HOLLAND BANK is composed of coral, and has various depths of water upon it. Its greatest length (under a depth of 10 fathoms) is $6\frac{1}{2}$ miles E.N.E. and W.S.W., and its breadth 4 miles. The shoalest patches are towards its N.E. end. The soundings on these patches are very irregular; the least water found was $2\frac{1}{2}$ fathoms, reduced to low water springs. From the centre patch, in lat. $10^{\circ} 39' N.$, long. $108^{\circ} 43' E.$, the S.W. summit of Ceicer de Mer bore about E.S.E. 15 miles, and High Rock about E. by S. $10\frac{1}{2}$ miles.

The S.W. hill of Ceicer de Mer bearing S.E. by E. $\frac{1}{4}$ E. leads just outside the depth of 10 fathoms, on the N.E. end of Holland Bank; and bearing E. by S. $\frac{1}{4}$ S., leads outside the same depth on the South end. Therefore, vessels passing northward of the bank, should not bring the S.W. or high and sloping hill of Ceicer de Mer to the eastward of S.E.; and those passing southward of the bank should not bring the same hill to the southward of East.

The soundings round the bank are very irregular, and afford no certain guide, but the bank is much steeper on its eastern edge than elsewhere. The lead, however, is not at all to be relied on in approaching that edge, for 20 fathoms may be had at one cast, and 4 fathoms the next. Excepting at the eastern part, if the lead be attended to and hove quickly, it will point out the edge of the bank before a ship gets into danger.

The following valuable remarks, from Horsburgh, cannot be improved upon:—"To avoid this bank on its western side, do not raise Pulo Ceicer de Mer more than to have the summits of the two hills visible from the poop of a large ship when the island is bearing E. $\frac{1}{2}$ S. and S.E.; for if the low part of the island between the hills be *in sight from the poop*, bearing from E. by S. to E.S.E., the vessel will be near the edge of the bank."

Caution.—Vessels should keep a good look-out when passing between Ceicer de Mer and High Rock, or High Rock and Holland Bank; for although many hundreds of soundings were obtained by the *Rifleman*, in the neighbourhood, and the result of the survey affords reasonable assurance that these channels are quite safe, yet with depths so irregular, and the bottom mostly of coral, the possibility of some small patch having escaped

the lead, even in the most careful survey, should always be borne in mind and guarded against as far as possible.

The **MINERVA BANK**, lying to the north-eastward of Pulo Sapatu, was discovered by the company's ship of this name, in 1821, "At noon, observed in lat. $10^{\circ} 32' N.$, steered N.E. $\frac{1}{2} N.$ 5 miles, and about half-past noon, the water appearing very much discoloured, kept the lead going quick; had 40 fathoms first cast, then 35, 30, and 28 fathoms; shortened sail, and hove to, head to the S.E.; next cast had 39, 40, and 42 fathoms, and continued this depth by repeated soundings. From noon till 2 p.m., when lying to, had steered N.E. $\frac{1}{2} N.$ 8 miles, which gave 6 miles northing, placing the bank in $10^{\circ} 38' N.$; and good sights taken at the same time made the long. $110^{\circ} 18' E.$ by means of three chronometers. The soundings upon the bank were all coral rock, and it appeared to extend to about $1\frac{1}{2}$ mile in a north-easterly direction, as in hauling to the southward the depth greatly increased. About a quarter past 2 p.m. bore away, and gradually increased the soundings from 45 to 50 fathoms, then no bottom at 55 fathoms.

Soundings were tried for in the *Rifleman* on the supposed position of this bank, but no bottom was obtained with 200 fathoms. Lieutenant Reed has, however, no doubt that it exists somewhere near its assigned position on the chart; but as 28 fathoms is the least water reported upon it, he did not deem it sufficiently important to occupy his time in making a closer search.

THE PARACEL ISLANDS AND REEFS.

The **PARACEL ISLANDS** and **REEFS** are an extensive group of low islands, reefs, and shoals, which extend from lat. $15^{\circ} 45\frac{1}{2}'$ to $17^{\circ} 8' N.$, and from long. $111^{\circ} 9'$ to $112^{\circ} 43' E.$ Vessels should carefully avoid coming within their limits, as the dangers among them are not accurately known. This will be seen by the following description, taken from the survey made by Captains Ross and Maughan, of the Bombay Marine, in 1808. It may induce caution if we remind our readers that H.M. gun-vessel *Staney* was wrecked on Drummond Reef of this group during a gale on 16th May, 1870, when 3 officers and 46 men were drowned, and only 9 of the crew saved. The ship *Caractacus* also went ashore during the same gale.

TRITON ISLAND, in lat. $15^{\circ} 46' N.$, long. $111^{\circ} 11' E.$, extends in a N. W. and S.E. direction about 3 or 4 miles (according to a plan of it by Captain Brown, of the *Triton*), and is thought to be the most southern and western danger of the Paracels.* Its North part is a sandy lump, about 20 ft. high,

* In June, 1815, Captain Maughan, in the *Investigator*, passed within a quarter of a mile of apparently some patches of coral, having, he supposed, about 6 or 8 fathoms water over

sloping down in a low point to the S.E., with high breakers projecting a great way in that direction; another reef projects from its N.W. end; there are no soundings near it.

BOMBAY SHOAL, lying between lat. $15^{\circ} 59'$ and $16^{\circ} 6' N.$, and long. $112^{\circ} 26'$ and $112^{\circ} 38' E.$, is a reef of breakers of oblong form, about 12 miles in extent E. by N. and W. by S., having apparently an entrance at the western part, with deep water inside; some of the rocks are level with the water, and have sandy patches inside of them. This shoal is steep-to, for at three-quarters of a mile at its South side, the *Bombay* had no bottom with 100 fathoms of line; and close around it Captain Ross in his survey could get no bottom. It seems to bear about S. by W. from Pyramid Rock, for although the *Bombay* made it several miles more easterly than the longitude stated above from the survey of Captain Ross, it probably is not so; because the *Jehangire* observed at noon, in lat. $16^{\circ} 5' N.$, long. $112^{\circ} 52' E.$, and no danger could be discerned from the mast-head.

JEHANGIRE BANK is named after the above ship, which got upon a coral bank in lat. $16^{\circ} 18' N.$, long. $112^{\circ} 35' E.$, and had 12, 10, and $9\frac{1}{2}$ fathoms water; the next cast was 30 fathoms, and in less than an hour had no bottom, drifting to the south-eastward by the lead, being calm at the time. This seems to agree with the account of Capt. Ross's pilot, who stated that there are soundings on coral banks in a narrow line between Lincoln Island and the Bombay Shoal, which, with those dangers, form the eastern boundary of the Paracels.

Bremen Bank.—The North German schooner barque *Charlotte*, of Bremen, Captain B. Steengrafe, reports a shoal under the following circumstances:—Left Hong Kong on the 18th of March, bound on a voyage to Bangkok. After a favourable passage of four days sighted the Paracels; being desirous of ascertaining the rates of chronometers, found old rates to be exactly correct by good observations and cross bearings. At 9 a.m. Lincoln Island bore E. by N., and Pyramid Rock South per compass; thence sailed S.S.W. 16 miles until noon. After having taken the meridian altitude of the sun, found ourselves upon a coral bank. Set the lead going immediately, and sounded carefully from $10\frac{1}{2}$ to $12\frac{1}{2}$ fathoms, within a few minutes to 1. Sailed over it a distance of 5 miles in S.S.W. direction; southern edge appeared to stretch W.N.W. and E.S.E.; bank visible from the topgallant yard as far as we could discern. Had with more than 20 fathoms line no soundings at about half a cable's length from the South edge. The true position of the point of the bank we were on was, by dead reckoning, lat.

them; but no soundings could be obtained with 110 fathoms of line at that distance, and a boat could not be hoisted out to examine them, on account of the high sea and blowing weather. These patches, seen at 2 p.m., are in lat. $14^{\circ} 12' N.$, long. $112^{\circ} 52' E.$; but it is uncertain that they were real dangers.

16° 24' N., long. 112° 24' E.; by observations lat. 16° 24' N., long. 112° 25' East. Had very fine weather at the time, light easterly winds and little swell from the same quarter, sky clear.

LINCOLN ISLAND, the S.E. point of which is in lat. 16° 39' 34" N., long. 112° 44' 23" E., is 1½ mile long, N.W. and S.E., three-quarters of a mile wide, and about 20 ft. high; it is covered with brushwood, and surrounded by a coral reef, dry at low water, which extends 1½ mile from its S.E. point, half a mile from its North and East sides, and about a cable's length from its S.W. side. A narrow coral shoal runs off to the southward from its S.E. point, which is said by Horsburgh to extend 11 miles; time did not admit of its being properly examined by the *Rifleman*, but judging from the soundings that were obtained, the dangerous part of this shoal does not appear to extend farther than 3 miles from the island. Good anchorage can be obtained in the N.E. monsoon under its lee in 8 to 10 fathoms, coral, about half a mile from the shore. The spring of excellent water in the centre of this island, mentioned by Horsburgh, is merely a well dug by the Hainan fishermen close to a stunted cocoa-nut tree, into which the salt water filters.

PYRAMID ROCK bears S.W. ¼ W., distant 7½ miles, from the S.E. point of Lincoln Island, and 10½ miles N.W. by W. from the South end of the bank extending southwards from that island. Between Lincoln Island and the Pyramid there are depths of 27 to 31 fathoms.

H.M.S. *Dido*, in 1844, observed a shoal about 10 miles to the eastward of Lincoln Island. It is shown on the chart as a doubtful danger in lat. 16° 45' N., long. 112° 54' E.

PASSOO KEAH, in lat. 16° 6' N., long. 111° 46' E., is a small sandy island, surrounded by a coral reef, having no soundings near it.

DISCOVERY SHOAL or REEF.—The West end of this dangerous shoal is in lat. 16° 11' 40" N., long. 111° 33' E.; from thence it extends E.N.E. 15 or 16 miles to its eastern extremity in lat. 16° 16' N., long. 111° 48½' E. The reef is of the shape of an extended oval, with an opening 1 cable wide on its South side, having in it overfalls from 2 to 20 fathoms, and a small opening on the North side. There are no soundings about 20 yards from the reef, and scarcely 2 fathoms water over any part of it, with many spiral rocks a few feet above the water's edge. The Hainan boats come here to fish from January to May.

Vuladdore Shoal, lying 9 or 10 miles E. by N. from the Discovery Shoal, is 7 miles in extent E.N.E. and W.S.W. It has a few small spiral rocks on it above water, with high breakers, and no soundings at the distance of a cable's length on either side. Captain Ross made the centre of this shoal in lat. 16° 18' N., long. 112° 2' E.; the Portuguese snow *Vuladdore*, in her passage from Macao to Manila, saw it in lat. 16° 19' N., long. 112° 5' E., bearing S. 15° W. 39 miles from the Amphitrite Islands. She had passed

to the westward of these islands on the preceding day, and in steering southward had no soundings, nor did she see any other shoal but that which has been named after her.

The Crescent Chain of islands and reefs, called by Captain Ross, Money, Robert, Pattle, Drummond, and Duncan Islands, extends from lat. $16^{\circ} 27'$ to $16^{\circ} 37'$ N., and from long. $111^{\circ} 28'$ to $111^{\circ} 46'$ E. They consist of six low sandy islands, for the most part connected by reefs, stretching nearly East and West in the form of a crescent, at the East end of which an elbow is formed by part of the reef turning round to the south-westward; on this part stand the two Duncan Islands, with an opening 4 miles between their contiguous reef and the Antelope Shoal, which lies about 2 miles to the eastward of Money, the western island of the group. This opening is on the South side of the chain, and inside there are soundings; but the ground is chiefly coral, with great overfalls from 25 to 5 fathoms. The best anchorage is close to the reef, on the North side of Duncan Island, where there are some broad patches of sandy bottom.

The Duncan and Drummond Islands were more particularly examined by the *Rifleman*, and the passage between them sounded. The two Duncan Islands are now joined by a sandy spit which is always uncovered; they extend a mile in an East and West direction, are 4 cables in breadth, and surrounded by a coral reef which extends in some places 4 cables from the shore, and dries at low water. On the westernmost of the islands is a coconut tree.

Drummond Island is nearly round, its diameter being about 3 cables; at 2 cables South of it is a rock which never covers. A reef of coral extends a short distance from the West side of the island, but runs for miles to the eastward and north-eastward of it. Both Duncan and Drummond Islands are covered with brushwood. Between them is a safe channel, upwards of a mile in width, with from 19 to 20 fathoms water. Horsburgh says this channel should not be taken in large vessels, the passage westward of Duncan Island being preferable; but the *Rifleman*, when passing between Duncan and Money Islands, suddenly got to shoal water, which appeared to extend across that channel, and therefore the channel between Duncan and Drummond Islands is certainly safer for steamers. Vessels may anchor to the northward of Duncan Island in from 16 to 18 fathoms, about half a mile off shore.

Observation Bank, in lat. $16^{\circ} 36'$ N., long. $111^{\circ} 40\frac{1}{2}'$ E., is small, lies on the North side of the Crescent Chain, and may be considered as part of it. Within this bank, about 3 miles to the southward, is an anchorage from 5 to 20 fathoms, on a coral bottom.

Hotspur Shoal, on which an American ship of this name was wrecked in 1860, is said to lie in lat. $16^{\circ} 51'$ N., long. $111^{\circ} 30'$ E.; it is likely, however, to be the North shoal, lying to the northward.

AMPHITRITE ISLANDS are in two groups, lying N.N.W. and S.S.E. of each other, and having a deep-water channel between them. The northern group consists of four low, narrow islands, connected by a reef of rocks that projects 2 or 3 miles beyond their extremes; upon the westernmost island there is a cocoa-nut tree, from which it has received the name of Tree Island. The western extremity of the reef surrounding these islands is in lat. $16^{\circ} 59'$ N., long. $112^{\circ} 12'$ E.; the reef extends about 10 miles E.S.E., the eastern extremity being in lat. $16^{\circ} 54'$ N., long. $112^{\circ} 22'$ E., and it forms the northern limit of danger in this part of the archipelago. There are no soundings on the North side, but there is good anchorage in 10 fathoms, sand, under the S.E. side of the chain, about half a mile from the rocks; no fresh water is procurable.

The southern group consists of two islands, called Woody and Rocky, lying very near each other. Woody Island, in lat. $16^{\circ} 50\frac{1}{2}'$ N., long. $112^{\circ} 19'$ E., is about 3 miles in circumference, covered with small trees. A reef projects around this island to the distance of three-quarters of a mile, connected with Rocky Island.

Rocky Island, in lat. $16^{\circ} 52'$ N., long. $112^{\circ} 19\frac{1}{2}'$ E., is small, and nearly of the same height as Woody Island; there are no soundings to the N.E. or eastward of it, but irregular soundings extend 6 miles to the S.W. of these islands, decreasing to 14 fathoms in some places. Close to the reef on the West side of Woody Island there are 25 fathoms; and the depths decrease gradually from 30 to 15 fathoms towards the Amphitrite Islands, where a vessel may anchor if requisite.

The North Shoal, extending E.N.E. and W.S.W. about 6 miles, is narrow and steep-to, having soundings only on the North side, 14 fathoms within half a cable's length of the rocks. The East end of this shoal or reef is in lat. $17^{\circ} 6\frac{1}{2}'$ N., long. $111^{\circ} 32\frac{1}{2}'$ E., and it appears to be the north-western danger of the Paracels.

Tides and Currents.—At the Crescent chain, and at some other of the Paracel Reefs, there are regular tides during the springs. The currents run generally strong before the wind in both monsoons, but in light winds between the monsoons they are continually changing their direction amongst the shoals. Ships ought, therefore, never to come within the limits of these dangers, if it can possibly be prevented, for they may be drifted upon some of the reefs during calms, close to which there is no anchorage. There are several channels between the different reefs or shoals, from 12 or 15 to 30 and 35 miles wide.

MACCLESFIELD BANK, discovered by the English ship of this name in 1701, is of greater extent than is generally supposed, for the *Fort St. David*

country ship is said to have obtained soundings in lat. $15^{\circ} 17' N.$, on its southern part; and in lat. $16^{\circ} 19' N.$ by noon observation, the *Stormont* had 14 fathoms on its northern part, and about 1 mile farther to the southward she had 14 fathoms water; the *Cirencester* also had a quarter less 10 fathoms, in lat. $16^{\circ} 19' N.$, long. $114^{\circ} 33' E.$, deepening gradually until in lat. $16^{\circ} 21\frac{1}{2}' N.$, then 55 fathoms, no ground. The bank, therefore, appears to extend from lat. $15^{\circ} 17'$ to $16^{\circ} 21' N.$; its length East and West being about 90 miles, the western edge being nearly in long. $113^{\circ} 40' E.$, and the eastern edge in about long. $114^{\circ} 53' E.$

The depths on this bank are generally very irregular, from 25 or 30 to 40 or 50 fathoms, coral rock; and in some places, where the soundings are a little regular, the bottom is coarse or fine sand. There appear to be gaps in some parts of the bank, where no soundings have been obtained with 80 or 100 fathoms of line; for several ships, in steering directly over it, after getting ground, have lost soundings for a considerable time, and obtained them again.

On the northern and eastern parts of the bank there are level patches of considerable dimensions, with regular soundings from 9 to 15 fathoms, sandy bottom; there are also some patches on the southern and western parts, with 14 to 17 fathoms upon them.

The greatest extent of the bank, East and West, appears to be near its northern extremity, for soundings have been obtained in long. $114^{\circ} 51' E.$ In lat. $15^{\circ} 56' N.$, and long. $114^{\circ} 51' E.$, the *Thetis* had $11\frac{1}{2}$ fathoms, and carried soundings 3 or 4 miles farther to the eastward, deepening to 20, 40, 60, and 75, then 80 fathoms, no ground, when in long. $114^{\circ} 55' E.$

The Admiralty chart shows soundings of 17 and 20 fathoms, in about lat. $15^{\circ} 58' N.$, long. $115^{\circ} 6' E.$, and a cast of 130 fathoms in long. $115^{\circ} 10'$, which is 17 miles eastward of Horsburgh's extreme eastern position. The chart also shows $5\frac{1}{2}$ and 6 fathoms between the parallels of $16^{\circ} 4'$ and $16^{\circ} 12' N.$ in about long. $113^{\circ} 54' E.$, with 30, 40, and 80 fathoms extending to the northward, the latter depth being in lat. $16^{\circ} 35' N.$

In 1857 the Siamese vessel *Bangkok*, Captain Moses, when crossing this bank in lat. $16^{\circ} 2\frac{1}{2}' N.$, long. $114^{\circ} 2\frac{1}{2}' E.$, got suddenly into $5\frac{1}{2}$ to 4 fathoms, coral and red sand, and as suddenly deepened to 10, 16, and 20 fathoms; the weather was fine and the sea smooth, otherwise with a swell he believes it would break.*

* H.M.S. *Rifleman* made three passages across the bank from North to South, in about long. $114^{\circ} 30'$, 114° , and $113^{\circ} 40'$. The following description of these passages will be of service.

On the first occasion, on her way from Hong Kong to the North Danger, she crossed the Macclesfield Bank in March, 1865. Soundings were struck in lat. $16^{\circ} 11' N.$, long. $114^{\circ} 26' E.$, in 115 fathoms, bottom sand and mud, a line of soundings was then carried in a

Between the western edge of the Macclesfield Bank and the eastern limit of the Paracel Reefs, it has been said there are other coral banks, with soundings of various depths upon them; yet, in this space of about 30 miles, probably no soundings are to be obtained.

ST. ESPRIT SHOAL.—The examination of the various positions ascribed to this shoal was made in May, 1866, by Navigating Lieut. John W. Reed, Commanding H.M.S. *Rifleman*, in the tender *Dove*. The shoal was stated to be “6 leagues in diameter, with 9 to 15 fathoms on its southern part, and on the northern part there are rocks even with the water’s edge,” but no such dangerous shoal exists near any of these ascribed positions, all of which were sounded over by the *Dove* under circumstances extremely favourable for observing the sea topping or breaking over dangerous patches, had any such existed.

The Esprit Shoal was found to be a coral bank $2\frac{1}{4}$ miles in length, East and West, and $1\frac{1}{2}$ mile in breadth; its centre being in lat. $19^{\circ} 33' N.$, long. $113^{\circ} 2' E.$ The general depths upon it are 9 fathoms, the least water obtained being 7 fathoms, with 60 to 80 fathoms close to. The *Dove* remained at anchor upon the shoal for two days, on both of which good observations were obtained for determining its position.

Captain Ross, of the *Discovery*, who passed over the shoal in 1813, placed it about 5 miles to the south-eastward, and Monsieur D’Apres 19 miles to the westward, of the above position. D’Apres’ position was well sounded over, and regular depths of 95 to 100 fathoms obtained. The *Assevedo’s*

S. by E. direction over the bank, and the least depth of water met with was 12 fathoms, the general depths being from 40 to 50 fathoms; but a patch of 15 fathoms was found near its southern edge in lat. $15^{\circ} 34' N.$, long. $114^{\circ} 30' E.$; and 5 miles farther southward no bottom could be obtained with 307 fathoms of line.

On the second occasion, in April, 1867, star observations placed the ship at $5^h 30^m$ a.m. in lat. $16^{\circ} 34' N.$, long. $114^{\circ} 13' E.$; from thence steered for the 4-fathom patch, reported to have been passed over in 1867, by Mr. Moses, commanding the Siamese vessel *Bangkok*, in lat. $16^{\circ} 2' 30'' N.$, long. $114^{\circ} 2' 30'' E.$; the deep-sea lead was kept constantly going, but no bottom was obtained with 50 to 60 fathoms of line. At noon found the ship to be in lat. $15^{\circ} 59' N.$, long. $113^{\circ} 58' E.$, and that she had passed about 2 miles to the westward of the ascribed position of the patch. Proceeding to the southward, soundings of 42 fathoms, coral bottom, were had on the northern edge of the bank in lat. $15^{\circ} 51' N.$, long. $113^{\circ} 57' E.$ Regular depths of 42 and 43 fathoms were carried until in lat. $15^{\circ} 30' N.$, long. $113^{\circ} 57' E.$, where 32 fathoms were obtained; 3 miles South of this position no bottom was reached with 103 fathoms.

On the third occasion, during her passage from Hong Kong to the reefs in May, 1868, she struck soundings in 40 fathoms on the northern edge of the bank in $15^{\circ} 38' N.$, and $113^{\circ} 40' E.$; from this position a line of soundings—40 to 33 fathoms—was carried across the bank in a S. $\frac{1}{2}$ E. direction for 11 miles, when no bottom with 50, and immediately afterwards no bottom with 100 fathoms of line could be obtained.

account placed the shoal in lat. $19^{\circ} 6' N.$, long. $113^{\circ} 4' E.$, and this position was also sounded over, but no bottom could be obtained with 200 fathoms of line.

The *Dove* also sounded over the position of the discoloured water seen from the *Althea* in 1806, lat. $19^{\circ} 36' N.$, long. $112^{\circ} 17' E.$, but regular depths from 65 to 70 fathoms were found in that locality.

Helen Shoal is a small patch $1\frac{3}{4}$ mile in length, E.N.E. and W.S.W., and a mile wide; its centre is in lat. $19^{\circ} 12' N.$, long. $113^{\circ} 53' 39'' E.$ The least water upon it is $6\frac{1}{2}$ fathoms, the general depths being 8 and 9 fathoms; around it no bottom could be obtained with 100 fathoms of line.

Currents.—The strong rippings mentioned by Ross, were not observed by the officers of the *Dove*, during the two days she was anchored on the St. Esprit Shoal. Strong rippings were, however, seen during the search over the various positions ascribed to the shoal, but on examination they appeared to be mere current rippings, the water being as deep there as elsewhere. The current was found to set generally to leeward.

Captain Ross was of opinion that the shoal was of small extent, and that the report of dry rocks on it is erroneous, as the swell at the time the *Discovery* was crossing it was high, and would have produced breakers on any very shoal parts; whereas no discoloured water was visible till in 10 fathoms, although the day was clear; but strong rippings broke on board the ship when in the vicinity of the shoal, which might be mistaken for breakers by persons unacquainted.

PALAWAN PASSAGE.

The following dangers lying in the fairway of vessels proceeding to the Palawan passage on their way to China, were (with the exception of the Louisa Shoal, examined by Captain Bate, H.M.S. *Royalist*, in 1850-54) surveyed in 1863 and in 1866 by Navigating Lieutenant J. W. Reed, commanding H.M.S. *Rifleman*.

The adjacent coast of *Borneo* has been described on pages 481 to 512, and Balabac Strait and the islands to the northward, including Palawan, in chapter xiii, pages 513 to 584. What follows will be a description of the outlying shoals, and of those lying on the edge of the Borneo and Palawan bank of soundings, which are passed in sailing through this channel to or from the China coast, commencing from the south-westward.

Caution.—Lieut. Reed, R.N. remarks, when engaged in the examination of the dangers the weather was remarkably fine—finer indeed than had been experienced in any previous season; little or no current was found, and the sea was in general so smooth that hardly a breaker appeared on the edges

of the dry reefs; this made it difficult to detect dangers, and it was only during the search for the Dhaulie Shoal that the weather was favourable for doing so. Up to the 8th of June, when the *Rifleman* arrived at Manila, the weather continued fine, with the exception of occasional light squalls of wind and rain, and on the 10th the first of the S.W. monsoon was felt, the weather still remaining very fine.

SOUTH LUCONIA SHOALS comprise a group of four coral shoals, the southernmost of which is about a mile in extent, and in the form of a horse-shoe, with the open part to the north-eastward; between the horns of the shoal are 26 fathoms. The general depths on the shoal are from 2 to 3 fathoms, but near the N.W. extreme is a rock nearly awash. The southern extreme of the middle part of the shoal is in lat. $4^{\circ} 59\frac{1}{2}'$ N., long. $112^{\circ} 39\frac{1}{4}'$ E., and bears from Barram Point W. by N. $\frac{1}{4}$ N., distant 81 miles.

The westernmost shoal of the group, lying about W. by N. distant 7 miles from the southernmost one, is nearly 2 miles long N.W. and S.E., and about three-quarters of a mile broad. The general depths over it are 2 and 3 fathoms, but near the S.E. extreme is a rock just below the surface of the water, and a similar one at the N.W. extreme; the latter is in lat. $5^{\circ} 2\frac{1}{4}'$ N., long. $112^{\circ} 31\frac{1}{4}'$ E.

Luconia Breakers.—A reef, nearly half a mile in extent, and upon which the sea breaks even in fine weather, lies on the eastern extreme of a shoal, over which are various depths under 5 fathoms. The shoal extends nearly 2 miles in a north-westerly, and about a mile in a south-westerly, direction from the centre of the breakers, which is in lat. $5^{\circ} 3' 24''$ N., long. $112^{\circ} 41' 36''$ E.

One mile north-eastward of the centre of the breakers is the South extreme of a narrow strip of shoal, with 2 to 3 fathoms water over it, which extends from thence about N. by E. for a distance of 2 miles. The North extreme of this shoal is in lat. $5^{\circ} 5\frac{3}{4}'$ N., long. $112^{\circ} 42\frac{3}{4}'$ E.

The whole of these shoals are steep-to.

There is good reason to believe that no dangers exist between the South Luconia Shoals and the coast of Borneo.* Many lines of soundings were obtained in the *Rifleman* from these shoals in directions between S.W. (round southward) and East, but no dangers could be discovered. The general depths were from 55 to 69 fathoms.

NORTH LUCONIA SHOALS.—Upon the old charts of the China Sea a

* The *Rifleman* steamed for three days over and about the reputed positions of two very doubtful dangers, named on the old charts of Horsburgh, Kirton Shoal and Euphrates Reef. The weather and other circumstances were extremely favourable for seeing shoal patches, but nothing was visible, nor could bottom with 600 fathoms be obtained on the position ascribed to the Euphrates Reef.

number of dangers were shown between the parallels of $5^{\circ} 20'$ and $6^{\circ} 2' N.$, and the meridians of $112^{\circ} 14'$ and $112^{\circ} 40' E.$; they were named Luçonia, Seahorse, George and Ambergrombie, and Friendship Shoals. These dangers were examined by H.M.S. *Rifleman*, and were found to consist of a mass of coral reefs and shoals, amongst which no vessel should venture. The above general name is now adopted as applying to the entire group, but the names given by the original discoverers have been retained for particular or conspicuous localities.

The southern extreme of the group is marked by two shoal patches, about 4 miles apart, but lying in the same latitude, $5^{\circ} 27\frac{1}{4}' N.$, and each of them is rendered conspicuous by rocks just below the surface of the water, upon which the sea breaks with the least swell.

The western patch, about a mile in extent East and West, and a quarter of a mile wide, has but 1 to 2 fathoms water over it, and near its western end, in long. $112^{\circ} 32\frac{1}{2}' E.$, are two rocks nearly awash, upon which the sea is generally breaking even in fine weather. About half a mile West of these rocks is a patch of 3 fathoms, on the eastern extreme of a coral bank, with 2 fathoms least water, which extends from thence—curving gradually to the north-westward—for a distance of 3 miles.

The eastern patch has, like the western patch just described, two rocks nearly awash at its western extreme, in long. $112^{\circ} 38' E.$, and upon which also the sea is generally breaking even in fine weather. The shoal patch upon which they lie has 2 fathoms water over it, and, about a mile eastward of the rocks, it forms the south-eastern extreme of a long, narrow coral bank, which extends from thence $6\frac{1}{2}$ miles, in a general direction about N.N.W., its average breadth being about a third of a mile. The general depths over this bank are 4 or 5 fathoms, but there are several patches of 2 and 3 fathoms, and a rather extensive patch near its north-western extreme, in lat. $5^{\circ} 32\frac{3}{4}' N.$, long. $112^{\circ} 35\frac{1}{2}' E.$, has as little as $1\frac{1}{2}$ fathom over it.

Seahorse Breakers, in lat. $5^{\circ} 31' N.$, long. $112^{\circ} 34' E.$, is the most conspicuous danger of the Luçonia Shoals. It is a reef of rocks and sand just above water, about a mile long, N. by E. and S. by W., and one-third of a mile broad. From these breakers shoals extended as far as the *Rifleman* was able to sound in 1863, viz., 18 miles North, 5 miles South, 5 miles East, and 13 miles West.

The northernmost of the shoal patches reached in 1863 was in lat. $5^{\circ} 48' 30'' N.$, long. $119^{\circ} 32' 15'' E.$ In 1866 the vessel was anchored near a $2\frac{3}{4}$ -fathom patch, in lat. $5^{\circ} 55' 15'' N.$, long. $112^{\circ} 31' 30'' E.$, on the northern edge of a coral bank, traced for 2 miles to the southward, but which no doubt extends to the northernmost patch surveyed in 1863, and just referred to; vessels should not pass between these positions.*

* Captain Bate in H.M.S. *Royalist* passed over the position ascribed to the George and Ambergrombie without finding it. He supposed that it and the Friendship were the same

Friendship Shoal is the northernmost of the Luçonia group; the *Rifleman* crossed it without getting less than $4\frac{1}{2}$ fathoms, although there appeared to be less depths in some places. The North part of the shoal is in lat. $5^{\circ} 59' 30''$ N., long. $112^{\circ} 31' 30''$ E., and though this position must be considered approximate, it is nevertheless near the truth. Lines of soundings were obtained in directions N.E., North, and N.W. from the North end of the shoal for a distance of 4 miles, but no shoal water was found. The survey of the Luçonia Shoals was not (October, 1867) completed to the northward and westward.

Caution.—No directions can be given that will enable vessels to pass safely through these reefs and shoals. Although not less than 2 fathoms were found upon those to the northward of the Seahorse Breakers, yet they should be avoided, as it is quite possible there may be knolls with less water upon them which have escaped the lead.*

Louisa Shoal, the S.W. rock of which is in lat. $6^{\circ} 19\frac{3}{4}'$ N., long. $113^{\circ} 18\frac{1}{2}'$ E., or $9^{\circ} 27' 12''$ East of Fullerton Battery, Singapore, by H.M.S. *Royalist*, in October, 1851, is a dangerous coral reef of quadrangular form, two-thirds of a mile in extent from East to West. The rocks on it are generally covered at high water, with the exception of two small clusters on its eastern and south-western extremes; the centre of the shoal is shallow. There are no soundings with 50 fathoms close to its outer edge, nor with 180 fathoms a quarter of a mile to the south-westward of the shoal, but within 20 yards of the S.W. rock there are 10 fathoms.

The *Tidal Stream* at the Louisa Shoal at noon, on the full and change days in the month of October, 1850, was setting to the W.N.W., and the maximum rise appeared to be about 4 ft.

VERNON BANK, discovered by H.M.S. *Vernon* in 1847, is a large coral shoal, having a dangerous group of rocks, named after H.M.S. *Fury*, upon one part, and a patch of $2\frac{3}{4}$ fathoms on another part of it. The bank lies between the parallels of $5^{\circ} 39'$ and $5^{\circ} 50\frac{1}{4}'$ N., and the meridians of $114^{\circ} 57\frac{1}{2}'$ and $115^{\circ} 7\frac{1}{2}'$ E., and is in form of an irregular triangle, having its base, 6

shoal; but the error was in the longitude of the George and Ambercrombie, which placed it too far to the westward. It exists, and forms part of the mass of shoals which extend continuously from the Seahorse Breakers to the Friendship.

* Captain Bate also passed over the position assigned in Horsburgh's chart, viz., lat. $5^{\circ} 54'$ N., long. $114^{\circ} 7'$ E., to the Cayo Marino, a 3-fathom shoal, without being able to discover it; nor could soundings be obtained when in the neighbourhood, with from 180 to 200 fathoms.

The Cava Shoal, placed in lat. $5^{\circ} 51'$ N., long. $114^{\circ} 30\frac{3}{4}'$ E., was searched for in vain by the *Rifleman*. On the spot mud bottom was obtained with 415 fathoms of line. She also anchored in 46 fathoms on the supposed position of a reef, on which the steamer *South-western* is said to have struck, in lat. $5^{\circ} 54'$ N., $115^{\circ} 4\frac{1}{2}'$ E., and sounded round it for miles, obtaining regular soundings. Commander Ward confidently asserts that the reef does not exist.

miles in length, to the S.W. and its apex to the N.W., extending in those directions about 12 miles.

The *Fury*, in 1858, crossed the western edge of this bank, and saw breakers about $1\frac{1}{2}$ mile in extent, which no doubt were on the Fury Rocks. This formidable danger is nearly 3 miles in extent, and consists of coral patches, with 2 to 3 fathoms water over them, and several detached rocks, one or two of which nearly uncover at low water. These rocks are pinnacle-shaped, with 4 to 6 fathoms around them, so that in fine weather there is seldom much break of the sea over them, and sometimes none at all probably. The centre of the rocks is in lat. $5^{\circ} 43\frac{1}{2}'$ N., long. $115^{\circ} 2\frac{1}{4}'$ E., and with the eye 18 ft. above the sea, the highest part of Labuan (303 ft.) is just visible, bearing S.S.E. $\frac{3}{4}$ E.

The soundings on the other parts of the bank are irregular, with several patches of but 4 and 5 fathoms, and on the West and N.W. sides of the bank is a sort of curved coral wall, convex to seaward, having $4\frac{1}{2}$ to 9 fathoms on it, 14 to 19 fathoms inside of it, and 20 to 30 fathoms close outside of it. As the Fury Rocks lie 2 to 3 miles inside the edge of the bank, the lead, if carefully attended to, will give sufficient warning to avoid them; but large vessels should on no account make free with this dangerous bank, and small vessels will do well to give it a wide berth, for the currents in the vicinity are very uncertain.

The $2\frac{3}{4}$ -fathom patch, near the N.E. extreme of the bank, is in lat. $5^{\circ} 49' 20''$ N., long. $115^{\circ} 5' 20''$. It is a small coral knoll, surrounded to some distance by soundings of 4 and 5 fathoms. This part of the bank should also be avoided.

Samarang Bank, its centre in lat. $5^{\circ} 35\frac{1}{4}'$ N., long. $114^{\circ} 53\frac{3}{4}'$ E., is an oval-shaped coral bank $6\frac{1}{2}$ miles long, E. by N. and W. by S., and $4\frac{1}{4}$ miles wide. The general depths on it are 4 to 6 fathoms, and the least water found was $3\frac{1}{2}$ fathoms. From the centre of the bank the highest part of Labuan (303 ft.) bears S.E. by E. $\frac{1}{4}$ E.

Saracen Bank.—H.M. surveying vessel *Saracen*, in 1854, on her passage from Labuan to Hong Kong, discovered an extensive coral bank, having generally from 2 to 4 fathoms water over it, with dry patches and several coral knolls with but a few feet water over them. The bank is 5 or 6 miles in diameter, and its centre is in about lat. $6^{\circ} 7\frac{1}{2}'$ N., long. $115^{\circ} 20\frac{1}{2}'$ E., bearing W. by S. $\frac{1}{2}$ S., distant 14 or 15 miles from Mangalum Island (page 505).

Dangers had been seen in this locality before, but their positions were quite uncertain. It seems very probable that other dangers may exist hereabout besides those known.

ROYAL CHARLOTTE SHOAL, of a nearly rectangular shape, is $1\frac{1}{2}$ mile in length, N.W. by W., and S.E. by E., and nearly a mile in breadth. On

its south-eastern side are stones 2 to 4 ft. above high water; the highest of them is in $6^{\circ} 57' 18''$ N., and $113^{\circ} 35' 30''$ E.; there are also one or two stones on its N.E. edge, which just show at high water. This shoal and also the Louisa, although lying off the coast of Borneo, may be said more properly to belong to Palawan, for they may be considered, both in their character and position, to form a suitable portal through which to introduce the navigator to this Channel.*

Swallow Reef and *Ardasier Shoal* are described hereafter.

Doubtful Dangers.—*Viper Shoal* is marked doubtful on the chart, in lat. $7^{\circ} 30'$ N., long. 115° E. The *Royalist* passed over its assigned position, and when on the spot could get no bottom with 500 fathoms, though the day was clear, and conditions good for detecting a danger. The *Saracen* subsequently passed over the same ground with a view to its discovery, and with the same result.

Ottawa Shoal.—This danger was reported by Mr. Gribble, commanding the Peninsular and Oriental steamer *Ottawa*, and supposed by him to be the Viper Rock. The following is an extract from the log-book of that vessel, dated December 6th 1860:—"Sighted from the mast-head broken water on the port bow, having every appearance of being a shoal about half a cable in extent from East to West, with no indication of shoal water near it. When abeam it was about 2 or 3 miles distant from the ship, and was then visible from the deck. Position of the shoal lat. $7^{\circ} 16'$ N., long. $115^{\circ} 5'$ E.

The *Rifleman* searched for this danger for three days, but could find no indication of it, nor could bottom be got with 1,000 fathoms of line. The area sounded over is comprised within the following limits:—8 miles East, 15 miles West, 5 miles North, and 5 miles South of the position given above.

North Viper Shoal or Seahorse, is shown on the chart as a shoal with rocks above water, 5 miles in extent, lying between the parallels of $7^{\circ} 59'$ and $8^{\circ} 4'$ N., and in long. $115^{\circ} 23'$ E. The position of this reputed shoal was not examined by the *Rifleman*. The *Saracen* passed near it without seeing any appearance of shoal water, but from the following account of a reef seen by Mr. Baird, this danger would appear to lie 17 miles N. $\frac{1}{2}$ E. of its ascribed position on the chart.

* SANDY ISLAND, reported in 1863 by Mr. W. Andrew, master of the barque *Thames*, to be in about $7^{\circ} 20'$ N., $114^{\circ} 10'$ E., was looked for in the *Rifleman*. At noon, from lat. $7^{\circ} 12'$ N., and long. $114^{\circ} 1'$ E., a course was shaped for the assigned position of the island; at 2^h 30^m p.m. the vessel was in the same latitude and 1 mile to the eastward of it; from thence a course was steered for the South Ardasier Shoal. No appearance of shoal water could be seen from the vessel on either of these courses, and certainly no island exists within 5 or 6 miles on either side of the lines passed over.

Commodore Reef.—Mr. Hugh Baird, commanding the ship *Commodore*, reports as follows:—Monday, December 22nd, 1862, at 8 a.m., saw what I took to be the Viper North Shoal, or Seahorse, the N.E. end bearing by compass N.N.W. 3 miles; it seemed to extend over 3 miles N.E. and S.W. Partly dry sand, and several rocks from 20 to 30 ft. above water, and heavy breakers all around it. At noon it bore W. by S., distant about 6 miles; lat. by observation $8^{\circ} 22' N.$, long. $115^{\circ} 31' E.$, placing the shoal 17 miles North of its position on the Admiralty chart.*

DANGERS ON THE WESTERN SIDE OF THE PALAWAN PASSAGE.

HALF-MOON SHOAL, having the Inclined Rock on its eastern side in lat. $8^{\circ} 51\frac{3}{4}' N.$, long. $116^{\circ} 16' 45" E.$, by H.M.S. *Royalist*, in July, 1853, is formed by a belt of coral even with the water's edge, of the average width of one cable's length, except at its S.W. extremity, where it is broader. It is of oblong shape, the long diameter being nearly 3 miles in a N.E. and S.W. direction, and the average width of the shoal one mile. On the eastern side, to the southward of the Inclined Rock, there are two breaks in the belt

* **ROGER BREAKERS.**—Heavy breakers were seen in about lat. $8^{\circ} 21' N.$, long. $116^{\circ} 25' E.$, from the Peninsular and Oriental steamer *Formosa*, commanded by Mr. Roger, on the 4th of January, 1858. There was a swell from the N.E., and the broken water, about 10 yards in extent North and South, was apparently caused by a rock a few feet under water. The vessel proceeded slowly, and soundings were occasionally tried for with 100 fathoms, no bottom. The weather was thick and rainy, but on clearing up observations and a bearing of the distant land confirmed the position of the breakers by dead reckoning.

Navigating-Lieutenant Reed, commanding H.M. surveying vessel *Rifleman*, remarks:—“This is another instance in which it was most desirable that a boat should have been lowered from the *Formosa* to examine the breakers and to find out if there was really any rock there or not. It was of the greatest importance to avoid placing a doubtful danger at the very entrance and in the centre of the fairway of the Palawan Channel. An hour or so would have decided the point beyond doubt, whereas several valuable days of the *Rifleman's* time were occupied in searching for the Ottawa Shoal and Roger Breakers without enabling us after all to decide the matter positively.”

Mr. Curling, commanding the Peninsular and Oriental steamer *China*, who has made many voyages by this route, asserts that the appearance of breakers where no real danger exists, is very common in the Palawan. This is further corroborated by the following extract from the log-book of the ship *Veloz*, Commander Mr. John Jones:—“At noon, 6th November, 1859, lat. $8^{\circ} 24\frac{1}{2}' N.$, long. $116^{\circ} 25' E.$ At 10h 30m a.m. the mast-head look-out reported breakers about a mile on the port beam. Lowered a boat, and sent the chief officer to examine the spot. It proved to be an extensive patch of seaweed, drift wood, and a great number of fish. No soundings at 50 fathoms. We were passing over the spot marked ‘Roger Breakers’ on the chart, but could not see any indication of it.”

forming channels into the basin, the southernmost of which has 4 to 9 fathoms in it, and is marked by a cluster of rocks, which generally show above water. Half-tide Rocks are interspersed over the belt, the largest of which is at the N.W. extremity of the shoal. The average depth in the basin is 14 and 16 fathoms, with numerous patches of coral scattered about it. From the shoal Balabac Peak (pages 522-3) bears S.E. $\frac{1}{2}$ S., distant 71 miles; Bulanhow Mountain (page 540) E. by S. $\frac{1}{4}$ S.; and the Elbow or nearest part of the bank of soundings fronting Palawan Island (page 656) S.E. $\frac{1}{2}$ E. 39 miles.

Tides.—It is high water at the Half-Moon Shoal, 5 days after full and change, at 10^h 45^m a.m., and the rise is about 4 feet.

ROYAL CAPTAIN SHOAL lies E.N.E. 23 $\frac{1}{2}$ miles from the Half-Moon Shoal, and N.W. $\frac{1}{3}$ W. from the edge or nearest part of the bank, contracting the channel, which is here the narrowest part, to 25 $\frac{3}{4}$ miles in width. Observation Rock, at its North extremity, which shows at half tide, is in lat. 9° 1' 45" N., long. 116° 39' 36" E.; from it Balabac Peak bears S. by E. $\frac{3}{4}$ E., distant 68 $\frac{1}{2}$ miles, Bulanhow Mountain S.E. by E. $\frac{1}{2}$ E.; and in clear weather the high land of Mantaleengahan (page 542) is visible. The shoal is elliptical, the length being 1 $\frac{3}{4}$ mile in a N.W. and S.E. direction, with a breadth of one mile. The belt, which is entirely covered at high water, and of irregular form in the inner rim, varies very much in width, the broadest part being at the S.E. extremity, where it is 2 cables. There are depths of 15 to 17 fathoms, sand and coral, with several coral patches, inside the basin. There is no entrance, but at high water a boat can cross the belt. The outer edge is steep-to, having no bottom with upwards of 100 fathoms, within half a cable's length of the reef. Only a few rocks on the belt show at low water.

Tides.—It is high water at the Royal Captain Shoal, 6 days after full and change, at 11.30 a.m.; the rise is about 4 feet.

BOMBAY SHOAL, on which the French frigate *Madagascar* was wrecked, in 1841, lies N.E. by N. 29 miles from the Royal Captain Shoal, and 27 $\frac{1}{4}$ miles from the nearest part of the bank of soundings. Madagascar Rock, on its N.E. extremity, is in lat. 9° 26' 7" N., long. 116° 56' 4" E., and from it Mantaleengahan Mountain bears S.E. $\frac{1}{2}$ E.; and Bulanhow S.S.E. $\frac{1}{2}$ E.

This shoal is in the form of an ellipsis, lying in a N.E. and S.W. direction one mile in length by three-quarters of a mile in breadth. The basin, in which there are 16 and 18 fathoms, sand, is completely enclosed by a belt, on which three or four rocks show at half tide, the most conspicuous being at the North extremity of the shoal. There are 30 fathoms outside the reef, within 20 yards of the S.W. and N.E. extremes; but beyond, there is no bottom in any direction with upwards of 150 fathoms line.

The Bombay is the northernmost and smallest of this description of shoals in the Palawan Passage.

Tides.—It is high water at the Bombay Shoal, 7 days after full and change at noon; rise about 4 feet. While the tide was rising, the current was observed setting to the N.E.

CARNATIC SHOAL is said to lie about N.E. by N. 47 miles from the Bombay Shoal, in lat. $10^{\circ} 6' N.$, long. $117^{\circ} 21' E.$, and to have as little as $3\frac{1}{2}$ fathoms over it. H.M.S. *Royalist*, in July, 1853, could not discover the shoal in the position assigned to it, or succeed in obtaining soundings with from 100 to 200 fathoms, when in the neighbourhood.

Other banks and dangers (outliers of the great prolific coral bed) are reported to exist to the north-eastward of this and the Bombay Shoal, by vessels which have deviated from the proper channel course, all which appear to have no soundings near them.*

DANGERS ON THE EASTERN SIDE OF THE PALAWAN PASSAGE.

Having described the dangers and shoals which limit the western boundary of the Palawan Passage, we shall now proceed with those on the eastern side, which lie immediately within the edge of the bank of soundings fronting the island. The coast has been described in pages 539 to 567. The S.W. part of the bank forms an Elbow on the parallel of nearly $8\frac{1}{2}^{\circ} N.$, from which Cape Buliluyan, the South point of Palawan, bears E. by S. $\frac{1}{4} S$, Balabac Peak, S.S.E., and Bulanhow Mountain E. by N. $\frac{1}{2} N.$ The bank also extends to the northward, fronting the Calamines group.

HEREFORDSHIRE SHOAL.—The ship *Herefordshire*, in 1815, struck upon a reef in lat. $8^{\circ} 35' N.$, long. $116^{\circ} 59' 19'' E.$, about 15 miles to the north-eastward of the above Elbow; an occurrence which might have been prevented had the lead been properly attended to, as the danger lies 4 miles within the edge of the bank. The position of this shoal was not fixed by H.M.S. *Royalist*.

NORTH REGENT SHOAL, N.E. by E. $\frac{1}{2} E.$ 5 miles from the Herefordshire, is a dangerous coral patch, 4 cables in extent, having in some places

* **HOLMES SHOAL.**—The *Rifleman* on leaving the Routh Shoal steered a S.E. $\frac{3}{4} S.$ course to pass over the doubtful position of Holmes Shoal; no bottom at 200 fathoms was obtained on its reputed position, lat. $10^{\circ} 32' N.$, long. $117^{\circ} 59' E.$, nor was any sign of shoal water seen in the vicinity; many others have reported to the same effect. It certainly does not exist where reported, and there are reasons for believing that the Fairy Queen Shoal, 18 miles to the westward, is the Holmes Shoal.

only 13 ft. water on it. It lies 6 miles within the edge of the bank, and $9\frac{1}{2}$ miles from the nearest shore, with the S.W. or Triple Hill S.E. $\frac{1}{4}$ E.; summit of Bulanhow Mountain a little open South of Caneepahan Hill, E. $\frac{1}{4}$ S.; and the Pagoda (page 541), E. by N. $\frac{1}{4}$ N.

N.W. $\frac{1}{2}$ W. $4\frac{1}{2}$ miles from the North Regent Shoal, and one mile inside the edge of the bank, is a coral patch, with 10 fathoms water on it; at $1\frac{1}{2}$ miles to the north-eastward of which, and 2 miles inside the edge of the bank, is another patch, 3 cables in extent, with only 5 fathoms on it. Also N.E. by E. $\frac{1}{2}$ E. $1\frac{1}{2}$ miles from the latter, is a 4-fathom patch, 3 cables in extent; and a 7-fathoms knoll lies half way between the two. The soundings in the vicinity of the two latter shoals are 27 and 30 fathoms, sand and shells; the soundings near the former, which are within 2 cables' lengths of the 10 fathoms, being 60 fathoms, mud, with 74 and 77 fathoms between them and the edge of the bank. Between the North Regent and the above shoals the depths are from 30 to 45 fathoms, mud, and sometimes sand and broken coral.

BREAKER REEF, lying N.E. $\frac{3}{4}$ E. 5 miles from the North Regent, is 3 cables in extent, and of triangular form, with a few rocks showing at low water. It is 8 miles inside the edge of the bank, and 7 miles from Cape Seeacle, the nearest shore, and from it S.W. or Triple Hill bears S.S.E.; Caneepahan Hill, S.E. by E. $\frac{3}{4}$ E.; and the Pagoda, showing to the southward of a double hill on I-wi-ig range E. $\frac{3}{4}$ N.

Rocky Ground, where there are only $2\frac{3}{4}$ fathoms, extends $1\frac{3}{4}$ mile to the westward of this reef; also northward of it $3\frac{1}{4}$ miles there is a patch with $4\frac{1}{2}$ fathoms; and another N.W. $\frac{1}{2}$ W. $2\frac{1}{2}$ miles from that, with $6\frac{1}{2}$ fathoms; the soundings in the neighbourhood being 30 and 40 fathoms, except to the south-westward of the latter, where there are 16 and 30 fathoms, coral, half a mile from it.

Paraquas Ridge begins at 11 miles N. $\frac{1}{2}$ W. from the Breaker Reef, and extends 8 miles to the N.E., parallel with and a mile inside the edge of the bank, when it then trends 2 miles to the eastward. It is a long irregular formed bank of coarse sand and shells, with a very narrow ridge of coral having gaps through it, and on which ridge the least water found was 5 fathoms; the average depth being 6, 7, and 9 fathoms, with from 20 to 30 fathoms on the bank. When on the extremes of the bank the bearings were as follows:—

	S. extreme in 26 fathoms.	N. extreme in 19 fathoms.
Bulanhow Mountain - - -	S.E. $\frac{1}{4}$ S. - - -	S. by E. $\frac{3}{4}$ E.
Caneepahan Hill - - -	S.E. by S. - - -	S. $\frac{3}{4}$ E.
Pagoda (Pagoda Cliff-) - -	E. by S. $\frac{3}{4}$ S. - - -	S.E. easterly.
Mantaleengahan Mountain -	E. $\frac{1}{2}$ S. - - -	E. by S. $\frac{3}{4}$ S.

The outer edge of this bank is steep-to, having in many places 60 and 70 fathoms within 2 or 3 cables' length of the ridge.

VANGUARD SHOAL is a coral patch 2 cables in extent, with only one foot water on it, lying E. by S. $5\frac{1}{4}$ miles from the shoalest part of the Paraquas Ridge, and 12 miles off shore, with Caneepahan Hill bearing S. $\frac{1}{2}$ E.; Bulanhow S. by E. $\frac{3}{4}$ E.; Pagoda S.E. $\frac{1}{2}$ E.; and Mantaleengahan E. by S. $\frac{1}{4}$ S.

Between this shoal and the Paraquas the soundings are irregular, varying from 30 to 50 fathoms. To the south-westward of the latter they are from 70 to 80 fathoms, mud, when on the edge; 20 and 30 fathoms, coarse sand and broken coral, a mile inside, and 40, 45, and 50 fathoms, mud, when fairly on the bank.

SCALEBY CASTLE SHOAL is a dangerous coral patch, 2 cables in extent, with 15 ft. water on it, and 32 fathoms close to its edge, lying in lat. $9^{\circ} 5' N.$, long. $117^{\circ} 17' 11'' E.$, N.E. by N. $7\frac{1}{4}$ miles from the North extreme of the Paraquas, and only $1\frac{1}{2}$ mile within the edge of the bank. From it Bulanhow bears S. $\frac{2}{3}$ E.; Pagoda S.S.E. $\frac{1}{2}$ E.; Mantaleengahan, a little open South of Illaan Hill, S.E. by E. southerly; Sharp Peak, a little open South of a high peak on the Mantaleengahan Range, S.E. by E. $\frac{3}{4}$ E.; and Eran Quoin E. $\frac{1}{2}$ S. It is distant $15\frac{1}{2}$ miles from Townsend Point, the nearest shore.

COLLINGWOOD SHOAL, lying N.E. by E. $15\frac{1}{4}$ miles from the Scaleby Castle, and 6 miles inside the edge of the bank, is half a mile in extent, and on it the least water found was 13 feet, with 26 and 28 fathoms close to its western or outer edge; the soundings in the neighbourhood being 40 and 45 fathoms, stiff mud. From this shoal Eran Quoin, the nearest land, bears S.E. $\frac{1}{3}$ S. 12 miles; Pagoda (which is very conspicuous on this bearing over the low land, and generally discernible when the elevated objects are obscured), S. $\frac{1}{3}$ W.; Mantaleengahan, S. by E. $\frac{3}{4}$ E.; and Gantung, a high notch peak (page 542) S.E. $\frac{1}{3}$ E.

To the N.N.W. of this shoal the edge of the bank projects a little beyond the general trend, and has on either side a less regular contour with bights, having soundings of 130 and 140 fathoms within a mile, and in some places only 3 cables' lengths from the coral patches.

Coral Patches.—From the Scaleby Castle Shoal to the parallel of $9^{\circ} 30' N.$, a distance of 35 miles, the coral patches on the edge of the bank of soundings are so numerous, that to give a description or bearings for each separately, would tend more to confuse than make clear the directions for the navigation of this part of the channel. Four fathoms is the least water that has been found on them, and they may generally be distinguished by an ordinary look-out from the mast-head. It is, however, recommended to avoid them, as it is impossible to say whether there may or may not be shoaler parts which have escaped detection. The average depth upon the

patches is from 6 to 7 and 9 fathoms, with 15 and 20 fathoms close to their edges.

York Breakers.—This is a dangerous coral shoal, in lat. $9^{\circ} 53\frac{1}{2}'$ N., long. $118^{\circ} 8' 26''$ E., on which the *Countess of London* is supposed to have been wrecked in November, 1816. It is 4 cables in extent, with less than 2 feet on it at low water, and, except in fine weather, generally breaks. It lies $6\frac{1}{2}$ miles inside the edge of the bank, and is steep-to, having 45 fathoms close to the edge, the soundings contiguous to it being 40 and 50 fathoms, mud. When on it, Victoria Peak bears S. by E. $\frac{1}{2}$ E.; Anipahan, the northernmost of two sharp peaks, over Long Point, S.E. $\frac{3}{4}$ E.; Mount Staveley E. by S. $\frac{3}{4}$ S.; Mount Peel E. by N.; and in clear weather Cleopatra Needle will be seen over Ulugan Bay, nearly in line with Carsoglan Hill E. by N. $\frac{1}{2}$ N. (See pp. 546, 547, 551.)

Coral Patches.—There is a coral patch, having only $3\frac{1}{2}$ fathoms on it, lying S.W. $\frac{1}{3}$ S. 4 miles from the centre of the York Breakers; and $1\frac{1}{2}$ mile westward of it is another, with 4 fathoms, the latter lying $3\frac{1}{2}$ miles inside the edge of the bank, with a bank of coarse sand intervening, on which the average depth is 18 and 20 fathoms.

The soundings in the neighbourhood of these shoals are from 40 to 50 fathoms, mud.

Middle Shoal.—From the York Breakers in the direction of Ulugan Bay, viz., E. by N. $\frac{3}{4}$ N., distant $16\frac{1}{4}$ miles, and at 12 miles off shore, is the Middle Shoal, 2 cables in extent, with $3\frac{1}{2}$ fathoms, coral, upon it, and 12 and 20 fathoms close to its edge. From it Mount Peel bears E. $\frac{1}{2}$ N.; Anipahan Peak S. $\frac{3}{4}$ E.; Mount Staveley S.S.E. $\frac{1}{4}$ E.; and the summit of Long Point S. $\frac{1}{2}$ W.

Directions.—To the northward of the parallel of $9^{\circ} 30'$ N., the soundings on the bank are more regular, and the coral patches lying near the edge of it, except in the neighbourhood of the York Breakers, have generally more water on them than those to the southward, seldom having less than 7 and 9 fathoms up to the parallel of $10^{\circ} 40'$ N., where they again begin to cluster, and have as little as 4 fathoms in some places. Vessels, therefore, bound to Ulugan Bay, or wishing to close with the land for the purpose of working up in shore, cannot do better than cross the bank about this parallel, with Mount Peel on an E. $\frac{1}{2}$ S. or E. by S. bearing, or where it is still clearer on a S.E. by E. $\frac{3}{4}$ E. bearing. The bank on this parallel extends 30 miles from the coast. The first soundings obtained on the edge will generally be 18 or 20 fathoms, coarse sand and broken coral, or perhaps a 9-fathoms cast on coral, when the bottom will be visible, after which the depth will be more regular, the 40 and 50 fathoms' casts being chiefly on a stiff muddy bottom; while in less water sand and mud, or sand and broken coral, will predominate. The nearer to the shore the fewer are the patches, and the more regular the soundings.

Crescent Reef, in lat. $10^{\circ} 40' N.$, long. $118^{\circ} 42' 26'' E.$, and upon which there are 4 fathoms, is a very narrow strip of coral, three-quarters of a mile in extent, in an E..N.E. and W.S.W. direction, lying $1\frac{1}{2}$ mile inside the edge of the bank, and 22 miles from the nearest shore. There are 40 and 44 fathoms within half a mile of its edge.

When on the centre of the shoal, Sangbowen, the North peak of Ulugan Bay, bears S. by E. $\frac{1}{4}$ E. ; Cleopatra Needle, S.S.E. $\frac{1}{2}$ E., ; summit of Cacunipa or High Island (page 552), S.E. by E. $\frac{3}{4}$ E. ; highest part of Boayan Island (page 552), E. by S. $\frac{1}{4}$ S., easterly; and Mount Capoas (page 554), E. by N. $\frac{1}{4}$ N.

The *Bank* immediately West of this shoal follows apparently the contour of the coast line, and takes a sudden trend in a westerly direction for about 10 miles, with soundings of 60 and 75 fathoms. To the northward of the shoal it trends nearly North for 9 miles, and then N.E. $2\frac{1}{4}$ miles.

South, $2\frac{1}{2}$ miles from the Crescent Shoal, there is a 7-fathoms patch, with soundings of 36 and 40 fathoms close to; and E.N.E. $2\frac{1}{2}$ miles from the same is another, 3 cables in extent, having only $4\frac{1}{2}$ fathoms on it, with 40 fathoms close to the edge. Between these shoals and the shore, the soundings vary from 30 to 50 fathoms, and the ground appears to be free from danger.

Capoas Cluster.—In the vicinity of the above patches, and between them and the Crescent Reef, the soundings are irregular, where also there appear to be several shoal spots of 5 and 6 fathoms, all lying from 1 to 6 miles within the edge of the bank. They are too closely grouped and too far off shore for bearings to be of any advantage to navigate between them.

N. by E. $10\frac{1}{4}$ miles from the Crescent Shoal is a 5-fathoms coral patch, one of the Capoas cluster, lying only 4 cables' lengths inside the edge of the bank, with upwards of 40 fathoms water close to it; and also a 6-fathoms patch $1\frac{1}{2}$ mile S.W. of it. From the former Mount Capoas bears E. $\frac{1}{2}$ S.-easterly, distant $32\frac{1}{4}$ miles; the northernmost of the Four Peaks on Cleopatra Range S.S.E. $\frac{1}{4}$ E., and the summit of Tapiutan Island (page 562) N.E. $\frac{2}{3}$ E.

N.E. by E. $8\frac{3}{4}$ miles from the 5-fathoms patch is a $4\frac{1}{2}$ -fathoms coral patch, apparently the northernmost of the Capoas cluster, 3 cables in extent, with 52 fathoms close to its western edge. It lies $1\frac{1}{2}$ mile inside the edge of the bank, with Mount Capoas bearing E. by S. $\frac{1}{3}$ S., Chinongab Peak (page 557) East-northerly; and the highest peak of Tapiutan Island N.E. $\frac{2}{3}$ E.

The least water that has been found on the Capoas cluster is $4\frac{1}{2}$ fathoms. The soundings in the immediate neighbourhood are 40 and 50 fathoms. Vessels should keep clear of this part of the bank.

The *Bank of Soundings* from the 5-fathoms patch above mentioned trends to the north-eastward for 9 miles, and then nearly North parallel with the line of coast.

From the northernmost of the Capoas cluster, the bank trends North a little westerly, preserving a distance of about 30 miles from the shore, to the parallel of $11^{\circ} 12' N.$, when it gradually takes a north-easterly direction, and does not approach the North point of Palawan nearer than 23 miles. The bank is steep-to, 40 and 50 fathoms being close to the 100-fathoms line. Here and there it has comparatively shoal ridges (15 to 20 fathoms) of coarse sand and broken coral, on which there are some $7\frac{1}{2}$ and 9 fathoms patches of coral lying close to the edge. The northernmost and shoalest of these that has been discovered, and on which there are 7 fathoms, lies $1\frac{1}{2}$ miles inside the edge of the bank, in lat. $11^{\circ} 28' 45'' N.$, long. $119^{\circ} 1' E.$ When on it the North Hill on Palawan bears E. by S.-easterly; West shoulder of the High Table Range (page 566) S.E. by E. $\frac{1}{2} E.$; Cadlao or Table-top Island (page 564) S.E. $\frac{2}{3} E.$; and the Horn on Matinloc Island (page 562) S.E. $\frac{1}{4} S.$ It is 26 miles distant from the nearest part of the island, and the depths in the vicinity vary from 20 to 40 fathoms.

The nature of the bottom near the patches is usually fine sand, but when fairly on the bank, especially off the North part of Palawan, stiff green mud predominates. The bank farther to the northward does not appear to be so steep as that abreast of the island, soundings with 160 fathoms having been found nearly 4 miles outside the 100-fathoms line.

The foregoing pages, relating to the shoals and dangers in the China Sea, contain descriptions of those which lie on the south-eastern verge of the main route, along the continental side, or those which form the north-western side of the Palawan route, which have been found by the recent examination to be free from danger.

In former times, the imperfect observations of passing vessels, and the too frequent very desultory notices of presumed discovery of dangers, caused the charts to be embarrassed with a multitude of reefs which have no existence, as has been shown.

But in the space between the two channels, as they may be termed, along the Asiatic side, and that parallel with Palawan, there still remains a labyrinth of clusters, shoals, and reefs, in many cases of doubtful existence, but in more of doubtful position, for this area has up to the present period been unsurveyed, and "*ought to be avoided by all navigators.*" This truth cannot be too strongly impressed upon all, for although it is possible that a ship might pass unharmed through this region of dangers, coralline, reefs, and sand-banks, yet the risk is very great, and the greatest caution will not be an excuse for venturing into such imminent danger.

The ensuing enumeration and description of shoals lying out of the proper track of ships, is therefore added with a view to making these remarks complete, rather as an object of utility.

SHOALS NEAR THE MAIN ROUTE.

The Bombay Castle, Orleana, Johnson, and Kingston Shoals of former charts, were found by Commander Ward, in H.M. surveying vessel *Rifleman*, to be patches on the edge of the Rifleman Bank, described on page 622.

OWEN SHOAL, in lat. $8^{\circ} 8' N.$, long. $111^{\circ} 59' E.$, was discovered in 1835, by Mr. Owen, commanding the ship *David Scott*, who had soundings of 5 to $4\frac{1}{2}$, and one cast of $3\frac{3}{4}$ fathoms in passing over it, a little past noon, steering S.S.E., and at 1 p.m. cleared the shoal, having then no bottom. The shoal appeared to be about 2 miles in extent, consisting of black and white speckled coral, in a state of rapid accretion, apparently by the vitality and energy of the madrepores, observed in recent formations of large pieces of coral brought up by the lead. The patches of speckled coral were bright and alarming while on the shoal, and although no breakers were perceived, as the sea was then very smooth, yet with a heavy swell, the sea probably rises in rollers over the shoal patches, when a large ship would be liable to strike on some of them.

AMBOYNA CAY was surveyed by Commander Ward, H.M.S. *Rifleman*, in 1864. It is in lat. $7^{\circ} 51\frac{3}{4}' N.$, long. $112^{\circ} 55' E.$, and is the dry portion of a small coral bank running N.E. and S.W. The cay is at the south-west extreme of the bank, and is 150 yards long, E.N.E. and W.S.W., 124 yards wide, and 8 feet above high water mark. It is surrounded by coral ledges, some of which dry at low water, but in no instance do they extend as far as 2 cables' lengths from high water mark; the sea breaks heavily upon these ledges in any swell.

About two-thirds of the rock forming the cay is covered with a rich coat of guano, and in some places 4 feet deep, the deposit of myriads of boobies, petrels, and other marine birds; the rest of the cay is comminuted coral. A large pile, composed of all the drift-wood to be collected on the cay, a few lumps of coral, &c., was erected in the centre, and can be seen as a sail at a distance of from 5 to 7 miles in clear weather.

The bank, to the north-eastward of the cay, forms a very narrow ridge a mile long by 2 cables wide. The soundings upon it are about 4 fathoms from a quarter of a mile from the reef until close to the end of the spit, when the water deepens rapidly from 9 to 17 fathoms, and then dips into 67 fathoms, no bottom; while at a distance less than a third of a mile, no bottom was obtained with 220 fathoms of line. There is no danger on the ridge if vessels do not get into less than 4 fathoms, although from the excessive clearness of the water the bottom looks alarmingly close to the ship's keel; the ledges surrounding the islet are steep-to.

Anchorage on the ridge in 5 fathoms, in the S.W. monsoon, was obtained

by the *Rifleman*, fairly sheltered from the prevailing wind. Fish appeared to be abundant, but only a few were caught.

Tides.—By observations at Amboyna Cay two days before neaps, the maximum rate of tide was 1.4 knots per hour, the flood stream setting about N. by W, the ebb West; flood commencing at 11 p.m., and the ebb at 6 a.m. Rise and fall doubtful.

LIZZIE WEBBER SHOAL.—Mr. Dallas reported that while returning in a small vessel, the *Lizzie Webber*, to the wreck of the *Fiery Cross* (in 1860), they struck upon a reef in lat. $8^{\circ} 4' N.$, long. $113^{\circ} 12' E.$ The reef, which was very little under water, is a narrow strip of sand and coral lying in a N.E. and S.W. direction.

This shoal is supposed to extend about 25 miles to the north-eastward of the above position, as reported by Mr. P. Orr, commanding the barque *Canada*, which was wrecked on it on the 24th December, 1864, at 12.30 a.m.

STAGS SHOAL, placed in $8^{\circ} 24' N.$, $112^{\circ} 57' E.$, was reported in 1802 by Mr. Trinder, commanding the brig *Amboyna*, as follows:—"The North end of the shoal extended S.E. and S.S.W. in form of a triangle, with rocks above water and breakers in various parts, the intermediate space apparently very shoal, and the southern extremity could not be discerned from the mast-head."

The *Rifleman*, from a position 5 miles North of that given above, was steered E.S.E. 12 miles, when she was in the latitude of the shoal, and 11 miles East of it, here no bottom was obtained at 200 fathoms; a West course was then steered for 21 miles, and again a S.E. by E. course until the longitude of the shoal was reached. Soundings, with 40 fathoms of line, were tried for, as quickly as possible, on the different courses, and on the spot assigned to the danger, bottom (dark oaze) was brought up from a depth of 1,085 fathoms.

The *Rifleman* had previously passed over the position, and H.M.S. *Reynard* also steamed about the locality, and it is certain from the result of these examinations that no shoal exists within 10 miles of the position assigned. The soundings obtained in the *Rifleman* in former years indicate that the shoal does not exist to the westward,—and it seems probable that the danger seen from the *Amboyna* was part of the *Lizzie Webber* or *Canada Shoal*,—25 miles E.S.E. of the position ascribed to the Stags,—and this is verified by the fact of the *Amboyna Cay* being found 11 miles farther West than reported by Mr. Trinder.

Pearson Reef, in lat. $8^{\circ} 56' N.$, long. $113^{\circ} 44' E.$, was seen in 1843 by Mr. Pearson, commanding the *Bahamian*, who reported that he passed about 3 miles to windward of an extensive shoal in the above position, about 2 miles long in a North and South direction, with some rocks above water on the southern edge.

Cornwallis South Reef is a doubtful danger, placed on the chart in lat. $8^{\circ} 50'$ N., long. $114^{\circ} 11\frac{1}{2}'$ E., and shown as being 3 or 4 miles in extent.

Ganges Reef is another doubtful shoal, 32 miles to the northward of Cornwallis South Reef, in lat. $9^{\circ} 22'$ N., long. $114^{\circ} 11'$ E.

Sin Cowe Island is reported by the fishermen to lie in lat. $9^{\circ} 41'$ N., long. $114^{\circ} 21'$ E. (approximate).

Fancy Wreck Shoal is a doubtful danger, 30 miles north-eastward of the Ganges Reef, in lat. $9^{\circ} 43'$ N., long. $114^{\circ} 41'$ E.

Cornwallis Reef, also doubtful, is shown on the chart as an extensive reef with rocks, 20 miles to the north-westward of the last-named shoal, in lat. $10^{\circ} 0'$ N., long. $114^{\circ} 23'$ E.

Pennsylvania, one of the many doubtful shoals, is placed in lat. $10^{\circ} 0'$ N., long. $115^{\circ} 10'$ E.; and about 20 miles N.N.W. of it, in lat. $10^{\circ} 18'$ N., long. $115^{\circ} 4'$ E. is another doubtful Ganges reef. About 14 miles N.N.E. of this latter, in lat. $10^{\circ} 32'$ N., long. $115^{\circ} 8'$ E., is *Ganges North Reef*, also a doubtful danger.

Third Thomas Shoal (1839) is placed on the chart in lat. $10^{\circ} 52'$ N., long. $115^{\circ} 55'$ E., and shown as being 3 or 4 miles in extent.

Flat Island, in lat. $11^{\circ} 1'$ N., long. $115^{\circ} 40'$ E., is said to be low and flat, surrounded with breakers, and having a reef projecting from its N.E. side. It is marked doubtful in the charts, but it is said that it has been seen by several ships. This is the northernmost danger in this part of the China Sea, and lies nearly midway between the North Danger Reef and the north-easternmost of the dangers bounding the Palawan channel.

SHOALS NEAR THE PALAWAN ROUTE.

Swallow Reef, seen by the *Swallow* in 1801, lies 28 miles N.N.E. from Charlotte Reef. It is formed of a belt of coral surrounding a shallow basin, is $3\frac{3}{4}$ miles long, E. $\frac{2}{3}$ N., and W. $\frac{2}{3}$ S., and $1\frac{1}{4}$ mile wide. At its eastern part are some rocks from 5 to 10 ft. above high water, the highest of which is in $7^{\circ} 23'$ N., $113^{\circ} 50' 23''$ E.; there are also one or two stones on the south-eastern side which show at high water; the West end terminates in a sharp point.

ARDASIER BANK, lying N.E. of Swallow Reef, is very extensive, and has only received a partial examination. It is probable that the South Ardasier, $7^{\circ} 34'$ N., $114^{\circ} 9'$ E., Gloucester, $7^{\circ} 50'$ N., $114^{\circ} 15'$ E., and North Ardasier Breakers, $7^{\circ} 56'$, long. $114^{\circ} 2'$, as also the breakers seen by Mr. Dallas in 1860, in lat. $7^{\circ} 38'$, long. $113^{\circ} 54'$ E., are shoal patches on different parts of one large bank. The south-eastern side, which forms one of the northern limits of the approach to the Palawan passage, has been surveyed in the *Rifleman*. The general direction of this part is N.E. by E. $\frac{1}{2}$ E. and S.W. by W. $\frac{1}{2}$ W. for a distance of 20 miles, but the outline of the edge is

very irregular. Several shoal patches of 3 to 5 fathoms were found near the edge; the shoalest spot discovered had only $2\frac{1}{2}$ fathoms water; this last is in $7^{\circ} 36' 37''$ N., $114^{\circ} 10' 10''$ E., very close to the position ascribed to the South Ardasier Breakers.

INVESTIGATOR SHOAL, examined by Captain Crawford, of the Indian Navy surveying ship *Investigator*, in 1813, is very extensive; its western point being in lat. $8^{\circ} 5' N.$, long. $114^{\circ} 31' E.$, and its eastern extremity in lat. $8^{\circ} 10' N.$, long. $114^{\circ} 50' E.$ It is about 4 miles in breadth, North and South.

Cay Marino is a doubtful shoal, placed upon the chart in lat. $8^{\circ} 30' N.$, long. $114^{\circ} 21' E.$

S.W. and N.E. Shea Shoals were seen by Mr. Shea, commanding the *Buckinghamshire*, in 1833. The first shoal appeared to consist of two reefs of rocks, with high breakers, extending $1\frac{1}{2}$ mile E. by S. and W. by N., and half a mile North and South, the centre of which was found to be in lat. $8^{\circ} N.$, long. $114^{\circ} 55' E.$, by observations of sun, moon, and stars.

The other shoal, seen on the following morning, appeared to consist of two dry white banks, with a ridge of rocks extending from them to the westward about 2 miles, which was considered to be in lat. $8^{\circ} 30' N.$, long. $115^{\circ} 19' E.$

Glasgow Bank.—Mr. Baird, commanding the ship *Glasgow*, is said to have discovered a bank in lat. $8^{\circ} 39' N.$, long. $115^{\circ} 31' E.$ It apparently extended 3 miles to its N.E. edge, and was composed of sand and rocky peaks, in some places 21 to 32 ft. above the sea.

Alicia Annie Shoal.—Captain R. Kirby reports having seen a reef in lat. $9^{\circ} 25' N.$, long. $115^{\circ} 19\frac{1}{2}' E.$, of lagoon form, 3 miles in length, N.W. by N. and S.E. by S. There is a slight rise of sand hill at its N.W. end, and a reef of rocks at its S.E. extreme, with several detached rocks around. There was a portion of wreck on the S.E. end, and a junk with four boats close by; inside the lagoon there was a boat apparently fishing. Soundings were tried for at a quarter of a mile from the S.E. end, but no bottom with 100 fathoms of line. First Thomas Shoal was made the next day, and the chronometer showed it to be 2 miles West of its position on the chart.

First and Second Thomas Shoals appear by the chart to have been seen in 1839. The first is placed in lat. $9^{\circ} 18' N.$, long. $115^{\circ} 53' E.$; the second is shown as an extensive shoal, 9 or 10 miles long North and South, and 4 miles broad; its southern part is in lat. $9^{\circ} 41' N.$, long. $115^{\circ} 47' E.$

Investigator N.E. Shoal, in lat. $9^{\circ} 15' N.$, long. $116^{\circ} 24' E.$, is shown on the chart as having some rocks awash upon it.

Pennsylvania and Sabina Shoals.—One of the doubtful Pennsylvania Shoals is placed upon the chart about 17 or 18 miles northward of the N.E. Investigator, in lat. $9^{\circ} 31' N.$, long. $116^{\circ} 23' E.$, and there are three other

patches of that name, the first in lat. $9^{\circ} 47' N.$, long. $116^{\circ} 44' E.$, the second about 4 miles, and the third about 10 miles to the north-westward from it.

The *Sabina Shoal*, placed upon the chart in lat. $9^{\circ} 43' N.$, long. $116^{\circ} 34\frac{1}{2}' E.$, was discovered by Mr. French, commanding the *Sabina*, of New York, in 1836, who saw "rocks with the sea breaking tremendously over them." Mr. French thought it was one of the doubtful Pennsylvania Shoals, which in all probability it is.

Mr. E. Routh, commanding the *Bombay*, with the *Henry Clay* in company, sighted breakers which his observations placed nearly in the position of the Sabina Shoal.

Lord Auckland Shoal appears on the chart as a bank with 8 to 30 fathoms water over it. The 8-fathom part is in lat. $10^{\circ} 21' N.$, long. $117^{\circ} 17' E.$; close to the eastward of the bank there is no bottom at 100 fathoms.

OTHER PENNSYLVANIA SHOALS—BROWN SHOALS.—Another Pennsylvania Shoal is placed on the chart in lat. $10^{\circ} 24' N.$, long. $116^{\circ} 33' E.$; and another, the Pennsylvania North Reef, in lat. $10^{\circ} 49' N.$, long. $116^{\circ} 54' E.$ The positions of these are very doubtful, and it is probable that the shoals seen by Mr. Brown, commanding the *Arabian*, in 1838, were the same. The following is Mr. Brown's account of them:—

"On the 8th of January, 1838, on our passage to China by the Palawan, standing to the northward, wind N.E., at 10.30 a.m. passed close to windward of a coral patch, with apparently 5 or 6 fathoms water over it, blowing fresh and a good deal of sea; could not lower a boat to determine. It lies in lat. $10^{\circ} 30' N.$, long. $116^{\circ} 41' E.$

"Same day, lying up East on the port tack, at 3.30 p.m., came suddenly into shoal water. Saw the coral rocks very distinctly under the ship's bottom. Hove the lead over, first cast had 5 fathoms, and mark above water for a few casts. Put the helm up and run to the southward for a few minutes, until we gradually deepened to 30 fathoms, no bottom. We appeared to be on the southern edge of an extensive coral flat, extending N.E. and N.W. of us some miles. By sights taken immediately we came off the shoal; this part of it lies in long. $117^{\circ} 0' E.$, or 4' East of the Bombay Reef, which we left yesterday; lat. $10^{\circ} 35' N.$, which we observed at noon.

"The following day at 9 a.m., standing to the northward, with a fresh wind from N.E., and a heavy head sea, came again into shoal water; coral rocks seen very close to our keel, but before we could get the lead forward we had passed over the ridge into 28 fathoms. From 9^h to 11^h 30^m a.m. ran 8 miles on a N.N.W. course in irregular coral soundings, least water, by the lead, 11 fathoms, but at times we apparently had much less from the proximity of the coral rocks. We entered upon the flat in lat. $10^{\circ} 39' N.$, long. $117^{\circ} 24' E.$; came off in lat. $10^{\circ} 46' N.$, long. $117^{\circ} 19' E.$ The longitude computed from a series of sights before and after noon; the latitude by a good meridian altitude, four observers, and clear weather. In passing

over this bank the water appeared very shoal East and West of us, lying in ridges in that direction."

Amy Douglas Shoal.—The *Amy Douglas*, commanded by Mr. Pensberry—under the Siamese flag—on her passage up the Palawan, passed over a shoal in lat. $10^{\circ} 52' N.$, long. $116^{\circ} 25' E.$ On February 12th, 1860, at noon, had good observations, and noticed about that time the water discoloured for about a mile on each side of the ship. Dropped the lead over the side and found 14 fathoms. Mr. Pensberry is of opinion that the water was much more shallow to the westward of the ship.

Fairy Queen Shoal, having 9 fathoms water over it, is placed on the chart in lat. $10^{\circ} 39' N.$, long. $117^{\circ} 38' E.$

Coral Bank.—H.M.S. *Rifleman*, when proceeding from Loai-ta Island (page 628), round the northern edge of the Archipelago, obtained soundings of 47 fathoms on a coral bank in lat. $11^{\circ} 28' N.$, long. $116^{\circ} 46' E.$; steering E. by S. $\frac{1}{4}$ S. 3 miles farther had 44 fathoms, and shortly afterwards 12 fathoms on a small coral patch in lat. $11^{\circ} 26' N.$, long. $116^{\circ} 53' E.$ Continuing the same course, the depths were 42 fathoms for a distance of 5 miles; at 8 miles 125 fathoms, and at 14 miles 175 fathoms. A few miles farther on no bottom was reached with 200 fathoms of line.

SEAHORSE or ROUTH SHOAL was examined by the *Rifleman*. It lies at the N.E. angle of the archipelago of reefs, and forms the N.E. limit of the Palawan Passage. It is a pear-shaped coral bank, 8 miles in length, N.N.E. $\frac{3}{4}$ E. and S.S.W. $\frac{3}{4}$ W., $4\frac{1}{2}$ miles in breadth at the North end and 3 miles at the South end; it is not dangerous, the least water upon it being $4\frac{1}{2}$ fathoms, which was found on a 5-fathom patch, about three-quarters of a mile in extent, at the North extreme of the bank in lat. $10^{\circ} 50' N.$, long. $117^{\circ} 46' E.$ Nothing less than 6 fathoms were obtained on any of the other patches surrounding the lagoon; the depths in the lagoon vary from 17 to 19 fathoms at the shoal edges to 35 fathoms in the centre.

The northern part of this shoal was passed over by the *Seahorse* in 1786, and the southern part by Mr. Routh, commanding the *Bombay*, in 1835.

A Sandy Shoal is placed upon the chart in lat. $11^{\circ} 2' N.$, long. $117^{\circ} 37' E.$

Templer Bank.—The *Minerva*, commanded by Mr. Templer, passed over a bank to the north-westward of the Seahorse Bank, in November, 1835, having from 10 to 17 fathoms water on it. The bank appeared to extend about 4 miles North and South, and as no discoloured water was seen to the eastward, but several apparently shoal patches were perceived to the westward, it is supposed that the ship passed over the eastern part of the bank. The centre of the bank is in lat. $11^{\circ} 7' N.$, long. $117^{\circ} 13' E.$

PART III.

THE EASTERN PASSAGES.

THE descriptions and directions given in the foregoing pages have been devoted to those coasts and channels leading towards the Coast of China, which lie to the *westward of Borneo*, and which are approached by the Straits of Malacca and Sunda, and are therefore generally known as the WESTERN PASSAGES.

The EASTERN PASSAGES, which remain to be described, are those to the *eastward of Borneo*, and may be taken either by the Strait of Sunda, and passing eastward through the Java Sea, or else by one or other of the straits between the islands East of Java.

In earlier times these various routes were known by different names, of which PITT'S PASSAGE, or that which passes East of Gilolo, between it and the West end of New Guinea, may be cited as the most generally known, and this for a reason happily non-existent now—that it avoided those straits and islands subject to the Dutch.

Our charts of these passages are very much more imperfect than those of the portions of the Indian Archipelago to the northward and westward, and this consideration should have much weight with the commander in the choice of a route.

Till recent years the British charts in general use, such as those drawn up by the late Captain Horsburgh, were very unsafe guides, and it was maintained by the Dutch in Java that they caused many disasters. This obloquy is now in a great measure removed; for, however imperfect the charts of the eastern parts of the Archipelago may still be, the labours and observations of many British and Dutch officers have been combined for their improvement, although no proper and systematic survey has been made of the entire area. Prominent among these stands the "Netherlands Commissie tot het verbetering der Zeekarten in de Oost Indie," with which the name of the late Lieutenant Peter Baron Mellvill van Carnbee, may be associated. These have given to the nautical world a very much more perfect representation of

the navigation of the south-eastern portion of the Indian Archipelago than was formerly attainable.

These charts were published chiefly by the respected and ancient firm of Wed. G. Hulst Van Keulen, of Amsterdam, and have since been copied and improved by our Admiralty and others.

In the future descriptions of the channels leading towards China, we commence with the great island of Java, which stands as a rampart between the Indian Ocean and the Archipelago, and then proceed with the islands and straits to the eastward and northward, in due order, as far as the irregular distribution of the islands will permit.

CHAPTER XVI.

JAVA, AND THE JAVA SEA.

JAVA.

THE Island of Java is beyond all comparison the most important portion of the Indian Archipelago. Its fertility, its population, their civilization and industry, place it far in advance of all surrounding islands.

It is about 575 miles long, with a breadth varying from 48 to 117 miles, the area being computed at 37,029 square geographical miles, or about one-third larger than Ireland, but it supports a population twice as numerous. It may be compared in form, size, and position to Cuba, but then it has ten times the number of inhabitants.

It is the principal colonial possession of the Dutch nation, and its governor is paramount over all other of the Dutch possessions in the East. It claims the singular merit among Oriental countries under European subjection of producing a considerable revenue to the Netherlands Government. Whatever opinions may be held concerning the restrictive and engrossing policy of the Dutch, the facts of the great increase of the productiveness, the exports, and the population, stand as an evidence that the systems there carried out have been beneficial to the inhabitants and to the home government.

A century ago the population of Java and the adjacent island of Madura was estimated at 2,000,000. At the end of the last century it had risen to 3,560,000. In 1815, during the temporary occupation by the English, the census gave 4,615,270 inhabitants. The Dutch have, since the restoration of the island, made many enumerations, and each census has shown a large and steady increase. In 1845 the population of both islands was 9,530,781. On December, 31st, 1872, the census gave 17,298,200 as the number of inhabitants in Java and Madura. This included 28,926 Europeans, and 185,758 Chinese settlers. It is thus one of the most densely populated countries in the world, and this is more apparent if the large area occupied by its lofty and inaccessible mountains is taken into account.

The material prosperity of its people has also advanced with the increase of their numbers, and the great exports of coffee, sugar, rice, &c., subject to a heavy export duty, brings in, as before said, an ample revenue for its local government, and also leaves a large amount for the home exchequer. Java is therefore much more important to Holland than India is to the British nation; and it is looked upon as their promised land; "Java is ons Kanään" has been said of it by a Dutch writer.

A ridge of lofty mountains runs from West to East throughout its entire length. The more lofty of the conical peaks are generally visible from sea, and of these there are about 33 which rise above 5,000 ft. above that level. Of these, *Salak*, 7,200 ft., and *Pangeranga*, 9,663 ft., in the rear of Batavia; *Gedee*, or *Tagal Peak*, 11,300 ft., between Tagal and Pekalongan; *Soembing*, 11,000 ft.; and *Merapie*, 9,290 ft., near Samarang; *Japara Peak*, 4,600 ft.; *Lawoe*, 10,700 ft.; *Ardjoena*, 12,000 ft.; and *Semiroe*, the loftiest summit, 12,400 ft., near the Strait of Madura, are the most noticeable for their elevation. They all appear to have been formed as active volcanoes, and the hidden fires are in some cases scarcely extinct, but none are now in activity.

The heights of these mountains have been observed by Lieuts. Rietveld, Escher, Eschauzier, Staring, Brutel de la Rivière, and Melvill van Carnbee, of the Dutch navy.

They are a continuation of that volcanic band alluded to in an early part of this volume as encircling that vast area limited by Malaya, Sumatra, Java, and the islands East of it, Celebes, the Philippines, Japan, Kamtchatka, along which volcanic agency is more or less evident or active.

The South coast of Java is abrupt and iron bound, affording but very little shelter, and being a lee shore, beaten by the whole force of the waves from the Indian Ocean, is carefully to be avoided; but it is free from storms. The chief ports and settlements are on the northern side, along which are large plains of unsurpassed fertility, between the mountains and the sea.

At the principal ports the Government have established very ordinary means for refitting. The *open ports* (1870) in the island for import and export trade are Batavia, Samarang, Sourabaya, Cheribon, Passeroean, and Tjilatjap. For export only, the following ports are open in Java, Anjer, Bantam, Indramayoe, Tagal, Pekalongan, Rembang, Probolingo, Bezoekie, Panaroekan, Banjoewangie, Pangool, Patjitan, and Wyncoopsbay. There are railways running inland from Batavia and Samarang, and along the entire length of the island is a fine road, 800 miles in extent, made by General Daendels. There is electric telegraphic communication throughout the island and with all parts of the world, as described with Batavia hereafter.

The island lies between the wind systems of the two hemispheres, and thus enjoys an immunity from those storms and cyclones which devastate the countries in higher latitudes; but it is very moist, and to this fact it probably

owes much of its fertility. Formerly it was considered to be very unhealthy, but later experience and an improved mode of living, adopted by Europeans, have shown that it is not more deleterious to the white man than any other tropical country, and it has besides the advantage of affording lofty sites for residence and sanatoria.

Although no very systematic and minute survey of its coast has been made by the Dutch Government, yet the zeal of the officers in its large fleet, well directed by the Commission for the improvement of the Indian charts, have given us tolerably perfect delineations of its shores and harbours. The work was carried on under the orders of Rear-Admiral Lucas, the commandant of the Dutch navy, by the officers before mentioned. The first chart was published in Amsterdam, in 1842, under the authorship of the late Mr. Jacob Swart and Lieut. P. Baron Melvill van Carnbee. To accompany this chart, they drew up the "*Zeemans-Gids voor de Vaarwaters rondom het Eiland Java,*" from which the following directions are derived, as translated into English by Lieut. G. Tichelman.

A ship bound to Batavia, being abreast of St. Nicholas Point, ought to steer E. $\frac{1}{2}$ S., or E. by S., to pass Bantam Bay, mid-channel between Babi Island and the reef which projects from Pontang Point; with this course, Menscheneter Island and Great Kombuis will be seen ahead, and the Hoorn Islands in a N.E. or E.N.E. direction, visible in clear weather at the distance of $3\frac{1}{2}$ or 4 leagues. The best track in the night is to keep in 14 or 15 fathoms, taking care not to borrow under 11 fathoms toward the Java shore, nor to deepen beyond 18 fathoms in the offing. It would, however, be rather imprudent for strangers in these waters to keep under sail all night; it would be better to anchor, as moderate depths are found from here to Batavia Roads. The tides set generally East and West along this part of the coast.

Pulo Babi lies due North from Pontang Point, and according to the trigonometrical survey of Lieutenant Staring, D.R.N., in 1841, the centre of the island is in $5^{\circ} 48' 45''$ S., and $106^{\circ} 16' 13''$ E. It extends $2\frac{1}{2}$ miles East and West, and a mile North and South; it is steep-to on all sides, except on the E.S.E., where a reef projects to a distance of 3 cables' lengths, and off the West point, at a distance of $1\frac{1}{2}$ cables' lengths, are some rocks. Half a mile West of the island there are from 17 to 15 fathoms; along the South side 24 to 17 fathoms; on the East side 20 fathoms; and along the North side from 25 to 11 fathoms water. In some old charts a rock is placed 4 miles S.E. from Babi, called Cheribon, but apparently does not exist, as Lieutenant Staring carefully examined the place without finding it; and the native fishermen also, who are very well acquainted with the existing dangers, declared that they knew of no such rock.

The **BAY** of **BANTAM** is about 8 miles East and West, and 6 miles North and South, and contains one large and several small islands, but no

hidden dangers, consequently there is no difficulty in navigating it. *Paniang* or *Panjang*, the name of the large island, is 2 miles in diameter, and lies in the western part of the bay. The island is bold to approach on all sides, except off the South point; the passage on the West side of Paniang is also navigable, and is $1\frac{1}{2}$ mile wide, and has variable depths from 5 to 9 fathoms. South by West from its S.W. point a small rock lies at a cable's length off, with 6 ft. water. S.E. of Paniang, and very near it, there are two small islands, the reefs from which project to the southward half a mile, and consequently ought not to be approached within that distance. W.N.W. from the North side of Paniang, close under the Java shore, there are two small islands, of which the largest is called *Pulo Kalie*; and more toward St. Nicholas Point, $1\frac{1}{4}$ mile E. by S. from it, lies a third island, called *Saliera*, sometimes called *Robben Island*, and in old charts *Notendop*, between which and the two former may be found the place called *Pangorian*. S.W. of Paniang, in Bantam Bay, there are three small islands, under the Java shore, the northernmost of which may be approached very near, there being at a distance of 2 or 3 cables' lengths 4 and $4\frac{3}{4}$ fathoms at low water, and this same depth will be found near the two southernmost islands at the distance of 5 or 6 cables' lengths, shoaling to $3\frac{1}{2}$ and 2 fathoms when approaching them. South of Paniang, 2 or $2\frac{1}{2}$ miles distant, lies a group of islands, called *Koebor*, *Karang-Padang*, *Lima-jamboe*, and *Lima-klappa*, in old charts called the *Dutch Churchyard*. These islands are surrounded by reefs of 1 and 2 cables' lengths in extent; and between them, as well as West from them, and close in-shore, there are several coral banks, for which reason it is advisable, when entering the bay by the West channel, and having passed Paniang, to steer about S.E. in 7, 5, and $4\frac{1}{2}$ fathoms, along the North side of the northernmost island of this group, to the anchorage. Eastward of Paniang there are two islands, called *Mujang Besar* and *Mujang Ketjil* (or *Pamoejang*, or *Madu*), with a free passage on both sides; but that between these islands and Paniang is preferable, having regular depths from 9 to 5 fathoms, and shoaling towards the anchorage to 4 fathoms. Both the *Mujang* Islands may be approached very near, being clear of danger; and when passing to the eastward of them, the best way is to keep closer to them than to the Java shore, within a mile of which, in some places, there are but 3 fathoms at low water, while in the other channels from $3\frac{1}{4}$ to 5 fathoms will be found.

BANTAM, once the native emporium of these seas, has been reduced from its former importance to an insignificant place. It is now an open port for exports only. The Dutch Government, gradually increasing in their power and authority over the province whose name it bears, finally deposed the last of its kings in 1843, and banished him to Surabaya.

The anchorage for large ships is W.S.W. or S.W. from *Mujang Ketjil*,

and South from the East point of Paniang in $3\frac{3}{4}$ to $4\frac{1}{4}$ fathoms depth at low water, and small vessels will find a good road in 3 fathoms, a mile distant from the beach, and half a mile East of Lima-klappa Island. Very near the shore are the two *Dua Islands*, with the depth of 2 or 3 fathoms near them. The flagstaff of the fort is in $6^{\circ} 1' 39''$ S., and $106^{\circ} 8' 48''$ E., according to the trigonometric survey of Lieutenant Staring, in 1841. The mouth of the river is closed by a mud-bank, upon which there are 2 fathoms water at the distance of a mile, and 1 fathom at the distance of 2 or 3 cables' lengths from it. In a S.S.W. direction from the centre of the bay stands the conspicuous hill of *Pinang*, or *Mount Bantam*, which is a good mark for vessels entering the bay. The mean rise and fall of tide is 2 or 3 ft., and at springs 5 ft., but with neap tides no rise is perceptible.

PONTANG POINT, forming the East side of Bantam Bay, is bluff, but a reef projects from it $1\frac{1}{4}$ mile. This reef, which has been represented in former charts much too large, is steep-to, as the depths decrease speedily from 8 and 9 to 3, $1\frac{1}{2}$, and 1 fathom, and stretches farthest in a N. by E. direction from Pontang Point, where the limit of 3 fathoms lies about East from the North point of Paniang Island. When passing along this point it is advisable not to come nearer than 12 or 11 fathoms, before the East point of Babi Island is well to the westward of N. by W. $\frac{1}{2}$ W. The northernmost point of the reef of Pontang lies 3 miles N.E. by E. from the point itself, and S. $\frac{3}{4}$ E. from the East point of Babi.

Between Pontang Point and Kaik Point the coast forms a bight, and in the middle of this bight are situated the village and the river of *Tanara*, from whence a reef with a tongue, projects 3 miles off. Outside of this tongue the depths of 2 and 3 fathoms increase speedily to 7 fathoms and more; and the northernmost point of the tongue, in 3 fathoms, at low water, bears E. $\frac{3}{4}$ S. from Pontang Point, and W. $\frac{1}{4}$ S. from Menscheneter Island. In this bight, close in-shore, lies the small island of *Tiankier*, in a N.N.E. direction, from which, at half or 1 mile distance, there are two coral banks above water.

MENSCHEN-ETER ISLAND (Man-eater, or Cannibal) is 3 miles northward of Tanjong Kaik, and on the West side of the reef which projects from it. The island is low, covered with trees, and little more than one-third of a mile in diameter. It is surrounded by a narrow reef which is very steep-to, and between it and the end of the reef, there is a very narrow channel, fit for proas, with soundings from 4 to 11 fathoms.

A *lighthouse* is proposed on Menscheneter Island. It will show a flashing light, visible 16 miles off.

Menscheneter Reef projects North of Kaik Point, and its northern edge consists of a steep sand-bank with rocky patches, called by the natives *Karang Walla*. Off the North end of the reef, in 5 fathoms water, and only 2 cables North of a depth of 2 fathoms, is placed a *white* buoy, surmounted by a ball,

N.E. by E. $\frac{1}{4}$ E., 7 cables from the North end of Menscheneter Island, and N. $\frac{1}{2}$ W. $3\frac{1}{2}$ miles from the extremity of Kaik Point. Vessels should keep well outside the position of this buoy at night, as the depths decrease so suddenly from 7 and 5 fathoms.

Cheribon Rock, mentioned on page 672, is now placed on the charts $4\frac{1}{2}$ miles from the East end of Babie Island.

Struisvogel, or Ostrich Bank, consists of five different coral rocks, stretching North and South about a mile, and East and West a little more than half a mile; on the shoalest place there are 2 fathoms at low water, but close to the bank 13 and 17 fathoms; and therefore it should be approached with great caution. It bears N.W. $\frac{3}{4}$ N. from the middle of Menscheneter, and S. $\frac{1}{2}$ W. from the West point of Great Tidong, the westernmost of the Hoorn Islands. A white Herbert's buoy, surmounted by a *globe*, is placed on Karang-Poerak, the North end of the reef; and an *iron beacon*, with a *cone*, stands on Karang-Bezoar, the South end of the bank.

Tangara Rock rises suddenly out of 13 and 14 fathoms, mud, having upon its shoalest spot, 3 fathoms, a *beacon* with a *triangle*, bearing N. $\frac{7}{8}$ E. from the middle of Menscheneter, and W.N.W. $\frac{2}{3}$ W. from the middle of Great Kombuis. Halfway between Struisvogel and Tangara, or $1\frac{1}{2}$ mile N.W. $\frac{1}{4}$ W. from the latter, there is another small coral rock, called the *Laut*; the least depth upon it is $3\frac{3}{4}$ fathoms at low water, and close to it from 12 to 17 fathoms, soft ground.

The CHANNELS which lead towards Batavia from the westward are two in number, the *Inner Westerly Channel* (het Westelijk Binnen-Vaarwater), and the *Outer Westerly Channel* (het Westelijk Buiten-Vaarwater).

The INNER CHANNEL, which appears to be most used, passes between the North end of Menscheneter Island and reef and the Kombuis Islands, then between Middelburg Island and the Ontong Java Reef, and westward of Onrust and Kuiper Island.

The OUTER CHANNEL runs to the northward of the Kombuis, Middelburg, and Amsterdam Islands, and then between Rotterdam and Haarlem, and afterwards between the white buoy on Rynland and the black buoys on Neptunus, Pas-op, and Pipa Reefs.

The INNER or Dutch Channel may, with a good look-out, be considered as free from dangers. To proceed through it, a ship should pass between Menscheneter Island and the Great Kombuis, due attention being paid to Struisvogel, Laut, and Tongara Rock, and not to borrow too much on the Java shore toward the buoy off Menscheneter Reef. A good berth should also be given to the Great Kombuis, as *Pedynab Reefs* project to a considerable distance from its western point. Upon the western point of these reefs is a *black buoy*, with a *ball*, from which the South point of Great Kombuis bears S.E. by E. $\frac{3}{4}$ E., and its N.W. point E.N.E. $\frac{1}{2}$ E., about a mile distant. Between this reef and that of the Menscheneter the channel is, in its narrow-

est part, 2 miles wide, with depths from 8 to 12 fathoms. Between Kaik Point and Ontong Reef there is a bight, in which the depths decrease regularly towards the Java shore, except near a rocky shoal off Serang Point, stretching East and West 1 mile, and having in some places $2\frac{1}{4}$ and 2 fathoms water; this shoal bears South from Groote (Great) Kombuis, E. by N. from Kaik Point, and S.E. by E. from Menscheneter Island, the depths increasing speedily toward the offing to 7 and 9 fathoms.

Loembing Rock.—Between the Great and Little Kombuis lies the dangerous *Midden* or *Loembong Klip*, a rock only a ship's length in extent, and carrying only $2\frac{1}{4}$ fathoms at low water. On the middle of it stands a *black* beacon, with a *cone*, bearing W.S.W. from the South point of Little Kombuis, and S.E. by E. $\frac{3}{8}$ E. from the South point of Great Kombuis. To the southward, a little more than a mile from Kleine (Little) Kombuis, there is *Tiga Shoal*, with $3\frac{1}{2}$ fathoms at low water; this is marked by a *black* buoy, surmounted by a ball, and from which the North point of Middelburg bears E. $\frac{1}{2}$ S.

Meinderts, Manders, or Mynder Shoal, is $1\frac{1}{2}$ cable's length in diameter, and has 2 fathoms depth upon its shoalest part. It is marked on its North and South sides by two *black* buoys, surmounted by *globes*. The northern of these bears S.E. $\frac{1}{3}$ E., 2 miles from the East end of Little Kombuis, and W. $\frac{3}{4}$ N. from the North side of Middelburg Island. S.E. of Mynder Shoal lies another small but dangerous shoal in the common track, discovered in 1840 by Lieutenant Staring, D.R.N. This shoal, called *Tanna Kenappan*, or *Ketapang*, has $2\frac{1}{2}$ fathoms on it at low water, and close around it 6 fathoms, which quickly increases to 7 and 9 fathoms. A *black* buoy, with a *ball*, has been placed on this shoal, from which the beacon of Ontong Reef bears S.E. by E. $\frac{3}{8}$ E., distant a little more than a mile; the South point of Amsterdam, just opening clear of the South point of Middleburg Island, E. $\frac{1}{2}$ S.; and the North point of Middleburg E.N.E. $\frac{1}{3}$ E. Besides this shoal, there are some others to the westward of Middleburg, but none of them in the common track of ships. Upon two of them, however, there are *beacons*. A ship beating up along the South side of the above-mentioned dangers should consider it as a fairway mark, not to bring the South point of Middleburg Island to the southward of E. $\frac{1}{4}$ N., and to keep the South point of Amsterdam always well open South of Middleburg.

The passage between the beacons on Middleburg and Ontong Reef is very narrow (not quite half a mile), in 8 or 10 fathoms water. The reef which borders the South coast of this island is very narrow, and carries a beacon, with a *cone* at its extreme end.

MIDDLEBURG ISLAND, 2 miles N. by E. from Ontong Java, forms the North side of the Inner Channel. It is surrounded by a reef, on the S.E. point of which is a *black* beacon, with *cone*; and $2\frac{1}{2}$ cables westward of the beacon is a black buoy, surmounted by a ball, on the South side of the shoals.

A red light is *proposed* to be established on the S.E. extreme of Middleburg Island, as it is the turning point into the Batavia Roads.

Amsterdam Island, to the eastward of it, is also surrounded by a reef, quite steep-to, but having a narrow 9-fathom channel between it and Middleburg.

BATAVIA.

The capital of the Dutch East India Possessions was first built on the low shore of the bay, called the *Reede van Batavia*, when that nation established itself in the East. In 1610 a fort was built and named Batavia, on the site of the present one, but at that time it stood on the edge of the sea, which was deep nearly up to its walls. The town was founded in 1619, on the ruins of the native one of Jacatra, and the Dutch, true to their home instincts, built their streets on the sea level, with straggling canals intersecting them. This arrangement, convenient and good in Holland, was most pestiferous within the tropics, and the place, up to recent times, was proverbial for unhealthiness.

In 1699 a series of earthquakes brought down a vast quantity of earth, which blocked up the previous channels, and obstructed the two piers which had been carried out along the course of the river. A large bank was formed off this entrance, and these piers were gradually extended as the land subsequently increased with the drifts brought on to it by the prevalent currents.

In 1753 the coast line had advanced to one-third of a mile from the walls of the Kasteel or Fort, and at 90 years later the shore line was a mile seaward of the fort. At present the piers are carried seaward $1\frac{3}{4}$ mile from the shore line at the time of the first establishment of the fort. The pestiferous canals were filled up in 1809—1817 by Marshal Daendels, under the vigorous administration of the French rule.

The population of Batavia, as ascertained by the first correct census by the British Government in 1814, was 47,217. Twenty years later it had risen to 118,000, and in 1850 it was ascertained to be 348,325—a marvellous increase. It is now about 650,000.

The railway between Batavia and Buitenzorg, about 30 miles in length, was opened in Jan., 1873. It is a great boon to the inhabitants, enabling them to easily reach the high and healthy land of the interior. The goods traffic is gradually increasing, quantities of tea, rice, coffee, and other productions being transported from the interior to Batavia.

Batavia is connected with all parts of the island by *electric telegraph*, and also with all parts of the world. Messages for Europe and China are sent by way of Singapore. A cable is laid to Padang, on the West coast of Su-

matra, and another from Banjoewangie, on the South coast of Java, to Port Darwin, thus bringing the Australian lines into the system. The rates, in 1874, were, to Europe £6 7s., and to Singapore £1 3s. For Australia the rates were, in, 1872, to Port Darwin, 20 words, 48 florins 75 cents; to Melbourne 50 florins, and to Sydney 52 florins.

As may be supposed, the low fore shore affords no facilities for commerce, and it is by the piers and the proas that come out to the shipping in the roads that commerce is carried on. There is no private establishment for repairing ships, and only vessels of very small tonnage can be taken into the river and careened. A project for the erection of docks, &c., was afoot in 1870, but since that time nothing has been done. The only place for repairs in Java is at Sourabaya. The naval establishment is at the island of Onrust, $5\frac{3}{4}$ miles north-westward from the pier-heads.

The **BAY of BATAVIA**, between the point, Ontong Java on the West, and Krawang Point on the East, is 21 miles in width, and between the lines joining those points it is 8 miles in depth. The bottom consists of soft mud, but in the vicinity of the shoals, rock. The soundings are from 10 to 4 fathoms, regularly shoaling towards the shore; and generally throughout the bay at a mile distant from the beach there will be found 3 fathoms. Except in a few places, the road is sheltered by a chain of islands, by which ships are always protected against a dangerous swell setting in. The road may be considered as very safe, for although ships roll considerably in the strength of the western monsoon, and are consequently compelled to strike their top-gallant masts and yards, no danger is to be apprehended of driving, from the excellence of the holding ground.

Most of the islands and shoals lying near the road consist of coral with white sand above water, and are covered with various kinds of trees; they are steep-to, and it would seem that some of them increase in extent, so that it will be necessary to re-examine the depths from time to time; and the more prudence is recommended to those who try to pass over shoals, on which but just sufficient depth is indicated. The coast of Java is generally flat, but 30 miles inland from Batavia the Goenong Gedeh, or the Blue Mountains, rise to a considerable height. Lieut. Melvill Van Carnbee found, in 1841, by angular measurement, the height of these mountains above the surface of the sea, viz.: Pangerango, 9,954 ft.; Salak, 7,322 ft.; Karang, 6,014 ft. In the western monsoon their peaks may be seen from the road in the morning, but are seldom visible during the eastern monsoon. From the common anchorage near Rynland Shoal, the highest peak of these mountains, called Pangerango, bears S. by E. $\frac{1}{4}$ E., the highest or easternmost peak of Salak S. $\frac{1}{2}$ W., and Mount Karang, in the Bantam residency, W. by S. According to the trigonometrical survey these peaks are in lat. $6^{\circ} 45' 15''$, $6^{\circ} 42'$, and $6^{\circ} 15' 45''$ S., and in long. $107^{\circ} 1' 45''$, $106^{\circ} 47'$, and $106^{\circ} 6' 45''$ E.

Beacons.—In 1855-6 a system of beaconage was adopted by the Marine Commission for Batavia Roads, by which the limits of the three principal channels leading towards Batavia were clearly marked. *Two* descriptions of beacons only (both painted *black*) were used; the one surmounted by balls or globes, and the other by cones. The beacons with *globes* to be left to *starboard*, and those with *cones* to *port*, on entering. The situation and use of these beacons will be described hereafter in their respective places. With these, and the new lighthouse on the pier-head at Batavia there will be no difficulty in entering. In recent years *buoys* on the starboard side of channels are generally painted *white*.

ONTONG-JAVA REEF which forms the western limit of Batavia Bay, is steep at its northern end, and consists there of a hard sand bank with some rocks, with only half a fathom at low water; the beacon with a globe, which stands upon its northern edge 20 ft. above high water, ought not to be approached nearer than in 8 or 9 fathoms. At the eastern side, abreast of the island Schiedam, Ontong Reef is more sloping, and may be more nearly approached if the lead be kept briskly going. A ship, after passing Middleburg, should steer S.E., S.E. by S., and S.S.E., edging away for Onrust Island. *Kelor Rock*, or the *Steen* (Stone) of Onrust, is the westernmost of several small coral rocks which lie off the North point of Onrust; they are small and steep-to; and on the shoalest place there are $2\frac{1}{2}$ fathoms near the beacon with a *cone*, which stands on its north-western extremity, about 4 cables' lengths N.W. from Onrust, and which must be passed on its western side. The *Mathilda Rock* lies less than half a mile W. $\frac{1}{2}$ N. from the former, and carries a *beacon* with a *globe*, on its N.E. side in 3 fathoms depth, but at low water there is no more than 2 fathoms upon its shoalest spot. The channel runs betwixt these two last-mentioned rocks, and it is advisable not to pass to the eastward of Kelor Rock, nor between the islands of Onrust, Kerkhof, and Purmerend, on account of the numerous shoals in that space. If a vessel should be working between Schiedam and Onrust, she will have to look out for a small rock, discovered, in 1846, by Lieutenant Tengnagel, D.R.N., from whence Onrust bears South, easterly, and Mathilda Rock beacon S.W. $\frac{1}{4}$ W. It carries 3 fathoms at low water, but there are $6\frac{1}{2}$ fathoms all round it and close to.

ONRUST, a small islet, not more than 400 yards in length, is the arsenal of Batavia, and has every convenience for refitting a ship. There is 24 ft. alongside the jetty, and the place is excellently managed.

There is a *dry dock* 400 ft. long, at which, previous to 1866, vessels could be repaired, but since that date only in very urgent cases are merchant vessels admitted.

The flagstaff upon the island of Onrust is in $6^{\circ} 2' 20''$ S., and $4^{\circ} 27'$ W., from the Time-ball at Batavia, or in $106^{\circ} 43' 40\cdot5''$ E of Greenwich.

Kuiper Island is a quarter of a mile South of Onrust. It is bold-to on the

S.W., but a reef surrounds it on the other sides. On the north-western point of the reef a *black* beacon with *cone* marks the North side of the Inner Channel. The powder magazines for merchant shipping are on Kuiper Island.

When past the Kelor, or Stone of Onrust, steer to the westward of Onrust and Kuiper Islands, giving a proper berth to a reef which projects 1 or $1\frac{1}{2}$ cable's length from the N.W. side of Kuiper, and of which the limits are indicated by the *beacon* with a *cone*. The S.W. side of Kuiper Island may be approached without danger; but do not keep too much to the Java side, on account of a small rock, called *Karang Kuiper*, which bears S.S.W. half a mile from the island, with $2\frac{3}{4}$ fathoms on its shoalest part, at low water. It has a *white buoy* with *globe* on its North side, and marks the starboard side of the Inner Channel. A little way farther to the S.S.W. from this beacon there is a *sandbank* with 1 fathom water upon it.

Soon after having rounded Kuiper steer S.E. by E. towards the lighthouse on the West pier in Batavia Road, and the white buoys with balls on *Reigersdaal* and *Rynland* Shoals will be seen ahead; pass between them in 6 to $7\frac{1}{2}$ fathoms right toward the shipping in the road, and anchor in 6 or 5 fathoms, mud, South from Rynland buoy. The western passage between Reigersdaal and the main is not to be recommended, on account of two shoals bearing S.W. from it, upon one of which there are $3\frac{1}{4}$ fathoms water.

The OUTER CHANNEL.—That which is called the Outer Channel leads along the North side of the Struisvogel Rocks and the Great and Little Kombuis, as a ship coming from the westward may pass on either side of these. Between the Struisvogel Rocks and the Hoorn Islands, it is 5 miles wide; and these islands may be approached from the southward to within half a mile, as their reefs do not reach farther off than $1\frac{1}{2}$ cable's length. To the westward, however, there is a rock called *Karbouw*, about a mile W. $\frac{2}{3}$ N. from the West point of *Tidong*, the westernmost of the Hoorn Islands, on which there is 1 fathom at low water. A leading mark to pass to the northward of Struisvogel Shoal, and of the Laut and Tangara Rocks, is to keep the Little Kombuis well open to the northward of the Great Kombuis. A ship may pass also to the southward of the Struisvogel between it and Tangara Rock beacon, but in this case the latter must be approached within 1 mile distance, on account of the Laut Rock, before described. The passage between Tongara Rock and Great Kombuis is also safe, only taking care to remain full a mile from the West point of that island, on account of the small coral rocks which project therefrom.

The HOORN ISLANDS (or *Het Wapen van Hoorn Eilanden*) are four in number, stretching W. by N. and E. by S. 4 miles; the two westernmost are called the Great and Little Tidong, and the two easternmost, bearing North and South of each other, are called Pajang Islands. Each of these groups is surrounded by reefs, which fall partly dry at low water, and which are

very steep-to at the outside. The reef round the Tidongs projects but very little to the southward; to the northward about $1\frac{1}{2}$ cable's length, and to the eastward about 3 cables' lengths, while that which surrounds the Pajangs projects North and South about 1, and East and West 2 or 3 cables' lengths. The soundings to the southward of the Hoorn Islands are, very near them, 30 and 40 fathoms, and, in the channel between them and the Angeneita Islands, which is full 2 miles wide, 35 to 50 fathoms.

The Angeneita Islands are a little more than 4 miles North of the Kombuis Islands, and are all very small islands, *Pulo Parrie* being the largest and easternmost; they are connected to each other by reefs, partly visible above water and extending in some places three-quarters of a mile. One mile East from *Pulo Parrie* are two small shoals very near each other, called the Jonks, one of which shows above water, and upon the other there are 2 fathoms at low water. The fairway of the Outer Channel, between the Angeneita and the Kombuis Islands, is close along the North side of the latter, in order to avoid five heads of rock which lie on the North side of the channel. The southernmost and easternmost of these is the *Serassa Rock*, marked by a *black buoy* on its western side, from which Little Kombuis Island bears S.S.W. $2\frac{3}{4}$ miles; *Pangan Rock*, of $3\frac{1}{2}$ fathoms, W. by N. half a mile; *Tanda Po Lakki Rock*, of $4\frac{1}{2}$ fathoms, West three-quarters of a mile; *Panyangdi Laut Rocks*, a dangerous patch one-third of a mile in extent, N. by W. 1 mile; and about midway between the buoy and the East end is *Parrie Island*.

Being so far advanced that Little Kombuis bears S.S.W. and *Serassa* buoy North, steer N.E. or N.E. by E. till *Dapoer Islet* bears E. by S., and then make right for it, because a straight course from the Little Kombuis toward *Dapoer* would lead among the coral rocks which lie North and N.W. from Middleburg, on some of which there are not more than $2\frac{1}{2}$ to 3 fathoms at low water. The northernmost of these rocks lies $2\frac{1}{2}$ cables northward of a line joining the Little Kombuis and *Dapoer*. It is marked by a large *white* Herbert's buoy, from which *Dapoer Island* bears E. $\frac{1}{2}$ N., distant $2\frac{1}{4}$ miles; Little Kombuis W. by S. $\frac{1}{2}$ S., $3\frac{1}{2}$ miles; Middleburg Island, East end S. by E. $\frac{1}{4}$ E., $2\frac{3}{4}$ miles; and *Serassa Rock* buoy N.W. by W. $\frac{1}{4}$ W. $3\frac{1}{4}$ miles.

A ship coming from the Little Kombuis may also pass between the shoals N.W. of Middleburg, and along the North side of this island as well as of Amsterdam; but she ought to have a steady breeze, for fear of being taken aback between the reefs, and it will always be prudent to have a boat ahead sounding. If a boat cannot be spared, and if she has a leading wind through this channel, she will avoid the shoals by steering (as soon as Little Kombuis bears S.S.W.) a S. by E. course until Little Kombuis bears W. by N., and is in line with the South end of Great Kombuis; keeping it

so will lead over a $4\frac{3}{4}$ fathom patch, lying N.W. by N. $1\frac{1}{4}$ mile from the N.W. end of Middleburg Island, and $3\frac{1}{2}$ cables northward of a $3\frac{3}{4}$ -fathom patch, which lies N $\frac{1}{2}$ E. 4 cables from the N.E. end of Middleburg Island.

From a position a mile N.E. of Amsterdam a south-easterly course may be steered for the Middle Channel.

Dapoer Island is surrounded by a reef, and 2 cables' lengths N.E. and S. by E. from it lie two separate dangerous coral banks, the former extending to a distance of 4 cables from the island, and the latter a $2\frac{3}{4}$ -fathom patch, at the distance of $3\frac{1}{2}$ cables—for which reason Dapoer should not be approached within a mile distance on these bearings.

A *lighthouse* has been proposed on *Edam Island*, but is not likely to be established. North of Edam, at three-quarters of a mile distance, there is a coral reef of considerable extent, with not more than half a fathom of water.

Monnikendam Reef lies E. by S. from Haarlem Islet, and N. by W. from Hoorn; it falls partly dry at low water, but has in some places 2 and 3 fathoms. A *white* Herbert's buoy marks the North side of the reef, and superseded the beacon existing here previous to 1872.

Middle Channel.—To take this channel, the vessel should not borrow too much on the eastern shore of Amsterdam, as a reef projects from that side 2 cables' lengths. Two and a half miles further, mind the small rock, called Obie, marked by a *white* buoy surmounted by a *globe*, lying half a mile East of Rotterdam. The channel leads to the eastward of this rock, between it and *Ayer Bank*, which has $2\frac{1}{2}$ fathoms water upon it at low water, and is indicated by a *black buoy* with ball, which bears West from the North point of Hoorn Island at $2\frac{1}{2}$ cables' lengths distance. Between Rotterdam and Kerkhof there are several small coral rocks with $1\frac{1}{4}$ to $3\frac{3}{4}$ fathoms upon them, for which reason a ship should not borrow too much towards that side of this channel. The easternmost of these rocks bears N.N.E. from Kerkhof, S.E. from Rotterdam, and S. by E. from Obie buoy. The *Wapen of Purmerend*, or *Ialan Rock*, is about 2 cables' lengths in extent, consisting of large rocks with 2 and 3 feet water upon them, and close to 8 fathoms; it has a white buoy with a *ball* at its N.E. point, which bears E. $\frac{1}{2}$ S. from Purmerend, and S. $\frac{3}{4}$ W. from Hoorn.

Saket Reef bears S. by E. half a mile distant from Purmerend Island; it is 2 cables in length, and carries 2 fathoms water on its shoalest part at low water, as well as a *beacon* with a *cone* on its S.W. point. There are two other reefs hereabout, one 2 cables' lengths to the East, and the other half a mile S.E. from Purmerend, upon each of which, at low water, there is but half a fathom patch.

The **EASTERN CHANNELS** leading to Batavia Road are very safe and convenient, and, like the western channels, the chief dangers are marked by beacons in the southern entrance. Those between the islands of Edam, Alkmaar, Enkhuizen, and Leiden, have soundings of 14, 12, 11, and 10

fathoms; the channel to the southward of Leiden is also safe, if attention is paid to the shoals which lie between it and the main, and to a small coral rock, $2\frac{1}{2}$ cables' lengths East of Leiden, upon which the Dutch ship *Amstel* struck in 1842. It is marked by a *black Herbert's buoy* surmounted by a *ball*. The rock was surveyed by Lieut M. L. Kool, D.R.N., who found it to be two ships' lengths in diameter, carrying $1\frac{1}{2}$ fathom, and speedily deepening to 3, 5, 7, and 9 fathoms. From the shoalest spot, the North point of Leiden was in one with the middle of Hoorn Island; the South point bore W. $\frac{3}{4}$ S., the West point of Edam, just behind the West point of Alkmaar, and the East point of Edam open to the eastward of Alkmaar. The rock is 218 yards from the reef round the island, and between them there is 7 fathoms depth.

Vader Smit Shoal.—The first shoal between Leiden and the Java shore is Vader Smit, a coral reef above water. It has a beacon and *globe* on its South point, which bears S. $\frac{3}{4}$ E. from Leiden, and N.W. $\frac{2}{3}$ N. from Priok Point. There is also a *white* Herbert buoy off its N.E. extremity. A depth of only 3 fathoms is found at half a mile West of the buoy, and the same distance N.W. of the beacon.

One mile East from Vader Smit, and S.E. by S. from Leiden, Lieutenant Eschauzier, D.R.N., discovered, in 1840, another rock, with $2\frac{1}{2}$ fathoms at low water. This rock was very dangerous to ships proceeding through this channel, and to avoid it they passed $1\frac{1}{2}$ or 2 miles to the eastward of Vader Smit, but it is now marked by a beacon with a *globe*. There is a depth of only $3\frac{3}{4}$ fathoms at 3 cables W.N.W. of the beacon. About a mile N.W. from Priok Point there are also two other patches of coral rocks, in 3 and $3\frac{1}{2}$ fathoms water. The best channel is to the southward of the beacons and the shoal East of Vader Smit, in $5\frac{1}{2}$ and 6 fathoms. The coast of Java, to the eastward of Priok Point, may be approached safely by the lead to 6 fathoms, as the soundings decrease regularly; though off Krawang Point it is better not to borrow nearer than 8 fathoms, as the depths decrease there very quickly to 3 fathoms.

Nierstuk is a rocky shoal of about 2 cables in length, usually covered by breakers, having 2 ft. depth at low water. It was very easily discovered by a discoloration of the water, or by the breakers which show with the least wind, but now it is marked by two white buoys 4 cables apart, one off its North and the other off its South end. It bears W.S.W. $\frac{1}{2}$ W. from Vader Smit, and about S.S.W. from Leiden. The passage between it and Vader Smit is more than a mile wide, with 6 and 7 fathoms depth. The passage between Nierstuk and the shoals of Neptunus, and Pas-op, is more than half a mile wide, with 6 and 7 fathoms depth.

The Neptunus consists of large rocks with 2 feet water; it is 1 or $1\frac{1}{2}$ cable's length in diameter, and is marked by a *black* buoy surmounted by a *ball* off its N.W. extreme, and by a *black* buoy off its S.E. end.

Pas-op Shoal is very small, with 14 feet on its shoalest place, and 5 and 6

fathoms close to it; it bears E. $\frac{1}{2}$ N. a full mile from Rynland Shoal. It is marked by a *black buoy* surmounted by a *ball* on its North side. This buoy lies $4\frac{1}{2}$ cables S.S.W. of the buoy on the N.W. extreme of Neptunus Reef, a depth of 6 fathoms' water being found between them.

Karang Pipa is marked on its western side by a *black buoy* surmounted by a *ball* which lies S.S.W. $\frac{1}{2}$ W. a quarter of a mile from the buoy on Pas-op and a mile E. $\frac{3}{4}$ S. from the Rynland Shoal buoy. It is a small coral rock with $2\frac{1}{2}$ fathoms at low water, and close around 5, 6, and 7 fathoms.

The three buoys surmounted by balls on the western side of Neptunus, Pas-op, and Pipa Reef are nearly in line N. by E. $\frac{3}{4}$ E. from the lighthouse on the western pier at the distances of $1\frac{3}{4}$, 2, and $2\frac{1}{2}$ miles.

Rynland Shoal is very small, and has 15 feet water on its shoalest part. It is marked on its North side by a *white buoy* surmounted by a *ball*, bearing N. by W. $\frac{3}{4}$ W., $1\frac{1}{2}$ mile distant from the end of the pier of Batavia River. The channel between Rynland and Pas-op Shoals is a mile wide, and 6 to $8\frac{1}{2}$ fathoms in depth.

BATAVIA.—The piers which confine the river run in a N. by W. direction from the observatory and time-ball, toward the Rynland Shoal. They extend for a mile beyond the line of shore into 18 feet water.

A LIGHTHOUSE, showing a bright *fixed light*, elevated 54 feet, stands on the West pier 4 cables lengths from the head, and is shown from a lens apparatus of the 4th order, and may be seen at more than 14 miles off according to the elevation. A small lamp light is shown on the pier-head.

The best positions for anchorage by night are with this light between S. $\frac{3}{4}$ W. and S. $\frac{3}{4}$ E. when to the southward of the Rynland, Pipa, and Nierstuk Shoals. Entering the roads by the western channel, and having passed the beacon on Karang Kuiper, steer S.E. until the light bears South, and then anchor. Two white buoys, in $4\frac{3}{4}$ fathoms depth, lie S. by E. and S. by W. of Rynland Shoal, and mark the South limit of the anchorage.

Batavia Observatory, where a time ball has been exhibited since 1839, stands East, 3133 yards from the boathouse near the river, or a little more than a mile and a half from the lighthouse on the pier-head. The geographic position of the time ball is in lat. $6^{\circ} 8' S.$, and the assumed longitude $106^{\circ} 48' 7\frac{1}{2}'' E.$, $6^h 51^m 58^s$ in time.

The Time Ball is hoisted every day at 5 minutes before noon, Batavia mean time, half-way up the pole; at 2 minutes to mean noon it is hoisted to the top, and precisely at Batavia mean noon it falls. For those ships that wish to rate their chronometers according to Greenwich mean time, the moment of 6 o'clock a.m., Greenwich mean time, is indicated in the same way; the ball being hoisted half-way up at $46^m 58^s$ p.m., Batavia mean time; and at $49^m 58^s$ to the top; and exactly at $51^m 58^s$ p.m., Batavia time, which corresponds to 6 o'clock a.m. Greenwich time, it falls.

The usual place for large ships to anchor is in 5 or 6 fathoms on a mud

bottom, about a mile distant from the pier-head, and between S.S.W. and S.E. from Rynland Shoal. They seldom moor, as the anchors generally bury themselves in the soft mud, for which reason it is advisable to sight the anchor sometimes during a long stay. Small vessels may anchor nearer to the pier-head, in 4 or $3\frac{1}{2}$ fathoms. There used to be a bar just outside of the middle mouth of the river, with only 2 or 3 feet depth at low water upon it; but since the pier was lengthened, and the river shut off by a dike to turn the current, this bank has disappeared. In the western monsoon there is sometimes such a heavy swell which breaks at the mouth of the river, that proas are unable to get out, and ships' loats may be exposed to great danger sent on shore after a blue warning flag is displayed at the boathouse.

Tides.—By accurate observations, made in 1839 at Onrust, it seems that the tides and the rise and fall of water are not subject to fixed rules. In the eastern monsoon, it appeared to be high water there in the evening; and in the western monsoon in the forenoon; the time of high water at full and change being generally 10 o'clock p.m. in the eastern monsoon, and at 10 a.m. in the western. The mean rise and fall was 2 feet, and the maximum and minimum 4 feet, and scarcely an inch.

Whenever the weather is so boisterous, especially during the western monsoon, that any attempt to land at the jetty, at Batavia, or along the shore, would be attended with danger, a blue flag will be hoisted at the Mizzen of the Guard Ship, and similar flags will also be shown at the Observatory, as well as at the palace of Wettereden. The signal "There is too much surf to land" will likewise be displayed at the Observatory.

The variation of the compass is at present $0^{\circ} 45'$ E. In 1847 it was $1^{\circ} 45'$ E., as computed from a great number of observations on board H.N.M. ships; thus showing that when compared with former years, it has changed from West to East, and is again decreasing in the latter direction. The mean height of the mercury in the barometer is 29.67 inches. The influence of the weather upon the barometer is very small, it being seldom raised by continued dry weather, or depressed by a boisterous moist temperature, more than from 1 to 3 lines above or below the mean. The mean temperature in the morning and evening is from 70° to 74° , and at noon from 84° to 86° Fahrenheit; although it occasionally rises to 90° or 95° . Batavia Road is rendered unhealthy by the pernicious influence of the noxious vapours generated along the marshy coast and the shoals at low water, which are uncovered, and it seems to be chiefly in the shifting months of the monsoons that the Batavia fever is most frequent. Ships, therefore, intending to make a long stay should not anchor too near the shore.

There is at Batavia an excellent establishment for purifying the water for the shipping in the road; this water is conveyed on board, at fixed and moderate prices, in whole or half leaguers, or in proas fitted with tanks. Artesian wells have also been recently sunk (1875).

Krawang Point is 16 miles N.E. by E. from the Batavia lighthouse. The shore bank around the point stretches off for 2 or 3 miles, and therefore it should not be made too free with. There are no detached dangers in the eastern portion of Batavia Bay, and therefore a vessel may safely anchor in any part of it.

The islands and dangers which lie in the Java Sea to the northward of those which lie across the mouth of Batavia Bay, will be described presently.

The **NORTH COAST** of **JAVA** is in general flat, covered with large trees to the beach, and a little way up the country there are several high peaks, which may serve as sea guides. Some of these are 10,000 and 11,000 ft. high, and their positions accurately laid down in the charts. It occurs often that they, especially in the eastern monsoon, are concealed by clouds or by the hazy state of the atmosphere, but in the western monsoon the highest of them may be seen more than 26 leagues. In October, 1842, Lieut. Melvill van Carnbee saw the Pangerango, or Blue Mountains, at the distance of 37 leagues. The soundings along the coast are regular, so that in most places the land may be approached to 8, 7, 6, and 5 fathoms, mud; but, in some places extensive shoals project from the shore; and there are a few dangerous rocks and shoals in the offing.

The **Eastern Monsoon** prevails along this coast while the sun is to the northward of the equator, and the western monsoon when the declination is South; their general tendency being towards that parallel where the sun is in the zenith. The former is in its greatest strength in the months of June, July, and August; and the western monsoon in December, January, and February. As in most intertropical countries, land and sea breezes will be found within a certain distance from the shore, and may be very advantageously employed in an adverse monsoon. These land and sea breezes, however, are not regular, as in the strength of the western monsoon the wind does not at all deviate from its common direction, and in the middle of the eastern monsoon seldom more than one or two points.

Ships passing between Batavia and Sourabaya and back must steer different courses in different seasons, in order to make a speedy passage; and although the rules prescribed here are not submitted as fixed laws, yet they should be followed as nearly as possible, according to circumstances.

Vessels going in the western monsoon from Batavia to Sourabaya ought to run out from the Rynland Shoal between N. and N.E., till Edam bears North. Then steer N.E. by E. 16 miles, and E.N.E. 20 miles, till in about $5^{\circ} 42' S.$, and $107^{\circ} 24' E.$, when they will be clear of the reefs of Sedarie; then steer East 36, and S.E. or S.E. by E. 28 miles, passing between the rock of Pama-noekan and Boompjes Islands, after which a direct course may be steered

for the point of Indramayoe. When they have verified their reckoning by one of these points the course will be East for 49 leagues, along the South side of Carimon Java Islands, till Mandeliké Island bears South; from thence steer S.E. by E. and E.S.E. to make Ouwer Point (in about long. 112° E.) care being requisite not to bring Mandeliké to the northward of West till clear of Taio Bank. From Ouwer Point the course is E. and E.S.E. along the shore, having a good mark in the Doodkists (coffins) to make Panka Point. In this monsoon it is of the highest importance, when past Mandeliké, not to keep too much in the offing, as the easterly currents will carry a ship speedily past Sourabaya Strait, in which case the hills upon the island Madura, called the False Doodkists, will be mistaken for those which lie near Panka Point. In such circumstances, a ship would have the greatest trouble to beat up against the westerly winds and contrary currents in order to fetch Sourabaya Strait, a case which has often happened.

Ships bound from Sourabaya to Batavia in the western monsoon have a difficult task to perform, when the wind blows with violence, and for a ship that sails indifferently it will be impossible.

It is always a safe rule to take advantage of every little veering of the wind which will give the most westing. Should it draw to the southward of West, work up with short tacks under the Java shore, to avoid the disadvantage of a high sea and easterly currents. If it comes to a gale with a high head sea, it would be advisable to bear up for one of the harbours, and wait a change in the weather, as in general such weather does not last long. Most of the roads along the North coast of Java are unsafe in this monsoon, such as those of Japara, Samarang, Pekalongan, Indramayoe, Tjassem, and Pamanoekan, being exposed to much sea, and some are difficult to enter. Cheribon Road affords good shelter from westerly winds; but in most instances it will be better to return and anchor behind Panka Point, for, if the wind comes to N.W. or N.N.W., a vessel might be much hampered by the Java shore, causing great trouble to get off, especially if in the Bay of Samarang. In the western monsoon, tolerable good shelter will also be found near or in Joana Road, or behind Cape Boegel and the Taio Bank.

Ships bound from Sourabaya to Batavia in the eastern monsoon should steer from Panka Point W.N.W. or W. by N. till past Mandeliké Island, and then about West from Indramayoe Point, which should be seen. From thence a westerly course for 8 or 9 leagues will carry them in sight of Pamanoekan Point, but not too far in the offing for fear of Pamanoekan Rock. When certain of having passed that rock, steer about N.N.W. till at least 8 miles to the northward of Sedarie Point, to avoid the Sedarie Reefs, and then try to get sight of the land near Krawang Point with a S.W. or W.S.W. course, after which make Edam Island, and passing between it and Krawang Point with a S.W. course, run into Batavia Road. When the ship has arrived off Sedarie Point, if becalmed there, seeing the land, mind the westerly current,

which might carry her much more to the westward than the reckoning would indicate, and might entangle her among the Nassau ledges and other dangers thereabout. H.N.M.S. Schrikverwekker, coming from the eastward to Batavia, was carried so far by the current in the night of the 17th of May, 1800, and was wrecked upon one of the reefs near Angenita Islands. And the Admiral Zoutman, Captain Heykop, which ship struck in March, 1839, upon a coral rock, bearing (by account) $16\frac{1}{2}$ miles N.N.W. $\frac{1}{4}$ W. from Krawang Point, and carrying 18 feet water. This rock seems to have been the Nassau Ledge. The captain remarks that long experience had taught him that if a ship be more than 7 or 8 leagues distant from this part of the coast, it is prudent to anchor, even in 25 fathoms, if the weather is not too threatening, as the lead is no proper guide in such a situation.

A vessel from Batavia to Sourabaya in the eastern monsoon ought to take every possible advantage of the land and sea breezes, and therefore should not stand too far into the offing. If she leaves Batavia Road in the evening, or in the night, and arrives abreast of Edam on its eastern side, a north-easterly course will carry her to about latitude $5^{\circ} 42'$, where she may expect the sea breeze. From thence she will get sight of the Points of Pamanoekan and Indramayoe with S.S.E., S.E., or E.S.E. courses, taking care to give a good berth either North or South to Pamanoekan Rock. Then let her try to get so much easting with the land wind that the next tack in-shore will allow her to stand along Cheribon Reef. When this succeeds, and on this tack Brebes Point, or Tegal, is made, the coast should not be approached from thence to Samarang, nearer than 10 miles, in order to avoid the Pemoelang and Korowelan Rocks, nor should she stand too far off on account of the Bappang Reef. If not bound to Samarang, when making long tacks off and the short boards in-shore, she will get sight of the Japara Mounts, and may try to gain so much easting as to weather with the sea breeze Mandeliké and Taio Bank. Take care, however, not to borrow too much on this bank, and therefore Mandeliké should not be brought to bear to the northward of West before Cape Boegel is distant 8 miles. From thence beat up with short tacks in the offing and long ones in-shore, along the coast toward Panka Point, in order to get sight of the Loodkist or Coffin Hills. In the night the small Mount Koekoesan, near the Coffins, is a good mark for bearing away towards Panka Point.

KRAWANG POINT, in $5^{\circ} 57' S.$, and $107^{\circ} 1' 7'' E.$, forms the N.E. boundary of Batavia Bay, as before mentioned. When bound to the eastward, pass this point at a distance of 4 miles in 15 fathoms; for though it may be approached to 2 miles in 10 fathoms, it is better kept at a greater distance, as to the eastward of this point the bank trends to the northward till it reaches an offing of nearly 3 miles.

Sedarie Reefs.—From Krawang Point steer E. by N. or E.N.E. to avoid the Reefs of Sedarie. The coast between Krawang and Sedarie Points

stretches about East and E. by S., forming two bights towards Sedarie Point, which is a low round projection. Its woody north-easternmost part is in $5^{\circ} 59\frac{1}{2}'$ S., and $107^{\circ} 24\frac{1}{4}'$ E., and about 4 miles to the eastward of the mouth of Sedarie River. Sedarie Reefs consist of some dry patches or shoals detached from the shore, with narrow channels between them. Upon the two northernmost of these patches $3\frac{1}{2}$ and $4\frac{1}{4}$ fathoms is the shoalest water, and altogether they extend 2 miles N.W. and S.E., and 1 mile across; and are composed of black sand with shells. The northernmost bank bears N.E. from Sedarie Point, 6 miles distant. The depths outside increase rapidly from 5 to 7 fathoms, and at the distance of 2 miles to the northward, to 10 fathoms, inside of which it is not advisable to pass; and there the low land of the point is just discernible. Upon the southernmost of these shoals, which consists of three small patches of sand with shells, near each other, the least water is $2\frac{1}{2}$ fathoms. Between the North and South patches there is a channel of 1 mile in breadth, lying N.W. and S.E., with 8 to 10 fathoms water, but decreasing to the eastward to 6 fathoms. Between the South patch and the main, a channel 1 mile wide and 4 fathoms deep, over mud, stretches 2 miles along the coast. It is best to pass to the northward of all these dangers.

Near the northernmost of these shoals, Lieutenant Escher took the following bearings: Mount Salak S.W. $\frac{1}{2}$ S., the Pangerango S.S.W. $\frac{1}{2}$ W., the Panimbang S. by W. $\frac{1}{3}$ W., the highest top of the Craggy Mountains S. $\frac{1}{2}$ W., the highest top of Tankobang Mountains, 6,427 feet, S. by E. $\frac{3}{4}$ E., the Tampomaas S.E. by S., and Cheribon Peak (just visible) S.E. From the outer edge of the Sedarie Reef the course is between S.E. and E.S.E. towards Pamanoekan Point, which lies in $6^{\circ} 12'$ S., and long. $107^{\circ} 49\frac{1}{2}'$ E., or $57^{\circ} 30'$ from Batavia. The shore may be approached to within 8 fathoms, and from 10 to 14 fathoms is a proper track in the night, in order to pass within the Pamanoekan Rock, on which the *Waerden Castle* was lost.

The **PAMANOEKAN ROCK** is very dangerous. Its position, and even its existence, was doubted, but numerous disasters hereabout showed that it certainly did lie somewhere in the vicinity. In the ancient sea atlas, by the celebrated J. Van-Keulen, the rock is marked nearly in its position and true character. It was surveyed in 1802 by Lieut. N. Doekes, and said by him to bear N.E. by N., a little easterly from Pamanoekan Point from 13 to 18 miles; the adjacent depth being 17 to 19 fathoms. According to his survey the rock is 109 yards in extent, with $2\frac{1}{2}$ fathoms water upon it, and Pamanoekan Point just visible, appearing as an island.

It has been many times sought for since without success. But on August 7th, 1848, the Netherlands barque *Celebes*, Capt. J. R. N. J. Biji, struck on it, and was fixed there for some time. Her draught was $15\frac{3}{4}$ feet English, and when aground Mount Tampomaas bore S. $\frac{3}{4}$ E., and Pamanoekan Point,

S.S.W. $\frac{1}{2}$ W. By a good chronometer observation the longitude was found as $107^{\circ} 50' 7''$ E., lat. $6^{\circ} 3'$ S. By these data it is only 10 miles from Pama-noekan Point, if the charts be correct. It is very small, as at less than half a ship's length all around the vessel, there was from 8 to 20 fathoms.

A *Fifteen-feet Patch* is marked on the charts at $9\frac{1}{2}$ miles eastward of Pama-noekan Rock, 20 miles N.W. by W. of Indromaya Point, and 19 miles W.S.W. of Rackit Island light.

Near Pama-noekan Point, about 2 miles distant W. $\frac{1}{2}$ S. from it and N.N.E. from the mouth of Tjassem River, good anchorage in the East monsoon may be taken in 4 fathoms water; but it is an open anchorage, and unsafe during the N.W. monsoon. From this anchorage the course of N.E. by E. leads clear of a reef which projects nearly to the distance of a mile from the point. Between the *Sadoelang Islands*, which lie from 8 to 16 miles to the westward of Pama-noekan Point, there are some shoals, which it is advisable not to approach. From Sedarie to to Indramayoe Point the coast is low, with some high land in the interior; it may be approached safely to 8 fathoms, but not nearer.

THE POINT OF INDRAMAYOE, in $6^{\circ} 12'$ S., and $1^{\circ} 29\frac{1}{2}'$ E. from Bavia, is of moderate height and woody, and at some distance has the appearance of an island; at its western side there is a good anchorage in 4 or 5 fathoms, but to the northward it should not be approached within 7 fathoms, as the reef projects there nearly a mile. Indramayoe is an open port for exports only.

RACKIT or BOOMPJES ISLAND, in $5^{\circ} 54'$ S., and $108^{\circ} 20'$ E., is full 6 leagues N. $\frac{1}{2}$ E. from Indramayoe Point. According to Lieutenant B. H. Staring, D.R.N., who surveyed it in 1840, Rackit Island is about a mile East and West in extent, and lies in the track of 25 fathoms.

LIGHT.—A *revolving white* light, showing a flash of 24 seconds duration, preceded and followed by an eclipse of 36 seconds, is shown from the S.E. point of Rackit; it is elevated 116 ft. above the sea, visible 23 miles off. The tower, of open ironwork, is painted white.

About N.N.E. from Rackit lies *Middle Patch*, a collection of rocks, close to each other, and partly visible above water; and still farther N.N.E. the *North Outer Patch*, in $5^{\circ} 46\frac{1}{2}'$ S., and $108^{\circ} 22\frac{3}{4}'$ E., the passages between these shoals and the island are each of them 3 miles wide, with 25, 26, and 27 fathoms depth, and are both safe. Vessels, however, should keep in the mid-channels, as the reefs project a little distance under water. Close to the northward of the Outer Patch there are 27 fathoms, and 4 miles N.N.E. of it 30 fathoms blue mud. When working through the channel, between Rackit Island and Indramayoe Point, in the night, do not approach the island nearer than 20 fathoms, nor the point nearer than 10 fathoms. The depth in the channel was found to be greater than the chart of 1841 showed; it is from 24 to 25 fathoms.

CAPE TANNA and Reef.—From Indramayoe Point the coast runs S.E. by E. 7 leagues toward Cape Tanna, in $6^{\circ} 30'$ S., and thence S. by E. 14 miles toward Cheribon, the flagstaff of which on the eastern side of the river lies in $6^{\circ} 45'$ S., and $108^{\circ} 34'$ E., or $1^{\circ} 46'$ E. from Batavia. The reef was surveyed, in 1802, by Captain Busscher, D.R.N., and, in 1841, by Lieut. Groll. Both the surveys show that the reef projects nearly 4 leagues to the eastward, with $3\frac{1}{2}$ fathoms on its extreme end, and $2\frac{1}{2}$ and 2 fathoms farther in; in some places it consists of hard sand, in others of softer ground, and part of it is sometimes covered with breakers.

CHERIBON.—The chief town of the important province of the same name, and an open port, is 16 miles southward of Cape Tanna, and the same distance S.W. of the East end of the Tanna Reef. It is the outlet of the remarkably fertile province, which, consisting chiefly of volcanic soils, produces abundance of coffee, indigo, teak-timber, &c. It had a bad reputation for unhealthiness, a third of its inhabitants having perished from a pestilence at the commencement of the present century. It is the residence of a Dutch governor and staff, and on the South side of the river is a fort for its protection, the flagstaff of which is a mark.

Light.—Since July 1st, 1867, a bright *fixed* dioptric light has been shown from the extremity of the northern mole of the harbour, elevated 26 feet above high water, and visible 8 miles off. It is merely intended as a guide to the roadstead at night.

The South prong of the Tanna Reef and Cheribon Peak, and the flagstaff, are in one, on the bearing of S.W.; the proper mark, therefore, to avoid that South prong is to bring the mount well to the westward of S.W., and to round the reef in 6 or 7 fathoms. Large ships find a good anchorage at 2 miles N.E. or E.N.E. from the fort, with a small but conspicuous Djatty bush, about W.N.W. in $3\frac{1}{2}$ to $4\frac{1}{2}$ fathoms, soft mud; and small vessels more in shore half a mile from it, in 3 to $2\frac{1}{4}$ fathoms. In the western monsoon this road affords a good shelter from the high sea, and is a safe anchorage at any time of year.

Cheribon Peak, 10,323 feet as ascertained by barometer, in 1840, by Dr. Junghun, being very conspicuous, is a good mark for ships sailing along this coast; it stands in $6^{\circ} 54\frac{1}{2}'$ S., and $108^{\circ} 28\frac{1}{2}'$ E.

Peak of Tegal.—Between Cheribon and Tegal the coast is low, but inland the country is mountainous, and the Peak of Tegal, or *Gunong Gede*, is the highest point of the whole island; it is in $7^{\circ} 13\frac{1}{2}'$ S., and $109^{\circ} 13' 3''$ E. A little more to the eastward, but nearer to the sea, there is another conspicuous mountain, called *Gadjah*, or the *Elephant*.

TEGAL, or Tagal.—The flagstaff of the fort at Tegal lies in $6^{\circ} 44'$ S., and $109^{\circ} 8' 7''$ E., and bears North by West from Mount Tegal. It is an open port for exports only. The anchorage is in 4 or 5 fathoms North by West from the fort, 1 or $1\frac{1}{2}$ mile off shore. *Tegal Rock* lies N.E. $\frac{3}{4}$ E. $4\frac{1}{2}$ miles from

Tegal, and about 3 miles from the nearest point of the shore. This rock is partly even with the water's edge, and extends East and West 710 yards, and North and South 300 yards. It is marked by a *white* beacon. From Tegal Peak this beacon bears about N. $\frac{1}{2}$ W., and the soundings at half a cable's length round it are 9 fathoms; shoaling regularly towards the shore, in 8 and 7, to the mid-channel in 6 fathoms. Tegal cannot be considered a safe anchorage during the N.W. monsoon.

It is proposed to show a *fixed red light* from an iron post at Tegal.

From Tegal to Samarang the coast runs about East with some small bights. Cape Pamalang should not be approached nearer than in 16 fathoms, to avoid the shoals of *Soegalie* and *Pemoelang*, which lie about 4 miles N.W. and N.N.W. from that point. The shoalest spots upon these shoals are 16 and 27 feet; and they bear about 16 miles E.N.E. $\frac{1}{2}$ E. from Tegal, and N.N.E. from Mount Gadjah.

Pekalongan, an open port for exports only, is at the mouth of a river, which lies in $6^{\circ} 51\frac{1}{2}$ S., and $109^{\circ} 43' 40''$ E.; the town being a little inland, and not visible from seaward through the trees.

Light.—A white plastered pyramid was erected in 1836, a little to the westward of the entrance of the river; and since September, 1866, this pyramid has been used as a lighthouse, showing a bright *fixed* light, elevated 26 feet, visible 8 miles off. It is a guide to the roadstead off the river.

When coming from the eastward, if a vessel should pass *Cape Goenong* at the distance of 2 miles, in 5 or 6 fathoms depth, the lighthouse will be seen bearing West by South; from thence steer W.N.W. $\frac{1}{2}$ W. in $5\frac{1}{2}$ fathoms, toward the road of Pekalongan, where she may anchor in $4\frac{3}{4}$ or $3\frac{1}{2}$ fathoms, soft ground, at $1\frac{1}{2}$ or $1\frac{1}{4}$ miles from the entrance of the river. Coming from the westward, Cape Pamalang should not be approached too near, to avoid the shoals of *Soegalie* and *Pemoelang*; but once past those rocks, Oeloedjami Point may be approached to $4\frac{1}{2}$ fathoms, at the distance of 3 or 2 miles, where the pyramid will be discerned, bearing E.S.E. about 8 miles, amongst some high trees on the beach which served formerly to guide a ship to Pekalongan Road. Pekalongan is not a safe anchorage during the N.W. monsoon.

Bappang, or Coreas Reef.—When not touching at Tegal, 14 to 20 fathoms is a good depth in the night to avoid the Bappang or Coreas Reef, which was examined, in 1847, by Captain Theedens, who anchored near it in 8 fathoms, and found its length and breadth to be about half a mile. Its general depth was $5\frac{1}{2}$ to 4 fathoms, but in one spot there was a single rock carrying only 14 feet; close round the reef there were $4\frac{1}{2}$ fathoms, and it lay in the stream of 23 fathoms, and 20 miles from the shore, and about 18 miles East of Pamalang Point; but this position is doubtful, as it has been placed 5 miles farther to W. by N.

Korowelan Shoal.—Another shoal called Korowelan, or *Korrowolaan*, with

3 $\frac{3}{4}$ fathoms depth, is situated more to the eastward about 6 miles off shore, abreast of Kendal. Between this shoal and the shore is a channel with 10 to 5 fathoms depth. A conspicuous *conical Herbert's beacon buoy* (which always stands upright), painted *red*, is placed on the shoal.

MOUNTAINS.—Between Tegal and Samarang the land is high in the interior; the most conspicuous mountains toward the latter place are the *Sindoro* (10,318 feet), and *Soembing* (11,030 feet), or the *Twee Gebroeders* (Two Brothers), both remarkable peaks, the easternmost being most remote, 26 $\frac{1}{2}$ miles from the shore. They bear S.W. by W., and S.W. $\frac{1}{4}$ S. from the entrance of Samarang River. The easternmost and highest peak (8,389 feet) of the *Prahoë*, or *Praaw Mountains* bears W.S.W. nearly from the mouth of that river. To the eastward of these stand the Samarang Mountains, called *Oenaran*, or *Onarang*, 5,147 ft., and *Merbaboe*, 10,220 ft., bearing S. by W. $\frac{3}{4}$ W., and S. $\frac{1}{4}$ W., from the mouth of Samarang River.

THE BAY OF SAMARANG, bounded to the eastward by the high land of Iapara, lies South from the islands of Crimon Java, or Karimon Java. This bay affords good anchorage in the eastern monsoon in 5 or 6 fathoms, mud, at about 3 or 4 miles from the beach, the flagstaff of Samarang bearing S. or S.S.E., the westernmost visible land about West, and the high land of Iapara N.E. by E. Small vessels may anchor in 4 fathoms, 2 or 1 $\frac{1}{2}$ miles distant from the shore. The road being open to West and N.W. winds, ships are exposed in the western monsoon to a high sea, for which reason this bay is not to be recommended in that season, particularly if compelled to make a long stay.

SAMARANG, which lies in the head of the bay, is one of the three principal cities of Java for European residence and commerce, and one of the ports of call for the Netherlands' Indian Steam Navigation Company's boats. It is an open port, and the seat of the governor of the important province of the same name. The shore of the bay upon which it is built is very low, the site being an alluvial plain, and the beach is only communicated with by means of a raised causeway. It, however, contains some handsome buildings, and is protected by fortifications from native attack. The great highway which traverses Java from West to East, passes through the place, and there is another road which crosses the island here, about 70 miles broad, from North to South. A railway runs into the interior from Samarang. The concession was first granted in 1872, but many delays have occurred in its construction.

At Samarang there are no establishments for repairing vessels. The harbour is quite open, and in the N.W. monsoon very dangerous, and communication between the shore and the harbour is often interrupted for several days. The Government continued deaf to the representations of the mercantile community of Java regarding the necessity of insuring the complete

safety of the harbour, although it has indeed met them half-way by building a new walled-in canal extending some way over the surf.—(1870.)

A harbour light is *proposed* to be established here on the completion of the harbour works. A white beacon is placed on Oedjoing Kalavaran, to indicate the N.E. limit of the Road of Samarang.

The flagstaff stands in $6^{\circ} 57' 20''$ S., long. $110^{\circ} 24' 37''$ E.

IAPARA ROAD is situated in $6^{\circ} 32\frac{1}{2}'$ S., and $110^{\circ} 35\frac{1}{2}'$ E., and is very safe in the eastern monsoon. The anchorage is inside of the islands Kelok and Panjang, in 4 to 6 fathoms depth. When coming from the westward the high land of Iapara appears like an island, the coast near Samarang being low, and forming a deep curve. From Samarang Road to Iapara Point the course is about N.N.E.; and between them lies *Visscher Island*, in about $6^{\circ} 36'$ S. Approaching from the northward, caution is required to avoid a $3\frac{3}{4}$ -fathom bank, which lies between 2 and 5 miles off shore, and between 3 and 5 miles north-westward of Panjang Island. Its centre is in lat. $6^{\circ} 28'$ S., long. $110^{\circ} 34'$ E. It appears to be about 3 miles in diameter, and leaves but a narrow channel between it and the dangers extending off shore.

It is proposed (May, 1877,) to show a small *fixed red light* at Japara.

KARIMON JAVA, or the **Crimon Java Islands**, are very numerous, covering a space of 12 or 13 leagues East and West, and 5 leagues North and South.

They were surveyed, but not completely, by the Dutch, in the frigate *Vreede*, Captain Dibbets, in 1803; many detached shoals and other dangers have since been discovered.

The largest and highest of these islands are *Karimon*, *Komodian*, and *Parang*, which are discernible at a great distance. There is a Dutch settlement at Karimon, which is sometimes visited by ships. The general anchorage is about 3 miles West from Karimon, and about midway between the islands Meniangan at the East side, and Glean and Boerong at the West side, in 20 to 30 fathoms water; but there is a sand bank 3 ft. above water, extending E.S.E. and W.N.W. about 3 cables' lengths, with the West end of the Great Karimon bearing N. 25° E.; Pulo Boerong, W. 17° S.; and Pulo Glean, W. $7\frac{1}{2}^{\circ}$ S.

Another sand bank, with $4\frac{1}{2}$ ft. water over it, stretches N.E. and S.W. for 4 cables' lengths in breadth, with the West end of Great Karimon E. $7\frac{1}{2}^{\circ}$ N. Pulo Boerong and Pulo Glean in one, S. 48° W.; Pulo Tjamara Ketjil, N. 30° W. The flagstaff stands in $5^{\circ} 54'$ S. and $110^{\circ} 31\frac{1}{2}'$ E. Between the different islands there are deep channels with 10 to 30 fathoms, but they should be cautiously used, for besides the reefs which project from the islands, there are some other dangerous rocks, which were discovered and surveyed, in 1825, by Lieutenant I. I. Baedrie, and in 1826 by Captain Elgenhuizen, D.R.N., and in 1862 by Captain Halverhout, D.R.N., in the steam frigate *Soembing*.

A coral reef, dry at low water, with both Krakab Islands in one, and bearing S.S.W. $\frac{3}{4}$ W., the highest land of Karimon Island E. by S.

The *Katang Reef* stretches East and West about 2 or 3 miles, and North and South about a mile, and although it does not dry at low water, it is easily discerned in clear weather. From this reef Katang Island bears E. by N., the highest land of Karimon E. $\frac{1}{2}$ S., Krakab-besar E.S.E. $\frac{1}{4}$ E., Krakab-ketjil S.E. by E. $\frac{1}{3}$ E., and the North point of Parang N.E. $\frac{3}{4}$ E.

The sand bank and coral rocks, called *Kappal*, are about 2 or 3 miles East and West, and a mile broad. Upon its shoalest part there are 2 and 3 ft. water. From its West point Krakab-besar bears N. by E. $\frac{2}{3}$ E., and Krakab-ketjil N. by E. $\frac{1}{4}$ E., Boerong E. $\frac{1}{3}$ N., the highest land of Karimon Island E.N.E. $\frac{3}{4}$ E., Niamok Island N.N.W., and the West point of Parang Island N. $\frac{1}{4}$ E.

There are also the following dangers to be guarded against.

A coral reef, with 6 ft. water on it, 2 cables in length North and South, with Pulo Katang bearing S. 62° E.; Karang Bessie N. 17° W.; and Pulo Njamok E. 17° S.

A coral reef, uncovering at low water, one-third of a mile long, N.N.E. and S.S.W., with Pulo Njamok E. $8\frac{1}{2}^{\circ}$ S.; Pulo Katang N. 17° E.; Karang-Katang W. by S. A reef of sand and coral extends for 3 miles to S. 62° W. from Pulo Njamok. From the outer end of this danger Pulo Katang bears N. 19° E.; Karang Bessie N. 19° W.; Pulo Krakab Ketjil E.S.E.

Karang Bessie, discovered in 1826, is an isolated sand bank, high out of the water, and about $1\frac{1}{2}$ mile long N.N.E. and S.S.W.

From these rocks the N.W. point of Parang bears N.E. by E. $\frac{1}{2}$ E., the highest land of Karimon E. by S., Kombang E. $\frac{1}{2}$ N., the South point of Njamok S.E. $\frac{1}{2}$ S., and the middle of Kombar Island N.E. $\frac{1}{2}$ E.

Besides these reefs and rocks, a shoal will be found between Kombar and Parang Islands; another 2 miles S.E. of Parang; again, at a mile N.E. of Tjamara-ketjil; and several other small rocks along the East coasts of Komodian and Karimon Islands. A vessel coming from the westward, and intending to touch at these islands, should make Karimon about E.N.E., and steer right for it, taking care to give Krakab-ketjil a berth of 6 miles to the southward, in order to avoid Kappal Reef; and then to pass between Boerong and Meniangan, steering for the anchorage. Between Karimon and Meniangan there is a channel with sufficient depth for large ships, but it is rendered very narrow by reefs that project from both sides. When passing along the western side of this group of islands, it would be prudent to keep at least 8 miles to the westward, to make sure of clearing Katang and Bessie Reefs.

Tides among the Karimon Islands.—In 1839 Mr. Michalofsky observed the tides among these islands, and states that they are very irregular, but that with rising water (in the eastern monsoon by night, and in the western

monsoon by day), the current runs most to the eastward, and with falling water to the westward. It is but once in the 24 hours high and low water, each tide lasting from 9 to 15 hours. At full and change it is high water in the eastern monsoon at 8 p.m., and in the western monsoon at the same hour a.m.; and there seemed to be a general, although irregular, retrograde motion in the time of high water. The mean rise and fall of the water was 4 ft., and the greatest 6 ft.

The **PASSAGE** between the Karimon Islands and the coast near Iapara is 10 or 11 leagues wide, with depths of 19 to 30 fathoms. Near the Java coast lies the island of *Mandeliké*, in $6^{\circ} 22' S.$, and $110^{\circ} 49' E.$ This island bears North from *Mount Moera*, about a mile off shore, and may be approached very near, it being steep-to at all sides. The passage between *Mandeliké* and the main is free from dangers, being a mile wide, and having $3\frac{3}{4}$ and $4\frac{1}{2}$ fathoms water.

Two miles East of *Mandeliké*, at *Cape Boegel*, the coast forms a deep curve, from which the *Bank of Taioe* projects 5 or 6 miles off shore; a large ship should therefore not bring *Mandeliké* to the North of West, until 6 miles past *Cape Boegel*. This bank consists of the same whitish clay which is found near *Mandeliké* and in most places along the North coast of Java; it stretches along the coast, toward *Joana Road*, where there are 4 fathoms water.

REMBANG BAY is bounded to the eastward by the Point of *Lierang* in $6^{\circ} 36\frac{1}{3}' S.$, and $111^{\circ} 28' E.$ Close to the beach are the towns of *Rembang* and *Lassem*, noted for their timber, and at the West end of the bight the village *Joana*, a little way up a small river. The South shore of the bight is lined with a great many islets and rocks. The flagstaff of *Rembang* stands in $6^{\circ} 40\frac{1}{2}' S.$, and $111^{\circ} 14' 40'' E.$ This is an open port for exports only. To steer for the road, and to avoid the rocks, of which some are lying $2\frac{1}{2}$ miles off shore, bring the flagstaff to bear South, and anchor on that bearing in 4 or $4\frac{1}{2}$ fathoms, about 2 miles from the shore. From *Lierang Point* the coast leads, with some small curves, about E. by S. to *Sourabaya Strait*, and may be approached to 6 and $5\frac{1}{2}$ fathoms, and in some places into $4\frac{1}{2}$ fathoms water. It is proposed to show a small *bright light* at *Java*.

PANKA POINT, or rather the flagstaff, is in $6^{\circ} 56' 2'' S.$, and $112^{\circ} 34' E.$, or $9' 56'' W.$ from the western pier-head of *Sourabaya*; it forms the western side of the strait which leads to *Sourabaya*, and is a low and sandy point. A little to the westward of it there are some conspicuous mountains, two of which are called the *Coffins* (*Doodkisten*), from their shape, and a third is of a square form; and these hills serve exceedingly well to recognize *Panka Point*, and in the western monsoon it is advisable to get sight of them in time, especially at night, because the current carries a ship speedily to the eastward of the strait.

The **STRAIT of SOURABAYA** was trigonometrically surveyed, in 1843-7,

by Lieutenant (now Captain) M. H. Jansen, D.R.N. (a name since famous in connection with Indian Hydrography and Meteorology), assisted by five other able officers; at its entrance, between Panka Point and Cape Wodon, the N.W. point of Madura, it is 15 miles wide, and that space is nearly all filled up by an extensive flat, called the Zee Bank, but leaving at the western side two narrow channels for the navigation of large ships.

The Lightvessel at the northern entrance of the western channel leading to Sourabaya exhibits a *white* light, elevated 28 ft. above the sea, visible 10 miles off. The light consists of three lanterns hoisted on the mast of the lightship, which appear as one light at a distance. The vessel, painted yellow, carries a black ball at the masthead, and has the name "Sourabaya" painted on the side. When, for trimming the light, the lantern is hauled down, the gong will be sounded, and a clear burning lantern hoisted temporarily. She lies in lat. $6^{\circ} 57'$ S., long. $112^{\circ} 40'$ E., midway between white buoys 2 and 3, which mark the western side of the Western Channel at the North entrance to Sourabaya Strait. From her Panka Point bears W. by N. $\frac{1}{2}$ N. $5\frac{1}{2}$ miles distant; Cape Wodon or Madura, W. by S. $\frac{1}{2}$ S. 8 miles distant; and Fort Erfprins S. by W. $\frac{1}{2}$ W. $4\frac{1}{2}$ miles distant.

All vessels require pilots, and should anchor, or heave to, off Panka Point, to wait for them. In the eastern monsoon a vessel may anchor at the entrance of the New Channel, to wait for high water, if necessary, to carry her over the bank, and the more so, because in this monsoon high water takes place in the morning. In the western monsoon high water occurs at night, or in the evening, and when a high swell makes it unadvisable to anchor outside of the bank, it is better to do so under Panka Point, bringing the flagstaff to bear N.W. 1 or $1\frac{1}{2}$ mile distant, in 3 or 4 fathoms.

To pass outside of the Zee Bank, keep the Little Square Mount (being the western of the hills near Panka Point) W. by S. $\frac{1}{2}$ S. open to the North of the Coffins till at the entrance of the channel, taking care that the two Coffins are in one, and appear to be as one long mountain ridge. To the eastward the N.W. extremity of Madura, Cape Wodon, should not be brought to the northward of East, in order to clear the Zee Bank, and the rocks of Iamoeang, which lie a little to the eastward of the channel, and which are covered by the sea at high water.

Ships are sometimes detained upon the bank or at the entrance of the channel by the singular tides which prevail there, and for which science has not yet been able to account, or the pilots even to reduce to rule. In the chart of the channels leading to Sourabaya, by Capt. M. H. Jansen, D.R.N., the depths are given at low water, and the following remarks are made on the tides—

"During the months in which the sun is on or near the equator, i.e., in March, April, September, and October, there are in this channel, at the full

and change, two tides in the 24 hours; but at the quarter moons, as well as during all the other months, there is only one tide, and it makes low water in the night with South declination, and in the day when the sun has North declination.

“The greatest rise and fall of spring tides is 6 ft., and it occurs only in those months when there is but one high water in the 24 hours, and 3 or 4 days after full and change. The least rise and fall is 4 ft., and this takes place at the full and change also, but only in the months when there are the two tides, which may be regarded as a change for the day high water to the night high water, and *vice versa*. At the quarter moons of these months the water rises about 5 ft., and in every other month $5\frac{1}{2}$ ft., above the depths marked in this chart.*

“In the month of—

		HOURS.	HOURS.
May	it is high water between	$9\frac{1}{2}$	and $0\frac{1}{2}$
June	„ „	8	„ $0\frac{1}{2}$
July	„ „	7	„ 0
August	„ „	4	„ 9
November	„ „	10	„ $12\frac{1}{2}$
December	„ „	8	„ 12
January	„ „	8	„ 12
February	„ „	7	„ 12

“At the spring tides, as well as at the quarter moons, it is high water always at $10\frac{1}{2}$ or $22\frac{1}{2}$ hours.

“During the months when the two tides occur, it is also high water at $10\frac{1}{2}$ ^h and $22\frac{1}{2}$ ^h. These two tides are, however, different in height; and when the sun’s declination is North, the morning tide is the highest; but when it is South, the evening tide. In those the quarters which give but one tide, give the higher water as at full and change.”

For more convenience, a stake will be erected at each side of the channel, inside of the bank, indicating how many feet of water there is upon the bank.

A vessel bound to Sourabaya may steer for the entrance of the channel across the Zee Bank, as before directed. The land about Grissee slopes gradually up from the eastward to Mount Gierie, but its western side is abrupt. When this steep western face of the mount bears S. by W. $\frac{1}{2}$ W., the trees of Menarie will be in the same direction, and this is the mark to enter the channel with the courses of S. by W. $\frac{1}{2}$ W., S by W., and South.

When a little way up channel, more trees will be seen on Menarie, and

* In most of the months there are 15 or 16 ft. water upon the bank, but when the sun has no declination, or when it is very small, 14 ft., and 14 ft. at full and change.

they should be brought, as soon as they are visible, in one with that same steep western side of Mount Grisee; and at length, when the low point of Menarie is entirely seen, keep it just open of the steep, and enter the strait on that mark. If there be a commanding breeze, she may be kept more towards Piering Point on the Madura side, because the Menarie Bank projects into the channel. In hazy weather, especially during the eastern monsoon, the Grisee hills are not always distinctly seen, but the buoys hereafter described render that of less importance than formerly. In the eastern monsoon, when high water happens between 8 o'clock a.m. and noon, and the springs at 10 or 11 o'clock, the period when the land wind ceases and the sea breeze has not yet set in, the best way is to work up with the land wind towards the shoalest part of the bank, in order to make use of the high water, when the sea breeze sets in. The current sets to the northward immediately after high water, and therefore if vessels that are outward bound can get with the land wind to this spot, they will be able in a few tacks, with the sea breeze, to pass outside the bank.

The shoalest part of the Zee Bank channel is nearly level. On the shallowest, in 1847, there were 10 ft., and with spring tides 16 ft.; with common tides it was 15 and 14 ft.

Generally the ground is so soft that a vessel receives no damage by remaining aground there; and there was an instance of a ship, drawing a quarter of a foot more than the depth of the channel, passing over the bank.

In the western monsoon, when it is high water between 8 o'clock, p.m., and midnight, the sea breeze generally prevails; in case of its being somewhat scant when going out, keep close along the western buoys, and then one tack will carry you over the bank.

The directions given above will be found useful in studying the tides and best time for entering the channel. We now proceed to describe the buoys, and a few of the directions given above will be repeated.

Buoys.—The northern entrance channels to Sourabaya Strait are marked by *white* buoys on their western sides, and by *black* buoys on their eastern sides, or by white buoys to starboard, and black buoys to port, in entering. The buoys are each surmounted by a staff and ball. The entrance to the Western Channel, at 7 miles E. by N. of Panka Point, is marked on either side by a white buoy and a black buoy, these buoys being 2 miles apart E. by S. $\frac{1}{2}$ S. and W. by N. $\frac{1}{2}$ N. from each other. The white buoy, on the western side of the channel, lies 7 miles nearly E. by N. $\frac{1}{5}$ N. from the flagstaff on Panka Point, and N. $\frac{1}{5}$ E. $3\frac{3}{4}$ miles from the new lightvessel.

The leading mark up the Western Channel is the western slope of Grisee Hills, in line with the outer edge of the trees on Menarie, S. by W. $\frac{1}{2}$ W. This mark will lead up between the white buoys and the lightvessel (each about 2 miles apart) on the western side of the channel, and the black buoys on the eastern side. By keeping to this mark a vessel will pass nearly a mile

eastward of the lightvessel, $1\frac{1}{2}$ mile eastward of *Fort Erfprins*, and 4 cables outside the shoal water extending off that fort; thence the course continued will carry her in safety nearly up to *Kresik*.

The *Eastern Channel* is marked in a similar manner to the *Western Channel*, but is much narrower, being only about half a mile across. It has three white buoys on its western side, and three black buoys on its eastern side; the outermost buoy lying three-quarters of a mile E. by S. $\frac{1}{2}$ S. from the outer black buoy of the *Western Channel*, $9\frac{1}{2}$ miles E. $\frac{1}{2}$ N. of *Panka Point*; 5 miles W. $\frac{1}{2}$ N. of *Cape Wodon*; and N.E. $\frac{1}{4}$ E. 4 miles from the lightvessel. From a position midway between the outer buoys of this channel the course is S. by W. $\frac{3}{4}$ W. for $4\frac{1}{2}$ miles, thence from abreast the third white buoy the course is more westerly, or about S.W. by S. for 3 miles into the *Eastern Channel*, which is entered abreast *Fort Erfprins*. In proceeding up this channel great caution is requisite to avoid the *Dyamnang Rocks*, on the eastern side; the second black buoy lies off their eastern side. From abreast *Fort Erfprins* the leading mark previously given will lead up the channel.

