admirably presented. . . . It is well up to the most advanced views of the day, and embodies all the essential points of advanced American gynecology. It is destined to make and hold a place in gynecological literature which will be peculiarly its own."—*Medical Record*, New York.

AN AMERICAN TEXT-BOOK OF LEGAL MEDICINE AND TOXICOLOGY.

Edited by FREDERICK PETERSON, M.D., Clinical Professor of Mental Diseases in the Woman's Medical College, New York; Chief of Clinic, Nervous Department, College of Physicians and Surgeons, New York; and WALTER S. HAINES, M.D., Professor of Chemistry, Pharmacy, and Toxicology in Rush Medical College, Chicago. *In Preparation.*

AN AMERICAN TEXT-BOOK OF OBSTETRICS.

Edited by RICHARD C. NORRIS, M.D.; Art Editor, ROBERT L. DICKINSON, M.D. One handsome imperial octavo volume of over 1000 pages, with nearly 900 beautiful colored and half-tone illustrations. Cloth, \$7.00 net; Sheep or Half Morocco, \$8.00 net. *Sold by Subscription.*

"Permit me to say that your American Text-Book of Obstetrics is the most magnificent medical work that I have ever seen. I congratulate you and thank you for this superb work, which alone is sufficient to place you first in the ranks of medical publishers."—ALEXANDER J. C. SKENE, *Professor of Gynecology in the Long Island College Hospital, Brooklyn, N. Y.*

"This is the most sumptuously illustrated work on midwifery that has yet appeared. In the number, the excellence, and the beauty of production of the illustrations it far surpasses every other book upon the subject. This feature alone makes it a work which no medical library should omit to purchase."—*British Medical Journal.*

"The obstetrician and the general practitioner will find this book not only a pleasant and interesting volume, but the most valuable of its kind, both on account of the wide experience of the several authors and because of the attractiveness and accuracy of its illustrations. . . . As an authority, as a book of reference, as a 'working book' for the student or practitioner, we commend it because we believe there is no better."—*American Journal of the Medical Sciences.*

AN AMERICAN TEXT-BOOK OF PATHOLOGY.

Edited by JOHN GUITÉRAS, M.D., Professor of General Pathology and of Morbid Anatomy in the University of Pennsylvania; and DAVID RIESMAN, M.D., Demonstrator of Pathological Histology in the University of Pennsylvania. *In Preparation.*

Illustrated Catalogue of the "American Text-Books" sent free upon application.

AN AMERICAN TEXT-BOOK OF PHYSIOLOGY.

Edited by WILLIAM H. HOWELL, PH. D., M. D., Professor of Physiology in the Johns Hopkins University, Baltimore, Md. One handsome imperial octavo volume of 1052 pages. Illustrated. Cloth, \$6.00 net; Sheep or Half Morocco, \$7.00 net. *Sold by Subscription.*

"The present volume constitutes practically a new departure in physiological text-books, on the lines which have already proved successful in medicine and surgery. Its value as a work of reference for the physician or pathologist is very great. We can commend it most heartily, not only to all students of physiology, but to every physician and pathologist, as a valuable and comprehensive work of reference, written by men who are of eminent authority in their own special subjects."—*London Lancet.*

"To the practitioner of medicine and to the advanced student this volume constitutes, we believe, the best exposition of the present status of the science of physiology in the English language."—*American Journal of the Medical Sciences.*

"The book is certainly the best thing in the way of physiological text-books that America has produced."—*Edinburgh Medical Journal.*

AN AMERICAN TEXT-BOOK OF SURGERY. Second Edition.

Edited by WILLIAM W. KEEN, M. D., LL. D., and J. WILLIAM WHITE, M. D., PH. D. Handsome imperial octavo volume of 1250 pages, with 500 wood-cuts in the text, and 39 colored and half-tone plates. Thoroughly revised and enlarged, with a section devoted to "The Use of the Röntgen Rays in Surgery." Cloth, \$7.00 net; Sheep or Half Morocco, \$8.00 net. *Sold by Subscription.*

"Personally, I should not mind it being called **THE TEXT-BOOK** (instead of **A TEXT-BOOK**), for I know of no single volume which contains so readable and complete an account of the science and art of Surgery as this does."—EDMUND OWEN, F. R. C. S., *Member of the Board of Examiners of the Royal College of Surgeons, England.*

"If this text-book is a fair reflex of the present position of American surgery, we must admit it is of a very high order of merit, and that English surgeons will have to look very carefully to their laurels if they are to preserve a position in the van of surgical practice."—*London Lancet.*

"This book marks an epoch in American book-making. All in all, the book is distinctly the most satisfactory work on modern surgery with which we are familiar. It is thorough, complete, and condensed."—*Boston Medical and Surgical Journal.*

AN AMERICAN TEXT-BOOK OF THE THEORY AND PRACTICE OF MEDICINE.

Edited by WILLIAM PEPPER, M. D., LL. D., Professor of the Theory and Practice of Medicine and of Clinical Medicine in the University of Pennsylvania. Two handsome imperial octavo volumes of about 1000 pages each. Illustrated. Prices per volume: Cloth, \$5.00 net; Sheep or Half Morocco, \$6.00 net. *Sold by Subscription.*

"I am quite sure it will commend itself both to practitioners and students of medicine, and become one of our most popular text-books."—ALFRED LOOMIS, M. D., LL. D., *Professor of Pathology and Practice of Medicine, University of the City of New York.*

"We reviewed the first volume of this work, and said: 'It is undoubtedly one of the best text-books on the practice of medicine which we possess.' A consideration of the second and last volume leads us to modify that verdict and to say that the completed work is in our opinion *the best* of its kind it has ever been our fortune to see."—*New York Medical Journal.*

"American physicians can look with pride upon the work of Dr. Pepper and his corps of associates. It brings our knowledge down to the present hour, and has been written from an eminently practical standpoint."—*Medical Record, New York.*

Illustrated Catalogue of the "American Text-Books" sent free upon application.

AN AMERICAN YEAR-BOOK OF MEDICINE AND SURGERY.

A Yearly Digest of Scientific Progress and Authoritative Opinion in all branches of Medicine and Surgery, drawn from journals, monographs, and text-books of the leading American and Foreign authors and investigators. Collected and arranged, with critical editorial comments, by eminent American specialists and teachers, under the general editorial charge of GEORGE M. GOULD, M.D. One handsome imperial octavo volume of about 1200 pages. Uniform in style, size, and general make-up with the "American Text-Book" Series. Cloth, \$6.50 net; Half Morocco, \$7.50 net. *Sold by Subscription.*

"It is difficult to know which to admire most—the research and industry of the distinguished band of experts whom Dr. Gould has enlisted in the service of the Year-Book, or the wealth and abundance of the contributions to every department of science that have been deemed worthy of analysis. . . . It is much more than a mere compilation of abstracts, for, as each section is entrusted to experienced and able contributors, the reader has the advantage of certain critical commentaries and expositions . . . proceeding from writers fully qualified to perform these tasks. . . . It is emphatically a book which should find a place in every medical library, and is in several respects more useful than the famous 'Jahrbücher' of Germany."—*London Lancet.*

ANDERS' PRACTICE OF MEDICINE.

A Text-Book of the Practice of Medicine. By JAMES M. ANDERS, M.D., PH.D., LL.D., Professor of the Practice of Medicine and of Clinical Medicine, Medico-Chirurgical College, Philadelphia. In one handsome octavo volume of 1287 pages, fully illustrated. Cloth, \$5.50 net; Sheep or Half Morocco, \$6.50 net.

"We know of no recent author who has as effectively succeeded in bringing the new facts and ideas together, weaving them with the substantial realities of the old, in better form. The concise character of the text, the clearness with which its ideas are expressed, the ingenious arrangement of its data, the completeness of its detail, the order of sequence of its topics, and the whole general appearance of the volume tell of careful, conscientious work done by him. His tables for aiding in differential diagnosis, his association of clinical symptoms with the morbid lesions that accompany them, his tested therapeutic formulæ, his appropriate illustrations, his bacteriology, and his modern orthography have made of it a fully up-to-date, handy text-book for the general practitioner."—*American Medico-Surgical Bulletin.*

ASHTON'S OBSTETRICS. Third Edition, Revised.

Essentials of Obstetrics. By W. EASTERLY ASHTON, M.D., Professor of Gynecology in the Medico-Chirurgical College, Philadelphia. Crown octavo, 252 pages; 75 illustrations. Cloth, \$1.00; interleaved for notes, \$1.25.

[See *Saunders' Question-Compends*, page 21.]

"Embodies the whole subject in a nut-shell. We cordially recommend it to our readers."—*Chicago Medical Times.*

BALL'S BACTERIOLOGY. Third Edition, Revised.

Essentials of Bacteriology; a Concise and Systematic Introduction to the Study of Micro-organisms. By M. V. BALL, M.D., Bacteriologist to St. Agnes' Hospital, Philadelphia, etc. Crown octavo, 218 pages; 82 illustrations, some in colors, and 5 plates. Cloth, \$1.00; interleaved for notes, \$1.25.

[See *Saunders' Question-Compends*, page 21.]

"The student or practitioner can readily obtain a knowledge of the subject from a perusal of this book. The illustrations are clear and satisfactory."—*Medical Record*, New York.

BASTIN'S BOTANY.

Laboratory Exercises in Botany. By EDSON S. BASTIN, M.A., late Professor of Materia Medica and Botany, Philadelphia College of Pharmacy. Octavo volume of 536 pages, with 87 plates. Cloth, \$2.50.

"It is unquestionably the best text-book on the subject that has yet appeared. The work is eminently a practical one. We regard the issuance of this book as an important event in the history of pharmaceutical teaching in this country, and predict for it an unqualified success."—*Alumni Report to the Philadelphia College of Pharmacy.*

"There is no work like it in the pharmaceutical or botanical literature of this country, and we predict for it a wide circulation."—*American Journal of Pharmacy.*

BECK'S SURGICAL ASEPSIS.

A Manual of Surgical Asepsis. By CARL BECK, M.D., Surgeon to St. Mark's Hospital and the New York German Poliklinik, etc. 306 pages; 65 text-illustrations, and 12 full-page plates. Cloth, \$1.25 net.

"An excellent exposition of the 'very latest' in the treatment of wounds as practised by leading German and American surgeons."—*Birmingham (Eng.) Medical Review.*

"This little volume can be recommended to any who are desirous of learning the details of asepsis in surgery, for it will serve as a trustworthy guide."—*London Lancet.*

BOISLINIERE'S OBSTETRIC ACCIDENTS, EMERGENCIES, AND OPERATIONS.