The *Java Bank*, abreast *Fort Erfprins*, is steep-to, shoaling suddenly from 15 to 2 or 3 feet. The channel is a mile wide, and if too fearful of the *Java Bank*, you will be in danger of the *Zee Bank*; and the more so, because the stream from *Solo River* runs along the western side of the fort, and then sets over to the *Zee Bank*. The most projecting part of the sand abreast *Fort Erfprins* lies E. by S. $\frac{1}{2}$ S. a mile from the fort, and can be easily cleared by passing 2 cables outside of the white buoy, lying E. $\frac{3}{4}$ N. from the fort, and steering nothing westward of S. $\frac{3}{4}$ W., the course previously recommended for passing through the channel.

In the narrows of the strait a mark to avoid the *Java* side is the steep side of *Mount Grissee* open of the low point of *Menarie*; and the mark for the opposite shore, or *Madura* side, is the small house upon the pier-head of *Sembilangan*, not open of the land. When a vessel has to enter these narrows with a faint breeze, which is often the case, it is advisable to keep on the *Menarie* side of the bank in 10 fathoms, because the stream setting out of the *Solo River* has often so much force, particularly a little before low water, that she may be swept by the united efforts of this current and the stream from the old channel, across the strait, and compelled to anchor. In the westerly monsoon it is also advisable to keep this side, to be certain to fetch above the fishing-stakes, when the wind is scant.

When working through this part of the strait, stand over toward the *Madura* side into 7 fathoms, and to the *Java* side while the steep side of the *Grissee* mount is open of the *Menarie* land. Ships that anchor in the narrows of the strait should do so under *Sawo Point*, 2 miles southward of *Fort Erfprins*, in not less than 10 fathoms, as in less water there are rocks under

the mud, which would endanger the safety of the ship by the loss of the anchor. The stream is very strong in the narrows, especially to the northward.

The fishing-stakes which are found in this strait, and which are a great obstruction both to its navigation and to the streams of tide, should be kept all to the eastward; pass them very near when going to the southward, and make the Fourteen-foot Bank. With a working wind the Madura shore may be approached by keeping the lead briskly going till amongst the fishing-stakes; but on the other side be careful to keep the flagstaff of Fort Erfprins open outside of the trees of Menarie, to avoid the steep Java Bank, which fills up the whole space formed by the curve between Menarie and Grisee. A red buoy marks the North side of an isolated $2\frac{1}{4}$ -fathom patch, in the middle of the strait, N. $\frac{1}{2}$ E. 2 miles from Kresik light. This patch is about 2 cables across; Kresik light bearing S. $\frac{3}{4}$ E. leads in mid-channel westward of it.

In the beginning of the eastern monsoon, the northerly sea breeze with which the Zee Bank has been crossed, will not blow farther than abreast of Sembilangan; and from thence to Boeloe Point, light baffling winds will be met with; but when the easterly wind comes out from the bight of Sotja, keep along the fishing-stakes, so as to make a good board to the southward in working towards Sourabaya. In a more advanced stage of the eastern monsoon the sea breeze will reach farther in, and will also be more northerly; so much so that, generally in the afternoon, vessels run right before the wind into Sourabaya. In the night the land wind blows from the West, and in the morning more from the southward. In the western monsoon the land wind varies between the N.W. and S.W., and towards the end of that monsoon more northerly.

Kresik or Grisee is a noted trading place, being frequently visited by coasting-vessels, which keep up a brisk trade; many of the Indian ships were built there, and it affords good means for repairing them. A pier projects for a considerable distance, and close to this pier is the usual anchorage.

A *fixed bright light* is shown at the pier-head of Kresik, elevated 42 feet, and visible 8 miles off.

From Grisee to Sourabaya the course is S.E. and S.E. by E., and close to two rocks situated near the Madura shore, called the *Buffels Rocks* (Buffaloes), the outermost of which is seldom covered by the sea, even at high water. The Madura shore may be approached by the lead till near the Buffels, and these rocks may be approached till within half a mile. The Java Bank, near the *Pisang Rocks* (which are marked by a *white* buoy on their northern side), is steep-to, the depth increasing towards them to 8 or 9 fathoms, and in some places near their edge to 10 or 11 fathoms; they are always covered, and on their shoalest part there is but a foot of water. They nearly touch the steep bank of Java, S.W. by W. from the Buffels. To keep clear of the Pisangs, do not bring Tanjongan Point to the eastward

of North, and tack immediately when the water deepens, as that indicates the proximity of this bank. The current sets direct on these rocks, for which reason it is advisable in calms and light winds to remain near the Madura shore, if possible; but when once past the Pisangs and Buffels, both shores may be approached to 7 fathoms till in Sourabaya Roads.

SOERABAYA, Sourabaya, or Surabaya, is in the southern part of the Strait of Madura, and, with the exception of that of Tjilatjap on the South coast, is the only sheltered harbour that Java possesses, the others being only open roadsteads.

It is the stronghold of Java, and the Dutch government have spent large sums in fortifying. It is a port of call for the Netherlands' India Steam Navigation Company's boats. The ground on which the town stands is a flat alluvium, of recent formation, and surrounded by marshy land, which is penetrated by the sea. A river, called the *Kali-Maas* (river of gold), the source of which is at a considerable distance in the interior of the island, separates into two branches just before reaching the town. While one of its streams divides Sourabaya into two equal parts, the other just enters it, and falls into the sea about half a mile to the East of the former. The principal branch is straitened from Sourabaya to the sea. The current in it is very strong, and always running down; the flood or ebb stream being neither of them felt, except by producing a difference of level.

This canal is the high road of intercourse between the roadstead and the town, which is accessible to all vessels of less than 12 ft. draught. Boats are tracked up against the stream, and on the left bank of the river is a track road for the purpose.

Besides a strong citadel built at the entrance of the town on the right bank of the river, there is an enceinte with bastions, entirely surrounding the town on all sides. This enceinte is very wide; but the importance of the town must not be judged by its dimensions, for there are no houses of stone excepting those along the quays, and these are only about 300 or 400 yards on each side of the canal. The rest of the enclosure is filled one-half by swamps and the other by the straw huts of the Malays.

The left bank of the canal is reserved for the houses of Europeans and the various government establishments; the right bank is occupied by the Arabs and Chinese. The Europeans who live there are generally military and civil functionaries of the government and some small merchants, who have only their houses of business in the town, their dwelling-houses being outside of the enceinte. It is the same with those carrying on business, who do not employ more than two hours at their office. All these buildings are scattered towards the river South of Sourabaya, and extend to 2 or 3 miles from the centre of the town.

There is an excellent Marine Establishment and good Hospital at Sourabaya. There were, in 1870, several private establishments for the repair of

ships, but all on the primitive heaving down system. The Government Floating Docks are excellently managed, but merchant vessels can seldom get access to them. A *time ball* is in operation at the Marine Establishment, longitude $112^{\circ} 43' 30''$ E.

Vessels may at once embark their cargoes without employing proas; and all sorts of supplies and refreshments are to be had in abundance, especially fresh water, which is filtered and purified, and carried on board in tanks, in the same manner as at Batavia.

The river is broad and elongated by two piers; and at high water there is sufficient depth for large proas and square-rigged coasting vessels, which come in to be careened and repaired. At low water, however, great care is requisite in entering the river, even with boats, there being sometimes only a foot of water upon the bank, and if not kept just in the mid-channel, they may be upset by the current. The road is esteemed to be very healthy, and affords, in all seasons, proper and safe berths for vessels of all sizes.

The anchorage is about half a mile North, or N.N.W. from the entrance of the river, in 9 fathoms water, Grisee bearing about N.W. by W. In the western monsoon it is better to anchor a little farther out in stiffer holding ground, and also to moor.

Vessels staying longer than 24 hours in Soerabaya Roads are compelled to moor with sufficient scope of cable, and clear of other shipping, under a penalty of 100 florins for vessels above 100 tons burden, or of 25 florins for smaller vessels. (Ordinance, March 28, 1862.)

The land is low fronting the strait, but at a considerable distance in the interior there are some high mountains, of which the principal peaks are the *Penang*, S. by W. $\frac{1}{4}$ W., distant 26 miles, 5,495 ft. high; *Arđjoeno*, S. by W. $\frac{1}{3}$ W., distant $36\frac{1}{2}$ miles, 11,627 ft. high; and *Semiroe*, S. by E., $55\frac{1}{2}$ miles, 12,385 ft. high.

The Solo River, which discharges its water into the strait of Sourabaya at a distance of 2 miles W.S.W. from Fort Erfprins, is one of the largest and deepest rivers of the Isle of Java, and is navigated by large proas far into the interior. In 1841 a part of this river, with the shoals at its entrance, was surveyed by Lieut. Groll, commander H.N.M. iron steamer *Etna*. He states that the channel, from the southward of Fort Erfprins to the entrance, leads close along the shore of Menarie, and at low water in from 3 to $1\frac{1}{2}$ fathoms in depth. Upon the bank which runs along the North side of this channel there are, at low water, but $5\frac{1}{2}$ or 6 ft., and part of it dries; it consists in some places of sand, and in others of mud, but higher up of clay and mud. The depth is greater inside than outside the entrance, amounting in many places towards the village Boenga to 5 and 7 fathoms. In the eastern monsoon the flood streams up as far as Boenga, and at Bodjo Negors the water is brackish and unpalatable. In the western monsoon there is more

water in the river, and, according to the natives, the current in this season always sets down.

MADURA ISLAND.

The North Coast of Madura, and the channels eastward, were surveyed, in 1822, by Lieut. F. A. Fokke, of the Dutch Royal Navy. The whole of the North coast of this island may be safely approached, there being at the distance of 1 mile 4 or 5 fathoms depth, at 2 or 3 miles 7 to 9 fathoms, and 6 to 8 miles 15 to 20 fathoms, and 16 to 20 miles 30, 40, and 45 fathoms, for the most part good holding ground.

This coast is moderately elevated, and except for some hills near its western end, of a uniform height; it has generally a fertile appearance, with some rocky sand patches at its eastern extremity. A fresh-water place is said to be not far from the East end.

BAWEAN or **Bavian** or **Lubec** Island bears due North from Sourabaya Strait, and its centre lies in $5^{\circ} 49'$ S., and $112^{\circ} 42'$ E., according to the mean of several chronometric observations. It is of considerable extent, being North and South $9\frac{1}{2}$ miles, and East and West 10 miles; towards the centre and West end very high; and having some small islands on both sides. It is dangerous to approach from the eastward, on account of extensive rocky shoals, which reach 6 to 10 miles off, and near which there are 25 and 30 fathoms water. The outermost of these is the extensive group of the *Tambaga Rocks*, which show, and lie about 10 miles E.N.E. of the peak of Bawean Island. These rocks form a group 2 or 3 miles in extent, and are the northernmost of the patches lying off the East side of Bawean. Separated from them by a channel, $1\frac{1}{2}$ mile wide, is another patch, 2 miles in extent, North and South. These are separated from Lor Island ($1\frac{1}{2}$ mile off the East extreme of Bawean) and its surrounding dangers by a channel $1\frac{1}{2}$ mile in width. *Bungarang Reef*, under water, lies 4 miles S.E. of Lor Island. The channels within these reefs are of doubtful safety. The South, West, and North coasts of the island should not be approached within 2 miles, except with great caution, as many sunken rocks lie off its shores. *Noko Reef* lies S.E. from the peak of Bawean, $1\frac{1}{2}$ mile off shore.

Sankapoera.—The principal place in this island is Sanka Poera, or Sanca Poura, on the shore of a bay, in its southern coast. There is good anchorage in this bay, in 7 to 10 fathoms water, between the reefs, the western extremity of the bay, Alang Point, which is high and conspicuous, bearing from West to W.S.W. There are several reefs in this bay, which stretch

across from both sides, and therefore a stranger should not bring Alang Point to the southward of W. $\frac{1}{2}$ S.

W.S.W. $\frac{1}{2}$ W., 3 or 4 miles from Alang Point, Lieut. Fokke discovered a ledge of rocks, carrying from 5 to 9 fathoms, but suddenly rising from the depth of 30 fathoms; and the *Bromo* found another at the same distance from that point, but bearing from S. by W. $\frac{1}{2}$ W. to S. by E. $\frac{3}{4}$ E., with 7 to 9 fathoms.

Milton Rock, 4 miles westward of Bawean Island, was found by Mr. George Butchard, in 1875, to consist of coral, to extend about 270 yards in a N.W. and S.E. direction, and to have 16 ft. on its shoalest part, deepening all round to $4\frac{1}{2}$ and 6 fathoms, and then to 18 fathoms. The following bearings for the position of this danger are given by Mr. Butchard:—S.W. point of Bawean Island, S.E. by E.; North point of Bawean Island (Tienio Point), N.E. by E.; Small Islet (Nusa), N.E. $\frac{1}{2}$ N. These bearings place the rock in lat. $5^{\circ} 44' S.$, long. $112^{\circ} 33' E.$

Nusa Island and Rock, the rock lying about a mile N.W. from the islet, are about 4 miles N.N.E. of Milton Rock, and 4 miles westward of *Tienio Point*, the N.W. extreme of Bawean Island. S.W. and N.E. of Tienio Point dangers lie at the distance of a mile.

The **Hastings Rock**, upon which the British ship the *Marquis of Hastings* struck, May 27, 1826, lies in $6^{\circ} 6' S.$ and $112^{\circ} 32' E.$, with the summit of the island of Bawean bearing N.E. by N., 20 miles distant. The rock is not visible, and probably but very small.

Nahmen's or Oosterling Rock or *breakers* were seen from the Dutch barque *Oosterling*, March 22, 1855, at about 25 miles N.W. of the centre of Bawean. It was not sounded on, but it appeared to be in lat. $5^{\circ} 33' S.$, long. $112^{\circ} 28' E.$

The **Arrogant Reef**, in $5^{\circ} 12' S.$, and $113^{\circ} 0' E.$ by a mean of the chronometers of H.M.S. *Arrogant*, and those of the *Dover Castle*, which agreed within 4 minutes of arc, lies about 11 leagues N.N.E., of Bawean, having been discovered, in 1802, by the former ship. It was examined by the boats, and found to extend about a quarter of a mile N.W. and S.E. with only 5 or 6 ft. water, where they could approach in safety from the breakers. There were from 5 to 12 and 25 fathoms round it at the distance of a cable's length. This reef is just in the track of ships from Batavia to Macassar &c.

GILIANG or **Pondi** is a small flat island, in $7^{\circ} S.$, and $114^{\circ} 10' 48'' E.$, and about 3 miles East from the East point of Madura. The passage between them has from 5 to 16 fathoms water, soft ground, but is a very narrow channel, occasioned by the shoal spit which projects from the East point of Madura, and upon the edge of which there are but 3 fathoms. A small shoal, with $3\frac{1}{2}$ fathoms water, lies a mile West from the North point of

Giliang; and a large bank with $1\frac{1}{2}$ fathom shoalest water stretches North and N.N.E. as far as 3 miles from the East point of Madura.

Tambaga Rock.—The two dangerous rocks of Tambaga, according to Lieutenant Fokke, lie 4 miles East from Sarotak Point, the south-eastern angle of Talango Island; N.E. by N. from Lawak; and S. by W. $\frac{1}{2}$ W. from Giliang. At low water, these rocks are even with the water's edge, and lie about a mile distant from each other, with 10, 20, and 24 fathoms close to. A third and very dangerous rock, previously known to exist, lies rather above a mile to the South of them. Its position was ascertained by Captain Gaeter, D.R.N., in the steamer *Draak*, in 1867. The British ship *Edendale* was wrecked on it. It has only 14 ft. water, and bears S.E. by E. from the westerly Tambaga Reef and S.W. $\frac{1}{4}$ S. from the eastern one, Gili Lawak bearing S.W. westerly.

A fifteen-feet patch lies a cable southward of the Tambaga Rocks.

Four miles N.E. of these Tambaga Rocks there is another, which was discovered, in 1822, by Lieut. Fokke, and named, after the vessel he commanded, the *Jacoba Flizabeth*; but it need not be avoided by ships, as the shoalest water upon it is 7 fathoms, with 22 and 50 fathoms all round.

SAPPOEDIE ISLAND, the Galioen, or Respondi, of the old charts, lies between $7^{\circ} 3'$ and $7^{\circ} 10\frac{1}{2}'$ S., and the West point in $114^{\circ} 19' E.$; it is larger and higher than Giliang. Both are well cultivated, and bear a fertile and pleasant aspect. About 5 miles to the N.N.E. of the N.E. end of Sapoedie is Pandyang, a small island with two small islets, lying within 9 miles westward from it. North 3 miles from the centre of the three islets, and N.E. $\frac{3}{4}$ N. of the West point of Sapoedie is a 6-fathom bank, discovered in 1864 by Capt. Kuffeler.

Sapoedie Strait, or the channel between Sapoedie and Giliang, is 6 miles wide, and the usual track for vessels bound to the Strait of Bali. Besides the above-described rocks of Tambaga and Jacoba, there are no dangers; and though the soundings are very irregular, varying from 10 to 30 fathoms, yet it is a very good channel, and preferable either to that West of Giliang, or East of Sapoedie. South of Sapoedie the depths increase rapidly to 50 and 100 fathoms; and the course to be steered to Cape Sedano is about S. by E.

There is a safe channel to the eastward of Sapoedie, with moderate depths between it and the isle of Ra-as (Great Hog Island). Lieutenant Boedrie, in H.N.M. schooner *Iris*, found a rocky shoal, upon which were but 2 fathoms. This spot bore W. $\frac{1}{2}$ S. from Sarok Island and N. $\frac{1}{4}$ E. from the West point of Ra-as. The shoal is round, about a cable's length in diameter, and very dangerous for all vessels passing through this channel from Sumanap to Kangeang or Macassar.

Lawak, or *Turtle Island*, lies in lat. $7^{\circ} 12' 20''$ S., and long. $114^{\circ} 3' E.$ It is a small sandy island, covered with trees, and discernible 8 miles off.

Between this island and the extremity of the long neck projecting from Gintang Island, 6 miles to the westward, are two rocks above water, E.N.E. and W.S.W., $1\frac{1}{4}$ mile apart. The easternmost lies 2 miles West of Lawak, and has a sunken rock just West of it. The western rock has a sunken danger on its eastern side.

SUMANAP (the Flagstaff) lies in $7^{\circ} 2' 30''$ S., and $113^{\circ} 55'$ E. It is a considerable town, and furnishes fresh water and provisions of all kinds. The adjacent country abounds with rice and timber, several coasting traders being built here. The bay is margined by a soft mud bank, so that ships are obliged to anchor at a great distance from the shore. Large ships anchor in 5 or $5\frac{1}{4}$ fathoms, 4 or 5 miles from the fort. Small vessels anchor more in shore, about $2\frac{1}{2}$ miles from Sumanap, in 3 fathoms, mud.

Ships coming from the southward, and intending to touch at Sumanap, should first make Lawak, pass on its eastern side, and stand along the South side of Talango for the anchorage. The passage between Lawak and Genting is not to be recommended, on account of the above-mentioned rocks; nor should Gintang, or Genting, be approached too near on its northern side, as two rocks, *Noko* and *Gemer*, lie $1\frac{1}{2}$ and 1 mile from it; both, however, are above water, and discernible at some distance. The channel leading to Sumanap, between Gintang and Radja, is safe, with 19 to 8 fathoms water; but a berth of about a mile should be given to these islands on both sides, as reefs project nearly to that distance. Channel passed, steer N.E. by E., in 8 fathoms depth, close round the South point of the bay, for the anchorage. The extremity of the reef off the West side of Gintang is marked by a *white* buoy with mast and ball, and that off the East end of Radya by a *black* buoy with mast and ball.

Along the Madura coast there is in most places soft mud, except upon the reef near the East point; but among the islands there will generally be found hard sand or rock at the bottom. Lieutenant Fokke gives the time of high water, in the middle of the East monsoon, at noon; but in November about midnight. In common tides the rise is 5 ft., and at springs 7 or 8 ft. Sometimes he experienced a current among the islands, of $2\frac{1}{2}$ miles per hour.

Gilingan Island lies S.W. $2\frac{1}{2}$ miles from the West end of Radya, and S.E. $1\frac{1}{4}$ mile from it is *Guntur Rock*. A *doubtful patch* lies S.E. $\frac{1}{2}$ S. $2\frac{1}{4}$ miles from Gilingan, and a 9-ft. rock was reported by the *Merapie* to lie in lat. $7^{\circ} 18'$ S., long. $113^{\circ} 54'$ E., with Genting Island bearing N. $\frac{1}{2}$ W. to N.E. $\frac{1}{2}$ N. This latter patch is not marked on the Admiralty chart.

Boender and **Tiandie** are two places in a bight of the South coast of Madura, about 6 leagues West of Sumanap. These places are sometimes visited by trading ships, to take in salt, which they produce in abundance. A great many dangerous rocks and reefs lie in this bay, and make it necessary to approach it with caution, the more so as the fishing stakes indicating

their position being sometimes washed away by the sea, no implicit reliance can be placed on them.

In the eastern monsoon the tide sets N.W. and S.E., and in the western monsoon E.N.E. and W.S.W. In common tides the rise is $4\frac{1}{2}$ ft., and in the springs 8 or $8\frac{1}{2}$ ft.

KANGEANG.—A chain of small islets and rocks stretch eastward of Saepoedie as far as Kangeang, an extensive island, the N.W. point of which is in $6^{\circ} 50' 30''$ S., and $115^{\circ} 12'$ E. In former charts all these island were represented very incorrectly, but the observations of various officers of the Dutch navy have made the islands better known.

The north-western part of Kangeang is high and rugged, but clothed with trees; the eastern point is less high, with a more even appearance; and in the S.W. part the land is low and bushy. It is a very fertile island, governed by the Sultan of Sumanap, and scantily peopled; but visited by trading proas from Baly, Sumanap, and Bawean. Sometimes this island is subject to invasions. Near the N.W. point of Kangeang lies the small island of *Manpoeriet*, or *Manropet*, which is of considerable height, and visible as far as that N.W. point, i.e., in clear weather, about 8 or 9 leagues; and it is surrounded by a coral reef, which projects at the N.W. and W.N.W. sides about 3 miles. Between Manpoeriet and the N.W. side of Kangeang, there is a bay of a mile wide, in which are several rocks, one of which, a dangerous coral patch of $3\frac{1}{4}$ fathoms, lies with Manpoeriet West point bearing N.W., and Katapang flagstaff W. and E. $\frac{1}{2}$ S. The village of Katapang is situated in this bay. According to Lieutenant Jolly, a ship having cleared the reef of Manpoeriet, may steer mid-channel into the bay, till Manpoeriet bears North, when a good anchorage will be found in 10 fathoms depth. This is a fair and safe berth in the S.E. monsoon, and it is not advisable for large ships to stand farther in, as coral reefs project in some places a mile off shore. There are some refreshments to be had there, and a *little* good water may be found in two wells upon the beach. In the N.W. monsoon a large ship will not obtain shelter against hard winds and high seas.

Kamirian, or Urk Island, in $7^{\circ} 2' 15''$ S., and $115^{\circ} 12'$ E., or $8^{\circ} 24'$ E. of Batavia, is of a circular form, very woody, not very high, with a sandy beach all round, but which projects most to the westward. The passages on both sides of Kamirian are safe, with 40 and 50 fathoms depth in the middle, 25 near the island, and 15 and 10 on the Kangeang side. These passages are of importance to ships coming from Australia and bound to Singapore or Bengal, and are often preferred to Salayer Strait when coming from Banda or the Moluccas, in the strength of the East monsoon, and going to Batavia. The passage to the eastward of Kamirian is 4 miles wide, and has no dangers, as the reefs project from the S.W. point of Kangeang about a mile only; and the passage West of Kamirian between it and Takat, is at least

4 miles wide, and has no dangers, the reefs on either side showing their edges by the discolouration of the water.

Karang Takat Bank, sometimes called the *Four Brothers*, is an extensive coral shoal, which stretches E.S.E. and W.N.W. for a length of 4 leagues, with three dry patches, elevated 2 or 3 ft. above low water. These patches are called by the natives *Takat Gomok*, *Takat Fimor*, and *Takat Tinga*; two of them are near the extreme ends, and one in the middle of the bank. According to Lieutenant Boedrie, in 1827, and Captain Machielson, in 1834, the southernmost part of the bank bears about W. $\frac{1}{2}$ N. from Kamirian, and the northernmost part of it S.W. by W. $\frac{3}{4}$ W. from the N.W. point of Kangeang. This shoal is very steep-to, as Lieut. Gregory, who passed very near it in 1836, in H.N.M. corvette *Boreas*, states that at the distance of half a mile E.N.E. from its north-westernmost point he had 39 fathoms, and at half a mile from its S.E. point, Urk Island bearing E. by S., there was no bottom with 45 fathoms. With a good look-out at the mast-head, this dangerous shoal will be discernible at a considerable distance by the colour of the water, except when in the direction of the sun.

The passage West of Takat, between it and the small islands of Kamoedie and Goa, is about 3 or 4 leagues wide, and is said to be safe; but as but little is known about this channel, the utmost care and prudence is to be recommended to vessels proceeding through it.

The English ship *Islay*, in 1843, passed close to the southward of Ra-as and of the islands to the eastward of it, and struck upon a coral rock there, with only 13 ft. According to the account of her captain (Galt), it lies 5 miles S.E. by E. from Little Ra-as, or Tund Island, and 6 miles S. by W. from Goa. There is also a rock between Tund and Ra-as.

Dangers Northward of Kangeang.—At 3 miles N.N.W. of Manropit Island is a *sunken rock*, and 15 miles westward of that island is another sunken rock of doubtful position, but placed on the chart in lat. $6^{\circ} 50' S.$, long. $114^{\circ} 51' E.$ *Sumbing Reef*, of 3 fathoms, discovered in 1863, is marked on the chart 6 miles North of the North side of Kangeang Island, in lat. $6^{\circ} 42' S.$, long. $115^{\circ} 22' E.$ At $15\frac{1}{2}$ miles N. $\frac{1}{3}$ E. of Sumbing Reef is a $4\frac{1}{2}$ -fathom patch, and N.E. by N. 11 miles from this patch is *Prince Maurits Reef*, in lat. $6^{\circ} 20' S.$, long. $115^{\circ} 31' E.$ A spot 4 miles long East and West, with 9 and 10 fathoms water over it, lies in lat. $6^{\circ} 5' S.$, long. $115^{\circ} 12'$ to $115^{\circ} 16' E.$

Kalkun or Turkey Islands, five in number, are low, and their locality little known. A passage between them and Kangeang has been used, but is also little known. The southern island is surrounded by rocks to the distance of 3 miles all round, and lies 13 miles N. by E. of the East end of Kangeang Island, in lat. $6^{\circ} 43' S.$, long. $115^{\circ} 41' E.$ It is 2 miles in length East and West. Two of the islands lie N.W. $\frac{1}{2}$ N., at the distance of 5 and 10 miles from the East end of the South Turkey Island, and a sunken rock lies in

the same direction 6 miles from the outer island, and 11 miles South of Prince Maurits Reef. The other two islands lie at 11 miles N.N.E., and 15 miles N.E. by N. from the South Turkey.

Looper Reef, of coral, in lat. $6^{\circ} 28' S.$, long. $115^{\circ} 55' E.$, and 10 miles E.N.E. from the N.E. Turkey Island, has $2\frac{3}{4}$ fathoms water on it, and was discovered by Capt. Looper, R.D.N.

Belliqueux Reef is the old name for all this locality. A $4\frac{1}{2}$ -fathom patch lies 12 miles E.S.E. of Looper Reef, and thence the water is considered dangerous westward of a line extending 25 miles to the southward to *Sakala* or *Hastings Island*, which lies 20 miles N.E. of the East end of Pandyang Island, the easternmost of the Kangeang Group.

A *rock* is marked in lat. $6^{\circ} 34' S.$, long. $116^{\circ} 44' E.$, 38 miles N.E. by E. of Sakala Island, and 45 miles E. $\frac{3}{4}$ S. of Looper Reef.

Peterborough Shoal, in lat. $6^{\circ} 37'$, long. $115^{\circ} 58'$, was discovered by a vessel of that name in 1871. The shoal appeared to be a narrow coral shoal, lying in an East and West direction. It was steep-to, and from it the N.E. Turkey Island, distant 10 miles N.W. by N., was just visible.

Cyclops Reef is marked in Dutch charts in lat. $6^{\circ} 48' S.$, long. $115^{\circ} 44' E.$ It has $4\frac{1}{2}$ fathoms water, and lies S.S.E. $7\frac{1}{2}$ miles from the South Turkey Island. *Sedulang Shoal* lies 6 miles eastward of it, and 10 miles N. $\frac{1}{4}$ E. of an islet of the same name. There are no reefs yet discovered between Sedulang Shoal and the islets lying off the Kangeang Group, or in the space of 9 miles southward of Cyclops Reef and Sedulang Shoal.

MADURA STRAIT.

Vessels bound from Sourabaya to the Strait of Madura will find pilots at Passeroean. There are two channels; the *Jansen Channel*, to the westward, is well buoyed, and leads along the Java shore; while the Old Channel (Trechter), lying more to the eastward, passes close to the Gezonken (sunken) Fort, commonly called Daendels Fort, and is not buoyed. But before we enter either of those channels, it will be satisfactory to give some remarks upon the tides in the Trechter, which affect them both equally.

The *Tides* in many parts of these seas are attended with considerable peculiarities and difficulties, and none more so than those which pass through the Trechter. They have been carefully investigated and elaborately described by Capt. M. H. Jansen, D.R.N.; but for the general purpose of these instructions the following briefly-stated facts will probably be sufficient. It has been seen that on the Zee Bank there are for a few months two tides in the 24 hours, but that, for the major part of the year, there is only one high water in that interval; in the Trechter, on the contrary, there are always two distinct tides, though they differ materially in height, according to the sun being North or South of the equator. Secondly, the rise and fall of the water in the Trechter, springs and neaps, are $8\frac{1}{2}$ and $5\frac{1}{2}$ ft.; which, being much greater than the corresponding rise and fall on the Zee Bank, it follows that the stream sets to the northward through the Trechter from two hours after high water, a circumstance very favourable to vessels entering from the southward, and equally troublesome to those that are bound to the eastward from Sourabaya.

The **JANSEN CHANNEL**, above mentioned, is liable to change, and therefore no permanent directions can be depended on for it. But the Dutch Government have well buoyed this channel in the early part of 1867, with *black* Herbert's buoys on its western side, and *white* buoys on its eastern side. The channel is about three-quarters of a mile wide at its northern end, and $1\frac{1}{2}$ mile wide between the buoys at its southern end. The northern black buoy lies 3 miles East of Sourabaya, and 3 cables N.E. of Kalabangkang Point; between this black buoy and the outermost white buoy, three-quarters of a mile E.N.E. of it, is the northern entrance of Jansen Channel. Thence the course is about S.E. by S. for $7\frac{1}{2}$ miles, till the outer edge of the trees on the Java shore come in line with the south-western slope of Madura bearing N.W., which is the mark for leading out of the South end of the channel.

Between the black buoy at the northern entrance, and the outer black buoy at the southern entrance of Jansen Channel, the distance is 14 miles, and, including these two buoys, the western side of the channel is marked by nine black buoys. From the southernmost black buoy the southernmost

white buoy on the opposite side of the channel bears N. $\frac{3}{4}$ W., distant 3 miles. The eastern side of the channel is marked by seven white buoys, all on Herbert's principle except the northernmost.

Jansen Channel, outward bound.—When bound to the eastward from Sourabaya, steer E. by N. to clear the Java Bank, which is steep-to, keeping the end of the Navy-yard to the southward of W. by S. If beating out, do not approach the Madura shore nearer than 7 fathoms; and on the Java side tack immediately that there is less water than 8 or 9 fathoms. If compelled to anchor, avoid doing so near Madura, as the bottom there is rocky. An 8-ft. shoal, marked by a *white* buoy, lies some distance off the shore; from it the 7-fathom line is sufficient security. In steering towards the northern entrance of the Jansen Channel, keep as near as can be done with safety to the Java Bank, in order to haul in close round the buoy off the point of Kalaban; for the eastern stream, instead of bending round the buoy, sets across the channel and upon the Tongue, which is the name of the long shoal that forms the eastern side of the Jansen Channel. When once in the channel the stream takes its direction. The depths in the Jansen Channel gradually decrease from 6 and 7 fathoms between the buoys at its North entrance to $2\frac{1}{4}$ fathoms between the buoys at its South entrance, and midway between these depths there is only 18 ft. water. Deeply laden vessels are, therefore, obliged to anchor there, and wait for high water. Along the whole length of the Tongue the banks are steep-to on both sides, and therefore, when working, vessels should tack short of the line of the stakes; and indeed in the narrow part of the channel, 3 miles within its North entrance, although a mile in breadth, it is advisable for them to drive with the tide, which runs there with great velocity—even 8 knots it has been asserted. The Java Bank, to the southward of this, is a little more gradual in its slope, but still too steep to make free with; and the *Kletta Rocks*, though buoyed, should not be approached without great caution. Still farther to the southward, the edges of the banks become flatter, and vessels may borrow on them by the lead.

OLD TRECHTER CHANNEL.—Vessels proceeding from Sourabaya by this channel, pass pretty close to the S.W. side of Daendels Fort, a large collection of stones, brought there for the purpose of building a fortress which should command the Pass, and thrown into the water. There is a *red* buoy off these dangerous stones. The channel leads along the S.W. side of the fort, and this is its narrowest and shallowest part, as no more than 2 fathoms depth will be found at low water. The rise and fall of the tides is in this place three-quarters to $1\frac{1}{4}$ fathom. From off the fort the Zadelberg Hills on Madura will be seen bearing N.W. $\frac{1}{2}$ N., N.N.W., and N.N.E. The easternmost is the highest of the three, and may be distinguished by two conspicuous trees at its foot; this hill is the great mark for the pilots throughout the strait; the middle one is not so high, and seems chiefly to be composed of

high trees; the westernmost is also of moderate height, and resembles a saddle more than the others. This passage should never be attempted without a pilot.

When leaving Sourabaya Road with a fair wind the course is E.N.E. to the Madura shore, in order to clear the mud bank which projects a considerable distance off the Java shore, East from the river, leaving nothing but a small channel between the two banks, and also to avoid the indraught of the Jansen Channel.

The land breeze seldom reaches far off shore, and therefore when leaving Sourabaya beat up along, in the eastern monsoon, the Madura shore, and borrow on the Java side only as near in as 9 fathoms; the mud-bank being here steep-to. To beat to the eastward, except with an eastern stream, is impossible; and, therefore, the Jansen Channel, throughout which the land breeze prevails, is by far the most eligible during the eastern monsoon.

When past Daendels Fort, proceed S.E. by S. and S.E., till it bears N.N.W. $\frac{1}{2}$ W., 4 miles distant, when the three hills of Zadelberg will be visible at the East side of the fort. Between the sunk fort and Passaroean a mud bank projects a considerable distance off shore, with a dangerous knoll, called the *Slatan*, which makes it advisable not to borrow on the Java shore nearer than 7 or 6 fathoms. A ship should also mind the dangers S.W. of Kambing Island, presently described, especially when working to the southward.

Passaroean.—To touch at Passaroean, the pilots have a mark of four or five conspicuous trees, in the vicinity of the town, and the mark for standing into the road is, or was, a small dark bush, at the mouth of the river, near a single house, bearing S. $\frac{1}{2}$ E. The anchorage is 3 or 4 miles N.N.E. to N.E. from the flagstaff, and N.W. by W. $\frac{3}{4}$ W. or W.N.W. from Warangan Point, in 5 or 6 fathoms, mud. *Pilots* may be procured here for Sourabaya.

A *red light* is, or is to be, shown from a lamp-post at Passaroean, lat. $7^{\circ} 37' S.$, long. $112^{\circ} 55' E.$

Kambing Island lies in $7^{\circ} 19' 36'' S.$ and $113^{\circ} 12' 40'' E.$; it is about a mile in extent, woody, not high, but visible in clear weather at the distance of 4 or 5 leagues. It is surrounded by a coral reef, close to which there are from 14 to 20 fathoms, and then shoaling gradually toward Madura into 4 fathoms. At 2 miles West from the West end of Kambing is a *sand-bank*.

A *small shoal* of $1\frac{1}{2}$ cable, bears S.W. by S., 2 miles from the West point of Kambing Island. There were 4 ft. water upon it at the time, being half tide, and therefore at low water 2 ft. It seems to correspond in place with that laid down in some charts as the *Kabeljaauw Bank*.

KOKO REEF, or ZWAANTJES DROOGTE.—A coral reef of half a mile in breadth, called by the natives *Koko*, and by the Dutch *Zwaantjes Droogte*; one part of it is always in sight, and consists of white sandstone. In 1855

a conspicuous iron screw pile beacon was erected on it, this is now superseded by the lighthouse, from which the outer buoy of the channel is visible, so that it is an excellent mark.

LIGHTHOUSE.—The lighthouse on Koko Reef, completed in 1872, exhibits a *revolving bright light*, at an elevation of 54 ft. above the sea. The light appears as a fixed bright light for $1\frac{1}{2}$ minute, and in the succeeding half minute shows a flash of 10 seconds duration, preceded and followed by an eclipse of 10 seconds. The flashes are visible about 14 miles off. In foggy weather, or if the light is out of order, a *bell* is sounded. The following dangers lie near the lighthouse.

Manilla Rock, or bank under water, two ships' lengths in extent, bears S.W. by S. and S.W. $\frac{1}{4}$ W. from the extremities of Kambing Island, 3 or 4 miles distant, having 2 fathoms water on its shoalest part, and 16 fathoms between it and that island.

Sirumpa Rock is 5 miles N.W. by N. from Koko lighthouse.

Bura Rock, with a sand-bank, is about $1\frac{1}{2}$ or 2 miles in extent, and bears N.W. $\frac{3}{4}$ N. 5 miles from Koko Reef, and about S.W. by W. 11 miles from Kambing. Upon the shoalest part there is 3 ft. water.

Eendragt Shoal.—A small rocky shoal, discovered in 1841 by Capt. H. H. Deuling, in the Dutch barque *Eendragt*, with the Koko bearing W. by N., 5 miles distant, and the island of Kambing N. $\frac{1}{2}$ E.

Ships bound to the eastward from Passaroean should generally make their easting along the Java shore, in order to profit by the land and sea breezes, which blow with more regularity and strength than on the Madura side; besides which, if becalmed or set to the westward by the current, they may anchor on the Java side. In the eastern monsoon, during the day S.E. by E. and E.N.E. winds prevail; in the night commonly a brisk S.S.W. or S.W. land breeze, and often in the forenoon followed by light baffling winds and calms. In the western monsoon, N.N.W. and W.S.W. winds blow very hard, sometimes declining in the evening, and often veering to S.W. and S.S.W. in the night; the current generally runs East or West, but that depends on the prevailing wind.

The winds, however, in the Strait of Madura, are more variable than on any other part of the coasts of Java and Madura, arising not only from the contraction of the passage, but, perhaps, from the influence upon the atmosphere of the several high mountains, among which are some active volcanoes, in the eastern part of Java. Very frequently variable and suddenly shifting winds and squalls are experienced in this strait.

A reef, called the *Karang Katang*, was discovered by Captain Kingdom, in the Dutch ship *Diederika*. It lies in the bay between Warangan Point and Probolinggo, about $2\frac{1}{2}$ miles off shore, with Probolinggo West harbour point S. $\frac{3}{4}$ E., and Gunong Loros E. $\frac{2}{3}$ S. It is very small, and has $3\frac{3}{4}$ fathoms least water, surrounded by depths of $9\frac{1}{2}$ fathoms.

KATAPANG, or *Krabben Island*, in $7^{\circ} 41' S.$, and $113^{\circ} 16' 10'' E.$, is not high, but woody; about a mile East and West, and half a mile North and South. It is surrounded by a broad coral reef, which projects fully a mile to the eastward, with 15 fathoms close to its East and N.E. sides, and 10 fathoms at the West and S.W. sides. When not bound to Probolinggo, or to one of the adjacent places, keep well to the northward of Katapang, but at the same time giving a good berth to Eendragt Reef.

A ship may safely approach the Java shore till Mount Ringit bears South, as no dangers have been found on the coast to the westward of it, except a little to the eastward of Cape Bedoelang, where there seems to be a shoal 2 miles from the shore. H.N.M. schooner *Argo* struck on it in September, 1846. It may be the same as that examined by Lieutenant Toutenhoofd, which lies above half a mile off the most projecting point between Bezoekie and Bedoelan, called Tanjong Binor. The reef is called *Karang Krantjie*, is awash, and from it Gunong Laros bears S. $\frac{3}{4}$ E.

PROBOLINGO flagstaff is in $7^{\circ} 44' 30'' S.$, and $113^{\circ} 12' E.$ The town lies in a bight of the coast, opposite Katapang, that island bearing N.E. $\frac{3}{4}$ N., Warangan Point W.N.W., and Mount Lamongan S.S.E. $\frac{1}{2}$ E. It is an open port for exports only. The coast may be approached in this bight safely, with due attention to the lead, there being at 2 miles distance 4 to 6 fathoms, at 3 miles 7 and 8 fathoms, and so on, gradually increasing. A vessel going to Probolinggo may pass either East or West of Katapang, but should not approach it within 2 miles. The common anchorage in the road is in 4 or 5 fathoms, with the flagstaff bearing about S.S.E., Katapang N.E. $\frac{1}{2}$ N., and Warangan Point about W.N.W. $\frac{1}{4}$ W. This place is often visited by ships in want of water or refreshments, both of which are excellent. The river is lengthened by a pier. The English ship *Albion*, sunk in the roads of Probolinggo, is marked by a buoy (1875).

A *red light* is, or is to be shown from an iron post at Probolinggo.

Mount Lamongan, or *Belierang*, is an active volcano, about 17 miles S.E. by S. of Probolinggo. It stands in $8^{\circ} 0' 30'' S.$, and $113^{\circ} 20' E.$; and its summit is 6,824 ft. above the sea, while that of the *Argopoera Mountain*, to the eastward, and the highest of the range, rises to 9,843 ft., according to Dr. F. Junghuhn.

BEZUKIE flagstaff is in $7^{\circ} 43' 45'' S.$, and $113^{\circ} 40' E.$ This town is the capital of the Residency which comprises the eastern part of Java, and is much frequented by ships. It is an open port for exports only.

A *bright light* is, or is to be, shown from an iron post at Bezukie.

A vessel bound to this place from the westward may steer inshore near Bedoelang Point, so as to bring *Mount Ringit*, or *Ringgit*, to bear E. by S., but not more to the eastward, on account of the shoal before described. It is easily distinguished by its superior height, its vicinity to the coast, and by its rugged, rough, and barren aspect; it is an extinct volcano, and its summit

stands in $7^{\circ} 43' 30''$ S., and $113^{\circ} 51'$ E. When this mountain bears E. by S., a hill named *Tempora*, to the westward of the town, will soon be discerned on the bearing of S.E., and the conspicuous white coffee storehouses, with red tiles, of Bezoekie. In approaching the anchorage the water will shoal from 20 to 8 fathoms, and a broad sandy bank spreads out from the shore, steep-to, and projecting farthest from Katang Point, where there is but $1\frac{1}{2}$ fathom or less. Abreast of Mount Tempora, in the western part of the road, some rocks and foul ground will be found. A mile to the eastward of Katang Point there are 11 to 13 fathoms, and this depth will be carried as far as Poetie Point. The anchorage is N. by W., or N.N.W., from the flagstaff. Mount Tempora W.S.W. $\frac{1}{2}$ W., about a mile from the shore, and in 9 or 10 fathoms water. In $7\frac{1}{2}$ fathoms, with Mount Tempora W. by S., a ship would lie too near the bank and too close to the fishing stakes.

PANARUKAN.—The flagstaff of Panarukan is in lat. $7^{\circ} 43'$ S., long. $113^{\circ} 53' 36''$ E. The town lies in a little bay at the foot of Mount Ringit. It is an open port for exports only. The western side of this bay is formed by a projecting point, on the extremity of which stands *Pilarong Hill*, and which, in one with Mount Ringit, bears S. by W. $\frac{1}{4}$ W. A *dangerous rock*, with only 10 ft. on it at low water, lies in this part of the bay at half a mile off the beach, with the flagstaff at Panarukan bearing S. $64\frac{1}{2}^{\circ}$ E., and the eastern high peak of Gunong Ringgit S. 65° W. The eastern coast of the bight leads N.E. and N.E. by E. to Cape Tyna, and is partly margined by a rocky reef, which begins 2 miles from Panarukan, projects half a mile from the shore, and reaches as far as the River Gomok. This reef dries at low water in some places, but has 5 fathoms close to it, and 10 and 12 fathoms depth at a mile distant. Ships coming from the westward and bound to Panarukan, may stand in for the road, with Mount Ringgit bearing South, and anchor in 17 to 15 fathoms water, on a mud bottom, full a mile from the shore; the flagstaff S. or S. $\frac{1}{2}$ E., and Mount Ringgit S.W. Good fresh water and beef are to be procured there; but fowls and other provisions are scarce. The anchorage is considered safe at any time of year.

A *red light* is, or is to be, shown at Panarukan.

CAPE TJINA or China Point is the northernmost point of the eastern part of Java, and is in $7^{\circ} 38'$ S., and $114^{\circ} 4'$ E.; it is all low, so that from the westward, the Sedano Hills are seen high above it. There is a small sandbank just to the westward of Cape Tjina, upon which there are but $1\frac{1}{2}$ and 2 fathoms at low water, and from which the cape bears N.E. by E., and Mount Ringgit W. by S. There is another shoal of $4\frac{1}{2}$ fathoms, hard sand, just to the westward of Cape Tjina. The cape bearing E.N.E. $\frac{1}{2}$ E., 1 mile distant, and Mount Ringgit S.W. $\frac{1}{2}$ W.; and 2 miles from the land to the southward; but the bank rises as suddenly as a wall from 13 and 12 fathoms, to 5, and less. To avoid this danger, it is advisable, when passing Cape Tjina at the West side, not to borrow too much towards the shore.

KOMBANG BAY.—To the eastward of Cape Tjina the coast runs about 8 miles to the southward, and forms Kombang Bay, in which are situated the kampongs (*villages*) of Aggel, Kombang, and Tianker. This bay reaches to Tianker Point. This bight is not free from dangers, as from Tjina there is a sandbank a mile off, with 2 fathoms water, though 14 to 9 fathoms are close to it. There is said to be another bank to the S.E., with 2 fathoms only at high water, called the *Enora*.

A dangerous shoal was discovered, in 1812, by H.M.S. *Hecate*. Her boat found $2\frac{1}{2}$ fathoms, rocks, and on some parts of it there appeared to be less water, and an appearance of breakers. Cape Tjina bore from it N.W. by W. ; Mount Ringgit, W.S.W. ; the first point to the westward of Cape Sedano (Tianker Point), E. by S. ; and Sedano Mount, E.S.E. Inside of this shoal there are 13 fathoms water, 3 miles from the Java shore. But as this shoal has been sought for without success, it is doubtful if it exists as stated ; nevertheless, vessels should not enter the bight between Tjina and Tianker without necessity, and then with very great caution.

The is a good anchorage in the eastern monsoon behind Tianker Point. In this part of the Isle of Java there are several small rivers, but at high water their contents near the entrance are brackish. The westernmost gives the best fresh water, which falls there over some rocks, situated above high water mark.

Between Tianker Point and the projecting point of *Loemoet*, 8 miles to the eastward, there is another bay, and the village of *Tiottek*, about a mile from the entrance of a river. The mouth of this river may be found by a very conspicuous dead tree, with two branches, on its eastern bank. The anchorage is in 9 or 10 fathoms, half a mile off shore, the dead tree bearing S.E. by S. or S.E., and Loemoet Point, or the East point of the bay, E. by S., about 4 miles distant. The river affords good water, and is often visited by trading proas ; but with a N.E. or E.N.E. wind the road is exposed to a high sea. The reefs near this village stretch off to the westward from Loemoet Point till abreast of the dead tree. They are all within a mile of the shore, and often afford shelter to the pirates, it being difficult to pursue them, and they find there fresh water in abundance.

CAPE SEDANO forms the north-easternmost point of the Isle of Java, in $7^{\circ} 49' S.$ and $114^{\circ} 26' 53'' E.$ From Loemoet Point to the eastward the coast curves gradually from E.S.E. to S.E., without any conspicuous points, the whole being considered as Cape Sedano. The true cape is a bluff rocky projection, which bears E.N.E. $\frac{1}{3}$ E. from the summit of Mount Sedano, and from which the coast runs more southerly. The perpendicular height of the mount above the sea is 4,760 ft. Near the cape there is a reef, which stretches 2 or 3 cables' lengths off shore, and inside of which frequently proas are anchored. The depth along this coast is considerable, being in places 50 and 60 fathoms, no bottom. Mount Sedano is high and rugged, and from different

points of view has a different appearance, showing sometimes a flat table top, and sometimes separate summits.

MEINDERS DROOGTE is $1^{\circ} 41' 30''$ S., and $114^{\circ} 22' 30''$ E., lies North nearly 6 miles from the north-eastern coast of Java, and consists of coral, part of which is always above the level of the sea. This dry part stretches N.W. and S.E. about a mile; it is very narrow, and resembles at some distance the trunk of a fallen tree.

LIGHT.—An iron pile lighthouse, with three galleries, was constructed in the Meinders Droogte Reef, in 1877, and from it is shown a *fixed bright light*, from a catadioptric (lenses and reflectors) apparatus of the fourth order. The lighthouse is 46 ft. high, and the light, elevated 56 ft., is visible 12 miles off.

Vessels should not approach the lighthouse for 3 or 4 miles on its eastern side, as a 2-fathom patch extends to the distance of $2\frac{1}{2}$ miles from it in that direction. It is separated from the dry reef by a narrow channel. On its S.W. side the lighthouse reef spreads a mile under water, consisting of large detached rocks, carrying 3 fathoms water, while there are 50 fathoms close to them.

About a mile W.N.W. $\frac{1}{4}$ W. from the above reef there is another patch of half a mile in extent, with 2 fathoms water in the shoalest place, and no bottom with 25 fathoms between them.

Lieutenant Rietveld discovered three other reefs bearing W. by N. and W.S.W. $\frac{1}{2}$ W., besides the last-mentioned, at the distance of 1 and 2 miles from the dry part of Meinders Droogte, but with not less than 7 fathoms in the shoalest place, and then 8, 10, and 15 fathoms. Two Dutch vessels were wrecked in 1866, on what were stated to be some detached shoals, but it was found that the *Isis* was S. 30° W., a third of a mile from the beacon, and the *Cornelis Anthony* was on the reef bearing W.N.W. from the beacon. To the southward of them there are 50 and 58 fathoms.

The Eastern Coast of Java, which forms the western shore of the Strait of Bali, will be described in the next chapter, in connection with that strait, and the islands East of it.

The **SOUTH COAST** of JAVA is unlike the North coast, which in most places consists of low plains near the sea, with regular soundings along the coast, and anchoring ground almost everywhere. The South coast is generally high, consisting of steep rocks and rugged points, always covered with foam and breakers, and the whole coast wearing a barren and desolate appearance. In general, great depths will be found in the immediate vicinity of the coast, and although in some places a less forbidding beach and a less depth of water may be found, yet they very seldom afford a fit spot for an-

chorage, as a terrific swell, especially in the N.E. monsoon, lashes with unceasing fury on to its headlands, or, carried by the full force of the ocean, rolls into its ports and havens. Notwithstanding this, the South coast of Java is not altogether destitute of places of shelter, for there are a few bays and harbours which afford, under every circumstance, a safe retreat, and have been made known by the surveys of some eminent officers of H.M.S. navy.

From the small extent in latitude of Java, and the consequent approximation of its North and South coasts, the mountains serve as leading marks equally on either side of the island. Throughout the western monsoon some of these mountains may be discerned at the distance of 15 to 25 leagues, but in the eastern monsoon they are generally concealed by a hazy sky, and therefore not distinguishable till very near. The situation and height of these mountains have been already described in the former pages.

The WINDS and SEASONS are described on page 14 *ante*; the CURRENTS on pages 30, 31.

The SOUTH POINT of Java, in $8^{\circ} 47' S.$, and $114^{\circ} 26' 13'' E.$, is the southernmost projection of the great peninsula which forms the south-eastern extremity of Java. From this point the coast curves in a little, E. by N. for about 8 miles towards the *Zuidoost Hoek*, or *S.E. point* of Java; and again, N.W. by W. for about 6 miles towards *Tambang Point*. This part of the coast seems to be fringed with reefs under water, to a mile off shore, with 20 and 25 fathoms close outside, and with 70 and 100 fathoms of line, no bottom, at 2 and 4 miles distance. Continual breakers will be seen there, and the impracticability of anchoring in such large depths makes it advisable to keep at some distance off this coast, especially in calms and light airs.

GRADJAGAN BAY.—Gradjagan is a large bay to the westward of *Tambang Point*. It is 10 or 11 miles wide, and about 6 miles across; and it is said to afford good anchorages during the eastern monsoon, in 14 to 8 fathoms water. On the western side of the bay, on a small river, stands the village of *Gradjagan*, but neither there, nor in the wells along the beach, is good water to be had; nor can ships' provisions be procured.

From Gradjagan Bay to *Nusa Baron*, or *Baron Island*, a distance of about 16 leagues, the coast is steep, rocky, and barren, forming a chain of small bights, lined with several islets and rocks, which make the approach dangerous. One of these bights, 16 miles to the eastward of *Baron Island*, is called *Vledermuis (Bat) Bay*, but from its rocky shore, large depths, bad shelter in most winds, and continual surf, is unsafe.

Baron or Barung Island.—The S. point of *Nusa Baron* is in $8^{\circ} 32' S.$, and the W. point in $113^{\circ} 15' E.$, and the island is 8 miles in length, and 4 miles in breadth. Its South side is low, fronting the sea, but the S.W., S.E., and E. sides steep, of considerable height, and rocky, and discernible at a considerable distance. The summit of *Mount Semiroe* bears from the East point

about N.W. by W., and its nearest distance from the shore of Java is $2\frac{1}{2}$ or 3 miles, with 20 and 30 fathoms between them. At the N.E. angle of the island there is a small bay, where tolerable anchorage may be found in the N.W. monsoon in 27 fathoms.

N.N.W. $\frac{1}{2}$ W. from the East point, and E.N.E. from the West point of Baron Island, the Java shore forms a projecting land-tongue; 5 miles to the eastward of which lies the village and the river of *Poeger*, where some provisions and water may be procured in the western monsoon.

Dampar Bay.—N.N.W. of Baron Island, the Java coast makes a bay, with 50, 30, and 20 fathoms water. The easternmost part of this bay has a sandy beach, which rises into sandhills or downs; the western shore is rocky, and it is said that dangerous sunken reefs project some distance from the shore. One rock lies 8 miles W.N.W. from the N.W. point of Barung Island.

To the westward of Dampar the country inland is mountainous, and in clear weather a good mark to correct the reckoning is the high hill of Semiroe, the conical summit of which is in $8^{\circ} 8' S.$, and $112^{\circ} 54' E.$, and discernible 20 leagues. The coast forms here several bights, of which the principal, *Pelolot Bay*, bears about S. $\frac{1}{2}$ W. from Semiroe Peak.

Sempoe Island is 8 miles to the westward of Pelolot Bay, and its West point lies in $8^{\circ} 28' 30'' S.$, and $112^{\circ} 39' E.$, or about S.W. by S. from Semiroe Peak. The island is 5 miles long, and consists, as does all the adjacent coast, of high rocks. It is separated from the main by a strait a quarter of a mile wide. From the island of Sempoe the coast runs about 17 leagues W. by N., and consists of a ridge of steep rocks, fronted by an uninterrupted line of surf.

SEGORO WEDIE BAY is one of the most splendid bays of the whole island of Java, as well with respect to its situation and fitness for trade as to the magnificent appearance of its extensive basin, surrounded by its high and picturesque land, or by the numerous islands in its entrance. The latitude of *Tawing*, a village at the northern part of the bay, is $8^{\circ} 16' 40'' S.$

The group of *Limo Rocks* (or Five Islands), which are full 2 miles S.E. of the entrance, are in $8^{\circ} 22' 45'' S.$, and $111^{\circ} 43' 48'' E.$ Outside of the bay, besides the Limo Rocks, there are several other small islands, but all within 3 miles of the shore, and as some of them are elevated from 120 to 400 ft. above the sea, they serve as leading marks towards the entrance of the bay. All these islands, as well as the adjacent coast, are steep-to, rising abruptly out of the water, so that a ship may pass on either side of them when entering the bay. There is said to be a dangerous rock of $3\frac{1}{2}$ fathoms called *Bergat*, with Goenong Island bearing W.N.W. $\frac{1}{2}$ W., Wot Jaloe Point N.N.E., Losari Island E. $\frac{1}{8}$ S., and the West point of Boyo S. by E. $\frac{1}{2}$ E., but this is doubtful.

There are no other concealed dangers in the entrance of the bays, as the Batang and Skel Rocks remain always above the surface.

Segoro Wedie Bay is separated into two bights, *Segoro* and *Damas*; the former is bounded to the southward by the sugarloaf shaped island *Rembeng*, and to the northward by the rock of *Pegat*. In this bight a ship will be sheltered, in 14 fathoms mud, from wind and sea in the eastern monsoon, on the eastern side of the bay. Fresh water may be procured, and communication may be kept up with the shore, by the ships' boats or by proas, as most convenient respecting the cargo.

The anchorages along the western side of the bay are not safe, and, with a southerly wind, even those on its eastern side are not exempt from a heavy swell that rolls heavily in; while with south-easterly gales, sudden gusts of wind come down from the mountains, but they are not of long duration.

Gemah and Boemboen Bays.—About 4 miles to the eastward of Segoro Wedie Bay there is a deep bight, between Wat Jaloe Point and Djong Pakis Point, about $6\frac{1}{2}$ miles wide at the entrance, and receding 4 miles to the northward, where it is divided into two parts by a rocky projecting interval. The western part is called *Gemah Bay*, and the eastern *Boemboen*.

In general the coast is here rocky, but very steep. In the eastern monsoon the bay is wholly open to the wind as well as to a high running sea, except under the south-eastern point of Lemiring, where a ship will find a tolerable shelter close in-shore near the village of Popoh. The northern and western sides of Gemah Bay are unsafe in that monsoon.

Popoh has about 150 inhabitants, and affords good water and wood, but no ship's provisions whatever. Inland communication is here much more convenient than from any of the other bays of the South coast, as it is only separated from the interior by a ridge of hills 300 or 400 ft. in height, which is comparatively low.

Boemboen Bay lies 3 miles to the eastward of Gemah Bay, and extends from *Pakis Point*, upon which stands a round hill of the same name, to *Selo Pajong* (a flat stone), which bears some resemblance, at a distance, to a dismasted wreck. There being no inhabitants, no provisions are to be had; but the bay is unfit to be used in the eastern monsoon.

Soembreng Bay.—From Segoro Wedie Bay the shore stretches West, and W.N.W. 8 miles to Soembreng Bay, forming different points and small bights, though not offering good anchorage.

Soembreng Bay, in about $8^{\circ} 20' S.$, and $111^{\circ} 34' E.$, is far inferior to that of Segoro Wedie, not only in regard to its smaller extent, but in its insecure anchorages and inconvenient landing-places. Two or three miles S.W. of this bay the three rocky and uninhabited islands, *Kalengan*, *Prendjono*, and *Kepanean*, serve as good marks for this or for Pangoel Bay.

It is 2 miles wide at its entrance, and contains no dangers except the

rocks round the small island of Sroyoe, near its S.E. point; and Gebos Reef which bears S.S.E. from that island, about 2 cables' lengths, but it shows itself above water. The depths in the entrance are from 35 to 40 fathoms.

At each end of the sandy beach, upon which there is always a high surf there is the mouth of a river. The eastern one has some rocks beneath the water's edge at high water, and very dangerous when there is the least swell. The water, however, is very good, and fire-wood may be had in plenty there. The communication with the interior is difficult from the steep ridge of mountains.

PANGOOL or Pangoel Bay is about 6 miles to the westward of Soembreng, and 5 leagues from Segoro Wedie; it affords a good anchorage in the eastern monsoon, and is frequently visited by coasting traders, being an open port, but for exports only. Its limits were defined by the Royal Ordinance, March 23rd, 1862, as lying within the line joining the beacon mark for the harbour and the N.W. point of Pulo Kongitan, or North Gialang, and bearing from each other N.E. $\frac{1}{4}$ E. and S.W. $\frac{1}{4}$ W.

At the distance of a mile from the S.E. point of the Bay of Pangoel lie the dangerous rocks of *Sero*; they are partly above water, and though the southernmost is sometimes covered, its high breakers usually show its place. The passage to the eastward, between them and the S.E. point of the bay, is a mile wide, and seems to be free from danger, as all the rocks are visible above water. The common anchorage in Pangoel Bay is at the N.E. side in 7 or 8 fathoms, sand, opposite the Government Salt Storehouse; but as a ship is exposed there to a dangerous swell, and the landing is troublesome, another anchorage, a little more to the southward, in a bight abreast of Kongilan Island, is preferable. This bight is scarcely half a mile wide, but it has good ground, sand and clay, in 7 to 5 fathoms. The bottom rises gradually towards a sandy island, upon which stands the coffee storehouses; and there is a pier, which much facilitates the transfer of cargoes, as well as the intercourse of boats.

From Pangoel the coast stretches to the westward for 24 miles to Patjitan, but forming some bights, of which *Lorok Bay* is the principal, although too small and too much exposed to afford any anchorage for ships. The coast is high, rocky, and lined by a continued range of breakers.

PATJITAN BAY.—Ships bound to Patjitan Bay ought to steer close along the shore, for fear of passing it in the night, the opening not being wide; care is also requisite not to mistake it for Lorok Bay, as they bear much resemblance to each other; but as these bays differ 15 minutes in longitude, an error of this kind is not probable, if any confidence can be placed in the chronometers, and if due attention is paid to the following directions. The middle of the bay lies in $8^{\circ} 15' S.$ and $111^{\circ} 3' E.$ Its limits were officially defined (March 23, 1862) as being inside the line joining the signal flagstaff on Ngamber Point, on the eastern side, and the hillock of Karang Semondo

on the West. The entrance is only 1 mile wide, but inside it expands to 2 miles in breadth and in length; and when it bears N. or N. by E. the bay is open and easily discovered. The fair track into the bay is mid-channel between the two points, on both of which a high surf always breaks. Patjitan Bay cannot be considered as quite safe, or as an agreeable resort, for ships must submit there to continued heavy rolling, sometimes gunwale under, occasioned by the perpetual high southerly swell. Notwithstanding all this, the anchorage has in most places good holding ground, consisting of black sand mixed with clay, in 8 to 14 fathoms. There are but two places in the bay fit for boats to land; the first on the western side, near a small patch of white sand, called *Temperan Beach*; the watering-place is also there, and near it the best anchorage in 8 or 9 fathoms water. The other landing-place is near the eastern point of the bay, in *Megelon Cove*, which, though very small, is large enough to contain a single ship. In this cove there is very little swell, and 12 to 10 fathoms, soft ground; farther in, a deep cleft will be discerned in the land, in the direction of N.E. by E., forming a little harbour, with depths of 4 to 2 fathoms, soft ground, and shoaling gradually to 3 ft., with a small white sandy beach without any surf at all. Both the little harbour and the cove in which it is situated are completely landlocked; but the communication with the chief town, Patjitan, is difficult from the intervening mountains. Patjitan is an open port for exports only.

The fine river *Pantier* falls into the bay at its N.E. side, but it is difficult to enter on account of its bar. The whole North side of Patjitan Bay is lined with a beach of white sand, but the high surf renders it impracticable for landing. It is high water, at full and change, about 3 o'clock, and the vertical rise is a little more than 7 ft.

From Patjitan Bay a barren, woody, uninhabited coast of chalk mountains, and fronted by a continuous line of breakers, stretches W. by N. and W.N.W. It forms, however, some small bights, of which *Hombo*, *Krakal*, and *Baron*, are the largest, but all of them useless to ships. Farther on, from near Brossot to Bollong Head, the shore is not so steep, and the beach rises into a chain of sand downs, about 25 ft. in height above the water. There is no anchorage near this part of the coast.

BAGLEN HEAD, or Meganties Point, lies in long. $109^{\circ} 24'$ E., and is a promontory of steep and inaccessible rocks, said in the old charts to resemble Beachy Head. Landing there is impossible from the high surf; and it is without doubt that there are some sunken rocks near it. Many instances are on record of boats and proas, in endeavouring to land, having been upset, and of large trading proas, as well as other vessels, having been wrecked there.

When coming from the eastward, Baglen Head seems to be surrounded by low land, and is a notable mark for ships bound to Tjilatjap. From the S.E. or southward it has the appearance of an island with peaked hills. It

bears much resemblance to Kambangan Island; but if the chronometers are not much in error, such a mistake is not probable, as the two points differ 24' in longitude.

SCHILDPADDEN or **Turtle Bay** is the long bight between Kambangan Island and Baglen Head. According to the Kambangan pilots, this bight is without dangers, and has good holding ground throughout, except near the range of breakers. Some rivers that discharge themselves into it cause irregular currents, with patches of discoloured water and ripples, and drive out trees and shrubs in abundance. In the eastern monsoon it affords no anchorage for ships, at least not without suffering from much wind and swell, near the village of *Jettis*; for though Baglen Head offers some partial shelter, by which landing is rendered less dangerous than at any other place, yet the promontory does not project enough to afford a safe anchorage. The only good anchorage in the whole of Schildpadden Bay is behind the eastern end of Kambangan Island.

KAMBANGAN ISLAND is separated from Java by a very narrow channel, and it occupies the whole space between the bays of Schildpadden and Penaniong. At each end of the island there is a harbour, Tjilatjap and Tjitando. The latter, to the eastward, is a place of considerable resort for vessels of all sizes; and on the right bank of the river, which empties itself into the former, stands the establishment of Kalie Poetjang.

To the northward the channel expands into Anakan Lagoon, which is fully 4 miles square, but from its extensive mud-banks it is navigable by proas and small vessels only. Kambangan is throughout its whole length high and rocky, but covered with large trees, and stretches from W.N.W. to E.S.E., its extreme length being 15, and its breadth 4 miles.

TJILATJAP or **Chailachap**, near the eastern part of Kambangan, is an open port, and the most important on the South coast of Java. It has increased remarkably in importance since the development of the commerce of the island, being the market for the entire products of the surrounding country. The surveys of the Dutch Government, and the marks established, will simplify its navigation, but a pilot is necessary.

The South point of Tjilatjap lies in $7^{\circ} 44' 40''$ S., and $109^{\circ} 5' 30''$ E.; and the flagstaff on Bollong Head is in $7^{\circ} 46' 12''$ E., and $109^{\circ} 7' 0''$ E., according to Lieut. Rietveld.

Vessels bound to Tjilatjap ought to steer for the eastern end of Kambangan. This island, from the southward, is very conspicuous; the East part being high and terminating in the bluff head of Bollong. In clear weather, and when the mountains are not hidden by clouds, the conical peak of Tegal will be an excellent mark; by bringing its summit N. by E. $\frac{1}{2}$ E., when Bollong Head will be seen in the same bearing; but if the peak should be made on the bearing of North, then the head will rise in the N.W. about 20 miles distant. When approaching to within 5 or 6 miles to the eastward of

Kambangan, some hills will be discerned, which are situated to the eastward of the rivers Serayoe and Adirejo, and near the shore, and have the appearance of an island.

LIGHT.—In order to distinguish the eastern point of Kambangan from Karang Bollong to the East of it, a stone tower was erected, but it was blown down. A new stone tower, 75 ft. high, was erected in 1861. There is now a lighthouse on this part of the island, on Tjimiring Hill, from which a *bright revolving light* is shown at an elevation of 665 ft. above the sea, and visible 20 miles off. It appears as a bright light for 8 seconds in every minute, and is obscured to vessels close under the land.

Besides this outer mark there are three pairs of leading marks or beacons, which show the direction of the inner channel, and two others farther in.

In coming from the eastward, and getting near the island, the rock of Bollong will be perceived, lying 87 yards from the N.E. point of Kambangan Island; this rock, at which the channel begins, is very small, covered with some trees, and hollow underneath.

Lieutenant Rietveld says—When Bollong Rock bears West, at 2 miles distance, good anchorage will be found; when the S.E. point of Noesa Kambangan bears S.S.W., 12 or 13 fathoms, sandy bottom; the East point approached within half a mile, 8 fathoms, sandy bottom; the East point bearing South, 5 or 6 fathoms, sand; and N.E. of Bollong Rock, or of the flag-staff, at low water, 4 fathoms. Inside or to the westward of Bollong Rock, there are again 6 and 8 fathoms, and throughout the whole channel good anchorage ground will be found, as indicated by the chart.

A government native pilot proceeds instantly on board of any vessel on her making the signal for a pilot, which should be accompanied by a gun.

With westerly winds there is no great swell under the lee of Kambangan Island, and vessels to the N.E. of Bollong Head, while waiting for a pilot, may anchor there as soon as they are sufficiently sheltered. In the south-eastern monsoon the pilot will come out, unless the wind and swell are too high, in which case that anchorage would not be safe, and then vessels should stand off and on in the offing, unless they are so far acquainted with the place as to be able to run inside of Bollong Head, where they will be protected from the wind, and not very much incommoded by the swell. While waiting outside, keep Bollong head to the West of S.W., as the outer or sea-bank stretches from the point N.E. of the Hard Sand-bank opposite Kambangan.

Beacons.—The channel within Karang Bollong is shown by several beacons as above mentioned. The principal are two *stone* towers, surmounted with hexagonal iron plates, 25 ft. in diameter, standing near Karang Tenga, and 288 ft. apart; being in one, S. 68° W., they lead up to Karang Rempak.

Two smaller but similar *beacons*, near Banjoe Njapa, 75 ft. apart S. 45° W. in one, lead through the narrows by Karang Rempak.

To the southward of Karang Rempak are two similar *inner beacons*, East and West, 45 ft. apart, leading between Karang Rempak and Karang Tenga.

These three pairs of beacons are alike in form and colour. The higher and inner ones are white, with three black perpendicular stripes. The outer and lower ones are white. When in one the white beacon covers a portion of the inner one, the black stripes on which are thus seen over it.

Besides these beacons there are two pair of *marks* farther in. The first two are on the North side of the channel; they stand on Karang Balie, and point out the end of the sea-bank. Their tops are triangular, the base of the triangle being perpendicular, and their upper points in opposite directions, so that when seen in one, these tops being at equal heights, form a square. Their bearing is N. 53° W., and show the above direction.

Another pair of similar beacons stand on the southern side of the channel, a little to the southward of the former, and are in one N. 60° W. 260 ft. apart. In using these marks, great caution is requisite, to keep the narrow channel, without touching on the banks.

As for a stranger a pilot is necessary, it is needless to give more directions than those which were generally useful previous to the establishment of the beacons in 1861.

The channel up to Tjilatjap is very narrow from abreast of Bollong Rock, where it makes a curve towards the S. W.; and between the end of the Hard Sand and Kambangan it is not 220 yards wide, but on both sides steep-to. In the middle of the channel there are from 4 to 9 fathoms, with a few spots which carry only 20 ft. It is too narrow to work in, and therefore a vessel must be warped in against the wind.

To avoid a rock which bears North of Mount Brambang, or S.S.E. from the coal store on the South point of Tjilatjap, and which carries only 2½ fathoms at low water, keep the point of Sodon in sight, well outside of Agong Point. This point, Agong, in one with the foot of the farthest visible mount, Boaya, leads just upon the rock, Sodon Point being then, of course, shut in. Keep nearest to the Kambangan side, where good anchorage will be found S.S.W. from the storehouses, on the line uniting the pier and the watering-place, and in 5 or 6 fathoms, with a sand and mud bottom. The deepest water will be found on the Kambangan shore, which is also steep-to. A vessel lies here as in a dock, sheltered from all winds, and without any swell; so that since the pier was completed, cargoes are shipped or disembarked with facility.

The bight of Tjilatjap, between the South point and Green point, contains a soft sloping mud-bank, stretching out as far as the pier, and drying at low water spring tides. With the South point of Tjilatjap in one with the flag-staff of Bollong, there are not more than 4 fathoms depth between those two above-mentioned points.

Tides.—The following information respecting the tides, currents, and winds in the neighbourhood of Tjilatjap, has been collected from Lieut. Rietveld's remarks.

The ebb tide runs between the easternmost beacons to the N.N.E. and N.E., and the flood to the S.W., over the Hard Sand-bank, and then partly turns to the W.S.W.

Abreast of Balie Rock, just to the westward of Rempak Point, the ebb tide sets to the North and N.E. over the sand-bank; also the flood to the South and S.W.; and in the West monsoon to the S.S.E., towards Banjoe Japa Rock, in the deepest part of the bight, from whence it follows the westerly trend of the channel. When the Hard Sand-bank is dry, the streams set of course along its edge.

To the westward of Tjilatjap Point the tidal streams follow the direction of the channel; the flood, more than half the length of Kambangan Island, into the Anakan Lagoon, where it meets the flood which sets in through Tjitando Bay and round the West point of Banting Mattie. The ebb runs in the contrary directions, sweeping round the bight of Banjoe Japa, and then N.E. through the narrows, and crossing the Hard Sand, or entering the sea in an East or E.S.E. direction.

The velocity of these streams is variable, $2\frac{1}{2}$, 3, 4, $4\frac{1}{2}$ knots, and the ebb even 5 and $5\frac{1}{4}$ in the rainy season. The time of high and low water is, at full and change, low water, $2^h 35^m$, and high water $8^h 45^m$; the length of the flood being about $6^h 0^m$; and the mean rise and fall about $3\frac{1}{2}$ ft. The greatest range of the tide that took place was 6 feet $3\frac{1}{2}$ inches.

In the morning, before 8 or 9 o'clock, there is usually a gentle land breeze from the West or W.N.W., which enables vessels to go out in the eastern monsoon. Then, in both monsoons, it is calm till 11 o'clock, which allows ships to warp or tow in, during the western monsoon. From the middle of July, however, till the beginning of October, there are continued easterly winds, without the least interruption; and in August and September they are accompanied by heavy rains, and sometimes storms, with no westerly or land breeze at all.

Deep-laden ships waiting outside for a fit opportunity to weigh often suffer severely from the sea. In both monsoons a small steam-tug (perhaps now established) would, therefore, be a great benefit to the trade of Tjilatjap.

The watering place on the Kambangan shore is near the anchorage, and affords good and pure water; a brick aqueduct and reservoir may be the process convenient.

The Island of Kambangan is all rock and wood, there is therefore plenty of fuel, and even trees fit for topmasts; there is also a profusion of game, such as deer, wild hogs, tigers, rhinoceroses, &c. Refreshments are to be procured plentifully at Tjilatjap, but few ships' stores at present. The favourable position of this port for general commerce has so wonderfully in-

creased the number of vessels by which it is visited, and so conveniently is it connected with the rest of Java, that perhaps at no very distant period it will be the principal entrepot of the whole island. On the sea-face of Karang Bollong are numerous caves, in which are found the edible birds' nests so highly prized by Orientals. The nests are formed, by a small species of swallow, of gelatinous seaweed. The caves are from 50 to 700 ft. beneath the hill tops, and inaccessible, except to men lowered by ropes.

The climate of Tjilatjap cannot be considered healthy, especially in the western monsoon; and malignant fevers prevail sometimes after a long drought, and during the rainy season.

At Tjilatjap are residing an assistant resident, a storekeeper, and some civil authorities of minor importance, and a small garrison at Karang Bollong, a military doctor, hospital, &c. The western entrances of Segara Anak, which are formed to the westward of Kambangan Island, and which are visited sometimes by coasting vessels to fetch a cargo of salt for Kalie Poetjang, are very narrow and intricate. Bessek Head, the S.W. extremity of Kambangan Island, lies in $7^{\circ} 41' 45''$ S., and $108^{\circ} 49'$ E.

Tjitando Inlet, the western entrance to the *Segara Arrakan*, or *Anakan Lagoon*, between Kambangan and the Java shore, is 2 miles long, and for a mile 2 cables' lengths wide; and both sides are high, steep, and rocky. *Wre Island* divides the inlet into two parts, and there are also some detached rocks, which make it still more intricate. The opening into this inlet, which lies 2 miles North of Bessek Head, Kambangan, is not discerned easily when coming from the southward, even at a short distance, from its tortuous course and its high shores; but steering a little northward of Bessek Head, *Wre* will easily be distinguished when standing in-shore.

Ships bound to this place in the eastern monsoon should make the land a little to windward of the western end of Kambangan, and then run along towards the Isle of *Wre*, but not forgetting the *Amboer*, a dangerous sunken rock, bearing N. by W. $\frac{1}{2}$ W., 700 yards from Bessek Head.

In the western monsoon a ship should first steer for Cape Mandararie, at the extremity of Penaniong Bay, and bearing W.S.W. $\frac{1}{2}$ W., 19 miles from Bessek Head. From Cape Mandararie the course of E.N.E. leads into the entrance of this inlet.

The steep sides of the Tjitando Inlet intercept all winds which do not blow straight through, and the little room it affords for working, along with its winding form, in most cases render towing or warping unavoidable. A ship must trust chiefly to the tides, and when she arrives at the mouth of the inlet, she should anchor and wait for the flood. It need scarcely be mentioned that with westerly and southerly winds there will be a heavy swell there, and, although the holding ground is good, a ship cannot be said to lie in safety.

With southerly winds, in either monsoon, the entrance of this inlet is very

troublesome and sometimes impossible; but with easterly winds, and no high sea, a ship may anchor near the South side of the Isle of Wré, and wait for a favourable tide.

Between the entrance of the inlet and Bessek Head there is a small bight called *Bator Cove*, which, though only half a mile wide, affords good shelter in easterly winds.

In the passage there is an irregular bottom of gravel and broken rocks, and not till in the Anakan basin will better ground be found, and there only for a small space. When abreast of Banting Mattie, a ship will be landlocked on all sides, and, being no longer exposed to the swell, she may anchor in safety; but she should be provided with chain cables, for the channels being passed entirely by warping or towing, it is necessary to bring up very frequently.

Wré Island, which divides this inlet in two parts, is high, rocky, and densely clothed with trees, stretching N.N.E. and S.S.W. nearly a mile in length, but varying in breadth from 440 to 55 yards. The passages to the East and West of Wré Island are called respectively *Tando* and *Sehel*. It is difficult to prescribe under what circumstances either of these channels should be preferred,—the position of the vessel, the wind and weather, the tide, and other considerations,—must decide the choice of the prudent seaman.

When proceeding through Tjitando or Channel, it should be considered that the reef projecting from Serang Point (which is the western extremity of Kambangan, and bearing E.S.E. from the South point of Wré) is not so dangerous as its heavy breakers would indicate at the first appearance; for outside of this reef there is hard sand ground, with 10 to 14 fathoms water, where, although much exposed to the swell, anchoring is not dangerous. In bad weather, indeed, this reef should never be approached, except to pass it with a leading wind and good headway. Within Serang Point lies the small island of Manok, and W.N.W. from it the dangerous rock of Tongak, which, is, however, visible at low water. The channel leads between this island and some rocks, and is only 328 yards wide, with from 5 to 18 fathoms depth in the middle. Between Tongak and Wré the passage is barred by rocks, and to the depth eastward of Manok there is only from 1 to 3 fathoms depth. Accordingly vessels should steer close along the West side of Manok Island; thence with a N.E. or E.N.E. course in 12 to 20 fathoms depth, along the projecting peninsula of Java, called Siragalo; and pass Cape Mattie with a North or N.N.W. course. *Siragalo Peninsula* is high and steep, and may be passed at the S.E. and East sides at half a cable's length, in 6 and 12 fathoms water; but the Kambangan side should not be approached too near, on account of the rocks of Gomboyok, which are dry at very low water, and bear S. by W. and S.S.W. from Cape Mattie, and E. by

N. and E.N.E. from the point of Siragalo. The eddy of the ebb tide along the Kambangan shore sets right upon those rocks. Cape Mattie lies half a mile North of Siragalo, and half a mile farther, on the Java shore, the river Tjitando falls into the sea. The anchorage off Cape Mattie is in 12 to 20 fathoms water, but a better berth may be found in 7 to 10 fathoms, sandy bottom, about 4 cables' lengths from the mouth of the river Tjitando. There being extensive reefs on the Java shore, and in the Anakan Basin, and the tides and eddies being very irregular, it is advisable to moor the ship.

The Tji Schel Channel to the westward of Wré Island is not so dangerous as that of Tando, and has throughout its whole length, irregular depths, from 4 to 12 and 16 fathoms, gravel and broken rocks. It is necessary, however, to keep in the mid-channel, as there are but 3 fathoms water to the North and N.E. of the Isle of Wré; for 330 yards distance, and to the westward of the peninsula of Siragalo, the Rawit Rocks, which are dry at low water, project 100 yards distance off shore.

This channel is longer than that of Tando, and has the further disadvantage that, when the wind is not favourable, vessels cannot get directly inside of Siragalo, and they are compelled to anchor, which occasions loss of time. In such circumstances it is better to wait to the S.W. of the North end of the Isle of Wré, because the North and East sides afford less shelter, and a nasty swell makes the eastern anchorage very inconvenient. When Siragalo has been rounded, proceed according to the directions for the Taudo Channel.

As both these channels are too intricate for strangers, they should not attempt them, unless in a case of high necessity, without a pilot.

The rise and fall of the water depend much upon the winds, and on the more or less efflux of the rivers which fall into the Anakan Sea; spring tides generally rise 5 to $5\frac{1}{2}$ ft., and the neap tides $3\frac{1}{2}$ to 4 ft. The currents are unequal in force, and the duration of the streams very irregular, except when the rivers are low, the flood and ebb then changing every 6 hours; but while the rivers are full, the flood runs 3, and the ebb 9 hours. At full and change, the times of high and low water are too variable to allow us to give the establishment.

PENANIONG BAY, formed between the western end of Kambangan and Cape Mandararie, is about 6 leagues in extent, and is divided into two unequal parts by the peninsula and point of Penaniong, the eastern Maurits Bay, and the western Vries Bay.

In Maurits Bay, between the peninsula and Kambangan Island, a ship may find sufficient shelter in the western monsoon. When entering Maurits Bay, a rock, perforated like the arch of a bridge, will be discerned, also three rocks in a line, like sugar-loaves; there are no dangers, the soundings decrease gradually till within a mile of the shore, where a ship may anchor,

or nearer if requisite; and fresh water may be procured easily in a small sandy bay.

From Cape Mandararie the coast stretches westward, and then W.N.W. and W. by N., to Cape Anjol, a distance of more than 40 leagues, without meeting between these points anything worth notice. Notwithstanding, there are two points where, at *Cape Santiang*, the coast curves in for some miles; and still more at *Cape Eurum*, about $107^{\circ} 36'$ E. longitude. Near *Boemie Point*, which lies in $108^{\circ} 17'$ E., there are two small islands, the westernmost of which is round, and the other low and more level.

This part of the South coast of Java seems to be free from dangers, although off most of the points there are reefs, on which the sea usually breaks with violence, and in every bight or curve a heavy surf rolls up a white sandy beach. In general, at 4 miles distance off shore, 50 to 30 fathoms will be found; and within that distance a 30 to 12 fathoms line will reach the bottom, which is mostly sand, and tolerably good holding ground, were it not for the very high swell. Vessels beating up along this coast should therefore keep under sail during the night, and not approach too near the shore; but in all cases their ground tackle ought to be kept in readiness for immediate use if required.

From Cape Santiang to the eastward the coast is low near to the sea, woody and cultivated, and of an agreeable appearance, but to the westward of that point to Cape Anjol it is much higher and mountainous.

Coasting along this part of Java, a ship may often correct her reckoning by the summits of the mountains; the positions of the Mounts Patoeha, Tiloe, Papadayang, and Tjikoray, between $107\frac{1}{2}^{\circ}$ and 108° E., have not been yet ascertained with accuracy, but a little more to the westward, in clear weather, the bearings of Pangerango (blue mountains) and Salak, of which the places and the elevations have been determined, will be satisfactory.

CAPE ANJOL, in the old charts called Wine-coopers (Wynkoops) Point, is situated in lat. $7^{\circ} 25'$ S., and long. $106^{\circ} 24\frac{1}{2}'$ E. The point is low, but nevertheless easily distinguished, and from the westward is very conspicuous. Near the point there is a low sandy island, with some trees on it. To the eastward of Cape Anjol the coast bends slightly round to Gadia Point, and has somewhat of the appearance of a wall with embrasures. About 3 miles off shore the depth is 19 fathoms.

From the cape the coast trends suddenly to the N.N.W. for about 3 leagues to Cape Monijel, and from thence N. by E. and N.N.E. 6 miles to Pantyoer Point and Zand Bay, which extends to Cape Ragat, where Wynkoops Bay begins.

WYNKOOPS BAY lies N.E. and S.W., and is entirely open to W. and S.W. winds. Its entrance points, Ragat and Payong, bear N.W. by N. and S.E. by S. $9\frac{1}{2}$ miles from each other; and the whole length of the bay is 10 miles. At the N.E. side of the bay are the government storehouses for coffee

and salt; and their position has been determined by many observations to be $6^{\circ} 59' 30''$ S., and $106^{\circ} 31'$ E., or $17'$ W. of Batavia. The limits of the road, defined officially March 23rd, 1862, are on the North, the parallel of the beacon to the southward of the government storehouses, to southward the parallel of the beacon of Palaboean-Raṭoe, and to the West the 12-fathom (Rynland) line. Wynkoops Bay is an open port for express only. There are many spots of good anchorage ground, but a large funnel-shaped space in the middle channel, leading from the entrance to the store, is more than 100 fathoms deep. Two cables' lengths due West from the stores there are some sunken rocks, with 3 and $1\frac{1}{2}$ fathoms water; and they so fend off the sea, that a communication may always be kept with the shore in boats. The bay is surrounded by high hills, which are clothed with trees to the water's edge. In some places ragged points project, with a few scattered rocks upon them, some visible and others invisible, and reaching half a cable's length or more off shore. The best roadstead is to the southward of the storehouses, and is called the Palaboen Radja. Regular soundings will be found there and along the coast as far as Gambang Point, with good holding ground of clay and sand; and vessels may safely anchor there in as far as 8 fathoms, or from half a mile to a mile off shore.

Between Gambang and Ponnay Points there is also good anchoring ground, but the water is too deep there, being at half a mile from the rocks 50 fathoms, and a little farther 100 fathoms, no ground. Between Ponnay and Ragat Points, the latter being the S.W. point of the bay, there is no anchorage, as there is no bottom at a quarter of a mile off shore with 50 fathoms. In the northern part of the bay vessels may also anchor to the westward of Pamoelang Point, up to the River Tjiboreno. In the western monsoon it is better to anchor in a greater depth, as the usual road is not then so safe, the winds raising a considerable sea. At the South side of the bay, if it be necessary to land in the eastern monsoon, smooth water will be found in some places, where native huts are seen near the beach, or behind the rocks; but at the N.W. side there is then no landing place at all.

At night the N.E. side of the bay is usually obscured by mists; and as the depth in the entrance is too great for anchoring, all vessels should stand off and on till morning; and this they can do without trouble, there being no tides worth mentioning.

With heavy rains the current from the River Mandirie sets to the S.W. along the coast, but is never stronger than three-quarters of a mile per hour; and in the N.E. corner of the bay there is none. From the River Tjiboreno also there is sometimes an outset of 2 miles per hour; but this N.W. part of the bay should never be visited without necessity, for although the ground is good enough, when close in, yet there is much danger there from the breakers.

In neap tides the rise and fall near the storehouses is 2 feet 7 inches, and in the springs about $5\frac{1}{2}$ feet. At full and change the time of high water is 5 o'clock, but the time, as well as the rise, depends much upon the influence of the rivers, which often disturb its regularity.

At full and change there is commonly a change of weather; baffling and variable winds, with sudden squalls, predominate about this time, and the sea runs higher.

The land wind during the night is either N.E. or S.E., according to the side of the bay; the sea breeze sets in usually at 9 or 10 o'clock in the morning, and in the eastern monsoon is not stronger in the roadstead than a topgallant breeze.

The little strength of the eastern monsoon in this bay is probably caused by the high mountains which surround it, and though in the monsoon the western wind blows with force, Wynkoops Bay is visited throughout both seasons by coasting vessels, as well as by large ships, for they are at all times sure of finding a good anchorage.

Ships coming from Europe in the eastern monsoon generally shape their course so as to make the land to windward of Sunda Strait, and it often happens they get first sight of the land near Cape Anjol or of Wynkoops Bay. Should a vessel in such a case require fresh water, it may speedily be procured in Wynkoops Bay, whilst beef, rice, and fowls may also be had there. This bay is also very convenient for shipping produce for Europe.

The only river of importance in the bay is the *Mandirie*, which is of considerable breadth, but a bar at its mouth is an impediment to its navigation, and the stream meeting the swell produces heavy breakers. The other rivers divide in rivulets and small branches, and disperse themselves on the beach without being noticed.

ZAND BAY, $1\frac{1}{2}$ mile to the S.W. of Wynkoops Bay, is about $3\frac{1}{2}$ miles across, between the points of Jaiar and Pantyoer; but further in contracts to $1\frac{1}{4}$ by 1 mile. The N.W. point of the little island of Mandra in this bay is in $7^{\circ} 11' 7''$ S. and $106^{\circ} 25'$ E. The depths at the entrance are irregular, from 40 to 50 fathoms, but just outside, in a line between Ragat and Pantyoer Points, and bearing N.W. $\frac{1}{3}$ W. from Mandra Island, there is a patch with 7 to 14 fathoms. A little inside of the entrance the depth decreases rapidly to 30, 20, and 10 fathoms, mud bottom, and to the north-eastward of Mandra to 7, 5, 4, and 3 fathoms, also mud.

Besides *Mandra*, which is a remarkable rock, surrounded by cliffs, with some trees, there is *Manok*, another small rocky island, less elevated and more oblong.

This bay is essentially rocky, yet in the middle there is a large and good anchoring ground, consisting of mud mixed with sand. Along the north-eastern side of the bay, the rocks do not run off more than a cable's length, except at Jaiar Point, where a reef, visible above water, projects for a dis-

tance of 3 cables' lengths. There are many rocks, both visible and sunken, on the South side of the bay and near Mandra Island; one of them, called the *Castor*, is particularly dangerous, from its being in 11 fathoms and near the anchorage; it carries 2 feet at low water, but is only made visible by the breakers during the sea-breeze, its top not being above 8 ft. in diameter. To the south-eastward of it 43 yards, there is another rock of the same kind carrying $2\frac{1}{2}$ fathoms. From the *Castor* Rock the North end of Mandra bears S.E. by E., Byoek Point S. $\frac{1}{4}$ E., and Pantyoer Point W.S.W. $\frac{1}{4}$ W. The best anchorage for a large ship in Zand Bay is about the middle, in 12 or 13 fathoms water, and with the following bearings: the North end of Mandra Island S.E. by S., Pantyoer Point W.S.W., Jaiar Point N.E. $\frac{3}{4}$ E., and Ragat Point N.N.E. $\frac{1}{4}$ E., or about half a point open of the farthest visible land to the northward. When anchored on these bearings a ship will be N.E. $\frac{1}{2}$ E., about 900 yards distant from the *Castor* Rock, and to avoid that danger it is advisable, when entering the bay, not to bring the North point of Mandra Island to the southward of S.E. by S.

Two sunken rocks lie southward of *Castor* Rock at 2 cables from the shore, and at the distance of 6 and 7 cables westward of the West point of Mandra Island. Another rock lies 2 cables W.N.W. of the West end of Manok Island, and the water East and South of this is dangerous.

At the N.E. and S.W. sides of the bay the mountains approach close to the sea, but the S.E. shore is more even, and high and marshy alternately. The hills and the low land are all covered with high trees, and near the beach with bamboos.

The largest river which discharges into Zand Bay is the *Latoe*, S.E. $\frac{1}{2}$ E. from the isle of Mandra. The vertical rise and fall of the water is there 4 feet 10 inches, and at half tide the river is navigable for boats.

The rivers *Kanter* and *Maringo*, at the eastern side of the bay, in which there are waterfalls of 400 and 200 feet in height, are barred by breakers across their mouths, and consequently not navigable.

To the southward of Zand Bay, between the points Pantyoer and Kapoo, there are two bights, also surveyed, in 1837, by Captain Ampt, and found to contain good anchoring ground, mostly white sand with shells, and mixed with some clay.

From the numerous rocks along this part of the coast these bights are avoided by all strangers, but they are really very convenient to anchor in during the night in the eastern monsoon for vessels bound to Wynkoop Bay, and not being able to reach that road. A ship will then be well sheltered here, and also with southerly or even south-westerly winds, but in the western monsoon it would be very dangerous to anchor in either of them. Both these bights contain wood for fuel, plenty of fish, and turtle in abundance.

Between Kapoo Point and Cape Monyol, which bear S. $\frac{1}{2}$ W. and N. $\frac{1}{2}$ E.

3 miles from each other, there is another bight, with regular soundings of 20, 15, and 10 fathoms, and good anchoring ground, but H.N.M. corvette *Castor*, having remained here a whole day at anchor, found that she was not sufficiently sheltered, and that the surf was so high that landing was deemed almost impossible. In proceeding to the southward, towards Cape Anjol, the greater is the swell and the higher the surf; and although the lead marks from 10 to 40 fathoms, between 4 and 8 miles off shore, the coast to the southward of Kapoo Point affords no safe anchorages. Upon the rocks of Cape Anjol the sea breaks with tremendous force, preventing all intercourse with the coast; and in the eastern monsoon, as soon as a ship comes abreast of this cape, she will find that the wind considerably increases.

From Wynkoops Bay the coast of Java stretches 9 miles West to *Gebang Point*, and from thence it trends more north-westerly. The coast is high and rocky, but becomes more level to the westward at *Hussa Point*, where there is a sandy beach; the whole coast is covered with trees. In the whole of that interval there is but little anchoring ground, and in many places very near the shore no bottom with 100 fathoms line. A little to the eastward of *Hussa Point* there is a bank of soundings carrying from 15 to 30 fathoms water, coarse sand and mud, and extending to *Trowers Island*.

From *Hussa Point*, off which a reef projects a mile to the south-eastward, and between it and *Malang Point*, there are many rocks near the shore, but mostly visible. To the westward of the latter point is the mouth of the *River Tjibinoeangan*, which is said to be navigable for small proas, provided there be no swell. From the point of *Mentoyong*, to the westward of that river, some shoals stretch out full 2 miles to the southward along with some sunken rocks, while, by keeping more to the southward, towards *Trowers Island*, 10, 15, and 17 fathoms water will be found. From the southern extremity of those shoals the following bearings were taken; *Hussa* E.N.E. $\frac{1}{2}$ E., *Sodon Point* W. $\frac{1}{2}$ S., and the western point of *Trowers Island* S. by W. $\frac{3}{4}$ W.

CAPE SANGIAN SIRA.—The coast from thence to *Cape Sangian Sira* and *Java Head*, as well as *Trowers* and *Klapper Islands*, with adjacent depths and dangers, have been described on pages 152, 153, *ante*, in connection with the account of *Sunda Strait*.

THE JAVA SEA.

The space comprised between the islands of *Sumatra*, *Borneo*, *Java*, and *Celebes*, is known by the name of the *Java Sea*. It is more than 800 miles from West to East, and has a breadth of 250 miles. For a great portion of its area there is no proper survey, and therefore it should be navigated with

more than ordinary caution, as defective charts are *stated* to have been one cause of disaster.

The East Coast of Sumatra between Sunda and Banka Straits has been described on pages 181 to 187 *ante*. The dangers which lie to the eastward of the direct track between these two straits will be now described. The *North Coast of Java* has just been given in detail.

The **THOUSAND ISLANDS** (Duizend Eilanden, Dutch).—The Thousand Islands have been surveyed by Lieut. Dijksrink, D.R.N., whose chart was published in 1862. They are about sixty in number, and approach within 2 miles of the Hoorn Islands (page 680), and the northernmost *Pulo Doea* and *North Island* is in lat. $5^{\circ} 24\frac{1}{2}'$, so that they extend $22\frac{1}{2}$ miles in a North and South direction.

Previous to the survey they were but little known. Among the southern groups there are many lurking rocks and reefs; this portion should therefore be carefully avoided, unless well acquainted. The channel between their South end and the northern side of the Hoorn Islands appears to be quite clear, and there are numerous passages between them to the northward, but, as before said, they should not be attempted by a stranger.

The northern part of the Thousand Island group is described on pages 183, 184.

The following are the dangers to the eastward of the Thousand Islands:—

Siren Rocks, reported in 1838 as a patch of breakers, in lat. $5^{\circ} 19' 30''$ S., long. $106^{\circ} 34' 45''$ E., has since been searched for carefully without any success, and its existence is now considered as disproved.

ARNEMUIDEN ROCK lies East of the North Watcher. As the position of the latter island has been altered in latitude and longitude, it is probable this may account for the differences in the positions of this well-determined shoal, which is in lat. $5^{\circ} 12' 30''$ S., long. $106^{\circ} 42'$ E.

Molenwerf Shoal, a doubtful danger, is marked in lat. $5^{\circ} 13'$ S., long. $106^{\circ} 50'$ E. **Etna Shoal** lies $4\frac{1}{2}$ miles southward of it.

The **Etna Shoal**, so called by Lieut. Groll, although covered by the sea, was very probably not far below its surface, as the swell occasionally broke upon it. It was impossible for a boat to go upon the shoal to sound, but close to were 20 fathoms mud, with much shells and coral sand. At $1\frac{1}{2}$ cable's length there were 13 fathoms, same bottom; although less sand when farther from the shoal. The position was determined to be $5^{\circ} 17' 18''$ S., and $106^{\circ} 55'$ E. Lieut. Groll found no other danger.

BROUWERS SHOAL has been determined by the Netherlands survey to be in lat. $5^{\circ} 17' 30''$ S., long. $107^{\circ} 0' 20''$ E., about 8 miles north-eastward of its position on the old charts.

The **SOUTH WATCHER**, or **Pulo Ampel**, or *Peniekie*, lies in $5^{\circ} 42' 47''$ S., and $106^{\circ} 42' 17''$ E., and bears N. $\frac{1}{3}$ W. 13 miles from Dapur Island, from whence it is just visible, but from the deck of a large ship the island may be

discovered in clear weather at the distance of 5 or 6 leagues. It is small, thickly covered with wood, and surrounded by a reef which projects to the N.E. about 450 yards, and to the South and West about 100 and 220 yards. This reef is very steep, with 8 fathoms close, and at two boats' lengths 24 and 23 fathoms, mud; it cannot, therefore, be approached by the lead. From the deck of a ship off the South Watcher, Dapur and the Thousand Islands cannot be seen, but from her tops they will be just visible.

- **NASSAU** or **Kroya Bank** was surveyed, in 1841, by Lieut. T. Groll, in H.N.M. steamer *Etna*, with great accuracy. It bears N.E. $\frac{1}{2}$ N. from Dapur Island, S.E. $\frac{1}{4}$ S. from the South Watcher, and N. by W. from Edam; in $5^{\circ} 49' S.$, and $106^{\circ} 49' E.$ The natives, who are commonly very well acquainted with the existing dangers, assert that there are no other shoals than this ledge between Edam and the South Watcher, which need be avoided by ships, although Lieut. Groll found some patches with $5\frac{1}{2}$ and 7 fathoms to the westward of Nassau. The shoalest ledge upon the *Nassau* was $1\frac{3}{4}$ fathom, according to Lieut. Groll, and round it 3 and 4 fathoms, coral bottom. It stretches E.N.E. and W.S.W. about 300 yards, with 17 fathoms very near it, and a little farther off, 16 fathoms, mud with shells. From this ledge Alkmaar in Batavia Roads was just concealed behind Edam, so that they afford a fair mark to avoid it by keeping these islands well open of each other.

A 6-fathom patch lies S.W. 25 miles from Nassau Bank.

A shoal of from 20 to 7 fathoms was sounded on by Th. Schut, of the Dutch frigate Maria Elise, Dec. 11, 1861. Its position is given as $5^{\circ} 50' 15'' S.$, long. $107^{\circ} 35' 30'' E.$, or about 43 miles W. by N. of Rackit Island light.

DIRECTIONS.—Ships leaving Batavia and bound to Banka Strait, ought to steer betwixt Rynland Shoal and the eastern reefs, and proceed on a northerly course through the Great or Edam Channel; this course leads between the Hoorn and Haarlem Islands, and Monnikendam sandbank on the port side, and Leiden, Enkhuizen, Alkmaar, and Edam on the starboard side, but avoiding the shoals near Dapoer and Edam.

From Edam steer for the South Watcher, avoiding the Nassau Ledge by keeping Alkmaar open to the westward of Edam. From the South Watcher do not steer too much to the westward towards the Thousand Islands, especially in the eastern monsoon, when a ship is liable to be driven in a calm amidst unknown dangers, where there is sometimes a current of 4 miles an hour. The South Watcher may be passed on either side, but off the North Watcher, beware of the Arnemuiden, and other shoals more to the eastward. To avoid them with certainty, give the North Watcher to the eastward a berth of 6 miles. A ship may also pass the North Watcher on its western side, but then she must borrow towards it, so as to clear the Two Brothers, and the Lynn Shoal, and to give a sufficient berth to the

Brouwer Bank. From the North Watcher shape a course for Lucipara' about N. by W.; but in the western monsoon, with S.W. and westerly winds, it will be prudent to steer more to the westward, borrowing toward the banks which project from the Sumatra coast as far as to 11 to 9 fathoms, but they should not be approached nearer than 9 fathoms, particularly in the night.

Ships that have passed through Sunda Strait, and are bound to Banka Strait, should steer a direct course N. by E. for the Two Brothers, after having passed also the Zutphen Islands and North Island, according to the directions before given. It is prudent to keep within a moderate distance of the Sumatra coast, in order to avoid the shoals in the offing; 11 or 12 fathoms is a good depth. With a working wind, a good mark in daylight is, when standing in-shore, to tack when North Island is just in one with the highest Zutphen Island; the depth will then be generally 7 or 8 fathoms, and a large ship should not risk a less depth when working between North Island and the Two Brothers.

The Islands and Reefs which lie off the North coast of Java to the eastward of Batavia have been described in previous pages. The following are between it and the South coast of Borneo.

The **SOLOMBO ISLANDS** are but little known. *Great Solombo*, or *Nusa Lumbo*, is about 100 miles E. $\frac{3}{4}$ N. from Bavian Island, described on page 704. It is said to be 5 or 6 miles in length from North to South, where it terminates in a high, flat-topped hill, about 550 ft. high, visible 24 miles off. This hill is in lat. $5^{\circ} 33'$ S., and *about* long. $114^{\circ} 27'$ E. The greater part of the island is a long projection of low land.

The middle island, or *Little Solombo*, is about 3 leagues to the northward of the former, its eastern extremity bearing N. $\frac{1}{4}$ E. from the hill of Great Solombo. Its centre is in $5^{\circ} 21\frac{1}{2}'$ S., $114^{\circ} 28'$ E. This island is neither so large nor so high as the former, and between them the channel is 6 miles wide, and considered to be safe. The North coast of Little Solombo should however, be approached with caution, as Capt. Millbank, of the *Shun Lee*, in 1869, saw what he thought to be the wreck of a barque on some rocks, off the N.W. side of that island.

Arends or *Arentes Island*, the northernmost of the group, is in $5^{\circ} 1'$ S., and $114^{\circ} 35'$ E., and bears N. by E. $\frac{1}{2}$ E., about 9 leagues from Little Solombo; a little islet lies off its South end. The channel between it and Little Solombo seems to be safe, but tide rips and a reef with fishing stakes is marked on the chart as extending 7 miles E.S.E. of its S.E. end. The South end of Arentes may be passed at the distance of 3 or 4 miles, but the western side should be approached with caution, on account of a rocky spot, upon which an American ship struck in January, 1794, the captain reporting that he had 18 fathoms just before and after striking, and one cast of 5 fathoms immediately after the shock; the track of 18 fathoms should therefore be

avoided. This rock must lie about 3 leagues West from Arends, but its position has not yet been accurately ascertained. Fishing stakes extend 4 miles off the N.W. end of the island.

The **Rosalie Rock** was discovered, in 1823, by Capt. Baptist, of the Dutch Indian ship *Rosalie*, on her passage from Sourabaya to Macassar. According to his statement, it lies in $5^{\circ} 56'$ S., and 8 leagues S.S.W. $\frac{1}{4}$ W. from Great Solombo, which brings it in longitude $114^{\circ} 15\frac{1}{2}'$ E. Rosalie Rock has the appearance of a small island of reddish sand, with one tree in the centre. It seemed to be about 6 ft. above the sea, and all round it small rocks above water, which was very deep, as the ship was at anchor in 42 fathoms, at 1 mile distant.

The islands and shoals which lie still farther to the eastward will be described in connection with the Strait of Macassar hereafter.

The **SOUTH COAST** of BORNEO is but little known, and has not been surveyed. Therefore what follows respecting it must be received with all caution. It was made to accord with the charts drawn up by the late Mevill van Carnbee and W. F. Versteeg, 1859.

TANJONG SAMBAR, the S.W. headland of Borneo, has been described in connexion with the Carimata Strait, in a former portion of this book, page 281. To the eastward of this, *Yeritam* or *Ajer Hitam Bay* extends for 22 miles, a small river of that name falling into its head. *Tanjong Ajer mata* is its eastern limit, to the East of which is a considerable river, the *Kwala Djellei*, has a broad entrance. Off the coast to the East of this, shoal water extends 20 miles seaward, and facing the western limits of the *Bay of Kotaringin*, the name of the Dutch province, and the river which falls into it, at 40 miles East of the mouth of the Djellei or Dieley. The *Koemai River* enters the next bay to the eastward, and the coast here assumes a southerly direction for 35 miles, terminating in *Tanjong Poeding*, or *Flat Point*, in lat. $3^{\circ} 30'$ S., long. $111^{\circ} 55'$ E.

From Flat Point the coast trends to E.N.E. for 70 miles to *Sampit* or *Pandaran Bay*, which from the map appears to be an extensive inlet, and is an open port for exports and imports; *Tanjong Malalajer*, lat. $3^{\circ} 30'$ S., long. $113^{\circ} 30'$ E., is 30 miles S.S.E. from the entrance to this bay, and at about 30 and 42 miles respectively to the E.N.E., are the mouths of the *Great Dayak* or *Kohajau River*, and the *Little Dayak River*. Off these rivers there is a very extensive sand-bank, said to extend for 20 miles and more off the land, and beyond this are some shoal patches 10 leagues from the coast. One of these, in lat. $4^{\circ} 0'$ S., long. $113^{\circ} 50'$ E., has $4\frac{3}{4}$ fathoms, with 8 fathoms close to it, and the land of Borneo is just visible from it, bearing N.E. $\frac{1}{4}$ N. All these remarks, however, are of the most vague description.

BARITO or **BANDYER RIVER**.—*Bandjermasin*, a port of call for the Netherlands' India Steam Navigation Company's boats, and an open port for exports and imports, was once a very important pepper port of the Dutch,

and stands about 13 miles up the Barito River, about 23 miles eastward of the Little Dayak River. It is the port of a principality acquired by the Dutch in 1785, and is now held by that nation. The river has been surveyed by P. H. Wedden, and the following directions by Capt. Godtare, adapted to that chart.

The entrance of the river is formed by *Tanjong Boerong* on the East side, and *Tanjong Bedalla Toea* on the western, these being $2\frac{3}{4}$ miles apart. At about a mile N.E. from the latter point is another, called by Captain Godt *Bearing Point*, being the visible extreme, used as a mark for sailing over the bar. This bar is 7 miles to the S. 35° E. of *Tanjong Bedalla Toea*. The channel lies between banks of hard clay and sand to the eastward, and of mud and clay westward, and the bar has from 11 to 16 ft. at high water, the bank on the western side being nearly dry at low water, and another rock lies near the bar on that side.

Buoys.—Two *white* on the eastern and two *black* buoys on the western side were placed, in 1876, to mark the channel across the bar of the Barito River. The outer black buoy, in lat. $3^{\circ} 39' 33''$ S., long. $114^{\circ} 25' 54''$ E., is in 7 ft. water, S.S.W. from the West entrance point of the river; the outer white buoy, in 7 ft. water, three-quarters of a mile N.E. by N. from the black buoy. About $1\frac{1}{2}$ mile within these outer buoys, and to the N.N.W. of them, lie the two inner buoys. The channel within these buoys is marked by eight ball beacons on the port side and five ninepin shaped beacons on the starboard side.

To enter, bring *Bearing Point* to N. 35° E., and *Tanjong Boerong* N. 58° E., and you will then be on the outer edge of the bar in 3 fathoms water. From hence steer N.E. $\frac{1}{2}$ N. in 16, 15, 13, and 14 ft. water, to bring *Bearing Point* N. 34° E., when *Tanjong Boerong* bears N. 66° E.; then steer N.E. $\frac{3}{4}$ N. until the former bears N. 25° E., and the latter E. by N., when you will be inside the bar in from 15 to 20 ft., and should steer N.E. $\frac{3}{4}$ N. for the mouth of the river, and clear of a narrow spit that projects a considerable distance from *Tanjong Boerong* to the westward. *Bearing Point* may be approached to within 30 or 40 fathoms if necessary. From hence local knowledge is necessary to take a ship up to *Fort Van Tuyl*, at the South end of the town. Mid-channel is the best track to keep clear of the trees, and to avoid the eddy tides near the points.

CAPE SALATAN, or *Tanjong Soengibaroe*, of the Dutch charts, in lat. $4^{\circ} 10'$ S., long. $114^{\circ} 41'$ E., is the southern point of Borneo, and the high land over it, called *Gunong Ratoos*, appears like islands when seen 10 or 12 leagues off. This high land forms a ridge of peaked hills, stretching eastward toward *Pulo Laut*, but close to the sea the coast is low and wooded. The district is called *Tanah Laut*, and is very populous.

The coast hereabout may be approached to 10 fathoms, but 14 fathoms is a good depth to preserve in passing *Cape Salatan*, and from hence towards

Pulo Laut it may be approached with caution to 7 or 8 fathoms; the former ought not to be passed at a greater distance than 8 or almost 10 leagues, on account of Arentes Island, on the South side of this passage, and a rocky spot to the westward of that island.

Dangers.—Between Arends Island and Pulo Laut there have been several isolated dangers reported. *Bampton Bank*, a small patch of 2 fathoms, lies 20 miles N.E. $\frac{1}{2}$ N. from Arends Island. At 15 miles northward of this danger is a 4-fathoms patch, surrounded by depths of 14 and 15 fathoms. It was discovered by Capt. Duaud, and named by him Oiseaux Bank. *Duaud Bank* bears from Cape Salatan S.S.E., distant 22 miles. There have been no dangers reported between these and Little Pulo Laut Islands, but at 5 miles off Tuka Point the Dutch S.S. *Coehoorn* reports having struck on a 2-fathoms patch in lat. $2^{\circ} 58' S.$, long. $115^{\circ} 25' E.$ At $11\frac{1}{2}$ miles N.E. by E. $\frac{1}{2}$ E. from this is a *sunken rock*, 4 miles off the land and 11 miles beyond this a $2\frac{1}{2}$ fathoms bank was discovered in 1869 by the S.S. *Betsy*, 5 miles off the land and 15 miles S.W. $\frac{1}{4}$ W. from the West entrance point of the Pulo Laut Strait.

LITTLE PULO LAUT, or the Lauriot Islands, are mostly high, and extend 9 miles from N.W. to S.E. The S.W. island, *Matta Siri*, is in lat. $4^{\circ} 51' S.$, long. $115^{\circ} 43' E.$, and about 850 feet high. The shore is rocky. On the N.W. side of the northernmost island, the *Laurel* filled up her water from some deep holes or wells under the trees at the foot of the mountains.

Moeso Siri, or the *Moreses*, in lat. $4^{\circ} 23' S.$, long. $115^{\circ} 50'$, is a group of three islands, the highest of which lies 15 miles N. by E. of the northernmost of the Little Pulo Laut cluster. It is formed like a pyramid, and has a regular peak at the summit.

There are three or four islets or rocks above water contiguous to them; they lie near each other, the largest in the centre. They ought not to be approached nearer than 3 miles in the night, for the outermost rock is about $1\frac{1}{2}$ mile to the southward of the high island, and is on with the body of it, bearing N.N.W. $\frac{1}{2}$ W.

PULO LAUT, which lies off the S.E. end of Borneo, and forms the S.W. side of the Macassar Strait, is 56 miles long from N.N.E. to S.S.W., and from its South point a reef of breakers projects almost to the nearest island, *Pulo Koenyit*, which is small and bold-to.

The **STRAIT of PULO LAUT**, which separates that island from Borneo, is said to be too narrow for large ships, but may be followed with a commanding breeze, and in daylight. The southern portion of it was surveyed by the Dutch officers A. H. Huijsman and G. A. de Lange, in 1848, and this shows a clear channel, with from 6 to 4 fathoms throughout its southern half; but beyond this, to the northward, it is more intricate. We have no available directions for it.

CHAPTER XVII.

ISLANDS AND PASSAGES EASTWARD OF JAVA.

OUR knowledge of the islands eastward of Java is not so exact as that of other parts of the Indian Archipelago, but much has been done through the zeal of the Dutch officers, who have been stationed here. They have recorded a vast number of excellent observations, and these have been collected by the Dutch commission for the improvement of the East India charts. Among these officers who may be cited as foremost in this good work, are P. Baron Melvill van Carnbee, Rietveld, Boom, J. Van Gogh, J. M. J. Brutel de la Rivière, P. F. Uhlenbeck, T. Van Capellen, R. F. de Sciiff, C. Bosch, &c., &c. These remarks have been collected in the Directions drawn up by Lieut. H. D. A. Smits, of the Dutch navy, 1848, which have been followed here.

BALY ISLAND AND STRAIT.

The Island of Baly or Bally is 82 miles long East and West, and about 50 miles in its greatest breadth, containing about 1,700 square geographical miles. An excellent and elaborate account of it and the adjacent island of Lombok, has been drawn up by Melvill van Carnbee, and published in the *Moniteur des Indes*, 1846.

It is very mountainous; a ridge, apparently a continuation of the Java-nese ranges, traverses nearly the whole of it from West to East. One of its peaks, in the eastern part, far overtops all the rest, and is seen very far off at sea, 70 to 80 miles in the wet or rainy monsoon, when the air is clear of clouds or fogs. In the opposite season its head is usually enveloped in clouds. This *Peak of Baly*, properly *Gunong Agong*, or *Agoeng*, lat. $8^{\circ} 20'$ S., long. $115^{\circ} 28'$ E., is 11,326 ft. high, inferior only to those of the Java peaks, and nearly equal to that of Tenerife. The island is chiefly volcanic, and resembles in a remarkable degree the geologic formations of the East end of

Java. The South point, or *Tafelhoek*, is a calcareous formation of very recent geological origin, according to M. Zollinger. Besides Agong, which broke out in 1843 into a state of activity, several other mountains are still showing the effects of that volcanic agency which has manifested itself in such terrible forms here. Earthquakes, as may thus be supposed, are very common. The most disastrous was that of November 22, 1815, seven months after the famous eruption of Sumbawa, which covered Baly with a bed of ashes more than a foot thick. That of November 22nd was felt as far as Sourabaya, and lasted an hour; and one of the mountains which lie in the rear of Beliling, on the North coast, was overturned and rolled down, and a subterranean lake burst out with incredible fury.

From its elevation, Baly is abundantly provided with water by numerous streams. Rice is consequently the chief article of cultivation. The people are a mild and tractable race, of industrious agricultural habits, and, on the coast at least, chiefly profess the Hindoo religion. The island is very populous. M. Huskus Koopman, the Dutch commissioner, in 1842, estimated it at 700,000, or more than 480 to the square mile, a remarkable density of population, which is a powerful argument as to their industry. This small island is divided into eight independent principalities, each of which abuts on the coast. It is very favourably placed for commerce and revictualling. Its trade is chiefly in the hands of Chinese and Buginese. The Dutch formed a trading post at Kotta, in the South Peninsula, in 1839, but it was given up. Owing to the frequent insults to the Dutch flag, the governor ordered an expedition to Baly in 1846; this attacked and took Beliling on the North coast, on June 28th in that year, after a strong resistance. Their bravery was forgotten on a subsequent attack, when the Dutch force was compelled to retreat. But the ultimate result was to cause the native princes to respect Dutch commerce, to endeavour to suppress piracy, and consent not to allow any European power to become possessed of their territory.

The **NORTH COAST** of **BALY** runs generally East and West, and belongs to the States of Beliling and Karang Assem, the latter occupying the East end of the island.

CAPE PASSIER, before mentioned, the N.W. point of Bali, forms the narrowest part of the strait, which, between Baly and Java, is here only $1\frac{1}{2}$ mile wide. A reef projects about half a mile from Cape Passier, and is marked by a *white* buoy, but the Java shore is steep-to, and may be approached without fear.

The coast to the eastward of this cape has three places to which vessels resort, Tebunkus, Beliling, and Sangsit, all on its western part. They can only be visited in the eastern monsoon.

St. Nicolas Bay lies 5 miles eastward of Cape Passier. The northern part appears to be free from dangers, but it has no convenient soundings; in the

southern part two dry reefs are seen, and it is probable that there exist other dangers thereabout.

Minjangan or *Herten Island*, contiguous to the shore, to the westward, is surrounded by a reef, which projects far to the eastward and westward. There is a dry patch of coral and sand off its western end, and at low water the whole reef is often visible. In the passage between Minjangan and Bali soundings may be had in 12, 15, and 20 fathoms, but there is a sunken rock in the strait S.S.E. from the West end of Minjangan. Ships may shelter in the strait during the western monsoon.

Banju Wedan Bay, to the eastward of St. Nicolas Bay, is nearly closed by a reef, and turns immediately to the eastward; proas may lie here hidden from the sea view. There is a warm spring at its head.

Gunong Sandan is 6 miles East of Banju Wedan Bay. It is close to the shore. The low point to the westward of Mount Sandan has a large reef running off W.N.W. and W. by N. along the shore, inside of which numbers of piratical proas may lie concealed.

Gunong Gondol, or *Mount Goendol*, 4 miles eastward, is a small peaked and bare hill, which may be known by its yellow aspect, standing on a low land-tongue projecting to the northward, so as to form a safe sheltering place, and at the same time a good lookout for the pirates.

To the northward of Mount Goendol there is an extensive reef of an oval shape, with 20 fathoms near its northern edge, then 9, 4, 3, 2, 3, and 7 fathoms rocky and sandy bottom, and 24 fathoms to the south-south-westward, which enables ships to pass (having a fair wind) between the reef and the shore, so as to overtake the pirates in their sheltering place on the East side. From the reef, Mount Goendol bears S.S.W., Plakkie Point, West-northerly, and Mount Sandan W. by N. nearly. Another small reef, with 4 and 6 fathoms, and 18 fathoms on its northern edge, bears N.W. by W. from Mount Goendol, distant $2\frac{1}{2}$ miles.

There is a single rock carrying 7 and 9 fathoms, with Mount Goendol bearing S.E. by E. $\frac{3}{4}$ E., Plakkie Point S.E. by E. $\frac{1}{4}$ E., and another more extensive reef stretching E.N.E. and W.S.W., with 4, 3, 2, $1\frac{3}{4}$, 4, and 7 fathoms on it, Mount Sandan bearing W. $\frac{3}{4}$ S., and the North point of Minjangan or Herten Island W. by N.

From the N.W. points of two other reefs, in soundings of $2\frac{3}{4}$ and 9 fathoms, Mount Sandan bears S.W. $\frac{3}{4}$ S., and the East point of St. Nicolas Bay W. $\frac{3}{4}$ N. The innermost reef is partly dry.

From the East point of another extensive reef, in $2\frac{3}{4}$ fathoms, Mount Sandan lies S. $\frac{1}{4}$ E., and the East point of St. Nicolas Bay W. $\frac{1}{2}$ N.

From the centre of a smaller reef, south-westward of the last mentioned, in 3 fathoms, Mount Sandan was found to bear S.E. by S., and Mount Goendol E.S.E.

Tebunkos.—The road of Tebunkos, or Teboenkoes, in $8^{\circ} 7' S.$ and $115^{\circ} E.$,

is said to be the best on the North coast of this island, being sheltered from N.W. and North winds by a dry coral reef, which fronts the shore at the distance of 380 yards, and inside of which first-rate ships may lie in safety, but they should moor W.S.W. and E.N.E. in mid-channel, so that vessels may swing clear of the shoal water on both sides. Between Antoran Point to the eastward and Cape Koanjer to the westward, many dangerous reefs project to a considerable distance from the land.

Bound to Tebunkos, keep the reef, which may be known by a small house and some trees on it, bearing South; round it very closely on either side, and moor to the southward of it in 13 or 14 fathoms.

The ebb runs westward, and the flood eastward; generally only one flood and one ebb tide are observed in 24 hours. At full and change of the moon it is high water at 5 o'clock, and the rise of the tide is 6 or 7 feet at the springs.

Beliling and Sangsit Roads.—Beliling or Bleleng, the chief village of the N.W. principality, is 7 miles E.N.E. of Tebunkos, and Sangsit is 3 miles farther on in the same direction.

There is anchorage all along the shore between Beliling and Sangsit Points, at $1\frac{1}{2}$ or 2 cables' lengths off shore, on a steep bottom of coral and sand. During the western monsoon the anchorage opposite to the Beliling fort is considered unsafe; it is better to lie then inside of the reef to the westward of Sangsit Point, which is about 4 cables' lengths distant from the latter, being steep-to, and having patches of only $1\frac{1}{4}$ fathom. At Beliling Point there is a steep reef, of which several rocks are visible above water. With the river bearing South you may stand in for the anchorage without fear. Beliling River will be known by the proas lying inside; its entrance is in $8^{\circ} 5' 30''$ S.

Light.—A red light was first shown at Sangsit in September, 1877.

The N.E. Coast of Bali is still more unsafe than that to the westward. The principal points being *Koeboe* and *Tjoelik*, at 18 and 6 miles respectively, from the East point of the island.

To the eastward of Sangsit the high mountains nearly reach the coast; near Tianiar the chain is split by a deep ravine; it then passes the village of Tiolik, and forms, under the name of *Mount Seraja*, the bold eastern extremity of Bali, sends out ridges southward towards Labuan Amok and Padang Cove, and slopes down to the southward in low, cultivated land. The coasts are steep-to on either side, though close inshore some anchorage may be found in considerable depths.

Mount Agung, or, as it is usually called, the Peak of Bali, is the highest point of the chain of mountains which terminates in the East point of Bali; its summit is often visible at the distance of 80 miles. The most remarkable summits of the chain are the four peaks of Mount Tabanan, about the centre

of the island, and the volcano Bator, although the latter is not very high, the smoke issuing from its crater may be perceived at a great distance.

Cape Karang Assem, the eastern point of Bali, is in about lat. $8^{\circ} 21' 30''$ S, long. $115^{\circ} 41'$ E., and is formed by the eastern slopes of *Gunong Seraja*, a mountain more than 4,000 ft. in height. *Kubu Manak*, a small island, lies off its eastern extremity.

Oedjong, the landing place for the chief town of the Karang Assem state, is 6 miles S.W. from Manak Island.

There is anchorage near the village of Oedjong in 20 fathoms, 3 cables' lengths off shore, the village and the peak bearing N.W. $\frac{1}{4}$ W., the N.E. point of the land N.E. by E., the islet of Asam S.S.W. $\frac{1}{2}$ W., and the East point of Pandita Island S. $\frac{1}{4}$ W.

Green or Groen Island is 5 miles farther to the S.W. The passage inside it is safe.

Amok Bay, or *Labuan Amok*, is very safe during the western monsoon, the bottom being not so steep, and there is little surf on the sandy beach; the soundings decrease regularly from 35 to 10 fathoms at 2 cables' lengths from the beach.

Padang Cove is separated from Amok Bay by Castor Point, and is nearly filled up with reefs, between which there remains only a small gullet about 82 ft. broad, where small craft may find anchorage in $2\frac{1}{2}$ or 3 fathoms.

Castor Point, between the cove and Labuan Amok, may be known by a temple standing on it. The village *Padang* is seen in the back ground, between tufts of trees. The S.E. coast of Bali is safe to approach, but there are no soundings near it, unless close in shore. The anchorage near Lebi, at 9 miles W. by S. of Padang, is said to be safe in both monsoons, and ships may anchor there in from 15 to 8 fathoms, abreast of the sandy beach.

Panteh Timor, or the eastern road of Bali Badong, is safe during the western monsoon; ships may moor inside of the reefs along the shore. The entrance between the reefs, however, is very narrow and intricate, and as the tides set with great velocity over the points of the reefs, it is dangerous to haul a ship inside.

From *Benoa Point*, the southern side, on which is a flagstaff, a reef runs south-eastward, the outer edge of which bears about North from the Brothers, two small islands lying close to the shore. The low island of Serangan extending between the points of the bay, is lined by a broad reef, which is steep-to, and has a sharp point projecting to the southward. Schooners and small craft may haul inside through the channel between these reefs. At full and change it is high water about 11 o'clock.

The Pandita, *Banditi*, or *Salombo* Group, situated between $8^{\circ} 39'$ and $8^{\circ} 48'$ S., and $115^{\circ} 22'$ and $115^{\circ} 31'$ E., appears from the southward as high table land, with a small peak on its East end. It is dangerous to approach these islands, as the tides run there with tremendous rapidity.

The channels on both sides of the group are safe, but the western is to be preferred, as the eddies are not so violent there, and there being anchorage near the Baly shore. There is also a patch, with soundings of 30 fathoms, on which ships have stopped a tide in fine weather, Kassoemba (which may be known by large store houses on the beach) bearing N.W.

TAFEL HOEK, or Table Point.—The southern part of Baly, called Tafel Hoek, is a high peninsula, joined by an isthmus to the body of the island; the isthmus, upon which there are two viliages, *Kotta* on the North side, and *Toeban* to the south-eastward, is barely a mile broad. On both sides of it there are anchoring roads, of which the westernmost is used during the eastern monsoon, and the other, just alluded to, during the opposite monsoon.

Panteh Barat.—The western road, or *Badong Bay*, is not, however, quite safe during the eastern monsoon, on account of the heavy rollers which enter about full and change of the moon, nor after very blowing weather; these rollers often cause the chains to part, or oblige the vessels to leave the road, and therefore they ought never to moor there.

Coming from the westward, a high tree, standing near *Toeban*, may be seen long before the low land can be discerned, and soon afterwards the flagstaff and a small house, the lower part of which is whitewashed. The shore is covered with heavy breakers, which project a long way opposite to the flagstaff. The anchorage is unsafe on account of the heavy swell which comes round Tafel Hoek, very far from the village of *Kotta*, and the landing is dangerous. Westward of the reefs are soundings in 12 and 15 fathoms, and close to their edge 6 and 7 fathoms. There is a bar W. $\frac{1}{2}$ N. from the flagstaff, with $2\frac{3}{4}$ (or $1\frac{3}{4}$) fathoms on it, at low spring tide; there remains a passage with depths of 3 and $3\frac{1}{2}$ fathoms between the bar and the reef. The bar diminishes greatly the swell of the sea, and the anchorage inside is safe, although lying in the midst of breakers. It happens, however, that vessels lying too near the bar, or when the breakers on it are very high, are sometimes obliged to leave this anchorage, and run for shelter to the northward of the bar, where the breakers do not reach. By keeping the high tree, which stands to the northward of the flagstaff, between E.S.E. and S.E. by E., you may work in-shore till in $5\frac{1}{2}$ fathoms; but, if not acquainted with the place, it is prudent to anchor in 8 or 10 fathoms, with the flagstaff bearing S.E. by S., and to send for a pilot.

It is high water at full and change of the moon at 11 o'clock, and the rise of tide amounts sometimes to 8 or 10 feet. The export of rice to China and Singapore is considerable, and supplies are to be got in abundance, also cattle and poultry, the watering place is near the flagstaff.

The S.W. coast of Baly, beyond this, which also forms the Strait of Bali, stretches to N.W. and W. by N. for 38 miles, whence it assumes a more northerly direction for 20 miles to Cape Passier, before mentioned. It is

generally lined by a reef with a great surf upon it, which, however, is the only danger near this coast, and in calm weather ships may anchor along it in from 12 to 18 fathoms. This facility of anchoring, together with the pretty regular land breezes, make it easy to work along this shore in the eastern monsoon.

Manok Bay lies about 4 miles to the southward of Cape Passier; the entrance is barely a ship's length wide, and inside of the bay there are three small islands, surrounded by a flat of mud and sand. To the eastward of the islands there are only 2 fathoms, and the cove near the watering place has only water enough for very small proas; fresh water is very scarce. The tides run with great velocity round these islands, and the perpendicular rise of the water is from 8 to 10 feet.

BALY STRAIT.

With the exception of the Strait of Allas, to the East of Lombok, the Baly Strait is to be preferred to all the passages eastward of Java, as there is anchorage on both sides of the Narrows, which may be gradually passed in a single tide. Another advantage of Baly Strait is, that ships bound to Europe during the western monsoon are not so much liable to fall in with the coast of Australia as when passing through any of the other eastern passages.

Winds.—From February to September southerly winds prevail in Baly Strait, and during the other months baffling westerly winds, succeeded by calms and heavy squalls, probably caused by the high land of Java. During the eastern monsoon fresh breezes occur from S.S.W. to S.W. to the eastward of Cape Sedano, while steady East and E.N.E winds, succeeded by land breezes from South to S.S.W. are found to the westward of the same cape; from July to November the S.W. winds to the northward of the strait blow rather strong, while at the same time fresh northerly breezes, varying between N.W. and N.E., prevail to the westward of the cape. This change of the winds takes place immediately to the eastward of Cape Sedano, or when the strait opens; but past the strait, or when approaching the coast of Baly, the wind diminishes in force, and veers gradually to S.E. Mount Goendol seems to be the limit of the S.W. winds, or of the influence of the strait in rendering the winds unsteady and variable. The southern part of the strait being much wider the wind is not so strong there, and near the shore of Baly the regular land breeze usually occurs.

The *currents* are noticed on page 31, *ante*.

The **EASTERN COAST** of JAVA, forming portions of that of the Dutch provinces or *Residentees* of *Bezoeki* and *Banjoewangi*, is about 70 miles in extent from Cape Sedano, the N.E. to the S.E. point of Java.

CAPE SEDANO is in $7^{\circ} 49' 12''$ S., and $114^{\circ} 27' 30''$ E. ; it is rocky and steep, and the middle one of three points near each other. The volcano of *Gunong Baloeran*, or *Telagu Woerong*, or *Tafelborg*, 4,347 feet, bears W.S.W. $\frac{1}{2}$ W., nearly from Cape Sedano, and N.N.E. $\frac{3}{4}$ E. from Mount Idjing.

The anchorages of *Tinjang*, *Toe*, and *Assam*, to the southward of Sedano, are much frequented by the pirates ; they are formed by detached reefs, and have only single entrances and little space inside, but at *Kajang*, $3\frac{1}{4}$ miles South of the cape, a large number of proas may lie concealed, and may escape either to the northward or southward.

Pirates also often take shelter inside the reefs of *Tiotek*, 10 miles to N.N.W. of Bape Sedano, which stretch parallel to the shore between the points of *Tiotek* and *Loemoet* ; they consist of 4 large reefs above water and some other shoal patches. Those passages between the three westernmost are the widest, and lead to the anchorages of *Labuan Gattal* and *Labuan Gollek* near which there is a watering place.

MEINDERS DROOGTE, or *Karang Maas*, in $7^{\circ} 41' 30''$ S., and $114^{\circ} 22' 30''$ E., has been before described on page 718, together with its lighthouse. It bears N.N.E. from Mount Sedano, E. $\frac{3}{4}$ N. from Mount Ringit, and N. $\frac{3}{4}$ W. from the easternmost point of Java. Ships passing between Java and the rocks ought not to approach close to their S. and S.W. sides, on account of the reefs.

Tanjong Tjandibang is 5 miles South of Cape Sedano. A *bank*, covered with only 3 feet water, lies about a mile off shore, Mount Sedano bearing W.N.W. $\frac{3}{4}$ W., Mount Idjing S.W. and *Tjandibang Point*, with some trees on it, S. by W. $\frac{1}{2}$ W. The 2-fathoms bank is the north-easternmost danger, and is known by its discoloured water. Mount Sedano bears N.W. $\frac{1}{2}$ N. ; Mount Idjing S.W. by W. $\frac{1}{4}$ W. ; and *Tjandibang Point*, North from the shoal.

It is also said that the 2-fathoms bank lies S. by E. of Cape Sedano, and N. by E. $\frac{1}{2}$ E. of *Duiven Island*, and about 3 miles off shore ; it consists of five rocks close together, with only $6\frac{1}{2}$ ft. water over them. It will be, however, prudent not to bring *Duiven Island* to the southward of S.S.W.

There are two reefs to the south-westward of the 2-fathoms shoal ; they bear about N. and S. from each other, and on the southernmost, in soundings of 5 fathoms, Mount Sedano was found to bear N.N.W. $\frac{1}{2}$ W. Another rock, close to which 19 fathoms were found, lies with Mount Idjing bearing S.W. by W. $\frac{3}{4}$ W., Mount Sedano N.N.W. $\frac{1}{2}$ W., and *Tjandibang Point* N. by E. From another shoal, to the southward of the former, Mount Idjing bears W.S.W. $\frac{1}{4}$ W., Mount Sedano N.N.W. $\frac{1}{4}$ W., *Tjandibang Point* N. by E., and *Duiven Island* S.S.E. $\frac{1}{3}$ E. All these dangers have also light-green discoloured water.

DUIVEN ISLAND, also named *Taboan* or *Gilboan*, is small, and sur-

rounded by a reef, which projects to the North and S.E. of the island, and bears E. $\frac{3}{4}$ N. from Mount Idjing.

LIGHTHOUSE.—An open iron framework, 30 ft. high, was completed in 1872, on the East side of Duiven Island, and from it is shown, at an elevation of 55 ft., a *fixed bright* light, visible 12 miles off. Lat. $8^{\circ} 2' 30''$ N., long. $114^{\circ} 27'$ E. Duiven Island is dangerous to approach, as the current sets strongly towards it, so that vessels can only be saved from driving upon it during a calm by their anchors holding against the reef in 60 fathoms depth. It was the practice for piratical proas to lie in wait on the North side of the reef for vessels coming out of Bali Strait. The passage to the eastward of this island is preferable, as there are dangers to the westward, but in light and favourable breezes the western branch may be adopted, there being anchorage N.N.W. from the island in 40 fathoms; or, by keeping a good look-out for the reefs, in 20 fathoms closer in shore. When going out by the western passage, if overtaken by the contrary stream before reaching the northern anchorage, vessels are better able to fetch the anchorage to the southward of Dodol.

The first anchorage is in the bight to the southward of the first point following after Batoe Dodol (which place may be known by a bridge over a creek, with a guardhouse near it), in 18, 12, and 10 fathoms, and in the eddy. There is also anchorage, but closer in shore, in the small bays to the southward of this, as far as the high tree on the Java shore, but it is difficult to reach them with light winds if the vessel is not near the shore.

The dangers of Baly Strait begin when you approach the high tree 2 miles N.N.E. of Banjoewanjie. This tree is difficult for a stranger to recognise, but a beacon is marked on the chart as situated on a point of the land near it. At three-quarters of a mile S. by W. from the beacon is *North Rock*, of 3 fathoms, a small patch lying 3 cables off shore. It lies with the high tree N. $\frac{3}{4}$ W., and the flagstaff of Fort Utrecht S.W. by W. $\frac{3}{4}$ W. Vessels coming from the northward, and bound to Banjoewangie during the eastern monsoon, are sometimes obliged to pass this rock at low water, and as there is often a great swell, it is considered very dangerous; but by keeping Mount Ikan about a ship's length open to the eastward of Pakkem Point they will pass to the westward of the rock.

The Deptford Shoal stretches here along the shore, being a reef of rocks with unequal soundings. Its North end lies in 6 ft. water, with the flagstaff of Fort Utrecht, Banjoewangi bearing S.W. by S., Pakkem Point in one with the western foot of Mount Ikan S. $\frac{1}{2}$ E., the high tree N. $\frac{3}{4}$ W., and a *white buoy* on its South end S. by W. westerly, $3\frac{1}{2}$ cables distant. This buoy lies half a mile N.E. of Banjoewangi Light.

Cameleon Rock, a small patch of 3 fathoms, marked by a white buoy, lies nearly a mile E.N.E. of Banjoewangi Light.

Further southward lies the *Great Rock*, which carries 2 fathoms water;

from the black buoy on it the pier at Banjoewangie is seen in one with Fort Utrecht W.N.W., the high tree North, and Mount Idjing N.W. $\frac{1}{2}$ N. Inside of this rock lies another, also marked by a *black* buoy. It is called the *Kaiman* or *Crocodile*, with 2 fathoms water, the fort bearing W. by N., the high tree N. $\frac{1}{2}$ E., and Pakkem Point S. $\frac{1}{3}$ W.

BANJOEWANGIE, the Dutch settlement in Baly Strait, from which the telegraph cable leaves the shore to cross the water to Port Darwin, is the chief town of its province, and 8 miles South of the Narrows. It is an open port for exports only, and is a place of call for refreshments for vessels proceeding by the eastern passages. The water is good when the pipes are clean, otherwise it soon becomes fetid. The town is not always readily distinguished in the afternoon, when the sun is behind it; a good guide then is the Bakungan Mountains, a triple topped range on the Baly shore, from which it bears West.

The road of Banjoewangie is limited by the last-mentioned reefs. There is very safe anchorage there during the western monsoon, in from 12 to 8 fathoms, when ships should moor North and South, and they may then take their cargoes on board without the least difficulty. But during the eastern monsoon the South and S.E. winds blow strongly in the afternoon, and often in the morning too, and cause a great surf on the shore, through which only very small proas can pass. It is not advisable to anchor a sailing vessel close in during the S.E. monsoon, for the difficulty in getting out may cause detention.

Light.—A *fixed* light, elevated 41 ft., is shown from Fort Utrecht, seen 12 miles off; lat. $8^{\circ} 12' 50''$ S., long. $114^{\circ} 22' 30''$ E. With the light between W. by S. $\frac{1}{2}$ S., and West, you may approach the road clear of all dangers.

The river cannot be entered unless at high water, and then the surf is generally most high. Mount Idjing bears from the pier N.W. $\frac{1}{2}$ N., and Mount Ikan south-easterly.

There is a patch of 5 and 6 fathoms on a hard bottom, to the eastward of which there are 9 and 10 fathoms, to the northward 7, 6, and 4 fathoms, and to the southward 8 and 9 fathoms. The patch bears E. $\frac{1}{3}$ N. from the fort, and North from Pakkem Point.

To enter the roads from the northward, keep the land immediately to the southward of Pakkem Point in view, and do not approach the shore in less than 15 fathoms before the fort bears West, nor bring the house on the pier in one with the fort, on account of the Groots Rock; this will lead to the eastward of all the dangers. Passing between the Cameleon Rock and the Deptford Rocks, keep Pakkem Point well open of the foot of Mount Ikan but it is not required to keep in sight the land to the southward of Pakkem Point.

When the fort or its fixed light is brought to bear West steer direct for it till in 12, 20, or 8 fathoms clear bottom, where you may bring up; but some

attention is required on account of the streams of tide while nearing the shore, as they run sometimes in a contrary direction to those in the middle of the strait.

To avoid the rocks to the southward keep the pier so as to view it always on its North side. The best anchorage is with the fort bearing West, the high tree N. $\frac{1}{2}$ E., and Pakkem Point, South.

A vessel desiring to have a pilot in the strait ought to give due notice beforehand to the pilot at Banjoewangie, of the place from and the date on which she intends to sail. He then will take care to have one ready on her making the signal, near the Java shore at anchor on the reef opposite Taboean Island. During the eastern monsoon the pilots seldom cruise, as only a few vessels then require their assistance.

Departing from Banjoewangie bound to the southward, do not approach too near to Pakkem Point, as a reef projects from it about 3 miles. Its outer extremity is marked by a *black* buoy with white ring, in 4 fathoms, with the highest Bakungan mountain bearing E. by N. $\frac{1}{2}$ N., and Fort Utrecht N.N.W. $\frac{1}{4}$ W.

Anchorage in 7 or 8 fathoms may be found all along the shore from Pakkem Point to Pampang Bay.

A dangerous spot was discovered S.E. 2 miles from Pakkem Point, in 1865 by H.N.M. steamship *Bromo*. It has $3\frac{1}{2}$ fathoms least water, and lies with the flagstaff at Banjoewangie N.W. $\frac{3}{4}$ N.; Mount Ikan S. $\frac{1}{2}$ W.; Mount Raoe W.N.W. $\frac{1}{4}$ W. It is only about 35 ft. in diameter, and has 15 or 16 fathoms close around it. Its eastern edge was found by Captain M'Kenzie to bear N. $\frac{1}{2}$ E. from Mount Ikan, Pakkem Point in one with Banjoewangie N. $\frac{1}{2}$ W. distant 5 miles.

Mount Ikan, 14 miles South of Banjoewangie, is an isolated flat-topped bluff, separated from the Sloko Hills by a low isthmus, causing it at a distance to appear like an island, forms a very safe bay, sheltered on the eastern side by this hill, which is about 400 or 500 ft. high, and on the North side by the projecting land of Java, so that the water is smooth in both the monsoons. The southern shore is covered with thick forests of *jattee* trees. There is anchorage from the entrance to 3 or 4 miles inwards, on the eastern side of the bay, in depths from 12 fathoms, regularly decreasing to 3 fathoms, the bottom coral sand, but not farther to the westward of the Mount Ikan shore than half a mile or a mile. The beach on the eastern side is lined with a small reef, consisting of coral and mud, and the W. and S. shores by muddy flats.

S.E. CAPE of Java is the extremity of the low Balambangan peninsula, on the northern side of which is a range of hills which terminate on the East at Cape Sloko. The points of the low land dip at 10 or 12 miles, causing a false point to be seen beyond that distance. An extensive coral reef borders the cape, but North of the Sloko ranges the shore is very steep, and a ship

working through may stand in boldly. There is no safe anchorage near the Java shore to the southward of Mount Ikan.

The *Prince of Orange Bank*, in the middle of the strait, is a 6-fathom bank, on which ships may anchor in case of calm and contrary tide. It is about 4 miles in extent, with soundings from 6 to 24 fathoms, black sand, mixed with stones and shells. It lies with the low East extremity of Java, S. by W. ; eastern summit over Cape Sloko, S.W. $\frac{1}{2}$ S. ; and the summit of Mount Ikan, W.N.W.

CAPE TAFEL, the South extreme of Baly Island, is a peninsula of table land, bordered by a high broken cliff and a few small reefs. Though about 300 ft. high, it may be styled low in comparison to the adjacent mountainous country. The western part is the higher and bolder, the eastern tapers into a low point, off which is a low island. Soundings of 20 fathoms may be found West and South of the West cliff at the distance of a mile. *Badong Bay*, North of Cape Tafel, affords shelter from S.E. winds, with anchorage in 8 to 6 fathoms, sand and mud, good holding ground ; but there is little or no protection from the heavy ground swell that rolls in from South.

DIRECTIONS.—Ships bound from the Strait of Madura to Baly Strait during the eastern monsoon work between Java and Meinders Shoal, the dangers near the former being all above water ; but to the West and south-westward of Meinders Shoal there is a reef extends about $1\frac{1}{2}$ mile, which may be known by light-green discoloured water.

After rounding Cape Sedano, the wind will change to S.W. or S.S.W., which will enable them to fetch the Baly shore about Minjangan Island or Mount Goendol, from whence it is easy to work towards the strait. Should adverse tides or approaching night forbid an entrance to the strait, ships should keep under an easy sail. If the stream runs to the northward they will not be liable to approach the shore, and by keeping Minjangan Island to the southward of S.S.E., and the high mountain of Idjing to the southward of West, they will avoid Taboean Island and the dangers near the coast of Baly.

When the tide changes, work with short tacks between Minjangan and Taboean Islands, and keep the Java shore on board, when in the Narrows, to avoid the reef off Cape Passier ; the Java shore is preferable also, because the sea is not so boisterous there as near Baly. When the tide is going to change, search for anchorage in the bays to the southward of Dodol, the Java shore being safe to approach as far as the high tree.

When past the high tree, keep Mount Ikan well open with Pakkem Point, or, rather, stretch over to the eastward so far as to get in view the land to the southward of Pakkem Point, and do not borrow towards Java in less than 15 fathoms before Fort Utrecht bears West, for which they may then steer as before directed. When working to the southward of Banjoewangie,

keep Mount Ikan to the westward of S. by W., to avoid the reef off Pakkem Point.

The southernmost safe anchorage on the Java side of the strait is in Pampang Bay, nevertheless keep on the Java shore until near S.E. point, as the sea is usually smoother there than near Baly, and no tide perceptible. Having approached the S.E. point, stretch over to Baly, and work along that shore with the land and sea breezes, occasionally anchoring in from 12 to 18 fathoms.

If bound through the strait, keep Mount Ikan well open of Pakkem Point, or, rather, keep the land to the southward of this point in view until you are to the northward of the high tree, when it is advisable to keep nearest to Java, to be the sooner in anchorage if required, and to avoid the reef off Cape Passier. You may pass on either side of Duiven Island at a moderate distance; the western passage is preferable in case of light winds, as there is anchorage to the N.W. of that island in 40 to 20 fathoms. Great care is requisite in approaching the Java shore, on account of the several dangers near it; and should a contrary tide come before you reach the anchorage to the northward of the Narrows, you must endeavour to reach the anchorage to the southward of Dodol. When nearing the 2-fathom shoal it is prudent not to bring Duiven Island to the southward of S.S.W. The N.E. part of Java may be approached within 2 miles.

Vessels working through the strait will save time by taking a pilot, for the tides are irregular and require local knowledge.

Tides.—Near to Duiven Island the establishment of the port at 3^h. Flood runs to the North, ebb to the South. During the N.W. monsoon, December, January, and February, the ebb is very weak, especially near the times of high and low water. It is also stronger by night than by day.

LOMBOK ISLAND AND STRAIT.

LOMBOK, Lombok, Sassak, or Selaparang, is the next island eastward of Baly, separated from it by the strait to which it gives its name. Although of a very different figure, it is very nearly of the same area as Bali, and of similar geologic formation. It has also a very lofty peak on its N.E. angle, which overtops the other mountains of which it is principally composed. This is called *Rindjanie Peak*, and was measured trigonometrically by Melville van Carnbee as 12,379 ft.; Horsburgh states that he found it by the same means to be only 8,688 ft., but the Dutch officer is confident in his own observation. It is an extinct volcano, in lat. 8° 21' 0" S., long. 116° 27' E., and appears double when seen from the southward.

This peak forms a portion of a chain of mountains, which traverse the

island from West to East; and to the southward is another and lower chain, which has a similar direction. From its elevation, like Baly, it is abundantly supplied with water in the rainy season, when its numerous rivers swell to an enormous volume, and send down vast quantities of water; but during the dry season the reverse is the case, and then scarcity prevails in many parts, so that vessels coming here at this period are compelled to bring water with them.

The people, though more advanced in civilization than in surrounding countries, are difficult to deal with. Europeans are established in the two principal places, Ampanam on the West coast the chief port, and Tring in the S.W. bay, and through them the barter or trade may be conducted. They owe in some degree an allegiance to the Dutch, but all caution should be used in any dealings with them. They make excellent *krises* or swords, and firearms, which are in great request in the islands around. Rice is the staple production, and the fertile valley in the centre of the island is skilfully and zealously cultivated. The island now prospers, but two-thirds of the inhabitants perished in the dreadful eruption of Sumbawa in 1815, the whole island being covered with ashes to the depth of 18 inches, according to M. Zollinger.

The *North coast* is steep-to and without anchorage. In the old charts two dangers are laid down to the northward of the islands, which seem not to exist, as many ships have made a fruitless search for them.

A range of small islands, named *Trawangan*, *Meno*, and *Sira*, lie off the N.W. point, or *Cape Roembek*. There are numerous rocks around them, and the coast runs East and West for about 44 miles.

The North point of the island is a green point, in $8^{\circ} 11' S.$, and the land thereabout has a fruitful appearance, and seems to be well peopled.

The N.E. point of Lombok is fronted by two low islands called the *Twins* (Tweelings), which are surrounded and united by a reef with a boat passage across it; the road to *Sogean* is inside of these islands, having anchorage in from 8 to 12 fathoms. Water is to be had at the village of *Sogean* on the river *Melanting*. The channel inside of these islands is safe, with soundings from 11 to 16 fathoms mid-channel, regularly decreasing towards Lombok over a sandy bottom, and generally increasing towards the reef round the islands, which is steep-to, with 16 fathoms near its edge. The Lombok shore, as well as the *Twins*, may be approached to the distance of a quarter of a mile, as a man from the masthead can see all the dangers on either side.

The *Rocky Islets* at 12 miles South of the *Twins* is a group of three low rocky (*Rotsige*, Dutch) islands bearing S.W. by S. from each other, and a dry sandbank; but they are all connected by a reef which projects about a mile to the south-eastward. The channel to the westward of the group is free from danger, with regular soundings from 15 to 17 fathoms throughout.

The channel to the eastward of them is much wider, but destitute of soundings, for which reason the former is more generally used. When proceeding to the southward, the Lombok shore ought to be kept at least a mile distant in order to avoid the shoal on which the *Surat Castle*, an English Indiaman, struck in March, 1796. It is a coral patch of 3 fathoms, lying a little to the South of the point of land that bears W. by S. from the South extremity of the Rocky Islands, and opposite to a fresh-water creek in the bight, to the southward of that point. There are overfalls from 25 to 10 and 6 fathoms, coral rock, about 3 or 4 miles S.S.W. from the Rocky Islands, but not less, it is believed, than 6 fathoms.

Sagara, near the village of *Lombok*, is only adapted for small vessels. It is sheltered by a dry sandbank and a narrow channel with soundings of 3 and 4 fathoms, from a point of land which projects to the northward, and forms a cove. The anchorage inside is safe in both the monsoons, and it is much easier to water there than at Laboe Hadje. There is a road across the island from this place.

Labuan Hadji or *Bally*, is 12 miles South of Lombok. The road is not quite safe during the eastern monsoon, as the anchors often drag when the sea breeze is very strong. The anchorage for large ships is in 17 or 15 fathoms, black sand, about $1\frac{1}{2}$ or 2 miles off shore, with Lombok Peak bearing N.N.W., the southernmost bluff island on the Sumbawa side of the strait E.S.E., and the next to the northward E. $\frac{1}{2}$ N. or E. $\frac{3}{4}$ N. These islands are the best guide to know when abreast of Labuan Hadji, for, being situated behind a top of cocoa-nut trees, it is not easily perceived from the offing. Ships ought never to go under 10 or 11 fathoms. Boats sent to fetch water anchor inside of the reef at the mouth of the river; the casks are filled about 100 yards from the beach, and then floated off to the boats. The water is good, but ought not to be filled when the tide is high, for it is then brackish, and during the south-eastern monsoon it is often tedious getting water off from the shore. Refreshments of every description are to be procured here in great plenty. The flood sets to the northward, and the ebb to the southward, about $1\frac{1}{2}$ or 2 knots at the springs; it is high water in the roads about 12^h 30^m at full and change, but nearly 3 hours sooner upon the shore, and the rise of tide is 10 or 12 ft.

Pedioe, *Peejow*, or *Pejoet*, is more frequented than Labuan Hadji, being more safe and convenient for watering, as the river is navigable by boats. On *Cape Louar*, the North point of the bay, there is a flagstaff in about 8° 47' S. and 116° 32' E. The anchorage is in 7 or 8 fathoms, with Lombok Peak bearing N. $\frac{3}{4}$ W., the southernmost island on the Sumbawa side of the strait E.N.E. $\frac{1}{2}$ E., the flagstaff on Cape Louar, North, Ringiet Point in one with the southern part of the Tafel Berg near the S.W. point of Sumbawa S.E. Ringiet Point, on this bearing, is a good mark to avoid the reefs to the southward of the anchorage, and this line ought not to be passed when

entering the bay ; the only other dangers to be avoided are the reef off Cape Louar, which is nearly dry, and a rock bearing S. $\frac{3}{4}$ W., about a cable's length distance from the flagstaff, and visible at low springs. Capt. Kingdom discovered also, in 1846, a sandbank with $3\frac{1}{2}$ to 5 fathoms on it and 8 fathoms all round, Ringiet Point bearing S.E. $\frac{1}{4}$ S. southerly, East Island S. by W. $\frac{1}{2}$ W., and the flagstaff on Cape Louar N.W. $\frac{3}{4}$ W.

The **SOUTH COAST** of Lombok, between Cape Ringit and *Cape Bambo Bambo*, the S.W. point, is about 50 miles from E. to W. There is a small bay, *Telok Longas* or *Blongas*, which it is said affords safe anchorage in the westerly monsoons, but quite exposed in the opposite season. The S.W. point is the extremity of a peninsula which forms a bight on the North side, in the head of which is Tring, one of the best anchorages in the island.

A *rock*, scarcely showing above high water off the South coast of Lombok, was discovered by Captain B. van Riethagen, in the bark *Sophia Louize*, in 1864 ; when it bore E. by N., the South point of Panditi Island bore W.N.W. $\frac{1}{2}$ W., and the S.W. point of Lombok N.W. It lies 5 miles off shore.

Labuan Tring.—In running for Labuan Tring from Ampanam a southern course will about lead down the bay, but in blowing weather it is preferable to haul out S. by W. $\frac{1}{2}$ W. at first, and when abreast of Karang Point, easily known by a little conical hill near it, and about $2\frac{1}{2}$ miles from Ampanam, steer South, or more easterly if required, as you approach the cove. The western side of the entrance to the cove is bluff, and readily distinguished ; the East point is low and sandy, with bamboos and brushwood. Entering the cove, keep nearest to the eastern shore, as a reef runs off the other. A good mark is, to bring the low point about S. by E., and run in with that bearing till a high bluff point on the East side of the cove be seen. Haul round the East point until it bears N.N.W. $\frac{1}{2}$ W., or N.W. by N., and bring up in about 10 fathoms, mud and clay, 2 or not more than 3 cables' lengths from the beach ; the water here will be quite smooth, although a great deal of swell may be in the entrance. A reef surrounds the island, which lies E.S.E. of this anchorage ; of this be careful by bringing up close to the beach, which is so steep-to that 4 fathoms will be found over a boat's stern when she touches the ground forward, except near the eastern extreme point. There is also a good berth in the West side of the cove close in-shore in 6 or 7 fathoms, mud, care being taken not to run beyond the small islet. There are three good wells near the huts on the eastern side of the cove. Firewood and bamboos may be cut in plenty, but any other supplies, excepting plantains and cocoa-nuts, are scarce.

AMPANNAM or *Ampanam* is the chief trading place of Lombok. It is on the West coast, at about midway between Tring and the N.W. point. It affords an excellent sheltered road during the eastern monsoons, but during the westerly monsoons it has no security whatever from the swell and wind.

At all seasons there is usually a very heavy swell, which makes the taking or discharging cargo difficult and even dangerous.

The large bay of Ampanam is a safe road during the eastern monsoon, as before said, and Labuan Tring Bay, in the S.E. part of it, sheltered from all winds. A group of islands and reefs fronts the southern shore of the bay; and there is a bank of coral and sand, with soundings of from 10 to 25 fathoms, on which the *Heroine* lay at anchor during a fresh S.E. breeze, the first island to the northward of the West point of Lombok bearing S. by E. about 3 miles. There is also anchorage a little southward of the North point of the projecting S.W. land of Lombok.

H.N.M. frigate *Boreas* watered here in June, 1838, and filled daily 2,000 gallons; at high water boats can enter the river, but otherwise the casks must be carried across a neck of land. Cattle are cheap, and all kinds of provisions are to be had there. The mouth of the river cannot always be discerned at a distance, but it may be known by the huts along its banks.

There is a rocky patch, with only $2\frac{1}{2}$ fathoms, to the north-westward of the flagstaff, probably the same on which, in 1811, the boats of H.M.S. *Psyche* had 3 fathoms, Lombok Peak bearing E. by N., and the North point of the bay N. by W. $\frac{1}{4}$ W. There are $2\frac{1}{2}$ fathoms on a shoal S.W. of Karang Point, and near the shore, having 6 fathoms all round.

The tides in the bay are seldom found to be strong; the rise of tide is from 5 to 7 ft., and it is high water, at full and change of the moon, about 8 o'clock.

The best marks for Ampanam Bay are, the peak of Baly bearing W.N.W., Lombok Peak between E.N.E. and N.E. by E., or the river bearing E. by N.; but it is not safe to approach the shore, after having passed the ridge, in less than 10 fathoms, as in some parts the soundings decrease very rapidly from 7 to 3 fathoms. During the western monsoon (from November to April) ships ought to anchor 2 miles off shore, so as to be able to run for Labuan Tring, if need be. On appearance of bad weather the chains should be buoyed, and everything ready to slip.

Trawangan, or *North Island*, before mentioned, is 13 miles N.N.W. of Ampanam. It is the highest of a group of three islands near the N.W. point of Lombok, in $8^{\circ} 20'$ S., and $116^{\circ} 1'$ E., and from its North point Lombok Peak bears E. by S. H.N.M. steamer *Hecla* anchored in 15 fathoms with this island bearing from North to N.W. by N., Rombek Point S. by W., Mount Agong, or the Peak of Baly, West, northerly, and a river S.E. by E.

Siva Reef lies N.E. 5 miles from Trawangan Island, and a doubtful reef is marked on the chart at 4 miles off shore, and 10 miles north-eastward of *Siva Reef*.

During the East monsoon, strong winds from S.S.W. to S.E. prevail in the Strait of Lombok, and during the western monsoon N.W. winds; during

the former the southerly currents are the strongest, and during the latter they run with more velocity to the northward.

The STRAIT of LOMBOK, between Lombok and Bali, is 36 miles from North to South, and from 10 to 25 miles in breadth. The Bali side has been previously described, and the Lombok shore is given above.

Entering Lombok Strait, with an adverse current during the eastern monsoon, most progress may be made by keeping the Baly side on board until the peak bears West. By stretching over then to Lombok, a ship will very likely fetch the road of Ampanam, especially if the Baly side of the strait be left early in the morning for the sake of the sea breeze from the southward. With a contrary current, it is difficult to get down on the Lombok side of the strait, and on the Baly side after the peak bears to the northward of West. The channels on both sides of Pandita Islands are safe, but the western one is to be preferred, as ships may anchor occasionally near Baly, and the rippings are not so strong there as to the eastward of these islands. Although the route through Lombok Strait is liable to great delay, it is often used by ships bound to China, which pass St. Paul and Amsterdam Islands in the latter part of January, or in the beginning of February; the passage through the Strait of Allas is, however, generally quicker. Care is then requisite not to fall to leeward of the intended strait. The high peaks of Bali and Lombok may be seen in clear weather about 8 leagues to the southward of the straits, the latter one showing from this view two summits over the high western part of the island.

ALLAS STRAIT.

Allas Strait, separating Lombok from Sumbawa, is about 45 miles long on a N.N.E. and S.S.W. direction, and from 9 to 15 miles wide. Although it has not been properly surveyed, it is probable that all its dangers are known, and it has some advantages over the straits to East or West of it. The Lombok side has been just described.

The West Coast of Sumbawa, about 45 miles long between *Tangong Labu Bua*, the N.W. point, and the S.W. point of the Table Hill, which forms that extremity.

Mr. H. Zollinger, who visited this coast in 1847, gives the following description of it:—

Kamoedong, *Tawar*, *Segattal*, and *Belo*, the north-easternmost of the islands which front the N.W. coast of Sumbawa, are low, with rocks contiguous to their points, and deep channels between them. There are soundings from 4 to 14 fathoms in the channel inside of these islands, and the bays of *Paddie*, *Boer*, and *Allas*, afford anchorage. The latter is a cove, 12 miles from

Labu Bua Cape, stretching about South, and deep enough for large ships. To the south-westward of Belo are the islands of *Bassar*, *Genang*, *Patakie*, *Oenet Passeran*, and *Tatagen*, all high, and *Belang*, a low island, and the southernmost of this group. Inside of the latter islands are soundings from 25 to 30 fathoms.

Taliwang Bay.—The road of Taliwang affords a secure anchorage during the south-eastern monsoon. From the bluff North point of the bay, Lombok Peak bears N.W. $\frac{1}{4}$ N., the southernmost island in the strait W.N.W. $\frac{1}{4}$ W., and Ringit Point S.W. by W. $\frac{1}{4}$ W., and the South point of the bay S.E. by E. $\frac{1}{2}$ E. $12\frac{1}{2}$ miles from Labuan Hadji, or Laboe Hadye; the bay may also be known by a peak near the beach, rising to a height of about 1,570 English feet. Water and wood are easily procured, and provisions are cheap, but they must be ordered a day before.

Ships in want of water and wood should anchor to the south-eastward of *Knoop Island*, in 15 or 16 fathoms; but when provisions only are wanted, they may anchor in 7 or 8 fathoms, S. by E. from a storehouse, standing near the bluff North point of the bay. The natives are polite and ready to assist.

The straits to the eastward of Java being all more or less subject to frequent calms, it is advisable to keep in soundings, on account of which the Lombok side of the strait is to be preferred, the more so as the currents are not so strong there as in the middle, and on the East side, of the strait.

The Strait of Allas is easily known in coming from the southward, the S.W. part of Sumbawa being high rugged land, whereas the East end of Lombok is composed of steep cliffs, facing the sea. The S.W. point of Sumbawa is a double table-hill, in $9^{\circ} 2' S.$, and $116^{\circ} 47' E.$, and Lombok Peak bears N. by W. $\frac{3}{4}$ W. from the entrance of the strait.

With the S.E. point of Lombok bearing W.N.W., and the S.W. point of Sumbawa S.E. by E., soundings are got in 64 or 70 fathoms, clean bottom; but farther to the southward and eastward the bottom is rocky, and no soundings less than 80 or 90 fathoms.

In the south-eastern monsoon, the winds blow strongly from the southward during the greatest part of the day, but they subside towards evening, when the land wind from Lombok begins. In the western monsoon, variable and baffling southerly breezes are often experienced in the Strait of Allas.

Bound to the southward, it is advisable to get under way very early in the morning, in order to clear the strait if possible, before the sea breeze sets in.

There is good anchorage on the western or Lombok side of the strait; in many parts the bank of soundings is very steep, extending only a short distance from the shore, and requiring careful attention to the lead while approaching it in the night time. Stock and fresh water can be obtained at a reasonable price at Bally, Pidioe, and Lombok, and at Allas on the Sumbawa side.

The prevailing current is from the southward, which, in the centre of the strait sometimes runs 3 or 4 knots. In June, 1845, H.M.S. *Fly* experienced an equally strong current from the northward.

At Bally the tides are described as regular, the flood coming from the southward, and setting along shore at from 1 to 2 knots per hour.

SUMBAWA ISLAND.

The Island of Sumbawa, Sombawa, or Soembawa, is one of the most remarkable in the world, possessing as it does the most tremendous volcano known. It is of very singular form, being deeply indented by arms of the sea, especially on its North side. Its character and proximity to Celebes and Gillolo, and their fantastic forms, point to their common igneous origin.

The elevation of the great volcano Tambora, or Tumbora, is 9,040 ft.

The great eruption of Tambora occurred between April 5th and 17th, in 1815, and it, for a time at least, destroyed the island, which from a fertile and thriving region become a desolate waste. The whole area was deeply covered with volcanic ashes to the depth of from 4 to 2 ft.; nearly two-thirds of the inhabitants perished, a large number buried alive in the ashes, the rest dying from want and starvation. According to M. van den Broek, there were only 20,000 to 25,000 men who survived, and it was not for many years that any immigration took place, and then a multitude of Buginese and Makassars took possession of the land, and restored it to more than its previous fertility. The area over which the ashes fell extended from near to Bencoolen in Sumatra to Timor, a distance of more than 1,500 miles apart, East and West, and over the South portion of Borneo, Celebes, &c., for a diameter of 900 miles.

The natives are a good-natured people, and the island produces a great quantity of sandal-wood; the trade in horses is considerable.

Madang or *Flat Island*, the centre of which is in $8^{\circ} 8' S.$ and $117^{\circ} 18' E.$, lies off the North side of Sumbawa. It is very low near the West end; the northern part is a little elevated, and may be seen from deck at a distance of 16 miles in very clear weather. It has reefs from the North and S.W. points, and a dry spot near its northern edge, from which the East point of the island bears about S. by E. The S.E. shore forms a small bight, opposite to which a single ship may find anchorage in 30 fathoms a mile off shore and half a mile from a reef.

Majo, or *Maio*, 7 or 8 miles E.S.E. of *Vlak*, is an extensive island, regularly high, with the exception of the East point, which appears at some distance as a low and separate island. A reef projects from the N.W. point;

and the bay on the West side of the island is full of shoals, behind which the pirates often take shelter. In former times the West part of Maio was inhabited, and there are several springs of good water on that side of the island. The frequent visits of the pirates obliged the inhabitants to leave this island for Sumbawa.

Setonda Island, off the N.E. point of Maio, is in $8^{\circ} 6' 30''$ S., and $117^{\circ} 43'$ E. It is of moderate height, with the top appearing somewhat flattened, when seen from the north-eastward; the reefs from the points are of very small extent. Viak, Maio, and Setonda, are all uninhabited, for the pirates often make their appearance there.

The Bay of Sumbawa to the southward of Flat Island, and to the eastward of Labu Bua Point, the N.W. cape of Sumbawa, has no other dangers than the reefs along the shore, which project most from the West point of the bay, about 2 cables' lengths, and are steep-to and dry at low water; the anchorage is in 20 to 16 fathoms, clay bottom, about 2 cables' lengths off shore. Entering from the northward and steering toward the centre of the bay, the soundings decrease regularly but rapidly from 40 to 17 and to 7 fathoms within a short distance from a dry sandbank opposite to the river's mouth; and as the bay is open from N.N.E. to N.W. by W., a vessel cannot be considered safe during the western monsoon. The landing is easiest to the westward of the river on a sandy beach, as the river can be entered only at high water. The village of Sumbawa is about 2 miles inland.

To the eastward of this bay, and opposite to the South coast of Maio, is the extensive Gulf of Salee. Mr. H. Zollinger, who explored the whole island of Sumbawa in 1847, gives the following description of it.

The large Gulf of Salee extends about 12 leagues in a S.E. direction, and is about 4 leagues wide. The entrances along the N.E. and S.W. points of Maio are both narrow; the western one being about a gun-shot wide. The South point of Maio is pretty bold, but reefs project from Menangis and Gayong Points, on the southern shore; and in the bight of Peniaring between these points there is shoal water.

Gayong Point forms the West side of an inlet with deep water inside, which stretches about 4 miles South, called *Bango*, or *Bunga*, with a small village. The entrance of this inlet bears S.W. by S. from Setonda, but it is too intricate for ships, having reefs on either side.

Liang and *Negalie*, two long, narrow, and hilly islands, stretch parallel to the coast, and form two narrow channels with deep water stretching about N.N.W. and S.S.E.; proas may enter them at both ends. The southern beach is inhabited by fishermen, and about 3 miles inland stands the large village of Lapie.

The next bay to the south-eastward is called *Tieris*; then follows *Kollong*, a large bay, bounded by a monotonous and barren plain, and by low hills to the southward; the S.E. winds pass freely over them, and blow strongly in

this part of the gulf. The bottom of the bay is mud mixed with sand, and its little depth of water does not permit vessels to stand close in shore; $3\frac{1}{2}$ miles inland is *Plampang*, a considerable and well fortified place, governed by a nearly independent prince.

The island, or rather isthmus, is not more than 8 miles broad.

The *Bay of Ampang* to the eastward of Kollong Bay is also shallow. There are several islands in this part of the gulf, called *Tengar*, *Tapan*, *Kebo*, *Dempoe* (easily known by two peaked hills), *Tepie*, *Rakit*, a large island. *Kowanko Bay*, to the eastward, is shallow; near its eastern beach is the small island *Balereh*, and the long and low island Kowanko, stretching E.S.E.; *Nissah Monteh* is contiguous to its West point, and fronts the bay to the northward.

There are also several inlets in the East part of the gulf, but most of them are closed by reefs; they are named *Tioerie Lora*, *Sonapa*, and *Gempoe*, fronted by the rocks of Poedo; rivers disembogue in the former and in Sonapa. The small village Gempoe stands about a mile from the beach; good fresh water is to be had here, and the country abounds with game.

The northern shore is uninhabited; it runs in a straight direction, and is steep-to, affording no anchorage. From August to October, pirates come to this bay for fire-wood, and greatly disturb the natives, who therefore build their villages far inland. They often attack proas and ships which pass near Maio Island.

The tides set with great velocity through the Strait of Salee, and probably also through the northern entrance to the gulf. The flood sets to the E.S.E. and the ebb to the W.N.W.; during the eastern monsoon the latter is strongest, and it is high water about the moon's meridian passage.

The chains of mountains generally follow the direction of the bays which they limit, causing S. or S.S.E. and N. or N.N.W. winds in the West part of the gulf, N.W. and S.E. winds near its centre, and E. or E.S.E. and W. or W.N.W. winds at its East end. During the eastern monsoon the northerly winds are light, on account of the vicinity of the high land of Tambora and Maio, but the southerly winds blow then rather strongly over the low land of Kollong. Pilots for this gulf are to be had at Sumbawa Town. There is plenty of wood on either shore, but provisions and fresh water are very scarce.

TAMBORA VOLCANO.—The Gulf of Salee is separated from the Bay of Dampo by the isthmus, on which stands the high volcano of Tambora, or Tumbora. The summit of the mountain is very large, and of a circular form, in the longitude of $117^{\circ} 48'$, and bearing S.E. by E. $\frac{1}{2}$ E. from Setonda Island.

Dampo Bay.—In former times the Dutch had settlements in the Bay of Dampo, but they have been abandoned. Mr. Zollinger, on his journey to the top of Tambora, found a fine spring of water, called by the natives Tam-poerokh, close to the beach on the western shore of the bay. Several inlets

afford good anchorage, the westernmost of which, Bioe Bay, is much frequented by pirates. In former times the Dutch had established a trade for sapanwood at Kamboe, and the road of Kila is very safe during the eastern monsoon, but the villages along this coast are all deserted now on account of the frequent invasions of the pirates.