Obstetric Accidents, Emergencies, and Operations. By L. CH. BOISLINIERE, M.D., late Emeritus Professor of Obstetrics, St. Louis Medical College. 381 pages, handsomely illustrated. Cloth, \$2.00 net.

"It is clearly and concisely written, and is evidently the work of a teacher and practitioner of large experience."—*British Medical Journal.*

"A manual so useful to the student or the general practitioner has not been brought to our notice in a long time. The field embraced in the title is covered in a terse, interesting way."—*Yale Medical Journal.*

BROCKWAY'S MEDICAL PHYSICS. Second Edition, Revised.

Essentials of Medical Physics. By FRED J. BROCKWAY, M.D., Assistant Demonstrator of Anatomy in the College of Physicians and Surgeons, New York. Crown octavo, 330 pages; 155 fine illustrations. Cloth, \$1.00 net; interleaved for notes, \$1.25 net.

[See *Saunders' Question-Compends*, page 21.]

"The student who is well versed in these pages will certainly prove qualified to comprehend with ease and pleasure the great majority of questions involving physical principles likely to be met with in his medical studies."—*American Practitioner and News.*

"We know of no manual that affords the medical student a better or more concise exposition of physics, and the book may be commended as a most satisfactory presentation of those essentials that are requisite in a course in medicine."—*New York Medical Journal.*

"It contains all that one need know on the subject, is well written, and is copiously illustrated."—*Medical Record*, New York.

BURR ON NERVOUS DISEASES.

A Manual of Nervous Diseases. By CHARLES W. BURR, M.D., Clinical Professor of Nervous Diseases, Medico-Chirurgical College, Philadelphia; Pathologist to the Orthopedic Hospital and Infirmary for Nervous Diseases; Visiting Physician to St. Joseph's Hospital, etc. *In Preparation.*

BUTLER'S MATERIA MEDICA, THERAPEUTICS, AND PHARMACOLOGY.

A Text-Book of Materia Medica, Therapeutics, and Pharmacology. By GEORGE F. BUTLER, PH.G., M.D., Professor of Materia Medica and of Clinical Medicine in the College of Physicians and Surgeons, Chicago; Professor of Materia Medica and Therapeutics, Northwestern University, Woman's Medical School, etc. Octavo, 858 pages, illustrated. Cloth, \$4.00 net; Sheep, \$5.00 net.

A clear, concise, and practical text-book, adapted for permanent reference no less than for the requirements of the class-room. The arrangement (embodying the synthetic classification of drugs based upon therapeutic affinities) is believed to be at once the most philosophical and rational, as well as that best calculated to engage the interest of those to whom the academic study of the subject is wont to offer no little perplexity. Special attention has been given to the Pharmaceutical section, which is exceptionally lucid and complete.

CASSELBERRY ON THE NOSE AND THROAT.

Diseases of the Nose and Throat. By W. E. CASSELBERRY, Professor of Laryngology and Rhinology in the Northwestern University Medical School, Chicago. *In Preparation.*

CERNA ON THE NEWER REMEDIES. Second Edition, Revised.

Notes on the Newer Remedies, their Therapeutic Applications and Modes of Administration. By DAVID CERNA, M.D., PH.D., formerly Demonstrator and Lecturer on Experimental Therapeutics in the University of Pennsylvania; Demonstrator of Physiology in the Medical Department of the University of Texas. Rewritten and greatly enlarged. Post-octavo, 253 pages. Cloth, \$1.25.

"These 'Notes' will be found very useful to practitioners who take an interest in the many newer remedies of the present day."—*Edinburgh Medical Journal.*

"The appearance of this new edition of Dr. Cerna's very valuable work shows that it is properly appreciated. The book ought to be in the possession of every practising physician."—*New York Medical Journal.*

CHAPIN ON INSANITY.

A Compendium of Insanity. By JOHN B. CHAPIN, M.D., LL.D., Physician-in-Chief, Pennsylvania Hospital for the Insane; late Physician-Superintendent of the Willard State Hospital, New York; Honorary Member of the Medico-Psychological Society of Great Britain, of the Society of Mental Medicine of Belgium, etc. *In Preparation.*

The author has given, in a condensed and concise form, a compendium of Diseases of the Mind, for the convenient use and aid of physicians and students. The work will also prove valuable to members of the legal profession and to those who, in their relations to the insane and to those supposed to be insane, often desire to acquire some practical knowledge of insanity presented in a form that may be understood by the non-professional reader.

CHAPMAN'S MEDICAL JURISPRUDENCE AND TOXICOLOGY. Second Edition, Revised.

Medical Jurisprudence and Toxicology. By HENRY C. CHAPMAN, M.D., Professor of Institutes of Medicine and Medical Jurisprudence in the Jefferson Medical College of Philadelphia. 254 pages, with 55 illustrations and 3 full-page plates in colors. Cloth, \$1.50 net.

"The best book of its class for the undergraduate that we know of."—*New York Medical Times.*

CHURCH AND PETERSON'S NERVOUS AND MENTAL DISEASES.

Nervous and Mental Diseases. By ARCHIBALD CHURCH, M.D., Professor of Mental Diseases and Medical Jurisprudence in the Northwestern University Medical School, Chicago; and FREDERICK PETERSON, M.D., Clinical Professor of Mental Diseases in the Woman's Medical College, New York; Chief of Clinic, Nervous Department, College of Physicians and Surgeons, New York. *In Preparation.*

CLARKSON'S HISTOLOGY.

A Text-Book of Histology, Descriptive and Practical. By ARTHUR CLARKSON, M.B., C.M. Edin., formerly Demonstrator of Physiology in the Owen's College, Manchester; late Demonstrator of Physiology in Yorkshire College, Leeds. Large octavo, 554 pages; 22 engravings in the text, and 174 beautifully colored original illustrations. Cloth, strongly bound, \$6.00 net.

"The work must be considered a valuable addition to the list of available text-books, and is to be highly recommended."—*New York Medical Journal.*

"This is one of the best works for students we have ever noticed. We predict that the book will attain a well-deserved popularity among our students."—*Chicago Medical Recorder.*

"The volume is a most valuable addition to the armamentarium of the teacher."—*Brooklyn Medical Journal.*

CLIMATOLOGY.

Transactions of the Eighth Annual Meeting of the American Climatological Association, held in Washington, September 22-25, 1891. Forming a handsome octavo volume of 276 pages, uniform with remainder of series. (A limited quantity only.) Cloth, \$1.50.

COHEN AND ESHNER'S DIAGNOSIS.

Essentials of Diagnosis. By SOLOMON SOLIS-COHEN, M.D., Professor of Clinical Medicine and Applied Therapeutics in the Philadelphia Polyclinic; and AUGUSTUS A. ESHNER, M.D., Instructor in Clinical Medicine, Jefferson Medical College, Philadelphia. Post-octavo, 382 pages; 55 illustrations. Cloth, \$1.50 net.

[See *Saunders' Question-Compends*, page 21.]

"We can heartily commend the book to all those who contemplate purchasing a 'compend.' It is modern and complete, and will give more satisfaction than many other works which are perhaps too prolix as well as behind the times."—*Medical Review*, St. Louis.

CORWIN'S PHYSICAL DIAGNOSIS.

Essentials of Physical Diagnosis of the Thorax. By ARTHUR M. CORWIN, A.M., M.D., Demonstrator of Physical Diagnosis in Rush Medical College, Chicago; Attending Physician to Central Free Dispensary, Department of Rhinology, Laryngology, and Diseases of the Chest, Chicago. 200 pages, illustrated. Cloth, flexible covers, \$1.25 net.

"It is excellent. The student who shall use it as his guide to the careful study of physical exploration upon normal and abnormal subjects can scarcely fail to acquire a good working knowledge of the subject."—*Philadelphia Polyclinic.*

"A most excellent little work. It brightens the memory of the differential diagnostic signs, and it arranges orderly and in sequence the various objective phenomena to logical solution of a careful diagnosis."—*Journal of Nervous and Mental Diseases.*

CRAGIN'S GYNÆCOLOGY. Fourth Edition, Revised.

Essentials of Gynæcology. By EDWIN B. CRAGIN, M.D., Attending Gynæcologist, Roosevelt Hospital, Out-Patients' Department, New York, etc. Crown octavo, 200 pages; 62 fine illustrations. Cloth, \$1.00; interleaved for notes, \$1.25.

[See *Saunders' Question-Compends*, page 21.]

"A handy volume, and a distinct improvement on students' compends in general. No author who was not himself a practical gynæcologist could have consulted the student's needs so thoroughly as Dr. Cragin has done."—*Medical Record*, New York.

CROOKSHANK'S BACTERIOLOGY.

A Text-Book of Bacteriology. By EDGAR M. CROOKSHANK, M.B., Professor of Comparative Pathology and Bacteriology, King's College, London. Octavo volume of 700 pages, with 273 engravings and 22 original colored plates. Cloth, \$6.50 net; Half Morocco, \$7.50 net.

"To the student who wishes to obtain a good *résumé* of what has been done in bacteriology, or who wishes an accurate account of the various methods of research, the book may be recommended with confidence that he will find there what he requires."—*London Lancet*.

DACOSTA'S SURGERY.

A Manual of Surgery, General and Operative. By JOHN CHALMERS DACOSTA, M.D., Clinical Professor of Surgery, Jefferson Medical College, Philadelphia; Surgeon to the Philadelphia Hospital, etc. Handsome volume of 810 pages; 188 illustrations in the text, and 13 full-page plates in colors. Cloth, \$2.50 net.

"We know of no small work on surgery in the English language which so well fulfils the requirements of the modern student."—*Medico-Chirurgical Journal*, Bristol, England.

DE SCHWEINITZ ON DISEASES OF THE EYE. Second Edition, Revised.

Diseases of the Eye. A Handbook of Ophthalmic Practice. By G. E. DE SCHWEINITZ, M.D., Professor of Ophthalmology in the Jefferson Medical College, Philadelphia, etc. Handsome royal octavo volume of 679 pages, with 256 fine illustrations and 2 chromo-lithographic plates. Cloth, \$4.00 net; Sheep or Half Morocco, \$5.00 net.

"A clearly written, comprehensive manual. One which we can commend to students as a reliable text book, written with an evident knowledge of the wants of those entering upon the study of this special branch of medical science."—*British Medical Journal*.

"A work that will meet the requirements not only of the specialist, but of the general practitioner in a rare degree. I am satisfied that unusual success awaits it."—WILLIAM PEPPER, M.D., *Professor of the Theory and Practice of Medicine and Clinical Medicine, University of Pennsylvania.*

DORLAND'S OBSTETRICS.

A Manual of Obstetrics. By W. A. NEWMAN DORLAND, M.D., Assistant Demonstrator of Obstetrics, University of Pennsylvania; Instructor in Gynecology in the Philadelphia Polyclinic. 760 pages; 163 illustrations in the text, and 6 full-page plates. Cloth, \$2.50 net.

"By far the best book on this subject that has ever come to our notice."—*American Medical Review*.

"It has rarely been our duty to review a book which has given us more pleasure in its perusal and more satisfaction in its criticism. It is a veritable encyclopedia of knowledge, a gold mine of practical, concise thoughts."—*American Medico-Surgical Bulletin*.

FROTHINGHAM'S GUIDE FOR THE BACTERIOLOGIST.

Laboratory Guide for the Bacteriologist. By LANGDON FROTHINGHAM, M.D.V.. Assistant in Bacteriology and Veterinary Science, Sheffield Scientific School, Yale University. Illustrated. Cloth, 75 cts.

"It is a convenient and useful little work, and will more than repay the outlay necessary for its purchase in the saving of time which would otherwise be consumed in looking up the various points of technique so clearly and concisely laid down in its pages."—*American Medico-Surgical Bulletin*.

GARRIGUES' DISEASES OF WOMEN. Second Edition, Revised.

Diseases of Women. By HENRY J. GARRIGUES, A.M., M.D., Professor of Gynecology and Obstetrics in the New York School of Clinical Medicine; Gynecologist to St. Mark's Hospital and to the German Dispensary, New York City, etc. Handsome octavo volume of 728 pages, illustrated by 335 engravings and colored plates. Cloth, \$4.00 net; Sheep or Half Morocco, \$5.00 net.

"One of the best text-books for students and practitioners which has been published in the English language; it is condensed, clear, and comprehensive. The profound learning and great clinical experience of the distinguished author find expression in this book in a most attractive and instructive form. Young practitioners to whom experienced consultants may not be available will find in this book invaluable counsel and help."—THAD. A. REAMY, M.D., LL.D., *Professor of Clinical Gynecology, Medical College of Ohio*.

GLEASON'S DISEASES OF THE EAR. Second Edition, Revised.

Essentials of Diseases of the Ear. By E. B. GLEASON, S.B., M.D., Clinical Professor of Otolaryngology, Medico-Chirurgical College, Philadelphia; Surgeon-in-Charge of the Nose, Throat, and Ear Department of the Northern Dispensary, Philadelphia. 208 pages, with 114 illustrations. Cloth, \$1.00; interleaved for notes, \$1.25.

[See *Saunders' Question-Compends*, page 21.]

"It is just the book to put into the hands of a student, and cannot fail to give him a useful introduction to ear-affections; while the style of question and answer which is adopted throughout the book is, we believe, the best method of impressing facts permanently on the mind."—*Liverpool Medico-Chirurgical Journal*.

GOULD AND PYLE'S CURIOSITIES OF MEDICINE.

Anomalies and Curiosities of Medicine. By GEORGE M. GOULD, M.D., and WALTER L. PYLE, M.D. An encyclopedic collection of rare and extraordinary cases and of the most striking instances of abnormality in all branches of Medicine and Surgery, derived from an exhaustive research of medical literature from its origin to the present day, abstracted, classified, annotated, and indexed. Handsome imperial octavo volume of 968 pages, with 295 engravings in the text, and 12 full-page plates. Cloth, \$6.00 net; Half Morocco, \$7.00 net. *Sold by Subscription.*

"One of the most valuable contributions ever made to medical literature. It is, so far as we know, absolutely unique, and every page is as fascinating as a novel. Not alone for the medical profession has this volume value: it will serve as a book of reference for all who are interested in general scientific, sociologic, or medico-legal topics."—*Brooklyn Medical Journal*.

"This is certainly a most remarkable and interesting volume. It stands alone among medical literature, an anomaly on anomalies, in that there is nothing like it elsewhere in medical literature. It is a book full of revelations from its first to its last page, and cannot but interest and sometimes almost horrify its readers."—*American Medico-Surgical Bulletin*.

GRIFFIN'S MATERIA MEDICA AND THERAPEUTICS.

Manual of Materia Medica and Therapeutics. By HENRY A. GRIFFIN, A. B., M. D., Assistant Physician to the Roosevelt Hospital, Out-Patient Department, New York City. *In Preparation.*

GRIFFITH ON THE BABY.

The Care of the Baby. By J. P. CROZER GRIFFITH, M. D., Clinical Professor of Diseases of Children, University of Pennsylvania; Physician to the Children's Hospital, Philadelphia, etc. 12mo, 392 pages, with 67 illustrations in the text, and 5 plates. Cloth, \$1.50.

"The best book for the use of the young mother with which we are acquainted. . . . There are very few general practitioners who could not read the book through with advantage."—*Archives of Pediatrics.*

"The whole book is characterized by rare good sense, and is evidently written by a master hand. It can be read with benefit not only by mothers but by medical students and by any practitioners who have not had large opportunities for observing children."—*American Journal of Obstetrics.*

GRIFFITH'S WEIGHT CHART.

Infant's Weight Chart. Designed by J. P. CROZER GRIFFITH, M. D., Clinical Professor of Diseases of Children in the University of Pennsylvania, etc. 25 charts in each pad. Per pad, 50 cents net.

A convenient blank for keeping a record of the child's weight during the first two years of life. Printed on each chart is a curve representing the average weight of a healthy infant, so that any deviation from the normal can readily be detected.

GROSS, SAMUEL D., AUTOBIOGRAPHY OF.

Autobiography of Samuel D. Gross, M. D., Emeritus Professor of Surgery in the Jefferson Medical College, Philadelphia, with Reminiscences of His Times and Contemporaries. Edited by his Sons, SAMUEL W. GROSS, M. D., LL. D., late Professor of Principles of Surgery and of Clinical Surgery in the Jefferson Medical College, and A. HALLER GROSS, A. M., of the Philadelphia Bar. Preceded by a Memoir of Dr. Gross, by the late AUSTIN FLINT, M. D., LL. D. In two handsome volumes, each containing over 400 pages, demy octavo, extra cloth, gilt tops, with fine Frontispiece engraved on steel. Price per volume, \$2.50 net.

"Dr. Gross was perhaps the most eminent exponent of medical science that America has yet produced. His Autobiography, related as it is with a fulness and completeness seldom to be found in such works, is an interesting and valuable book. He comments on many things, especially, of course, on medical men and medical practice, in a very interesting way."—*The Spectator*, London, England.

HAMPTON'S NURSING.

Nursing: Its Principles and Practice. By ISABEL ADAMS HAMPTON, Graduate of the New York Training School for Nurses attached to Bellevue Hospital; Superintendent of Nurses, and Principal of the Training School for Nurses, Johns Hopkins Hospital, Baltimore, Md. 12mo, 484 pages, profusely illustrated. Cloth, \$2.00 net.

"Seldom have we perused a book upon the subject that has given us so much pleasure as the one before us. We would strongly urge upon the members of our own profession the need of a book like this, for it will enable each of us to become a training school in himself."—*Ontario Medical Journal.*

HARE'S PHYSIOLOGY. Fourth Edition, Revised.

Essentials of Physiology. By H. A. HARE, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia; Physician to the Jefferson Medical College Hospital. Containing a series of handsome illustrations from the celebrated "Icones Nervorum Capitis" of Arnold. Crown octavo, 239 pages. Cloth, \$1.00 net; interleaved for notes, \$1.25 net.

[See *Saunders' Question-Compends*, page 21.]

"The best condensation of physiological knowledge we have yet seen."—*Medical Record*, New York.

HART'S DIET IN SICKNESS AND IN HEALTH.

Diet in Sickness and in Health. By MRS. ERNEST HART, formerly Student of the Faculty of Medicine of Paris and of the London School of Medicine for Women; with an INTRODUCTION by SIR HENRY THOMPSON, F.R.C.S., M.D., London. 220 pages; illustrated. Cloth, \$1.50.

"We recommend it cordially to the attention of all practitioners; both to them and to their patients it may be of the greatest service."—*New York Medical Journal*.

HAYNES' ANATOMY.

A Manual of Anatomy. By IRVING S. HAYNES, M.D., Adjunct Professor of Anatomy and Demonstrator of Anatomy, Medical Department of the New York University, etc. 680 pages, illustrated with 42 diagrams in the text, and 134 full-page half-tone illustrations from original photographs of the author's dissections. Cloth, \$2.50 net.

"This book is the work of a practical instructor—one who knows by experience the requirements of the average student, and is able to meet these requirements in a very satisfactory way. The book is one that can be commended."—*Medical Record*, New York.

HEISLER'S EMBRYOLOGY.*

A Text-Book of Embryology. By JOHN C. HEISLER, M.D., Professor of Anatomy in the Medico-Chirurgical College, Philadelphia. *In Preparation.*

HIRST'S OBSTETRICS.

A Text-Book of Obstetrics. By BARTON COOKE HIRST, M.D., Professor of Obstetrics in the University of Pennsylvania. *In Preparation.*

HYDE AND MONTGOMERY ON SYPHILIS AND THE VENEREAL DISEASES.

Syphilis and the Venereal Diseases. By JAMES NEVINS HYDE, M.D., Professor of Skin and Venereal Diseases, and FRANK H. MONTGOMERY, M.D., Lecturer on Dermatology and Genito-Urinary Diseases in Rush Medical College, Chicago, Ill. 618 pages, profusely illustrated. Cloth, \$2.50 net.

"We can commend this manual to the student as a help to him in his study of venereal diseases."—*Liverpool Medico-Chirurgical Journal*.

"The best student's manual which has appeared on the subject."—*St. Louis Medical and Surgical Journal*.

JACKSON AND GLEASON'S DISEASES OF THE EYE, NOSE, AND THROAT. Second Edition, Revised.

Essentials of Refraction and Diseases of the Eye. By EDWARD JACKSON, A.M., M.D., Professor of Diseases of the Eye in the Philadelphia Polyclinic and College for Graduates in Medicine; and—

Essentials of Diseases of the Nose and Throat. By E. BALDWIN GLEASON, M.D., Surgeon-in-Charge of the Nose, Throat, and Ear Department of the Northern Dispensary of Philadelphia. Two volumes in one. Crown octavo, 290 pages; 124 illustrations. Cloth, \$1.00; interleaved for notes, \$1.25.

[See *Saunders' Question-Compends*, page 21.]