Bima Bay, 15 miles eastward of Dampo Bay, stretches deeply inland, and forms a safe harbour, where ships lie quite landlocked and sheltered on all sides by high land. In the wide entrance there is only a temporary anchorage. The shores which bound the bay approach each other about 4 miles from the entrance, forming a narrow channel for about 3 miles in length and not half a mile in breadth, with soundings from 32 to 20 fathoms, but leading to a spacious cove, in the centre of which lies the high island Kambing. The Dutch have a battery near the beach on the East side of the bay. The narrow entrance is defended by two small bentings, where the Dutch colours are hoisted. To the southward of Bima the bay forms another spacious cove with an islet near the southern beach.

During the eastern monsoon, very strong southerly winds, accompanied by heavy squalls, continue to blow, sometimes for many days, outside of the narrow channel; and yet, inside, quite calm under the high land, and impossible to enter the bay. The land winds blow regularly during both the monsoons, and there is therefore no difficulty in quitting it.

Kambing Island lies due South from the Narrows in $8^{\circ} 26' 45''$ S., and $118^{\circ} 41'$ E. Having passed the Narrows, the village of Bima will be soon discovered; steer directly for it until in 11 fathoms, when a low point on the opposite side of the bay will be seen open with the South point of Kambing Island. Do not run farther in, as the depths decrease rapidly from 9 to 2 fathoms on the edge of the muddy flat opposite the village.

It is high water at full and change of the moon at noon, and the rise of the tide is 6 ft. The landing is difficult, on account of the extensive mud-flat opposite to the battery; water is scarce and bad.

From the N.E. point of the bay the South point of Apie Island bears E. $\frac{1}{4}$ N., its N.W. point N.E. by E., and its southern peak E. by N. When southerly winds prevent the entrance of the bay, it is advisable to anchor on the East side of the outer bay, as otherwise you are obliged to stand off during the night, and many days may be lost in a fruitless attempt to work in.

Sangeang Island or Gunong Api is a high, volcanic, double-peaked island, off the N.E. Cape of Sumbawa, between the latitudes of $8^{\circ} 6'$ and $8^{\circ} 14'$ S., and the southern or highest peak is in $119^{\circ} 2'$ E. It bears S. by E. $\frac{1}{4}$ E. from the North peak. The island is very steep to on every side. Proas sometimes land there to cut wood. Its N. and N.E. sides should not be approached within a mile.

The Eastern Coast of Sumbawa stretches at first about South to Sapi

Bay, where it takes an easterly direction till past Midden and Todo Islands, and then turns again to the southward as far as the southern entrance of the strait. Near the North point of Midden Island lies *Keppeh*, a small islet, with two rocks, between which and Setan is the most frequented channel, being about 3 miles wide; about 6 miles to the southward of *Keppeh* lies Kamara Island, close to Sumbawa.

Sapi Bay is formed by a deep bight in Sumbawa, and sheltered by Midden Island and some adjacent islets. The bay is $1\frac{1}{2}$ mile wide, with soundings from 20 fathoms, gradually decreasing to 17 and 14 fathoms in the centre, and to 5 fathoms in the southernmost part of the bay; the shore of Sumbawa is lined by a reef, but the islands may be approached within a short distance.

Sapi Town is situated by the side of a creek, at the south-western extremity of the bay; ships may procure there every kind of refreshments, which the natives will barter for toys, fire-arms, empty bottles, &c.; but single vessels ought to be guarded against any treachery of the inhabitants.

Rees and *Britannia Bays* are formed by the projecting points of Sumbawa to the northward of *Sapi Bay*, and at either of them ships may procure wood and water.

The outer verge of soundings stretches nearly in a direct line from *Keppeh* to *Api Islands*; the soundings decreasing pretty regularly towards Sumbawa from 60 to 20 fathoms, from half to a quarter of a mile off shore; but towards Banta there are no soundings, unless very deep. Nor are soundings to be had in the southern part of the strait South of Setan, beyond half a cable's length from it; there are 20 and 25 fathoms between it and the *Low Rocks* adjacent, deepening to the northward. Hereabouts the bottom is all rocky, with overfalls and rapid tides setting past Setan, 4 and 5 knots, and producing strong rippings like breakers, which render ships ungovernable.

In about $118^{\circ} 26'$ E. there is a deep inlet or bay, with a narrow entrance. Inside is a pearl bank, which was thickly covered by the eruption of Mount Tambora. Mr. Zollinger visited this bay, which is called *Tiempia*, and got a few oysters containing pearls of a small size. He sounded in 2 fathoms in the Narrows; but according to the natives there are 4 fathoms in the basin. Pirates frequent this bay, and they often take shelter inside of *Sido* and *Tengani*, the *Ragged Islands* of the old charts.

SAPI STRAIT.

This passage through the chain of islands, between Sumbawa on the West, and Comodo to the eastward, is about 20 miles in width. Its shores were cursorily examined by Lieut. W. T. Baars, D.R.N., in 1837-8.

The *Strait of Sapi*, *Sapie*, or *Sapy*, was much frequented in former times, but at present the Strait of Allas is preferred, being both wider and easier. The northern entrance of the former is divided into two branches by Banta Island, but the channel between it and Comodo is seldom used, as it is to leeward during the western monsoon, and has no soundings, while the ebb tide sets strongly upon Comodo, which is a high and steep land, and surrounded by rocks and reefs. Between Api Island and Banta the sea is clear, but H.N.M. steamer *Hecla*, when rounding the N.W. point, at the distance of a mile, June 2, 1844, fell in with a reef when the island bore S. by E. $\frac{1}{4}$ E. to E.S.E. Another rock lies just N.W. of this islet, lying off the South end of Banta.

Gili Banta, or Banta Island, may be known by its northern peak gradually sloping to its low southern point. This peak is in $8^{\circ} 22' 30''$ S., and $119^{\circ} 15'$ E. The West side of the island forms a pretty large bay,

Setan, or *Macota*, is a small, peaked island, with several rocks to the northward, bearing S.S.E. $\frac{1}{2}$ E. from Api Peak, and S. by W. from Banta Peak. The *Middle Rocks* lie W.N.W. $\frac{3}{4}$ W. from Setan, S.S.W. $\frac{1}{3}$ W. from the eastern extremity of Banta, and S.E. $\frac{1}{2}$ E. from the Black Rocks, and the latter bear W.N.W. from Setan. The Low Rocks, nearly level with the water's edge, lie about 3 miles S.W. from the South point of Banta, and 3 miles N. $\frac{1}{2}$ W. from Setan. When Banta Peak bore N.E. $\frac{1}{4}$ N., and Setan S.E. by E. $\frac{1}{4}$ E., the *Boreas* had the Low Rocks bearing N.E. by E., visible from the shrouds.

As the Low Rocks are nearly even with the water's edge, the track between them and Setan is not so safe as that between the latter and Keppeh. In this passage keep near Todo Island, rounding its N.E. point about the distance of a mile, for some ships have been in danger of being drifted on the rocks near Setan by the rapid tides.

Although the tides set rapidly through the middle of the strait, the flood to the northward, and the ebb to the southward, they become much weaker within the edge of the bank of soundings, near the north-eastern part of Sumbawa, where there is very little tide in the bays. The rise of tide in Sapi Bay is 10 ft. ; in Britannia Bay 11 or 12 ft. ; and it is high water about 1 o'clock at full and change of the moon.

The winds are variable in Sapi Strait, forming a kind of land and sea-breeze, those from the westward prevailing in the western monsoon ; and during the opposite season, strong breezes blow into the strait from the southward a great part of the day.

The *eastern branch* of the strait, between Gili Banta and Comodo, is seldom used, there being no soundings; the passage, however, between Banta and Peak Island is safe, and the latter is very steep-to; it bears E.S.E. from the South Point, and S. $\frac{3}{4}$ E. from the East point of Banta. Several rocks lie between Peak Island and Comodo, and it seems that there is no safe channel inside.

Opposite to, or about East from Kamara Island, a small island lies close to Comodo. It is said that the passage inside of it is safe, and that there is good anchorage in the bays to the southward of it, a cable's length off shore.

No other dangers are known in the southern part of the strait, except a *shoal* to the southward of *Pulo Kamara*, in its S.W. part, rather in the bight which this island forms with Sumbawa, having only 6 ft. water on it.

Chimney or Schoorsteen Island.—Contiguous to the S.W. point of Comodo stands a high and bold island, with a nob or upright rock resembling a chimney on its declivity, which renders this island a good mark to reconnoitre the strait in coming from the south-eastward. The West point of this island bears S. by E. from Banta Peak, and is in $8^{\circ} 46' S.$ and $119^{\circ} 22' E.$ A rock lies about a mile southward of the chimney, and another near the South point of Komodo, 3 miles to the eastward.

Ships steering for Sapi Strait, with light variable or easterly winds, may fall in with the West end of Sandalwood. This island is of middling height, and may be seen in clear weather 9 or 10 leagues, and the peak near its West end about 20 leagues. The West point of Sandalwood lies in $9^{\circ} 42' S.$ and $119^{\circ} E.$ With westerly winds, which blow strongly, and produce easterly currents, the South coast of Sumbawa may be approached, as it is mostly high, except opposite to the bottom of the Gulf of Salee, near the middle, where there is a low point, covered with trees. Remark also the shoal water stated to exist by Capt. Villoch.

Entering the strait, bring the East point of Kamara to the westward of North, on account of the Ida Shoal, and steer for the passage between Setan and Todo, rounding the N.E. point of the latter island at about a mile distance, to avoid the rocks to the north-westward of Setan, and in order to be the sooner in soundings; the currents not being so strong there, an anchorage may be obtained when the tide is contrary. If during the western monsoon the route through Salayer Strait is to be pursued, borrow towards the East side of Api, and keep well to windward, because by the strong easterly current, sometimes of 32 miles in 24 hours, ships are thrown to leeward of the islands fronting the South end of Salayer, and obliged to pass them to the southward.

In going from Salayer Strait towards the Strait of Sapi, during the south-eastern monsoon, endeavour to fall in with the North point of Comodo, and pass through the eastern channel on the Banta Island side, if not in want

of water ; but in all other cases the western channel seems preferable Two islets lie in the eastern half of the channel.

The **SOUTHERN COAST** of *Sumbawa* is very little known, and the representations we have of it are derived from the ancient charts. In 1864 Don J. Frederico Villoch sailed along its southern side, and has given the following general observations on it. The mountainous coast of Sumbawa, as seen from different points, varies greatly ; generally it appears rocky and covered with bushes. At $1\frac{1}{2}$ mile from its S.W. extreme is a small islet, about three ships' lengths in extent, and near to it to S.W. is one still smaller, and the first point which projects toward them to S.E. is low, even, and terminates in a perpendicular point. The coast from this trends E.N.E. 14 miles, and then S.W. about half that distance, then South for another 4 or 5 leagues, the land being lofty and mountainous, but sloping down to the sea in an extremely low point. From this it runs East and West for 30 miles, when two conspicuous points project to southward, the bluff land between them being remarkable.

At the last of these points a sandbank terminates. It commences at 6 or 7 miles to the West of it, and reaches 10 or 11 miles to the South. Its colour is so marked that it may be compared exactly with the Great Bahama Bank. This is a good point for correcting the reckoning, a difficult matter, on account of the strength of the current, as well as from the frequency of fogs. Its edge is well defined, the colour of the sea changing very suddenly, as if its edges were perpendicular. Beyond this bank to the eastward the coast is lofty and perpendicular, appearing to be quite clean and safe.

COMODO ISLAND, on the East side of Sapi Strait, is but little known. According to the chart of Lieut. W. C. Baars, 1837-8, it is about 25 miles long N.N.E. and S.S.W., and about 8 miles broad, being separated from Floris by the intricate strait of Mangarei. It is high and steep, of volcanic formation, and said to be part of the principality of Bima in Sumbawa.

The North coast of Comodo and the N.W. coast of Floris were first explored in 1843 by Kapt.-Lieutenant Coertsen's squadron. The North coast of Comodo forms a large bay ; when entering it their first soundings were in 35 fathoms, with the North extremity of Api Island N.W. by W. $\frac{1}{4}$ W. and the N.W. point of Comodo W. by S. They steered along shore at the distance of about a mile, and sounded in 32, 35, 30, 28, and 25 fathoms, opposite to a bight where the ships anchored.

The steamer *Hecla* came to in 18 fathoms, hard bottom, with 11 fathoms a cable's length closer in shore, the N.W. point of the bay bearing N.W. by N., the North extremity of two islands contiguous to the N.E. point of Comodo N.E. $\frac{3}{4}$ E., and a small islet N.E. $\frac{1}{4}$ N.

It was easy to land, the coast having a slow ascent ; and fruit trees were in abundance, particularly tamirind and palm trees. The land abounded with deer.

The next day they passed between two islands off the N.E. point of Comodo; rocks above water being seen in the channel nearest to the southern island, they borrowed toward the northern islet.

MANGARAI or Mangerye Strait.—The *Hecla* experienced strong southerly winds at the entrance of the Strait of Mangarai, but the current was so strong that she was drawn in, at the rate of 11 miles an hour! about S. $\frac{1}{2}$ W.; the other vessels, at some distance to the northward, having a light northerly sea breeze. The Strait of Mangarai showed a continued chain of reefs, sandbanks, and islands, with three high peaks, and with apparent channels between them. At 9 a.m. the S.E. extremity of the strait, formed by a high and bold rock, was seen bearing S. by E. $\frac{1}{2}$ E.; at the same time the S.E. point of Comodo, a bold rocky point in the shape of a woman's breast, bore S.S.W. $\frac{3}{4}$ W. The course was then altered to North, but the current, which caused violent rippings and deep whirlpools, was so strong at the time, that the vessel, working with full power, hardly advanced, and could not be kept on its course, veering 4 or 5 points to and fro. After a fruitless search for a passage between the N.E. point of Comodo and the adjacent island (the several islands at the entrance of the strait having been examined by the other ships), they altogether returned through the same channel which they had passed in the morning.

The *Resource*, Captain W. Bligh, went through the strait bound to the northward August, 1789; this, however, appears to be the single case of a ship attempting this most dangerous and intricate passage.

FLORIS, or Ende, or Mangarai, is about 200 miles long from West to East, and from 40 to 50 miles broad, with an area of 4,040 square miles. Its name is perhaps more properly *Flores*, as given to it by the early Portuguese. It has not been surveyed, but it consists of a chain of volcanic hills and mountains, in continuation of the great band passing through Java and Sumbawa. Two of its peaks are active volcanoes, one of them about 7,000 feet high. The people, an inoffensive race, have frizzled hair, and appear to be an intermediate race between the Malays and Papuas, but distinct from either. Cotton and sepan wood are its chief products, but it has little trade. At Potta, on the North coast, the Dutch have (or had) a fort and small post for the suppression of piracy, and there was a Portuguese settlement at Larantuka, near the S.E. end.

The ensuing directions are chiefly those drawn up by the Dutch officer, Lieut. Smits.

Badiak Cove, on the N.W. coast of Floris, is quite sheltered by a chain of islands. It is situated in $8^{\circ} 28' S.$ and $119^{\circ} 48' E.$ Enter by the passage to the southward of all the islands, and anchor in 13 fathoms, the S.E. point of the bay bearing S. by E. $\frac{1}{2}$ E., a point of Floris N. by E. $\frac{1}{4}$ E., the N.E. point of Kanassir N. $\frac{1}{2}$ E., Badiak between W.N.W. and W.S.W., and the

watering place E. by S. This cove is a perfect hiding-place for pirates, several narrow channels between the islets affording them an easy escape in case of a surprise, and the hills in the vicinity an extensive view to seaward. A run of very clear water, from the foot of a cataract, led into a small inlet about 50 paces long, where *sampangs* can enter to fill the water-casks. The cove will be easily found by keeping the northernmost of the islands contiguous to the N.E. point of Comodo W. by N.

There are four islands close to *Cape Kandisang*, the N.W. point of Floris. Between this point and the next island the channel is only half a mile in breadth, which is reduced by the reefs on either shore to 2 cables' lengths; and the high land, producing squalls and variable winds, renders it a perilous passage. It leads, however, into a spacious bay, near the N.E. point of which lies *Bodo Island*, in $8^{\circ} 19' 30''$ S., and $119^{\circ} 59'$ E.

Seraya Island, 2 miles in diameter, lies 3 miles N.W. of Cape Kandisang. Two and a half miles North of its North point is a sunken rock. Sunken rocks also lie 2 miles N.E. by E. of Cape Kandisang, 2 miles S.W. of Bodo Island, and *Vesuvius Rock*, with 2 fathoms water over it, 3 miles North of Bodo Island.

The bays of *Terang* and *Barrie* are separated from each other by a point of land to which *Longso Island* is joined by a reef. The small islet *Koko*, which has an extensive reef, nearly closes the entrance of the Bay of Terang, leaving only two narrow channels between the reefs of Longso and Koko, and between the latter and the reef which stretches along the N.W. point of the bay. Farther inside there are some other shoals with soundings of 9 fathoms between them. All the reefs are steep-to, and mostly dry at low water.

The anchorage in Barrie Bay is in 12 fathoms N.W. or W.N.W. from the village, but deeper in the bay ships lie better sheltered and more conveniently for watering. In 1847 a colony of about 200 Bimanese was settled here, in order to keep away the pirates from this sheltering place.

The Bay of Reo, so called after the village which stands on the S.E. shore in $8^{\circ} 15'$ S., and $120^{\circ} 32'$ E., is bounded to the westward by a high and bold point called *Bessie*, and to the eastward by *Kediending Point*; reefs run off both points about half a mile, and there is a dry sandbank opposite to the mouth of *Yzer River*. The bottom is very steep, and the anchorage in from 30 to 7 fathoms, close in shore. The Yzer River is navigable for proas far upwards, and the stream carries down a considerable quantity of iron ore and also some gold dust.

POTTA.—The road of Potta, in $8^{\circ} 17'$ S. and $120^{\circ} 45'$ E., is bounded to the westward by *Cape Baya*, a bold point bearing due East from Bessie Point. The shore is here so steep-to that in some parts no bottom is felt with 50 fathoms at 2 cables' lengths outside the reef which lines the beach. The anchorage is in 18 fathoms. Cape Baya, bearing N.W. by W. $\frac{3}{4}$ W.,

Potta Village N. by E. $\frac{3}{4}$ E., Passier Point (the East limit of the bay) N.E. $\frac{1}{4}$ N.

The Dutch bark *Diederika*, Captain J. J. Kingdom, in 1847, at 6 p.m., saw *breakers* bearing S. $\frac{3}{4}$ E., distant half a mile, in lat. $8^{\circ} 21' S.$, and long. $121^{\circ} 13' 30'' E.$, about 4 miles off the shore.

A small *sandbank*, bearing S.E. about 8 miles, observed lat. $8^{\circ} 22' 40'' S.$, when this danger was South, distant 1 mile, Paloweh Island bore E.N.E. This sandbank lies about 6 miles off shore, and is surrounded by rocks.

Paloweh is a high island and bold to approach; the peak is situated in $8^{\circ} 19' S.$ and $121^{\circ} 42' E.$ The channel between it and Floris is safe, and about 6 miles wide. The coast of Floris to the southward may be known at a great distance, as it consists of high white rock.

Linguette or *Sukur Island* has a high, sharp peak near the East point, and a hill on its S.W. declivity; the summit of the peak lies in $8^{\circ} 6' S.$ and $122^{\circ} 8' E.$ There is no anchorage near this island, and the reefs projecting from the N.W., S.W., and S.E. points are of little extent; there is a rock above water with a single tree on it on the reef off the S.E. point. *Pura Rock* lies 4 miles South of Linguette.

The **Doffer Islands**, two in number, are joined by a reef; they appear at a distance as three islands, the middle part of the westernmost island being low. From the West point of West Doffer, Linguette Peak bears N.W. by N. nearly. There are sunken rocks lying to a distance of 5 miles West from Doffer Island.

The **Bastaard Islands** are high, particularly the *Great Bastaard*. The mountain on the South part may be known by two ravines. Close to the eastward of it lie six small islets, and to the north-eastward of the easternmost of these, the *East Bastaard*. The coast of Floris to the southward and eastward of this group forms several deep bays, and one of its low points approaches close to the islets to the eastward of the Great Bastaard; the channel between these islands and the point is nearly a mile wide, and the two easternmost islets are joined to each other by a reef. The coast forms several deep bays, and has the appearance of a wall in decay. Nowhere was anchorage found among these islands; it would therefore be dangerous to cruise among them in a sailing vessel. Macassar proas frequent these places, as there is much tripang there, but they are often annoyed by the pirates. Sunken rocks lie a mile South of the S.W. end of the Great Bastaard, and also 2 miles South of the S.E. end; there is also a sunken rock off the West end of the East Bastaard.

Giliting lies at the head of the bay, S.W. of Bastaard Islands; two sunken rocks lie near the shore, and *Reteh Bank*, of 2 fathoms, 4 miles W. by N. of the town.

FLORIS HEAD, or the Iron Cap.—The N.E. extremity of Floris is a

high and steep promontory of considerable extent, called Floris Head, situated in $8^{\circ} 4' 45''$ S., and $122^{\circ} 53'$ E.

The Angelica Reef is stated to lie about 30 miles N.W. by W. from Floris Head; but this position is uncertain. According to Lieutenant Hooft, May, 1844, with the reef bearing E. by N. to N.W., the peak of Linguetto bore S.S.W. $\frac{3}{4}$ W., Poloweh Peak S.W. $\frac{1}{2}$ W., Floris Head S.E. by E. $\frac{2}{3}$ E., lat. observed $7^{\circ} 48' 39''$ S., and had no soundings in 80 fathoms. The reef seemed to extend E.S.E. about 3 miles, and appeared to be about half a mile broad near its extremities, which are nearly even with the water, but only 2 cables' lengths near the centre.

The *Haai* run aground during the night, near the S.E. point of this shoal. When aground she had 6 ft. near the bow, 2 fathoms at the rudder, and 40 fathoms on the edge of the shoal about two ships' lengths to the north-north-eastward; Floris Head bore S.E. by E. $\frac{1}{2}$ E., Ilimandri Peak S.E. $\frac{1}{3}$ E., Lolotobie Peak S.S.E. $\frac{3}{4}$ E., Linguetto Peak S.S.W. $\frac{3}{4}$ W., Paloweh (indistinctly seen) S.W. $\frac{1}{4}$ W., and Toea N.W. by W.; lat. observed, $7^{\circ} 48' 30''$ S.

The reef appeared to extend about 4 miles, and is divided by two narrow channels, which traverse it in a North and South direction, with some dry rocks on the centre.

Pasier Leiyeran or Angelica Shoal is now marked on the charts as 4 miles in diameter, its centre being in lat. $7^{\circ} 46'$ S., long. $122^{\circ} 18'$ E.

Bangalore Reef, on which the ship *Bangalore*, from Amboina, bound to Allas Strait, was wrecked in 1802, is said to extend North and South about 3 miles, with rocks resembling proas under sail. It is very probable that the ship was lost on the West part of Angelica Shoal.

The ISLANDS between Floris and the southern part of Celebes and Salyer are but little known. They were great resorts of pirates, but since 1843 they have been almost cleared out, and they were partially examined by Lieutenant Uhlenbeck, in H.N.M. steamer *Hekla*, in 1843.

The easternmost islands of this group and of the *Tyger Islands* are *Kobona* or *Post Horse* (Postpaard), in $7^{\circ} 25'$ S., and $122^{\circ} 3'$ E., with a reef projecting about $1\frac{1}{2}$ mile from its East point, and *Kabia*, *Pereh*, or *Baars Island*, in $6^{\circ} 56'$ S., and $122^{\circ} 15'$ E.

Madu, or *Pandiang Island*, in $7^{\circ} 28'$ S., is separated from Kalatoa Island by a channel of 3 miles in breadth. Reefs, with much discoloured water and steep-to, run off the points on the West coast of both these islands; the channel between them is free from dangers.

Kalatoa Island is about 6 miles in diameter, with high land at its South end. To the eastward of this high land, and off the S.E. end of the island, is *Cornelia Road*, in $7^{\circ} 24'$ S., long. $121^{\circ} 44'$ E. The anchorage is in sand and coral, in 24 fathoms water, 2 cables off shore.

There are several islands and dangers to the north-westward of Kalatoa,

which are said to extend almost to the islands Latonda and Salayer, and far to the northward, although it appears that there is a passage along the coast of Salayer.

The reefs which line the West coast of Bonerato project in some parts of the bay about 4 cables' lengths from the shore.

The strait between Bonerato and Kalao is safe. *Kalao* is a mountainous island, most elevated at each end; a reef, which is partly dry, and ranging from 12 fathoms, runs off the West point in a W.S.W. direction about 5 miles.

The *Marianne Shoal*, in $7^{\circ} 27' S.$, and $121^{\circ} 13' E.$, extends about 5 or 6 miles East and West, and 3 or 4 miles North and South, having rocks above water on the southern part. From the wreck of the *Marianne*, in 1820, Kalao and Bonerato bore from N. to N.W. by W. $\frac{1}{2}$ W., and Madœ E. by N.

About midway between this reef and Madœ lie two small islets, called *Kajoe* or *Kayu*, which are surrounded by a reef.

Dyampea, or *Tjampeah*, is the largest island of this group; it has a rugged appearance, and terminates to the eastward in a low point. There is an extensive reef on the North side of this island, with overfalls from 30 to 5 fathoms. *Kambarraghie Bay*, on the South coast of Djampea, formed by a projecting point of the land and by several islets which front the South coast, and inside of which there are passages for proas, was much frequented by the pirates. The bay is environed by picturesque mountains, covered with canary and other kind of high trees, and it is considered safe in both monsoons.

Maringi Bay is 5 miles farther to the eastward, at the eastern foot of the peak of Djampea. At from 12 to 18 miles northward of Bonerato is a group of three islands, *Latonda*, *Little Latonda*, and *Kampa*, surrounded by a reef. Between them and the East point of Tjampeh, which is 17 miles West from Latonda, a reef is shown on the chart.

To the westward of the East end of Dyampea are three small islands, *Badjak*, *Batu*, and *Kamarie*; and at 14 miles North of the same point is *Kajoewaddie*, which has a peak on its West point. *Sisir*, a low island, lies 4 miles N.W. from the N.W. end of Dyampea; it is surrounded by a reef, but leaves a clear channel between. At 5 miles to the West of it a reef is reported, and at 7 miles W.S.W. is a 2-fathom rock. *Vesuvius Rock* lies in lat. $7^{\circ} 8' 30'' S.$, long. $120^{\circ} 23' 30'' E.$, $11\frac{1}{2}$ miles S.W. by S. of Sisir, and 36 miles S. $\frac{1}{2}$ E. of it is a doubtful patch.

Mamalak Island, or *Mamalakki*, in $6^{\circ} 40' S.$ and $120^{\circ} 13' E.$, is the westernmost island of this group; it is surrounded by a reef, and the channel between it and Roessa and Tambelaoeang is dangerous.

The channel between Mamalak and the Postillon is 19 or 20 leagues wide, without dangers, and is the usual track of ships from Sapi Strait bound to the Strait of Salayer or Makassar.

During the eastern monsoon ships will experience here a daily set of the current to the westward, from 16 to 30 miles, and during the western monsoon it runs with rather greater velocity to the eastward. Ships working towards Makassar during the eastern monsoon should bring Api Island to bear S.S.W. or S.W. by S. before they cross over; and during the western monsoon it is often very difficult to weather the strait of Salayer after having passed through Sapi Strait, on account of which the passage through the Strait of Allas is now generally preferred.

The route along the coast of Floris and to the northward of Paloweh and L'inguette is generally adopted by ships bound from Sapi Strait to Pitts Passage, and also by ships bound to Amboina late in the monsoon, in March or April, or returning from there in June, July, and August. It is prudent not to stretch over far to the northward on account of the islands and dangers before mentioned, and of some others which are doubtful.

SOUTH COAST of FLORIS.—As the trade on the South coast of Floris is carried on exclusively by proas, and the trade with Sandelhout Island being of little importance, the strait between these islands is seldom frequented, unless by ships navigating between Singapore, or Java and Timor, or Australia.

The *Strait of Mangarai*, or *Mangara*, before described, lies between Comodo and *Rindia*, an uninhabited island, which abounds with wild buffaloes and horses.

There is a deep bay in the South coast of this island, but full of reefs.

Molo Strait separates *Rindia* from Floris; its entrance may be easily known by a high island in $8^{\circ} 46' S.$ and $119^{\circ} 44' E.$ *Alligator Bay* is formed by a neck of land projecting to the southward. The S.W. point of this bay is low and green, and the S.E. point may be known by a perpendicular black cliff, to the south-eastward of which there is a low point, with a remarkable hole in a rock, appearing from the seaside like a sail. The bay is $2\frac{3}{4}$ cables' lengths broad, by half a mile in length, and a considerable stream or river falls into the sea in its N.E. part, where there is a steep bank, extending about a cable's length from the river's mouth; the beach is steep-to in every part of the bay, and no other dangers exist. Although the tides were nearly imperceptible, the rise of the water was observed 12 ft. at the springs.

The South point of *Mangrove Bay* may be known by a brown spot near its extremity, and the North point has a green appearance. Then follows to the northward a bold, rocky, and wooded point, and the next point is high and overhanging.

Cape Sosa, the S.W. point of Floris, appears at a distance as an island, and is situated in $4^{\circ} 49' S.$ and $119^{\circ} 55' E.$ The land falls back north-eastward and forms a bay, near the East point of which lies *Toren* (tower) *Island*, easily known at a great distance by a sugarloaf peak standing near

its western extreme in $8^{\circ} 52' 30''$ S. and $120^{\circ} 11'$ E. *Nanga Ramo Bay*, in which is anchorage, sheltered from the eastward, lies 13 miles E.N.E. of Tower Island. The coast then forms a more extensive bay, terminating in the southernmost point of Floris, on which stands the sharp peak of *Rokka*, in $8^{\circ} 54'$ S. and $120^{\circ} 59'$ E., which has been seen at the distance of 31 leagues; and in $8^{\circ} 50'$ S. and $121^{\circ} 12'$ E. stands the high volcano of *Romba Peak*, southward of which is Keo Bay. The land hereabout is imperfectly known; it appears to be fruitful and well peopled, but the inhabitants are said to be uncivilized and savage. Along the shore a great surf was observed by the steamer *Hecla*, and she ran into discoloured water when in chase of some proas, Romba Peak bearing N.E., and the extremities of the land E. $\frac{3}{4}$ S. and W. by N., half a mile off shore.

ENDE BAY is formed by the high isthmus of Api Head, on which is an active volcano, and bounded to the westward by a bold point, in long. $121^{\circ} 20'$ E. *Ende Island*, opposite to the centre of the bay, has the shape of a gunner's quoin, with the highest part turned towards the South; and appears at a distance as a projecting point of the land.

The coasts here are steep to on all sides; near the southern beach of the bight of *Ambogaga* the first soundings in 36 and 26 fathoms are within 2 cables' lengths off shore. Water is scarce, as well in the village as in the river of Braai. Proas find shelter from westerly winds on the N.E. side of Ende, where good anchorage is found opposite to the ruins of a Portuguese fort, and water may be had there.

The bay to the eastward of Api Head has not been visited, but it is supposed to be safe during the western monsoon. From hence the coast stretches about E. by N., with many remarkable mountains inland, among which the principal are a high volcano, in $8^{\circ} 49'$ S. and $121^{\circ} 52'$ E.; a lofty peak near the shore, which may be distinguished at a great distance in coming from the westward, in $8^{\circ} 48'$ S. and $122^{\circ} 5'$ E.; a mountain with a flat top, in $8^{\circ} 44'$ S. and $122^{\circ} 25'$ E.; and *Lobetobie*, the northern head peak of which forms a sugar-loaf, in $8^{\circ} 32'$ S. and $122^{\circ} 47'$ E.

SUMBA or SANDALWOOD ISLAND, the *Tanna Tyumba* of the Malays, has not been surveyed. It is estimated to have an area of 3,800 square miles, and its people are of the Malayan race, but a distinct nation. The land is mountainous, and like the neighbouring countries is perhaps volcanic. But little is known of it, and there is no trade to boast of.

The North-East coast, about 90 miles in extent, offers a very monotonous view, showing a calcareous wall with a nearly level top about 1,200 ft. high, and from 2 to 6 miles inland, covered with long grass. At *Palmedo*, *Sassa*, and *Tapi Points* the land has a more regular aspect, and the hills about *Roeboe* are rather elevated parts of the wall, but those near Nangamessie and Palmedo are peaked. The East part of Sandalwood appears to be a plain

covered with grass and bushes, and gradually sloping down towards the low points *Tapi* and *Mandieli*.

From *Tapi Point* to *Mandieli* the coast is covered by a reef projecting about 4 miles, with an island upon it formed by some flat rocks about 25 ft. above water, called *Mano*.

Nangamessie Harbour, in the bay between *Atta* and *Mandolo Points*, is formed by reefs projecting from the shore, which are steep-to and mostly dry, and by a detached reef, with only 1 and 2 fathoms water over it, on the East side of the entrance, which is separated by a narrow but deep channel from the rocks of the shore. The space between the reefs is 1 or 2 cables' lengths.

Mandolo Point and *Cape Roeboe* are bold, and *Cape Sassa* rises nearly perpendicularly to a height of 250 ft. on its North and West sides.

The entrance of *Palmedo River* bears S.W. by W. $\frac{1}{4}$ W., about 12 miles from *Cape Sassa*; boats drawing from 5 to 7 ft. can enter at high water. The road may be known by the *Kron Berg*, which is the highest point of the back land, and the top of which is wooded and peaked; and further to the westward another woody peak of about the same height will be seen.

The N.E. Coast of Sandalwood may be approached within 1 or 2 miles, with the exception of the East point of the island. From seaward no villages are visible except *Lenna*, near *Palmedo*, and *Taimano*, near *Nangamessie*.

There is a high peak in the West part of Sandalwood, which may be seen about 20 leagues, and most part of the South coast is seen at the distance of 9 or 10 leagues. The West point of the island, called *Reef Point*, on account of a great reef projecting from it, is in about $9^{\circ} 40'$ S. and $118^{\circ} 59'$ E., bearing S. by W. $\frac{1}{2}$ W. from the southern entrance of *Sapi Strait*.

Cape Blackwood, the South point of Sandalwood, is in $10^{\circ} 20'$ S. and $120^{\circ} 29'$ E., and as high and inaccessible as the rock of Gibraltar, with a low connecting land-tongue, on either side of which lies a spacious bay. The West one seems to be well sheltered by the islands fronting the point, but there are no soundings 3 or 4 miles off shore.

There is a safe harbour sheltered by reefs from all winds on the South coast, in long. $119^{\circ} 28'$, near the populous village *Tida*. There is also safe anchorage near *Treba*, and in the spacious bay of *Wedielo*, near the South end of this island.

Fly Islands are two small islands lying at 14 and 20 miles westward of *Cape Blackwood*; the eastern one is high and rugged, with a small islet off its western end; and the western one low, with a sunken rock West of it.

Niagara Breakers were seen by Captain Fray in 1869, in lat. $10^{\circ} 44'$ S., long. $120^{\circ} 5'$ E., with the largest of the *Fly Islands* bearing N.E. by N., and *Cape Blackwood* N.E. $\frac{1}{4}$ E.

A 10-fathom patch was discovered in 1869 by the S.S. *Corona*, at about 150

miles southward of Sandalwood Island, in lat. $12^{\circ} 26' S.$, long. $118^{\circ} 40' 30' E.$

Savu Islands.—The channel between Sandalwood and Savu is about 15 leagues wide, and has no other dangers than the reef which projects far from the East point of the former island.

Savu, or *Rai Hawu*, may be seen at 8 or 9 leagues distance; it has a sandy and barren aspect, and *Banjoan* is low and wooded.

H.M.S. *Serpent* coasted along the South shores of these islands to verify their positions, and found them fairly correct. They are bold, except that from the East point of Rai Diuwa or Benjoan, an extensive reef was seen on which the sea was breaking heavily. (1869).

Hockie or **Dana** (New Island) is of coral, low, and covered with scrub, having a ridge along its north-eastern side of about 120 ft. elevation, the western part of which is a detached knoll like a short horn. This latter is in lat. $10^{\circ} 49' S.$, $121^{\circ} 16' E.$ Under this ridge, and facing the N.E., is a broad sand beach, which is the only practicable landing-place in fine weather. Off the northern part of this beach is the anchorage in 12 fathoms, sand, with the knoll bearing S.W., and the East point S.S.E. Wild goats abound on the island, but no fresh water could be discovered.

Ships late in the monsoon bound to China, and passing St. Paul and Amsterdam Islands in the latter end of September, October, November, or December, generally proceed through the Ombay Passage. They ought to make the East point of Sandalwood, and to pass between it and Savu, or between the latter and Rotti, if they fall to leeward with N.W. or westerly winds. In former times it was usual to steer for the West end of Sandalwood, and to pass between it and Floris; but the route to the eastward of Sandalwood is preferable, particularly with variable winds, nor can it be required to pass to the westward of Sandalwood unless the wind blows strong from the north-westward with a lee current, when it may be desirable to pass to windward.

STRAITS between Floris and Ombay.—The several straits between Floris and Ombay Islands are narrow, and subject to strong currents and frequent calms, succeeded by heavy squalls from those high mountainous islands, and are therefore but seldom used.

The straits of Floris, Solor, and Lamakwera or Zemandro, are often used by the Dutch vessels of war bound to Timor, and it seems that formerly the Strait of Bolling, or the Dutch Gut, between Lombatta and Adenara, was much frequented. The straits of Alloo and Pantar are very intricate, very deep and embarrassed with strong currents.

In March, 1868, from twenty to thirty vessels had been over three weeks endeavouring to get through Ombay Passage—with the usual luck of losing by day what was gained at night. At length the masters of the *Lord Macauley* (drawing 20 ft.), and the *Westminster* (drawing 22 ft.), resolved to

turn back and try what could be done at Zemandro Strait; after two days they reached the entrance. At noon, Sangi Island bore East of them, and with the strong current and the assistance of a 4-knot breeze they were clear through, and past the dangers at the northern end of the strait in $2\frac{1}{2}$ hours. The *Gossamer* on this occasion passed through Allor Strait.

The STRAIT of FLORIS, between the East coast of that island and the West coasts of Solor and Adenara, stretches N.N.E. and S.S.W., about 12 leagues. The southern part of the strait, along the coast of Solor, is generally called *Lobetobie Strait*, and the northern part the *Gut of Larantuka*. The narrowness of these straits and their strong currents make it unadvisable to resort to them unless in case of necessity.

If intending to pass through the Strait of Floris during the western monsoon, after passing Sandalwood haul in for the coast of Floris, and approach it pretty closely. In coasting to the eastward, *High* or *Hoog*, a high round island in the mouth of the strait, must be passed on the West side. The island is in about $8^{\circ} 40' S.$, and $122^{\circ} 51' E.$, and is steep-to, having no ground near it at 90 or 95 fathoms. There is a ledge of rocks a little to the eastward of it, part of which is visible above water, and other islands and rocks front the South part of Solor. At a small distance inside High Island two other rocky islets form the passage, which are seen when the strait is open; they bear W.S.W. and E.N.E. from each other, distant half a mile or more, having soundings of 40 and 30 fathoms mid-channel, but the common passage is on the East side of these two islets.

The S.E. point of Floris, at the foot of the high peak or *volcano of Lobetobie*, is of a green aspect, resembling a gunner's quoin, from which a reef projects with 9 fathoms near its edge. The peak of *Ilimandri* bears N.N.E. of the point.

At Larantuka, a village, where the Portuguese have a settlement, good water and refreshments for two or three vessels may be had. The anchorage in the Bay of Larantuka, about 1 or $1\frac{1}{2}$ cable's length off shore, is considered more safe than nearer Adenara, but the bottom is the same.

The *narrows* of Floris Strait are about 3 cables' lengths wide, with soundings in 16 fathoms, mid-channel, 12 and 11 fathoms nearer to Adenara, 14 and 15 fathoms on the Floris side of the strait, and deepening suddenly to 19 fathoms, no bottom when to the northward of the narrows.

The flood sets to the northward and the ebb South. The tides change regularly every six hours. H.N.M. frigate *Triton*, December, 1838, observed the ebb to run 2 or $2\frac{1}{2}$ knots, but the flood 5, the latter to set in very irregularly, with violent riplings, which make it dangerous to anchor in the entrance of the strait. It was high water at 12 o'clock two days before full moon.

Ships from the southward, when leaving the narrows, should haul in for Adenara, because the tide, setting strong round the point of Floris, will be

liable to drift them on the reef which projects from this point, or to horse them into the Bight of Floris outside the point, which is shoal all over.

Ships coming from the northward may anchor off the village of Adenara, either to get out the boats and take every precaution requisite before they proceed into the strait, or to procure refreshments. When Serbette bears N.W. by W., and Komba N.E. $\frac{1}{2}$ E., Adenara village bears S.E. by S.

Serbette Island, situated in the northern entrance of the strait, is $8^{\circ} 8' 30''$ S. and $123^{\circ} 1'$ E., bearing S.E. by E. $\frac{1}{4}$ E. from Floris Head, and N. by E. $\frac{1}{2}$ E. from Ilimandri Peak, is a low island, uninhabited, and visible from the deck about 8 or 10 miles. It is surrounded by an extensive reef, partly dry, from the eastern extremity of which Ilimandri Peak bears S.W. $\frac{1}{2}$ W., and Wokka Peak S.E. $\frac{1}{4}$ E. The reef extends about the same distance nearly 2 miles to the westward, and the channel inside between it and Floris is apparently clear.

KOMBA ISLAND, or *Batutara*, is high, and stretches North and South about 3 miles. The peak on the southern part is in $7^{\circ} 48'$ S., and $123^{\circ} 34'$ E. It is an active volcano, and was seen during an eruption by Captain the Hon. H. Keppel, R.N. From the West coast of this island Wokka Peak bears S.S.W. $\frac{1}{2}$ W., the N.W. peak of Lomblen S. $\frac{1}{2}$ W., and Lobetobie Peak S.E. $\frac{1}{2}$ E.; and from its East coast the two tops of the latter mountain bear S. by E. $\frac{3}{4}$ E. and S.S.E., and the West peak of Lomblen S. $\frac{3}{4}$ W. It is an excellent guide for ships coming from the Banda Sea and bound to the Strait of Floris, which bears S.W. $\frac{1}{4}$ W. It may be passed on either side in steering for the Strait of Floris during the eastern monsoon, because the currents are strong to the westward.

Jessie Shoal lies 24 or 25 miles N.E. $\frac{3}{4}$ E. of Pulo Komba. The high land of Lomblen is visible from it. The rock is level with the top of the water, but no breakers were seen. It must be the same danger as the Mackie Shoal, discovered in 1826.

SOLOR STRAIT.—Vessels bound to Timor, after passing through the Strait of Floris, generally proceed through the Strait of Solor, between the islands Solor and Adenara; it stretches about East and West, and is 3 miles wide. There is no anchorage, except close in-shore, and the Solor side of the strait is preferable, as the squalls are not so frequent there, Solor being less elevated than Adenara.

Lawang, on the North side of Solor, has the ruins of a Dutch fort. Good water may be had on the opposite shore, North of Lawang.

The village of *Lamakwera*, near the N.E. end of Solor, is in $8^{\circ} 26'$ S. and $123^{\circ} 9'$ E. The ebb sets to the northward and the flood to the southward; sea-breeze southerly, and land-breeze northerly and light. In approaching the anchorage, the lead ought to be kept going as the soundings decrease rapidly towards the village.

There is a reef a little to the westward of Lamakwera, of $2\frac{1}{2}$ fathoms, the

North and N.E. points of Solor bearing W. $\frac{1}{2}$ S. and S.S.E. $\frac{1}{2}$ E. There is a safe passage between the reef and Solor.

BOLENG STRAIT, the "*Dutch Gut*," was much frequented by the Dutch Company's ships, and, according to their charts, there are soundings all through it, and anchorage in 20 to 9 and 6 fathoms in the Bay of Lomblen. The northern entrance of the strait bears about S.S.W. $\frac{1}{4}$ W. from Komba Island. In the centre of this entrance are the Boleng Islets, about $2\frac{1}{2}$ miles West of the N.W. point of Lomblen, and surrounded by a reef. The N.W. end of Lomblen is also fringed with a reef, but in mid-channel the depth appears to be good—no bottom at 50 fathoms. Dutch charts show but an exceedingly narrow passage between the Boleng Islets and Adenara. The Lomblen side of the strait appears the safest, and it is said that there is anchorage in Lomblen Bay in 19 to 9 and 6 fathoms.

LOMBATA or *Lomblen Island*.—The S.W. point of Lomblen bears S. by E. $\frac{3}{4}$ E. from the N.E. point of Solor. The South and West coasts of this island are high and bold, volcanic, and of a barren aspect. *Soangie Island*, easily known by a hole which opens when it bears N.W. $\frac{3}{4}$ W., is in $8^{\circ} 35' S.$ and $125^{\circ} 13' E.$, and bears S.S.E. from the S.W. point of Lomblen, and W. $\frac{3}{4}$ S. from Lamarap Peak; it has a green aspect, and may be approached within a short distance.

ALLOR or *Maurissa Strait*.—In approaching the Strait of Allor, along the South coast of Pantar, the seaman is struck with the appearance of four islands, but the easternmost proves to be the high S.W. part of Pantar, the second the West part of the same island, joined to the body of the island, by a low land-tongue, though, according to Lieut. P. F. Uhlenbeck, D.R.N., it is detached; the next is *Nubatan* or *Babi Island*, which may be called low in comparison to the surrounding land; several rocks and reefs project from it, especially from the South point; another reef projects a considerable way from the North point in a N.N.E. direction. The fourth is Nabokam or Rusa, which has a reddish, rocky, and barren aspect, and is dangerous to 3 miles off its S.W. coast. When Little Island is in one with the West part of Pantar, the opening of the strait will be discerned.

The high S.W. foreland of Pantar has a reef running off in a southerly direction, on the outer edge of which lies a large rock with heavy breakers; the passage between Klein Island and Pantar is thought to be very dangerous, and seems never to have been examined. A high rock is joined by a reef to the westward of Middle Island. The western isthmus of Pantar and Little Island has nearly the same level aspect; but the N.W. point of the isthmus may be known by a group of seven trees on it. The N.W. coast of Pantar stretches about N.E., forming several bays, and a reef runs off the North point about 2 miles, with many rocky points visible above water:

Green Island is small, round, and high, consisting of reddish rock. It

appears from the eastward like a sand-hill, but when viewed from the southward it has a green appearance. *Flat Island* is very low ; its North side is covered with shrubs, but the southern part is barren. The *Pantar* perceived only one low island, but the *Hecla* saw two, possibly united at low water. A reef, with several ledges of rocks a little above water, projects about N.E., 4 miles from Green Island. The western edge of this reef runs along the West coast of Flat Island, and joins it to Green Island.

The N.E. point of Lomblen is fronted by a reef with heavy breakers ; but a little to the southward of this point the coast is clear as far as the next projecting point, which is also fronted by high rocks, and near which there are no soundings.

A $2\frac{1}{2}$ -fathom patch lies in the middle of the narrow part of the strait, between the N.E. point of Lomblen and the West point of Pantar.

The *Currents* in this strait are most violent at times, and render a ship quite ungovernable, should it fall calm, as is frequently the case. Added to these evils, the depth is usually unfathomable, and affords no anchorage. The Dutch sloop of war *Pantar* was thus drifted to and fro for several hours in the greatest peril, in June, 1839, and only saved by a southerly breeze springing up at midnight. These considerations should weigh with a commander before he ventures to take this strait.

The strait of Allor may be easily known, as well from the North as from the southward, by the high double peak *Lobetolle*, near the N.E. point of Lomblen, in $8^{\circ} 12' S.$ and $123^{\circ} 43' E.$, bearing N.N.W. $\frac{1}{4}$ W. from the middle channel. Green Island is also a good guide in coming from the northward ; and Lomblen and Pantar being both very high land, the strait will be easily discerned.

It is not advisable to attempt this passage, when bound to the southward during the eastern monsoon, as it would be difficult to get through in one tide, the winds then generally blowing strong from South to S.S.W.

Great care is requisite when sailing along the entrance of Allor Strait, not to approach Lomblen within 4 leagues distance, as ships are liable to be horsed in the strait by the current, as happened with the Dutch frigate *Maas*, in 1839. In general, great attention is to be paid to the currents when passing near any of the eastern straits, as ships have often been carried into them. The *Pantar* observed high water between 9 and 10 a.m., two days before full moon.

PANTAR, Putar, or *Pandai*, which forms the eastern side of Allor Strait, is but little known. Its western side was examined by Lieut. L. J. de Vrieze, in 1839. The people are rude, half-naked heathens, with dark brown complexions and frizzled hair, and are not to be trusted. It is high and most probably volcanic.

The STRAIT of PANTAR is formed between the island and the West

side of Ombay. The N.W. end of Ombay is high bold land, and the distance from it to the N.E. point of Pantar is 5 miles; but in the northern part of the strait there are three islands. The northernmost of these, called *Panjang* or *North Island*, in about $8^{\circ} 8' 40''$ S. and $124^{\circ} 17'$ E., is low, and on the middle of it there is a small hummock. Another island, in the form of a cone, bears S. $\frac{1}{2}$ W. from the former, and the third, called *High Island*, is much larger, and terminates in a double peak, nearly as high as the N.W. end of Ombay or the peak of Pantar; and the land abreast of it forms a bay on both sides the strait. There is a deep inlet to the N.E., and a Malay village near the beach in the back part of this bay. *Twerin* or *South Island*, situated in the southern entrance of the strait, in about $8^{\circ} 29'$ S. and $124^{\circ} 14'$ E., is high. The proper channel through is between the islands in the North part of the strait and the Ombay shore, and out to the southward on either side of South Island; but the passage West of the latter is preferable. The narrowest part of the channel is between the N.E. point of High Island and the North point of the inlet that stretches into Ombay, and is 2 or 3 miles wide.

A high mountain, forming a saddle, stands on the southern part of Pantar; its southern peak is in $8^{\circ} 32'$ S. and $124^{\circ} 6'$ E.

The **OMBAY PASSAGE**, between Ombay and the North coast of Timor, is 16 miles wide in the narrowest part. It has apparently deep water throughout, and there is no danger known, but it has not been surveyed.

The most eligible route for ships late in the season bound to China is by the Ombay Passage, to proceed to the westward of Buru, then through Pitt and Dampier Straits, or the Gilolo Passage. After making the East point of Sandalwood Island, pass between Timor and Ombay, and haul close round the East point of the latter island to the northward.

OMBAY, Ombai, or Allor, extends nearly E. and W., about 19 leagues; it is all high, but most so at the eastern part, and is covered with beautiful high trees to the summit of the highest ridges of its mountains. The inhabitants are of the Malay Negro race, with dark complexions and frizzled hair. Like the Dyaks of Borneo, they are ferocious head-hunters, but content themselves with the lower jaw. On the coast some of the people profess Mahomedanism.

It is about 50 miles long from West to East, and its West end is deeply indented by a large bay. It is of volcanic formation, but is not known to contain any active volcano. The S.E. point is formed by a bluff white rock, in $8^{\circ} 21'$ S. and $125^{\circ} 14'$ E. A sunken rock lies near this point; and off Biluka, 15 miles to the westward, two sunken rocks lie near the shore.

WETTA is also high and bold, extending E.N.E. and W.S.W. about 19 leagues. *Dog* (or *Honden*) *Island*, off the N.W. point of Wetta, is in $7^{\circ} 41'$ S. and $126^{\circ} 1'$ E.; and *Liban*, or *Babi*, is another high island, separated by a channel of about 2 miles broad from the S.W. end of Wetta. The West

coast of Wetta is faced by reefs, and the channel inside Babi is said to be unsafe. The mail steamer *Normanby* reports (in 1875) having struck on a reef extending three-quarters of a mile from the South end of Libau Island. A break was also observed on what was supposed to be a sunken rock, lying 3 miles East of the South point of Libau Island.

The *Nautilus Reef*, of 1839, N. by E. 3 miles from the North end of Libau Island, is partly dry, extends S. by W. and N. by E., about 3 miles, and a mile broad. The reef consists of sand and small rocks, with some dry coral patches, and there are soundings of 20 fathoms, 1 or 2 cables' lengths to the eastward of it, regularly decreasing towards the shoal, over a bottom of white sand.

The East point of Wetta is in about $7^{\circ} 45'$ S. and $126^{\circ} 47'$ E.; it is not advisable to approach this island closer than 4 miles, as H.N.M. schooner *Janus*, 1840, saw breakers near the S.E. part, about 2 miles from the shore.

H.N.M. sloop *Dourga* anchored abreast of the village *Sawu*, which is near the middle of the South coast, in 50 fathoms, and found it sheltered from south-easterly winds, by a projecting point of land.

KAMBING, an island which lies on the N.E. side of the Ombay Passage, is said to be about 12 miles long, North and South, and, like the rest of this neighbourhood, has not been surveyed. Its name means "goat island," and is applied to it from the number of a small species of deer found on it. Its surface is hilly, and near to its South end is a peaked mountain, on the summit of which is a mud volcano. This remarkable feature consists of twelve hillocks, from which, at regular intervals, is a discharge of gas and mud, the mud forms the cones, and the saline water trickling down the sides is a great attraction to the deer.

Kambing Island extends N.N.E. and S.S.W. about 8 miles; from its N.W. point the peak of Babi bears N.E. $\frac{1}{4}$ N. In 1844 Lieutenant Hooft's squadron approached the West side of this island, within 4 cables' lengths abreast a village situated in the mountains; the boats got no bottom at 65 fathoms, about two ships' lengths off shore, and had 9 fathoms rock bottom almost at the beach. The boats were at first received in a hostile manner, and the natives rolled large stones from the tops of the hills in order to impede the ascent along a steep path, but afterwards the commanding officer succeeded in establishing an intercourse with them. They appear to be but little civilized, and they had no firearms nor ornaments which might reveal any former intercourse with Europeans. In some parts of the West coast there are narrow beaches about 150 paces broad, but the land then ascends like a steep wall; wherever the ground permits cultivation, palm-trees and fields of jagon are seen. A sounding of 1,780 fathoms, mud, has been taken at 5 miles South of the S.E. end of the island.

H.N.M. steamer *Hecla*, with the other ships in tow, coasted within a short distance along the North and East sides of this island, without finding an-

chorage. The shore was found to be steep-to on all sides, except near the N.E. point, from which a reef projects about 2 miles. The North and East coasts appear to be still more inhospitable than the West coast, and do not offer even a landing-place. No villages are seen there, and no other boats than very small *lippas*.

The channel betwixt Kambing and Babi is 5 or 6 miles wide, and that between Kambing and Ombay about 5 leagues; both are subject to strong currents, and in the northern part of the latter, in lat. $8^{\circ} 10' S.$, long. $125^{\circ} 20' E.$, a rock has been reported.

KISSA or Kisser Island.—The centre of Kisser Island is in $8^{\circ} 6' S.$ and $127^{\circ} 10' E.$ The Dutch fort *Vollenhoven*, on the West side of this island, was evacuated long since, but is kept in good condition by the Malay inhabitants, who are Christians. Near the edge of the reef there is no bottom with 80 fathoms, and the soundings on it are very irregular, 5 and 10 fathoms, with overfalls of 30 fathoms.

Roma Island.—The West point of *Roma* or *Teralta* bears East about 11 leagues from the East point of *Wetter*, and is in $7^{\circ} 38' S.$ and $127^{\circ} 19' E.$ The *Dourga* anchored in 7 fathoms on a sandbank, which projects half a mile to the northward of *Medta Island*, which is very small, and bears South 3 leagues from the West point of *Roma*, and about 3 miles from *Kamong Dieroesoe* on *Roma*. During the north-western monsoon ships many anchor in the bight to the northward of that village, to leeward of the West point. It is necessary to moor the ship with a cable on the shore here as well as at *Kisser*, to prevent her being driven to sea when the land breeze blows hard.

TIMOR or TIMUR is the largest of this eastern range, being in area about one-fourth that of *Java*, or double that of *Jamaica*. It is about 370 miles long, and 50 in its greatest breadth. It lies in an oblique direction to the westward chain of islands, and unlike them, is of different geologic formation; instead of volcanic rocks, it consists of sedimentary clay slates and madreporic limestone, containing many caverns. But it is subject to frequent earthquakes, one of which, in 1794, did much damage to *Koepang*.

It is also very different in climate to the islands West of it; instead of the luxuriant vegetation there seen, *Timor* is covered with a stunted growth more resembling the northern part of *Australia*. This fact very much diminishes its value as a colony. The inhabitants seem to be a race intermediate between the Malay and Papuan Negro. They resemble in many respects the *Dyaks* of *Borneo*. They are seemingly divided into three tribes, differing chiefly in dialects. Their character and that of the climate and soil of *Timor*, have made it a comparatively unimportant possession of the European powers, the Dutch and Portuguese, who have settlements on it.

But it is interesting as a link between *Asia* and *Australia*, and it is this political view which has caused the above-named European powers to retain possession of their posts, although, probably, at a considerable annual

sacrifice. The western part is nominally at least, under the Dutch, whose chief port, and also the principal place on the island, is Koepang or Kupang, at its S.W. end. It forms part of the Banda Residentie, which extends hence to the Arru Islands, having the Banda Islands as their chief place. All the north-eastern portion is or was claimed by the Portuguese, but in 1860, according to the last cessions to the Netherlands, Portugal has now only the North coast with the Island Kambing. These, however, are far from profitable, for while, in 1867-8, the receipts of the government were £27,900, the expenses were £99,000.

The climate of Timor, especially the western portion of it, resembles that of northern Australia, differing essentially from the healthy climate of the Moluccas and from the islands to the westward of it. The westerly monsoon, which ordinarily sets in in the middle of November, continues till April, brings heavy rains and overcast weather, which is very detrimental to European constitutions. While during the easterly monsoon in the rest of the year, the weather is almost always clear, and the rains moderate, so that, notwithstanding the great heat, the air is not unhealthy. This great variation in climate, from extreme humidity to intense dryness, is much greater in Timor than in the adjacent countries. In eastern Timor, during the dry season, not a drop of rain falls, and the natives, their cattle, and the vegetation alike suffer from the intense drought. But it is free from wind, storms, and cyclones, although thunder and lightning are of daily occurrence in the wet season.

SAMAQ, **Semao**, or *Samauw*, a small island 20 miles long and 7 broad, lies off the S.W. end of Timor. The eastern side consists of a chain of mountains of moderate height, the rest is a sterile, sandy plain. A remarkable fig-tree, called by the natives Noemoek, making a small forest of three thousand stems, is an object of veneration. The native *raja* of Timor resides here.

The Strait of Samao, separating the island from Timor is about 3 miles broad and 15 miles long, affording good anchorage and shelter in the south-west monsoon, when there is none in the road or anchorage at Koepang, opposite to it. The strait has soundings of 30 to 60 and 70 fathoms in mid-channel. Between Bolk, and Tanal Point on the eastern side of the strait, also at Haiyina Sissi the N.E. point of Semao Island, long and dangerous spits project from the shore reefs; they are, however, easily seen when the sun is in a favourable position.

Point Oijsma, the S.W. end of Timor, is in lat. 10° 20' S., long. 123° 26'; it has a reef extending to the S.W. with heavy breakers, and soundings of 12 to 18 fathoms near its edge.

KOEPAHQ or **KUPAQ**, on the South side of a deep bay is, as above said, the chief Dutch settlement. They first took the place from the Portu-

guese in 1613, and erected the *Fort Concordia*, which remains to this day, but is in a ruinous condition. It is a port of call for the Netherlands' India Steam Navigation Company's boats. An aqueduct carries a good supply of excellent *water* to the beach. *Coal* can generally be obtained at a settlement on the South side of Koepang Bay; the price is about £5 the ton (1877). The flagstaff is in lat. $10^{\circ} 10' S.$, long. $123^{\circ} 34' 30'' E.$

A *red light* is shown from a post on a house at Koepang, elevated 40 ft.

Pakoela Point, the North point of the bay, is low, having sunken rocks extending nearly a mile from it, and may be known by a tree, which stands separate from the others, and is visible long before the low point can be discerned. *Tikoes* is a small, round, wooded isle, situated on the edge of the reef which lines the North point of the bay, and when the point bears E.S.E. $\frac{1}{2}$ E., it is seen just touching the islet. *Kera* is a low, sandy isle, in the middle of the entrance of the bay, surrounded by an extensive reef, on either side of which there are clear channels. When this island bears S.S.E. 1 mile, and Tikoes E.N.E. 3 or 4 miles, soundings will be got in 60 fathoms, sand and coral, decreasing to 50 and 38 fathoms about half a mile from Kera; come no nearer to it on account of its surrounding reef, which projects much farther from the West and S.E. sides. It is partly dry at low water, which is always discoloured.

Selamo Peak, in $9^{\circ} 57' S.$ and $123^{\circ} 39' E.$, has a remarkably rugged appearance, and may be seen long before Samao and Rotti are discerned in coming from the westward.

The reefs between Tikoes and Boerong, and those which project to the south-eastward of the latter isle, are partly dry at low tide, and they are steep-to from 10 or 8 fathoms to 2 or $1\frac{1}{2}$ fathoms. To avoid the first, these islands ought not to be brought in opposite bearings.

Good water may be easily got to the N.N.W.-ward of Boerong, where boats can approach close to the beach. There is also a small river near the village of Selamo, but boats cannot approach unless at high water. Captain Stokes says that the good water is above the fall, and that water should not be taken within the tidal influences; that so taken in the South corner of the bay is liable to produce dysentery.

Ships may procure here cattle, poultry, and fruits. They ought not to go nearer in than 16 fathoms, as it shoals rapidly from 9 to 2 fathoms. When it is blowing weather from N.W., ships are often obliged to leave this anchorage and to search for shelter near Boerong or under Samao; but the latter anchorage is foul, rocky, and steep, and, as the currents set with great strength through the Strait of Samao, ships are liable to be driven into deep water if the anchor should drag.

The channel to the southward of the island of Kera is also safe, and the reefs which surround that island are easily perceived by the colour of the water; they project about $1\frac{1}{2}$ mile to the westward, and the sea generally

breaks heavily on the northern edge. The northern passage is, however, preferable, there being soundings in it from 40 to 25 fathoms, which will enable ships to anchor when overtaken by a calm. In the southern passage the first soundings are got about 3 miles from Koepang.

The *tides* in the bay are weak. It is high water, at full and change of the moon, about 11 o'clock; the rise at the springs is 9 ft., and at neap tides only 4 or 4½ ft.; the flood comes in from the westward.

ROTTI lies 17 miles South of the S.W. point of Timor. Between them is the island of *Lando*, joined to Rotti by shoal water. It is a dependency of the Dutch Government of Koepang, but is governed by several (fifteen it is said) native princes or rajahs in a feudal manner, which the rugged nature of the country allows, each seigneur residing isolated in his rocky territory in the hill fortresses. They are industrious, and are a better looking race than the people of Timor.

The Strait of Rotti lies between Lando and Timor. Rotti is of middling height, visible 12 to 14 leagues distance; it is fronted by several islands, and has many fine bays and inlets.

With the exception of Beatrice shoal, the strait of Rotti seems to be free from dangers. In some parts there are soundings in 60 fathoms, decreasing towards Rotti.

Beatrice Shoal, in lat. 10° 31' 30" S., long. 123° 35' E., was discovered by Commander John Hutchinson, of H.M. Surveying Vessel *Beatrice*, and subsequently Mr. Waleson, the harbour-master of Koepang, succeeded in finding on it a knoll with only 5 ft. water, over which the sea almost always breaks. The shoal is an oval-shaped coral bank, lying E.N.E. and W.S.W., half a mile in extent. Soundings of 3 to 6 fathoms are found on its central part (where probably the knoll is), deepening to 8 and 10 at either end, where there is tolerable anchorage; outside this the reef falls steeply into deep water. The centre of the shoal is on the following bearings:—N.E. point of Oessoe Island (the island East of Landu) W. ½ N., 7½ miles; the conspicuous double hill over the point, W. ¼ N.; the high, flat-topped hill of Rotti, S.W. ¾ W.; S.W. point of Timor (entrance of Semaó Strait), N.W. ¾ N.; White Cliffs of Timor, N.E. northerly.

The West coast of Rotti is fronted by some islands between which there is a passage. These islands are low, the southern ones particularly so. The exception is a rocky islet with steep cliffs, lying in the channel between Dana Island and the main, which is conspicuous at 20 miles distance, when all the neighbouring land, except the hills of Rotti, has dipped. The only anchorage recommended about the islands is on the North side of Noesa.

Douw is the westernmost island, and is famous for its goldsmiths, the most expert in the archipelago. Their filagree ornaments are much prized for their beauty and neatness. Two smaller islands lie adjacent to the N.W. point of Rotti.

When passing the N.E. point of Oessoë the water was suddenly shoaled by H.M.S. *Serpent* to 5 fathoms, the point then bearing N.W., $1\frac{1}{2}$ mile distant. The shoal was not examined. An unexamined coral bank, on which the least water obtained whilst crossing it was 15 fathoms, lies $3\frac{1}{2}$ miles W.N.W. of Dana, the southernmost of the islands off Rotti. No examination was made of it.

The islands of Lando and Rotti form two safe roadsteads; the entrance to *Rango*, on the North side of Rotti, is from the eastward, and is difficult to go out during the eastern monsoon. The entrance to *Karbafo Bay* is from the westward, rounding the reef which projects from the S.W. point of Lando; ships lie there quite landlocked.

H.N.M. schooner *Circe* anchored, in 1846, in the road of *Baa*, on the North coast of Rotti, in 15 fathoms, with Tormana Rocks bearing N.E. $\frac{1}{2}$ E., the flagstaff S.E. $\frac{1}{2}$ S., and the extreme West point of the land seen between two islets W. $\frac{3}{4}$ S., in $10^{\circ} 44' 42''$ S., and $123^{\circ} 1' 40''$ E.

The English ship *Abercrombie*, bound to China, after being dismasted to the southward of Sandalwood, anchored in *Boykaai Bay* on the South coast of Rotti, January 1812, in 21 fathoms, soft bottom, 3 cables' lengths off shore, and procured there water and refreshments. This is perhaps the same bay which was visited by Captain R. Spratley, of the *Cyrus* whaler, which is formed by the islands *La* and *Mano*, fronting the coast, and inside of which there is safe anchorage in $10^{\circ} 52'$ S. and $123^{\circ} 5'$ E. It is high water in Cyrus Harbour, at full and change of the moon, at 12 o'clock, and the tide rises 5 or 6 ft.

There exist several shoal patches, and probably dangers, off the East side of Rotti, but they are very imperfectly known. The *Satellite Rocks* are about 4 miles from the nearest part of the island off the N.E. point of Rotti, a hummock on the centre of which bore W. $\frac{1}{4}$ S. and the S.W. point of Timor N. $\frac{1}{4}$ E.

The SAHUL BANK is said to be dangerous in some places, but there is reason to believe that it is not so extensive as laid down in the charts, where it reaches from $10^{\circ} 40'$ to $11^{\circ} 30'$ S., commencing near the East point of Rotti, and stretching to the eastward upwards of 2 degrees.

As the dangers of this bank have never been examined, it should be avoided, and vessels should not stretch over so far to the southward in sailing along the South coast of Timor.

The NORTH COAST of TIMOR extends for nearly 40 miles in an irregular N.N.E. direction to *Gomok Point*, E.S.E. of which is *Timu Peak*. *Nolloi* anchorage lies North of Timu Peak, in lat. $9^{\circ} 52'$ S., long. $123^{\circ} 52'$ E. At 15 miles to the N.E. of Gomok Point is *Sutrana* or *Sotroma Road*, which lies off the mouth of a small river S.E. of *Jula Island*. A sunken rock lies about a mile westward of the mouth of the river.

Menango, a sandbank or rock which appears only in old Dutch charts, has

since been seen by Captain C. Hart, who describes it as a small patch a little above water, or even with the water' edge, situated in lat. $8^{\circ} 41' S.$, long. $123^{\circ} 51' E.$ It lies 6 miles off shore, and 6 miles S.W. of Gula.

Gula or *Goela* is a small island of middling height in $9^{\circ} 15' S.$ and $124^{\circ} E.$, distant 6 or 8 miles from Timor, and bearing N. by W. from Timoe Peak, which is in $9^{\circ} 33' S.$

Tulang Ikan Bay is in long. $124^{\circ} 16' E.$ Sunken Rocks lie just off the shore at 2 and 5 miles westward of it.

Liefou, a portuguese settlement, in $9^{\circ} 12' S.$ and $124^{\circ} 24' E.$, or $24' E.$ of Goela Island, according to the observations of D'Entrecasteaux, has an open roadstead, which is separated from *Tolanican Bay* by a low point. There is anchorage near the village of *Koesie* in 22 fathoms, 2 cables' lengths off shore, the houses bearing about South, Liefou Point E.N.E., 2 miles distant, and Gula West. A vessel might anchor near Sotrana in 30 to 40 fathoms, foul and rocky ground, about $1\frac{1}{2}$ cable's length off shore, with the houses bearing S. by W., Gula Island N.W. westerly, extremities of the land N.E. by E. and W. $\frac{1}{2} S.$

Atapopa is a Dutch settlement, in lat. $8^{\circ} 59' S.$, long. $124^{\circ} 50' E.$, 28 miles eastward of Liefou, which cannot be seen at more than 2 miles distance, as the land rises immediately behind it. The land thereabout is remarkably rugged, in some parts rocky and barren, but generally wooded. To Dutch Point, 7 miles westward of Atapopa, the coast is foul, and for 5 miles to the eastward. The outer anchorage is in 36 fathoms, half a mile off shore, N.W. from the village of Dolilo, and with a tomb at Atapopa in line with a gap, S. by E. $\frac{1}{2} E.$ This is also the leading mark through the narrow entrance in the reef into the inner harbour.

Gedeh is a Portuguese settlement in $8^{\circ} 57' S.$ and $124^{\circ} 55' E.$, as observed on board H.N.M. frigate *Boreas*, in 1838. It lies in a valley surrounded by picturesque mountains, and is frequented by whalers. It is fronted by a rock, which bears N.N.E. from the flagstaff, and with soundings near it. The *Boreas*, coming from the westward, had no soundings till within 4 miles of the road, then 65, 55, and 50 fathoms, decreasing to 35 fathoms, a cable's length off shore; being becalmed, she was towed round the West point of the bay, and steered for the rock in soundings of 42, 50, 45 to 26 fathoms, brownish sand, where she came-to, the flagstaff bearing S.S.E. $\frac{1}{4} E.$, distant 2 cables' lengths, the rock N.E. $\frac{3}{4} N.$, N.E. point of the road N.N.E. $\frac{1}{2} E.$, and Pantar Peak N.W. by W. $\frac{1}{2} W.$ It is very tedious work to water here, on account of the great surf on the beach. The best landing place is abreast of the fort, where the boats come to their grapnel. The tides in this road and farther to the westward close in-shore, change, but are very weak. A sunken rock lies 2 miles off shore, on the North side of the anchorage, with Mount Sukekit bearing S.W. by S.

DIELLI, or Dilli, belonging to the Portuguese, is the principal port on

the North side of Timor, where the Netherlands India Steam-Navigation Company's boats and other ships proceeding through the Ombay passage sometimes stop for supplies. Lieutenant Kolff gave a sad picture of it in 1825, when he visited it in the *Dourga*, and Mr. A. R. Wallace, the naturalist, who visited it in 1861, says "it is a most miserable place compared with even the poorest of the Dutch towns. The houses, the custom-house, and the church are all built of mud and thatch; the fort is only a mud enclosure." Dilli is much frequented by whalers, and has a considerable trade in wax and sandalwood. The flagstaff is in $8^{\circ} 34' S.$ and $125^{\circ} 37' E.$ From the low situation of the town under the high land, it is with difficulty perceived when coming from the northward, but to the eastward of it there is a bluff projecting point by which it may be known. Off this bluff, at the distance of half a mile, is a reported 3-fathoms patch. The houses and the flagstaff will be visible when about 4 miles distant from the Timor shore, with the peak of Kambing bearing N. $\frac{1}{2}$ E. Large ships, which only stop for refreshments, should anchor at a fit distance outside of the reefs which form the inner harbour, as the channel between the reefs is very narrow, and there is little space inside of them.

A good outer anchorage is on the *Brilliant Bank*, on which 15 fathoms least water is found, with the signal-tower bearing E.S.E. 2 miles distant, and Fatukama, the East point of Delhi Bay, N.E. by E. $\frac{3}{4}$ E. This bank is three-quarters of a mile long E.N.E. and W.S.W., and was first made known by Captain Walker in 1867.

The inner harbour is formed by the reefs running off the bay points and another detached reef between them, which are mostly dry at low water, and consist of sand and coral. The western entrance, on the North side of which is a *white* buoy, is the widest and most used, but it is difficult to run out through this channel when there is no land breeze. The new lighthouse is on the reefs forming the South side of the western entrance, and the white buoy above mentioned, bears N.E., distant 2 cables' lengths from it.

To enter the harbour of Dielli from the westward, pass mid-channel between the lighthouse and the white buoy in soundings from 10 to 6 and 14 fathoms. The instant a ship hauls round the reef near the West point of the bay, sail should be reduced. Steer for the custom-house, which is a large building standing near the beach, to the westward of a high tree, and keep it in one with the gate of the church, which will lead you close to a coral patch, on which a bamboo has been planted in 10 or 11 ft. When inside of this patch, haul in for the West part of the harbour, and come-to in 9 fathoms at an equal distance from the custom-house, and the bridge to the westward, and abreast of a white house. The shore is here steeper and softer than near the custom-house, where there are two coral patches, with 3 and 6 feet water over them. Between the reefs the bottom is hard, but inside mud.

The eastern channel is only half a cable's length wide, but it has a leading wind during the western monsoon, both for ships entering or going out. To enter it, keep the high tree in one with the house standing between the church and the custom-house. There are soundings from 20 to 7 fathoms in this channel. Haul close round the point of the reef, to avoid the patches abreast of the custom-house. Another good anchorage is in 15 fathoms, with the flagstaff of the fort bearing S.E. $\frac{1}{4}$ E., the church S.E. $\frac{1}{2}$ S., the battery near the inner point W. $\frac{1}{2}$ S., and the South point of Kambing Island N. by W. $\frac{1}{2}$ W. It is high water, at full and change of moon, at 1^h 30^m, and the rise of the tide is 6 ft. at the springs. Cattle and vegetables may be had here, but rice and poultry are neither cheap nor abundant.

Between Manatuti Point and Laméh Point, 18 miles to the eastward, is a deep bay, in the western part of which is Mantotte, 4 or 5 miles southward of Manatuti Point. *Lamsana*, a snug cove a few miles farther to the eastward, sheltered by reefs from all winds, has good anchorage in 8 or 9 fathoms. Wemasee anchorage is just westward of Laméh Point. Laméh Point has sunken rocks off it. *Laga* anchorage is 10 miles to the S.E. of it.

Between the bluff point eastward of Dilhi and Manatute Point, 20 miles to the eastward, the coast should not be approached within 5 miles, as sunken rocks lie off it.

Abreast the S.E. point of Ombay is the narrowest part of the strait of Malloea, or the Ombay passage, which is there 5 leagues wide.

The *currents* in the Ombay Passage are noticed on page 31.

The **SOUTH COAST** of TIMOR, although little frequented, is safe to approach within a moderate distance. In coasting along this side of island during the night, keep at a moderate distance from the points of land, as several of them have projecting reefs. This coast stretches about N.E. by E. and S.W. by W.; the land is low near the coast, but gentle hills rise a little inland and a chain of high mountains is in the interior, which may be seen 27 leagues. The land is mostly covered with trees, except in some parts which appear cultivated. Ships in sailing along this coast have found many small islets that were safe to approach, and soundings of 15 to 25 fathoms within $1\frac{1}{2}$ mile of the shore.

Nusa Besie, or *Jackee Island*, in about 8° 25' S. and 127° 16' E., fronts the East point of Timor. It is low and flat, appearing as a land-tongue, before it opens with Timor. There is anchorage between it and Timor, but the currents set with great velocity through the channel.

H.B.M. ship *North Star* saw six remarkable white cliffs of different dimensions in 124° 17' E., probably Batoe Poetie, which H.F.M. sloop *Casuarina*, Commander L. Freycinet, made in 124° 15' 30" E.

Ships crossing over between Wetter and Amboina generally run in sight of Gunong Api, to secure the passage along the Lucipara and Turtle Islands.

GUNONG API, in $6^{\circ} 43'$ S. and $126^{\circ} 43'$ E., is a high conical mountain, visible 15 or 16 leagues. It is in a state of ignition, with smoke generally issuing from the crater at the summit, and is bold to approach.

DIRECTIONS.—In addition to the remarks given on pages 80—85 *ante*, the following will be useful. Leaving Amboina in the eastern monsoon (April to September) steer for Gunong Api, give a wide berth to the Lucipara Islands, on account of which it is preferable to pass to the westward of them, as the current generally sets strong to the westward during this monsoon. From thence, if bound to Europe, steer to make Honden Island, and proceed through the Ombay Passage and the channel to the eastward or westward of Savu. Being so far to the southward as Rotti or Savu, the S.E. winds will begin gradually to increase in strength.

If bound to Java, the passage through the strait of Salayer would be preferable; but when the route along the islands to the eastward of Java is be taken, steer for Komba Island, and proceed to the westward along the North coast of Floris, towards the Strait of Madura; or when on the meridian of Allas Strait, cross over so as to pass between Urk and Kangeang, or between the former and Takat Shoals, and proceed along the North coast of Madura, directions for which passages have been given in former pages.

The general passage for ships bound from Java to Amboina during the western monsoon, is through the Strait of Salayer.

Ships leaving Amboina for Europe or Java during the *western monsoon*, generally proceed by the northern route, i.e., to the northward of Celebes and Borneo, or in the latter part of the monsoon through the Strait of Makassar. Should Amboina be left in March, the southern passage may be adopted, i.e., to work along the North coast of the islands to the eastward of Java, as there, generally, the winds begin to shift and the currents to diminish in strength. It is advisable to stand up toward Buru, and from thence to work over near St. Matthew Islands. Having approached these and Veldhoen Island, a southerly or S.S.W. course ought to be followed in crossing over to the islands to the eastward of Java. If bound to Europe, pass through the Strait of Allor; and when clear of it, proceed through the channel between Sandalwood and Savu, or between the latter and Rotti.

Leaving Amboina in the strength of the western monsoon bound to the westward, and having occasion to take the southerly passage, though it may not be possible to weather the strait of Allor, nor probably the Ombay passage; yet a ship ought to use every means to pass on the North side of Timor, for if she fall to leeward, and be obliged to round the East of that island, she will find great difficulty in beating to the westward between it and the coast of Australia, where strong winds from W.N.W. to W.S.W., with squally weather and a heavy sea, usually prevail from November to April. If a ship should unavoidably fall to leeward, work to the westward along the South coast of Timor.

CHAPTER XVIII.

ISLANDS AND PASSAGES EASTWARD OF BORNEO.

WE are now advancing eastward into regions of which much less is accurately known than perhaps of any other part of the maritime world. The extensive archipelagoes which lie between the more frequented islands of Java and Borneo, and the North Pacific, are but little visited for commercial purposes by European nations. Their inhabitants, more or less uncivilized, have few European wants, and but few products for exportation. There has been no regular survey made of any large portion of this area. A few detached places have been well examined, and positions accurately determined, by Dutch and English officers. To fill up the voids which occur in our recent knowledge, we are obliged to have recourse to the older voyages, or to the recitals of scientific travellers not specially appertaining to hydrography.

What follows, therefore, in this chapter must be generally received with caution; neither the date of much of the information, nor its confessedly imperfect nature, can induce confidence. It will be needless to recite the numerous authorities consulted; but should more intimate knowledge, or greater detail be required, other works, not usually available at sea, must be consulted.

THE STRAIT OF MAKASSAR.

The great channel eastward of Borneo, which takes its name from the port or rather the nation, on the S.W. extreme of Celebes, is 360 miles long, and with a breadth varying from 150 to 65 miles, the narrowest portion being its northern entrance. This large area is separated into several channels by extensive shoals and numerous islands which lie chiefly in the central portion. Many of these are of the most dangerous character, and when it is

remembered that this strait and the coasts which limit it have not been properly surveyed, and that many dangers may, and probably do, remain undiscovered, it behoves every commander who passes through it to use more than ordinary caution.

It may be said, generally, that there are two channels most available, the one along the Borneo coast, which appears to be preferable, and that on the Celebes side, the latter having unfathomable depths close-to, and not affording any anchorage, while the reverse is the case on the opposite side.

The **EAST COAST** of **BORNEO** is subject to the Dutch, who exercise sovereignty over it, in virtue of several treaties with the native sovereigns entered into since 1816. The total area in Borneo thus claimed by the Netherlands as belonging to that nation, embraces two-thirds of the entire island, or a territory one-half larger than Great Britain and Ireland. But their sway over by far the greater portion is of the slightest character, and this sovereignty over a vast tropical wilderness can be but of little advantage to them.

The charts, or rather maps, which have been published by the Topographical Bureau at Batavia, show how little is known of the coast in question; and, therefore, the few remarks which follow are of a vague character, and are made in accordance with the charts published by the Dutch Commission.

PULO LAUT, or **Great Pulo Laut**, has been before mentioned, page 741, and the strait which separates it from the S.E. extreme of Borneo is there described. The island is 53 miles long North and South. Its N.E. part is lofty, forming a peak called *Gunong Seabeloeng*, and its eastern part is apparently clear of danger, with soundings of 13 to 15 fathoms, muddy bottom, at 6 or 8 miles off. Off its South point lies a small island, *Pulo Kunyit* (Koenjit), the South end of which is in lat. $4^{\circ} 6' 20''$ S., long. $116^{\circ} 5'$ E.

At 9 miles S.E. from this is a small island *Dwaalder*, and $6\frac{1}{2}$ miles farther in the same direction are the *Two Brothers*, or *Gebroeders*, all surrounded by reefs, but having 14 to 16 fathoms water between them. *Dwaalder* is higher at the East and West ends than in the middle, so that it appears like a saddle when seen from the southward. From its eastern side a reef projects about the length of the island. It is in lat. $4^{\circ} 13' 40''$ S., long. $116^{\circ} 11'$ E. At $7\frac{1}{2}$ miles due East of *Dwaalder* is the *St. George Bank*, with 12 and 14 fathoms close up to it. To the N.N.W. of this, and 9 miles East of *Kunyit*, are the *Bira Birakan Islands*, surrounded by an extensive reef.

Pulo Seboekoe, or *Sebuku*, an island 16 miles long, lies off the East coast of **Pulo Laut**, but we have no particulars of the strait within it; it is high in the centre. From its North point, *Tanjong Mangkop*, a reef projects for 2 miles. At 4 miles West of *Mangkop Point* is *Manti Island*, and 2 miles West of this small island is a sunken rock.

Tanjong Pamantyanan, the North point of **Pulo Laut**, has a reef around it,

but it may be rounded at the distance of $1\frac{1}{2}$ miles in 8 or 10 fathoms. In the bay formed by the North part of Sebuku and the projecting point of Borneo, Tanjung Dewa, $3\frac{1}{2}$ miles to the North of it, and facing the northern part of the Strait of Pulo Laut (see page 741), there is shelter from all winds, except those from North and East. The northern part of this bay is shoal, but the soundings are regular to the watering place under the high land on the West side, where you may anchor abreast of it in 6 fathoms, about $1\frac{1}{2}$ mile off shore, with the N.E. point of the bay bearing E. by S. $\frac{1}{4}$ S., and a small island covered with trees, on the East side of the bay, bearing S.E.. Oysters may be got, and the woods abound with wild hogs and deer; but care should be exercised when a party lands, as the natives are treacherous, although under Dutch supervision.

The **THREE ALIKE ISLANDS**, or *Pulo Sambarglap*, lie 15 miles East of the South end of Sebuku. Their centre is in lat. $3^{\circ} 39' S.$, long. $116^{\circ} 41'$. They bear N.E. 45 miles from Dwaalder, and form a group of three islands, *alike* in appearance, exclusive of an islet and some contiguous rocks, visible 5 or 6 leagues off. The channel between them and Sebuku is quite safe, and they are also quite clear to the eastward for 17 miles, where is the Twee Vrienden Reef presently described.

The southern entrance to the strait of Makassar has an extensive range of shoals and islets which lie to the northward of those existing off the North coasts of Bali, Lombok, and Sumbawa. Of these the following is a description as far as is known.

The Sibbald Bank appears to the south-westernmost. It is not extensive; but Captain Forbes sounded in from 20 to 5 fathoms, coral, so that there may be less depth now. Its shoalest part, 5 fathoms, is placed in $5^{\circ} 46' S.$, long. $117^{\circ} 4' E.$, or 83 miles N.E. by N. from Hastings Island. Around this shoalest patch is 6 fathoms at 2 miles to the S.E., 8 fathoms at 2 miles W.S.W., and 10 fathoms at 2 miles to the N.E. There is deep water beyond these depths, and another 5-fathoms patch lies 9 miles eastward, reported by Lieutenant Howe, R.N. This patch lies in lat. $5^{\circ} 45' S.$, long. $117^{\circ} 12' E.$ At 2 miles North of it is a depth of 7 fathoms, and for 5 miles S.S.E. of it the depths are 6 and 7 fathoms; outside these soundings is deep water, but a detached 7-fathoms patch lies 12 miles S.S.E. of the 5-fathoms patch.

The Aurora Bank, *coral*, with several casts of $4\frac{3}{4}$ fathoms on it, and perhaps less, is apparently about three-quarters of a mile broad, in lat. $5^{\circ} 25' S.$, long. $116^{\circ} 58' E.$

Nusa Komba, a low island, in lat. $5^{\circ} 14' S.$, long. $117^{\circ} 4' E.$, has a reef extending for 6 miles to the South of it. At 9 miles North of it is *Sibaru*, or *Sibaroe*, the southernmost of a group of four low wooded islands, called *Nusa Siri*, extending 5 miles to the northward, the northern one in $5^{\circ} 0' S.$ $117^{\circ} 5' E.$, and may be seen at a considerable distance. *Trinidad Shoal*, of $4\frac{1}{2}$

fathoms, lies midway between Sibaroe and Nusa Komba, and $6\frac{1}{2}$ fathoms has been reported at 6 miles S.W. by S. of Sibaroe. A 10-fathom bank, 8 miles wide from East to West, lies to the northward of Noesa Siri Islands, and on this bank are two $4\frac{1}{2}$ -fathom patches, one lying 6 miles North, and the other 6 miles N.W. of the northernmost island of the Noesa Siri Group.

Pudsey Dawson, a $4\frac{1}{2}$ -fathom patch, is in lat $4^{\circ} 42'$ S., long. $117^{\circ} 4'$ E.

Laurel Reef is a narrow reef, extending from an 8-fathom patch, in $4^{\circ} 20'$ S., to a $3\frac{1}{4}$ -fathom patch in $4^{\circ} 34'$ S.; the last-named patch is very steep-to, and at 5 miles northward of it is a $2\frac{1}{2}$ -fathom patch, named *Batu Batong*, in lat. $4^{\circ} 29'$ S., long. $117^{\circ} 7'$ E. At 9 miles eastward of the Laurel Reef another similar reef is marked, but its existence is very doubtful.

The *Martaban Shoal*, so named after the ship which discovered it, is placed in $4^{\circ} 11'$ S., long. $117^{\circ} 10'$ E., 20 miles to the northward of the Laurel Shoal.

The ship *Sea Serpent*, in lat. $3^{\circ} 56'$ S., long. $117^{\circ} 28'$ E., anchored on a coral bank about a quarter of a mile long, the least depth found being from 4 to 6 fathoms. There was no discolouration of the water.

A bank that dries, with a reef extending southward of it for about 1 mile, was discovered in lat. $3^{\circ} 31' 50''$ S., long. $117^{\circ} 29' 40''$ E.

At 10 miles E.S.E. and 11 miles S.E. of the last-named bank are two others.

Twee Vrienden Reef, about 2 cables in length, and in some places 6 feet above water, reported in 1876, was discovered by a vessel of that name striking on it. Its estimated position is lat. $3^{\circ} 40'$ S., long. $117^{\circ} 8'$ E.

Franklin Bank is in lat. $3^{\circ} 2'$ S., $117^{\circ} 33'$ E.

The *Triangles* or *Lari Larien Isles* are three small islands, nearly in the middle of the strait, of which the southernmost, in lat. $3^{\circ} 5'$ S., long. $117^{\circ} 50'$ E., is a small sandy island, with several bushes on it. At 4 miles to the northward of it are the two other islands near together. Union Bank, a small bank of 8 fathoms, is 25 miles eastward of the Triangles.

Laars (Dutch) the *Boot Bank*, is an extensive shoal, or collection of coral banks, of very irregular figure, the South end of which is in lat. $6^{\circ} 2'$ S., long. $118^{\circ} 14'$ E.; its West end, 10 fathoms, in lat. $5^{\circ} 44'$ S., long. 118° E. Between its western end and the Sibbald Bank are some 10-fathom patches. In lat. $5^{\circ} 47'$ S., long. $118^{\circ} 17'$ E., is a 5-fathom patch, S.S.W. 5 miles, S.E. 12 miles, and E.N.E. 15 miles from which, other similar patches have been reported. A low wooded island, *Saftana*, *Zalineff*, or *Pulo Dewakan*, is situated on the North end of Laars Bank, in lat. $5^{\circ} 26'$ S., long. $118^{\circ} 26'$ E. At 6 miles S. $\frac{1}{2}$ E. of it is another similar island, named Laars Island, islets and rocks lying between. Dangerous rocks also extend for 5 miles to the southward, and 10 miles to the westward of Laars Island. The general soundings on these banks are from 10 or 15 fathoms to 4 fathoms, which appears to be

the least water found, and that towards its northern part. A depth of 12 fathoms, coral, was found by the *Vittor Pisani*, to the southward of the Boot, in lat. $6^{\circ} 4' 30''$ S., long. $118^{\circ} 15'$ E. The bank appeared about a mile broad.

The best track for crossing the Boot Bank is southward of lat. $5^{\circ} 40'$; but in thick weather a wide berth should be given to the islands by keeping well to the southward, for there is probably no danger on the southern part, though the depths of 5 or 6 fathoms, when there is much swell, may not be pleasant for a large ship.

Tonyn Island, or *Benkoeloean*, is low and woody, in lat. $5^{\circ} 31'$ S., long. $118^{\circ} 36'$ E., or 7 miles East of Laars Island. It is surrounded by coral rocks.

To the westward and north-westward of Pulo Saflana, between the Laars Bank and those previously described, is a range of islands and banks, of which but little is known. The northernmost is shown on the Dutch charts, *Edam* or *Medemblik*, in lat. $5^{\circ} 0'$ S., long. $117^{\circ} 56'$ E., and to the southward, in an extent of 23 miles, are those named *Middelburg*, *Hoorn*, *Amsterdam*, or *Doandoenganketjil* and *Doandoenganbezaar*, the last in lat. $5^{\circ} 23\frac{1}{2}'$ S., long. $117^{\circ} 55'$ E. These southern islands have been called the *Hen and Chickens* in the old charts. To the westward of this range is *Rotterdam Island*, or *Kaloekaloekoan*, about 33 miles E. $\frac{1}{4}$ N. from Nusa Komba. It is said to have good water on it, and that there are two reefs 12 miles to the West, and 10 miles to the S.W. of it. Sunken rocks, discovered near the islands above mentioned, lie as follows. Rotterdam Island should not be approached, except with great caution, to within the distance of 2 miles; a sunken rock also lies $3\frac{1}{2}$ miles S.E. of it. Edom Island has a 5-fathom patch at 4 miles West of it, and a series of rocks extending 5 miles N.N.W. from it. Middleburg Island has a sunken rock 3 miles West of it, and between this island and the northern danger extending from Horn Island, the distance is 2 miles. Between Horn and Amsterdam Island is unsafe. At 7 miles W. $\frac{1}{2}$ S. from Doandoanganbezar is a sunken rock.

To the eastward of the islands and shoals just mentioned, the water was examined by H.M.S. *Nassau*, in 1872. *Marisindeh Island* is in lat. $5^{\circ} 5'$ S., long. $118^{\circ} 11'$ E.; at 6 miles to the southward of it is the northern end of a dangerous bank, which thence extends 3 miles to the southward. At 27 miles E.N.E. of Marisindeh is *Taka Bakang* or *Teignmouth Bank*, 3 miles in diameter; it lies 23 miles to the westward of the dangers of the Spermonde Archipelago.

The Brill Shoal, or *Taka Romata*, the south-easternmost of this range of islets and shoals, is very dangerous. Its South end is in lat. $6^{\circ} 8'$ S., long. $118^{\circ} 55'$ E. It is probably a coral reef, with very steep sides, about 5 miles long, North and South. The rocks are awash on its northern part, and in many parts the verge has only 2 ft. water.

The banks and islands which lie against the S.W. part of Celebes will be described presently.

The **COAST of BORNEO**, northward of Pulo Laut, is but little known, and has been very seldom visited by Europeans. A peculiar race, a kind of sea gypsies, live about the mouths of the rivers. They are called by Mr. Earl the Orang Badju, dwelling in boats of 8 or 10 tons burden, each boat containing a family of about 15 inhabitants, who employ themselves in catching and curing fish and trepang. They are very trustworthy, and are very useful in carrying despatches or any similar offices.

Kloempang, or *Kalumpang Bay*, lies immediately North of the point which protects the entrance to the Pulo Laut Strait. *Pulo Nanka*, and an islet to the North of it, lie in the entrance, round the North end of which is the channel which leads to an apparently well sheltered roadstead. A rock lies a mile off the East end of this islet. To the North of this the land is skirted by a broad shelf, with breakers on its outer edge 4 and 5 miles from land.

Shoal or Flat Point, Tanjong Mirra, in lat. $2^{\circ} 35' S.$, long. $116^{\circ} 32' E.$, is the southern extremity of a piece of wooded level land, about 9 leagues in length. To the South of it is the entrance to *Bamukan Bay*, a large bay, into which several rivers fall, and which form the outlet of the district of *Tamah Boemboe*. A reef projects from Shoal Point for $4\frac{1}{2}$ miles in a southerly direction, having some rocks and bushes above water, but the flat which fronts the point may be borrowed on with safety to 6 fathoms on the East side, about 2 leagues distant from the point, the bottom being soft, and the depth very gradually decreasing. Steering a direct course along the coast, the water shoals about 2 fathoms abreast the point, and returning to the former depth when past it.

Ragged Point, *Tanjong Ares*, is in lat. $2^{\circ} 8' 30'' S.$, long. $116^{\circ} 37' E.$, and 27 miles N. by E. from Flat Point. The land between them being level and moderately elevated, is terminated to the northward by Ragged Point, which is bluff, with some gaps among the trees, and surrounded by a reef.

Shoals.—This portion of the Strait of Makassar is the most intricate, as there are several shoals which contract the passage on this side to its narrowest part. These shoals have not been properly examined, and the soundings not being regular, there is great difficulty in avoiding them at night. The *Hercules Shoal* is one of these, in lat. $2^{\circ} 20' S.$, long. $116^{\circ} 45' E.$ It bears S. $35^{\circ} E.$ from Ragged Point, and N. $47^{\circ} E.$ from Flat Point, distant $11\frac{1}{2}$ miles from shore. It is composed of sand, coral, and stones, with from 3 to 9 ft. water on it, and from 15 to 17 fathoms close-to. At 7 miles to the N.E., and 8 miles N.W. by N. of the Hercules Shoal, are other detached dangers.

Addington Shoal appears to be the southernmost. It is a very dangerous coral patch of 14 ft. water, with Flat Point bearing N.W. $\frac{1}{4}$ N., distant 20

miles. It apparently forms part of an extensive series of patches, with deep water between them, the extent being nearly $2\frac{1}{2}$ miles in a N.W. and S.E. direction. There are several distinct shoals, one a patch of sand above water, on the N.W. side.

When abreast this dangerous shoal, it is best to keep within 4 or 5 leagues of the coast, and not to bring Flat Point to the westward of N.W., North, or N.W. $\frac{1}{2}$ N., until to the northward of its parallel, which is about lat. $2^{\circ} 50'$. Breakers were also seen to the N.E. of it, in lat. $2^{\circ} 40'$ S., long. $117^{\circ} 0'$ E., extending North and South about 5 miles.

The **LITTLE PATERNOSTERS**, or **Pulo Palabalagan**, lie in the middle of the strait off this part. They are called the Little Paternosters, to distinguish them from the other group North of Sumbawa. They are most vaguely placed on the charts, but are said to consist of thirteen small isles, with banks of sand and coral above and under water, scattered over a space 80 miles in breadth, on the parallel of $2^{\circ} 20'$ S. The southernmost isle is in lat. $2^{\circ} 42'$ S.; the north-easternmost in lat. $2^{\circ} 10'$ S., long. $117^{\circ} 56'$ E.; and the north-westernmost in lat. $2^{\circ} 8'$ S., long. $117^{\circ} 35'$ E. On these two isles there is fresh water; they are all covered with low trees, and should not be approached, as their neighbourhood is dangerous, breakers and shoals lying fully 8 miles to the northward of the N.W. islet, and for 30 miles East and West of them are numerous scattered reefs.

The *Blenheim Reef*, in lat. $2^{\circ} 24'$ S., at 21 miles E.N.E. of Flat Point, is apparently the westernmost of the above shoals, and therefore forms the eastern side of the fairway. The *Hannah Shoal*, about 26 miles E. by S. of Ragged Point, in lat. $2^{\circ} 18'$ S., long. $117^{\circ} 2'$ E., forms a portion of these western limits. *Emily Anina Islet*, in $2^{\circ} 4'$ S., long. 117° E., is doubtful.

Pasir or **Passier River**, on the coast of Borneo, the mouth of which is in lat. $1^{\circ} 51'$ S., is a considerable stream, about 40 or 50 miles up which is the town of Pasir, formerly of some importance, a considerable native trade being carried on with the Spice Islands; but it subsequently became a den of infamy and piracy. In 1772 the English proposed to establish a factory here, but did not carry it into effect. The anchorage off the mouth of the river or Kwala Pasir, is in $4\frac{1}{2}$ or 5 fathoms, 3 leagues off shore, to the northward of the river. There are some shoals in the South part of the bay, between Ragged Point and the river, from 3 to 6 miles off shore, to avoid which, in coming to Pasir, you should get into the latitude of the anchorage before approaching the shore, and then steer West for it. Supplies may be got at the town, but ships must be guarded against attack. At the N.W. part of the bay is the broad entrance of *Pasir Lama*, called *Adang Bay*. All the land is low and wooded near the sea, but inland it is hilly.

Jason Reef, off this coast, is 5 miles in extent, North and South, and 4 miles East and West; its N.E. end is in lat. $1^{\circ} 47'$ S., long. $116^{\circ} 55'$ E. The eastern part is 9 leagues eastward of the entrance to the Pasir River. There

is a depth of from 12 to 23 fathoms to westward, and 18 to 20 fathoms immediately to the eastward of them.

From *Tanjong Telakai*, the N.E. point of Adang Bay, the coast trends to the north-eastward for 26 miles to *Balik Papan Bay*; the coast is low, but at 30 miles N.W. of the bay a detached mountain is seen, *Gunong Balik Papan*, and to the North of Adang Bay the land rises in hummocks. A rock lies in the middle of the entrance to the bay.

The **RIVER KOETEI** or *Koti*, or **Mahakkan**, one of the most considerable in Borneo, forms a delta commencing in lat. $0^{\circ} 57' S.$, and extending thence for 40 miles to the northward, the low land intersected by its numerous branches and mouths, being called *Pulo Pamarang*, or *Pamarung*, or *Dondrekin Eiland*, by the Dutch, and it was surveyed by a Dutch officer, G. W. E. Moeth, in 1856. The various branches diverge from a point more than 25 miles from the bars of the southern entrances, and the town of *Sangason* stands on the South side of the stream. At 9 or 10 miles still higher up the river is the larger Bugis town of *Samarinda*, the capital of the state of Koetei; *Tengaroeng* or *Tongarron* being 30 miles in direct distance to the N.W., but much more following the windings of the river, which is here very tortuous. The Sultan of Koetei entered into a treaty with the Netherlands Government, October 12th, 1845, by which he acknowledged the sovereignty of that nation, and by which he undertakes to suppress piracy, and accords the free navigation of the river as high as *Samarinda*. A Dutch expedition under Major Muller, ascended the river in 1825, to cross the country to the West coast, but they were cut off by the Dyaks. Mr. Dalton, an Englishman, went up two years after, and lived 15 months among the Dyaks. The river in the rainy season brings down large drifts of trees and vegetation, carrying them out to sea, when they appear frequently at a distance like small islands or prahus under sail.

Pamarung Islands form the delta as before said. The south-westernmost mouth, *Muara Dyawa*, is in lat. $1^{\circ} 0' S.$, long. $117^{\circ} 20' E.$ It runs to the northward, and has 10 ft. least water on the bar, but is deeper within, although between the bar and *Sangason* there are some places with only 6 feet depth. Numerous branches debouche to the eastward of these, one of the largest behind *Oedjong Becapay*, 14 miles from *Muara Dyawa*. *Tanjong Bayor*, the easternmost, and central point of the delta, is in lat. $0^{\circ} 43' S.$, long. $117^{\circ} 38' E.$ The shoal water extends fully 6 to 10 miles outside the dry land to the northward and eastward, but its outer edge is here more steep-to than the southern portion of the islands and flats of the delta. The tides rise here from 8 to 9 ft. A detached $2\frac{1}{2}$ -fathom patch lies 14 miles S.E. by E. of *Tanjong Bayor*.

The Coast of Koetei, to the northward of the Pamarung Islands, is little known, and but seldom seen. At 25 miles North of them is a cluster of islets and rocks, which extend along the shore to lat. $0^{\circ} 10' N.$ A slight

projection of the land, *Oedjong Santang* lying on the equator. In lat. $0^{\circ} 22' N.$, and at 8 miles off shore, is a detached rock, *Karang Sangatta*; and in lat. $0^{\circ} 35' N.$, long. $117^{\circ} 55' E.$, is Bungalun Rock, marked doubtful in position on the chart. These should be thought of should a vessel venture into this great bay, at the head of which, in lat. $0^{\circ} 45' N.$, there is anchorage in 5 to 10 fathoms, muddy bottom, near the shore, but be careful of another detached rock, $1\frac{1}{2}$ mile from the land. The coast from this trends to the eastward for 68 miles, with no place worthy of remark except a large bay in long. $118^{\circ} 0'$, called *Sankoelirang* or *Telokh Saka Bay*, at the back of which is a mountain of the same name. *Bira Birahan*, a small islet, lies 8 miles off shore, in long. $118^{\circ} 27' E.$ At 6 miles E.S.E. of it is a shoal, varying from 10 fathoms to 18 ft., in lat. $0^{\circ} 42' N.$, long. $118^{\circ} 35' E.$ It was discovered in 1869 by the Dutch barque *Johanna Anthonia*.

TANJONG KANIONGAN is the north-western limit of the Strait of Makassar. It is in lat. $1^{\circ} 4' N.$, long. $115^{\circ} 56' E.$ It is the eastern extremity of a range of high even land, which extends to the westward, joining the great central chain of mountains. At 7 miles south-westward of it a rocky shoal lies against the shore, and immediately around the cape itself there is shoal water, but outside this the depth is very considerable. From the cape the land trends to the W.N.W., and has some extensive shoals and several islets, with channels intersecting them at 8 or 10 miles distant. These islands, and the rest which lie off the northern side of the peninsula, are very differently represented in the more recent Dutch charts, to what is given by older authors, and they cannot in any way be considered as forming the entrance to the strait.

The **ISLAND of CELEBES**, one of the most singular in the world, forms the eastern limit of the strait. Except in some small portions, it has never been surveyed, but on the coasts not examined there appears to be few dangers to navigation; the water is very deep close-to as far as is known, but the paucity of observations will give but little knowledge of its real character.

The grotesque form of the island, four long peninsulas joined together, is familiar to every schoolboy. From this cause it has few or no rivers worth mentioning, and its mountainous character is such, that the fertilizing effects of these streams is carried at once into the deep waters of the ocean. Thus there is but little agriculture, and the total population of the island does not much, if at all, exceed a million, while, if it were as fertile as Java, it ought to be fifteen times as many, the area of Celebes being one-half larger than Java. The best known portion of the island, is the southern peninsula, and it is by far the most populous and important. A chain of mountains runs through it, and terminates to the southward in the highest point of the island, *Lompoe Batang*, 8,200 ft. high, and near to the southern coast.

The people of Celebes are of the same race as those of Sumatra, Java, and Borneo, but are divided into a very great number of tribes, possessing every variety of civilization, from the savage cannibal and head-hunter to the man of letters. The most civilized portion is that in the S.W. peninsula. The great feature of the natives of Celebes is their propensity for the sea. This probably arises from the proximity of every part of the island to the sea, its sterility, and the abundance of fish which may be caught around it. From whatever cause it proceeds, the inhabitants of Celebes are at present the most skilful and adventurous native mariners and merchants of the archipelago. Their little vessels of peculiar build, called *Padewakan* by the Malays, and of the burden of from 40 to 50 tons, conduct the carrying trade from one end of the archipelago to the other, their outward and homeward voyages being guided by the monsoons. Besides the trade conducted in Celebes itself, the people of this island are to be found as settlers in every part of the archipelago where there is trade and protection, and many vessels belonging to them sail from such settlements."—*Crawford*.

The whole of the island is, nominally at least, subject to the Dutch, and it is divided into three provinces. The government of Mangkasser, embracing the southern and part of the south-eastern peninsula; the Residence of Ternati, attached to the Moluccas, around the shores of the eastern Gulf of Tomaiki, and the residence of Manado, embracing the shores of the Gulf of Tomini and the long northern peninsula. The capital of the whole is Makassar or Mangkasser.

BONTHEIN, on the South coast of the southern peninsula, is a Dutch town, at the head of a bay, in lat. $5^{\circ} 32' S.$, long. $119^{\circ} 55' E.$ It is connected by a post road with Macassar, 50 miles in length. Behind it rise the highest mountains in Celebes, *Gunong Loempoe*, *Ballang*, or *Bonthein Peak*, before mentioned; its summit is 11 miles due North of the town. There is good anchorage in 7 or 8 fathoms, sandy bottom, at about 2 miles off from the village. The land rises from the shore towards the slopes of the mountains, and on its upper portion potatoes and European vegetables are grown.

Boelecomba, another Dutch village, is 14 miles eastward of Bonthein. Boelecomba Hill, in longitude $120^{\circ} 8' E.$, is not very conspicuous when first seen in coming from the westward; but when abreast of it, it becomes an excellent mark, being a high conical hill standing by itself on the low land near the sea to the N.W. of the village. There is good anchorage off it with the bell buoy N.N.W. $\frac{1}{4}$ W. and the flagstaff of Boelecomba N.N.W. $2\frac{1}{2}$ or 3 miles in $6\frac{1}{2}$ or 7 fathoms, sand and mud. Water may be procured in the river on the East side of the bay, by sending boats about a quarter of a mile up it. A coral reef projects nearly 2 miles from the western point of the watering bay, and is steep-to.

Melassar Bay is 20 miles westward of Bonthein, *Cape Boelo Boelo*, the southernmost point of Celebes, lying between. Its eastern extreme point is

called *Klambang*, in lat. $5^{\circ} 40' S.$, $119^{\circ} 40' E.$ Between this and an islet on the West side, the bay is 3 miles wide at the entrance. Shoal water extends for $1\frac{1}{4}$ mile westward of Tanjong Klambang, but 3 and 4 fathoms are found close to the island on the West side. *Toeratte Bay* is to the westward of Melassor Bay, but appears to be foul and rocky. The southern coast of Celebes is fronted by a bank of tolerably regular soundings, 2 or 3 leagues broad in some parts, which is a good guide by night, but 12 to 15 fathoms are found close to the headlands.

POINT LAYKAN, or *Tanjong Laikan*, the south-westernmost point of Celebes, is in lat. $5^{\circ} 36' S.$, long. $119^{\circ} 26' 30''$. It should have a berth of 3 miles on account of a coral bank which extends for $1\frac{1}{2}$ or 2 miles from it, but the water shoals near it to 15 or 12 fathoms, and there are 4 and 5 fathoms on its edge.

TANA KEKE, an island about 3 miles in diameter, lies 10 miles north-westward of Point Laykan. It has a level appearance, and may be seen 18 or 20 miles off. It is separated from the S.W. part of Celebes by a navigable channel about 2 miles wide, with 10 fathoms least water between the reefs on either hand, soft bottom, but frequently coral. A *black conical* Herbert's buoy, 8 ft. high, is placed on the N.E. part of the reef, against Tana Keke Island, in $4\frac{3}{4}$ fathoms water; and a similar buoy, but painted *white*, lies on the westerly projecting point of the Malang Beang Shoal in $3\frac{3}{4}$ fathoms. Between these two buoys there is a safe channel through the Tana Keke Passage.

There is a 6-fathom patch about in mid-channel in the southern entrance. Avoiding this on passing through, keep in mid-channel, or rather nearest to Tana Keke. Three islands, called the *Three Brothers*, lie to the N.W. of Tana Keke. The bank of soundings stretches to the West of these for 6 leagues, the outermost patch of $4\frac{1}{2}$ fathoms lying in lat. $5^{\circ} 22\frac{1}{2}' S.$, long. $118^{\circ} 55' E.$ At 18 miles southward of this patch, and about the same distance south-eastward of Tonym Island, is a bank of 13 to 17 fathoms, surrounded by deep water.

Cape Magindari is 12 miles N.N.W. from Cape Laykan, and forms the eastern limit of the strait within Tana Keke. From this the coast trends to the northward, and at 6 miles from it is a small island, *Glissong*, close to the coast.

MAKASSAR or **MANGKASSER**, the metropolis of Celebes, was surveyed by Sir Edward Belcher, in 1844. He established an observatory near to the North angle of the fort, in lat. $5^{\circ} 8' 9'' S.$, long. $119^{\circ} 21' 18''$.

The Fort of Makassar, *Kasteel Rotterdam*, stands on the S.W. angle of the town, disconnected by a ditch and high rampart, within which the military reside. The town, which is walled, is very regularly built, extending about one-quarter of a mile by half a mile over its squares, and having 3 gates on its southern face, which were closed at 9 o'clock. The Chinese appear to con-

stitute the majority of the population of the town, but the huts of the natives extend far to the northward, and appear to be thickly inhabited, as are all the coast and the islands. The fishing propensities of the natives are evident everywhere. The beacons, which are frequently found in 16 and 17 fathoms, induce a belief in shoal water. Makassar is reckoned particularly salubrious. The atmosphere is very dry; it seldom rains, and is similar to the climate of Lima. Nevertheless the horizon and atmosphere on the mountains is very hazy. The sea breeze generally sets in regularly about 10 o'clock, commencing from the southward, and veers to the westward before sunset, when it fails, and is succeeded about 10 o'clock by a cool land breeze. Stock is plentiful and reasonable in price, as well as vegetables.

Makassar is a port of call for the Netherlands' India Steam Navigation Company's boats. It was declared a free port by an ordinance from the Dutch Governor-general, dated September 9th, 1846, which took effect on January 1st, 1847. The roadstead of Makassar, though only an open one, is not subject to storms, and has safe anchorage, and the native trade has always been considerable. Subsequently to the enfranchisement of Makassar two other places on the N.E. end of Celebes, *Menado* on the North side and *Kema* on the opposite side were declared free ports on September 28th, 1848. In entering these roads all vessels are required to hoist their national flag, which will be responded to on the shore, and a correct description of the ship and her destination must be handed to the officers.

Lights.—On Fort Rotterdam a *fixed bright light* is shown, which is visible 11 miles off, and about $1\frac{1}{2}$ mile to the southward a second light was established in 1870. Previous to the establishment of this light a lightvessel marked the South end of the Great Lelij Shoal. It illuminates in a seaward direction an arc of 180° , divided into three sections, of which the central one, measuring 30° , shows a *red* light, and the others, each of 75° , a *white* light. The lantern is placed at an elevation of 39 ft. above the level of high water; the red light being visible 3 miles, and the white light 8 miles.

From the lighthouse, the beacon on Pienjing Shoal bears $S. 67^\circ 30' W.$, and the beacon on South end of Great Lelij Shoal $N. 65^\circ 30' W.$; the red sector of light being about midway between these beacons.

The new light will serve, in conjunction with the harbour light at Macassar, to render Macassar roads easy of access from the South and S.W. For this purpose, having entered the red sector of light, steer for the light on an easterly bearing, until Macassar harbour light bears N.E. by N., when steer for it, taking care, on approaching the latter light, to alter course more to the northward, in order to enter the roads.

The anchorage is within a line of shoals, the southernmost of which is called the *Great Lely*, or *Lelei*, a mile in extent, and for a great part nearly awash, its eastern angle being more than half a mile West of the castle, the depths between varying from 7 to 10 fathoms. It is a coral reef covered

with sand. The *Little Lelei* and other shoals extend for more than 2 miles to the northward, but leave a clear channel of 9 fathoms depth between them, which can be taken by bringing the North angle of the castle to bear E. by S. $\frac{1}{2}$ S. In coming to it from the southward the castle should not be brought to the northward of N.N.E. $\frac{1}{2}$ E. till past the dangerous *Pienjing Reef*, marked by a beacon, which lies off the extremity of a sandy spit jutting out to the westward three-quarters of a mile on the South side of the Goa River, and $2\frac{1}{4}$ miles distant from the castle. The anchorage is abreast the town in 7 or 8 fathoms.

The South end of the Great Lelij Shoal is marked by a beacon with a triangular head, and Hoofd Reef, the S.E. extreme of Little Lelij Reef, is marked by a *black* buoy, moored in 2 fathoms, with a pyramid on the shore bearing E. by N., and the Fort lighthouse S.S.E. $\frac{3}{4}$ E., half a mile distant. The eastern end of Little Lelij Shoal, and also the reef extending off Fort Rotterdam, are each marked by a beacon.

In advancing from the westward, care must be taken to guard against a sunken rock, marked on the Dutch charts at $2\frac{2}{3}$ miles nearly due West of the fort; it is there called *Bonie Banko*. At 4 miles W. by N. from the fort is *Sammalona* or *Devil's Island*, surrounded by a reef. There are several other islands scattered on the great flat which extends from 20 to 30 miles off the coast for 70 miles northward of Tana Keke.

The SPERMONDE ARCHIPELAGO, as these islands are called, are best understood by the chart; it would be impossible to describe them verbally. The whole of the space for 50 miles North of Makassar, and for 20 to 33 miles off shore, is a complete labyrinth of shoals. The westernmost of these is *Pulo Kapo Posang*, in lat. $4^{\circ} 43' S.$, long $118^{\circ} 55' E.$, and this bears N.W. $\frac{1}{2}$ W. 36 miles. A sunken rock on the reef which surrounds it lies nearly 2 miles westward from it, and at $2\frac{1}{4}$ miles still farther West is a rock which dries at low water, but separated from the main reef by a deep channel. To the N.E. of this the limits of the reef have not been traced, but the northern edge trends generally East and West, on the parallel of $4^{\circ} 18' S.$, and is very steep-to, the depths at a short distance outside being unfathomable.

There are channels through the Archipelago towards Makassar, and at the northern entrance to this a Herbert's *buoy*, painted *black*, with a white horizontal band, is placed on the N.E. part of the *Tomisa Reef*, in 5 fathoms water. There are also some white stone beacons marking the reefs.

Pareh Pareh Bay, at 68 miles northward of Makassar, has a landlocked basin at its head. The channel leading to it runs to northward 2 miles, and is clear on the port side, but has some shoals on the opposite shore, abreast of the village of Pareh Pareh, in lat. $4^{\circ} 1' S.$, long. $119^{\circ} 34' E.$ From this the coast trends to N. by W. for about 33 miles, when it assumes a westerly direction for 27 miles, forming an extensive bight, terminated on the N.W. by Cape Mandhar. At 8 miles eastward of the cape is an anchoring place

off the village of *Balanipa*, lat. $3^{\circ} 32' S.$, long. $119^{\circ} 5' E.$ The anchorage is on a projecting spit of $2\frac{1}{2}$ to 6 fathoms, with the village or rather the mouth of its river, bearing N.W. three-quarters of a mile distant. Immediately East of Cape Mandhar is *Madyena Road*, an anchorage open to the southward, but there is an opening through the reef opposite the village, which is in lat. $3^{\circ} 32' S.$, long. $118^{\circ} 59' E.$

CAPE MANDHAR or *Mandar*, lat. $3^{\circ} 35' S.$, long. $118^{\circ} 54'$, is high land, and on its western side is quite bold-to, but shoal water extends some distance to the southward and eastward from it. The coast trends to N. by W. from it for 7 miles to *Penamboeang*, a village facing a bay open to the westward, in lat. $3^{\circ} 27' S.$, long. $118^{\circ} 51' E.$ There is anchorage in this bay in 12 to 20 fathoms within 300 yards of the shore, protected from the northward and southward. *Tynrana Bay* is 10 miles northward of *Penamboeang*, and has two lofty islets on its West side, *Taai Manoe*, to the South of which is the village in lat. $3^{\circ} 19' S.$ The depth in the bay, open to the N.W., to the East of these is from 10 to 20 fathoms. From this the coast of Celebes, but little known and unsurveyed, trends irregularly to lat. $2^{\circ} 52'$, where on the northern side of *Lebanie Bay* are the anchorages of *Tapullang*, to the East of a cape of that name, and of *Kait*, a mile to the westward of it. The bank is very steep-to, and has 30 fathoms within a quarter of a mile of the shore. Good water may be procured here. H.M.S. *Virginie* watered here in 24 hours, and could have procured buffaloes and other stock by waiting for them.

Cape William, in lat. $2^{\circ} 40' S.$, $118^{\circ} 47' E.$, is 12 miles northward of Cape Kait, and is a high projecting headland, having a large bay to the eastward. When this cape bears East 10 leagues distant, the south-easternmost of the Little Paternosters will be seen, and should be avoided. *Meindert's Shoal*, of 5 fathoms, lies 7 miles W. by N. of Cape William. *Mamoedya Bay*, to the eastward of Cape William, is protected from the northward by an island called by the same name. It affords good anchorage either with the village bearing E.S.E. a mile distant, or inside a rocky shoal, in 11 fathoms three-quarters a mile to N.E. of the centre of the village.

The coast to the northward of this for many miles is unknown and unvisited. The first place of which we know anything is *Kajeli* or *Kayeli*, in lat. $1^{\circ} 40' S.$, said to be famous for gold, sheep, &c., but anyone landing here, or on any part of this coast, should use the greatest caution against treachery.

The **BAY of PALOS**, the entrance to which is in lat. $0^{\circ} 37' S.$, has been examined by officers of the Dutch navy, and its several anchorages have been surveyed by Lieuts. Van Loo, Castendyk, &c. It is a deep gulf penetrating the coast in a S.S.E. direction for nearly 20 miles, with a breadth of from 4 to 6 miles, thus affording much shelter. Its shores, especially the eastern side, appear to be thickly peopled. On the eastern side are the

anchorages or bays of *Wari*, 6 miles within the entrance points, *Membora* 10 miles farther South, and *Palos* at its head. The anchorage here is to the eastward of the village, which is in lat. $0^{\circ} 57' S.$, long. $119^{\circ} 49' E.$ A high table mountain lies E.S.E. from the village. Near the entrance of the bay, on the western side, is the roadstead of *Dangola*, abreast of the village. A rock is shown in the Dutch maps as lying about 13 miles N.N.W. from the western headland of the bay, but its position is uncertain.

The northern peninsula of Celebes here separates from the main body of the island, assuming first a northerly and then an easterly direction. The isthmus connecting it is here very narrow, but of undetermined breadth, as the head of the great Gulf of Tomini is very little known. Melville van Carnbee makes its breadth to be only 10 miles.

CAPE TEMOEL or *Samsa* is the West extremity of a peninsula of high land, projecting considerably from the line of coast, on the equator, in longitude $119^{\circ} 36' E.$ When first made from the northward it makes like islands, as the land which connects it with the coast is lower than the hills which form it. Captain Horsburgh states that he was all the month of February endeavouring to round it to the northward. A shoal extends to the northward of the cape about $1\frac{1}{2}$ mile. About 5 miles N. by W. from the cape lies a small round island, the *South Watcher*, or *Zuid Wachter* of the Dutch, having a reef projecting from its South end, and from its N.E. end a reef of rocks and sand extends towards the Celebes shore more than one-third the distance between them. It is not advisable to go inside the island, as it seems unsafe. A shoal, seen by Captain Spratley, bears S.W. $\frac{1}{2}$ S. from the South Watcher and West from Cape Temoel $3\frac{1}{2}$ miles distant. It is about 2 miles in length E.N.E. and W.S.W., and deep water within a mile of it.

The **Seven Islands**, in lat. $0^{\circ} 32' N.$, are flat, low, and woody, not easily distinguished unless when near them, except the outermost, called the *North Watcher* (*Noord Wachter*), in about lat. $0^{\circ} 36' N.$, long. $119^{\circ} 42' E.$, distant 13 miles from shore, and seems not so large as the others, but may be seen 15 or 18 miles off. This island is surrounded to the distance of a mile on its West, North, and East sides by a coral reef; beyond this reef the channel between it and *Pulo Pangalasian*, 6 miles to the S.E., is clear of danger. At 15 miles E.N.E. from the North Watcher, and 3 miles off shore, the Dutch charts mark a danger, called *Rynsdroogte*.

CAPE DONDA, or *Dondo*, which may be taken as the N.E. limit of the strait of Makassar, is in lat. $0^{\circ} 59' 30'' N.$, long. $120^{\circ} 12' E.$, $22\frac{1}{2}$ leagues N.E. by N. from Cape Temoel. The mountains over this cape being very high and bold, and having a steep declivity to the water's edge, terminating in several bold headlands, make it difficult to distinguish this cape. The cape or N.W. extreme of the peninsula, according to the Dutch charts, is an island, with a rock 2 miles westward of it. A doubtful rock is marked at 9

miles to the N.W. of it. Some shoal water is said to exist to the southward of it, but generally along this coast no soundings can be got close to the shore, nor does there appear to be any in the bays with sandy beaches near the Seven Islands or Cape Temoel.

DIRECTIONS for the Strait of Makassar.—The great extent of this strait and the breadth of its channels prevent any specific directions being given for it, or marks for avoiding its dangers. The imperfection of our knowledge adds to these difficulties. A few general remarks must suffice.

The Little Paternoster group, as before stated, separates the strait into two channels, of which the western one, along the Borneo coast, is 10 or 11 leagues broad, and the other about 12 leagues. There are some dangers in the former, but still it is more frequented and preferred to the eastern side, along the Celebes shore, as the depths are moderate, and anchorage may be found in most parts, whereas the coast of Celebes is almost entirely steep-to, and the offing, as far as is known, unfathomable, besides which there are but few anchoring places, as will be seen from the foregoing directions.

In October and November it is probable that the Celebes side is preferable, for light southerly breezes prevail here at this time, when the wind is different on the Borneo side, and when strong southerly currents prevail in the middle of the strait, their velocity has been found to decrease a little as the Celebes shore is approached.

To sail along the Celebes side, and coming from the southward or westward in the westerly monsoon, approach the S.E. part of Great Pulo Laut as if you were proceeding along the Borneo side, and thence by an E. by N. or E.N.E. course, traverse the strait and make the coast of Celebes, about Cape Mandhar, taking care to avoid the Triangles, the Union Bank, and the cluster of little known banks which lie in about $117^{\circ} 30' E.$, and which should be left to northward, avoiding also the Martaban and Laurel Shoals to the southward. The lead should be kept going, and a good look-out kept for these dangers. Proceeding along the coast of Celebes, northward of Cape Mandhar, you should keep at least 2 or 3 leagues off shore in light winds, to prevent being drifted near the shore; but when beating to the northward against a steady wind and lee current, you should work near the coast in most places, particularly in the bay to the South of Cape Temoel, where you will be out of the strength of the stream. Ships coming from the southward in the easterly monsoon should pass between Tana Keke and the S.W. part of Celebes, if intending to touch at Makassar.

The Borneo side is generally preferred, as above stated, until the Little Paternosters are passed. To proceed by this route, and having passed the S.E. part of Great Pulo Laut, the channel on either side of the Three Alike Islands, may be chosen according to circumstances, and a course steered towards Flat Point, avoiding the Addington Shoals.

The best track between these points with a working wind is to stand out into 15 or 16 fathoms, about 4 or 5 leagues from shore, and back again into 7 or 8 fathoms, about 2 or 1½ leagues distant. The bottom is generally soft mud, but in some parts overfalls may be got from 10 to 7 fathoms in the fair channel, about 4 or 5 leagues from shore.

The **NORTH COAST** of **CELEBES**, 320 miles long, is very little known. The peninsula forms the Dutch Residentie of Menado, the chief port, at its N.E. extremity. This peninsula varies in breadth 20 to 50 miles. A range of mountains traverses its whole length, rising into some lofty peaks at its East end. The North coast is steep, and the land falls more gradually towards the Gulf of Tomini, on the South. From its character there are no rivers properly so called, but numerous streams descend from the mountains. The country is very thinly populated, not with aborigines, but with Bugis and immigrants from Ternate and Tidore. There is little or no trade, and that is all centred at the free port of Menado. Although most of its mountains are not volcanic, yet earthquakes are frequent, and some active volcanoes are found near Menado. Gold is procured near Gorontalo; rice is also grown, and excellent cordage is made near Menado.

CAPE RIVERS, 40 miles N.E. by E. from Cape Dondo, may be taken as the N.W. Cape of Celebes. It was surveyed by Rear-Admiral Sir Edward Belcher. It has two small islets close to it, and the land that forms it having a regular declivity, with a gap not far from its extremity, gives the cape an isolated appearance when first seen. To the eastward, between it and Trees Cape, there is a projecting headland with white cliffs fronting the sea.

Slime Islet, the outermost islet off the cape, is a high rocky pile of apparently upheaved grey basalt, about 80 ft. above the sea level, with a few shrubs on it, the whole being coated and whitened by the dung of marine birds, hence its name. Its position was established as 1° 20' 24" N., long. 120° 43'. Immediately within this is another islet of similar construction, and about 150 ft. high, and a space of half a mile, with a deep channel, intervenes between it and Cape Rivers. The reefs extend southerly from those islets as far as the eye can reach, and the coast from the cape suddenly receding into deep and lonely bays, leaves a good harbour or channel within. The coast between it and Cape Dondo forms a concavity, and is mountainous at a short distance inland. At 15 miles South of Cape Rivers, and in the S.E. angle of the bay is the anchorage of *Negri Baru*. The tide rises at Slime Island 9 ft.

Kabitan Island, 20 miles south-westward of Cape Rivers, is 7 miles long

W.N.W. and E.S.E., and about a mile broad. Its eastern end is in lat. 1° N., long. $120^{\circ} 35'$ E., and 2 miles off the South side of the island, at 2 miles West from its eastern end is a sunken rock. Between Kabitan and Cape Rivers there are some islets extending to a distance of $3\frac{1}{2}$ miles from the North side of Kabitan, and three patches of sunken rock in $1^{\circ} 6'$ N., $120^{\circ} 36'$ E., $1^{\circ} 10'$ N., $120^{\circ} 35'$ E., and the most extensive is $1^{\circ} 13'$ N., $120^{\circ} 38'$ E. *Dondo Islets* lie close to the coast, in lat. $1^{\circ} 10'$ N.

The richness of the mountainous regions of Celebes afford many interesting views along the North coast to the eastward; here there are many cultivated spots both on hill and dale, which, by their bright grassy tints and contrasts of colour exhibit an effect scarcely less interesting than that of more civilized regions.—(Sir Edward Belcher.)

At 5 miles eastward of Cape Rivers a sandbank fills the head of a small bay, and off the eastern point of the bay lies a small islet named Da Iangan. A sandbank lies a mile off the shore at 3 miles eastward of the islet. Several small islets lie off the coast to the eastward.

Cape Kandi is 40 miles eastward of Cape Rivers, and the coast here turns to the southward for 10 miles to the anchorage of *Bool*, where it is said that fresh water may be got, but some dangers project from the shore, and there is a 3-fathom rock on which a ship has struck.

At 17 miles eastward of *Bool*, and within a mile of the shore, lie the two small *Radya Islets*; between these and *Palelee Bay*, 9 miles to the eastward, is *Lintido Point*, which is high. Off *Kaboe Point*, the eastern point of the bay, distant a mile, is a sunken rock, in lat. $1^{\circ} 7' 30''$ N., long. $121^{\circ} 53'$ E. Between *Kaboe Point* and *Huledebongo Point*, 10 miles to the eastward, a rock is marked doubtful at 3 miles off shore. Between *Huledebongo Point*, which has rocks extending $1\frac{1}{2}$ mile from it, and *Bolole*, a high point 8 miles to the eastward, is *Beau Bay*. At 4 miles northward of *Bolole Point* is the South end of a reef which thence extends 8 miles to the north-eastward to a point in lat. $1^{\circ} 15'$ N., long. $122^{\circ} 19'$ E. *Bolontio Point* is 8 miles eastward of *Bolole Point*, and 6 miles E.S.E. of it are the *Damuma Islands and Reefs*, extending to a distance of 3 miles off the shore.

Timor Bank, of $2\frac{3}{4}$ fathoms, is in $1^{\circ} 5'$ N., $122^{\circ} 31'$ E. It lies 5 miles North of the two small *Radya Isles*, which lie East and West of each other, 3 miles North of *Donda Point*, a rock lying in the channel between them and the point.

Kwandang Bay is between *Dondo Point* and *Cape Besar*, 16 miles to the eastward of it. It is very extensive and very foul. Two islets lie at 1 and 2 miles North of *Cape Besar*, and outside the line joining *Cape Dondo* and *Cape Besar* are three isolated patches lying off the mouth of the bay. One of these lies 5 miles W. by N. of *Cape Dondo*, another 7 miles E. by N. of *Dondo Point*, and the outer one 12 miles E.N.E. of *Dondo Point*, and 7

miles N.W. of the outer islet off Cape Besar, which is in lat. $1^{\circ} 1' N.$, long. $122^{\circ} 46' E.$ A *doubtful patch* is marked at 6 miles N.E. of Cape Besar.

Bongkie is a small islet in lat. $1^{\circ} 5' N.$, long. $122^{\circ} 52' E.$, 8 miles off shore, and for 25 or 30 miles eastward of this the shore should not be approached but with the greatest caution, on account of the imperfectly examined *Josina Reefs*, which extend to a distance of 10 miles from the shore. There is some very high ground southward of the *Josina Reefs*, 12 miles inland. *Domisil Bay* is in long. $123^{\circ} 43'$, and some islets extend 2 miles off its eastern point. *Oekie Bay* is 8 miles eastward of this, and *Moloro Islet* $1\frac{1}{2}$ mile off shore, 5 miles eastward of *Oekie*. *Bolano Bangka* is on a point 7 miles eastward of *Moloro Islet*, and at 3 and 5 miles eastward of it are two rocks. Midway between *Bolano Bangka* and *Lombok*, 10 miles to the eastward, are two islets 2 miles from the shore. Two rocks lie at 1 mile North and $2\frac{1}{2}$ miles N.N.W. of *Maririe Point*, the western entrance point of *Lombok Bay*, which is small.

From *Lombok Bay* the coast trends to the N.E. 16 miles to *Sapa Point*, between which and *Talapan Point*, 9 miles to the N.E., is the entrance to *Amurang Bay*, 10 miles deep. For 15 miles to the eastward of *Talapan Point* the shore is bordered by rocks to 7 miles distance. *Talapan Point* is in lat. $1^{\circ} 20' N.$, long. $122^{\circ} 25' E.$

The *District of Minahasa* or *Menado*, which embraces the eastern extremity of the peninsula for a distance of 55 miles, is a romantic region of volcanic mountains, some of which are in a state of activity. The highest is *Klobat*, 6,694 feet in height, the volcano *Seputan*, 5,570 feet, and *Mount Sempo*, 4,744 feet. Cacao and coffee have been extensively cultivated, the latter of very fine quality.

MENADO, or **Manado**, a **Free Port**, and port of call for the Netherlands India Seam-Navigation Company's boats, is the chief place. It was constituted so, with *Kema* on the opposite side, by the Dutch Governor-General of the Indies, by an ordinance dated *Batavia*, September 28, 1848. The Dutch first built a wooden fort here in 1655. *Manado Tua*, a very steep, conical, well wooded island, apparently an old volcano, about 2,750 feet high, is the westernmost of a cluster of islands which lie N.W. of the Bay of *Menado*. It is 17 miles N.W. from the town, and is a good guide for making it.

The whole bay of *Menado*, which faces the N.W., is steep-to, decreasing suddenly from 150 fathoms to 60, 10, and 1 fathom. The anchorage should be approached *along* the beach obliquely; let go the anchor when the line at the taffarel gives 60, veer eight shackles, and secure by stream anchor on the reefs. This will berth you in 15 fathoms, and the operation must be completed before 4 p.m., or the land squalls may drive you off into 150 fathoms. The holding ground off the mouth of the river is best, and affords better scope. In the months of November, December, and January, the

rollers are said to be terrific, but no instance has occurred of a vessel being wrecked or driven on shore. The fort, called *Fort Amsterdam*, is at the North end of the place, and is in lat. $1^{\circ} 29' 25''$ N., long. $124^{\circ} 46'$. Rise of tide 6 ft. High water, full and change, nearly noon.

North Cape, or *Papalumpongang*, is 17 miles north-eastward of the North point of Menado Bay. From this to *Cape Coffin* or *Polisan*, the N.E. extreme of Celebes, the distance is $13\frac{1}{2}$ miles. The whole of the land is composed of lofty ranges, surmounted by peaks, of which Klabat is the most conspicuous. It has been seen clearly from Ternate and Meyo, and from 60 miles to the westward.

The **STRAIT of BANKA**, which is formed by this coast and a cluster of two larger and five smaller islands, is from 3 to 6 miles wide. About the middle are two rocks, one of which is $1\frac{1}{4}$ mile from the South side, the *Koerier Rock*, of 19 feet, the other 2 miles to the North of it. *Banka Island*, the largest and easternmost of the group, is about 1,100 ft. high.

Limbe Island lies against the East end of Celebes, and forms a narrow and somewhat intricate strait. It is about 12 miles long, and in the middle there is an island encircled by a reef, which occasions an eddy; and the tides being very strong, the passage through the strait is not advisable in a large vessel. Close on the West side of the strait is a lofty volcano, the lava from which has extended to the eastern point of Celebes, called by the Dutch *Verbrandehoek*. To the S.W. of this peak rises the lofty peak of *Gunong Sodara*, or the *Two Sisters*, 4,300 feet high, and still farther to the S.W. is *Mount Klobat* or *Klabat*, before mentioned. In the South part of the narrows of Limbe Strait there is good anchorage, where ships caught in Kema Road with S.E. winds may find shelter.

KEMA, a *free port*, and, like Menado, regularly visited by steamers, lies at the S.E. foot of Mount Klobat. It is in lat. $1^{\circ} 21' N.$, long. $125^{\circ} 3' E.$ There is a good road from it to Menado. There is good anchorage in the road abreast of the fort, in 10 or 12 fathoms, with Mount Klobat bearing N. $36^{\circ} W.$, and the Two Sisters N. $28^{\circ} E.$, about a mile off shore, the depth thence gradually decreasing to the town, where good water and other refreshments are to be procured. The tides rise 5 and 6 ft. about this part.

From Kema the coast trends to S.W. by S. for 25 miles to the *Boentin Isles*, a cluster which extends some distance from the shore, the track being outside of them. The coast may be approached within 3 miles, and in most places nearer. From this to *Cape Tolo* the distance is 80 miles; we have no particulars of it beyond the Dutch maps.

The **GULF of TOMINI** or of Gorontalo, is the great bay which separates the northern and eastern peninsulas of Celebes. From Cape Tolo to its head it is 230 miles deep, and is 50 miles wide at the entrance, and 90 miles at its head. It is very little known, especially at the western part.

Gorontalo, on the North side of the gulf, 63 miles westward of Cape Tolo,

is the chief port of the gulf, and the residence of the Dutch Commissioner. The country around it produces gold dust, wax, &c. Its position is given as $0^{\circ} 25' N.$, long. $122^{\circ} 50' E.$ by Melvill van Carnbee. There are two small coves just within the entrance of the river on the eastern side. Into either of these a ship may haul, and moor to the large stones that lie on the beach, protected from the rapid stream that runs down after much rain; or she can anchor in mid-channel close to the fishing stakes in the entrance to the river. The village is about 2 miles up, and abounds with refreshments of all kinds. A *red light* is or is to be shown at night from an iron post at Gorontalo. *Pagowat* is 62 miles westward of Gorontalo, in long. $121^{\circ} 55' E.$; the anchorage is within the reefs that border the shore, in 9 to 20 fathoms. *Tomini* is in the N.W. bight of the gulf; we have no particulars of it. *Parigi* is at the head of the gulf, with the Table Mountain, which overlooks the head of the Bay of Palos, rising in its rear. The *Togean Islands*, on the South side of the gulf, are frequented by the fishermen for trepang and tortoise shell, which are carefully prepared.

Cape Talabo, the eastern extremity of the eastern peninsula, is in lat. $0^{\circ} 46' S.$, long. $123^{\circ} 27' E.$ It is a steep headland.

The GULF of TOLO or Tomaiki is almost unknown, and there is no port or place of any interest on its northern shore. A cluster of islands lies to the southward of Cape Talabo, of which the principal is *Bangaai*. A chief deputed by the Sultan of Ternate resides here, and a considerable native trade is carried on from it with the shores of the Gulf of Tolo and the adjacent islands in wax, tortoise shell, and trepang. Of the other islands, *Peling*, *Lububa*, *Bankela*, &c., the charts must furnish descriptions.

Cape Nederburgh forms the S.E. limit of the Gulf of Tomaiki, in lat. *about* $2^{\circ} 54' S.$, long. $122^{\circ} 16' E.$ To the southward of this the coast is fronted by numerous islands, of which *Padea* and *Manui* are the principal. The inhabitants of the latter construct the fishing-boats, which are sold to the baju fishermen. Wowoni (Weywongy of the old charts), 28 miles to the southward of Manui, is larger and more mountainous than the former islands, and was formerly inhabited by a peaceable industrious people, but it has been depopulated by the incursions of pirates.

Kendari or Vosmaer Bay, in $3^{\circ} 57' S.$, $122^{\circ} 32' E.$, was discovered by the enterprising Sub-Resident M. Vosmaer, in 1831, during his examination of these shores. He gave an interesting account of the country around it, and of its warlike people continually "head hunting." In 1835 he established here the elements of a permanent factory, under the hopes of creating a trade in its neighbourhood.

BOETON or Buton Island lies off the S.E. extremity of the peninsula, and is the residence of the Sultan of this and the surrounding islands. The Dutch Government have also an assistant resident here. The island is about 80 miles in length, and is generally of moderate height, and hilly in the

southern parts. The South point is in about $5^{\circ} 41'$, long. $122^{\circ} 48' 30''$ E. The island is composed chiefly of a coralline limestone; the soil is not fertile, but produces the finest cotton in the whole Indies. In the North part facing Celebes the shore is marshy and covered with mangrove swamp. Along the West and South coast the shore is often abrupt and rocky, except in the bays which have generally a beach of white sand.

The *East Cape* of Boeton is a long, low, level point, in lat. $5^{\circ} 15'$ S., long. $123^{\circ} 16'$, projecting far into the sea, and having behind it, in the interior, a piece of remarkable table land close to its western side. To the northward of this is an extensive bay, called on the Dutch charts *Kaliesusu Bay*, formerly *Dwaal Bay*. In its North extreme there is a road or harbour, with soundings of 30 to 55 fathoms at the entrance. Care is required in entering between the shoals on the East and those fronting the islands which bound the western side of the road, which seemed to be sheltered from the sea by shoals projecting from the point on the East side. Refreshments may be procured at the village on the N.E. side of the bay. The *N.E. Coast* of Boeton appears to be safe, and may be coasted within moderate distance. A little inland from the N.E. point of Boeton there is a small peaked hill like a sugar-loaf. The North point is in lat. $4^{\circ} 23'$ S., long. $123^{\circ} 4'$ E.

BOETON STRAIT, which separates Boeton from Moena or Muna, is about 66 miles in length, and is very narrow in some parts, although the depth does not appear to be less than 10 or 12 fathoms. In early times it was much used, but now the more open passage around the South end of Boeton is generally followed. The southern entrance is on either side *Kadalua Island*, from which reefs extend to some distance.

Off the S.W. part of Boeton are two small islands. The southernmost is *Siumpu*, the *South Island* of the old charts. According to Melvill van Carnbee it is in lat. $5^{\circ} 40'$ S., long. $122^{\circ} 30'$ E. It is of moderate height, formed of stratified rock, and not well made out in coming from the westward. A coral patch, with 3 fathoms, lies with the East end of *Siumpu* bearing N.N.E. and the South point of Boeton N.E. by E. $\frac{1}{2}$ E. A reef of black rocks was reported in 1870 as lying 2 miles North of the West end of *Siumpu*. *Middle Island*, a small island, lies between *Sempoe* and *Kadalua*, or *North Island*, $7\frac{1}{2}$ miles to the northward. *Kadalua* should not be approached within a mile, as sunken rocks exist off its South, West, and N.E. points.

(The groups of islands to the south-eastward of Boeton, and those scattered over the Banda Sea, will be described hereafter.)

Boeton, the chief place on Boeton, is just inside the strait on the East side, in lat. $5^{\circ} 28'$ S., long. $122^{\circ} 36'$ E. It is the residence of the Sultan, and some Dutch officials are to be found here. Poultry, vegetables, &c., may be got. The tides are moderate, and will assist a vessel in drifting through in light winds, and convenient and good anchorage may often be got. A shoal pro-

jects a little way from the N.W. end of Boeton, and, when clear of it, the channel leading out takes an easterly direction, passing between Wowoni (or Weywonij) and Boeton. The strait is not made out from the northward until you are up with it; a remarkable rock, hollow below, with bushes on it, lies against the Boeton shore; both sides of the strait rise perpendicularly from the sea.

Passing along the S.E. end of Boeton, if the wind is westerly, keep the Boeton coast on board to the East point, to prevent being set over toward Wangi Wangi and the Tukan Bissi Isles by southerly currents and light airs, which frequently prevail in the offing. It is said that the ship *Noordbeck* was wrecked on a reef which lies 15 miles S.E. of the East cape, in lat. $5^{\circ} 30'$. Care is also required when between the latitudes of $6^{\circ} 39'$ and $6^{\circ} 31'$, as *Penguin Reef*, with as little as 9 ft. water on it, leaves a channel only 4 miles wide between it and the S.E. coast of Boeton.

Moena, *Muna*, or *Pangasané*, the island westward of Boeton, is 50 miles long North and South, and is subject to Boeton. Its chief town is in the interior, but its only port is at the North end, called *Tiora*, or *Tiwora*, which gives its name to the strait between it and the southern part of this peninsula of Celebes.

Tiora Strait is intricate and unknown to European navigators. The shoals and islands are very numerous, and there are no inducements for taking it, especially in a large vessel.

Kabeina, or *Cambyna*, is a large island to the westward of the South end of Moena. It rises steeply and rugged from its western extremity towards a high peak in its centre, which is about 4,000 ft. high, lat. $5^{\circ} 19'$ S., long. $121^{\circ} 54'$ E. The island is about 12 miles in diameter, and off its South and S.E. ends there are one or two small islands, with rocks 2 or 3 miles S.E. of them. About 2 or 3 miles from its West end lie three islands, very low, with breakers projecting 2 or 3 miles South from them. A rock also lies $1\frac{1}{2}$ mile off shore, S.W. of the central peak. In coming from or to the Strait of Salayar, these rocks should be guarded against.

The GULF of BONI separates the two southern peninsulas of Celebes, and is 90 miles wide at its entrance, and extends 150 miles northward. It has been visited by Sub-Resident Vosmaer, in 1831, but had not been circumnavigated till James Brooke, Esq., afterwards the Rajah Sir J. Brooke, sailed around it in his yacht the *Royalist*, between November 29th, 1839, and May 1st, 1840. In the first chapters of his interesting work, published in 1848, a narrative of this cruise is given, and affords much information.

CAPE LASSA, or Berak, is the S.W. point of the gulf, and the northern point of the Strait of Salayar. It is in lat. $5^{\circ} 36'$ S., long. $120^{\circ} 29'$ E. It is 18 miles eastward of Boelecomba, mentioned on page 802, *ante*. *Balunruéh*, or *Balanranga*, an island 400 ft. high, is 27 miles due North of Cape Lassa; off it are several coral reefs. The village of *Songi* is up a river abreast of

this. The course to the northward was among numerous reefs and shoals, threading the way with some difficulty. Of the outlying known dangers, *Boni Rock* is 20 miles N. by E. of Cape Lassa. *Rykdorps Bank*, 10 miles in extent E. and W., is nearly 30 miles N.E. by N. of Cape Lassa. *Limpogeh Island*, in lat. $4^{\circ} 55'$ S., long. $120^{\circ} 45'$ E., is small, and has a sunken rock 2 miles South of it, and numerous isolated dangers between it and *Lambeina Reef*, 21 miles to the N.N.W. of it.

Point Patiro, lat. $4^{\circ} 39'$ S., was passed half a mile distant; off it is a patch of white sand and coral, the channel being inside it; off this cape the flood comes from the South, the ebb North, but not strong, though the rise is considerable.

Boni, the chief town of the district, is two hours journey inland from *Bajue*, or *Badyoa*, which is 10 miles W.N.W. of Cape Patiro. The State of Boni, once the most powerful in Celebes, presented the curious spectacle of an aristocratic elective monarchy. *Palette*, 11 miles North of Point Patiro, is wooded, and superior in elevation to the adjoining coast. Between these points the Lambeina Reef extends off shore to a distance of 10 miles; a small islet is situated on its eastern part. *Chinnana River* is 7 miles North of Palette. The town is some distance up the stream, which drains some large lakes, the only ones known in Celebes. *Peneki Bay* is 14 miles northward of the mouth of the Chinnana River; the coast here is a low mangrove flat.

Cape Marasanga or *Siva*, in lat. $3^{\circ} 44'$ is low and covered with light green trees, but beyond this the scenery changes its character, and the low shore is replaced by lofty hills and wooded mountains, *Mount Latimojong* crowning all. The whole of the coast South of Cape Marasanga is embarrassed by coral reefs of unknown extent. The district of *Luwu*, which surrounds the head of the gulf, is one of the most ancient of the Bugis States. It is a mountainous region, but the shores are more clear of outlying shoals. *Jenemaiji*, or Red Water Point, in lat. $3^{\circ} 18'$ S., is so named on account of a discoloured stream which discharges itself near it. From this the coast runs N.W. 20 miles to the town of *Palopo*, at the head of a bay in the N.W. part of the gulf. It is the capital of Luwu, but is only a miserable collection of 300 houses. At 12 miles N. by E. from Cape Dyenee, are two sunken dangers, and N.N.E., at the distance of 15 miles, is another.

Beraoe, or *Buru*, at the head of the gulf, in lat. $2^{\circ} 41'$ S., long. $120^{\circ} 41'$ E., seems to be the chief place of the neighbourhood. Two sunken rocks lie to a distance of 2 miles from shore, at 2 miles S.W. of Beraoe. In the N.E. angle of the gulf is the town and river of *Usu*. It lies on the North side of a bay, the southern side of which is entirely distinct in character from the northern, the former being bold and abrupt, the latter an alluvial plain. *Pulo Paloeih* (or separated mountain) is an island off the South point of Usu Bay. It is bold and wooded, and divided from the main by a moderate channel.

At 5 miles S.W. of it a *doubtful rock* is marked. The scenery of all this coast to the southward is most picturesque, bold wood-covered hills, with high mountains behind. *Cape Tabako* is in lat. $3^{\circ} 20'$ S. *Cape Susua*, lat. $3^{\circ} 27'$, is bold and prominent, as are two others, *Libnandala* and *Labekara*, to the southward; the coast is very bold-to. Midway between Capes Labuandata and Labekara is a reef 3 miles off shore. *Batu Lakie Head*, a slightly projecting headland, 18 miles S.E. of Cape Labuandata, has a rock marked doubtful at 3 miles S.S.E. of it. *Cape Bungie*, in lat. $3^{\circ} 54'$ S., is a projecting promontory, in the bay northward of which is the small island of *Roko*. Off its western side is another small islet. In $4^{\circ} 8'$ S. is *Padamarang Island*, 5 miles in diameter. *Lambasina Islet* lies a mile West of its N.W. point, and a second islet, W.N.W. 6 miles from its N.W. point, has a rock off each end and another, 5 miles W.S.W. from it. Within Padamarang Island, is *Kongka Bay*, nearly filled by reefs. *Maniang Islet*, 5 miles S.E. of the S.E. point of Padamarang, and 4 miles off shore, forms the outer western point of the channel leading up to *Pasatue*, a village at the head of Kongka Bay.

The *Minkoka District*, the Baaikonka of the Dutch, occupies the head of this bay. The country is attractive, and partially cleared. The mountains sink to a strip of alluvial plain near the sea. The people resemble the Bugis in person, but are a separate race.

Cape Takarie is 36 miles South of Padamarang Island. There is a small bay just northward of it. Sunken rocks lie 1 or 2 miles off shore at intervals for 15 miles northward of Cape Takarie, and 11 miles westward of it is the North end of a reef, in lat. $4^{\circ} 42'$ S., long. $121^{\circ} 17'$ E., which thence extends 7 miles to the southward. *Bassa Island* is low, 15 miles southward of Cape Takarie, rocks lie to 2 miles W.N.W. and to 8 miles N.N.W. from it.

Cape Boenging Katto, the S.E. extreme of the gulf, is in lat. $4^{\circ} 55'$, long. $121^{\circ} 45'$ E., and is 15 miles East of Bassa. A *sunken rock* is reported 7 miles S.W. by W. from it.

SALAYAR or SALEYER STRAIT, between Cape Lassa, on the S.W. side of the Gulf of Boni and the North end of the island of Salayar, is a great highway for the commerce between the Moluccas and the Java Sea. Several islands lie in the strait, and in the old charts are called North, Middle, and South Islands. *Sarontang*, a small islet, lies 5 miles S.S.E. of Cape Lassa, and should not be approached within a mile on its South side. *Lukan Loweh* is another islet, 5 miles S.W. of Cape Lassa. There appears to be a clear channel 3 miles wide between these islands, but the channel generally used is 5 miles wide to the southward of Sarontang, between it and *Doang Island*. This latter island is $1\frac{1}{2}$ mile in diameter, and lies 2 miles from the North point of Salayar Island, the channel between being dangerous because of sunken rocks.

Dangers in Salayer Strait.—At 5 miles westward of Lukan Loweh is a $6\frac{1}{2}$ -fathom patch, 4 miles off shore. A sunken rock lies between this and the shore. *Rankap*, a 4-fathom patch, lies 8 miles West of Lukan Loweh.

The **Mansfield Shoal**, in lat. $5^{\circ} 43\frac{1}{2}'$ S., long. $120^{\circ} 13\frac{1}{2}'$ E., lies to the westward of the strait, is not very well known, and is dangerous. It is extensive, and lies about 18 miles W.N.W. of the North end of Salayar; Sarontang, just seen from the mast-head, about E. by N. $\frac{3}{4}$ N.; and Boelecomba, or Peaked Hill, on Celebes, N. by W. It is said to have on some parts not more than 3 to $3\frac{1}{2}$ fathoms, with deeper soundings up to the Celebes shore, but none to the southward.

A 7-fathom patch, probably the same as *Amboina Shoal*, which was reported as dangerous, lies 8 miles eastward of Mansfield Shoal.

To sail through the Strait, intending to pass outside of the Mansfield Shoal, which is the best track with a S.W. wind, keep out of soundings, about 16 or 18 miles from the Celebes coast, when Bonthein Peak bears between N. $\frac{1}{2}$ E. and N. by W.; and when the North end of Salayer is discerned, by keeping its extreme point East, but nothing to the southward of this bearing, you will clear the shoal to the southward. Steer direct for Sarontang Island, and pass it well to southward. Along the Celebes coast, inside the Mansfield Shoal, there are moderate depths for anchoring.

SALAYAR ISLAND is about 40 miles long, North and South, but is narrow. It is very populous, and is a dependency of Celebes. The people are industrious, and raise considerable produce. The teak tree has been planted, and flourishes. It is said that this island is the division of the climate systems of the eastern and western parts of the Archipelago (see page 20 *ante*), the rainy season being reversed, and by which they conform to the West with the north-westerly, and in the East with the south-easterly monsoon.

The **North Point** of Salayar is in lat. $5^{\circ} 47'$ S., and the land over it being rather higher than the islands adjacent, and joined to the main body of the islands by a low neck, makes the North point appear isolated when first made either from the eastward or from the westward, a fact that should be attended to in making for the strait. There is a large village on the N.W. side of the point, but with shoals and rocks stretching out from it, consequently it is a very bad anchorage. *Pasi*, or *Hoog Island*, an island of considerable length, lies on the S.W. side of Salayar, parallel with and a short distance from it.

In the northern part of the strait, dividing it from Salayar, and on the eastern side, is a kampong and fort, abreast of which is good anchorage in 10 to 12 fathoms. There is a reef around the North end of Hoog Island, and to the West of it is the *Whale* or *Souteland Reef*, about a quarter of a mile in extent, with 12 ft. on it, and $4\frac{1}{2}$ fathoms close-to, and reported by the master of the *Evelyn* to lie about 4 miles W.N.W. from the North end

of Pasi Island, otherwise known as Hog Island. From the shoalest part of Whale Shoal the North end of Pulo Salayer bears N.N.E.; and the S.W. extremes of Pasi Island and Pulo Salayer are in line. It is of undetermined extent, but is about 9 miles West of Hoog Island. A 2-fathom patch lies 5 miles off the West coast of Salayar, in lat. $6^{\circ} 18' S.$

The *South Point* of Salayar is in about lat. $6^{\circ} 27' S.$, long. $120^{\circ} 28' E.$, and is surrounded by an extensive reef. At 3 miles westward of it is *Baoloeang*, a small island, with a reef projecting far off from its N.E. point, but leaving a deep channel, 35 to 38 fathoms, between it and Salayar.

The *Tiger*, or *Tyger Islands* of the old charts, lie to the southward of the Gulf of Boni, and southward of the track eastward from Salayer Strait. The steamer *Hertog Bernard*, when steaming to the eastward of Salayar, in 1871, in search of the American whaler *Xantho*, stranded near an island group which appears on old charts under the name of the Tyger Islands. This group consists of a large number of coral islands, mostly high, surrounded by far extending reefs, and visible from on deck to a distance of from 2 to 3 geographical miles. The largest and most north-easterly, named North Tiger Island, lies in $6^{\circ} 21' S.$, and $121^{\circ} 3' E.$ from Greenwich. From North Tiger Island, a chain of reefs stretch out S.S.E. to Kala Tua; to the East of these reefs is no anchoring ground; they rise up steep from a depth of 100 fathoms. The wreck of the *Xantho* was found on the eastern side of these dangers, and lies in $6^{\circ} 30' S.$, and $121^{\circ} 17' E.$ from Greenwich. The commander of the *Xantho* has reported that to the East of the reefs a safe passage exists between Kala Tua and Post-horse Island, in a N.N.Westerly direction.

Tamboeloengan, or *Tambelaoeang*, a little known island, lies 8 miles S.S.W. of the South point of Salayar, and is about 3 miles long; 2 miles farther South is the North end of *Roesah*, or *Roessa*, another undescribed island, with a peak at its North end. Between this small island and the low islet of *Sisir*, 17 miles to S.S.E., and described on page 773, there are several reefs, with probably clear channels between them. *Mamalakkie*, described on page 773, is 10 miles westward of Roesah. These islands were formerly marked as the *Tonyn* or *Tonin Islands*, but they are not now known by that name. The islands to the southward and eastward are alluded to on pages 772, 773 *ante*.

The whole of these islands and groups which lie between the Java and Floris Seas, do not appear to have been examined for many years, and, therefore, the very imperfect accounts we have of them can be of little service.

There are two groups still to be mentioned, which lie to the westward of those just described, to the North of Sumbawa.

The **POSTILIONS** lie about 70 miles S.S.W. of the S.W. point of Celebes, and the same distance North from Sanjeang, off the East end of Sumbawa

(page 764). They consist of an extensive range of low islands extending 36 miles in a S.E. and N.W. direction, and are almost entirely unknown. The North island is in lat. $6^{\circ} 31' S.$, long. $118^{\circ} 42' E.$ The N.W. island has a small lump in the centre. The easternmost limit of the islands is in lat. $6^{\circ} 48' S.$, long. $119^{\circ} 12\frac{1}{2}' E.$ There is apparently a safe channel between them and the Great Paternosters, but little is known of it, and a series of islands extends for 60 or 70 miles S.W. of the South end of the Postilions.

At about 40 miles West of their south-westernmost point is the N.E. end of a more extensive range, the Great Paternosters.

The **GREAT PATERNOSTERS** consist of several groups of coral islands, mostly low and wooded, extending nearly N.E. and S.W. 110 or 120 miles. They are but little known, and should be avoided till they are better described. Many of them are surrounded by reefs and shoal coral patches. The S.W. isles are about $6^{\circ} 56' S.$, long. $117^{\circ} 5' E.$ The N.E. Paternoster is in about lat. $6^{\circ} 36' S.$, long. $118^{\circ} 17' E.$ Near the N.E. Paternosters, in lat. $6^{\circ} 30' S.$, and long. $118^{\circ} 18' 30'' E.$, the water was observed to be discoloured, and a coral reef supposed to exist.

THE MOLUCCA ISLANDS.

The designation of Moluccas has been extended to all the islands between Celebes and New Guinea, but properly it should be confined to the chain of *five* islands running North and South on the West side of Halmahera or Jilolo, having Ternate to the North and Batchian on the South. These islands are the native country of the **CLOVE**—a spice considered to be of such value in the middle ages, that the search for it was one of the chief incentives to the first voyages of Columbus, which, in addition to giving us the knowledge of a new world, have also attracted a navigation which has made known to us regions equal in extent to that new world. These small islands, unattractive in themselves, have therefore played an important part in the progress of navigation and hydrography.

The Moluccas, as now understood, are claimed by the Dutch, who hold the sovereignty over the whole of them with greater or less power. They are divided into—1. The *Residentie van Amboina*, which embraces that island, the West part of Ceram, Buru, and the neighbouring islands; 2. The *Residentie van Banda*, comprising that small group, the East part of Ceram, and all the groups to the South and S.E.; 3. The *Residentie van Ternate*, embracing the three Sultanats of the Moluccas or Spice Islands proper, the islands of Jilolo or Halmahera, a portion of Celebes, and the islands to the S.W. of them. The details of the area and population of these several provinces was given for the first time with any accuracy by that accomplished

hydrographer Melvill van Carnbee, in the "Moniteur des Indes" for 1846-9. The interesting figures there given must be the guide to those who require further information.

This section will be a description of the islands and passages as far as they are known, commencing with the westernmost. The authorities for these are, besides the numerous notices collected and issued by the Dutch commission for the improvement of the Indian Sea charts, the surveys of Lieut. Gregory; the voyage of M. M. Modera, S. Müller, &c., in the Dutch corvette *Triton*, in 1828; that of M. Kolff in the *Doerga*, in 1825-6; Freycinet, in 1822-5; Dumont d'Urville in the *Astrolabe* and *Zeléé*, in 1837-40, when a large number of important observations were made; Sir Edward Belcher's voyage of the *Samarang*, 1844, Capt. Owen Stanley, R.N., 1839; Mr. A. S. Bickmore, 1865; Voyage of the *Challenger*, 1874, &c., &c. Besides these, the works of Temminck, Eysinga, &c., have been consulted, and many particulars are extracted from our old Oriental Navigator of 1806.

The **XULLA ISLES**, a group of four or more islands to the eastward of the eastern peninsula of Celebes, do not appear to be at all known, as no good account is to be found of them. Their name is apparently given by the Portuguese, and is sometimes written *Zulla* or *Soela*.

Xulla Taliabo, the westernmost, is high and bold, with but few inhabitants. Its north-western point is marked as in lat. $1^{\circ} 45' S.$, long. $124^{\circ} 19'$, from whence it extends eastward for 60 miles, and is separated from the next island by the strait of *Sapaloeloe* or *Surinam*.

Xulla Mangola, the next to the eastward, is generally high, especially at its N.W. end, where it is lofty and rugged. It is about 50 miles long. Off its East end is the smallest of the group, *Lifa Matoelah* or *Lissamatula*, separated by a narrow channel. It is moderately high and level, having along its North and East sides several white cliffs, which are conspicuous at a considerable distance. The S.E. point is in lat. $1^{\circ} 51' S.$, long. $126^{\circ} 30' E.$, and off it is an isle which forms like a saddle in coming from the northward.

Xulla Bessi, the southernmost, is of considerable height, and may be seen 12 or 13 leagues off, and has a level appearance when seen at a distance. It is about 30 miles long, and its S.E. point is in *about* lat. $2^{\circ} 28' S.$, long. $126^{\circ} 2' E.$ It is well cultivated and inhabited, producing much wax and honey. There is a village, *Sabi*, near the S.E. point, where a ship may procure some refreshments. There is a Dutch resident here.

Sannana Bay, on the N.E. coast of Xulla Bessi, was surveyed by Lieut. J. C. G. Brennwalla. It is a good harbour, half a mile in diameter, almost surrounded by coral reefs, with a narrow entrance facing the East, with 7 to 11 fathoms in it. Immediately opposite the entrance is a building called the large mosque, which, bearing West, would lead through. At a short distance North of this is the *Fort de Verwachting*, which is W. by N. $\frac{1}{2}$ N. from the entrance, and in lat. $2^{\circ} 2' S.$, long. $125^{\circ} 56' E.$ Inside the harbour the

depths are from 7 to 14 fathoms, clay bottom, and good anchorage in the centre, with the fort bearing N. 67° W., the great mosque West, and the little mosque on the South side S. 40° W. Tides rise 9 ft.

The *channel* between Bessi and Mangola is about 3 or 4 miles wide between the coral reef which extends North of the former island, with anchorage in from 30 to 35 fathoms near the Mangola shore, which is bold to approach. The currents are strong in the channel, and influenced by the tides. In coming through from the eastward, keep on the eastern side until near the small island West of the passage, when you may haul to the southward.

Greyhound Strait leads past the western end of Taliabo. The western coast of this island trends nearly North and South about 13 miles, having a haycock island, *Seho*, in lat. $1^{\circ} 58'$, close to its S.W. point, and another island off its N.W. point; from the latter, several islands lie near the Taliabo shore, to the N.E. and eastward. *Masunie* or *Middle Island*, which separates the straits into two channels, bears West 9 miles from the North island above mentioned. It is low, swampy, and covered with trees, and surrounded by shoal water.

A *sunken rock* lies at 2 miles westward of the South end of the western islet, lying off the N.W. extreme of Taliabo, and the *Quintet* touched on a shoal of $1\frac{1}{2}$ fathom, lying 3 miles south-westward of the sunken rock. From the shoal Pulo Massuni bore N. 59° W.; Pulo Lembau, E.N.E.; and Pulo Seho S. 28° E. There are 3 fathoms water on the edge of the reef, S.E. of Pulo Massuni, and it is 3 miles East of the eastern side of the island.

BOURO, Boeroe (Dutch), or *Buru*, a large and lofty island, is 42 miles south-eastward of Xulla Bessi. It is 80 miles long by 50 in its greatest breadth, and is therefore one-half larger than Bali or Lombok, but compared with them is of but little value. It is a vast mass of mountainous land, rising to the height of from 7,000 to 8,000 ft., the most elevated in the Molucca Sea. *Mount Tomahoe*, 8,530 ft. above its N.W. point, is very lofty. *Cape Balatetto* or *Palpatu*, the N.W. cape, is in lat. $3^{\circ} 6'$ S., long. $126^{\circ} 4'$ E. The West coast trends about South for 32 miles to *Cape Lisateke*, 6 miles to S.W. of which is a *rock* awash. The southern coast curves irregularly E.S.E. and E.N.E. for 88 miles, and then northward toward Cayeli Bay.

Cayeli or Cajeli Bay, on the N.W. coast, is the chief place of the island. *Fort Defensie*, in the S.W. part of the bay, according to Admiral Sir E. Belcher, is in lat. $3^{\circ} 22' 49''$ S., long. $127^{\circ} 6' 27''$ E. The southern and western shores are fronted by an extensive coral reef to the distance of about a mile, and on the eastern side lies a large coral reef, which extends nearly one-third across the bay.

There is a rugged mount or double peak, two very high conical hills inland, called the *Mother* and *Daughter*, which from the sea appear as one. The Daughter is only seen separate when well into the depth of the bay.

The eastern side is streaked with white, by reason of its bare rocks. It lies on the S.E. side of the depth of Cayeli Bay, $4\frac{1}{2}$ miles S.E. $\frac{1}{4}$ S. from the fort, and is an excellent mark for rounding the eastern head from the S.E.; as long as its head can be seen above the trees at the eastern point, the shipping will be perfectly clear of danger. The instant it begins to *rise*, after passing the point, a course may be shaped for the North point, which apparently shows as the left of an island on the N.W. shore. When in mid-channel steer with the town off the port cathead until Mother bears S.E. by S. Then steer South for the fort; shorten sail when about 1 mile from it, and anchor at the first cast 25 fathoms, bottom mud, good holding ground.

The limit of danger, westerly, is the two eastern turrets of the fort in line. Sir Edward Belcher found soundings in every part of the bay, both going in and coming out; on the latter occasion it never exceeded 50 fathoms until he hauled up E.N.E. Entering, it ranged from 64, 42, to 60 gravel, anchored with the fort, South, Red Island, or Pulo Papeoa, East. The latter is $1\frac{1}{2}$ mile E. by N. from the fort, and behind it is a landlocked anchorage in 6 fathoms, entered between the reefs North of the island, the channel first trending S.E., then South. H.M.S. *Sulphur* was here in August and September, 1840. Sir Edward says that Bouro or Cayeli Bay possesses great advantages over Amboina as regards supplies of poultry, eggs, water, and wood. The harbour is also snug, sheltered from the monsoons, and less troubled with the diurnal rains of Amboina. Deer are plentiful in the interior. A great variety of beautiful woods, adapted for cabinet purposes, and now (1868) greatly appreciated, are also plentiful, including the most valuable ebony of these seas. The cajeput oil is principally obtained from this island and sent to Amboina. The Dutch resident was much perplexed at the frigate's visit.

It is high water, at full and change, at $1^h 32^m$; rise of tide $4\frac{1}{2}$ ft.

Amblau or Amblauw, a small island 6 miles in extent, lies 6 miles off the S.E. end of Bouro. Its East end is in lat. $3^\circ 50' S.$, long. $127^\circ 17' E.$ A reef of rocks is *reported* to lie in the strait, but its position is not known.

Manipa is a lofty island, 2,100 ft. high, midway between Bouro and the western peninsula of Ceram, its centre being in lat. $3^\circ 17' S.$, long. $127^\circ 34' E.$ The best channel is the *Manipa Passage*, between it and Bouro. It is about 16 miles wide, is without soundings, and clear of danger. It is the passage generally used in going from Bouro to Ceram or Amboina. At $1\frac{1}{2}$ mile West from the West extreme of Manipa is the small islet of Suangi, 327 ft. high, in lat. $3^\circ 16' 30'' S.$, long. $127^\circ 29' E.$ On the South side of Manipa is the Dutch fort, off which, and within a small islet, there is anchorage close to the shore. Kelang is 2,400 ft. high, and lies to the N.E. of Manipa, being separated from it by a safe channel 3 miles wide, through which the tides or currents set very strongly at times with great noise and

strong rippings. *Babi* is low, and separated by a narrow but closed passage from the N.E. Cape Kelang. To the East it is separated from the West point of Ceram, *Tanjong Hatan*, by a narrow passage called the *Nassouwsche Gat*.

AMBOINA or Amboyna, a *free port*, is, as before observed, the seat of the Dutch Government of the adjacent islands, although it is not very populous, Melvill van Carnbee giving its total inhabitants as 29,592 in 1841, of which about 9,000 live in the chief town. They are a brown complexioned race, who have lost many of the distinctive characteristics they were found to have when the island was first discovered. The Malay is now the universal language, and a large proportion of them have been well educated and cared for by the Dutch Government, so that they are allowed to be the most moral, well conducted, and peaceable people of the whole Archipelago.

The island is 29 miles long E.N.E. and W.S.W., and consists of two portions, nearly separated by a narrow and low isthmus, across which the Dutch commenced and nearly succeeded in cutting a canal. The northern and largest portion is called by the natives *Hitoe* or *Hitu*, and the southern peninsula, on which is the capital of the Moluccas, is *Leitimor*.

“Amboyna is a beautiful island, nearly divided in two by a broad sea inlet running between high hills, covered with forest or yellow grass, and along the shores are Malay villages, nearly hidden by cocoa groves. Fourteen miles up, on the South side, is the town of Amboyna, the bay continuing 6 miles farther, narrowing just above the town, and again broadening into a lake-like sheet of water, bounded by soft and lovely vegetation at the foot of low wooded hills. We anchored almost alongside of a pier crowded with Dutch soldiers and Malays, excited at our arrival. Though the town from the anchorage looked picturesque enough with trees and palms springing up above the roofs, we were rather disappointed, as it by no means looked like the large place we had heard it was; but when on shore we found it was very much larger than Banda.”—(Lord George Campbell: Log Letters from the *Challenger*.)

The island is composed of primitive and volcanic rocks, and, like many other productions, the clove cultivation is peculiarly adapted to the disintegrated soil of volcanic origin. The little energy of the inhabitants, about 30,000 in number, is almost exclusively devoted to the growth of this staple product, as the island is not much cultivated in other respects. The total produce of the clove is about 500,000 lbs. to 600,000 lbs. per annum. This industry, however, is not now so well cared for, since the soil of other lands has been found suitable for clove cultivation. Shells of rare species are also much collected and exported. The rocky and hilly portions of the island do not attain a very great elevation, Gunong *Salhoetoe*, in the N.E. part of Hitoe, being 4,010 ft., and Gunong *Latoea*, in the S.W. part, 3,363 ft. The highest points of *Leitimor* are Gunong *Nonna*, 1,972 ft., 2 miles S.S.W. of

the city, and Gunong *Horie*, 2,030 ft., 3 miles E.S.E. of the same. The southern peninsula is traversed by some good roads.