"Of great value to the beginner in these branches. The authors are both capable men, and know what a student most needs."—*Medical Record*, New York.

KEATING'S DICTIONARY. Second Edition, Revised.

A New Pronouncing Dictionary of Medicine, with Phonetic Pronunciation, Accentuation, Etymology, etc. By JOHN M. KEATING, M.D., LL.D., Fellow of the College of Physicians of Philadelphia; Vice-President of the American Pædiatric Society; Editor "Cyclopædia of the Diseases of Children," etc.; and HENRY HAMILTON, Author of "A New Translation of Virgil's Æneid into English Rhyme," etc.; with the collaboration of J. CHALMERS DAcOSTA, M.D., and FREDERICK A. PACKARD, M.D. With an Appendix containing Tables of Bacilli, Micrococci, Leucomaines, Ptomaines; Drugs and Materials used in Antiseptic Surgery; Poisons and their Antidotes; Weights and Measures; Thermometric Scales; New Official and Unofficial Drugs, etc. One volume of over 800 pages. Prices, with Denison's Patent Ready-Reference Index: Cloth, \$5.00 net; Sheep or Half Morocco, \$6.00 net; Half Russia, \$6.50 net. Without Patent Index: Cloth, \$4.00 net; Sheep or Half Morocco, \$5.00 net.

"I am much pleased with Keating's Dictionary, and shall take pleasure in recommending it to my classes."—HENRY M. LYMAN, M.D., *Professor of the Principles and Practice of Medicine, Rush Medical College, Chicago, Ill.*

"I am convinced that it will be a very valuable adjunct to my study-table, convenient in size and sufficiently full for ordinary use."—C. A. LINDSLEY, M.D., *Professor of the Theory and Practice of Medicine, Medical Dept. Yale University.*

KEATING'S LIFE INSURANCE.

How to Examine for Life Insurance. By JOHN M. KEATING, M.D., Fellow of the College of Physicians and Surgeons of Philadelphia; Vice-President of the American Pædiatric Society; Ex-President of the Association of Life Insurance Medical Directors. Royal octavo, 211 pages; with two large half-tone illustrations, and a plate prepared by Dr. McClellan from special dissections; also, numerous other illustrations. Cloth, \$2.00 net.

"This is by far the most useful book which has yet appeared on insurance examination, a subject of growing interest and importance. Not the least valuable portion of the volume is Part II, which consists of instructions issued to their examining physicians by twenty-four representative companies of this country. If for these alone, the book should be at the right hand of every physician interested in this special branch of medical science."—*The Medical News.*

KEEN ON THE SURGERY OF TYPHOID FEVER.

The Surgical Complications and Sequels of Typhoid Fever.

By WM. W. KEEN, M.D., LL.D., Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia; Corresponding Member of the Société de Chirurgie, Paris; Honorary Member of the Société Belge de Chirurgie, etc. Octavo volume of about 400 pages. Cloth, \$3.00 net. *Nearly Ready.*

This monograph is the only one in any language covering the entire subject of the Surgical Complications and Sequels of Typhoid Fever. It will prove to be of importance and interest not only to the general surgeon and physician, but also to many specialists—laryngologists, gynecologists, pathologists, and bacteriologists.

KEEN'S OPERATION BLANK. Second Edition, Revised Form.

An Operation Blank, with Lists of Instruments, etc. Required in Various Operations. Prepared by W. W. KEEN, M.D., LL.D., Professor of the Principles of Surgery in Jefferson Medical College, Philadelphia. Price per pad, containing blanks for fifty operations, 50 cents net.

KYLE ON THE NOSE AND THROAT.

Diseases of the Nose and Throat. By D. BRADEN KYLE, M.D., Chief Laryngologist to St. Agnes' Hospital, Philadelphia; Bacteriologist to the Orthopædic Hospital and Infirmary for Nervous Diseases; Instructor in Clinical Microscopy and Assistant Demonstrator of Pathology in the Jefferson Medical College, etc. *In Preparation.*

LAINÉ'S TEMPERATURE CHART.

Temperature Chart. Prepared by D. T. LAINÉ, M.D. Size 8 x 13½ inches. A conveniently arranged Chart for recording Temperature, with columns for daily amounts of Urinary and Fecal Excretions, Food, Remarks, etc. On the back of each chart is given in full the method of Brand in the treatment of Typhoid Fever. Price, per pad of 25 charts, 50 cents net.

"To the busy practitioner this chart will be found of great value in fever cases, and especially for cases of typhoid."—*Indian Lancet*, Calcutta.

LOCKWOOD'S PRACTICE OF MEDICINE.

A Manual of the Practice of Medicine. By GEORGE ROE LOCKWOOD, M.D., Professor of Practice in the Woman's Medical College of the New York Infirmary, etc. 935 pages, with 75 illustrations in the text, and 22 full-page plates. Cloth, \$2.50 net.

"Gives in a most concise manner the points essential to treatment usually enumerated in the most elaborate works."—*Massachusetts Medical Journal.*

LONG'S SYLLABUS OF GYNECOLOGY.

A Syllabus of Gynecology, arranged in Conformity with "An American Text-Book of Gynecology." By J. W. LONG, M.D., Professor of Diseases of Women and Children, Medical College of Virginia, etc. Cloth, interleaved, \$1.00 net.

"The book is certainly an admirable *résumé* of what every gynecological student and practitioner should know, and will prove of value not only to those who have the 'American Text-Book of Gynecology,' but to others as well."—*Brooklyn Medical Journal.*

MACDONALD'S SURGICAL DIAGNOSIS AND TREATMENT.

Surgical Diagnosis and Treatment. By J. W. MACDONALD, M.D., Edin., L.R.C.S., Edin., Professor of the Practice of Surgery and of Clinical Surgery in Hamline University; Visiting Surgeon to St. Barnabas' Hospital, Minneapolis, etc. Handsome octavo volume of 800 pages, profusely illustrated. Cloth, \$5.00 net; Half Morocco, \$6.00 net.

"The rapid advances made in the art of surgery have caused the literature of the science to grow apace. Systems of surgery in many volumes, and text-books of large dimensions, are now deemed necessary to cover the field. The practical part of the surgeon's work is, however, almost limited to two questions which he must answer every time his professional advice or help is sought. The first question is, 'What is the disease or injury?' The second question is, 'What is the proper treatment?'"

"While I would not for a moment underestimate the importance of a profound study of the principles of surgery, of surgical pathology, or of bacteriology, the present work will be confined to a solution of the two questions just mentioned, with the view of putting into the hands of students and practitioners a single volume containing the most practical part of practical surgery."—*From the Author's Preface.*

MALLORY AND WRIGHT'S PATHOLOGICAL TECHNIQUE.

Pathological Technique. By FRANK B. MALLORY, A.M., M.D., Assistant Professor of Pathology, Harvard University Medical School; and JAMES H. WRIGHT, A.M., M.D., Instructor in Pathology, Harvard University Medical School. Octavo volume of 396 pages, handsomely illustrated. Cloth, \$2.50.net.

"I have been looking forward to the publication of this book, and I am glad to say that I find it to be a most useful laboratory and post-mortem guide, full of practical information, and well up to date."—WILLIAM H. WELCH, *Professor of Pathology, Johns Hopkins University, Baltimore, Md.*

MARTIN'S MINOR SURGERY, BANDAGING, AND VENEREAL DISEASES. Second Edition, Revised.

Essentials of Minor Surgery, Bandaging, and Venereal Diseases. By EDWARD MARTIN, A.M., M.D., Clinical Professor of Genito-Urinary Diseases, University of Pennsylvania, etc. Crown octavo, 166 pages, with 78 illustrations. Cloth, \$1.00; interleaved for notes, \$1.25.

[See *Saunders' Question-Compends*, page 21.]

"A very practical and systematic study of the subjects, and shows the author's familiarity with the needs of students."—*Therapeutic Gazette.*

MARTIN'S SURGERY. Sixth Edition, Revised.

Essentials of Surgery. Containing also Venereal Diseases, Surgical Landmarks, Minor and Operative Surgery, and a complete description, with illustrations, of the Handkerchief and Roller Bandages. By EDWARD MARTIN, A.M., M.D., Clinical Professor of Genito-Urinary Diseases, University of Pennsylvania, etc. Crown octavo, 338 pages, illustrated. With an Appendix containing full directions for the preparation of the materials used in Antiseptic Surgery, etc. Cloth, \$1.00; interleaved for notes, \$1.25.

[See *Saunders' Question-Compends*, page 21.]

"Contains all necessary essentials of modern surgery in a comparatively small space. Its style is interesting, and its illustrations are admirable."—*Medical and Surgical Reporter.*

MCFARLAND'S PATHOGENIC BACTERIA.

Text-Book upon the Pathogenic Bacteria. Specially written for Students of Medicine. By JOSEPH MCFARLAND, M.D., Professor of Pathology and Bacteriology in the Medico-Chirurgical College of Philadelphia, etc. Octavo volume of 359 pages, finely illustrated. Cloth, \$2.50 net.

"Dr. McFarland has treated the subject in a systematic manner, and has succeeded in presenting in a concise and readable form the essentials of bacteriology up to date. Altogether, the book is a satisfactory one, and I shall take pleasure in recommending it to the students of Trinity College."—H. B. ANDERSON, M.D., *Professor of Pathology and Bacteriology, Trinity Medical College, Toronto.*

MEIGS ON FEEDING IN INFANCY.

Feeding in Early Infancy. By ARTHUR V. MEIGS, M.D. Bound in limp cloth, flush edges, 25 cents net.

"This pamphlet is worth many times over its price to the physician. The author's experiments and conclusions are original, and have been the means of doing much good."—*Medical Bulletin.*

MOORE'S ORTHOPEDIC SURGERY.

A Manual of Orthopedic Surgery. By JAMES E. MOORE, M.D., Professor of Orthopedics and Adjunct Professor of Clinical Surgery, University of Minnesota, College of Medicine and Surgery. Octavo volume of 356 pages, handsomely illustrated. Cloth, \$2.50 net.

A practical book based upon the author's experience, in which special stress is laid upon early diagnosis, and treatment such as can be carried out by the general practitioner. The teachings of the author are in accordance with his belief that true conservatism is to be found in the middle course between the surgeon who operates too frequently and the orthopedist who seldom operates.

MORRIS'S MATERIA MEDICA AND THERAPEUTICS. Fourth Edition, Revised.

Essentials of Materia Medica, Therapeutics, and Prescription-Writing. By HENRY MORRIS, M.D., late Demonstrator of Therapeutics, Jefferson Medical College, Philadelphia; Fellow of the College of Physicians, Philadelphia, etc. Crown octavo, 250 pages. Cloth, \$1.00; interleaved for notes, \$1.25.

[See *Saunders' Question-Compend*s, page 21.]

"This work, already excellent in the old edition, has been largely improved by revision."—*American Practitioner and News.*

MORRIS, WOLFF, AND POWELL'S PRACTICE OF MEDICINE. Third Edition, Revised.

Essentials of the Practice of Medicine. By HENRY MORRIS, M.D., late Demonstrator of Therapeutics, Jefferson Medical College, Philadelphia; with an Appendix on the Clinical and Microscopic Examination of Urine, by LAWRENCE WOLFF, M.D., Demonstrator of Chemistry, Jefferson Medical College, Philadelphia. Enlarged by some 300 essential formulæ collected and arranged by WILLIAM M. POWELL, M.D. Post-octavo, 488 pages. Cloth, \$2.00.

[See *Saunders' Question-Compend*s, page 21.]

"The teaching is sound, the presentation graphic; matter full as can be desired, and style attractive."—*American Practitioner and News.*

MORTEN'S NURSE'S DICTIONARY.

Nurse's Dictionary of Medical Terms and Nursing Treatment. Containing Definitions of the Principal Medical and Nursing Terms and Abbreviations; of the Instruments, Drugs, Diseases, Accidents, Treatments, Operations, Foods, Appliances, etc. encountered in the ward or in the sick-room. By HONNOR MORTEN, author of "How to Become a Nurse," etc. 16mo, 140 pages. Cloth, \$1.00.

"A handy, compact little volume, containing a large amount of general information, all of which is arranged in dictionary or encyclopedic form, thus facilitating quick reference. It is certainly of value to those for whose use it is published."—*Chicago Clinical Review*.

NANCREDE'S ANATOMY. Fifth Edition.

Essentials of Anatomy, including the Anatomy of the Viscera. By CHARLES B. NANCREDE, M.D., Professor of Surgery and of Clinical Surgery in the University of Michigan, Ann Arbor. Crown octavo, 388 pages; 180 illustrations. With an Appendix containing over 60 illustrations of the osteology of the human body. Based upon *Gray's Anatomy*. Cloth, \$1.00; interleaved for notes, \$1.25.

[See *Saunders' Question-Compends*, page 21.]

"For self-quizzing and keeping fresh in mind the knowledge of anatomy gained at school, it would not be easy to speak of it in terms too favorable."—*American Practitioner*.

NANCREDE'S ANATOMY AND DISSECTION. Fourth Edition.

Essentials of Anatomy and Manual of Practical Dissection. By CHARLES B. NANCREDE, M.D., Professor of Surgery and of Clinical Surgery, University of Michigan, Ann Arbor. Post-octavo; 500 pages, with full-page lithographic plates in colors, and nearly 200 illustrations. Extra Cloth (or Oilcloth for the dissection-room), \$2.00 net.

"It may in many respects be considered an epitome of Gray's popular work on general anatomy, at the same time having some distinguishing characteristics of its own to commend it. The plates are of more than ordinary excellence, and are of especial value to students in their work in the dissecting room."—*Journal of the American Medical Association*.

NORRIS'S SYLLABUS OF OBSTETRICS. Third Edition, Revised.

Syllabus of Obstetrical Lectures in the Medical Department of the University of Pennsylvania. By RICHARD C. NORRIS, A.M., M.D., Demonstrator of Obstetrics, University of Pennsylvania. Crown octavo, 222 pages. Cloth, interleaved for notes, \$2.00 net.

"This work is so far superior to others on the same subject that we take pleasure in calling attention briefly to its excellent features. It covers the subject thoroughly, and will prove invaluable both to the student and the practitioner."—*Medical Record*, New York.

PENROSE'S DISEASES OF WOMEN.

A Text-Book of Diseases of Women. By CHARLES B. PENROSE, M.D., PH.D., Professor of Gynecology in the University of Pennsylvania; Surgeon to the Gyneccean Hospital, Philadelphia. Octavo volume of 529 pages, handsomely illustrated. Cloth, \$3.50 net.

"The book is to be commended without reserve, not only to the student but to the general practitioner who wishes to have the latest and best modes of treatment explained with absolute clearness."—*Therapeutic Gazette*.

"Taking it all in all, this is in our opinion one of the best works upon this subject that has appeared, and Mr. Saunders may feel justly proud of having the work issued from his press."—*Matthews' Quarterly Journal*.

POWELL'S DISEASES OF CHILDREN. Second Edition.

Essentials of Diseases of Children. By WILLIAM M. POWELL, M.D., Attending Physician to the Mercer House for Invalid Women at Atlantic City, N. J.; late Physician to the Clinic for the Diseases of Children in the Hospital of the University of Pennsylvania. Crown octavo, 222 pages. Cloth, \$1.00; interleaved for notes, \$1.25.

[See *Saunders' Question-Compends*, page 21.]

"Contains the gist of all the best works in the department to which it relates."—*American Practitioner and News.*

PRINGLE'S SKIN DISEASES AND SYPHILITIC AFFECTIONS.

Pictorial Atlas of Skin Diseases and Syphilitic Affections (American Edition). Translation from the French. Edited by J. J. PRINGLE, M.B., F.R.C.P., Assistant Physician to the Middlesex Hospital, London. Photo-lithochromes from the famous models in the Museum of the Saint-Louis Hospital, Paris, with explanatory wood-cuts and text. Complete in 12 Parts. Price per Part, \$3.00.

"I strongly recommend this Atlas. The plates are exceedingly well executed, and will be of great value to all studying dermatology."—STEPHEN MACKENZIE, M.D. (London Hospital).

"The introduction of explanatory wood-cuts in the text is a novel and most important feature which greatly furthers the easier understanding of the excellent plates, than which nothing, we venture to say, has been seen better in point of correctness, beauty, and general merit."—*New York Medical Journal.*

PYE'S BANDAGING.

Elementary Bandaging and Surgical Dressing. With Directions concerning the Immediate Treatment of Cases of Emergency. For the use of Dressers and Nurses. By WALTER PYE, F.R.C.S., late Surgeon to St. Mary's Hospital, London. Small 12mo, with over 80 illustrations. Cloth, flexible covers, 75 cents net.

"The directions are clear and the illustrations are good."—*London Lancet.*

"The author writes well, the diagrams are clear, and the book itself is small and portable, although the paper and type are good."—*British Medical Journal.*

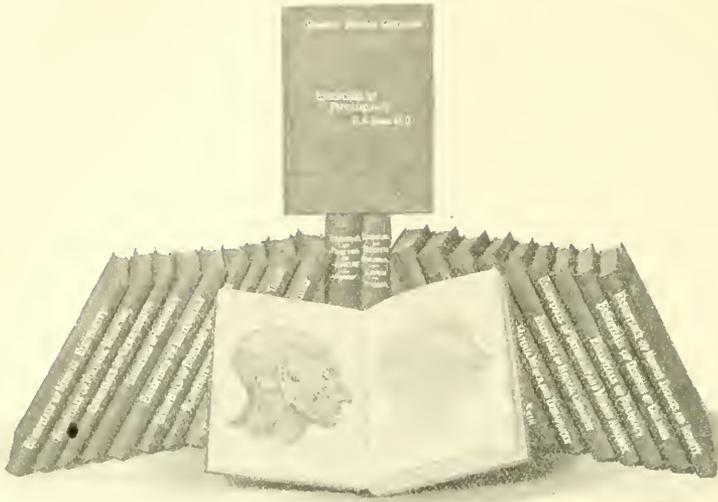

RAYMOND'S PHYSIOLOGY.

A Manual of Physiology. By JOSEPH H. RAYMOND, A.M., M.D., Professor of Physiology and Hygiene and Lecturer on Gynecology in the Long Island College Hospital; Director of Physiology in the Hoagland Laboratory, etc. 382 pages, with 102 illustrations in the text, and 4 full-page colored plates. Cloth, \$1.25 net.

"Extremely well gotten up, and the illustrations have been selected with care. The text is fully abreast with modern physiology."—*British Medical Journal.*

RÖNTGEN RAYS.

Archives of the Röntgen Ray (Formerly Archives of Clinical Skiagraphy). Edited by SYDNEY ROWLAND, M.A., M.R.C.S., and W. S. HEDLEY, M.D., M.R.C.S. A series of collotype illustrations, with descriptive text, illustrating the applications of the new photography to Medicine and Surgery. Price per Part, \$1.00. Now ready: Vol. I., Parts I. to IV.; Vol. II., Part I.

SAUNDERS' QUESTION COMPENDS

Arranged in Question and
Answer Form.

THE MOST COMPLETE AND BEST
ILLUSTRATED SERIES OF
COMPENDS EVER ISSUED.

Now the Standard Authorities in Medical Literature

with Students and Practitioners in every City of the United States and Canada.

OVER 165,000 COPIES SOLD.

THE REASON WHY.

They are the advance guard of "Student's Helps"—that DO HELP. They are the leaders in their special line, well and authoritatively written by able men, who, as teachers in the large colleges, know exactly what is wanted by a student preparing for his examinations. The judgment exercised in the selection of authors is fully demonstrated by their professional standing. Chosen from the ranks of Demonstrators, Quiz-masters, and Assistants, most of them have become Professors and Lecturers in their respective colleges.

Each book is of convenient size (5 x 7 inches), containing on an average 250 pages, profusely illustrated, and elegantly printed in clear, readable type, on fine paper.

The entire series, numbering twenty-three volumes, has been kept thoroughly revised and enlarged when necessary, many of the books being in their fifth and sixth editions.

TO SUM UP.

Although there are numerous other Quizzes, Manuals, Aids, etc. in the market, none of them approach the "Blue Series of Question Compends;" and the claim is made for the following points of excellence:

1. Professional distinction and reputation of authors.
2. Conciseness, clearness, and soundness of treatment.
3. Quality of illustrations, paper, printing, and binding.

Any of these Compends will be mailed on receipt of price (see next page for List).

Saunders' Question-Compend Series.

Price, Cloth, \$1.00 per copy, except when otherwise noted.

"Where the work of preparing students' manuals is to end we cannot say, but the Saunders Series, in our opinion, bears off the palm at present."—*New York Medical Record*.