Winds, &c.—From a meteorological register kept at Amboina, extending over a period of four years ending 1874, it would appear that the N.W. monsoon commences about November and lasts till April; but only during January, February, and part of March do the winds blow steadily, and then between North and N.W. The S.E. monsoon blows from May to the beginning of September, after which it becomes variable to the end of November. In December the wind is variable from North through West to South, and in March and April from N.W. to S.W.

Rain falls in every month of the year, the driest being from October to April inclusive, with an average of 13 days rain and 8 inches fall for each of these months. The other months average 21 days rain, with a fall of 27 inches. The mean temperature for the whole year ranges from 74° to 86° Fahrenheit.

Earthquakes occur from December to June.

Tanjong Wawolle, the western extreme, is in lat. 3° 40½' S., long. 127° 54' 30" E.; off it are three islands called the *Drie Broeders* (three brothers), or *Pulo Tega*, between all of which and also between them and the point, there are safe passages. The North shore of Amboina is clear of danger throughout, and the channel between it and Ceram, 4 or 5 miles wide, is subject to strong but irregular currents. Off the N.W. point of Amboina is a small island, *Pulo Pombo*, and from this to the S.E. extreme of the northern part of the island the distance is 8 miles in a S. by W. direction. *Bagualla Bay* indents the eastern face of the island, and at its head is the low isthmus. There are numerous shoals in it, and it is entirely open to the East.

The BAY of AMBOINA, which trends to N.E. by E., enters between *Tanjong Allang* on the West and *Noesanive* on the East; they are steep-to, and bear East and West from each other 6 miles apart. About 3 cables' lengths S.S.E. from the latter point there is a narrow bank of soundings of from 15 to 50 fathoms, on which a ship might anchor during a calm. It is detached from the shore.

Inside the S.E. point is a slender bay, called formerly *Portuguese Bay*, but there are no soundings to be obtained at a cable's length from the shore on either side except in the upper part near to the narrows.

AMBOINA or Amboyna, the capital of the Moluccas, is 8 miles up the bay on its southern shore, or about 15 miles from Point Allang. The town is regularly built, clean, and neat, with wide and regular streets. It has a governor's palace and a long esplanade, planted with nutmeg trees, terminating at *Fort Victoria*, at the N.E. end of the town.

The houses are built in the Dutch style, but chiefly of one story, on account of the frequency of earthquakes. The Chinese quarter, which is extensive,

is in the western part, and has a very large and well stocked market, furnishing most of the luxuries as well as the necessaries of the climate, but the people do not seem to be so industrious as they are in other parts of the world.

“The Dutch Government have a large coal depôt here. One day we proceeded farther up the harbour for the purpose of taking in a supply, lying alongside a jetty during the operation; it was, however, a slow and tedious process, for no inducement could make the coolies get in anything like a reasonable quantity per day. It was a pretty place, and as we had the additional facilities of lying alongside a pier, many excursions were taken. On completing our coaling we returned to our first anchorage off the town. The passage down the harbour afforded one of the most astonishing and beautiful sights to behold. The bottom was absolutely hidden by a continuous series of coral sponges, actinæ, and other marine productions of varied forms and brilliant colours. The waters were clear as crystal, and the depth varying from 8 to 10 fathoms.”—(W. J. J. Spry, R.N., Cruise of H.M.S. *Challenger*.)

This citadel was built by the Portuguese, and, besides the military quarters, contains storehouses for the produce of the clove plantations. A wooden jetty extends from the wharf in front of the fort, off which is the usual anchorage. The town contains about 8,000 or 9,000 people, but seems to be declining. The summer-house on the S.W. angle of Fort Victoria, the observatory of Sir Edward Belcher, was found by him to be in lat. $3^{\circ} 41' 30''$ S., long. $128^{\circ} 10' 18''$ E. corrected), which agrees closely with the observations of Lieutenant H. A. Meijer, of the Dutch royal navy, who surveyed the bay in 1840. A survey of the island was made in 1842 by Lieutenant H. van Guffron.

The bay, as before observed, has very deep water along the middle, for at between 3 and 4 cables' lengths of the jetty there are 60 fathoms water. The bay here is about 2 miles wide. There is anchorage abreast of the fort, in case a ship is driven from the anchorage to the south-westward, off the town.

The best time for entering the bay in the *westerly monsoon* is in the morning between daybreak and 8 or 9 a.m.; and by keeping a N.E. by E. course from between the heads nearly in mid-channel, you will generally carry a breeze up to the anchorage off the town. During the night light variable airs or calms generally prevail, accompanied with an outset, which renders the progress up the bay tedious and difficult, for ships are liable to be drifted about by the eddies, or probably out of the bay after getting half-way up with a favourable breeze. There is, however, no danger to be apprehended during the night, for although a ship may seem to be drifting toward the beach when calm, yet the depth of the water allows a ship to be set parallel to the shore close to. Strong gales are often experienced in the westerly

monsoon, about full and change of the moon, which are generally preceded by a great swell tumbling into the bay.

In the *easterly monsoon*, as the current frequently sets strongly past the points of the bay to the westward, a ship coming from this direction ought to work up in the offing until Noesanive Point bears N.N.E. or N. by E. She should then steer round it pretty close, keeping along the southern shore of the bay at a moderate distance under low sail; for the sudden gusts of wind which come off the high land sometimes might endanger the masts with light sails set.

The anchorage is off the town or the fort, in about 20 fathoms, at 2 cables' lengths off shore. It is customary to run the stream cable on shore, and for this purpose heavy anchors are already laid down, to which cables can be attached at low water. The edge of the shoal off the town of Amboina is well marked by fishing stakes, which may also be seen in many parts of the bay. H.M.S. *Challenger* anchored in 24 fathoms 1 cable W. by N. from the pier.

Water, fruit, and vegetables may be got, but stock cannot be depended on at all times. The watering place is opposite to the town $1\frac{1}{2}$ mile distant, but there is another in the Inner Harbour.

"Beef is indifferent in quality and expensive, being 2s. per lb.; fowls, 1s. 6d. each; ducks, 3s. to 4s. each; eggs, 2s. 6d. per dozen. Fish is plentiful and cheap, but fruit is scarce.

"The coaling wharf is at Tanjong Mungayeu, a little more than a mile south-westward of the town pier, and there are 4 fathoms alongside it. Ships intending to coal at the wharf should steer in with their heads to the south-eastward, and at half a cable's length off the wharf end drop the port anchor in 10 fathoms, hauling alongside by means of the wooden piles placed at convenient distances along the shore. The red buoy to the north-eastward of the wharf is lightly moored, and intended only for the off-fasts of the small steamers frequenting the port. Large vessels will therefore find it necessary to have their stream anchors to windward, as the wharf is slightly built, and the N.E. wind presses them strongly against it. A large quantity of coal is stored here, principally from Newcastle-on-Tyne, the price being £3 per ton. Labour can be obtained at a Dutch rupee, of 1s. 8d. per day, but only about 60 tons a day is shipped.

"There is a monthly *mail-steamer* from Makassar or Sourabaya, which touches at Koepang and Dilli in Timor, and at the Banda Islands, on the voyage to Amboina; also at Ternate and either Kema or Menado in the Celebes, on her return.

"*Tides*.—It was found to be high water, full and change (in October) in Amboina Harbour, at 2^h 5^m, the day tide being lower than the night tide; they are, however, irregular, and influenced by the wind."—(H.M.S. *Challenger*, October, 1874.)

The Inner Harbour is entered by a narrow channel, 300 yards wide, between the sandy flat on the South side and the steeper North shore. There are 6 to 10 fathoms water in it. It is $1\frac{1}{2}$ mile above the town, and the channel, as before stated, is on the northern side; within, it widens into a large basin, 3 miles long by $1\frac{1}{2}$ broad, with tolerably even depths over it, varying from 12 to 18 fathoms. It is well sheltered from all winds, but, probably from this cause, is considered to be unhealthy for ships' crews, much sickness prevailing with the small vessels coming inside, while those in the outer harbour continue healthy. The watering river is on the North side, and may be known by a house on either side of it, at a small distance. Casks are readily filled by means of a hose, but a loaded long boat can only float out at high water. The head of the harbour, as before mentioned, is separated from Baguala Bay on the eastern end of the island by a narrow sandy isthmus. At one time the Dutch attempted to cut a canal. It has been partially filled up, still up to the present large prahus are floated up and carried across the remainder to avoid going round the whole of the island.

OMA or Haruku lies 6 miles eastward of the eastern part of Amboina. The channel is quite safe. It is about 9 miles long, and the clove is well cultivated. It has no harbour or roadstead, the chief place being *Haruku*, at its S.W. end. *Fort Zeelandia* here is in lat. $3^{\circ} 37' 45''$ S., long. $128^{\circ} 25'$ E. The North coast of the island should not be approached within 2 or 3 miles.

SAPAROEAE or Honimoa, the next island to the eastward, is larger than Oma, and, like Amboina, is of an irregular figure, two peninsulas joined by a narrow isthmus. The channel between Oma and Honimoa is only a mile wide in its narrowest part, destitute of anchorage, and subject to strong currents or tides. Should a vessel venture through, which is not to be recommended, keep on the Oma shore. Some shoals are marked on the Dutch charts as lying a mile East off the N.E. point of Oma.

Pulo Dombo or Pigeon Island, a small islet, lies off the South point, known formerly as the Dolphin's Nose. This is in lat. $3^{\circ} 39\frac{1}{2}'$ S., long. $128^{\circ} 39'$. A bay, 3 miles deep, lies to the East of it, and *Pulo Melano* or *Moelana* about 2 miles to the S.W.

Saparoea village, the chief place, lies at the head of the bay of which the Dolphin's Nose is the S.W. point. *Fort Duurstede* protects it. There is good anchorage near this fort in the westerly monsoon in about 12 fathoms. Steer in about mid-channel, between the reefs that line both sides of the bay, but no soundings are to be got until within a mile of the fort, and anchor in 10 fathoms with it bearing N.W. 450 yards distant. The fort is in lat. $3^{\circ} 35' 50''$ S., long. $128^{\circ} 38' 18''$ E. High water, full and change, at 1^h 0^m; springs rise 6 ft. The island, like the others, is well cultivated, and has several roads traversing its central portion to its North shore.

NUSA LAUT, about 800 ft. high, the easternmost of the Amboina group, or the *Clove Islands*, is separated from Honimoa by a *safe* channel, 2 miles wide. Foul ground surrounds it to the distance of a quarter of a mile. There is no shelter whatever, but anchorage may be had in favourable weather at the North side, and off the N.W. part, where there is a fort. A road goes all round the island, a circuit of 18 or 20 miles. It is believed to produce the best cloves of all the group.

The **STRAIT** which separates these islands from the South coast of Ceram is of very various width. Its northern part, along the shores of Ceram, is believed to be quite clear at a mile off the land, but a berth should be given in working through it, to the shoals which lie to the northward of Oma and off the N.W. part of Honimoa. The eastern islands are comparatively low, and, when viewed at a long distance from the southward, do not appear separated from the very much higher land of Ceram to the northward; it is not until closer up with them that they are perceived to be distinct islands.

The **BANDA ISLANDS** are the home of the nutmeg tree, as the islands just described are of the clove. It is a singular fact that these two spices of such universal use should be only produced on two such insignificant groups of islands, lying so near the equator as those in question. There has been no regular hydrographical survey of the group, but the Dutch authorities and Captain Owen Stanley have given us sufficient data to use the charts with confidence.

The islands, subject to the Dutch, by whom a Resident is appointed, have been cared for in a most expensive and exclusive manner. The nutmeg monopoly was formerly maintained by the government, by purchasing the produce at a fixed price, and supplying the proprietors of the perks (parks) with slaves at a fixed price, and rice from Java at its cost. Since the abolition of slavery, however, any one is free to clear the jungle and plant the spice-giving trees. The annual produce is about 600,000 lbs. of nutmegs and 150,000 lbs. of mace. Many obsolete obstructions to the extension of commerce have been removed, but the islands still preserve their character of *exclusively* producing the best nutmegs. The nutmeg trees are in fruit and blossom all the year round; the flower is yellow, and the fruit like a small unripe peach. When fit to gather, the outer rind splits open, disclosing the nut with its covering of mace.

The Banda Islands have been frequently described, and most recently by Mr. W. J. J. Spry and Lord George Campbell, who visited the islands on board H.M.S. *Challenger* in September, 1874. They were much struck during their three days' stay with the neatness of the town, the beauty of the scenery, and hospitality shown by the inhabitants. We take the account of a visit by Mr. A. S. Bickmore, in company with the Dutch Governor-General, Mr. Arriens, in September, 1865.

They are ten in number; the largest, Lonthoir or Lontar, or Great Banda,

is a crescent-shaped island, about 7 miles long, and a mile and a half wide in its broadest parts. Its eastern horn curves towards the North, and the other points to the West. In a prolongation of the former lie Pulo Pisang, "Banana Island," and Pulo Kapal, "Ship Island." The first is only about two-thirds of a mile long, and half as wide, and the last is merely a high rock, resembling the poop of a ship, hence its name. Within the circle of which these islands form an arc, lie three other islands. The highest and most remarkable is the Gunong Api, or "Burning Mountain," apparently attaining a very considerable elevation, because its sides rise so abruptly up from the sea. Between the Gunong Api and the northern end of Lonthoir lies Neira, about two miles long and less than a mile broad. North-east of the latter is a small rock, called Pulo Krakka, or "Women's Island." The centre of the circle of which Lonthoir is an arc, falls in Zonne Gat or Sun Strait, a narrow passage separating Gunong Api from Neira. The diameter of this circle is about six miles. Without this another concentric circle may be drawn, which will pass through Pulo Ai (Wai), "Water Island," on the West, and Rosengain on the S.W.; and outside of this a third concentric circle, which will pass through Pulo Swangi, "Sorcery," or "Spirit Island" on the N.W., Pulo Run (Rung), "Chamber Island," on the West, and the reef of Rosengain on the S.W. The total area of the whole group is only 17.6 geographical square miles.

In the five islands now named—Lonthoir, Rosengain, Ai, Run, and Neira—grow all the *good* nutmegs consumed in every part of the world. De Barros, in 1852, said that they had been frequented for ages by the Malays, in proof of which, the names of the different islands mentioned above are all of Malay or Javanese origin. The aboriginal population at that time is given at 15,000, which, if correct, would have made this group far more densely peopled than any other island or number of islands in the whole archipelago at the present day.

The climate and proximity of the great volcano render the islands very unhealthy, the annual deaths in the group amounting to 1 in 21. The frequent eruptions, always followed by famine and death, and the earthquakes, which also devastate the group, have kept down the population to a very great degree. The most fatal of these visitations occurred in 1629, 1683, 1686, 1691, 1743, 1816, and 1852. So terrible were the ravages of the eruption and earthquake of 1691, that all the more wealthy people hastily abandoned it, and it was only by the firmness of the Dutch Governor that the abandonment of the place was prevented. Some of these have commenced their destruction without an instant of warning, and the ashes and hot stones have buried the island in dust and ashes, and poisoned its water in a moment.

Winds, etc.—From inquiries amongst the natives and Dutch residents, it was gathered that the North-West Monsoon, which sets in about the middle

of November, occasionally blows with violence, but that the South-West Monsoon seldom blows so fiercely. Rain falls in both monsoons, the dry months being September and October, when light variable winds and calms prevail.

The population of the group in 1840 was only 5,081, of which Neira had 1,225, Lonthoir 372, Ai 148, and Run 42. These, amounting to 1787, were the free population; but to make up the total there were 2,183 slaves and 1,029 convicts from Java, Sumatra, and Borneo, so that the people had decreased one-fifth in the previous 115 years.

GREAT BANDA is about 7 miles long, by $1\frac{1}{2}$ broad. It is divided into three districts, *Lonthoir*, or *Lonthar*, at its West end, and the rest into the *Voorland*, or "front," on the North side, and the *Achterland*, or the "back," on the South and East.

The shore of the western horn of crescent-shaped Lonthoir is composed of a series of nearly perpendicular crags, 200 or 300 feet high; but on the North side the luxurious vegetation of these tropical islands does not allow these rocks to remain naked, and from their horizontal crevices and upper edges hang down thick wide sheets of a bright unfading verdure. The western entrance to the harbour is between the abrupt magnificent coast of Lonthoir on the right, and the high, overhanging peak of Gunong Api on the left, and, as we advance, these separate and open to our view the steep lofty wall that forms the northern shore of Lonthoir. This is completely covered with one dense mass of vegetation, out of which rise the erect columnar trunks of palms.

This western end of Lonthoir is about 400 feet high, and is composed of coral rock of very recent date. Nearly the whole island is composed of such eruptive rocks, and Lonthoir may be regarded as merely a part of one immense crater about 6 miles in diameter, if it were circular, though it may have been more nearly elliptical. Pulo Pisang and Pulo Kapal already noticed as falling in this circle, are two other fragments of the old crater walls—all the rest have disappeared beneath the sea. Here, then, is another enormous crater, greater even than that seen among the Zeugger Mountains on the eastern end of Java, whose minor and major axes severally measure three miles and a half and four miles and a half, and whose floor of naked sand is well named by the Malays "the Sandy Sea." Banda Neira represents the extinct craters rising in that Sandy Sea, and Gunong Api has a complete analogue in the still active Bromo. The enclosed bay, where vessels now anchor in 8 or 9 fathoms, is the bottom of this old crater, and, like that in the Zeugger Mountains, is composed of volcanic sand.

The radiating ridges on the outer side of Lonthoir represent the similar ridges on the sides of every volcano that is not building up its cone by frequent eruptions at its summit.

Every island in the group is now belted with a fringing reef, except at a

few places where the shore is a perpendicular precipice, and the water of great depth. The western entrance through which we came to the roads is already quite closed up by a broad reef of living, growing coral.

The Western Channel, half a mile wide, which separates it from Gunong Api, is called the *Lonthoir Channel*. It has 6 and 7 fathoms in the fairway, but from the North shore, abreast of Lonthoir village, shoal water extends for half a mile off. The channel, therefore, is under the Gunong Api shore.

GUNONG API, the "burning mountain," is simply a volcanic cone, in lat. $4^{\circ} 31' S.$, long. $129^{\circ} 54' E.$

The whole mountain is one great cone, about 2 miles in diameter, of small angular blocks of trachytic lava and black volcanic sand, the crater at its top being a conical cavity in this mass. The form of the summit is nearly elliptical; the depth of the crater is about 80 feet, its diameter being roughly estimated at from 100 to 150 yards. The area at the top is about 200 yards long, by 390 wide, composed of heaps of small lava-blocks, which are whitened on the exterior, and in many places quite encrusted with sulphur. Through these heaps of stones steam and sulphurous acid gas are continually rising.

The first European who reached the summit, so far as I am aware, was Professor Reinwardt, in 1821; the second was M. Salomon Müller, in 1828, and from that time till the 13th of September, 1865, when we ascended it, only one party had attempted this difficult undertaking, and that party was from the steamer *Etna*, whose name we had found on a large rock in the old crater. Some of the crew of H.M.S. *Challenger* ascended the mountain in 1875, and took 2 hours in reaching the summit.

The height of this volcano we found to be 707.5 metres, 2,321 feet. Its spreading base occupies less space, 2 miles square. In size, therefore, it is insignificant, compared to the gigantic mountains on Lombok, Java, and Sumatra; but, when we consider the great amount of suffering, and the immense destruction of property that have been caused by its repeated eruptions, it becomes one of the most important volcanoes in the archipelago."—*Bickmore*.

NEIRA, or **Banda Neira**, is separated from Gunong Api by a channel of irregular breadth, called *Zonnegat*, or Sun Strait. It being so contracted, and the tides within it being so rapid, it is seldom used except by small vessels. From the north-eastern part of Great Banda it is separated by the *Slaman*, or *East Gat*, a name given to it from a ruined Portuguese fort on the N.W. end of Great Banda. Neira is about $1\frac{3}{4}$ miles long from N.N.W. to S.S.E., and the capital of the group is at its South end. Its highest point is the *Papenburg*, 640 feet at its northern part. The southern part is composed of hills, which gradually slope down to the South shore, on which the town or village is built. On the S.W. point are the Pakhuizen, or Magazines, and above this point, on the summit of a hill, is Fort Belgica.

Fort Belgica is in form a regular pentagon. At the corners are bastions surmounted by small circular towers, so that the whole exactly resembles an old feudal castle. Its walls are white and almost dazzling in the bright sunlight, and beneath is a broad neatly-clipped glacis, forming a beautiful green, descending lawn. Below this defence is *Fort Nassau*, which was built by the Dutch when they first arrived in 1609, only two years before the foundations of Belgica were laid, and both fortifications have existed, much as they are now, for more than two centuries and a half. To the right and left of this fort extends the town of Banda Neira, with rows of pretty shade-trees on the bund, or front street bordering the bay. The town is prettily laid out, and contained, in 1874, 6,000 inhabitants, including 600 Europeans. At one end is the Dutch garrison, and at the other the Chinese, Arabs, &c. There are three piers running into the sea. The roads are in excellent order, being kept so by convicts; a row of green trees on each side of the road gives them a refreshing coolness. Banda is a free port.

H.M.S. *Challenger* entered the harbour northward of Great Banda, between Pisang Island and Point Burang, and anchored in 7 fathoms, with the East extreme of Banda Neira bearing N.E. $\frac{3}{4}$ N., the South extreme of Gounung Api W. $\frac{1}{4}$ N., and Fort Nassau N. $\frac{1}{2}$ W.

The edges of the shoal water on either side of the southern channel into Banda Harbour, between Gounung Api and the western end of Great Banda, are marked by *beacons*, each consisting of a pole surmounted by a triangle.

Supplies are scarce and expensive, fowls are 3s. to 4s. each, eggs 2½d. each. Beef can only be occasionally procured. Vegetables and fruit are to be had in small quantities. *Coal* is generally to be had, but the supply cannot always be depended on.

Tides.—From the Dutch observations, it is high water, full and change, at the mole head in Banda Harbour, at 12^h.; springs rise 14 ft. The tides are strong, but not regular; it is therefore proper to moor at once.

Batu Pulo Matti is the N.W. point of Neira, and off it is *Pulo Krakka*, or *Porto Krak*, an islet lying in the northern entrance to the Sun Strait.

Pulo Pisang lies half a mile northward of the N.E. point of Great Banda, and is joined by a reef to *Pulo Kapal*, the Ship Rock. Between Pisang and Great Banda the channel is very deep. *Pulo Way* or *Ai* bears West 7 miles from Gunong Api, and E. by N. $\frac{1}{2}$ N. 4 miles from *Pulo Run* or *Rung*, the passage between the latter being said to be unsafe, as a reef extends off the North side of Pulo Run. *Pulo Swangy*, the northernmost of the group, bears N. $\frac{1}{2}$ W. from Pulo Way. *Rosengain*, or *Rosengeyn*, the easternmost of the Banda Islands, lies about 4 miles eastward of Great Banda.

Rosengain Reef, which breaks, lies 5 miles S.E. by S. of the island of the same name. It is in lat. 4° 38' S., long. 130° 5' E.

The islands, generally, are subject to gusts of wind from the mountains, and the weather is hot and oppressive in the day, but the nights are cool.

In the *Westerly Monsoon*, the only practicable channel is by the Lonthoir Channel, which, as before said, has shoal water on its southern side; so that it is necessary to keep the Gunong Api shore on board. The extremity of Pulo Way kept just touching, but open with the extremity of Gunong Api, will lead a ship up to the anchorage. As this is only used for coming in in this monsoon, so it is the channel used for going out in the opposite season.

In the *Easterly Monsoon*, the broader Slaman Channel is used. Give a berth of half a mile to the shore of Great Banda and to that of Banda Neira. You may pass on either side of Pulo Pisang and Pulo Kapal, but not between them, and when to the southward of them the channel is about 2 miles wide.

The anchorage is off the Residentie House and the New Pier at Neira, in 7 or 8 fathoms, with Pulo Way just shut in with the point of Gunong Api and Fort Belgica, about N.N.W., distant one-third of a mile from the wharf. The Orpheus Bank, with only 15 ft. water over it, will be avoided in coming in by not shutting in the north-eastern point of Great Banda with the low S.E. point of Banda Neira.

THE BANDA SEA.

The space between the S.E. portion of Celebes and the islands lying off it on the one hand, and New Guinea on the other, with the islands just described, with Ceram on the North, and the chains of islands extending eastward from Timor, has been termed the Banda Sea. It is difficult to describe in geographical sequence a series of islands so widely scattered. Most of the islands are supposed to belong to the Dutch, and during the period when a strict monopoly of trade was maintained at the Spice Islands, that Government established and kept up a number of forts on the chief islands for the protection of this monopoly. Since this system has been partially abandoned, the interest in them, which must have been costly, has led in most cases to their virtual abandonment, but still the natives acknowledge the sway, now so slightly exercised over them, and they usually appear to passing ships or traders under Dutch colours.

The Banda Sea is of great depth in places, as H.M.S. *Challenger* obtained a sounding of 2,800 fathoms in lat. $5^{\circ} 24' S.$, long. $130^{\circ} 38' E.$ In the serial temperatures taken in the deep soundings, the same temperature, 37.5° , was found from a depth of 900 fathoms to the bottom, indicating that the Banda Sea is enclosed by a rim or border, with only 900 fathoms in its deepest channel.

Some of the islands are still very little known or visited, especially those in the western part; of the others which lie between the Moluccas and N.W. Australia, the charts have had many improvements from the observations and partial surveys by Captains J. Lort Stokes and Owen Stanley, R.N., and especially the remarks of Lieutenant D. H. Kolff, of the Dutch navy; but very much is required before we can give a perfect description of the region. We commence, as before, with the western portion—that next to Boeton off Celebes, is described on page 814, *ante*.

TOKEN BESSI, or **Tukan Bissi Islands**, an extensive but little known archipelago, lies to the S.E. of Boeton. They are of moderate elevation, but are quite unsurveyed. *Wangi-Wangi*, or *Wantiyi*, the north-westernmost, and perhaps the largest, is 10 miles eastward of Cape East of Boeton. Between them the depth is very great, 1,070 fathoms. The island is high, and may be seen 7 or 8 leagues off, and may be approached within 2 or 3 miles on the North and West coasts, there being no soundings nor any appearance of danger above $1\frac{1}{2}$ mile off shore. It is inhabited, and abounds with cocoa-nuts. The South side of Wangi-Wangi is bordered by three or four islands, and S.S.W. 8 miles from the western one is the N.W. end of a shoal, in lat. $5^{\circ} 24' S.$, long. $123^{\circ} 24' 30'' E.$, which thence extends to the S.E. towards the Kadupa Group. *Kadupa*, or *Combado*, another cluster, lies 13 miles S.E. from Wangi-Wangi, and the southernmost, *Binonko* or *Pinunoko*, is in about lat. $6^{\circ} 17' S.$, long. $124^{\circ} E.$

The space between the southern island and the northernmost is supposed to be foul, but is quite unknown. Some small islands, tree covered, called the Boompjes, are marked on the Dutch charts.

Hegadis, in lat. $6^{\circ} 7' S.$, long. $122^{\circ} 40' E.$, is the westernmost of the groups around the S.E. end of Boeton. It is of moderate height, and about 3 miles in diameter. Reefs extend East and West of it, and off its South end are some islets, called the *Lagu Rocks*. At 9 miles to the South of it is a *sunken rock*, of doubtful position. A *Six-Foot Bank*, of considerable extent, is shown to the eastward of it; and East of the bank, 40 miles East of Hegadis, an island, vaguely marked as *Groenwout Island*, on the old charts.

The **Boeton Passage**, mentioned on page 814, is about 20 miles wide in its narrowest part, between these islands and shoals and the South end of Boeton; and, as far as is known, is safe, with the exception of Penguin Reef, lying 5 miles off the coast of Boeton.

Some shoals are marked to the southward and south-eastward of Binonko, but nothing certain can be said of them. The *Emperor of China Rock* is said to be 33 miles S.S.E. of Binonko, and another rock, *Koko* or *Kaka*, is vaguely stated to lie at 12 miles S.E. of the same, or under the name of the *New Rock*, in lat. $6^{\circ} 39' S.$, long. $124^{\circ} 40' E.$, at 37 miles South of Velthoen Island.

Velthoen, the south-easternmost of the islands off Boeton, is in lat. $6^{\circ} S.$,

long. $124^{\circ} 46'$ E. It is low, covered with trees, and about 5 miles in extent, and should not be approached within 2 or 3 miles. When seen to the westward the coast has a white chalky appearance, probably coral, which might be mistaken for breakers.

An island of small size is marked doubtful midway between Velthoen and Binonko.

St. Matthew Islands, the north-easternmost, are two in number. They extend in a N.W. and S.E. direction for 15 miles, the centre being in lat. $5^{\circ} 24'$ S., long. $124^{\circ} 16'$ E. The southernmost is the largest, separated from the other by a space of 4 miles of breaking reefs. They are about 30 miles eastward of the northern Token Bessi. The channels between are not safe, having several reefs, and with our imperfect knowledge demanding a good look-out.

Ships bound westward in the S.E. monsoon should steer for the northern of the Token Bessi's, and round it within 3 or 4 miles, for by steering wide of these islands, you may not be able to weather or beat round the South end of Boeton against the northerly currents which prevail at times. *Wetter*, and the other islands on the South side of the Floris Sea are described on pages 782, &c.

LUCIPARA, *Lousapara*, or *Lucapin*, is a cluster of five low islands, covered with trees, the North islet in lat. $5^{\circ} 28\frac{1}{2}'$ S., long. $127^{\circ} 31'$ E., according to the Dutch frigate *Maria Reygersbergen*. They cannot be seen more than 12 miles from the deck. Within 5 miles to the E.S.E. of this are several small islets, and at about 2 miles S.W. from them is a reef called *William I. Reef*, from a steamvessel of that name, which was wrecked on it in 1837.

The **Turtle Islands** are three in number, very low and small, and dangerous to approach by night, being surrounded by coral reefs. The northernmost island is in about lat. $5^{\circ} 20'$ S., long. $127^{\circ} 48'$ E.; the other two islands lying at 3 miles to the S.W., and 5 miles to S. $\frac{1}{2}$ W. They lie 11 miles N.E. from the Lucipara Islands.

GUNONG API, before mentioned on page 792, a volcano or burning mountain, as its name indicates, is a high conical hill, visible 45 to 50 miles off. Its summit is in lat. $6^{\circ} 43'$ S., long. $126^{\circ} 43\frac{1}{2}'$ E., bearing S.W. by S. 88 miles from the Lucipara Islands. It is generally active, and the smoke issuing from its crater will indicate its proximity. It is bold-to.

The **SERWATTY ISLANDS**.—The several groups of little known or visited islands, which lie between Timor and Timor Laut, are generally known as the *Servatty Islands*. The people are of the Malay race, and are described by Mr. George Windsor Earl, who visited them, as a peaceable and industrious race, who raise vegetables, sugar, and hogs, and are divided into three castes—lords, land owners, and serfs.

ROMA, which lies 64 miles S.E. $\frac{1}{2}$ S. from Gunong Api, is a hilly island, about 12 miles in circumference. There is said to be good anchorage in a

bay on the N.W. side, but this part of the island has but a scanty population. On the S.W. side lies a fine and fertile valley, through which runs a small river. In the West monsoon there is good anchorage for a vessel opposite to the mouth of this river, from which abundance of timber, firewood, and good water may be obtained. On the other sides of the island the shores are steep and rocky, which renders even boat landing very difficult. The chief village lies on the side of a hill about 400 ft. above the sea, and is very picturesque. The population, who are chiefly Christians, are very industrious, and collect large quantities of wax, besides cultivating the soil, so that provisions may probably be obtained. The anchorage of *Serussa* is on the S.E. side of the island, northward of the small island *Nussa Medta*, which lies within $1\frac{1}{2}$ mile of the shore. The South shore of Roma is dangerous to a mile off. Its West point is in lat. $7^{\circ} 38' S.$, long. $127^{\circ} 20' E.$

A *doubtful island*, with a rock off its North end, is marked at 8 miles North of the West end of Roma, and several uncertain islands within 20 miles to the eastward of it.

Medta is a small island, placed on the chart about 3 miles S.W. of the South end of Roma. The island is covered with trees, but without fresh water. Abundance of turtle are caught around this and the other islands. A rock is marked near its N.W. side.

LETTI, or LETTE, is about 23 miles E.N.E. of the East Cape of Timor, and to the S.S.E. of Roma. It is about 8 miles in extent. A high ridge of hills extends along the centre of the island from East to West, the sides of which, sloping towards the sea, are covered with trees, and the whole island presents an appearance of great fertility, but it suffers much sometimes from drought. It was surveyed by Captain Owen Stanley. As above said, it is generally hilly, but low near the shore, where the chief part of the inhabitants reside in villages on the more elevated and projecting points. Reefs line the island on the North and N.W. sides through an opening, which is the entrance to the anchorage off the village of *Tombra*, which appears to be the chief place. This inlet or basin is from 400 to 500 ft. wide, with 6 to 9 fathoms, sandy bottom. It is bounded on either side by reefs, visible at low water. In the westerly monsoon the best anchorage is off the village of *Batu Meau*, on the East side of the island, opposite Moa. The people are not so civilized as those of Roma, neither are they so prosperous.

Moa lies next eastward of Letti, and is about 18 miles long East by South and West by North. The S.W. point of the island is surrounded by reefs, but on every part of the East side of the island there is good and convenient anchorage during the appropriate monsoon.

The S.W. point of the island has reefs steep-to, so that there is a very heavy surf, especially in the rainy monsoon. The people, who profess much

attachment to the Dutch Government, turn their chief attention to breeding cattle, and grow only a small quantity of vegetables and Indian corn. On the N.E. point of the island is a solitary high mountain, called *Korbou*, or *Buffalo Peak*, 4,100 ft. high, in lat. $8^{\circ} 12' S.$, long. $128^{\circ} 2' 30'' E.$, resembling in appearance, though so much lower, the Peak of Tenerife. The rest of the island is generally flat and coralline; on the South and south-eastern sides there is very little cultivation. The buffaloes are the best that can be procured among these islands.

Lakor is separated from Moa by a strait, in which is good anchorage. The island bears a perfect resemblance to a dry coral bank, raised about 20 ft. above the sea, so that there is but little scope for cultivation. The sandy spots are planted with cocoa-nut trees; most of the necessaries of life are imported from the other islands, so that the population is small and poor. The *Dourga* anchored off the western village, on the North shore, in 7 fathoms, with a warp on to the shore reef. At 8 miles eastward of Lakor is a small cluster of islets, called *Okenao*.

Luan, about 32 miles E.N.E. from Lakor, is a group about 14 miles in circumference, and, being high, is visible at a considerable distance. An extensive reef, studded with islets, surrounds it, within which there is a depth of 2 fathoms, affording sufficient anchorage to small traders. The islets to the N.E. of Luan are not inhabited, and are about 4 miles distant from the the main island. Close outside these the reef is steep-to, and may be safely approached. The people, forming 200 or 300 families, nominally Christians, are tolerably civilized. The chief product of the islands is tortoise-shell, of good quality. Trepang is also one of the chief articles of trade, as well as edible birds' nests. Louan is the chief island. *Matumara*, a small islet, lies 2 miles South of it; and *Klapa*, the second largest islet, is 3 miles eastward of Louan.

Sermatta, or *Sermattan*, next eastward of Luan, is about 15 miles long, and composed of a high ridge of hills, extending East and West, the sides of which run steeply down to the sea. As the island is thinly inhabited, and affords no shelter to shipping, it is unimportant to strangers. The inhabitants are subject to the people of Luan. East end lat. $8^{\circ} 16' S.$, long. $129^{\circ} 0' E.$

DAMMA lies 65 miles N.N.W. of Sermatta. It is high and hilly, and on its N.E. extremity is a volcanic peak, from the crater of which smoke issues almost without interruption. At the foot of this mountain, near a cave, in the Bay of Kulewatta, are some warm sulphureous springs, useful as a bath in rheumatic cases. The island is about 15 miles long from N.W. to S.E., and on its East side is *Kulewattu Bay*, before mentioned, extending about 4 miles inland, and in many parts quite unfathomable, with precipitous shores. *Wilhelmus Bay*, on the North side of the island, was formerly the seat of the Dutch residency. It is much exposed, and a heavy swell tumbles home

in it in all seasons, but there is secure anchorage near the mouth of a small fresh-water river. Several islands are marked to the southward and two to the westward of it, but we have no particulars of them.

Teon, or *Tauw*, is 37 miles E.N.E. of Damma, is hilly, and of moderate height. It is uninhabited. *Nila*, which is much larger, is about 18 miles N.E. of Teon, the water between being dangerous. It consists of a high, round hill, with anchorage for small vessels on its North side. It is visible 6 leagues off. In the channel between it and Teon there are numerous reefs, so that it is quite unsafe. It is inhabited by a few heathens. Tortoise-shell is procured in great abundance on all these islands. Two shoals are shown on the old charts to the northward of Nila, and the captain of the Dutch brig *Doesborgh* reported, in 1870, a shoal N.W., distant $5\frac{1}{2}$ miles; particulars not stated; and Captain Griffin, in 1874, reports a danger with the peak of Nila bearing W.S.W. $\frac{1}{2}$ S., and Seroea N.E. $\frac{1}{4}$ N.

Serua, or *Seroea*, in lat. $6^{\circ} 17' S.$, long. $130^{\circ} 0' E.$, is 32 miles N.E. of Nila, and is said to have anchorage on the North side; but most of these islands are steep-to, and generally have a rocky bottom in those few places where they have been sounded.

MANO or **Bird Island**.—This island, lying N.N.W. and S.S.E., is about 1 mile long and half a mile wide; it is prism-shaped, its sides sloping from the sea at an angle of about 30° to the summit, which is 980 ft. high. The eastern slope and the northern part of the summit are wooded, the western slope and southern part of the summit are bare. Smoke was seen rising from the West side by H.M.S. *Challenger*. The South point of the island is in lat. $5^{\circ} 34' S.$, long. $130^{\circ} 19' E.$ At 22 miles E.N.E. $\frac{1}{2}$ N. from it, H.M.S. *Challenger* found a depth of 2,800 fathoms.

BABA is 43 miles E.N.E. of Sermatta. It is hilly and tolerably high, and surrounded by several smaller islets, the most important of which are *Wetang* to the West, *Daai* to the North, *Maselar* to the S.E., and *Davelaar* to the East. The best anchorage near Baba during the East monsoon is on the West side of the island off the village of *Tepa*; and, in steering towards this, the *Dourga* ran close along the North shore of *Wetang*, and then stood over to Baba, when she worked up close under the land to the anchorage, bringing up in 15 fathoms, good holding ground. Care is necessary in working up to the anchorage during this monsoon, as heavy squalls sometimes come off the land. When easterly winds prevail, it is said that the most secure roads are under the coast of *Wetang*. There is a bank of $5\frac{1}{2}$ to 10 fathoms between them, on which a vessel will be sheltered from all winds. There is also anchorage at the East end of Baba, with the N.E. point of the island bearing about North, and the South point S. by W., and the entrance of a fresh-water river S.W.; but the bottom is generally foul about this island. The western side of Baba is so precipitous and overgrown with

forest, that there is but little cultivation. *Matang* is more fertile, and is well cultivated.

The people are divided into two portions, one to N.W., the other to S.E., the centre of the island being uninhabited. They are a barbarous people, who have forgotten nearly all the old Dutch influences for good, and, like those of Timor Laut, are not to be trusted.

The TENIMBER ISLANDS.—This group is the easternmost of those which extend from Timor towards the Ki and Arru Islands. It consists of numerous islands, of which Timor Laut, or "Timor of the Sea," is the principal. They are almost all low and coralline, with the exception of Serra and Vordate, which have some hills. The inhabitants are of the Malayan race, and are good looking when young. They are very particular with their persons, and have great cleanliness in their dwellings, &c., a rare virtue. They are industrious, and raise much vegetables, farinaceous roots, cocoa-nuts, hogs, goats, and poultry; but they are not to be trusted. Capt. Owen Stanley has given a vivid picture of his visit to a village in the S.E. part of Timor Laut.

TIMOR LAUT, according to the charts, is 95 miles long from S.W. to N.E. Its eastern coast is formed of a range of hills, wooded to the very summit, and indented by deep bays, which would afford anchorage during the N.W. monsoon, were it not for a coral reef that appears to extend along the coast at the distance of 2 or 3 miles from the shore.

The *South Point*, or S.W. point, is rather low, in lat. $8^{\circ} 19' S.$, long. $130^{\circ} 43'$, and is fronted by a dangerous reef, projecting from it 2 miles, requiring great caution when in its proximity during the night, particularly as the currents are variable and strong at times. The land about the point is covered with trees, and the shore to about a mile eastward presents a rocky face, the East end of which has the appearance of the entrance of a river, and is remarkable by a large detached fragment of rock resembling the hull of a ship. From the South point the coast extends in a N.E. by E. direction 12 or 13 miles, and afterwards more northward, the whole extent to the North end being above 100 miles. A wooded islet lies 2 miles West of the South Point.

Oliliet, on the East coast of Timor Laut, was visited by Captain Owen Stanley, R.N., in H.M.S. *Britomart*. He places it in $7^{\circ} 55' S.$, long. $131^{\circ} 23' E.$ It is built on a hill, 413 ft. high, about the middle of the East coast. The hill is nearly perpendicular, and only capable of being ascended by ladders. The houses are all built on piles, and are thatched and surmounted at the gables by richly carved large wooden horns. It does not appear to be a place from which any quantity of sea stock can be procured, for although there were many pigs seen, they did not seem inclined to part with them. Water may be got on the beach, but a merchant vessel should be very cautious in sending her boats for it to guard against treachery. To the N.E. of

Oliliet there are six other villages perched on cliffs overhanging the sea, and most difficult to approach.

Of this coast, beyond what has been stated, nothing more is known, and the whole of the western shore appears to be a complete terra incognitá.

Laarat or Laroc Island, off its N.E. point, is nearly 20 miles long; its eastern shore is surrounded by a reef, but off which there is anchorage in the westerly monsoon.

Vordate Island, which is higher than the rest, is separated from Laarat by a safe channel, 2 miles wide. The island is well cultivated; the anchorage off its South end is not very good, owing to the great unevenness of the bottom. H.M.S. *Britomart* came here in 1839 and anchored. They found that the natives were very well off, had many European goods, but were not to be trusted. Like the adjacent islands, the people acknowledge some sort of sovereignty in the Dutch. Many of them profess Christianity, especially the chiefs. They have been converted for many years by the Dutch from Amboina.

Of the other islands which lie to the northward of Timor Laut, *Maru* and *Mulu*, we know nothing; the northernmost is represented in lat. $6^{\circ} 35'$ S., long. $131^{\circ} 40'$ E. The same may be said of the islet and reefs which extend for many miles off its N.W. side, and having *Serra*, a high land to the S.W., the S.W. point of which is in lat. $7^{\circ} 38'$ S., long. $130^{\circ} 44'$ E., and is quite bold-to. The strait between this and Baba, 60 miles to W.S.W., is deep and clear.

The ARRU ISLANDS, which lie 130 miles E.N.E. from Timor Laut, are an extensive group or archipelago extending 110 miles from North to South, and with a breadth of from 40 to 50 miles. They were visited by H.M.S. *Britomart* in 1839-41, and from the descriptions by her commander Owen Stanley and other officers, and especially from the notices given by Mr. Geo. Windsor Earl at the same period, we owe nearly all that can be said of them. H.M.S. *Challenger* anchored off Dobbo for a week in September, 1875, when some interesting additions to the natural history collection were made, including some fine specimens of the king bird of paradise. The name is properly *Pulo Arau*, "islands of the casuarina trees."

The Arru Islands are under Dutch authority, being visited periodically by the officials from Banda. They are inhabited by a negro race, bearing more resemblance to the northern tribes of Australia than to the Papuans of New Guinea, but they seem to have acquired more civilization than is usual with this race. Many strangers, Malays, Javanese and others from Celebes and the Moluccas are settled among them. They are vigorous traders, mother-o'-pearl shells, trepang, birds' nests, and tortoise-shell being the chief articles. The islands are of limestone formation, and the land rises from an elevation scarcely above the sea-level to the eastern side. The shores abound in

caverns, the resort of the swallow which builds the esculent nest. They are covered with tall trees, the casuarina being prominent among them.

The land is only a few feet higher than the level of the sea, except in spots where patches of limestone rock rise to the height of about 20 ft. ; but the immense trees which cover the face of the country give it the appearance of being much more elevated. Most of the islands consist of fresh-water swamps, and the jungle is so thick that it is seldom penetrated by the natives ; the communication between the different villages, all of which are erected on the sea-shore, being carried on by means of boats.

The produce of the Arru Islands consists chiefly of pearls, mother-o'-pearl, tortoise-shell, birds of paradise, and trepang ; but the trade of *Dobbo* on the N.W. side does not entirely depend upon the produce of the Arru Islands alone. The Bugis prahus import large quantities of British calicoes, iron hardware, muskets, gunpowder, &c., from Singapore ; to obtain which, Dobbo is visited by natives of Ceram, Buru, New Guinea, and all the adjacent islands, it being the only spot in this part of the world where British manufactures can be procured. The tortoise and mother-o'-pearl shells, ambergris, birds of paradise, ebony, cloves, massay-bark, rosamald, an odoriferous wood, and kaya buku, a wood much prized in Europe for cabinet work are obtained here. British calicoes and iron are the only articles taken in exchange for these by the prahus of New Guinea.

Of the timber of the Arru Islands there are several varieties highly spoken of by the Bugis, who build and repair prahus here, for its durability and ease with which it is worked. Although of immense size, the trees are almost invariably sound, and as they can be felled within a few yards of the beach, it is not impossible that timber may at some future time form a valuable article of export.

The western islands of this group are thinly inhabited. The eastern islands are said to be more thickly inhabited ; the natives appear to be a harmless race, and although their country in produce is so rich, the greater portion are in a state of poverty. This is to be attributed to the inconsiderate use of spirituous liquors, large quantities of which are brought by the traders from Java and Makassar ; indeed, with rice, it forms the bulk of their cargoes.

Weather.—From native report, the S.E. monsoon commences at the Arru Islands about the beginning of May, and lasts until the end of August or middle of September ; light winds then prevail to the middle or end of November, when the N.W. monsoon sets in. The rainy season is during the N.W. monsoon, but there is rain on every day of the S.E. monsoon. The finest months are September and October, when but little rain falls. This account of the weather agrees with that given by the missionaries of Redscar Bay, New Guinea.

Ngor Island is the southernmost of the group, its South extreme being in

lat. $7^{\circ} 10'$ S., long. $134^{\circ} 23'$ E. The North part of this island was the first land sighted by H.M.S. *Challenger* in approaching from the southward. *Batu Goyang* and *Krei Islands* to the N.W. of Ngor, between it and White Rock, could not be seen in their assigned positions.

Trangan Island, forming the S.W. land of the group, is low and flat; the only elevations on its western side are a small wooded, flat-topped hill (S.W. hill) conspicuous from the southward, in lat. $6^{\circ} 49'$ S., long. $134^{\circ} 8\frac{1}{2}'$ E.; and a low summit (North Hill) but slightly higher than the surrounding land, and conspicuous only from the westward. It is in lat. $6^{\circ} 40'$ S., long. $134^{\circ} 6'$ E.

Close off the South point of the island are two small islets, the southern one, *White Rock*, in lat. $6^{\circ} 58'$ S., long. $134^{\circ} 13'$ E., is bare, about 20 feet high, and shows white when seen against the green background. The other islet has a few scattered trees upon it.

The South point of Trangan Island is not remarkable, but just East of it are some very conspicuous red cliffs. From the South point the western coast of the island trends N.W. for 2 or 3 miles to a bare point, where, turning northward, it forms a bay. Upon the western bluff point (Red Patch Point) of this bay is a red patch, by which it is easily distinguished. Its extremity is in lat. $6^{\circ} 51\frac{1}{2}'$ S., long. $134^{\circ} 4\frac{1}{2}'$ E., and it was seen from the north-westward at a distance of 18 miles.

The coast northward of Red Patch Point is low and flat, as far as the N.W. point of the island next South of Maika Island, which seemed to end abruptly with the trees growing to its outer extremity, and it is easily recognized. About 5 miles southward of this point, is an apparent bluff that stands out from the dead level of the trees, and is the only prominent object northward of North Hill.

Maika and Babi Islands are both flat and thickly wooded; they were seen at a distance of about 15 miles.

Blackburne Shoal, lying W.S.W. 8 miles from Red Patch Point, is about 1 mile in extent, and upon it there appeared to be as little water as 6 ft., with shallow water to the north-eastward. The outer part of the shoal is in lat. $6^{\circ} 54\frac{1}{2}'$ S., long. $133^{\circ} 57'$ E.

From 10 miles S.W. of the South point of Ngor Island to the Blackburne Shoal, the soundings varied from 19 to 12 fathoms; northward of the shoal the depths were from 7 fathoms to 13 fathoms W.N.W. 13 miles from North Hill, after which the water deepened to 35 fathoms. Off the N.W. point of the island next South of Maika Island, 10 fathoms were found N.W. $4\frac{1}{2}$ miles from the point, when the depth rapidly increased to 40 fathoms, and 45 fathoms 8 miles West of Maika Island. Ten miles W.S.W. of Babi Island no bottom was found at 150 fathoms, and there are 58 fathoms 3 miles W.S.W. of the N.W. point of Wama Island. Westward of Dobbo

Harbour the water deepens rapidly, when Babi Island opens of Wama Island.

Kobroor Island, the central one, is the largest, and is 55 miles long. Off its N.W. end is *Wokan* or *Wokam*, off the S.W. side of which is *Wama* on the North shore of which is Dobbo, the chief trading port.

Dobbo Harbour is formed by the channel between *Wckan* and *Wama*. The village is in lat. $5^{\circ} 47'$ S., long. $134^{\circ} 14'$ E. Mr. Hill, R.N., of H.M.S. *Britomart*, gives the following.

The native traders found at Dobbo from the northward, generally prefer making the small island of *Babi*, lat. $5^{\circ} 52'$ S., long. $134^{\circ} 10'$, after getting hold of which a N.N.E. course is steered for the N.W. point of *Wama*, distant $6\frac{1}{2}$ miles, and may be known by a native village and a small Dutch fort.

Vessels bound to Dobbo from the southward, when in the parallel of $6^{\circ} 8'$ South, and long. $134^{\circ} 4'$ East, with 11 or 12 fathoms of water, will find a deep opening to the eastward, and a little more to the northward will be seen the island of *Babi*, which is low. Having reached the N.W. end of *Babi*, and being 4 or 5 miles to the westward of it, steer N.E. or more easterly, until you see the village and fort of *Waula*, on the N.W. point of *Wama*.

Water may be procured at the point, by sinking a cask a few feet deep, but it is not very good from the stream. The native chiefs of the islands of *Wama* and *Wokan*, who have both gold-headed sticks with the Dutch arms on them (as a symbol of authority), expect a trifling present of arrack and tobacco from vessels visiting the harbour.

The following is by Commander Tizard, who was here in H.M.S. *Challenger* in September, 1874. Steering into Dobbo Harbour with the end of the spit upon which the village is situated, bearing E.S.E., a depth of $5\frac{1}{2}$ fathoms was obtained when the rock off the N.W. point of *Wama* Island bore S. by W.; and $3\frac{1}{2}$ fathoms, with the spit end bearing E.S.E. and the rock bearing W. $\frac{1}{2}$ S.; from which it was inferred that the 3-fathom line extends farther from the shore than has been hitherto supposed.

The *Challenger* anchored in 16 fathoms, with the rock off the N.W. point of *Wama* Island bearing West, the western point of *Wokan* Island N.W. $\frac{1}{2}$ N., and the end of Dobbo Spit S.S.E. $\frac{3}{4}$ E. Fishing stakes were seen in various parts of the harbour, stretching from the shore nearly to the edge of the reef.

The native estimate of the number of inhabitants in the village of Dobbo was 300, in September, 1874, principally Bugis from the southern part of Celebes; but during March the number is said to be increased to as many as 1,500, by the crews of large trading proas from the Makassar coasts, which carry from 30 to 40 men each.

Supplies are scarce, and consist of a few fowls, eggs, and fish. Upon the

islands of Ougia and Wassia there are deer, a pair having been originally placed upon each island by the Dutch.

Alligators are said to abound on the islands, particularly in the swamp at the back of Dobbo.

The principal exports are trepang, pearl-shell, birds' nests, tortoise-shell, and birds of paradise. The price of pearl-shell is 2s. per lb., tortoise-shell 15s. per lb., and birds of paradise are sold to the Chinese traders by the natives for 2 dollars each. The coin used is the Dutch dollar at 4s. 2d., and the rupee at 1s. 8d. Gold, particularly sovereigns, is eagerly accepted.

Tides.—From observations obtained at Dobbo (in September, 1874) it would appear to be high water, full and change, at about 2^h 30^m. Springs rise 6 ft., but the time of high water is uncertain. The flood stream in Dobbo Harbour comes in from the eastward, and the ebb stream from the westward. In the S.E. monsoon the flood is weak, but the ebb runs from 1 to 1½ knot an hour.

Having to run in or out, great attention should be paid to the tides. If turning in with the flood, and standing towards the southern shoal, you should tack the first shoal cast, as the tide sets strong over that bank; in turning out with the ebb, the same attention should be paid to the northern shoal, as the ebb sets strong over that bank. The people of Wama profess to be pilots, but those seen by the *Britomart* did not appear to be the least trustworthy or of any use.

Coal Store.—A Dutch coal store on the East end of Wama Island was visited. The coals, estimated at 300 or 350 tons, were in a shed 90 ft. long by 30 ft. wide, and 20 ft. high, and close to the beach, which appeared steep-to. Boats can probably load at any time of tide, and a vessel approach within a half or 1 mile of the beach upon which the shed stands.

A passage or strait about one-quarter of a mile wide, was found running in an easterly and westerly direction through the islands, winding slightly. From its western entrance, which may be distinguished by a small rocky islet on the southern side, the North point of Maika Island bore W. ¼ S., the right extreme of Babi Island N.W. ¾ W., the left extreme of Wama Island N.N.W. ¾ W., and the right extreme of Wama Island N. by W. ¼ W. In the centre of the passage were found depths of 4 and 5 fathoms.

The island North of this strait is named by the natives Wokan, who stated that it was part of the island forming the North side of Dobbo Harbour.

The island South of the strait (Kobroor) was called Wanembai. The inhabitants were numerous and friendly, and cultivate plantains, cocoa-nuts, sugar-canes, pine-apples, &c., in patches of partially cleared ground enclosed by rough rail fences. The land is greatly diversified by hill and dale, although from the sea it appears perfectly flat, but it seldom rises to more than 100 ft. in height.

Each house contains 10 or 12 families, the space being partitioned off by

boards a foot high into divisions about 6 ft. square, each portion being the residence of a family.

It was also said that at an island named Gomo Gomo, at the back of Koproor, and two days journey from Dobbo, goats and an abundance of poultry might be procured.

The high mountains of Great Ki, which rise to a height of about 3,000 ft., are visible before Dobbo Harbour is lost sight of.

The northernmost point of the Arru Islands is in *about* lat. $5^{\circ} 20'$ S., long. $134^{\circ} 40'$ E. 60 miles distant from the coast of New Guinea.

The **KI** or **KEI ISLANDS** are 70 miles westward from Dobbo, in the Arru Islands. The name, which has been variously spelt as above, or *Key*, *Kii*, or *Ky*, perhaps means island or the tribes which inhabit them, as it is prefixed to most of the places on them. The Ki group consists of two large islands, called the *Great* and *Lesser Ki*, and a number of smaller ones lying to the N.W. of the latter. The Great Ki is about 40 miles long, high and mountainous; but the Lesser Ki is nowhere more than 50 ft. above the level of the sea. The natives of the islands differ very considerably, both in personal appearance and in language, from those of the Arru Islands, and are evidently the same race with that inhabiting the Serwatty and Timor Laut. During the stay of the *Britomart* at Ki the inhabitants maintained the high character they have acquired for industry and hospitality to strangers. The population is between 8,000 and 10,000.

H.M.S. *Challenger* left Dobbo on the 23rd of September, 1874, and reached Little Ki Island the following evening, having obtained two soundings between the groups of islands in 800 and 580 fathoms, green mud. As the largest island of the group was approached, several boats full of natives boarded the ship, but as they were all more or less afflicted with skin disease, they were soon cleared out. On anchoring at Ki Doulan this malady was found not to be so prevalent. The Rajah and numbers of natives visited the ship. The chief trade of the place is boat-building, for which they are locally famous. The natives are an active race, as they proved by running over the rigging like cats, in a manner that could scarcely be imitated by the seamen themselves. None of the women were to be seen; being Mohammedans, they are naturally and religiously jealous of them, and kept them out of sight. Some fine pigeons, weighing two pounds each, were taken.

Great Ki, as before said, is about 40 miles long from N.N.E. to S.S.W., and is not more than 6 miles across where broadest. Its South point is in lat. $5^{\circ} 56'$ S., long. $132^{\circ} 53'$ E. At 8 miles from this, on the East side, is a small harbour, *Hier*.

The North point of Great Ki Island is bluff and readily distinguished; its extreme was found to be in lat. $5^{\circ} 16' 45''$ S., long. $133^{\circ} 10' 45''$ E. On the East and West sides of the point are small bays, in which huts were seen, and probably anchorage may be found in them,

The N.E. point, lying S.E. $\frac{1}{2}$ E. 2 miles from the North point, is low and sandy, with casuarina trees growing upon it. Off the point are two small islets, the outer being about 40 ft. high. From the N.E. point, the eastern coast of the island runs to the southward for 3 miles, and then, receding to the westward, forms a small bay, on the South point of which is the village of Ali Bandang; whence the land extends about S. by W. $\frac{1}{2}$ W. to a conspicuous point in lat. $5^{\circ} 34' S.$, long. $133^{\circ} 8' E.$

The N.W. point is W. by S. $\frac{1}{2}$ S. 2 miles from the North point, and off it there is a detached rock 30 or 40 ft. high. The western side of the island is nearly straight in a S.S.W. direction for a considerable distance, without any conspicuous object on its shores.

The whole of the island is mountainous, the range traversing its centre and sloping down on either side, the peak at the North end being 2,200 ft. high.

Little Ki Island in reality consists of three low wooded separate islands, each about 10 or 12 miles long North and South, and 5 to 8 miles wide; the two eastern of these are separated from the southern part of the Great Ki Island by a strait varying in breadth from 6 miles at its southern entrance to 12 miles in its northern. In the South part of this strait, 10 miles North from the South end of Great Ki Island, and 5 miles off one of its projecting points, is an extensive shoal. *Hogian* is the southern of the Little Ki group, and is separated from Ki Doulan to the northward by a narrow strait. To the westward of Ki Doulan and *Hogian*, and separated from them by a narrow strait, is Letman Island, on which is a hill 200 ft. high at its N.E. end. Between the North side of Letman and the West side of Ki Doulan are three large and numerous smaller islands and rocks.

Ki Doulan Harbour.—N.W., 8 miles from the North point of Ki Doulan Island, is *Ramadan Island*, $1\frac{1}{2}$ mile in diameter, and midway between is another small island, which forms the West side of entrance to Ki Doulan Harbour, the North point of Ki Doulan forming the eastern side of the entrance. Doulan Laut Island, with a shoal off its eastern point, is about 2 miles in diameter, and shelters Ki Doulan Harbour on its western side. Commander Tizard, who visited the harbour in H.M.S. *Challenger*, in Sept., 1874, gives the following information:—

Ki Doulan Harbour was not readily distinguished from the north-eastward, from the similarity of the two outer islands, Pulo Ramadan and Pulo Bandang, each having a small islet off its S.E. side.

There is a small summit about 200 ft. high upon the South point of Pulo Oboor, called Buket Krain, and another, Buket Kalamit, of about 250 ft., upon the main shore of Little Ki, S.S.W. $3\frac{1}{2}$ miles from Buket Krain.

The first anchorage of the *Challenger* was off the village of Tamandam on the North point of the harbour, with Tranjong Serbat bearing E. $\frac{3}{4}$ S., Buket Krain S.S.W. $\frac{3}{4}$ W., and the East extreme of Pulo Bandang N.N.W. The

second anchorage was in 19 fathoms, off Ki Doulan village, a quarter of a mile from the shore, and about a cable from the edge of the shoal water, with the mosque at Ki Doulan bearing East, Loobi Rock S.W. by S., and the left extreme of Doulan Laut W. $\frac{1}{2}$ S.

From the village of Ki Doulan a wharf or jetty, built of loose coral stones, extends off to the edge of the shoal water. A few fowls and eggs, cocoa nuts, and a small quantity of pumpkins and plantains were procured. Some fine pigeons weighing about 2 lbs. each were also shot. Sago palms grow upon the island, and supply the staple food of the natives.

One day's observations (September 25th), at full moon, gave the time of high water, full and change, at Ki Doulan Harbour, at 1^h 26^m. Springs rise 7 ft. The same report as to the winds and weather was given at Ki Doulan as at the Arrou Islands.

Southern Channel.—A deep channel, was found from the harbour westward, South of Doulan Laut Island, by which the *Challenger* proceeded to sea. Between the reef off Doulan Laut Island and the reef westward of Pulo Oot 9 and 10 fathoms were obtained upon what seemed to be a ledge joining the two reefs; westward of this the water deepened rapidly, and 90 fathoms was obtained between the N.W. point of Little Ki Island and the islet of Pulo Gadang.

Margaretha Harbour.—According to Count Lovera di Maria, commanding the Italian vessel of war *Vettor Pisani*, 1872, is situated about 5 miles to the southward of Ki Doulan Village, on the West side of Ki Doulan Island, is a capacious and well-sheltered harbour formed by Ki Doulan, Letman, and Oboor Islands; the best anchorage is off Tuallah Village, in 7 to 11 fathoms good holding ground.

The passage leading from Margaretha Harbour to the southward, between Letman and Ki Doulan, is about 1 $\frac{1}{2}$ miles in length, and from 1 to 3 cables wide, with depths of 2 $\frac{1}{4}$ to 2 $\frac{3}{4}$ fathoms.

Vessels entering Margaretha Harbour from the northward should steer in with Buket Kalamit (197 ft. high), in line with Buket Krain, bearing S.W. $\frac{3}{4}$ S., until Loobi Rock bears East, whence a S. by W. course for 3 $\frac{1}{2}$ miles will lead to the anchorage off Tuallah.

The **ARAFURA SEA** is the area southward of the foregoing islands, between them and the North coast of Australia. There is nothing to describe in it, more than information given by the charts. The only dangers or shoals in the open sea are the *Victoria Shoal*, lat. 9° 13' S., long. 131° 22' E., a doubtful position, and the *Lynedoch Bank*, discovered in the ship of that name, Captain W. Stead, October 26th, 1838, in 9° 55' S., long. 130° 40' E. The latter had 13 to 7 fathoms least water when found, three-quarters of a mile long, and composed of *coral*, which may have grown up to a less depth than the above.

The *Money Shoal*, 27 feet, is another small detached spot, lying 62 miles

N.E. from the entrance of Port Essington, lat. $10^{\circ} 19' S.$, long. $132^{\circ} 47' E.$ These appear to be all the shoal spots which have been found.

The depth of the Arafura Sea increases from 20 to 30 fathoms, on the meridian of Cape Valsche and Cape Wessel to 450 fathoms off the South end of Timor Laut. From Melville Island, in Australia, to the latter, the depths also appear to gradually increase.

One feature of this sea, which has been frequently noticed, is the quantity of fish spawn, or of microscopic animalculæ, which discolour its waters. It being the highway to India from New South Wales, viâ Torres Strait, it has become of more importance since that important channel has been well surveyed, and thus opened to commerce. Captain Henry Toynbee passed through it in his well known ship the *Gloriana*, in September and October, 1855. He notices the discolouration of the water from animal life.

September 27, 1855.—At noon this day the sea was all shades of yellow, blue, and green, caused by what I suppose to be fish spawn; it had a fishy smell, and its shape, when seen through a small microscope, was like that of grass seed.

29th.—Much fish spawn was seen again to-day; in some parts it was quite dark enough to be mistaken for a sand-bank; it floated in lines pointing in the direction of the wind.

In conclusion he says—I have little to say on our passage through the Arafura Sea. Most of the reported dangers are under water, and we found none of them. We had soundings of 15 fathoms about 50 miles to the westward of Booby Island; 27 fathoms forty miles further to the West; and 38 fathoms seventy-five miles further; then the depth decreased to 29 fathoms at the spot where we passed the line between Wessel Island and Frederick Henry Island. From this point it gradually increased again, so that it is probable that a line of less soundings connects these islands. We averaged 109 miles per diem through this sea, which quite equalled my expectations, and were in $11^{\circ} S.$, on the meridian of Cape Leeuwin on our thirty-third day from Sydney. Thence we gradually increased our southing until we were in lat. $13^{\circ} 51' S.$, where we had a good S.E. trade. On the 18th of October we were in $10^{\circ} S.$ lat. and $90^{\circ} E.$ long; and between the 25th and 26th we crossed the line, in $87^{\circ} E.$ On the 5th of November we anchored at the Sandheads.

To the westward of Little Ki Island are several clusters of small islands. H.M.S. *Challenger*, in September, 1874, passed among these islands in proceeding towards Banda from the Ki Islands, and found the charts most inaccurate. Many islands were not marked at all. We give below the information gained.

In about $6^{\circ} S.$ and $132^{\circ} 30' E.$, or 15 miles S.W. by W. from the S.W.

end of Hagian Island of the Little Ki group, is an island, and several lie northward of it, at 8 or 10 miles westward of Little Ki.

The Tionfolokker Group consists of three large and four small islands with a few outlying rocks. They lie in a N.E. by N. and S.W. by S. direction, and extend over about 20 miles in length, and about 8 miles in width. The south-westernmost island is 550 feet high and round-backed; its southern point is in lat. $5^{\circ} 47' S.$, long. $132^{\circ} 9' E.$

The other islands are low and flat, but covered with trees, and they can be seen at a distance of from 12 to 15 miles.

A reef extends for 3 miles southward from the two islands lying north-east of the high south-western island of the group; on the edge of this reef are some rocks which are always above water. No other dangers were seen, but vessels should not venture amongst the islands.

Three Brothers Islands.—This group of three islands occupies a triangular space, the apex of the triangle being to the southward, and its sides are from 6 to 7 miles in length.

Ta Island, the southernmost, is round shaped, about one mile in diameter, and 390 ft. high; its South point is in lat. $5^{\circ} 42' S.$, long. $131^{\circ} 54' E.$ The island appeared to be inhabited.

Dol Island, the north-eastern and largest, is low; it is $1\frac{1}{2}$ mile long in a N. by W. and S. by E. direction, and nearly one mile in width; its southern point in lat. $5^{\circ} 37\frac{1}{2}' S.$, long. $131^{\circ} 58\frac{1}{2}' E.$, is N.E. $\frac{1}{2}$ N. 6 miles from Ta Island.

Onelin Island, the north-western of the group, is also low, but covered with trees; it is round and about half a mile in diameter, and is in lat. $5^{\circ} 36\frac{1}{2}' S.$, long. $131^{\circ} 53\frac{1}{2}' E.$

Each island is fringed with a coral reef which did not appear to extend far from the shore; and the passages between the islands seemed free from danger.

Nusa Tello Islands lie to the North of the Three Brothers. The southernmost of them is *Kanalur Island*, 5 miles long, in a N.E. and S.W. direction. No dangers were observed eastward of the Three Brothers Islands, or between that group and Kanalur Island. It has an islet off its N.E. extreme, and rises to the summit in a succession of beach-like terraces. The peak, which is 1,600 ft. high, is in lat. $5^{\circ} 20\frac{1}{2}' S.$, long. $131^{\circ} 57' E.$, and it was seen from the southern entrance of Ki Doulan Harbour. The island is probably inhabited as smoke and cocoa-nut trees were seen upon it.

At 8 miles northward of Kanalur is *Kandar*, a smaller island; and 5 miles northward of this is *Boen*, with two small islets within 2 miles N.E. of it. *Toppers Hoedje* is marked P.D., at 10 miles N.E. by E. of Boen, as is also *Little Fortune Island*, 9 miles N.N.E. of Boen.

Toa or *Tehor Island* is 6 miles long North and South, and 3 miles wide at

its North end. Its South extreme is in lat. $4^{\circ} 50' S.$, long. $131^{\circ} 46' E.$ At 6 miles E. by N. of this point is a small islet.

Matabella Islands.—The group is hilly and rocky, and the South extreme of the Matabellas is a small table hill. *Kassuwi* or *Corsair* is the central and largest of the Matabellas; it is 6 miles long N.W. and S.E.—its South extreme being in $4^{\circ} 30' S.$, $131^{\circ} 40' E.$ At 5 and 7 miles S.E. by S. from this point are two small islets, called the *Bare Islets*. *Kukar*, another small islet, lies 6 miles East of them. Separated from the North extreme of *Kassuwi* by a strait $1\frac{1}{2}$ mile wide are *Watubella* and *Ingar Islets*, joined by a bank, and extending 6 miles in a N.W. and S.E. direction.

GORAM ISLES are three in number, and are separated from the Ceram Laut group to the N.W. by a narrow channel. They are distinguished by the natives as Goram, Manovolko and Salawatta or Soeroeaki, or Salavako. They are rather high, and very fertile. Rice is only grown on the main island, as that is considered to be an hereditary right.

Goram is the easternmost; its S.E. point is in lat. $4^{\circ} 3' S.$, long. $131^{\circ} 28' E.$, and it is about 9 miles long. It has the largest population, and most trade of the group. The people resemble those of Ceram, and being well acquainted with the neighbouring coasts, willingly go on board foreign trading vessels as pilots. Coin is unknown, cotton twist being the best object to barter. There is a small harbour, called *Onдор*, in the reef on the N.W. side of Goram, which is the chief trading place. Between the two coral reefs which form it there are 16 and 18 fathoms. Going northward by keeping the Matabellas their own breadth open of the West entrance of Goram, will lead outside of them. A N.E. by E. course leads in, and the channel can be seen, but a gun fired will bring a pilot off. When you have entered, bear more to the northward, and come to off a stone pier in 10 fathoms. Fowls, fruit, and sago can be procured. There is a clear passage between the two western islands, and also between the N.W. island and Ceram Laut. There is another harbour, open to the East, near the S.E. point, called *Kailakat*.

CERAM LAUT, "Ceram to sea," lies off the S.E. end of Great Ceram, and is a cluster of islets lying on one coral reef, 15 or 18 miles long, which, as usual, is very shoal on its edges, and drops at once into deep water. The western island, which is the largest, is high and hilly, and, according to Captain Kolff, has an exceedingly high tree on it, under which the chiefs of *Kilwari* are interred, and which forms a good land mark for seamen. Lat. $3^{\circ} 50' S.$, long. $131^{\circ} 0' E.$

Kilwari, or *Kaliwaru*, is a small sandy island overspread with houses, on the N.W. side of Ceram Laut, to which it is joined by a sand-bank. The two villages are under the native rajah to the East, and the other a small portion to the West under a Dutch commander, and are separated from each other by a stone wall, 6 feet high and 2 feet thick, a similar defence surrounding

the island. Coral reefs extend for a considerable distance from the island, but boat landing may be effected in a bay on the North side. The people are of the Malay race, and are chiefly fishermen, and take considerable quantities of tortoise-shell and trepang, which with other articles are largely collected and bartered here.

Ghissa or *Gesir* is a low, sandy, uninhabited island, surrounded by a reef off Kilwari, the channel between being narrow, but said to be safe.

The **Keffing Isles**, two in number, lie close to the S.E. extreme of Ceram, and are connected with it by sunken reefs. *Little Keffing* is well peopled, each village being governed by a separate rajah. The East point is in lat. $3^{\circ} 52' S.$, long. $130^{\circ} 53' E.$ The island is low, and the groups of huts among the cocoa-nut trees have a very picturesque appearance. To the East of these islands and the reef which surrounds them, there is a small island, with a deep channel between.

CERAM, one of the largest islands of the Malay Archipelago, is 162 miles long East and West, and about 40 miles across where broadest. A chain of mountains runs through its eastern length, so that it may be said to consist of one cordillera, some of the peaks of which rise to the height of 6,000 to 8,000 ft., and one of them, *Nusa Heli*, to 9,250 ft. It has no active volcano or extinct crater, as far as is known, and has no good harbour on either shore, except that of *Amahai*, North of the Amboina group. The whole island is covered with one stupendous forest, but generally of useless timber. The coasts are occupied with an enterprising race of Malay fishermen, who vigorously collect tortoise-shell and trepang from as far as New Guinea and Australia. But they are a wild and untractable people, who, though they may be hospitable to Europeans who visit them to their profit, are inveterate head-hunters, and live in constant feuds. They should not, therefore, be trusted. The island, as a whole, is very thinly inhabited. A small portion of its East end, *Tobo*, is under, nominally at least, the Dutch Residentie of Banda; the rest belongs to the Residentie of Amboina.

On the North coast of Ceram, during the East monsoon, the weather is fine with regular land and sea breezes. The West monsoon is the wet and squally season, although it brings fine weather at Amboina, a very singular exception; but at Ceram the West monsoon is the rainy and squally season, in conformity with its general character everywhere else in these seas from December until April. The wind is frequently fresh from West and W.N.W. during the day, dying away towards night, and veering to the W.S.W. with a light breeze in the morning.

Waru Bay, on the eastern coast of Ceram, has anchorage off the village, which is in its southern part, in lat. $3^{\circ} 26' S.$, long. $130^{\circ} 45' E.$ It affords good anchorage, where water and other refreshments may be procured. For 5 miles eastward of this village the water is foul from the coast, and there is also a small shoal 5 miles W.N.W. of it, the anchorage lying between these

reefs. N.N.E. 10 miles from Waru is Parang Island, dangerous to approach, and having a reef 2 miles off its West end. *Semgum*, or *Lengowa Point*, is 22 miles northward of Waru; and at 10 miles N.W. from Semgum Point is Lama Point, at 22 miles westward from which is the anchorage in Kobie Bay, a small bay, sheltered by the land from winds between S.E. and West. Leuwarden Reef, the West end of which is 7 miles E. by N. from Lama Point, is 2 or 3 miles in extent, and *very dangerous*, the West side being a white sand-bank, and the eastern side a ledge of rocks, some above water. There are no soundings near it, nor in the channel inside it, which is considered to be safe.

Wahaay Bay.—The fort at the head of this bay, according to the Dutch charts, is in lat. $2^{\circ} 45' 30''$ S., long. $129^{\circ} 30'$ E.

It was visited by Captain R. L. Hunter, in the *Marshall Bennett*, in 1840. He says it is something to the westward of the situation assigned to Flat Point of the charts. Wahaay, however, is at no point, nor is the land near it at all remarkable for flatness; in fact, the houses are on the rise of a hill of some height. It presents from the offing a straight coast, therefore it is necessary in running for it to keep within 4 or 5 miles of the shore, that the houses may be seen; the adjoining land also appears more cleared here than elsewhere.

Wood here is plentiful of all kinds, large or small, for spars, plank or any purpose, and excellent water near the ship, and very convenient.

For refreshments a tolerable supply of fowls can be procured, and we obtained sweet yams enough to supply all hands daily during our stay. Pine apples and plantains are plentiful. Fish frequently are in abundance, and sometimes wild deer. Pigs, goats, sheep, and ducks, are scarce and expensive.

Close to it on the western side is a similar but larger opening in the reefs; at the head of the bay, which it leads to, is a village called *New Hatiling*. There is a shoal in the middle of the bay; the anchorage is inside this.

It is high water on full and change days at 6 p.m., only one tide in 24 hours, and the rise 8 ft.

Sawaai Bay is in lat. $2^{\circ} 51'$ S., long. $129^{\circ} 9'$ E. *Tanjong Para* forms its western point; it is low, and has several small islands surrounded by shoals, the outer one named *Pulo Basar*, lying 2 or 3 miles off. There are also some islands and shoals in the S.E. part of the bay. The channel into the harbour or road is to the westward of the latter, by steering South for a mount called the Friar's Hood, at the bottom of the bay, near the village *Selema*; and having rounded the reef and islands fronting the road, haul along shore to the eastward, and anchor near it, with *Pulo Atui*, the westernmost island, bearing North. The water is deep, 40 to 25 fathoms, but it is good anchorage, in the S.E. monsoon, bottom mud.

Ella Island and shoals, 5 miles in extent, lie off the western entrance of Pha Point.

Cape Talanuru is the N.W. extremity of Ceram, and is in lat. $2^{\circ} 52' S.$, long. $128^{\circ} 11' E.$ From this the western part of Ceram trends off to the S.W. and South for 45 miles in a long irregular peninsula, in a similar manner to Amboina, Saparua, and other volcanic islands in the neighbourhood, and as is seen on a much larger scale in the singular forms of Celebes and Halmaheira.

Bonoa, an island of about 12 miles long, with a reef off its northern end, lies off this N.W. part of Ceram, forming *Bonoa Strait*, 5 miles wide in its narrowest and S.W. part. It is quite clear on the North side, but the Ceram coast is skirted by a series of islets and rocks, which require care. *Ada Reef* lies 3 miles West of the West extreme of the North coast of Bonoa.

The islands which lie between this and Bouro, forming the East side of the Bouro or Manipa Strait, have been mentioned on pages 823-4, *ante*.

The South Coast of Ceram has but few particulars to interest the seaman. It is deeply indented by the different bays at its western end. *Seal Point*, its S.W. extreme, is the end of the long peninsula above mentioned, and 4 miles North of the *Three Brothers*, which lie off the N.W. end of Amboina. *Piero Bay*, 28 miles wide, penetrates the S.W. part of Ceram, opposite to Amboina, and thus forms a wide portion of the strait limited to the South by Amboina and the islands East of it.

Amahai Bay, East point, is 30 miles N.E. by E. from the N.E. point of Saparua. The bay extends in an E.N.E. direction for 23 miles, and on the North side of its eastern point is a secure anchorage called *Amahai Roads*. It was surveyed in 1862 by Lieut. Koning. The outer bay is named by the natives *Elpapoetie Bay*, and in the centre of it there are no soundings, and the shores are very steep-to.

The Inner Bay is limited by *Tanjong Koeakho* on the West, of moderate height, and on the East by *Tanjong Mapoei*, higher, and covered with trees. At the head of the bay is the small village of *Amahai*, where there is a small Dutch fort and garrison, the flagstaff of which is in lat. $3^{\circ} 19' 30'' S.$, long. $128^{\circ} 56' 7'' E.$ It is high water at noon, and the rise is 3 ft. In coming in, you may pass round Point Koeakho within a ship's length, and avoid the reef which projects from the eastern side nearly two-thirds over, and may be seen by the colour of the water. There are some bamboo stalks on it, and there is sometimes a bathing-house. Anchor with Point Koeakho bearing N.W. by W., and Point Mapoe N.N.E., the cupola on the reef N. $\frac{3}{4}$ E., and the flagstaff of the controller's house E.S.E. $\frac{3}{4}$ E. in 8 fathoms with 40 fathoms of cable.

WESTERN PART OF THE ISLAND OF NEW GUINEA.

The COAST of NEW GUINEA, which fronts the Molucca Islands, is chiefly known to us from the voyage of Lieut. Kolff, in 1826. We take the following from the extracts made from his work by Mr. George Windsor Earl. It is very much out of the way of the ordinary track of ships, and is never visited by European vessels for trade, and will therefore need but few remarks. Should the Dutch Government act on the knowledge recently acquired of this fine island (the greatest area of the world now entirely unknown, with the exception of a portion of Africa) there may be a necessity for further nautical information on it. The eastern part of the island, including the discoveries of Captain Moresby, in H.M.S. *Basilisk*, during the years 1873-4, are described in the South Pacific Directory, chapter xix.

FREDERIK HENDRIK ISLAND, on the S.W. coast, is about 100 miles long, separated from the mainland by *Prinses Marianne* or *Dourga Strait*, first determined to be a channel in 1835. The island is everywhere low, apparently marshy, and covered with a dense forest. The entire South coast is fronted by a mud-bank, extending about 8 miles out to sea, having 3 fathoms on its verge, from which the depth rapidly increases to 9, 14, and 27 fathoms. About 50 miles to the N.E. of Cape Valsche the mud-bank begins to decrease in breadth, so that vessels are enabled to approach the shore.

Cape Valsche, or False Cape, according to Lieut Kolff, is in lat. $8^{\circ} 22' S.$, long. $137^{\circ} 40' E.$ The northern part of Dourga or Prinses Marianne Strait is about 15 miles wide, the eastern part being in lat. $7^{\circ} 23' S.$, long. $138^{\circ} 54' E.$, and there was no danger discovered by the Dutch ships in beating through. On the North side of the strait, about 5 miles within the entrance, is a creek, within which the water is fresh at three-quarters ebb, but difficult to be got on account of the hostility of the natives, who should be avoided on all occasions.

The coast from the entrance to the strait extends in a N.N.W. direction to the *False Utanata River*. The land is low and covered with forest, and a mud-bank, which lines the shore, prevents approach within from 4 to 8 miles. The coast is thickly peopled by inhospitable natives.

The *Triton Sandbank*, the South side of which is in lat. $6^{\circ} 0' N.$, long. $138^{\circ} 4' E.$, lies 23 miles off shore, and has 10 fathoms, mud, immediately to the southward. *Providential Bank*, lat. $5^{\circ} 38' S.$, long. $137^{\circ} 52' E.$, has 4, 6, and 7 fathoms immediately to the South of it. It lies 18 miles from the main.

False Utanata River, in lat. $4^{\circ} 46' S.$, long. $136^{\circ} 57' E.$, is of considerable size, but a bar of sand extends across its mouth, on which, during the S.E. monsoon, there is a heavy surf. A vessel may anchor in 13 fathoms to the westward of the bar; but a strong swell from the southward, and the reefs which lie to the N.W., render this anchorage unsafe in the S.E. monsoon.

False Wakia River, 7 or 8 miles to the northward, is of a similar description. The shores of these rivers are thickly peopled, but no intercourse with them was obtained. The coast to the northward of this forms a deep bight, terminating in *Cape Steenboom*, lat. $4^{\circ} 44' S.$, long. $136^{\circ} 23' E.$, across which, in a line between the cape and the river, lie several shoals, the outermost of which lies 9 miles S.E. from Cape Steenboom.

Utanata River, in lat. $4^{\circ} 40' S.$, long. $136^{\circ} 15' E.$, is about 2 miles wide at its mouth, and is fronted by a bar, on which there is above 6 ft. at low water. The natives here were more friendly, perhaps arising from more frequent intercourse with the Ceramese and Makassar traders. To the N.W. of the Utanata lies the *Wamuka River*, lat. $4^{\circ} 39' S.$, long. $139^{\circ} 11' E.$ It is rather smaller than the former, and, like it, is covered by a bar.

Cape Buru, or *Boeroe*, lat. $4^{\circ} 28' S.$, long. $135^{\circ} 10' E.$, is a steep promontory, visible at a distance of 30 miles, with no soundings 4 miles outside. At 25 miles N.W. by W. from it is *Mount Lakahia*, near the coast, 4,526 ft. high. This is the western of a chain of mountains which thence extends inland to the eastward, and is known as the *Charles Louis Range*. At 40 miles North of False Utanata River the elevation is 11,500 ft., and at 56 miles N.E. of the same river the elevation is 14,000 ft.

Cape Perier is N.W. by W. $\frac{3}{4}$ W., 42 miles from Cape Buru, the coast between having a few small indentations. Between Cape Perier and *Cape Baudin*, 10 miles N.W. from it, is the entrance to *Etna Bay*, which is 20 or 25 miles deep. Between Etna Bay and Triton Bay, 30 miles to the westward, the coast is fronted by several islands having narrow straits between. The easternmost of these islands, named *Chausot*, is 1,600 ft. high, and lies 5 miles westward of Cape Baudin. The westernmost is named *Aidumea*; it is 10 miles long, N.W. and S.E., and forms the eastern side of the entrance to Triton Bay.

Triton Bay is an inlet extending 6 miles to the N.E. into the mainland. A chain of five small islands stretches 4 miles W.S.W. from the West point of *Aidumea*, and the fair channel lies between the outermost of these and *Semieuw*. *Fort Du Bus*, a Dutch establishment, is at the head of a small cove on the North side of Triton Bay, lat. $3^{\circ} 46' S.$, long. $134^{\circ} 3' E.$ The cove is 2 miles deep and a mile wide, having at the entrance a depth of 32 fathoms, which decreases to 5 fathoms, mud, at its head, where a vessel may moor a cable's length from the shore. The channel into the cove is close to the S.W. side, as a mud bank, nearly dry at low water, extends from the N.E. side, three-fourths of the width of the cove. High water, full and change, $1^h 8^m$; rise and fall 7 ft. Water and refreshments may be obtained here through the Dutch commandant. *Iris Strait*, the channel by which the *Triton* entered the bay, is formed by *Aidumea Island* to the South and by *Dramaai Island* and the mainland to the North. Its South entrance is 2 miles

wide, in lat. $4^{\circ} 2' S.$, long. $134^{\circ} 6' E.$, from which it stretches N.W. by W. about 6 miles. At 45 miles W.N.W. of the entrance to Triton Bay is the N.W. corner of *Arguna Bay*, which is little known.

Pulo Adi, or *Wessel Island*, which extends W.N.W. and E.S.E. about 25 miles, lies 33 miles to the S.W. of the entrance to Triton Bay. The S.E. point of the island is in lat. $4^{\circ} 16' S.$, long. $133^{\circ} 34' E.$, and W.S.W. of this point at 9 miles distant is *Vogel* or *Bird Island*, surrounded by a reef.

The *Nautilus Strait* separates Adi from the southern shore of the *Orange Nassau* peninsula, on the South side of which is *Speelman Bay*, before which lie some islets named *Buloffs* and *Karawari*. In *Nautilus Strait* the western end of *Wessels Island* should not be approached within a mile. Sunken rocks also lie at 3 miles W.N.W. and 5 miles N. by E. of this point. There is anchorage North of the N.W. point of *Wessels Island*, southward of some islands. *Plana Islands*, two in number, are 5 and 8 miles northward of the centre of *Wessels Island*. The district here is under the control in some measure of the *Mysolè* chiefs. The S.W. part of this portion of the western peninsula of New Guinea is not known beyond the coasts, which are tolerably well defined on the chart.

Cape Kaffoera, lat. $4^{\circ} 5' S.$, long. $132^{\circ} 47' E.$, is 23 miles West of *Nautilus Strait*, and here the coast is high and bold, and trends to *Cape Sapey*, 28 miles to the N.N.W. Near the shore, along the stretch of coast, the land reaches an elevation of over 3,000 ft., and no bottom was found with 100 fathoms of line at 4 miles westward of it. *Cape Kaloeman* or *Kalomuns* is in $4^{\circ} S.$, and has several islands northward of it.

Between *Cape Sapey* and *Dree Cap Peninsula*, 60 miles to the N.W. $\frac{1}{2}$ N. from it the district is known as *Charles Albert Archipelago*. *Gudin Island*, 6 miles long N.W. and S.E., is 1,200 ft. high, and has a hill at each of its extremities. *Cape Foullyoy*, 10 miles northward of it, is in lat. $3^{\circ} 17' S.$, long. $132^{\circ} 32' E.$ It is high, and has a 3-fathom patch $1\frac{1}{2}$ mile West of it. At 10 miles N.N.W. of it is *Jacobs Island*. *Gide Isles* lie to 7 or 8 miles off the S.W. part of *Dree Cap Peninsula*, and eastward of them, at 10 and 15 miles distance, are *Roze Island* and *Coster Island*.

Mc Cluer Gulf, or *Telok Berow*, is an extensive inlet, which reaches within 5 miles of the shores of the Great Geelvink Bay, almost insulating the N.W. part of New Guinea. This part is under the influence of the *Salawatti* chiefs, and, like the rest of the vicinity, is very little known. From the N.W. point of *Mc Cluer Gulf*, thus named from Lieut. *Mc Cluer*, who sailed up it in 1791, to the western extreme of New Guinea, there are several bays, but we have no hydrographical particulars of them. The natives are stated to be numerous, treacherous, and hostile.

Patippi Bay is 7 miles deep, and has its entrance in lat. $2^{\circ} 41' S.$, long. $132^{\circ} 10' E.$, facing the West. It is on the North side of *Drei Cap Peninsula*.

Wass Island, 6 miles westward of the entrance to Patippi Bay, is a small islet close to the land, and protecting an anchorage eastward of it. At 16 miles eastward of the entrance to Patippi Bay is *Segaar Bay*, with numerous islets and rocks lying N.W., North, and East of its entrance. It is high water in Segaar Bay at 6^h 30^m. Springs rise 4 to 6 ft.

The channel between this portion of New Guinea and the East end of Ceram, and the islands which trend south-eastward from it, and to northward of the Ki and Arru Islands, is apparently clear, and from 65 to 90 miles in breadth. The first island in proceeding north-westward through it is *Sabuda* or *Wonie Melat*, off the entrance of McCluer Gulf, the South point in lat. 2° 40' S., long. 131° 37' E. To the S.E. of it is a group of islets called *Pisangs*.

MYSOLE or **Misool**, a large island 45 miles long and 15 to 20 broad, is but little known, though of such considerable extent. The interior is said to be inhabited by Arafura negroes, and the coast by a mixture of the negro and Malay races. It is generally level land, and of moderate height, and the shores are lined almost all around it by a range of small islands, the outermost of which to the N.W. and E.S.E. lie many miles off. On the South side is *Efbe*, which forms a harbour, visited by Capt. Forrest in 1775, where he was well received by the inhabitants at a small village. Numerous other islets lie off the South side of Mysole to a distance of nearly 10 miles in the eastern half of the island. *Efbe*, the largest island, is in lat. 2° 5' S., long. 130° 11' E.

To the eastward of the S.E. point of Mysole a range of islets and scattered rocks extend for 14 leagues, terminating to the East in *False Pisang*—"banana-island," a common Malay term in these seas.

Off the North coast of Mysole are numerous islets and several sandbanks, only to be understood by the chart, which extend more than halfway across the channel between the island and Popa, leaving, however, a clear route 15 miles in width, and leading towards Pitt Strait.

The Kanari or *Canary Islands* lie to the N.W. of Mysole, and are an extensive chain of flat, wooded, uninhabited islands, leaving a narrow passage between some of the groups which lie close to Mysole. *Great Canary* is the westernmost and largest, in lat. 1° 49' S., long. 129° 35' E.

On this island Captain Forrest, on his voyage to New Guinea in 1775, in search of the nutmeg tree, found good water, in a pond situated on the South end. He anchored in Round Harbour, so called by him, lying between two small islands, which are at a small distance on the East side.

To the southward of those islands which front the South shore of Mysole and the North coast of Ceram the passage, which is 50 miles wide, is safe, and was partially examined by Lieutenant Brütel de la Rivière, D.R.N., in 1850.

Between Mysole and Popa are the groups, little known, called the *Vienna Isles*, and *Nosela Islands*.

FitzMaurice Shoal, of 2 fathoms, is marked in two positions northward of the Canary Islands. *Pigeon Island* is in lat. $1^{\circ} 42' S.$, long. $129^{\circ} 45' E.$, and the shoal is marked 5 miles N. $\frac{1}{2}$ W. from it, and at 10 miles N.W. from it.

In the strait between Mysole and Salwatti are several islands and dangers. *Pinon* or *West Brother Island* lies in the centre of the East part of the strait northward of the False Pisangs. There is a sand-bank N.W. 7 miles from it. *Efmatal Island*, 10 miles off the New Guinea coast, is 20 miles to the E.N.E., and N.W. 10 miles from Efmatal is an extensive sand-bank with a depth of 2 fathoms water near the New Guinea coast. *Orse Islets*, in lat. $1^{\circ} 33' S.$, long. $130^{\circ} 51' E.$, are 2 miles off the coast of New Guinea, and 10 miles eastward of the southern entrance to Galewo Strait. Vessels should not pass inside of them, as some banks lie to the East and West. *Vettor Pisani Isles*, two small islets near together, the southern, being in lat. $1^{\circ} 40' S.$, long. $130^{\circ} 29' E.$, lie in the middle of the strait midway between the North point of Mysole and the Orse Islets. A $2\frac{3}{4}$ fathom bank, *Hesketh Shoal*, was reported in 1876 as lying about $1\frac{1}{2}$ mile northward of these islets and between them and the Schilpad Isles. From it Schilpad North Island, the largest and highest of the group of that name, bore from it N. by E. $\frac{1}{2}$ E., distant 5 or 6 miles, in latitude $1^{\circ} 38' S.$, long. $130^{\circ} 28' E.$, 12 miles from the nearest part of Mysole Island. A sandbank lies 5 miles off the North shore of Mysole, W.S.W. of Vettor Pisani Isles. *Schilpad* group, six or seven small islands, lies about 5 miles northward of Vettor Pisani Isles, and a chain of islets extends N.W. from them for a distance of 10 or 12 miles. A sunken rock lies N. by W. 10 miles from the Schilpad group, and another at 15 miles N. $\frac{1}{2}$ W. from it.

POPA, *Popo*, or *Poppo*, 42 miles North of the West end of Mysole, is inhabited. Its East point is in lat. $1^{\circ} 8' S.$, long. $129^{\circ} 53' E.$ Including the adjacent islands which surround its S.W. and West sides, it is 18 miles from East to West, and 9 miles in breadth. It has two remarkable hills on its West part, which may be seen at a great distance, the one of a semi-circular form, like a beehive; the other of an oblong shape; the rest of the island being entirely flat. The group of islets off its S.W. part are sometimes called the *Tatas*. At its N.W. end is a considerable island, called *Calap* or *Kalap*. *Deception Island*, of the old charts, to the N.E. of Calap, adjoining the N.W. part of Popa, appears like four separate islands in passing along the North side of it, having four separate points, each resembling an island until they are closely approached. Close to, and among these isles which surround the western part of Pulo Popa, there are soundings, but none at 2 or 3 miles distance.

Grosvenor Bank, 5 miles in extent, with 3 fathoms least water, lies 15 miles W.S.W. of the *Tatas*, in lat. $1^{\circ} 19' S.$, long. $129^{\circ} 23' E.$

SALAWATI or *Salwatti*, a large island adjacent to the West end of New Guinea, is lofty, and inhabited by above 4,000 *Arafura* negroes. The charts will give all particulars known.

Galewo Strait, which lies between *Salawati* and *New Guinea* is only known from the examination made of it by Lieut. McCluer, who went through it in the *Panther* and *Endeavour*. It was called *Revenge* or *Watson Strait*, Captain *Watson* of the *Revenge* being the first person who went through it in 1764. It is much embarrassed by numerous small islands and shoals, and being out of the direct track of ships it is seldom or never used. At the North part of it a chain of islands stretches across from the N.E. point of *Salawati* to *Cape Spencer* on *New Guinea*. It has been called *Foul Point* by the Dutch, and reefs project from it to the N.W., and from the adjoining islands to the distance of $1\frac{1}{2}$ or 2 miles. There are soundings and various depths throughout *Galewo Strait*, and there is anchorage in many places, but at its N.W. part the water is deep very near to the shore.

The *North Coast* of *New Guinea* eastward of *Cape Spencer* is generally high, but in some places is low near the coast. A short distance inland a chain of mountains covered with trees, and from 4,000 to 5,000 feet high, extends parallel with the coast as far as the N.W. point of the *Great Geelvink Bay*.

BATANTA or *Battanta*, another considerable and lofty island, is also little known. It lies North of *Salawati*, and is separated from it by *Pitt Strait*. The island is about 30 miles long E. by N. and W. by S. *Cape Mabo*, its West extremity, is in lat. $0^{\circ} 56' S.$, long. $130^{\circ} 24' E.$, bearing N.E. by E. $\frac{1}{2}$ E. from the East end of *Pulo Popa*, 34 miles distant. Off this cape is a small but high island, *Fisher Island*, bearing from it W. $\frac{1}{2}$ N. 2 miles. *Batanta* and *Salawati* to the South of it are lofty, and may be seen after a ship has passed *Pulo Popa*.

PITT STRAIT was thus named by Capt. *Jas. Dewar*, who went through it in the ship *Warwick* in 1760. The shores of *Batanta* and *Salawati*, which form this strait, are both lofty and steep, and the tides are remarkably rapid, attended with strong eddies, which render the passage at all times dangerous, especially if it should happen to fall calm.

There are no soundings going through the strait, except near *Salawati*, on the East side of *Roggewyn Island*, which is a small island at the West entrance of the strait, and must be passed on the North side in going through; and also at a small distance from a shoal or reef of rocks, the *Batanta Reef*, 9 miles E. by N., from the East end of *Batanta*. You must be careful not to approach them, as the want of anchorage may expose you to danger;

for these reasons Pitt Strait is seldom frequented, and Dampier Strait is preferred, being shorter and wider, with anchoring ground in the narrowest part.

After a ship is in Pitt Strait, in case of night coming on, without moon-light, she may haul in for the Salawati shore, where she may anchor, should occasion require, but it is improper to anchor if it can be avoided. Some ships have been thrown by the eddies against the North shore of Salawati, their yards touching the trees, and apprehending great danger. Steer right through this strait, keeping as near the middle as you can, till near the East end of Batanta; then haul over to the southward toward Jackson's Island, to give a berth to the reef off the East end of Batanta. It runs a considerable distance from that end of the island, having $3\frac{1}{2}$ and 4 fathoms on some parts of it, but there is a greater depth on the West and South sides of it, where a ship may anchor, if the tide is carrying her towards the shoal part of the reef. *Jackson's Island* is high, and lies off the N.E. end of Salawati.

When past the reef you may steer for *Point Pigot*, which is the S.E. point of the Island Waigiou; and when to the eastward of it you are in the Pacific Ocean, taking care to avoid the *Buccleugh Shoal* at 12 miles N.E. by E. from Point Pigot; and another shoal, 3 miles South of the western of two islets, which lie off Point Pigot to the southward.

WAIGIOU is a considerable island, 64 miles long, to the northward of Batanta. Its North shore is just South of the equator. It is generally hilly in the interior, the highest peak, *Cone de Beuffle* or *Buffalo's Horn*, was estimated by the officers of the French surveying ship, *La Coquille*, under D'Urville, at 1,516 ft. The climate is moist and hot, and the people on the coast, which in some places is low, are said to be a cross between the Malay and the Papuan negro. Sago is their chief food; rice is unknown.

Captain Forrest explored the northern coast of Waigiou in January and February, 1775. The coast is described as generally bold, but reefs extend from some of the points and small isles near the shore. Within the harbours fresh water may be obtained.

Piapis is situated about 3 leagues from the S.W. end of the island. Rocks, on which the sea generally breaks, project to the W.N.W., about a quarter of a mile from the western point of the entrance. They may be avoided by steering in about S.E., and keeping towards the West point. Off the latter is a haycock rock, about 15 ft. high, and standing in 10 fathoms of water.

The entrance, rather more than a quarter of a mile in breadth, has from 30 to 20 fathoms water. The depth thence decreases. A ship may haul round the haycock rock, and anchor to the S.W. of it, in 15 or 20 fathoms, muddy bottom. Fresh water may be procured at a pool on the island within, which has a hill on it. Between this island and the western shore there are rocks, leaving a passage of 8 fathoms close to the island, and of 6 fathoms

close to the shore in a cove at the S.W. side, where a ship may be careened. At the bottom of the eastern branch there is good timber for masts, and a small brook of water may be found near two peaked hills. On the small but high island *Sipsipa*, which forms the eastern point of the entrance, there is a pool of fresh water.

Nearly midway between the harbours of Piapis and Offak, there is a small island called the *Shoe*; thus named from its appearance. Three remarkable peaks will be seen in sailing along the coast; of these the first or western peak is represented at 2 miles to the eastward of Piapis; the second or middle peak to the S.S.E. of the Shoe; and the third or East peak to the southward of Offak. The latter, from its peculiar figure called the *Buffalo's Horn*, is mostly covered with trees, and very steep.

Offak Harbour is 31 miles to the eastward of Piapis. Being surrounded by high land, it is not readily discernible at a distance. At the entrance, on the eastern side, is a sugar-loaf hill, about 500 feet in height, and the Buffalo's Horn above mentioned standing inland will be seen. The latter in a line with the Sugar-loaf bears S.S.W.

The breadth and depths of the entrance are nearly the same as those of Piapis. The course in is about S. by W., keeping some rocky islets, like haystacks, which lie near the eastern point, on the port side. Within, the harbour extends considerably; on one side to the eastward, on the other to the S.W.

To the southward, fronting the entrance, are two islands connected by a reef; the outer one has a pool of fresh water on it, and a reef extends from its western end. On the South side of the isle and reef are from 12 to 6 fathoms, over a muddy bottom; but there are from 26 to 20 fathoms midway between it and the entrance. A little way within the eastern point is a small sandy cove with 10 fathoms, and a stream of fresh water.

Pulo Manouaran, at a league from the coast, lies $3\frac{1}{2}$ leagues from the entrance of Offak Harbour, in the direction of N.W. by W. The isle is of moderate height, and has a pool of fresh water on it, and an islet close to its N.W. point. There are soundings from it to the East and West, and a safe channel within, varying in depth from 10 to 20 fathoms.

Rawak.—This harbour is situated at about 5 leagues from Offak. It is formed by the isle called *Pulo Rawak*, which is separated from the island of Waigiou by a narrow channel. The larger entrance, about half a mile wide, is from the eastward, with depth decreasing from 17 to 10 fathoms. A ship may be sheltered here from all winds, excepting those from between East and N.E. Water may be obtained from two streams on the Waigiou shore, which is inhabited.

At 3 miles E.N.E. of Rawak Island is a shoal, and in the same direction 6 miles from it a $4\frac{1}{2}$ fathom bank.

Boni Harbour, 6 miles eastward of Rawak, has its entrance filled with shoals.

DAMPIER STRAIT, or Gemen, or Gamien, is formed by Batauta Island

to the South and Waigiou to the North. It is named from the great English navigator who first explored it. It is 70 miles long from Cape Mabo, the West point of Batanta, to Cape Pigot, the S.E. point of Waigiou. But the narrower and difficult part of the strait is only 30 miles long, and is northward of Batanta. *Gamen* is the largest of several islands on the North side of the strait, and appears as part of the South coast of Waigiou, being separated from it only by narrow channels leading into an extensive inlet.

Chabrol Bay is to the eastward of this inlet. It extends in a W.N.W. direction across the island to within $1\frac{1}{2}$ or 2 miles of the western arm of Offak Harbour, and within $2\frac{1}{4}$ miles of *Ports Duperrey* and *D'Urville*, nearly cutting through the island. On the western side of Chabrol Bay two other bays branch from it; and at its northern extremity is a safe harbour named *Port Blossenville* by the officer of *La Coquille*, lat. $0^{\circ} 5' S.$, long. $130^{\circ} 40' E.$

King William Island, to the southward of *Gamen*, and on the North side of the strait, is high, with a white patch on its eastern extremity; it may be seen 12 or 13 leagues off, and when first discerned in coming from the eastward, three hills on it appear like separate islands. Contiguous to the East end of King William Island, is *Hump Island*, with a round rocky islet a short distance outside of it, and two shoals N.W. from it. Several small islets lie near the Waigiou shores.

Augusta and *Pigeon Islands* are very low, and lie in the middle of the strait to the southward of the West end of King William's Island; the westernmost is *Augusta*, and the easternmost *Pigeon Island*. *Foul Island* lies between the East end of King William's Island, and the North shore of Batanta, but nearest to the latter. It is a small, level island, and the channel is between it and King William Island. Due East of Foul Island is a small white sandbank, part of which is covered with tall trees, and is called *Mansfield Island*. This island is on the South side of the strait. There are several others between it and Batanta, but scarcely to be distinguished from Batanta, being very near that island. The passage between King William Island and Waigiou is unsafe.

Woodford Shoals are two 4-fathom patches, which lie respectively at 7 and 10 miles S.W. from *Augusta Island*, and are described presently.

On leaving *Pulo Popa*, if the wind should be northerly, haul up N.E. or N.E. by N., so as to be able to lie round the N.W. end of Batanta, observing not to approach near the *Tameay Isles*, a chain of islands lying to the westward of Batanta, 8 or 9 leagues from Cape Mabo; these islands are not well known, therefore it is proper to give them a good berth, by borrowing on Batanta, the West end of which is perfectly clear of danger; and when 3 or 4 leagues to the N.E. of Fisher's Island, there are soundings as far as Foul Island. Being to the northward of Fisher's Island, a ship should not exceed 3 or 4 leagues distance from Batanta, as to the westward of *Augusta Island* there are some coral patches, called the *Woodford Shoals*, not perfectly

known. There is a spot on which the *Augusta* had only 3 or 4 fathoms, which bears W. by S. 2 leagues from Augusta Island; another spot, on which the *Mansfield* had 6 fathoms, bears about W.S.W. 4 miles from Augusta Island; and it is probable there may be less water on some of these patches. The soundings in these straits are in general irregular, the bottom gravel, with coral and shells in some places; you have from 30 to 60 fathoms, until 2 or 3 miles to the eastward of Pigeon Island. There is a bank extending eastward from this island 4 or 5 miles, with moderate depths on it for anchorage, the bottom mostly sand and gravel. There is $5\frac{1}{2}$ fathoms coral rock, with Pigeon Island W. by S. $1\frac{1}{2}$ mile; but deepens to 10 and 12 fathoms, sand, when 3 or 4 miles eastward from this island. To the northward the water deepens fast towards the East end of King William's Island, there being no ground at 1 mile distant from it, with 90 fathoms of line. It also gets deeper in standing towards the shoal which surrounds Foul Island; this is called *Vansittart's Shoal*, extending 3 miles to the N.W. of Foul Island, and then trenches directly to the southward, till it reaches Batanta; from its N.W. extreme the North verge of it extends in a line directly East, towards the East end of Batanta, Mansfield Island lying on the northern edge of it. When you have passed at the distance mentioned from the Batanta shore, and Augusta Island bears N.E. by E., you should then edge over towards it and Pigeon Island, to keep at a proper distance from the N.W. part of the Vansittart's Shoal, by not coming nearer Foul Island than 5 or 6 miles, when it bears East, nor within 4 miles when it bears to the southward. Augusta and Pigeon Islands may be approached on the South side to a small distance if necessary, as the coral flat does not extend far out to the southward from them. There is a channel between these two islands, but it is narrow and intricate. Augusta Island is the easiest for landing on, to cut wood; but on the ebb tide care is requisite, to prevent boats from receiving injury on the sharp coral rocks. If you see Mansfield Island, it is a good guide for the shoal spots which the *Augusta* and *Mansfield* were upon. Keep it on with the South part of Foul Island, and you will go clear to the southward of them both; and when within 3 miles of that island, pass on the South side of them, at any convenient distance. When to the eastward of Pigeon Island, and you have it bearing West from 3 to 5 miles, you shoal to 10 or 12 fathoms, but borrow over toward Foul Island, you will deepen, there being 60 fathoms irregular, close to the North and N.W. verge of the Vansittart's Shoal, the verge of which is thought to be steep and dangerous. When Foul Island bears S. by E. or South, there are no more soundings, and you are clear of danger; only do not near Batanta so as to be in a line with Foul and Mansfield Islands, as that line borders on Vansittart's Shoal.

When past Foul Island steer for *Point Pigot*; along the Waigiou shore you will see several small islands lying close to that point, which appear like

inlets of a river. If the wind be from the northward, keep near Point Pigot, so as to be able to keep at a tolerable distance from New Guinea, when clear of the strait. *Point Pigot* is the S.E. end of Waigiou; it is moderately high, and two small islands, with a sandbank 3 miles S.S.W. of the westernmost, lie at a very little distance from it; its latitude is $0^{\circ} 19' S.$, long. $131^{\circ} 11' E.$ The N.W. point of New Guinea is low, but after you have got a few leagues to the eastward of Point Pigot, all the North coast is very high and mountainous. Between Point Pigot and New Guinea the passage is about 8 leagues wide; when outside, a ship should make to the eastward till she gets sufficient easting to pass to the eastward of the Pelew Islands, giving a reasonable distance to the North coast of New Guinea.

Bucclough Bank is 8 miles eastward of the eastern side of Waigiou Island. It is 5 miles in diameter, the shallowest part, of 2 and 3 fathoms, lying on its western side, N.E. by E. 10 miles from Point Pigot, and the same distance S.E. from Cape Lamarche, the N.E. point of Waigiou.

In Dampier's Strait the tide seems very irregular, and very strong at times; between Pulo Popa and Batanta, in the S.E. monsoon, there is often a current setting to the northward, but at times there is no current. In the N.W. monsoon, from September to April, the prevailing current is southerly; although, at times, it may be liable to deviations.

Between Point Pigot and New Guinea the tide appears to run sometimes 12 hours in and out; but the tide setting to the eastward is generally the strongest in this part in both monsoons.

In the narrow part of Dampier's Strait, between Foul Island and Augusta and Pigeon Islands, the tide to the S.W. appears to be the strongest, in the southerly monsoon, and continues to run longer than the tide out of the strait.

In July and August, at anchor, about 4 miles eastward of Pigeon Island, the tide to the eastward has been observed seldom to run longer than 5 hours; often weak, with a long interval of slack water; but, at other times, its velocity, for a short time, when strongest, has been from $4\frac{1}{2}$ to 5 miles an hour.

At the same times and places it has been observed that the tide to the westward frequently runs 10 and 11 hours, gradually augmenting in strength in the first part, setting about W.S.W.,—from thence S.W. by S., when strongest about 5 miles an hour, or a little more on high spring tides, and about 4 miles on the neaps. After running strong S.W. by S. to S.W. for a few hours, it abates gradually, until it changes and runs to the eastward.

PITT'S PASSAGE, the great channel North of Boeru and Ceram is sometimes called by the Dutch the *Ceramese Sea* (*Ceramsche Zee*). It is quite free from danger, as far as is known, and the charts will show all its hydrographical features.

OBI MAJOR or Ombirah, "great gain Island," lies on the North side of Pitt's Passage. It is about 30 miles long East and West, and 15 miles wide. It is lofty, the highest part being about 5,000 ft. high. Over the N.W. point of Obi Major is a remarkable bluff, with a knob-like summit, higher than the surrounding forest, which is probably a clump of trees; the knob is in lat. $1^{\circ} 24' S.$, long. $127^{\circ} 24' E.$ Five miles southward of this bluff is a projecting point which looks like an island. It is surrounded by several smaller islands, of which *Gomona*, on the South side, is most conspicuous from this passage. It is 850 ft. high, round-backed, and its centre is in lat. $1^{\circ} 50' S.$, long. $127^{\circ} 38' E.$, bearing from the East point of Lisa Matula of the Xulla Islands, East 55 miles.

Sophia Reef lies midway between the North point of Gomona and Rocky Point, the West point of Obie Major, which should not be approached within 2 miles.

Obie Latta is 6 miles in diameter, and attains an elevation of about 2,400 feet; upon it are three or four sharp, well-defined peaks, of nearly equal height, the highest point being in lat. $1^{\circ} 25' S.$, long. $127^{\circ} 18' E.$ Its centre is 8 miles N.N.W. of Rocky Point.

Typha Island, off the N.W. point of Obie Major, is 10 miles long E.S.E. and W.N.W., is about 1,000 ft. high, and rises in a single round-backed hill, its summit being in lat. $1^{\circ} 12' S.$, long. $127^{\circ} 23' E.$

Numerous tide rips were passed through westward of the Obie Islands by H.M.S. *Challenger*.

The **Bahia Reef** lies 25 miles N.W. by W. from Obie Latta, and 30 miles S.W. from Mandolie. It is a *dangerous* coral reef, announced in December, 1858, as having been discovered by the ship *Bahia*, striking and dragging heavily on it, lat. $1^{\circ} 10' S.$, long. $126^{\circ} 50' E.$

Lukisong or **Loyang**, "Landscape Island," lies off the East end of Obi Major. It is sometimes called in the old charts *Great Pulo Gasses*. Its South end is in lat. $1^{\circ} 43' S.$, long. $128^{\circ} 2'.$ It is 9 miles long N.N.E. and S.S.W., and of moderate height, well wooded, stretching with a remarkably even slope that forms its northern extremity. The channel inside it is very narrow, and subject to calms, owing to the adjacent high land, and is therefore not recommended for ships. A small island, *Long Island*, lies off the North end of Lukisong or Lookisong.

Pulo Gasses is 7 or 8 miles eastward of Lukisong, and nearly of the same height, a flat table-land for about three-fourths of its extent, sloping down to each end with a spit of rocks, stretching about a cable's length from the S.E. end, which is in lat. $1^{\circ} 38' S.$, long. $128^{\circ} 14' E.$ The island has a sandy beach, but no soundings at 1 or 2 miles off. The channels on either side are safe; that to the westward may be used with a westerly wind, but that to the eastward is wider, and seems better with a working wind.

The *Courier Rock*, a five-foot shoal, seen in 1845, bears N.W. $\frac{1}{2}$ N., about 26 miles from Gasses, and 8 miles North of the N.E. point of Obi Major.

Talbot Shoal was reported in 1873, by the master of the vessel of that name, in lat. $1^{\circ} 51' 30''$ S., long. $128^{\circ} 8'$ E., with the East side of Gasses bearing N.N.E., and High Peak on Gomona W.N.W.; where the latest charts mark no bottom at 70 fathoms. The sea was nearly smooth, and ship sailing from 5 to 6 knots per hour, steering S.S.W. She grated over for about three times her own length. The extent of the shoal S.S.W. and N.N.E. would be about 500 ft. Before we had time to pass the lead we were in deep water. This shoal lies directly in the fairway between Manipa Straits and the entrance to Gillolo Passage. The bottom must be of dark-coloured rocks, as there was not the slightest discolouration of water, or any appearance whatever to indicate danger. Time of accident, 3.30 p.m. Tide, half-ebb.

Kekik, a high island, bears N.E. by E. $\frac{3}{4}$ E. 20 miles from Gasses, in lat. $1^{\circ} 30'$ S., long. $128^{\circ} 35'$ E. *Laun*, about 6 miles eastward of Kekik, is also a high island, with an islet off each side of it, and another in the form of a button, between it and Kekik.

Pisang, the highest of these islets, forms two hills resembling each other, and may be seen 30 or 35 miles off; in lat. $1^{\circ} 23'$ S., long. $128^{\circ} 49'$ E. The *Nabob Shoal*, of $3\frac{1}{2}$ fathoms, lies 16 miles North of Pisang.

The **Boe or Bu Islands** lie 24 miles E.N.E. of Pisang. They form a group of ten or twelve small, low islands, 15 or 16 miles West from the West end of *Popa* (page 859), the channel between being safe. These islands are inhabited, and produce cocoa-nuts. A few goats and some dried fish *perhaps* may be procured.

Captain Jacob B. Brown, of the American barque *Agate*, writes to the "Shipping and Mercantile Gazette" as follows:—"On a voyage from New York for Shanghai, January 25, 1877, the barque *Agate* struck upon reefs off Boe Islands, which, in the latest charts, are laid down as deep water. These islands are laid down in $1^{\circ} 10'$ S., and $129^{\circ} 20'$ E. There are various reefs making off from Boe Islands, extending, by good observation, to $1^{\circ} 14\frac{1}{2}'$ S.; depth of water, 2, $2\frac{1}{4}$, $2\frac{1}{2}$, and 3 fathoms. Most of the islands appear to be connected by coral reefs. This group of islands lies in the direction of E.S.E. and W.N.W. A rock appears from the mast-head between the Boe Islands and *Popa*, about 4 miles from the former. I should recommend extreme caution in navigating about these islands. There is a safe anchorage between the two westward of the reefs in 12 fathoms of water."

The *McCleure Bank*, a dangerous coral shoal, 19 ft., has been said to lie in the channel to the westward, 2 miles in extent, and bearing W. by S. 20 miles from the Boe Islands, and E.N.E. from Pisang.

The **GILOLO PASSAGE** or Strait, between Halmaheira on the West, and the islands of Mysole, Waigiou, &c., on the East, may be said to commence

to the northward of the islands just described, and is preferred by some to the narrower Dampier Strait, to the eastward, for passing into the Pacific Ocean from Pitt's Passage. Having avoided the neighbourhood of Talbot Shoal above described, enter it between Gasses and Kekik, haul close around the South end of the former, to prevent being carried past the channel by the current, which frequently sets to the eastward. After rounding Gasses, the loftier parts of the Dammer Islands, off the South end of Halmaheira, will rise in sight from the deck. They first appear in form of a saddle, the southernmost being in lat. $1^{\circ} 11' S.$, bearing N.N.E. 26 or 27 miles from the North end of Lukisong. They will be described presently, the islands and shoals which lie in the passage will follow.

Black Rocks or *Fairway Ledge*, bears about E.N.E., 6 miles from the southernmost of the Dammer Islands. They are a low ridge of rocks, about 2 miles in extent E.N.E. and W.S.W., a part of which, near the East end, is about the size of a small ship's hull above water. The breakers continue toward Dammer beyond the rocks. They, therefore, should be carefully avoided in the night, by giving a wide berth to them, for there are no soundings to guide.

Anchorage.—Captain Collins, of the American vessel *Brewster*, reports as follows:—

At the southern entrance of Gillolo Passage, 5 miles South of the 'Black Rocks,' I was becalmed, and experienced a three-knot current, setting about S.S.E., which drifted the ship towards Toppershead or Button Island. When within 4 miles of it, saw bottom plainly; let go my kedge anchor in 14 fathoms—Toppershead Island bearing S. by E., distant $3\frac{1}{2}$ to 4 miles.

This bank extends East and West, how far I was not able to ascertain, but another vessel anchored about 3 miles East of me, on the same bank, therefore I think it extends as far as from Lawn Island to Kekik Island. Found 50 fathoms between the bank and the islands, and 15 fathoms within a cable's length of Toppershead Island.

There were nine other vessels in company, and had they known of this anchorage they could all have availed themselves of its convenience, and thus escaped the anxiety and trouble incidental to being drifted about at the mercy of the tides and currents. In my own case, I think I should have lost the ship on Toppershead Island, had it not been for the anchorage on the bank.

I am sorry that I cannot give you a more accurate description of it. I lay at anchor 24 hours (2nd of December, 1868), after which the current changed, setting strong to the N.W., enabling me to proceed on my passage. The vessel anchored with me had 12 fathoms; it may possibly be much shoaler in some parts.

The Wida or Weedah Islands form two compact groups of low wooded islands, the southernmost bearing N. $\frac{1}{2}$ W. from Kekik, and N.N.E. from

the South point of Halmaheira, 10 or 12 miles, in lat. $0^{\circ} 40' S$. The northern group is 8 or 9 miles W.N.W. of the other. They lie on the western side of the passage, and seem to be safe to approach, though very steep-to.

Veldman Roek is 6 miles northward of the eastern group, in lat. $0^{\circ} 27' S$., long. $128^{\circ} 24' E$.

To the northward of Popa there is a line of islands, of which we have no account. On the Dutch charts they are named *Vlaming*, the south-westernmost *Schooteroog*, *Klaarbeck*, and *Kommerust* the north-easternmost, which lies 12 miles W.S.W. of the western island of the Tameay group.

GEBI or Gebeh, a large island, on the N.E. part of Gilolo Strait, is long and narrow, about 21 miles long E.S.E. and W.N.W. It is hilly, but not exceeding 500 ft. high; the formation is probably sandstone, not volcanic. The aborigines are Papuans, but there are settlers from the Moluccas, who own the sovereignty of the Sultan of Tidore. Their chief employment is fishing for trepang and pearl oysters. The north-western part is rather low, but the other end is high, and terminates in a bluff point. The N.W. point is very nearly, or quite, *on the Equator*, Capt. Duperrey placing it in lat. $0^{\circ} 2' N$., long. $129^{\circ} 19'$, while Lieut. McCleure gives it as $0^{\circ} 0'$. It bears from Moar off Cape Tabo, on Halmaheira, E. by S. $\frac{1}{2}$ S. 21 miles, and this forms the narrowest part of the Gilolo Passage.

Fow Island lies off its S.W. side. It has a peaked hill on its South point, and is separated from the southern shore of Gebi by a narrow channel, about a quarter of a mile wide, which forms a *safe harbour*, much frequented by the whalers, with depths of from 10 to 15 fathoms. There is a passage into it on either side of Fow Island, by passing close to the latter, for a shoal lies in mid-channel in the West entrance, with good depths around. In the South entrance there are two small shoals close to each other, the best channel being between them and the East side of Fow. In the bay to the eastward of these shoals there is anchorage in 15 to 20 fathoms, near the Gebi shore, the chief village, *Ketchepee*, being about 2 miles distant, on the East side of the island.

At 1 mile off the Gebi shore to the S.E. in the bottom of the bay, distant $1\frac{3}{4}$ to 2 miles, is a fresh-water stream or creek with excellent water, into which our boats went at half-flood and filled the casks from alongside, but at low water as there is a bar, your boats must anchor outside, land the casks and roll them a short distance up the hill, in which case you have to raft them off, which may be done with ease and expedition, as the water is perfectly smooth, and must be so during the whole of the N.W. monsoon. A ship tolerably well manned would have no difficulty in filling twenty or thirty tons in the course of the day. From the mouth of the creek the South point of Fow Island bears by compass W. $\frac{1}{2}$ N., and may also be known by a bluff cliff or headland, the only one in the bay, rising in a gentle slope of table-land from the top of the cliff towards the hills to the S.E.

Spars fit for yards and masts abound on either shore; vegetables, fruits, and fish are also procurable in abundance from the natives, who are very friendly and kind, many of them speaking English, Fow Harbour being much frequented by whalers.

On the N.E. side of Fow a narrow channel fronting Gebi Harbour stretches into the island close to the peaked hill, and forms an excellent port or basin, with 4 or 5 fathoms in the narrow entrance, and from 10 to 16 fathoms within. The fresh water rivulet is on the Gebi shore opposite the North point of Fow. Tide rises 5 ft. at springs.

The N.E. side of Gebi is steep-to without anchorage, and the islands *Yoe* and *Utū* or *Oetoe*, about 3 miles northward of the East point, are small and low.

Gagy is of considerable extent, being about 22 miles S.E. by E. from the S.E. end of Gebi, North end, lat. $0^{\circ} 20' S.$, long. $129^{\circ} 55' E.$ It is moderately elevated, formed of uneven hummocks, having some small islets S.W. of it, called *Doif* (or Dove), and a large group called the *Bangapally Islands*, to the eastward, off the S.W. end of Waigiou. Between these and *Gagy* there is a passage, and the channel between *Gagy* and Gebi is very safe, having an islet near the South end of the latter. This channel is sometimes taken by ships going outward, and may probably be advantageous to those coming towards Pitt's Passage during the S.E. monsoon.

Syang, in lat. $0^{\circ} 20' N.$, long. $129^{\circ} 52' E.$, is 40 miles N.E. by E. $\frac{1}{2}$ E. from the N.W. end of Gebi. It is a low, flat island, about 3 miles in extent, with fresh water at a rocky point near its N.W. end, from whence a reef projects three-quarters of a mile. *Eye Island*, off the North end of *Syang*, is small and low, and covered with trees. There is said to be a bank, having 10 or 11 fathoms over it about 5 or 6 miles East of *Syang*.

Wyang or *Vayag*, 9 miles S.E. from *Syang*, is the northernmost of a range extending off the N.W. end of Waigiou. *Yen* is the easternmost. *Ruib*, the largest and highest, lat. $0^{\circ} 2' S.$, is the southernmost, and is surrounded by rocks which contract the passage between it and Waigiou. This has been called the *Bougainville* or *French Passage*, as it was explored by the French expedition under Bougainville.

The channels among these islands are probably safe in many parts, but require care, as the French corvette *Uranie* found a coral bank of 6 fathoms, 5 miles N.W. by N. from the North end of *Ruib*.

Ormsbee Shoal, least water 15 fathoms, bearing N. $\frac{1}{2}$ W. from *Wyang*, in lat. $0^{\circ} 42' N.$, long. $130^{\circ} 0' E.$, that island and *Syang* being visible from the masthead. Nearer to Halmahera there are several shoals, which will be described with that island.

Captain J. W. Roy, of the *Chusan*, writes as follows to Lloyd's agent at Iloilo:—"As some doubt appears to exist as to the extent of the Ormsbee Shoal, North of the entrance of Gillolo Passage, I beg to hand to you a few

remarks made while passing the South end of the above shoal on my passage from London to Shanghai.

“On the 30th of December, 1872, at 8.30 a.m., centre of Syang Island bore due South; steered due East $7\frac{1}{2}$ miles by patent log; the centre of the island then bore S.S.W. These angles place the ship at the last bearing N.N.E. 17 miles from Syang Island. At the same time saw rocks under the ship's bottom; sounded immediately; had 7 and 9 fathoms; then no ground.

“This appears to be the southern extremity of the shoal, lat. $0^{\circ} 38' N.$, long. $129^{\circ} 58' E.$; the bank to the North of the ship at that time appeared to have much less water, and very smooth. I am sorry that I cannot give you a more accurate description, as I had to take advantage of the light breeze then blowing.”

DIRECTIONS.—Having entered the Gilolo Passage by the strait on either side of Gasses, as mentioned previously, if passing to the eastward of that island, steer about N.N.E. $\frac{1}{2}$ E., or if by the western entrance, about N. by E., so as to pass between Point Tabo of Halmaheira and Gebi. In the night, be careful to give a berth to the Tramway Ledge and to the Wida Islands; but it is advisable to keep on the western side of the passage when the winds are light, as the current sometimes sets to the N.E. or eastward. If the wind be at N.N.W., so as to occasion delay in working to the westward of Gebi, pass to leeward between it and Gagy, and then out into the Pacific through any of the channels near Syang. But the western channel, and between the Catharina Isles and Syang should be followed if possible, so as to weather the Aiu and Asia Islands.

HALMAHEIRA or **GILOLO** is one of the most singularly formed islands in the world, being a representation of Celebes on a small scale—a junction of four peninsulas jutting to the eastward and also to the North and South; but it is not more than one-tenth of the area of the larger island, and about half the size of Timor.

The name has been very variously designated. The Dutch, who claim the sovereignty, now term it *Halmaheira*, otherwise *Almahera*, as above, which probably means “mainland,” in distinction from the range of the true Moluccas on the western side. The name by which it has been generally placed in geographical works is *Gilolo* or *Jillolo*, by the Dutch *Djailolo*, which was applied by the early Portuguese to the whole island, from the name of a kingdom, and now of a town on the S.W. side of the northern peninsula, near to Ternate.

Its surface is broken, mountainous, and volcanic, the highest point being 6,500 ft. high. From its physical character, and the depth of the surrounding ocean, the fertilizing powers of the climate run away into deep water, and thus the island from this cause and the absence of irrigation is not productive. It is covered with a tall forest, among which it is singular that the

clove tree is not found, though its native place is in the islands adjacent to it on the West. The absence of this and of other articles of commercial production, have left the natives (a rude and inoffensive people) in a comparatively uncivilized state. The original natives are a brown complexioned race, speaking peculiar languages, but the coast is usually occupied by Malays, who, like the rest of their race, are much addicted to a seafaring life.

The island is subject to the Dutch nation, and is divided between the governments of the Sultan of Ternate, who has the northern and half the southern peninsula, and that of the Sultan of the next island, Tidore, who holds the central portion of the island. Its three bays on the eastern side are open, and have no good harbours, but this is of less importance in a sea never troubled by storms. Our hydrographical knowledge of this and its adjacent islands is most imperfect, and what will be said here is little more than an enumeration of the points.

Dammer Island, before mentioned, lies off the South point, and to the southward of it there are numerous islets and rocks, extending to a considerable distance to the South and S.W.

Tanjong Libobo or *Cocoa-nut Point*, lat. $0^{\circ} 51' S.$, long. $128^{\circ} 23' E.$, is the southern point of Halmaheira. There is a knob on it, but the land near it is rather low and uneven. *Pulo Babi* (or *Ordal*), which lies off this point, is small, and lies in the entrance of the strait between Dammer and Halmaheira, which is too narrow for ships. The Wida Isles, which lie to the N.N.E. of Libobo Point, have been before mentioned.

Wida or Weedah Bay, as the south-easternmost bay of Halmaheira is called, takes its name from a village lying on its western side near the head. It is 63 miles wide in the entrance, and about the same depth. We have no useful particulars concerning it.

Cape Tabo, in lat. $0^{\circ} 10' N.$, long. $128^{\circ} 51' E.$, is the north-easternmost point of this bay. It has a gradual slope, ending in a bluff to seaward, and, when bearing N.W. by N., some white cliffs are seen near it. The land about it is lofty, and over the point there rises a quoin-shaped hill, the highest point to the westward. *Pulo Moar*, off the extremity of Cape Tabo, is low, flat, and woody, and connected with the cape by rocks and breakers. Close to the East point of those there is a small islet, in lat. $0^{\circ} 9' N.$, long. $128^{\circ} 56' E.$ There are several villages near this part of Halmaheira.

The Shanpee Islands, a group three or four in number, lie 15 miles North from Cape Tabo. They extend 3 or 4 leagues North and South, and are mostly level, of considerable size, with a small elevation between the central part and northernmost island. The *Recovery Rock*, a round islet or rock, about half a mile in circuit, with a few shrubs on it, lies about 10 miles S.W. by W. from the next group, the *Catherine Islands*. These are three small low islands near each other, forming the western side of the North

entrance to the Gilolo Passage. They are about $1\frac{1}{2}$ mile long, lying W. by N. and E. by S., low, and steep-to on the southern side, which appears to be steep as a wall, except near the East end, where there is a small sandy cove. The *Canton Packet Shoal* consists apparently of white sand and black rocks, very near the surface, about mid-channel between the Shanpee and Catherine Islands, lat. $0^{\circ} 40' N.$, long. $129^{\circ} 4' E.$ The *Ardassier Rock* is N.W. of the Catherine Islands, in lat. $0^{\circ} 45' N.$, long. $129^{\circ} E.$ The *Aurora Bank* is the easternmost of these, and is of small extent. Although 8 fathoms was the least depth found on it on its discovery, yet a whaler has stated that there is only 5 ft. in some parts, which must very much diminish the safety of the Gilolo Passage in rough weather.

Bitjoli or Bitzoli Bay is the eastern or central inlet of Halmaheira, separating its N.E. from the S.E. peninsulas. It has numerous islets and rocks scattered over it. It takes its name from a village on its South shore, where there is a Dutch sub-resident. *Chiawo Bay* is the north-easternmost of the inlets, which give Halmaheira its bizarre configuration. We have no account of it. On the north-eastern side of the northern peninsula is *Gunong Karakan*, the highest point of the island.

Tanjong Batu Bessao is in lat. $2^{\circ} 14' N.$, long. $127^{\circ} 33' E.$ This part of Halmaheira is high, bold land, with three high, remarkable peaks. There are several islands, called collectively the *Talenading Islands*, to the N.W. of the point, the northern of which, *Dili*, is in $2^{\circ} 17' N.$, $127^{\circ} 33' E.$ They are of moderate height.

MORTI, or **Morotai**, or **Morty**, is the northernmost of the Molucca group. It is about 58 miles long North and South, and 10 to 12 miles broad. The North cape is in lat. $2^{\circ} 44' N.$, long. $128^{\circ} 21' E.$ It slopes down from the high table land into a point which forms this cape. The northern end is skirted by a reef which extends 1 or 2 miles off, having no soundings close-to, with some small islands adjoining.

Riao or *Riow Island* lies off the western side of Morti, separated by a small strait. In the bay between the N.E. part of Riao and Morti there is said to be anchorage, with fresh water, abundance of wild hogs, deer, pigeons, &c., on the islands contiguous.

The Western Coast of Halmaheira trends to S.S.W. for about 63 miles, to the point which forms the north-western extremity of the bay, in which lies the village of *Gilolo* or *Djailolo*, which, as has been before mentioned, gave its name to the island. After the terrible earthquake of 1840, which devastated the adjacent and chief island Ternate, this place was proposed as a fitting one to remove the seat of government to, but nothing was carried into effect.

The point of Gilolo nearest to Hieri Island lies from Hieri Peak N.E. $\frac{3}{4}$ N. 8 miles. Over this point is a hill, 1,050 ft. high; 3 miles north-eastward of

the hill there is a remarkable sharp peak of 3,450 ft.; and about 8 miles still farther northward a flat-topped hill with four peaks on it will be seen.

Dodingo Bay, to the eastward of Ternate and Tidore, has the village of *Sedangoli* on its North side, and that of Dodingo at its head—places of some importance among others which are quite insignificant. From this bay the western coast of Halmaheira trends to S.S.E. for about 110 miles to the South point, before alluded to. There is nothing particularized concerning it.

The **MOLUCCA ISLANDS** properly consist of the five islands next enumerated, which lie against the West coast of Halmaheira. The name is unknown among the native languages, though applied by the early Portuguese discoverers. The term has had a much more widely-spread significance by including the islands East and N.E. of Celebes, but originally it was restricted, as above said, to the five islands in question. They were formerly considered the principal of the Spice Islands, but had ceased to be so from the destruction of the trees by the Dutch. They are, however, regaining their reputation for spice-bearing and nutmegs; cinnamon is also grown to a great extent; pepper is largely cultivated, as also are coffee and cocoa; the sago-bearing palm flourishes in every part of the island. They also now produce what the others do not, and which is more thought of by the passing seamen, viz., a tolerably good supply of provisions, in sheep, fowls, vegetables, and a greater variety of fruit; pine-apples, oranges, lemons, bananas, &c., being plentiful in their seasons.

TERNATE ISLAND lies between the parallels of $0^{\circ} 45' N.$ and $0^{\circ} 52' N.$, and the meridians of $127^{\circ} 16\frac{1}{2}' E.$ and $127^{\circ} 22' E.$ The peak is 5,600 ft. high, and in lat. $0^{\circ} 48\frac{1}{2}' N.$, long. $127^{\circ} 19' E.$ Its shores appeared steep-to, and with no dangers beyond a few reefs extending off from one quarter to half a mile.

In the Ternate Channel the flood stream, coming from the north-eastward, formed numerous tide-rips and eddies, which gave the appearance of broken water over a sunken reef.

Ternate is the northernmost and principal of the group, the head quarters of the Dutch government of its region, and the seat of the Sultan, who claims sovereignty over a large part of Halmaheira. It is of very small extent, being, in fact, the mere pedestal on which stands the lofty volcano of the same name. This volcano produced no fewer than fourteen eruptions, between 1608 and 1840, and at times has nearly caused the total abandonment of the island. The peak was ascended without much difficulty by a party from H.M.S. *Challenger*. The clove, for which this island was celebrated, and which was apparently its native seat, has long been almost extirpated from its soil.

Ternate is a free port, and is visited regularly by the Netherlands India Steam Navigation Company's boats, the town being on the East side of the

island. *Fort Oranje*, which protects it, is in lat. $0^{\circ} 47' N.$, long. $127^{\circ} 21' E.$ The anchorage is abreast the town. The *Scaleby Castle* anchored in November in 22 fathoms, coarse sand and gravel, with the flagstaff of the fort bearing N.W. by N. Water was only procurable in small quantities at this time. It was during this night that one of the most violent of the explosions before alluded to occurred at the volcano. The town is built along the shore, half hidden among fruit trees and cocoa-palms. As usual, there are the Dutch, Chinese, and Malay quarters. Behind the town lies a considerable extent of level ground, before the wooded slope of the mountain commences, and a great portion of this is occupied by plantations growing every spice, fruit, and palm, under the tropical sun; cloves, pepper, cinnamon, nutmeg, coffee, cocoa, pine-apples, durians, oranges, limes, citrons, bananas, bread-fruit, and endless others, with palms of every kind, are here planted on a green sward, level as a billiard-table."—*Lord George Campbell*

The *Challenger* was here in October, 1874, and made purchases of a fine collection of parrots and other natural history objects. The crew received much hospitality at the hands of the inhabitants. As on the other islands visited in this region, the beautiful tropical vegetation was highly appreciated by those who went into the interior of the island.

The anchorage chosen by H.M.S. *Challenger* in Ternate Road was in 13 fathoms, with the extreme of the North pier extending from the Resident's house, N. $\frac{1}{2}$ W.; the extreme of the middle pier, N.N.W. $\frac{1}{4}$ W.; the extreme of the South or coaling pier, N.W. by W. $\frac{1}{2}$ W.; and Maytara Island S.S.W. Vessels making more than a temporary stay should moor, as the holding-ground is bad, and the tide streams strong.

Three piers extend from the island to the edge of the reef, which is composed of sand and coral. The northern pier is used as a landing place, the middle pier is for the shipment of merchandise, and the southern is the coaling pier. These piers are lightly built, and would be easily destroyed by a ship pressing against them.

Two large *coal* sheds stand upon the shore abreast the coal wharf; they are capable of holding 1,000 or 1,500 tons, but at the time of the *Challenger's* visit a small quantity only was in stock.

There is a depth of 5 fathoms at the outer end of the pier; and small anchors are buried on the land to which hawsers may be secured, but, from the frailty of the pier, anchors off the bow and quarter are necessary.

Supplies are plentiful and moderate in price (October, 1874). Beef, 1s. per lb.; fowls, 8s. per dozen; ducks, 2s. 9d. to 3s. each; geese, 6s. to 7s. each; sweet potatoes, 5s. per picul of 133 lbs.; potatoes (imported), 25s. per picul. Fruit in its season is abundant; the durien, mangostein, mangoe, pine-apple, orange, lemon, banana, jack-fruit, and pomegranate grow luxuriantly. The coffee and cocoa beans are cultivated, also the arica and sago palms, the latter supplying the principal food of the inhabitants.

Birds of paradise skins can be procured in considerable numbers at the rate of 6s. or 7s. each. As a spice island, Ternate is growing in importance, and produces nutmegs, pepper, cinnamon, and cloves.

The Dutch dollar and rupee are the coins in general circulation. An English shilling is only accepted as half a rupee. Gold in small quantities can be changed at its full value.

Magnetic sand.—The whole of the sand upon the island proved to be of such a highly magnetic character that no compass observations could be made.

Tides.—It is high water, full and change, at Ternate, deduced from one day's observations, at 5^h 10^m; springs rise about 4 ft.

The flood stream comes from the northward, and the ebb stream from the southward, and they run for two hours after high and low water by the shore.

Winds, &c.—From a register, kept by the surgeon of the Dutch settlement at Ternate, extending over a period of 8 years, from 1860 to 1867 inclusive, it was deduced that the N.E. monsoon blows through January, February, and March, the wind varying from N.E. to N.W. After a month of variable winds, the S.W. monsoon commences in May and ends in October, its direction being from S.E. to S.W. During November and December the winds are again variable.

Rain fell on 216 days of each year, or 18 days per month; the average fall during the N.E. monsoon being rather less than during the S.W. monsoon.

The mean temperature for each of the above 8 years was 80.7°.

On comparing the records of the weather at Ternate with those at Amboina and stations eastward, it would appear that during the periods of their greatest strength, the N.E. monsoon passing through the Molucca Passage turns eastward and becomes the N.W. monsoon in the Banda and Arafura Seas; and that the S.E. monsoon blowing through the Arafura and Banda Seas, bends into the Molucca Passage, and joins the S.W. monsoon in the Pacific.

These changes in the direction of the winds in this locality will be seen to be a corroboration of those shown on the Admiralty Wind Charts.

Hieri Island, lying to the northward of Ternate, is circular in shape, and about $1\frac{3}{4}$ mile in diameter; the peak, which is in lat. 0° 54' N., long. 127° 18' E., is 2,200 ft. high. Off the North point of Hieri Island is a rock, and north-westward of the island is a small islet, both close to the shore.

TIDORE or **Tidor** is the next southward of Ternate, and is separated from it by a safe channel. It is larger than Ternate, and, like that island, is entirely of volcanic formation. The mountain, of which it is chiefly composed, is 6,000 feet high, and its extinct crater is in lat. 0° 39' N., long. 127° 22' 30" E.

The capital of the island, *Soa Sia*, is on the East side. The Sultan is tributary to the Dutch, but at one period held great sway over a large portion of central Halmaheira, which is still subject to his influence. The people of Tidore, about 6,000 in number, are Mohamedans, having been so from early ages. The town is walled, and contains, besides the Sultan's walled residence, a large mosque, &c. The anchorage is off the town in 30 fathoms, sandy bottom, but in several places the ground is foul, with deep water close to the shore.

Mareh or *Potbakker Island*, 1,160 ft. high, is the next in succession to Tidore, the passage between them being safe and the island bold-to. Two small sandbanks, dry at low water, lie almost 5 miles East from the middle of this passage. These banks may be readily seen by their white colour during the sunshine or daylight, and they are the only known danger in the passage. They may easily be avoided by keeping on the Halmaheira side in coming up.

Motir, or **Mortier**, or *Moone*, is the next southward, and is about 4 miles in diameter, the passage northward of it being about 3 miles wide. It is 2,800 feet high, the highest point being in lat. $0^{\circ} 28' N.$, long. $127^{\circ} 23' E.$

Makkian is a larger island than the last, and is also bold-to. Its peak is in lat. $0^{\circ} 19' S.$, long. $127^{\circ} 23' E.$ On its South shore is the village of *Mofagila*, where there is a Dutch resident. The *Scaleby Castle* anchored here with the fort bearing S.W. off shore a quarter of a mile in 35 fathoms, sand and shells. *Miskien* is the next island southward, and *Kayo* or *Kiow* succeeds it southward. They are together about 11 miles from North to South. To the westward of them is a cluster of islets, called the *Guaricha* or *Latta Islands*. By daylight they are not dangerous, as most of them are visible.

At Makian, in 1846, a tremendous volcanic eruption took place, splitting the peak in two, destroying villages and their inhabitants by thousands. The island again repopled, once more in 1862 the volcano burst out, killed some 6,000 people, leaving scarce one to tell the tale; and the ashes discharged so covered Ternate, 40 miles distant, that nearly all vegetation there was destroyed.—*Lord George Campbell.*

At 6 miles S.W. from the S.W. end of Makkian is a 5-fathom bank, and 11 miles in the same direction from it is Laigoma, the easternmost of a cluster of islets and rocks which extend for 20 miles to the West and W. by S. The western part of the group should on no account be approached, as several *sunken rocks* lie around it.

The **Wolf Rock** lies about 28 miles W. $\frac{1}{2}$ S. from the South end of Makkian, lat. $0^{\circ} 20' N.$, long. $127^{\circ} 9' E.$ It is nearly level with the surface, the sea breaking over it, when it is visible in the hollow of the swell. It is thus a *very dangerous* neighbour. From it the Peak of Ternate bears N.E. $\frac{3}{4}$ N. 43 miles. One of the Guaricha isles bears S.E. by E. 12 miles, and a

small island off the North part of this group bears E. by S. about the same distance.

BATCHIAN or **Batjan**, one of the five original Molucca or Clove Islands, is by much the largest of them, and is the southernmost. Like the others, it is of volcanic formation. It is said that fossil coal of good quality has been found on it. The island is of irregular figure, about 52 miles long from N.W. to S.E., and has numerous islands off its West end. The Sultan of Batjan is the third prince in rank subject to the Netherlands in these seas, but he has very little power over his subjects, and piracy under his flag used to be common under the protection and seclusion of the bays and harbours formed by the islands around it. The population of Batjan is about 3,000. The chief town, *Batjan*, is at the head of a bay on the S.W. side, and here the Dutch have a post, called *Fort Barneveld*. *Mount Laburs*, upon Batchian Island, is a remarkable flat-topped mountain, 7,150 ft. high, in lat. $0^{\circ} 44' S.$, long. $127^{\circ} 32' E.$

“On the 14th of October, 1874, we passed the islands of Batchian and Tawali, which are great volcanic masses heaped up into ridges, about 1,000 feet in height, and separated by a long, narrow strait, abounding in the grandest scenery. Here on Batchian the clove tree grows wild. North of this island is Makian, an old volcano; in fact, we were just now surrounded with extinct craters.”—*W. J. J. Spry, R.N., Cruize of H.M.S. Challenger.*

The **Strait of Batchian** is formed by the islands of *Bottan Lumang* and *Mandolie* or *Marigorang*, the latter of which is flat-topped and about 1,000 ft. high. The southern part of it is broad, and there is good anchorage in most places, with sheltered anchorage on the adjacent shores, but the tide runs very strongly through the narrows in the North part of the strait. The strait may be said to continue past the N.W. part of Batchian, between that coast and the island of *Great Tawali* or *Kasiruta*. This channel could only be used with the greatest caution. Great Tawali has several islets off its S.E. end, of which the Sow Islets, low and not remarkable, are the southernmost. A sunken rock lies just South of the southern Sow. Great Tawali is 20 miles long N.N.E. and S.S.W., and 10 miles broad at its middle. It is high, and also flat-topped, with a peak rising above the surrounding hills to a height of 2,650 ft.; the peak is in lat. $0^{\circ} 20' S.$, long. $127^{\circ} 5' E.$

Tappi and *Latta Latta Islands* are separated by a strait 5 miles wide and 10 miles long from the N.W. side of Great Tawali Island. Tappi Island is generally high; the highest peak, of 1,300 ft., is in lat. $0^{\circ} 15' S.$, long. $127^{\circ} 4' E.$ Off the South and West extremes of Tappi are two small islets, about 200 ft. high; and 3 miles northward of its North point are three small rocks close together, 130 ft. high, and in lat. $0^{\circ} 11' S.$, long. $127^{\circ} 1' E.$ From a position 10 miles West of the Peak of Tappi, the islands of Ternate, Tidore, and Mortier were seen, and also one of the islands, probably Guari-cha, northward of Little Tawali.

Strong streams of flood and ebb were experienced by H.M.S. *Challenger* westward of the Batchian Islands, the flood coming from the northward and the ebb from the southward.

The tide sets through among these islands to the northward and southward about 6 hours each way, but not always regular, and it rises about 6 ft.

The **STRAIT of PATIENTIE**, between Batchian and the southern peninsula of Halmaheira, is about 50 miles long, and of very various breadths. It is a useful passage for vessels sailing between Ternate and Amboina in the S.E. monsoon, although there is no good anchorage in it, as there is in that of Batchian to the westward.

The northern entrance is between a projecting point of Halmaheira and *Batu Sombo Island*, close to the Batchian shore, an opening 7 miles wide. Between the S.E. point of the island and *Bristly Point* on Batchian, lie two islands near the shore, and to the southward of the point and southernmost of these islands there is a large bay, with good anchorage and plenty of wood and water. Further in the strait is *Lary Island*, long, low, and flat. It is covered with trees, and is close to the Halmaheira shore, on which, opposite to its N.E. point, there is a fresh water river, where plenty of wood and water may be obtained. The passage between the island and the Halmaheira shore is very narrow and shallow, and the tide is sometimes exceedingly rapid. Farther South is *Helang*, or *Amsterdam Island*, in the middle of the Narrows. After passing these islands, going southward, stand over to the eastern side of the strait, and keep along that coast, on account of a shoal said to lie nearly in mid-channel between the East point of Batchian and Halmaheira. The East point above mentioned is in lat. $0^{\circ} 48' S.$, long. $127^{\circ} 53' E.$, and has deep water close-to in some parts, but some islets and projecting spits should have a proper berth.

The **MOLUCCA PASSAGE**, or **Molucca Sea**, the wide space between the islands just described and the eastern side of Celebes, described on page 812, requires but little description. The islands to the South of it, the Xulla Group, are described on page 821, and Obi Major on p. 866. Between the N.E. part of Celebes and the N.W. shore of Halmaheira, the breadth of the narrowest part of the strait is 120 miles.

Mayor or Meyo Island, in the middle of the passage between Ternate and Menado on Celebes, is about $3\frac{1}{2}$ miles long East and West, and rises gradually from the shore to a round-backed summit, 1,280 ft. high, in lat. $1^{\circ} 20\frac{1}{2}' N.$, long. $126^{\circ} 22\frac{1}{2}' E.$ There is said to be anchorage on both the North and South sides, sheltered from the monsoons.

Tifore, or *Tyfore*, 17 miles S.W. of Mayor, is about 2 miles long in an East and West direction, and $1\frac{1}{2}$ mile broad. On its N.W. end is a saddle peak 530 ft. high, the eastern and highest summit being in lat. $1^{\circ} 1' N.$, long. $126^{\circ} 8' E.$ About one cable's length off the N.W. point of the island is a small islet. On the eastern side of the island there is a bay in which,

according to the statement of the Malays at Ternate, whose proas frequently take shelter in it, there is a depth of 20 or 30 fathoms, with a ridge of coral across its entrance, upon which there are from 1 to 3 fathoms. There are no soundings to be got in the strait between Tifore and Meyo, and no danger was observed by H.M.S. *Challenger*. The current sets to the N.E. during the greater part of the year.

The islands to the North of the N.E. extremity of Celebes, and those South of Mindanao, will be described in the succeeding chapter.

DIRECTIONS for the **Eastern Passages**, or those eastward of Borneo, to the description of which the latter pages of this work have been devoted, have been given in pages 67—102. The choice of the most advantageous straits or channels in the different monsoons is there indicated, and as will be understood, this choice must depend very greatly upon the consideration of the sailing powers of the ship, combined with the direction and strength of the winds encountered. To follow the directions given in the remarks referred to will not be difficult in combination with the hydrographical descriptions in this chapter, as the latter follow in regular geographical order, and are thus readily followed in any voyage, whether going northward or southward. The illustrative chart facing page 42 will also aid in facilitating the application of those general directions with the subsequent descriptions.

CHAPTER XIX.

IN the foregoing pages the various islands and channels which form the southern part of the chain of the Eastern Passages, or those between Borneo and New Guinea, have been described. What follows in the present chapter will be descriptions and brief remarks on the islands North of the Moluccas, of which the Sulu Archipelago and the important Philippine Islands, are the principal. The information is derived from a variety of sources, and considerable improvement in our knowledge of the Sulu Archipelago was gained by an examination made by H.M.S. *Nassau*, in 1872. It may, however, be observed, generally, that the hydrographical knowledge of the islands described in this chapter is not as perfect as could be desired. We commence with the southward and proceed northward towards the northern portion of the Philippine Archipelago.

ISLANDS NORTH OF THE MOLUCCAS.

Bejaren is about 26 miles N.E. from the East end of Banka Island, lying against the north-eastern extremity of Celebes, and described on page 812. The channel southward of it is quite safe, and is much used. When seen from an eastern or western direction it is wedge-shaped, with the cliff to the southward; but seen from the southward it rises to a single sharp hill with a thumb-like summit projecting nearly 500 ft. above the main portion of the hill. The peak is 1,240 ft. high, and in lat. $2^{\circ} 6\frac{1}{2}'$ N., long. $125^{\circ} 21\frac{1}{2}'$ E. A fire was seen on the N.W. side of the island by H.M.S. *Challenger*.

Tagulanda is about 10 miles N. by E. from Bejaren, the channel between being clear of danger. The island is about 7 miles long, and has two summits which show from East and West; the eastern summit is round-backed and 2,550 ft. high; the western peak, 2 miles West of the eastern, is more abrupt, and 2,450 ft. in height. To the S.W. of it, in lat. $2^{\circ} 20'$ N., long. $125^{\circ} 21'$ E., and connected by a reef, is the islet *Duang* or *Roang*, which shows from the East and West as two sharp volcanic peaks, but from the southward

as three peaks; the eastern, of 2,450 ft., is the highest. Smoke was seen rising from the middle summit, and the island to within 300 or 400 ft. of the sea is covered with lava and scoriæ, the lower part being wooded. At 5 miles N.W. of Roang is *Passigi*, small, flat, and covered with trees, the tops being about 100 ft. high.

Siao or *Seauw* is larger than *Tagulanda*, and is made very conspicuous by a high conical volcanic peak, lat. $2^{\circ} 44'$ N., long. $125^{\circ} 22'$ E. There is a village, named *Undung*, about the middle of the western side of the island, off which to the W.S.W. is a sunken rock. *Makaléhé*, a small island, round-backed, with palm trees (probably cocoa-nut) growing on its highest ridge, lies 8 miles West of *Siao*. This island was seen 25 miles off by H.M.S. *Challenger*, but *Maquiliere* Island was not visible at the same distance. *Mandang*, with other islets, lie on the eastern side of *Siao*. Some rocks project from the S.W. side of *Mandang*, between which and *Siao* there is an opening a mile wide. The channel between *Siao* and *Tagulanda* is about 12 miles wide, and quite safe.

A group of small islands lies between *Sangir* and *Siao*. They are sometimes called the *Karakitang*, or *Passage Islands*. The westernmost of the northern cluster is *Karakitang*, and is high; the easternmost is *Pala*, and projects into a low point to the eastward. The channel to the southward of them, between this and *Siao*, is considered to be dangerous, as there is a cluster of four rocky islets nearly midway between the two islands; one of these is called the *Quoin*. If this channel is taken, the North end of *Siao* should be passed close-to, to avoid them; but it is better to pass southward of that island. The easternmost of these islands is called the *Rabbit*, which is 18 miles S.E. of the South end of *Sangir*. There are two other small islets or rocks to the East of the *Rabbit*, and others to the westward; several of them are small spiral rocks, and some appear like haycocks.

SANGIR or *Sanguir* is 24 miles long N.W. and S.E., and is of volcanic formation, a link in that great chain which passing through *Java* continues northward through the *Philippine Islands*. It contains many extinct craters, and several active volcanoes. The northern part consists of high mountains. The chief peak is *Mount Abu*, at the N.W. end. The people are somewhat civilized, simple, and inoffensive, speaking a peculiar language. The South point, *Cape Palumbatu*, is in lat. $3^{\circ} 21'$ N., long. $125^{\circ} 39'$ E. The island is surrounded by numerous smaller islets, of which we have no account. The western side is indented by several small bays, with soundings of from 40 to 60 fathoms at from 1 to 2 miles off shore. It is clear of danger, but the bottom is mostly coral. There is an anchorage off a small river or watering place in a bay, in lat. $3^{\circ} 29'$ N., long. $125^{\circ} 28'$ E., with the village bearing E.N.E., the piece of land like an island, but joined to the main island N.E., distant $1\frac{1}{2}$ mile, the point of *Pulo Keama*, off the South end of *Sangir*, S. 36° E. The watering river is there a little to the southward of the land

resembling an island. The tides run to the northward and southward about 2 miles an hour, and rise 6 or 7 ft. The water should be filled before high water, as the ebb soon runs out dry. Poultry and vegetables may be got. There is also said to be a harbour on the East of Sangir, formed by the adjoining small islands, several of which are at a considerable distance.

There are some small islands which lie scattered in the space between Sangir and the South point of Mindanao, but they have safe channels among them. The southernmost is called *Louisa Island*, 13 miles N. by W. from Sangir. The *Louisa Shoal* is N.W. 4 miles distant. There is a good channel outside the isles off the N.E. part of Sangir, but great caution is requisite in the bight. To the northward of the last-mentioned island is a group called the *Carcara-long Islands*, six in number, extending from lat. $4^{\circ} 15' N.$ to $4^{\circ} 46' N.$ They are named respectively the *Haycock*, *Armadores*, *Anda*, the two *Saddle Islands*, and *Ariaga*, the northernmost. *Haycock Rock*, in lat. $4^{\circ} 11' N.$, long. $125^{\circ} 5' E.$, lies N.W. by W., 24 miles from Louisa Island, and W. by S. $\frac{3}{4}$ S., 12 miles from Haycock Island. There is also a dangerous patch of rocks, seen by the *Iphigenia*, two above water a mile apart, and a third under water a mile to the southward of the southernmost, in lat. $4^{\circ} 11' N.$, long. $126^{\circ} 8' E.$

The **TULUR ISLANDS** are the last of the Dutch possessions that have to be noticed. They lie 65 miles north-eastward of the Sangir group, are not much known, but are also called the Talaut or Salibabo Islands, the latter being the name of the principal island. They are inhabited by a partially civilized and simple race, who raise yams, cocoa-nuts, hogs, goats, and poultry.

The southernmost island is *Kaboroan* (Kabroang), and has a peaked summit on its eastern end. At its S.E. point is Kaman Village, in lat. $3^{\circ} 49' N.$, long. $127^{\circ} 2' E.$ *Satibabo* or *Lirong* is to the W.N.W. of Kaboroan. On its N.W. end is a table hill, and the principal village is in a small harbour at the bottom of Salibabo Bay, at its S.E. end. Sailing in for the road by the South channel, between Kaboroan and the S.E. point of Salibabo, a berth must be given to a spit that projects rather more than half a mile from the shore, about halfway between the point and the harbour. The harbour is readily known by the houses and cocoa-nut trees, but is not adapted apparently for large vessels. There is a safe channel between this island and the others to the N.E., but the S.E. end of Karekelang should be approached with caution.

The *Northumberland Reef* lies about 12 miles S.E. from the peak of Kaboroan. It is about 2 miles in extent, and has a patch of sand above water.

Karakelang is the largest and northernmost of the Talout Islands, and is 24 miles long N.E. and S.W. The northern part is lined with a dangerous reef, which projects 3 or 4 miles from the North point.

The *Meangis Islands*, 36 miles N.E. of Karekelang, consist of five islands,

of moderate height, with some smaller ones adjoining. The southernmost, Kakarutan Island, is in lat. $4^{\circ} 39' N.$, long. $127^{\circ} 7' E.$ At 2 miles eastward of it are some small islets, and 5 miles N.N.E. of it a sunken rock, which also lies S. $\frac{1}{2}$ E. $2\frac{1}{2}$ miles from Central Island. *Namusa*, the largest island, 3 miles long North and South, and 670 ft. high, has its North point in lat. $4^{\circ} 48' N.$, long. $127^{\circ} 6' E.$ At 5 miles W.N.W. from this point is North Island. Karatin Island lies 5 miles South from North Island, and has a sunken rock off its N.W. end. These islands are but little known, and a good look-out is required when near them. H.M.S. *Challenger* passed within 5 miles of them in February, 1875, and exchanged some tobacco for lories brought off by the natives in their canoes. A S.E. current had drifted the ship further South than was intended.

The CELEBES SEA is the area between these last described islands, the Sulu Islands, the coast of Borneo, and the North coast of Celebes. Its shores have been described, but the following may be interesting as relating to its depth, &c.

“Proceeding through the passage between Banka Island, off the North coast of Celebes, and Bejaren Island, the positions of those and the neighbouring islands were fixed, and a sounding obtained in 2,150 fathoms, red clay, when only 23 miles West of Maquiliere Island. The serial temperature proved that the water in the Celebes Sea is cut off from communication with the surrounding seas below 700 fathoms, the temperature of the water below that depth being uniform at $38^{\circ} 6'$, this agreeing with the observations of Commander Chimmo. On the 22nd of October another sounding was obtained in 2,600 fathoms, when about 40 miles from the land of Point Pola, South coast of Mindanao, with the same result as to temperature.”—Voyage of H.M.S. *Challenger*, Geographical Magazine, November, 1875.

THE SULU ARCHIPELAGO.

This labyrinth of islands between Borneo and the Philippine Islands is variously termed the Sulu, Sooloo, Soolo, Soeloe (Dutch), Jolo (Spanish), Suluk (Malay). An examination of the group was made in 1872 by Commander Chimmo, R.N., in H.M.S. *Nassau*. Previous to this our knowledge was very scanty, and chiefly derived from the visit of the United States' Exploring Expedition, in 1842.

The Archipelago consists of nearly 150 islands, many of them mere rocks, clustered around the three larger islands, which alone are of any importance. Basilan to the E.N.E., Sulu in the central part, and Tawi-Tawi in the W.S.W. part. Although the islands are supposed to be under the rule of the Spaniards, the Sultan and his subjects are in constant rebellion, and a

blockade of the ports was going on at the time of the visit of H.M.S. *Challenger* to Samboangan in 1875. Previous to holding communication with these people it is necessary to hoist a flag of truce.

The commerce, chiefly with Manila, is mostly in tortoise-shell, pearl oyster, pearls, sharks' fins, trepang, and swallows' nests. The people profess the Mohammedan religion, and the only people who can reside among them as traders are the Chinese, who pay a large tribute in their shipping transactions.

Tapul Group.—*Siassi Island*, the peak of which is in lat. $5^{\circ} 32'$ N., long. $120^{\circ} 52'$ E., and 1,714 ft. above the sea, is the highest island between Sulu and Tawi-Tawi. There are several large villages built on the reefs that fringe the S. W. and East coasts, the inhabitants of which carry on the pearl fishery. *Tara Island* lies on the reef to the North of Siassi, and $1\frac{1}{2}$ mile North of this is a solitary rock, 8 ft. above high water mark.

Tapul and *Bulipongpong*, two fertile and well cultivated islands, lie to the northward of Siassi; the former is 1,657 ft., and the latter 984 ft. high. They are apparently clear to the westward, but reefs extend to the southward and eastward of both.

A 3-fathom patch, a mile in extent, lies 2 miles northward of Siassi, with the East extreme of Manubol Island bearing S. $\frac{3}{4}$ W., and the North extreme of Tara Island E. by S. $\frac{1}{2}$ S. Another patch, about 3 cables in extent, awash at half tide, with deep water around it, lies $1\frac{1}{4}$ mile S. $\frac{3}{4}$ E. from Tara Island; and a third patch, of 3 fathoms, lies $1\frac{3}{4}$ mile E.S.E. from it.

Lapac, three-quarters of a mile to the westward of Siassi, in the distance on a S.E. bearing looks like two islands. The reef from this island nearly joins that of Siassi. The Imperial German ship *Elisabeth*, Captain Von Wiekede, obtained good anchorage in 11 fathoms, in the channel between Siassi and Lapac Islands, abreast a house almost hidden by trees, on Siassi Island. The southern portion of this channel, which lies between the coral reefs extending from these islands, is 1 cable wide, with depths of 6 to 9 ft. on the bar at the South entrance, where it is only half a cable wide; but from an examination by Captain Schick, in the German schooner *Minna*, 1876, there appears to be $6\frac{1}{2}$ fathoms in the southern entrance of the channel.

One-third of a mile from the S.W. point of Lapac is a dangerous patch of rock, with 8 fathoms between it and the shore. The island of *Manubol*, on the South part of the Lapac Reef, has a large fishing village on the north-eastern side. Good anchorage was found by H.M.S. *Frolic*, in 1874, off the West side of Lapac Island; and immediately off the northern entrance of the passage, between Lapac and Siassi Islands, good shelter is said to be found by vessels, in the S.W. monsoon. There is also good anchorage in from 7 to 12 fathoms, sand and coral, to the southward and westward of the small island West of Lapac, and immediately off the village. Supplies may

be obtained at Lapac, such as bullocks, goats, and fowls, at a moderate rate, but vegetables are scarce, as is also water.

Selun, a small island $2\frac{2}{3}$ miles N.W. of Lapac, is about a quarter of a mile long, 153 ft. high, covered with trees, and steep-to, with a clear channel between it and Lapac. *Tapaam*, a low island, lies S.W. of Lapac. The channel between is about $1\frac{1}{2}$ mile wide, and navigable.

Tapaam Passage, which is formed by Tapaam and Lapac to the eastward, and Bubuan and Maniacolat to the westward, is about $6\frac{1}{2}$ miles wide at its narrowest part, viz., between Maglumba, a small island, 123 ft. high, off Maniacolat, and the N.W. side of Tapaam. This passage is clear for a steamer, and would be convenient for a sailing ship, as the tides make fairly through it, and in calms or light winds a vessel could always anchor to await the change of tide. *Crest of Wave Shoal* is in the fairway of the Tapaam Passage, and the shoalest part of $4\frac{1}{2}$ fathoms lies about N.E. $\frac{1}{2}$ E., $4\frac{3}{4}$ miles from the little conical island of Parangaan, on the S.W. side of the passage. As a rule, it is easily discerned by discolouration, or by the tide rippings. *Tapaam Shoal* is a small patch of $6\frac{1}{4}$ fathoms, coral and sand, nearly midway between Tapaam and Bubuan.

Tagao Island lies 7 miles southward of Bubuan. It is a small island, with a sunken rock one-third of a mile S.E. of it. *Magpeo*, another small island, surrounded by shallow water, lies 2 miles northward of Tagao. *Keenapoussan Group*, 10 miles to the southward of Babuan Island, consists of three low, densely wooded, coral islands of Tabawan, Bintoulan, and Keenapoussan, between the two former of which there is a narrow 5 fathom channel. As the reefs to the southward of these islands are steep-to, and the lead consequently gives no warning, care should be taken when navigating in this vicinity. The tides here are also strong. The best anchorage is with the West extreme of the village on the North side of Tabawan about S.S.E., three-quarters of a mile off shore. The tides are regular here, and not very strong.

The **TAWI-TAWI**, or **Tau-i-Tau-i**, or *Tawee-Tawee* Group, are those nearest to Cape Unsang. The principal island of the cluster is Tawi-Tawi, 35 miles long, and its northern side, according to the Spanish charts, appears nearly clear of danger.

Bongalao Island is the most western of the Tawi-Tawi Group. It is about $2\frac{3}{4}$ miles long by $1\frac{1}{2}$ mile broad, and the highest peak is 1,151 ft. above the sea, but other peaks attain nearly the same altitude. *Observation Islet*, immediately South of Bongalao, is in lat. $5^{\circ} 0' 33''$ N., long. $119^{\circ} 44' 20''$ E. *Sanga Sanga Island* is about 6 miles long in a N.E. and S.W. direction, and $3\frac{1}{2}$ miles across at the widest part; it lies immediately to the northward of Bongalao, between it and Tawi-Tawi Island, and separated from each by a very narrow boat passage. Unlike Bongalao, this island is not high, has no conspicuous hill on it, and is covered with trees. There are a few small

patches of cultivation on the S.E. side over Pandan Bay, where there is a Panglema or chief, but there is none in any other part of the island. *Pandan Bay* is a snug anchorage, well sheltered from all winds, with good holding ground, taking care if going close in to avoid the rock awash and the 6-foot coral patch in the middle of the entrance. The best anchorage is, however, outside the bay, in from 11 to 13 fathoms, mud, with the Panglema's House (on the East side of the bay) N.N.W. $\frac{1}{2}$ W., and South point of Sanga Sanga W.S.W. There are no supplies to be obtained. Care should be taken in approaching Pandan Bay, to avoid some dangers on the South coast of Tawi-Tawi.

Papabag Island lies on the South side of the entrance to Pandan Bay, and East of Bongalao Island. There are said to be numerous wild cattle here, but none were seen during the *Nassau's* visit in February, 1872.

Balambing, a town on the South coast of Tawi-Tawi, was destroyed by the Spanish squadron in 1871, since when, on the smoke of a steamer being seen, the inhabitants take to their boats. They are pirates when opportunity offers, and build boats at a place called Lupa Buan, about 10 miles to the N.E.

Bilitan is an island about $3\frac{1}{2}$ miles long, the North extreme being about $6\frac{1}{2}$ miles S.S.E. of Balambing; there appeared to be some large villages in the interior of this island, and judging by the number of boats passing between it and Tawi-Tawi and the islands to the S.W., there is great traffic carried on between them. The reef, with a few narrow, tortuous channels through it, joins Bilitan to the S.E. end of Tawi-Tawi, and from the S.W. end of Bilitan a dangerous coral reef, with sand cays, extends for 9 miles to the S.W. *Simonor Island* is about 5 miles in diameter from N.W. to S.E., and its N.E. end lies W.S.W. 9 miles from the S.W. end of Bilitan. It is thickly inhabited, but has no anchorage near, as the fringe of coral reef surrounding it is steep-to. At 2 miles N.E. of its N.E. end is *Laa*, a small island, surrounded by a reef, which thence extends for 5 miles to the W.N.W., having $2\frac{1}{2}$ fathoms on its western extremity, and a second island 2 miles W.N.W. from the first. This reef with the S.W. extremity of that extending from Bilitan forms a channel on the East and North sides of Simonor. *Manuc Manca* is separated from Simonor by a deep channel 2 miles wide. It is thickly inhabited, and the reef surrounding it steep-to.

There is good anchorage anywhere along the South coast of Tawi-Tawi from Bongalao to Balambing in about 13 fathoms, sand and coral, muddy bottom being sometimes obtained, but there are several dangers, as before mentioned, which require caution. When anchored North of Laa Island in H.M.S. *Nassau*, the natives came off from Simonor in large numbers with fowls, goats, cocoa-nuts, sweet potatoes, and fish.

Sibutu Island, the North end of which is in lat. $4^{\circ} 54' 40''$ N., long. $119^{\circ} 27' E.$, lies W. by S. $\frac{3}{4}$ S. about 18 miles distant from the Observation

Islet South of Bongalao; it runs nearly North and South, and is about 14 miles long, with an average breadth of 2 miles. With the exception of the single peak on the East coast, which has an altitude of 524 ft., and is a perfect cone, the island is flat and densely wooded. A reef, steep-to, fringes the coast, and then runs nearly 8 miles South of its southern point, some small islands covered with trees, lying near its S.W. extreme.

From 2 to $2\frac{1}{2}$ miles West of Sibutu a chain of islets and reefs runs to the southward and parallel to it, of which *Omapui* and *Tumindao Islands* are the principal. There is a deep channel between Sibutu and these islands, but it has not been examined. From the N.E. point of Omapui the reef trends to the N.W. for about $2\frac{1}{4}$ miles, and then to the S.W. These islands are frequented for the beche-de-mer. The natives report that wild cattle are very numerous in Sibutu, and that Omapui abounds with wild pigs.

Unsang Anchorage, off the extreme East point of Borneo, affords good shelter in the S.W. monsoon, the bottom in the bay being moderately even, and holding ground of sand and mud, remarkably good. The N.E. extreme of the island South of the anchorage is in lat. $5^{\circ} 14' 54''$ N., long. $119^{\circ} 15' 11''$ E., and lies N.W. by W. $\frac{3}{4}$ W. from the Observation Islet, South of Bongalao, distant 32 miles.

Two and a half miles N. by E. $\frac{1}{2}$ E. from the observation point is *Rocky Bank*, two rocks on a 3-fathom bank. Three-quarters of a mile to the westward of Rocky Bank is *Sandy Bank*, half a mile in extent, composed of sand and mud, its western edge being within $1\frac{1}{2}$ cables of the shore.

No fresh water was found at any time of tide. Fish are plentiful. There were no traces of natives during the stay of the *Nassau*. Casuarina trees for steaming purposes may be cut in any quantity close to the beach.

René Bank, of 4 fathoms, lies in lat. $5^{\circ} 31' N.$, long. $119^{\circ} 9' E.$, N.E. by E., 5 miles from Tambisan Island, on the East side of Tanguusu Bay. Discolored water was seen at 6 miles N.E. of it in lat. $5^{\circ} 37' N.$, long. $119^{\circ} 15' E.$, approx.