1. **ESSENTIALS OF PHYSIOLOGY.** By H. A. HARE, M.D. Fourth edition, revised and enlarged. (\$1.00 net.)
2. **ESSENTIALS OF SURGERY.** By EDWARD MARTIN, M.D. Sixth edition, revised, with an Appendix on Antiseptic Surgery.
3. **ESSENTIALS OF ANATOMY.** By CHARLES B. NANCREDE, M.D. Fifth edition, with an Appendix.
4. **ESSENTIALS OF MEDICAL CHEMISTRY, ORGANIC AND INORGANIC.** By LAWRENCE WOLFF, M.D. Fourth edition, revised, with an Appendix.
5. **ESSENTIALS OF OBSTETRICS.** By W. EASTERLY ASHTON, M.D. Fourth edition, revised and enlarged.

Pamphlet containing specimen pages, etc. sent free upon application.

PRACTICAL, EXHAUSTIVE, AUTHORITATIVE.

SAUNDERS'
New Series of Manuals

FOR

STUDENTS AND PRACTITIONERS.

THAT there exists a need for thoroughly reliable hand-books on the leading branches of Medicine and Surgery is a fact amply demonstrated by the favor with which the SAUNDERS NEW SERIES OF MANUALS have been received by medical students and practitioners and by the Medical Press. These manuals are not merely condensations from present literature, but are ably written by well-known authors and practitioners, most of them being teachers in representative American colleges. Each volume is concisely and authoritatively written and exhaustive in detail, without being encumbered with the introduction of "cases," which so largely expand the ordinary text-book. These manuals will therefore form an admirable collection of advanced lectures, useful alike to the medical student and the practitioner: to the latter, too busy to search through page after page of elaborate treatises for what he wants to know, they will prove of inestimable value; to the former they will afford safe guides to the essential points of study.

The SAUNDERS NEW SERIES OF MANUALS are conceded to be superior to any similar books now on the market. No other manuals afford so much information in such a concise and available form. A liberal expenditure has enabled the publisher to render the mechanical portion of the work worthy of the high literary standard attained by these books.

Saunders' New Series of Manuals.

VOLUMES PUBLISHED.

- PHYSIOLOGY.** By JOSEPH HOWARD RAYMOND, A.M., M.D., Professor of Physiology and Hygiene and Lecturer on Gynecology in the Long Island College Hospital; Director of Physiology in the Hoagland Laboratory, etc. Illustrated. Cloth, \$1.25 net.
- SURGERY, General and Operative.** By JOHN CHALMERS DACOSTA, M.D., Clinical Professor of Surgery, Jefferson Medical College, Philadelphia; Surgeon to the Philadelphia Hospital, etc. 188 illustrations and 13 plates. (Double number.) Cloth, \$2.50 net.

- SURGICAL ASEPSIS.** By CARL BECK, M.D., Surgeon to St. Mark's Hospital and to the New York German Poliklinik, etc. Illustrated. Cloth, \$1.25 net.
- MEDICAL JURISPRUDENCE.** By HENRY C. CHAPMAN, M.D. Professor of Institutes of Medicine and Medical Jurisprudence in the Jefferson Medical College of Philadelphia. Illustrated. Cloth, \$1.50 net.
- SYPHILIS AND THE VENEREAL DISEASES.** By JAMES NEVINS HYDE, M.D., Professor of Skin and Venereal Diseases, and FRANK H. MONTGOMERY, M.D., Lecturer on Dermatology and Genito-Urinary Diseases in Rush Medical College, Chicago. Profusely illustrated. (Double number.) Cloth, \$2.50 net.
- PRACTICE OF MEDICINE.** By GEORGE ROE LOCKWOOD, M.D., Professor of Practice in the Woman's Medical College of the New York Infirmary; Instructor in Physical Diagnosis in the Medical Department of Columbia College, etc. Illustrated. (Double number.) Cloth, \$2.50 net.
- MANUAL OF ANATOMY.** By IRVING S. HAYNES, M.D., Adjunct Professor of Anatomy and Demonstrator of Anatomy, Medical Department of the New York University, etc. Beautifully illustrated. (Double Number.) Cloth, \$2.50 net.
- MANUAL OF OBSTETRICS.** By W. A. NEWMAN DORLAND, M.D., Assistant Demonstrator of Obstetrics, University of Pennsylvania; Chief of Gynecological Dispensary, Pennsylvania Hospital, etc. Profusely illustrated. (Double number.) Cloth, \$2.50 net.
- DISEASES OF WOMEN.** By J. BLAND SUTTON, F.R.C.S., Assistant Surgeon to Middlesex Hospital and Surgeon to Chelsea Hospital, London; and ARTHUR E. GILES, M.D., B.Sc. Lond., F.R.C.S. Edin., Assistant Surgeon to Chelsea Hospital, London. Handsomely illustrated. (Double number.) Cloth, \$2.50 net.

VOLUMES IN PREPARATION.

- NOSE AND THROAT.** By D. BRADEN KYLE, M.D., Chief Laryngologist to the St. Agnes Hospital, Philadelphia; Bacteriologist to the Orthopaedic Hospital and Infirmary for Nervous Diseases; Instructor in Clinical Microscopy and Assistant Demonstrator of Pathology in the Jefferson Medical College, etc.
- NERVOUS DISEASES.** By CHARLES W. BURR, M.D., Clinical Professor of Nervous Diseases, Medico-Chirurgical College, Philadelphia; Pathologist to the Orthopaedic Hospital and Infirmary for Nervous Diseases; Visiting Physician to the St. Joseph Hospital, etc.

. There will be published in the same series, at short intervals, carefully-prepared works on various subjects by prominent specialists.

Pamphlet containing specimen pages, etc. sent free upon application.

SAUNDBY'S RENAL AND URINARY DISEASES.

Lectures on Renal and Urinary Diseases. By ROBERT SAUNDBY, M.D. Edin., Fellow of the Royal College of Physicians, London, and of the Royal Medico-Chirurgical Society; Physician to the General Hospital; Consulting Physician to the Eye Hospital and to the Hospital for Diseases of Women; Professor of Medicine in Mason College, Birmingham, etc. Octavo volume of 434 pages, with numerous illustrations and 4 colored plates. Cloth, \$2.50 net.

"The volume makes a favorable impression at once. The style is clear and succinct. We cannot find any part of the subject in which the views expressed are not carefully thought out and fortified by evidence drawn from the most recent sources. The book may be cordially recommended."—*British Medical Journal*.

SAUNDERS' POCKET MEDICAL FORMULARY. Fourth Edition, Revised.

By WILLIAM M. POWELL, M.D., Attending Physician to the Mercer House for Invalid Women at Atlantic City, N. J. Containing 1750 formulæ selected from the best-known authorities. With an Appendix containing Posological Table, Formulæ and Doses for Hypodermic Medication, Poisons and their Antidotes, Diameters of the Female Pelvis and Foetal Head, Obstetrical Table, Diet List for Various Diseases, Materials and Drugs used in Antiseptic Surgery, Treatment of Asphyxia from Drowning, Surgical Remembrancer, Tables of Incompatibles, Eruptive Fevers, Weights and Measures, etc. Handsomely bound in flexible morocco, with side index, wallet, and flap. \$1.75 net.

"This little book, that can be conveniently carried in the pocket, contains an immense amount of material. It is very useful, and, as the name of the author of each prescription is given, is unusually reliable."—*Medical Record*, New York.

SAUNDERS' POCKET MEDICAL LEXICON. Fourth Edition, Revised.

A Dictionary of Terms and Words used in Medicine and Surgery. By JOHN M. KEATING, M.D., Fellow of the College of Physicians of Philadelphia; Editor of the "Cyclopædia of Diseases of Children," etc.; Author of the "New Pronouncing Dictionary of Medicine;" and HENRY HAMILTON, Author of "A New Translation of Virgil's *Æneid* into English Verse;" Co-Author of the "New Pronouncing Dictionary of Medicine." 32mo, 280 pages. Cloth, 75 cents; Leather Tucks, \$1.00.

"Remarkably accurate in terminology, accentuation, and definition."—*Journal of the American Medical Association*.

SAYRE'S PHARMACY. Second Edition, Revised.

Essentials of the Practice of Pharmacy. By LUCIUS E. SAYRE, M.D., Professor of Pharmacy and *Materia Medica* in the University of Kansas. Crown octavo, 200 pages. Cloth, \$1.00; interleaved for notes, \$1.25.

[See *Saunders' Question-Compend*s, page 21.]

"The topics are treated in a simple, practical manner, and the work forms a very useful student's manual."—*Boston Medical and Surgical Journal*.

SEMPLE'S LEGAL MEDICINE, TOXICOLOGY, AND HYGIENE.

Essentials of Legal Medicine, Toxicology, and Hygiene. By C. E. ARMAND SEMPLE, B.A., M.B. Cantab., M.R.C.P. Lond., Physician to the Northeastern Hospital for Children, Hackney, etc. Crown octavo, 212 pages; 130 illustrations. Cloth, \$1.00; interleaved for notes, \$1.25.

[See *Saunders' Question-Compends*, page 21.]

"No general practitioner or student can afford to be without this valuable work. The subjects are dealt with by a masterly hand."—*London Hospital Gazette*.

SEMPLE'S PATHOLOGY AND MORBID ANATOMY.

Essentials of Pathology and Morbid Anatomy. By C. E. ARMAND SEMPLE, B.A., M.B. Cantab., M.R.C.P. Lond., Physician to the Northeastern Hospital for Children, Hackney, etc. Crown octavo, 174 pages; illustrated. Cloth, \$1.00; interleaved for notes, \$1.25.

[See *Saunders' Question-Compends*, page 21.]

"Should take its place among the standard volumes on the bookshelf of both student and practitioner."—*London Hospital Gazette*.

SENN'S GENITO-URINARY TUBERCULOSIS.

Tuberculosis of the Genito-Urinary Organs, Male and Female. By NICHOLAS SENN, M.D., PH.D., LL.D., Professor of the Practice of Surgery and of Clinical Surgery, Rush Medical College, Chicago. Handsome octavo volume of 320 pages, illustrated. Cloth, \$3.00 net.

"An important book upon an important subject, and written by a man of mature judgment and wide experience. The author has given us an instructive book upon one of the most important subjects of the day."—*Clinical Reporter*.

"A work which adds another to the many obligations the profession owes the talented author."—*Chicago Medical Recorder*.

SENN'S SYLLABUS OF SURGERY.

A Syllabus of Lectures on the Practice of Surgery, arranged in conformity with "An American Text-Book of Surgery." By NICHOLAS SENN, M.D., PH.D., Professor of the Practice of Surgery and of Clinical Surgery in Rush Medical College, Chicago. Cloth, \$2.00.

"This syllabus will be found of service by the teacher as well as the student, the work being superbly done. There is no praise too high for it. No surgeon should be without it."—*New York Medical Times*.

SENN'S TUMORS.

Pathology and Surgical Treatment of Tumors. By N. SENN, M.D., PH.D., LL.D., Professor of Surgery and of Clinical Surgery, Rush Medical College; Professor of Surgery, Chicago Polyclinic; Attending Surgeon to Presbyterian Hospital; Surgeon-in-Chief, St. Joseph's Hospital, Chicago. Octavo volume of 710 pages, with 515 engravings, including full-page colored plates. Cloth, \$6.00 net; Half Morocco, \$7.00 net.

"The most exhaustive of any recent book in English on this subject. It is well illustrated, and will doubtless remain as the principal monograph on the subject in our language for some years. The book is handsomely illustrated and printed, and the author has given a notable and lasting contribution to surgery."—*Journal of the American Medical Association*.

SHAW'S NERVOUS DISEASES AND INSANITY. Third Edition, Revised.

Essentials of Nervous Diseases and Insanity. By JOHN C. SHAW, M.D., Clinical Professor of Diseases of the Mind and Nervous System, Long Island College Hospital Medical School; Consulting Neurologist to St. Catherine's Hospital and to the Long Island College Hospital. Crown octavo, 186 pages; 48 original illustrations. Cloth, \$1.00; interleaved for notes, \$1.25.

[See *Saunders' Question-Compends*, page 21.]

"Clearly and intelligently written."—*Boston Medical and Surgical Journal*.

"There is a mass of valuable material crowded into this small compass."—*American Medico-Surgical Bulletin*.

STARR'S DIETS FOR INFANTS AND CHILDREN.

Diets for Infants and Children in Health and in Disease. By LOUIS STARR, M.D., Editor of "An American Text-Book of the Diseases of Children." 230 blanks (pocket-book size), perforated and neatly bound in flexible morocco. \$1.25 net.

The first series of blanks are prepared for the first seven months of infant life; each blank indicates the ingredients, but not the quantities, of the food, the latter directions being left for the physician. After the seventh month, modifications being less necessary, the diet lists are printed in full. Formule for the preparation of diluents and foods are appended.

STELWAGON'S DISEASES OF THE SKIN. Third Edition, Revised.

Essentials of Diseases of the Skin. By HENRY W. STELWAGON, M.D., Clinical Professor of Dermatology in the Jefferson Medical College, Philadelphia; Dermatologist to the Philadelphia Hospital; Physician to the Skin Department of the Howard Hospital, etc. Crown octavo, 270 pages; 86 illustrations. Cloth, \$1.00 net; interleaved for notes, \$1.25 net.

[See *Saunders' Question-Compends*, page 21.]

"The best student's manual on skin diseases we have yet seen."—*Times and Register*.

STENGEL'S PATHOLOGY.

A Manual of Pathology. By ALFRED STENGEL, M.D., Physician to the Philadelphia Hospital; Professor of Clinical Medicine in the Woman's Medical College; Physician to the Children's Hospital; late Pathologist to the German Hospital, Philadelphia, etc. *In Preparation*.

STEVENS' MATERIA MEDICA AND THERAPEUTICS. Second Edition, Revised.

A Manual of Materia Medica and Therapeutics. By A. A. STEVENS, A.M., M.D., Lecturer on Terminology and Instructor in Physical Diagnosis in the University of Pennsylvania; Demonstrator of Pathology in the Woman's Medical College of Philadelphia. Post-octavo, 445 pages. Cloth, \$2.25.

"The author has faithfully presented modern therapeutics in a comprehensive work, and, while intended particularly for the use of students, it will be found a reliable guide and sufficiently comprehensive for the physician in practice."—*University Medical Magazine*.

STEVENS' PRACTICE OF MEDICINE. Fourth Edition, Revised.

A Manual of the Practice of Medicine. By A. A. STEVENS, A.M., M.D., Lecturer on Terminology and Instructor in Physical Diagnosis in the University of Pennsylvania; Demonstrator of Pathology in the Woman's Medical College of Philadelphia. Specially intended for students preparing for graduation and hospital examinations. Post-octavo, 511 pages; illustrated. Cloth, \$2.50.

"The frequency with which new editions of this manual are demanded bespeaks its popularity. It is an excellent condensation of the essentials of medical practice for the student, and may be found also an excellent reminder for the busy physician."—*Buffalo Medical Journal*.

STEWART'S PHYSIOLOGY.

A Manual of Physiology, with Practical Exercises. For Students and Practitioners. By G. N. STEWART, M.A., M.D., D.Sc., lately Examiner in Physiology, University of Aberdeen, and of the New Museums, Cambridge University; Professor of Physiology in the Western Reserve University, Cleveland, Ohio. Octavo volume of 800 pages; 278 illustrations in the text, and 5 colored plates. Cloth, \$3.50 net.

"It will make its way by sheer force of merit, and amply deserves to do so. It is one of the very best English text-books on the subject."—*London Lancet*.

"Of the many text-books of physiology published, we do not know of one that so nearly comes up to the ideal as does Prof. Stewart's volume."—*British Medical Journal*.

STEWART AND LAWRENCE'S MEDICAL ELECTRICITY.

Essentials of Medical Electricity. By D. D. STEWART, M.D., Demonstrator of Diseases of the Nervous System and Chief of the Neurological Clinic in the Jefferson Medical College; and E. S. LAWRENCE, M.D., Chief of the Electrical Clinic and Assistant Demonstrator of Diseases of the Nervous System in the Jefferson Medical College, etc. Crown octavo, 158 pages; 65 illustrations. Cloth, \$1.00; interleaved for notes, \$1.25.

[See *Saunders' Question-Compends*, page 21.]

"Throughout the whole brief space at their command the authors show a discriminating knowledge of their subject."—*Medical News*.

STONEY'S NURSING. Second Edition, Revised.

Practical Points in Nursing. For Nurses in Private Practice. By EMILY A. M. STONEY, Graduate of the Training-School for Nurses, Lawrence, Mass.; late Superintendent of the Training-School for Nurses, Carney Hospital, South Boston, Mass. 456 pages, illustrated with 73 engravings in the text, and 8 colored and half-tone plates. Cloth, \$1.75 net.

"There are few books intended for non-professional readers which can be so cordially endorsed by a medical journal as can this one."—*Therapeutic Gazette*.

"This is a well-written, eminently practical volume, which covers the entire range of private nursing as distinguished from hospital nursing, and instructs the nurse how best to meet the various emergencies which may arise, and how to prepare everything ordinarily needed in the illness of her patient."—*American Journal of Obstetrics and Diseases of Women and Children*.

"It is a work that the physician can place in the hands of his private nurses with the assurance of benefit."—*Ohio Medical Journal*.

SUTTON AND GILES' DISEASES OF WOMEN.

Diseases of Women. By J. BLAND SUTTON, F.R.C.S., Assistant Surgeon to Middlesex Hospital, and Surgeon to Chelsea Hospital, London; and ARTHUR E. GILES, M.D., B.Sc. Lond., F.R.C.S. Edin., Assistant Surgeon to Chelsea Hospital, London. 436 pages, handsomely illustrated. Cloth, \$2.50 net.

"The book is very well prepared, and is certain to be well received by the medical public."—*British Medical Journal*.

"The text has been carefully prepared. Nothing essential has been omitted, and its teachings are those recommended by the leading authorities of the day."—*Journal of the American Medical Association*.

THOMAS'S DIET LISTS AND SICK-ROOM DIETARY.

Diet Lists and Sick-Room Dietary. By JEROME B. THOMAS, M.D., Visiting Physician to the Home for Friendless Women and Children and to the Newsboys' Home; Assistant Visiting Physician to the Kings County Hospital. Cloth, \$1.50. Send for sample sheet.

"The idea is good, and the lists are copious."—*London Lancet*.

"Its practical usefulness places it among the requirements of every practitioner."—*Chicago Medical Recorder*.

THORNTON'S DOSE-BOOK AND PRESCRIPTION-WRITING.

Dose-Book and Manual of Prescription-Writing. By E. Q. THORNTON, M.D., Demonstrator of Therapeutics, Jefferson Medical College, Philadelphia. 334 pages, illustrated. Cloth, \$1.25 net.

"Full of practical suggestions; will take its place in the front rank of works of this sort."—*Medical Record*, New York.

VAN VALZAH AND NISBET'S DISEASES OF THE STOMACH.

Diseases of the Stomach. By WILLIAM W. VAN VALZAH, M.D., Professor of General Medicine and Diseases of the Digestive System and the Blood, New York Polyclinic; and J. DOUGLAS NISBET, M.D., Adjunct Professor of General Medicine and Diseases of the Digestive System and the Blood, New York Polyclinic. Octavo volume of about 600 pages. Cloth, \$3.50 net. *Nearly Ready*.

VIERORDT'S MEDICAL DIAGNOSIS. Third Edition, Revised.

Medical Diagnosis. By Dr. OSWALD VIERORDT, Professor of Medicine at the University of Heidelberg. Translated, with additions, from the second enlarged German edition, with the author's permission, by FRANCIS H. STUART, A.M., M.D. Handsome royal octavo volume of 700 pages; 178 fine wood-cuts in text, many of them in colors. Cloth, \$4.00 net; Sheep or Half Morocco, \$5.00 net; Half Russia, \$5.50 net.

"A treasury of practical information which will be found of daily use to every busy practitioner who will consult it."—C. A. LINDSLEY, M.D., *Professor of the Theory and Practice of Medicine, Yale University*.

"Rarely is a book published with which a reviewer can find so little fault as with the volume before us. Each particular item in the consideration of an organ or apparatus, which is necessary to determine a diagnosis of any disease of that organ, is mentioned; nothing seems forgotten. The chapters on diseases of the circulatory and digestive apparatus and nervous system are especially full and valuable. The reviewer would repeat that the book is one of the best—probably *the best*—which has fallen into his hands."—*University Medical Magazine*.

WARREN'S SURGICAL PATHOLOGY AND THERAPEUTICS.

Surgical Pathology and Therapeutics. By JOHN COLLINS WARREN, M.D., LL.D., Professor of Surgery, Medical Department Harvard University; Surgeon to the Massachusetts General Hospital, etc. Handsome octavo volume of 832 pages; 136 relief and lithographic illustrations, 33 of which are printed in colors, and all of which were drawn by William J. Kaula from original specimens. Cloth, \$6.00 net; Half Morocco, \$7.00 net.

"There is the work of Dr. Warren, which I think is the most creditable book on Surgical Pathology, and the most beautiful medical illustration of the bookmaker's art, that has ever been issued from the American press."—DR. ROSWELL PARK, in the *Harvard Graduate Magazine*.