Nymphe Bank was discovered by a Prussian corvette of that name in 1873. It is described as half a mile in extent, and breaking heavily. Lat. $5^{\circ} 43' N.$, long. $118^{\circ} 41' E.$

Peri Bank, of $5\frac{1}{2}$ fathoms, is in lat. $5^{\circ} 47' N.$, long. $118^{\circ} 57' E.$

Sunday Bank lies N. by W., distant 32 miles from Hog Point, which is visible from it. The shoalest water on this bank (10 fathoms, sand and coral) is in lat. $5^{\circ} 50' 35'' N.$, long. $119^{\circ} 9' 30'' E.$

Talantam Bank is composed of sand and coral, the shoalest part of 5 fathoms being in lat. $5^{\circ} 42' N.$, long. $119^{\circ} 26' 30'' E.$ It is about 3 miles long N.W., and S.E. $1\frac{1}{2}$ mile wide, with an average depth of 8 fathoms. With wind against the tide there are heavy overfalls round this bank.

The Pearl Bank, on which are Taja and Zan Islands, is a formation of coral and sand, lying about E. by N. and W. by S., 15 miles long, with an

average width of 6 miles, and very steep-to. The opening leading into the lagoon formed by the coral reef on Pearl Bank, has a bar extending across it with 9 to 13 ft. water. This reef has several small islands, the highest (50 ft.) being near the S.E. extreme. There is fair anchorage on the bank either to the N.E. or S.W., in the S.W. and N.E. monsoons respectively, but tides are very strong, running with a velocity of from 3 to 5 knots an hour.

Doc-Can lies E. $\frac{3}{4}$ N. about 12 miles from the eastern islet on the Pearl Bank. In the centre of this island is a large lagoon, with several islets in it. A bank with from 5 to 8 fathoms extends about 2 miles to the N.W. of Doc-Can Island. *The tides* here are very strong, the flood running N.N.W., ebb S.W., 3 to 5.5 miles an hour. There is anchorage South and West of Doc-Can, but none North of it; outside the 20-fathom limit the bank is steep-to; on the southern side of the island, a ship should anchor directly 9 or 10 fathoms is obtained, as deeper water will be found between those soundings and the edge of the reef.

Laparan Island is situated to the eastward of Doc-Can, with a channel a quarter of a mile wide dividing them; it runs North and South, is 5 miles long, and from 2 to 3 miles broad, and covered with trees. To the westward it is fronted by a coral reef, with several small islets on it, the reef being steep-to. There is no anchorage to the westward of Laparan.

Cap Island lies 9 miles E.N.E. from Laparan. It has sunken rocks extending 3 miles westward from its northern end, and a 2 $\frac{1}{2}$ -fathom patch at 3 miles eastward of the same point. *Deoto Bato*, 2 $\frac{1}{2}$ miles long in a N.N.W. and S.S.E. direction, lies in the southern part of the strait which separates Laparan and Cap Islands. Numerous small islands lie to the south-eastward between these islands and the Tapul Group, which will be best understood from the chart.

SULU is about 30 miles long, and 8 or 10 miles broad. The officers of the U.S. Expedition came to the conclusion that they had seen nothing in their circumnavigation to be compared to this enchanting spot. It appeared to be well cultivated, with gentle slopes rising here and there into eminences from one to two thousand feet in height. Although under cultivation, it had the freshness of a forest region. The effect of this was destroyed in part by the knowledge that this beautiful archipelago was the abode of a cruel and barbarous race of pirates.

Sulu or Soung, at the N.W. end of the island, is or was the residence of the Sultan or Rajah, and the emporium of the archipelago. H.M.S. *Egeria* visited the place in 1876, and found that the town had been destroyed. According to Sir Edward Belcher, it is built on piles, like Bruni on the N.W. coast of Borneo, running in three lines out to sea, the outer houses being in 4 fathoms, the intervals allowing the *Samarang* to lie in the main street.

The chiefs, however, reside on terra firma. There are or were two batteries, one on each side of this main water communication. It is in lat. $6^{\circ} 2' N.$, long. $121^{\circ} E.$

The anchorage in the road is in 18 or 20 fathoms, on a loose sandy bottom, with the Sultan's house bearing S. $26^{\circ} E.$, Mount Temontangis S. $26^{\circ} W.$, Tulian Rock S. $67^{\circ} W.$, and the S.W. point of Paliangan, the largest and westernmost island in the offing N. $60^{\circ} W.$ The bottom being insufficient holding ground, ships are liable to drive in N.W. squalls. Bullocks, poultry, and live stock of all kinds, with abundance of vegetables and fruits, may be procured; also wood and water. But in any communications here, the utmost caution should be used, as before urged. Water may be procured in abundance in *Talian Bay* at the N.E. end of the island.

In coming to Sulu Road from the N.E. care should be taken to avoid the *Takut Pabunuan Shoal*, with 3 and $3\frac{1}{2}$ fathoms or less water, and extending N.E. and S.W. for 6 or 7 miles. The southern part is in lat. $6^{\circ} 14' N.$, long. $121^{\circ} 16' E.$, about 18 miles N. by W. from the East end of Sulu, and 16 miles westward of the *Duo Bolod*, two rocks 700 feet in height, nearly midway between Sulu and Basilan. They are quite bold-to. *Leaving* Sulu Road, the best route to the S.E. is round the West end of the island, leaving the high island of Tapul before mentioned, and the low islands of Taluk and Kabinguan to the southward, and the islands nearer to Sulu to the northward. One of the detached coral patches mentioned before, however, lies near this track. It has $8\frac{1}{2}$ fathoms, and bears from the westernmost high land of Sulu S.S.E. and West from the South point of Pata Island, which is high. The tides set fair through this channel, and sometimes very strong. Off the West end of Sulu, in December, they have been found to set N.W. and S.E. at 4 miles an hour. During the N.N. monsoon there is generally a N.W. or westerly current in the neaps between Sulu and Basilan. In March the current generally sets to the eastward.

Dalrymple Harbour, on the N.E. side of the island of Sulu, is formed by the island of Tulyan on the North and the coast of Sulu to the South, and, being the only well-protected harbour in this fertile island, may at some future day be a place of importance. Good anchorage will be found during the N.E. monsoon under the lee of Tulyan Island; the natives report that during the N.E. monsoon the wind seldom blows home.

Tulyan Island, about 1 mile in length from S.S.W. to N.N.E., and 8 cables in an East and West direction, is steep on the West side, running up to a height of 513 ft., the summit being clothed with long grass. The Spaniards had a guard of soldiers on this island for some time, but the natives from the mainland made such frequent excursions, spearing the sentries and cattle, that they found it advisable to remove the settlement, since which time it has not been inhabited.

Buol was the largest town in this part of the island of Sulu, but was partially destroyed by the Spaniards in 1872.

A large ship visiting Dalrymple Harbour should round Tulyan Island to the northward, and approach the anchorage by the eastern passage, avoiding the $4\frac{1}{2}$ -fathom patch $3\frac{1}{2}$ cables S.W. of Martin Bluff, having passed on the island side of which, a course about S.W. $\frac{1}{2}$ W. until the southern point bears West, leads up to the anchorage in 8 or 9 fathoms. The extreme eastern point of the island should then bear about N.N.E. $\frac{3}{4}$ E. Supplies are not to be obtained.

Maimbun Bay, on the S.W. side of Sulu Island, is much used as an anchorage during the N.E. monsoons; the bottom, however, appears to be studded with loose coral. The rock charted 2 miles South from Point Cabalian (the West entrance point of Maimbun Bay), is said not to exist. A shoal (Batolaqui Shoal), awash at high water, was seen from the *Swinger*, at half a mile E.S.E. from Point Cabalian.

The Pangutaran Group, to the N.W. of Sulu, consists of several islands, of which that which give the name is the largest and westernmost. There is a village on the coast at 5 miles S.W. of Sulu, and near the shore, N.E. of this village, is a sunken rock. W.N.W. 3 miles from the point on which the village stands is an islet, with a sunken rock $1\frac{1}{2}$ mile westward from it. *Marongos*, a small island, lies N.W. 6 miles from Sulu, and in a N.E. direction from it lie three other islands, within a distance of 8 miles. A bank lies a little to the S.E. of the centre one of the three. *Palliangan*, 5 miles long N.E. and S.W., has its South extreme at 3 miles W. by N. from Marongos. Off its S.W. extreme are some dangers, and at 4 miles W.S.W. from this point is a 3-fathom patch. There is a clear channel between the Pangutaran Group and *Ubian*, and this is the proper course in the S.W. monsoon, as the currents run strongly to the northward along the West sides of the islands. To the northward of Pangutaran the springs sometimes run 6 knots, and if hosed to the eastward of the island, there will be some difficulty in getting to the S.E., as the two adjacent islands, *Kulassein* and *Panducan*, are connected by reefs, and the strait between is very narrow.

Ubian is inhabited, the largest town Suang-bunah being on the S.W. side, well protected by a coral reef. From *Ubian* a shallow bank, with from 7 to 11 fathoms over it, runs in a W.S.W. direction for nearly 19 miles to Cap Island. This bank affords a good stopping place for a ship taking the Pangutaran passage; its northern edge is very steep, and the lead should be kept going when approaching from this direction. There is anchorage between *Ubian* and *Malicut*, a small island $3\frac{1}{2}$ miles S.W. of it, in from 5 to 10 fathoms, but the bottom is hard and even. There is also anchorage about 1 mile W.S.W. of the North end of *Malicut* in 7 to 9 fathoms, but the tides run strong at springs.

The interval between Sulu and Basilan, a space 43 miles wide, is occupied

by several groups of islands, which have open and clear channels between them. The south-easternmost of these openings, between *Point Tandu*, the East point of Sulu, and *Bengao*, the island next eastward of it, is $5\frac{1}{2}$ miles wide, and, as far as is known, is safe, the only danger being a reef off the N.W. point of the latter island. The channels between this and Belauan, separated by *Batanguingi* and *Tongkuil Islands*, are also safe.

In the space to the northward of Sulu Island are several detached rocks and dangers. *Teomabal Island*, 12 miles East of Panducan, has a reef extending 8 miles E.N.E. from it, and 5 miles northward of the eastern end of this reef is a detached $1\frac{3}{4}$ fathom bank. *St. Lucia Shoal*, of $3\frac{1}{2}$ fathoms, is in lat. $6^{\circ} 24' N.$, long. $121^{\circ} 14' E.$ *Wilhelmina Rock*, awash at high water, lies 7 miles E. $\frac{1}{2}$ N. from this, and at 8 miles S.E. from the St. Lucia is a rock awash, with a $3\frac{1}{2}$ -fathom patch just northward of it, and shallow water extending for 6 miles to the S.W.

Belauan or *Belawn* is the south-easternmost of a cluster, and is apparently low land, and on the N.W. island is a high, round mount. The East point of Belauan is in lat. $6^{\circ} 7' 30'' N.$, long. $121^{\circ} 52' E.$ A mile to the N.E. of it are two small islets, called *Dipulul*. *Tataran* is also of moderate height, and is 6 miles northward of the East point of Belauan.

The channel between *Tataran* and *Lanauan*, which is 533 feet in height, is 6 miles in breadth, and the edge of the bank of soundings on which the islands stand is very steep to the eastward of them. This occasions a ridge or line of strong rippings, appearing sometimes like breakers when the current runs swiftly, but there is no danger, the least depth being 9 and 10 fathoms. *Tapiantana Island*, which forms the N.E. limit of this channel, has a high hill, forming a regular peak on its western part, with low land stretching out to its East point, which is in lat. $6^{\circ} 17' N.$, long. $122^{\circ} E.$ *Bubuan Island*, to the northward of Tapiantana, is very similar to it, and has a mount of similar form 983 ft. high. To the eastward of them are the *Salipen Islands*, from the North side of which a reef extends towards the South point of Basilan. The channel between the South end of Basilan and the reefs which lie off it is safe, but in some parts is very narrow, so that that South of Lanauan is much to be preferred.

BASILAN, the largest of the eastern group, belongs to the Spanish Government. It was a nest of thieves and pirates, the most expert in the archipelago, and in consequence was taken possession of by the Spaniards, and attached to the province of Samboangan in Mindanao. It is about 20 miles long, and is a mountainous country. The highest point, on the South side, is 3,970 ft. high; the East end rises to 2,540 ft., and the western point to 1,116 ft.

Point Matanal, the eastern extremity, is in lat. $6^{\circ} 37' N.$, long. $122^{\circ} 19' E.$ Above it is the high land before mentioned. The N.E. shore of the island is quite bold to, and trends to W.N.W. for 20 miles to the mouth of a narrow

strait, formed by *Malaunavi Island*, in which is the Spanish post of *Isabela* or *Passanhan*.

Passanhan or *Isabela Harbour*, at the N.W. side of *Basilan Island*, can be entered from the North or South, and there is sufficient depth of water for large vessels. The channel has an average width of $1\frac{1}{2}$ cable; the shoals which in some places narrow it are marked by buoys, as is also the shoal off the southern entrance. Large vessels should moor in the stream; smaller vessels may lie closer to the shore of the harbour.

The tides during the stay of the *Hertha*, in the month of April, were regular, of six hours' duration each, and no slack water; they are, however, frequently influenced by the wind. The flood set S.W. and the ebb to the N.E., at the rate of $1\frac{1}{2}$ or 2 knots.

Isabela, the residence of the Spanish Governor of *Basilan*, is situated on the western slope of a chain of hills, 590 ft. high, and densely wooded. The bar of the rivulet *Passanhan*, West of the town of *Isabela*, is impassable even for small craft. It supplies the only drinking water to be obtained, but so high up that boats cannot ascend. Provisions cannot be obtained. There is a coal depôt for the use of the Spanish vessels of war, at a small island adjoining the mainland; no other store of coal is kept.

The population consists of 5,000 or 6,000, chiefly Malays and Chinese, who live in bamboo huts, the Malays, according to their custom, over or near the water. Some convicts are kept on the island where the coal depôt is placed.—(Ship *Hertha*, Imperial German Navy, 1875.)

The bay to the West of this, called *San Rafael Bay*, has anchorage in 12 to 15 fathoms, protected in some degree by the shoals which extend westward from the island.

To the westward of *Basilan* there are numerous islands, the channels between which appear to be safe, but should only be used with caution. *Bubuan*, 983 ft. high, lies off the South point in lat. $6^{\circ} 21' N.$, long. $122^{\circ} 0' E.$ The *Basilan* coast, to the N.W. of this, is clear, as also the channel 3 miles wide to the North of it, but to the eastward there are some shoals which very much contract the passage to the eastward. *Malusa*, a settlement of the Spaniards on the S.W. coast of *Basilan*, is deserted (1875), and its vicinity should be avoided, the inhabitants being hostile. On the S.E. side of *Basilan*, between the island *Cauluan* and *Matanal Point*, there is a bank of soundings against the shore of the wide bay which opens to the S.E.

Sibago Island, which lies $6\frac{1}{2}$ miles N.E. by N. from *Point Matanal*, is high, with low land projecting from the hill. It is in lat. $6^{\circ} 45' N.$, long. $122^{\circ} 24' E.$ *Langil Island* is 3 miles to the W.N.W. of *Sibago*; it also has low land extending from its high hill, and the two islands when seen in nearly the above or opposite bearing, appear as one saddle hill. *Cocos*, a high and small island, is 5 miles W. $\frac{1}{2}$ S. from *Langil*, and 5 miles off *Basi-*

lan. The *Helena Bank*, coral, lies about $1\frac{1}{2}$ mile N.W. from Cocos, which is in lat. $6^{\circ} 46' N.$, long. $122^{\circ} 14' E.$

The STRAIT of BASILAN, between that island and the South point of Mindanao, is about $6\frac{1}{2}$ miles wide where narrowest. To the south-eastward are the islands just mentioned, and to the westward are the clusters which lie to the N.W. of Basilan and northward of Pilas.

Pilas is all low level land, except the North part, where there are two hills about 710 ft. high. It is about 6 miles long North and South, and a small island, *Tagowlu*, lies on its eastern side.

Of the islands West of Pilas the *Salleolukit Isles* are the westernmost, and are 25 miles westward of the West point of Basilan. A 3 miles N.W. of this is this *Favourite Rock*, 12 ft., in lat. $6^{\circ} 44' N.$, long. $121^{\circ} 22'$, which is the farthest to the N.W. The *Griffin Rocks* lie 6 miles N. by E. from Salleolukit. They must have a berth to the eastward, as the sea does not always break on them. There is another rock, *Batu Balu*, about $7\frac{1}{2}$ miles to the S.E. of Salleolukit. Besides these there are several other shoals to the westward of Pilas and *Sangboys Islands*, the latter lying 18 miles N.W. by W. from Basilan; they are two high islands close to each other, and are sometimes called the *Hare's Ears*. The hill on the South, or Great Sangboy, resembles a dome.

Teinga or *Teynga* is about 3 miles N.N.E. from the North Sangboy. It is in lat. $6^{\circ} 54' N.$, long. $121^{\circ} 38' E.$, and is the northernmost of the Sulu Archipelago. It is very low, covered with trees. A reef extends a short distance South of it, and another a considerable distance to the North of it. There is also a 6-fathom spot at $6\frac{1}{2}$ miles E. by N. $\frac{1}{2}$ N. from it, reported by the ship *Wild Rover*, in 1870.

Between Pilas and Basilan are *Mataga* or *Mataha*, low and woody, and *Buluk* to the northward of it, a considerable island, with a sloping hill at the North part, and low land to the southward. With Pilas Island it forms a safe channel 3 miles wide. About midway between Mataga and Baluk there is said to be a bank or dangerous rock.

The Santa Cruz Islands, on the North side of the strait, adjacent to the South point of Mindanao, are two in number and small. There are numerous coral reefs in their vicinity. One of these has 13 ft. water, and lies 4 miles S.W. $\frac{1}{4}$ W. from the western island, the eastern peak of Basilan bearing S.E. by E. There are other patches between this and the island to the eastward. There is another coral reef of 16 feet, with the western Sta. Cruz Island bearing E. by S. $\frac{1}{4}$ S. 7 miles. A 6-fathom patch lies 3 miles off the North coast of Basilan, at 14 miles westward of Cocos Island.

With the exception of these reefs, and that near the Cocos Islands, the Strait of Basilan appears to be safe, although the depths in it are very irregular, with rocky bottom in many places.

THE PHILIPPINE ISLANDS.

This noble archipelago belongs to the Spaniards by right of discovery. Twenty-nine years after the discovery of America by Columbus, and two years after the conquest of Mexico, Fernando Magalhaens, or as he is commonly called Magellan, after having passed round Cape Horn, and discovering the Ladrone Islands, came in sight of Samar, one of the Philippines, on Sunday, March 17th, 1521, the feast of St. Lazarus, and thus named them the Archipelago of St. Lazaro, which was subsequently changed by Villalobos 21 years later, to their present appellation, in honour of Philip Prince of Asturias, the unworthy son of Charles V. Magellan, coming to Zebu or Cebu, began the work of conquest and conversion simultaneously, and was shot by the Indians in a foolish fray on the island of Mactan, adjacent to the East coast of Zebu, on August 26th, 1521. Thus died the first circumnavigator, his ships being brought to Spain by his cousin and historian Barbosa. A monument is erected to his memory at Zebu, as hereafter described.

The archipelago numbers thirty-one islands of importance, exclusive of numerous tiny islets, rocks, and reefs. They extend from North to South over sixteen degrees of latitude, a circumstance which endows them with a striking variety of climate, which in its turn is exemplified in the growth of products belonging to both the temperate and torrid zones, the palm and the fir, the pine-apple, the potato, and wheat flourishing alike on their shores. The situation of these fertile islands, occupying as they do a central point between Japan, China, Annam, the English and Dutch settlements in the East Indies and Australia, not to speak of their favourable position for communication with the West coast of America, ought to ensure them a world-wide trade. But hitherto, in spite of the early trade with Manilla in the 16th century, commerce has languished hopelessly through the elaborate and short-sighted restrictions imposed by Spanish protectionists. There is, however, good ground for anticipating better days, for a decree of the 5th of April, provided that the differential duties, which were framed in a spirit of the most extraordinary hostility to all foreign traders, should expire at the end of two years, that all export duties should be abrogated, and that the more annoying port dues should be consolidated into one single charge. The most important products of the islands are tobacco, coffee, cacao, cocoa-nut oil, sugar and Manila hemp. Manila, Samboanga, Zebu, Ilo Ilo, Tacloban, and Legaspi are open ports.

The rest of the islands, excepting Mindanao and the Bashi Islands, are known collectively, as the *Bisayas*, or *Visayas*, a native word signifying "painted man," as the people were found to be so when first discovered by the Spaniards. But they are all under one government, that of the Captain-

General, resident at Manila, whose jurisdiction not only extends over all the islands, but also over the Marianas in the Pacific. The people are of different races. The mountain tribes are called *Negritos*, diminutive negroes, who also inhabit the island Negros, adjacent to Zebu. Another race are the Igorrotes, a copper-coloured race, who resemble the Dyaks of Borneo, and are eager head-hunters. The great mass of those subject to the Spanish rule are the Tagals inhabiting Luzon, and the Bisayans, who live on the other islands, each having a variety of dialects and customs. A large Chinese population also exists.

The number of the population has been variously and vaguely estimated. the latest account being that given by Dr. Meyer, in 1875, who states that the population of the archipelago, according to the latest Spanish accounts, numbered 7,451,352; of these 4,540,191 were in Luzon, and 1,052,586 in Panay.

The seasons may be divided into the wet and dry, the former extending from June to November, and the latter from December to May.

Tides.—It is only in recent years that the tides of these islands have been understood. Owing to their great irregularity, it required a long series of observations at frequent intervals to gain sufficient knowledge to make known the system. These observations have been made, and the conclusion come to, that in the course of the lunar day in the Bay of Manila there are two high waters and two low waters of *different relative heights*, and that the difference between the height of the two high waters has reference to the age of the moon. Senor Don Francisco Carrasco, who has written an elaborate paper on the subject (translated in Nautical Magazine for July, 1868), thus speaks of these differences:—

“If we follow the curve during the lunar month, we see that at the beginning of the lunation there is a high water of great comparative importance; and another most minute one, corresponding to the passage of the moon over the inferior meridian (antipodes). The important high water goes on decreasing in height with the age of the moon, when the heights of both high waters are nearly equal; the first goes on decreasing and the second increasing until full moon, when the great tide of new moon is converted into the least and this into the largest. Starting from this conclusion, the same phenomenon presents itself in the large tide diminishing, and the smaller one increasing, so as to become equal at the last quarter, and at the next new moon returning to its former greater height and the other to its lesser.” The rise of the tide varies from $3\frac{1}{2}$ to 6 or 7 ft. in Manila Bay.

MINDANAO, or **Magindanao**, is the southernmost of the Philippine Islands, and next to Luzon is the largest. It is very little known, but some trade is done with Labuan. Up to a comparatively recent period the Spaniards only held the North and N.E. portion of it, leaving the great bay on the South, and this part of the island in the hands of those pirates whose

name of Llanuns or Illanuns derived from the bay, spread terror over the surrounding seas.

Mindanao is about 270 miles long from East to West, and 245 miles from North to South. Its mountains are of great altitude, and, like many other islands of the eastern seas, clothed with the richest forest growth nearly to their summits. There are many volcanoes, some extinct, others more or less active. Among the latter is *Mount Calalan*, in the S.E. part. It is intersected by these mountains in many directions, and in the valleys they form are many extensive lakes, a circumstance to which the island owes its name. It is or was divided by the Spaniards into four provinces, that of *Caraga* on the N.E. side, *Neuva Guipuzcoa* on the S.E., *Misamis* on the N.W., and the small district of *Samboangan* on the South end of the western peninsula. Of the people little can be said here. M. Meyer estimated the population to number 191,802, in 1871. The whole of the interior is occupied by those piratical people of very various races, but known generally as the Illanos or Illanuns before mentioned. They profess Mohammedanism. The climate is hot and humid, but from its lying so near the equator, it is beyond the reach of typhoons. This renders the coast much more safe than it otherwise would be, although in the extensive bays which indent it there are many places of shelter.

CAPE SARANGANI, or **Panguitan**, is the South point of Mindanao. It is in lat. $5^{\circ} 35' N.$, long. $125^{\circ} 21' E.$ The land adjacent is lofty, and may be seen 30 or 40 miles off. Off it lie the *Sarangani Islands*, two in number, bearing E.N.E. and W.S.W. of each other, and about South from Cape Panguitan. The easternmost is much the lowest, and has a hill on its South end. *Linitan* is a small low island, about 3 miles northward of the eastern Sarangani Island, and has reefs projecting from its North, South, and East points.

The Channel between the cape and the Sarangani Islands is about 5 or 6 miles wide, clear of hidden danger. There is a passage between the islands, the eastern side of which is the best, as there is a shoal projecting nearly into mid-channel from the western side in the narrowest part.

To the north-westward, 20 miles distant from the South point, is a deep bay, with a bank lying S.W. of its western entrance point. It is known as the *Bahia de Sarangani*, and from this the southern coast trends to the north-westward towards the great bay which so deeply indents the South side of the island. A sunken rock lies 3 miles off the land in lat. $6^{\circ} 12' N.$, long. $124^{\circ} 7' E.$, and a bank West of Leno Bay, in lat. $6^{\circ} 41' N.$, long. $123^{\circ} 55' E.$

Illana Bay is 40 miles wide in its opening, and in its eastern part is the island of *Bongo*, lying off the mouths of the *Rio Grande*, the largest river of Mindanao. It is near the mouth of this river, at *Cotabatu* or *Cota Batto*, 6 miles from its bar, that the Spanish fort has been established. In the

eastern part of this bay, at 5 miles N. $\frac{1}{2}$ E. from the North end of Bongo, is the Pinatayan Bank, extending to 2 miles off Point Matimioz. The piratical people of Illana Bay have been known to drag their vessels over the isthmus to the North shore, to escape pursuit. We have no particulars of the great bays which lie to the westward of this, named the *Puerto de Dumanquilas* and the *Seno* or *Bay of Sibuguey*.

Circe Bank, of $3\frac{1}{2}$ fathoms, lies on the eastern side of the entrance to Sibuguey Bay in lat. $7^{\circ} 17' 30''$ N., long. $122^{\circ} 37' 30''$ E. To the south-westward of it are two other banks, one of $2\frac{3}{4}$ fathoms, N.E. by E. 10 miles from Tanalutan Island, and another, Samar Bank, of $2\frac{1}{4}$ fathoms, at 4 miles E.N.E. of the same island.

SAMBOANGA and its vicinity were surveyed by Sir Edward Belcher in the Samarang in 1844, the examination including the Santa Cruz Islands before mentioned. The fort at the eastern end of the town is regularly built and equipped. It is in lat. $6^{\circ} 54' 55''$ N., long. $122^{\circ} 6' 30''$ E. There is a church at the western end. The anchorage off the town is not good, the bottom being foul and the bank steep, the depth of 12 fathoms being close in. Samboanga, a free port, is a penal colony of the Spaniards, and is not specially adapted for the refreshment or refitment of passing vessels. Bullocks, fowls, yams, fruits, rice, and vegetables are procurable. The water is excellent, and easy to obtain; it runs behind the beach in a fine stream, but it should be filled early in the morning, before the whole female population commence their washing.

Light.—There is a small pier or mole, at the head of which a *red fixed* light is shown, elevated 32 ft. It is in about lat. $6^{\circ} 54'$ N., long. $122^{\circ} 4'$ E.

Tides.—From information acquired from the Spanish surveying vessel at Samboangan, it appears that the times of high water and turn of the streams are extremely irregular, the time of high water, full and change, varying from 7 to 10 hours after the meridian passage of the moon; and the same phenomena is observed here as in the China Sea, viz., that in the S.W. monsoon the day tide is the highest, and in the N.E. monsoon the highest tide is at night.

La Caldera is 12 miles westward of Samboanga. It is a small harbour, at the head of which is a small fort, where the Spanish flag is hoisted to vessels passing through the Strait of Basilan, and here also is anchorage for ships when they cannot lie in the open roadstead in front of Samboanga. Fresh water, but not good, can be procured here. At 2 miles to the N.W. is a place called *Daumalong*, with a small stockaded fort. This occupies the S.W. point of Mindanao, and is the N.W. entrance point of Basilan Strait.

The *North-West Coast* of Mindanao is more irregular than any other por-

tion of the Bisayas Islands. The charts will show its configuration. The province of Misamis on the northern side of this portion is the most important of the island. The principal inlet is the *Bahia de Iligan*, an extensive bay, at the head of which, on the western side of a deep inlet, with a low marshy head called the *Laguna de Panguil*, stands the pueblo of *Misamis*, the chief place of the province, lat. $8^{\circ} 10' N.$, long. $123^{\circ} 49' E.$ It has some trade, and is protected from the Moro pirates by a small fort built on the beach. It is said that the bay and inlet afford safe anchorage even for the largest ships. The *Bay of Macajalar* or *Macahalao* is 40 miles N.E. of Misamis, and at its South part is the third Spanish post on this coast, that of *Cagayan* which is some distance up the river.

Camiguin Island lies to the North of this, and, with the exception of some shore reefs, is apparently clear. Mr. W. J. J. Spry, R.N., thus describes the visit of H.M.S. *Challenger*:—"To the East we could see at the distance of 50 or 60 miles the island of Camiguin, its volcanoes giving out both smoke and steam. From this distance the volcanoes seemed just on a level with the water, the most prominent part of the island being an older volcano, which rises up behind the active cone to a height of upwards of 5,000 feet.

"On the morning of the 26th January, 1875, we gradually approached the island, and at noon were close under the volcano, when parties of naturalists landed to explore, and the vessel proceeded on, and came to anchor off the little village of Abaji. It seems early in the year 1871 this island was visited with several violent earthquakes, which resulted in the first eruption; from this date the accumulation of the mountain has been going on gradually, and apparently with little violence. The general colour of the cone is a rich chocolate brown; it has now reached some 2,000 ft. in height, and its base has gradually extended until it entirely covers the town of Camiguin, formerly the largest on the island (with a population of 10,000 inhabitants). Now only a few ruined walls remain of this town, which was formerly in one of the most prosperous and fertile of the small islands of the archipelago. Since the eruptions, the island has become almost desolate; only a few hundred inhabitants remain; most of the houses are in ruins, and the paddy fields and groves of flax are deserted and overgrown with a second jungle. For miles on either side of the volcano the trees are blighted and vegetation is destroyed by the sulphureous exhalations. Temperatures were taken in 185 fathoms; but that shown 57° was in no way other than usual at similar depths in these seas."

From this the North coast of Mindanao runs irregularly to the East and northward, forming the *Golfo de Butuan*, which affords good shelter, and terminates in *Point Bilaa*, which forms the narrowest part of the Surigao Passage. A 2-fathom bank extends nearly 2 miles northward of Point Bilaa, and between it and Gipdo Island, 6 miles north-eastward of it, are two

rocks lying $1\frac{1}{2}$ mile apart, and in the centre of the channel. One of these is 6 feet below water. This portion of Mindanao forms the province of Caraga, which is said to possess the chief gold mines of the island. It is very hilly, covered with a dense vegetation, and is very thinly inhabited.

Surigao, the chief place of the province, is 4 miles to E.S.E. of the above-mentioned point, and lies on the North side of a small bay of difficult access. You may anchor in 14 or 15 fathoms, fine grey sand, with the village bearing S. by W. 1 or $1\frac{1}{2}$ mile. If brought more westerly, it is a chance if the anchors hold, on account of the violent tides. If intending to water here, and the wind being at southward and westward, carry all possible sail, taking care to haul close round Surigao Point between *Rozol*, or the Southwood Island and Mindanao, keeping this coast aboard until the village bears as above. The currents rush past it with great rapidity during the N.E. monsoon, when this side of the island becomes a lee shore. There are some building-yards here, and the native vessels are well constructed of the excellent timber from the adjacent hills and interior mountains, where it is said that teak is abundant. The people are mild and docile, but several forts are kept up to prevent piracy.

At $5\frac{1}{2}$ miles northward of Point Bilaa is a small island, $1\frac{1}{2}$ mile E. by N. from which is a rock which breaks. *Gipdo*, a high island 5 miles long, N.N.W. and S.S.E., forms the eastern side of the passage leading to Surigao, the land of Point Bilaa forming the western side. In the middle of this passage are two small rocks E.N.E. and W.S.W. a mile apart. Two miles North from the N.W. end of Gipdo is a small island with a rock just North from it. *Sibanag* has a rock off its southern end 3 miles North from the last named rock.

The STRAIT of SURIGAO or Panaon, which passes between this North part of Mindano, and the South point of Panaon is 12 miles broad where narrowest. To the eastward it is fronted by the group of Surigao Islands, of which *Dinigat*, or Gurbo, or Bella Vista is the largest, and is 40 miles long. This island offering a direct resistance to the course of the great equatorial current drifting to the westward across the Pacific in one season, or in the reverse direction at another, causes the channels separating them and leading to the Surigao Passage to be most dangerous, from the violent tides and currents which rush through them. It should therefore be never attempted from choice, for, in addition to the tidal and drift currents, the course through must be carried nearly at a right angle, so that it is almost impossible to have a fair wind throughout, and in a calm the danger is much increased, as there are neither soundings nor good anchorage. These remarks are especially applicable late in the season, or when there is a chance of the N.E. monsoon setting in prematurely. But if a ship, in proceeding to China, should be carried into it by the westerly current not later than the early part of October, she might venture through.

The *Eastern Coast* of Mindanao is not described, nor visited by commerce, although the interior country affords much good timber, and abounds with trees producing large quantities of wax and honey. It is a lee shore much to be avoided, as before said, during the eastern monsoon.

A singular fact remains to be noticed. Dampier tells us that there is a large island, 38 miles long, 34 broad, lofty, and covered with forest, called the *Island of San Juan*, lying 30 miles eastward of this coast. Modern knowledge is not sufficient to affirm satisfactorily that it does *not* exist, though it does not appear to have been seen since. Its existence is therefore incredible.

Panaon is 17 miles long from N.N.W. to S.S.E., and at its North end is a narrow strait separating it from the S.E. point of Leyte. At the North end of the island is the village of *Liloan*, and this strait is called the *Puerto di Liloan*. It has 7 fathoms least water, and there is anchorage in the small bay off the village.

LEYTE is the next large island to the N.W. of Mindanao, and is 115 miles long N.N.W. and S.S.E. It is generally mountainous, and several of its peaks are quiescent volcanoes. Forests cover a great portion of its surface; among the trees, that which produces the "brea," or pitch, is the most remarkable. Since the active measures which have been taken for the suppression of piracy by the Moros, the population of this island has increased in a remarkable manner. The people are all of the Visaya race, and have long been converted to Christianity. The town of Leyte, which gives it its name, is at the N.W. extremity, but the chief place is *Tacloban*.

Tacloban, opened to foreign commerce in 1873, is situated at the N.E. end of the island of Leyte, and at the South entrance of the straits which separates Leyte from Samar. It is a safe harbour during both monsoons, but the passage to it through the Juanico Straits is somewhat difficult for sailing vessels, owing to the strength of the current running between the island of Samar and the island of Leyte. To steamers drawing 14 ft. of water there would be no difficulty in making this harbour.

Leyte is thinly inhabited, and the people of *Tacloban* are poor and miserable, as are those of the rest of the island. It is mountainous and covered with forest. Volcanic craters are found, and sulphur abounds in some places. Cocoa-nut oil is made, but the trees are sometimes destroyed by hurricanes.

The Strait of *San Juanico* separates Leyte from Samar. It is about 30 miles in length, and not more than a mile wide in its narrower portions, and the two sides of the strait being so similar and parallel, lead to the inference that the two islands were once united. In making for this strait, of the navigation of which we have no particulars, the Samar or northern shore must be kept on board. Its N.W. portion is called the *Canal de Janabatas*.

To the westward of this the North shore of Leyte forms a deep bay, at the head of which is the poor village of *Carigara*, where the first cacao tree was planted in the Philippines.

Palompon Harbour is an entrance through the reefs on the western shore of Leyte, in lat. $11^{\circ} 4' N$. *Port Bello* lies S.E. of and on the opposite side of the promontory to Palompon. It is in lat. $10^{\circ} 50' N$. *Ylongos* is on the S.W. coast of Leyte, in lat. $10^{\circ} 24' N$.

SAMAR is larger than Leyte, and forms a separate province. It was called *Ibabao*. Its eastern shore being washed by the Pacific, has but little shelter, and its north-western side forms the principal entrance from the great ocean to the Bisayas and other islands of the archipelago. The S.E. point is continued seaward by a chain of islands, the outer point of the south-easternmost, called *Punta Sangui*, is in lat. $10^{\circ} 54' 30'' N$., long. $125^{\circ} 50' E$. It is mountainous and lofty, its northern peaks being visible from Zebu serving as a good mark for the adjacent channels. Like the other islands it is covered with forest, and in its central portion is a considerable population of Indians, but not Negritos. Cocoa-nut oil, cacao-bean, abaca or Manila hemp, wax, pearl oysters, and tortoise shell are the productions, and the people trade with the Pelew and Mariana Islands. *Catbalogan*, on the North side of a bay on its western shore, is the chief town and residence of the Alcalde.

Puerto de Palapa, on its N.E. end, affords good shelter to vessels about to pass through the San Bernardino Strait. It is formed by the island of *Batag* on the East, and the islands of *Laguan* and *Cahayagan* on the West, and is a channel about 8 miles long. Off each of its eastern entrance points reefs extend for some distance, but the channel midway is quite clear, with depths of from 7 to 12 fathoms. From this the opening is nearly a mile wide, and extends westward for $3\frac{1}{2}$ miles, when it turns to northward, and between the islands on either side there are good depths of water for anchorage, and a free outlet into the strait to the northward. Good water is to be got on Laguan Island, which forms the S.W. side of the port, and there is a narrow but useless channel to the South of it, which leads into *Laguan Bay*. In this bay a vessel may anchor in 6 or 7 fathoms between Laguan and the Samar shore, sheltered from East and N.E. winds, but exposed to the N.W. and West.

From this northern entrance, to the *Balicuatro Islands* which form the eastern limit of the Strait of San Bernardino, the distance is 39 miles due West. To the eastward of *Viri*, the northernmost of these islands, there is a bank of soundings, varying from 7 to 35 fathoms, which has been traced for 16 miles to the E.N.E., and may be a guide in approaching the strait.

The Western Coast of Samar.—At the northern part of the coast between Points Lipata and Quinabasaran there is a slight bay, which, although

having little depth, affords good anchorage, particularly in the season of the N.E. winds, and although at a good distance from it, large rocks are scattered over the sandy bottom, yet when nearer the coast these are not so numerous, and the ground is much cleaner. In the interior of the bay there is a rivulet from which a vessel may complete her water.

About $1\frac{1}{4}$ mile from Quinabasaran Point, and E.S.E. from the North end of Puerco Island, is the mouth of the *River Mobo*, across which there is a narrow opening with a depth of 2 fathoms at low water. A steam launch might enter here and obtain water at the cascades, some little distance up the river.

About 4 miles S.S.E. of the River Mobo is the little port of *Canaguaion*. It may be used by any vessel in case of necessity, and is formed by a bend in the coast and two islets in its mouth that leaves two narrow channels for entering and leaving.

The STRAIT of SAN BERNARDINO, which separates the N.W. part of Samar from the S.E. extremity of Luzon, is named from the small islet which lies in its eastern entrance. This narrow passage is all to which the name is applicable, but it has been extended to the whole of the track between the islands leading towards Manila, formerly the only point of general maritime interest in the Philippines. It was formerly the great highway for the Spanish galleons on their way to Manila from Acapulco.

Tides.—The greatest range of tide occurs generally in June and December, and is about 6 ft.; the smallest range of tide is about $3\frac{1}{2}$ ft., generally in March and September.

The phases of the moon have but slight influence on the time of high water or on the tidal range. The highest tides follow the moon's greatest declination; the lowest tides follow the moon's least declination; at the moon's greatest North or South declination there is only one flood and one ebb in the twenty-four hours; at the moon's least declination there is one flood and one ebb in twelve hours.

The points on which the pilots are mostly agreed is that in the channel the water begins to rise at about two hours after the moon is up. That the greatest rise and fall is 8 ft. That from the eastern mouth of the strait to about the meridian of Bondog the flood sets westward, and the ebb eastward when it falls: and that from that meridian to the western mouth of the strait the reverse of that takes place. That from the eastern mouth of the strait to the above meridian, the stream of flood runs longer than that of ebb in the N.E. monsoon; the reverse being found in the S.W. monsoon, and the opposite condition to this is found in the western part of the strait. That the night tides are commonly higher than those of the day.

With the foregoing considerations the navigator may be advised that on

entering the strait, he should immediately look to the state of the tide, and follow up his observations closely while he is in it, and to depend more on what he sees than on any calculation. (See also page 896.)

In making for the strait from the Pacific, *Cape Espiritu Santo*, in lat. $12^{\circ} 32\frac{1}{2}'$ N., long. $125^{\circ} 13'$ E., the N.E. point of Samar is in general made for. It is bold high land, and may be seen 12 or 13 leagues off. But should the wind be northerly it would be better to make directly for the entrance of the strait, or you may become embarrassed with the islands and shoals on the North side of Samar. The entrance to the *Embocadero* or strait is contracted by the Balicuatro Islands before mentioned. The islet of *San Bernardino*, covered with trees, many of which are ebony, lies to the N.W. of these, directly in the entrance of the strait, lat. $12^{\circ} 46'$ N., long. $124^{\circ} 15'$ E. There is a small islet close to it on the North and some rocks on the East side, otherwise it is clear, and on either side there is a channel 4 or 5 miles wide, with soundings of from 30 to 60 fathoms. Having passed this island, the fairway of the strait will bear to S.S.W. between *Capul Island*, off the N.W. end of Samar, and *Tielin Juag* and *Colinton Islets*, on the Luzon side; these are bold-to, but at 2 miles S.W. by S. from the latter island is the *Calantas Bank*, surrounded by depths varying from $3\frac{1}{2}$ on the East to 26 fathoms on the North side. Avoiding this, the passage is clear either to the N.W. by W. to clear the North end of Ticao in proceeding towards Manila, or to the southward towards Zebu or Ilo-ilo. There is a channel to the East of Capul Island, between it and *Puercos Island*, which is 2 miles wide, with reefs on the port hand, but a rock of $2\frac{3}{4}$ fathoms, called *El Diamante*, lies in its southern entrance, 2 miles S.S.E. of the South end of Capul. There is no anchorage around Capul, except at a bay at its South end, but it may be had around Puercos Island.

TICAO, the first island to the westward, is 24 miles long. *Port San Jacinto*, about the middle of its N.E. side, is an anchorage sometimes used in passing the strait. It may be known by a building or fort with round bastions on a rocky cliff, the land rising behind it. It is in lat. $12^{\circ} 34'$ N., long. $123^{\circ} 44'$ E. The anchorage in the road is in 15 or 16 fathoms, sand and gravel, a little more than half a mile off shore, with the house or fort bearing S.W. $\frac{3}{4}$ W., a pyramidal rock to the southward of it, South, the sugarloaf hill on Luzon N. $\frac{1}{4}$ W., and the mouth of Sorsogon Harbour N. by E. $\frac{3}{4}$ E. 13 miles. The bank is steep, so anchor as soon as possible. There is very little stream in the road. High water at $6\frac{1}{2}$ hours; rise 6 ft. The South point of the entrance to the harbour is fronted by a reef which stretches along shore to the southward; and a reef projects nearly half a mile from a point where there is a black rock, about a mile to the North from the North point of the harbour's mouth. The latter is contracted by a reef on the South side, but inside the harbour there is room for several ships. The northern

arm being very shoal, vessels are obliged to anchor on the South side, with the entrance partly open. The watering place is about 2 miles to the northward. Good beef and fruits may be procured. It was in this port that the galleons from Manila awaited a favourable wind for their voyage to Acapulco. At 3 miles to the N.W. is *Togagauno Bay*, and at the N.W. end of the island is the bay or port of *San Miguel*, protected from the East.

MASBATE is the next of the Visayas Islands, south-westward of Ticao. It is somewhat of a crescent form, 36 miles long, and has a chain of mountains running along its entire length, from the slopes of which the rivulets bring down sufficient gold to make the washings for it payable. It is very thinly inhabited. *Puerto Barreras*, near the N.W. point, offers safe anchorage, but requires great care in entering. Its S.E. point, *Cape Caduljuan*, has a reef around it, a continuation of that fronting the East coast of the island. The land surrounding this port is for the most part mountainous and of a red colour, from whence it seems that various handsome patterns of wood are obtained. There is no watering place in the bay, and therefore a vessel must send well up the river for it. The town is at a considerable distance from its mouth, and has thirty or twice that number of families in it from Balino, very poor in spite of the beautiful place, and the washings for gold hard by. The natives are held in such terror that the inhabitants dare not even go to fishing in the bay.

The N.E. part of Masbate from the Bay of Mobo as far as Port Magdalena has anchoring ground of 30 to 35 fathoms at half a mile off shore. The *Port of Magdalena*, in lat. $12^{\circ} 27\frac{1}{2}'$ N., long. $123^{\circ} 33'$ E., is very small, but is an excellent anchorage, for notwithstanding being open to the N.W. it may be considered safe in all seasons. Even a large vessel may be secured with as many fastenings as required to trees, and although she might be blown on shore with the few winds to which it is exposed, she would come to no harm on mud. The margin of the port has no settlement, but about $1\frac{1}{2}$ mile to the westward is the town of *Balino*, containing about eighty families, in the inlet of which there is shelter for small boats, and a small river. Some vegetables, fowls, and honey, are all that is to be had there.

Between Masbate and Sibuyan are several known dangers. *Bennet Bank* is a patch of sand and mud, a mile in diameter, its centre being in lat. $12^{\circ} 24'$ N., long. $123^{\circ} 6'$ E. It bears S.W. $\frac{3}{4}$ S. 15 miles from Bugui Point, the N.W. point of Masbate. At 7 miles S.S.W. from it is a sunken rock. A $4\frac{1}{2}$ -fathom patch lies 4 miles West of Mirabeles Point, the North point of entrance of Nin Bay. *Las Llagas* is the name given to five patches, separated by deep water, lying in the middle of the strait. Of these the northernmost, in lat. $12^{\circ} 15'$ N., long. $122^{\circ} 54'$ E., has only 4 ft. water over it. At 3 miles South from this is a $2\frac{3}{4}$ -fathom patch, and S. $\frac{1}{2}$ W. of this is a patch of $3\frac{3}{4}$ fathoms. There is a depth of 107 fathoms between the two last men-

tioned. The easternmost has only $1\frac{3}{4}$ fathom water over it, and lies in lat. $12^{\circ} 13' N.$, long. $122^{\circ} 59' E.$, 5 miles E.S.E. from the northernmost. A sunken rock lies 4 miles S.W. from the eastern patch.

Cervera Bank, of $1\frac{3}{4}$ fathom, lies S.E. by E. $\frac{1}{2}$ E. 8 miles from Cambalayan Point, the East point of Sibuyan, in lat. $12^{\circ} 21' N.$, long. $122^{\circ} 49\frac{1}{2}' E.$ At $1\frac{1}{2}$ mile East from it is another small bank. *Perseus Bank* is $4\frac{1}{4}$ miles S.S.W. from Cervera Bank, and another bank is marked at 2 miles S.W. from it.

Cresta de Gallo is a small islet, S.E. $\frac{3}{4}$ S. 6 miles from Point Cautit, the South point of Sibuyan. Shoal water extends a mile North from it, and $3\frac{1}{2}$ miles to the S.S.W. *Prueba Bank*, of 6 fathoms, lies South from Point Cautit, and N.W. from the Cresta de Gallo, and there are two $4\frac{1}{2}$ -fathom patches, one lying N.N.E. 3 miles, and the other S.E. by E. the same distance from the Cresta de Gallo.

ZEBU or Cebu is an island of some importance and interest, as its port has been thrown open to foreign commerce. The island is 120 miles long, and narrow, with ranges of hills of no great height traversing it in a longitudinal direction. The town of Zebu, the oldest in the Philippine Islands, and the seat of government of the southern Philippines, lies in an extensive and well cultivated plain, at the foot of the mountains, and is considered healthy.

The population consists of 80,000, principally Malays and Chinese. The huts of the poorer Malays, mostly fishermen, on the sea shore, constitute the western part of the town, while beyond them stand numerous massive houses, with good streets. The town is well built, and has large barracks, two churches, and a lazaretto. Zebu has also a naval station.

The exports consist chiefly of sugar, hemp, tobacco, coffee, and piña lace; the imports embrace European goods, rice, and coal. Coal is imported from Australia; a vessel cannot depend upon a supply with certainty. There is coal on the island, but not properly mined. Provisions are plentiful. In 1874, 6,933 tons of shipping entered at Zebu.

The channel between Zebu and Leyte is clear as far as is known, with the exception of the following banks, which are easily avoided. *Calangaman Island* is low, and lies S.E. $\frac{1}{4}$ E. 15 miles from the N.E. extreme of Zebu. Its western end should not be approached within 3 miles. *Capatancillo* is another small, low island, 2 miles off the coast of Zebu, and S.W. 12 miles from Calangaman. Shoal water extends 4 miles N. by E. from it. About midway between Zebu Island and that of Mactan, E.N.E. of the city, are the *Camote Islands* against the Leyte shore, but which leave good channels around but not between them.

The Port of Zebu is protected by the small island of Mactan or Magtan, before mentioned. It is about 9 miles long, and the town lies in about mid-

way through the strait on the shore of the larger island. The strait forming Port Zebu is easily navigated, as there is always the ripple on the edges of the banks, and their colour marks the channel. Fort Zebu is a triangular building, painted red, and armed with small guns.

On the small island of Mactan, Magellan was killed, soon after he first discovered the Philippines in 1521. In memory of the great navigator, Queen Isabella II. has erected a conspicuous monument.

Light.—A small fixed light, elevated 46 ft., is shown on Bagaca Point, the West side of the northern entrance to the Port of Zebu. It is difficult to distinguish from fishing lights shown in the vicinity. Lat. $10^{\circ} 4' N.$, long. $123^{\circ} 59' 20'' E.$

The narrow channel entrance bears about S.S.W. from the light, and in entering, the South or Mactan side should be kept, as a shoal extends a great part of the way over the channel from the opposite side, but in mid-channel there is nothing to pick up a ship in her route to the town, the fort forming the outer point of the city. From this to the southern entrance the route is also clear, but in mid-channel in the southern opening is the *Bajo Lipata* (mentioned below), which must be cautiously approached.

The best anchorage off Zebu is S.S.W. of the fort, in 5 to 7 fathoms, mud; nearer the southern reef the water is deeper, and bottom hard. From the anchorage off the fort a south-westerly course should be steered until the dome of San Nicholas church bears N. $\frac{1}{4}$ E., when a course of S. $\frac{1}{4}$ W. leads in the fairway between Lipata Bank and the reef on Mactan Island.

The harbour is difficult of access for large vessels from the North, owing to the narrowness of the channel, unless with a leading wind. With a fair wind it is not dangerous, the passage between being deep enough, and only requiring to be less imperfectly buoyed off. To the South the entrance is more open and easy of access, though care is required to avoid the Lepata and Narvaez shoals.

H.M.S. *Challenger* visited Zebu in January, 1875, one object of her visit being to obtain some specimens of the beautiful sponge *Euplectella* or Venus' baskets, said only to be obtained near Zebu. "The pinnacle, taking guides who knew the bank where they grow, went out to get some. The natives lowered their apparatus—a bamboo triangle of two sides, on which thirty-six fish-hooks are fastened; with this they always brought several up, sometimes as many as ten. They were very fine specimens, the skeletons covered with brownish animal matter, but so that the skeleton tracing was not hidden, while the top is usually bare. One day's drying in the sun will take the animal matter off, leaving the bleached skeleton clean."—*Lord George Campbell*.

Dalaguete Village, about 40 miles southward of Zebu, is marked by a conspicuous church, which may be seen a long distance both from the North

and South. On Tañon Point, the southern point of Zebu Island, there is also a large village, with a church. *Sumilon Island*, lying to the N.E. of Tañon Point, is about 150 ft. high.

Bohul forms a part of the province of Zebu. It is about 50 miles long, and possesses no point of commercial interest. Its North and West coasts are bounded by rocky shoals, and to the N.E. the channel between it and Leyte is nearly closed, but a narrow passage will be found close to the Leyte shore, between it and the small island of Camigao. A $1\frac{3}{4}$ -fathom patch lies 7 miles North of Point Acio, the eastern point of Bohul, 2 miles off shore. *Fuegos* or *Siquijor Island*, 20 miles to the S.W. of Bohul, has also nothing to be described. A sunken rock lies 2 miles off its N.E. coast, N.E. from the highest peak.

Cervera Rock is 2 cables long, N.E. and S.W., and has 13 ft., coral and sand, on its shoalest part. From the rock, the S.W. extreme of Bohul Island bears N. 60° W., the North extreme of Pamilacan Island N. 82° E., the South extreme S. 88° E., the Mount N.E. of Pangalo N. 4° E.

NEGROS was formerly called Baglas. It is 110 miles long, and although larger, is not so rich or populous as Zebu. Its interior is but little known, but is peopled by the Negritos, who have given the name to the island. The villages are generally built on the sea shore, with the exception of *Tanay* and *Iloc*, which are in the interior. The chief place of the island is *Jimamailan* or *Himamaylan*, about the centre of the western coast, seated on an open bay at the mouth of a small river, over the bar of which small craft are floated by means of bamboos placed under their keels. The only harbour deserving of mention is *Bacolot*, opposite to the island of Guimaras, against the Panay shore. From the North point an extensive reef extends for 20 miles, connecting it with *Bantayan Island*. The western side is in general safe and sandy, but the eastern side is very dangerous, especially in the South, where the *Strait of Tanon* separates it from Zebu. This is not more than 2 miles in width, and subject to most violent currents.

BURIAS is a long, narrow island, 40 miles from N.W. to S.E. by 5 miles broad. Its surface is rocky and hilly; rice, maize, and abaca (hemp), are the chief products. It was long without inhabitants, or only visited by piratical Moros, but is now used as a place of transportation for criminals from Manila, and, in order to create an excellent population, abandoned women are also sent here.

Busin.—At its N.W. end is the harbour of *San José* or *Busin*, formed by the island of San José, with Fort San Pascual on a hill commanding the narrowest part. There is a safe entrance from the N.E., as well as a narrow one from the westward; but the following off-lying dangers require mentioning. At 2 miles North from the East end of Busin Island, and 4 miles W.S.W. from the small island of *Anima Sola*, is a sunken rock. Numerous islets and dangers extend N.W. to the distance of 2 miles from the West end

of Busin, and N.N.W. $2\frac{1}{2}$ miles from this end is a small detached islet, with a bank N.N.E. a mile from it. *Templo Island*, 3 miles long W.N.W. and E.S.E., with sunken rocks off each of its extremities, lies 3 miles West of Busin. *Sombrero Islets* are 2 miles West of Templo Island; and *Sand Island*, 2 miles West of Sombrero Islets, has sunken rocks to 2 miles off its North end.

By night the entrance of Busin Harbour is facilitated by *three fixed lights*—one at the North entrance, a second at the West entrance, and the third on the end of the bank. Brought in one with the last they lead through the respective channels. The N.E. side of Busin is quite bold-to, but a reef projects from its S.W. side.

Busainga Harbour is on the N.E. coast, 6 miles South from the *Anima Solo Rock*, which lies off the North point of Burias. A fixed *blue* light is shown here.

Boca Engano Harbour is about 15 miles from the S.E. point. Its position is marked, by night, by a *blue* fixed light.

Malaguing Gilog Harbour is on the S.W. coast, about 12 miles from Boca Engaño. Its situation is also shown by a *blue* light at night.

We have no particulars of these three last-named ports or anchorages.

PANAY is, next to Luzon, the most important of the Philippines, and is the largest of the Visayas Islands. It is, for its area, the most fertile and densely populated. It is somewhat of a triangular form, 95 miles long, and with an area of 3,960 square geographical miles. A chain of high mountains runs from North to South throughout its whole extent; but little is known of the interior. From its physical features, being abundantly elevated, and lying in the midst of the archipelago, it is a flourishing island; and the opening of its chief port Ilo-ilo to foreign commerce, will lead to a great advance in its commercial prosperity. It is divided into three provinces, Capiz on the North, Ilo-ilo on the East, and Antigue on the western shore. The population of the whole island was estimated to number 1,052,586 in 1875.

Between the S.W. point of Masbate and the N.E. point of Panay is the island of *Jintotolo*, with a reef off its western part, and 8 miles W.S.W. from it are the two *Zapatas*, nearly of the same size and height. *Zapata Menor* being 270, and *Zapata Mayor* 260 ft. high, the former bare, and the latter wooded and partially cultivated. *Jintotolo* is flat, and thickly wooded to the water's edge, the trees being about 120 ft. high; it is apparently uninhabited.

The **Capiz Coast**, or North side of Panay, is about 80 miles in extent.

There are numerous off-lying reefs about its western part, and therefore it should not be made free with. At 19 miles West of the eastern point is the island *Olutaya*, surrounded by a reef, with no good channel inside it, but that between it and *Zapata Menor* is quite safe. *Punta Bulacaue*, the N.E.

point of Panay, is low, and in lat. $11^{\circ} 36' 30''$, long. $123^{\circ} 13' E$. It is surrounded by a reef, and at from 5 to 6 miles N.N.E. of it there is a dangerous reef of 18 ft. least water, called the *Cucaracha*. A dangerous $1\frac{3}{4}$ -fathom patch also lies 3 miles off shore, at 10 miles W.S.W. from it.

The *Silanga Islands* lie off the N.E. point of Panay. This portion of the Philippine Islands, comprising the strait between Panay and Negros with the South and S.W. coasts of the former island, were surveyed by Lieut. D. Claudio Montero, of the Spanish navy, in 1854, and therefore the charts are deserving of more confidence here.

The *Gigantes Islands*, North and South, are the north-easternmost of these. A bank extends eastward from the northern one, but there is a 12-foot channel between them, and the channels West of them are open. *Calagnan* and *Sicojan Islands*, both high, lie about 8 miles S.W. of them. A 4-fathom bank lies $2\frac{1}{2}$ miles South from the South point of the latter. The most conspicuous land-mark here is the *Pan de Azucar*, or Sugar-loaf Island, the summit of which is in $11^{\circ} 17' N$. A series of islands extends south-westward from it towards the Strait of Iloilo, but they are generally bold-to. *Tagil* is next South of the Pan de Azucar, separated from it by a narrow but shoal channel. Between the South end of Tagil and the Panay shore is the anchorage of *Bacahuan*, in the strait separating the islands.

A written description of the shoals which encumber the channel North of Negros and S.E. of the Gigante Islands would be useless; they can only be understood from the chart.

Tagubanhan Island is the last of the larger islands, and has a safe channel on either side. At $1\frac{1}{2}$ mile North from its N.W. part is *Apiton*, where there is a watering place. From this to the *Calabazas Islets* is 5 miles, and at $1\frac{1}{2}$ mile S.S.W. of them, and the same distance off the Panay shore is a sunken rock, the *Pepitas*.

Turia Rock lies in this part of the channel, and is *very dangerous*. It presents a surface of 33 yards, over which there is no more than $5\frac{1}{2}$ ft. water, with 8 fathoms close to.

The commander of the gun boat *Prueba* took the following bearings from a spot 73 yards North of the said rock, in $4\frac{1}{4}$ fathoms:—the S.E. part of Anauayan Island N. $47^{\circ} 20' E$.; the South part of Ilacaon Island, S. $85^{\circ} 52' E$.; the North part of the Calabazas Isles, N. $63^{\circ} 14' W$.; Visita Manapla, S. $11^{\circ} 10' E$.; and the North part of the southernmost of the Binanan Isles, S. $29^{\circ} E$.; placing the rock in lat. $11^{\circ} 2' 15'' N$., long. $123^{\circ} 5' E$.

ILOILO having been opened to foreign commerce, as before said, possesses more interest than most other ports in the Philippines. The town or village stands on a low point of land at the eastern entrance of a creek near the S.W. end of the strait which forms the harbour. H.M.S. *Challenger* visited Iloilo in October, 1874, and obtained a supply of coal. A few English merchants were there doing business in sugar and hemp. The town was

found to be not at all attractive, part of it being flooded at high water, and the streets generally in a dirty condition. In 1875, 52 vessels entered Iloilo, aggregating 35,453 tons, of which 14,886 were British.

The *Isla de Guimaras*, 22 miles long by $\frac{3}{4}$ in breadth, forms in front of Iloilo a sheltered passage, running N.E. and S.W., with a breadth varying from $2\frac{1}{2}$ to 6 miles, with deep water and good anchorage. The best entrance which is from the South, is considerably narrowed by the *Otong Bank*, which stretches from the Panay shore to the W.S.W. for a considerable distance, above 4 miles, and is increasing to the westward. The channel is clear to the southward of it, and there is a narrower one to the northward. It is no obstacle when once made out during the S.W. monsoon, and with a contrary or N.E. monsoon, vessels can work or drag through with the tide, keeping well over towards Guimaras, anchoring, if necessary, on the edge of the sand, which affords good holding ground. This southern entrance should be used by all large ships if unprovided with a pilot. The edges of the Otong Bank are marked by fishing stakes, and at its N.E. end there is good anchorage.

If blowing hard in the southern channel a vessel may proceed to Port Buluagan or Santa Ana, on the West side of Guimaras, which is easy of access, and capable of admitting vessels of large tonnage, and affords good shelter under almost any circumstances.

The *Fort of Iloilo* occupies the extremity of a low spit, with deep water close-to. It is in lat. $10^{\circ} 41' 50''$, long. $122^{\circ} 36' E$. The town lies on the beach to the N.W. of it, and to the North of it is the entrance of the river or creek, on the South point of which is a post-house, or Ventay, a small bamboo watch-box. It is high water, full and change, at 12 o'clock; rise $5\frac{1}{2}$ feet.

The strait beyond this assumes a more northerly direction, with the shore bold-to on the eastern side. At 7 miles to the north-eastward in the eastern entrance of the Narrows, is a cluster of remarkable rocks, called the *Siete Pecados*, the Seven Sins Rocks. At $1\frac{3}{4}$ mile East of them is the West end of the *Iguana Bank*, a narrow spit $2\frac{1}{2}$ miles long East and West, with 6 feet least water. The best channel is to the North of it, but it is also clear to the southward. *Punta Dumangas* forms the N.E. point of the entrance.

Having arrived at the southern entrance of the strait according to the directions subsequently given, you will at once see at daybreak whether it is ebb or flood tide; if ebb, it is necessary to stop at anchor till it turns (that is with the wind at N.E.), as with the flood tide you can easily work up in short tacks under the Guimaras shore. A bank lies in the bay, on the West side of Guimaras, 3 miles South from Iloilo Fort. Making Iloilo Strait from the southward, Bondulan Point, which is high and bold, should be brought to bear N.E. $\frac{3}{4}$ N., and steered for until the remarkable clump of trees in Iloilo is seen. These trees brought about half their width open of the point,

until the southern angle of the fort opens of Bondulan Point, will lead clear of the Oton Bank. In thick or hazy weather, when you cannot see the fort (which is very seldom the case), you must never bring the point of *Bondulan* on Guimaras to the East of N.E. $\frac{1}{2}$ E. ; but keeping the fort a little open of this point is the best leading mark with a fair wind. When past Point Bondulan, and the wind is fair, you ought to keep the fort a little on the port bow.

The best anchorage to load is with the fort bearing S.W. $\frac{1}{2}$ W., and the small bamboo watch-box near the port entrance of the river N.W. $\frac{1}{2}$ N. It is dangerous to keep near the starboard entrance of the river, as the surf is heavy at times, and the tide runs strong. At spring tides high water a vessel drawing 16 ft. can come out, but at ordinary tides only 15 ft. Always have a pilot for entering the river.

The depth of water on the bar at the entrance of the creek or river Iloilo is about 10 ft. at low water, but within the river there are nearly $2\frac{1}{2}$ fathoms with the sides of a vessel nearly touching the mangroves, and off the town it deepens to 5 fathoms. A vessel drawing about 15 ft. can enter or leave; and when, as is proposed, a dredging machine is employed to clear away the mud which has been allowed to accumulate at the shallower parts near the entrance, vessels of almost any burthen will be able to complete their cargoes. The banks of the creek being of soft mud, there is little or no risk to be apprehended from grounding. Proceeding about $1\frac{1}{2}$ mile up the creek, the coasting craft bring up at the jetties of their respective owners, and have the great advantage of discharging and loading at the stores without employing boats. Coasting vessels can go beyond this point as far as Molo by passing a drawbridge.

The channel for entering the river is marked by *four beacons* (1864), formed each of three piles, two on each bank. The direction of the channel is N. 7° W., and the depth in the channel is 14 ft. at lowest tides, deepening to 17 ft. inside the bar. Great care should be used to guard against the violent currents in the entrance.

The country around Iloilo is well cultivated, the inhabitants quiet, and apparently industrious. The chief exports are sugar, sapan wood, tobacco, hides, hemp, and rice. The women make large quantities of *pina* goods from the fibres of the pine-apple leaf, and from cotton, silk, and hemp. Fresh beef is cheap and good, and by giving a few days' notice two or three hundred bullocks could be procured, each weighing about 200 lbs., at the rate of about 7 dollars a bullock. Fowls, eggs, &c., may be obtained.

Provisions and coolies are much cheaper, and good water can always be got to the North and South of the village of *Tilas*, opposite to Iloilo on the Guimaras shore. The tide changes very suddenly, and runs down very strongly.

Port Santa Ana, or *Buluagan*, on the West coast of Guimaras Island, 10

miles S.S.W. of Iloilo, affords excellent shelter. It is a landlocked basin, a mile in extent, with from 3 to 9 fathoms water. The entrance channel runs East and West. The South side is the best, as there is a sunken rock on the North side of the entrance, and a spit runs off from the North point. Within the harbour, towards its head, is another sunken rock, which must be looked to in seeking an anchorage. There is a river of good water at the head of the bay.

DIRECTIONS.—The ensuing remarks by Mr. Vice-Consul Loney, as to the routes toward Iloilo, will be applicable generally to the navigation of the inner channels of the Philippine Islands either to the port in question or towards Manila or Zebu.

South-West Monsoon.—Vessels making the voyage from Australia or any place to the southward of the Philippines, will find it the best course in the S.W. monsoon to enter the Philippine Archipelago by the Strait of Basilan (page 894), between that island and Samboangan; and in passing Point Batalampon, the S.W. point of Mindanao, to keep well up to Point Gorda, 58 miles to the northward, and the N.W. point of the western peninsula of Mindanao, and make the *Murcielagos Islands*, 17 miles farther to the N.E., and thus avoid being swept off to the westward by the strong currents setting from off the Mindanao coast during both monsoons.

After passing the *Murcielagos*, the high land of Negros soon becomes visible, and the course is clear and safe along its western side towards the island of Guimaras. When off the S.W. point of Guimaras, the route is direct for the narrow channel between that island and Iloilo. On making and entering this channel, care should be taken to keep on the Guimaras shore, so as to clear the Otong Shoal. This shoal, being of soft sand, may be approached pretty closely, in the event of its being necessary to beat through. The tides run through the passage with considerable strength; but if unable to make head against the ebb, bring up on the edge of the shoal, and wait for the flood to the northward.

The North-East Monsoon.—During this monsoon it is generally considered to be the best route for ships from Australia to Manila, to make a detour to the eastward of the Philippines, and enter the Archipelago by the Strait of San Bernardino. In coming from Australia to Iloilo, it will therefore be advisable, during the period of northerly wind, to beat up outside as far as Samar, and enter the Bernardino Straits by that island and Masbate. If bound from Manila, or ports to the northward, vessels may also safely proceed towards Iloilo through the Mindoro Passage, and onwards through the chain of islands off the N.E. coast of Panay. After passing Tablas and Romblon, the latter with an excellent light and a good harbour, make for the Silangas Islands, the group off the N.E. end of Panay, a good mark for which is the high conical island, the Pan de Azucar, which is visible from a great dis-

tance. In approaching these islands during the N.E. monsoon, vessels should keep along between the islets of Jintotolo and the larger Zapata; and during the S.W. monsoon move in towards the Panay shore, between Olutaya and Zapato Menor. After leaving the Zapatas, the course is to the northward or southward of the Gigantes, as preferred, and the channel through the group of islands is generally entered between Sicogon and Calaguan, from whence the route is continued past Culebra, Pan de Azucar, Bagabu, and Tagubanhan, though for vessels of heavy tonnage it may possibly be found preferable to adopt the outer and broader passage between the groups of islands and Negros, keeping within 2 or 3 miles of the Negros shore, in order to avoid the dangerous *Turia Rock*, described on p. 910.

If the inner route among the islands be taken, good anchorage will be found throughout, more particularly at Pan de Azucar and at Bacauan or La Concepcion. At Bacauan assistance and supplies may be had through the commandant of the district, and at Apiton good water and live stock can be obtained. After passing Tagubanhan, and emerging into the broad channel (after passing the *Turia Rock* above mentioned), the best course is to steer direct for the highest land visible on the island of Guimaras, care being taken to clear the Calabazas and the Pepitas Rock, and then proceed as above directed.

It should be remarked that the coast from the Gigantes to Iloilo affords good anchorage, and vessels have been known to ride out heavy gales in the open channel between Negros and Panay.

The ebb tide to the North of the Pepitas Rock runs to the eastward, but to the South of it it sets to the West. It runs through the Silanga Islands, and as far as the Seven Sins, about 3 or 4 miles an hour, but in the strait, owing to its being so constricted, it is said to run at 6 or 7 miles an hour.

From Manila to Iloilo, the best and safest route, according to Captain Ganswyk, is to proceed along the West coast of Panay, or close along the coast of the Province of Antiques), at any season, because the West monsoon is not very regular, and seldom or ever blows strongly between the Cuyos Archipelago and Panay, or to the North of Basilan. To the North and along the East coast of Mindoro is safe and easy, and if it should happen that you meet with strong S.W. winds near Tablas, it is time enough then to keep off and go along the East coast of Panay. The South coast of Panay is free from dangers till near the Oton Shoal, and the wind scarcely ever blows on the land. The bights along the coast have deep water, and you can work close in-shore, or from point to point, with perfect safety; but there is no good anchorage, as the coast is steep, and the holding ground not good. You may sail close to the West side of Panay, or the coast of Antiques anywhere to the South of *Balbatan Island*, lat. $11^{\circ} 36' N.$, which is very steep, only avoiding *Maralison Island*, lat. $11^{\circ} 20' N.$, which has a reef

to the East and West, and sunken rocks near the shore at Nalupa, in lat. $11^{\circ} 11' N.$, and at San José in lat. $10^{\circ} 44' N.$ There is also a 6-fathom patch near Tibiao in lat. $11^{\circ} 18' N.$ When you double the S.W. point of Panay during the night, you must not go too close to the islands off it, *Juraojurao*, off the South extreme, and *Nugas*, which is 4 miles to the W.N.W., as both of them have reefs around them to the southward, but not to a great distance. When clear to the eastward of these islands, and not too far South, you may safely steer N.E. by E. 32 miles without any danger; but at that distance it is necessary to lie-to during the night; or, if the night is very clear, to run in towards the shore of Panay, and steer carefully along the coast, at the same time keeping the lead going, and as soon as you are in shoal water to anchor at once till daylight, because if you keep over towards the Guimaras shore (particularly during the N.E. monsoon), you will find no anchorage, and will lose ground. Thence proceed as above directed.

The voyage from Iloilo to Manila, during the north-easterly monsoon (from November to March), usually occupies the better class of square rigged vessels from 10 to 15 days, and from 4 to 6 on the return voyage. Owing to the protection afforded by the chain of the Silanga Islands, and by other harbours on the route, the Iloilo vessels do not (as is usually the case between the ports on the northern part of the more exposed coast of Luzon and the capital) lay up during the stormy months from September to November, and communication, though less frequent during these months, is seldom altogether suspended.

The Coast of Antique, as the western coast of Panay is called, from its being the province of that name, runs nearly North and South. General directions for it have been just given. It is commercially unimportant, for the people are not so industrious as those of other parts of this fertile island. During the S.W. monsoon it is in general highly dangerous to approach it, and at this period the coasters scarcely venture out for fear of pirates. There are one or two points where ships call for water and provisions. It is composed of alternate hills or mountains, and plains, and when the rice grounds are green some parts appear very pleasant. Generally the temperature is agreeable, and the climate healthy.

Aniguig, near the South point, may afford some refreshments; it is in a deep bay. The country inland and for some distance is formed by a ridge of rugged mountains, called the *Cresta de Gallo*, the Cockscomb Mountains forming part of the great chain which runs through the length of the island.

San Jose de Buenavista, 17 miles from the S.W. point of the island, and in lat. $10^{\circ} 45'$, is with the village of *Antique*, 3 miles southward, considered to form the capital of the province. It is a miserable place, founded in 1733, with a few forts to guard against pirates. There is good anchorage off it, but it is not safe, and, as a sunken rock exists, should not be approached at

night. It is a convenient place for water and refreshments, as a Spanish resident will lend his aid. In coming here with a brisk wind, sail must be reduced in time, as the bank is very steep, decreasing rapidly from 30 to 7 or 8 fathoms, the proper depth.

To the northward of San José the coast may be approached with caution, and in daylight to within 3 or 4 miles. But caution should be used, as the coast is not well known. *Napula* (or *Nalupa*), in lat. $11^{\circ} 10\frac{1}{2}'$, is 25 miles North of San José, and 5 miles southward of *Tibiao*, a small pueblo on a projecting point. Also while proceeding southward from the village of *Tibiao* on the West coast of Panay Island, Captain Fagg obtained soundings on a coral reef well known to the small coasters, off the pueblo or village of *Napula*; some parts of the reef appeared awash, but he had $1\frac{1}{2}$ fathom with the village of *Nalupa* bearing E. by S., distant about 2 to $2\frac{1}{2}$ miles. In lat. $11^{\circ} 20'$ is the high island of *Maralison*, and 4 miles farther North is the low point of *Lipata*, surrounded by a reef; 9 miles North of this is the larger islet of *Balbatan* or *Maniguig*. A bank exists near the coast, $7\frac{1}{2}$ miles North of Point *Lipata*. Point *Pucio*, the westernmost point of Panay, is in lat. $11^{\circ} 46\frac{1}{2}'$ N., long. $121^{\circ} 50'$ E., and has a rock near it.

The outlying rocks off the West Coast of Panay belong more particularly to the Sulu Sea, and are hereafter described.

THE SULU SEA.

The space included between the Sulu Archipelago on the South, to Mindoro on the North, and having the Philippine Islands on the East, and Palawan on the West, is distinguished by the term of the Sulu Sea, or sometimes as the Sea of Mindoro. Although of great depth (1,778 fathoms), this sea is thought to have no greater depths than 250 fathoms in the passages which join it with the surrounding seas. The deep sea temperatures, taken by Commander Chimmo, showed that from a surface temperature of 84° in each sea the thermometer fell to 55° at 200 fathoms, and 37° at 1,600 fathoms in the China Sea. While in the Sulu Sea, although it was the same at 200 fathoms, yet the bottom temperature was 50° , or about equal to that at a depth of 300 fathoms in the China Sea. He therefore argues, from this and other data, that the water filling the deep basin of the Sulu Sea cannot be drawn from a greater depth than 250 or 300 fathoms out of the surrounding seas.

Winds.—The N.E. monsoon in the Sulu Sea prevails from December to June. The first burst of the S.W. monsoon was experienced at Ilo Ilo on the 10th of June (1871), when it blew a heavy gale from that direction,

with torrents of rain, the wind shifting to the N.E. again two or three days afterwards, and blew generally from that direction at Zebu and Camiguin in the middle of July.

Crossing the Sulu Sea in H.M.S. *Nassau*, during July, the wind was light, from W.N.W. to N.W., with heavy clouds in the S.W. and gloomy weather. On her arrival at Cagayan Sulu, the wind shifted to S.E., after which it blew from N.W. to S.W., squally, with heavy continuous rain. Between Cagayan Sulu and Labuan the winds were light and variable.

Currents.—During the N.E. monsoon the current runs regularly in the direction of the wind, and varies in strength according to the force of the wind. In the early months of this monsoon, when the wind blows strongest, the current runs with the velocity of a mile an hour, decreasing to about half a mile an hour in May and June.

The eastern limits of the Sulu Sea have been just described; the coast of Palawan is given in former pages, from the surveys and remarks of Captain Bate. The Sulu Group is also described previously.

The North-East Coast of Borneo is so little known that to describe its shores and dangers would be useless. We, therefore, only notice its more important harbours and their off-lying dangers. Unsang Anchorage has been mentioned on page 888.

SANDAKAN HARBOUR.—In 1873 a trading settlement was established at Sandakan Bay, very centrally situated for collecting the valuable productions of that neighbourhood. The subsequent hostile operations of the Spaniards against the people of the Sulu Archipelago have given additional importance to this place, and the bay is visited by a steamer from Labuan.

Caution is necessary in approaching Sandakan Harbour, as the shoals in the neighbourhood are imperfectly known; to the north-westward they are said to extend 7 miles from the shore. The entrance of Sandakan Harbour may be recognized by Bahalatalis Island, situated on the western side of the entrance of the harbour, in lat. $5^{\circ} 50' N.$, long. $118^{\circ} 11' E.$ The south-eastern side of the island descends abruptly from a height of 980 ft., while the north-western side slopes gradually. The islets on the reef extending North from this island are densely covered with wood.

The shoal of 13 ft., lying on the eastern side of the entrance seaward of Towsan Dooyon Island, does not show by discoloured water. The S.E. point of Bahalatalis Island bearing S.S.W. leads clear of dangers on either hand, and when the island is passed the vessel may steer direct for the anchorage abreast Buy Island.

Good anchorage will be found well inside the entrance on the western shore, in from 9 to 6 fathoms, with a high peak bearing N.W. The *Hertha* anchored in mid-channel in $10\frac{1}{4}$ fathoms, mud, with the N.E. point of Buy Island, bearing S.S.E., about 10 miles distant from the European settlement.

There are two small villages in the harbour, also a station of the Labuan Trading Company. Firewood and good water can be obtained from the natives, but no other supplies.

Tides.—The flood tide in Sandakan Harbour sets at the rate of a half to $1\frac{3}{4}$ knot for 6 hours, the last 3 hours being after the turn of low water; and the ebb at the rate of a half to $1\frac{1}{2}$ knot for 18 hours.

There are several islands lying to the north-eastward of the entrance of Sandakan Harbour. *Taganac Island* is 15 miles N.E. from Bahalatolis Island, and E. by N. 8 miles from Taganac is Baguan Island. Each of these islands is less than a mile in diameter. *Clotilde Rock* rises about 10 ft. above the level of low water, and is about 100 yards long N.N.W. and S.S.E., and about 20 yards broad. From the rock Baguan Island bears S.E. by S., southerly, $9\frac{1}{4}$ miles, and Taganac Island S. by W. $\frac{1}{2}$ W. 9 miles; these bearings place it in lat. $6^{\circ} 9' 50''$ N., long. $118^{\circ} 25' E.$ *Laurel Rock* is about double the height and size of Clotilde Rock. It lies N.E. by N. 4 miles from Baguan Island. At 11 miles westward of Clotilde Rock is another rock, 3 miles N.E. of the Bukkungan Islets.

CAGAYAN DE SULU is a small group in the south-western part of the Sulu Sea, bearing about 100 miles N. by W. from Cape Unsang, on Borneo, and 75 miles East of Mallawalle Island, South of Banguay. It seems to belong to no power, unless claimed by the Sulu Sultan, and *was* a resort for pirates. There are several islets to the northward; the northernmost, *Quinapusan*, is 11 miles N. $\frac{1}{2}$ W. from the chief island, and the southernmost, *Mutigins*, 5 miles to the S.W., are two in number, one in form of a saddle, with anchorage near them, and they are safe to approach.

The chief island, Cagayan, is large, 1,000 ft. high, and well clothed with trees. It is of volcanic origin, and a portion of it appears as a complete crater, having one or more very deep circular basins within the edge, but they are quite barred from approach from the sea. Captain Sir Edward Belcher's observatory was set up on a small islet, at the entrance of this most romantic basin, lat. $6^{\circ} 58' 5''$ N., long. $118^{\circ} 24' 11'' E.$, being nearly on the meridian of the great island. Reefs appear to extend fully a mile from the western shore, with rocks dry at low water.

“Cayayan is about 25 miles in circumference, nearly on every point surrounded by a fringe reef of coral, in a very active and progressive state, and which affords protection to canoes, and rafts made of bamboo, to travel from one point to another in smooth lanes of water, enabling the natives to pursue their fishing, on which they chiefly exist, without being subject to heavy seas.

“The men fish, while the women do all laborious work, such as carrying water, pounding rice, &c. We found them very friendly all round the island, constantly coming on board, and accompanying us when on shore,

and very useful as guides (for a trifle) in cutting down trees and clearing away bushes.

“There are safe anchorages around the island in both monsoons; that in the N.E. is safe and good on the S.W. side in from 8 to 10 fathoms; another good anchorage on the S.W. side of Keenapoussan in 10 fathoms; a third about a mile South of the little islet at the entrance to the crater on the S.E. side in 12 fathoms, but all coral bottom.

“The water on the East side of the island is the deepest, having 240 fathoms 1 mile off the land, and strong tide rips around here often frighten the mariner; but they are about the deepest water.

“The S.E. side of the island is by far the most picturesque and interesting, but not the best anchorage; the land here slopes to the South, is richly wooded, and many parts cleared, having plantations of bananas and sweet potatoes; but no dwellings were visible from the ship, nor did any natives visit us, as they so readily did at the S.W. end on our first arrival.

“I do not know any island I have seen over the world more favourably situated for trade, or more suitably adapted for cultivation. Rice, sugar, cocoa, coffee, maize, potatoes, and vegetables, would all grow if cultivated. Cotton-tree and tobacco-leaf were already growing there. The soil is excellent, rich, of trap formation, with sufficient sand to make it loose and friable. Cattle of all sorts—horses, cows, sheep, pigs, and poultry—would fatten and thrive here. Enterprising men, with some Chinese labourers, would soon make it a valuable island, and not a disagreeable one, to live on.”—*Captain Chimmo, R.N.*, 1871.

Keenapoussan, a small island, 811 ft. high, is the northernmost of the Cagayan Sulu group. Anchorage will be found on the S.W. side of the island, in from 7 to 10 fathoms, coral and sand, with Keenapoussan summit N.E. $\frac{1}{2}$ N., and Pomelikan summit S.S.E. $\frac{1}{2}$ E. *N.E. Bank*, with only 4 fathoms on its shoalest part, lies N.E. by E. about $3\frac{1}{2}$ miles from Keenapoussan. *N.W. Bank* has a 4-fathom patch N.W. $\frac{1}{2}$ W. $3\frac{1}{2}$ miles from Keenapoussan, and runs in a N.W. and S.E. direction.

Between Bisu Bintoot and Bisu Bohan there is a safe channel, but Bisu Bohan, Bohan, and Mandah are connected by a reef dry at low water. All these islands, with the exception of Bintoot, are thickly wooded, Mandah having a sharp peak 283 ft. high. Bintoot appears a vast block of dark sandstone. There is a good channel between Pomelikan and Bintoot, but the latter island should be kept aboard, as a reef runs off Pomelikan to the southward and westward about 3 cables.

Tides.—At Cagayan Sulu, during the N.E. monsoon, it is high water, full and change, at 6^h 10^m, springs rising 6 ft.; the tides are, however, irregular and uncertain, the tidal stream being scarcely perceptible.

Muleege Islands lie 8 miles South from the West end of Cagayan Sulu. They are two small islands, 410 and 232 ft. above the sea respectively, and

bear N.E. by N. and S.W. by S. from each other. The channel between them should not be attempted. *Mambahenauan*, another small island, lies 20 miles S. by E. $\frac{1}{2}$ E. from Muleegee Islands.

The *Muleegee Patches* consist of a number of coral banks with from 5 to 10 fathoms; the shoalest lies W. $\frac{1}{4}$ N. 26 miles from the great Muleegee Island. A patch of $6\frac{1}{2}$ fathoms was sounded on in lat. $7^{\circ} 3' 36''$ N., long. $117^{\circ} 56' 24''$ E. The *Pudsey Dawson Dangers* are a series of coral patches, the western of which, with 15 ft., bears E. $\frac{3}{4}$ S. nearly 19 miles from the East extreme of Mallawalle Island, in Banguay South Channel; from this danger, on the bearing of E. by N. $\frac{1}{2}$ N. for about 13 miles, are several banks with from $2\frac{1}{2}$ to 10 fathoms on them. These banks are principally coral and sand, with deep water between; as a general rule they are not steep-to, and thus, if the lead be kept going, warning of their vicinity will be given. Dangerous reefs also lie westward and southward of the Pudsey Dawson dangers, and are only to be understood by studying the chart.

Viola Reef, having only 4 ft. at low water spring tides, and on which the Spanish vessel *Viola* struck and remained several hours, is reported as lying in lat. $7^{\circ} 50' N.$, long. $117^{\circ} 40' 50'' E.$ Another rock of doubtful position is marked at 5 miles N.N.W. of the Viola Rock.

St. Michael Islands consist of four islets; they lie about 40 miles to the northward of Cagayan Sulu; the largest, *Bancawang*, is about three-quarters of a mile long, and at 2 cables from the N.E. point is nearly divided by the sea. The N.E. point rises to a peak, 123 ft. high. Bancawang is connected with a small coral islet, lying $1\frac{1}{2}$ mile to the northward, by a reef extending from the North and West sides, with sand cays and large boulders on it. The islet is steep to the S.E.

Manuk Manukan, the larger of the two S.W. islets of the group, is thinly covered with trees, the tops of which are 32 ft. above the sea, and lies about W.S.W. $5\frac{3}{4}$ miles from the N.E. point of Bancawang.

There is no safe anchorage around any of these islands; in the progress of the survey, H.M.S. *Nassau* anchored in 6 fathoms, South of Manuk Manukan, and had 70 fathoms over the stern.

Two and a quarter miles N.W. of Manuk Manukan is a coral reef of $2\frac{1}{4}$ fathoms, which is considered to be connected with Manuk Manukan by shoal ground, and therefore to be avoided.

The *West Bank* is 4 miles to the westward of Manuk Manukan, and runs about N.N.W. and S.S.E. $3\frac{3}{4}$ miles long. The least water found was $6\frac{1}{2}$ fathoms, near the South end. The eastern extreme of the extensive *S.W. Bank* lies S.W. $\frac{1}{2}$ S. $4\frac{3}{4}$ miles from Manuk Manukan. H.M.S. *Nassau* anchored on this bank on several occasions in good holding ground. Red bream and large cod-fish in great numbers were caught on most of the banks when in depths exceeding 10 fathoms.

Java Reef, between St. Michael Isles and Bancoran, was discovered by

Captain Kempton in 1869. He found a depth of $2\frac{1}{2}$ fathoms least water, surrounded by depths of 5 and 6 fathoms. From the bank, St. Michael's Island bore S.W. by S. $\frac{1}{2}$ S.; Bancaran Island, N.E. $\frac{1}{2}$ N.; and Mount Mantaleengahan, in Palawan, N.W.

Bancoran Island, the centre of which is in lat. $7^{\circ} 57' N.$, long. $118^{\circ} 40' E.$, is about $4\frac{1}{2}$ cables in extent, flat, and covered with trees, the tops of which are 140 ft. above the sea.

Tub Bataha.—This dangerous line of reefs consists of small islets, sand cays, and large boulders, all connected by sand ridges, and fringed with steep-to coral reefs, running S.W. and N.E. for a distance of about 16 miles.

The N.E. islet, which is the highest, is 15 ft. above the sea, with verdure in the centre, and lies in lat. $8^{\circ} 53' 48'' N.$, long. $120^{\circ} 0' 45'' E.$

The S.W. islet is 10 ft. above the sea, with the trunk of a large embedded tree on the N.E. side. Apparently a channel exists through the reef about 5 miles North of the S.W. islet, but it was not examined. Both of these islets were teeming with sea birds, numbers of them flying round the ship before the reef was sighted.

To the eastward of Tub Bataha two rocks are marked, one in lat. $8^{\circ} 46' N.$, long. $119^{\circ} 57' E.$; and the other, *Temerario Rock*, lat. $8^{\circ} 48' N.$, long. $120^{\circ} 5\frac{1}{2}' E.$

Jessie Beazley Reef lies about 14 miles N.W. by W. from the northern islet of the Tub Bataha; this position can only be considered approximate, as the reef was alone seen from the mast-head of H.M.S. *Nassau* on passing the Tub Bataha.

South Tub Bataha was supposed to exist in lat. $8^{\circ} 4' N.$, long. $119^{\circ} 50' E.$ H.M.S. *Nassau* tried for soundings there, finding no bottom with 180 fathoms; 6 miles W. by N. of this position, at noon, with good observations, bottom was obtained in 1,878 fathoms, pale yellow sand. As the observations were made on a clear day, and a good look-out kept from the mast-head, there is no doubt this shoal has been misplaced on the charts.

Nicholson Rock is marked in lat. $8^{\circ} 52' N.$, long. $119^{\circ} 43' E.$, 12 miles W. $\frac{1}{2}$ N. of the South end of Tub Bataha.

Clotilde Breaker is in lat. $8^{\circ} 11' N.$, long. $119^{\circ} 16' E.$

Rosalia Rock, discovered in March, 1868, is in lat. $8^{\circ} 54' N.$, long. $119^{\circ} 6' E.$

The **CAGAYANES ISLANDS** were very imperfectly described and delineated on the Spanish charts, until Sir Edward Belcher made a cursory survey of them in March, 1846. Cagayan, the largest and southernmost of the group, is about 5 miles long; at its broadest part, which is towards the southern end, it is 2 miles across; the highest hill, 285 ft. above the level of the sea, lies 68 miles West of Negros West point. The remaining islets of this group are low, and covered with trees. A reef which curves to the eastward, and is steep-to on all sides, extends $8\frac{1}{2}$ miles to the northward of Boombong. The Observatory was fixed on a small rocky islet in the channel

between the two largest islands, lat. $9^{\circ} 35' 30''$ N., long. $121^{\circ} 15' 30''$ E. The bays or creeks situated in the interior of the extensive sound formed by the two great islands are very picturesque and retired, and have at their entrance, or chord of the bay, a depth of not less than $3\frac{1}{2}$ fathoms. If the entrance to this sound from the northward should be found clear from danger, or even accessible by dint of pilotage, this group would form an important naval position, but not more than 12 ft. could be found by the *Samarang*. The cottages of the inhabitants are scattered about in the little nooks or bays, but are not neat or cleanly, although the people they saw were clean limbed, light coloured, vigorous, and very respectful and courteous in manner. Sir Edward was assured that bullocks, vegetables, and fowls, could be procured, and inferred that whalers frequently visit the pueblo, a pretty large village, with a whitewashed fort and a church. The islands are surrounded by a reef, which extends nearly 9 miles to the northward.

Calusa Island, lying 10 miles W. by N. $\frac{1}{2}$ N. from the South point of Cagayan, is about 60 ft. high, covered with trees, and visible 8 miles off. There is a deep channel between it and Cagayan. *Cavilli* and *Sandy Islands*, with their outlying reefs, extend $8\frac{1}{2}$ miles in a N.E. by E. and S.W. by W. direction, with a deep channel $1\frac{1}{2}$ mile wide between. As these islands are steep to on all sides, the mariner should be cautious when navigating in their vicinity, the lead giving no warning.

Between the Cagayanes group and the South end of Panay there are several shoals. The southernmost was announced in 1839, as the *Nicholson Bank*, 3 fathoms (perhaps less), 9 or 10 miles North of the larger Cagayan. Another was announced by Captain Wedge, of the *Sultana*, in 1845, with only 9 ft. least water, in lat. $9^{\circ} 59' N.$, long. $121^{\circ} 24' E.$ Another, an extensive reef, on which the *Golconda* struck in 1837, and the *Bell* in 1839, reaches to within 23 miles S. by W. of the South extremity of Panay. The charts must afford all further information.

Piedra Blanca, or *white rock*, lies in lat. $10^{\circ} 27' N.$, long. $121^{\circ} 3' E.$, about 20 miles S. $\frac{1}{2}$ E. from the S.W. point of the Gran Cuyo, but far to the westward of the ordinary track of vessels.

Queen of the Seas Bank, an 8-fathom patch, was discovered by Captain Smiley Reid, in 1868. The bottom was distinctly seen, and the bank appeared to be about $1\frac{1}{2}$ or 2 miles in diameter. From the bank, Carlandagan Island bore N.W., and Quiminatin N.E. $\frac{1}{4}$ N., which places the shoal in lat. $10^{\circ} 26' N.$, $120^{\circ} 29' E.$, or 15 miles eastward of the position now assigned to it.

The **CUYOS ISLANDS**, or *Islas de los Amantes*, is an extensive archipelago between Panay and Palawan. The charts of them will give the only account we have; there is no good description. *Gran Cuyo* is the largest and one of the southernmost. Its centre is in lat. $10^{\circ} 52' N.$, long. $121^{\circ} 2' E.$ It is well cultivated with rice in some parts; the village is on the N.W. side.

Many of the other islands are high and rocky; the easternmost is in lat. $10^{\circ} 58\frac{1}{2}'$ N., long. $121^{\circ} 16'$ E., 9 miles N.E. of Gran Cuyo. *Quinuluban*, the northernmost, is in lat. $11^{\circ} 27'$ N., long. $120^{\circ} 51'$ E., and is a high island, with others near it, to the southward.

There are safe channels among the various islands, with depths varying from 30 to 60 fathoms, but a large ship should not get entangled among them, as many of the reefs extend a long way around them, and there are detached coral patches either not known or not properly placed. Of the sunken dangers known there is a $1\frac{3}{4}$ -fathom patch, S.W. by W. $\frac{1}{2}$ W., 21 miles from the peak of Cuyo Island, and S.E. $10\frac{1}{2}$ miles from Paya, a small island, the south-westernmost of the group. *Canipo Island* is N.N.W. 10 miles from Cuyo, and the space between is nearly filled up by a shallow bank. A sunken rock is placed in lat. 11° N., $120^{\circ} 38'$ E., W.N.W. 25 miles from Cuyo Island. *Agatuya* is an island 3 miles long North and South. A sunken rock lies N.W. 3 miles from its North extremity, and S.W. the same distance from *Dit*, another small, high island. A 4-fathom patch was discovered by Captain Mackenzie, of the ship *Chinaman*, in 1871, in latitude $11^{\circ} 17'$ N., $121^{\circ} 6'$ E., 10 miles E.N.E. of *Dit*.

The **Sombrero Rock**, midway between the S.W. end of Panay and the Cuyos Islands, is not larger than a long boat, and can only be seen when within 8 or 9 miles; it generally shows black. Soundings appear to extend from the Sombrero Rock to the Cuyos. It is in lat. $10^{\circ} 43'$ N., distant 20 miles from Panay, and can only be made out at the distance of 8 or 10 miles. It bears from Point Naso N.W. 29 miles, from the centre of Gran Cuyo E. by S. $\frac{1}{2}$ S., and from Paguayan, the easternmost of the Cuyo Islands, S.E. distant 24 miles.

Pontud Bank is a small dry patch, in lat. $11^{\circ} 20'$ N., long. $121^{\circ} 41'$ E., S.W. by W. 16 miles from Balbatan Island. A 7-fathom coral patch lies 4 miles N.N.W. from it; and *Sultan Bank*, with $5\frac{1}{2}$ fathoms water over it, lies 13 miles West of the 7-fathom patch.

The Panagatan Shoal lies to the S.W. of Semirara. It is also called the *Camden Reef*, and is a coral reef, 4 miles in extent East and West, and 4 miles broad. There are three coral islands on it, all covered with trees, that to the westward being the highest, only 12 ft. above high water. No fresh water found; but they are visited by fishermen. The S.E. point of the North island is in lat. $11^{\circ} 50' 40''$ N., long. about $121^{\circ} 16'$ E. Its native name is derived from the enormous shells of the tridacna or *Chama gigas* which abound on it.

Falmouth Bank, of 11 and 12 fathoms, lies 15 miles West of Panagatan Shoal. *Leonidas Bank*, of $5\frac{1}{2}$ fathoms, lies 15 miles N.N.W. of Falmouth Bank, and 12 miles S.W. of Ambolon Island. Three shoal patches lie eastward of the Calamion Islands, one of $5\frac{1}{2}$ fathoms 7 miles E.S.E. from the East end of Bulalacao. *Magellanes Bank*, of $5\frac{1}{2}$ fathoms, 8 miles East of

Delian, in lat. $11^{\circ} 51' N.$, long. $120^{\circ} 29' E.$, and a $4\frac{1}{2}$ -fathom patch S.S.E. 10 miles from Magellanes Bank, and 14 miles eastward of the $5\frac{1}{2}$ -fathom patch just mentioned.

MINDORO is 76 miles from North to South, and its northern coast is about the same length. Its western shore has been described (p.p. 586—592) as forming a portion of the limit of the China Sea. It is an island of great natural fertility, its climate is very hot, and the rains almost incessant. *Cape Calavite*, its N.W. extremity, is formed by the slopes of a lofty mountain, and from this the North coast trends nearly eastward, and at 25 miles from Cape Calavite is the *Abra de Ilo*, where is good anchorage, and between them are the ruins of a remarkable church. They stand on a narrow plain called Punta de San Tomas, now deserted, but their existence shows that the island must have been once populous before the incursions of the pirates about the middle of last century. This coast of the island is exceedingly unhealthy, and is uninhabited. It is believed that to sleep a single night on it is certain to produce a putrid or tertian fever. At 12 miles eastward of the *Abra de Ilo* is the *Puerto Galera*, only fit for boats, and thus named because it was a refuge for the galleys in pursuit of the pirates. Inland of this is the loftiest mountain of Mindoro. The coast to the eastward is deserted and inaccessible, and only visited occasionally by the wild inhabitants to take the honey which is abundant among its rocky cliffs. *Calapan*, the chief place of the island, is 14 miles E. by S. of the *Puerto Galera*, and is on a point from which an extensive reef projects. It is a miserable place, with a small fort. *Point Dumali*, its N.E. point, is bold and steep-to, and when coming from the eastward may be recognised by a remarkable white patch on the face of it about 400 ft. high.

Mindoro is at present very unimportant. The remnant of its once civilized population now live in the interior, a miserable and degraded remnant, and the alleged unhealthiness of its shores prevents immigration to restore its former fertility.

SIBUYAN is 13 miles in diameter; it is only inhabited by Indians, nearly uncivilized, and therefore it is quite unimportant. On its N.E. side is a reef of sand and rocks, which uncovers at low water, 5 or 6 miles in extent. It runs parallel with the coast, leaving a channel half a mile wide within it, having from 6 to 10 fathoms water, and which perhaps affords some shelter.

The channel between Sibuyan and Masbate, with its shoals, has been before noticed (page 905).

ROMBLON is 8 miles West from the western point of Sibuyan. It is 10 miles long, and at its N.E. end is an excellent small harbour, and a well kept village. There is a fort here built by a priest to resist the piratical Moros, which he did so effectually as to gain the name of Capitan Terror.

There are *four small fixed lights* shown at Romblon, but no account is given of their use or application. They are on the *Sabang, Agbatan, Binagon* and *Rosas Points* beacons.

TABLAS, next West of Romblin, is 33 miles long, but is narrow. We have no account of its coasts. It has three small villages, and a fort for protection against the Moro pirates.

Marinduque is 25 miles long and 11 broad. It is lofty, and *Mount Marlangas* is of considerable elevation, rising over its southern cape. The island is fertile, rice the chief product; the principal outlet of which is at *Malauigi*, an open road on its southern coast. On the N.E. side is a town and harbour, called *Sta. Cruz de Napo*, spacious and sheltered, and on the N.W. side is that of *Sant' Andres*, a shoal lying in front of it.

Port St. Andrews, in the N.W. part of the island, has a very narrow entrance, with some dangers extending from the shore on the northern side. Within is a deep well sheltered basin. There is no town here, but at $4\frac{1}{2}$ miles to the southward is *Buac*, with 1,100 inhabitants. *Gazan* is nearly 20 miles further down the coast.

Of the islands to the northward of Tablas, *Dos Hermanas* are flat and about 150 ft. high, *Maestro de Campo* being high and steep-to. *Banton* and *Simara Islands* are readily recognized from the northward of *Maestro de Campo*; the former is high, peaked, and rugged, and apparently uncultivated, while the latter is moderately elevated, flat-topped, and well cultivated, with a village, church, and fort on its South side.

LUZON, LUCON, or, as it is sometimes corrupted, "Luconia," is by much the largest and most important of *Las Islas Filipinas*. It is of an exceedingly irregular figure, participating in this character with the other volcanic islands of the archipelago, such as *Mindanao, Halmaheira, and Celebes*, the volcanic agency being apparently continuous throughout all these, and extending northward towards *Japan and Kamtchatka*. Measured along its greatest length it is 550 miles in extent, but the great mass of the island is in the northern peninsula, which is 135 miles broad in some parts. Its form has been compared to the bent arm "brazo doblado," and its aggregate area is nearly equal to double that of *Ireland*.

It is divided by the Spaniards into nineteen provinces, of which that of *Tondo*, which contains the capital, *Manila*, is by far the most important; the others need not be enumerated. The whole commerce of the island and most of the civilization and European residents are centred in its capital.

From its great extent in latitude, between latitudes $12^{\circ} 30'$ and $18^{\circ} 43' N.$, it lies in the main strength of the monsoons, which exert their whole force on either coast alternately. Throughout its length ranges of volcanic mountains extend, commencing in the South with the active volcano of *Balusan*, on the North side of the Strait of *San Bernardino*, and continuing through

many lofty peaks along the southern peninsulas, exhibiting more or less the results of former or recent activity. On the south-western side of the northern peninsula and on the opposite coast are separate ranges, and in the northern portion are those of the *Sierra Madre* or *El Gran Cordillera*, which runs generally parallel with the eastern coast, terminating in the North at Cape Engaño. On the western side, and in a similar direction, are the *Cordillera Central* and *del Norte*, which are generally known as the *Montes Caraballos*.

These mountain chains, although of no great elevation, probably nowhere 6,000 or 7,000 ft., have an important influence on the climate of the eastern or western coasts, in a similar way that the Ghauts, in about the same latitudes, have on the meteorology of the Indian peninsula. There are numerous volcanoes along this chain, of which those to the S.E., such as *Mayon*, above Albay, *Taal* in the centre of a lake, *Bonolano*, &c., are the best known. Earthquakes are consequently frequent, and have been in some cases very destructive.

The seasons are divided into the wet and the dry. In the *western portion* the rains last from the beginning of June until the middle of September, while at this season there is fine weather in the eastern and northern parts of Luzon. This monsoon is not so regular on the western coast as farther at sea, and in other portions of its course, being much interfered with by the various islands and mountains. In October the westerly monsoon gives place to the northerly winds, which then bring similar rains, derived from the evaporation in passing over the Pacific, on to the eastern coast. When these rains set in the fall is so abundant, that the whole country becomes inundated and generally impassable, and the flat plains are then little better than vast lagoons. A surprising fertility is the consequence of this abundance of moisture, combined with the tropical heats which are constant throughout the year. From the wetness of the climate for so large a portion of the year roads and bridges are deficient, and a great portion of the commerce is carried on coastwise, a traffic which is much aided by the peculiarly indented coast line of its more densely peopled parts. The heat is very great, but the humidity qualifies this. The great heats commence about the middle of March, when the winds from East and S.E. set in, and which last about two months. At the changes of the seasons hurricanes and typhoons are frequent and very violent.

Of the North and eastern coasts we know very little; our hydrographical knowledge of it is almost entire ignorance. This portion of the island is scarcely subject to Spain, has no trade or productions, and being moreover a lee shore for so large a portion of the year, it is avoided by ships at all times, on account of this and of the strong currents which prevail close to them.

The **SOUTH COAST** of **LUZON** is imperfectly known. *Cape Santiago*, its

western extremity, in lat. $13^{\circ} 46' N.$, long. $120^{\circ} 40' 20'' E.$, is low, with reefs extending a quarter of a mile from it, and *Minerva Rock*, 4 miles S.E. of it. *Verde Island*, 9 miles to the S.E. of the East end of Maricaban, is 4 miles long N.W. and S.E., and 1,500 ft. high. By taking care not to shut in its North point by Maricaban, the Minerva Rock will be cleared by at least 3 miles. Between Cape Santiago and the western end of Maricaban Island, which is surmounted by rocks, 11 miles S.E. by E. from it, is the entrance to *Balagan Bay*, the S.W. part of which is called *Pagapas Bay*. In these bays there is good anchorage. *Maricaban Island* is 7 miles long, high, and covered with trees. On its eastern end there is a mountain, which is remarkable for being on land which is higher than any part of the island. At the western end there is another, not so high, terminating in a peak, and is very distinct from the neighbouring heights of Point Santiago. Vessels may anchor on a sandy bottom off all the beaches on the northern and southern sides of this island; but it is necessary to do so close to them, for they are very bold. To the northward of the western end of the island there is a small islet extending North and South surrounded by rocks. Rocks and islets extend to 2 miles off the East end of Maricaban. The channel northward of Verde Island is generally preferred, as a rock is said to exist about $1\frac{1}{2}$ mile S.E. $\frac{1}{2}$ E. from the South point of Verde Island, and a reef running 5 cables North of the Bacos Islands.

The entrance to *Batangas Bay* is between the East end of Maricaban Island and *Matoco Point*, high and covered with trees, 5 miles to the eastward. The best anchorage is in its N.E. part, near the town of Batangas or Bauang. The *River Rosario* is 10 miles eastward of Matoco Point, the coast between being sandy. *Point Malabrigo*, 4 miles S.E. by E. from Rosario, is covered with trees. Northward of it is some high ground, 3,500 feet high, called the Sierras of Rosario, which forms a useful landmark in approaching from the eastward. The next high ground to that at Point Malabrigo is at Sigayan promontory, 10 miles N.E. by E. of it. There is anchorage near the coast between these places. The eastern extreme of Sigayan promontory is called *Cape Bantigui*. One and a half mile N.W. from it is a small bay with some wooded islets in it. *Pagbilao Island* lies $11\frac{1}{2}$ miles N.E. from Point Bantigui. Its irregular shape forms a bay on its southern coast, and the island itself, nearly filling up the bay in which it lies, forms two harbours, Pagbilao to the westward and *Lagummanoc* to the eastward. The first of these is much embarrassed by shoals, and requires a pilot. Vessel not drawing above 24 ft. can enter Lagummanoc, but great caution is necessary in doing so, for the reefs which extend from its two points very much reduce the breadth of the entrance.

From the S.E. point of Pagbilao Island, in lat. $13^{\circ} 53' N.$, long. $121^{\circ} 48' E.$, for 28 miles to the south-eastward to Point Tuguián, the coast should not be approached within a distance of 2 or 3 miles, as numerous sunken rocks

lie off it. Between Point Tuguian and Point Pinamuntangan, $26\frac{1}{2}$ miles to the south-eastward, a shallow bay is formed. In the southern part of this bay, 5 miles N. by W. from the last named point, is a patch of rocks 2 miles in extent and 3 miles off shore. Mulanay, a mall bay, with the town of *Yendo* on its shores, is in lat. $13^{\circ} 30' N.$, long. $122^{\circ} 25' E.$ This bay is backed by high ground, and to the southward of it the peninsula is high, terminating in *Mount Bondog*, 1,250 ft. high, 24 miles to the southward.

Bondog Head lies 2 miles S.S.E. from Mount Bondog, and from it the coast trends about N.E. for 8 miles to Point Arena, and has several sandy bays with anchorage. A shoal, 3 miles N.E. from Bondog Head and a mile off the shore, should be avoided. *Sombocagon Bay* is 4 miles N.N.W. from Point Arena, and several sunken rocks lie near the intervening coast. In this bay country boats resort for anchorage, but there is a large rock in the midst of it, leaving a channel between it and the shore. In the N.W. part of the bay is the town of the same name. The North point of the bay has a reef extending from it to the S.E. in a semicircular form, under which there is good sheltered anchorage in 4 fathoms, fine sand.

Alibijaban Island, on the western side of the Gulf of Ragay, and 6 miles North of Arena Point, is 3 miles long North and South, and surrounded by rocks. There is a channel $1\frac{1}{2}$ mile wide between the rocks off its western side, and those extending a mile from the main. N.N.W., 5 miles from the North end of this island, is the *Palad Bank*, 3 miles off shore. The entrance of *Pusgo Harbour* lies N.W. 7 miles from Palad Bank, and has Point Pusgo on its eastern side, a mile southward from which is a $1\frac{3}{4}$ -fathom patch, the best entrance to the harbour being on the western side of this patch.

Guinayan is a town at the head of the Gulf of Ragay, on its western side, 25 miles above Point Pusgo. In approaching this place there are two dangers to be avoided, one lying S.E. by E. 8 miles from it, and a $1\frac{3}{4}$ -fathom patch $3\frac{1}{2}$ miles E. $\frac{1}{2}$ S. from it. *Ragay* is on the eastern shore of the gulf, E.S.E. from Guinayan. The S.E. entrance point of the Gulf of Ragay may be considered as Tamba Point, which lies S.E. from the North end of Burias Island. Between Tamba Point and St. Bernardino Strait are several harbours worthy of mention. *Visita* and *Marigondon* are towns near the coast, respectively in lat $13^{\circ} 1' 30'' N.$, and $13^{\circ} 0' 30'' N.$ *Donson* lies 4 miles above the mouth of a small river, off which is shallow water. At $5\frac{1}{2}$ miles S.E. of Donson River is the entrance of *Port Putiao*, in lat. $12^{\circ} 53' N.$, long. $123^{\circ} 40' E.$ The channel into Port Putiao is in the middle of the mouth leaving the islet off the point on the left hand. But it is necessary to enter lead in hand and with small sail to keep the channel, for there are rocky shoals on both sides which dry at low water. In the mouth there are 25 to 10 fathoms, mud.

The port of *Parlatuan*, 2 miles to the eastward, has scarcely 3 fathoms mid-channel, although it has 5 and 6 fathoms inside. To get into it a vessel

must be towed and sound to keep the channel and avoid the rocks which appear at low water.

Sosogon Bay, 12 miles deep, is the best port to be found hereabouts, and on its shores are several towns, where provisions may be obtained. Bagatao Island, 2 miles long W.N.W. and E.S.E., lies across its entrance, and the best passage in is between its western end (lat. $12^{\circ} 52' N.$, long. $123^{\circ} 46' 30'' E.$), and Malumahuan, a small island, $1\frac{1}{2}$ mile to the westward. There is anchorage on a sand-bank South of the West end of Bagatao Island, in 12 or 14 fathoms. When inside the port a vessel may anchor where suitable. If large she must not approach the vicinity of Sorsogon, for from the third part of the extent the depth decreases 20 fathoms. But there is the satisfaction of knowing that the whole of the ground is mud, and that in the event of touching it, a vessel cannot do herself much harm. Water is got from the East side of the outer harbour. It was in this bay that at one period the great galleons which went to Acapulco were built, and here also were established roperies for the making of cordage from the Manilla hemp, the produce of a species of banana.

Bulan is a town 13 miles southward of Bagatao Island. The coast between has anchorage off it; but, at $2\frac{1}{2}$ miles northward of Bulan, a shoal bank of sand stretches some distance off the coast. At the town of Bulan (formerly Gate) is a river, the bar of which has but 5 ft. on it at low water. Within this, however, it is navigable with but little change of depth. The town is seated on the right bank at a short distance inside. On the bare sandy point which extends out a tolerable distance is a fort.

Butag Bay, 3 miles to the south-eastward of Bulan, is $1\frac{1}{4}$ mile wide between Points Angas and Barugo, off each of which are some rocks. A town lies at the head of the bay. The shore of the bay is mountainous in some parts towards the shore and well wooded, and the depth of the water in it admits of vessels of all kinds. *Tagiran Point*, formed of a hill with a flat top, is $7\frac{1}{2}$ miles S.E. by S. of Butag, and there are several bays where anchorage may be obtained, lying between. This point is in lat. $12^{\circ} 32' N.$, long. $123^{\circ} 58' 30'' E.$, and several bays with anchorage in them, lie to the eastward of it. *Calantes Bank* is a small coral rock, $5\frac{1}{2}$ miles E.S.E. from Tagiran Point. It is mentioned on page 904. The small islands of *Calintan*, *Juac*, and *Tielin*, off the S.E. end of Luzon, have many rocks near their shores, but the narrow strait which separates them from the coast of Luzon has plenty of depth for any vessel.

The EASTERN COASTS of LUZON,* washed by the Pacific, are very

* "LEGASPI, opened to foreign commerce in 1873, is situated at the S.E. end of the Island of Luzon. It is an open roadstead much exposed to the violence of the N.E. mon-

irregular, and in their southern portion very deeply indented by large bays and inlets. The Strait of San Bernardino, which separates it from Samar, and is the great inlet from the Pacific to the Bisayas Islands, has been described on page 903.

The *Volcano of Bulusan*, lat. $12^{\circ} 47' N.$, stands as a sentinel on the northern side of this *Embocadero* or strait, and being in constant activity, its flames have been a good mark by night for approaching it.

Magnoe Bay has its entrance at 2 miles westward of Tielin Island (page 929). At the southern point of Tielin Island a shoal extends out S.E., and as its neighbouring isle, Juac, has another extending in the contrary direction, they leave but a small channel between them, which is used by the trading craft of the country. Magnoe Bay is not large, but may afford anchorage to any vessel, whether the weather may be fine or blowing between North and S.S.W. ; but to all other winds she would be exposed and subject to a considerable swell. The town is very small and poor. To the northward it has a river, and may afford water and a few provisions. The southern point of entrance of Magnoe Bay has shoal water extending off it for more than half a mile to the northward. Having passed Point Padan, which is next to the E.N.E. from the North point of the Bay of Magnoe, there is neither bay nor place for anchorage as far as that of Albay. The whole coast is composed of ravines with rocky terminations or sandy beaches, and although off these the ground may be clean, at some distance there is a rocky ridge which extends from Point Padan as far as the shoals of Montufar, leaving only some few breaks or cuts which the pilots, who know them, pass through in their small craft for *Bulusan*, lat. $12^{\circ} 42' N.$; *Gubat*, $12^{\circ} 56\frac{1}{2}' N.$; *Bagacay*, $13^{\circ} N.$; or for any part of the coast, inside the ridge.

The Gulf of Albay is 22 miles deep in an East and West direction, and lies between the three islands of Rapurrapu, Batan and Cacararay, on its North, and the coast of Luzon on its South side. Its entrance is between Ungay Point, the S.E. point of Rapurrapu, lat. $13^{\circ} 11' N.$, long. $124^{\circ} 9\frac{1}{2}' E.$, and Montugan Point, 5 miles South from it. The latter point has sunken rocks off it. The narrow channels between the islands forming the North side of the harbour are intricate and dangerous, and some sunken rocks also lie off the South side of the islands. The South shore of Albay Gulf forms two large bays, in the eastern of which are the villages of Nabug, Sugob, and Bacon ; and in the western, called Poliqui Bay, are Manito and Caguayan, on its eastern shore, and Poliqui on its western. Sunken rocks lie all round

soon. There being also deep water close to the shore, vessels at anchor run great risk of dragging during the gales which often prevail on that part of the coast. Coral reefs are also said to exist in the Bay of Legaspi, though not entered on the chart."—Mr. Consul Ricketts, 1873.

There is no mention made of this place on the charts.

Poliqui Bay, at 1 or 2 miles off shore. *Albay Town*, in lat. $13^{\circ} 9' N.$, long. $123^{\circ} 43' E.$, lies 2 miles inland from the head of the bay. A village lies on the coast East of it, at the mouth of a river. N. by E. 5 miles from this village is that of *Livoc*, with rocks on the shore. Two detached rocks also lie 3 miles S.E. of the mouth of the river in which Livoc is situated. *Port Sula*, at the S.W. end of Cacraray Island, lies 5 miles East of Livoc.

Tobaco Gulf, next North of Albay Gulf, has its chief town, named *Tobaco*, just within its western entrance point, which is in lat. $13^{\circ} 22' N.$, long. $123^{\circ} 43' E.$ This gulf is 7 miles broad East and West. The island of San Miguel shelters it from the northward, and round the western end of this island is the entrance to the gulf, a mile broad. The North side of this island is bordered by dangers to a mile off, and the channel eastward of it, between it and Cacraray, is unsafe. The West end of San Miguel should not be approached when bearing South of S.S.E. Besides Tobaco, the villages of Malilipuy, Bagacay, and Pilis, are built on the shores of Tobaco Gulf. On the South side of Canamuan Peninsula, 17 miles to the northward, is *Lagonoy Gulf*, with several villages on its shores.

The *Volcana of Albay*, in perpetual agitation, lies 5 miles W.N.W. from Livoc, and is constantly threatening the neighbourhood, which is fertile and well cultivated. The roads too are better here than in other parts.

CATANDUANES ISLAND is 34 miles long by 15 to 18 broad. It is lofty and fertile. The heat of the climate is tempered by the sea breezes. Rice, cotton, abaca, and maize are produced. The abundant forests of its interior yield good timber for ship-building. There are several islands in the strait named *Maqueda Canal*, which is 10 to 20 miles broad, separating it from *Punta Rungus* on Luzon, above which rise the lofty mountains of *Canamuan*.

Iot Point, the North point of Catanduanes Island, is in lat. $14^{\circ} 8' N.$, long. $124^{\circ} 13\frac{1}{2}' E.$ *Matulin Island* lies 5 miles E.N.E. of it, and is surrounded to of 1 or 2 miles by sunken rocks. *Horadada Rocks*, above water, lie 6 or 7 miles N. by W. from Iot Point, and *Abriop Bank* 2 or 3 miles N.W. from Horadada Rocks.

Panay, 4 miles long N.E. and S.W., lies off the N.E. coast of Catanduanes, in lat. $14^{\circ} 4' N.$ Along its western side, which is bordered by rocks, is the entrance to a small bay, in which are situated the villages of Bagamanoe, Payo, and Biga. On the East coast of Catanduanes is *Tambongon*, in lat. $13^{\circ} 59' N.$, and *Port Baras* in lat. $13^{\circ} 39' N.$ Sunken rocks lie off the coast at Pandaran Point, in lat. $13^{\circ} 51' N.$, at Jimoto Bay in lat. $13^{\circ} 46' N.$, and at Binurun Point in lat. $12^{\circ} 41' N.$

Nagumbuaya is the S.E. point of Catanduanes Island. It is in lat. $13^{\circ} 32' N.$, long. $124^{\circ} 31' E.$ Between this and another point 10 miles to the westward is a deep bay, into the eastern part of which a large river flows, having Cabugao and Balo villages at its mouth. On the S.W. coast of Catanduanes is anchorage off the village of Caloblong. On its western coast is no place

of importance. Palumbanes Island lies 5 miles West of its N.W. point, where is a small bay named Carao.

Puerto de Sisiran is on the North shore of Canamuan peninsula, the entrance being 32 miles W. by S., of the North point of Catanduanes. It is safe, and sheltered by a group of islands, the entrance to it being in lat. 14° N., long. $123^{\circ} 41'$ E. The channel leads South, and when round the East point of the island haul West, and anchor to the N.E. of the village of *Basi* on the Luzon shore. At 24 miles to the S.W. is the peaked mountain *Ysaroc* and *Psarroc*, near the head of the bay of San Miguel.

In approaching this bay care should be taken to avoid some sunken rocks, which lie at 7 miles north-eastward of its eastern entrance point. They extend for $1\frac{1}{2}$ mile N.W. of a small island. To the southward of them is *Tagun Bay*, West of Lahuy Island.

Botavanan Island, in lat. $14^{\circ} 10'$ N., long. $123^{\circ} 20'$, lies 23 miles N.W. by W. from the entrance of Sisiran; the coast between is broken up into three deep bays. At 5 miles S.W. by W. from Botavanan Island is Pinitan Point, with sunken rocks extending a mile N.W. from it. Between this point and Siruma Island, 5 miles to the S.W., is the entrance of *Siruma Bay*, at the head of which is a village of the same name.

San Miguel Bay.—The entrance of this bay is 5 miles wide between Siruma Island just mentioned and the Canimo Islands to the westward. At the head of the bay is *Cabusao*, at the mouth of a river which has formed a bank extending for 5 miles to the N.N.E. *Colasi*, on the western shores of the bay, lies S.W. from Siruma Island. This bay is open to the northward, but some sheltered spots may perhaps be found on its eastern side. The western shores of the bay are low and unhealthy.

The *Canimo Islands* form the N.W. side of the entrance to St. Miguel Bay. The channel between them and the shore is closed by reefs. West of the largest and northern island of this group is the mouth of the Daet River, in lat. $14^{\circ} 5'$ N., long. $122^{\circ} 59'$ E. Gold is reported to be found in the streams hereabout, and a town to exist. Mount Labot, 5,092 ft. high, lies S.W. 15 miles from Canimo Island.

Off this part of the coast an extensive bank is reported to exist; its S.E. end is in lat. $14^{\circ} 38'$ N., long. $123^{\circ} 38'$ E., thence, with a width of from 5 to 7 miles, it extends for 20 miles to the N.W.

Matandumaten Island is small, and lies 12 miles northward of the entrance to St. Miguel Bay. To the N.W. of this is the *Calagnas Group*, with sunken rocks extending 3 miles from their S.E. side. *Cacbalisay Island* is the eastern of the group, and 5 miles S.E. from its eastern end is a small islet with a sunken rock off its South side.

Quinamanocan Island, 7 miles N.W. of Canimo Island, lies within a mile of the shore, and 22 miles north-westward of this is a small group with a bank off their northern side called the Tonaos Isles. They lie 8 miles West of

Maculabo, the western of the Calagnas Isles. *Mount Bagacay* is in lat. $14^{\circ} 11\frac{1}{2}'$ N., long. $122^{\circ} 48'$ E., and on the coast 8 miles N.N.W. from it is *Paracale* village. *Mambulao* is at the head of a bay, the entrance to which faces the N.W., and lies 7 miles westward of Paracale. The *River Capalonga* enters the sea in long. $122^{\circ} 22'$ E., 16 miles westward of the Tongao Isles. To the westward of the mouth of this river is Jaulo Island. *Dagdap Point*, with a rock off it, lies 9 miles W.S.W. Jaulo Island, and between them lies Sogod Bay. *Paranjo Point* is 4 miles S.W. from Dagdap Point, and about 3 miles West of it is Palupari Island, the intervening space being dangerous. At 4 miles S.S.W. of Paranjo Point is Silanja Point, the space between being occupied by a bay, at the head of which is the town of *Calagua*. Silanga Point is separated by a channel 2 miles wide from the East end of *Alabat Island*, which, with a width of about 4 miles, thence extends for 15 miles in a N.W. direction, sheltering *Lamon Bay* to the southward. The West end of Alabat Island is surrounded to a distance of a mile by sunken rocks. *Panguiren* is on the South side of the West end of Alabat Island, and at 8 miles West of it on the main is the town of Mauban. *Majajaquin* and *Talolen* are villages in the S.E. head of Lamon Bay, and *Gamaea* is 7 miles West from them. *Cabaleta Island*, 5 miles long N. by W. and S. by E., is separated by a strait 3 miles wide from the N.W. end of Alabat Islets lie a mile off the North end, and $1\frac{1}{2}$ mile off the N.W. end of Alabat.

Balesin Island, $1\frac{1}{2}$ mile in diameter, lies N.W. $1\frac{3}{4}$ miles from Dagdap Point, and at 13 miles N.E. of it is the West end of *Jomalig Island*, which thence extends for 12 miles to the E.S.E. Two small islands lie East 2 miles, and S.E. 3 miles from its eastern end.

The Polillo Islands, consisting of one large island 30 miles northward of Alabat, with some others on its East coast, are very little known. The centre of the large island is occupied by an extensive mountain, named Malolo. It is probable that there is shelter during the N.E. monsoon close under the lee shore of Polillo, perhaps in a small bay where the principal village lies S.W. of Mount Malolo. To visit this bay Mount Malolo should be kept bearing South of E. by N. on approaching the coast, as many rocks lie within 4 miles of the shore to the southward, and leave the channel inside them a mile wide and 4 miles long near the shore.

On the Luzon shore, on the parallel of the South point of Polillo, is the small harbour of *Lampon*, having 15 ft. water in the entrance, with 3 or 4 fathoms inside. The strait separating Polillo from the main island has soundings, although deep water. The N.W. coast of Polillo is bordered by sunken rocks, as is also the coast of the mainland to the westward. The *Gulf of Dingala* is in lat. 15° N., long. $121^{\circ} 32'$ E., 17 miles W.S.W. of Panampatam Point, the N.W. point of Polillo. *Dumages River* lies 4 miles southward of the Gulf of Dingala.

The *North-east Coast* of Luzon is but very little known, and never visited.

The Nueva Provincia, although nominally under Spanish sway, is really occupied by independent tribes, who have no commercial relations with the world, and scarcely a village is marked on the official maps on the 230 miles of coast intervening between the above and the N.E. point. Beaten incessantly by the whole fetch of the Pacific surf, at best it must be an iron-bound coast, and is so indicated, and probably with very strong currents drifting past it. This must be especially the case in the N.E. monsoon, which brings the rainy season here, and when the remark before made is remembered, that the mountain ranges intercepting the S.W. monsoon, bring the rain on to the opposite coast, although in a less continuous manner, it will be inferred that they reach the eastern shore very much mitigated in their force, and are probably felt as light and baffling winds, or as more violent squalls. In the absence of any recorded experience, it may be the safest course to entirely avoid it as far as possible.

Baler Bay, in lat. $15^{\circ} 49'$ N., has a village of the same name in its inner angle, and may afford shelter from southerly winds. The *Seno de Casiguran* is a large bay open to the S.E. and from its eastern point, *Cape San Ildefonso*, in lat. $16^{\circ} 1'$ N. a range of cliffs extends for 36 miles N.E. by N. to the entrance of the *Puerto de Tumango*, in the northern bend of which is the village of *Dauilican*, in lat. $16^{\circ} 50'$, which may have shelter from the north-eastward. From hence to Cape Engaño there is nothing to remark, more than what the charts explain. *Mount Moises*, 4,085 ft. high, lies 7 miles W.N.W. of Paranan Bay, and in lat. $17^{\circ} 13'$ N. *Mount Cresta* lies 10 miles West of *Divilican Bay*, and in lat. $17^{\circ} 21'$ N.; *Mount dos Cuernos*, in lat. $17^{\circ} 30'$ N., is 4,008 ft. high, and near the coast; *Mount Cetaceo*, in lat. $17^{\circ} 44'$ N., is within 5 miles of the coast; *Mount Cagua*, a volcanic peak, is in lat. $18^{\circ} 13'$ N., and between it and Cape Engaño are two other elevations of 3,451 and 2,086 ft. respectively.

CAPE ENGANO is the N.E. point of Luzon; its name "deceit" may be the reason why the term should also be applied to the N.E. point of Palabi Island.

PALAU ISLAND, N.E. point, is 7 miles to W.N.W. of the N.E. point of Luzon, and is sometimes called Cape Engaño; it is moderately elevated. A coral reef, with high breakers and several rocks above water, extends E.N.E. about 3 miles from the point of the cape; and patches of shoal water project a mile beyond it. This reef fronts the eastern side of the island at the same distance, extending southward about 4 miles, until abreast a round hill forming its South point, and joins the N.E. end of Luzon. Close to the northward of the cape are two islets, the outermost of which, called *Lava*, is a square, steep mass of lava, about half a mile in extent, and may be seen at the distance of about 27 miles.

The channel between Cape Engaño and Camiguin Island to the N.N.W.

is about 20 miles wide, and clear of danger. As the currents set strong to the northward in the S.W. monsoon, it will be prudent for vessels proceeding to the eastward to keep on the South side of the channel.

Port San Vicente is formed by a small island of the same name, lying between the N.E. end of Luzon and the adjacent island of Palau. There is room in this port for three or four ships, sheltered from all winds; but the entrance is narrow and intricate, being formed between shoals on each side, which project from the S.W. part of Palau, and from Vicente Island; a vessel is therefore obliged to warp in. There is good anchorage in 5 fathoms opposite the mouth of the port, and sheltered from all winds but those between West and S.W.

The N.E. extremity of Luzon forms a peninsula, which projects about 15 miles beyond the line of the North coast, so that between Cape Engaño and *Pata Point* is a deep bay with a chain of mountains inland, and a considerable space of moderately elevated, or rather low land fronting the sea, interspersed with villages and intersected by rivers. There is a continued beach along this coast with regular soundings, generally 30 or 40 fathoms, about 1½ or 2 miles off the western part, and similar depths extend 3 and 4 miles off shore when farther eastward.

There is a missionary station on the coast S.W. 17 miles from the S.W. end of Palau Island, and W.N.W. from the volcanic Mount Cagua. At 8 miles westward of this station is the village of Bugay, N.W. 13 miles from which is the mouth of the Rio Grande de Cagayan.

The Rio Grande of Cagayan rises in the eastern range of mountains called the Sierra Madre, and, after a course of some 120 miles, enters the China Sea at Aparri, 13½ miles eastward of the mouth of the Abulag. There being but 14 or 15 feet of water at flood tide on the bar of this river, large ships anchor outside. The rapidity of the current and the sudden floods render the navigation of the Rio Grande at times exceedingly dangerous. It may nevertheless be termed the highway of the tobacco-producing province of Cagayan. Small steamers run to Guagua, Bulacán, and Manila. There is good anchorage in 10 or 11 fathoms, about 2 miles N.N.E. from the mouth of this river. The point on the S.E. side is known by the church and convent of the town of *Aparri* built on it; abreast of which or North from the church is the best anchorage, with the volcanic mountain on Camiguin Island bearing N.N.E. easterly.

From the mouth of the Rio Grande de Cagayan the sandy coast continues for 14 miles to the bar of the *Abulag* and *Pamplona Rivers*. Point Pata is 15 miles N.W. of Pamplona Bar, and appears as a round hill of middling height. Hence to Cape Bojeador the coast is steep, without any soundings until near the shore. The coast to the westward is described on pp. 605-6.

The BABUYAN or Five Islands form a kind of circular chain fronting

the North coast of Luzon. The channels between them are *said* to be safe, without soundings, and their coasts are generally steep-to.

Dalupiri Island, the westernmost of the group, has a level appearance, extends 6 or 7 miles in a N.W. and S.E. direction, and may be seen from a distance of 30 miles. About $1\frac{1}{2}$ mile off its South point is *Rijutan Islet*, surrounded by shoals.

Fuga Island, distant about 8 miles S.E. of Dalupiri, is lower, and of an even appearance, terminating in low land at the eastern part. It is about 10 miles long, East and West, and there are irregular soundings along its S.W. side, where a vessel may occasionally anchor.

The *Bay of Musa* is formed between the West end of Fuga and two small islands adjacent, called *Barrete* and *Mabag*. The best channel into the bay is from the southward, between Barrete and the West point of Fuga, the depths being 14 and 16 fathoms outside, and 9 to 12 fathoms in mid-channel. Barrete Island has a reef lying off its West side, and another projecting from its South point. Water may be procured, but with difficulty, some distance inland. Musa Bay, although sheltered from the sea, is only fit to run for in case of necessity.

Calayan Island, lying about 15 miles N.E. of Dalupiri, is formed of mountainous and uneven land, highest in the centre, with low gaps in some places; it is steep-to, without any safe anchorage, and may be seen in clear weather at a distance of 45 miles. Some rocks above water extend about a mile from the South and East points; and about $1\frac{1}{2}$ mile off the N.E. point is an islet called *Panuctan*, about a mile in extent North and South.

Wyllie Rocks, consisting of two clusters above water, with high breakers between, are dangerous to vessels passing through the Babuyan group at night. The southernmost rock, which is the largest, bears N.N.E. distant about 5 miles from Panuctan Islet; the other cluster lies about $1\frac{1}{2}$ mile in a N.N.E. direction from the largest rock. Sunken rocks lie between the Wyllie Rocks and Panuctan.

BABUYAN CLARO, the most northerly and highest of the Babuyan Islands, is about 25 miles E.N.E. from Calayan. On its West end is a volcano, between which and the mountains on the eastern part is a concave curve in the form of a crescent, when viewed from the North or South; but when the island is seen at a great distance from the eastward, it appears as one round mountain with a detached hummock to the northward. A reef projects from the West point of the island. The South point is steep and rocky, and about a mile off it is a black rocky islet, in the form of a sugar-loaf.

CAMIGUIN ISLAND, about 10 miles in extent N.N.E. and S.S.W., is high and hilly, and lies about 26 miles South of Babuyan Claro. Its shore in some places is bordered with coral rocks, having soundings of 30 to 35 fathoms about a mile off; and the land is low close to the sea, along its

eastern and northern sides. The southern part of the island is formed of a high mountain, formerly a volcano, visible at a distance of 60 miles. To the westward of this mountain some steep cliffs front the sea, about 2 miles to the southward of the South point of Port San Pio Quinto.

Port San Pio Quinto may be considered the only place amongst these islands tolerably safe for a large ship, for the bottom in it is not so rocky as in Musa Bay, Fuga Island. The port is formed by a concavity in the land about 3 miles wide and $1\frac{1}{2}$ mile deep, a little southward of the middle of the West side of Camiguin, and is sheltered from the westward by Pio Quinto Islet, which lies in the middle of the entrance. This islet is high, about $1\frac{1}{2}$ mile in circumference, steep to seaward, and has on each side a safe channel leading to the port.

It is high water, full and change, in Port San Pio Quinto at 6^h 0^m, and springs rise about 6 ft.

GUINAPAE ROCKS (or Southern Pillars), bearing E. by S. about 10 miles from the North point of Camiguin, consist of two rocks like towers, one larger than the other, with some smaller rocks contiguous. There are no soundings within a short distance of their eastern side; between them and the nearest part of Camiguin is a channel 6 miles wide, which is safe on the island side.

DIDICAS ROCKS (or Northern Pillars), about 7 or 8 miles N.E. $\frac{1}{2}$ E. of the Guinapae, are a group of four sharp-pointed rocks, much higher than the latter, and when seen at a considerable distance appear like ships under sail. They are about 2 miles in extent N.E. and S.W., and among them are many rocks of various sizes, which render their approach dangerous in light winds; for the currents run strong to the northward, producing ripples like breakers in the vicinity of and among these dangers, and there are no soundings near them where a vessel could anchor in case of necessity.

The **BASHI** or **BATAN ISLANDS**, so called by Dampier from the name of an intoxicating liquor much used by the natives, lie northward of the Babuyan group, and consist of a chain of islands, mostly high, extending from lat. $10^{\circ} 58'$ to $21^{\circ} 13' N.$, and the channels among them are *thought* to be safe and free from hidden danger. During the N.E. monsoon strong winds prevail amongst these islands, and the currents are occasionally very strong; the flood sets to the S.W., the ebb to the N.E.

These islands, with those just described, form part of that great volcanic band before alluded to, which may be traced far to the northward. The islands of Batan and Sabtan are mountainous, with many broad cultivated spots; the highest peak, apparently an old volcano, is about 5,000 ft. above the level of the sea, and thickly covered with trees. Abundance of vegetables and fruits are to be got. Cattle, pigs, poultry, sheep, and goats are also

abundant. Deer are found on Sabtan and Ibugos, and quail on all the islands. Wood is reasonable and plentiful, as well as water; but this latter necessary is difficult to procure.

Balintang Islands, said to lie in lat. $19^{\circ} 58' N.$, long. $122^{\circ} 14' E.$, and the southernmost of this group, consist of three small but high-peaked islets or rocks, visible about 27 miles off, in clear weather, and, when in one, bear E. by S. and W. by N. The westernmost islet is much larger than the others, and a hole is seen through it when bearing N.E. They are steep-to, and may be passed on either side at 2 or 3 miles distance, but the sea beats violently against them in bad weather.

The Balintang channel, between these islets and Babuyan Claro, is about 25 miles wide, and is frequently used by vessels when proceeding by the eastern passages to China.

BATAN ISLAND is about 9 miles long, N.N.E. and S.S.W., and Mount Irada, on its northern extremity, is 3,806 ft. above the sea. The rest of the island is mountainous, and has several broad and cultivated spots.

Captain Sir Edward Belcher in the *Samarang* anchored in the bay of San Domingo, on the western side of Batan Island, on a fair clear bottom of fine coral sand, the best berth being with the convent barely open, when moored off the northern point of the bay in 13 fathoms; this, however, is not very secure with a northerly wind. Although the holding ground is good, this bay can only be resorted to in the N.E. monsoon.

The authorities recommended the anchorage off *San Carlos*, about 2 miles to the N.W., as the best for obtaining a supply of water; but this position is exposed. The next anchorage is that of *San Vincente*, which is the port of *Ivana*, or landing-place for that village; it, however, ought not to be resorted to, as it is very confined, and must be quitted the moment a northerly wind threatens.

Sabant Island is separated from the S.W. end of Batan, by a channel 2 miles wide, which appears clear of danger. Off the North end of Saban are two ledges of rock, with a passage between them carrying 14 and 10 fathoms water.

Ibugos Island is small and rather low, excepting a hill on its South end, where there is a village. It is separated from the West side of Sabtan by a channel from a mile to half a mile wide, which affords indifferent anchorage, the bottom being rocky, with sandy patches between. There are no facilities for watering. *Dequez Island*, also small and rather low, lies nearly half a mile westward of the N.W. point of Ibugos.

As the current sets strong to the northward between the above islands in the N.E. monsoon, it is advisable to work westerly round Dequez, and not to cross the channel between Batan and Sabtan until the dividing neck of San Carlos is clearly open, E.S.E., as the stream dividing at Mabatui Point

sends one current southerly; the other, which is an eddy, is favourable from thence north-easterly to San Domingo.

Ibayat Island, about 8 miles long, N.N.E. and S.S.W., lies 14 miles N.N.W. of Batan, and the channel between is free from danger; *Mount Sta. Rosa* at its North end rises 680 ft., and *Mount Riposet* at its north-eastern part, 800 ft. above the level of the sea. The island is without anchorage; the interior is, however, highly cultivated. Abundance of refreshments can be easily obtained.

Diogo is a small island, 848 ft. above the sea, lying $3\frac{1}{2}$ miles eastward of Ibayat, and the channel between is clear of danger.

Madubis Island, lying N.N.E. 6 miles from the North end of Ibayat, is about $1\frac{1}{2}$ mile long in a N.E. and S.W. direction, high and steep-to. One mile S.S.W. of it is Siayan Island, about $1\frac{1}{2}$ mile in circumference, having off its N.E. side several detached rocks. The channel between Mabudis and Siayan is rendered unsafe by detached rocks; that between Ibayat and Siayan is about 4 miles wide, and free from danger.

Y'Ami, the northern island of the Bashi group, is about a mile in circumference and tolerably high. The position of the islet lying off its S.W. point (by Sir Edward Belcher) is lat. $21^{\circ} 4' 56''$ N., long. $121^{\circ} 58' 24''$ E.

North Island, lying 2 miles S.S.W. from Y'Ami, is high and steep-to, except on its eastern side, off which, at a cable's length, there are three islets and some detached rocks. The channel between Y'Ami and North Island is safe, and carries soundings with rocky bottom, but too deep for anchorage; that between Mabudis and North Island is 9 miles wide, and free from danger.

The North Bashi Rocks could not be found by Capt. Sir E. Belcher, who states "they have no existence in the position assigned them in the charts, nor in the visual radius from the mast-head of the *Samarang*, 108 ft. above the level of the sea."

The islands on the North side of the Bashi Channel will be described hereafter.

DUGAY TROUIN REEF was reported by the captain of a vessel of that name in 1875, to lie N.E. of Luzon, in lat. $19^{\circ} 5' N.$, long. $124^{\circ} 43' E.$

THE COAST OF CHINA.

The coast line of this important empire, which contains more than one-third of the population of the globe, is about 2,500 miles in extent, and has been well surveyed by our Admiralty. The charts and directions between Canton and the Yang-tze Kiang will be as safe guides as in any other portion of the globe. This is a triumph of hydrography, and was a result of the inglorious war commenced in 1839-40, consequent upon the destruction of the opium at Canton, April 3, 1839. On July 5th, 1840, Chusan was taken possession of by a British fleet, among the officers of which were Admirals Sir Richard Collinson and Henry Kellett. To their energy and skill the commencement of the noble survey is due. The survey continued between the years 1840-6, and the result is a fine series of charts and instructions, describing, with minute accuracy, a coast which might be claimed as almost first discovered by them, as there were no prior nautical surveys of by far the largest portion.

While foreign commerce was so sedulously confined to the single port of Canton, the only attempts at true delineation were the partial surveys of the rivers by that excellent surveyor Daniel Ross, 1807—1816. Some other observers, such as R. Wallis, D. Inverarity, &c., added a few particulars. In other respects we were almost entirely indebted to the noble work of Jean Baptiste du Halde, a Jesuit missionary, who arranged the vast mass of information collected by his brother missionaries in China, and published them in four splendid volumes in 1735. The series of maps accompanying this work deserve some notice. The whole of the empire was carefully surveyed, by astronomical observations and triangulation by these Jesuit missionaries, under the authority of the Emperor Chang-hi; commenced in 1708, and completed in 1718. These maps and their text deserve most honourable consideration.

Now, however, the Admiralty surveys, chiefly conducted by Capt. Collinson, have totally superseded these imperfect representations of the coast line, while the survey made by the squadron when in the upper Yang-tse Kiang, and other observations have given us a much clearer insight into the inner geography of China.

To add to the completeness of our knowledge, in the year 1877, H.M.S. *Nassau*, Commander Napier, commenced to examine the several dangers discovered near the shore by the hugging of the land during the strength of the N.E. monsoon by the numerous large steam-ships engaged in trade between the Treaty Ports.

The troublesome wars which were forced upon the British Government by the insolence and duplicity of the Chinese authorities, added to the great internal disorganization, terminated in the Treaty of Tientsin, which was concluded by Lord Elgin on June 26, 1858, and this placed the external commerce of China on a satisfactory basis. A fresh treaty was entered into after Peking was entered by the British and French armies, on October 24, 1860, and a new treaty not yet completed will further open the country to foreigners.

The whole coasting trade of the empire is open to foreign commerce, though, of course, this is but of limited utility. The wonderful commerce which has sprung up since its establishment, and its probable future development, may be judged by the fact that in 1863 there were only four or five ordinary lights on the Chinese coasts, which are now pretty well lighted.

The following is a list * of the Treaty Ports and the tonnage (coast trade) entered at each during the year 1875:—Shanghai, 847,443; Chinkiang, 599,118; Kinkiang, 515,503; Chefoo, 295,313; Hankow, 283,375; Amoy, 277,259; Ningpo, 267,428; Swatow, 206,633; Tientsin, 167,217; Foochow, 133,823; Newchwang, 117,194; Canton, 102,700; Takow, 34,914; and Tamsui, 26,516. The two latter ports are in Formosa. There are 343 foreign firms and 3,579 foreign residents at these ports, 211 firms and 1,611 residents being British, 46 firms and 541 residents American, and 52 firms and 367 residents German. Pakhoi, at the head of the Tongking Gulf, and Hoi-how, in Hainan, two recently opened ports, are described previously.

The coast generally is low, but with bold headlands, in the S.W. portion. At the entrance of the Canton River it commences to be high and rocky, and thus continues to Chusan, where it becomes very low, and so continues as far as the Gulf of Pechili, with the exception of the bold, rocky, gold-bearing promontory of Shantung. The ensuing descriptions commence with the S.W., and follow those of the shore of Tong-King and Hainan, given on pages 468 *et seq.*

* Report on the trade of China for the year 1875, by H. Kopsch, F.R.G.S.

CHAPTER XX.

THE COAST OF CHINA, BETWEEN HAINAN AND HONG KONG.

NOW-CHOW, in about lat. $20^{\circ} 58' N.$, long. $110^{\circ} 36' E.$, bearing S.W. about 45 miles from Tien-pak, and lying off the north-eastern part of the peninsula of Lien-chew, is a small port dangerous to enter, but when in it there is good shelter. This place was a rendezvous of the Ladrones (pirates), whose vessels anchored in great numbers alongside the forts and town, their crews being part of the inhabitants.

The anchorage of Now-Chow, some 5 miles in width, and abounding in sand-banks, especially requires surveying. At certain seasons it is likely to remain the place of call for vessels bound to Hainan, and the approach to it from either side requires much care. The difficulties of proceeding to the southward are mentioned on page 475.

Now-Chow Island is about 300 ft. high, 9 miles long, 3 miles broad, and well cultivated. Strangers should be careful to avoid the sand-banks on the northern shore. The North point of the island is 5 miles W. by N. from the eastern point, and the space between is full of rocks, awash. Off this point is a dangerous horn of sand, and it would be advisable to obtain a pilot from a fishing boat, or anchor, and send to the town for one, before proceeding farther. Low water would be the best time to enter, as the shoals are then visible.

The town stands in a small bay on the western point of the island, which is S.W. by S. 6 miles from the northern point. Here may be obtained good pilots for the dangers in the vicinity of the island.

In addition to the bank in the centre of the channel, there is a bank with only 6 ft. water, extending from the island. The least water found (4 fathoms) by H.M.S. *Algerine*, in 1868, was off the North end of the island, 7 fathoms were carried through the channel, it then deepened to 10, towards the fort. The best anchorage is off the village, on the S.W. side of the island, but not too close to the fort, as the water is deep. Wood and water can be obtained at Now-Chow.

Quan-Chow-Wan Bay is extensive, and has its narrow entrance at 8 miles within and off the N.W. point of Now-Chow Island. By some it is recommended as a superior stopping place to Now-Chow, but the banks off its entrance will prevent its becoming much used. From the Now-Chow anchorage, with clear weather, the mountain *Kam Loong* (Golden Dragon) or Toong hong Shan, bearing about S.W. by W., over 20 miles distance, may be seen; the successive bearings of which are of great service when entering Quan-chow-wan by the southern channel, the channel most recommended. This bay was formerly a great resort for pirates.

TIEN-PAK, or Tihen-Pien, is the principal place on the South Coast of China, where salt is produced, and several hundred junks are employed transporting it to Canton.

The high land on the N.E. side of the road, called *Lintoa*, has the appearance of a high round mountain in coming from the eastward; its southern extreme is called *Sey-ho*, or *Sye-ho Point*. From this point, E. by S. $1\frac{1}{2}$ mile and 1 mile distant from the high land, lies a reef of rocks, on which the sea often breaks. From Sey-ho Point, S.W. about half a mile, lies *Pauk-pyah*, a large white rock, having between it and the point 6 and 7 fathoms water; *Foong-kye-chye*, a small island, lies about $1\frac{1}{2}$ mile to the westward of it. *Ty-fung-kyoh*, about 2 miles to the south-westward of the latter, is of considerable height, being the outermost island of the road, in $21^{\circ} 22\frac{1}{2}'$ N., long. $111^{\circ} 10\frac{1}{2}'$ E.

The city of Tien-pak is walled round, and is of considerable extent. A ship touching here in distress may procure temporary masts, and get iron-work done in the city; refreshments of all kinds may be got from the villages contiguous to the harbour.

A small ship in want of shelter from a N.E. or East gale, may keep near the reef of rocks to the eastward of Sey-ho Point, then steer between that point and Pauk-pyah, and anchor in 4 fathoms, sand and mud, about three-quarters of a mile westward of the point. She must not go farther to the northward. Large ships ought to pass about a mile to the southward of Pauk-pyah and Foong-kye-chye, in 7 or 8 fathoms water, and anchor in 6 fathoms water between the latter and Ty-fung-kyoh, or rather a little inside this island, which will shelter them from the S.W. winds.

To the N.W. of the bar about $1\frac{3}{4}$ mile lies *Marble Rock*, and nearly 4 miles farther westward there is a reef of black rocks; neither of these can be approached, the water being very shoal on that side of the bar.

It is high water, full and change, on the bar of Tien-pak Harbour at 12 hours, and the tide rises 8 ft. After the 1st of September, there is almost a constant westerly current along this coast, running from half to $1\frac{1}{2}$ mile per hour.

Ty-Chook-Chow is an island lying about 7 miles E. by N. from Sey-ho Point, and 3 miles distant from the coast. It has rocks on the North side,

stretching to the north-westward and towards the coast; but there is anchorage on its West side.

Chin-Chew, bearing N.E. by E. $\frac{1}{4}$ E. $5\frac{1}{2}$ miles from Ty-chook-chow, is high, and covered with grass; it should not be approached on the South side nearer than $1\frac{1}{2}$ or 2 miles, in 10 and 11 fathoms water, for a reef of rocks, on which the sea generally breaks, projects S. $\frac{1}{2}$ E. from it about three-quarters of a mile.

SONG-YUI POINT, bearing from Chin-Chew E. by N. $\frac{1}{2}$ N. about 10 miles, is the S.W. extremity of the Great Bay, at the N.E. part of which is Hai-ling Harbour; close to it there are 9 or 10 fathoms water. *The Brothers*, distant 3 miles N.N.E. from Song-yi Point, are two islets near the high island, having rocks projecting from them about half a mile.

HUI-LING-SAN HARBOUR.—Hai-ling-shan, or *Hui-ling-san*, is a high island, extending E.N.E. and W.S.W. about 12 miles, separated from the coast on the North side by a narrow passage, and having an extensive shoal bay to the N.E., and a harbour on the West side. Two small islands, sometimes called the *Twins*, and by the Chinese *Mamee-chow*, bear from Song-yui Point E. by N. $\frac{3}{4}$ N., distant 10 miles, and lie close to the S.W. point of Hai-ling-shan, being united to it by a reef and sand-bank. They form the outer point of Hui-ling-san Harbour; and, in coming from the eastward, being on with each other, appear as a single island.

Bluff Point, bearing E. by N. 3 miles from the Mamee-chow Islets, is high, and has 9 and 10 fathoms water close to; and 4 miles N.E. by E. $\frac{3}{4}$ E. from that point are two rocky islets close together, appearing as three small hummocks. A little inland from these stands Sugar-loaf Hill, which does not show its peak when seen to the eastward of Bluff Point.

Close to the East point of Hai-ling-shan, and bearing E. by N. $\frac{3}{4}$ N., distant $5\frac{1}{2}$ miles from the two rocky islets, there is a small island, having 7 fathoms water close to it, and to the East end of Hai-ling-shan; but S.W. by S. $1\frac{1}{4}$ mile from the small island, there is a reef of rocks nearly covered at high water. On the East part of Hai-ling-shan, contiguous to the sea, there is a remarkable patch of red sand, discernible when off the Mandarins Cap.

To sail into the harbour, if coming from the eastward, pass about a quarter of a mile from the South side of the Mamee-chow in 8 fathoms water, and round them about the distance of a cable's length in 7 fathoms. Steer direct for *Deep Water Point*, which bears N.N.E., distant rather more than half a mile, which pass at rather less distance than a cable's length, for the edge of a $2\frac{1}{4}$ -fathom bank is within a quarter of a mile of it.

From this point steer N.N.E. $\frac{3}{4}$ E. about a mile, for a fort on the summit of a small hill covered with trees, until abreast of *Teep-chow*, a small island about mid-way between them, to the westward of which, about a quarter of a mile distant, large ships should anchor with the fort bearing N.E. by N.

The West side of the bay, between the Mamee-chow and the Brothers, should not be approached under 5 fathoms water, the bottom being sandy, with shoal water under that depth.

The bay between Teep-chow and Deep-water Point has only $2\frac{1}{2}$ fathoms water; here, adjacent to a small joss-house in ruins, fresh water may be procured. The harbour for small vessels is in the bay formed between Teep-chow and the fort, where the depths are 8 and 9 ft. *Chino Village* stands in this bay, where water and refreshments are obtained; carpenters and caulkers may be got to work on board, and smith's work can be executed at the village.

In Hui-ling-san Harbour it is high water, full and change, about $8\frac{1}{2}$ hours, and the tide rises from 7 to 8 ft.

Ty-oa Point and Bay are about 16 miles E.N.E. from the East end of Hai-ling-shan, and N.N.W. $\frac{1}{4}$ W., $16\frac{1}{2}$ miles from Mandarins Cap. The depths decrease regularly coming from Mandarins Cap, to $4\frac{1}{4}$ fathoms at low water close to Ty-oa Point. Inside the point, and in the extensive bay to the north-westward, the water is shoal.

The following islands and rocks lie off the coast, between Hai-ling-shan and Hawcheun :—

MANDARINS CAP, called Fan-shee-ak, "White Rock," by the Chinese, in lat. $21^{\circ} 28' N.$, long. $112^{\circ} 21\frac{1}{2}' E.$, is a barren white rock, about 200 ft. high, converging gradually to the summit, and terminating in a sharp peak. Near it, to the northward, lie two other rocks, one of which is very small. From Mandarins Cap, Nam-oa Harbour bears N.E. by E. distant 13 miles, and the South end of St. John Island E. by N. $\frac{1}{2}$ N., nearly 24 miles. On the South and West sides there are 15 and 16 fathoms, mud bottom, within a cable's length of the rock, and 13 fathoms a little to the northward.

Currents.—In August and September, when easterly winds frequently prevail, the current sometimes sets to the westward 3 miles per hour off Mandarins Cap, abating only to $1\frac{1}{2}$ mile per hour when the tide, under ordinary circumstances, would be setting to the eastward. The westerly current constantly prevails along this coast during the easterly monsoon, and frequently in the S.W. monsoon, particularly if the wind veer to the eastward.

Nam-Pang, bearing N.W. by W. $\frac{3}{4}$ W., distant $10\frac{3}{4}$ miles from Mandarins Cap, is high at the West end, and about $1\frac{1}{2}$ mile in length. It is safe to approach all round. *Round Island*, bearing West $3\frac{1}{2}$ miles from Nam-pang, is small, and named from its appearance. To the S.S.W. of it about 2 miles there are *two rocks awash*. The *Quoin* is an islet resembling a gunner's quoin, lying near the East side of Nee-wok Island, and $2\frac{3}{4}$ miles N.N.W. of Nam-pang. *Nee-wok* is an island of moderate height, about a mile in length, bearing from Nam-pang N.W. $\frac{3}{4}$ N. about $3\frac{1}{2}$ miles.

Ty-wok, about $1\frac{1}{2}$ mile N.N.W. of Nee-wok, is high, appearing like a

saddle when viewed from the S.W. S.W. by S. 1 mile from Ty-wok, and N.W. $\frac{1}{2}$ W. from the summit of Nam-pang, there is a rock with 7 fathoms all round, which is generally visible 3 or 4 ft. above water, and the sea always breaking upon it, renders it conspicuous in passing.

MONG-CHOW, bearing N.N.E. $11\frac{1}{2}$ miles from Mandarins Cap, is a high island, about $2\frac{1}{2}$ miles in length, and covered with verdure. There is a town near its summit, only discoverable from the S.E.; some rocks lie off its N.E. point. Small vessels may anchor in 3 fathoms at low water, on the West side of this island, during easterly winds; and fresh water may be procured at a small beach on that side, near the South point.

HAWCHEUN, or *False St. John*, is a high island, extending N.E. and S.W. about 11 miles. The S.W. end, in lat. $21^{\circ} 35' N.$, long. $112^{\circ} 31\frac{1}{2}' E.$, is a bluff point, having 7 and 8 fathoms water close-to; and close round it on the West side there are two small bays, with sandy beaches, having $3\frac{1}{2}$ fathoms water, where small vessels may take shelter. A large ship will be sheltered from easterly winds by anchoring in 5 or 6 fathoms, soft mud, about a mile off.

NAMOA HARBOUR is formed between the S.W. end of Hawcheun and Namoa Island, and, although rather small, it is safe and convenient for refitting a ship, after being disabled by a typhoon, or otherwise requiring shelter. The South or large entrance is about $1\frac{1}{2}$ mile eastward of the high bluff S.W. point of Hawcheun, and is preferable to the eastern entrance for ships drawing above 16 ft. water; having 6 fathoms in it, gradually decreasing to the sandy beach at the village of Namoa fronting it, and no danger whatever. It is three-quarters of a mile wide, having an islet on the East side, called *Passage Island*, joined to the West point of Namoa by a few rocks. With an easterly wind the best anchorage for a large ship is about halfway between Passage Island and Green Point, which has a round mound on it covered with grass, and forms the N.W. point of Namoa. Here she will have $4\frac{1}{2}$ or 5 fathoms, soft mud, at low water, according as her berth is near to or farther from Namoa, and will be sheltered by this island, which is 500 ft. high, to the eastward, and by the high land of Hawcheun to the northward, round to S.W., from whence, if it blow strong, a long ground swell rolls in, rendering it necessary to move further in, to the western part of the harbour, where there are $4\frac{1}{2}$ to 4 fathoms, mud, at low water.

The eastern entrance, between Namoa Island and the S.E. part of Hawcheun, has $4\frac{1}{2}$ fathoms, gradually decreasing inside to $3\frac{1}{2}$ fathoms at low water springs; and, although it is the most contracted of the two, will be found convenient for small ships. The channel is, with the exception of a few narrow passages, of about 90 or 100 ft. wide, staked completely across; but vessels very soon shoot through them. The best berth for a small ship is in 3 fathoms, abreast the sandy beach on Namoa, which forms Green Point,

not so far in as to open the South entrance, but to see it over the narrow neck of that point.

There are several watering places about the harbour, the largest and most convenient of which is in Watering Bay, a sandy bay on Hawcheun, bearing from Green Point N.N.E.; here the water comes close to the beach.

Barren Island, about a mile to the northward of Green Point, has a white conical rock inside of it; both are connected with Hawcheun at low water, and separate Watering Bay from Namoa Bay, in which is Namoa Village, consisting of about 100 brick houses, at a small distance from the shore. Here a few refreshments and fish may be procured; but guard against the crews of any Ladrone boats, which may be about the coast.

It is high water, full and change, in Namoa Harbour, at about 10 hours, and the rise of tide is 7 to 8 ft.; and then a small drain of ebb sets out through each of the channels.

Directions.—To enter Namoa Harbour by the eastern entrance, if coming from the eastward, after rounding the South end of St. John pretty close, steer about W. by N.; or, if the ebb is running, more northerly, which course will lead near the Boat Rock, which bears from St. John, South point W. $\frac{3}{4}$ N., distant 7 miles. It has 7 fathoms water close-to, is about the size of a small boat, never entirely covered, and the sea generally breaks on it. To the northward of this rock about three-quarters of a mile lies Round Island, the southernmost of a chain of five rocky islets fronting the East side of Hawcheun. Having passed a short distance southward of Boat Rock, steer about W.N.W. for the entrance of the harbour, distant 3 miles, taking care to avoid the rocks, which have 7 fathoms close to them, projecting nearly three-quarters of a mile from the S.E. part of Namoa.

The **FIVE ISLANDS**, fronting the East side of Hawcheun, are mostly small, and bound the West side of the channel between it and St. John. *Round Island*, the southernmost of them, and *Boat Rock* bearing S.E. by E. $\frac{1}{2}$ E. nearly three-quarters of a mile from it, have been mentioned above; there are also other rocks, high above water, near its South side. *Wasp Island*, next to the northward of Round Island, is the largest of the group; high at each end, and nearly separated in the middle, with some rocks close to its East side. *Cricket*, the third island, is high, and covered with grass. The fourth, called *Pipachow*, is of middling height, covered with grass, having some rocks above water projecting off its South end; there are $4\frac{1}{2}$ fathoms water close to these rocks, and also between them and the other island to the southward, and the same depth close to the East side of Pipachow. The fifth, or northernmost island, lies nearest the Hawcheun shore, with 4 fathoms at low water between it and that shore.

There is no hidden danger near these islands, and a vessel drawing not more than 15 ft. water may either pass or anchor between them and Hawcheun, keeping rather nearer to the island. Here she will find shelter in 3

or $3\frac{1}{2}$ fathoms, soft ground, at low water, and can be supplied with refreshments from the town of Hawcheun, which stands in a small bay fronting the islands. All the space between these islands and St. John is clear from hidden danger, with depths of 5 and 6 fathoms, soft ground.

To the northward of the Five Islands the depths increase to $4\frac{1}{2}$ and 5 fathoms, in a direct line towards the West point of St. John, and continue the same in passing about mid-channel between this point and the island lying off the N.E. end of Hawcheun. Here is the narrowest part of the channel, which is about a mile wide, where vessels may be sheltered during bad weather. The entrance of the channel, generally called *St. John Road* or *Bay* between the South part of St. John and the Five Islands, is more open to blowing weather; for some ships at anchor there have been obliged to cut their cables and put to sea.

ST. JOHN ISLAND, or *Chang Cheun-cham*, in length about 15 miles N.N.E. and S.S.W., has been generally considered as two islands, for in coming from the eastward or westward, the high land on each extremity appears separated by a large gap, which, on a near approach, is found to be a low, narrow isthmus of sand, uniting the high land, and having a bay on each side.

There are 7 and 9 fathoms near the East side of the island, and no hidden danger, excepting a small rock, visible only at low water, lying off a bluff point, about 2 miles to the southward of the N.E. point of the island, from whence the land stretches to the south-westward. About a mile off the N.E. point of the island there are some rocks, always above water, with a passage of 8 and 9 fathoms between them and the point; and to the northward of them there are 5 and 6 fathoms.

On the North side of the island there are two small bays separated by a narrow peninsula. The western bay, called *Sam-chow-tong*, or *Tree Island Bay*, is the largest, with several small islands in it, and only $2\frac{3}{4}$ fathoms water within the point; there is a village in this bay, where refreshments may be obtained. All this side of the island is free from danger.

The large bay on the West side of St. John, opposite the sandy, low isthmus, extends into the island about 4 miles; but a ship cannot enter it, the water being shoal 18 to 12 ft.

Shitoe or Satye Bay, on the S.W. side of St. John, has 6 and 7 fathoms water at the entrance, and a small vessel may go farther in, and anchor in 4 or $3\frac{1}{2}$ fathoms; but it is too narrow for a large ship, unless she were to warp in.

Wycaup is a small, high, rocky island, fronting the S.E. end of St. John Island, being separated from it by a narrow passage. There are 13 and 14 fathoms water close round this island on the outside.

Lieuchieu is an island of moderate height and barren aspect, separated from Wycaup and the S.E. part of St. John by a safe channel $2\frac{1}{2}$ miles wide.

The **WIZARD ROCKS** lie off the South end of Ty-kam, between St. John and Coucok Island, 12 miles N.E. $\frac{1}{2}$ N. from Lieuchieu. The outermost, named the *Flies*, consist of a group of five or six rocks, about 30 ft. high, having 10 fathoms mud, at the distance of a cable's length from them. The *Great or South Wizard Rock* bears from the Flies N. by W. $\frac{3}{4}$ W., distant 1 mile; and $1\frac{3}{4}$ mile northward from it lies a white conical rock, called the *Inner or White Wizard*. Near the South Wizard the depths are 6 and 7 fathoms, and near the White Wizard about 5 fathoms, soft ground. S.W. three-quarters of a mile from the White Wizard, there is a rock, covered at high tide, making it necessary for a ship passing between them to keep nearest to the South Wizard. There is another rock, always above water, bearing W. by N. from the White Wizard, having 4 fathoms near it; and there is a passage with $4\frac{1}{2}$ fathoms water between the White Wizard and the South point of Tykam.

Tykam Island, lying to the northward of the Wizard Rocks, is of considerable height, of darker aspect than the other land, and in clear weather appears with red streaks. Between this island and Tonquay, the next island to the westward, the water is shoal, and also in the large space to the westward of Tonqua.

COUCOK, the next island to the eastward of Tykam, is high, and 4 miles in extent East and West. Its S.W. point has a remarkable rock close to it, resembling a boat under sail. The West side of the island is formed by a steep hilly ridge stretching North and South, having good anchorage under it in 6 fathoms. Fresh water may be obtained at the westernmost of two small bays on the North side of the island.

Tymong Island lies to the northward of Coucok, having an islet, called *Samcok*, joined to the S.W. point by rocks visible at low water.

Tylou is a high island, with a large *white patch* on its eastern side, resembling a ship's mizen or mizen stay-sail, when viewed in some directions. The island is separated from Coucok by a channel about 2 miles wide, with 7 and 6 fathoms water in it. By passing close round the East point of Coucok, it appears that vessels of moderate draught might anchor to the northward of that point in 5 fathoms, sheltered from most winds.

CANTON RIVERS.

As vessels bound to Canton River from the southward in the S.W. monsoon endeavour to make Great Ladrone Island bearing about North, and then proceed towards the river by the Great West Channel, a description will first be given of the islands and anchorages on the West side of this channel, from San-chau Island to Cum-sing-mun Harbour (including the

Broadway and the Si kiang), and then returning to the Ladrone Islands the mariner will be taken through the different passages eastward of these islands to Hong Kong, and to the entrance of the river.

SAN-CHAU, which forms the West side of entrance to the Broadway, is the next large island north-eastward of Tylou Island, and its S.E. point bears W. by N. $15\frac{1}{4}$ miles from the Little Ladrone. The space between San-chau and Tylou is shoal, with some islets and rocks adjoining the N.E. end of the latter. The depths decrease gradually off San-chau.

MONTANHA, or *Wung Cum Island*, forming the East side of entrance to the Broadway, is a large high island N.E. of San-chau, and close to its N.E. side is Ko-ho Island. These two islands form the South side of the Typa anchorage; and the Great West Channel is bounded by them on the West, and by Potoe and the other islands adjacent on the East.

The **BROADWAY** is the chief and eastern entrance, and the only one yet surveyed, of the Si-kiang. It has sufficient depth to admit a vessel of moderate draught a considerable way up, and may be found useful to such as intend to make a long stay near Macao, or to those who have parted from their anchors, and draw too much water to attempt the Typa anchorage. Its entrance is 9 miles south-westward of Macao, between the islands of San-chau and Montanha.

The *Water Islands* are two small islets lying close off the South end of Montanha; and N.W. $\frac{3}{4}$ N. a mile from them lies Inside Islet, having a small inlet, called *Lark Bay*, between it and Morgan Point (608 ft. above the sea), the West extreme of Montanha. These islands are on the East side of the Broadway entrance, and Coffin Island, bearing S.W. by W. $\frac{1}{4}$ W., distant 4 miles from the Water Islands, is on the western side. At 5 miles in a S. $\frac{3}{4}$ E. direction from Montanha Peak and $2\frac{1}{2}$ miles from the Water Islands is a shoal patch of 12 ft.

Tides.—It is high water, full and change, at the entrance of the Broadway at 11^h, and springs rise $7\frac{1}{2}$ ft. The neaps are very irregular, there being then only one flood and one ebb, of any considerable strength, during the 24 hours. The direction of the flood outside is governed principally by the winds; with strong easterly winds it comes from E.S.E.; and when south-westerly winds prevail, from South. The ebb runs generally to the S.W. Inside the river the tides take the direction of the channel.

Directions.—The best time to enter the Broadway is with the first of the flood, and if at anchor in Macao Road and obliged to run for it with a N.E. or East wind, about three-quarters ebb will be the best time to leave the road, that the first of the flood may be met at the entrance, where it flows sooner than in the road. Having rounded the East point of Ko-ho Island, about $1\frac{1}{2}$ mile distant, in $4\frac{1}{2}$ fathoms, steer at any convenient distance round Apomi Point, the high S.E. extreme of Montanha.

When abreast the point, the Water Islands will be seen in one with each

other, near the western extreme of a bay with a sandy beach. Steer to pass about half or three-quarters of a mile southward of these islands, in $2\frac{3}{4}$ or 3 fathoms, then haul round the western island, preserving the same depth and distance. Do not exceed the distance of 1 mile westward from this island, for beyond that the water shoals fast to $2\frac{1}{4}$ fathoms, towards the San-chau shore. From abreast the islands about a N.N.W. $\frac{1}{2}$ W. course, giving a berth of three-quarters of a mile to Inside Islet, will lead up to abreast Morgan Point, the West point of Montanha.

From the above point the water shoals gradually towards Ross Island on the West side of the channel. There is generally a line of fishing stakes extending westward from the point, with passages among them for vessels. *Mong-chau*, or *Ballast Island*, bears N.N.W., distant $2\frac{1}{2}$ miles from Morgan Point. N.W. $\frac{3}{4}$ N. about $1\frac{1}{4}$ mile from Morgan Point, and fronting the first of the above passages, there is a rock which shows at low water about the size of a small boat. The channel is about a cable's length westward of this rock; for W. $\frac{1}{4}$ S. about a mile from it there is another rock, which also shows at low water, and shoal banks bound the channel on both sides. *Pak-tang*, a small island with a sharp hummock on its N.E. end, lies on the western bank, W. $\frac{1}{2}$ N. distant 3 miles from Ballast Island. The bank, composed of mud, has only 6 ft. on it, and extends $1\frac{1}{2}$ mile from Pak-tang towards Ballast Island, contracting it to about the breadth of from half a mile to a mile, with $2\frac{3}{4}$ and 3 fathoms in it.

If intending to proceed farther up than Morgan Point steer N.N.W. towards the rock fronting the first passage to Macao. When abreast the rock, steer N.N.W. $\frac{1}{2}$ W. $1\frac{1}{2}$ miles, and the vessel will then be abreast Ballast Island, in $2\frac{3}{4}$ fathoms. This is a safe and convenient anchorage, about 6 miles S.W. by W. of Macao, and the boats are kept in sight when passing to and fro from that place. Fresh water may be obtained in a small bay to the northward, under Beacon Hill, which is 690 ft. high, and has a remarkable stone on its summit.

TYPA ANCHORAGE.—The eastern entrance to this anchorage is between two high islands, that on the South side name Ko-ho or Apomee, and that on the North side named Typa or Kaikong. Ko-ho is separated from the N.E. point of Montanha by a narrow gut with 24 ft. water in it, decreasing to 9 or 10 ft. farther in towards the Typa. The anchorage is between the West end of Typa Island and the East end of Macarira Island, and affords secure shelter in $3\frac{1}{2}$ to 4 fathoms. H.M. ships *Herald* and *Modeste* refitted during the operations in China in 1841.

Tides.—In this anchorage, and in Macao Harbour, it is high water, full and change, at 10^h 0^m. The springs rise about 7 ft.; in the Typa they run $1\frac{1}{2}$ and 2 knots per hour, when not influenced by the winds. The ebb runs out of the Typa entrance, but it sets across it when outside the points.

Directions.—Vessels entering or leaving the Typa should weigh at half

flood. In entering steer for the North extreme of Ko-ho, and pass it pretty close, the deepest water being on this side of the entrance; continue on until the summit of Sylock Island is in line with the North extreme of Ko-ho. Keep this latter mark on, or the North point of Sylock just in sight, bearing about E. $\frac{3}{4}$ S., leads in the deepest water; and when the East end of the middle hill on Typa Island opens westward of a rocky mount forming the S.W. point of the same island, haul gradually to the northward, and anchor near the West point of Typa, with the South point of Sylock open of the North extreme of Ko-ho.

Here the depth is $3\frac{1}{4}$ to 4 fathoms at low tide, and vessels are sheltered from all winds by the high lands around. The deepest water is near the West point of Typa, for the bay abreast, at the East end of Macarira, is shoal. The watering cove is at the head of this latter bay, and from the North point a reef of rocks projects nearly a quarter of a mile eastward; a vessel ought not to go so far northward as to approach this reef. In the middle and eastern parts of the Typa the depths are only 14 and 15 ft. at low tide, in the fair channel leading to the anchorage, but no injury can be received by grounding, the bottom being remarkably soft.

MACAO HARBOUR.—Macao stands on a small peninsula projecting from the S.E. end of Macao Island. The peninsula is nearly 2 miles long, less than a mile wide at its broadest part, and is connected with the island by a low, narrow, sandy isthmus, across which extends a barrier wall to exclude foreigners from the interior of the island. The town is built on the declivities round the harbour, the shore beneath being embanked, so as to form a marine parade, backed by a terrace of white houses. Fort Guia stands on the hill to the N.W. of the town.

LIGHT.—A *bright light*, revolving every 64 seconds, is shown from Fort Guia. It is elevated 330 ft., and said to be visible 15 to 20 miles off. It is stated to be in lat. $22^{\circ} 11' N.$, long. $113^{\circ} 33' 30'' E.$

This settlement, known to the Chinese as *Ngao-mun*, was established by the Portuguese in 1557, but has never been recognized as a possession of Portugal by the Chinese government; the British government, however, has recognized the jurisdiction of its law courts as supreme. In December, 1873, the Portuguese government abolished the system of Coolie emigration which has been existing since the suppression of the slave trade. This traffic, if all is true that has been reported of it, equalled the old iniquities of the African slave trade.

The Inner Harbour is formed between the peninsula and Patera Island to the westward. Its entrance is narrow, but the depths are 20 ft. at low water close to Fort San Iago or Barra, which is built on the S.W. point; and from thence the soundings are 19 and 16 ft. along the western shore to the town. There is an excellent landing pier. Steamers ply daily to Hong Kong, and every other day to Canton.

Pedra Arèca, a rock lying S.E. 4 cables from Fort Barra, is marked by a beacon, and *San Francisco Bank*, $1\frac{3}{4}$ mile East of the fort, is a mud patch with two heaps of ballast, with 4 and 5 ft. on them, and 10 ft. close to.

Pilots.—Canton River pilots are procured at Macao, and each receives a chop from the residing mandarin, to deliver to the officer stationed at the Boca Tigris, describing the force of the ship and to what nation she belongs.

MACAO ROAD is shoal, the depth being generally from 3 fathoms at low water springs on the West side, to $4\frac{1}{2}$ or 5 fathoms close over to Samecock and the other islands that bound the East side. There is, however, said to be much less water in it of late years, but as the bottom is soft loam or loose mud there is no danger of a vessel striking on her anchors, for they immediately bury in it.

Vessels of large draught usually anchor in deep water near the islands, with Macao bearing between W. by N. and W.N.W., distant 6 or 7 miles, which render the communication with that place difficult and dangerous in blowing weather. With Ko-ho Point S. by W. $\frac{1}{2}$ W., and Macao W.N.W., distant 4 or 5 miles, a large vessel may anchor in about 4 fathoms at low water, and be more conveniently situated for procuring a pilot. If drawing under 18 ft. she can anchor with Macao on the same bearing about $1\frac{1}{2}$ mile off the Typa entrance.

Small vessels may anchor in the S.W. monsoon in the entrance of the Typa, off the Ko-ho shore, a little outside Ka-o Islet, in about 3 fathoms at low water. In the N.E. monsoon they can anchor abreast a sandy beach, between the Cau-chau or Nine Islands and Macao, in 3 or $3\frac{1}{2}$ fathoms; here they will generally have smooth water and an easy communication with the shore.

Directions.—The route to Macao Harbour for small vessels, through the Typa anchorage, has 7 ft. at low tide in the fair track between the Typa and the harbour, and 8 to 12 ft. between Typa Island and Macao. A vessel should steer a direct course from the Typa to the harbour, and to avoid the sunken rock, *Pedra-mea*, lying about a quarter of a mile eastward of the N.E. point of Macarira, keep the N.E. point of Montanha open eastward of Macarira; or, in passing it, keep rather towards the Typa Island side of mid-channel.

From thence, steer direct for the entrance of the harbour, avoiding *Pedra Arèca* Rock, from which the South point of the outermost of the two high Ma-lo-chau Islets, to the S.W. of the entrance, bears W. by S. $\frac{1}{2}$ S. $1\frac{1}{4}$ mile, and the point of Fort Barra N.W. about 4 cables. The N.E. point of Montanha in line with East point of Macarira leads westward of the *Pedra Arèca*, and a vessel will not be too near it if she does not go eastward of a line drawn from the West point of Typa Island to Fort Barra Point. This point should be rounded pretty close in entering and the eastern shore kept aboard

to the anchorage abreast the town, where a disabled ship may be hove down and repaired.

Entering from the outer roads, fort Barra Point in line with the South extreme of Anang village, W. by N., will lead between San Francisco Bank and Pedra Arèca in 9 feet least water, deepening as the harbour is approached.

CUM-SING-MUN HARBOUR.—From Macao the eastern shore of Macao Island trends N.N.E. about 11 miles to Bluff Head, where it turns abruptly westward, and forms a deep bight called Cum-sing-mun Harbour. This harbour is safe for small vessels, and it would be a desirable haven for vessels of large draught to run for from the anchorage off Lintin, at the approach of a typhon, were it not for the extensive shoal flat they would have to cross, the depths being only 2 to 3 fathoms at 2 miles outside the entrance; but they increase quickly to 7 and 8 fathoms when within half a mile of Bluff Head, which is the proper side to steer for in coming from the S.E., and also to keep nearest to when running into the harbour.

The entrance, about half a mile wide, is between the South part of Kee-ow Island and Bluff Head. Between this head and the small islet and sunken rocks, near the island shore, the depths are irregular, from 14 to 6 fathoms; but inside, about half a mile West, or W. by S. from the small islet, the bottom is soft, affording safe anchorage in 6, 5, or 4 fathoms, taking care, however, to avoid the shoal patches shown on the chart.

GREAT LADRONE (*Man-san* of the Chinese), being the outermost island directly fronting the estuary of Canton River, is generally used as a land-fall by vessels bound there from the southward during the S.W. monsoon; and with the Little Ladrone adjoining to the westward, and Potoe to the north-westward, bounds the East side of the Great West channel, leading to the river.

This steep, bold island may be easily known by its N.W. part forming a round mount or dome (1,465 ft. high), which, being more elevated than the other parts, can be seen, in clear weather, about 27 miles from a vessel's deck, and 40 miles from the mast-head; none of the other islands have a similar appearance, although most of them are high. The island is about 2 miles in diameter, with a rocky aspect close to the sea, but it is safe to approach, the depths near it being 14 or 15 fathoms; on the S.W. part there is a small inlet, named Pumice-stone Bay, where fishing boats take shelter in the N.E. monsoon.

LITTLE LADRONE (*Pocking-han* of the Chinese), is of a convex sloping form, not so much elevated as the Great Ladrone, and separated from its West side by a narrow channel of 9 to 18 fathoms water, but too confined for a vessel unless in a case of necessity. Near the West side of the island the depth is about 10 fathoms, decreasing gradually to 7 fathoms about half

a mile southward of Potoe; there are 12 fathoms near its South point, and 14 and 15 fathoms near the South and S.E. sides of the Great Ladrone.

A small rocky islet lies close to the N.E. part of the Little Ladrone; and North nearly three-quarters of a mile from this islet there is a black rock covered at high tide, with 10 fathoms close around; it will be prudent therefore, in passing this locality at high water when the rock is covered, to keep about mid-channel between the Little Ladrone and Tong-ho island, which lies $2\frac{1}{2}$ miles to the northward. This is the only danger near the Little Ladrone, excepting a high rock close to its N.W. side, having a depth near it of 9 and 10 fathoms.

Potoe, or *Passage Island*, bearing N.N.W. $\frac{1}{4}$ W. $5\frac{1}{2}$ miles from the south-west end of the Little Ladrone, is a flat sloping rock, visible about 9 miles. There are 5 to 6 fathoms near it on all sides, but it ought not to be approached too close in light winds, as the eddies occasioned by the freshes out of the river may render a vessel unmanageable, and probably drift her towards it, or Wong-mou, the adjacent island. The channel between it and the S.E. point of Montanha is about 5 miles wide, and safe.

Wong-mou Island, lying $1\frac{1}{2}$ mile E.N.E. of Potoe, is $1\frac{1}{4}$ mile long, North and South, and has a peaked hill on its northern part; at nearly half a mile from its West side there are some rocks above water. *Liungnib*, lying a mile eastward of Wong-mou, has a round islet off its South end.

About three-quarters of a mile N.W. from the North end of Liungnib lie two rocks, which cover at springs, and break in blowing weather; therefore, in passing the North end of this island, keep at least a mile from it.

PU-TOI or Pak-leak Island lies N.E. by N. nearly $1\frac{1}{2}$ mile from the Great Ladrone, and on its N.E. point is a remarkable cone hill, 855 ft. high, which is visible from Macao. The island is of irregular shape, and on its southern side the hills are much covered by black rocks. On its northern side are some small bays in which fresh water may be procured; and near its N.E. point there is a rocky islet, on which the fishermen have a hut and fishing stage. A rock, awash, lies close off its South extreme.

Clio Rock, on which H.M.S. *Clio* struck, 12th December, 1841, lies about 2 cables from the West side of Pak-leak, with the N.W. extreme of the island bearing N. by W., distant 4 cables' lengths.

TONG-HO ISLAND, about $2\frac{1}{2}$ miles N. by E. $\frac{1}{2}$ E. from the Little Ladrone, is $1\frac{3}{4}$ mile long, East and West, and of moderate and unequal height. On its N.E. side there is a small cove into which the ship *Boddam*, drawing 21 $\frac{1}{2}$ feet water, was taken by her pilot and remained in safety during a typhoon. The cove is about 2 cables wide, with 24 feet water at the entrance, 17 and 18 ft. well inside, at low-water springs, and the bottom all soft mud. Here a vessel may lie at anchor, or if she has none, be run into the mud without risk. Being the chief rendezvous of the fishing boats in bad weather, or a place of refuge from the pirates, it is protected by a fort on the N.W. point

of entrance. Good water may be obtained at Boddam Cove, also beef, fish, poultry, and some fruit.

Boddam Cove will not be readily distinguished until the vessel is within about 2 miles of the N.E. part Tong-ho. Steering for the entrance, take care to give a berth to a rock lying off the N.E. point of the island, and to a sunken rock lying about $1\frac{1}{2}$ cable N.E. of the fort point; when the head of the cove bears S.W. by W., the vessel will be S.E. of the rock. Having brought the cove fairly open on the above bearing, steer for the point on the N.E. side of entrance, and pass it within the distance of half a cable; for the N.W. point, where the fort is built, is bordered by rocks.

Bouncer Rocks are two rocks close together, lying N.E. by N., two-thirds of a cable from the S.E. entrance point of the cove; the outer rock is awash at low water.

Good water may be obtained at Boddam Cove, also beef, fish, poultry and some fruit.

CHUK-WAN ISLANDS.—These two islands lie about E. by N. $1\frac{1}{2}$ mile from Pak-leak, and the larger island, the eastern one, has a high rocky islet, named *Sharp Island*, lying off its S.E. point, and a small bay on its North side. There are 14 fathoms water between *Hoa-ock* and the western island, and 11 and 12 fathoms northward of the group.

RALEIGH ROCK, on which H.M.S. *Raleigh* struck, 14th April, 1857, is a small pinnacle, which breaks, when there is a moderate sea, at low water springs, with 9 and 10 fathoms close to. Its position is lat. $22^{\circ} 2' N.$, long. $113^{\circ} 47' E.$, nearly in mid-channel between Pak-leak and South White Rock, distant $2\frac{1}{2}$ miles from the latter. When on the rock the gap in the centre of South White Rock is in line with the right extreme of a small wedge-shaped island off the eastern side of Lafsami Island bearing N.E. by N.; the highest part of Ai-chau Island E. $\frac{1}{2}$ N.; and the peak of the Great Ladrone is over the western slope of Pak-leak S.S.W. $\frac{1}{2}$ W.

North and South White Rocks are two high white rocks half a mile apart, lying North about $3\frac{1}{2}$ miles from the western or small Chuk-wan island. From the southern rock the N.E. point of the eastern Chuk-wan bears S.S.W. $\frac{1}{2}$ W., distant $4\frac{1}{2}$ miles. About a mile S.E. of the southern rock is a small black rock, visible only at low springs, having 9 fathoms water close around.

The White Rocks may be seen in fine weather in time to avoid them, and the depth is about 9 fathoms near their eastern side, 8 fathoms on the western and northern sides, and 9 fathoms in the channel, between them and Chuk-wan; but since the loss of the *Raleigh* by striking on the Raleigh Rock, it will be prudent not to use this channel until it has been more accurately examined.

AI-CHAU ISLANDS lie N.E. by E. $\frac{1}{2}$ E., 4 miles from the eastern Chuk-wan, and the eastern or larger island is separated from the smaller one on its

West side by a very narrow channel with 4 and 5 fathoms in it at low water. *Hill Islet*, lying N.E. $1\frac{1}{2}$ mile from the northern part of the eastern *Ai-chau*, has 11 and 12 fathoms water at a short distance from the rocks around it.

The **SAMOUN**, or Three Gates, form a group of three small islands $2\frac{1}{2}$ miles eastward of *Ai-chau*, and extend about $3\frac{1}{2}$ miles in a N.W. and S.E. direction, with narrow passages between them. Near the N.W. part of the N.W. island, called *Hak-chau*, there are two peaked islets; and on the northern side of the group, between the eastern and middle islands, there is another high rocky islet, named *Gauze* with a bed of rocks lying southward of it; the South end of the eastern island is the highest part of the group, and forms a round mount. There is a small harbour on the S.W. side of the largest island, which would afford shelter to two or three vessels during a N.E. gale. The anchorage is in 6 to 10 fathoms, muddy bottom.

LINGTING ISLAND, bearing W. $\frac{3}{4}$ N., distant 15 miles from the N.E. head of the Lema Islands, is of rugged appearance, about $1\frac{3}{4}$ mile long, East and West, and rises to a peak near its centre. Two rocks, one awash and the other above water, bearing N. by E. and S. by W. of each other, lie eastward of the North point of the island; the outer one, awash, is distant nearly a mile E.N.E. from the North point, and the other S. by W. about half a mile from the North point, and the other S. by W. about half a mile from the outer one, with depths near them of 13 fathoms, but foul ground between.

The Needle Rocks, on which H.M.S. *Doris* struck in 1813, are two heads lying within a few yards of each other, about $1\frac{1}{2}$ cable's length S.W. of the low rocky N.W. extreme of Lingting, and they are so sharp that it is difficult to keep the lead fixed on their points; at low springs they have about 6 ft. water on them, at which time, with a swell, they may probably show either breakers or a rippling. From the outer rock the S.W. extreme of the Lema Islands is just shut in with the S.W. point of Lingting, and the highest part of Lamma Island is a little way over the low N.W. point. A vessel will avoid them when passing round the N.W. end of Lingting by not approaching it within half a mile, or by keeping the S.W. extreme of the Lema Islands a little open S.W. of Lingting.

The depths close to the North point of Lingting are 18 or 19 fathoms, decreasing to 14 and 15 about a mile distant; to the southward and westward of the island there are 10, 11, and 12 fathoms over soft bottom.

When passing northward of Lingting at night, give its North side a berth of $1\frac{1}{2}$ mile to avoid the rocks of its N.E. side.

TY-LO ISLAND is the southern of the range of small islands bounding the East side of Macao Road. It is high near the western part, sloping a little to the eastward, and lies N. $\frac{1}{2}$ E. from the North end of *Liungnib*, from which it is separated by a good channel $2\frac{3}{4}$ miles wide, but in using it take

care to avoid the rocks off the northern point of the latter. *Ty-lock*, about half a mile northward of *Ty-lo*, is a small rocky islet, with a large rock on its summit.

Sam-Cock Island, or the *Pyramid*, the largest of the above range, and lying $1\frac{1}{2}$ mile N.N.E. from *Ty-lock*, is of moderate height, rugged in appearance, and in the form of a pyramid. Between it and *Ty-lock* there is a small islet named *Sy-lock*, and two rocks above water; but the channels between these are so narrow, that they should not be attempted on account of the strong eddies, which frequently render vessels unmanageable. On the northern part of *Sam-cock* there is a small bay or cove for boats, and the island affords fresh water.

Chung-chau-si, *West Water Island*, the northernmost of this range, lies N.N.E. about $1\frac{1}{2}$ mile from *Sam-cock*, and there is 7 fathoms water near it to the eastward, and 5 and 6 fathoms to the northward and westward.

Four-feet Rock.—This small dangerous needle rock, with only 4 ft. on it and 10 fathoms close around, lies E.S.E. 3 miles from *Chung-chau-si*, and from it the summit of *Ty-lo* bears S.W. by W., the centre of *Sam-cock* W. $\frac{1}{2}$ S., and the small islet lying off the N.W. end of *Chung-chau* N.N.E. $\frac{1}{4}$ E. When *Chuck-tu-aan Island* (3 miles S.E. by S. from *Chung-chau-si*) and the small islet off the N.W. end of *Chung-chau* are on the same bearing, about N.N.E. $\frac{1}{2}$ E. and S.S.W. $\frac{1}{2}$ W., the rock will be between the two, but nearest the former; therefore if a vessel has occasion to enter *Macao Road* by this channel, and keeps about three-quarters of a mile off *Lafsami* and the South side of *Chung-chau*, she will pass in mid-channel, and have 10 or 12 fathoms water, decreasing to 7 fathoms as she nears *Chung-chau-si*.

CHUNG-CHAU, or *Water Island*, which with the islands southward of it bound the S.W. side of *Lantao Channel*, lies about S.W. by W. $2\frac{1}{2}$ miles from the S.W. point of *Lantao*, is high, and near its North point there is a peaked hill. It is $1\frac{1}{2}$ mile long, N.W. and S.E., and there are no hidden dangers near its northern side.

Nau-tau-mun, or *Bullock's Head Gate*, the next island to the S.E. is small but high, and is separated from *Chung-chau* by a narrow channel through which H.M.S. *Doris* ran, and found shoal water near *Chung-chau*.

LAF-SA-MI ISLAND, separated from *Nau-tau-mun* by a narrow channel, is larger than either *Chung-chau* or *Nau-tau-mun*. It is inhabited on the south-western side, where fresh water is to be had in a small bay. This island from some views forms a peak; and at a short distance eastward of its South point there is a rocky islet, on which the fishermen have huts, and a winch for heaving up their nets.

CHI-CHAU ISLAND, the largest of two islands lying $2\frac{1}{2}$ miles E.S.E. of *Laf-sa-mi*, forms the South side of the East entrance of *Lantao Channel*. The island is high, of round appearance, inhabited on the West side, and separated by a narrow channel from the smaller and lower island,

on its western side; a sunken rock lies off its N.E. point, and a patch of 4 fathoms about a quarter of a mile off its North point.

SOKO ISLANDS.—*A-chau*, the southern of the two Soko Islands, is distant nearly 4 miles S.E. $\frac{3}{4}$ E. from the South point of Lantao, and forms the North side of the eastern entrance of Lantao Channel. The South point of *A-chau* is high, and rises very steep, having 7 fathoms water close to; the depths between it and *Chi-chau* are 11 to 13 fathoms, deepening suddenly to 25 or 30 fathoms in a hole or swatch close to *Chi-chau*.

The other island, lying a short distance northward of *A-chau*, is about a mile long, East and West, and very narrow in the middle. A sand spit extends nearly West upwards of $1\frac{1}{4}$ mile from its West side, and on the West extreme of the spit there are $2\frac{3}{4}$ fathoms at low water, decreasing quickly to 2 and $1\frac{1}{4}$ fathoms towards the island. A rocky islet and two rocks above water lie between the two Soko Islands; there is also at nearly a mile eastward of *A-chau*, a high rocky islet.

KYPONG ISLANDS are the southernmost group of the Archipelago fronting the estuary of Canton River. *Pak-tsim*, the largest and north-eastern island, bearing E. by S. 16 miles from the Great Ladrone, has near its western extreme two high remarkable peaks, called the *Asses Ears*, which make it easily known, as they rise from the same base almost perpendicularly from the sea to the height of 980 ft., and sloping suddenly down on the N.E. side, are united to a piece of moderately elevated land, which terminates that part of the island. *Tsi-mi-wan*, the next island to the S.W. is of considerable size, and separated from the S.W. point of *Pak-tsim* by a channel about half a mile wide.

A range of islets extends $4\frac{1}{2}$ miles in a south-westerly direction from *Tsi-mi-wan*; the south-westernmost islet (90 feet high) called *Gap Rock*, but *Man-mi-chau* by the Chinese, has a small gap in it. Between the South end of *Tsi-mi-wan* and *Peaked Rock* (180 feet high), the easternmost islet of the range, there is a passage $1\frac{1}{4}$ mile wide, with 18 fathoms least water in it. A rugged rock, 50 ft. high, lies about $1\frac{1}{2}$ mile N.W. $\frac{1}{2}$ W. from the South end of *Tsi-mi-wan*. The passage, about half a mile wide, between *Nut Island* and the islet nearest to it to the southward, has 10 to 26 fathoms water. There is also, between *Gap Rock* and the other islets to the eastward, an opening a mile wide, with 16 to 18 fathoms water, and safe to pass through with a steady wind.

Kwe-tau, or *Tortoise Head*, lying about three-quarters of a mile from the East point of *Pak-tsim*, is a white rocky islet, having other rocks between it and the point, neither of which ought to be approached. *Gay-une* is another islet, rather more than a mile northward of the North end of *Pak-tsim*: there is a passage between it and the latter, which, however, ought not to be attempted unless from necessity; for there is said to exist some straggling rocks on which the sea breaks at times.

Cambridge Rock, on which a vessel of this name struck, August 30, 1820, requires the greatest care to avoid when vessels are passing through the Tai-ta-mi Channel between the westernmost of the Lema Islands and the above rocks. The rock is of a spiral form with only 17 ft. water on it, and sometimes breaks. It lies N. by W. $\frac{1}{4}$ W. $2\frac{1}{4}$ miles from Kwei-tau, N.N.E. $\frac{1}{2}$ E. $1\frac{3}{4}$ mile from the North point of Pak-tsim, and from it the highest part of Chi-chau Island is in line with Hill Islet N.W., and the S.E. side of Gay-une Islet is on with N.W. extreme of Rugged Rock, S.W. $\frac{1}{2}$ W. There are 4 and 5 fathoms on the rocks surrounding the spiral rock; from thence the depths increase to 23 fathoms in the Tai-ta-mi Channel, which is $2\frac{3}{4}$ miles wide, and safe by borrowing towards the Lema Islands when passing through.

LEMA ISLANDS consist of three large and one small island, extending in an E.N.E. and W.S.W. direction $12\frac{1}{2}$ miles. The easternmost and largest island, named Tamkan, is 6 miles long and a mile broad, of moderate height and undulating, and separated from Ye-chau, the middle island, by the narrow Yat-moun Channel.

The Yat-moun Channel, by Capt. Bate's survey of 1850, is free of danger, and carries a depth of 12 to 19 fathoms, but it is said that there is a sunken rock in mid-channel, and that this passage should not be attempted unless from necessity.

Ye-chau is the middle and highest of the Lema Islands, and when viewed from most positions it appears flat on the top. Close to its N.E. part is a small rocky islet, named Round Island, visible when the Yat-moun Channel is open.

Poun-tin, the third or southern of the large islands, is separated from Ye-chau by the narrow Ye-chau Channel, with 19 to 30 fathoms water in it. This island (1,210 ft. high) forms more in a peak than either of the other two, and has a point projecting westward with a hummock on it, named *E-chau Head*. To the southward of this head lies *Tai-ta-mi*, a small but high island, with a narrow channel between it and Pountin. *Tai-ta-mi* forms the N.E. boundary of the Tai-ta-mi Channel, which has Cambridge Rock, Pak-tsim Island, and the Kwei-tau Rocks bounding its S.W. side.

Directions.—The Lema Islands on their southern side are all steep and rocky, not affording even a single bay for a boat to shelter in, and the soundings are 22 or 23 fathoms about $1\frac{1}{4}$ mile from their coasts; on their northern sides the depths are generally 15 or 16 fathoms close to the shore. Vessels in the N.E. monsoon should endeavour to pass between the North end of Tam-kan and Putoy, which lies 6 miles northward, and its North end, when viewed from the E.N.E., forms a small peaked hummock.

Notwithstanding the Lema Islands appear barren, there are a few men residing on them, preparing charcoal from small quantities of brushwood found between the rocks, which they send to Macao for sale. Fresh water

may be obtained along the North side of Tam-kan at several places; and close to the westward of its N.E. point, in a little cove, called Joss House Bay, there is a Chinese place of worship, and about this part the Compradore's boats await vessels after the end of August, when the easterly winds set in. The Yat-moun and Ye-chau Channels should not be used unless in a case of emergency, or when the wind blows directly through, as they are narrow, with deep water, and have generally a strong current sweeping through them. Yat-moun is the widest, and of moderate depth, but if the *Cordelia Rock* is in existence, it is very dangerous.

LAMMA ISLAND lies off the S.W. side of Hong Kong, and its S.W. point bears N.W. by W. $\frac{1}{2}$ W. 13 miles from the N.E. head of the Lema Islands, and N.E. $5\frac{1}{2}$ miles from the North point of Lingting. The island is of rocky appearance, about 4 miles long, North and South, and 2 miles wide. The North end of the island is about a mile distant from the S.W. part of Hong Kong, and over it Green Island light shows of a green colour.

From the North point of the long bay, on the West side of the island, the shore trends N. $\frac{1}{2}$ E. a mile to another point, off which, at half a mile from the shore, are some sunken rocks. The S.E. point of the island is remarkable from its being a small round hummock of bright green appearance on the top, and rocky near the water's edge; this part of the island, as far as the eastern point, is rocky close to the shore, with 13 or 14 fathoms water half a mile off.

The cove on the East side of the island, to the northward of its eastern point, is about $1\frac{1}{4}$ mile deep and two-thirds of a mile wide. It carries a depth of 8 to $3\frac{1}{2}$ fathoms, and a vessel may anchor in 6 or 7 fathoms water, over rocky bottom, about half a mile within the entrance, and ride in security, being land-locked. *George Island*, 234 ft. high, lies close to the northward of the North point of the cove.

A rock awash at low water, with deep water around it, lies N. by W. $\frac{1}{4}$ W. about one cable from the rock which is above water near the N.W. point of Lamma Island. The S.W. point of Lamma Island open of the West point, bearing S. by E. $\frac{1}{2}$ E., leads to the westward of this danger, and Tree Island open of the North point of Lamma Island, bearing E. $\frac{3}{4}$ N., leads to the northward.

LAMMA CHANNELS.—East Lamma Channel, between Lamma Island and Hong Kong, is about a mile wide, and has general depths in it of from 17 to 23 fathoms; but a vessel will find a good and sheltered anchorage between George Island and the North point of Lamma in 7 or 8 fathoms. There appear to be no dangers in this channel, but a rock (doubtful) is said to lie off the S.E. point of Mas-kong or Round Island, on the Hong Kong shore.

The West Lamma Channel, between the western side of Lamma and the

islands lying off the East side Lantao, has general depths of 5 and 6 fathoms on a mud bottom. Entering it from the East Lamma Channel, the soundings will decrease rapidly to 7 and 6 fathoms after rounding the North point of Lamma, off which, at one-third of a mile to the N.N.E., is a rocky patch of 8 fathoms, surrounded by depths of 14 to 21 fathoms.

Water.—About a mile N.E. of the North point of Lamma Island, and near the western point of a deep cove, named *Aberdeen* or *Shekpywan Harbour*, on the Hong Kong shore, there is a cascade of good water conveniently obtained.

CHUNG ISLAND is near the S.E. side of Lantao, N. $\frac{1}{2}$ W. 5 miles from Lingting. Its North and South parts are high, but it is narrowed near the middle, which is low, by two bays, one on the East, the other on the West side of the island. A vessel of moderate draught will find good shelter during an easterly gale, in the western bay, in $3\frac{1}{2}$ fathoms. There is no danger in passing the South end of the island, the depths being 7 and 8 fathoms close-to, and 5 and 6 fathoms near the south-western part; but East, about 3 cables from the eastern point of the island, is a small rock, which dries at low water, and has 6 and 7 fathoms close-to. Capsingmoon Passage, between Chung Island and Lantao, with the dangerous Passage Rock, is described hereafter.

To the northward of Chung, and at a short distance from Lantao, there are several small islands and rocks above water; but the channels between them and the Lantao shore are narrow, shoal, and unfit for large vessels. Fresh water can be procured in the bay on the western side of Chung.

The **PU-TOY GROUP**, lying off the South end of Hong Kong, bounds the northern side of the Lema Channel. *Pu-toy*, the southern island of the group, bears N.N.W. $\frac{1}{4}$ W. 6 miles from the N.E. head of the Lema Islands. It is of moderate height, the appearance in general barren, there being only a small quantity of brushwood in the valleys. On its western side there is a cove for boats, and a small rocky islet.*

Lo-chau or *Beaufort Island*, lying northward of Pu-toy, and separated from it by a narrow channel, is high, flattened at the top, and steep all around; about its north-western brow there is a small peak, with a few large and remarkable rocks on it. At half a mile off its S.W. side are some large rocks above water, having no hidden dangers near them. *Sun-kong*, about $1\frac{1}{2}$ mile East of Lo-chau, is a small but high island, rising in a peak, 466 feet high, towards the centre; near its north-western part there are some

* Com. C. M. Buckle, R.N., who cruised for some days about the islands southward of Hong Kong in H.M.S. *Cormorant*, 1865, remarks that there are a number of small rocks amongst them, some above and some below low-water mark, which, owing to the smallness of the scale of the chart do not appear.

rocks considerably above water. *Wag-lan*, about three-quarters of a mile East of Sun-kong, is a small barren rocky islet, the easternmost of this group, having 16 and 17 fathoms water at a short distance to the eastward.

HONG KONG.

HONG KONG ISLAND (*Heang Keang*, the Island of Fragrant Streams), so called from the numerous water courses on its sides, is about 9 miles long, N.W. by W. and S.E. by E., 2 to 5½ miles broad, and with an area of about 29 square miles. It lies between Lamma Island and the main, from which it is separated by a narrow channel a quarter of a mile wide, named Lyemun Pass. The appearance of the island is somewhat picturesque, but on the whole it is generally barren and unprepossessing. Victoria Peak, 1,825 feet high, in the N.W. part of the island, serves as a *signal station*.

Three important lighthouses have been recently established. The two on the eastern end of Hong Kong Island are described hereafter.

Green Island Lighthouse, first illuminated in July, 1875, is a round white tower, 20 ft. high, and stands on an island lying off the N.W. end of Hong Kong Island. The light is *fixed*, elevated 95 ft. above the level of the sea, and visible 14 miles off. It shows *red* to the westward between N. by W. ½ W. and S. by W. ½ W., *green* to the northward between N. by W. ½ W. (indicating the western edge of Kellet Bank) and N.N.E. ¼ E., and also *green* to the south-eastward between S. by W. ½ W. and S.E. To the eastward the light is obscured by the island.

HONG KONG, 3 miles in extent, is on the North side of Hong Kong Island. For some years, owing to the excessive heat of the city, a site was occupied as a sanatorium at *Kowloon*, on the northern shore of Victoria Harbour. By the treaty of Tientsin this was ceded to Britain, and the tract, about 5 square miles, has been laid out for villa residences.

In the year 1841, when the island became a British possession by the treaty of Canton, the population numbered only 5,000; in 1876 it was estimated at 122,000. In 1865, of the 125,504 inhabitants, 2,034 were European and American, and the remainder all or nearly all Chinese.

Hong Kong being a free port, it is impossible to give any statistics of its trade. It may be looked upon chiefly as a depot, only a small quantity of the goods imported being consumed upon the island, the greater portion being re-exported to other ports. Amongst the articles principally dealt in, may be enumerated—opium, sugar, flour, cotton, rice, tea, cotton and woollen goods, silks, oil, salt, provisions, &c., besides which there is an export of granite, almost the only article produced in the colony.

The trade with the Australasian colonies has much improved since the

steamers of the Eastern and Australian Mail Steamship Company have regularly established their line, and these have been largely supplemented by occasional vessels leaving this for Cooktown in the northern extreme of Queensland. Of the 3,562,774 tons of shipping entered during the year 1875, 45.2 per cent. arrived in junks, 43.7 per cent. in steamers, and 11.1 per cent. in European and American-built sailing vessels.

Climate, &c.—Hong Kong lies just within the tropic, and is subject to an excessively hot and a somewhat cool season, coinciding with the S.W. and N.E. monsoons; it has also a dry and a rainy season. July and August are the hottest months, the temperature ranging from 80° to 94°, with a difference of 10° between day and night. The city being situate on the North side of the island under the peak, is completely sheltered from the influence of the S.W. monsoon, which, on the southern side of the island, agreeably tempers the violent heat. November to January is the coolest period, and the air is often bracing; the temperature occasionally falls below 40°, and ice has been known on the peak, but this is rare; sudden changes frequently take place, a day of almost tropical heat being followed by a cutting northerly wind, for when calms and variables prevail, it is hot even in winter, and it requires the N.E. wind and overcast sky to reduce the temperature, and gales from the latter quarter are common in the autumn and spring months, blowing for two or three days. March and April are rainy and foggy, and the damp is so penetrating that the greatest care is required to prevent clothes, books, instruments, stores, &c., from being destroyed or injured by mildew. Typhoons seldom occur before June or July, for they advance northward as the season progresses, and may be expected most severe at Hong Kong about the autumnal equinox.

The *wet season* commences in May, and continues until the beginning of August, and during this period the rain falls almost without intermission, frequently causing floods which do great damage.

Although visited by sickness caused by malaria, it has been shown by statistics that for salubrity Hong Kong may compare favourably with most of the ports of the East, and its healthiness has been greatly increased of late years by its sanitary arrangements and excellent water supply. The annual rate of mortality amongst the foreign residents between 1858 and 1865 was about 5½ per cent., ranging in various years between 2 and 8 per cent. The most unhealthy years have been those most deficient in rainfall. Dysentery and intermittent fever are not uncommon, and the bilious remittent fever, sometimes so nearly allied to yellow fever, occurs in the summer season, small-pox prevailing in January, February, and March. Neglect of the usual conditions of health, such as exercise, diet, proper clothing, and the like, conduce to, and exposure to the rays of the sun, even in winter, almost invariably results in, sickness.

The Harbour consists of the space enclosed between the northern shore of

the island and the mainland immediately opposite. It is only exposed to the force of strong westerly gales, and their effect is mitigated by the large number of outlying islands, so that altogether it may be deemed one of the safest in the world. Eastward of the harbour the peninsula of Kowloon forms an inner harbour which is nearly landlocked, and which affords protection to vessels in all weathers, but the situation is not a convenient one. On the approach of a typhoon the native craft almost invariably seek shelter over towards the northern side of the harbour. The anchorage is most commodious, and is entered from the sea by fine deep-water channels both from the eastward and westward. The depth of water varies from 3 to 8 fathoms, deepening to 11 fathoms off Kowloon Point.

There are port regulations for the berthing of vessels under the superintendence of the harbour-master. The anchorage for the merchant shipping is abreast the centre and lower parts of the city, on either side a fairway channel, marked by buoys; that for the men-of-war lies eastward, between the Government establishments and Kowloon, the Cathedral roughly indicating the dividing limit.

Supplies of every kind can be obtained in abundance, and there is a well-regulated market. Excellent water from the well-constructed water-works is efficiently supplied to the city and shipping. Every appliance necessary for refit and for the repairs of ships, and steam machinery will be found at the dock establishments, stores, &c.; and there is a good hospital for seamen, and a well-conducted sailors' home.

Docks.—There are two large granite docks at Aberdeen or Shekpywan Harbour, a narrow inlet formed between the S.W. shore of Hong Kong, and a small island off it named Aberdeen or Taplichau. They lie on the Hong Kong shore of the harbour, and one of them is capable of receiving the largest class of vessels drawing 24 ft. There is also a dock at Kowloon, and a patent slip at East point. The dock charges are very high, owing to want of competition, and therefore many prefer to have their vessels docked at Whampoa in the Canton River, where the charges are more moderate.*

The dimensions of the *Aberdeen Docks*, belonging to the Hong Kong and Whampoa Dock Company, are as follows:—

Dock No. 1.—Length over all, 330 ft.; length on blocks, 308 ft.; breadth over all, 80 ft.; breadth at bottom, 42 ft.; width of caisson gate, 60 ft.; depth over sill at spring tides, 18½ ft.; depth over sill at neap tides, 16 ft.

Dock No. 2.—Length over all, 400 ft.; breadth over all, 90 ft.; width of caisson gate, 70 ft.; depth over sill at spring tides, 24 ft.; depth over sill at neap tides, 21½ ft.

* A rock breaks at low water about 50 yards to the westward of the North point of Aberdeen Bay. There is also another rock a little more than half that distance off a point to the South of it, on which a vessel was lost.

The above are the extreme depths for which credit is claimed, but the level is much influenced by the wind at all times, and from October to January inclusive, the average height is about $1\frac{1}{2}$ ft. greater at springs than during the remainder of the year.

A *steam-tug*, of 100 horse-power nominal, is always in readiness to tow sailing vessels round from Hong Kong free of charge, and will take them back or to sea at reduced rates. The work-shops on the premises possess every appliance necessary for the repairs of ships and steam machinery. There are also powerful lifting-shears on the jetty, alongside which vessels can lie in 24 ft. water, and take in or out boilers, masts, &c.

The Union Dock Company has also a dock at Kowloon, which, being within the harbour is of immense advantage to vessels which may reach port in such a state as to require instant docking. Its dimensions are :—Length over all, 300 ft. ; breadth of entrance, 80 ft. ; and depth over sill at ordinary spring tides, 21 ft.

The *patent slip* at East Point, on the northern shore of Hong Kong, is said to be capable of taking vessels of 1,000 tons.

Tides.—It is high water, full and change, in Hong Kong Road, at $10^h 15^m$, and springs rise about $4\frac{3}{4}$ ft. Around the island the tides are irregular, flowing and ebbing without any apparent change of direction at the surface, and at neaps there sometimes appears to be only one tide in 24 hours. In the harbour the tidal streams are regular.

At Hong Kong, during the summer months, the highest tide is three days after, in winter three days before the full and change. In September, October, and November, and the three corresponding spring months, March, April, and May, the highest water is at the latter end of the quarter. In March the tide is very low. At all seasons of the year the tides are most irregular off the mouth of the Canton River. It so occurs that the night tides are the higher, and consequently stronger, during the N.E. monsoon, and similarly the day tides in the S.W. monsoon. The rise from low water at Hong Kong is $7\frac{1}{2}$ ft., except in strong East and S.E. winds. A tide of 10-ft. rise at Canton or Whampoa is generally owing to a freshet or a strong southerly wind.

Directions.—Hong Kong Road is generally approached by sailing vessels from the westward, which side is protected by Green Island and Kellett Bank, the latter extending nearly $1\frac{1}{2}$ mile northward from the island, with an even depth of $3\frac{1}{2}$ fathoms. It may also be approached from the eastward through the Lyemun Pass during the N.E. monsoon, but the winds are generally baffling under the high land, for which reason it is not generally used by sailing vessels.

When abreast Green Island, if the vessel be of heavy draught, keep the peak of Lamma Island (Mount Senhouse, 1,140 ft. high) open westward of Green Island $S. \frac{3}{4} E.$ until Devil's Peak (on the mainland near Lyemun Pass)

is in line with the White Rock on the South point of Won-chu-chau or Stone-cutters Island, when a S.E. by E. course will lead northward of Kellett Bank, and direct for the anchorage.

Vessels of proper draught can proceed over Kellett Bank, on which the least water is 20 ft., or through the 4-fathom channel between Green Island and the South part of the bank, by passing about $1\frac{1}{2}$ cable northward of the island, and then steering for the road.

The narrow channel between Green Island and Hong Kong is sometimes used by steamers, also by sailing vessels when a fresh fair wind blows *right through*. It has depths of 10 to 12 fathoms in the middle, shoaling to 8, 6, and $4\frac{1}{2}$ fathoms after passing the small islet eastward of Green Island.

TYTAM BAY.—There are several small bays on the southern shore of Hong Kong, all of which are safe for small vessels; but at the S.E. part of the island is a deep inlet, named Tytam Bay, $2\frac{1}{2}$ miles deep, $1\frac{1}{4}$ mile wide at entrance, free from danger, and carries a depth of 10 to 6 fathoms. Tytam Head, the western point of entrance, is a high bluff, with 13 and 14 fathoms near it; from thence the western shore of the bay trends about N. by E. three-quarters of a mile to a small sandy bay, with a rocky islet fronting the beach. About half a mile northward of the islet the land forms a round projecting point, and northward of this point is a larger bay, with a sandy beach, in which is Tytam village.

Tylong Head, or *Cape d' Aguilar*, off which are two green islets, forms the eastern point of entrance to Tytam Bay, and from thence the eastern shore of the bay bends round to the northward for 2 miles, and terminates in a small inlet, called *Tytam Harbour*, carrying 4 to 6 fathoms, but its head, to the N.W., is shoal and rocky. This bay would be useful to a vessel, with the probability of a dark and tempestuous night, for by running in she will at any rate be snug, even if there should be a typhoon during the night. Water may be obtained at Tytam village on the western side of the bay.

There is very little tide in Tytam Bay, but the rise and fall is about 7 or 8 feet at springs, and about 3 or 4 ft. at neaps. The ebb sets to the eastward between Lo-chau and Hong Kong.

Directions.—If bound to Tytam Bay from the eastward, the route may either be taken to the northward of Wag-lan, Sun-kong, and Lo-chau, through the Shingshimun Pass, or to the southward of these islands through the Lema Channel; then round Castle Rock to the westward of Lo-chau. but the northern passage is preferable, for after opening the bay a vessel may haul to the northward in any convenient berth; whereas, by taking the southern route, if the wind be northerly, she will have to turn in.

Cape d' Aguilar Lighthouse is described hereafter.

LANTAO, or **Ty-ho**, the large high island lying westward of Hong Kong, is 14 miles long, N.E. by E. and S.W. by W., and its greatest breadth is

5½ miles. About the centre of the island the land is very high, making in peaks, the highest and westernmost of which rises 3,050 ft. above the sea.

West Coast.—Close to the western shore of Lantao, at 1¼ mile from the South point, there is a peaked hill, which at high water is insulated. From this hill to the point a mud flat extends about a third of a mile off shore, with only 2 fathoms water on it.

About 1¼ mile N.N.W. of the peaked hill, and three-quarters of a mile from the nearest shore, there is a rock above water, having near it a depth of 15 fathoms, and between it and the shore 7 fathoms, decreasing quickly towards the latter. N.E. by N. 1¼ mile from this rock is a bluff point, and eastward of the latter a bay, in which is the village of Ty-ho.

North Coast.—On the northern side of Lantao are two projecting points, three-quarters of a mile apart, between which is the bay and village *Sah-lo-wung*; and directly fronting the eastern point of the bay and about a quarter of a mile distant is a small islet, having a rock awash off its N.W. side. Between this islet and Saw-chau, 2½ miles to the northward, the depth is too small for a vessel of large draught at low water. Immediately eastward of the above small islet, between it and Chu-lu-cock Island, is another bay in which is *Tung-chung* village. *Red Point*, the N.E. extreme of Chu-lu-cock, has a remarkable rocky appearance, and is frequented by a company of stone-cutters, who cut the granite rocks into slabs for building. The South point of this island is so near to the Lantao shore, that in passing it is difficult to distinguish it to be an island. In *Tung-chung Bay* the water is shoal.

About 1½ mile E.N.E. of *Red Point* lies a small green island 230 ft. high, and three-quarters of a mile further in the same direction another small island, 200 ft. high, which are the *Brothers* of Dalrymple, or *Motoe* of the Chinese. A rock, 30 ft. above water, lies about half a mile southward of the East Brother, and about 1½ mile off the Lantao shore. A small reef borders the western and northern ends of the West Brother. From the East Brother the N.E. part of Lantao bears E. by N. 4 miles.

South Coast.—The southern coast of Lantao forms two large but shoal bays. The larger and eastern bay, to the north-eastward of the *Soko Islands*, has in it a small islet and some rocks above water, and a populous village at its head. Here H.M.S. *Cormorant* rode out an easterly gale, in September, 1865, which lasted 48 hours. The anchorage was much exposed, but the holding ground was good, hard, stiff mud, mixed with sand and shells. The western bay is less capacious than the other, and carries a depth of 2 to 5 fathoms.

Off the East entrance point of the eastern of the above bays, and separated from it by a narrow channel, is a high green island named *Patung*, and close to its West side are some rocks above water. A small vessel will find good anchorage westward of these rocks, with them bearing about S. by E., three-quarters of a mile distant.

CAP-SING-MUN PASSAGE, or *Throat Gates*, formed between the North point of Lantao and the main, is separated into two channels by *Mah-wan Island*. The channel on the West side of Mah-wan is generally used by steam-vessels, but it is narrow with dangerous eddies; the channel southward of that island should be used by sailing vessels, as it is wider, with good anchorage, a regular tide, and the advantage in the N.E. monsoon of being to windward.

Bunsansiah or *Passage Rock*, in the southern entrance of the Capsingmun Passage, is a pinnacle rock awash at low water, having depths of 8 to 10 fathoms close around it. From its centre, Chunghue Rock is in line with the South extreme of Chunghue Island, bearing E. by N., and the East extreme of Cowechau Island is in line with the West extreme of Lamma Island, S. by E. $\frac{3}{4}$ E.

A sailing vessel proceeding through the Cap-sing-mun Passage from the westward, should keep close over to the mainland to avoid a reef, extending a third of a mile from the N.E. point of Mah-wan; then steer in mid-channel between that island and Chung-hue Island, which lies a mile to the eastward, and after rounding the South end of the latter, if bound for Hong Kong Road, steer for the West end of Won-chu-chau or Stone-cutters Islands.

SAW-CHAU, lying 3 miles northward of Lantao, and S.E. $4\frac{1}{2}$ miles from Lintin, is a small narrow island nearly a mile long, with a sharp hummock on its North end. About 1 mile northward of it is *Tong-ku Island*, higher and more rocky in appearance; and S.W. by S. from the South point of Tong-ku, and W. by N. from the North point of Saw-chau there are two rocks above water, about a mile distant from each island; the western is named *White Rock* from its white appearance.

URMSTON BAY, or Tong-ku Harbour, bounded by the islands Tong-ku and Saw-chau to the West, and Castle Peak land to the East, is a safe anchorage, and tolerably sheltered from all winds. The best berth is in about 8 or 9 fathoms, with Tong-ku Peak just open of the South end of Lintin, and nearer to the main land than to Tong-ku. This safe bay or harbour was named Urmston by the captains of the fleet, who anchored there in August and September, 1823, at the recommendation of Sir James Brabazon Urmston, President of the Company's factory at Canton during the discussion with the Chinese relative to the affair of the *Topaze* frigate in 1821—22, at Lintin; the anchorage was found secure, with smooth water when it blew a gale from the eastward. Fresh water was procured in abundance.

Directions.—The approach to Urmston Bay for vessels of large draught is between the East side of the spit extending from the South side of Lintin and the islands Saw-chau and Tong-ku, and then northward of Tong-ku, the

depth there being 7 and 8 fathoms. The passage southward of Saw-chau has only $3\frac{1}{4}$ fathoms, and that between Saw-chau and Tong-ku $2\frac{1}{2}$ fathoms.

The channel between White Rock and the East side of Lintin Spit is about 2 miles wide, with 7 and 8 fathoms, decreasing towards the spit to 5 fathoms. Working northward, do not stand so far West as to shoal to 5 fathoms, or to bring the East side of Lintin northward of N. by W. With the South end of Sau-chaw bearing E.N.E., and Lintin Peak North, a vessel will be on the southern edge of the spit in $4\frac{3}{4}$ or 5 fathoms, sand and mud.

LINTIN ISLAND, lying W.N.W. of Urmston Bay, is about 7 miles in circumference, and its summit terminates in a high conical peak. A spit of sand extends about $4\frac{1}{2}$ miles southward from the South side of the island, having $3\frac{1}{2}$ fathoms water on its outer part, but only 9 ft. within $2\frac{3}{4}$ miles of the island, and rather less in some places. The spit is steep-to on the West side, with 10 fathoms near it, 7 fathoms touching its edge, then 3 fathoms; and on the East side the water suddenly deepens from 3 to 7 or 8 fathoms. When within 5 miles of the island, if the vessel is of large draught, do not, when standing eastward towards the spit, bring the West end of Lintin, westward of N. $\frac{3}{4}$ W., or tack immediately after deepening to 9 or 10 fathoms; but in the night do not deepen to above 7 or at most 8 fathoms.

A sandbank also extends $13\frac{1}{2}$ miles in a N.N.W. direction from the North side of Lintin, and on its northern part is a narrow ridge called Lintin Bar, the southern end of which, in $2\frac{1}{2}$ fathoms, bears W. by N. $\frac{3}{4}$ N. from Fan-si-ak Islet, and N.N.W. $\frac{1}{4}$ W. about $6\frac{3}{4}$ miles from Lintin Peak. The least water on the bar is 12 ft., and its northern end, in $2\frac{3}{4}$ fathoms, lies N.W. by N. $10\frac{1}{2}$ miles from Fan-si-ak, with Sam-pan-chau just open westward of the West extreme of Anung-hoy Island.

The anchorage off Lintin is about $1\frac{1}{2}$ mile from the sandy beach on its S.W. side, in 10 or 12 fathoms; under 10 fathoms the water shoals quickly towards the island.

Water.—Fresh water may be obtained at the eastern extremity of the beach on the South side of Lintin; at times a few bullocks and vegetables may be procured from the inhabitants of the village.

Tides.—It is high water, full and change, at the anchorage off Lintin, at noon, and springs rise 7 or 8 feet. The streams run nearly North and South, and the ebb in the freshes sometimes $5\frac{1}{2}$ or 6 knots per hour. In the N.E. monsoon the neaps are very irregular, sometimes only one flood perceptible during 24 hours with a small rise when the other flood should prevail.

FAN-SI-AK ISLET.—Two rocky islets, the easternmost of which is the largest, and called Fan-si-ak, and the other White Rock, lie North $4\frac{3}{4}$ miles from the peak of Lintin. When these islets are in one, E. by S. $\frac{3}{4}$ S., the southern extremity of Lintin Bar is on the same bearing. The East side of

the channel between the South extremity of the bar and Lintin is bounded by sand-banks, with irregular soundings of $2\frac{1}{2}$ and $3\frac{1}{2}$ fathoms on them at low water.

LANKEET FLAT, extending from the North end of Lintin Bar, across the channel to the shoal mud bank on the West side, and N.W. towards Lankeet Island, consists of sand and mud, with hard bottom in some places. The depths on it are 3 and $3\frac{1}{4}$ fathoms at low water, and $4\frac{1}{2}$ to $4\frac{3}{4}$ fathoms at high water springs; a vessel therefore drawing more than 20 ft. should not pass over it until about half flood. Close to the northward of this flat there are generally some fishing stakes, and boats fastened to them, and there are others between Lintin and Lankeet. Care should be taken not to run over the boats, which generally show lights in the night.

LANKEET ISLAND, bearing N.N.W. $\frac{1}{2}$ W. 19 miles from Lintin Peak, is formed of two hills, sloping into a low point at the West end, where there is a well of fresh water by a small temple close to some trees; the island at this part is covered with earthen vessels containing human bones. A spit or flat extends S.E. by S. $2\frac{1}{2}$ miles from its South side, with only 2 and $2\frac{1}{4}$ fathoms over it at low water. Between this spit and a long narrow sand to the westward is the Lankeet entrance of the western channels.

To proceed up this entrance to an anchorage in Lankeet Road, keep the highest peak of Ty-cock-tau just open of the outermost of the rocks projecting off the West end of Lankeet N.W. $\frac{2}{3}$ N.; with this mark on, a vessel will have $4\frac{3}{4}$ or 5 fathoms at high water, about 4 miles from Lankeet; and will carry the same depth till nearly abreast the West end of the island, where she will have about 6 fathoms in Lankeet Road. This is a convenient place for a vessel to moor when circumstances require her stores or sick to be landed. All the space between Lankeet and Ty-cock-tau is shoal.

SAM-PAN-CHAU, or Boat Islet, bearing N. by E. $\frac{1}{2}$ E. $1\frac{1}{2}$ mile from the East end of Lankeet, is small, of middling height, resembling a boat turned bottom upwards, and is the best guide for crossing over Lankeet flat, between the northern part of Lintin Bar and Lankeet. An extensive rocky bank, partly above water, projects N.W. from it, and joins the shoal bank extending from Lankeet to Ty-cock-tau. There are regular depths of 7, 8, and 9 fathoms to the eastward of Sam-pan-chau.

DIRECTIONS to CANTON RIVER.—The Lema Channel, formed by the Lema Islands on the South, and the Pu-toy group on the North, is about 6 miles wide, and safe to navigate, with regular depths of 17 to 19 fathoms, and soft bottom. This channel should, if possible, be always adopted by sailing vessels bound to Kong or Canton River in the N.E. monsoon, to effect which they ought to make the N.E. head of the Lema Islands, bearing to the westward. If the weather be thick, and the wind blows strong at East or S.E., it may be prudent to heave-to, when land cannot be discerned above 3 or 4 miles. The depths are 19 to 21 fathoms, close to the head, and

about 18 fathoms at the entrance of the channel. If the weather will not permit the vessel to enter the channel, do not shoal under 25 or 26 fathoms, as in these depths she will drift clear outside all the islands.

If, however, the vessel should happen to be near the entrance of the Lema Channel in the evening, and a typhoon is expected, she should run immediately for Tytam Bay (on the South side of Hong Kong), or for the Tathong Channel, or the East Lamma Channel, as may be most convenient; in either of which she will be secured from the tempest, if an anchorage is gained before night.

During S.W. or westerly winds it will sometimes be found difficult to turn through the Lema Channel from the eastward, as there is generally a set from West to East, occasioned by the ebb coming from the westward out of the numerous channels, and the flood from the S.W.; with a strong S.W. wind the stream runs about $1\frac{1}{2}$ knot per hour to the eastward, only slacking a little when it ought to change its direction. Pu-toy Island may be approached with safety to a quarter of a mile, and the whole North side of the Lema Islands to half a mile.

Through **LANTAO CHANNEL**.—From about a mile southward of Pu-toy a West course for 19 miles will lead to the entrance of Lantao Channel, passing northward of Lingting and southward of Lamma, the depths decreasing from 17 fathoms off Pu-toy to 12 and 13 fathoms after passing Lingting, and to 7 and 8 fathoms as the channel is approached; there are 12 fathoms in the middle of the entrance, decreasing to 7 or 8 fathoms towards A-chau. Lingting, which is of considerable height, and terminates at the summit in a conical peak, may be passed on either side as the wind requires. If passing southward, give a wide berth to the sunken rocks off its N.W. point; and to those off its N.E. point if passing northward; but the channel northward of this island is preferable, for in daylight it has no hidden danger, and a vessel may work from side to side. In the night give the North side of the island a berth of $1\frac{1}{2}$ mile to avoid the two small rocks off its N.E. point.

Chi-chau, when seen from the eastward, has a remarkable appearance, and is a good guide; it makes like a high, round, detached island with distant rugged land westward of it, which are the islands of Lafsami and Chung-chau. Having entered the Lantao Channel, the course through is N.W. by W., and the depths will be variable, not under 8 or 9 fathoms, nor above 25 fathoms. The ebb tide runs through in strong eddies, particularly in July or August, when its rate is sometimes $4\frac{1}{2}$ knots per hour on the springs. With a light wind at times, it is difficult to manage a vessel hereabout. On some occasions two or three boats, assisted by the sails, have been baffled in their attempts to tow the vessel's head round. After passing between Chi-chau and A-chau, the water will deepen from 10 to 17 fathoms in mid-channel near the islands which front the S.W. point of Lantao, and

there are 7 fathoms close to the point. Having rounded the point at a moderate distance, steer to the northward for Lintin, or to the westward for Macao Road, as circumstances require; in the latter case the depths will gradually decrease to $5\frac{1}{2}$ or 5 fathoms.

In turning through the Lantao Channel, when standing northward, do not shoal under 7 fathoms in a vessel of large draught, nor pass the line of bearing between the South points of Lantao and A-chau. Between the northern Soko Island and the Lantao shore there is a good channel, 1 mile wide, which may be taken by a vessel when blowing fresh from the northward. In this case, after passing the South point of Patung, a small rocky islet will be seen in the bay on the southern shore of Lantao; steer to the north-westward until this islet is shut in behind the western point of the bay, when keep towards the South point of Lantao, and the depth will be $4\frac{1}{2}$ fathoms, muddy bottom, between the point of the sandy spit and the Lantao shore.

From the small islet off the North side of Chung-chau, Lintin Peak bears N. $\frac{1}{3}$ E. 13 miles; the sand spit extending off the South side of Lintin is on the latter bearing, therefore a vessel will clear it if this islet is kept S. by E. until Lintin Peak bears N. by E., then steer for the West point of Lintin. In a dark night a N.N.W. or N.W. by N. course (according to the tide) should be steered from the middle of the Lintao Channel until the water shoals to 6 fathoms, then steer North, keeping a good lookout for the fishing stakes. On this latter course, if the water deepens above 7 fathoms, keep a little westerly until the vessel is near or above Lintin, where she can anchor. By not deepening above 7 fathoms, she will not be too near Lintin sand spit, there being 9 and 10 fathoms close to. The ebb tide, from the West end of Lintin to the eastward, sets South; but over on the western shore its direction is S.E.

Through TAI-TA-MI CHANNEL.—Proceeding towards the river through the Tai-ta-mi Channel, between the Lema and Kypong Islands, after clearing Cambridge Rock, steer northward for Linting, passing between it and the Samoun group, and then proceed through the Lantao Channel; or pass between the Samoun group and Ai-chau, and then steer for the Lantao Channel or to the N.W. direct for Lafsami. Having approached Lafsami, keep within a mile of its western side, and of the South part of Chung-chau, to avoid the 4-ft. needle rock; after passing Chung-chau steer for Lintin or for Macao Road.

If the channel be taken between the Great Ladrone and Gap Rock, or the narrow passage between the latter and the Kypong Islands, steer to northward, and proceed along the West sides of Ai-chau and Lafsami. Or if bound for Macao Road, there is a more direct passage about a mile wide, with 13 fathoms water, between Pak-leak and Chuk-wan, then on the North sides of Tong-ho and Liungnib, and to the southward of Ty-lo, which tracks

lie nearly in a direct line towards the road. Although this channel is safe in the daytime, great care must be taken to avoid the Raleigh Rock. There is a safe passage between the Great Ladrone and Pak-leak, with 14 to 9 fathoms water, but recollect the sunken rock lying half a mile from the North side of the Little Ladrone, and also the Clio Rock; a vessel taking this route should pass southward of Potoe.

Through **GREAT WEST CHANNEL**.—This channel, on the West side of the Ladrone Islands, is generally used by vessels bound to Canton during the strength of the S.W. monsoon, and to do this they endeavour to fall in with the Great Ladrone bearing about North, or N. by E.; but late in the season when the winds incline to the eastward, or at any other time when they are expected to come from the northward or eastward, it will be prudent for a sailing vessel to make the N.E. head of the Lema Islands, and proceed towards the river by the Lama and Lantao channels. Here the risk of being horsed to the westward by the freshes setting out of the Great West Channel is avoided, and a northerly wind will lead to an anchorage in the river. When typhoons happen on the coast, they generally commence in a moderate gale from the northward, which is a leading wind for these channels, and as the wind commonly veers to the eastward before it blows hard, a vessel with the first of the gale may get well up the river above Lintin, where these storms are less violent than outside among the islands.

As the approach to the Canton estuary is probably more safe than that of any other large river in the world, there being no sandbanks at the entrance, and the channels amongst the islands outside being mostly all free from hidden danger, a stranger should not hesitate to push through the nearest convenient channel without a pilot, if the weather is tolerably clear. But the streams must be attended to, as they set in different directions amongst the islands to the south-eastward according to the prevailing winds; a strong easterly wind generally producing a westerly current or tide, which abates in strength when the ebb should be setting to the S.E. If an outside pilot can be obtained at a moderate rate he may be useful to run the vessel into some cove or place of shelter, if a storm should be approaching, or if she be in a disabled state. Macao Road should not be used if there is an appearance of bad weather, but run well up the river above Lintin.

About South 30 miles from the Great Ladrone, the depths increase to 27 or 28 fathoms; about 60 miles from it, to 42 and 44 fathoms; and soundings extend on the same meridian to about lat. 20° N.; from hence they continue westward towards Hainan Head; but converge towards the land, with deeper water eastward of the meridian of the Ladrone Islands. A vessel falling in with the land in thick weather may easily distinguish whether it be that of the islands eastward of the Great Ladrone; for the Kypong and Lema Islands have soundings of 23 and 24 fathoms close to; whereas the

islands between the Great Ladrone and St. John to the westward have only 10 and 11 fathoms at a considerable distance outside. These are also large and of regular appearance, resembling a coast more than islands; but those to the eastward are detached, high, and uneven, excepting Tam-kan, the largest of the Lema Islands, which is long and of an undulating form.

The freshes out of Canton River set almost constantly from the South end of Montanha, along the shores of the islands to the westward, at the rate of 1 to 2 knots an hour, particularly with strong easterly winds; and although at times there seems to be on the surface a flood tide setting eastward, or into the entrance of the river, the freshes underneath continue to run westward, by which sailing vessels are rendered ungovernable, even in fresh winds. Many vessels from this cause, after getting near Montanha, or between it and Potoe Island, have been drifted nearly to St. John Island whilst making every endeavour, with moderate winds, to keep their heads to the eastward. Steering, therefore, for the Great West Channel, never borrow near San-chau, or the other islands to the westward, unless it is blowing strong from the S.W. to avoid being drifted to the westward. The freshes abate at times, and then weak tides set to the eastward; but as these are not of long duration, a vessel should keep on the eastern side of the channel in deep water towards the Ladrone Islands and Potoe, and anchor instantly if she finds the current drifting her westward.

In the strength of the S.W. monsoon, as before stated, endeavour, if the wind be steady between S.E. and S.W., to make the Great Ladrone, bearing about North, and never fall in with the islands to the westward; this is the more necessary after the middle of August, when easterly winds are likely to prevail several days together, as they are, more or less, at all seasons. If a vessel falls to leeward about St. John, in September or October, she will generally make a tedious passage to Macao if she keeps close along the islands, where the current or freshes setting westward will oblige her frequently to anchor; as these freshes prevail only in shoal water, near the islands, the best plan to adopt is, to stand well off the land, and take every advantage of the favourable shifts of wind, to get to the eastward.

Having passed through the Great West Channel, or if the vessel has anchored in Macao Road, with a leading wind she may weigh with the ebb, if she can haul over north-eastward for Lintin; for the tide will then act upon her port bow, and keep her off the western shore; whereas, with an easterly wind, the flood is likely to drift the vessel into shoal water near that shore. With a fair wind, steer about N.N.E. $\frac{1}{2}$ E. from Macao Road for Lintin; if it be night, from $4\frac{1}{2}$ to 5 fathoms are good soundings; for at low-water springs greater depths ought not to be expected, until several miles north-eastward of the road.

Turning up against a northerly wind on the flood, tack from the West side of the channel in about 4 fathoms, according to the vessel's draught, the

lead being a safe guide along the western shore, where the bottom generally consists of mud. The islands eastward of Macao Road may be safely approached, having 5 fathoms near them, and when past Chung-chau-si the depths will increase to 9 and 10 fathoms towards Lantao. Working from hence to Lintin in the night, stand in to $4\frac{1}{2}$ fathoms in the West part of the channel, and do not deepen above 7 or $7\frac{1}{2}$ fathoms to the eastward. Here the tides become stronger as the vessel proceeds upwards.

In Macao Road, and between it and Lintin, the tides are frequently irregular, setting in a different direction at the surface to what they do underneath, by which vessels are rendered unmanageable in light winds. The ebb is stronger, and continues longer than the flood; the freshes often running out below, when a flood tide at the surface is setting into the river.

LINTIN to the BOCA TIGRIS.—When within 7 miles of Lintin steer for its West point, bearing about N. $\frac{1}{2}$ E., and when abreast the point run northward in soundings from 5 to $6\frac{1}{2}$ fathoms; with a westerly wind borrow on the West side of the channel; if it is easterly keep in 6 to $6\frac{1}{2}$ fathoms with the flood tide. It will be safe to proceed 9 or 12 miles above Lintin, even in the night, with a working wind, the lead being a certain guide, by tacking from the West side of the channel in $4\frac{1}{2}$ fathoms, and from the East side in $6\frac{1}{2}$ fathoms; but when about 6 or 7 miles northward of Lintin, tack in $5\frac{1}{2}$ fathoms from the East side of the channel, for the deepest water is near the edge of Lintin Sand, and if a large vessel begins to shoal on its edge to 5 fathoms, she will not have room to tack.

Lantao is frequently obscured by clouds or haze, but when its summit is visible the West peak of that island affords a good mark for running up this channel in the day. Steering N. by W. or N. by W. $\frac{1}{2}$ W. from the West end of Lintin, draw gradually the high West peak of Lantao on with the West end of Lintin, and continue to bring it more easterly until it is on with Lintin Peak, or a little open eastward of that peak, and keep it so, until the vessel is more than halfway from Lintin towards Lankeet. Then if the wind is contrary, Lantao West peak may be brought nearly to the East end of Lintin, in tacking from the East side of the channel, and well westward of Lintin Peak when tacking from the West side; but on a nearer approach to Lankeet, the West peak of Lantao must not be brought westward of Lintin Peak.

When within 5 miles of Lankeet, the West peak of Lantao must not be brought more westerly than touching the East end of Lintin, when in the West side of the channel; and to a considerable way open with the same when on the eastern side. Here the depths decrease, and there is only about a fathom more water on the East side than on the West side of the channel. A vessel will pass eastward, in 14 ft. water, of all the mud banks at the entrance of the western channels between Cum-sing-mun and Lankeet, by

keeping the northern and highest peak of Kee-ow Island West of S. by W. $\frac{1}{2}$ W., and the summit of Lankeet West of N. by W. $\frac{1}{2}$ W. The pilots sometimes get vessels on these banks in the night; but with those of large draught they are more inclined to borrow close over to the eastward, whereby they have frequently grounded upon Lintin Bar; it will therefore be prudent, when the pilot appears confused or uncertain of his position, to anchor before the vessel shoals her water.

From a position about half a mile off the West end of Lintin, a N. by W. $\frac{3}{4}$ W. course would lead fair through the channel to the East side of Sam-pan-chau, were the tides to run in that direction; but from Lintin they set N.N.W. and S.S.E. nearly as far as the North end of Lintin Bar, and from thence to Sam-pan-chau about N.W. by W. and S.E. by E.

Steering northward, with the West peak of Lantao open a little eastward of Lintin Peak, or keeping in between $4\frac{1}{2}$ and $5\frac{1}{2}$ fathoms, Lankeet Island will be seen making like a saddle, and shortly afterwards two small islets or rocks will appear close to its eastern end. These rocks will be nearly on with the middle of the opening of the Boca Tigris when first seen, and should not be brought more easterly; nor in working ought they to be brought to touch the point of Tiger Island, which forms the West side of the opening, until within $4\frac{1}{2}$ miles of Lankeet; being then northward of Lintin Bar, a vessel may edge over to the eastward. There is no good cross mark to know when clear of the bar; but a pagoda on the western shore bearing S.W. $\frac{3}{4}$ W., will lead northward of its extremity. From the northern end of the bar Sam-pan-chau is a little open with Anung-hoy Point N.N.W. $\frac{1}{2}$ W., and the little hill on the East end of Lankeet is N.W. $\frac{1}{2}$ N., distant about 5 miles.

Shortly after the rocks off the East end of Lankeet are on with the middle of the opening of Boca Tigris, or rather more westerly, if the vessel is within 6 or 7 miles of Lankeet, Sam-pan-chau will be recognized and will then appear under the land, a little eastward of the high round summit of Anung-hoy, a high round hill, sloping to a point on the West side, and forming the eastern boundary of the Boca Tigris. Anung-hoy Peak in line with Sam-pan-chau hummock, N. by W. $\frac{3}{4}$ W., leads westward of Lintin Bar, and eastward of Lankeet Spit. With a working wind keep Sam-pan-chau between the eastern shoulder of Anung-hoy hill and the West point of the same; but that islet must not be opened westward of Anung-hoy Point until clear of the North end of Lintin Bar.

With an easterly wind, to prevent being set by the tide towards Lankeet, keep on the East side of the channel, with Sam-pan-chau shut in a little eastward of Anung-hoy Point, or nearly on with it. When within 4 miles of Lankeet a vessel may stand well to the eastward in working, opening Sam-pan-chau considerably westward of the point, being then to the north-

ward of the extremity of Lintin Bar; do not, however, stand so far over as to bring Anung-hoi Point to touch Chuen-pee, but tack before they come on, for farther eastward the water is shoal. After opening Sam-pan-chau with Anung-hoy Point, which, with a westerly wind, need not be done until abreast of Lankeet, steer then direct for the land of Anung-hoy, giving Sam-pan-chau a berth to the westward of half a mile or more at discretion, in 9 or 8 fathoms; the depths from hence will be 9, 8, and 7 fathoms to the entrance of the Boca Tigris, increasing to 13 and 16 fathoms abreast South Wantong.

If in a vessel of moderate draught, a cast of $3\frac{1}{2}$ or 4 fathoms hard ground be got before Lankeet is seen, in a clear night, she may be certain of its being on Lintin Sand, and will deepen fast on hauling westward into the channel.

Through Fan-si-ak Channel.—If a vessel is drawing 23 feet water, it would be imprudent to attempt the channel on the East side of Lintin, it being very narrow just above and about Tree Island, with a considerable swell in it when blowing strong from the northward. The southern part of the channel between White Rock and the East side of Lintin South spit is about 2 miles wide, with 7 and 8 fathoms, decreasing towards the spit to 5 fathoms. In working northward, do not stand so far West as to shoal to 5 fathoms, or to bring the East side of Lintin to bear North of N. by W. When northward of Tong-ku, if the vessel is of 20 or 21 ft. draught, keep the eastern shore aboard, avoiding the spits of shoal water at the points of the islands, until off the North end of Mah-chau, the shoal off the South end of which will be avoided by not shutting Tree Island in with Mah-chau, or by not bringing the highest peak of Mah-chau westward of N. $\frac{1}{2}$ W., when White Rock is in one with the North end of Fan-si-ak, which is the mark for the South end of Mah-chau spit.

From hence to Tree Island, when standing towards Lintin Bar or Fan-si-ak Bank, keep the lead going, and tack in 4 fathoms or less, according to the vessel's draught; but the lead will be the best guide, as the bank is much curved in shape. Standing eastward, do not bring the North or highest peak of Mah-chau westward of South, and when the South point of Sui-chau bears N.E. do not bring the tree on Tree Island westward of N. by W. $\frac{1}{2}$ W., to avoid the shoal spit of 2 and 3 fathoms, which extends S.S.E. from that island nearly a mile. When thus far, endeavour to pass between Tree Island and the fishing stakes No. 1 (in the Admiralty chart) placed near it; this island is safe to approach close to the rocks, but on the Channel Banks, on the western side of these stakes, the water shoals suddenly to $2\frac{1}{4}$ fathoms, irregular soundings, sand and mud.

Being close to the West end of Tree Island, do not bring the tree to bear more southerly than S.E. $\frac{1}{2}$ E., this bearing being close on the edge of the shore bank. Standing westward, White Rock should not be brought east-

ward of the saddle on the East end of Lintin, or the East end of the fishing stakes No. 3 (in the chart to the northward of N.W. by N., the lead not being a sufficient guide for the Channel banks. If the fishing stakes be not removed, they appear to be a preferable guide to the land mark, being always discernible, but either may be used in clear weather. When within half a mile of the stakes No. 3, the passage becomes wider, extending from the shore bank to Lintin Bar, with 4, $4\frac{1}{4}$ and $4\frac{1}{2}$ fathoms in it at low water, shoaling gradually on either side, so as to render the lead a guide in tacking, the bottom being very soft mud.

If close to Tree Island with a leading wind, steer direct for the centre of the fishing stakes No. 3, and pass them on either side, as circumstances require.

There is another range of fishing stakes (numbered 4), bearing S.W. $\frac{1}{2}$ W. of No. 3, which will, when near them and bearing South, warn a vessel of her proximity to Lintin Bar.

If the vessel is under 20 feet draught a wider range may be taken, but she ought, if possible, to follow the above directions, and at any rate pass between Tree Island and the fishing stakes No. 1, or close to their western end, and avoid the Channel banks. If drawing 17 feet or under she may pass up or down any part of the channel, keeping to the eastward of Fansiak well over towards Mah-chau, avoiding the shoal spits which project from the ends of the islands.

Tides.—In the Fansiak Channel it is high water, full and change, $1^h 0^m$, but the rise is irregular, especially at neaps, the rise and fall being then only $2\frac{1}{2}$ to 3 ft., and from 6 to $8\frac{1}{2}$ ft at springs; velocity from 3 to 4 knots, and from 2 to $2\frac{1}{2}$ knots at neaps.

A vessel proceeding up with a working wind should weigh instantly the tide slackens sufficiently for her to make any progress, in whatever part of the channel she may have anchored. The passage between Lintin and Fansiak should not be attempted in vessels of large draught, having only $2\frac{1}{2}$ to $2\frac{3}{4}$ fathoms in it at low water.

The **CHU KIANG** or **PEARL RIVER**, commonly called **CANTON RIVER**, rises about 30 miles North of Canton (or 100 miles from the sea) in two streams, which unite at 10 miles above that city; at this junction a long narrow stream connects it with the North river by two branches, one at Sam-chui, the other 10 miles North of that place. The *Tung Kiang* or East river, formed between the islands Chuen-pee and Ty-cock-tau, or perhaps more strictly between Ty-cock-tau and the island of Anung-hoy, is divided by the Wan-tong Islands into two channels, the eastern of which is generally used by vessels of large draught, and is named Boca Tigris, and the western is called Bremmer Channel.

CHUEN-PEE POINT, the South extreme of Chuen-pee Island, is close to a small peak called Chuen-pee Hill, and N.N.E. $\frac{1}{4}$ E. $1\frac{3}{4}$ miles from Sam-pan-chau. On the N.W. point of the island is a small watch-turret, with a fort under it; and midway between this point and Chuen-pee Point is a ledge, named *Pratt Rock*, lying a quarter of a mile off shore, with 6 to 9 fathoms close outside.

Anchorage.—There is a small bay with sandy beach on either side of Chuen-pee Point, and fresh water may be obtained in that on the eastern side; but vessels of large draught cannot anchor near it, the soundings being shoal on a sandy flat, extending eastward and south-eastward from the point. The anchorage is in 6 to 7 fathoms, about one-third of a mile from the beach on the western side of the point. At this anchorage it is high water, full and change, at about 2^h 0^m, and springs rise 7 to 8 $\frac{1}{2}$ feet.

Anson Bay, between Chuen-pee and Anung-hoy Islands, is very shoal, affording only a harbour for boats in Junk Creek.

Bower Point, the S.E. extreme of Ty-cock-tau, form the western point of entrance to Canton River. From this point to Sam-pan-chau, the West side of Chuen-pee Channel is bordered by a shoal flat, over which boats can only pass to *East* and *West Ow-chau*, the two small islets lying southward of the point.

Anung-hoy Point, the S.W. point of Anung-hoy Island, forms with Keshen Point, half a mile to the N.W., the eastern side of the Boca Tigris. The principal fortifications for defending the strait are built on this face of Anung-hoy, and Anung-hoy Peak rises immediately behind them to the height of 1,500 ft. These are the first to attract attention, and consist of a long range of white granite masonry pierced with embrasures at the water level, with a wall running up the steep in a semicircle, as a protection from attack in rear.

Wantong Islands.—North and South Wantong are two small islands lying nearly in mid-channel abreast Anung-hoy Point, and form the western side of the Boca Tigris. They bear N.N.W. and S.S.E. from each other, distant a third of a mile apart, and are surrounded by a bank which extends $1\frac{1}{2}$ mile in a S.E. by S. direction from the southernmost island, at which distance the depth is only 4 fathoms. These islands are completely encircled with white granite batteries.

Directions.—From mid-channel abreast San-pan-chau with a leading wind a N.W. by N. course for $4\frac{1}{2}$ miles will lead to the entrance of the Boca Tigris; but with a turning wind be careful, when standing towards Chuen-pee, not to borrow too close to Pratt Bock. When standing westward towards the shoal flat extending south-eastward of South Wantong, tack before the eastern extreme of Tiger Island touches the eastern part of the fort in North Wantong.

The **BOCA TIGRIS** has deep water and uneven bottom, and is much con-

tracted by the *Chain Rock*, above water, lying E.S.E. a quarter of a mile from the East point of North Wantong; and although the passage between it and Anung-hoy Point is too narrow for working a large vessel, she can always back and fill through with the tide. The tides runs strong through in eddies, and vessels generally keep nearest the eastern shore in passing. If detained here by the Chinese authorities, the best position to anchor is in 7 or 8 fathoms, abreast of and about a quarter of a mile northward of the fort and turret on North Wantong, taking care to avoid the Wantong Rock, lying North nearly a cable's length from its eastern point.

The *Bremer Channel*, westward of the Wantong Islands, carries a depth of 10 to $5\frac{1}{2}$ fathoms, and was frequently taken by Her Majesty's ships during the operations in Canton River in 1841. If intending to use this channel, the first village seen to the northward of Bower Point open South of the first bluff point above *Ty-cock-tau* Fort (this latter point has the appearance of an island), will lead southward of the South extreme of the shoal flat off South Wantong; and the East extreme of Tiger Island just open westward of the West end of South Wantong will lead along its western edge in 5 fathoms. When abreast of North Wantong, about $1\frac{1}{2}$ cable from its West point, steer about North to avoid the shoal flat on the western shore.

Duff Rock.—This dangerous pointed rock, with only 18 ft. water over it, and 7 to 9 fathoms around it at low water, lies N.N.W. $\frac{2}{3}$ W. nearly a mile from the eastern end of North Wantong, with the small round hummock on the western part of South Wantong seen over the western slope of North Wantong (between the small redoubt with a tree on it and the point), and the high land of Geefou Island touching the western brow of Tiger Island. A vessel will pass eastward of the rock by not bringing Sam-pan-chau to touch the East end of North Wantong, until she has approached Tiger Island so near as not to see the high land of Geefou to the westward of it.

TIGER ISLAND.—N.W. $\frac{1}{2}$ N. $1\frac{3}{4}$ mile from the East end of North Wantong is the Tiger's Claw, the S.E. extreme of a remarkable high island, called by the Chinese *Ty-fu* and by Europeans *Tiger Island*, the summit of which appears cleft. A shoal extends S.E. from the Claw, and at the distance of a quarter of a mile the depth is only $3\frac{1}{4}$ fathoms. There is a fort on the N.E. side of the island. This island, the upper end of which is a remarkable mass of rounded granite with precipitous sides, rises to the height of about 400 feet. On its eastern face stands a battery similar to that of Anunghoy, which completes the defence of the river entrance.

Bate Rock, discovered by the late Captain W. T. Bate, R.N., in 1857. lies 2 cables northward of the North side of Tiger Island, with the fort on that island bearing S.E. $\frac{1}{4}$ S.; the highest part of the island (eastern summit) S. $\frac{2}{3}$ E.; and the N.W. extreme of the island nearly in line with a small granite boulder on the summit of the hill on the western shore of the river

S.W. $\frac{1}{2}$ W. It has only 14 ft. on it, is steep-to, there being 10 fathoms mud close to the eastward, and 7 fathoms between it and the island. To pass outside or N.E. of the rock, keep the East extreme of North Wantong open of Tiger Island Fort.

Towling Flat.—About a third of a mile eastward of the fort on Tiger Island, is a projecting elbow of Towling Flat, which, together with Towling Sand, are much increased, and have extended considerably to the westward since the survey of this river in 1840. The sand is now an island covered with vegetation, and never wholly under water even at the highest tides, Tomb Point (the next point N.W. of Chuen-pee Point) must be kept *well* open of Keshen Point.

Vessels turning to windward from the Boca Tigris towards Tiger Island may stand to the eastward and shut in the high land of Chuen-pee with Anung-hoy until abreast the S.E. point of Tiger Island. If of large draught they had better back and fill, between the island and the flat, as the tides are strong.

The Small Bar is the name given, in the chart of this river, by Lieut. D. Ross, I.N., 1815, to a small bank of hard ground lying nearly in mid-channel, about $4\frac{3}{4}$ miles northward of Tiger Island. It is now more than a mile in extent, North and South, and near its centre, West, two-thirds of a mile from Blake Point, a patch was found with only 10 ft. on it; the depths on the other parts of the bank were 2 to 3 fathoms.

Second Bar.—The channel for vessels of large draught becomes very narrow abreast of Second Bar Creek, on the eastern shore of the river, and the services of a pilot are requisite. The Second Bar is a large collection of shoals, 3 miles in length in a N. by W. $\frac{1}{2}$ W. direction, lying between Second Bar Creek and Second Bar Pagoda. There are two channels over it, on either side of the central banks or middle grounds, which have varying depths of 13 to 17 ft. on them, and several shoal patches of 9 to 11 ft. The western channel is about 2 cables broad, and carries 18 to 26 ft. at low water; but there are two patches in it of 14 ft. water, lying respectively W. $\frac{3}{4}$ N. and W. by S. of the opening of Second Bar Creek. The West point of Tiger Island in line with Grassy Tongue, S. by E. easterly, leads through in not less than 14 ft. at low water, touching on the banks.

The eastern channel is always taken by the pilots, as it is easier, more direct, and along the shore. Its southern part is entered at 7 cables above Amherst Point, but a shelf steep-to, extending 2 cables off the intervening shore, must be avoided. Having passed this shelf stand in North a little easterly towards Second Bar Creek to get the leading mark on, which is Wantong Tower on with the grassy edge of the land at Amherst Point, S. by E. $\frac{1}{2}$ E., when abreast of Second Bar Creek. From hence the channel is only about a cable wide for a mile, and this mark will lead through in not less than 17 to 20 feet at low water, provided the vessel be sheered to the

eastward about half a cable to avoid a 14-ft. patch on passing the first little creek, about half a mile above Second Bar Creek; after which the leading mark may be regained or the tower kept a little shut in with the point. The banks are cleared when Second Bar Pagoda bears W. by S.

The Town of Tung-kuan, about 10 miles eastward of Second Bar, may be reached by two principal creeks, each of which has several outlets.

Blenheim and Whampoa Passages.—At 3 miles above Escape Creek, and $5\frac{1}{2}$ miles above Second Bar, the river divides into two main branches, the Whampoa and Blenheim Passages, which meet again at Honam Point, just above the city of Canton, and opposite the foreign settlement. By the Blenheim, or southern passage, the distance to Honam Point from the junction is $16\frac{1}{2}$ miles, and by the Whampoa, or northern passage, 14 miles. Canton lies on the latter below Honam Point, and 8 miles below the city is Whampoa, the anchorage for foreign vessels. Above Whampoa the river in some parts is not navigable, even at springs, by vessels drawing more than 13 ft., so that those of heavy draught have to proceed to Canton by Blenheim Passage.

WHAMPOA.—At 2 miles above Escape Creek, and near the East bank of the River, is First Bar Island, low and flat, westward of which are the four flat islands, smaller but similar, and then the larger Danes Island, the western part of which is covered with hilly ground which marks the position of Whampoa. The navigable pass into the Whampoa Passage is that which is next westward of First Bar Island, carrying from 20 to 30 ft. water.

Whampoa is known to foreigners as Bamboo Town. Above the town lie the premises of the Union Dock Company, next the hill with a chapel embosomed in foliage at its foot forming the Parsee burial ground, and the British Vice-Consulate perched on the brow of a hill, behind which lie the basins and workshops of the Hong Kong and Whampoa Dock Company. Fronting these is English Reach, and above it, south-westward, American Reach. Opposite is Sulphur Point, formed by the confluence of Elliot Passage (of which American Reach is a part), and the direct channel to Hong Kong. Whampoa New Town extends from Sulphur Point along the left bank of American Reach.

The Anchorage is in English and American Reaches, the best position being between the North sides of Danes and French Islands, and Whampoa New Town opposite. It is a safe anchorage with a moderate tide, in from 5 to 6 fathoms, soft mud bottom; there is, however, scarcely room for two large ships to moor abreast, which occasions the lower part of the shipping, when there are many arrivals, to lie moored in English Reach, abreast the entrance of Junk Creek.

Tides.—At Whampoa, it is high water, full and change, in the month of March, at 1^h 40^m, in April, at 1^h 15^m, and in May and June, at 0^h 30^m; and the rise at springs is 7 to 8 ft. In March the day and night tides rise to the

same level. From April to October the day tides are the higher; and from November to February the lower. In May and June the level of spring tides is 4 ft. higher, and that of neaps 2 ft. higher than in March.

Docks.—There are nine docks of various classes. The Hong Kong and Whampoa Dock Company have four, of which two are of granite, one of wood, and two mud docks available for small vessels at low charges. The Union Dock Company possess four other docks. *Dock A*, the principal dock at Whampoa, is on the N.W. side of Danes Island, under the cemetery hill, and was formerly called Couper's Dock. Its length over all is 550 ft., breadth 80 ft., depth over sill at springs $16\frac{1}{2}$ to 17 ft., and at neap tides $13\frac{1}{2}$ to 15 ft. It can be used as either one or two docks, being fitted with two caissons, and can be pumped out in about 4 hours. There is a pair of shears, capable of lifting 50 tons, on the jetty alongside which vessels can lie at all times of tide. Both A and B, the other granite dock, are, as regards capacity but not depth over sill, the largest docks in China, and are fitted with every appliance in the way of caissons, powerful steam-pumps, &c., to ensure safety and despatch in the work.

Directions.—Having entered Canton River by the Boca Tigris, be careful when approaching Duff Rock not to bring Sam-pan-chau to touch the East end of North Wantong, until the high land of Geefu Island is shut in with the western part of Tiger Island. In passing through the channel between the latter island and Towling Flat, observe that Tomb Point, on Chuen-pee Island, kept well open of Anung-hoy North Fort, will lead westward of the western edge of the flat; and the eastern end of North Wantong kept open of Tiger Island Fort will lead N.E. of Bate Rock. With a working wind, a vessel of large draught had better back and fill through this channel, as the tides in it are strong.

After passing Tiger Island, keep the watch tower on Chuen-pee Fort open of Anung-hoy North Fort, until Bower Point, the East extreme of Ty-cock-tau, is in line with the eastern side of Tiger Island; then steer up the river with this latter mark on, and it will lead in the deepest part of the channel, but nearest to Towling Island, in 7 or 8 fathoms water. When the remarkable high part of Geefu is on with the highest land to the westward, or bearing S.W., keep more eastward, and open Bower Point again. Thence steer to the northward, pass on either side of the small Bar, and attend to the soundings on the chart.

The two Fairway marks for crossing the Second Bar are given in page 982; but the services of a pilot are here indispensable to a vessel of 20 ft. draught, unless the channel be previously buoyed; for the knolls or shoal patches being formed of sand and gravel mixed with mud, are subject to alter in position by the freshes of the river and the spring tides, which also render the navigable channel changeable. A pilot can be obtained from amongst the fishermen on the spot, who then buoy the channel with their

sampan, but sufficient time should be given them to sound with their bamboos and to take their stations properly, or else a vessel is likely to take the ground. Vessels often ground and lie in a dangerous state for a tide; and this often proceeds from two or three pushing over together, as there is no time to be lost after the water has risen sufficiently for a vessel drawing 23 or 24 ft. to pass over.

Vessels of large draught proceeding up the river from an anchorage below the Second Bar in the N.E. monsoon, or with a weather tide, should be under weigh by the last quarter flood, to save the tide across the bar; for the channel between the knolls being very narrow, they must back and fill through; if of moderate draught they may weigh much earlier. The difficulty in crossing the bar is in ascertaining correctly the shoal patches on either side the channel, and it will be best to place the boats on them at the first of the flood. When the Second Bar Pagoda bears W. by S., the bar is crossed, and the bottom will be soft and loose, unlike that on the bar, which is in parts hard and stony.

After passing the Second Bar, keep between a third and half a mile from the eastern shore until First Bar Island is approached, when the river begins to be contracted and its navigation requires great caution. When Whampoa Pagoda is observed just on with the northernmost clump or hill on Danes Island, haul out more into the middle of the river to avoid the shoal ground off the South side of First Bar Island.

As no safe marks can be given for leading between First Bar Island and the easternmost of the Flat Islands, towards the First Bar, it will be prudent for a stranger, if without a pilot, to buoy the S.E. extreme of the spit extending off the eastern Flat Island, and also the Brunswick Patches. The best route appears to be when the South Chop-house on the southern shore of the river bears S.S.W., to haul over to First Bar Island to avoid the spit, and then steer in about N.W. $\frac{1}{2}$ N., passing along the western face of the island at about a cable. The open pile beacon on the S.E. end of No. 1 Flat Island marks the extremity of a mud bank. When Whampoa Pagoda is seen clear to the northward of the Flat Islands, steer for the northern shore, which must be skirted at about half a cable, passing through the narrow 4-fathom channel northward of the Brunswick Patches.

As the northern patch is approached, or when the large house inland bears about N. by W., be careful in preserving the distance of half a cable from the shore, and when the house bears eastward of N. by E. the danger will be passed. Thence steer towards Whampoa through Cambridge Reach, borrowing towards the northern shore. Entering English Reach, the southern or Danes Island shore is generally preferred to avoid the shoal flat off Junk and Watson Islands, taking care to give a berth to the cluster of rocks, covered at half-flood, near Jardine Point, the East

point of entrance to French River. The anchorage off Whampoa is in 5 to 6 fathoms, over soft mud bottom; but there is scarcely room for two large ships to moor abreast, which occasions the lower part of the shipping, when there are many arrivals, to be moored in English Reach.

Whampoa to Canton.—The lower part of the City of Canton is 8 miles, and the Shamien or Foreign Concession 10 miles above Whampoa. If proceeding by the Whampoa Channel, as this passage is called, it is better to take a pilot for the first time, although for gun-boats the Admiralty charts are a sufficient guide if no radical changes in the channels of recent occurrence have been reported. Some caution may be required in passing the Whampoa barrier if the tide be strong, in which case it is preferable to hug the South bank at the mouth of Fiddler's Reach. Another part where care is required is just below Canton, where the city is first fully opened out clear of Napier and Kuper Islands, for a reef extends nearly a cable into the river from the South bank. When, therefore, the small Suburbs Pagoda on the S.E. or nearest angle of the city wall comes in line with Gough's Hill, which is a little to the right of the tall, square, conspicuous red pagoda of five stories, N.N.W. $\frac{1}{2}$ W., sheer out from the South bank into mid-stream. The rocky ground above the Dutch Folly, as the small island abreast the centre of the city is called, has been recently buoyed and lighted, and now therefore presents no difficulty to navigation.

Close to the Dutch Folly are two wooden buoys to mark the fairway between some rocks. One is in 8 ft. water, painted in red and black vertical stripes, to mark the starboard side of the channel; the other is in 4 ft., with green and black vertical stripes, to mark the port side entering.

Lights and Beacons.—On the sunken rocks above the Dutch Folly are three square stone beacons, from which, at night, *fixed* lights are exhibited. Two *red* lights are on Nos. 1 and 2 red beacons on the starboard hand entering, and one *green* light is on the port hand on No. 3, a green beacon.

To Canton through Blenheim Passage.—In the Blenheim Passage leading to Canton the only two parts where difficulty is experienced are the passage of the Barrier and Parker Point Bar. From Escape Creek above Second Bar, a mid-channel course is pursued until nearing the southern shores of the Flat Islands. Close these, keeping very near to island No. 3, and also the south-eastern face of Danes Island, but sheer well off as soon as French Creek westward of Danes Island opens out, and steer well over towards Terrace Head in Kellett Reach, a hill 147 ft. high, on which the ground is cultivated in terraces from base to summit. At the head of Kellett Reach is Larkins Point, an earth cliff 40 ft. high, and $1\frac{3}{4}$ cable below it is Junk Rock, under water, 120 yards from the eastern shore. Above Larkins Point fishing stakes extend halfway across the river from the South bank, but they present no obstruction as the channel is now along the northern shore for some distance.

Bremer Point, having a group of hills with cliffs at their base, is next closely rounded to avoid a shallow middle ground tailing from High Island half a mile down stream. High Island, of 88 ft elevation, lies in the centre of the river, narrowing the northern or navigable channel to 1 cable. The *Comus sunken rock*, 60 yards from the North bank, further narrows this channel; it lies S.W. of the highest of the hills of Bremer Point, and $1\frac{1}{4}$ cable East of the North point of High Island, which is very steep-to. Above High Island is Brown Reach, which has a depth of 24 to 25 ft., and where H.M.S. *Blenheim* anchored. Above Galbraith Hill Point, on the South bank of Brown Reach, the river splits round the low flat island of Changshan. Senhouse Reach, the channel South of Changshan, is seldom used, the deepest water at its western part being only 11 ft. The northern channel is Maitland Passage, which carries deep water as far as the short cut which connects it with Elliot Passage on the North; then the depth decreases to 13 ft. (20 to 21 ft. at high water springs), on either side a narrow middle ground of 10 ft. Keep along the North shore past Changshan, above which more fishing stakes are seen southward of the fairway. Above the next hilly ground on the South bank, and between it and Hamilton Creek, the river is broad and deep, and without obstruction, and therefore affords excellent anchorage. Above this, vessels drawing 13 ft. cannot go.

If proceeding to Canton the deep water must be quitted for a narrow gully along the North bank, carrying 10 to 12 ft., which leads up to the Barrier Passage. Caution is required here, for the channel is irregular both in its conformation and depth, and the middle ground of 7 to 9 ft., which bounds it on the South, is of the same character; this shoal, which extends from the Barrier to fully half a mile below it, being entirely northward of the centre of the river.

The Barrier is an artificial obstruction of stones and piling, constructed to prevent the approach of large ships to Canton, during the first China war. Recently, however, the passage through it by the northern bank has been widened to 100 ft., and deepened to 11 ft., besides being rendered more practicable by the establishment of improved beacons and lights.

Two wooden beacons, painted *white*, and surmounted by a *black* disc 2 ft. in diameter, have been recently erected on the North side of the Barrier. A scale to show the depth of water is affixed to each beacon, and lights will be shown at night to indicate the passage.

The course for the first half mile above the Barrier lies along the North bank, and there are shoals of 7 to 9 ft. in the centre of the river, caused by this obstruction to the current, which are probably of a shifting character.

Parker Point Bar is situate at a crossing from this branch of the river into that from Canton, of which Elliot Passage, leading to Whampoa, is a continuation. It is shoal in consequence of being out of the scour of the tides of either branch. Its shoalest part, 8 to 9 ft., is between Parker and 49th

Points. Vessels of 17 ft. draught have passed over after examination and buoys of the best channel.

Macao Fort Passage is a reach of $3\frac{1}{4}$ miles, leading straight up from Parker Point Bar to the Foreign Concession at Canton. Macao Fort, a picturesque object on an islet in the reach, may be passed closely on the East side, but N.N.E. of the northern extremity of the fort lies a sunken rock exactly in mid-channel, between the fort and the shore. After passing this, keep in the centre of the river, for there are rocks below water on either side, close to the bank; and abreast Birds' Nest Fort, just below the Honam suburb, on the East bank, two other sunken rocks lie close together, 130 yards from the shore.

The ebb stream in Macao Fort Passage, at springs, runs from 3 to 4 knots an hour.

Elliot Passage is an intermediate branch of the river leading to Whampoa from Canton, and is indeed the direct continuation of the Macao Fort Passage. It was originally a fine, deep-water channel, but the large Barrier 6 miles above Whampoa, of similar construction to those in the other passages, has caused the bed of the river, for 1 mile on either side the Barrier, to silt up, and not more than 8 ft. can with certainty be carried through the Barrier Channel, which is close along the South Bank. At Whampoa, Elliot Passage is entered from American Reach. Both this and other intersecting creeks in the vicinity may be navigated with the aid of the Admiralty chart, having been surveyed in 1857.

CANTON, the capital of the province of Kwang-tung, stands on the North bank of the river, about 31 miles above Boca Tigris, 70 miles from Macao, and 74 miles from Hong Kong. It is surrounded by a strong wall 5 miles in circumference, the foundation of which is of red feldspar rock, and the upper part brick. The wall varies from 25 to 40 ft. in height, and is 20 ft. thick, having an esplanade on the inside, and is accessible on three sides of the city.

To the West of the city a concession was obtained after the bombardment and destruction of Canton on December 28-9, 1856, and an area of 24 acres was levelled and planted, and a quay wall built. Of this area, four-fifths have been appropriated to the British Government, and one-fifth to the French, the latter portion occupying the eastern part. Besides the consular offices and the residence of the Vice-Consul, there is a church, library, reading-rooms, &c., and there are two cemeteries within a moderate distance of the concessions. The Consul, for political purposes, resides within the city at an official yamun.

Off Shamien the river is broad, forming a commodious anchorage for large steamers, the deepest water, 18 to 22 ft., and good holding ground, being within 150 yards of the river wall of Shamien, but sailing vessels are restricted to the anchorage of Whampoa.

Supplies.—The markets of Canton are well supplied with provisions at moderate prices; beef, poultry, and fish, fruit and vegetables at all times, to which are added, in winter, mutton and game in plenty.

War and rebellion, the opening of Hankow as a shipping port for tea, and the facility with which smuggling can be carried on, have robbed Canton of the pre-eminence it so long enjoyed in commercial prosperity; of late years foreign trade has declined about one-half, and the native traders are rapidly absorbing in their own hands the dealings which before were the means of enriching foreign houses of business. Tea and silk are the principal exports, the imports are cotton goods, rice, opium, &c.

Climate.—Canton enjoys a much more temperate and salubrious climate than most places situated within the tropics, and neither epidemics nor malaria prevail there. In ordinary years the temperature ranges from 42° in winter to 96° in summer; the extreme range is from 38° to 100°, but these are rarely reached. The seasons correspond with the period of the monsoons, the hot season being from May to October, and the cool season from the middle of October to the latter part of April. The S.W. winds set in early in April, but do not gain force until May, when rain becomes abundant, and the thermometer rises to 85°, and even higher. June is a dry and sultry month, whilst in July and August frequent showers are of almost daily occurrence, which, with the strong monsoon, temper the extreme heat, which averages 80° to 88°. September is again sultry, but the nights begin to grow cool, and October, though warm, is usually not an unpleasant month. The first steady blast of the N.E. monsoon, in the early part of November, sending down the temperature to 55., brings a sensation of bitter cold to the constitutions of Europeans, relaxed by the preceding heats; but the weather of the ensuing months, in which constant sunshine, a moderately cold, but agreeable temperature, and clear skies, prevail almost uninterruptedly, is not to be surpassed in any quarter of the globe. Ice sometimes forms in January, and the thermometer has been registered at 29°. A fall of snow, 2 inches deep, occurred in February, 1835. Fogs are common in February and March. Great precaution must as a necessity be observed, even by long residents, to avoid exposure to the sun and chills, and this with temperance in diet will ordinarily ensure immunity from sudden disease. Fever and ague, and sunstroke, are brought on by very slight exposures, and bowel complaints are the natural consequences of imprudent indulgence in fruits, cold beverages, &c., and much attention should be paid to suitable clothing. Chlorodyne, Lamplough's saline mixture, and quinine will always be found useful in this and similar climates.

Tides.—It is high water, full and change, in the river off Canton, in March, at 2^h 40^m, in May and June at 1^h 40^m, in September and October at 2^h 12^m; the springs rise about 5½ ft., neaps, 4½ ft. During the N.E. mon-

soon the tides rise 2 to 3 ft. higher in the night than in the day ; but in the S.W. monsoon the day tides are the higher.

The **SI KIANG** or **WEST RIVER**, also called the *Blue River*, is 500 miles in length from its source to its mouth, which is 9 miles S.S.W. of Macao, and receiving in its course some large tributaries, drains with them the entire province of Kwang-si. At Sam-shui, 75 miles from the sea, where its course turns from South to East, it receives the waters of the *Peh-kiang*, or *North River*, which rises in the northern part of the province of Kwang-tung. From the North River and from the West River, below Sam-shui, are several communications with Fat-shan, Canton, and other parts of the Canton River.

DELTA of the SI KIANG and ADJACENT RIVERS.—Between Macao, Sam-shui, and Canton, on the western side of the estuary of Canton River, is a large tract of alluvial land, the delta of these rivers. A network of streams and canals intersect this space, which, from the greater elevation of land on the Si kiang, discharge themselves into Canton River, and thus, together with the Tung kiang or East River, which drains a large central portion of the Kwang-tung Province, flowing into Canton River at its eastern side, cause the great volume of water in its estuary so disproportionate to its size. The greater portion of the delta has been reclaimed in times long past, by embankments, and the process is going on at the present day.

The principal channels traversing this delta fall into the Canton estuary, between Cum-sing-mun and the second bar ; some small upper branches in the vicinity of Fat-shan, falling into Canton River between Canton and the upper part of Blenheim Passage. The principal of these streams, the Tam-chau Channel, traverses the entire length from Sam-shui (at the junction of the Si kiang with North River) in a S.E. direction, with branches to all the principal towns and districts in the delta. In the central district of Shun-tuk nearly all the channels are connected, and one, which passes South of the town of Tai-lung, joins them to the Si kiang 2 miles South of Kum-chuk. Besides these there is the narrow channel used by the *Nemesis*, which, entering from the Broadway 5 miles above Moto Fort, runs through Liau-si-wan, and joins the Wang-mun or the first channel North of Cum-sing-mun.

Between Cum-sing-mun and Lankeet are the Wang-mun, Tam-chau, and Ty-cock-tau Channels. They enter the West side of the estuary through extensive mud banks, their course running through level lands dotted with many island-like hills. The waters are kept in their channels by artificial embankments, without which almost the whole of the rice fields would be flooded at high water. The rice lands are principally East of Tai-lung ; West of that town the land, although having the same features (level with island-like hills), is more elevated (above high water level), and cultivated with mulberry plants.

The embankments are wide, but being planted with fruit trees, with here and there houses of labourers, leave but a paved path, about 6 ft. wide, for foot passengers. The rivers and numerous canals are the ordinary mode of transport, as every field is approachable by a canal. The towns are also entered by water, the channels being staked across; in some cases an entrance is left wide enough to admit a large junk, the opening being closed by rude gates, as at Tam-chau; in others these barriers consist of rows of stakes, with their heads above high water, closely driven across the whole breadth of the river, leaving but a narrow and circuitous channel near one bank, through which the current runs with great strength, and often the stakes are level with low water.

The general course of the Tam-chau Channel is from the N.W., as is also that of the Ty-cock-tau Channel, which falls out of the Saiwan Channel below the town of Saiwan. The Saiwan Channel is entered from Canton River, North of Whitcomb Island; the course up it is more westerly, and it joins the Tam-chau Channel N.E. of Tai-lung. Money penny Creek leads from the latter into the Fatshan branch above Haycock Island.

The Tai-lung, which is South of the town of that name, runs West from the Tam-chau Channel, and by a winding course joins the Si kiang by the Junction Channel. The Wang-mun receives three branches, the Nemesis from the S.W., and the Sailam and Kerr Channels from the N.W.; the latter also joins the Si kiang through the Junction Channel. Besides these main channels there are smaller channels at right angles to them, forming connections at different points of their course. The principal of these have been explored, and all found to have more than 6 ft. in them at low water springs.

To describe this network of streams, which have been well examined by our officers, would be a hopeless task without the elaborate plans they have drawn up of their courses and connections; and these charts, moreover, are the best guides. We therefore omit the details which have been given, the principal of which are those by Commander C. J. Bullock, the late Captain Bate, Captain Nolloth, &c.

Tides.—In the month of February it was high water, full and change, in Cum-sing-mun Harbour, at 12^h 6^m, and at Lankeet Island at 11^h 20^m. In March it was high water in the Tai-lun Channel (Kerr Point) at 1^h 30^m, in the Wang-mun at 11^h 50^m, and in the Junction Channel at about 2^h. At all these places springs rose 6½ ft., neaps 5½ ft., and neaps ranged 3¼ ft.

In the Saiwan, Tam-chau, Tai-lung, and Junction Channels the flood sets to the westward, and the ebb to the eastward towards Canton River. In the summer, when the day tides are the higher, it appears to be high water nearly all day at springs in some of these channels, owing to the day tide only falling about 2 ft.

CHAPTER XXI.

EAST COAST OF CHINA, BETWEEN HONG KONG AND THE RIVER MIN.

TATHONG CHANNEL is formed between the West side of Tamtu Island and the East side of Hong Kong; close to the latter, about $1\frac{1}{4}$ mile northward of Tylong Head, lie two small rocky islets, and between these islets and the South extreme of Tamtu is the *Tathong East Rock*, above water.

Cape D'Aguilar Lighthouse, sometimes called Tylong Head lighthouse, is situated at the S.E. extreme of Hong Kong Island. It is a stone tower, 57 ft. high, which, together with the necessary buildings, is painted white. The light is fixed, elevated 198 ft. above the sea, and visible 23 miles off as follows:—visible to the eastward between N.E. and S.E. $\frac{3}{4}$ E., excepting where the Ninepin and Waglan Islands intervene; *obscured* between S.E. $\frac{3}{4}$ E. and S.E. $\frac{1}{4}$ S. by Soon Kong Island; *visible* between S.E. $\frac{1}{4}$ S. and S.S.E.; *obscured* from S.S.E. to S.W. by S. by Lochow, Pootoy, and Lema Islands; *visible* from S.W. by S. to W. by S. $\frac{3}{4}$ S., except to vessels when S.W. of the Samoun group; and *visible* over Tathong Channel, with the exception of a small portion obscured by Shicko Head. Position lat. $22^{\circ} 12' 15''$, long. $114^{\circ} 15' 45''$ E.

Cape Collinson Lighthouse, on the eastern side of Hong Kong Island, was illuminated on the 1st of March, 1876, and shows a *fixed* light, at an elevation of 200 ft., visible 8 miles off. This light appears *bright* in the Tathong Channel between N.N.W. and S.S.E., and shows *red* to the westward of those bearings. The red light covers the Tathong and Bokhara Rocks to the southward, and the dangers extending out from Sywan Bay to the northward, so that vessels approaching Victoria Harbour from the southward and eastward will clear all the dangers on the western side of Tathong Channel by keeping in the bright light.

Bokhara Rocks are two rocky heads, with nine fathoms between them. The *S.W. rock* (on which the S.S. *Bokhara* struck) is a pinnacle rock with 3

fathoms on it at low water, from which Tathong Rock bears N. by W. $\frac{1}{4}$ W., and Cape D'Aguilar lighthouse W.S.W. A *black and white chequered* buoy has been moored in 9 fathoms close to the western edge of S.W. Bokhara Rock, with Tathong Rock bearing N. by W. $\frac{1}{4}$ W., and Cape D'Aguilar W.S.W.

N.E. Rock is a pinnacle rock with 18 ft. water over it, situated about $1\frac{1}{2}$ cable N.N.E. $\frac{1}{3}$ E. from S.W. rock.

From the centre of N.E. rock, Tathong Rock is in line with the extreme of Cape Collinson, bearing N. by W. $\frac{3}{4}$ W.; the N.W. point of Beaufort Island is just shut in behind the rocky islet to the southward of Cape D'Aguilar, S.W. southerly; and Cape D'Aguilar lighthouse bears S.W. by W. $\frac{3}{4}$ W. distant $8\frac{1}{2}$ cables.

Directions.—Vessels bound to the southward through Tathong Channel, and wishing to pass between Bokhara Rocks and Hong Kong Island, should, after passing to the eastward of Tathong Rock, bring the summit of Beaufort Island in line with Cape D'Aguilar bearing S.S.W., and steer with that mark on, until Tathong Rock is in line with the left extreme of Taitoo Island N. $\frac{1}{3}$ W., which mark should be kept on, until abreast of Cape D'Aguilar. If passing to the westward of Tathong Rock, the latter mark should be brought on as soon as convenient after passing that rock.

Vessels passing to the eastward of Bokhara Rocks should not open Tathong Rock to the northward of Pottinger Peak, until the southern extreme of Tytam peninsula is open South of Cape D'Aguilar.

The most direct route for steam vessels leaving Hong Kong by Lyemun Pass and through Tathong Channel is to pass West of Tathong and Bokhara Rocks, and, after passing Cape D'Aguilar steer so as to pass midway between Putoy and Sunkong Islands, where there is a good channel with 15 to 20 fathoms, mud.

Vessels having run out from Hong Kong Road through the Lyemun Pass, and wishing for anchorage either for the night or in consequence of bad weather, will find a good berth in the bay on the North side of Tamtu in 6 fathoms; but bear in mind that the water shoals to $2\frac{3}{4}$ fathoms at 3 cables' lengths from the Joss House on the North side of the bay.

Tamtu or *Tunglung Island*, 820 feet above the sea and 3 miles in circumference, is separated from the mainland by a channel called *Fotaumun Pass*, of 3 fathoms water, which is only $1\frac{1}{2}$ cable wide between the rocks which lie off both points in the channel. S.E. $\frac{1}{3}$ E. distant 4 cables from the North point of Tamtu lies a sunken rock, from which the West end of Steep Island (the first small islet to the north-eastward) just shows clear of a remarkable headland, *Yih Bluff*, bearing N.N.E. $\frac{1}{2}$ E.

Steep Islet is $1\frac{1}{4}$ mile northward of the eastern entrance of the Fotaumun Pass, and 4 cables from the shore; at $1\frac{1}{2}$ mile further North are the *Trio*

Islets. There is an indentation in the coast, with 8 fathoms water, between Trio and Steep, but it is exposed to easterly winds and swell.

NINEPIN GROUP lies 4 miles eastward of the Fotaumun Pass. The two largest islets bear North and South of each other, and the channel between is 2 cables wide. The southern face of the South Ninepin is a precipitous cliff, 330 ft. high; off its S.W. side is a smaller islet, with a peaked rock off its North point. The surface of the North Ninepin is nearly of the same elevation. An islet lies off its S.W. extreme.

Ninepin Rock, or East Ninepin, 222 ft. high, is nearly a mile eastward of the North Ninepin, and assumes the appearance that its name indicates only when seen in a N.W. or S.E. direction; otherwise the name is liable to mislead.

One-foot Rock, lying S. $\frac{3}{4}$ W., not quite 7 cables from the Ninepin, has only a foot over it at low water. The South end of South Ninepin on with Fotaumun Pass, W. $\frac{3}{4}$ N., leads South of it.

North Rock, lying N.W. $\frac{1}{4}$ N., distant 9 cables from the Ninepin, is nearly awash. There is a *reef*, which breaks at low water, nearly a cable's length S.E. of it.

At the Ninepin group it is high water, full and change, at 10^h 0^m, and the rise is 5 ft.

PORT SHELTER.—To the northward of the Ninepin group the mainland forms a deep bay, containing Port Shelter and Rocky Harbour. The western of the two, Port Shelter, runs back 5 $\frac{1}{2}$ miles to the northward, and its head is separated from the S.W. portion of Mirs Bay by an isthmus 1 $\frac{1}{2}$ mile wide, overlooked by the *Hunchback Hills*, 2,315 feet above the sea, which with *Sharp Peak*, 1,540 feet high, on the West side of the entrance to Mirs Bay, form conspicuous marks by which this portion of the coast may be recognized.

When steering for Port Shelter, pass eastward of Trio and Table Islets, as rocks extend 3 cables from the point to the westward of them. Nearly a mile northward of Table Islet is the southern point of Jin Island, with a peaked rock lying 2 cables southward of it; and E. $\frac{3}{4}$ N. rather more than a cable's length from Peaked Rock, is a rock awash at high water.

Shelter Island, 1 $\frac{1}{4}$ mile N.W. of Table Islet, should likewise be left to the westward when steering for Port Shelter, as the ground is foul between it and the main. There is good anchorage on the N.W. side of Shelter Island in 3 fathoms, but give the North point of the island a berth of a cable and avoid the 9-ft. patch, lying 6 cables to the northward in the centre of the bay. Southerly, distant 1 cable from the West point of Shelter, is a rock awash at low water; and there is a patch of 2 $\frac{3}{4}$ fathoms lying half a mile westward of it.

ROCKY HARBOUR is formed by Keui and Jin Islands on the West, and by High, Basalt, and Bluff Islands to the East and S.E. Anchorage will be

found in the N.E. monsoon on its eastern side, in the neighbourhood of a small cove northward of Green Islet, where there is a mandarin station and a village. Inside the cove the depth is 6 fathoms, but the space is confined, owing to sunken rocks. In the S.W. monsoon vessels will be better sheltered by anchoring to the N.W. of Day Islet.

Three-feet Patch.—Midway between Day Islet and the North end of Bluff Island is a rocky 3-ft. patch, from which the West point of Bluff Island is on with the summit of North Ninepin, S. $\frac{1}{4}$ E., and the southern summit of Day Islet bears W.N.W. The North Ninepin and Bluff Islands touching leads westward of it; and the West end of the islet lying off the S.W. end of North Ninepin, in one with the West point of Bluff Island, leads eastward; also, a vessel will be northward of it when Pyramid Rock opens clear of the N.E. extreme of Bluff Island, S.E. by E. $\frac{3}{4}$ E.

Three-fathoms Patch lies 6 cables northward of the 3-ft. patch, with the summit of Day Islet W.S.W., Pyramid Rock S.E. $\frac{1}{4}$ S., and Green Islet, the small islet on the eastern shore, E. $\frac{3}{4}$ N., and distant 3 cables.

The channel between Basalt Island and Bluff Island is 4 cables wide, and has 5 fathoms in it at low water. The former island is 8 cables long, North and South, and 572 ft. above the sea; the southern faces of both islands are very precipitous.

The channel between Town Island and Basalt Island is also 4 cables wide, but it should not be used without a leading wind, or in a handy vessel, as the chow-chow water, or whirling eddies, might lead them into difficulty. These rippings, occasioned by the meeting of adverse currents, are frequently so violent as to render a vessel unmanageable when within their influence.

High Island, $7\frac{1}{2}$ miles in circumference and 910 ft. above the sea, is separated from Town Island by a channel of $3\frac{1}{4}$ fathoms water, but in some places it is barely a cable wide. At $1\frac{1}{2}$ cable eastward of the latter is *Hole Island*, so called from its being perforated.

FUNG BAY.—*Conic Isle*, lying not quite a cable from the shore, N.N.E. $2\frac{1}{4}$ miles from Hole Island, has immediately westward of it a small bay $3\frac{1}{2}$ cables wide and three-quarters of a mile deep, which might be used in the N.E. monsoon. Fung Bay, the next inlet to the northward, is $1\frac{3}{4}$ mile wide, and has two islets and a rock in the middle of it; but it is too much exposed to the eastward to be of any use.

MIRS BAY is a deep inlet 15 miles to the N.E. of Hong Kong, and its entrance, between Fung Head on the West and Mirs Point on the East, is $5\frac{1}{2}$ miles wide; its extent northerly is 11 miles, and in an East and West direction 18 miles. *Gau-tau*, a rocky islet, 90 ft. high, lies about 2 miles within the entrance, and S.W. by W. about half a mile from it is a rocky ledge, part of which is always uncovered.

The hills near Mirs Point rise to the height of 1,200 ft., and just off its

South extreme is a small islet, named *Griffin Rock*. To the eastward of the islet are some rocks, at a cable's length from the shore; the first point to the northward of them is perforated.

Grass Island.—The point on the West side of entrance of Mirs Bay, $1\frac{1}{4}$ mile N. by W. of Fung Head, has two islets off it, and from thence the western coast of the bay trends suddenly to the westward, then northerly $1\frac{1}{2}$ mile, where there is an opening 3 cables wide leading into Long Harbour; the navigable channel, however, has only 2 fathoms in it, and is barely a cable wide, with shoal water extending from both shores.

On the North side of the opening lies Grass Island, 420 ft. high; and at $3\frac{1}{2}$ cables eastward of this island is a large black rock, named North Gau, with a *reef, awash* at high water, lying N.W. $\frac{1}{2}$ N. 4 cables from it. There is also a very dangerous 6-ft. rock, on which the German war ship *Cyclop* struck between Grass and North Gow Islets. It lies about a cable westward of the islet which lies near the West side of North Gow.

Port Island, 420 ft. high, is nearly 6 cables northward of Grass Island, and its N.E. point, which is narrow, projects 3 cables from the body of the island. There is a convenient *watering place* on the northern side of this island.

LONG HARBOUR runs $3\frac{1}{2}$ miles in a southerly direction from its entrance, 6 cables wide, which is a mile S.S.W. of Port Island. Both shores are steep-to, with the exception of the S.W. end of Grass Island, where there is a cove with a rock off its North point; to the northward of this rock, and half a cable from the shore is a rocky patch of $3\frac{1}{4}$ fathoms; some rocks also, which show at low tide, extend nearly a cable's length from high-water mark at the S.W. end of the island.

Jones Cove, the next inlet westward of Long Harbour, is a mile deep, N.N.E. and S.S.W., and 3 cables wide; but it, as well as Long Harbour, is open to a considerable swell from the N.N.E.

Tolo Channel, leading into Tolo Harbour, is the next inlet westward of Jones Cove. Its entrance, between Port Island and Bluff Head, is nearly $1\frac{1}{4}$ mile wide, and from thence the channel trends S.W. by W. 7 miles to White Head, forming a sound, with shores steep-to, the depth varying from 6 to 14 fathoms on the North shore.

Withing the channel, at $3\frac{3}{4}$ miles from Bluff Head, is *Knob Reef*, with a flat reef 2 cables to the S.W. of it; and $2\frac{1}{4}$ miles farther in lies *Bush Reef*, North of which, $3\frac{1}{2}$ cables, is Harbour Island. Although there is a navigable channel on either side of these reefs, the one northward of them is preferred.

At *White Head* (which is a peninsula with the Hunchback Hills, 2,315 ft. high, with very precipitous face, rising immediately behind it), the Tolo Channel separates into three arms, *Tide Cove* to the S.W., *Tolo Harbour* to the N.W., and *Plover Cove* to the N.E. Plover Cove would in all proba-

bility be found the most eligible place to ride out a typhoon ; it runs back $2\frac{1}{4}$ miles to the eastward beyond Harbour Island, and carries a depth of 6 to 4 fathoms.

Round Island is N.W. by N. $2\frac{3}{4}$ miles from Port Island, and is the easternmost of an extensive group lying in the N.W. part of Mirs Bay ; the largest of the group are *Double*, *Crescent*, and *Crooked Islands*. Double Island, the southernmost, lies N.W. 6 cables from Bluff Head, and the channel, which separates its S.W. point from the main, is only large enough for boats.

On the N.W. side of Crooked Island is a large village, and on the East end a remarkable peaked head, between which and the mainland to the northward, the depths are 9 to 4 fathoms, muddy bottom. On the West side of the island is a good anchorage named Crooked Harbour ; and to the southward, formed by Crescent and Double Island, is a secure basin, named Double Haven, the northern entrance into which is 3 cables wide ; within it the depth is 7 fathoms.

PENG-CHAU ISLAND, 3 miles in circumference and 148 ft. high, is in the N.E. corner of Mirs Bay, N. $\frac{1}{4}$ E. $4\frac{1}{2}$ miles from Gau-tau. The geological formation of this island is totally different from the adjacent land, being alluvial, shale stones forming its beaches. The distance between it and the main land to the eastward is rather more than a mile, forming a convenient anchorage, sheltered from all winds. E.N.E. from the island is the remarkable peak, *East Cone*, 750 ft. high, overlooking Typung Bay, the distance across being $1\frac{1}{4}$ mile, and the land but little elevated. Under the peak is the village of *Namoa*, and in the bay South of it is a peaked rock and a sunken reef.

Anchorage.—The N.W. part of Mirs Bay, northward of Crooked Island, gradually shoals to the westward, and affords good anchorage. The northern portion of the shores of the bay are steep-to. Anchorage in the N.E. monsoon will be found all along the eastern shore of the bay to the southward of Peng-chau ; but the number of fishing platforms on stakes in 8 and 9 fathoms water render the navigation awkward in the dark. There is anchorage in south-west winds to the westward of the South Gau, in 8 or 9 fathoms.

Tides.—In Tide Cove, in the S.W. part of Mirs Bay, it is high water, full and change, at 10^h 0^m, and springs rise about $6\frac{1}{2}$ ft. ; but during neaps the water remains nearly at the same level. With the flood, there is a great indraught into Mirs Bay and Rocky Harbour, which must be guarded against in shaping a course from the Tuni-ang Group to pass outside the Ninepin Group.

Directions.—As the ebb stream runs to the southward along the western shore at the entrance of Mirs Bay, a vessel working to windward with a S.W. wind will get to the westward speedily by keeping near the land passing

between the Ninepin Group and Tamtu; but as soon as the Lema Channel opens out she will meet with a set to the eastward.

During August and part of September, if a vessel is eastward of the Lema Island, she will find it difficult to proceed along shore to the westward if the wind is from that quarter; she ought therefore either to stand off to the southward for two or three days (if near full and change of moon, when bad weather may be apprehended), or anchor in Mirs or Harlem Bay for an easterly wind, which in these months usually happens every few days, close in with the coast.

TUNI-ANG GROUP.—From Mirs Point, the South coast of the peninsula separating Mirs and Bias Bays trends N.E. by E. 8 miles to Teyih Point, and between are two sandy bays, off the westernmost of which, at 4 cables from the shore, is Coast Islet, having 4 fathoms water between it and the land. At 6 miles eastward of Mirs Point, fronting the peninsula, is the Tuni-ang group, consisting of eight islets, including Single Island and Acong Rock. The largest island, the northernmost, is 5 miles in circumference, and its summit rises like a cone to the height of 960 feet; off its western end are two islets.

Peak Rock, lying a quarter of a mile westward of Net Island, with 4 and 5 fathoms water between, appears like two islets with a shingle beach connecting them. N.W. $\frac{1}{4}$ W., 4 cables from Peak Rock, is a ledge of rocks, the northern edge of which is always visible; and between them is a reef which breaks at low water.

Immediately southward of Tuni-ang Island are three islets, called by the Chinese Saman (or three passages), which form a good harbour, named *Samun Road*, sheltered from all winds, except those from W.N.W., round by the West to S.W. by S. *Samun*, the southern islet, is 3 miles in circumference, and distant 1 mile from Tuni-ang; the channel between it and Cone Islet to the northward has 9 and 10 fathoms water. The passage between Cone and Tuni-ang is crooked, and has only $2\frac{1}{2}$ fathoms water.

The *Acong* is a remarkable pyramid rock lying 6 cables N.E. of Single Island, with 15 fathoms water between them. There is a rock with 16 feet over it lying N.N.E. $\frac{3}{4}$ E. about a mile from the Acong, on which bearing it is on with the S.E. point of Single Island. When on this rock, which rises so abruptly that there was great difficulty in finding it, Cone Islet bore N.W. by W. $\frac{3}{4}$ W., and was in one with a remarkable gap in Tuni-ang.

Anchorage.—In the N.E. monsoon the trading junks anchor in 9 fathoms southward of Net Island and Peaked Rock, and abreast a fort on Tuni-ang; but the ground is foul within 2 cables' lengths of the fort point.

Middle Rocks.—N.E. $\frac{1}{3}$ E. from the summit of Tuni-ang is the Middle Rock just awash at high water. From it the Acong Rock bears S. $\frac{3}{4}$ W.; Bate Island, off the East point of Bias Bay, N.N.E.; and Lokaup Island N.W. by N. 4 miles. At 3 cables S.W. of this rock is a reef which breaks only at

low water, and from which the East end of Cake Islet (on the East side of Lokaup) is in line with the Pillars, N. by W. $\frac{3}{4}$ W.

The channel between Tuni-ang Island and Teyih Point, the West point of the entrance to Bias Bay, is $1\frac{1}{2}$ mile wide; both shores are steep-to, with the exception of the reef, already mentioned, lying off Peak Rock near the N.W. point of Tuni-ang, and a rocky ledge extending south-westerly from the first point East of a remarkable white rock on the North shore. The hills on this side attain an elevation of 2,600 and 2,800 feet.

BIAS BAY, a capacious and deep inlet similar to Mirs Bay, has a chain of islands fronting its western shore, which is indented by two large bays, at the head of the principal of which is *Typung Harbour*. This harbour, so named from the walled town of *Typung* on its northern shore, although contracted is capable of affording good shelter for moderate-sized vessels, except with easterly winds, when the anchorage under Lokaup Island should be preferred. On the northern side of the harbour there is a smooth conical hill, off which a shoal commences extending half a mile from the shore; the southern side, which is bold-to, must therefore be kept aboard. Vessels drawing more than 15 ft. should not proceed farther westerly than the third point on the South side, as the bottom of the harbour is shoal.

Dumbell Bay, the next inlet northward of *Typung Harbour*, runs back westerly 6 miles from Big Island, and carries a general depth of about 3 fathoms.

Fan-lo-kong Harbour, in the north-eastern part of Bias Bay, has an entrance $1\frac{1}{2}$ mile wide, with a depth in mid-channel of 4 fathoms. The village of *Fan-lo-kong* is on the northern shore. This will probably be found the best anchorage in Bias Bay in a typhoon.

Pagoda Island bears from Tsang-chau N.W. by W. $\frac{3}{4}$ W. 4 miles. The water shoals towards Pagoda; to the W.S.W., 3 cables off, are some rocks.

Lokaup Island, the southern of the chain of islands in Bias Bay, has on its South end some pyramidal rocks. It bears N. by E. 6 miles from Tuni-ang, and the channel between it and the West point of the entrance of the bay is 3 miles wide, with a depth of 9 fathoms. The island is about 2 miles long, and nearly separated in two places; the highest part, 330 ft. above the sea, is near the South end. There is anchorage on either side of it, according to the prevailing winds.

There are six islets around Lokaup, three on the West, two on the North, and one on the East side. The North islet, named the *Pillars*, is remarkable from the two square pillars on its South side; there is a reef off the West end of the islet South of the Pillars.

Middle Group.—About a mile northward of the Pillars is Middle Group, consisting of six islets. *Green Island*, 254 feet high, the southernmost, has an islet off its West end; and at three-quarters of a mile northward of it is Reef Islet, to the S.E. of which is a reef that breaks at low water. There is

also another rock awash at low water, lying North 3 cables from Reef Islet, and there is another N. $\frac{1}{3}$ W. $1\frac{1}{4}$ miles from Reef Islet, and N.W. $\frac{1}{2}$ N. from Red Islet.

Harbour Group, consisting of nine islets, is not quite a mile northward of Middle Group. The southernmost are two small islets named the *Twins*, to the N.E. of which, at 2 cables, is *Shoal Island*, having rocky ground extending north-westerly 3 cables from it. At a quarter of a mile westward of the Twins is *Tree-a-top Islet*, and westward of it, at half a mile, is a sugar-loaf shaped island. *Narrow Island* is three-quarters of a mile long, North and South. *Round Island* lies rather more than 2 cables northward of Narrow Island, with a depth of 5 and 6 fathoms between them; to the northward of it at 2 cables lies a flat rock nearly a-wash and steep-to. N. by W. 6 cables from Round Island is *Cone Islet*, a conical rock surrounded by reefs; vessels wishing to anchor to the westward of Narrow Island will find this channel or that between Tree-a-top Islet and Sugar Loaf Island the best to enter by.

To the westward of Sugar Loaf is *Big Island*, off the North face of which is a small islet, and further North a flat rock, with a reef, which shows only at low water; when upon this reef the highest part of Narrow Island bears S.E. by E., and Nobby Reef N.E. by E. To the N.W. of Big Island, 4 cables, is Sand Patch, a low rock surrounded by sand; between it and the island there are $3\frac{1}{2}$ fathoms water. There is also a *rock awash* at high water on the South side of Big Island.

BIAS POINT, the eastern point of the entrance of Bias Bay, is fronted to nearly a mile by rocks, between which and the land the channel is unsafe, but the passage between them and the rock lying off the S.E. end of Bate Island may be used, being 8 cables wide, with a depth inside of $4\frac{1}{2}$ and 5 fathoms.

Bate Island is 8 cables long, North and South, and half a mile wide; besides the rock off its S.E. end, there is another awash at high water, lying N.N.E. 6 cables from its North end, with the South point of Lokaup S.W. by W. $\frac{1}{2}$ W., and the rock off the S.E. end of Bate Island E. by S.

From Bias Point the eastern coast of the bay trends northerly $8\frac{1}{2}$ miles to *Tsang-chau Island*. There is anchorage in the N.E. monsoon between Bate and Triple Island, lying $2\frac{1}{4}$ miles to the northward. Tsang-chau is a low flat islet with a smaller one S.E. of it, lying 6 miles northward of Triple.

MENDOZA ISLAND, 480 feet high, and $2\frac{3}{4}$ miles in circumference, bears S.E. by E. $\frac{1}{4}$ E. $7\frac{1}{2}$ miles from Bate Island, and a vessel will find shelter from a S.W. wind on its northern side. Off its western side is a small islet separated from it by a channel a cable wide, and of 9 feet water. *Tsincoe Island*, 167 feet high, lies 6 cables northward of Mendoza, with 11 fathoms water between; near its centre is a remarkable cleft.

FOKAI POINT, bearing N.E. by E. $3\frac{3}{4}$ miles from Mendoza, is the South

extreme of a promontory connected to the main by a low sandy isthmus; the land near the point is high, and has the appearance of an island when viewed from eastward or westward. On the summit of the Fokai Hills is an artificial mound 670 ft. above the sea, and on the hill over the S.W. point is a large fort. On the East side of the isthmus are three rocky islets; and E. by N., 8 cables from the northernmost islet, is a reef showing at low water, from which the East extreme of Fokai Point bears S. by W. $\frac{1}{2}$ W., and the Pauk Piah Rock E.S.E.

HARLEM BAY, formed on the West side of the Fokai promontory, affords secure anchorage in the N.E. monsoon; but it cannot be considered safe during a typhoon, when the winds are liable to shift suddenly to different points of the compass. A good berth will be found northward of *Hebe Islet* in any convenient depth of water. This islet is flat-topped, and 70 ft. high, and a ledge of rocks, which covers at high water, extends 3 cables north-eastward of it. The natives here are not so shy of intercourse as at other places along the coast; they will supply fish and vegetables.

At 6 cables westward of the West extreme of Fokai Point, and 10 or 12 feet above the sea, is *Middle Rock*, which may be passed on either side. On the western foot of the Fokai Hills is a fort, with a tall chimney on the hill behind it. S.W. by W. 3 cables from Hebe Islet lies a rocky patch, of $3\frac{1}{2}$ fathoms water, bearing North from Middle Rock, and N.W. $\frac{1}{3}$ N. from the West extreme of Fokai Point.

Tides.—It is high water, full and change, at Tuni-ang Island (page 998), at 8^h 0^m; at Tsang-chau Island in Bias Bay at 8^h 30^m; and at Hebe Islet in Harlem Bay (two days before full moon) at 10^h 0^m. In the month of April the current in this neighbourhood sets constantly to the westward, its rate increasing upon the flood, but did not exceed a knot. When, however, the monsoon drift current recedes from the coast, the tidal influences prevail, and it is commonly reported that the flood stream sets westward and ebb eastward, or directly the reverse of their set North of Breaker Point.

Directions.—Bound to Bias Bay from the eastward, pass about a mile westward of Mendoza Island, and then steer N.W. by W. for the opening between Lokaup and Bate Islands, shoaling from 13 to 10 fathoms water over muddy bottom. From thence either proceed up the bay to an anchorage in 5 fathoms, about $1\frac{1}{2}$ miles from the eastern shore, 3 miles northward of Triple Island, or to the southward of Lokaup to an anchorage in the bay, or in Typung Harbour. There are several populous villages on the eastern shore where no doubt refreshments could be obtained.

If bound to Harlem Bay, round Fokai Point about half a mile off in 13 fathoms water, and either haul up between the shore and Middle Rock, or pass between that rock and Tsincoc Island.

SAM-CHAU INLET.—From Fokai Point the coast trends N.E. by N. 12

miles to *Ross Head*, and at the distance of 9 miles is *Coast Islet*, lying 4 cables off shore. Shoal water, over rocky bottom, extends 6 cables southward of this islet, and here, close to a flat rocky head, is an opening a cable wide into the extensive inlet of *Sam-chau*, the channel, carrying 5 and 6 fathoms, being close to a narrow cliff on the southern shore; but in strong easterly winds the sea breaks across it. The entrance bears W. by N. $\frac{1}{2}$ N. from *Siting Islet*, and E. $\frac{1}{2}$ N. from *Harlem Peak*, which, being 2,070 ft. above the sea, forms a conspicuous landmark. S.S.W. $\frac{1}{4}$ W. nearly $2\frac{1}{2}$ miles from *Coast Islet* is a *sunken rock*, from which *Si-ting* bears East nearly 6 miles, and *Harlem Peak* N.W. $\frac{1}{2}$ W.

Commander P. Cracroft, of H.M.S. *Reynard*, who visited this inlet in chase of pirates, says, "The mouth of the inlet is but little wider than the breadth of a ship; there is also an inner bar with an equally narrow passage; and across both these bars the tide runs 5 knots. The depth in the channel varies from 6 to 8 fathoms, and deepens to 10 fathoms above the upper bar, where there is ample room for a vessel to swing; but such is the intricacy of the navigation, that a personal examination should be made, and the state of the tide carefully ascertained before attempting the entrance."

PEDRO BLANCO ROCK (*Ty-sing-cham* of the Chinese), in lat. $22^{\circ} 19\frac{1}{2}'$ N., long. $115^{\circ} 7'$ E., when bearing North appears as two rocks; the summit is of a white colour. It is bold to approach, having 20 fathoms close to the southward, and 18 fathoms to the northward, decreasing gradually to 13 fathoms in the neighbourhood of the *Pauk Piah Rock*, which bears from it N.N.W., distant 15 miles.

The *Pauk Piah* is a flat rock, 4 feet (Capt. Morant, R.N., says 24 feet) above high water, from which the summit of the *Fokai Hills* bears W. $\frac{1}{3}$ N. 7 miles.

WHALE ROCKS.—S. by W. $2\frac{1}{2}$ miles from the *Pauk Piah* are the two *Whale Rocks*, rising abruptly from the depth of 12 fathoms, and upon which the sea sometimes breaks. From them, the West extreme of *Fokai Point* is on with the summit of *Bate Island*, W. by N. $\frac{1}{4}$ N., the summit of *Fakai* bears N.W. by W. $\frac{1}{2}$ W., 7 miles, and the summit of *Mendoza West* a little northerly.

Tung-Ting and *Si-Ting* are two rocky islets about 50 ft. above the sea, lying S.E. $\frac{1}{2}$ S. and N.W. $\frac{1}{2}$ N. from each other, distant $1\frac{1}{2}$ mile apart; there are sunken and detached rocks around them both.

N.W. by W. $1\frac{1}{2}$ mile from *Si-ting* is a rocky patch which sometimes breaks. There is also the *Single Rock* which breaks only at low water, or when there is a heavy sea, and from which *Si-tang* bears S.W. by W. $\frac{1}{2}$ W.; *Tung-ting* S.W. by S.; *Hat Islet* N. by E., and *Harlem Peak*, W., northerly.

HONG-HAI BAY, about 15 miles N.E. of *Fokai Point*, is extensive, but in the upper part the water shoals to 6 and 4 fathoms, and it is open to

S.W. and South winds. There are several islands in the bay, the largest of which, Hong-hai, is in the middle of it.

Vessels are recommended not to pass to the westward of Tung-ting and Si-ting, nor into the N.W. part of this Bay, as they will find a heavier sea there than outside; there is, also, usually a long ground swell near Inside Island, rendering it advisable not to stand farther in than Hong-hai Island.

In Hong-hai Bay is an inlet, not identified, but probably that which is 9 miles N.E. of Fokai Point, which was visited by Captain P. Cracroft, R.N., in H.M.S. *Reynard*, 1849. Its bar extends nearly across the entrance, leaving an opening, on the South side, of very little more than a ship's breadth. There is an inner bar also on the South side, with an equally narrow passage, hugging a point which resembles "Devil Point," at the entrance of Hamoaze; and over these bars the tide sets, at springs, with the great velocity of 5 or 6 knots.

The depths in the channel vary from 4 to 8 fathoms, deepening to 10 fathoms above the inner bar, where there is ample room for a ship to swing, but the navigation is so intricate that a careful examination should be made before attempting the entrance, and the state of the tide correctly ascertained.

Hong-hai Island, bearing N.E. $\frac{1}{2}$ E. 8 miles from Si-ting, is half a mile long, East and West, 3 cables wide, 240 feet high, and has shelter on its northern side from southerly winds. Two rocks, visible at low water, lie 3 cables from the shore, S. by E. $\frac{3}{4}$ E. from its summit. *Hat Islet* is a peaked rock $2\frac{3}{4}$ miles westward of Hong-hai. It is called by the Chinese *Ke-sin-she* (fowl's heart), which it more resembles than a hat; there are detached rocks about it. *Inside Island*, 5 miles N.W. of Hong-hai, is 460 ft. high, a mile long North and South, and but little more than a cable wide. At 3 cables off its S.W. end are some detached rocks.

Shoal Bay is formed at the head of Hong-hai Bay, 3 miles N.N.E. of Hong-hai Island. Its entrance is 2 miles wide, and within the water shoals to less than 3 fathoms. At three-quarters of a mile eastward of *Club Point*, the East point of the entrance to Shoal Bay, there is a rocky ledge, part of which is always above water.

TY-SAMI INLET, bearing E. $\frac{3}{4}$ N. 9 miles from Hong-hai Island, has an entrance channel half a mile wide, with $2\frac{1}{2}$ fathoms in it at low water. The northern shore of the channel is shoal-to, and rather more than half a mile off the beach are some rocks, which show at low tide. Ty-sami Mound, 970 feet above the sea, is an artificial cone on the highest part of the hills near the eastern point of Hong-hai Bay.

In Hong-hai Bay it is high water, full and change, at 10^h 0^m, and the rise is $6\frac{1}{2}$ ft.

Goat Island, lying S.E. 3 miles from Tsiech Point, the eastern outer entrance point of Hong-hai Bay, is the southernmost and largest of a nume-

rous group, amongst which there are no navigable channels. S.W. $\frac{1}{2}$ W. from its summit, and S.S.E. $\frac{1}{2}$ E. from Tysami Mound, there is a dangerous rock, which shows only when the tide is low and the wind high. At rather more than a mile inland from the beach northward of Goat Island, is the walled town of *Tsieching*. There is good anchorage in the N.E. monsoon on the N.W. side of Goat Island, which, with the group of islets northward of it, shelters well from the heavy sea. This roadstead is much used by opium vessels, which approach as close to the shelving beach as the depth of water will allow.

Reef Islets lie S.E. by E. 3 miles from Goat Island. The southern or largest islet has reefs extending a cable's length in a southerly direction from its East end. In using the channel between Goat Island and these islets, take care to avoid a *sunken rock* on which the sea breaks at low water, bearing E. $\frac{1}{4}$ N. $1\frac{1}{3}$ mile from the summit of the island, and N.W. $\frac{3}{4}$ W. 2 miles from the North end of the islets.

Vessels may pass between the Reef Islets and some rocks awash named *Middle Reef*, lying $1\frac{3}{4}$ mile to the northward, the depth being 7 and 8 fathoms, but bear in mind that reefs extend rather more than 2 cables northerly from the islets, the northern danger bearing W. $\frac{1}{2}$ S. from Chelang Point. It will not be prudent to pass in-shore of Middle Reef.

CHELANG POINT, 5 miles E. by N. $\frac{1}{4}$ N. from the Reef Islets, is very remarkable, of moderate height, composed of red sand, with many ragged rocks scattered over it. The point has two islets and a reef close off it, and the depth is 13 fathoms within a mile of the outer islet, which is 80 feet high.

On the western extremity of this headland is a fort, and westward of the fort a small bay, which will afford shelter in the N.E. monsoon; but a sunken rock, with only a foot water over it, lies N.W. by W. $5\frac{1}{2}$ cables from the fort. *Flat Rock* is $1\frac{3}{4}$ mile W. by N. from Chelang Point, and there is a small sunken rock lying N.W. from it, and West from the fort. The land on either side of Chelang Point for some distance is of a remarkable red colour with black mounds.

Kin-yu or *Kemsue* is a rocky islet, half a mile long N.E. and S.W., lying N.E. $\frac{1}{2}$ N. $3\frac{3}{4}$ miles from Chelang Point, and under its highest or N.E. part there is a high rock. Its shores are bold-to, but the islet is too small to afford shelter.

HIE-CHE-CHIN BAY, formed between *Paukshao Point* on the West, and *Tongmi Point* on the East, has 7 to $5\frac{1}{2}$ fathoms water at entrance, shoaling to 3 or $3\frac{1}{2}$ fathoms within a mile of its head, over soft muddy bottom. It affords shelter from westerly and northerly winds, and from the N.E. monsoon, but is quite exposed to the southward and S.E.; the eastern side of the bay is high and mountainous. The village of *Kinsiang* stands in the N.E. bight of

the bay, immediately under Round Hill. Two rivers empty themselves at the head of the bay.

Near Tongmi Point is *Chino Peak*, a remarkable conical hill, 455 ft. high, which, with the islets of Tung-ki and Si-ki, render this side of the bay easy to recognise when well within it. But when in the offing some have, in approaching Chino Bay, mistaken at first for Chino Peak, Round Hill, on the northern shore of the bay, which is also a remarkable conical hill, 1,456 feet high. When first seen, Round Hill rises like an island, and is a good mark when approaching from the south-westward. The land about Chino Bay, when first made from the same direction, appears of a somewhat uniform height.

Tung-ki.—Chino Peak bears N.W. $\frac{3}{4}$ N. nearly $2\frac{1}{2}$ miles from Tung-ki, which is 18 ft. above the sea, having some detached rocks on its eastern side, and three rocks awash at low water, half a cable from its N.W. side.

Suwonada Rock, upon which a steamer of that name struck, August, 1969, lies in nearly mid-channel between Tongmi Point and the Tung-ki Rocks. It consists of two or three pinnacle rocks, with 11 ft. on them at low water springs, and 8 or 9 fathoms close to. This dangerous patch lies N. by W. $\frac{3}{4}$ W., $4\frac{1}{2}$ cables from the West extreme of the Tung-ki Rocks; Tongmi Point bearing N.W. by W. $\frac{1}{4}$ W., and Si-ki Rock S.W. by W.

No indication of these rocks is afforded by discoloured water, and it is recommended that the passage between Tung-ki Rocks and the mainland should not be used for the purposes of navigation. A mile North of Tung-ki, and East three-quarters of a mile from Tongmi Point, is a cluster of rocks nearly awash.

Si-ki Islet, 80 ft. high, rises abruptly, and is cleft at the summit; Tung-ki bears from it E.N.E. 3 miles, and Chino Peak N.N.E. $\frac{1}{3}$ E. Between the two islets the soundings are 11 and 12 fathoms.

Paukshao Bay, on the western side of Hie-che-chin Bay, affords good shelter, unless the wind comes eastward of South, there being 5 fathoms water with Paukshao Point bearing westward of South. Paukshao Point is of moderate height, with numerous rocks scattered over its surface. The other point to the westward has a high battery on it. There is said to be a sunken rock lying N.E. about half a cable's length from Paukshao Point.

Chino Bay is on the eastern side of Hie-che-chin Bay, to the northward of Chino Peak, and on its shore there is a fort and small village, abreast which the water is shoal, the 2-fathoms line of soundings being half a mile off the land. West from Chino Peak is the *Chino Reef*, extending 4 cables from the shore; the outer rock does not show at high tide unless there is a considerable swell.

A dangerous coral rock, on which the *Sarah Lucy* struck, lies $8\frac{1}{2}$ cables S.E. of the Yellow Stone. There are only 7 ft. water on it, $4\frac{1}{2}$ fathoms, mud,

close-to. To pass westward of the rock, keep the East White Stone open westward of the Yellow Stone.

The best anchorage in Chino Bay is in $3\frac{3}{4}$ fathoms farther northward about East of the Yellow Stone, which is the southernmost of all the rocks, with the exception of the Sarah Lucy, in the N.E. part of the bay. The walled town of *Keishi-wei*, bearing E. by N. 3 miles from the Yellow Stone, will be seen over the low land from this anchorage; there is a creek leading up to it which will admit junks at low water.

Between the Yellow Stone and the rocks three-quarters of a mile N.N.W. of it, there is a channel of $4\frac{1}{2}$ fathoms water: but vessels are recommended not to approach that part of the bay northward of the Yellow Stone, as there are several sunken rocks. Vessels drawing less than 18 ft. may stand into the bay to the northward of the West White Stone, where the depth is $3\frac{1}{2}$ to $2\frac{1}{4}$ fathoms, the water shoaling gradually towards the beach.

HUTUNG POINT.—From Tongmi Point the coast takes an E by N. $\frac{1}{2}$ N. direction about $15\frac{1}{2}$ miles to *Cupchi Point*, and at the distance of $4\frac{1}{2}$ miles is *Black Rock Point*, with black rocks off it, and a square white rock on its S.W. side. N.W. $1\frac{1}{2}$ cable from the White Rock is a sunken rock.

About $2\frac{3}{4}$ miles eastward of Black Rock Point is the mouth of the River Hutung, which falls into the sea on the West side of Hutung Point, but it has only 6 ft. water over the bar. On its South bank is a fort, and close to the fort a remarkable dome-shaped building, apparently intended for a fire beacon; this is a good mark in hazy weather, being so easily recognized, indeed there is nothing resembling it on this part of the coast. S.S.E. $1\frac{1}{4}$ mile from the fort is a small islet, surrounded by reefs and detached rocks, one of which, to the eastward, is of a curious shape, and is named *Figure Rock*.

At 3 miles eastward of Hutung Point the hills come down to the beach, and on one of their peaks is a conspicuous knob. At a mile off the beach is a flat rock with sunken dangers between it and the shore; there is also a rock awash to the S.E. of it.

CUPCHI POINT has a rugged summit, 210 ft. high, and near the sea there is a dilapidated fort. South $1\frac{1}{2}$ mile from the point is Turtle Rock, 14 feet above high water, and inside of it are two islets and four patches of rock. The junks pass between Turtle Rock and the rock next to the northward, though sunken rocks lie westward of both, and much discoloured water, which, however, helps to detect them. The U.S.S. *Palos* discovered off Turtle Rock a shoal, with only 2 fathoms of water. From the shoal Cupchi Point bore N. $\frac{3}{4}$ E. 3 miles, and the hill marked on the chart as 726 ft. high, N.W. $\frac{3}{4}$ W. As this danger lies in the track of navigation, vessels should be cautious to give it a wide berth, when passing the Turtle Rock.

Between the islets and the point the channel is 2 cables wide, but the bottom is rocky and uneven, and a rock on which the steamer *Five Brothers*

was wrecked, February 28th, 1859, lies 60 fathoms South of the point. The least water on this rock is 12 ft., and as many sunken dangers are in its vicinity, it would be imprudent for a stranger to attempt the passage. A ledge of rocks extends 2 cables from the point westward of the fort, its outer end breaking at low water.

A remarkable little black conical hill, named *Black Mount*, rises 230 ft. above the sea from a red sand down, at $4\frac{1}{2}$ miles N.E. of Cupchi Point, and half a mile from the beach. Reefs extend half a mile from the shore along this part of the coast.

Anchorage.—There is good anchorage during the N.E. monsoon to the southward of the Shag Rock, which lies half a mile off shore N.N.W. of Cupchi Point; it is 3 ft. above high water, and has $2\frac{1}{2}$ fathoms around it, except on its S.E. side, where there is a projecting reef. On the main, abreast this rock, is a fort standing on the East side of entrance to a river leading to the walled town of *Kiahtsz*. The town is $1\frac{3}{4}$ mile from the fort, and southward of it is a pagoda two stories high. There are 9 ft. at low water on the bar of the river.

Nearer the entrance there is a second fort over a point, and a martello tower on the sandy point opposite, to the southward of which, sand-banks extend more than half a mile. Situated exactly in mid-channel between these sand-banks and the inner fort point is a dangerous rock, steep-to, which uncovers at low water, and may be passed on either side.

TUNGAO ROAD.—The village of Tungao stands in a bight of the coast N.E. by E. 15 miles from Cupchi Point, the intervening shore being low and sandy. On the bar of the river, West of the village, the sea breaks heavily at low water, and outside the bar the water shoals suddenly; so that vessels approaching the anchorage in Tungao Road should not bring the fort at the village to bear eastward of N.E. $\frac{1}{2}$ N., when within $1\frac{1}{2}$ mile of it; this will be found a good roadstead in the N.E. monsoon, well sheltered and with good holding ground. There are two pagodas in the neighbourhood, one on the low land at the East side of the river's mouth; the other on the hills 2 miles to the northward.

S.E. $2\frac{1}{2}$ miles from the village is *White Rock*, which forms a good mark by which this part of the coast may be recognized; halfway between White Rock and the village is a creek with a fort upon the hills East of it. The land near the coast is low, with several fishing villages in the sandy bays, the boats belonging to which are numerous, and being of different shape and smaller than those of Hai-mun and Cupchi, will enable a vessel to identify her position in a fog.

Hai-Loong Rock is directly in the track of vessels proceeding from the anchorage in Tungao Road round Breaker Point when keeping in-shore to avoid the N.E. monsoon, and lies S. by W. $\frac{2}{3}$ W. 1 mile from the White Rock, with pinnacles 11 ft. below the surface of the water slipping off into

6 fathoms on either side. The islet inside Breaker Point bears from it E. by N. northerly, and the North pagoda N.N.W. $\frac{1}{4}$ W.

BREAKER POINT, lying 7 miles eastward of White Rock, and E. by N. $\frac{3}{4}$ N. 23 miles from Cupchi Point, may be known by a black dome-shaped hill, rising 280 ft. from a red sand drift on the point, whence the hills trend northward and westward, dipping suddenly at their extremity. The shore should not be approached within half a mile. A *lighthouse* is proposed at Breaker Point. At 2 miles westward of Breaker Point is a small islet, having *Flat Reef*, two conspicuous masses 12 ft. above high water, to the south-eastward of it, distant 9 cables. A quarter of a mile W. by N. $\frac{1}{2}$ N. from Flat Reef is *Black Rock*, 15 ft. ; and N.N.W., half a cable, another, 12 feet above high water. *Corea Rock*, having 14 ft. water over it, lies two-thirds of a mile S.W. $\frac{1}{2}$ S. from Flat Reef. One and a half cables westward of the Corea Rock is a *rocky patch*, with 3 to 5 fathoms water over it, and 7 fathoms around.

Sunk Rock has but 7 ft. water over it. From it the apex of the islet westward of Flat Reef bears N. $\frac{1}{2}$ E., distant half a mile. When on Sunk Rock, Black Rock and the rock (12 ft. high) respectively to the West and N.W. of Flat Reef are in line. Another rock was reported in 1874, by the British steam-ship *Ningpo*, South, 3 miles from Flat Island, and S.W. $\frac{1}{2}$ S. from Breaker Point. The steam-ship *Ulysses*, also, is reported to have struck on a rock $1\frac{1}{2}$ mile East of this position. The dark hills seen over the high sandy coast is very deceptive at night, and Dome Hill can then very seldom indeed be recognised; strangers cannot do so readily by daylight, and at night are very liable to mistake for it a round-shaped hill at the extremity of the back range. For these reasons soundings only can be relied upon to enable vessels to pass the above dangers safely at night; when by keeping in depths of 11 or 12 fathoms, not less than 11 fathoms, they will pass from 1 to 2 miles to the southward of Corea Rock.

Tides.—From observations on the tidal streams, from January to May, between Hong Kong and Breaker Point, the ebb ran to the eastward. To the eastward of Breaker Point, however, the flood set to the eastward, which is its direction throughout the N.E. coast of China. It appears that the tidal wave from the Pacific Ocean strikes first upon Breaker Point.

Tong-lae Point is $4\frac{1}{2}$ miles N.E. $\frac{1}{2}$ N. from Breaker Point, and about a mile westward of it is the entrance to a creek leading to the walled town of Tong-lae. On the eastern side near the entrance is a fort, under which indifferent shelter might be found in the N.E. monsoon by a vessel of not more than 12 ft. draught, but she would be in an awkward position should the wind veer southward of East. Sunken rocks abound along this portion of the coast, one of which lies 6 cables off the land, with the fort bearing N.W. by N., and Rocky Point N. by E. $\frac{3}{4}$ E. Rocky Point is the low extreme of the land N.E. $1\frac{1}{4}$ mile from Tong-lae Point; hence the coast trends

northerly, and at the distance of $4\frac{1}{2}$ miles is a headland with reefs extending a quarter of a mile S.E. of it.

HAI-MUN BAY.—N.E. $\frac{1}{2}$ E. 7 miles from the above headland is Hai-mun Point, and between them Hai-mun Bay. The town is built on the left bank, 1 mile within the entrance of the river, which has 10 ft. over its bar. There are three pagodas on the land to the northward of the bay, two of which are on the hills, and can be seen in clear weather from Namoa Island.

At 9 cables southward of Hai-mun Point are two rocks, on which the sea breaks. From the southern, *Parkyns Rock*, Rocky Head Point, on the East side of entrance of Hai-mun River, bears N.W. A *rocky ledge*, with only $2\frac{1}{2}$ fathoms on its South end, extends 6 cables from the fort on the East point of a sandy bay, $1\frac{1}{3}$ mile E.S.E. of Rocky Head Point, and near the anchorage of Hai-mun River is another rock showing at low water, from which the South extreme of Hai-mun Point bears E. by S., Rocky Head Point N.E. $\frac{1}{4}$ N., and the West peak of Pagoda Range N.W. by N.

CAUTION.—On many occasions vessels have nearly been lost by mistaking Hai-mun Point for the Cape of Good Hope in thick weather, when the Island of Namoa was not visible. These points bear a marked resemblance to each other, both having three distinct high points with sandy beaches between. In such weather, the low white sandy shore of Hope Bay is often not visible.

Hope Bay is between Hai-mun Point and the South extreme of the Cape of Good Hope, which bears E. by N. $\frac{3}{4}$ N. distant about $8\frac{1}{2}$ miles. For $3\frac{1}{2}$ miles N.E. of Hai-mun Point vessels should not close this part of the shore nearer than three-quarters of a mile; beyond that distance the sandy beach is steep-to. There is a secure anchorage in the N.E. monsoon on the southern side of the cape, to the N.W. of Tide Point. Sunken rocks extend a cable from the fort point; otherwise this bay is clear. At the western extreme of this sandy bay is Peaked Rock, S.W. by S. of which, distant 4 cables, is a small sunken pinnacle rock, on which H.M. gunboat *Cockchafer* struck in 1868. It has 4 ft. on it at low water, with 5 fathoms close-to on either side. At $1\frac{1}{2}$ mile N.W. of Peaked Rock is the entrance to a creek which communicates with the River Han, 3 miles above Swatow.

The **CAPE of GOOD HOPE** is the eastern, and Pagoda Hill the northern boundary of the entrance to the River Han. The cape, 163 ft. high, is the N.E. extreme of a hilly peninsula, the highest part of which, High Cape summit, is elevated 433 ft. Vincent Range lies to the N.W. of the cape, and North $1\frac{1}{4}$ mile from the highest part of Vincent Range is *Signal Hill*, on the summit of which, 377 ft. high, is a rudely constructed semaphore.

Dove Rock has only 7 ft. on it. From it the South summit of Double Island bears W. by N. $\frac{1}{4}$ N., distant 5 miles, and Green Islet S.S.W. $\frac{1}{2}$ W.

4½ miles. Its position may easily be recognized in calm weather by the tide setting over it.

The northern face of the Cape of Good Hope is half a mile long, and terminates to the westward in a bold point, on which is an old fort. N. ½ E., half a mile from the fort, is *Green Islet*, 72 ft. high, from the N.E. side of which rocks extend a cable. *Bill Islet*, 50 ft. high, bears N.N.W. 2¾ miles from the cape, and is nearly 1 mile off shore. At a third of a mile S. by E. ¾ E. from this islet is *Squat Rock*, about 15 ft. high; and a quarter of a mile S.W. by W. from *Squat Rock* is a reef awash.

Sugarloaf Channel.—*Peaked Rock*, bearing N.W. ¾ N., 2½ miles from *Bill Islet*, lies off the South point of entrance to *Sugarloaf Channel*, which is formed between the West side of *Sugarloaf Island* and the coast abreast it. This channel, although only 2 cables wide, is excellent, either side being quite steep to a quarter of a cable, and is always used by steamers, and frequently by sailing vessels.

Peaked Rock, 25 ft. high, can only be seen when it is standing out clear of the land. *Sugarloaf Island*, which bears not the least resemblance to its name, is 200 ft. high; and *East*, distant 2 cables from its South extreme, are two rocks nearly awash at high water.

Double Island (the *pilot station*) bearing N.W. by N., 4 cables from the North extreme of *Sugarloaf*, only appears double when seen from the S.E. The white walls and tops of houses are the best guides to recognise it from seaward. At 3 cables S.S.E. ½ E. from the summit and 1½ cable off shore, are rocks which cover at 5 ft. rise of tide; the channel between them and *Sugarloaf* cannot be recommended. *Fisherman Island*, half a mile westward of *Double Island*, forms with it the continuation of *Sugarloaf Channel*.

Caution.—Between *Double Island* and the anchorage off *Swatow* are numerous rows of fishing stakes, some of which stretch across the fairway.

The RIVER HAN.—*Pagoda Hill*, the northern boundary of the entrance to the river, will be easily recognized by the pagoda on its summit, 257 feet above high water. *Kakchio Promontory*, 4 miles westward of *Double Island*, when seen from seaward has the appearance of one continuous hill, the southern part being 486 ft. high, and the northern 296 ft.; the numerous ravines by which it is cut up are only seen when close to. On its northern side is the English Consulate (in lat. 23° 20' 43" N., long. 116° 39' 3" E.) with a number of European houses, but they can only be seen when close up to the anchorage.

Off the North extreme of the promontory, and separated from it by a very narrow channel, is *Bottefurh Rock*, 50 ft. high; and at two-thirds of a cable farther to the N.N.W. is the *Wyoming Rock*, with only 4 ft. at low water, marked by a red buoy, in 4 fathoms, 20 ft. N.W. of the rock. *Madras Rock*, having 8 ft. on it at low water springs, was discovered by the P. and O. ship *Madras* striking on it when hauling off the adjacent beach. From the rock

Bottefurh Rock bears E. by N., the English Consulate flagstaff S.E. by E. $\frac{3}{4}$ E., and the extreme of the western pier S.E. by S., distant $1\frac{1}{2}$ cable.

Chen-to Rock, with 5 ft. water over it, is reported as a small cluster from which the British Consulate bears S. by W. $\frac{3}{4}$ W.; the Customs flagstaff N. by W. $\frac{1}{2}$ W., the Harbour Pilots' Pier S.E. by E. $\frac{1}{4}$ E., and the North extreme of Bottefurh Rock W. by N. $\frac{1}{2}$ N.

SWATOW stands on the northern bank of the river, nearly a mile distant from Kakchio, and the whole of the Hongs are on this side. The anchorage for foreign vessels is immediately fronting the town, where 6 to 7 fathoms are found, with good holding ground.

The Port of Swatow, opened to foreign trade by the Treaty of Tientsin in 1858, is the shipping port of Chau-chu fu, 35 miles inland, and since its establishment as a centre of foreign commerce, has been the means of creating a large emporium at San-ho-pa, at the confluence of two branches, 40 miles farther up the river Han. Jetties project into the stream to a distance of some 200 yards. They are, in most cases, built of rough blocks of granite. The military mandarin resides at the small, picturesque fort on the West of the town, in close proximity to the custom house.

The Han above Swatow is navigable 25 miles above where the Admiralty survey terminates, to a place called Tiaka, where a bridge crosses the river. Tiaka is about 12 miles from Chau-chu-fu, the capital of the province. Another branch of the river runs to Chau-chu-fu from Swatow, but it is so shallow that it is only available for flat-bottomed boats.

Supplies.—The markets are fairly supplied with beef, mutton, poultry, fish and fruit, and in winter with wild-fowl. Small repairs to ships, spars, &c., can be executed, and there is a hulk capable of heaving down vessels of 300 tons or more. There are no docks, the nearest being at Amoy, and the rise of the tide is insufficient for the examination of the bottoms of ships grounded on the soft mud. There is constant steam communication with Hong Kong, Amoy, and Foochow, from which places stores of all kinds, not procurable at the port, may be provided in a few days.

The foreign trade of Swatow has been very rapidly developed, but several causes have concurred towards confining it almost exclusively in the hands of native or Singapore Chinese.

The climate, and especially Double Island, shares with Amoy the well-merited repute due to its maritime situation. Double island affords sea-bathing, and attention has been drawn to this spot as a possible sanitarium for Hong Kong and the southern ports. The position of Swatow at a point opposite the Bashee Channel renders it peculiarly exposed to typhoons, the principal range of which is in this narrow seaway.

Tides.—Springs rise 9 ft., but the tides are much influenced by the prevailing winds. During the S.W. monsoon, for a number of days there may be only 2 or 3 ft. rise. Vessels drawing 17 ft. have been known to wait ten

days off Double Island, there not being sufficient rise of tide to enable them to stand out.

Directions.—A vessel of heavy draught running for the entrance of the River Han before the N.E. monsoon should pass outside or eastward of the Dove Rock. To do this, do not bring the East extreme of Fort Island to the eastward of N. $\frac{1}{2}$ E., until the clearing mark, the East extreme of Green Islet on with the North part of High Cape summit, S.W. $\frac{1}{2}$ S., is made out, when steer for it until Sugarloaf Channel is well open. Bill Islet and Squat Rock will then be easily recognized, and by steering in with Bill Islet on with the extreme of the Cape of Good Hope bearing S.S.E., it will lead between the Outer Flat and the spit extending eastward from Double Island in not less than 15 ft. at low-water spring tides. When nearing Double Island great attention must be paid to keep this mark exactly on, as the channel is only 2 cables wide. Vessels of light draught, 12 and 14 ft., can easily run in for the entrance North of Double Island.

Fort Island lies E.N.E. $1\frac{3}{4}$ mile from Pagoda Hill. *Brig Island*, so called from a rock at its South extreme, which appears like a brig when seen in an East or West direction, lies N.E. $\frac{3}{4}$ E. $4\frac{3}{4}$ miles from Fort Island.

NAMOA ISLAND, 12 miles long East and West, and $5\frac{1}{2}$ miles wide at its broadest or eastern part, is separated from the main by a channel about $3\frac{1}{2}$ miles wide, with depths varying from 3 to 6 fathoms. The three peaks of this island, West Peak, 1,830 ft., Namoa Peak 1,934 ft., and Saddle Peak 1,794 ft. above the level of the sea, form the most prominent landmarks in the neighbourhood. Notwithstanding its barrenness, the island is exceedingly populous, the fisheries affording a livelihood to the greater portion of the inhabitants.

Caution is required to avoid the large fishing stakes which almost surround this island in deep water, some of which are large enough to carry away a vessel's jib-boom. The anchorage in Clipper Road is in 6 to 7 fathoms, very good holding ground.

Local knowledge is necessary when approaching the anchorages on the westward of Namoa from the southward, as the knolls of the S.W. end of Namoa are said to shift. The eastern channel between North point of Namoa and Fort Head is much wider and has general depths of 7 to 4 fathoms.

Nangaou Bay, the next bight eastward of Shoal Bay, on the North coast Namoa, has at its head a walled town, the residence of the magistrate of the district. Vessels drawing less than 18 ft. may stand into this bay until Pagoda Island, on its eastern side, bears E. by N.; but during the N.E. monsoon there is a considerable swell in it. Rocks extend 3 cables from the north-eastern point of Namoa.

South Bay, on the South coast of Namoa, affords good shelter in the N.E. monsoon; rocks extend $1\frac{3}{4}$ cable southward from its eastern point. Vessels

drawing 18 ft. may run into this bay until the extreme of the point bears S.E. About half a mile S.E. of the point is *Crab Island*, a low flat islet.

Hart Rock, with $4\frac{1}{2}$ fathoms on it at low water, lies 7 cables off East Point of Namoa, with North point of Namoa N. 39° W. and West end of Ruff Rock just open of Dome Island.

LAMOOCK ISLANDS are a group of four islets, and two patches of rocks occupying an extent of $7\frac{1}{2}$ miles in a N.E. and S.W. direction. From the Boat Rocks at their S.W. end, the West point of Namoa bears N.W. $\frac{1}{2}$ W. 22 miles; and from North Rock at their N.E. end, the East point bears N.W. $13\frac{1}{2}$ miles, and the south-eastern Brother N.E. by E. $25\frac{1}{4}$ miles.

Boat Rocks are two square rocks, 15 ft. above high water, about the size of boats, with several reefs between them. *White Rock*, lying N.E. $1\frac{1}{2}$ mile from Boat Rocks, is sufficiently large to afford shelter to boats.

High Lamock, near the centre of the group, is covered with brushwood. The channel between it and White Rock is safe, the depths varying from 8 to 14 fathoms. The distance between High and East Lamock Islands is a mile, but about the middle of the channel is a rock, with a reef, which shows at low tide, extending southward $1\frac{1}{2}$ cable from it. The three northern islets lie close together; North Rock, the northern one, which has a pyramid on it, is without vegetation.

LIGHTS.—On High Lamock Island there are exhibited two fixed lights, viz. :—a high white light, and a low red light.

High Light is a *fixed bright* light, elevated 241 ft. above the sea, and in clear weather should be seen from a distance of 22 miles. The lantern is on a round tower of cast iron, 25 ft. in height (lantern vane 54 ft. above base), and painted black; the dwellings and boundary wall are white.

Low Light is a *fixed red* light, elevated 55 ft. above the level of the sea, and in clear weather should be seen from a distance of 7 miles. The light exhibited from a window in a white building erected on the southern slope of the island, is shown only between the bearings S.W. by S. and S.W. $\frac{1}{2}$ W., covering the White and Boat Rocks, and is intended as a guide for clearing these rocks.

Times Rock, on which several vessels have struck, is a dangerous coral pinnacle, with only 9 ft. at low water. From it the North Rock of the Lamock Islands bears S.W. $\frac{3}{4}$ S., distant nearly $1\frac{1}{4}$ mile, and Dome Island W. by N. $\frac{1}{2}$ N., 12 miles.

In passing inside the Lamock Islands, attention to the tide as well as to the vessel's course is necessary.

LAMON ROCKS.—Between Namoa and Lamock Islands are several islets, the northernmost of which is the highest, and from its appearance is called *Dome Island*. The two southern islets, *Ruff Rock* and *Oeste Rock*, lie East and West of each other; to the southward of the Ruff are the *Dot* and *Sul Rocks*.

A reef extends one-third of a mile southward of the Sul. *Plat Island* is flat topped, and is lower than the Ruff or the Oeste.

Mackinnon Rock has only 5 ft. water. From it the N.W. point of *Plat Island* bears W.S.W., distant three-quarters of a mile; the East extremity of *Oeste Rock*, S. by E. $\frac{1}{4}$ E. 2 miles; the summit of *Ruff Rock*, S.E. $\frac{1}{2}$ E. 2 miles; and the summit of *Dome Island*, N.E. by E. $\frac{3}{4}$ E.

Sinta Rock, with only 2 ft. over it, lies S.E. $\frac{3}{4}$ S., nearly 5 miles from *Dome Islet*, with the S.W. extreme of *Ruff Rock* in line with the summit of *Plat Island*, bearing W.N.W.; East point of *Namoa N.* by W.; and the highest part of *High Lamock E.* by S. $\frac{3}{4}$ S.

Yeng Rock, awash at low water, is 5 miles N. $\frac{2}{3}$ E. from *Sinta Rock*, with the North end of *Crab Islet* in one with the S.W. extreme of *Namoa*, bearing W. by N. northerly; *Dome Islet W.* by S. $\frac{1}{4}$ S.; *High Lamock S.E.* $\frac{2}{3}$ S., and East point of *Namoa N.N.W.* $\frac{1}{2}$ W. The North point of *Namoa* seen clear of East point, leads north-eastward.

Glengyle Rock, lying one-third of a mile off the S.E. point of *Namoa*, breaks and lies with *Namoa East point* bearing N. $\frac{1}{2}$ E.; *Oeste Rock S.S.W.* $\frac{1}{2}$ W., and *Three Chimneys W.S.W.* Its position was ascertained by H.M.S. *Nassau* in 1875.

Half-Tide Reef, between *Dome Islet* and *Namoa*, lies rather more than a mile from the *Namoa* shore, S.E. by S. from *Three Chimney Bluff*. The channel between these rocks and *Namoa* is obstructed by fishing stakes.

Chelsieu Rock appear as large boulders, and bear East nearly $6\frac{1}{2}$ miles from the North point of *Namoa*.

Diogyu Reef, just awash at high water, is rather more than 3 miles N.W. by N. from *Chelsieu Rocks*. The reef is horse-shoe shaped, 120 yards long, and appears to form a natural dock. It has apparently deep water close to.

CHALLUM BAY is fronted by the North side of *Namoa*; and its entrance affords better shelter during the N.E. monsoon than *Nangaou Bay*, and it is also a good anchorage when the wind blows strong from East or E.S.E.

Chauan Bay entrance is 10 miles N.E. $\frac{1}{3}$ E. from the North point of *Namoa*, may be useful during the southerly monsoon. A vessel should not attempt to cross the bar at less than half tide, when at the deepest part she would have 12 to 14 ft. In the N.E. monsoon it runs far enough back to the N.E. to allow an awkward sea to arise, and a vessel should then endeavour to reach *Owick Bay*, 2 miles eastward of *Chauan Head*, which has a sandy bottom, and is protected to the eastward by a narrow isthmus, having two rocks off its South extreme. The bay should not be entered during the typhoon months, as the anchorage is unsafe during S.W. winds. Immediately eastward of this bay is a remarkable sand patch, which will help to point out its position.