"The handsomest specimen of bookmaking that has ever been issued from the American medical press."—*American Journal of the Medical Sciences*.

"A most striking and very excellent feature of this book is its illustrations. Without exception, from the point of accuracy and artistic merit, they are the best ever seen in a work of this kind. Many of those representing microscopic pictures are so perfect in their coloring and detail as almost to give the beholder the impression that he is looking down the barrel of a microscope at a well-mounted section."—*Annals of Surgery*.

WEST'S NURSING.

An American Text-Book of Nursing. By AMERICAN TEACHERS. Edited by ROBERTA M. WEST, late Superintendent of Nurses in the Hospital of the University of Pennsylvania. *In Preparation*.

WOLFF ON EXAMINATION OF URINE.

Essentials of Examination of Urine. By LAWRENCE WOLFF, M.D., Demonstrator of Chemistry, Jefferson Medical College, Philadelphia, etc. Colored (Vogel) urine scale and numerous illustrations. Crown octavo. Cloth, 75 cents.

[See *Saunders' Question-Compends*, page 21.]

"A very good work of its kind—very well suited to its purpose."—*Times and Register*.

WOLFF'S MEDICAL CHEMISTRY. Fourth Edition, Revised.

Essentials of Medical Chemistry, Organic and Inorganic. Containing also Questions on Medical Physics, Chemical Physiology, Analytical Processes, Urinalysis, and Toxicology. By LAWRENCE WOLFF, M.D., Demonstrator of Chemistry, Jefferson Medical College, Philadelphia, etc. Crown octavo, 218 pages. Cloth, \$1.00; interleaved for notes, \$1.25.

[See *Saunders' Question-Compends*, page 21.]

"The scope of this work is certainly equal to that of the best course of lectures on Medical Chemistry."—*Pharmaceutical Era*.

CLASSIFIED LIST
OF THE
MEDICAL PUBLICATIONS

OF
W. B. SAUNDERS,
925 Walnut Street, Philadelphia.

ANATOMY, EMBRYOLOGY, HISTOLOGY.		EYE, EAR, NOSE, AND THROAT.	
Clarkson—A Text-Book of Histology,	9	An American Text-Book of Diseases of the Eye, Ear, Nose, and Throat,	3
Haynes—A Manual of Anatomy,	13	Casselberry—Dis. of Nose and Throat,	8
Heisler—A Text-Book of Embryology,	13	De Schweinitz—Diseases of the Eye,	10
Nancrede—Essentials of Anatomy,	18	Gleason—Essentials of Dis. of the Ear,	11
Nancrede—Essentials of Anatomy and Manual of Practical Dissection,	18	Jackson and Gleason—Essentials of Diseases of the Eye, Nose, and Throat,	14
Semple—Essentials of Pathology and Morbid Anatomy,	25	Kyle—Diseases of the Nose and Throat,	15
BACTERIOLOGY.		GENITO-URINARY.	
Ball—Essentials of Bacteriology,	6	An American Text-Book of Genito-Urinary and Skin Diseases,	3
Crookshank—A Text-Book of Bacteriology,	10	Hyde and Montgomery—Syphilis and the Venereal Diseases,	13

NERVOUS AND MENTAL DISEASES, ETC.

Burr—Nervous Diseases, 7
 Chapin—Compendium of Insanity, . . . 8
 Church and Peterson—Nervous and Mental Diseases, 9
 Shaw—Essentials of Nervous Diseases and Insanity, 26

NURSING.

An American Text-Book of Nursing, 29
 Griffith—The Care of the Baby, . . . 12
 Hampton--Nursing, 12
 Hart--Diet in Sickness and in Health, 13
 Meigs—Feeding in Early Infancy, . . 17
 Morten—Nurse's Dictionary, 18
 Stoney—Practical Points in Nursing, . 27

OBSTETRICS.

An American Text-Book of Obstetrics, 4
 Ashton—Essentials of Obstetrics, . . . 6
 Boisliniere—Obstetric Accidents, Emergencies, and Operations, 7
 Dorland—Manual of Obstetrics, . . . 10
 Hirst—Text-Book of Obstetrics, . . . 13
 Norris—Syllabus of Obstetrics, 18

PATHOLOGY.

An American Text-Book of Pathology, 4
 Mallory and Wright—Pathological Technique, 16
 Semple—Essentials of Pathology and Morbid Anatomy, 25
 Senn—Pathology and Surgical Treatment of Tumors, 25
 Stengel—Manual of Pathology, 26
 Warren—Surgical Pathology and Therapeutics, 29

PHYSIOLOGY.

An American Text-Book of Physiology, 5
 Hare—Essentials of Physiology, . . . 13
 Raymond—Manual of Physiology, . . . 19
 Stewart—Manual of Physiology, . . . 27

PRACTICE OF MEDICINE.

An American Text-Book of the Theory and Practice of Medicine, 5
 An American Year-Book of Medicine and Surgery, 6
 Anders—Text-Book of the Practice of Medicine, 6
 Lockwood—Manual of the Practice of Medicine, 15
 Morris—Essentials of the Practice of Medicine, 17
 Rowland and Hedley—Archives of the Roentgen Ray, 19
 Stevens—Manual of the Practice of Medicine, 27

SKIN AND VENEREAL.

An American Text-Book of Genito-Urinary and Skin Diseases, 3

Hyde and Montgomery—Syphilis and the Venereal Diseases, 13
 Martin—Essentials of Minor Surgery, Bandaging, and Venereal Diseases, . 16
 Pringle—Pictorial Atlas of Skin Diseases and Syphilitic Affections, . . . 19
 Stelwagon—Essentials of Diseases of the Skin, 26

SURGERY.

An American Text-Book of Surgery, 5
 An American Year-Book of Medicine and Surgery, 6
 Beck—Manual of Surgical Asepsis, . . 7
 DaCosta—Manual of Surgery, 10
 Keen—Operation Blank, 15
 Keen—The Surgical Complications and Sequels of Typhoid Fever, 15
 Macdonald—Surgical Diagnosis and Treatment, 16
 Martin—Essentials of Minor Surgery, Bandaging, and Venereal Diseases, . 16
 Martin—Essentials of Surgery, 16
 Moore—Orthopedic Surgery, 17
 Pye—Elementary Bandaging and Surgical Dressing, 19
 Rowland and Hedley—Archives of the Roentgen Ray, 19
 Senn—Genito-Urinary Tuberculosis, . 25
 Senn—Syllabus of Surgery, 25
 Senn—Pathology and Surgical Treatment of Tumors, 25
 Warren—Surgical Pathology and Therapeutics, 29

URINE AND URINARY DISEASES.

Saundby—Renal and Urinary Diseases, 24
 Wolff—Essentials of Examination of Urine, 29

MISCELLANEOUS.

Bastin—Laboratory Exercises in Botany, 7
 Gould and Pyle—Anomalies and Curiosities of Medicine, 11
 Gross—Autobiography of Samuel D. Gross, 12
 Keating—How to Examine for Life Insurance, 14
 Keen—Surgical Complications and Sequels of Typhoid Fever, 15
 Rowland and Hedley—Archives of the Roentgen Ray, 19
 Saunders' New Series of Manuals, 22, 23
 Saunders' Pocket Medical Formulary, . 24
 Saunders' Question-Compend, . . . 20, 21
 Senn—Pathology and Surgical Treatment of Tumors, 25
 Stewart and Lawrance—Essentials of Medical Electricity, 27
 Thornton—Dose-Book and Manual of Prescription-Writing, 28
 Van Valzah and Nisbet—Diseases of the Stomach, 28

In Preparation for Early Publication.

AN AMERICAN TEXT-BOOK OF DISEASES OF THE EYE, EAR, NOSE, AND THROAT.

Edited by G. E. DE SCHWEINITZ, M.D., Professor of Ophthalmology in the Jefferson Medical College, Philadelphia; and B. ALEXANDER RANDALL, M.D., Professor of Diseases of the Ear in the University of Pennsylvania and in the Philadelphia Polyclinic.

AN AMERICAN TEXT-BOOK OF PATHOLOGY.

Edited by JOHN GUITÉRAS, M.D., Professor of General Pathology and of Morbid Anatomy in the University of Pennsylvania; and DAVID RIESMAN, M.D., Demonstrator of Pathological Histology in the University of Pennsylvania.

PETERSON AND HAINES' LEGAL MEDICINE AND TOXICOLOGY.

An American Text-Book of Legal Medicine and Toxicology. Edited by FREDERICK PETERSON, M.D., Clinical Professor of Mental Diseases in the Woman's Medical College, New York; Chief of Clinic, Nervous Department, College of Physicians and Surgeons, New York; and WALTER S. HAINES, M.D., Professor of Chemistry, Pharmacy, and Toxicology in Rush Medical College, Chicago.

STENGEL'S PATHOLOGY.

A Manual of Pathology. By ALFRED STENGEL, M.D., Physician to the Philadelphia Hospital; Professor of Clinical Medicine in the Woman's Medical College; Physician to the Children's Hospital; late Pathologist to the German Hospital, Philadelphia, etc.

CHURCH AND PETERSON'S NERVOUS AND MENTAL DISEASES.

Nervous and Mental Diseases. By ARCHIBALD CHURCH, M.D., Professor of Mental Diseases and Medical Jurisprudence in the Northwestern University Medical School, Chicago; and FREDERICK PETERSON, M.D., Clinical Professor of Mental Diseases in the Woman's Medical College, New York; Chief of Clinic, Nervous Department, College of Physicians and Surgeons, New York.

HEISLER'S EMBRYOLOGY.

A Text-Book of Embryology. By JOHN C. HEISLER, M.D., Professor of Anatomy in the Medico-Chirurgical College, Philadelphia.

KYLE ON THE NOSE AND THROAT.

Diseases of the Nose and Throat. By D. BRADEN KYLE, M.D., Chief Laryngologist to St. Agnes' Hospital; Bacteriologist to the Orthopedic Hospital and Infirmary for Nervous Diseases; Instructor in Clinical Microscopy and Assistant Demonstrator of Pathology, Jefferson Medical College, Philadelphia.

HIRST'S OBSTETRICS.

A Text-Book of Obstetrics. By BARTON COOKE HIRST, M.D., Professor of Obstetrics in the University of Pennsylvania.

WEST'S NURSING.

An American Text-Book of Nursing. By AMERICAN TEACHERS. Edited by ROBERTA M. WEST, Late Superintendent of Nurses in the Hospital of the University of Pennsylvania.