Jokako Peak, 880 ft. above the sea, and conical shaped, is the highest part of the land at the back of *Owick Bay*. *Bell Island*, 3 miles eastward of

Owick Point, is perforated at its South end, which will be seen on a S.E. or N.W. bearing. There is an islet between it and Jokako Point, having a reef off its North end. *Jokako Point* is an isolated hill 640 ft. above the sea: off it are two islets; the nearest, *Cliff Islet*, bearing S.E. by E. one mile, and the other, *Square Islet*, E.N.E. $1\frac{3}{4}$ mile. Square Islet is perforated. A reef extends a cable N.N.W. from Cliff Islet. *Cone Peak*, elevated 800 ft. above the sea, with a peaked rock off its eastern point, bears N.N.E. $\frac{1}{4}$ E. $5\frac{1}{2}$ miles from Jokako Point.

The Brothers are two islets lying S.E. by E. about 12 miles from Cone Peak, and N.E. $\frac{2}{3}$ E. $28\frac{1}{2}$ miles from Lamock Light. They are 180 and 120 ft. in height, and $1\frac{1}{2}$ mile apart in a S.E. $\frac{1}{2}$ E. and N.W. $\frac{1}{2}$ W. direction. The south-eastern islet, the larger and higher of the two, has a fine bluff at its South extreme, and a reef extending north-westward from it; the smaller islet has a remarkable square top.

TONGSANG HARBOUR is one of the best on this coast, and its position will be readily recognised by *Fall Peak*, a remarkable peak, 930 ft. above the sea, which rises on its eastern shore and makes something like a saddle, but with a deeper indentation; upon the island at the entrance is a pagoda which bears from the S.E. Brother, N.W. by N. $14\frac{1}{4}$ miles. A mud bank, of $3\frac{3}{4}$ fathoms, lies outside the entrance, with the pagoda bearing N.W. $\frac{1}{2}$ N. and Fall Peak N.E. $\frac{2}{4}$ N.; but by keeping the Sisters, two islets in the northern portion of the harbour, well open of the East end of Middle Island (the island N.E. of Pagoda Island) a vessel will pass eastward of the bank.

Junks anchoring for the tide bring up between Pagoda and Middle Islands, but in running for this anchorage take care to avoid the rocks which extend south-eastward 2 cables from the East point of the northern portion of Pagoda Island. The walled town of Tongyung stands on a peninsula on the western shore of the entrance abreast Pagoda Island. The inhabitants of and about Thunder Head will bring off supplies of bullocks, poultry, fish, and vegetables.

Caution.—When running into Tongsang Harbour, sail should be reduced in time, if the wind is fresh outside, for violent squalls come down from Thunder Head. The coast on the eastern side of Thunder Head must not be approached within a cable.

Rees Rock, covered at high water springs, lies S.E. by E. $\frac{2}{4}$ E. rather more than half a mile from Fall Peak, with the chimneys on Chimney Island, forming the eastern side of Rees Pass, bearing N.E. by N.; a rock, on which the sea breaks at low water, lies a cable eastward of it.

Pass Islets bear N. $\frac{2}{4}$ E. $1\frac{1}{2}$ mile from Rees Rock, the ground between them being foul.

Rees Pass is between the Pass Islets and Rees Islands, and on its eastern side, W. by S. from the chimneys, and 3 cables from the shore of Chimney

Island, is a shoal of only two fathoms water. The Rees Islands are barren, and only inhabited by fishermen. H.M. brig *Plover* rode out a heavy gale veering from N.E. to E. by N., in this pass. *Simplicia Wreck Rocks* are 6 cables N.E. of South-East Island, a reef, which shows at low water, lying a cable N.E. of the outer rock.

Caution.—In the neighbourhood of the Rees Islands the sea rises rapidly after the commencement of a breeze, and overtops, leading to the supposition that there must be some change in the soundings.

Dansborg Island, lying 2 miles N.E. of *Simplicia Wreck*, has three peaks of nearly equal heights. *Skead Islet* is $1\frac{1}{3}$ mile W.N.W. of this island, and between them, at the distance of 4 cables from the islet, is another small islet with a reef extending from its West point; a reef also projects from the East point of *Skead Islet*. *Ching Rock*, which covers at high tide, lies 14 cables from *Skead Islet*. The eastern *Simplicia*, open East of *Skead Islet*, leads eastward of the reef.

Goo Rock covers at a quarter flood. It lies 2 miles S.W. by W. $\frac{1}{3}$ W. of the *Ching*. *Awoota Rock* is close to the main, N.W. $\frac{1}{2}$ W. $2\frac{1}{2}$ miles from the *Chimneys*.

Black Head, or Hu-tau-shan, $5\frac{1}{2}$ miles northward of *Dansborg Island*, comprises five separate hills, the southern of which, **Black Head**, is most remarkable. On the northern hill is a walled town. There is good anchorage south-westward of **Black Head**, but not much shelter unless the wind be well to the northward. Should the wind draw round to the eastward, the sooner this anchorage is quitted the better. Refuge will then be found by running through *Rees Pass* and anchoring close under *Chimney Island*, or in *Tongsang Harbour*.

The Coast from **Black Head** to *Red Bay*, 10 miles to the N.E., with the exception of one hill and two hillocks, is a sandy plain. *Knob Rock*, 150 ft. high and steep-to, bears S.E. by E. $\frac{2}{3}$ E. $3\frac{1}{2}$ miles from *Spire Islet*.

Red Bay will be found a fair roadstead in the N.E. monsoon, and may be readily recognized by two high black rocks off its eastern point. At the head of the bay is a village on the right bank of a creek.

In navigating this portion of the coast during the N.E. monsoon, the wind will be found to hang to the northward from 2 to 10 a.m., and in the eastern quarter the remaining period. Deeply laden vessels will find it more advantageous to seek shelter in one of the harbours or roadsteads above mentioned during a strong N.E. wind, than to keep underway, as ground can seldom be gained in consequence of the depth of water.

Mount Edmond (lat. $24^{\circ} 7' N.$, long. $117^{\circ} 50' E.$, is about 1,500 ft. high, and from its isolated position is a conspicuous and useful landmark. About 6 miles to the S.W. of **Mount Edmond** there is another conspicuous mountain about 1,200 ft. high.

Cork Point to China-ha Point.—The coast line from **Cork Point**, the

N.E. point of Red Bay, takes a N.E. $\frac{1}{3}$ N. direction $18\frac{1}{2}$ miles to Chin-ha Point. Halfway between Cork and Chin-ha Points is House Hill Point, the southern extremity of a small islet connected with House Hill at low water. *House Hill* is low, with the ruin of a house on its summit, and bears N.W. by W. $\frac{1}{2}$ W. from Lamtia Island. There are two small inlets here; both have bars across the entrance, and are frequented by pirates. *Lamtia Island* bearing N.E., distant 9 miles from Cork Point, is of basaltic formation, and its southern side rises abruptly from the sea; a reef extends N.W. by N. half a mile from it. *Notch Island*, of similar formation, lies N. by W. 3 miles from Lamtia, and has a rocky spur extending S. by E. a quarter of a mile from it, and also one N.W. by W. $1\frac{1}{2}$ cables.

CHAPEL ISLAND, in lat. $24^{\circ} 10' 18''$ N., long. $118^{\circ} 13\frac{1}{2}'$ E., is 47 miles N.E. $\frac{2}{3}$ N., from the S.E. Brother, and $11\frac{1}{2}$ miles S.S.E. from the Chauchat Rocks at the entrance of Amoy. It is of basaltic formation, with steep sides and grassy top, and perforated at its southern end; there is also a remarkable mound on either end. With this island bearing South, and when about midway between it and the entrance to Amoy, Captain Ross, of the Indian Navy, passed over a sand-bank of 6 fathoms water, but no less could be found.

LIGHT.—A *fixed and flashing* white light, the flashes being shown *every half minute*, is exhibited on Chapel Island. It is elevated 527 ft above the level of high water, visible all round, and in clear weather should be seen from a distance of 22 miles. The illuminating apparatus is dioptric, of the first order. The tower, 63 ft. high, is round and painted black; the keeper's dwelling and wall are painted white.

Merope Shoals are between Chapel Island and the coast. *South Merope* has only 5 ft. on its shoalest part, at its southern end, from which Chapel Island bears N.E. by E. $\frac{1}{2}$ E. $7\frac{3}{4}$ miles, and Lamtia Island N.W. by W. 5 miles; thence it extends, with depths of 3 and 4 fathoms, nearly 5 miles to the N.E. *North Merope* is formed of pinnacle rocks, the highest of which dries 8 ft. at low water; these rocks have deep water between them, and bear W. by N. $8\frac{1}{4}$ miles from Chapel Island; the eastern edge bears N.E. from Lamtia Island.

Tingtae Bay, 4 miles northward of North Merope, affords shelter for small vessels in the N.E. monsoon. The pagoda of *Nantai Wushan*, 1,720 feet above the sea, stands on the hills immediately at the back of this bay. The coast here continues in a north-easterly direction 3 miles farther to Chin-ha Point, when it takes a sudden turn to the N.W., forming Amoy Harbour.

Erl King Shoal, reported by the master of the English steamship *Erl King*, 1869, of 3 fathoms water, lies S. by E. $2\frac{1}{4}$ miles from Chin-ha Point, with Chapel Island bearing S.E. $\frac{1}{2}$ E., and Lamtia Island, S.W. $\frac{1}{2}$ W.

CAUTION.—Vessels bound to Amoy from the southward and passing be-

tween the off-lying dangers and the coast should use the utmost caution.

Chin-ha-Point has a dangerous rocky patch above water, about a quarter of a mile in diameter, N.E. by E. $6\frac{1}{2}$ cables from it. Vessels should pass well outside the reef. Notch Island, or Table Head, just open of Chin-ha Point leads to the S.E., and the eastern extreme of Wu-seu Island bearing N. $\frac{1}{2}$ W. leads to the eastward of it.

Wu-seu Island, 330 ft. high, is on the western side of entrance to Amoy Outer Harbour, and on its summit are or used to be three chimneys (the usual pirate signal on the coast of China. Its N.E. and S.E. faces are steep cliffs. It will be prudent not to pass westward of Wu-seu, as the channels inside are only partially surveyed. A rock, which is sometimes covered, lies between Wu-seu and Chin-ha Point, with that point bearing S. $\frac{1}{4}$ W., and Nantai Wushan Pagoda W.N.W.

The *Chauchat* are three flat rocks nearly awash at high tide, lying about half a mile eastward of Wu-seu. A rocky 8-ft. patch lies $4\frac{1}{2}$ cables E. by S. $\frac{1}{4}$ S. from Chauchat, with the extremes of Wu-seu bearing from S.W. by W. $\frac{1}{4}$ W. to W.N.W., and the eastern extreme of Tae-tan N. $\frac{1}{4}$ E. A vessel should pass eastward of the rocks by keeping Tae-pan Point open northward of Tsing-seu N.W. by W. Chow-chow water is found westward of them.

The *Chin-tseao* are two rocks, the eastern of which is 60 feet high, and the other covered at high water, lying N.W. by N. half a mile from the North end of Wu-seu; between them and the main are several islets and half-tide rocks.

TSING-SEU is a table-topped island lying three-quarters of a mile N.W. of the Chin-tseao; it rises precipitously from the sea, and forts are built upon its summit, which is 250 ft. above high water.

A LIGHTHOUSE, 33 ft. high, octagonal in shape, and painted in red and white vertical stripes, is established on the northern slope of Tsing-seu Island. The buildings surrounding it are painted white. From the lighthouse a *fixed light* was first shown in December, 1875. It shows *red* to the southward, over Chauchat Rocks and Woosiu Island, between South and S.E. by E.; *white* over the entrance and up the harbour, between S.E. by E. and N.W. $\frac{1}{2}$ W.; and *red* to the northward over the Tae-pan Shoal, between N.W. $\frac{1}{2}$ W. and West. The light is elevated 130 ft., the bright light being visible 15 miles off, and the red light 8 miles.

This lighthouse stands on the western side of the entrance to Amoy Outer Harbour, Chih-seu Island standing on its eastern side. The channel westward of Tsing-seu is not safe.

On the western side of Amoy Outer Harbour, between Tsing-seu and Tae-pan Point, is *Tae-pan Shoal*, which will be avoided when standing westward by keeping the pagoda on Ki-sue Island open N.E. of Tae-pan Point. To avoid the shoals on the N.E. side of the harbour, do not bring the East end of Seao-tan to the southward of S.E. by E.

AMOY HARBOUR

BY CAPT. H. BELLETT R.N.
H.W. & C. X.L.G. Row 10 feet
Chart 24 of 25
1864 E.

AMOY ISLAND

LITTLE QUEMOY I.

Scale: 0 1 2 Nautical Miles

Taywan I. 12° 15' N. of Taywan I. above Quemoi, Rocks

Scale of 1000 feet
1 inch = 1000 feet
1:1000

Chih-seu is a small islet 60 ft. high, lying N.E. $\frac{1}{3}$ E. 8 cables from Tsing-seu. This islet is connected to two other small islets, Hwangkwa and Tao-sao by a rocky bed which blocks the passage.

Seao-tan is an island $6\frac{1}{2}$ cables long, East and West, 200 ft. high, with three chimneys on it, and a sandy bay on its northern side. It lies E.N.E. of Hwangkwa, and the channel between, 3 cables wide, is frequently used. On Seao-tan is a *Signal Station*, which communicates with Amoy.

Tae-tan Island and Light.—Tae-tan, the highest island of this group, and lying N.E. of Seao-tan, is about 8 cables long, N.N.W. and S.S.E., with a low sandy isthmus in the centre; the highest part is at its East end. The channel between this island and Seao-tan is 2 cables wide, but as vessels are likely to have baffling winds, it would not be prudent for a stranger to use it.

There is a white, octagonal lighthouse, 16 ft. high and about 300 ft. above the sea, on Tae-tan Island, fitted with Argand lamps, and exhibiting a *fixed* light, seen 10 miles off in clear weather, but the light cannot be depended on. The light is shown to the northward between West and S.E.

It is said that since the survey of this locality in 1843, the soundings on the bank westward of Tae-tan have much decreased, and that a vessel drawing more than 12 ft. must wait for water to run through this channel.

AMOY HARBOUR.—Amoy Island, about 22 miles in circumference, occupies the northern portion of the great bight between Chin-ha and Hu-i-tau Points; in the eastern portion is the island of Quemoy and Hu-i-tau Bay. The City of Amoy stands on the S.W. part of the island, abreast the Island of Kulangseu, which affords protection to the inner harbour.

Amoy was captured by the British forces on August 26th, 1841, and by the treaty of Nanking, which followed, was thrown open to foreign trade. The harbour is one of the best and most easy of access on the Coast of China, so that the services of a pilot, either in entering or departing, are scarcely necessary. There is good holding ground in the outer harbour, and vessels can anchor in the inner harbour, within a short distance of the beach, in perfect security.

The Chinese City occupies the south-western corner of the island of Amoy, near the mouth of the Lung-kiang, which leads westerly to Chang-chau-fu. The population is estimated to exceed 200,000, and, unlike the turbulent Cantonese, is quiet and inoffensive. There is a seamen's hospital on this side, at which the charges are $1\frac{1}{2}$ dollar a day for seamen, and 3 dollars for officers.

The British Consul and staff, together with the medical officer and chaplain attached to the Consulate, reside on Kulang-seu, the chief consular building being situated on a cliff commanding an extensive view seaward and of the harbour, while the Vice-Consulate is built at its foot.

The docking accommodation is very good, and ably managed by the Amoy Dock Company. There are three docks. The chief establishment is situated on the Amoy side, nearly abreast Dock Islet. There is also a wharf, with 18 feet water alongside at springs, fitted with masting shears. The dock, which is capable of taking a vessel 300 ft. long, is 316 ft. in length at coping, and 304 ft. on floor; depth from coping to sill, 20 ft.; length of caisson on deck, 64 ft.; on floor, 54 ft.; width of dock at entrance gate, 60 ft.; on floor, 34 feet; there are 18½ ft. water at entrance at springs, and the rise and fall is 17 to 18 ft. The second dock is on the Kulangseu side, near the Lintau landing place; it is 240 ft. in length. The third and smallest, called the Bellamy Dock, is near the entrance of the inner harbour, abreast the Brown Rock; it is 186 ft. long.

A *sunken rock*, on which there are only 6 ft. at low water, lies N.W. $\frac{3}{4}$ N., 1½ cable* from the entrance of Amoy Dock.

The *Harbour* lies between Kulangseu Island and the S.W. shore of Amoy Island, and is from 2 to 3½ cables in breadth, and 1½ mile in length. *Kulangseu*, 302 ft. high, when viewed from the entrance of the outer harbour, appears as one huge boulder. The British Consulate, standing on its S.E. part, is very conspicuous. Over the consulate is the *Signal Station*.

Buoys.—*Coker Rock*, the outer danger at the entrance of the eastern channel into Amoy inner harbour, has 2 ft. water on it, and is marked by a *red* and *white vertical** striped buoy, from which Cornwallis Stone bears E. by S. $\frac{3}{4}$ S., and is distant a little more than half a mile; the West extreme of Thumb Rock is just touching the white staff on the point North of it, N.W. $\frac{1}{2}$ N., and this high water rock (6 ft. high) off Beveridge Point is just open South of two small rocks of the same height lying off the English Consulate, nearly West. *Coker Rock* lies in mid-channel.

Brown or *Ashme Rock*, of 13 ft., is marked by a buoy in *red* and *white horizontal* stripes, from which *Coker Rock* bears S. by E. $\frac{2}{3}$ E. one-third of a mile, and the South extreme of the easternmost house on Kulangseu is just on with the top of Thumb Rock W. by S., which latter is distant 1½ cable.

Harbour Rock lies in the anchorage, having only 9 ft. water at low tides, and 6 and 7 fathoms between it and the shore; from the rock the apex of Dock Island bears N.E. $\frac{1}{4}$ N., distant 1½ cable, and Monkey Island Pagoda, N.W. $\frac{1}{4}$ W., 7¼ cables. There is a buoy 36 ft East of this rock.

Kellett Spit is the extreme North of the foul ground extending in a northerly direction from the North point of Kulangseu. A *red* buoy is placed in 5 fathoms on its extreme end. It has been the scene of many accidents.

* In the Chinese official list, corrected to August, 1874, it is stated that there is a large iron buoy about 60 fathoms from the *Coker Rock*, and a small iron buoy 30 ft. S.W. of the pinnacle of the rock, but how coloured is not mentioned.

Anchorage.—The outer harbour of Amoy has extensive anchorage in 7 to 16 fathoms, good holding ground, and unless vessels are badly found it is not probable that any gale could hurt them. The usual anchorage is westward of Cornwallis Stone; a good berth is in about 6 fathoms, muddy bottom, with Cornwallis Stone bearing East, and Thumb Rock N.W. $\frac{1}{2}$ N. This is almost as near the town as a vessel can approach without the necessity of mooring. Moorings are laid down for H.M. gunboats.

There is also good and safe anchorage in 7 to 17 fathoms in the channel on the West side of Kulangseu.

Typhoons are scarcely known, but when experienced along the coast, Amoy is visited by heavy north-easterly gales, with hot winds, veering round East and South. Vessels then in the neighbourhood generally run for Amoy Harbour to repair damages.

Tides.—It is high water, full and change, in Amoy Inner Harbour, at 12^h 0^m, ordinary springs rise 18 $\frac{1}{2}$ ft., neaps 14 $\frac{1}{2}$ ft. During the N.E. monsoon the evening fall is only 15 ft., the previous rise having been 19 ft. This occurs from September till March, when for a short time the morning rise and evening fall may be said to be equal. During the S.W. monsoon this phenomenon is reversed, the evening tide having the greatest fall, the morning the least. The greatest velocity at springs is 4 knots.

Owing to a greater rise of tide from August till December than the other months of the year, a vessel may be taken into Amoy Dock, drawing 18 $\frac{1}{2}$ ft. In April there are only 16 ft. on the blocks, which is the lowest during the year. It gradually falls to this level from December, and again increases to the month of August.

DIRECTIONS.—When bound to Amoy from the southward, after rounding the Lamock Islands and the Brothers, steer about N.E. by N. for Chapel Island, keeping between 10 and 12 miles off the coast to avoid South Merope Shoal. The Nantai Wushan pagoda is a good landmark by which the entrance of Amoy may be recognised when in the neighbourhood of Chapel Island, which may be passed close-to on either side, thence a N. by W. $\frac{1}{2}$ W. course will lead towards the entrance of the harbour. As the 8-foot patch off the Chauchat Rocks is approached, keep Tae-pan Point well open North of Tsing-seu to pass eastward of it; thence steer between Tsing-seu and Chih-seu into Amoy outer harbour.

Approaching the harbour from the eastward, give Dodd Island a berth of a mile, and after passing Leeo-lu Head, which is steep-to, be careful not to shut in the island with the head until Ki-seu Island opens South of Tae-tan Island, W. by N. $\frac{3}{4}$ N., to clear Quemoy Spit. Thence steer for Tsing-seu, keeping Tae-tan Point well open North of Tsing-seu as before.

The entrance to Amoy in clear weather is easily distinguished by the high land on the South side, on the summit of which is the Nan-tai Pagoda, an excellent land-mark, but often covered with clouds, especially in the S.W.

monsoon. After Chapel Island is made the six islands forming the outer harbour soon come in sight.

The channel into the inner harbour, between Kulangseu and Amoy, is so narrow, and sunken rocks lie off both its shores, that a stranger should not attempt it without a pilot. The best anchorage is between Dock Islet off the city point and Hauseu Island. The inner harbour, however, may be reached without difficulty by passing through the channel westward of Kulangseu, taking care to give Druid Head, the S.W. point of the island, a berth of at least 1 cable's length, and recollecting that shoal water extends half a mile from the main land on the opposite shore. After passing Druid Head, keep well over towards Watson and Hauseu Islands, and in crossing over to the eastward for the city beware of Kellett Spit, extending from the North point of Kulangseu, especially if the ebb tide is running strong.

Pilots (Chinese) are generally to be met with inside Chapel Island who are licensed to pilot vessels (1869) as far as Cornwallis Stone, the limit of the inner harbour, whence European pilots take charge. Their boats may be recognized by their carrying a flag, and having "Licensed Pilot" painted on the bows.

Entering the harbour.—It is always advisable to enter the eastern or Blonde Channel into Amoy Harbour on the ebb. In entering, steer for Cornwallis Stone, and after passing it keep the Amoy shore aboard on the ebb and during the N.E. monsoon. The Coker and Brown Rock buoys watch well; leave them at half a cable on the port hand. The South Chalk Island just open northward of Hauseu Island, N.W. $\frac{3}{4}$ N., clears the Alibi Rock, the Isère Rocks, and all the dangers on the East side of Kulangseu.

The wider channel on the West side of Kulangseu may be used without difficulty, but a vessel of large draught in entering should keep Druid Head a little eastward of North to avoid a 3-fathom spit, which extends off Anson Bluff, on the eastern side of the channel. Cass Spit, extending from the S.E. point of Sung-seu Island, has only 8 ft. at low water on its extreme, which is one-third of a mile from the point; to clear it, do not shut in the white tower, which is on the low wooded point West of the Chalk Islands, with the N.E. point of Sung-seu, N. by W.

In working through this channel, standing westward towards Cass Spit, keep the white tower open of the N.E. point of Sung-seu. Standing eastward, Druid Head and the small joss house may be approached to three-quarters of a cable. If obliged to tack between the small joss house and Modeste Point, keep Druid Head well in sight. Kiu-sung-seu is fringed with low water rocks, and may be approached to about a cable. In making the eastern board towards the Isère Rocks, tack when the small joss house is midway between First Rock and Modeste Point. When northward of the buoy on Kellett Spit, or when the cathedral cross is in line with Dock Islet,

steer to the eastward for the anchorage off the city, keeping the South Chalk Island open North of Hauseu to clear the Isère Rocks.

On entering Amoy, if foggy, after passing between Tsing-seu and Chih-seu and unable to see Kulangseu, care should be taken to ascertain the direction of the tide as it runs here very strong, and vessels are often so drifted out of their course as to be compelled to anchor. As a rule, the ebb tide for the first three hours will be found setting strongest through the narrow channel North of Kulangseu and obliquely across the outer harbour, about S.E. ; and the last of the tide, making stronger through the broad channel South of Kulangseu, will generally be found setting more easterly and directly through the fairway.

In working out with the ebb tide it is not advisable to stand in close to Tsing-seu or Chih-seu on account of the eddies and chow-chow water ; the tides at springs run very swiftly between the islands and set obliquely, N.E. and S.W., across the outer harbour. A sailing vessel beating out of Amoy on the ebb should be careful not to be becalmed under Tsing-seu, as the tide runs strong towards it.

Vessels of large draught should pass northward of Kellett Spit buoy, as immediately inside it are only 18 ft. at low water. Many vessels have passed over the Isère Rocks with impunity, owing to the great rise of tide, but some in doing so have been greatly injured, and in the case of the *Isère* a total shipwreck was the consequence.

The formation of the bottom in Amoy Harbour appears as irregular as the sudden and abrupt falls on Kulangseu. The residents are of opinion that the patches are mushroom shaped, and consequently when cables wind round them they are irrecoverable.

When there is much shipping in the inner harbour, the easiest way often to get out is to go round to the westward of Kulangseu.

The channel around Amoy Island is so narrow and winding that directions would be useless ; the chart is the best guide. The Bay of Sungseu, on the North side of which the city of that name is built, runs back 7 miles to the westward from Kulangseu ; it is, however, shoal, and only navigable for small craft.

Coal is supplied from Hong Kong for H.M. ships, and stored, and is put on board by contractors at any hour of the day or night, weather permitting. Fresh beef, vegetables, and water are readily procured.

QUEMOY ISLAND is separated from Amoy by a channel 5 to 7 miles wide, in the middle of which is Little Quemoy Island. Between Tae-tan Island and Little Quemoy the channel is deep, but narrowed by reefs.

The channel between Little Quemoy and Quemoy is half a mile wide. To enter, bring the N.E. point of Little Quemoy on a N. $\frac{1}{2}$ E. bearing, and steer for it until the pagoda on Quemoy bears East, then haul to N.E. by N. for

a mile, and anchor in about 9 fathoms secure from all winds. Vessels drawing less than 15 ft. may borrow over on the Little Quemoy shore.

Quemoy Bank extends 3 miles southward from the West point of Quemoy. It is steep-to, and the lead will give no warning. *Leeo-lu Bay*, on the South coast of Quemoy Island, is said to afford good shelter from N.W., round northward, to East, but the tides are uncertain, and several dangers exist near the shores.

Hu-i-tau Bay, formed between the eastern side of Quemoy and the mainland, affords good shelter in the N.E. monsoon. Hu-i-tau Point, the eastern point of entrance, is 80 ft. high, and at $1\frac{1}{4}$ mile south-eastward of it is a sunken rock, on which $2\frac{3}{4}$ fathoms were found.

Vessels requiring shelter during the N.E. monsoon in this bay, will find good anchorage on its eastern side between Oyster Islet and Oyster Rock, taking care to avoid the latter, which only shows at low water springs. There is also anchorage westward of Oyster Islet in 5 fathoms, but the islet should not be brought to the southward of East, as a rocky ledge of only 6 feet water lies 6 cables W.N.W. of the islet.

Vessels seeking shelter in a southerly wind can run up the bay to the northward of White Rocks and Thalia Bank, and find anchorage in $5\frac{1}{2}$ fathoms at half a mile N.E. of Flak Islands. To avoid the northern edge of Thalia Bank, do not bring Flak Island to the northward of W. by N. $\frac{3}{4}$ N.; and by keeping Oyster Islet open northward of the fort, the bank will be avoided which extends from the North side of the bay.

The channel between Thalia Bank and Quemoy is foul with several reefs, and should not be attempted without some previous knowledge. To clear the South end of Thalia Bank, keep the chimney on the North end of Quemoy on a W. by N. $\frac{3}{4}$ N. bearing until White Rock bears North, then steer N.W. until the rock is N.E. by E., when shape a course to pass half a mile from the points of the bays on the Quemoy shore.

The channel North of Quemoy having 8 ft. in it at low water, might be used at high tide; but no vessels should attempt it without a pilot.

CHIMMO BAY is between Chimmo Point on the South, and Yungning Point on the North. The former of these points lies $8\frac{1}{2}$ miles N.E. of Hu-i-tau Head. This bay can only be termed a roadstead, and is dangerous in the southerly monsoon. *Yungning Islet* is steep-to, but the reef lying W. $\frac{3}{4}$ S. 3 cables from it, covers at high water. Within the bay the depths shoal gradually, but vessels drawing 15 ft. and upwards must not bring Yungning Islet to the southward of E. $\frac{3}{4}$ S. It is high water, full and change, in Chimmo Bay, at 10^h 20^m; springs rise 16 ft. The tide sets with considerable strength along the coast, between Hu-i-tau and Chimmo Bays; but both the period and the rate vary considerably with the monsoon. The state of the tide will be known by the numerous fishing nets moored off the coast.

CHIN-CHU HARBOUR.—The coast from Chimmo Bay trends N.E. by N. 8 miles to Chungchi Point, the southern point of entrance to Chin-chu Harbour. At $1\frac{1}{2}$ mile southward of Chungchi Point is *Bell Islet*, with a building on it something like a bell.

Pilots.—Chin-chu Harbour is the only place where pilots can be got for Hai-tan Strait or Hungwha Sound, and it is advisable that all vessels bound there should take one, as the navigation is very intricate.

Kusan Pagoda, 760 ft. above the sea, on the North side of Chimmo Bay, is an excellent mark for recognizing the locality of Chin-chu Harbour when approaching it from the southward. From a position about $1\frac{3}{4}$ mile eastward of Chungchi Point, steer North until Choho Pagoda opens northward of Seatoi Island, bearing W. $\frac{3}{4}$ S., when the pagoda should be steered for on that bearing, and it will lead along the northern edge of Seatoi Bank. The ship *Omega*, drawing 11 ft., struck on a bank $1\frac{1}{2}$ mile eastward of Seatoi, but not less than $2\frac{1}{2}$ fathoms were found upon the Seatoi Bank in March, 1844; the southerly monsoon may, however, cause the sand to accumulate at times.

If running for the harbour from the northward, and intending to anchor southward of the Boot Sand, after passing about three quarters of a mile South of Passage Island, steer in with Choho Pagoda W. $\frac{3}{4}$ S. until the peak on Tatoi Island bears N. by W. $\frac{1}{2}$ W., and the eastern end of Seatoi Island S.S.W. $\frac{1}{2}$ W., then haul to the southward, and pass a cable eastward of the East point of Seatoi. Round the South side of Seatoi at half a cable, and when its western summit is on with the highest part of Tatoi, the vessel will be in the narrowest part of the channel, which is here barely a cable across.

Having passed Seatoi, a W.N.W. course will lead to the anchorage above Pisai Island in mid-channel. By keeping this island westward of W. by N. $\frac{1}{2}$ N., the reef off Choho Pagoda will be avoided; and the southern edge of the Boot will be cleared by not bringing Seatoi to the southward of E. by S. $\frac{3}{4}$ S.; the outline of this bank, however, is generally visible. The opium vessels run in between the Lynx and Taheen Rocks, with the South extremes of Seatoi Island and Ota Rock in line with the North extreme of Pisai. The anchorage is North about $1\frac{1}{2}$ or 2 miles from Pisui, where the channel is 3 cables wide.

If wishing to anchor on the North side of the Boot, steer to pass northward of Tatoi Island, and if drawing less than 15 ft. a vessel may run up until Choho Pagoda bears S. by W. $\frac{1}{2}$ W., where she will have smooth water in any weather, as the Boot forms an excellent breakwater. The North edge of the Boot will be avoided by keeping the White Rocks southward of East. A sunken rock lies $1\frac{1}{2}$ cable from the northern shore, and N. by W. $\frac{1}{2}$ W. from the summit of Tatoi. There is good anchorage in N.E. or northerly

gales in $3\frac{1}{2}$ and 4 fathoms, with the summit of Tatoi S.E. by S. ; but in a S.W. gale the former anchorage is to be preferred. The Boot may be crossed by a vessel of light draught at high tide, but it should be sounded first, as the sands are liable to shift.

The entrance of the small river, leading to the town of Chin-chu, is 3 miles W. by N. $\frac{3}{4}$ N. from Pisai Island. On the left bank near the entrance is a circular fort, 4 or 5 miles above which is the town standing on the North bank of the river. The channels to it are shoal and intricate, and the large junks have to wait in the neighbourhood of Pisai for tide before they can cross the flats, which are covered with artificial oyster beds.

Tong-bu Bay.—About 10 miles N.E. by E. of Chung-chi Point is the town of Tong-bu, south-westward of which is a large open bay or roadstead, affording anchorage in 7 to 4 fathoms, with good shelter in the N.E. monsoon ; it cannot, however, be recommended, on account of the exceedingly rocky character of the coast.

Juno Rock is a cluster of rocky heads covered with coral, with 12 ft. at low water, and $5\frac{1}{2}$ to 6 fathoms around, from which the West corner of Tong-bu wall bears N.E. $1\frac{3}{4}$ mile.

Pyramid Point, at 3 miles eastward of Tong-bu, appears a bold, black face of land ; to the S.E. of it is a rock which never covers. To the eastward of the Pyramid are several reefs, from the outermost of which the Pyramid bears S.W. by W. $\frac{3}{4}$ W. 6 cables.

Port Matheson, called by the Chinese *Gulai*, is the next inlet to the N.E. of Chin-chu. It is only a roadstead, and that a bad one in the southerly monsoon. There are no dangers in it except a rock lying North 4 cables from the largest islet on the southern shore.

Meichen Sound, the next inlet North of Port Matheson, is 6 miles across at the entrance, which may be recognized by the *Ninepin Rock* lying nearly in the middle of it. A reef extends South from the Ninepin, and at the distance of a mile in that direction is *Square Rock*, one of a cluster of rocks, which does not cover at high tide ; thence the reef extends south-westward $1\frac{1}{2}$ cable, and its outer part dries at low water. A large spar is moored about $1\frac{1}{2}$ mile S.W. of square Rock.

East, 6 cables from the Ninepin, is a flat patch of rocks awash at high water, and between this patch and Rogues Point is good anchorage in the N.E. monsoon. In the southerly monsoon vessels will find a good harbour to the N.W. of Saddle Island, which bears N.W. by N. $3\frac{1}{4}$ miles from the Ninepin.

It is high water, full and change, in Meichen Sound, at 0^h 30^m ; springs rise 17 ft.

Sorrel Rock, bearing E. by N. $3\frac{3}{4}$ miles from Rogues Point, is 60 ft. high, and has a detached rock three-quarters of a cable South of it.

Pinghai Bay, the next inlet N.E. of Meichen Sound, is $6\frac{1}{2}$ miles wide at

entrance, between the Rowan Islands on the West and Ping Point on the East, and shoals gradually from 5 to 3 fathoms. *Ping Rock*, 90 feet high and conical shaped, lies 4 cables southward of the latter point; there is a sunken rock S.W. by W. a quarter of a mile from it. The anchorage in this bay is in 3 fathoms, off the town of Pinghai, with the Ping Rock bearing S.E. by E.

Loutz Rock is about $5\frac{1}{4}$ miles E.S.E. from Ping Rock, and between them, $1\frac{3}{4}$ mile from Loutz, are two sunken rocks, named *Loutz Shoal*, from which the Ping is in line with Marlin Spike Peak N.W. by W. $\frac{1}{4}$ W.; and the islet lying N.E. of the Loutz in one with the South Yit, E. $\frac{3}{4}$ N. N.N.W. 2 cables from the above islet is a half-tide rock, and another S. $\frac{3}{4}$ W. 8 cables from the islet and East from the highest part of the Loutz.

The **OCKSEU** or **WOKEU GROUP** consists of two islands, with a barren rock in the centre joining the eastern island. The north-western island, the largest, is 260 ft. above the sea, round-topped, with smooth sides, and bears from the Sorrel Rock E. by S. $\frac{1}{4}$ S. $15\frac{1}{2}$ miles, and from the South Yit S. by W. $\frac{1}{2}$ W. $10\frac{1}{2}$ miles. A strong tide ripple, or reef, appeared to break about $1\frac{1}{2}$ mile W.N.W. of the western Ockseu Island.

LIGHTHOUSE.—On the high or West Ockseu Island stands a round stone tower 64 ft. high, painted black. The surrounding buildings are painted white. The light, first exhibited in December, 1875, is a *bright revolving light*, showing a flash every minute. It is elevated 286 ft. above the sea, and through a clear atmosphere is visible 24 miles off.

LAM-YIT ISLAND, the southern and largest of the archipelago, called the Eighteen Yits, fronts the deep and extensive inlet, Hungwha Sound. Off the South point of the island is *South Yit Islet*, to the N.W. of which will be found a snug and excellent anchorage, in 7 to 10 fathoms, in the N.E. monsoon. N.W., 2 miles from the South Yit, is a flat rock, always above water; and S. by E. 4 cables from this rock, is a reef awash at low tide.

Lam-yit Channel is on the West side of Lam-yit Island. A sand-bank extends $2\frac{1}{4}$ miles in a southerly direction from the West point of Lam-yit from its South end, the South Yit bore E. $\frac{3}{4}$ S.; its western edge will be avoided by keeping Lam Point (the West point of the island, which will be known by its three chimneys) to the eastward of North. On the western side of the channel there is also a rocky patch of $1\frac{3}{4}$ fathom, the eastern edge of which bears S. by W. 2 miles from *Clam Islet*, the largest islet between Lam-yit and the main.

Anchorage.—The *Plover* rode out a strong N.E. gale between Lam Point and Clam Islet; but better shelter will be found southward of Lam Point, where the junks anchor. For vessels of large draught there is anchorage in 4 or 5 fathoms, at $1\frac{1}{2}$ mile northward of the point.

HUNGWHA SOUND.—Besides Lam-yit Island, there are many islands and rocks within Hungwha Sound, bordering its shores, the principal ones

being near the entrance points. The only passages that must be used to enter it are, the Lam-yit and Hungwaha Channels, and Hai-tan Strait.

Pilots can be obtained at Chin-chu. Hungwaha River flows into the western part of Hungwaha Sound.

Hungwaha Channel.—The *Eighteen Yits* are a scattered group of islands lying N.E. and eastward of Lamyit Island, and extending over a space of 10 miles. On no account ought vessels to stand in among the Yits, as the ground is very uneven.

Cliff Island lies $1\frac{1}{2}$ mile northward of the North extreme of Lam-yit. From this dangers extend for nearly $1\frac{1}{2}$ mile to the N.E. by E. At 2 miles E.N.E. of Cliff Island is *North Yit Rock*, surrounded by dangers, and lying a mile northward of the N.W. point of *Red Yit*, the largest of the Eighteen Yits. The best channel into Hungwaha Sound will be found by passing northward of the North Yit and Cliff Island, and southward of the *Passage Islands*, which lie 2 miles northward of Cliff Island. *Henry Rocks*, $2\frac{1}{2}$ miles eastward of the North Yit, and S.S.W. $1\frac{1}{2}$ mile from White Island, are a dangerous cluster of sunken rocks, lying W. by N. and E. by S. 1 mile in length. *Kerr Island* lies N.E. by E. $2\frac{1}{2}$ miles from White Islet, and has numerous dangers lying South and S.E. of it. With White Island bearing W. by N., however, all these dangers will be cleared.

Hungwaha Channel leads out to seaward North of the Eighteen Yits, and the northern side of which is bounded by the island and reefs off Vangan Point.

Entering Hungwaha Channel from the eastward, pass (taking care to avoid the Sedan and Comet Rocks) between Double Yit and Sentry Island, and westward of Sand Island and the rocky islets on its N.W. face, off which there is anchorage, should daylight or the tide fail; but the best shelter is off Station Island, to the North of Chim Island.

On no account whatever pass between Sand, Sentry, Reef, and Chim Islands, as this locality has not been sufficiently examined, and beware of the reefs eastward and southward of Reef Island. Some of these have been accurately placed. The *Comet Rock*, with 9 ft. water, lies $1\frac{3}{4}$ mile S. by W. $\frac{3}{4}$ W. from the summit of Reef Island. *Breaker Rock* lies $1\frac{1}{4}$ mile South of the same. *Sedan Rock*, the outermost yet discovered, is of small extent, with 8 feet water over it, steep-to, having 11 to 13 fathoms close around. From its shoalest part, Red Yit Island summit is just open northward of the North extreme of Double Yit Island, bearing W. $\frac{1}{2}$ N.; and Chim Island summit is in line with the eastern extreme of the reef lying 3 cables westward of Bent Island, bearing N. by W. $\frac{1}{2}$ W.

HAI-TAN ISLAND.—This large and irregular shaped island, lying between the parallels of $25^{\circ} 24'$ and $25^{\circ} 40'$ N., is separated from the mainland by the fine navigable strait bearing the same name. Its northern part is high, the peak of Kiangshan Hills rising 1,420 ft. above the level of the sea,

whilst the eastern and western shores are low, and indented by deep sandy bays. Numerous small islands and rocks occupy Hai-tan Strait, between the island and the coast, and although it is not to be recommended to sailing vessels except with a commanding breeze, being very intricate, yet the coasting steamers and junks invariably use it; one of the latter was found lying there, having being detained 27 days waiting for an opportunity to get out at the northern end.

There is very good anchorage under Hai Head, the S.E. point of Hai-tan Island, in the N.E. monsoon. It is reported free of rocks. H.M. gun-boat *Dwarf* in 1872 anchored in $3\frac{1}{2}$ fathoms, with the outer point S.E. by E., and the easternmost village on the bay N.N.E. This anchorage is frequented by junks.

To enter the South end of Hai-tan Strait, after passing Junk Sail, steer North for Low Islet until the East end of Junk Sail and the West end of Station Island are in line, keeping them so until Pass Island bears South; but be careful to shut the points in somewhat at the moment of passing the Ashuelot Rocks,* or when Low Island will be coming on an East bearing. Then steer N. $\frac{1}{2}$ W. or N.N.W. as may be desirable to pass East or West of Flag Island.

Since the date of Kellett's and Collinson's Survey in 1843, the channels North of Flag Island have materially altered, the old channel on the East having decreased in depth of 17 ft. at its northern part, and a new channel, the Wilson, on the western side of the strait, has 22 ft. at low water springs. Between the two a middle ground 3 miles in length has grown up with only 4 to 6 feet water over it. The banks are generally discoloured, and their edges show, but not invariably. In thick weather, especially when coming from the northward, the Wilson channel, is preferable.

The Cow's Horn, a remarkable peak on the main to the northward of the strait, kept in line with the summit of Slut Island N. $\frac{1}{2}$ W., leads clear of all dangers to within a mile of the northern entrance.

The best channel out of Hai-tan Strait is eastward of Slut, between Slut and Shingan Islands. The course is N.E. $\frac{3}{4}$ N. Reefs extend from both shores, narrowing the channel to 4 cables. Between Slut and Shingan there are often strong tide rips and overfalls, which render the steerage very difficult. For *Pilots*, see page 1025.

Tessara Islands are a group of four islets lying N.N.E. 6 miles from Slut Island. There is nothing here sufficiently extensive to shelter a vessel in N.E. monsoon, and it cannot be considered safe for large vessels to pass by any of the channels inside Tessara Islands.

Red Rock is a small islet with reefs about it, lying S.E. by S. 3 miles from

* Station Island kept open of the point inside Junk Sail Rock, leads through the channel westward of Ashuelot Rocks.

Tessara Islands. Vessels should not close the Hai-tan shore to the eastward of this rock.

Norton Rock, about 50 ft. high, with a rock awash half a mile westward of it, lies East $6\frac{1}{2}$ miles from Tessara Islands.

TURNABOUT ISLAND, lying E.S.E. about 4 miles from Hae Head, in lat $25^{\circ} 26' N.$, long. $119^{\circ} 58' 42'' E.$, has two small islets off it, and *Sunda Rock*, dry 3 ft. at low water spring tides, bears North from its northern extremity, distant $3\frac{1}{2}$ cables, with foul ground inside.

Also a rock, awash at low water spring tides, lies South of the South point of Turnabout Island, distant $1\frac{1}{2}$ cable.

Vessels should not approach Turnabout Island within three-quarters of a mile. The lighthouse keepers report that several steam vessels have been hazarded, by rounding the South point of the island too closely.

A LIGHTHOUSE, 54 ft. in height, black, surrounded by white dwellings, is built on the summit of Turnabout Island, from which is shown a *fixed bright light*, visible all round. It is elevated 256 ft. above the sea, and should be seen, in clear weather, a distance of 23 miles.

WHITE DOG ISLANDS, called by the Chinese *Pih-keun*, are 22 miles N.N.E. $\frac{1}{4}$ E. from the peak of the Kiangshan Hills on Hai-tan Island, and $8\frac{1}{2}$ miles S.E. of the entrance of the River Min. They consist of two large and one smaller islet, named Middle Dog, South Dog, and Tong-sha Island. *Tong-sha*, the western and largest of the group, has a reef of rocks running off its West extreme, terminated by a square islet called the Breakwater. The highest part of the island is flat-topped, and 590 ft. above the sea

Rocks and reefs extend both northerly and westerly from the Middle Dog, but the outer ones always show; a rock on which the sea generally breaks, lies N.E. by E. $\frac{1}{2}$ E. 11 cables from its N.E. point. The channel between Middle Dog and Tong-sha is safe. The islands are inhabited by a few fishermen, and were, at the time of the survey, occasionally visited by pirates.

A LIGHTHOUSE, white in colour, and 35 ft. high, is erected on the N.E. end of Middle Dog Island. It shows a *fixed bright light*, varied by a *bright flash every half minute*, visible all round, except to the westward, where it is intercepted by the higher ridges of the White Dogs. It is obscured by Tong-sha when bearing between E. by S. $\frac{3}{4}$ S. and East; by the northern hill of Middle Dog when between E. $\frac{3}{4}$ N. and N.E. by E. $\frac{1}{2}$ E; and by the southern hill of the same when between N.E. by E. and N.E. $\frac{1}{2}$ N. It is elevated 257 ft. above the sea, and in clear weather should be seen from a distance of 23 miles.

Anchorage in the N.E. monsoon, for vessels of any draught, will be found under Tong-sha Island. Small vessels will be well sheltered in 18 ft., close under the Breakwater, and here whole fleets of Chinese junks remain during foul weather. As the water decreases gradually towards Tong-sha, large

vessels may approach as convenient, bearing in mind that the rise and fall is 18 ft. H.M.S. *Cornwallis* anchored here for five days, with strong north-easterly winds, and rode easy, with the Breakwater bearing N. $\frac{1}{2}$ W., the village N.N.E., and the Middle Dog E. $\frac{1}{2}$ S.

The Passage from Lam-yit to White Dog Islands may be considered as the most difficult portion of the coast that a vessel has to contend with in the N E. monsoon, and it is believed there are few men who know the coast of China but will allow that Turnabout Island is well named. The attempt of the flood to force its way through Hai-tan Strait forces the water back, and occasions a strong current off Kwing Bay, at the N.E. end of Hai-tan. It is a great misfortune that this bay does not afford shelter, as it would prove an uncommonly good halfway house ; it is, however, one of the worst places on the coast of China the *Plover* dropt anchor in, being full of rocks, with a heavy swell. Sailing vessels have, therefore, no alternative but to stand boldly off and trust to a slant on the Formosa side, or take the Hai-tan Strait. The open sea is, however, preferable, notwithstanding that some vessels have got successfully through the strait ; yet it requires local knowledge and a handy vessel to prevent great detention.

CHAPTER XXII.

FORMOSA AND THE PESCADORES ISLANDS.

FORMOSA ISLAND, 210 miles in length and 80 miles wide at its broadest part, is high and mountainous throughout its whole extent, except at the central part of the West coast, where a broad alluvial plain stretches from the mountains to the sea, and on which is situate the Chinese capital of Tai-wan-fu.

The Chinese have long been in possession of the plain and the harbours and villages of the West and North coasts, but the East coast is still peopled by aboriginal and warlike tribes, not subject to the Chinese, yet who hold intercourse with them of a more or less friendly character. The population is estimated to number $1\frac{1}{2}$ million.

Coal is found in many parts of the island, and in the North is worked by European machinery. It is of a quick burning nature, gives out much heat, and fairly answers for steamers, if mixed with a harder kind. Sulphur is also found. Among the products of the island may be mentioned rice, camphor, wheat, coffee, tobacco, tea, and sugar. The cultivation of the tea plant seems to be on the increase. The climate is not healthy for Europeans, being very damp during a greater portion of the year.

In consequence of repeated acts of outrage and murder towards the shipwrecked crews of foreign vessels, in revenge for former injuries, a treaty was concluded on 15th October, 1867, with the hostile tribes of the South part of Formosa, by the United States Consul of Amoy, by which the southern end of Formosa was thought to be rendered safe to those driven on its coasts by distress. The outrages continued, however, and a Japanese force was sent there in 1871 to punish the natives.

The **BASHEE CHANNEL**, frequented by vessels making the eastern passage to China, is 80 miles wide between the Batanes (page 937) and the South end of Formosa, but its navigable breadth is greatly contracted by the dangerous Gadd Rock, which must be remembered when sea room is needed to avoid the track of a typhoon.

Gadd Rock, or *Cumbrian Reef*, in the fairway of the Bashee Channel, is in lat. $21^{\circ} 42\frac{1}{2}'$ N., long. $121^{\circ} 39'$ E., Little Botel Tobago bearing from it N. $\frac{1}{4}$ W. $14\frac{1}{2}$ miles. It may be considered one of the worst hidden dangers known, being steep-to, with deep water all round. At low water the sea would probably break, but the locality is generally covered by violent tide ripples.

When passing southward of Gad Rock in thick weather or in the night, make allowance for a northerly current, which is generally experienced in light winds and during the S.W. monsoon. Several vessels during light winds have been drifted by the current between Formosa and Botel-tobago.

BOTEL-TOBAGO is high, $7\frac{1}{2}$ miles long, N.W. and S.E., appears in form of a saddle, or with a gap in it when viewed from a S.S.W. or N.N.E. direction, and is visible about 50 miles from the mast-head. The island is well inhabited, and its highest part is crowned with trees; the N.E. peak is 1,850, and the West peak 1,820 ft. above the sea.

Indifferent anchorage was found by H.M.S. *Sylvia* in 1867, about half a mile from the beach, on the North side of the island, in 21 fathoms, black sand and rock. The coast is rocky in almost every part, and needle rocks are seen in many parts of the island; and if the ground under water assumes the character of that which is above, a vigilant look-out for rocks is necessary when rowing along the coast. When circumnavigating the island deep water was found at a mile off shore. The island is densely inhabited, but the natives were timid.

Little Botel-Tobago is a small island of considerable height, lying about S.S.E. $3\frac{1}{2}$ miles from the southern part of Botel-Tobago; foul ground appears to extend all round this island.

Alceste Shoal, formerly marked on the chart in about lat. $22^{\circ} 5'$ N., long. $121^{\circ} 18'$ E., is supposed to have no existence.

Vele-rete Rocks, in lat. $21^{\circ} 45'$ N., long. $120^{\circ} 49\frac{1}{2}'$ E., lie 9 miles S. by W. from South Cape, and on nearly the same parallel, and about 47 miles westward of Gadd Rock in the Bashee Channel. The highest is S. by W. 9 miles from the South Cape of Formosa, and with two others is from 15 to 25 feet above the sea. The channel between them and the South end of Formosa is safe; but very heavy tide ripples are often experienced.

Caution.—The northern current of the Japan stream sets with great strength over these rocks to the north-eastward.

SOUTH CAPE or **NAN-SHA**, in lat. $21^{\circ} 54'$ N., long. $120^{\circ} 50'$ E.; is low, and, together with the one which is three-quarters of a mile E.N.E. of it, formed of coral limestone. At 4 miles to the N.W. is a peculiarly rugged hill, 1,035 ft. high, from which the land slopes down gradually to the cape. Farther northward is a high, double-peaked mountain, visible 60 miles in clear weather.

EAST COAST of FORMOSA, extending 200 miles to the N.N.E., is mountainous, and with the exception of Sau-o Bay is without harbours, and deep water will be found close in to the land. The mountains rise almost immediately from the sea; their sides in some places are cultivated, and scattered houses are seen.

This coast is not visited by the full strength of the N.E. monsoon, which probably results from the mountainous character of the country preventing the breeze blowing home. Sailing vessels, however, experiencing strong gales at 20 miles to the eastward, might feel cautious in venturing in-shore. Nor is there any necessity to run to leeward; but if, when beating up, they should experience the breeze declining in strength, with less sea on the western board, particularly between 9 a.m. and 3 p.m., or up to sunset, they will find it advantageous to hug the coast within a moderate distance; but good judgment and caution are requisite, as sudden loss of wind, attended by inconvenient swell, might be attended, if followed by calm, with imminent danger.

Double Peak, a mountain on the coast 58 miles to the northward, is about 2,500 ft. high. *Samasana Island*, $15\frac{1}{2}$ miles from the coast abreast Double Peak, is in lat. $22^{\circ} 39' 26''$ N., long. (assumed) $121^{\circ} 28' 48''$ E., and lies N. $\frac{3}{4}$ W. 34 miles from Botel-Tobago. H.M.S. *Sylvia*, in 1867, anchored in the North bay in 13 fathoms. The anchorage is not recommended. It is advisable to avoid the lee side of the island, as calms, eddies, and variable winds are likely to cause delay. *Black Rock Bay*, in lat. $23^{\circ} 6' 30''$ N., and long. (assumed) $121^{\circ} 26'$ E., and 22 miles northward of Double Peak, might afford shelter from S.W. and southerly gales, but the bottom is rocky and uneven. The coast North of Black Rock Bay is rugged and rocky. The lower slopes of the hills are covered with grass; behind the hills the mountains attain an elevation of 5,000 and 6,000 ft., and are clothed with dense forest. *Chock-e-Day*, 60 miles northward of Black Rock Bay, is in lat. $24^{\circ} 6\frac{1}{2}'$ N. The inhabitants were nearly naked, and used threatening gestures to the surveying party. The coast from Chock-e-day to Dome Point, 20 miles to the northward, is the boldest and most precipitous that can be conceived, the mountains rising 7,000 ft. almost perpendicularly from the water's edge. *Dome Point*, 650 ft. high, is 3 miles South of Sau-o Bay.

Boudruet Rocks, reported to be about 65 ft. high, and in lat. $24^{\circ} 10'$ N., long. $122^{\circ} 34'$ E., would be 48 miles from the nearest point of Formosa.

Reported Dangers.—A shoal, which would lie in lat. $24^{\circ} 17'$ N., long. $122^{\circ} 48'$, was reported in 1844 as showing heavy breakers. Another shoal in lat. $24^{\circ} 30'$ N., long. $122^{\circ} 49'$ E., 3 miles in extent, E. by N. and W. by S., is reported as lying N.W. by W., distant about 10 miles from Kumi. The ripples are very strong in this vicinity, and it is possible that the above dangers are not existing, the ripple having been mistaken for breakers.

Sau-o Bay, in lat. $24^{\circ} 38'$ N., long. $121^{\circ} 50'$ E., will be found an excellent

place of shelter for vessels working up this coast against the N.E. monsoon. *Sau-o or Arlyi Rocks*, 98 ft. high, lie off the entrance of Sau-o Bay, about a mile from the northern promontory. To the N.W. of the Arlyi Rocks is much foul ground, with rocks awash, generally breaking. *Breakwater Reef* (or *Tong-sim-tai*), about 2 cable in extent, N.E. and S.W., lies a little more than half a mile from the shore, and nearly in the centre of the bay.

The inhabitants of Sau-o Bay are mostly Chinese fishermen. Fresh supplies were obtained.

There is good holding ground in the outer part of the bay in 10 to 13 fathoms, black sand and mud, E. by S. of Breakwater Reef, and with the South point of the bay about South, but the anchorage is unsafe with easterly winds. The best anchorage is under Breakwater Reef, but in rounding its North end a berth of 2 cables must be given, to avoid the *Serpent Rock*, of 11 ft. water, which lies $1\frac{1}{2}$ cable N.W. of the highest rock on the reef (the clearing mark is the easternmost rock of the Sau-o Reef in a line with a conspicuous rocky islet off the North point), when vessels may haul to the southward, and anchor in 7 fathoms, with the conical or high rock bearing E.S.E. distant about $2\frac{1}{2}$ cables; or if of 12 ft. draught with the rock bearing East. The water shoals rapidly. It is high water, full and change, at 5^h 50^m and the rise 3 to 6 ft. The tidal streams are weak in the bay; the flood sets along the coast South and the ebb North, with a velocity of $1\frac{1}{2}$ knot per hour.

Approaching Sau-o Bay from the northward, pass half a mile eastward of the Sau-o or Arlyi Rocks, the highest of which may be seen 8 or 10 miles off in clear weather, and when Breakwater Reef bears W. $\frac{1}{4}$ N. haul up for it. From the south-eastward vessels can boldly approach the South point, off which reefs extend 2 cables.

Kaleewan River.—At 6 miles to the northward of Sau-o Bay and 10 miles S.W. $\frac{1}{2}$ S. of Steep Island has only 3 ft. on the bar at low water, the rise of tide being from 2 to 3 ft. The banks and country on either side of the river were everywhere under cultivation, principally with rice, Indian corn, and millet; sugar-cane also in small quantities. The inhabitants behaved with great civility.

Steep Island, 14 miles northward of Sau-o Bay, is inhabited by Chinese, and cultivated in terraces to its summit, which is a sharp conical peak, about 1,200 ft. above the sea. S.W. $1\frac{1}{2}$ mile from Steep Island is a small islet, with a rock to the S.W. of it.

SANTIAU POINT, the N.E. extreme of Formosa, is 10 miles N. by E. $\frac{3}{4}$ E. from Steep Island. The point itself is low and flat, but a little inland is a hill range which terminates in a bluff. Here the coast line turns abruptly to the N.W. for 30 miles, and midway is the harbour of Kelung, described hereafter.

Petou Point, N.W. by N. 7 miles from Samtiau, is a peninsula 400 feet high, and from a distance appears like an island. The small boat harbour and fishing village of Petou is close to the westward of it. The coast from thence to Kelung Harbour is steep-to, all the off-lying rocks, which are of sandstone, showing above water. The most remarkable feature on this coast is *Dome Peak*, which makes in that form from the N.E.

Chimmo Bay is 5 miles westward of Petou Point, and in it a vessel might anchor if in distress, or forced in by a northerly wind. The point on its eastern side is foul.

Directions for making the passage along the East coast are given in pages 91—94.

The WEST COAST of FORMOSA has been surveyed by Messrs. Wilds and Stanley, of H.M. surveying vessels *Swallow* and *Dove*, and Commander E. Brooker, of H.M.S. *Sylvia*, in 1867.

Kwa-liang Bay is 6 miles W. by N. from South Cape (page 1033). In the N.E. monsoon good anchorage will be found in 10 or 12 fathoms, about half a mile from the shore, anywhere on the North and N.E. sides of the bay.

SOUTH-WEST POINT, 1 mile West of Black Point, is the angle of the coast where it turns to the northward. The small bay of Chim-kong-o, North of it, has 23 fathoms at half a mile off shore, and 52 fathoms at a quarter of a mile off its North point, where are strong tide ripples.

Tossapon Hill is on the south-western promontory. The fort, erected in consequence of the treaty mentioned on page 1032, is situated over Black and S.W. Points, and is therefore plainly visible from the sea, and had the Chinese flag flying on it.

Gooswa Promontory extends in a N. by W. direction 7 miles from S.W. point. The promontory is backed by an inland range, *Ba-swa*, rising to the height of 2,235 ft., 8 miles N.N.E. $\frac{1}{2}$ E. of S.W. point. The bold shore of the promontory consisting of dark rocky cliffs is steep-to. Its most conspicuous feature is the sand beach of Chim-kong-o Bay. *Aou-wa-nah* is a nook at the head of the small bay which lies immediately North of Gooswa promontory. The reefs from either shore meet within a cable, forming the entrance to a basin about 2 cables in diameter, having a depth of 5 to 3 fathoms. To the northward, the coast is inhabited by Chinese, who move about armed for protection against the natives, with whom they carry on a perpetual warfare.

Liang-kiau or Expedition Bay, 3 miles in extent, between Bay Hill and Lang-kiu Point, 2 miles North of it, is open to all westerly winds, but affords good anchorage in the N.E. monsoon. The approach to the bay is quite clear, but a sandy spit runs out three-quarters of a mile from the North point of the bay, on which account vessels are recommended not to hug the shore

too closely. Lang-kiu is the principal town or village of the district, and the most southern settlement in which Chinese authority is recognized.

Caution.—About 5 miles N. by W. from Liang-kiu Bay, when not in soundings, the leadsman struck what must have been a peaked rock at 9 fathoms, which caught the lead line and nearly pulled the leadsman out of the chains.—(H.M.S. *Flamer*, 1865.)

San-Liau Bay, North of Liang-kiu Point, affords anchorage in 3 fathoms at 3 cables from the shore. All the low shore of Liang-kiu Point is bordered by an extensive reef. *Le-liang-swa*, 2,500 to 4,000 ft. high, is a mountain range on the coast North of Liang-kiu, extending 6 miles North and South.

Hong Kong, 6 miles North of Liang-kiu Point, is a large Chinese village. *Che-tong-ka*, N. by W. 13 miles from Gooswa Promontory, and $4\frac{1}{2}$ miles from Hong Kong, is on a point, bordered by a reef; the coast is bold and steep-to. Vessels can anchor anywhere along the coast in 8 or 9 fathoms. *Pong-li* is a small Chinese town, 7 miles N.N.W. $\frac{1}{2}$ W. of Che-tong-ka, and a short distance inland, about a mile northward of a remarkable square clump of trees on the beach, called *Kay-a-kaou*.

Lambay Island, or Seo-liu-kiu, in lat. $22^{\circ} 20\frac{1}{2}'$ N., long. $120^{\circ} 22\frac{1}{2}'$ E., is flat, the most elevated part being 258 ft. No anchorage can be obtained near this island, but a mud-bank, having 15 to 26 fathoms water over it, is reported at 3 miles eastward of it. Reefs extend a mile off the N.E. and S.E. points of the island.

Tang-Kang River has its entrance N.N.E. 7 miles from Lambay Island and 11 from Pong-li; at low water there are only 4 ft. on the bar. The town stands near the entrance, and has about 20,000 inhabitants.

Ape Hill, 1,110 ft. high, called by the natives Ta-kau, is N. by W. $\frac{1}{2}$ W., 18 miles from Lambay Island. It appears like a truncated cone; its barren, rugged sides rise with a steep slope from the sea, facing which is a large white land-slip. At $4\frac{1}{2}$ miles N.E. of Ape Hill is another remarkable hill, 700 ft. high, named *Whaleback*; and N.N.E., 12 miles, there is a small triangular-shaped hill, and a large detached piece of table-land resembling a quoin on a North and South bearing. These are the only landmarks on this part of the coast, which is all very low, and of these Ape Hill is the most useful, as it stands out on the coast line, and is frequently seen distinctly when all the others are shrouded in mist.

Saracen Head, 173 ft. high, 2 miles South of Ape Hill, is surmounted by a *Signal Staff*. It is a huge nearly level block of a mole-like appearance, bounded on the sea face by a line of precipitous cliffs rising from the water's edge, and which, jutting through the beach to seaward for about 300 yards, forms a sheltered harbour for small vessels in the strength of the N.E. monsoon. This mole is separated from the hill by a deep channel about 60 yards wide, which is the entrance to the little port of Ta-kau-kon.

Anchorage in the N.E. monsoon is good and safe under Ape Hill, which stretches out so as to afford smooth water. In the S.W. monsoon heavy rollers come in, making it undesirable to remain at anchor there.

Ryder Rock, half a mile off shore, with Ape Hill bearing E. by N., was reputed as above water in 1876.

TA-KAU-KON, or Harbour of Takow, the Consular port of Tai-wan-fu, is the only harbour on the West coast of Formosa available for vessels of 12 feet draught. It is a small basin just within the entrance of a great lagoon. The entrance to it is immediately North of Saracen Head, where the fair channel is only 200 ft. wide.

The Bar is formed by a narrow ridge of sand, curving outwards and extending from under the bluff of Saracen Head round towards the shore at half a mile North of the entrance. There are 10 to 11 ft. over its North and South parts at low water springs, but over the central part, N.W. of the entrance, only 7 to 9 ft. It consists of loose sand, and is said to be constantly shifting.

The harbour is immediately within the entrance. The anchorage is too confined to allow a vessel to swing, it is therefore necessary to moor head and stern. In 1873 there was water only for vessels drawing 9 ft., larger vessels having to anchor outside the bar. The Chinese town or village stands on the South side at the back of Saracen Head. Here is the British Consulate. Water can be obtained from a spring on the North shore, and care must be taken that it is not procured from the wells on the South side. Fresh beef of inferior quality is supplied, also vegetables, besides pigs, fowls, ducks, eggs, rice, sugar, and fish.

Takau was opened to trade in 1864, but as its importance arises from the fact of its being the port of Tai-wan fu during the S.W. monsoon, and the only accessible one where ships can then lie with safety, its trade is chiefly limited to that period. The *pilots* are Chinese, and are under the superintendence and regulations of the European harbour master. The signal station on Saracen Head is under the direction of the harbour master. It is high water, full and change, at Takau, at 8^h 30^m, springs rise 4 ft.

Directions.—If obliged to run for the entrance in bad weather, bring it to bear E. by S. $\frac{1}{2}$ S., and run boldly in. Keep close to the outer North rock (steep-to), and haul close round the point, but not within 10 yards, as there is a rock inside, within that distance, with only 4 ft. on it at low water. As the rocks are neared, starboard the helm and round the northern head close-to, shooting into a little sandy bay, where a vessel may touch the ground with her fore-foot without sustaining any damage. Great care is required if entering at springs on the ebb, which runs at the rate of 4 or 5 knots through the entrance. The harbour is also difficult of exit in the S.W. monsoon. It is said to be shallowing year by year. At present, at the outside, it can contain twelve vessels of 12 ft. draught, moored head and stern; but it is sus-

ceptible of great improvement at small expense, and as Formosa becomes more opened to commercial enterprise this place must advance in importance.

The Coast, northward for 20 miles between Ape Hill and the old Dutch *Fort Zealandia*, is nearly a straight line of beach, pierced by four small streams, the banks of which are densely populated by fishermen, who appear to be well fed and clothed and a happy and contented people.

The old Dutch ruined fortress, built in 1630, and now surmounted by a large tree, visible 8 or 9 miles from a vessel's deck, is the only conspicuous landmark in this neighbourhood, except a large clump of trees $1\frac{3}{4}$ mile N.W. of the fort, on the outer sand-bar. The fort stands about two-thirds of a mile from the sea, and about it has grown up, along the continually rising mud and sand-banks, the village of Amping.

AMPING ROAD, off an opening in the beach, which is the nearest approach to Tai-wan fu from the sea, is an open roadstead, where, during the strength of the N.E. monsoon, from December to March, capital sheltered anchorage with smooth water may be found, in $5\frac{1}{2}$ fathoms, at 2 miles S.W. of Fort Zealandia. During the rest of the year the chances of S.W. winds render this position an unsafe one, and anchorage should be sought farther out, but in the strength of the S.W. monsoon no vessel could lie off a coast so fully exposed to its full force, and the heavy rollers which accompany it. Then also the bar is most dangerous, and cannot be passed by the cargo boats for days and weeks together.* Catamarans are used as at Takau, and are managed by the Chinese with great skill. Trade ceases entirely for four months, viz., from June till September, all goods being then sent to Takau for shipment. The anchorage should be approached from the northward with caution, and the lead used constantly.

Amping has a population about equal to Takau, a resident Mandarin, and a superintendent and tide-waiters of Chinese customs. The British Consul, a Medical Missionary, and a Surveyor of Customs reside at Tai-wan fu. Excellent fresh water is supplied from the latter place.

Between Amping and Tai-wan fu, 2 miles S.E. from the fort, is a large expanse of mud flat which at times during the S.W. monsoon is entirely covered with water. A narrow creek or canal runs up to the West gate of the city, by which cargo boats can go up at high water.

TAI-WAN FU, the capital of Formosa, is a prefectural city of 70,000

* The bar was last crossed in 1869 by H.M. gunboat *Bustard*, drawing 7 feet, but its channel is constantly shifting, and, like the harbour within, shoaling rapidly. The same change is taking place all about this part of the coast, for where good harbours existed formerly, with 15 to 20 ft. water, there is not now sufficient to float a junk. According to Dutch and other records, the sea at one time extended to the fort inside the city. H.M. ships are now prohibited from entering this harbour, by order of the Commander-in-Chief.

inhabitants, surrounded by a wall 20 ft. high, quadrangular, and 5 miles in extent.

Vuyloy Shoal, about half a mile in extent, and with only 8 to 12 ft. on it at low water, lies upwards of a mile off shore, S. by E. $4\frac{1}{4}$ miles from the entrance of Port Kok-si-kon, W. by N. $\frac{3}{4}$ N. $4\frac{1}{2}$ miles from Fort Zealandia, and S.W. by W. $\frac{1}{2}$ W. $2\frac{3}{4}$ miles from Joss Islet. With southerly winds the sea breaks heavily on it, but with off-shore or N.E. winds there is but little break. The soundings are $4\frac{1}{2}$ to 5 fathoms at $1\frac{1}{2}$ mile westward of the bank, and 3 fathoms between it and the shore. Vessels bound from Kok-si-kon to Ta-kau, will pass westward of this shoal by keeping 3 miles off the sand bars fronting this part of the coast, or not shoaling to less than $4\frac{1}{2}$ or 5 fathoms, until Fort Zealandia bears East. This will also clear two sand-banks which uncover at low water. They lie W.N.W. $2\frac{1}{2}$ miles from Fort Zealandia, and three-quarters of a mile West of the tree clumps.

Tides.—The flood stream sets in a N.N.W. direction for $1\frac{1}{2}$ to 2 knots an hour along this part of the coast. The ebb runs S.S.E., except near the entrance of Kok-he-mung, $3\frac{3}{4}$ miles N.W. of Zealandia Fort, where its direction is S. by W. out of the harbour.

PORT KOK-SI-KON, the North point of entrance to which, *Gull Point*, is 32 miles N.N.W. of Saracen Head, is the outlet of several small, shallow streams, which here unite and form a channel through the mass of sand-banks fronting the coast. This channel or port runs N.E. and S.W., and, taking the 3-fathom line as its boundary inside, is three-quarters of a mile long and only 2 cables broad, with $4\frac{1}{2}$ fathoms in the middle; it will be, therefore, necessary to moor N.W. and S.E. The bar has 12 ft. on it at low water springs. The deepest part is generally marked by the natives with bamboos; but as the channel is both wide and straight, and the bottom remarkably even, it is by no means difficult of access for vessels of 12 or 13 ft. draught at high tide. The channel and sand-banks are said to have altered since the survey. It is high water, full and change, at 11^h 30^m, rise about 3 ft.

Directions.—The high land of Formosa, immediately over Port Kok-si-kon, may be distinctly seen in very clear weather from the Pescadores, but as it is generally obscured, and the coast low and sandy, it will be prudent at all times, when bound to that port from the westward, to be certain of the vessel's position before losing sight of East Island, or one of the southern islands of that group.

The mast heads of a large fleet of junks usually at anchor in the small harbour of *Kok-he-mung*, 5 miles S.E. by E. of Kok-si-kon, will serve as a guide on approaching the coast; and when 2 or 5 miles from the shore, three clumps of huts and trees (the southernmost clump abreast West Point being the largest and most conspicuous), Joss Islet, and Fort Zealandia, are objects sufficiently well defined to mark the locality. Joss Islet has a clump

of dark trees on its southern end, and the Joss House on it has a white front to seaward. *Ung-lo* and *So-co*, to the south-eastward, are remarkable hills, and may generally be seen when the mountains in the interior are hidden. The clouds sometimes rest upon them, when they appear as the highest land in the vicinity. *Ung-lo*, 1,080 ft. high, is the southern termination of a long table range which falls steeply for a few hundred feet, and rises again to the round hill of *So-co* 880 ft. high.

The Coast for 20 miles to the northward of Fort Zealandia has no distinguishing feature, the highest bushes and huts being but a few feet above the low level land. *Kakaou*, 7 miles northward of *Kok-si-kon*, is a small and narrow inlet, as is also *Paw-tay-chui*, N.N.E. $\frac{1}{4}$ E., 11 miles from *Kakaou*. Four miles W.N.W. of the entrance to *Paw-tay-chui* are the *Ay-aw Banks*. *Ay-aw Creek* is at the northern part of the bay, formed by the *Wanckan Banks* and the low opposite shore. The creek is approached from the S.W., between the *Ay-aw Banks* and the *South Wanckan Shoal*.

Wanckan or Chin-ne-yah Banks form the westernmost part of the Island of Formosa. The South end is in lat. $23^{\circ} 31' N.$, long. $120^{\circ} 2' E.$, 24 miles northward of *Kok-si-kon*. To the southward the bank at low water dries nearly 2 miles, and continues in a N. by E. direction for 11 miles. The Chinese say that there are many junks and ships lost on them during the year. When coming from the North or South there are no land-marks to guide the navigator, and the strong tides experienced render a ship's position at all times doubtful.

The *Pescadores Channel* is narrowed to a breadth of 3 miles between *Outer Wanckan Shoal* and the *Nine-foot Reef* which lies W. by S. $\frac{1}{4}$ S. from it, and which is 4 miles S.S.E. $\frac{1}{2}$ E. of *Three Island*, the easternmost islet of the *Pescadores Group*.

The Coast from the hut on the sandy patch of the South extreme of the *Wanckan Banks* to *Lokiang*, in lat. $24^{\circ} 3' N.$, is low, and has no distinguishing feature, the bushes and huts being only a few feet above the land. This uninteresting seaboard becomes even more dreary at low water, when the mud and sand-flats uncover for miles.

East 8 miles from *Lo-kiang* is a peak, 701 ft. high, and between them is a sand-hill. To the westward of the town of *Lo-kiang* is a small outlet, marked by two bamboo beacons; in this creek a great number of junks find anchorage. From *Lo-kiang* the coast trends N.N.E., with extensive mud flats; but having passed the village of *Goché*, 13 miles to the northward, the flats uncover only for a distance of half a mile. *Goché* is situated at the northern extremity of the great alluvial plain, which extends as far southward as *Tai-wan fu*, a distance of 80 miles.

Off *Wanckan*, and as far as *Goché*, a distance of 50 miles, the soundings off the low coast being shallow and irregular, ships should not stand into a

depth of less than 10 fathoms; and the strong tides which run round the Wanckan banks and reefs should also be borne in mind. From about 3 miles North of Goché to Tongsiau the coast can be approached to a mile, when soundings of not less than 10 and 12 fathoms will be found. The tides along this coast are less strong than off Wanckan.

Tyka or Tai-kia, the principal town of the first hilly district North of the plain. It stands 3 miles from the sea on the banks of the Tyan-kiang, a small stream, 8 miles northward of Goché. The entrance is marked by beacons. The town is situated between two detached hills northward of the Goché range, and which are described as the most striking features of the coast; the southern hill, *Stone Peak*, is 501 ft. high; the northern is a remarkable square topped hill, 743 ft. high, seen from the sea in all directions.

The *Mow-lung-sui*, a considerable stream, on which, a mile above its entrance, is the large village of *Tong-siau*, is 8 miles north-eastward of the Tyan-kiang. Between the two, 7 miles inland, a rocky-topped range rises to the height of 2,227 ft. *Mount Sylvia* is E. $\frac{1}{4}$ S. 35 miles from Tong-siau, and 15 miles nearer in the same direction is *Mount Royalist*, 9,000 ft. high. Petroleum springs have been discovered 15 or 20 miles inland, a few miles beyond the first flat-topped ridge.

Port Heong-san, in lat. $24^{\circ} 41' N.$, is available for vessels of light draught, and affords room for several large junks. *Table Hill* or *Hong-san-ki*, 360 ft. high, and $7\frac{1}{2}$ miles N.N.E. $\frac{1}{2}$ E. from Heong-san, is a conspicuous object.

PAKSA POINT, the N.W. point of Formosa, lies 10 miles N.N.E. $\frac{1}{2}$ E. from Table Hill. An elevated sand hill stands at its extremity. The point is not bold; shoal water extends $1\frac{1}{2}$ or 2 miles northward of it, which has been observed to break at $1\frac{1}{4}$ miles off shore.

From Paksa to Tam-sui Harbour, a distance of 22 miles, the coast line curves in an E.N.E. direction; the first 14 miles being low with sand hills, and along this part reefs project about half a mile off shore, with soundings of 7 fathoms well clear of them, and there are numerous creeks in some of which junks are seen lying. The low land is succeeded by table land about 600 ft. high and steep-to, until within 2 miles of Tam-sui.

DIRECTIONS.—As far as Lieutenant Gordon was enabled to examine the N.W. coast, it was his opinion that a great advantage would be obtained, if, instead of hugging the coast of China or beating up in the middle of Formosa Strait during the N.E. monsoon, sailing vessels were to reach well over, and at all events during the day stand close in to the Formosa shore, particularly on the ebb tide. The latter stream was always found setting strong to the N.E., whereas the flood ran very weak to the S.S.W., the former having the advantage over the latter of at least 8 miles every 24 hours.

The time of high water, full and change, on the N.W. coast of Formosa is at noon. The bottom is dark sand, with, occasionally shells and broken

stones; soundings of 30 to 40 fathoms near the shore, and 25 to 17 fathoms at 10 to 20 miles off. The water commences shoaling about $1\frac{1}{2}$ or 2 miles off shore, and the depths decrease rapidly. The sea near the coast in moderate weather is smooth, the wind blowing along the land.

TAM-SUI HARBOUR is formed in the lower reach of Tam-sui River. South of the river entrance is a remarkable double hill, the North peak of which is 2,014 ft. above the sea. The river has a funnel-shaped entrance, where is the bar, and the shores of which are low, with sand hills, bordered on the South side by sand and mud flats, and on the North by a stony flat, on which is a small Chinese lighthouse, only used occasionally.

The bar is a mile in extent; the fairway channel over it is direct, 1 to 2 cables in width, and has a depth of 7 to 8 ft. at low-water springs. The river within is three-quarters of a mile broad, but the South side is filled with mud banks. The deep water channel is only a cable wide between the banks off the low points of entrance, and within preserves the same breadth along the North shore for the distance of a mile with 12 to 15 ft. water. The white fort and entrance beacon are on the North point of entrance; the old Dutch red fort, which is the British consulate, is half a mile higher up on the same side, and above is the town of Hoo-wei, at the lower part of which is the custom-house. Foreigners have not unfrequently been insulted in this town, the lower classes of which are lawless and turbulent.

Five miles above Hoo-wei the main branch of the Tam-sui River runs to the S.E., on the right bank of which, about 13 miles from the entrance, is the town of Mang-kia or Bang-ka, the largest in the North of Formosa. About 5 miles above Mang-kia a smaller branch enters from the southward, and numerous other tributary streams feed this river, which is said to take its rise 70 or 80 miles above Tam-sui Harbour, and wind its course among the high mountain ranges of the interior. A confluent branch takes a turn at Kang-tow, 6 miles from the entrance, and after several small rapids ends a few miles from Kelung, where the coal mines are situated.

The exports of Tamsui and Kelung consist chiefly of tea, rice, camphor, and coal, amounting, in 1871, to £160,367. Good water and provisions of all kinds are to be obtained; bullocks, pigs, goats, poultry, vegetables, and fruit in profusion. Water is brought off in sanpans at $1\frac{1}{2}$ dollars the ton.

Tides.—It is high water, full and change, in Tam-sui Harbour at 11^h 45^m., springs rise 7 to 10 ft.

Directions.—If approaching Tam-sui from the westward, steer midway between the two mountains, one of which rises on either side the entrance, until the leading marks to cross the bar are discerned, but as the channel across the bar is liable to shift from the effects of freshets or gales, no vessel should enter Tam-sui for the first time without a pilot, one of whom can generally be obtained off the port, or at the village just inside the white

fort.* If intending to anchor, do not stand into less than 8 fathoms, unless in a steam-vessel, for the anchorage off the harbour is unsafe, as the holding ground of loose shifting sand is not good; and a vessel, though with a good scope of cable out, is likely to drive even in moderate weather. When the wind freshens from the N.E. a heavy sea rolls in, breaking even in 3 fathoms water, and a sailing vessel must immediately proceed to sea, for should the wind veer to N.W. it might be impracticable. In summer also it is exposed to short, sharp south-westers, which rise suddenly with little or no warning, but which are not of very common occurrence; in the event of one, it is necessary to put to sea without delay.

The recent survey in the *Sylvia* showed the deepest water over the bar to be in nearly the same direction as it was in 1845, when Lieutenant Gordon surveyed it, but 5 ft. shoaler. Since then the entrance has been entirely altered by a typhoon, which swept over the harbour in September, 1871, but it is probable that the freshets of the ensuing rainy seasons have re-established the channel in its old position. The leading mark for entering the harbour previous to this change was a *white* beacon placed near a small fish hut on piles, near White Fort, just open to the right of the old red brick square Dutch fort, E. $\frac{1}{4}$ S., both situated on the northern side of the river. The passage over the bar is usually marked with bamboos, but these are unintelligible to a stranger.

The entrance beacon on the North bank, W. $\frac{1}{2}$ N. half a mile from the Red Fort, is 40 ft. high, and pyramid shaped, consisting of three poles with a triangular facing towards the bar; the whole painted *white*. The beacon in line with the Red Fort is the leading mark for entering the harbour.

On entering the river pass the white beacon at about three-quarters of a cable, and run up along the North shore at the same distance. The anchorage for large vessels is off the custom-house; the best berth for men-of-war is nearer the Red Fort. It is necessary to moor, and ships should be prepared with a spare anchor in the winter months, as the freshets have been so strong, after continuous rain, as to cause a vessel to drift out and be wrecked on the bar. The holding ground is not very good. Of the advantages of this harbour, it may be said that it is quite secure from all storms; and although there is only a depth of 8 ft. over the bar, yet, the rise being from 7 to 10 ft., vessels of moderate draught may enter or leave daily throughout the year.

The North end of Formosa is high and mountainous, except the North and N.W. points, which are low, and have reefs extending a considerable distance off. From Tam-sui the coast trends to the N.E., 10 miles to *Syau-ki Point*,

* These pilots have not always proved trust-worthy, shipmasters should therefore be on their guard and procure a licensed pilot, if possible. The charge is five dollars.

and then 4 miles East to *Foki Point*; a reef fronts it, and in some places extends nearly half a mile off shore. The shore rises gradually, and is very flat for several miles inland to the Tam-sui range. *Masou Peninsula* is 8 miles S.E. of *Foki Point*. Its N.W. point is formed by a remarkable hill of sandstone, 250 ft. high, perpendicular to the N.W. To the westward of this peninsula is the deep bay and valley of Masou, in the middle of which is an islet with three rocks lying S.E. of it. Immediately eastward of Masou Peninsula is a bay 3 miles across, with numerous reefs running off the points within it; and 2 miles farther on the entrance of Ke-lung Harbour.

The coast between *Foki* and *Petou Points*, 20 miles apart, forms somewhat of a bay into which the N.E. monsoon rolls a heavy sea; in this bay, about 6 miles eastward of Masou Peninsula is *Ke-lung Island*, a remarkable black rocky island rising precipitously on all sides to the height of 580 feet. This excellent landmark guides to Ke-lung Harbour, the entrance to which bears from it S.W. $2\frac{1}{2}$ miles. Off its N.W. end is a conical rock 100 feet high, and extending S.W. by S. from the island is a spit of gravel or rock, a mile in length.

KE-LUNG HARBOUR is easy of access and well sheltered in all winds, except those from the northward, which send in a heavy sea. Ke-lung Island directs to the entrance which is marked by beacons, and the hidden dangers within are marked by buoys.

Audacious Rock, on which H.M.S. of that name struck in 1876, is a small pinnacle, with 21 ft. over it, and 10 fathoms at the distance of 50 yards in all directions. From the shoalest part, the islet, 100 ft. high, adjacent to the West side of Ke-lung Island, bears E. $\frac{2}{3}$ S., distant 17 cables; and the second peak West of *Image Point* (293 ft. high), S. by W. $\frac{1}{4}$ W., distant $2\frac{1}{2}$ miles. *Petou Point*, just overlapping the South point of Ke-lung Island, bearing S.E. by E. $\frac{1}{3}$ E., leads about 2 cables north-eastward of *Audacious Rock*. The summit of the distant range of hills (southward of Ke-lung town) in line with the Saddle between the first and second peaks West of *Image Point*, bearing S. $\frac{1}{4}$ W., leads about 2 cables westward of the rock in 15 fathoms water.

Palm Island, three-quarters of a mile long, East and West, is 2 miles S.S.W. $\frac{1}{3}$ W. from Ke-lung Island. Close to its N.W. extreme, and almost connected with it, is *Macedonian Mound*, 140 ft. high. *Bush Island*, low and rocky, about 10 ft. high and covered with shrubs, lies 3 cables West of *Palm Island*. Its extreme North end is marked by a beacon, 43 ft. high, painted black.

Image Point, the West point of entrance to the harbour, is a low projecting shelf half a mile W.S.W. of *Bush Island*, and remarkable from the number of detached pieces of sandstone rock which the action of the sea has worn into grotesque figures. The point is or was marked by a white beacon and may be rounded at a cable. There are 7 to 16 fathoms in the

entrance, which is 4 cables wide between Image Point and the reef off Bush Island.

Inflexible Reef, on which several ships have struck, is a sunken ledge of rocks. On its outer edge are two knolls of 4 and 6 ft., from the westernmost of which Image Point bears N.W. by W. 4 cables, and the left extreme of Bush Island N. by E. This knoll is marked by a *red* buoy on its western edge, in $7\frac{1}{4}$ fathoms.

Crag Peak, a remarkable sugar-loaf hill, about 150 ft. high, lies on the western shore of the harbour, half a mile southward of Image Point. From it projects another shelf of sandstone, on which is the mushroom-shaped rock to which has been given the name of *Ruin Rock*. A sunken ledge with 3 to 9 ft. on it extends $1\frac{1}{2}$ cable eastward of this point, the outer edge of which is marked by a *white* buoy (coral shoal buoy), in $5\frac{1}{2}$ fathoms. The town of Ke-lung stands at the head of the bay a mile above Ruin Rock. The coal mines are about a mile E.S.E. of the town.

The trade of Ke-lung is extensive, principally with the Rivers Min, Chin-chu, Amoy, and Tongsang. For the latter place quantities of coal are shipped, and for the former rice, ground-nut oil, camphor, and camphor wood. Good water is easily obtained on the western shore of the harbour, in the second small bay within Crag Peak. Pigs, poultry, and sweet potatoes may be purchased. The Ke-lung coal is a small bituminous mineral, good for domestic purposes and for steamers making short passages, but it is otherwise unsuitable. (See page 1032.)

It is high water, full and change, in Ke-lung Harbour at 10^b 30^m, and the rise, when uninfluenced by the weather, is about 3 ft.

Directions.—The entrance of Ke-lung may be boldly steered for even in a N.E. gale with thick weather, if the land about it, especially Ke-lung Island, can be well made out. Avoiding Audacious Rock, Crag Peak, a conspicuous landmark within the harbour, may be steered for on any bearing between S. $\frac{1}{4}$ W. and S. by W. $\frac{3}{4}$ W., and will lead in within the entrance clear of all danger. After passing Image Point, which it is preferable to hug, steer for the sandy bay to the S.E., getting the point on a N.W. $\frac{1}{2}$ N. bearing, and anchor in 6 to 7 fathoms, mud, good holding ground, with the West extreme Bush Island N. by E., or Crag Peak S.W. $\frac{1}{2}$ W. This anchorage is $1\frac{1}{2}$ cable South of Inflexible Reef, and if the buoys are in position the *red* buoy will bear North.

If proceeding into Junk Harbour, round Ruin Rock at 2 cables, passing outside the *white* buoy, and anchor with the rock S.E. by E. $\frac{1}{2}$ E. A gun boat may proceed higher up.

A sailing vessel must use much caution in leaving this harbour during the N.E. monsoon, in consequence of the heavy sea rolling in, and there being no anchorage outside. With a light wind short tacks should be made, and the entrance kept open until an offing is gained.

Coal Harbour, or Petaou Bay, a small inlet of the coast $1\frac{1}{4}$ mile south-eastward of Palm Island at the entrance of Ke-lung, and bearing from Ke-lung Island S. $\frac{3}{4}$ E., is so called from its proximity to the coal mines on the hill sides of the southern shore of Quar-see-kau Bay. It lies open to the northward, and is surrounded with reefs and rocks, and shoal at the head; it might, however, be available to a vessel in distress, if embayed to windward of it.

It offers anchorage and shelter for one or two vessels only, and should the mines ever be worked by Europeans, the coal, which is of good quality, could be conveyed to Harbour Rock at its head by means of a railroad along the West shore of the bay, at the base of the hills. A short pier from the North side of the rock would enable a vessel to lie alongside in 3 or 4 fathoms water, and receive or discharge her cargo.

ISLANDS NORTH-EAST OF FORMOSA.

From the northern extremity of Formosa there extends for 170 miles in an E. by N. direction, a chain of rocks and islands of small size, bold of approach, and for the most part widely separated, lying on or near the edge of the bank of soundings extending from the coast of China.

Pinnacle Island, called by the Chinese Tsaou su or the Chair-bearer, owing to its resemblance to coolies carrying a sedan chair, is in lat. $25^{\circ} 25\frac{1}{2}'$ N., long. $121^{\circ} 58\frac{1}{2}'$ E., and 19 miles N.E. by N. from the entrance of Ke-lung Harbour. It is a rugged mass of rock, 170 ft. high, with perpendicular sides, and around it are three semi-detached pinnacle rocks about half the height of the island, two of which are visible in almost every direction. They all stand upon a low reef, the western point of which extends, probably 2 cables.

Craig Island, in lat. $25^{\circ} 29'$ N., long. $122^{\circ} 8'$ E., is 10 miles E.N.E. of Pinnacle Island. Its eastern point is a steep cliff from the summit of the island, 240 ft. in height, off which lie the two high craggy rocks, surrounded by a large reef, from which the island has probably received its name. H.M.S. *Serpent* anchored off the North side of the island in 9 fathoms, in June 1866.

Agincourt Island, 9 miles N. $\frac{3}{4}$ W. from Craig Island, is in lat. $25^{\circ} 38'$ N., long. $122^{\circ} 5\frac{1}{2}'$ E. It has a round summit, 540 ft. high, stretching out into high, bold headlands on the North and South, and off the S.W. point is a reef.

Hoa-pin su, the North face of which is in lat. $25^{\circ} 47'$ N., long. $123^{\circ} 0'$ E., is an island 3 miles in extent, and 1,181 ft. high. The S.W. point, when seen on a S.E. by E. bearing, appears low and shelving. The western part

of the island rises symmetrically to a sharp peak, and is separated by a deep gap from the eastern peak which is somewhat lower, very rugged, and steep on its southern side; the S.E. point is a high cliff. The island may be said to slope to the N.W.

The Pinnacle Group, which is connected by a reef and bank of soundings with Hoa-pin su, allowing a channel of about 12 fathoms water between it and the Channel Rock, presents the appearance of an upheaved and subsequently ruptured mass of compact grey columnar basalt, rising suddenly into needle-shaped pinnacles. Although a safe channel exists between Hoa-pin su and the Pinnacle Islands, it ought not (on account of the strength of the tides destroying the steerage), to be attempted by sailing vessels if it can be avoided.

Ti-a-usu, N.E. northerly, 15 miles from Hoa-pin su, is about $1\frac{1}{2}$ or 2 miles in extent, and its summit is a round hill about 600 ft. high, with a lower hill of similar shape on its N.E. side, which both show very prominently when the island is first made from the eastward.

Raleigh Rock, in lat. $25^{\circ} 35'$, long. $124^{\circ} 35' E.$, and 50 miles E. $\frac{3}{4}$ S. from Ti-a-usu, is a narrow elongated mass of bare rock, rising abruptly from a reef to the height of 270 ft., and perpendicular on all sides. Reefs stretch off its West, East, and North sides. In the distance it appears like a junk under sail.

The Bank of Soundings appears to terminate a little eastward of Raleigh Rock, for at 12 miles N.E. by E. of it no bottom was obtained with 150 fathoms of line. In the vicinity of the islands, the depths were found very irregular, varying from 60 to 90 fathoms, over a bottom of grey sand, or rock, or stones, so that it would not be possible to determine a ship's position in thick weather by means of soundings, beyond the fact of her being on the bank.

MEIACO SIMA GROUP form the westernmost portion of the long chain of islands which extend in an easterly and north-easterly direction from Formosa to the southern extremity of Kiusiu, Japan.

KUMI ISLAND,* conspicuous by the peculiar sharpness of its single peak, 770 ft. high, and table base, is 60 miles E. by S. of Sau-o Bay, Formosa. The island is 6 miles long, East and West, and its peak is at the southeastern part. The principal town and port is on the North side, but the entrance from the sea is narrow and shallow. Tolerable anchorage is found in fine weather, in 17 fathoms, sandy bottom, apparently over coral, at 3 cables from the shore, northward of the town.

Chung-chi and Sandy Islands are the south-western outliers of the western

* Reefs, reported to have been seen lying westward of Kumi, are described on page 1034.

group of the Meiacó simas. Chung-chi, 33 miles S.E. by E. $\frac{3}{4}$ E. from Kumi Peak, is a high uninhabited mass of basaltic rock. Sandy or Hasyokan Island, 13 miles S.E. by E. from Chung-chi, is 3 miles in extent, East and West, with a few trees and huts on it, and stands on a coral reef, which extends a mile from its S.W. point. There is no safe passage between the two islands; between Chung-chi and Ku-kien san several coral patches have been observed, and Sandy Island is stated to be connected with Loney Island, 16 miles north-eastward, by numerous reefs and shoals.

KU-KIEN-SAN is 16 miles in extent, and rises at its highest part to an elevation of about 2,000 feet, its shores affording several commodious harbours, which, with good charts, are safe of approach. *Seymour Bay* is on the southern coast, 2 miles East of Seymour Point, the S.W. angle of Ku-kien san. Here is perfect shelter in the N.E. monsoon, and a fine stream enters the sea in deep water, where a vessel might water, without the intervention of boats or casks.

At the middle of the western coast is *Herbert Island*, 700 ft. high, detached from the extremity of a long peninsula, which separates two narrow inlets. *Port Cockburn*, on the South, carries very deep water, 30 decreasing to 20 fathoms up to its head, which is 3 miles from the entrance; but there are many coral reefs off its shores. The harbour is almost landlocked, and only open to N. W. by N. *Port Herbert*, North of the peninsula, is fringed by broad reefs throughout its whole extent. It has 3 fathoms in the middle of its entrance, which opens out into a broad basin within, with a depth of 22 fathoms, from whence a narrow channel, about 2 cables in width between the reefs, and carrying 14, 7, and 10 fathoms, leads S.E. by S. $1\frac{1}{2}$ mile to the head of the inlet, where is anchorage, clear of a coral reef, in 6 fathoms. This harbour is also nearly landlocked, and open only to N. W. by N. *Port Gage* is a small bay, also on the West side of Ku-kien san, 3 cables across, open to West and S.W.

Isaac Island, 40 ft. high, is 2 miles northward of Ku-kien san. *Koubah Island* is a mile off the East point of Ku-kien san.

PA-CHUNG SAN, 8 miles eastward of Ku-kien san, is about 10 miles in extent across the body of the island, and the hills on its North side rise to the height of 1,500 feet, from which range a narrow peninsula stretches 12 miles N.E. by N., terminating in Adams Point, off which is an islet on the reef. South-westward of Pa-chung is *Roberton Island*, 60 ft. high, $4\frac{1}{2}$ miles westward of which is Koubah Island, before mentioned; the two are connected by a coral reef, which is steep-to, and on the edge of which are three islets. Roberton is also connected by reefs with *Baugh*, *Inglefield*, and *Loney Islands* to the S.W., which also lie off Ku-kien san; and *South Rock*, which is high and marks the edge of the reef, is S.E. of Roberton, and $3\frac{3}{4}$ miles from Pa-chung.

On the North side of Pa-chung are several good bays, where anchorage might be found in the S.W. monsoon, but which are certainly not adapted for refit.

Port Haddington is a spacious bay on the West side of Pa-chung-san. Off Hamilton Point, the North point of entrance, will be noticed a remarkable little rocky hummock, upon which was left, at the time of the survey, a very large pile of stones. The bottom for more than half a mile off the point is rocky and dangerous; but as all the dangers of this port are visible from aloft, there is no risk with a proper look-out. This is a well sheltered port during the N.E. monsoon, but not so safe in the S.W. monsoon; for although it is landlocked, there is a long fetch for the sea with a S.W. gale, and in the latter season typhoons are said to be very violent about this region.

A convenient watering-place was established by H.M.S. *Samarang*, by sinking a cask and suspending the suction hose of Hearle's pump over it, so as to prevent the sand from being sucked in. Here wood is abundant. The inhabitants are a poor, contented, and an unarmed race, in appearance similar to the Loochooans, to whom they are subject, but resembling the Japanese more in manner, customs, and language.

It is high water, full and change, at 6^h 45^m, and the rise and fall about 7 ft.

Directions.—From the westward, Port Haddington may be sought and reached more expeditiously by working up on the N.W. side of Ku-kien-san, rounding Isaac Island and running down off the danger line from Melros Point (the northern part of the peninsula which forms the North side of the bay) round the reef, which extends 6 cables off Hamilton Point, and shoot into 15 fathoms. The chart exhibits several awkward patches, but a vessel which works decently can thread her way between them, if the sun be bright, as all the shoals may easily be traced from aloft.

There is a passage from Port Haddington into Broughton Bay, which was used by H.M. sloops *Lily* and *Contest*, in 1852; it abounds in coral reefs.

About 15 or 20 miles E. by N. $\frac{1}{2}$ N. of the N.E. extremity of Pa-chung are two low islets, *Mitsuna* and *Tarara*, from which extensive reefs stretch northward and westward, and the ground is shallow and foul at 10 miles N.N.E. of them. The vicinity of these shoals ought therefore to be avoided by night, but by day the dangers are clearly denoted by breakers.

TAI-PIN SAN GROUP, the eastern division of the Meiaco simas, comprises the large island of Tai-pin san and four small off-lying islets, and is distant 50 miles from Pa-chung san in an E. by N. $\frac{1}{2}$ N. direction. Tai-pin san is 15 miles long, N.W. and S.E., and is surrounded on all sides except the South by a very extensive chain of coral reefs, upon which lie the four small islands. Off the S.W. point is *Ashumah* or *Kurimah*; to the westward is *Erabou* or *Yerabu*, 4 miles in extent; off the North point is *Corumah* or *Ykima*, and 2 miles eastward of the same is *Hummock* or *Ogame*.

Safe anchorage during the S.W. monsoon might be found inside the reefs of Hummock Island, and also safe in the N.E. monsoon; but the passage in or out at that season would be attended with risk, and there can be no inducements for any vessel to visit Tai-pin san; neither wood, water, nor any other necessaries could be procured.

YKIMA ISLAND (Doubtful), is placed on the charts as 3 miles in extent with an islet off its N.E. side, and in lat. $24^{\circ} 26'$ N., long. $125^{\circ} 26'$, which position is 20 miles South of the eastern point of Tai-pin san.

CAUTION is requisite in approaching the Meiaco sima group from the N.E., East, or South, particularly with fresh breezes, and in the absence of the sun, by the aid of which the coral reefs below water can be detected. They are here, from their greenish hue, being covered by seaweed, less distinct than at other places, and therefore, where they are not marked on the chart, it must not be presumed that the space is free from danger; for the lead will not afford timely warning.

Vessels should not venture near these islands after dark until the dangers have been more closely examined. From the western limit of Chung-chi Island to the eastern range of the breakers of Tai-pin san, the space is dangerous. Independent of the many reefs which connect the islands, the constant strong winds, with haze and rain during the N.E. monsoon, render the approach at that season, unless in a clear day, very hazardous.

Of the dangers on the northern side of the group, all that is known has been said, and no off-lying shoals appear to exist westward of Pa-chung san. But it is not considered prudent that any vessel should run the risk of being hampered by these islands and shoals, and therefore, when beating up to the northward, should not come farther eastward than to sight Chung-chi Island. The currents, as these islands are approached, press more southerly and easterly than on the coast of Formosa, and stronger breezes are met as a vessel advances eastward; indeed it blows incessantly at this western group.

PESCADORES ISLANDS.

The **PESCADORES** or Panghou Archipelago consist of twenty-one inhabited islands, besides several rocks, and extend from lat. $23^{\circ} 11\frac{1}{2}'$ to $23^{\circ} 47'$ N., and from long. $119^{\circ} 16'$ to $119^{\circ} 40''$ E. From their basaltic formation the land is generally flat, and no part of the group is 300 ft. above the level of the sea. Panghou or Ponghou and Fisher, the two largest islands, lie near the centre of the archipelago, and between them is an extensive and excellent harbour. The general depth of water on the western side of the archipelago is 30 and 35 fathoms; there are, however, some places with 60 fa-

thoms. To the eastward of the group the depth is 40 fathoms, and the current strong.

These islands contained, in 1843, a population of about 8,000, and are extensively cultivated, potatoes, maize, millet, and ground nuts being produced in considerable quantities, as well as a few other vegetables, but the soil is not good; owing to the violence of the wind there are no trees, but the islands are well supplied with fruits and vegetables from Formosa. Bulls are numerous, being used to till the ground. Fresh water was abundant in the months of June and July, but it was stated that at some seasons it was scarce. Dried fish forms the only article of export, and the imports are rice, sugar, fruits, and vegetables from Formosa; tea, &c., from Amoy.

JUNK ISLAND, the most southern of the Pescadores, is 2 miles long, East and West, and $1\frac{1}{2}$ mile wide, and the soundings in its vicinity are 15 and 16 fathoms. The highest part of the island is 260 ft. above the sea, and from it High Island bears N. W. $\frac{1}{2}$ N. $8\frac{3}{4}$ miles, Reef Island N. E. by E. $5\frac{1}{4}$ miles, and East Island E. by N. 13 miles. A reef of rocks extends 6 cables from its S. W. side, and within them is a small artificial harbour for junks. Its eastern face is fronted by bold cliffs; and its western extreme is a long shelving point.

Reef Islands are three in number, one of which, *Steeple Island*, is a remarkable pyramid. The other two are rather more than a mile each in circumference, and are connected at low water by a stony ledge; reefs extend half a mile to the southward of them, and South one-third of a mile from the West end of the eastern island is a pyramidal rock 80 ft. above the sea. There is also a low flat rock, nearly level with the water's edge, lying S. W. by S. $1\frac{3}{4}$ mile, and a small peaked rock with a reef northward of it lying S. E. 2 miles from the East end of this island.

East Island is 8 miles eastward of the Reef Islands, and between them and distant 5 miles from the latter is a smaller island, named *Pe-ting*, $1\frac{1}{2}$ mile in circumference, with a reef extending in an easterly direction, not quite a mile from its North point. East Island is $2\frac{1}{2}$ miles in circumference, and a small islet lies half a mile from its north-western shore.

Nine-foot Reef lies N. by E. $\frac{3}{4}$ E. $12\frac{3}{4}$ miles from the North end of East Island, and from it Dome Hill on Poughou Island bears W. by N. $\frac{1}{2}$ N. $10\frac{1}{4}$ miles, and Three Island N. N. W. $\frac{1}{2}$ W. 4 miles. The lead gives no warning.

ROVER GROUP, consisting of two large islands, *Pa-chau* and *Tsiang*, and several rocks, are sufficiently extensive to afford shelter under their lee in either monsoon. *Pa-chau*, the western island, is $2\frac{1}{2}$ miles long, North and South, and a mile broad, and its summit rises like a dome with a large pile upon it. A reef extends $1\frac{3}{8}$ mile in a westerly direction from the S. W. point of the island, and its extreme shows at all times of tide. *Tsiang*, the eastern island, is only $1\frac{1}{4}$ mile long N. E. and S. W., and about $1\frac{1}{2}$ mile broad,

and the channel between it and Pa-chau is barely a cable wide. The East point of this island is remarkable from an isolated cliff, called *Rover Knob*, 100 ft. high, which forms the most striking feature in the group; and 7 cables eastward of the cliff is a ledge of rocks, part of which are always above water.

The channel between the Rover group being so narrow and intricate, the only excuse for a stranger using it would be his vessel being caught at anchor to the northward of the group in a breeze from the northward, and unable to fetch clear either eastward or westward.

High Island, bearing W. by S. $\frac{2}{3}$ S., $9\frac{3}{4}$ miles from the highest part of Pa-chau, is dome-shaped, 247 ft. high, and three-quarters of a mile in circumference. At 1 mile eastward of it is a low flat island, and between the two are several rocks, one of which has a remarkable gap in it, and rises 60 feet above the sea. A rock nearly level with the water's edge lies S.E. $\frac{1}{4}$ E. $1\frac{3}{4}$ mile from the summit of High Island.

Yih-pan Island, 158 ft. high, 2 miles in circumference and uneven in appearance, is 4 miles northward of High Island, and S.W. $\frac{1}{2}$ S. $11\frac{1}{2}$ miles from the lighthouse on the S.W. end of Fisher Island.

Table Island, bearing S.S.E. $\frac{3}{4}$ E. nearly 5 miles from the lighthouse on Fisher Island, is aptly named, the summit being a dead flat 200 ft. above the sea. The island is not quite 2 miles long E. by N. and W. by S., and is seldom 3 cables wide. *Tablet Island* is about a mile northward of Table Island, and between them the depth is 12 to 19 fathoms. A shoal of only 9 feet least water extends N.W. $\frac{1}{2}$ W. $1\frac{1}{4}$ mile from the N.W. side of the island. From its north-western limit Dome Island bears N.E. by N. $\frac{3}{4}$ E.

PANGHOU or Ponghou Island, the largest of the Pescadores, is $9\frac{1}{2}$ miles in extent, North and South; it is, however, separated into three portions by narrow channels, which have only 2 ft. in them at low water, and are further blocked by stone weirs. The whole of the western face of the island is fronted by coral reefs. On its south-eastern side, between *Hou* and *Leechin Points*, are two bays with fishing villages, either of which afford anchorage in the N.E. monsoon. *Dome Bay*, on the S.W. side of the island, will also afford good anchorage in 6 fathoms. *Makung Harbour* is formed at the S.W. part of Ponghou, and although much confined by coral reefs it has sufficient depth for vessels of large draught. The town of Makung stands on the North side of an islet, close to the N.E. of the entrance, and will be easily recognized by a citadel and a line of embrasures. The large junks waiting for a favourable wind to take them to Formosa, anchor S.W. of the town in 7 and 8 fathoms, with Black Rock lying midway between Fisher Island and Makung, bearing N.E. by N. The harbour runs back 3 miles to the eastward from *Chimney Point*, the South point of entrance, on which is an old Dutch fort.

Running for Makung Harbour from the westward, pass about half a mile

southward of *Litsitah Point*, the South extreme of Fisher Island, and then steer E. $\frac{1}{2}$ N. for the town of Mukung. The only dangers to be avoided in entering this passage are, the shoal with 9 ft. on it, extending N.W. $\frac{1}{2}$ W. $1\frac{1}{4}$ mile from Tablet Island; and a reef, just awash at high water, at half a mile westward of Dome Island.

FISHER ISLAND, which in a collection of voyages in Dutch, published in 1726, is called D'Visser's Island, lies westward of Ponghou, and between them is the excellent and extensive harbour of Ponghou. The island is 5 miles long, North and South, and $3\frac{1}{2}$ miles broad. The S.E. point, *Siau Head*, is a bold cliff, 170 ft. above the sea. A reef breaks at low water at 7 cables from the western shore of the island, and its outer extreme bears N. by E. $\frac{1}{4}$ E. from the lighthouse.

Litsitah Point Lighthouse, on the S.W. extremity of Fisher Island, is a round iron tower, painted black, and 33 ft. high. The keepers' dwellings are painted white. The light is a *fixed bright light*, elevated 205 ft. above the level of the sea, and visible 15 miles off. It was established in December, 1875, and superseded an old native light which had been established a century.

Vessels seeking shelter in a N.E. gale will find smooth water off the southern shore of Fisher Island between the lighthouse and *Siau Head*, where there are two sandy bays. *Niu-kung Bay*, between the N.E. end of Fisher Island and Pehoe Island, will afford shelter in the S.W. monsoon.

PONGHOU HARBOUR.—The eastern coast of Fisher Island trends northward from *Siau Head*, and forms several small bays which are steep-to to a cable's length of the beach until $2\frac{1}{4}$ miles North of the head when reefs extend nearly 3 cables off shore. To avoid these reefs the fall of *Siau Head* must not be brought southward of S. by W. $\frac{1}{4}$ W.

The harbour northward of the anchorage is much choked with coral patches. There is a passage out to the northward between Fisher Island and Pehoe Island, and it may be used on an emergency by vessels of 15 ft. draught, but a local knowledge is necessary to render it available.

The archipelago, to the northward of Fisher and Pehoe Islands, does not afford any inducement for a vessel to enter it.

Tortoise Rock, 9 ft. above high water, and steep-to, lies about $2\frac{1}{2}$ miles from the N.W. point of Fisher Island, and N. by E. $\frac{1}{8}$ E. $7\frac{1}{2}$ miles from the lighthouse. There is a shoal patch of $1\frac{3}{4}$ fathom at 6 cables S. $\frac{3}{4}$ E. from the rock, and N.W. $\frac{3}{4}$ N. from the N.E. point of Fisher Island.

Sand Island, three-quarters of a mile long, North and South, and a quarter of a mile broad, bears N.E. by E. $\frac{1}{4}$ E. $2\frac{3}{4}$ miles from the Tortoise Rock, and it will be known by a hummock which rises on the low land in the centre of the island, and also by its yellow appearance; a rock lies off its S.W. end, and reefs extend N.W. 3 cables from its N.W. point.

Bird Island bears E.N.E. from Sand Island, and a long sandy point, off

which is a small sand island with a house upon it, forms its southern extreme. Shoal water extends 3 miles northward from the North point of Bird Island, and near its centre is North Island, which has a house upon it to shelter the fishermen, and upon a reef half-way between them is another house. The northern edge of the shoal water uncovers at low tide. Shelter during a north-easterly wind might be found on the West side of Bird Island; and from southerly winds, to the northward of the reefs extending from the North point of the island. *N.W. Outlier* is a shoal patch of 5 fathoms, lying N. by W. $\frac{3}{4}$ W. from Sand Island, and West $3\frac{1}{2}$ miles from North Island. *Sable Island*, bearing S.E. by S. 5 miles from the N.E. end of Bird Island, is a small islet with a sand patch on its South cliff, and surrounded with rocks.

Organ Island is 3 miles S. by E. $\frac{1}{2}$ E. from Sable Island. N.E. $\frac{3}{4}$ N. 1 mile from it is a reef, from which Sable Island bears N.W. by N. *Ragged Island* is nearly a mile S.E. by E. from Organ Island.

Round and Three Islands.—Leechin Point, the East extreme of Ponghou, is low and shelving, and $1\frac{1}{2}$ mile eastward of it is Round Island, bearing S. by E. $\frac{2}{3}$ E. $3\frac{1}{2}$ miles from Ragged Island; and S. $\frac{1}{2}$ E. $1\frac{1}{2}$ mile from Round Island is Three Island. N.W. by W. $\frac{1}{3}$ W. from Three Island, and S.W. from Round Island, is a reef which covers at half tide.

Tides.—It is high water, full and change, in Makung Harbour, at 10^h 30^m; springs rise $9\frac{1}{2}$ ft., neaps 7 ft. The tidal streams among the Pescadores run with great strength, but they are much affected by the prevailing winds. Vessels navigating in this neighbourhood may safely allow that the effect of the current and tidal stream together will set them, according to the prevailing monsoon, 17 miles in one tide. Tide races are common, and overtop with great violence.

CHAPTER XXIII.

RIVER MIN TO SHANGHAI.

The RIVER MIN, $8\frac{1}{2}$ miles N.W. $\frac{1}{2}$ W. from the anchorage at the White Dogs, is formed between sandbanks, which extend 7 miles from the land, that partly dry at low water. The range of banks terminates to the eastward at *Outer Min Reef*, a detached rocky patch, two peaked heads of which show at the last quarter ebb. Woufou Island, 6 miles long East and West, and 4 miles broad, is situated within the entrance, and near its N.E. point is the little island of Hokeang, with its two contiguous islets called the Brothers. Vessels of 12 ft. draught can go up to Fuchow.

Pilots.—A staff of European pilots conducts the navigation of foreign vessels entering or leaving the River Min, but notwithstanding the skill of many of these individuals, wrecks are of not unfrequent occurrence among the shifting sandbanks and intricate channels of the river. Pilot-boats are always cruising in the vicinity of the White Dogs and Matsou, or between Tongsha and the entrance; they are of Chinese rig, and carry a flag, white and red horizontal.

Caution.—To those well acquainted with the port, it is easy of access with proper care and attention, but in face of the frequent changes of the entrance, it would be imprudent in others to risk taking their ships in without a pilot. There are unlicensed Chinese pilots at the White Dogs, but these are not to be trusted, notwithstanding their numerous testimonials.

Tides.—It is high water, full and change, at the White Dog Islands, at 9^h 0^m, springs rise 18 ft.; at Temple Point, River Min, at 10^h 45^m, springs rise 19 ft., neaps 14 $\frac{1}{2}$ ft.; and at Losing Island it is high water at noon. It is high water at the White Dogs about 2 hours before the tide has done flowing at the Rees Rock.

Considerable alteration has taken place in the entrance to the River Min, previous to 1868, when the entrance was again surveyed by Commander E. Brooker, of H.M. surveying vessel *Sylvia*. The banks between North

Breakers and Rees Rock had shoaled to 9 ft., and thus closed the principal or South channel, whilst the North channel, heretofore irregular and uncertain, opened out with a clear, direct, and accessible passage, having 15 ft. on its outer bar at low water springs.

With a 16-ft. rise of tide the best time for entering the Min is from half-flood to half-ebb. The North sands of the entrance begin to cover at a quarter flood. At low water springs they dry about 3 ft. ; at neaps they do not show. In fine weather the North and South breakers appear from half-ebb to half-flood, and the Outer Knoll, which has only 10 ft. on it, seldom until after the last quarter ; but in bad weather a line of breakers extends from the Outer Knoll across the North bank, and a continuous line from the South breakers to Black Head.

Outer Min Reef is nearly half a mile in extent, and only shows at low water. In clear weather it may be passed outside at a mile by keeping the summit of Tong-sha S.E. by S. till Rees Rock is open southward of Wou-fou Island.

Rees Rock is a small black rock which never entirely covers. It is marked by a beacon built of granite, which is "used as a range for the Middle Channel and as a general landmark."

South Channel is now disused by large ships. The leading mark in was Rees Rock in line with the North extreme of Hokiang, N.W. by W. $\frac{1}{4}$ W.

BUOYS of North Channel.—*Outer or No. 1 Buoy* is a fairway buoy in 8 fathoms, off the northern entrance of North channel, and is about 3 miles N.W. $\frac{1}{2}$ W. from the outer part of Outer Min Reef. It is a large buoy, 10 feet in diameter, painted in *red* and *black* horizontal stripes, and surmounted by a black cage, 18 ft. above the water. From the buoy, Sharp Peak bears W. $\frac{1}{2}$ N. nearly, and Rees Rock S.W. $\frac{2}{3}$ W.

Middle or No. 2 Buoy is a fairway buoy in 4 fathoms, and about $2\frac{1}{2}$ miles S.W. by W. $\frac{3}{4}$ W. from Outer Buoy, to which it is in all respects similar, except that its cage is in the form of a truncated cone. From it, Sharp Peak bears W. by N. $\frac{2}{3}$ N., and Rees Rock S.W. $\frac{1}{2}$ S.

Inner or No. 3 Buoy is also a fairway buoy in $7\frac{1}{2}$ fathoms, and lying about $2\frac{1}{2}$ miles W. $\frac{1}{3}$ S. from Middle Buoy, with Sharp Peak bearing N.W. $\frac{1}{2}$ W., and Round Island S.W. $\frac{2}{3}$ W. It is precisely the same as Outer Buoy.

The small Round Island in line with the first gap left of the Serrated Peak, W.S.W., leads over the Outer Bar and up the North Channel, until Kushan Peak is in the middle of the saddle of Square Peak, bearing W. $\frac{3}{4}$ S. With these latter marks, run in until the highest part (white patch) of West Brother is on with the right fall of East Brother N.W. by W. $\frac{3}{4}$ W., which leads over the Inner Bar, in 10 ft. at low water. This bar is very narrow, and the marks must be carefully attended to. The Inner Bar is to the southward of Sharp Peak Island, the peak of which, 616 feet

high, is a prominent landmark. On the south-western extremity of the shelf off Sharp Peak Island is a sunken rock, having 8 ft. on it at low water springs, and on which the British ship *Erne* struck in August, 1872. A *red nun buoy*, 6 ft. in diameter, is moored in 14 ft., low water springs, on the southern extremity of the rock, with Sharp Peak Point bearing E. by S. $\frac{1}{4}$ S., and Sharp Peak N. by E., easterly.

South Coast Passage.—South of Woufou there is a passage, over the flats at the entrance, and along the mainland, by which the Min is entered, about 6 miles below Pagoda Island, and 10 miles above Sharp Peak. Large junks use it, and the English pilots, occasionally, to save time, as the distance is about 5 miles shorter than by the main channel. The deepest water is found with square Peak on Wou-fou Island bearing from N.W. by W. $\frac{1}{2}$ W. to N.W. by W. $\frac{3}{4}$ W., till the highest peak left of Serrated Peak is in line with the outer rock off Sand Peak Point, W. $\frac{3}{4}$ S. Keep on this leading mark until close in, passing the outer rock at a cable, from which steer well open of Meewah Town Point.

The River.—On the North side of the first reach of the river, off the point under Woga Fort, which is a circular building on the summit of the southern hills of Woga, is the *Zephyr Rock*, with only 5 ft. on it, at three-quarters of a cable from the shore: there are 5 fathoms inside it.

Off Temple Point are two patches of 2 fathoms; also, in mid-channel, 3 cables off the point, is the Temple or Six-foot sunken rock, marked by a *red buoy* on the southern extremity of the rock, to the southward of which vessels should pass. When on this rock, Woga Point is in line with Sharp Peak.

On the South bank, on the mud spit which extends westward from West Brother and abreast the Six-foot Rock, is a patch of rocks which cover at a quarter flood.

The best position for anchorage is said to be with East Brother S. $\frac{1}{2}$ E., and Sharp Peak Point E.S.E. In the N.E. monsoon, the high land of Woga in line with or a little open of Temple Point is a good line to anchor on; in the S.W. monsoon Woga Creek is the best anchorage.

Kinpai Pass is dangerous to strangers, particularly at or near spring tides, for then the violence of the current produces eddies among the rocks, that occasionally cross the channel, and renders the vessel totally unmanageable, even in a fresh breeze; it therefore should never be taken without a pilot or personal knowledge, and then at slack tide. On the flood a dangerous eddy extends from Kinpai Point above it, in the direction of the Ferry; and for this reason the passage North of the Middle Ground is considered the best. The *Wolverine Rock*, with 13 ft. over it, lies S.W. by W. $\frac{1}{2}$ W. from the North extreme of Kinpai Point, and $1\frac{1}{2}$ cable from the shore. The *Vixen Spit*, at the eastern end of the Middle Ground, lies S.W. 3 cables from the point, and the distance, from $1\frac{1}{2}$ fathom on its South edge to the southern shore, is about a cable.

Enter the pass South of Pass Island and the other islet S.W. of it, and when past White Fort, close the northern shore, which is steep-to, until Serrated Peak is in line with the Ferry house on Woufou, S. $\frac{1}{2}$ W., which is the leading mark across between the Middle Ground and Quantao Shoal. This is also a good line for vessels to anchor on when coming down the river, and waiting for an opportunity of dropping through the Pass.

The danger of this passage is in passing the northern shoulder of the Middle Ground, which forms a sharp angle with only 1 foot on it at low water springs, and 4 fathoms close-to; from this point to the shore the distance is only $1\frac{1}{4}$ cable. After clearing this spot, in passing either up or down, the tide will tend rather to set the vessel from the bank into the stream. The highest part of Pass Islet in line with White Fort bluff outer extreme is a near clearing mark for the northern shoulder of the Middle Ground. It is recommended to shut Pass Islet in altogether until past that point, opening it again immediately afterwards. Vessels drawing 8 ft. (and sometimes 12 feet) can pass over the Middle Ground at half tide.

At Slack water, Kinpai Point and the small islet off it (not marked on the chart) may be rounded closely and the South shore kept on board for half a mile, when a vessel may edge across the stream W. $\frac{1}{2}$ S. towards the other shore, and steer for Wedge Island, thus clearing the shoal that extends 3 cables off the Ferry house on the Kinpai shore.

Tongue Shoal, which is steep-to, skirts the Wou-fou shore, extending more than half across the river. Its elbow, with only 7 ft. water, which is the most necessary part to avoid, is half a mile N.N.E. of Half-tide Rock, and may be cleared by keeping the Ferry house midway between Kinpai Bluff and the tower, until the highest point of Kowlui Head comes in line with Half-tide Rock.

Half-tide Beacon.—Half-tide Rock, which is near the upper end of the Tongue Shoal, is marked by a granite Beacon like a monument. From this to Tintao, 2 miles higher up, the bottom is very irregular.

Mingan Pass.—Proceeding upwards, the river narrows at the Mingan Pass, where the land rises on either side to 1,500 or 2,000 ft. About three-quarters of a mile above Mingan, and on the same side of the river, is Couding Island, off the East point of which H.M.S. *Scout* grounded on a rock at the end of a ledge projecting 25 yards from the islet, with 7 ft. near its extreme.

Buoys.—At the upper or South end of the gorge, where it opens out, and on the East side of the river, are *Spiteful* and *Flat Islets*, which must be left on the port hand. The *Spiteful Rock*, showing at low water, is part of a rocky ledge projecting about 30 yards from the S.W. point of the island, and is marked by a *black* nun buoy. There is also a *red* nun buoy on the opposite side, at the extremity of the spit extending north-eastward from Losing

island, from which Spiteful Island bears N.E., and Flat Island S.E. $\frac{3}{4}$ E.; a course between the two buoys leads clear of all danger.

To pass between Spiteful Rock and Losing Spit, and avoid the latter, do not shut in Younoi Head with Flat Island until Black Cliff Head, just passed (marked with a white spot) comes in line with the northern edge of Spiteful Island.

Pagoda, Rock, Beacon, and Light lie off the South point of Losing Island. The rock dried formerly at low-water springs. The beacon is an iron pile, 28 ft. high, surmounted by a cage, and a red light, 14 feet above high water, is exhibited from it from sunset to sunrise.

FUCHAU FU (or Foochow), 34 miles within the entrance of the River Min, was opened to foreign commerce by the Treaty of Nanking in 1842. The city is built on a plain, and lies about 3 miles from the river side, to which it is connected by a line of suburbs. The foreign hong and British and other foreign consulates are principally at Nantai, on the opposite or South bank of the river, which is connected with Fuchau by a massive stone bridge. So also are the church, hospital, cemeteries, &c.

The anchorage for foreign vessels is at Losing Island, generally called Pagoda Island, 10 miles from the city of Fu-chau. Foreign vessels, with the exception of small schooners or steamers of very light draught, are obliged to anchor here, farther approach to the city being prevented by difficulties of navigation and lack of sufficient depth of water, the natural shallowness having been largely increased of late years through shoaling caused by the barrier constructed in 1841, with the object of preventing access to the city by the British ships of war. The channel of the river is very tortuous, and is said to be constantly changed by heavy freshets.

The dock here is owned and managed by Europeans. Its length is 300 feet, breadth 95 feet, and depth 22 feet. It has an average depth of water at springs of 17 ft., and neaps of 14 ft. Steam power is used for pumping dry. An imperial dockyard and arsenal is also established.

Supplies.—Coal is to be obtained, both British and Kelung, from floating hulks and from coal stores on shore. There are some general stores in the place, and boarding houses kept by Europeans. Beef and poultry are the staples of animal food. Foochow bacon and hams are much prized, and largely shipped to all parts of China. Game and wild-fowl are to be had in their season, and occasionally venison. Fish abounds in great variety, and oysters are very plentiful in the cool months, but are dangerous if eaten raw. Fruit and vegetables are abundant, and excellent potatoes are largely grown for the supply of foreigners.

The principal foreign imports are cotton and woollen manufactures, metals, and opium; and the native imports bean cake, beans and peas, tea, mats, oil, sugar, &c. The exports are tea, paper, oranges, woods, &c., but tea is the only staple of importance.

On leaving the river, take care that the set of the tide across the channel between Sharp-peak Point and Rees Rock does not force the vessel on the shoals on the North side of the channel. Fair anchorage in 6 fathoms, to stop during a tide, will be found with Rees Rock bearing S.S.E.

The junks generally use the *Woga Channel* between Woga and Sharp-peak Islands, but to the northward of the latter island there are several sandbanks which show at low tide, with not more than 6 to 9 ft. water between the banks. Small steamers may proceed to sea by this channel with considerable advantage in the N.E. monsoon, as they are enabled, with fore and aft sail, to fetch up between Matsou and Chang-chi, and if bound to Formosa a very weatherly departure is ensured. A pilot, however, should be taken and due caution exercised, because the banks are liable to change, and personal knowledge is requisite for the safe navigation of the channel.

MATSOU ISLAND lies N.E. of the entrance of the Min, and North 10 miles from the western White Dog; and between the two and N. by E. $\frac{1}{4}$ E. $6\frac{1}{2}$ miles from the latter is a precipitous black rock, the *Sea Dog*, 60 ft. high, and surrounded by rocks.

Hebe Reef.—S.W. by S. 1 mile from the Sea Dog is a rock which shows when there is a heavy swell on and at low-water springs. When on it the West end of Matsou bears N.N.W. $\frac{1}{4}$ W., and Breakwater Rock at Tongsha Island S. by W. $\frac{3}{4}$ W. The East end of Reef Island (off the East point of Matsou) in line with Changchi Peak N. by E. $\frac{1}{2}$ E. leads to the westward.

Between the Sea Dog and the East end of Matsou are two other rocks above water, the *Sea Cat* and *Flat Rock*.

Pilot Rock was examined by H.M.S. *Nassau* in 1878. It breaks at low water, and lies 3 miles East of Sea Cat Island, with Changchi Island peak bearing N. by W. $\frac{1}{2}$ W. and Sea Dog Island S.W. by W. $\frac{3}{4}$ W.

Flat Rock should not be approached on its southern side, as two dangerous pinnacle rocks lie 6 and 9 ft. below the surface of the water at nearly half a mile to the southward. These pinnacles are named the *Norman Court Rocks*, and between them and Flat Rock is a $2\frac{1}{2}$ -fathom patch. A rocky ledge, with 6 fathoms over it, extends S.E. by S. $1\frac{1}{2}$ cable from Norman Court Rocks.

Ayma Rock, on which the American barque *Benjamin Ayma* struck in Jan. 1878, lies 5 miles westward of the West side of Matsou Island. It is a small 3-ft. patch, steep-to, with 9 and 10 fathoms close around. The South extreme of Changchi Island, in line with the North extreme of Matsou leads southward of it, and Crab Island bearing North leads eastward of it.

Anchorage will be found on the western side of Matsou during the N.E. monsoon, and good shelter in the deep bay on its northern face in the S.W. monsoon.

CHANGCHI ISLAND, at $1\frac{3}{4}$ mile N.E. of Matsou, has on it two remarkable sharp peaks, the highest being 1,030 ft. above the sea. Off the northern

face of the island are several islets, the largest of which, Gordon Islet, bears North $2\frac{1}{2}$ miles, but there is no safe passage between them. N.E. $1\frac{1}{2}$ mile from the North point of Gordon is a small black rock, with a reef lying westward of it.

At half a mile S.S.E. $\frac{2}{3}$ E. from the islet off the South point of Changchi are two rocks always above water; and West $1\frac{1}{4}$ mile from the South point is the *Pastel Rock*. The *Frio Rocks*, about 50 ft. in height, lie N.E. by E. $\frac{1}{2}$ E. 2 miles from the N.E. point of Changchi.

The bay on the South side of Changchi affords good shelter in the N.E. monsoon, but a heavy swell rolls in at times. Vessels entering from the northward can round its eastern point close-to, and anchor within the point, in 6 fathoms. Either this or the anchorage on the western side of Matsou, which is preferable, should be used by sailing vessels bound to the River Min during the N.E. monsoon, as they may always get to the bar from hence the precise moment they require it, whilst from the White Dogs a vessel will barely fetch.

Alligator Island, or Tungsha, in lat. $26^{\circ} 9' N.$, long. $120^{\circ} 26' E.$, is a barren rock, about 40 ft. above the sea, bearing East $22\frac{1}{2}$ miles from Matsou Island, and N.E. by E. $\frac{1}{3}$ E. 26 miles from the South end of the White Dogs.

Larne Rock, lying N.W. by W. $12\frac{1}{2}$ miles from Alligator Island, is low and flat, with a reef lying 2 cables North of it. *Larne Islet*, bearing N. by E. $5\frac{1}{2}$ miles from Larne Rock, has ledges extending from its North and South ends. It is about 200 ft. above the sea, with large boulders sticking up here and there; near its summit are three houses.

Black Rock, 40 ft. high, is 7 miles W.N.W. of Larne Islet, and 6 miles E. $\frac{1}{4}$ N. of Ragged Point on the mainland. A reef shows at low water E.N.E. $5\frac{1}{2}$ miles from the Black Rock, and from it Larne bears S. by E. $\frac{1}{2}$ E. 5 miles, the North end of Tung-ying Island E. by S., and Cony Islet N.W. $\frac{2}{3}$ N.

Tung-ying, the easternmost island on this part of the coast, bears E. $\frac{1}{2}$ N. 13 miles from Larne Islet, and its peak rises 855 ft. above the sea. Its appearance is level and flat, with steep cliff shores, and a large village stands on its western side; off its South extreme is a ledge of rocks. It is proposed to establish a *lighthouse* on its summit.

There is good anchorage in the N.E. monsoon in 10 fathoms, at half a mile southward of the small island lying off the N.W. point of Tung-ying. This island appears as part of Tung-ying, except on a N.E. by N. or S.W. by S. bearing.

Cony is a remarkable conical island, lying W.N.W., 19 miles from Tung-ying. A reef extends 3 cables off its N.E. shore, otherwise the channel, nearly $1\frac{1}{2}$ mile wide, between it and the two islands North of it, is safe. A rock awash at low water, lies East $1\frac{1}{2}$ mile from the cone, and another S.E.

$\frac{1}{2}$ E. $1\frac{3}{4}$ mile; from the latter, S.W. of which there is uneven ground, the South end of Spider Island bears W. $\frac{3}{4}$ N.

Spider Island is $3\frac{1}{4}$ miles westward of Cony, and its highest part is 620 feet above the sea. There is a large village in a bay on its South side, a reef off its S.W. point, and four small islets off its N.E. face. Between it and the main, which is $5\frac{1}{2}$ miles distant, there are three other and larger islets; between the first and Spider Island is a half-tide rock; the centre one, named *Isthmus Island*, has a sandy isthmus, and a mud bank extends westerly from it, but the channel between it and the first islet is clear. The passage between Isthmus and Inside Islet, $1\frac{1}{2}$ mile to the westward, is obstructed by a reef, some rocks of which uncover at half-tide, and which extends 6 cables E.N.E. from Inside. The channel between the latter islet and Cox Point has 6 to 4 fathoms, and is a mile wide. West of Spider and southward of Isthmus are the two groups of Larva Rocks, with a channel between them; two rocks on each are above water. The channel between Isthmus and Larva is contracted to a mile by reefs extending northward from both the latter groups.

There is good shelter from N.E. winds on the West side of Spider Island.

Ting-hae Bay, formed on the West side of a peninsula of the mainland, 13 miles westward of Changchi, affords safe anchorage in $2\frac{1}{2}$ to 3 fathoms in the N.E. monsoon.

Fronting this bay to the southward and S.E. are many islands and rocks. The outermost (four islets above water, named *Square Rocks*) lie 3 miles to the southward, with reefs extending northerly from them. To the N.E. of them is *Crab Islet*, surrounded by reefs, which extend off its N.W. part at least half a mile. In the channel between Crab Islet and Ting-hae Point are two islets.

Wanki Bay, 6 miles E.N.E. of Ting-hae, is frequented by junks, but although it affords them good shelter it cannot be recommended for larger vessels. There is a rock, which shows at low water, lying near the centre of the bay at 7 cables off shore, with Pe-kyau Point E. $\frac{1}{2}$ N., and the nearest Claret Rock S.E. by S.

Claret Rocks are $1\frac{1}{2}$ mile southward of the East point of Wanki Bay. Three of them are from 20 to 30 ft. above the sea, but they are all surrounded by sunken rocks, the southernmost of which lies S.W. $\frac{1}{2}$ S. half a mile from the South Claret. A stranger should pass South of the Claret Rocks, and haul up when the village in Wanki Bay bears North.

Ragged Point is the N.E. extreme of a narrow peninsula, in some places only half a mile across, which runs $5\frac{1}{2}$ miles E.N.E. of Wanki Bay. A quarter of a mile eastward of the point is *Diplo Islet*, with a reef extending three-quarters of a cable eastward of it. Steamers frequently anchor under the small island westward of Ragged Point.

Sam-sah Inlet.*—The entrance to this inlet, at 10 miles westward of Spider Island, is $1\frac{3}{4}$ mile wide, with deep water and strong tides. There is a rock in mid-channel W. $\frac{1}{4}$ S. 6 cables from Castle Point, from which the centre peak of Cone Island bears N. $\frac{1}{4}$ W. and Steep Rock N. by E. $\frac{3}{4}$ E. ; to pass eastward of it, keep the West end of Cone Island in line with the highest peak of Crag Island.

On the eastern side, close to the entrance, is a small bay with a fort in it, and here the junks remain for a tide, but the water is very deep, and shoals too suddenly for vessels that cannot take the ground.

At 4 miles southward of the entrance of Sam-sah Inlet is the opening to another inlet, 10 miles deep ; there are 30 fathoms water at the entrance, but circumstances did not admit of its being examined.

Off the entrance to these inlets, about 4 miles north-westward of Ragged Point, and 7 miles south-westward of Spider Island are three islets, named *Rag Islands*, and a mile northward of the easternmost is the *Bittern Rock*, which covers at high water. The *Plover* anchored westward of the westernmost islet and found tolerable shelter. Off the Rag Islands the tides run with great strength, and a long swell rolls home into Sam-sah Bay with N.E. winds.

Double Peak Island is $3\frac{1}{2}$ miles long, N.N.E. and S.S.W., and near its northern end are two remarkable peaks, the highest of which rises 1,193 ft. above the sea. It lies 3 miles N.E. of Spider Island, the only danger in the channel between being the rocks lying off the North end of the latter island.

There are two cone-shaped islets between Double Peak and Cony Island, with channels between too narrow for sailing vessels, but there is a good passage between the southernmost of these islets and the reefs extending north-eastward of Cony Island. A rock above water lies a cable N. by W. from the West point of Double Peak Island. At $1\frac{1}{2}$ mile westward of the North end of Double Peak is *Flap Island*, a low flat islet, with a sunken rock off its southern point. There is no passage fit for vessels between this islet and the mainland.

There is good anchorage in the N.E. monsoon on the S.W. side of Double Peak Island, to the S.E. of a small islet, with a rock above water on each side of it, lying three-quarters of a mile westward of the West point of the island ; the two cone-shaped islets northward of Cony Island sheltering from the eastern swell. There is also good shelter abreast the first sandy bay within the point westward of Flap Island. Here were found six piratical junks plundering part of a convoy they had captured.

* Sam-sah Inlet is not known by that name to the natives or European coasters. The true Sam-sah lies farther North, being a small cove at the N.E. angle of Fuh-ning Bay, at 2 miles N.W. of the North point of Fongho Island. There is anchorage, in the N.E. monsoon, in the cove half a mile eastward of it, in 3 to 5 fathoms, but it would be scarcely safe to proceed into it without the services of a pilot,

From Flap Island the coast trends northward for 10 miles to *Fielon Island*, and off it is *Bittern Island* and several rugged rocks, which vessels of large draught should give a berth to, and not close the shore under the depth of 6 fathoms. Between Bittern Island and the main there is good anchorage in $3\frac{1}{2}$ fathoms for small vessels in either monsoon. On the N.W. side of the island is a sandy cove, where fresh water will be found. From Fielon Island the coast falls back to the westward, forming a deep but shallow bay, on the shore of which is the city of *Fuh-ning*. In the northern part of the entrance is a group of islets extending 2 miles from the coast.

Pih-seang Islands lie E. by N. $8\frac{1}{4}$ miles from the North point of Double Peak Island. The northern islet, named *Town Island*, is the largest, and the little cove at its S.W. angle will afford shelter to one or two small vessels. Between the northern and southern islets of the group there is a channel free from rocks, but the intervening space is thickly studded with fishing stakes. A reef extends half a mile in a north-easterly direction from the easternmost of the Pih-seang Islands, which lies S.E. 2 miles from Town Island. The sea breaks on the reef.

Fuh-yan Island, 1,700 ft. above the sea, lies North 12 miles from the Pih-seang group, and between it and the coast is a good roadstead, named *Lishan Bay*, where good water is plentiful and easily obtained. It is high water, full and change, at $10^h 15^m$; springs rise 16 ft.

Dangerous Rock, in lat. $26^\circ 53' N.$, long. $120^\circ 34' 18'' E.$, has its summit 8 ft. above high water, or 24 ft. above low water springs. It is 9 miles E.S.E. of Fuh-yan, and 14 miles N.E. of Town Island, Pih-seang group.

Tae Islands lie E. by N. 16 miles from the eastern point of Fuh-yan. The eastern one, 618 ft. above the sea, is the largest, and remarkable for its table top. Shelter in the N.E. monsoon can be had under this island as close as a vessel can safely go (say half a cable's length), but it is bad. S.S.W. $\frac{1}{4}$ W. 3 miles from the easternmost Tae Island are two rocky islets named *Strawstack*, about 100 ft. high; they almost join. Close to the N.E. point of the northern Tae Island is a remarkable rock, the *Mushroom*, 260 ft. high. A rock has been reported by the master of the steamer *Waratah* as lying about 4 miles westward of the Strawstack, and visible at low-water springs.

Between the Tae group and Fuh-yan are the *Incog Islands*, too small to afford shelter; they are low and flat, with steep cliffs. At 3 miles N.W. of these islands is *Solitary Rock*, with a reef extending 2 cables in an easterly direction from it; the soundings between this and the main, from which it is distant $3\frac{1}{2}$ miles, vary from 7 to $5\frac{1}{2}$ fathoms. A slight examination was made in 1866, of the Incog Islands and the channel between these and Solitary, by Commander Charles Bullock, R.N., H.M.S. *Serpent*. The channel was found clear, and the islands appeared to be steep-to all round the group.

Vessels passing inside the Tae Islands should keep well to the westward, as the ground in their vicinity has not been well explored. *Two reefs*, which show at low water, have been found; from one, with the rocks on it 8 ft. above high water, the Mushroom Rock bears E.S.E., and the West end of the eastern Incog Island S.W. by W. $\frac{1}{2}$ W., on which bearing it is in line with the East end of Fuh-yan; and from the other, the table top island of the Tae group bears E. by S. $\frac{1}{4}$ S. and the West rock of the group N.E. by E. $1\frac{1}{4}$ mile.

Seven Stars are a group of rocks and islets, $2\frac{1}{2}$ miles in extent, which may be passed on the outside safely at a mile. The southern islet, about 200 ft. high, which is the largest, and split into two, is 7 miles N.E. by E. $\frac{1}{4}$ E. from the eastern Tae Island, and S.S.E. from Cleft Rock. A rugged islet, 70 ft. high, lies a mile N.E. by E. of it; and a mile farther are three low flat rocks, the easternmost of which covers, and bears S.E. $\frac{1}{2}$ E. 3 miles from *Cleft Rock*; the latter, 50 ft. high, and having the appearance its name implies, is 8 miles N.E. by N. from the eastern Tae Island.

Pih-quan Harbour lies N.W. 14 miles from the Tae group. Its entrance is between Ping-fong and Chin-quan Islands and the main. To the northward there is a high and very remarkable, sharp, conical hill, *Pih-quan Peak*, in lat. $27^{\circ} 18' 48''$ N., long. $120^{\circ} 28' 42''$ E., having on its summit the appearance of a cairn. The harbour is $1\frac{1}{2}$ mile wide, carries a depth of 3 fathoms, and affords good shelter in the N.E. monsoon to vessels under 15 ft. draught. Care is required, however, in entering, as a sunken rock, reported in 1877, lies in mid-channel, from which the islet at the South end of Chin-quan Island bears W. by N., and Ping-fong Rock (West side of Ping-fong Island) N. by E. H.M.S. *Growler*, in October, 1874, obtained shelter with the West extreme of Ping-fong Island bearing S.E. $\frac{3}{4}$ S., and the S.E. extreme of Chin-quan Island bearing S.W. $\frac{1}{4}$ W., in 3 fathoms at low water, muddy bottom, and good holding ground. The tidal streams are very strong.

Ping-fong has three chimneys on its summit; off its S.E. point is a low rock, which is never covered, and between this rock and Ping-fong is a sunken rock. Vessels bound from the northward may round this low rock at a cable's length, and then haul up for the South point of Ping-fong, giving it and also the S.W. point a berth of 2 cables. The Pih Pass, between the North end of Ping-fong and the main, is fit only for such junks as use sculls. Fresh water can be procured in the sandy bay at the foot of the three chimneys on Ping-fong.

NAMQUAN BAY, lying westward of Chinquan Island, is shallow, but anchorage will be found on the western side of Chinquan Island. Namquan town is on the North shore of Nam-quan Bay. Immediately westward of Nam-quan Bay is the entrance to Nam-quan Harbour, an inlet which runs about 15 miles in a general N.W. direction, when it appears to expand into a wide basin called Gordon Bay.

Within the North point of entrance is a town, 2 cables off which is a sunken rock. Having arrived within the point anchor in 14 fathoms, as the mud banks rise almost vertically. On the South side of entrance is a small fort with a few houses. The narrowest part of the channel is 6 cables wide, and the strong tides and baffling winds make it necessary to have a boat ready to tow the vessel's head round.

H.M.S. *Nimrod*, when proceeding up Nam-quan Harbour, January, 1857, struck on a rock with only 9 ft. water on it, lying about 11 miles from the entrance, and $1\frac{3}{4}$ cable eastward of a small islet on the western shore.

The Coast from Nam-quan Harbour trends N.E. by N. 21 miles to Ping-yang Point, and at the distance of 12 miles is *Tanue Bay*, which is too shallow to afford shelter to any vessel drawing over 10 ft. water. A low rock, named *Gap Islet*, lies $1\frac{1}{2}$ mile southward of Tanue Point; and N.E. $\frac{3}{4}$ E. $4\frac{3}{4}$ miles from it is *Farmer Rock*, which shows at low water, and lies $3\frac{1}{4}$ miles off shore, with Ping-yang Point bearing N.N.W., and Tanue Point S.W. by W. $\frac{1}{2}$ W. $3\frac{1}{2}$ miles.

From Ping-yang Point the coast takes a north-westerly direction, and is fronted by mud banks taking a N.N.E. direction, which dry 3 miles from the land at low water, and on which are several small islets and rocks 5 or 6 miles from the shore. At the distance of 11 miles from the point is the embouchure of the *Shwin-gan River*, by which the commerce of Wan-chu fu is maintained.

The bar at the entrance of the Shwin-gan has only 9 ft. on it at low water, and off it are the four *Tsang Islets*, the southern of which is the largest.

NAMKI ISLANDS lie N.E. by N. 30 miles from the Tae group, and on the south-eastern side of the largest, 740 ft. above the sea, there is a good harbour, called Port Namki. Vessels should not pass among the islets forming the S.W. part of this group, as there are many reefs which cover at high water. The westernmost islet, *Turret*, makes like a cone, and has reefs to the North and West of it. The southern islet, *Castellated Rock*, lies S.S.W. 5 miles from the rest of the group. In the N.E. monsoon, and with S.E. winds, a swell rolls into Port Namki. There is a bay on the North side of the West point of Namki which the junks frequent, and which is a good smooth water anchorage. Good water can be obtained in Port Namki.

PIH-KI-SHAN ISLANDS.—N.N.E. miles from Namki is another group, the largest island of which is named Pih-ki-shan. The four islets close to its S.W. side protect the anchorage on its South side from the easterly swell. Vessels should not, however, choose this anchorage, unless from necessity. Fresh water may be obtained.

At 11 miles W. $\frac{1}{2}$ N. from Pih-ki-shan, with five small islets intervening, is another group of one island and four islets. The island, called *Tung-pwan*

or *Brass Basin*, has anchorage off its S.W. face in 8 fathoms in the N.E. monsoon, but the shelter is not so good as that on the South side of the Tae-pih Islands, lying 3 miles to the N.W. of it, under which the water will be smooth in 4 fathoms.*

In working up to the northward of the Tae-pih and Tung-pwan groups, shoal water will be found to extend 8 miles from the foot of the hills on the main; at which distance is the 2 fathoms' line of soundings. On the eastern edge of this line, at $6\frac{1}{2}$ miles northward of Tae-pih, is the Pang-peto Reef, visible at low water; from it the western of the Tae-pih Islands bears S.S.W. $\frac{1}{2}$ W., and the southern of the Tseigh Islands E. by S. $\frac{1}{2}$ S.

TONG WHANG GROUP.—The *Tseigh Islands*, three in number, 8 miles N.N.W. of Pih-ki-shan, lie on the South of a large and numerous group. Between the Tseigh and Pwan-peen Island, the next island northward, is a navigable channel for vessels, 3 cables wide. Tong-whang, the largest island of the group, is 6 miles long N.E. and S.W., $2\frac{1}{2}$ miles at its extreme breadth, and its eastern face is high and precipitous; there is a junk channel between it and Pwan-peen. *Coin Island*, the eastern of the Tong-whang group, has three rocks lying N.W. of it, and to the W.S.W. is a low flat islet, named *Flask*, with rocks off its southern end, and two rocky islets to the north-westward, between which there is a safe channel of 8 fathoms water.

The entrance to *Bullock Harbour* is between the Tseigh group and a high island with bold cliffs, named Fakew. It has excellent anchorage in 4 to 10 fathoms, sheltered from all winds.

Vessels have no business in the space between the Pih-ki-shan and the Tseigh Islands, as the clusters of rocks there are interspersed with reefs covered at half-tide.

The San-pwan pass between Tong-whang and Miaow to the westward of it is of great value to small vessels steaming up against the N.E. monsoon; but in September, 1866, the north-eastern end of the pass was so filled up with fishing stakes and nets, that there was great difficulty in finding a passage for a gunboat.

WAN-CHU RIVER.—N.W. by W. 8 miles from Niaow Island is Wan-chu Island, fronting the mouth of the Wan-chu River. A mud spit extends

* It is stated by Nav. Lieut. Barns, R.N., who was cruising in these parts in 1866, that several of the names on the chart have been wrongly inserted or misapplied. For instance, Tung-pawn is not known to the Chinese by that name, but one of the Tae-pih group is so called. The natives call the Pih-ki-shan Islands Pah-ki, and Bittern Island Pih-ki-shan. And in the River Min, Wou-fou Island is properly Lowgai, and Pinnacle Island the true Woufou.

6 miles south-eastward from this island, leaving only a shallow channel of 7 ft. water between it and Niaoow, close to the latter.

At the entrance of the river it is high water, full and change, at 9^h; at Wan-chu fu it is high water at 9^h 30^m; and the rise at each place is 15 to 16 feet. The velocity of the flood is from 3 to 4 knots at springs; that of the ebb 4 to 5 knots.

Bound to this river from the southward, when abreast Coin Island steer N.W. $\frac{1}{2}$ N., leaving the Cliff Rocks to the northward and the North rock of Great San-pwan (Chwang-pien) Island to the South. Having passed the latter, edge away West for the South point of Hutau Island, leaving a remarkably steep bluff island, called Hokeen, to the South. Off the South point of Hutau, and abreast Hokeen, is a *sunken rock* lying $1\frac{1}{2}$ cable off shore, but it will be avoided by opening the S.W. point of Hutau to the southward of White Rock in Hutau Bay. South of White Rock there is a middle ground confining the channel, which is North of it, to a width of 7 cables. There is good anchorage in 4 and 5 fathoms to the S.W. of White Rock, but the bay within the rock is shoal.

From half a mile off the S.W. point of Hutau the entrance of the river bears W.N.W. 5 miles, and it will be known by an isolated range of hills with a square fort at the East, and a small walled town at the West end. The depths will vary from 3 to 4 fathoms in the channel outside the entrance which is more than a mile wide, but upon either side the edges of the extensive mud banks shoal suddenly, and at low water large tracts of them are dry.

Having passed the range of hills keep the left bank or Notch shore of the river aboard, until the first hill on the flat island (Wan-chau Island) bears S.W. by S., when the vessel will have cleared a little ground at half a mile from the South shore, and $1\frac{1}{2}$ mile E.N.E. of this hill; the highest part of Hutau in line with the South foot of the hills at the entrance bearing E. $\frac{1}{4}$ S. is the mark for its northern edge.

From abreast this middle ground, in the vicinity of which and fronting a village the depth decreases to 11 feet, keep mid-channel, passing a large walled town on the North shore of the river in 4 to 5 fathoms, then gradually haul over to the first point on the South side, where the hills come down to the water's edge, passing a point with a circular fort and a building like a large jar upon it close-to. The leading mark across, in 5 fathoms, is Salamis Point, East of Jar Point, in line with a remarkable gap, S.W. by W. $\frac{1}{2}$ W.

Vessels ought not to go more than $2\frac{1}{2}$ miles above Jar Point; they will then find anchorage in from $3\frac{1}{2}$ to 7 fathoms water. At this position, with the West extreme of the largest island bearing about North, there is a sunken rock off the South bank. From this anchorage the distance to Wan-chu fu is $5\frac{1}{2}$ miles, but the channel is too intricate for a stranger. Provisions are

cheap and abundant, and the authorities and people well disposed toward foreigners. Wood is procurable at 25 cents per picul.

In 1869 the upper channel was partially re-examined and found to have considerably altered since the survey of 1843. The spit extending from the large island had greatly diminished, along which a narrow channel ran in a N.N.W. direction, with soundings varying from 3 to 5 fathoms, deepening towards the high land and a dark bluff, close to which was 7 fathoms. The depth over the flats on the South side is only 3 ft.

Southern Channel.—There is said to be a good channel into the river on the southern side of Wan-chu Island and Flats, carrying from 3 to 5 fathoms, between the S.W. point of Niaow (Miaow) and the rocks lying a mile westward of it. It has a bar of 9 ft. *Pilots* can be obtained at a village on the West side of Niaow.

Junk Island, lying on the North side of Hutau, is low and rocky, and the channel between them, and between Junk Island and the main, can only be used by small junks. North of Junk is *Lot-sin Bay*, in the southern parts of which there is good anchorage. At 2 miles eastward of Hutau is *Quang-ta Island*, under the West side of which H.M. brig *Plover* anchored.

Kemong Harbour.—Westward of the East point of Ta-on is a bight named Kemong Harbour, with an islet off each point, in which the junks are fond of taking shelter. It is, however, confined, and vessels will have better anchorage to the eastward under either Taluk or Seoluk Islands. A rock lies awash in the middle of the entrance to the harbour.

Seoluk, Taluk, Chin-ki, Towan, and Pe-shan Islands form a group off the coast from 3 to 14 miles eastward of Ta-ou. Taluk, the centre and highest of the group, 770 ft. above the sea, is 30 miles N.N.E. of Pih-ki-shan. At the anchorage between the islands of Chin-ki and Taluk it is high water, full and change, at 9^h 20^m.; springs rise 13 ft.

Taow-pung Island, at 9 miles N.N.E. of Pe-shan, is 7 miles long N.N.E. and S.S.W., and 1½ mile broad, and forms the East side of *Yeyvan Bay*, which is shoal and affords no shelter. The island is separated from the main by *Penetration Pass*, a narrow channel through which all the country trade passes.

At 2½ and 3 miles respectively to the S.W. of Song-men Point, the South end of Taow-pung, are two flat rocks above water, a mile apart. To the south-eastward of the point are three islets, and the nearest, named *San-shi*, has a reef off its West side; the outer islet of the three has a shoal off its North end. There is a navigable channel, a mile broad, between *San-shi* and the rocks off the point. At 3 miles north-eastward of *San-shi* are the *Stragglers* and *Shetung Islets*; the northern and highest islet of the latter group has a reef lying 3 cables from its S.W. point, and many rocky islets off its South end, between which and the *Stragglers* there is a channel carrying a depth of 6 fathoms. Indifferent shelter in the N.E. monsoon may be

found under Shetung. *Soudan*, the easternmost islet of the group, is flat-topped, and has a reef off its South side.

Chikhok Island lies North 6 miles from *Soudan*, and as it rises abruptly in a cone to the height of 760 ft. above the sea, and has a broad yellow stripe on its south-eastern side, it forms altogether one of the best landmarks in this locality; and S.W. by W. $\frac{1}{2}$ W. of it is the most conspicuous hill on the coast seen from the offing. N.N.W. $1\frac{1}{2}$ mile from Chikhok is *Low Chikhok Island* with a half tide rock lying N.W. 3 cables from it.

Tai-chau Group extends 9 miles northward of *Hea-chu*, the southernmost island, and consists of two large and ten smaller islands. Between the two large islands is an excellent harbour, the approaches to which, both from eastward and westward, are free from danger. The southern of these islands, 750 ft. high, is called *Hea-ta*, the northern *Shang-ta*, which is well inhabited. Between *Shang-ta* and the *Shang Rock*, $1\frac{3}{4}$ mile to the N.N.E., there is a safe passage.

About 2 miles southward of the West point of *Hea-ta* are two rocks, the western of which lies S.S.W. $3\frac{1}{4}$ miles from the highest part of *Hea-ta*, and shows at all times of tide; the other, which bears N.E. $\frac{1}{2}$ N., $4\frac{1}{2}$ cables from the western rock, and S. by W. $\frac{3}{4}$ W. from the highest part of *Hea-ta*, covers at high water.

Several watering places will be found on *Shang-ta*, but the supply from any one of them is not abundant. The best anchorage in the harbour between the two large islands of the *Tai-chau* group, during the N.E. monsoon, is to the S.E. of the islets, extending from the S.W. point of *Shang-ta*. It is high water, full and change, at this anchorage, at 9^h 0^m; springs rise 14 feet.

Squall Islands, two in number, the southernmost of another, the *Tungchuh Group*, lie 6 miles N.W. by W. of *Shang Rock*, the northern islet of the *Tai-chau* group, and so close as to appear as one, except on an E.N.E. and W.S.W. bearing. Rocks lie off the N.E. and N.W. points of the northern island, and a reef extends from the S.E. of the southern island. Junks take shelter under the western point of the southern island during N.E. winds.

Crate Island is a small cliff islet $2\frac{1}{2}$ miles eastward of the *Squall Islands*, and the channel between has 8 fathoms in it; but the western end of *Crate* is not steep-to. A group of rocks lie 3 miles W. by N. of *Squall*.

Chuh-seu Island, lying N. by W. $\frac{1}{2}$ W., $4\frac{1}{2}$ miles from the *Squall Islands*, is remarkable, having a sharp cone, 670 ft. above the sea, over its southern point, and a *beacon* on its western summit. Between *Chuh-seu* and the *Squall Islands* are four rocks; and S.E. by E. $\frac{1}{3}$ E. $2\frac{1}{4}$ miles from the highest part of *Chuh-seu* is a solitary rock named *Fir Cone*.

Good anchorage and a convenient watering place, with abundance of water, will be found under and to the S.W. of the cone of *Chuh-seu* in 6 fathoms, between it and an islet with a reef off its N.E. point.

TAI-CHAU BAY, to the N.W. by W. of the Tai-chau Islands, is wide and shallow, and at its head is the entrance to the Tai-chau River, 17 miles West of the cone of Chuh-seu. On the South bank of the river is the walled town of *Haimun*, 4 miles above which the river separates into two branches, one taking a N.W., the other a S.W. direction. The city of *Tai-chau fu* is on the North branch of the river, about 24 miles in a direct line from Haimun. There are only 8 ft. at low water across the bay to the entrance of the river, but inside the headlands at the entrance the depths are $4\frac{1}{2}$ and 5 fathoms. The inhabitants reported that vessels of 12 feet draught could not cross the bar, except at high water, and that the tide, which rises from 18 to 20 feet in this locality at springs, would carry them up to the city.

Tung-chuh Island, lying East, a little northerly, 5 miles from Chuh-seu, is 700 ft. high. The two *Reef Islands* lie S.S.W. $2\frac{1}{2}$ miles from its South point; a reef extends north-easterly from the southernmost of the two. Midway between Reef and Chuh-seu is a cluster of rocks. *Gau-tau Island*, remarkable for four barren peaks, lies 3 miles N.W. of Tung-chuh, and there is a half-tide rock 3 cables North of its N.E. extreme. Shelter may be had in the N.E. monsoon under the South side of Tung-chuh, but vessels had better gain the anchorage under Chuh-seu, or endeavour to reach Barren Bay.

Barren Bay, formed between Gau-tau and Kin-men Islands, is $2\frac{1}{2}$ miles wide at its north-eastern entrance, and besides the half-tide rock just noticed off the eastern promontory of Gau-tau, there are rocks off the eastern point of Kin-men, and a mud spit off the N.W. point of Gau-tau. Immediately to the S.W. of Kin-men, and separated by a deep-water channel rather more than a cable across, is *Nine Pin Island*, divided near the centre by a sandy isthmus, on which is the rock from which the island is named. Very poor shelter will be found between Gau-tau and Nine Pin. South, 2 cables from the West end of Nine Pin, is a rock which will be seen at half tide.

Fall Island, lying nearly 2 miles northward of Kin-men, has off its West end two rocks above and one below water. The channel is safe between these islands, and also between Fall and Chain Islands, but the latter are not steep-to.

Chain Islands, three in number, bear N.W. by W. $4\frac{1}{2}$ miles from Fall Island. South, 2 cables from the centre island, is a half-tide rock; and there is a rock awash and two small islets lying off the West end of the southern island. Between Chain and Pine Cone to the southward are four detached rocks where the ground has not been examined.

Vessels should keep eastward of the whole group just described, for the space inside Chuh-seu, Kin-men, Chain, and Sanmun Islands is shallow, and has in it several rocks covered at high water.

HEISHAN GROUP, consisting of three inhabited islands and eight rocks, lie N.E. by E. $\frac{1}{2}$ E. 17 miles from Tung-chuh, and occupy a space 5 miles North and South, and 2 miles East and West, but they are too small and

too detached to afford shelter. The southernmost island, 320 ft. above the sea, is the largest. The northernmost island is named *Mushroom*, and N.E. $\frac{2}{3}$ E. $1\frac{3}{4}$ miles from Mushroom is a *sunken rock*, of 8 ft. water, from which the Cheng Rock appears in one with the S.E. end of Cliff or Sha-ho Island, bearing S.S.W. $\frac{1}{3}$ W. A quarter of a mile N.N.W. from Mushroom is a *rock awash* at low water.

Montagu Island, or *Tanto-shan*, lies 19 miles N.N.W. $\frac{1}{2}$ W. of the Hie-shan group; the northern portion is called *Gore Island*. There is an islet off the S.E. point, and sunken rocks obstruct the channel to the westward.

To the southward of Montagu, and at 2 to 4 miles from the eastern coast of the large island of Nyew-tew, are six islets; the southernmost, called the *Twins*, are 8 miles from Montagu, and the others are $1\frac{1}{2}$ to 6 miles from it, with clear channels between them. Abreast *Dike Islet*, the middle and innermost islet of the five, is *Nose Islet*, nearly connected with Nyew-tew at low water, and vessels passing between them must recollect that neither are steep-to.

Heroine Rock, awash at low water, was reported in 1851, and has since been placed in several different positions on the chart. Commander Matthews, of the U.S. ship *Ashuelot*, in 1875, examined these different positions, and fixed the position of the rock:—South end of Sanchesan or Triple Island, W. $\frac{1}{3}$ S.; S.W. end of Lea Ming Island, N.W. by W. $\frac{3}{4}$ W.; and the West extreme of Montague Island N. $\frac{3}{4}$ E. This appears to be the only sunken danger in the locality.

SAN-MUN BAY entrance is 20 miles N.N.W. of the Heishan Islands, and it will be readily recognised by the remarkable *Thumb Peak*, 800 feet above the sea, called by the Chinese *Tafou*, and by the opium vessels *Albert Peak*; it rises from the northern end of Tafou Island, on the northern side of the bay.

Vessels wishing to stop a tide or driven in by bad weather, will find good shelter in the N.E. monsoon immediately westward of Lea-ming Island, which forms the North point of entrance of the bay. In running for this anchorage, give a berth of 2 cables to the S.W. point of the island, to avoid a reef lying off it. The soundings will shoal suddenly after the North peak of the island is brought southward of East; the bottom is soft mud. S.W. $\frac{2}{3}$ S. $2\frac{1}{2}$ miles from Lea-ming, is Sanchesan or Triple Island, and the depth between them is 10 and 11 fathoms.

At the anchorage under St. George Island, San-mun Bay, it is high water, full and change, at 10^h 20^m; and the springs rise about 15 ft.

SHEIPOO ROAD.—Vessels bound to the roadstead off the town of Sheipoo may pass close to the northward of the islets off Gore Island, the northern portion of Montagu Island, and steer to the westward for the two forts on the summit of Tungmun Island. On the North side of the road-

stead are the three *Bangao Islands*, and South 3 cables from the eastern point of the centre one, Wangchi, are the *Bangao Rocks*, which always show. There is deep water close to these rocks, except to the westward, where it shoals to $2\frac{1}{4}$ fathoms; to avoid which do not bring the higher fort to the southward of West.

Cliff Island, or *Seao-Seao*, lying nearly in the centre of the roadstead, has anchorage off its N.W. end in 4 fathoms, but with a strong wind a considerable swell rolls in. A reef of rocks extends westerly from Cliff, and the channel between it and the islands off the main has 3 fathoms water. South of Cliff is an islet with foul ground between, and S.S.E. 6 cables from its East point is a sunken rock. There is a narrow channel between this danger and the shoal ground extending from Montagu and Gore Islands, the extremity of which is marked by a flat rock with a sunken rock $2\frac{1}{2}$ cables N.W. of it. This latter is 5 cables E. by S. of Cliff.

Sheipoo Harbour is between the mainland and Nyew-tew Island, and at high water has the appearance of a splendid basin, but when the tide is out the mud dries off shore a long distance, giving it the appearance of a river. At its western end is an entrance into San-mun Bay, and on its South shore there is another leading into the bay West of Lea-ming Island, which is very narrow. The town of Sheipoo stands on the main forming the northern boundary of the harbour near the sea, and derives its importance principally as a convenient stopping place for the coasting trade; the walls are in a dilapidated state, and the houses and shops are not good.

There are three very narrow entrances, with rapid tides and chow-chow water in them, leading from Sheipoo Road into Sheipoo Harbour. Two of these entrances are formed by Tungmun Island. In the centre of the middle entrance between Tungmun and Sin Island, and just within it, is a rock, on which H.M.S. *Sphinx* struck in 1853. It lies in the narrowest part of the channel, and the least water on it was 10 ft., with irregular soundings around, the deepest water being towards Sin Island; it appeared very small, and is probably quite smooth. This passage is not recommended for large vessels, and, if used, they should keep well over on the South shore.

The northern entrance between Tungmun and the main, although tortuous and narrow, is safe; there is also less chow-chow water than in the middle entrance. The South entrance, between Sin and Nyew-tew, is long and narrow, and near its mouth is a small flat islet, with a reef extending eastward from it. Vessels pass north-eastward of this islet; but it is said the Chinese junk-men never use it, and they report rocks in mid-channel.

The Coast from Sheipoo trends northerly about 25 miles to the entrance of Nimrod Sound, and is fronted by several islets, none of which are large enough to afford shelter, and the depths about them generally are under 3 fathoms.

Half-tide Rock lies N.E. by N. 6 miles from the East point of Montagu,

with the Bear (an islet near the main with a sharp peak at its western end, but not always easily made out) bearing N.W. $\frac{1}{2}$ N., distant 11 miles. Should high tides and smooth water prevent this rock being seen, the East point of Montagu kept westward of S.W. will lead to the eastward.

KWESHAN ISLANDS are eleven in number, besides several rocks. The central and largest island is 3 miles long, and deeply indented, and its greatest breadth is $1\frac{1}{4}$ mile; in two places, however, it is not much more than a cable across. Near its western end the land rises to a sharp peak, 490 ft. high. The other islands are much smaller. The whole group is thickly populated. *Patahecock*, the south-easternmost island of the group, is 450 ft. above the sea, and remarkable on account of its flat and table-like appearance. The north-western island of the group is the second in size, and 400 ft. high. The peak of the largest island bears South of the N.W. island, and between the two is a mud-bank. By keeping the West extreme of the N.W. island to the eastward of N.N.E., not less than 3 fathoms will be found with good holding ground, and not much swell.

South $1\frac{1}{2}$ cable from the peak of Kweshan is another island, which is also high, with steep cliffs; off its western point is a *half-tide rock*, and a reef runs off from its South end. The *Holderness Rock* lies W. $\frac{1}{4}$ N. 1 mile from the highest part of this latter island, and having only 6 ft. water over it, occasionally breaks; from it the highest part of N.W. Island bears N.N.E. $\frac{1}{4}$ E. Another sunken rock, with only 4 ft. on it, lies S. by W. $\frac{3}{4}$ W., three-quarters of a mile from the summit of the same island.

It is high water, full and change, in the neighbourhood of the Kweshan Islands, at 9^h 30^m, springs rise about 14 ft. The change in the direction of the stream does not take place until 2 hours subsequent to the change of depth. The flood stream comes from the southward at the rate of about 2 knots per hour, and will sensibly assist a vessel in getting into the Chusan Archipelago. Between the Hieshan and the Kweshan Islands the flood against a strong northerly wind causes an angry sea. The ebb stream out of San-mun Bay will be useful in working to windward, provided the vessel heads up to the northward of N.N.W.

From the N.E. extreme of the Kweshan Group, the *Mouse Rocks*, nearly level with the water's edge at high water, bear N.N.W. 6 miles; the *Whelps*, 50 ft. high, a cluster of four small islets, W.N.W., nearly 10 miles; and a low flat reef, named *Starboard Jack*, about 15 ft. high, with two rocks off its eastern end, N.W. $\frac{1}{4}$ W. $9\frac{1}{2}$ miles. Mr. Joseph G. Dathan, Master, R.N., of H.M.S. *Encounter*, observed that the Mouse bore S. 75° E. of Starboard Jack, which would place the rock 6 cables farther to the South.

Pylades Rock.—Mr. Arthur Meldrum, Ningpo pilot, reports a sunken rock which he had many times seen, with about 6 ft. water, lying nearly 2 miles S.S.W. $\frac{1}{2}$ W. from the Whelps. When on the rock, Mesan Island shows between the two South Whelps, and the peak of Patahecock is on with the

N.E. point of the island which is nearest to the Holderness Rock. The rock is well known to the Ningpo pilots.

The Corkers are several isolated rocky patches, 3 miles in extent, and well above water, lying between the Whelps and *Buffaloes Nose*, an island 6 miles to the N.N.W. From the outer or eastern rock, which is occasionally covered, *Buffaloes Nose* bears N.N.W. $\frac{3}{4}$ W. ; there are two islets 1 cable to the westward of it, which will point out its position if the rock should be covered. The distance between the Corkers and Starboard Jack is about 3 miles, and the channel between has depths of 6 to 5 fathoms.

Buffalo Nose Channel.—*The Tinker* is a steep cliff rock, 80 ft. high, lying N. by E. $\frac{1}{2}$ E. $2\frac{3}{4}$ miles from Starboard Jack. The Buffalo Nose Channel, the entrance of which is between them, has 6 and 7 fathoms in it, and will be found the most eligible to take in entering the archipelago during the N.E. monsoon, as the vessel will be well to windward. There is a sunken rock off the Tinker S.E. by E. 2 cables from it.

Mesan, the largest of a group of four large and several smaller islets or rocks, lies at three-quarters of a mile N.N.E. of the Tinker ; it is about 400 ft. high, its barren summit forming one of the most remarkable features in the Buffalo Nose Channel. There are 7 and 8 fathoms water between it and the Tinker, but sunken rocks extend a short distance from both shores. *Lanyett* is the next island N.N.W. of Mesan.

At 3 miles E.N.E. of the Mesan Group is *Front Island*, the southernmost of a chain of islets extend N.N.E. $3\frac{1}{2}$ miles Beak Island. Between Front Island and a castellated rock 2 miles to the westward is the entrance to *Harbour Rouse*, which will be found a convenient stopping place in the northern monsoon for a vessel that has missed her tide through the Beak Head Channel ; the depth in the harbour varies from $5\frac{1}{2}$ to $2\frac{1}{2}$ fathoms.

Buffalo Nose Island, lying N.W. $\frac{1}{2}$ W. 16 miles from the N.E. extreme of the Kweshan Islands, and 6 miles from Starboard Jack, is $1\frac{1}{4}$ mile long North and South. There are three peaks on the island, the central one, 500 feet above the sea, being the highest. Near its northern end the island is perforated, from whence its native name (Niupi-shan) is supposed to be derived. The anchorage westward of Buffalo Nose is secure ; during the N.E. monsoon, however, the wind blows directly through, and occasional violent squalls are experienced. Fresh provisions and water may be obtained at this anchorage, but the supply of the latter cannot be depended upon.

Ploughman Group is composed of three islets, of which the largest lies W.N.W. nearly a mile from Buffalo Nose, the depth between them varying from 5 to 18 fathoms. Junks usually pass inside the Ploughman and Buffalo Nose, and to the westward of the Corkers ; there are, however, many reefs, and the tides are strong, and vessels will do better to keep eastward of Buffalo Nose.

NIMROD SOUND.—Six miles W.N.W. of Buffalo Nose is the entrance of

Nimrod Sound, a deep inlet of the coast running 27 miles inland in a W.S.W. direction. Within the South point of entrance are the *Hunters*, a group of six islands, and 3 miles N.W. by N. of these, on the opposite side of the channel, which carries 5 to 6 fathoms, is the *Castle Rock*, on the edge of the mud-flat, which extends $2\frac{1}{4}$ miles from the North shore, and which commences at Barren Island, $5\frac{1}{2}$ miles above.

Castle Rock may be passed at 4 cables; the other islands and banks of the sound are for the most part steep-to. Their position will be best understood by studying the chart. At its head the sound is separated into two branches by the Treble Islands. Pass northward of these islands, keeping in mid-channel to avoid the Half-tide Rock, 3 cables from the North shore.

In the shallow bight on the North shore, to the N.W. of the Treble Islands, is the village of Tung-ju, from whence there is a paved footpath communicating with the Fungwha branch of the Ningpo River, the distance from hence to Ningpo being 20 miles in a direct line. On the South side of the sound, at 3 miles S.W. of the Treble Islands, is also a paved footpath leading to San-mun Bay. Having passed the Treble Islands, good anchorage will be found in 6 or 7 fathoms, mud, off the village of Tung-ju.

Tides.—It is high water, full and change, in Nimrod Sound, at 10^h 30^m, springs rise about 20 ft.

CHUSAN ARCHIPELAGO, of which Chusan is the principal island, lies near the mainland between the parallels of 29° 39' and 30° 50' N. The archipelago may be entered from the southward by four channels named the Buffalo Nose, the Beak Head, the Vernon, and the Sarah Galley, of which the two former channels may be considered the best to enter by, and the Vernon to go to sea. Northward of Chusan, the second between Chin-san Island and the chain of islands extending westward from Video, is generally taken if bound to Ning-po and Chusan during the N.E. monsoon, being clear of danger with the exception of the Mariner Reef at its western entrance. The water of the archipelago is very muddy, and causes the boilers of steamers to prime.

Luhwang, the largest of the islands in the S.W. part of the archipelago, is $9\frac{1}{2}$ miles long N.W. and S.E. It is well cultivated, and maintains a large population.

The southern face of Luhwang has two small deep indentations with sandy bays, and a reef projects 3 cables from the point abreast the Mesan and Lanyett Group, described previously. Reefs also extend half a mile from the North extreme of the latter group, narrowing the channel between them and Luhwang to less than a mile. The coast line of Luhwang immediately westward of the reef point trends to the N.W., forming a wide bay with three islets in it, extending to Duffield Pass. South 1 mile from the easternmost islet is a mud bank, of $3\frac{1}{4}$ fathoms water, which extends to Mesan, to avoid which a vessel may keep the islet aboard; a rock lies half a cable from its

South extreme. *Duffield Reef* lies off the western extremity of Luhwang at the eastern side of the entrance to Duffield Pass, and consists of three rocks above water with a sunkén rock between them and Luhwang.

There is good holding ground in 9 to 5 fathoms on the S.W. side of Luhwang outside the line of these islets and Duffield Reef Point. Within this line the soundings are irregular from $2\frac{1}{2}$ to 4 fathoms.

Fu-to Island, to the westward of Luhwang, has a spit off its North extreme, and to the N.E. three islets, with a *rock* 1 cable to the N.W. of Chloe Island, the northernmost. *Tree-a-top Island* is $3\frac{1}{2}$ cables southward of the South extreme of Fu-to, with a deep water channel between. This island, 180 ft. high, and about 4 cables in circumference, has a pile of stones on its summit, but no tree.

Duffield Pass, the nearest but not the best channel in, is between Luhwang and Fu-to. On the Fu-to shore are several islets; among them the water shoals to $4\frac{1}{2}$ and 5 fathoms, and a vessel may anchor and stop a tide if necessary. Off the fourth point on the Luhwang side is a reef extending a cable from the shore; otherwise this side of Luhwang is very steep-to, the depth being 35 fathoms within a cable of the mud. Two small islets, named *The Notches*, lie in the centre of the pass, abreast this reef, and between them and Fu-to is a half-tide rock; unless this rock shows, vessels should not tack inside the Notches, so as to pass westward of them.

Young Hebe Rock, with only 16 ft. over it, lies 2 cables eastward of Hebe Island at the North end of the pass. On the Luhwang side, N.E. from Hebe Island, and a cable from the shore, is *Bird Rock*, which formerly had a stone pillar on it; there are two islets at 2 cables southward of it.

Gough Pass, formed between Fu-to and the Central Islands, is far preferable either to Duffield or Roberts Pass, for both shores are steep-to, and the lead, if hove quickly, will give warning of approach to the shoal extending half a mile S.S.W. from the southern islet of the Central Islands. The south-western of the Central Islands is a small islet connected at low water with the largest of the group by a reef and spit. At half a cable North of the northern island is a reef.

Roberts Pass, between the Central Islands and the mud which dries 1 mile from the embankment on Mei-shan Island, is 2 miles long, N.E. and S.W., and 4 cables wide; the depths in it vary from 6 to 40 fathoms, but as the lead gives no warning, its boundary on the Mei-shan side will not be known except at low water. On the N.E. side of Mei-shan are the two *Damson Islets*, from the northernmost of which, *Cliff Islet*, a bank of 3 fathoms extends nearly a mile to the N.E.

Junk Channel, between Mei-shan and the Ketau shore, is 10 miles in length and $2\frac{1}{4}$ cables wide, and carries a depth of 5 and 6 fathoms except at the South entrance, where it shoals to 10 ft. Anchorage will be found any-

where along the Ketau shore, between Mei-shan and Ketau Point, until abreast of Sing-lo-san Island, where the water deepens.

Caution.—As there is no anchorage besides the above, but in very deep water, until that under Elephant Island is reached, it would not be prudent for sailing vessels to proceed farther unless the wind and tide will ensure their gaining that position.

Tides.—In the above passes the first of the flood often comes from the northward, and runs sometimes for three hours before it takes the direction of the ocean tide.

BEAK HEAD CHANNEL (*Taou-sau-mun* of the Chinese), the next passage N.E. of Buffalo Nose Channel, is considered one of the best by which to enter the archipelago from the southward. Its eastern entrance is $2\frac{3}{4}$ miles wide, between Beak Head, the East extreme of Beak Island, and Vernon Point, the East end of Vernon Island. Beak Island is nearly 5 miles long, in some parts very narrow, and remarkable for two hummocks near its West end. Off Beak Head are three islets; and south-westward of the head are several islets and a rock, between which and Luhwang Island is Harbour Rose (page 1076), which will be found a convenient stopping place for a vessel that has missed her tide through Beak Head Channel. The channel between Luhwang and Beak Island has $3\frac{1}{2}$ fathoms least water; but there would be no object in using it while there are passages so superior.

Off the N.E. face of Beak Island are two reefs, lying respectively 3 cables and half a cable from the shore. Off the North face are Gull, Shag, and Puffin Islands; a reef also extends 3 cables from the N.W. end of Puffin. Near the West end of Beak Island the channel is narrowed to half a mile by the reef of rocks, extending from between Gull and Shag halfway across the channel, the northernmost of which is always above water, and also by two small islets lying off the South side of *Conical Hill Island*, which lies between Shag and Vernon. Between Conical Hill Island and Vernon are two islets, the reefs off which render the channel between these islands intricate.

A N.W. by W. $\frac{1}{4}$ W. course for $8\frac{1}{2}$ miles from the eastern entrance of Beak Head Channel will lead southward of Conical Hill and Conway Islands, and from thence a N.W. course will clear the channel; take care, however, in light winds, to give the *Pai Rock*, the last islet on the North side of the channel at its western entrance, a wide berth, as the flood sets directly towards it. There is good anchorage in 9 and 10 fathoms on the N.W. side of Conway.

To the northward of Conway Island is a group of islets and rocks, through which there is a passage into the Vernon Channel; but owing to the rapidity of the tides, it should not be attempted without local experience. On the Luhwang side of Beak Head Channel is a reef, and an islet with a small pinnacle on it; the reef, which is generally uncovered, bears S.E. $\frac{3}{4}$ S. 2 miles from Cape Luhwang, and by keeping the cape westward of N.W. $\frac{1}{2}$ N.

it will be avoided. The mud dries 7 cables from the Luhwang shore, in the bight to the southward of this reef, which makes landing difficult except at high water.

VERNON CHANNEL (*Hea-che-mun* of the Chinese), the next channel northward of Beak Head, is formed by Vernon Island on the South and Taou-hwa Island on the North. This will be found a convenient passage from Chusan during the northern monsoon, the distance from Elephant Island, off Tinghae Harbour, to the open sea being only 17 miles; it should not, however, be attempted by sailing vessels with light winds, as they are liable to be becalmed, and experience flaws under the high land of Taou-hwa, and in some parts the soundings are 60 fathoms, and the tides strong.

The Vernon Channel at its eastern entrance is $1\frac{1}{2}$ mile wide, but 5 miles within it is divided into two passages by John Peak Island, which has a rock, lying half a cable from its N.E. extreme, which uncovers at the last quarter ebb. The passage between John Peak and Taou-hwa is only $3\frac{1}{2}$ cables wide between this rock and two small islets and some rocks which bound its North side. The passage between John Peak and Vernon is half a mile wide, and good anchorage will be found on the South side of John Peak. Caution is necessary to avoid the fishing stakes West of John Peak Island. The shore of *Taou-hwa* is bold and precipitous, and the peak of the island, elevated 1,680 ft. above the sea, is visible at times when the lower land is obscured by mist. Near its western end the land becomes low, rising, however, again, and surmounted by a peculiar perpendicular crag, called *Miller's Thumb*, 606 ft. high, which will be recognised nearly throughout this part of the archipelago.

Vernon Island has on its N.E. side a wide bay, with two islets and a reef in it, where vessels may anchor in 4 and 5 fathoms, and procure water from the several cascades on Taou-hwa Island; the water may be obtained without removing the casks from the boats. The East end of Vernon is rugged, with large boulders of granite; at this end there is a cove, which runs back three-quarters of a mile to the westward, and affords shelter for boats.

SARAH GALLEY CHANNEL is the next passage northward of the Vernon, but it is by no means so eligible as those just described. Near the entrance, at 4 miles N.E. by E. $\frac{3}{4}$ E. from the South point of Taou-hwa Island, is the *Jansen* or *Laoush Rock*, a steep cliff islet, with rocks extending $1\frac{1}{2}$ cable from its South end; there is also a half-tide rock lying W. by N. $\frac{3}{4}$ N., $1\frac{1}{4}$ mile from the North extreme of Laoush, with the highest part of Ousha Island bearing N.N.E. $\frac{1}{4}$ E. $1\frac{3}{4}$ mile.

The coast line of Ousha is steep cliffs, and off its N.W. end is a ledge of rocks; the southern end of the island is the highest, and rises in a round peak. The channel between the N.E. point of Taou-hwa and Peak Island is not navigable, owing to reefs and strong tides; neither is there a fit passage between Peak Island and Tang-fau. Vessels may pass between Peak Island

and the two patches of rock lying westward of Ousha; but there are some rocks off the North end of Peak which must be avoided.

The *Cambrian Pass*, between Ousha and the large island of Chukeya, or Chus Peak, is 2 cables wide, but it should not be used without a commanding breeze, on account of the strong tides.

Vessels entering the Sarah Galley Channel from the southward generally pass westward of Laoush Rock and Ousha Island, and from thence the channel is between Ousha and the two patches of rock to the westward, which are almost covered at high water; they lie N.N.E. and S.S.W. of one another, 2 cables apart, and half a mile distant from Ousha. After passing these rocks the course is N. $\frac{1}{2}$ E. $2\frac{1}{4}$ miles, leaving Teen and Yung Islets, off Tangfow, and a reef between them, to the westward; and Hut Islet, off Chukeya (so called from a house on its summit), with a reef of rocks off its South extreme, to the eastward. The channel here is three-quarters of a mile wide.

From thence steer N.W. by N. for $1\frac{3}{4}$ mile, leaving an island with two hummocks to the southward, and Druid Island to the northward; but be careful, after passing Hut Island, that Flat or Liwan Island (the southern small island at the inner entrance to the channel) is not brought westward of W. by N. $\frac{1}{3}$ N., as the water shoals suddenly on the North side, and the mud dries nearly all the way across from Druid Island to South Chukeya Island, leaving only a small boat channel.

When in the vicinity of Liwan the East end of Chusan will be seen, having on it a small temple built of large stone slabs. Between Liwan and Chusan is Lokea Island, the southern shore of which is not steep-to; and this is the case with the whole of the islets on the South side of Chusan between this and Pih-lou, after which they become steep-to. After passing the smaller islets South of Ta-kan, the shoal water will be avoided, when standing northward, by not bringing the rocks off the southern part of Pih-lou southward of West, or on with Trunk Point on Elephant Island. Liwan as two rocks off its South end. There is anchorage in 5 fathoms at 8 cables W. $\frac{1}{2}$ S. from it.

Chukeya Island is about 7 miles long, North and South, and near its centre is a smooth-topped cone, 1,164 ft. high, named Chukeya Peak, which is one of the most prominent objects seen in making this part of the archipelago. The South end of Chukeya is a ridge as high as the peak.

There are also several indentations on the eastern side of Chukeya, and the southern one, *Wolf Bay*, affords anchorage at times in the N.E. monsoon. On the North side of the bay is a black islet, and $1\frac{1}{2}$ mile from the shore is a peaked rock, off which, at 2 cables to the N.E., are two reefs, showing at half tide. Off Pelican Point, the North point of the small islet North of Wolf Bay, is a reef visible at low water; and E.N.E. 3 cables from the point is Nob Rock, always above water.

To the eastward of Chukea, at the distance of 5 and 8 miles, are two islets named *Pihiting* and *Tongting*. *Tongting*, the outer one, about 40 ft. high, has detached reefs S.W. of it. *Pihiting* is a similar islet. *Pelican Rock* lies E. by S. $\frac{1}{4}$ S. $2\frac{1}{4}$ miles from Pelican Point on the Chukea shore, and only shows at low-water springs.

North, $6\frac{1}{2}$ miles from *Pihiting*, is *East Islet*, 30 ft. high, and from it *Loka*, the northernmost of the islands on the N.E. face of Chukea, bears W. by S. 4 miles. *East Rock*, nearly awash at low water, lies E. by S. 2 miles from East Islet, with *Tongting Islet* bearing S. by E. $\frac{1}{4}$ E. 7 miles, and the summit of Poo-too (which will be known by a look-out house on it, and the high land of Chusan forming a table top at the back of it) W. by N. $\frac{1}{4}$ N. N.W. by N. 6 miles from East Islet is *N.E. Islet*, a conical rock, in form something like a haycock; it also lies N.E. $\frac{1}{4}$ E. 2 miles from the N.E. end of Isthmus. The *Ninepins* are four pinnacle rocks with reefs around them lying 1 to $1\frac{1}{2}$ miles East-south-eastward of N.E. Islet, and N.E. by E. $\frac{1}{2}$ E. 5 miles from the summit of Poo-too.

Isthmus Island, the outer north-eastern island of the Chusan archipelago, is three-quarters of a mile from the N.E. point of Poo-too, and the channel between has deep water. A half-tide rock lies E. by N. $\frac{1}{2}$ N. 4 cables from the S.E. point of Isthmus, with the East and S.E. extremes of Poo-too in one bearing S.W. $\frac{2}{3}$ S., and the South summith of Isthmus W. $\frac{1}{2}$ N.

Poo-too Island lies $1\frac{1}{2}$ mile from the East extreme of Chusan, and the channel between is called by the Chinese *Leenhwa-yang*, or the Sea of Water-lilies. The island is $3\frac{1}{2}$ miles long, North and South, and in one place only half a mile across. The temples on it are numerous, but the two largest, on its eastern side, are falling into decay. A narrow projecting point extends from the eastern side of the island, forming to the southward a deep sandy bay, in which there are 3 fathoms water; the islet off the point has a sunken rock off its East side, and at a little more than a mile E. by S. from the S.E. extreme of the point is a pinnacle rock, with 6 feet water over it, discovered by the S.S. *Hochung* in 1877. The western face of Poo-too is shoal, the $2\frac{1}{2}$ -fathom line of soundings being 3 cables from the shore. An islet lies off the North end of Poo-too, and some rocks half a mile farther northward; vessels may pass between the rocks and the islet. A stream runs into the above bay, on the eastern side of Poo-too. There is anchorage off the eastern side of Poo-too in 12 and 14 fathoms water, but several vessels have had a difficulty in purchasing their anchors; it is also much exposed, and by no means desirable in bad weather.

To the eastward of the South point of Poo-too, and off the N.E. end of Chukea, are four islands named *Loka*, *Pih-sha*, *Lakeah*, and *Lakeati*. There is a passage between them and Chukea, and a good channel between them and Poo-too.

Channel East of Chusan.—Whang Head, the East point of Chusan, opposite Poo-too, is a low peninsula. Thence the coast trends 4 miles to another head which forms the S.E. point of Chusan. Shoal water extends a mile from this shore.

The N.W. and West faces of Poo-too Island are shoal-to, leaving, however, a channel between them and Whang Head nearly a mile wide. The northern part of this channel has only 4 fathoms in it, and in working through, when southward of Whang Head, do not bring the ship's head eastward of North, as the Chusan shore is shoal.

The channel off the S.E. end of Chusan is 2 cables wide, and in the centre is a reef with a stone pillar on it. The flat extending towards Poo-too has only $1\frac{1}{2}$ fathom on it at low water, and some hard casts; therefore vessels drawing over 12 ft. should not attempt this passage, but use the Sarah Galley Channel. In working through it from the southward between Lokea and Kin-ho Island, bear in mind that the shoal water extends $3\frac{1}{2}$ cables from the former, and 6 cables from the latter; the above pillar or beacon in one with a cliff islet northward of it, is a good mid-channel mark. After passing westward of the beacon, bring the cliff islet in line with a building on Whang Head; this will lead over the flat in the deepest water, and when the South end of Poo-too bears East it may be steered for.

CHINKEAMUN HARBOUR, at the S.E. end of Chusan, carries on a considerable fishery to the eastward of Poo-too Island. The harbour, formed between the island of Lokea and the Chusan shore, is $1\frac{1}{2}$ cable wide. The S.W. entrance to the harbour, between Lokea and Maoutze Island, has not more than $2\frac{1}{4}$ fathoms in it at low water; the mud extends westward $4\frac{1}{2}$ cables from Lokea, and a rock lies S.S.E. a cable from the East end of Maoutze.

Chinkeamun is 11 miles eastward of Ting-hai Harbour. The *Shei-luh Channel*, close along the southern shore of Chusan has deep water in it, but in some places it is so narrow as to be practicable only for small steam vessels or boats.

CHUSAN ISLAND, so called from its supposed resemblance to a boat, is 51 miles in circumference; its extreme length in a N.W. and S.E. direction being 21 miles, and its greatest breadth $10\frac{1}{2}$ miles. The island is beautifully diversified with hill and dale and well cultivated. Besides the principal harbour of Ting-hai there are three other commercial ports, viz., Chinkeamun at the S.E. end of the island, Ching Keang or Singkong on the N.W. side, and Shaaou at the North end.

Tinghae is situated on the western part of the South coast of the island. The town is $1\frac{3}{4}$ mile in circumference, and surrounded by a wall $14\frac{3}{4}$ feet high and 13 ft. wide, surmounted by a parapet $14\frac{1}{2}$ ft. high and 2 ft. wide. A canal nearly encircles the city. The principal exports are fish, coarse

black tea, cotton, vegetable tallow, sweet potatoes, and some wheat. The water is not good at Ting-hai, and is sometimes scarce.

Ting-hai Harbour, formed on the South side of Chusan, is fronted by many small islands, between which are the several channels leading to it. The outer and westernmost island is *To-maou* or *Tower-hill*, East of which and distant 1 and $4\frac{1}{2}$ miles respectively are the large island *Teijo* or *Elephant Island* and *Pih-lou*. Within, or to the northward of these, reckoning from the westward, are the islands called *Ha-tse* or *Bell*, *Pwanche* or *Tea*, *Seaou-keu* or *Deer*, and *Ao-shan*. The two small islands *Tawoo* or *Trumball*, and *Wae-woo* or *Macclesfield*, lie inshore or to the N. E. of Tea Island, fronting the city, and there are many small islands and rocks among those larger ones above named.

The harbour is difficult of access in all its approaches, owing to the strong tides and sunken rocks. The best approach is through Tower Hill and Bell channels, the latter being between Tower Hill and Bell Islands, and between Bell Island and Tea Island; in these no hidden danger has been found; but the tides are strong, and sailing vessels in light winds must be careful that they are not set by their influence between Tower and Elephant, or between Tea and Elephant Islands, where the ground is foul and the channels narrow and deep.

Tower Hill Channel—The best approach to Ting-hai Harbour is through Tower Hill Channel. After passing Ketau Point steer to pass a convenient distance from the South extreme of Tower Hill Island. Should the tide fail, anchorage will be found under the islands eastward of Tygosan Island; for which purpose pass 3 cables southward of Square Stone Islet, to avoid the reef lying $1\frac{1}{2}$ cable S.W. of it, and anchor before the channel between Little Tygosan and Chuen-pi Islands opens, as the water shoals suddenly off the East end of Entrance Island.

Having rounded Tower Hill Island, haul up, steering first for Bell Island, then for Tea Island. The soundings in Bell Channel, between Bell and Tower Hill Islands, vary from 30 to 40 fathoms; but off the N.W. end of the latter is a mud bank of 3 fathoms water extending $1\frac{1}{2}$ cable off shore.

There is good anchorage in 10 and 12 fathoms between Bell and Tea Islands, nearer the latter, but vessels intending to remain here should not open the channel between Bell and Chusan, as the tides are stronger and the ground loose. On proceeding from hence to Ting-hai Harbour, take care to avoid *The Nab*, a sunken rock with 14 ft. over it at low water, lying $2\frac{1}{4}$ cables from the Chusan shore, and South of a small hillock in the valley near the shore. The marks for it are Taching Point, the West extreme of Tea Island, in one with the East side of Taewang or Bell Rock, S. $\frac{1}{4}$ W., and the South point of Guardhouse Isle nearly in line with the summit of Tawoo or Trumball Island. A 3-fathom patch lies about $3\frac{1}{2}$ cables W.S.W. of the Nab, and E. by N. $\frac{1}{2}$ N. nearly 4 cables from Ap-tan-shan Island.

The Spithead anchorage on the Chusan shore, between the Nab Røck and Guardhouse Isle, will be found a convenient place for watering; the anchoring ground is steep-to, and the tides are irregular, and off the entrance to the watering creek is a mud flat of 3 fathoms water. With light winds, vessels should avoid the strength of the ebb when passing through the channel between Tea and Guardhouse Islands, for it is liable to set them through the Melville Channel. A ledge of rocks, covered at high water, extends 1 cable from the high-water mark at Kouching Point, the North extreme of Tea Island.

Proceeding towards Ting-hai Harbour, and being abreast of Guardhouse Isle, steer towards Wae-woo or Macclesfield Island, taking care to avoid the Middle Ground, which has only 2 ft. on its shoalest part. Tower Hill in line with the slope on the southern rise of Tea Island will lead along the southern edge of this shoal, in 4 fathoms. The Wae-woo Channel is only $2\frac{3}{4}$ cables wide between the 3 fathoms line on the edge of the Middle Ground and Wae-woo and Tawoo Islands. The usual anchorage is abreast Taotau, the suburb of Ting-hai, but vessels must moor, as the eddies are strong. The channel between Chusan and Guardhouse Isle is only fit for boats.

Caution.—Spring tides set at the rate of 3 and $3\frac{1}{2}$ knots per hour in the Tower Hill Channel, and with light winds and a strong flood vessels have been swept away to the westward, and carried by the tide beyond Just-in-the-Way, and even through the Blackwall Channel; and after rounding Tower Hill and entering the Bell Channel many have been borne by the ebb amongst the islands between Tower Hill and Elephant Island, or between the latter and Tea Island, where the channels are narrow, the water deep, and the ground foul. In these cases the bower anchors and chains should not be used, but a good kedg and stout hawser, which (as the holding ground is good, and if care be taken to conn the vessel and not break her sheer) will bring a vessel up and prevent her being driven into these narrow passages, where some have been brought up in from 30 to 40 fathoms water, with two anchors down and three or four round turns in the hawse.

Having rounded the North end of Tea Island with a strong ebb, it is necessary to guard against its taking the vessel through the Melville Channel, and if not able to pass northward of Macclesfield Island, send the boats a-head and endeavour to keep the vessel to the northward of Takeu and Sarah Islands, where the water is not so deep.

The Melville or southern passage to Ting-hai Harbour is between Elephant and Deer Islands, but as two sunken rocks lie in the centre of the channel and narrow it to $1\frac{1}{4}$ cable, it should not be attempted unless there be a commanding breeze, and the mariner have a thorough knowledge of their position. Its navigation is rendered more difficult in the neighbourhood of these dangers by the tides rushing through four different channels into this, and

forming eddies which render a vessel unmanageable even with a good breeze at the springs. A boat a-head will be found useful at the neaps.

KIDDISOL ISLAND, lies 2 cables southward of Yanglo Point, the S.W. extreme of Chusan. There is a patch of $2\frac{1}{2}$ fathoms off its S.W. end. From hence to Sinkong Point, 4 miles to the N.W. by N., the coast line of Chusan is mud, with the exception of a small hillock at the edge of low water. Anchorage in 10 and 12 fathoms will be found all along the Chusan shore between Yanglo and Sinkong Points, but in standing towards the shore be careful, as the water shoals suddenly after 10 fathoms.

Ching Keang Harbour, on the western side of Chusan, and distant 7 miles in a direct line across country from Ting-hai, is formed between the islands *Wa-teo*, *Lin*, and *Latea* (otherwise called *Outer*, *Middle*, and *Inner Hook*) and Chusan. Upon the islands, and on the point near the southern entrance, are extensive stone quarries. There is a white rock off the S.W. point of *Wa-teo*, and a mud bank extends from the island nearly to the rock and also bounds its West side. Between *Wa-teo* and Chusan the entrance to the channel is 6 cables wide, with 7 and 8 fathoms water in it, forming a snug anchorage much frequented by the junks as a stopping place, and defended from pirates by a fort. Abreast of *Lin*, the small island next North of *Wa-teo*, the channel is less than a cable wide, with 7 fathoms water. The town stands on the Chusan shore, on the banks of a stream, which at high tide is navigable for boats. Here the channel is also less than a cable wide, and the depths 5 to 4 fathoms.

Kintang or Silver Island is between the West end of Chusan and the entrance of the Yung or Ning-po River. Near its S.E. extreme is a remarkable saddle hill, 1,432 ft. high, which with the Cap Rock forms one of the marks for the Melville Rock. Another remarkable peak, 1,520 ft. high, is $1\frac{1}{4}$ mile northward of the saddle hill. *Alligator Point*, the South end of Kintang, has a reef, which covers at half tide, extending 2 cables to the southward. There is a *beacon*, painted white, on the extremity of the reef. *Algerine Point*, the S.E. extreme of the island, has an islet connected at low tide by a mud flat, from which a ledge of rocks extends S.S.E. 2 cables, the South end of which covers at high water. The eastern face of Kintang is bold-to, without any anchorage along it. The western side affords good temporary anchorage, but it is advisable to take up a position within half a mile of the shore to be out of the strength of the tide.

Off the North end of Kintang there is a group of seven islets, amongst which there is anchorage; off its N.W. end is Taping Island, separated by a narrow channel of 4 to 6 fathoms. Southward of Taping is the small harbour of *Ta-outse* or *Lukon*, a former station for opium vessels, which affords good anchorage in 7 to 10 fathoms, sheltered by the small island of *Ta-outse*. The entrance is between Kintang and *Ta-outse* Island, and the channel is barely 2 cables wide. Between *Ta-outse* and Taping there are

not more than 8 ft. at low water. This harbour is small, but affords good anchorage, and may be recommended as a sanitary station for vessels obliged to make a lengthened stay in the River Yung. Supplies of all kinds can be readily obtained by native boats from Ning-po. Kintang is well cultivated and produces abundant supplies, but they all appear to be sent to Ning-po.

Steward Rock, 5 ft. high, lies in the middle of Blackwall Channel, between Chusan and Kintang Island. The depths in its vicinity are 25 to 45 fathoms, except on a rocky patch 2 cables to the eastward, where the least water that has been found is 6 fathoms.

Blackwall Channel, between Kintang and Chusan, is divided at its northern entrance by Blackwall Island into two passages, both of which are very difficult, owing to the rapid tides.

There is anchorage off the N.W. face of Blackwall Island, from which extends, $1\frac{1}{2}$ mile, a tongue-shaped shoal of 3 to 5 fathoms, exposed to northerly winds. A reef extends westward $1\frac{1}{2}$ cable from the West end of Blackwall, to avoid which do not open Steward Rock eastward of Rondo Islet.

Broken Island is connected at low water to the N.W. extreme of Chusan by a mud bank. *Crack Islet* lies about half a mile from its North point. A mud spit runs of north-westerly 4 cables from Crack Islet.

Dunsterville Group, N.W. $3\frac{1}{2}$ miles from Broken Island, is a batch of low islets which may be approached as convenient, the soundings between them and Crack Islet varying from 5 to 4 fathoms. The tides are strong in this neighbourhood, the flood running to the West, the ebb to the East.

SHAAON HARBOUR, or North Bay, formed between Chang-pih or Fisher Island, and the North end of Chusan, is 2 miles long, $1\frac{3}{4}$ mile wide, and has a varying depth from 5 to 9 fathoms. Broken Island, as before stated, is steep-to on its N.E. side; from the western part of Chang-pih shoal water extends half a mile. The southern shore of Chang-pih is an extensive mud bank, a considerable portion of which has been enclosed from the sea by embankment; off its S.E. end the water is shoal, the 3-fathom line being half a mile from the shore.

The Chusan shore is bordered by a mud bank, which renders landing, unless at high water, difficult, except in one place near the eastern end of the harbour, where there is a causeway. Near the causeway are some houses, but the principal village is some distance up the valley. A small islet lies off the North end of Chang-pih, and a group of islets, named Cluster or Midway Islands, off the N.E. end.

Vessels bound to the eastward from Shaaon Harbour may pass either through the Kwei Channel, between Lan-sew or Sheppey Island and Chusan, or to the northward of Lan-sew, which is the better channel of the two, but both are difficult for a stranger. A sunken rock lies 3 cables from the S.E. point of Chang-pih, with the South extreme of Chang-pih bearing W.

$\frac{1}{2}$ N., the largest of the Cluster Islets, N.E. of Chang-pih, N. $\frac{1}{2}$ W., and the summit of Lan-sew open of the rocks off Ma-aou Point E. by N. $\frac{1}{4}$ N.

The Kwei Channel, never to be attempted during the strength of the tide, is between the large island of Lan-sew, 4 miles East of Chang-pih and the Chusan shore, and, although $1\frac{1}{2}$ mile broad, the navigable passage is greatly contracted by the numerous rocks and islets on either side. At its western end it is only three-quarters of a mile between the two rocks off Ma-aou Point and the Houblan Islets extending from the West side of Lan-sew. In the centre, the Lan-sew shore is bold, but two chains of islets from Chusan stretch half way across. The eastern end is narrowed to 2 cables between Kanlan Point on the Chusan shore and the small islet with a reef of its S.E. end, lying South of Sewshan or Grain Islet off Lan-sew.

There is the Kwimun Channel, close in to the Chusan shore, but it is crooked, and a sunken rock lies near the centre.

The island of Lan-sew appears formerly to have been two, the intervening space having been gained from the sea by embanking; it is now called by the Chinese Lan-shan and Saw-shan, and is $3\frac{1}{2}$ miles long and $2\frac{1}{2}$ miles broad.

Channel North of Lan-sew.—When leaving the anchorage in Shaaon Harbour by the Chang-pih Channel, and intending to pass North of Lan-sew, steer about N.E. by E. for Kwi-si, a barren island with a round peak upon it. The southern side of this island is steep-to, and the distance between it and the N.W. point of Lan-sew is $1\frac{1}{2}$ mile; a mud bank dries $1\frac{1}{2}$ mile from the western side of the latter, and is steep-to, the lead giving no warning, but its northern edge will be avoided by keeping the North end of Mo-un (the largest islet off the North end of Lan-sew) open of the North extreme of Lan-sew.

Having passed Kwi-si steer for the next island, Kwan, the South shore of which keep close aboard, to avoid a reef which lies half a mile to the southward and covers at high water; from the reef Kwi-si Hill bears W. by N., and the highest part of Lan-sew S.S.W. $\frac{1}{2}$ W.; the ground between this reef and Lan-sew is foul. Although the channel is half a mile wide, it is difficult to shoot through, owing to the eddy tides and flaws off Kwan, which is 600 ft. in height. When the reef is passed, take care to avoid a ledge of rocks extending a short distance from the N.W. point of Mo-un, which bounds the channel to the southward.

To the eastward of Kwan are nine islands lying off the S.E. end of Tae-shan to the northward; there is a reef off the southern end of the nearest. From thence an East course may be steered to sea along the southern coast of Keu-shan Island and the Fisherman's group. The channels North of Kwi-si and Kwan are described hereafter.

Anchorage.—Vessels wishing to anchor on the East side of Lan-sew Island may haul to the southward after passing the first islet East of Mo-un,

running between it and Gan-ching, a cluster of rocks to the eastward. At the East end of Lan-sew is a low cliff, named Hartey Island, which may be passed at a cable, when hauling to the southward, anchorage will be found in 5 fathoms, the water shoaling gradually towards the shore. H.M.S. *Pylades*, in 1840, anchored here in $5\frac{1}{2}$ fathoms, with the East end of Hartey Island N. $\frac{3}{4}$ W. 6 cables, and Grain Islet S.W. by W. In the northerly monsoon there is a better anchorage at 7 miles to the N.E. in Peaked Rock Bay on the southern shore of Keu-chan.

Cliffs and Doub Rocks, to the eastward of Lan-sew, at the distance of 2 miles and 5 miles respectively, are two clifly islets. South 2 cables from Cliffs, the western islet, is a ledge of rocks nearly awash at high water, and the ground in its neighbourhood is foul; there are rocks, also, which show at low water, lying $1\frac{1}{2}$ cables from the N.E. point of the same islet.

The N.E. Coast of Chusan, East of Lan-sew, trends S.E. 11 miles to Whang Head, a low peninsula forming the East end of Chusan. At the distance of 3 miles is *Thornton Island*, with a narrow passage between it and Chusan, and a deeply indented bay westward of it, in which the mud dries out a long way, rendering it difficult to land except at the extreme points; an islet and rocks lie off the N.E. face of Thornton. At $2\frac{3}{4}$ miles farther to the S.E. is *Tsae*, a larger island with a remarkable fall in the hills near its centre. The Chusan shore hereabouts is shoal-to.

To the eastward of the North part of Tsae are three islands at the distance of half, $1\frac{1}{2}$ and $3\frac{1}{2}$ miles. The nearest, named *Meih-yun*, the largest of the three, has a patch of rocks lying N.N.W. 4 cables from its North point. *Meih-ting*, the central islet, has a pinnacle rock lying E. by N. half a mile from it, and a rocky patch at 2 cables westward of its North extreme. The outer islet, *Jow Rock*, is a narrow cliff with a rock lying one cable from its North side. There are islets also N.W. of Tsae.

Half way between Tsae and Whang Head is a low island, named Ta-chen, and the depth in its vicinity is 3 fathoms. A reef lies three-quarters of a mile S.E. of Ta-chen, and a quarter of a mile from the Chusan shore, with the N.E. point of Ta-chen in one with N.E. point of Tsae N.N.W., and the North end of the Poo-too group E. by N.

Between Ta-kan and Maoutze there are not more than 6 ft. at low water, and the same depth between the two latter; between Ao-shan and Deer Island there is a deep water channel, but it is confined by mud banks and obstructed by reefs.

LAN-SEW BAY, 10 miles across and 10 deep, is formed between the N.E. face of Chusan and the extensive chain of islands running in an E.N.E. direction towards Video Island. The navigation of the southern part of this bay, from the N.W. point of Chusan to Poo-too Island, has been noticed above, and on page 1088.

The **NORTHERN PART** of the **CHUSAN ARCHIPELAGO** consists of numerous islands and rocks, which extend northward of Chusan a distance of 40 miles to the entrance of the Yang-tze kiang, and front Hang-chu Bay. All of them are inhabited, with the exception of the outlying Barren Isles and Leuconna, and small supplies may be obtained, but the natives, except at Tae-shan Island, were in a very miserable condition, owing to the constant visitation of pirates. Many good anchorages will be found among them, in depths gradually increasing from 5 fathoms off Hang-chu Bay to 30 fathoms on the outer part of the bank. The outer islet, Jow Rock, is a narrow cliff with a pinnacle rock between it and Meih-ting.

As vessels bound to the Yang-tse kiang usually pass eastward of this archipelago, and as, in the northern monsoon, they endeavour to make the island of Video if they cannot weather the more northerly Barren Isles, we shall commence with the eastern islands, and then continue the description westward.

VIDEO ISLAND, in lat. $30^{\circ} 8' N.$, long. $122^{\circ} 46' E.$, bearing E. by N. $\frac{1}{2}$ N. 22 miles from the summit of Poo-too, and N.E. by N. 19 miles from Tong-ting Islet (page 1082), is about 1,500 ft. high, nearly square, and has a bold precipitous appearance, and a remarkable white cliff which shows when the island bears N.W. by N.; when first seen from the S.W. the island appears flat and shelving to the westward. It is proposed to establish a *lighthouse* on this island.

At 5 miles E. by N. $\frac{1}{3}$ N. from Video are four rocks called the *Four Sisters*; and E. by N. 9 miles from Video are two rocks named the *Two Brothers*. As the soundings in this vicinity are above 30 fathoms, any cast below that depth will, in thick weather, point out that a vessel is among the chain of islands.

Leuconna Island bears N.N.E. $\frac{1}{4}$ E. 18 miles from Video, and when seen from the southward it makes like three abrupt, round-topped hummocks.

Beehive Rock, a remarkable rock 35 ft. high, has 14 and 16 fathoms water around it, and a rock awash lying 3 cables to the eastward. Leuconna bears from it E. by N. $\frac{1}{2}$ N. $12\frac{1}{2}$ miles, and Video S. by E. $\frac{1}{4}$ E. 13 miles.

Barren Isles, three in number, in lat. $30^{\circ} 43' N.$, long. $123^{\circ} 7' 14'' E.$, are three-quarters of a mile in extent, East and West, and about 50 feet high, and at 2 cables S.E. of the eastern isle is a reef awash at high water. This reef appears to extend three-quarters of a mile S.E. of the isle. Barren Isles lie E. $\frac{1}{4}$ N. 16 miles from East Saddle Island, and N.N.E. $\frac{3}{4}$ E. 20 miles from Leuconna.

FISHERMAN'S GROUP.—North of Chusan, a chain of islands extends from Video W. by N. $\frac{1}{2}$ N. 45 miles, terminating in the Volcano Islands, facing Hang-chu Bay. Between Video and the Fisherman's Group, the first islands westward, there is a channel 2 miles wide; but among the Fisherman's Group, consisting of four islets and several rocks, vessels ought not to

go. Perhaps the best channel through the chain is close to the westward of this group, S.S.W. $\frac{1}{2}$ W. $9\frac{1}{2}$ miles from the Beehive. From this to *Keu-shan*, westward, is 10 miles, with many intervening islands, but the channels between ought not to be attempted, as, from the character of the land, there are, no doubt, many sunken rocks.

Shelter will be found under Hall Island, the largest of these intervening islands, at 7 miles westward of Fisherman's Group; but a vessel had better go on to Keu-shan Island, and anchor on the South side in Peaked Rock Bay, bearing in mind that the head of the bay is shoal.

Keu-shan, the first large island of this chain, is 8 miles long, East and West. *Peaked Rock Bay* is westward of Eden Point, the S.E. end of the island. Along the southern side of Keu-shan are several islets and rocks, to which give a berth of 2 cables. Off the western part of Keu-shan is *Chang-tow Island*, the peak of which rises over the West side of the island to the height of 920 ft. above the sea, rendering it one of the most conspicuous objects of the chain. Between the islands is a narrow channel, named Chang-tau Strait, carrying 5 fathoms, but the South point of Chang-tau is not steep-to.

Tae-shan Channel is West of Chang-tow, and between it and Tae-shan. Its approach from Lan-sew Bay is $1\frac{1}{2}$ mile wide between the West part of Keu-shan and the Doub and Cliff Rocks (page 1089). From the Cliffs the southern entrance to the Tae-shan Channel bears North, and is formed by the islets of *Pou-no* and *Pou-ti* to the West, and *Funing Island*, with the *Cliff Islet* South of it, to the East; off the West end of the latter is a reef, covered at high water. N.W. by W. 6 cables from Funing are two low rocks, and the space between them and Funing is shallow. Between these rocks and the South point of Chang-tau is Chang-tau Strait.

The Tae-shan channel is a mile wide. Both shores are shoal-to, and a sunken rock lies S.S.E. 2 cables from the projecting point on the Tae-shan shore. A mile N.E. of this point is *Gan-su Island*, which has a double peak on it, and there are two islets on each side; the channel lies between it and Chang-tau, under the North head of which is low rock.

The directions for passing South of Tae-shan Island, between Kwan and Lan-sew, have already been given in page 1088; but it remains to describe Tae-shan and the channels between it and the Volcano Islands.

TAE-SHAN ISLAND, 8 miles long and 5 broad, and the third in point of size in the archipelago, Chusan and Luhwang only being larger, is very populous, and carries on an extensive manufactory of salt from sea water. The centre of the island is an extensive plain, with many villages; the hills also separate near the eastern extreme, leaving a level plain across the island. Off the S.E. end of the island are nine islets, among which vessels have no business to go. There is a passage close to the eastward of Kwan; but owing to strong tides and the flaws under the bluff land of this island,

vessels had better pass South of Kwan and between it and Kwi-si Islands, where there is a channel a mile wide; the mud dries 3 cables from the West end of Kwan.

At Towtow Point, the West end of Tae-shan, the hills come down to the water's edge, and midway between it and Chang-pih are *Miles* and *Ellicott Isles*, with 5 and 7 fathoms in their vicinity. The *Show Islands*, one of which is high, lie 6 cables westward of Towtow Point; the channel between having 4 fathoms at low water. On the North side of Tae-shan are four islets, which are too small to afford much protection in the N.E. monsoon, but during the summer good anchorage will be found off the town near the centre of the island. The bay is very capacious, but the whole of it is shoal, and the tides are very strong.

VOLCANO ISLANDS.—East Volcano, with four peaks on it, lies 6 miles westward of Towtow Point, and is 4 miles long North and South. East of its South point is an islet; and between it and the Show Islands off Tae-shan are the two *Beecher Islets*, with steep cliffs, lying close together, and also two low rocks $1\frac{1}{2}$ mile North of the latter. *Kestrel Rock*, awash at three-quarters ebb, was passed by H.M.S. of that name in 1876. It lies nearly in mid-channel between Beecher and Show Islands, the South extremes of Beecher Islands were in line bearing W. by N. northerly, and the centre of Miles Island S. $\frac{1}{4}$ E.

Vessels passing between the Show Islands and East Volcano should be careful not to stand too close to the latter, as the water shoals to 2 fathoms at $1\frac{1}{4}$ mile off shore. East 3 cables from its North point is a half-tide rock, steep-to.

Anchorage.—There are many sunken rocks among the group of islets which extend $5\frac{1}{2}$ miles off the N.W. face of East Volcano, among which vessels ought not to go, but they will find anchorage with shelter from northerly winds on the South side of West Volcano, the southern of the group of the East Volcano, the anchorage being to the northward of a flat rock, lying westward of the South point of the latter. The northernmost islet of the group has a reef lying $1\frac{1}{2}$ cable northward of it.

WEST VOLCANO LIGHT.—Since October, 1872, there has been exhibited from a lighthouse recently erected on the western island or rock of the Volcano group, a *fixed bright light*, elevated 93 ft. above the sea, which, in clear weather, should be seen at a distance of 15 miles. The illuminating apparatus is of the fourth order, dioptric. The tower is of stone, 33 ft. high, and painted black; and the keeper's dwelling is painted white.

Tides.—It is high water, full and change, at the Volcano Islands, at 11^h 30^m, springs rise 15 ft. The flood sets W.N.W. and the ebb E.S.E. The velocity of the tide will be found to increase as Hang-chu Bay is approached, and in light winds a wide berth should be given to all the islets hereabouts.

Skead Islet, lying $4\frac{1}{2}$ miles northward of the Show Islands, has a smaller islet on its N.W. side and another on its S.E. side. The depths from 2 to 4 miles around Skead are unknown, but towards the Rugged Islands, to the northward, they vary from 5 to 7 fathoms.

Mariner Reef.—A notice was published in the "North China Herald," in February, 1857, of a rock or reef, on which the merchant brig *Mariners Hope* struck, when running between Tae-shan and Chin-san Islands towards Ning-po. The vessel was 12 hours on the reef, which was stated to be about a third of a mile long, East and West, 2 cables broad, and had 7 fathoms at her bows, with only 5 ft. under her stern, at low water. Skead Islet bore S. $\frac{3}{4}$ E., distant 3 miles; South extreme of Chin-san, E. $\frac{3}{4}$ S.; large Volcano, S.W. westerly; and extremes of Rugged Islands from N.N.W. $\frac{1}{4}$ W. to N.N.E. $\frac{1}{2}$ E.

CHIN-SAN ISLAND, 8 miles long East and West, lies W. by N. 13 miles from the Beehive Rock, and $5\frac{1}{2}$ miles to the N.E. of Tae-shan. The channel South of this island, and between it and the chain of islands extending from the Fisherman's group, is sometimes taken during the northerly monsoon by vessels bound to Ning-po or Chusan, and it appears preferable to that through Lan-sew Bay, being broad and clear of danger, with the exception of the Mariner Reef just described. There are several islets lying off the eastern and northern face of Chin-san; the best anchorage in the northerly monsoon is westward of the south-eastern islet, between it and Chin-san; and there is also tolerable shelter on its western side, off Pennell, the S.W. point of Chin-san.

SADDLE GROUP.—This important group of islands lies off the estuary of the Yang-tse kiang, directly in the track of vessels entering from the southward.

East Saddle, the outer southern island of the group, is 32 miles northward of Video, W. $\frac{1}{4}$ S. 16 miles from the Barren Isles, and N. by W. $\frac{1}{2}$ W. 17 miles from Leuconna Island. *South Saddle* on the West, and contiguous to it is rugged, the highest part, at the N.E. end, rising 680 ft. above the sea.

A *rock*, which shows at low water, lies in the bay on the East side of the island, with the highest part of the rocky islet close to the eastern point of the bay in line with a conical hill over the West point of East Saddle.

Eight miles N.W. of East Saddle is *North Saddle Island*, 780 ft. high. Between them is *False Saddle Island*; and south-westward of North Saddle are the *Side Saddles*, two narrow islets which will afford shelter, but not so good as under South and East Saddle. North Saddle forms the North end of the Chusan Archipelago, and from it the Amherst Rocks at the mouth of the Yang-tse kiang bear N.W. $\frac{3}{4}$ N. 26 miles, the soundings gradually shoaling from $12\frac{1}{2}$ to 6 fathoms.

Anchorage.—The most convenient anchorage in the northern monsoon amongst the Saddle group is under East Saddle, and in the event of being

caught in a southerly wind a vessel might run between the islands, taking care to keep South Saddle close aboard, within $1\frac{1}{2}$ cable, as there is a large patch of 3 fathoms occupying the centre of the channel, and three rocks awash North of it. Water can be obtained at the East end of East Saddle.

Tides.—It is high water, full and change, at an hour before noon, and the rise is 14 ft. ; the tides are said to be regular, the flood setting to the N.W., the ebb to the S.E.

LIGHT.—On the N.E. extreme of North Saddle Island there is exhibited from a lighthouse a *revolving bright light*, attaining its greatest brilliancy every minute, elevated 273 ft. above the sea, and in clear weather visible from a distance of 24 miles. The tower, of brick, is 54 ft. high, upper part black, lower part white; the keepers' dwellings are painted white. To the southward, south-eastward, and south-westward, this light is obscured by several of the more lofty islands of the Saddle and Parker groups, which intercept it between the bearings of E. by N. $\frac{1}{2}$ N. and N.W. $\frac{1}{2}$ W. ; but it is visible in all other directions.

Childers Rock, lying $4\frac{3}{4}$ miles South of the East part of East Saddle Island, uncovers at low tides, with the Barren Islands bearing E.N.E., Leuconna Island S.S.E. $\frac{1}{3}$ E., and the summit of Senhouse Island W. by N. The lead will give no warning of approach to this danger, the depth being 24 fathoms close-to.

Bit and Cairnsmore Rocks are in the channel, 4 miles wide, between the Saddles and the Parker group next westward. *Bit Rock*, not much elevated above high water, and with a rock awash reported to lie 1 cable S.E. of it, is 4 miles West of South Saddle and South of the chain of rocks and islets extending from Side Saddle. On approaching from the South, Bit Rock is not easily distinguished at first; it has a remarkable patch of rock with one part standing upright like a mile-stone, a little to the northward of it.

Cairnsmore Rock, a dangerous pinnacle not more than 30 or 40 ft. in diameter, and on which the ship *Cairnsmore* was wrecked in 1858, rises almost perpendicularly from soundings of 12 fathoms at about $2\frac{1}{3}$ miles eastward of the East end of Raffles Island. When examined, the precise depth on the pinnacle could not be ascertained, as the wreck, with her fore-mast standing, quite covered it, but there cannot be more than 11 ft. over it at low water springs.

From the rock, the S.E. point of Senhouse bore South; a small rugged rock lying close to the S.E. point of Raffles, and in line with the point, S.W. by W. $\frac{1}{4}$ W. ; and the northern rock of the group lying off the North part of Chesney Island, N.W. by W. $\frac{1}{4}$ W.

Caution.—Vessels navigating the channel between the Saddle group and Raffles Island are cautioned to keep well over towards the Saddle Islands to avoid the above danger, as the lead will give no warning when approaching it. In sailing North, when the Bit Rock opens South of the South

Saddle they will be northward of the Cairnsmore ; and in sailing South, when the same rock opens North of the South Saddle they will be southward of it.

PARKER ISLANDS.—*Raffles Island*, the largest of this group, bears West 11 miles from South Saddle Island. At half a mile from the N.E. point of Raffles, and 2 miles W. by N. of the Cairnsmore, is a sunken rock. *Senhouse Island*, with steep cliffs, lies $1\frac{3}{4}$ mile S.E. of Raffles ; there is a good channel between them, and anchorage will be found on the South side of Raffles in the northerly monsoon.

Brooke Island is a mile S.W. of Senhouse Island, and the channel between should not be used, as the wind is liable to fail under the latter ; there is, however, a good passage 2 miles wide West of Brooke, between it and the *Bonham Isles*. Off the North end of Raffles is Chesney Island, from which rocks and islets extend 2 miles farther northward. A rock, on which the ship *Tonbridge* struck, is reported to lie $2\frac{1}{2}$ miles northward of Chesney Island, so that this locality must be carefully avoided. N.W. of Raffles, and distant from it $1\frac{3}{4}$ mile, are the *Elliot Islets*, on the S.W. side of which H.M. brig *Plover* anchored, and found fair shelter, with the wind blowing hard from the northward. From the Elliot, Gutzlaff Island bears W. by N. $\frac{1}{2}$ N. $10\frac{1}{2}$ miles.

Morrison Island, 7 miles S.W. of Raffles, with smaller islands about it, is very precipitous. The south-western islet of the Parker group is 2 miles S. by W. of Morrison ; and East of this is a chain with deep water passages between extending to Senhouse.

RUGGED ISLANDS lie W.S.W. 15 miles from Raffles. Formed like a pair of callipers, 10 miles in length, and opening to the westward, the group affords shelter in both monsoons, but the tides set through it with considerable velocity. *Tayung*, on the South, the largest and highest of the group, is 660 ft. above the sea, and differs from the rest by being round topped, whereas the others are, as their name denotes, rugged and barren. Under the South side of an islet West of Tayung is *Pirate Bay*, which affords snug anchorage during the northerly monsoon, and a better shelter than the bay within the S.W. and N.W. horns of the group. A reef, which generally breaks, lies off the East side of Pirate Bay.

On the North side of this group the largest island is Tripoint, remarkable for its triple peak ; and East of it is Spire Islet, on which is a curious pinnacle. The islands are inhabited by fishermen, and the various anchorages are frequented by the trading junks.

At $3\frac{3}{4}$ miles N.E. by N. from the N.W. Horn of the Rugged Islands is an islet having a reef running out from the N.W. of it, with several rocks above water called the *Hen and Chicks*.

A shoal of only 10 ft. has been reported to lie S.W. 7 miles from Gutzlaff Island, which would place it E. by N. $\frac{1}{2}$ N. not quite 2 miles from the Hen

and Chicks. The chart shows indications of a bank of $5\frac{1}{2}$ fathoms in this vicinity, extending from between 2 and 6 miles eastward of the latter, with 6 to 7 fathoms around.

GUTZLAFF ISLAND, 210 ft. high, and N.E. $\frac{1}{2}$ E. $8\frac{1}{2}$ miles from the Hen and Chicks, is a round, smooth-topped island, surmounted by a low light-house, and the most conspicuous object off the southern entrance of the Yang-tse kiang. A small islet lies half a mile N.N.E. of it, and "it has been reported, from many sources, that a bank with only 2 fathoms on it extends a mile from its western side."

A LIGHT was first exhibited on Gutzlaff Island in the year 1869. It is a *fixed bright light*, elevated 270 feet above the level of the sea, and in clear weather should be seen from a distance of 20 miles. The lantern is 24 ft. high, and painted white; there is no tower. When it is desired to attract the attention of passing vessels, a gun or guns will be fired and signals made. During fogs guns will be fired in answer to the fog signals of passing vessels. Gutzlaff Island is a *Telegraph Station*.

Tides of the Chusan Archipelago.—In the Vernon Channel, at the South end of the Chusan Archipelago, it is high water, full and change, at 9^h 40^m, and springs rise 14 ft.; in Ting-hai Harbour, at 11^h 0^m, springs rise 12 ft., neaps 9 ft.; at Pootoo Island at 8^h 15^m, springs rise 12 ft.; in Lan-sew Bay at 10^h 0^m, springs rise 13 ft.; at the Volcano Islands at 11^h 30^m, springs rise 15 feet; and at East Saddle Island at 11^h 0^m, springs rise 14 ft.

Under Luhwang Island the flood sets to the N.W. at the rate of 2 knots per hour, and the ebb to the S.E. at $1\frac{1}{2}$ knot. In Duffield, Gough, and Roberts Passes, the first of the flood, at full and change, often comes from the northward, and sometimes runs in that direction 3 hours before the tide through Buffalo Nose Channel overcomes that through the Beak Head, Vernon, and Sarah Galley Channels. In Duffield Pass the tide sometimes runs 5 knots; in Gough and Roberts Passes it is not so strong; in Beak Head Channel 4 knots is about the maximum; and in Vernon Channel it has been known to run 6 knots. Off Roundabout Island the tidal streams are not so violent, but the eddies take command of a sailing ship at springs.

In the southern entrance to Sarah Galley Channel, between Laoush and Ousha Islands, the flood ran W. by S. at the rate of 2 knots, the ebb E.S.E. $1\frac{1}{2}$ knot; the moon was then 18 days old. In the Cambrian Pass, between Ousha and Chuksa Islands, H.M. steamer *Vixen*, with the *Cambrian* in tow, could not stem the ebb.

In the Tower Hill Channel, as before stated, with a strong flood, vessels have been swept to the westward, and carried by the tide beyond Just-in-the-Way, and even through Blackwall Channel; and after rounding Tower Hill and entering Bell Channel, many have been borne by the ebb, between Tower Hill and Tea Islands. Having rounded the North end of Tea Island with a strong ebb, it is necessary to guard against its taking the vessel

through the Melville Channel, and if not able to pass northward of Macclesfield Island, send the boats a-head and endeavour to keep the vessel to the northward of Sarah Island, where there is shoal water to anchor. In the channel between Bell Island and Chusan, the tide at times runs with great strength, so much so that on one occasion the *Madagascar* steamer had great difficulty in stemming it.

In the Blackwall Channel the eddies are as strong as they are off Roundabout Island, taking a sailing ship round against both helm and sails. In the Kintang Channel, between Kintang Island and Deadman Island, the tides sometimes run 4 knots.

In the northern part of the Chusan Archipelago, with Lan-seu Island bearing West 5 miles, the flood ran to the W.N.W. the first hour, then N.W.; total amount of tide 11 knots. The ebb, S.E. by S. the whole tide; total amount $5\frac{3}{4}$ knots.

KINTANG CHANNEL, between the South Coast of Kintang Island and the mainland, is about $2\frac{1}{2}$ miles wide, but is narrowed to $1\frac{1}{2}$ mile by an extensive mud bank (which borders its southern shore), and by a ledge of rocks extending 2 cables from Alligator Point, the South extreme of Kintang, which is marked by a beacon, painted white, from which Long-nose Point bears N.W. by W. about 7 cables, and Just-in-the-Way E. $\frac{1}{4}$ S. This mud bank dries upwards of three-quarters of a mile from the shore, is steep-to, and the lead gives little warning; there are some small islets lying on its outer edge, near the westernmost of which is a boat creek, from whence there is a paved footpath leading to Tein-tung, and so on to Ning-po, the whole distance being about 18 miles, the last 6 miles of which may be performed by canal.

Just-in-the-Way is a small islet, 20 ft. high, with rocks extending $1\frac{1}{2}$ cable from its S.S.E. side, lying in the eastern entrance of the Kintang Channel. To the S.E., between it and Tygosan Island, there is fair anchorage in 12 to 16 fathoms, which will be found a convenient stopping place should there not be sufficient tide to take a vessel on to the River Yung, the anchorage outside of which is much exposed.

The Deadman is a square island, lying W. $\frac{1}{2}$ N. $2\frac{1}{2}$ miles from the South extreme of Kintang, and $4\frac{1}{2}$ miles westward of Just-in-the-Way. The channel between it and Kintang is rather less than $1\frac{3}{4}$ mile wide, with deep water and strong tides. The *Ko Channel*, between the Deadman and the main, is half a mile wide, but is not recommended, as the tides run with great strength, and the limit of shoal water on the South side is not well defined.

A pinnacle rock lies in the channel between Dumb Island and the main. From the rock Ko Point bears S.S.E. $\frac{3}{4}$ E. $1\frac{1}{4}$ cables; West extreme Dumb Island, N.N.W. $\frac{3}{4}$ W.; South extreme of Deadman Island, E. by N.

Blonde Rock, a short half mile northward of the Deadman, shows at low water springs. The marks for it are, the easternmost islet off the N.E. point

of the Deadman in one with San-shan Islet S.E. $\frac{1}{4}$ S.; and the West end of Dumb Islet S.W. $\frac{1}{2}$ W. Beacon Hill, at the East side of entrance to the citadel) is in line with Cone Hill bearing S.W. $\frac{1}{4}$ S., which leads westward River Yung, in line with the citadel bearing W.S.W., leads northward of the rock. It is marked by a wooden *beacon*, with cage, said to be painted white.

TSE-LE or **SQUARE ISLAND**, off the Yung River, is $2\frac{3}{4}$ miles N.W. by W. from the Deadman; there is a patch of $2\frac{3}{4}$ fathoms water at 6 cables S.E. by S. from its North end.

LIGHT.—A *fixed bright light*, visible all round, at an elevation of 123 ft. above the sea, is exhibited from a white octagonal tower, 33 ft. in height, on the summit of the island. The lightkeepers' dwellings are painted white. A *fog-bell* is sounded once every 15 seconds in foggy weather.

H.M.S. *Conway* anchored W.S.W. of this island, with Pas-yew, the western of the Yew Islands, bearing South. This anchorage in the summer season is safe, but during the autumn and winter violent gales with thick weather rise rapidly, causing an uneasy sea, in which a vessel will have difficulty in weighing her anchor; consequently, the anchorage at Just-in-the-Way or that in Ta-outse Harbour, at the N.W. end of Kintang, should be resorted to at this season.

Pas-yew or **Tiger Island Light**.—A *fixed red light*, visible all round, at an elevation of 148 ft. above the sea, is exhibited from an octagonal tower, painted with alternate red and white vertical stripes, on Pas-yew Isle, the western of the three islets fronting the entrance of the River Yung. A *gong* is sounded during foggy weather, giving five strokes in quick succession at intervals of about one minute. The tower is 30 ft. in height. The lightkeepers' dwellings are also painted in red and white vertical stripes.

YUNG RIVER has its entrance fronted by three islets, called the Yew Islands or Triangles, which form three passages into the river. The town of Chin-hai is built close to the S.W. side of Citadel Hill, on the western side of the entrance to the river, of which it is the maritime town. From Chin-hai the river trends in a S.W. and West direction for 11 miles to Ning-po fu, and is about 2 cables wide, with depths varying in mid-channel from 5 to 2 fathoms. Vessels of 17 ft. draught can proceed up to the city from Chin-hai at springs, at half-tide, and anchor off either face of the foreign settlement. European pilots can be obtained at Chin-hai. The Yung separates into two branches at Ning-po.

NING-PO is situated at the point where the two branches of the river join, the city walls extending along the river side up both branches. It was thrown open to foreign commerce by the treaty of Nanking in 1842. It is situated in Chekiang, the smallest of the eighteen provinces of China, which occupies the southern and terminal portion of the great central plain. Within the limits of Chekiang, which enjoys a favourable climate and varied soil, all the most celebrated staples of China are produced,

besides the advantage of means of intercommunication, natural and artificial. Silk, tea, cotton, rice, dye-stuffs, drugs, and minerals (including iron and coal) are among its principal natural productions. The importance of Ningpo has rapidly increased of late years. Nearly four-fifths of the whole foreign trade is done through Shanghai.

The advantage of Ningpo over Shanghai as a place of residence for Europeans is its proximity to the sea, and the neighbourhood of numerous hilly regions, where pure air and moderate temperature can always be enjoyed.

Native shops established in various parts of the settlement supply foreigners with provisions at prices more moderate than at Shanghai. Game is plentiful during the winter, and fish, including mackerel, is obtained of superior quality and in great abundance.

Tides.—At Chin-hai it is high water, full and change, at 11^h 20^m, and springs rise 12½ ft. At Ning-po fu it is high water at 1^h 0^m, and springs rise 9 ft.

DIRECTIONS.—A vessel bound from Ting-hai Harbour, Chusan, to the River Yung, should, after clearing the Bell Channel, steer W. by S. for Just-in-the-Way, recollecting that the S.E. face of that islet is foul, and that a reef extends a cable's length from Insular Point, the North extreme of Tygosan. As before stated, if the tide should fail, there is fair anchorage to the S.E. of Just-in-the-Way. From hence the peak of Tower-hill Island in line with Insular Point will lead southward of the rocks off Alligator Point, after which keep over towards the Kintang shore, until well past the Deadman, or until Beacon or Look-out Hill at the eastern point of entrance to the River Yung is in line with the citadel W.S.W., which will lead northward of the Blonde Rock, and southward of the 2¾-fathom patch lying S.E. by S. 6 cables from the North end of Tse-le.

A notice from the Chinese authorities, dated May, 1874, states that a conical buoy, surmounted by a red cage, elevated 11½ ft. above the water-line, is moored in 6½ fathoms, 90 ft. N. by W. from the peak of *Sesostris Rock*, with Tiger Island flagstaff W. ¾ S. and Seaou-yew Island summit N.E. ½ N. Should this buoy not be in position, it will be prudent for a stranger before entering the River Yung, if unable to obtain a pilot, to mark the *Sesostris Rock* by a boat. It will also be advisable to examine the entrance of the river, which may have changed since the survey.

The Yew Islands, as before stated, form three passages into the Yung River. The eastern passage is between the islands and Look-out Hill, the East point of entrance, and the first danger in it is the *Nemesis Rock*, which lies E. by N. ¾ N. a quarter of a mile from the summit of Ta-yew, and is covered at half-flood. By keeping Pas-yew open of the South point of Ta-yew, this danger will be avoided.

Having passed the East point of Ta-yew, keep it and Seaou-yew aboard, to avoid the *Sesostris Rock*, with only 8 ft. on it, lying in mid-channel, until

Peak Islet (a remarkable rock on the East side of the river opposite the of the rock.* From the rock the Friendly Islands (7 miles N.W. of Chin-hai) are in one with Talung Island (a high bluff island beyond it) bearing N.W. $\frac{1}{2}$ W.

Having cleared the Sesostris, steer to pass between half and $1\frac{1}{2}$ cable southward of Pas-yew, and then for the point under the citadel, taking care that the tide does not set the vessel over to the eastern bank of the river, where the water shoals to 2 fathoms at half a mile off shore.

The middle passage, or that between Seaou-yew and Pas-yew, is probably the best of the three. A mud spit, the extremity of which is marked by a *black* buoy, extends north-westerly $1\frac{1}{2}$ cable from the West end of Seaou-yew, and shoal water, 3 fathoms, some distance beyond it, but this bank will be avoided by keeping the citadel open westward of the West end of Pas-yew until a small hill on the southern shore bears S. by E. $\frac{1}{4}$ E., which is the leading mark through; then steer as before so as to pass southward of Pas-yew.

The passage between Pas-yew and Chung Point under the Citadel, has 2 fathoms in it at low water, and is the broadest and best for small vessels when the tide has risen sufficiently high for them to enter; the only danger being the *Tiger's Tail Rock*, which covers at high tide, and lies rather more than a cable N.W. $\frac{1}{2}$ N. from the summit of Pas-yew, with the S.E. foot of the Citadel Hill in line with Cone Hill, bearing S.S.W. $\frac{3}{4}$ W.; the rock is now marked by a *beacon*, of iron, surmounted with a cage. Chung Point is steep-to on its East side, and vessels will find good shelter under the fort.

Fishing stakes are moored to the West side of Peak Island in deep water. The bend of the river above Chin-hai is often rendered most difficult to navigation by the immense number of junks at anchor there or dropping with the tide. The passage between them is left so narrow that the greatest caution is necessary to avoid collision. Above Chin-hai, keep mid-channel, giving the points a good berth. Vessels drawing 12 ft. water should go up on the flood, as they are liable to take the ground in many places.

The Coast from Chin-hai trends in a N.W. direction, and is fronted by a mud bank, which dries at low water for nearly three-quarters of a mile from the sea embankment, and is steep-to. At the distance of 7 miles from Chin-hai, and three-quarters of a mile from the shore, is a group of five islets, named *Friendly Islands*, inside of which there was shelter in 3 fathoms at the time of the survey, but the water is said to be shoaling fast. Take care, when rounding the West end of the largest islet, to avoid a spit extending 3 cables to the S.E. from it.

* The merchant barque *Moltan* is said to have struck on a rock having 9 ft. on it and 18 feet close-to, lying with Friendly Island just showing northward of Pas-yew, and the northern extreme of Look-out Hill bearing East.

At 4 miles to the N.W. is *Talung Island*, a high bluff, 920 ft. high, forming the southern horn of the Tsien-tang estuary, or Hang-chu Bay.

Caution.—From Talung the coast trends more to the westward, and for upwards of 30 miles is fronted by a dangerous mud bank, which, at the distance of 8 miles from Talung, dries 7 miles off shore, and on its edge are some small knolls. The *Kite* transport was lost upon this bank in 1840, the tide, which here begins to increase its velocity to 6 knots at the springs, turning her over the moment she tailed on it.

Middle Ground.—N. by W. $3\frac{1}{2}$ miles from Tse-le Island is a Middle Ground, with less than 2 fathoms on it, to avoid which vessels, in proceeding to the northward from the River Yung, must keep over towards the Kintang shore, and, if drawing 18 feet water, should not bring Tse-le to the southward of S.S.W. There is a passage to the southward of this Middle Ground for vessels of 15 ft. draught, but there are two patches, on which H.M.S. *Contest* grounded, lying in a N.W. direction from Tse-le, one with 12 ft. on it at 9 cables, and the other with only 5 ft. at $2\frac{1}{2}$ miles from the island.

Nanho or South Island, bearing N. $\frac{3}{4}$ W. $14\frac{1}{4}$ miles from Tse-le, is the outer and largest of the first group of islands met to the westward when steering to the northward from Chin-hai; it is flat-topped, 216 ft. above the sea, three-quarters of a mile in extent East and West, and cultivated. As the water deepens close around this island to 26 and 32 fathoms, vessels cannot anchor near enough to get shelter, but the holding ground is good. About half a mile North of it is a small rock which always shows.

West Stork is a small islet lying W. $\frac{1}{2}$ N. $3\frac{3}{4}$ miles from Nanho, and there are 8 and 9 fathoms water between them.

Seven Sisters Islets, 2 miles farther West, lie North 9 miles from Talung Island, and although small, will afford shelter from northerly winds. The channel between them and the dangerous mud bank just described, is 4 miles wide, and the depth in it varies from 6 to 2 fathoms, shoaling towards the bank. A reef shows at low water, at half a mile N.N.W. of the western islet; and a shoal of 2 to 3 fathoms extends 4 miles north-westward from it.

Seshan Islands form three distinct groups. *East Seshan*, the easternmost group, lies North 18 miles from Nanho Island, and consists of one island about 400 ft. high, with six islets around it. *Middle Seshan Island*, lying 6 miles W.N.W. of East Seshan, is the largest of a straggling group consisting of eight other islets, the southernmost of which is a small rock nearly awash, at nearly 4 miles S.E. of the highest; the western islet, *House Islet*, is an abrupt cliff with a house on its summit. Neither of these two groups are sufficiently large to afford shelter; but fair anchorage will be found in the neighbourhood of the three islets forming the West Seshan group, at 10 miles W.N.W. from Middle Seshan Island.

Fog Islets.—In the centre of Hang-chu Bay, at 14 miles W.S.W. of Middle Seshan Island, are five low rocky islets, the depth of water about which is 5 to 6 fathoms.

CHAPU is a town of considerable importance, standing in a bight on the North shore of Hang-chu Bay, 17 miles S.W. of West Seshan. It is the port of Hang-chu fu. It will be readily known by the hills in its vicinity, as well as by the islets which protect the roadstead off it from the eastward; on the eastern of these islets is a remarkable white house.

Vessels steering for this roadstead should round the southern islet at about a quarter of a mile, and haul up for the houses which will be seen westward of the hills. The anchorage is sheltered from E.N.E. to S.S.W.; but the tide runs 5 knots at springs, and the rise and fall is 25 ft. The mud dries half a mile from high-water mark, is steep-to, and the lead gives no warning. At 4 miles southward of the southern islet is a shoal on which the ship *Bentinck* tacked in 3 fathoms, and where there is probably less water; should the tide therefore set vessels in this vicinity, it will be prudent to anchor.

Wan-tao-kwan is situate in a small bay westward of the second point of land, about 20 miles south-westward of Chapu. Off the point are two small islands, between which and the point is a narrow passage, carrying 4 to 5 fathoms at low water, but which can only be passed through at slack water on account of the extraordinary velocity of the tide.

When bound northward from the River Yung, endeavour to leave with the first of the flood, and when northward of Tse-le Island, if drawing more than 18 ft., do not bring that island southward of S.S.W., then in line with Look-out Hill, to avoid the Middle Ground. In working up for the East Seshan group some casts of $3\frac{1}{2}$ and 4 fathoms were obtained with the eastern islet N. by E. 8 miles; it is therefore advisable that vessels of large draught should not stand into Hang-chu Bay unless bound for Chapu Road, in which case pass about 3 miles southward of East Seshan, and steer for the South islet of the Middle Seshan group. After passing West Seshan the low land on the North side of Hang-chu Bay will be seen, and to the southward the Fog Islets, a group of five low rocky islets, bearing W. by S. $\frac{1}{3}$ S. 14 miles from Middle Seshan, the depth about them being 5 and 6 fathoms.

If bound for the Yang-tse keep eastward of the Seshan Islands, steering between East Seshan and Rugged Islands. The tides in the vicinity of the Volcano Islands will be found to have increased their velocity, the flood setting W.N.W., the ebb E.S.E. Rugged Islands afford shelter in both monsoons, but the tides set strong through them. From thence steer to pass on either side of the Hen and Chicks, recollecting the 10-ft. shoal; it will be prudent, if the vessel is of large draught, to pass eastward of Gutzlaff Island, as a bank of only $2\frac{1}{2}$ fathoms water is said to extend a mile from its western side.

Tides.—It is high water, full and change, at the Seshan Islands at 11^h 45^m. and springs rise 14 ft. ; at the Fog Islands in Hang-chu Bay at the same time, and the rise is 17 feet ; in Chapu Road at noon, and the rise is 25 feet.

The tidal stream increases in strength as Hang-chu Bay is approached ; near Nanho Island and the Volcano group the flood runs W. by N., and the ebb E. by S. sometimes 3 knots, and in light winds, unless great care is taken, vessels are liable to get entangled among the Dunsterville or Volcano groups. At the Fog Islands, the rate increases to 4½ knots, at Chapu to 5 knots ; and in the S.W. part of Chapu Bay to 7 knots, with a rise of 35 ft. At 25 miles above Chapu, the tide was found to run 11 knots at springs, and 8 knots at neaps, with a rise and fall of 40 ft. In the vicinity of East Seshan, and of the Rugged group, the flood runs 2½ and 3 knots ; South of Gutzlaff the first of the flood makes to the southward of West.

HANG-CHU FU, the capital of the province of Chehkiang, stands on a plain about 2 miles from the North bank of the River Tsien-tang, 20 miles above its entrance, and 80 miles from the sea. The tide rises 6 or 7 feet opposite the city, and it is said about 30 ft. within its entrance. Captain Collinson, when making some explorations of its mouth in Hang-chu Bay, in order to ascertain the practicability of an approach to Hang-chu fu, found the tide to run 11½ knots an hour. The peculiar phenomenon of the eagre occurs off the city, the first of the flood coming up in a huge smooth wave, 6 to 12 ft. in height. The southern termination of the Grand Canal is at Hang-chu fu, but it has no opening into the river ; there is also continuous water communication with Shanghai.

THE YANGTSE KIANG.

GENERAL DESCRIPTION.—This noble stream, which ranks first amongst the rivers of the Old world, and next only to the Amazons and Mississippi in the New, is alike the most useful and important of the rivers of China, and constitutes one of the chief elements in the prosperous development of its commerce ; whilst it has also become, during the short period that has elapsed since its opening to foreign navigation, a highway of the highest importance to European trade. Its sources, though hitherto unvisited by scientific explorers, are known to exist among the mountains of Tibet, on the eastern side of those ranges, from the western declivities of which the Brahmaputra and the great rivers of Burmah and Siam take their rise ; whence the river, called the Muhlusu, flows in a south-easterly direction for upwards of 1,000 miles, and being joined by a large tributary, the Yalung Kiang in Yunnan, it turns suddenly to the N.E. and East through the central regions

of the Chinese empire, traversing its entire breadth in a course, inclusive of its windings, of fully 3,000 miles, from the remote province of Sz'chuen to the Eastern Sea, and discharges itself at a point 1,900 miles in a direct line from its source.

Nearly 1,800 miles of the river have now been surveyed, or two-thirds of its entire length, viz., 200 miles from the sea to Nanking, by the British fleet in 1842; 400 miles farther to Hankow, by the expedition accompanying His Excellency the Earl of Elgin in 1858; thence 124 miles to Yohchau on the Tung-ting lake, by that under Vice-Admiral Sir James Hope in 1861; and further explored for 1,100 miles to Pingshan in the province of Yunnan, in long. $104^{\circ} 25'$ W., by the enterprising traveller Captain Blakiston, R.A., and his party, March to June, 1861, 360 miles of which has been subsequently surveyed, as far as Kwei-chau fu in lat. 31° N., long. $109^{\circ} 34'$ E., by Sub-Lieutenants L. S. Dawson and F. J. Palmer, R.N., in April, 1869.

Hankow is the highest port on the Yangtse at present open to navigation by foreign vessels, but it is said that sea-going steamers could reach the city of Ichang, 950 miles from the mouth of the river.

TREATY PORTS.—The treaty ports on the Yangtse at present open to foreign commerce are four, viz., Shanghai, Chinkiang, Kiukiang, and Hankow, at the respective distances of 60, 193, 480, and 600 miles from the sea. Consular Officers are stationed at these ports, at each of which is a concession for the residence of foreigners. Nanking, although not at present open as a treaty port, is nevertheless specified in the Treaty of Tientsing among the river ports to be eventually thrown open, and now may be, at any time, under "the most favoured nation" clause.

Rise and Fall of the River.—The Yangtse is subject to great periodic changes of level. It has been thus described:—"The waters begin to rise early in the year (February or March), and attain their highest level in July or August, at which season the higher portions of the river assume the appearance of an immense lake, by the inundation of the low lands. No banks are visible; junks and boats of all descriptions are seen sailing over what in the chart is dry land. At many parts between Nanking and Hankow, it exceeds 20 miles in breadth, and sometimes no land can be seen from the deck on either side as far as the bases of the distant hills bounding the horizon, on which the sun is seen to set. The houses to the very roofs are under water, and for miles only the roofs and trees are visible, the inhabitants of the villages encamping on the hills till the waters recede. At the end of January the river is at its lowest level, and that to which the soundings on the Admiralty charts refer. The height of the summer above the winter levels may be considered to be for Nanking 12 ft., Kiukiang 30 ft., and Hankow 40 to 50 ft. At Kiukiang, the rise was 21 ft. between March and June, at Yohchau 20 ft.

In the months of September and October the river is not difficult to

navigate, if proper care and caution are employed, the water being then many feet higher than its winter level. In September it commences to fall, and in November and December sinks very rapidly eight or ten inches a day, on account of which these two latter months are considered the most difficult period for navigation, for the bed of the river becomes altered by the summer inundations and rapid currents, so that if a vessel having touched the ground be not floated off at once, there is great probability of her remaining aground until the water rises in the ensuing spring. It is, therefore, deemed imprudent to attempt the navigation of the river at this season without a pilot.

The latest information is to the effect that the Admiralty charts are sufficiently correct to enable a gun-vessel drawing $8\frac{1}{2}$ ft. water, to proceed from Chinking to Hankow, at the season when the river was lowest, without a pilot. Small steamers may take all the short cuts from June until the time the waters commence to fall.

The most constant part of the river is the entrance of the Southern channel, for beyond some slight extension of the bar seaward, no alteration of any consequence has taken place within 30 years; but the character of the same channel higher up, between Kintoan and the mouth of the Wusung River, which latter is 40 miles from the entrance, has no permanency whatever, and of late years has been subject to many changes, which have resulted in considerable deterioration, caused mainly by the opening out of a deep channel North of the Tungsha Banks.

The Estuary of the Yangtse is 70 miles broad from North to South. Its delta, 60 miles in extent, is divided into two almost equal portions by the main stream of the river, the northern part of which, *Tsung-ming Island*, is 32 miles long in a W.N.W. and E.S.E. direction, 5 to 10 miles broad, and is stated to be the largest alluvial island in the world, containing a population of about half a million, although in the 14th century it did not exist above water. There is said to be a large city on the island, but it is not visible from the sea.

The Tungsha Banks lying south-eastward of Tsung-ming form the southern portion of the delta. These banks are rapidly growing up, and two new islands which appeared in 1862 are still increasing in size, one, *Grass Island*, being about 2 miles, and the other, *House or Dry North Island*, 12 miles to the S.E. of *Block House*, the only island previously existing. In 1869 five new islands were discovered to have grown up along the northern edge of the Tungsha on the borders of the main channel; and Tsung-ming has also extended eastward about 6 miles since 1842.

The Yangtse enters the sea by three channels, of which two only are navigable; these are the *North Entrance*, now quite unknown, and used only by junks; the *Main Channel*, by which the waters of the river are now dis-

charged North of Shawsishan Island, and which of late years has greatly increased in depth and volume, and now is reported to be the best; and the *South Channel*, which has heretofore been the only one affording a sufficient depth of water for navigation by foreign sea-going vessels, as it is also the nearest and most convenient approach to Shanghai.

Great Yangtse Bank, extending seaward in an easterly direction for 150 miles, is a vast bank of clean river sand about 30 miles in breadth. It lies rather off the northern entrances, and is of grey or dark speckled fine sand, its depth varying from 17 to 20 fathoms; the surrounding bottom is chiefly mud, or mud and sand. When more fully examined it will no doubt be a good guide to vessels making the Yangtse from the eastward. South of this bank, a deep water gully of from 25 to 30 fathoms runs up towards Shawsishan Island from the south-eastward, terminating 20 miles E. by S. of that island. The water North of the bank is also deeper, although it shelves off very gradually to the north-eastward.

The breakers said to have been seen from the steamship *Costa Rica*, in lat. $32^{\circ} 10' N.$, long. $125^{\circ} 3' E.$, have been carefully searched for, but not found; 25 fathoms were obtained on the spot, with even depths all round, in a space of 15 miles square.

The **North Entrance**, which, in 1842, was in lat. $31^{\circ} 52' N.$, long. $122^{\circ} 0' E.$, has never been examined since that date, when it was only partially surveyed. It leads into the Yangtse, North of Tsung-ming, where the river flows into the sea by what is called the North Branch. It is exceedingly probable that the banks and channels in this locality have entirely changed since the survey, and on no account should vessels approach it, even in the finest weather, under a depth of 8 fathoms.

The following notice of a buoy moored near Drinkwater Point was issued in 1877.—“A buoy, with *red* and *black* horizontal stripes, surmounted by a black globular cage, has been moored in the North channel in $5\frac{1}{2}$ fathoms at low water springs, $15\frac{1}{2}$ miles W. $\frac{1}{3}$ N. from the Shawsishan Lighthouse. Entering by this channel, when 3 miles from the lighthouse, bring it to bear E. $\frac{1}{4}$ N., and keep it so until you have increased the distance to 8 miles, then steer directly towards the buoy.”

The **MAIN** or **SHAWEISHAN CHANNEL**.—In 1842 the waters of the Yangtsee divided at Bush Island, the greater part flowing through the southern channel, which then carried a good depth of water, but of late years the latter has been filling up owing to the diversion of the greater body of water to the northward of Bush Island, which has had the effect of altering entirely the features of the unnavigable mass of swatchways and shallows which formerly existed in the space between Tsung-ming and Tung-sha, and scouring out a deep, broad, direct channel, which, fortunately for navigation, emerges at Shawsishan Island. This channel, when examined by Captain Charles Forbes, R.N., in 1869, was found to have a uni-

form breadth of fully 3 miles, carrying a depth of 5 to 8 fathoms in an almost direct course to the sea, its South point of entrance being marked by Shaweishan Island and Light, from which its bar, of 4 fathoms at low water and one mile across, extended between 3 and 8 miles W. by N. from Shaweishan.

To enter, pass northward of Shaweishan, taking care to avoid a 16-foot patch at the north-eastern extremity of the Tungsha Banks, which lies W. by S., $2\frac{1}{2}$ miles from the island, after clearing which, bring Shaweishan on an East bearing, and keep it so until 15 miles distant, when the course may be altered to W. by N. for the next 5 miles. Tsung-ming may then be closed, and its shore passed at the distance of a mile or two until abreast Bush Island, but care must be taken not to overrun the above distances on the flood, nor to dip Shaweishan Light, if at night, before hauling in for Tsung-ming.

Shaweishan Island and Lighthouse, in lat. $31^{\circ} 24\frac{1}{2}'$ N., long. $122^{\circ} 14\frac{1}{2}'$ E. and N.N.W. $\frac{3}{4}$ W., 41 miles from North Saddle Light, is a small steep-sided island, 190 feet high, fronting the main entrance to the Yangtse, and surmounted by a lighthouse. When bearing S.S.W. it makes as a flat-topped island with the highest part to the eastward, and when bearing West as a peaked island. When bearing N.W. $\frac{1}{2}$ W., distant about 5 miles, it appears like two islands, the westernmost being the smaller. It is seldom seen when entering the river from the southward.

A fixed light, visible all round, is exhibited from the summit of Shaweishan Island at an elevation of 229 ft. above high water, which in clear weather can be seen at a distance of 22 miles. The lighthouse is round, painted black, and 55 ft. in height, and the lightkeepers' dwellings are painted white.

Amherst Rocks, 10 ft. above high water, lie S.S.E. $17\frac{1}{2}$ miles from Shaweishan, N.W. $\frac{3}{4}$ N. $23\frac{1}{2}$ miles from North Saddle Light, and N.N.E. $\frac{1}{2}$ E. $24\frac{1}{2}$ miles from Gutzlaff. They are a dark cluster of rocks, of which the largest is very prominent, and when first seen always makes as a single black rock, but should there be numerous fishing boats cruising in their vicinity, they might not be distinguished if not on the alert.

Ariadne Rock, with 9 feet on it at low water, is apparently of the same jagged formation as the Amherst Rocks, from which it bears W. by S. 7 miles, and South $17\frac{1}{2}$ miles from Shaweishan Island. There are 5 fathoms water close round within 30 feet of the rock. With a strong ebb tide, the position of this danger can easily be distinguished by the commencement of discoloured water; the brown water resembles the shape of a comet, the nebula being over the rock. The Amherst Rocks are well in sight from it on a fine day, but if they be not seen, the Ariadne Rock is a great danger in entering, particularly on the northern and western streams, for the lead is no guide.

Gutzlaff Island and Light, forming the southern conspicuous object at the entrance of the Yangtse, is described on page 1096. If kept on a South bearing it will lead up to the outer part of the bar at the entrance of the South channel in not less than 19 feet at low water springs, and on a S. by W. bearing in not less than 21 feet.

Cape Yangtse, forming the South point of entrance to the estuary, is 17 miles W. by N. from Gutzlaff Island. The whole coast here is very low and quite level, having been entirely gained from the sea, and the mud dries out half a mile at low water from the embankment. There is anchorage in $4\frac{1}{2}$ fathoms southward of the cape, and fair shelter from northerly winds, unless the wind draws well to the eastward. There was formerly a beacon on the cape, but it has long since disappeared, and there is now no distinguishing mark whatever.

The coast for 20 miles northward of Cape Yangtse is fronted by an extensive mud bank which commences at the cape, and its eastern edge or elbow in 2 fathoms was (in 1864) 13 miles from the shore, and 12 miles N. by W. $\frac{1}{2}$ W. from Gutzlaff. From this elbow the bank trends to the N.W., and gradually narrows up to Kintoan Beacon. It is of very soft mud, and on its outer part large floating fishing stakes in long rows, attached to nets, are generally met with.

The **SOUTH ENTRANCE** of the **YANGTSE**, which is the recognised channel and fairway into the river, is bounded to the southward by the South bank, just described, and to the northward by the southern edge of the Tungsha Banks, and the shallows extending therefrom in the direction of the Ariadne and Amherst Rocks.

The Outer Bar, about 5, narrowing to 3, miles in breadth and 8 or 9 in length, has, according to the Admiralty survey of 1864, not less than 20 feet least water at its outer part, nor less than 18 feet at its inner end, 3 miles below the light-vessel; but seldom will so little be found, and although it has extended seaward since 1842, the alteration is almost imperceptible.

The **Tungsha Lightvessel**, painted *red*, is moored in $3\frac{1}{2}$ fathoms at low water in the entrance of the river, at the inner part of the bar, under the North bank. She has one mast, surmounted by a 10 ft. black ball. She exhibits a *bright revolving light*, giving flashes at half minute intervals, elevated 40 ft. above the sea, which in clear weather can be seen 11 miles. Her position is in lat. $31^{\circ} 7' 20''$ N., long. $122^{\circ} 1'$ E., with Gutzlaff S. by E. $\frac{3}{4}$ E., Shawsishan N.E. by N., and Kintoan Lighthouse N.W. by W. $\frac{1}{2}$ W.

A *gun* will be fired from her to attract attention when vessels are observed running into danger, and the course which should be steered will be signalled by the Commercial Code. In foggy weather a *Steam Fog-horn* will be sounded at intervals of 10 seconds. When necessary to lower the lantern for trimming, a small light will be hoisted and a flash light burned.

Kintoan Lighthouse, 70 ft. high, and painted black, is erected on the south-

ern shore of the Yangtse, N.W. by W. $\frac{1}{2}$ W. $16\frac{1}{2}$ miles from the Tungsha Lightvessel. No light has been shown from it since the lightvessel was established.

KINTOAN LIGHTVESSEL, placed in position in March, 1878, is moored in mid-channel N.E. of Kintoan Lighthouse. She is painted red, and shows a *fixed bright light* at 35 ft. above the sea, visible 11 miles off. A bright light is shown at her forestay to show in which direction she is riding.

A *Fog-bell*, weighing 10 cwt., is sounded on the Kintoan Lightvessel in foggy weather. It will be struck *three double blows every minute*; the interval between the blows in each pair will be *five seconds*, and between two successive pairs of blows *fifteen seconds*.

If the lightvessel should be driven from her station to one where she would not serve as a guide to shipping, the usual light will not be exhibited, but a fixed *red light* will be shown from the bow and stern. By day, the globe will be struck as soon as possible, and until struck a red flag will be shown above it.

Kintoan Small Beacon and Light.—This beacon is a wooden tripod, 40 ft. in height, and situate 5 miles N.W. $\frac{1}{4}$ W. from Kintoan lighthouse. It carries a *fixed light* showing *white* over the channel to the south-eastward, or between the South shore and the bearing of E. by S. $\frac{1}{2}$ S., and *red* across the channel towards Blockhouse Shoal, between the same bearing and S. by W. $\frac{1}{2}$ W. The white light is visible 6 miles, and the red light 4 miles. The light is elevated 32 ft.

Beacon Spit, said to have disappeared in 1871, is a 3 fathoms patch in the centre of the fairway, East of Kintoan Lighthouse, and a little detached from a 3 fathoms spit, which in 1869 was growing out from the South bank. The channel was further narrowed to less than a mile by a similar spit extending from the North side. The Kintoan Bar which first appeared in 1862, N.E. by E. of the lighthouse, appears to be extending both ways, and the channel to be deteriorating. The new lightvessel however is a good guide.

The **Tungsha Bank**, forming the North side of the South or fairway channel, is rapidly growing up. Its south-eastern spit, which borders the entrance and Outer Bar, extends about 8 miles eastward of the lightvessel, with a depth of 13 to 16 feet, and it may be cleared by not bringing the lightvessel to the westward of W. by N. $\frac{1}{2}$ N. The south-western edge of the bank is extremely irregular, and being steep-to should be approached with caution; it forms a complete breakwater to the channel, which affords secure anchorage everywhere in ordinary weather.

House Island, formed on the Tungsha Bank, has extended considerably, and is now a leading feature on the North. The house on the eastern part of this island bears East 9 miles from Kintoan Beacon, and N.W. $\frac{3}{4}$ N., $9\frac{1}{2}$ miles from the outer lightvessel; the bank extending from the West side is steep-to, and should be approached with great caution. The bank is evi-

dently growing to the S.E. from this island, for where the survey of 1842 gives $3\frac{1}{2}$ fathoms, there are now only 10 feet.

Block House Island is N. by W. $\frac{1}{2}$ W. $6\frac{1}{4}$ miles from Kintoan Lighthouse, and N.W. by W. $\frac{1}{2}$ W. 10 miles from House Island. It is covered with grass and low bushy trees, and is becoming larger every year. To the eastward about 3 miles is Grass Island, lately formed, and three others to the northward. It is probable that in a few years these will become united, and Grass Island and House Island become connected.

Block House Shoal.—The navigable channel between Kintoan Lighthouse and Block House Island has for some years past undergone a series of important changes, the latest formation being Block House Shoal, a middle ground of 6 ft. water, 7 miles in extent, the South point of which (marked by a buoy is N.E. by N. of the lighthouse. The channel northward of the shoal is not now navigable, whilst the fairway which lies between it and the South shore, and which in 1869 first became narrowed to less than half a mile, is reported to be filling up. There is no permanency in the chaacter of the channel at this part, mariners must therefore trust to the pilots.

A *red buoy*, 6 ft. in diameter, surmounted by a staff with a truncated, pyramidal cage, 12 ft. above the sea, has been moored on the S.E. extremity of Block House Shoal, in 16 ft. at low water. From the buoy Kintoan Lighthouse bears S.W. $\frac{3}{4}$ S., and Small Beacon W.N.W. westerly.

OUTER ANCHORAGE.—In fine weather a vessel may anchor anywhere between Gutzlaff, Amherst, and the Saddle Islands, but should always have one of them in sight, so as to take a good departure. It is recommended that an anchorage should not be taken at night under the Saddle Islands, during the N.E. monsoon, unless there are appearances of bad weather, as it will frequently take all the daylight of the next day to work up to the entrance. In the summer season, if bad weather is approaching, which the barometer usually foretells, a stranger should not attempt to run in unless certain of getting within the bar, or making the lightvessel; but either an anchorage should be sought under these islands, or the vessel kept at sea or standing off and on, as it is dangerous to enter the river when a gale is coming on. It is preferable to anchor rather than to stand out to sea, as the weather is sometimes thick and foggy, the tides strong, and the vessel's position not easily ascertainable under such circumstances.

The anchorage at the Saddle Islands is described on page 1093; the best anchorage at the Parker Group is northward of Senhouse, the south-eastern island, in 10 fathoms; or between Senhouse and Raffles in 6 to 7 fathoms, all the approaches being apparently steep-to.

TIDES.—It is high water, full and change, in the vicinity, and eastward of Gutzlaff Island, at 11^h 30^m; and springs rise about 15 ft. The highest tide occurs on the second day after full and change. At the lightvessel at the entrance of the Yangtse it is high water at noon, and springs rise 16 ft.,

neaps 11 ft., and neaps range 7 ft. At the entrance of the Wusung River it is high water at 0^h 30^m; springs rise 15 ft., neaps 10 ft. At Shanghai it is high water at 0^h 40^m; springs rise 10 ft., neaps 7 ft., and neaps range 4 ft.

The tidal streams at the entrances of the Yangtse from Gutzlaff to Shawsheishan rotate, performing one revolution (with the sun) in 12 hours. To the southward of Gutzlaff the tides are also rotatory, but not with that regularity which is observed about the Amherst Rocks. There is also reason to believe, although the fact has not yet been conclusively established, that they preserve the same character some distance to seaward, and far to the northward. During its revolution the direction of the stream changes about two points every hour, excepting when veering from N.W. to N.E. about the time of high water, and from S.E. to S.W. about the time of low water, when the change is more rapid. The northern stream for the most part makes and completes the flood, and the southern stream for the most part makes and completes the ebb, although the first part of the flood is made by the southern stream, and the first part of the ebb by the northern, called sometimes "tide and half-tide."

In the river the streams are sharp in turning, the flood making at 1^h 30^m after high water, and the ebb at 2^h 30^m after low water. There is very little slack, the ebb running 7 hours, and at springs attaining during that period a distance of 24 miles. The period of greatest velocity, 5 knots, is the 5th hour after high water. The flood runs 5 hours, and with much less strength, seldom exceeding a velocity of 4 knots, the distance attained during the whole tide being 16 miles.

TABLE showing the direction and velocity of the tidal streams at the entrance of the Yangtse-kiang.

Time of Tide.	3 Miles North of Gutzlaff.	Lightship at Springs.	Lightship at Neaps.	Outside of the outer Bar.	Between Shawsheishan and Amherst.

Also at the Amherst, 1st hour flood S.E., 2nd hour South, 1 knot.

The foregoing table compiled from various sources will afford the best guide to a knowledge of these rotary tides, and will be found valuable should it be deemed desirable or necessary to stand in and make the light ship in thick weather. If a good departure be obtained before the outer islands or lights are lost sight of, the entrance may be confidently steered for, provided the course and distance run be kept corrected each hour, or oftener, by making allowance according to the table. Perfect reliance may be placed upon the direction of the stream, as given therein, which will seldom be a point in error, but the rate of the stream is a matter of judgment, and though capable of much precision, can only be correctly approximated by a careful consideration of all the attendant circumstances.

PILOTS.—Properly qualified pilots are licensed by the harbour master of Shanghai. No sailing directions can do away with their usefulness to the stranger, where the safety of the vessel depends so much upon a correct knowledge of the tides. The pilots can be obtained day or night, except when all are distributed on board vessels, when the schooners anchor near the lightvessel.

The cruising stations are: Outermost Station—between Leuconna Island, Barren Islands, and East Saddle Island; Middle Station—between North Saddle Island, Elliot Island, and Amherst Rocks; Inside Station—from the lightvessel to 8 miles outside.

The charges established under a code of regulations, by agreement between the Chinese government and the foreign ministers, and which came into force on the 1st of January, 1867, are as follows:—

For steamers or sailing vessels in tow, to or from the light-ship, for each foot of draught, 4 taels; for sailing vessels not in tow, to or from Gutzlaff, 5 taels, and to or from the light-ship, $4\frac{1}{2}$ taels. Two-thirds of the above rates respectively, shall be charged upon vessels proceeding from sea to Wusung, or *vice versa*, instead of to Shanghai.

The Shanghai Pilot Company's schooners are known by a *black ball* with number underneath in foresail and mainsail; flag *white* and *red* horizontal. The Mercantile Pilot Company's vessels have white hulls and the same flag, with the word "Pilot" on mainsail.

DIRECTIONS from the Southward.—If bound to the Yangtse during the S.W. monsoon, endeavour to make the island of Video, and having passed eastward of it at the distance of a mile or two, steer about N. by W., making some allowance for tide, which (although in this locality little is known accurately respecting it) may be taken to set westward on the flood, and eastward on the ebb. This course will lead 2 to 3 miles eastward of Beehive Rock, 13 miles distant, and a further run of 18 miles will bring a vessel up to the passage between the Saddle and Parker Groups, which is the most direct route into the Yangtse kiang. To avoid the Cairnsmore sunken rock, the only known danger in the passage, hug the Bit Rock, from which to the

Tungsha lightvessel the course is N.W. $\frac{1}{2}$ W., close along the South bank, and across the centre of the bar.

If preferring for any reason to pass outside the Saddle Islands, a N. by E. course should be steered from Video, the only danger to be avoided being Childers Rock, $4\frac{1}{2}$ miles South of the south-eastern extremity of East Saddle. The Saddles may be rounded as convenient, and after passing the North Saddle light, it may be brought to bear astern S.E. by E. $\frac{1}{4}$ E. Easterly, the opposite course to which will lead through the fairway of the bar up to the lightvessel.

During the N.E. monsoon, if not intending to call at Ning-po, vessels should pass eastward of Chusan, and enter the archipelago to the northward of that island. It is best, however, to endeavour to make the Saddle Islands as being the most weatherly land-fall, but if unable to fetch so far to the northward, and the parallel of 30° N. has been reached, the high dome-shaped island of Video, 500 ft. high, will then be a conspicuous object, for it may be seen in clear weather about 30 miles; it has a remarkable white cliff, which shows when the island bears N.W. by N., and in thick weather any cast below 30 fathoms will point out that the vessel is in the vicinity of this or the neighbouring islands, provided she be southward of the Great Yangtse Bank. The most remarkable land to the southward of Video is the island of Chukeya, on which there is a round-topped peak 1,164 ft. high, and eastward of Chukeya are several islets, of which Tongting, the outer one, is about 40 ft. high, with detached reefs S.W. of it.

If unable to turn to windward, anchorage will be found on the southern side of Ousha Island, in the entrance to the Sarah Galley Channel. If unable to weather the North end of Chukeya, the South side of Pootoo Island will be found the best stopping place; the anchorage in 12 fathoms is under the hill, with three chimneys on it; the mud bank from the shore is very steep, shoaling quickly from 12 to 2 fathoms. From this position, in a handy vessel the best route will be through Lansew Bay, and through the channel between Lansew and Tae-shan Islands; but large vessels had better pass eastward of Video, and enter the archipelago farther to the northward. If unable to fetch to windward of the Barren Islands, and should the tide or weather be unfavourable for entering the river, a convenient anchorage can be found among the Saddle Group, which, with other available anchorages, are described on pages 1093-4.

It may be here noticed that as the entrance of the Yangtse is somewhat difficult for a stranger to make even in fine weather, the difficulty is greatly increased if it be necessary to beat up against a contrary wind, especially in bad weather; no vessel should therefore attempt to do so without a pilot, or unless it be sufficiently clear to ensure keeping the islands in sight until they dip. But with a leading wind and a good departure either from Gutzlaff or

the Amherst Rocks, together with strict attention to the course and distance made good, a vessel may stand in for the lightvessel.

The In-shore Passage from Hong Kong to Shanghai during the N.E. monsoon is described on pages 96-7.

From the Northward or Eastward.—Vessels bound into the Yangtse from the Gulf of Pe-chili are recommended to make Shaweishan, not approaching the coast within the depth of 15 fathoms until within 60 miles of that island, when the water may be shoaled to 10 fathoms with safety, by which means there will be no difficulty in further making the Amherst Rocks in daylight. In N.E. winds, if strong, and the thick weather which usually accompanies them, there is a great probability of overrunning the distance owing to the strong southerly set (notwithstanding that the tides are revolving), and so getting to leeward, and having to work up from the Saddle Islands. Although it is better to do this than incur any risk, it is suggested in such a case that if the Amherst be not made before dark, especially if Shaweishan or its light be not seen, the vessel should be hove-to till dawn, sufficiently far to the northward to allow for drift and a set of a mile an hour, keeping a careful reckoning.

In N.W. winds and fine weather, the Amherst should always be made. In November and December, when these winds prevail, vessels from Japan should keep well to windward, for if they are of long continuance there is every probability of being driven to leeward of Video; in such case, should the weather be thick, the Great Yangtse Bank will be a good guide in approaching the entrance of the river, owing to the nature of the bottom, which is of clean river sand.

Whether intending to enter by the main or southern channel, Shaweishan is the best landfall to make when bound from the northward or eastward. By keeping it on a N.N.W. bearing it will lead towards the Amherst Rocks, which may be passed at half a mile on either side. These rocks bearing E.N.E. astern will lead South of the Ariadne Rock, distant 7 miles from them; when a West course may be steered till the lightvessel heaves in sight, making allowance for the state of the tide. Should a vessel in thick weather find herself being set over to the Tungsha Bank, she should immediately steer South for the channel, and anchor.

The Entrance of the Yangtse in hazy weather is somewhat embarrassing, for after the outer islands are lost sight of neither land nor marks are visible, but in clear weather the navigation is not difficult by day, and since the establishment of the three fine lights on the North Saddle, Gutzlaff, and Shaweishan Islands, it is equally easy, if not more so, at night.

Leaving the Saddle Islands, keep North Saddle bearing S.E. by E. $\frac{1}{4}$ E. easterly until Gutzlaff bears South, distant 16 to 17 miles, recollecting that if Shaweishan shows plainer than Gutzlaff, the vessel is too far to the northward, and in danger of entering a false channel through the Tungsha Banks,

5 to 7 miles northward of the fairway, and may be dangerously near to the Ariadne Rock, in which case the Amherst Rocks will also be visible. Gutzlaff, 210 ft. high, when first seen, will appear like a small round lump, and its lantern, which is mounted on a tripod, painted white, may not be visible. Shawsishan, 196 ft. high, a little larger than Gutzlaff, and surmounted by a lighthouse painted black, is not often seen when a vessel is in the right position for approaching the bar and fairway.

With Gutzlaff on the above bearing and distance, if the day be clear, the lightvessel will be visible from the mast-head (she is rarely seen beyond 7 miles from the deck), when steer for her between the bearings of W.N.W. and N.W. to cross the bar, making due allowance for tide, the channel course being N.W. by W. As long as North Saddle and Gutzlaff are in sight, the reckoning should be tested frequently by cross bearings, so as to verify the allowance made for tide, and thus give greater confidence in entering the river.

In working up from the Saddle Islands, do not bring Gutzlaff eastward of South, until 16 miles northward of it, when it may be brought to bear S. by E. The vessel will then be on the edge of the South Bank, and may now stand to the westward, nearly into her own draught, bearing in mind the direction of the streams. All vessels should keep as near as possible to the South Bank, the edge of which, from below the lightvessel up to Kintoan Beacon, appears remarkably even.

The foregoing directions are for vessels of about 18 ft. draught, and will lead over not less than 20 ft. at low water springs; small craft may close with the South Bank when Gutzlaff bears South, distant between 12 and 15 miles, and steer up with the lead for their guide, for the edge of the South Bank is very even and may be depended on nearly up to Kintoan beacon. Or, having passed Gutzlaff Island, if the weather be fine, a vessel may safely steer in with the island bearing S. by E., astern, and this will lead over the eastern edge of the South bank in about 15 ft. at low water, or 31 ft. at high water springs.

Too much attention cannot be paid to the set of the streams at the entrance of the Yangtse, and also to the lead. So long as the weather is clear, Gutzlaff forms an admirable mark, and it has only to be kept westward of South until it is distant 16 miles, when a vessel may steer N.W. by W. for the lightvessel; but in thick weather and a working breeze with a variable tide under her lee, it is difficult to ascertain when 16 miles have been made, and she will be liable to be horsed over to the Tungsha Banks, where several vessels have been wrecked. These banks should always be approached with caution, as their southern edges give no warning, unless it be by the lead indicating hard bottom; and, as the tide may be setting across and not into the river, it will be as well to ascertain the vessel's true rate over the ground

by using the deep sea lead for a ground log instead of the log-ship, and taking the opposite to the bearing of the line as the course made good.

Whenever the ground log is not used, it is recommended to allow hourly for the tides, both as to direction and velocity. Experience has shown that the lightvessel can be made by following this method, always being careful to verify the ship's position by bearings of Gutzlaff and the Saddle Islands as long as they remain in sight. The break on the head of the Tungsha banks will sometimes be seen after passing the Ariadne Rock, but in thick weather the southern side of the channel is no doubt the one to border on. At night or in thick weather the lead will be a useful guide. The bottom on the North bank is hard mud with sparkling grains of sand, but soft in a few places. On the South bank the bottom is soft mud with dark gray sand.

Mr. George Stanley, R.N., remarks that the nature of the bottom is very little guide, for after six weeks' sounding, during the survey of 1864, it was impossible to detect any difference between mid-channel and the North and South banks; the only positive difference being that sand with black specks may be found on the Tungsha Bank, but never on the South bank. A stranger taking it as an infallible rule, that sand with dark specks are to be found on the North bank, would at once be in doubt if the lead showed two or three successive casts of brown mud.

Captain Charles Gribble remarks that although there may be little or no difference in the appearance of the bottom on the North and South banks, there is a difference in the *feel* of the bottom, that on the South bank being very soft, that on the North hard.

Lightvessel to Wusung River.—The lightvessel is moored over against the North side of the channel, off a bight in the North bank, and a mile below is a 9-foot spit of the Tungsha, the extremity of which in 17 ft., is half a mile E.S.E. of her. Vessels should therefore pass to the South of the lightvessel, from which the channel course is N.W. by W.; but if beating up after passings the lightvessel, tack in $3\frac{1}{2}$ fathoms when standing towards the South bank. The deepest water is near and along the southern edge of the North bank, but in standing towards it do not wait for the second shoal cast to go about. Generally the edge of the North bank is lined with heavy fishing stakes, planted in 4 and 5 fathoms, with only a few feet water a ship's length inside them.

The house on House Island and the lightvessel are excellent marks for fixing a ship's position by cross bearings until Kintoan lighthouse (now disused, see pages 1108-9), is well in sight, which it will be when the hull of the outer lightvessel is just dipping. At night bring the lightvessel astern on a S.E. by E. bearing, and keep it so till the light dips; this will lead well over on the North side of the channel, but in the best water opposite Beacon Spit, E. $\frac{1}{2}$ S. from the Kintoan lighthouse, where the channel is much con-

tracted.* Here the South shore will be plainly in sight, and the Kintoan lightvessel (page 1109) a guide in mid-channel. When the lighthouse bears W. by S. steer W.N.W., so as to pass about half to three-quarters of a mile South of the Blockhouse shoal buoy, and then stand up channel again on a N.W. $\frac{3}{4}$ W. course, bearing in mind that the edge of the South bank is less steep than that of Blockhouse Shoal. As previously mentioned, the channel above Kintoan is reported to be shoaling, and the banks to be constantly shifting, so that a stranger must trust rather to the pilots than the chart.†

At night it is preferable to hug the South shore near the lighthouse, passing it at a mile. Blockhouse Island will soon rise after passing Kintoan lighthouse, having at first the appearance of a cluster of fishing boats, and gradually showing itself a low island covered with bushy trees. When the large house on this island bears North, the vessel will be in the narrowest part of the channel, which here is only 4 cables wide.

After passing Blockhouse, the South shore, the bank of which is steep-to, should be gradually closed to not less than a mile, and kept at that distance until the marks and buoy for Wusung Spit are seen, and should not be approached under 5 fathoms. It is then necessary to keep well out into the channel and get Paushan Pagoda, a peaked tower near the small walled town westward of the entrance, on a W. by N. $\frac{1}{2}$ N. bearing, which will lead up to the Wusung River, just clearing the dangerous shelf which borders the shore eastward of the entrance. Wusung lighthouse will also be in sight just over the point after passing the Blockhouse Shoal, but the *red* light it exhibits at night down the channel of the Yangtse is not visible more than 5 miles. If bound to Shanghai, the directions are continued on page 1120.

The **WUSUNG RIVER**, on which is situate, 12 miles from its entrance, the great commercial port of Shanghai, is about 60 miles in length, and is the lowest tributary of the Yangtse kiang. It flows from the lake Tien-shan or Miau, through which is a water communication with the Grand Canal, leading northward to the important city of Suchau, and southward to Hang-chu fu. Its real name is the Wongpu or Hwangpu, but it has taken its commonly received name from the small town of Wusung, situated about a

* In 1869. The only information subsequently received concerning the alterations of the channel is contained in the following extract:—"The first sign of land will be three remarkable trees on the South bank of the river, $7\frac{1}{2}$ miles below Kintoan lighthouse, and marked 'Clump' on the chart. To the south-westward of House Island the spit extends in a S.E. direction, the bottom on that side being hard. Blockhouse Shoal has extended in a S.E. direction, and also on its S.W. side. When close to Kintoan lighthouse, keep the South shore about three-quarters of a mile distant, and follow the trend of the land until the red buoy on Wusung outer buoy is sighted."—H.M.S. *Avon*, May, 1871.

† These directions refer to the channels as they existed in June, 1859, and as they are shown on the Admiralty charts.

mile within the entrance of the river on its left bank, and on the North side of a creek also leading to Suchau.

The **Outer Bar** of the Wusung River commences about a mile from the entrance, carrying not less than 20 ft. at low water springs, with occasional deeper soundings, over a narrow channel between the shallow and extensive mud flats which border both shores of the river at its mouth. The North side of the bar channel is marked by the *Spit* or *Wusung Buoy*, on the edge of the western shoal, about half a mile above its extremity. This is a large *red* and *black*, vertical striped, nun buoy, 8 ft. in diameter. It lies in 21 ft. at low water springs, with Paushan Point N.W. by W., and Wusung lighthouse S.W. by W.

Vessels should cross the outer bar with Wusung lighthouse bearing S.W. by W. $\frac{1}{2}$ W., westerly, so as to avoid the dangers on either side, the chief of which is the *Lismore* wreck, in 2 fathoms, on the edge of the South flats. The channel subtends an angle of about $13\frac{1}{2}^{\circ}$ from the lighthouse, so that a course on a S.W. by W. $\frac{1}{4}$ W. bearing of it will hug the northern flats, and a course on a W.S.W. bearing of it the southern.

Lismore Wreck Light.—A pile lighthouse was erected in 1875 over the *Lismore* wreck, and a fixed red light shown from it, but the water deepening around the lighthouse rendered it unsafe, and in 1878 it was decided to remove it, and mark the wreck by a small junk, moored 200 yards North of it, from which will be shown two lights, the upper one *red*, and the lower one *bright*. A fog-bell was sounded during thick weather at the pile lighthouse, and we presume is still used on the junk.

Wusung Light and Left Bank.—The western side of the mouth of the river has a grassy embankment pierced with embrasures, with a ruin at the point of entrance called Fort A. A quarter of a mile above Fort A is Wusung lighthouse, a square tower of brick, 45 ft. high, with a total height of 58 ft. It exhibits a *fixed light*, showing *bright* from the river bank N.W. of the lighthouse to N. $\frac{1}{3}$ W.; *green* on the North side of the navigable channel between N. $\frac{1}{3}$ W. and N.E. $\frac{3}{4}$ E.; *bright* over the navigable channel of the entrance between N.E. $\frac{3}{4}$ E. and E. by N. $\frac{3}{4}$ N.; and *red* over *Lismore* wreck and the South side of the navigable channel between E. by N. $\frac{3}{4}$ N., and the bank of the river. It is elevated 50 ft. above the sea, and in clear weather the white light should be seen from a distance of 12 miles, and the *red* light, which also shows over the Yangtse to seaward, about 8 miles. The illuminating apparatus is dioptric, of the fourth order, and the tower is painted black.

A yellow joss house with poles about a mile above Fort A marks the village of Wusung, situated on the northern side of the creek leading to Suchau, and another mile up is the French coal depôt and flagstaff, and just

above the latter the Chinese customs' station, a conspicuous square white building surmounted by a turret and knob, and in front of which is the mast or signal staff, from which is exhibited, by flags and balls, the depth of water on the inner bar. Abreast and just above the custom house is the best anchorage for vessels intending to remain, in which case they should moor, but quite clear of the fairway of the bar, in order to avoid the risk of collision, as the flood tide sweeps along this shore, requiring rather a sharp turn to be made to cross the bar. Vessels waiting for tide only to cross the inner bar should anchor lower down off Wusung.

The East bank of river at the entrance is very low and not approachable, being the shallow side of the river, and bordered by mud flats, which to the northward extend nearly a mile. Here several ships have been wrecked. Over these flats the Wusung light shows red. At the outer point is Fort B, a small ruin, from which upwards the margin of the shore is reedy as far as Pheasant Point, a sharp elbow, about a mile above; this point is steep-to.

The Inner Bar is above Pheasant Point, and appears to be formed by the eddy which that point causes on the flood. It presents no obstacle to vessels drawing 11 ft. water, for the passage over it, with that depth at low water springs, is two cables broad. But for another foot of depth the channel is very narrow, a matter of importance to vessels of deep draught crossing. Its entrance is abreast or immediately above the custom house, and the leading mark for the best water, 12 ft. at low-water springs, is two poles on the bank of the river, $1\frac{1}{4}$ mile above Pheasant Point, kept in line E. $\frac{3}{4}$ S. The front pole is a low one, with a pyramidal top; the back one, a little removed from the bank, is a high pole with a rectangular top. At night a *red* low light is exhibited on the river bank, with a high *white* light on the low pole behind it, indicating the same line of direction. These lights are visible 2 miles in clear weather. The bar channel shifts occasionally, and varies slightly in depth.

Any deep draught steamer requiring to cross the bar at night, may, by making application to the officer in charge of the customs' station, arrange to have a light hoisted on the signal staff, to show when there is water enough for her to cross.

Inner Bar Signals.—The depth of water on the bar is shown, during daylight, from the flagstaff, 100 ft. high, at the custom house. In clear weather these signals may be seen by vessels over the land before crossing the outer bar. The flag employed is square, half red and half white, in combination with one or more black balls, distinguishing the depth, as follows:—

* The code (coloured) can be obtained at the Harbour Master's office, Shanghai.

Red next mast, no ball	13 feet.	Red over white, black ball under	18 feet.
Same , black ball over	24 ,,	White next mast, no ball	15 ,,
Same , black ball under	14 ,,	Same , black ball over	23 ,,
Same , balls over & under	25 ,,	Same , black ball under	16 ,,
Same , two balls under	26 ,,	White over red, no ball	19 ,,
Red over white, no ball	17 ,,	Same , black ball over	21 ,,
Same , black ball over	22 ,,	Same , black ball under	20 ,,

In addition, a double cone is hoisted at the cross trees when the water is rising.

Extending from the Inner Bar 2 miles up the river is the *Middle Ground*, a shoal which divides the river into two channels, and which is rapidly increasing in height. A great portion is visible at half-tide, and a considerable patch of reeds, Gough Island, never covers. Between it and the eastern bank of the river is the narrow ship channel leading to Shanghai. *Junk Channel*, S.W. of the Middle Ground, saves half a mile in distance, but its upper end, at the tail of the Middle Ground, is very narrow, with only 6 or 8 ft. at low water, so that it should only be taken with a rising tide.

Above the Middle Ground the banks are of the same low character as at the entrance, and there is nothing deserving of more particular description than can be mentioned in the subsequent directions.

Tides.—At the entrance of the Wusung River it is high water, full and change, at 0^h 30^m; springs rise 15 ft., neaps 10½ ft., and neaps range 6 ft. At Shanghai it is high water, full and change, at 0^h 40^m; springs rise 10 ft., neaps 7 ft., and neaps range 6 ft. Vessels drawing 18 ft. can cross the Inner Bar at any high water, but if of larger draught they will generally have to wait for spring tides. The greatest draught ever brought up to Shanghai was H.M.S. *Imperieuse*, drawing 24 ft., but a vessel of that draught would have to wait for the springs to pass either up or down the river.

DIRECTIONS.—As pilots are always in attendance at the entrance, it would not be prudent for a stranger to enter Wusung River without one, for its shoals are constantly undergoing changes from the alluvial deposits. Approaching the entrance, a peaked tower or Pagoda near the small walled town of Paushan, and just seen over, will be observed to the westward, and this pagoda must be kept W. by N. ½ N. (but nothing to the northward of that bearing) to clear the shoals off the river's mouth, until the Wusung lighthouse is brought S.W. by W. ½ W. westerly, on which course vessels should steer in over the bar by day; at night the white light is visible over the channel, a change to red or green denoting that a vessel is out of the channel and in danger. In entering pass close eastward of the Wusung buoy (leaving it on the starboard hand), for the deep-water channel here is narrow, and composed of hard substances. After passing the Wusung buoy on the ebb tide, it is necessary to be careful that a vessel be not set too near the South bank, which shoals very suddenly and is rocky.

Standing into the river, keep well over to the western shore, and keep it aboard as far as Wusung Creek, when a mid-channel course may be steered rounding *Pheasant Point*. Vessels, except of very shallow draught, should never be tempted by the apparent breadth and clearness of the channel to pass on the East side of the junks, which sometimes lie thickly anchored in the fairway below Wusung, but should pass through the midst of them or by the western shore, which is steep-to.

As vessels of large draught are obliged to cross the Inner Bar at high water, whilst the flood tide is still running strongly, care must be taken to alter course in good time, say, when the beacon poles bear E. by S. $\frac{1}{2}$ S., and not to allow the high pole to come to the southward of the low pole, for they are very close together. This caution applies with peculiar force to sailing vessels, for the flood sweeps up the river and towards the Middle Ground with great strength, 4 knots at springs and 2 knots at neaps. If intending to wait for high water, be careful not to anchor too near the bar, and if the vessel is of large draught, it will be better to anchor below Wusung, so as to give plenty of time and room to turn the ship; for with a strong flood a vessel may be abreast the bar before her head is the right way. No vessel of any size should attempt to pass through the junks or across the bar in light winds if the tide is running strongly; and it should be borne in mind that both flood and ebb streams continue to run at least an hour after the time of high and low water by the shore.

To cross the Inner Bar in the deepest water, 12 ft.* at low water springs, bring the high and low beacon poles in line (or at night the white and red lights), E. $\frac{3}{4}$ S., and when over the bar close the shore to three-quarters of a cable, altering course as requisite so as to preserve the same distance along the East bank of the river up to Black Point, 3 miles above Gough Island. The narrowest part of the channel is abreast Gough Island, the dry part of the Middle Ground, but at this part the river bank is very steep.

Black Point, which is halfway to Shanghai, serves as a guide in passing up the river, to ascertain the vessel's position, the banks being exceedingly low and flat, so also does the old earthwork at the mouth of a creek a little higher up. Here the eastern shore must be kept well aboard, as a shelf stretches two-thirds across from the opposite side; the creek, however, should not be passed within a cable. Continue along the East bank at a moderate distance until the houses of the foreign settlement at Shanghai are in full view, and after passing the lower wharves, if not intending to anchor to wait for the ebb tide, edge over W. $\frac{3}{4}$ N. towards the opposite shore,

* Vessels passing Gough Island are cautioned to keep in mid-channel as a bank has been found to extend about half a cable off the mouth of a creek, 1,720 yards S.E. by E. $\frac{1}{2}$ E. from the high beacon of the Inner Bar. In mid-channel at low water the least depth obtained in November, 1877, was 25 feet.

steering for the new dock well below the American Church, distinguished by its square tower, and keep well on that side the river until Suchau Creek opens, when the course is mid-channel, round Putung Point.

In the lower part of Shanghai Reach fishing boats constantly anchor in a line across the river, but a passage is always kept clear for vessels. A vessel will generally pass southward of the shipping which lie in the upper part of this reach.

Vessels going up with the last of the flood generally anchor below the shipping, and remain till the ebb stream makes down, which does not take place till $1\frac{3}{4}$ hour after high water by the shore; the flood stream makes about an hour after low water. Steamers, therefore, or sailing vessels with a commanding breeze crossing the Inner Bar at high water or with a rising tide, will find the flood stream still strong in Shanghai Reach, which is often so crowded with shipping that it would be almost impossible to pass through without collision; and pilots are not allowed to bring a vessel up beyond the lower anchorage until they have ascertained from the harbour master where her berth is to be. Tugs are now available for hire, by the employment of which the risks of collision, before so frequent, are in a great measure averted.

The space in front of the British Consulate, at the entrance of the Suchau Creek, is generally clear of vessels, and always looks inviting, especially at slack water, but it should be avoided, as the chow-chow water, caused by the sharp bend of the river at Pootung Point, renders this locality insecure as an anchorage. The holding ground also is indifferent, the anchors are liable to come home, the water is 8 to 15 fathoms deep, and a vessel is constantly swinging round and round, so that whilst endeavouring to moor, before the swivel can be got on, she may have taken several round turns in her cables.

The best berths are abreast and above the Chinese custom house, along the West bank of the river on which the city stands. The tides here run with regularity and with less strength, and a fairway along the eastern bank is left clear. Vessels ought to be moored with at least 36 fathoms on each cable, and a mooring swivel should be invariably used. A heavy fine is imposed on vessels neglecting this precaution. It is necessary to moor taut, as the anchors are generally found to come home after some time, and great care must be taken in laying the anchors, especially in long ships, in order to ensure a clear berth.

There is a regular berth appropriated for the British senior naval officer's ship; the mooring buoy is off the custom house in $9\frac{1}{2}$ fathoms.

SHANGHAI is situate on the left bank of the Hwang-pu, 12 miles above Wusung. Vessels of 24 feet draught can sometimes be taken up to the settlement at spring tides, but there is no trade above Shanghai in foreign bottoms. The port of Shanghai extends to Wusung, and the anchorage for foreign vessels, called the harbour, extends for 4 miles down the river.

This is under the regulation of the harbour master, an officer appointed by the Chinese authorities, who retains a complete conservancy of the harbour, its dues, customs, and duties, a condition which was ratified at the Treaty of Tientsing in 1858. The harbour is divided into nine sections (from Upper Limit, about a mile above Suchau Creek, where a mark is placed defining the foreign boundary), in which vessels lie three abreast, and lettered according to their positions.*

Shanghai, it is well known, is the most important centre of foreign commerce in China. It has risen within a quarter of a century from the insignificant rank of a third-class city to the fame and wealth of one of the chief commercial emporia of the world. It was always a considerable place of trade, from the fact of its being the nearest seaport to the great city of Suchau on the Grand Canal, 45 miles to the westward. Situated on the delta of the Yangtse, and having water communication with the whole empire, its site is most commanding. Its name signifies "Upon the Sea," and although it is now 25 miles from the coast, Chinese annals state that it was once upon the seashore, and the low land which now intervenes has been gradually formed by alluvial deposits. For 50 miles around the city there is water communication with the interior in every direction by the numerous creeks which intersect the neighbouring plain.

The foreign settlement is entirely distinct from the native city in its boundaries, government, and commerce. The French concession is northward of and contiguous to the city. The British concession, which includes all the other European communities and consulates, lies between the Yang-king Pang and the Suchau Creek, and here stands the British consulate, a large square building near the bridge which crosses the latter creek.

The quay along the river side in front of the palatial residences of the foreign consuls and merchants, nearly a mile in length, is called the Bund, in the centre of which, recognisable by its Chinese architecture, is the custom house, presided over by the foreign inspectorate. In this building are the offices of the harbour master, and of the engineer who has the superintendence of all matters connected with lights, buoys, beacons, &c. The custom house possesses the only wharf at this part of the settlement where cargo boats can load or discharge at all times of tide.

The American concession, locally known as Hongkew, extends a mile up the lower bank of Suchau Creek and along the river side eastward, where are situate two of the principal docks, the Sailors' Home, and many of the leading firms of Shanghai. The Pootung side of the river opposite the settlement is also common to all foreigners. At the point is a look-out house 130 ft. high; the British cemetery is a little below, and above is the

* Thus:—S Shantung side, C centre, P Putung side, O L outside limit; a list is published daily in the *Shipping Gazette*, so that any vessel in the river can be easily found.

large engineering establishment of Messrs. Muirhead & Co., and the finest dock in Shanghai.

Time Gun.—A gun is ordinarily fired from the senior naval officer's ship at mean noon precisely, a red and white triangular flag being previously hoisted. Vessels can also have their chronometers rated by various firms on shore. The best observing place is the British Consulate, near the flagstaff, in lat. $31^{\circ} 14' 42''$ N., long. $121^{\circ} 28' 55''$ E.

Docks.—There are three large docks at Shanghai. Two of them, docks A and B, also known as the Old and New Docks, lie at Hongkew,* on the left bank of the river, about half a mile apart. They belong to the Shanghai Dock Company, and their dimensions and depth of water are as follows:—

Dock A—Length over all, 374 ft.; breadth, 60 ft.; depth over sill at springs, 18 ft.; depth over sill at neaps, 13 ft. *Dock B*—length over all, 385 ft.; breadth, 52 ft.; depth over sill at springs, 14 ft.; depth over sill at neaps, 9 ft. Every appliance for repairing iron or wood vessels and machinery is on the premises.

Muirhead's Dock is on the Pootung side, opposite the city. Its dimensions are, length over all, 380 ft.; length on blocks, 340 ft.; Width at top, 125 ft.; width of dock entrance, 75 ft.; depth on sill at springs, 21 ft.; depth on sill at neaps, 16 ft.

There is also a complete engineering establishment attached, where all repairs of vessels and machinery can be effected.

Trade, Supplies, &c.—Independently of an enormous traffic in general merchandise, the characteristic feature of Shanghai is the export of silk, for which staple this is the main entrepôt, and since the opening of the Yangtse, the trans-shipment of tea brought down from Hankow by steamer or of imports and Chinese produce for the various river and northern ports cause a great concentration of foreign shipping here.

Shanghai *water* is very impure and sometimes brackish, containing a large quantity of organic matter, and its use is a fertile source of sickness to the crews of vessels. If obliged to use it, the grosser particles may be precipitated by a small quantity of powdered alum. Water is sometimes procured from the Ta-hoo lakes and sent on board for 5s. a ton. If good water cannot be procured in the hot season, condensed water should be used if cholera is prevalent.

Provisions are plentiful and moderately cheap, and the markets are well supplied with beef, mutton, game, fish and poultry. Vegetables are considered unsafe articles of diet, in consequence of sprinkling them during cultivation with liquid manure, and the fruit is of poor quality; for these rice is the best substitute.

* Also spelt Honque.

Coals for men-of-war are sent alongside from the naval store in lighters and put aboard by coolies under contract with the Chinese.

The general hospital is on the French Bund. Seamen are received into the third class wards at a charge of $1\frac{1}{2}$ Mexican dollars per day, which covers all expenses necessary for medical treatment. For the two higher classes of wards $1\frac{1}{2}$ and 3 taels per day are charged respectively.

CLIMATE.—The advantage enjoyed by Shanghai from its position in the temperate zone of China is in a great measure neutralised by its low-lying site, scarcely raised above the level of the river, and exposed to noxious marshy exhalations.

Crews of ships stationed at Shanghai suffer both from the malarial influences of the climate and the impurity of the water, especially in the hot season, when fever, dysentery, and cholera generally prevail, at which time precautionary measures are found to be instrumental, in a great degree, in staving off fatal results. Frequently, under double awnings, the temperature rises to 95° by day, remaining above 85° during the night, and at midsummer, for a period of two to three weeks, it often rises much higher. This is the most trying period, and many cases of sunstroke then occur. In July, 1863, the native population were dying of Cholera at the rate of one thousand a day, It is therefore of the highest importance that officers in command should be prepared to adopt needful precautions. Properly filtered water is indispensable to health, and when mixed with oatmeal, for drinking purposes, has been found to be very beneficial. Rigid attention to diet should be strictly observed, excesses of every kind being in the highest degree prejudicial. There is published in the "Treaty Ports of China," page 394, from the pen of the late Dr. Henderson, an article on health, which contains most valuable reflections on that important subject, the preservation of health in China, which is well worthy the perusal of officers stationed at the ports. Without entering into particulars it may be stated that not more than half the amount of food is required to sustain the vital energies in the hot months as during the cold, that then the food cannot be too simple, and that extreme moderation in, almost abstention from, the use of fruit and vegetables in season is necessary, indulgence in them being incompatible with health, rice being quite sufficient for all purposes of nutrition. During summer and autumn the power of the digestive organs is weak, and a moderate indulgence in stimulants is requisite, but iced drinks during meals are very injurious. Tea is far too little used; it has a gently stimulating influence, and is not followed, as in the case of alcoholic drinks, by a corresponding depression. It is tonic and astringent, and its use and that of coffee excite respectively the nervous and cerebral functions. But above all things, after a lengthened stay, change to a more bracing climate is essential to the due preservation of health

Winds and Weather.—By a meteorological register kept at Shanghai, the prevailing winds from 1848 to 1854 appear to have been as follows:—

January	- N.E. to N.N.W. and generally N.N.W.	May	- - E.S.E. to S.S.E.
February	- N.E. to N.W. and generally N.W.	June	- - S.E. to S.S.E.
March	- N.E. to S.E. and vari- able.	July and August	S.S.E.
April	- E.N.E. to S.E. chiefly S.S.E. and variable.	September	- N.E. to E.
		October	- - N.E. to N.W.
		November	- N.W. and variable.
		December	- N. to N.W.

January is in general fine at Shanghai. In February, thick fogs occur. March is damp and disagreeable. April has more rainy days than any other month, except June, which is the wettest month. In May there is but little rain, and that little occurs in heavy showers. July is hot, dry, scorching, with considerable rain in the form of evening thunder-showers. July and August are the hottest months. In September the S.W. monsoon is wholly broken up, and the temperature is very changeable. In November the winter fairly sets in, the first frost appearing from the 12th to the 20th. December is the driest month of the year, and the weather clear and freezing, though fogs are of occasional occurrence. In May, June, and July fogs also occur.

The summer gales are strongest from the S.E., and generally give good notice, the barometer beginning to fall sometimes as much as 24 hours previously. The rules for judging the barometer on the Chinese coast generally hold good for the neighbourhood of Shanghai; a rapid fall betokens a gale, and a high range the continuance of northerly winds. Typhoons rarely occur. In August, 1871, one passed over travelling to the north-westward, the greatest force of wind being 9. Commencing at N.E. the wind shifted to W.N.W. and S.W. Many vessels afterwards arrived either totally or partially dismasted.

WUSUNG TO HANKOW.

The navigation of the Upper Yangtse must be manifestly conducted with much local and recent knowledge. The Admiralty directions for this portion will therefore not be given, as the changes in the river channels alone would render them of little value after any time has elapsed. Many difficulties and troubles have arisen, so that in June, 1866, the following letter was sent to Lloyds by their agents at Shanghai, Messrs. Dent and Co.—

Many disasters have occurred to tea ships that have gone to Hankow this season of 1866. These disasters are so serious that we think the attention of the underwriters and shipowners should be directed to the dangers attending the navigation of the Upper Yangtse for sea-going ships.

During the winter months the river falls so low that in some places the river steamers find only 10 feet of water; the channel is continually shifting, forming shallows and banks where a few weeks previously was deep water; thus the lightship on the Lang Shan crossing, one of the most difficult parts of the river, had recently to be moved half a mile. The water begins to rise towards the end of March, but sometimes falls again till the middle of May, and from that period till the end of July the rise goes on steadily with a very strong current. It follows, therefore, that ships can only go up and down with any degree of safety when towed by powerful steamers, adapted to take the vessels alongside, and in charge of captains and pilots continually employed on the river.

It is, however, not only the passage up and down that is attended with danger; there is also great danger to ships while at anchor off Hankow, owing to the strength and eddies of the current, caused by the proximity of the anchorage to the mouth of the River Han; this season the current has been unusually strong (6 to 7 knots) and hence the greater number of accidents.

CHAPTER XXIV.

FROM THE YANGTSE KIANG TO THE LIAU-TUNG GULF.

The great length of coast described in the present chapter, about 1,000 miles in extent, was very little known to Europeans till within the last few years. The early visits of the British embassies to China had added little to the information given by the Jesuit missionaries, and it is only since the warfare which led to the treaty of Tientsin, that hydrographical knowledge of the coasts has been obtained. The low shores of the province of Kiang-tse, the southern portion of the great delta of the Hoang-ho, is still a *terra incognita* barred from access to shipping by vast ranges of shoals, extending 80 or 90 miles off the dry land, but which, as is the case with most other diluvial areas, is probably intersected by numerous channel, which must for all time be most difficult to navigate in the absence of buoys and marks.

The Tung-hai, or *Eastern Sea* of the Chinese, although recognised by geographers, is scarcely known by that name to navigators. It comprises the space lying between the Yellow Sea and the Pacific, being separated from the former by an imaginary line joining the mouth of the Yangtse and the Korea, and from the latter by the chain of islands stretching from Kiusiu (Japan) to Luchu and Formosa. Its climate is temperate, though subject to gales and occasional snow storms in winter; the summer season is fine, and it is not within the limit of the typhoons. Its currents, beyond the influence of the Yangtse and coast tides, seem to be irregular, except in its eastern part, through which the Japan stream flows north-eastward from Formosa towards the Pacific along the southern shores of Japan, and northward with some regularity, especially in the summer season, through Korea Strait.

The Whang-hai, or *Yellow Sea*, is bounded on the West by the deep bight of the coast formed between the Yangtse and the Shantung promontory, and on the East by the coast of Korea. This sea was little frequented by foreign vessels previous to 1858, but since that year all the prominent features of its coast have been surveyed or examined, and the dangers of it are now sufficiently well known, to answer the requirements of safe navigation

between the treaty ports of China and Japan. The Korean coast and 200 miles of an unapproachable shore North of the Yangtse still remain unexplored, but they are rarely approached by the mariner, and it is to be hoped that a better knowledge of these localities may lead to the discovery of some new harbours, of which the coasts are somewhat deficient, although there are many excellent anchorages. There is a considerable coasting trade carried on principally with Shanghai, Ningpo, and Tientsin, and also with Ta-kusan in the Korea.

Gulfs of Pe-chili and Liau-tung.—The head of the Yellow Sea branches out into a double-headed gulf, one head extending to the West 150 miles, the other about the same distance to the N.E., forming a great inland sea, known to the Chinese as the Peh-hai or North sea. The southern part of this sea has received from foreigners the name of the Gulf of Pe-chili, and the north-eastern part that of the Gulf of Liau-tung. At its entrance the coasts approach within 55 miles of each other, and the space between is called Pe-chili Strait, the southern part of which is occupied by the Miautau group.

The shores of the Gulf of Liau-tung were almost a *terra incognita* to Europeans until the year 1793, when H.M.S. *Discovery* and *Alceste* navigated its southern portion and anchored in Halu-shan Bay. In August, 1855, H.M.S. *Bittern* sailed along the eastern coast and anchored in Fu-chu Bay and off the port of Newchwang. Subsequently, in July, 1859, a survey was made by Commander J. Bythesea, H.M.S. *Cruiser*, and Major A. Fisher, Royal Engineers, of part of the western coast from the Great Wall of China to the Chi ho, 25 miles South of the Pei ho. The remaining shores were surveyed in the fall of the year 1860 by Commander J. Ward, Lieut. C. Bullock, R.N., and officers of H.M.S. *Actæon*, *Dove*, and *Cruiser*.

The Gulf of Pe-chili borders the north-eastern margin of the great plain along the shores of the provinces of Shantung and Chili, receiving several rivers, chief amongst which is the Yellow River. At its head is the entrance of the Pei ho, on which river stands Peking, the capital of the empire, and also the opulent city and treaty port of Tientsin. The Gulf of Liau-tung is the continuation of a great valley of Manchuria, lying between two mountain chains in the province of Shing-king or Liau-tung, which encompasses its sides. The Liau ho falls into the head of this gulf, on which river, at its entrance, stands Yingtze, the treaty port of Newchang.

WINDS and WEATHER.—The climates of the Eastern and Yellow Seas are in most respects identical, although there is considerable variation between their remote extremes, viz., the region about Formosa and Lu-chu in the one and that of the coast of Shantung in the other.

In the Yellow Sea, near the coasts, the winds throughout the greater part of the year are local. Between Shanghai and the Korea, and almost em-

bracing the Shantung promontory, in December and January, it blows almost constantly from the N.W. (seldom ranging beyond North and W.S.W.), with gales of long duration from North to N.W., sometimes with fine, but generally with overcast, gloomy weather attended with rain. Towards the China coast the wind follows more the trend of the shore, and between Shanghai and the Gulf of Pe-chili, Captain Goodenough, of H.M.S. *Renard*, which ran the mails in that season, states that a fresh N.N.E. wind blew almost incessantly until the end of February, when it veered more to the eastward. There are, however, breaks in this regularity. Snow is rare at Shanghai, but the mountains and coasts of Shantung and the Korea are covered with it in January, February, and part of March, and high lands remain covered later.

In the Eastern Sea, in the spring and until June, moderate winds from East prevail, bringing rain and drizzle, generally when the wind veers a little to the northward, also occasional stiff N.E. breezes; S.W. winds occur but rarely, but bring fine weather for short intervals. Later in the season the winds are variable, inclining chiefly to S.E., with occasional N.W. breezes. Towards Japan it is recorded that westerly winds prevailed at the end of July. Early in September, the winds prevail between E.N.E. and South, and strong easterly gales have been known, but are very unusual.

In the Gulfs of Pechili and Liau-tung it appears that the climate is temperate and agreeable in summer, and severe and stormy in winter, but the latter is of only four months duration. The coasts are then covered with snow, which begins to melt in March, snow storms occurring as late as the end of February, and showers until the middle of March, when the winter season breaks up. At the head of the Gulf of Liau-tung the ice lasts $4\frac{1}{2}$ months, from the middle of November to the end of March.

A dry season then commences, with scarcely any rain during the summer months; light winds, exceedingly variable and of short duration in any quarter, prevailing. About the autumnal equinox, there are symptoms of unsettled weather, and westerly winds prevail, with occasional short gales.

TIDES and CURRENTS.—The tidal wave appears to come in to the Yellow Sea from the south-eastward in the form of a tongue, making high water at the Shantung promontory only 2 hours later than at Gutzlaff Island, although it is several hours later on the intermediate coasts. The rise at Gutzlaff is 15 ft., but at the promontory only 6 ft.; whilst opposite on the Korean coast it rises to 20, and in one place even 30 ft.; a phenomenon almost exactly similar to that which occurs in the English and Irish Channels.

The flood sets West, and the ebb East, along the Shantung coast, to within 100 miles of the ancient or southern outlet of the Yellow River; but the rotatory tides of the Yangtse have been observed off shore, 120 miles North of the latter. In lat. $33^{\circ} 15' N.$, long. $122^{\circ} 16' E.$, 70 miles from the coast,

and 127 miles North (true) of the Ariadne Rock, it was high water, full and change, about 1 o'clock, and the rise and fall about 9 ft. During the whole rise and fall of the afternoon tide, it set from N.N.W. to N.N.E. at a maximum of nearly 2 knots, and being nearly slack for two hours; and during the whole a.m. rise and fall, it set weakly to the southward for 13 hours; making one complete revolution in 24 hours. These tides were observed in December, and are recorded chiefly with the hope that more light may be thrown upon them by others. A stiff S.W. wind was blowing at the time, which may account for the weakness of the southerly current, as it is well known that in the northerly monsoon the southerly set predominates.

The **YELLOW RIVER** or **WHANG HO** is little inferior to the Yangtse in magnitude, being nearly 2,500 miles in length, but beyond 250 miles from the sea it is totally unnavigable, and is alike, at present, the most useless and impracticable river in the world. Flowing through the midst of a densely peopled and highly cultivated country, this remarkable river offers no facilities for navigation throughout a great extent of its course, and it has gained the apt and striking name of "China's Scrow," on account of the exposure of the great plain (which its lower course traverses) to disastrous inundations, which are a perpetual source of wasteful expenditure to the government and of peril and calamity to the people. It is but little used by the Chinese for navigation, and the cities on its banks are in constant jeopardy of being submerged. Foreign skill and science are necessary to teach the people how to restrain its fury, and western steamers alone can stem its impetuous current and make it a channel for commerce.

Between the Yangtse and Yellow Rivers the coast for 150 miles is low, and intersected by numerous streams. The Grand Canal connects the two rivers at their nearest point of approach to each other, where they are only 75 miles apart. The canal is raised considerably above the plain at Whaingan on the Yellow River, a little below the Hungtse lake, and 45 miles above the river's mouth, and thence falls to the level of the Yangtse at Chin-kiang fu.

The whole of this low coast is fronted by extensive flats and shoal banks, projecting in some places above 60 miles from the land, and rendering the approach dangerous for vessels of large draught until better known, although there may probably be channels among the banks in the neighbourhood of the coast frequented by the native trading vessels. They all lie West of the meridian of 122° E., except off the northern entrance of the Yangtse and Tsung-ming. H.M.S. *Highflyer*, July, 1859, had soundings of 12 fathoms, abreast of and 100 miles from the mouth of the Yellow River.

On various Chinese maps four hills or islands are represented at from 30 to 50 miles northward of the Yellow River entrance. Two of these were sighted by the *Dove* on making the coast in December, 1861, and their positions approximately fixed. The north-eastern one is in about 35° N., long. $119^{\circ} 40'$ E., and probably agrees with the Chinese *Ying-yu-mun*. It is about

a mile in extent, has a flat rugged top with abrupt sides, as if of sandstone formation, and is 100 or 200 ft. high.

A smaller islet or rock, of conical shape, probably the Chinese *Nai-nai-shan*, was also seen from the mast-head, about 10 miles S.W. of Ying-yu-mun. If the other two exist, they are *Mun-li-shan* lying South of Ying-yu-mun, and *Kai-shan*, S.E. of it and the more distant of the two. To the South and East of Kai-shan (probably Yu-chu of the Admiralty chart), and between it and the Ta sha, many ridges of sand are delineated on a Chinese map.

The coast North of these islands, though not steep-to, may be approached with a proper degree of caution. The water is clear (as to sedimentary matter), and the bottom gravelly to the northward of the banks above mentioned.

The southernmost point of the coast of Shantung approached by a European vessel is in lat. $35^{\circ} 10' N.$, long. $119^{\circ} 18' E.$ The shore here is low and undulating, with detached hill ranges, 1,000 to 1,500 ft. high, which recede from the coast at a point 10 miles North of this, and were also seen stretching to the southward, to within 60 miles of the Yellow River. A track survey only was made from this to Kyau-chau Bay, and many of the names on the Chinese maps could not be identified.

The character of the whole of the shore, hereabouts, is generally low at the coast line, with projecting reefs; there are sandy bays between the points; and isolated hills standing on low plains, which gradually attain toward the northward the altitude of mountains.

Tower Point, in lat. $35^{\circ} 20' N.$, is so named from a conspicuous square tower standing on a low hill. The point is low and rocky, and two reefs extend a considerable distance off it, but they may be passed at a mile in 7 fathoms. There are also reefs of considerable extent skirting the coast for 6 miles North of Tower Point. About N.W. by W. 12 miles and N. by W. 6 miles from the point are two conspicuous isolated hills, 6 miles apart, respectively 1,000 and 800 ft. in height; that nearest the coast slopes towards the sea, and terminates eastward in a bluff, which is the southern point of entrance of a large open bay 9 miles across and 7 miles deep, the north-eastern point of which is low and very rocky, with an island off it similar in character. West 3 miles from the latter point a reef was seen fully a mile in extent, and beyond it, under some low cliff-sided hills on the North shore of the bay, is a junk anchorage.

North-east of this reef point is the anchorage of *Wang-kia-tai*, a long narrow bay affording shelter from North and N.E. winds in from 3 to 5 fathoms, mud. The temple of Lung-wang, on the shore of the bay, is in lat. $35^{\circ} 39' N.$, long. $119^{\circ} 48' E.$ The shores of the headland East of Wang-kia-tai are low and rocky, except on the sea coast, where there are two hills 600 and 400 feet high, the latter or south-eastern having a nipple on it.

Pinnacle Range, 1,600 ft. in height, is on the coast, about 11 miles N. by E. of Lang-yi tau. Between this and Lang-yi tau is a large bay with sandy shores. The next 13 miles of shore to the north-eastward has not been explored, but from thence to Staunton Island the coast has been regularly surveyed, commencing from the cape northward of Tolosan. Pinnacle Range would appear to be the Chinese Lingshan. *To-lo-san Island*, lying about N.E. by E. 15 miles from Lang-yi-tau, rises to an elevation of 1,700 ft.

Tcha-lien-tau, in lat. $35^{\circ} 54\frac{1}{4}'$ N., long. $120^{\circ} 53'$ E., is S.S.E. $\frac{1}{4}$ E. $16\frac{1}{2}$ miles from Cape Ya-tau, the nearest land, and E. by S. $19\frac{1}{2}$ miles from Tai-kung tau, off the entrance of Kyau-chau Bay. The island is 1 mile in length, N.E. and S.W., and very narrow; at its centre is a small even-topped hill, 182 ft. high, and its eastern end is a detached bluff.

Tai-kung tau is an island, 341 ft. high, 10 miles E.S.E. of Cape Evelyn, the South point of entrance to Kyau-chau Bay, and S.W. $\frac{1}{3}$ S., 16 miles from Cape Ya-tau. It is of smooth and rounded outline, and from all points of view greatly resembles a haystack. W.N.W. half a mile from it is a round islet, 103 ft. high; and W.S.W. 6 cables from the islet is a rock which covers at high water, surrounded by a reef extending 4 cables to the S.S.W., which at other times of tide is partly dry and partly awash. It is recommended to give this island a berth of 2 miles when passing westward of it.

Siau-kung tau, lying 5 miles E.N.E. from Tai-kung tau, and S.W. $\frac{1}{4}$ S. $10\frac{1}{2}$ miles from Cape Ya-tau, is a large, flat, square mass of rock, rising sheer from the sea to the height of 78 ft., and apparently bold-to on all sides, with 15 fathoms water at 3 cables' distance.

Round Island, 172 ft. high, lying South of the West point of entrance to Kyau-chau Bay, at 2 miles from the shore, is of semi-circular profile, and conspicuous on that account. About a quarter of a mile West of it, and connected at low water, is another island, larger, but only 100 ft. high, having a level top, and inhabited. Off the East side of Round Islet are two low islets.

Dangerous Rock, bearing N. $\frac{3}{4}$ E. 3 miles from the summit of Round Island, and S.E. $\frac{3}{4}$ S. $1\frac{3}{4}$ mile from the West entrance point of Kyau-chau Bay, is just covered at high water springs, and has deep water on all sides. At 1 mile W.S.W. of it, and half a mile off shore, is another rock which covers at 5 ft. rise of tide. Between these two rocks there is a passage of 13 fathoms water, with the point bearing N.N.W., but it is more prudent to keep outside or eastward of Dangerous Rock.

Swallow Bank, of 26 ft. least water and half a mile in extent, lies N.E. $\frac{3}{4}$ N., 4 miles from Round Island, and E.S.E. 3 miles from the West point of entrance. This bank appears to be formed by deposits from the bay. To pass North of it, keep the summit of Sishan touching Cape Evelyn W. by N. nearly. A good mark to lead between it and Dangerous Rock is the highest

and northern summit of Chi-po-san, touching Pile Point a little eastward of Cape Evelyn, about N.W. by W.

Wei Hai or Kyau-Chau Bay, the entrance of which is on the West coast of the Yellow Sea, in lat. $36^{\circ} 2' N.$, long $120^{\circ} 18' E.$, is a spacious harbour, and one of the best sheltered on the East coast of China, its area at high tide being about 140 square miles, and the anchorage perfectly landlocked. It is partially frozen over during the severe winter season.

There will be no difficulty in recognizing the entrance to this bay in clear weather, either when approaching from North or South, for at 17 miles eastward of it, the *Loshan Mountain*, which is 3,530 ft. high, and extends North almost the same height for a mile, forms an unmistakable landmark. On a nearer approach the rugged top of the *Lungshan Mountain*, 1,146 ft. high, will appear as a prominent and singular feature, and a little farther westward, and immediately over the North side of entrance, is *Nubble Hill*, 490 feet high, with a large stone on its summit. At 11 miles westward of the entrance, the *Tamo-shan*, or *High Double Mountain*, of smooth outline, rises to the height of 2,249 ft., and is very conspicuous, showing a double summit from the eastward; this range runs North, and meets the summit of Sishan, a mountain 1,096 ft. high. At 3 miles W.N.W. from *Cape Evelyn*, the South point of entrance, is *Chi-po-san Island*, which is the first low land recognized after passing the entrance.

Bay Rock, covering at 3 ft. rise of tide, lies W. by N. $\frac{1}{2}$ N. $1\frac{1}{2}$ mile from Cape Evelyn, and S.W. $\frac{3}{4}$ W. nearly 2 miles from the South point of Yunnui-san. This rock may almost be called a hidden danger, as it is covered at low water neaps. To pass North of it, keep Tai-kung-tau well open of Cape Evelyn.

Horse-shoe Rock is the most off-lying danger on the East shore of the bay, from which it is distant half a mile. It covers at 5 ft. rise of tide, and from its N.W. horn the West extreme of Yunnui-san bears S. by W. $\frac{1}{3}$ W. 2 miles, and the summit of Chi-po-san W.S.W. $3\frac{1}{4}$ miles. The summits of Tung-lau-shan and Gau-shan in line, and open westward of Woman's Island, N.E. $\frac{1}{2}$ E., lead 3 cables to the westward of it.

Woman's Island, 15 ft. high, and on the same shore of the bay, is nearly $2\frac{1}{2}$ miles S.W. $\frac{1}{2}$ W. from Gau-shan summit, and $2\frac{3}{4}$ miles N.W. $\frac{1}{2}$ N. from Nubble Hill. Its North and West sides are fringed with rocks, which dry at low water, and it is connected with the mainland by an extensive mud flat. At 4 cables S.W. by W. $\frac{1}{2}$ W. from the centre of the island is a rock which covers at 10 ft. rise of tide.

Supplies.—Almost any necessary supplies can be obtained at the village of Ching-tau-kow, which stands in a bight on the North side of entrance of Kyau-chau Bay, 1 mile West of Nubble Hill. Clear and good water can be obtained by digging above high water mark in the sandy bay on the East side of Chi-po-san and South of its summit.

Directions.—Vessels navigating in the vicinity of Kyau-chau Bay may soon find shelter in heavy north-easterly gales. Having made out the land, it will be best to hug the shore to insure smooth water, and, if necessary, anchorage may be found in 8 to 10 fathoms, muddy bottom, anywhere between the entrance of the bay and Lo-shan Harbour, which is S.W. of Lo-shan Mountain. The low islet *Chuen-si-san*, about 15 ft. high, lying three-quarters of a mile off the shore, in a S.E. direction from the summit of the Lung-shan Mountain, and 8 miles eastward of the entrance, should always be left to the northward.

The first anchorage where junks resort is S.E. 2 miles from Tungshan, on the North side of the entrance in Ching-tau-kau Bay. Small vessels can anchor amongst the junks, but vessels of large draught should anchor in 8 or 9 fathoms, muddy bottom, with the small island on the East side of the bay bearing about N.N.E. one-third of a mile.

The large bay on the South side within the entrance, between Cape Evelyn and Chi-po-san Island, which might be considered an outer harbour, affords excellent shelter from easterly winds, round South to N.W.

The coast eastward of Kyau-chau Bay, which extends E. by N. 22 miles and terminates in *Cape Ya-tau*, is the southern face of a mountainous peninsula, which is indented with several bays, and has many off-lying islands and reefs, but there is anchorage all along at a moderate distance from the shore, the soundings for the most part decreasing gradually. During the summer months it would be highly imprudent to anchor on this exposed coast, with the chance of being caught in a S.E. or easterly gale. In the summer of 1865 the winds from E.N.E. to S.E. were very frequent, at times blowing a hard gale, but these gales are seldom of more than 12 hours' duration. In winter the winds are from N.N.E. to N.W., chiefly in the latter quarter near the land, but in the former in the offing, although a S.W. gale of a few hours' duration, veering to South, is not unknown.

Supplies can be obtained from any of the villages along the coast at moderate prices. Grapes and pears are cheap and plentiful. Good bread can also be procured, and late in the season hares and wild fowl may be obtained. Water is not good. In Loshan Bay, in August, H.M.S. *Swallow* watered at a small stream N.W. of Boulder Hill, but the supply was poor, and it had to be carried a considerable distance in barricoes. Several cases of dysentery, one terminating fatally, were ascribed to this cause.

Cape Adkins, the north-eastern point of Loshan Bay, is a steep, cliffy head, the smooth summit of which, 239 ft. high, terminates a small range or ridge of hills running eastward of Boulder Hill. On the northern part of the cape, which is rather low, is a small square tower; the southern point of the cape is an abrupt cliff, bold-to. A small round islet, connected with the mainland at low water by a spit of shingle, lies 1 mile N.N.E. from the cape.

Ka-tih-niau, an isolated island, lies off Loshan Bay, 12 miles E. by N. of Cape Yatau, and about the same distance from Cape Adkins. From the other two islands in the offing, Teha-lien-tau and Surveyor's Island, it bears respectively N. by E. $\frac{1}{2}$ E. $17\frac{1}{2}$ miles, and W. by S. 22 miles. It is a small island, 243 ft. high, with a smaller island, about 100 ft. high, lying 3 cables S. by W. from it, with a passage between carrying 12 fathoms.

Surveyor's Island, 23 miles off-shore, is in lat. $36^{\circ} 16' 30''$ N., long. $121^{\circ} 24' 15''$ E. It rises out of 17 fathoms water, and is divided into two distinct portions by a narrow neck which is perforated; the southern and higher part, which is very rugged, being 297 ft. high. In the spring months this island is often obscured by fogs, which are very prevalent in the offing, although it may be quite clear along the coast.

The coast runs N.N.E. from Cape Adkins to Ting-tsi Harbour, a distance of 11 miles. The country is hilly, the shore mostly low, and not generally approachable on account of rocky and shallow ground, and it is fronted by several off-lying islands and reefs. *Cliff Island*, 121 ft. high, is N.E. by E. 3 miles from Cape Adkins, and S.W. of it is a low island, and another of less elevation to the westward. *Long Island*, half a mile N.E. of Cliff Island, is 180 ft. high. *End Island*, off the eastern point of Long Island, and connected with it at low water, is smooth and grassy, and 68 ft. high. *Outer Island* is $1\frac{1}{2}$ mile N.E. of End Island, and S.E. $\frac{1}{2}$ E. 6 miles from Temple summit, 820 ft. high. It is narrow, smooth and grassy, and 116 ft. high. *Outer Rock*, 24 ft. high, is on the middle of a reef, 2 cables in extent, which lies half a mile South of Outer Island. E. by S. a quarter of a mile from this, with the island summit N. by W., is a sunken rock, which generally breaks at low water. *Reef Island*, N. by E. $\frac{1}{2}$ E. 3 miles from Outer Island, is 30 feet high. *Anchorage* in 3 to 4 fathoms may be obtained between Reef Island and Outer Island, with shelter from S.W. winds; but there is no part of the coast for 36 miles North of Cape Adkins where there is shelter from winds between South and N.E.

Tingtsi River.—*Bar Island*, or *Tu-shing*, 99 ft. high and 2 cables in extent, is 7 miles N.N.E. from Outer Island. It has a round, grassy summit, presenting the same aspect from every direction, with cliffy sides fringed with rocks. It lies off the entrance of the *Ting-tsi River*, and as it is inside the sand banks of its bar, it should not be approached on passing within 2 miles. Ting-tsi River entrance has the appearance of a deep inlet. It does not appear to be much frequented, as only a few small junks were seen. On some Chinese maps the river is named Lih-ho. At the head of the inlet stands the town of Kin-kia, formerly an important trading place. The entrance, 4 miles westward of Bar Island, is about 3 miles across, but the navigable channel is less than half a mile wide, and subject to changes. *Green Head*, at the South point of entrance, is 4 miles W. $\frac{1}{4}$ S. from Bar Island. *River Islet*, 30 ft. high, is on the North shore, 1 mile northward of the narrow pro-

montory extending north-westward from Green Head. The river is barred by a long spit, 2 to 4 cables in width, which stretches in an E.S.E. direction from Green Head nearly 4 miles. The depth on it at low water is 4 ft. At high water springs a direct course can be steered in, with a depth of 15 ft., across the Bar Spit, with the summit of Green Head W. by N. $\frac{1}{4}$ N., and just open to the southward of the more conspicuous hill behind it, which mark also leads clear and to the southward of the sand-patch 1 mile W.S.W. of Bar Island, and which may generally be discerned by the discoloured water. When Bar Island is E. by N. $\frac{1}{2}$ N., haul up N.W. to pass between the shoals off Green Head and the narrow sand bank, very steep-to, which commences 1 mile W.N.W. of Bar Island, and extends in the same direction for 2 miles. River Islet may then be steered for, and good anchorage, perfectly sheltered, be obtained southward of the islet in 4 to 6 fathoms. But a greater depth of water, 7 ft. at low water and 18 ft. at high water springs, may be carried in by steering direct for Bar Island on a W. by S. course, and when at 2 to 3 cables' distance from the island changing the course to S.W. until the leading mark, given above, is brought on.

The Coast now changes its direction from N.E. by N. to E. by N., and continues in the latter direction up to the Shantung Promontory, a distance of 60 miles. For the first 12 miles the shore, as far as the town of *Hai-yang*, is low and sandy, broken in three places by projecting ledges of rock, stretching out some distance, and off the western of which, at 1 mile from the shore, is a detached reef; this shore cannot be approached, for the depth is only 3 fathoms at 3 miles distance. Three miles in-shore is seen a flat-topped range, 796 ft. high, and N. by E. 9 miles from Bar Island, a spur of which stretches towards the sea.

Sutherland Rock, lat. $36^{\circ} 41' N.$, is 24 ft. high, and lies 3 miles S. by E. from *Tau-tsui Head*, E. by N. $\frac{1}{2}$ N. from it is another rock awash at low water. *Tau-tsui Head*, $4\frac{3}{4}$ miles East of Arthur Head, is a bold headland at the extremity of a hilly promontory jutting out from the mainland for about 2 miles in a North and South direction. Between the rocks and *Tau-tsui* are even depths of 8 to 10 fathoms, decreasing to 6 fathoms when the promontory is passed. Outside the rock the ground has not been sufficiently examined, and it should not therefore be passed within a mile.

Staunton Island, or *Su-shan tau*, lying S.W. by W. 15 miles from the south-eastern point of the Shantung Peninsula, is $6\frac{1}{2}$ miles S.E. by S. from *Tsing-hai-wei Point*. The island is a ridge of steep hills, about a mile in length N.W. by W. There is a fishing village and landing place on its North side, directly under the centre hill, 353 ft. high, which is its highest part. There is also a landing place in a bay formed by a rocky promontory on the South side, with the summit bearing East.

Channel Rocks lie respectively N.W. by N. $1\frac{1}{4}$ miles, and N. by W. $\frac{3}{4}$ W.

$1\frac{3}{4}$ mile from Staunton Island, and are North and South of each other three-quarters of a mile apart.

Tides.—The following observations on the tides were made in 1865, during the survey of H.M.S. *Swallow*. It is high water, full and change, at Tau-tsui Head, at 3^h 20^m, and springs rise $12\frac{1}{2}$ ft. The flood stream in the neighbourhood of Staunton Island sets West, and the ebb East, at the rate of $1\frac{1}{2}$ mile an hour, which appears to be the velocity observed all along the coast, but between Staunton Island and Channel Rocks the rate is 3 knots. It may be stated as approximately correct, that on the southern side of the Shantung peninsula the flood stream sets westward, whilst on its northern side it sets eastward.

Actæon Shoal.—A dangerous shoal, lying southward of the Shantung promontory, was sounded on by H.M.S. *Actæon*, 19th February, 1860. The least depth obtained was 22 ft. in lat. $36^{\circ} 31\frac{1}{2}'$ N., long. $122^{\circ} 28'$ E. approximately, but less water probably exists.

As there is no reasonable doubt of the existence of this shoal (which is laid down on Chinese maps S.E. of Cape Macartney, North of the parallel of Staunton Island, and called the Siau-sha or small Sand-bank, vessels, particularly those of large draught, approaching its vicinity should keep a careful lead going, and as it may exist to the East, or more probably to the N.E. of the position assigned to it, they should at present not pass West of the meridian of $122^{\circ} 48'$ E., unless they pass inside or West of the position of the shoal.

SHANTUNG PROMONTORY.—A chain of high peaked hills, 2 to 3 miles in breadth, rises eastward of the sandy plain of Yung-ching, and running 6 miles in an easterly direction, forms the Shantung promontory. These hills when first seen from N.W. or S.E. make like a number of pointed detached islets of peculiar appearance. Five of them are very prominent; the highest, called *Tu-ching-shan*, 910 ft. high (which is also the Chinese name for the promontory) is the western peak; it is very pointed and precipitous, except to the North, on which side it has a gentle slope. *Sharp Peak*, 680 ft. high, halfway between this and the extreme of the promontory, is also remarkable, with deep valleys on either side.

SHANTUNG LIGHTHOUSE, built on the N.E. extreme of the promontory, in lat. $37^{\circ} 24'$ N., long. $122^{\circ} 42'$ E., is a circular white tower, 64 feet high. The light first exhibited in the year 1875 is a *fixed light*, showing *bright* to the north-westward between N.W. by W. $\frac{1}{2}$ W. and N.N.W. $\frac{3}{4}$ W.; *red* from N.N.W. $\frac{3}{4}$ W. to N. by W. $\frac{1}{2}$ W. over and eastward of Alceste Island; *bright* from N. by W. $\frac{1}{2}$ W. through East and South to S.S.W., and *red* from S.S.W. to S.W. $\frac{1}{2}$ W., to warn vessels that they are approaching the coast. The light is obscured by hill peaks between N.W. by W. $\frac{1}{2}$ W. and N. by W. $\frac{1}{2}$ W. and also by Alceste Island between N.N.W. and

N.N.W. $\frac{1}{2}$ W. The light is elevated 200 ft., and should be visible in clear weather 20 miles off.

Rodney Rock lies 4 cables from the shore off the N.E. end of Shantung Promontory. It is awash at low water, and lies in a direct line between the centre of the lighthouse and the eastern extreme (within the reef) of Alceste Island. From it the N.E. promontory bears S.E. by S., Abrupt Bluff, West, and the western extreme of Alceste Island, N.W. by N., 16 cables distant.

Alceste Island, or *Siau-ching-shan*, 210 ft. high, triangular in shape, flat-topped, and bounded by cliffs, lies $3\frac{1}{2}$ miles N.N.W. $\frac{1}{2}$ W. from the extreme of the Shantung promontory, and $1\frac{1}{4}$ mile off shore. A cluster of reefs extends 4 cables North from its East point, the outer reef of which is awash, but the others are higher. There is also a small pinnacle rock a quarter of a mile South from the same point, with a small rock awash close to the S.E. of it. The tides are strong inside Alceste.

Anchorage at Shantung Promontory.—The following are the safest and most convenient anchorages. From S.S.W. to S. by W. of Ears Rock, in 5 to 8 fathoms, with the Temple Saddle bearing E.N.E. In 5 to 6 fathoms in the bay between Ears Rock and Flat Rocky Point, avoiding the patches and reefs. At any part of Shang-kau Bay in 4 to 6 fathoms, and under Shu-atau Head in 5 to 7 fathoms, with shelter from N.E. winds. In Aylen Bay W.S.W. to S.W. by W. of Martha Point in 4 to 5 fathoms, or in the centre of the bay in 6 to 7 fathoms. In 6 to 9 fathoms, between Martha Point and Shantung Promontory; and in the northern part of Yung-ching Bay (only partially examined) in 4 to 7 fathoms.

Small craft can also find anchorage in Litau Bay, or the inlet on the South side of Chalk Saddle in 3 to 4 fathoms. There is no good anchorage on the North side of Shantung Promontory; but anchorage can be obtained off its north-eastern face in 5 to 8 fathoms, 2 to 4 cables from the shore; and also in the bay on its S.W. face, 1 mile from the extreme of the promontory, in 5 to 10 fathoms, with a rock or islet there bearing North, and the end of the beach under the rugged hill, W. by N.

Directions for passing Shantung Promontory.—Vessels bound to the northward into the Gulf of Pe-chili in the spring, are liable to pass Shantung Promontory in foggy weather, without making it. It has been generally observed that the effect of the tides is nearly neutral, as regards being set East or West in a two or three days' run; nevertheless, in rounding at such a time, a vessel's position may be ascertained if there is any doubt about it by constant use of the lead. In regard to the Actæon Shoal, circumstances of wind and weather should be taken into account in deciding on which side of it to pass, for it is clearly a danger for large vessels. Thick weather is not of unusual occurrence here, and this, together with the strength of the tidal streams, renders it prudent to keep the vessel's position fixed by cross bearing, as the coast between the promontory and Wei-hai-wei cannot

always easily be identified, and it sometimes becomes necessary to anchor at night.

Ki-ming Island.—From the high land of the Shantung Promontory a low sandy coast, broken by rocky points, trends W. by N. 14 miles to Wei-hai-wei. The island of Ki-ming or Nan-ming tau, 9 miles W. $\frac{1}{2}$ N. of Alceste, lies 1 mile off a rocky point which projects considerably from the shore. It is 370 ft. high, flat-topped, surrounded by extensive reefs on three sides, and joined to the shore by a rocky flat, over which are not more than 3 to 4 fathoms, but the island may be passed to the northward at 2 cables in 12 fathoms. A large lagoon (salt) opens into the sea eastward of this point.

Wei-hai-wei Harbour, 23 miles westward of Alceste Island, is formed between *Leu-kung-tau*, an island 510 ft. high, and a deep bight of the coast, and is the most eastern anchorage on the North shore of the Shantung peninsula. It is easy of access, and capable of affording shelter to a considerable number of vessels of moderate draught, but the anchorage is contracted for large vessels. It has two entrances, one on the West, the other on the East side of *Leu-kung-tau*, thus affording a facility for access or departure with almost any wind. The town of Wei-hai-wei stands on the side of a hill on the West shore of the bay. The western entrance, although much narrower than the other, has the deepest water, and should be used by all vessels drawing above 18 ft. Round Island and three or four adjoining rocks lie off the northern point of the western entrance. The outer rock, 15 feet high and steep-to, is three-quarters of a mile E.N.E. from the point; between it and Round Island is a rocky patch, which covers at high water. No other hidden dangers are known. At half a mile E.S.E. from the eastern end of *Leu-kung-tau* is a reef of rocks, steep-to, but as a portion of them always shows above water, they may be easily avoided. The best anchorage is near the West point of *Leu-kung-tau*, in 5 to 7 fathoms on excellent holding ground of mud, sheltered by the island from the N.E. In Wei-hai-wei harbour it is high water, full and change, at 9^h 30^m, and springs rise about 9 ft., neaps 6 $\frac{1}{2}$ ft. In working through the eastern entrance the lead may be safely trusted, there being no hidden dangers known. The shore of the mainland may be approached to a mile, and that of *Leu-kung-tau* to 3 cables.

The land north-westward of Wei-hai-wei, and which forms the harbour on that side, is a hilly peninsula, 900 to 1,200 ft. high, with rocky shores. Its northern point is *Cape Cod*, 4 miles from *Leu-kung-tau*. *Eddy Island*, $1\frac{3}{4}$ miles W.N.W. from *Cape Cod*, is somewhat low with scarped cliffs, and lies 1 mile N.E. from the extreme of a narrow, jutting peninsula, 2 miles in length, on which is a remarkable peaked hill with even slopes. From this the coast recedes south-westward for 7 miles to the mouth of a little stream which small junks can enter, and then bends westward again, skirting a low sandy plain for 16 miles farther to *White Rock Point*, which is 6 miles E.S.E.

of Chifu Harbour. This point is the N.E. extreme of Yungmatau, a narrow island which thence extends 4 miles to the S.W. by W. Around the South end of this island is the entrance to *Lungmun Harbour*, which would safely hold a large number of small vessels moored. The course from Eddy Island to White Rock Point is W. $\frac{3}{4}$ S., 21 miles, and the shore between them should never be approached to a less depth than 9 to 10 fathoms.

Kung-kung Island and Lighthouse.—A group of islands and rocks, of moderate elevation, is spread over an extent of 7 miles, at the north-western part of the extensive bay south-eastward of Chifu, and gives shelter to the spacious harbour of the same name which it forms. *Kung-kung tau*, the largest of the group, is even-topped in character, and has on its summit, 200 ft. high, a lighthouse 45 ft. high, which bears N.W. $\frac{1}{2}$ W. $7\frac{1}{2}$ miles from White Rock Point. From this lighthouse is shown a *fixed bright light*, elevated 242 feet above the sea, and visible in clear weather at a distance of 22 miles.

East Sand-spit, which greatly shelters the anchorage from easterly winds, extends three-quarters of a mile S.W. $\frac{3}{4}$ S. from the S.W. point of Kung-kung.

The German man-of-war *Arcona*, when passing Chifu Harbour, observed a shoal about 1 mile long, on which $4\frac{1}{2}$ fathoms were obtained. From the shoal North Rock bore W. by N. $\frac{1}{4}$ N., S.E. Island W. by S. $\frac{1}{2}$ S., and White Rock S. by W. $\frac{1}{4}$ W.

North Rock, the outer and north-eastern islet of this group, bears N.E. $\frac{1}{4}$ E. $4\frac{3}{4}$ miles from Kung-kung tau lighthouse. A small rock just awash at high water, and therefore nearly always visible, lies N.E. by E. $\frac{1}{2}$ E. 3 cables from North Rock, and is steep-to, there being 9 fathoms close outside it.

Double Rock, S.W. by W., $2\frac{1}{2}$ miles from North Rock, when seen from the eastward appears, as its name denotes, to be double, the northern part like a wedge; the southern part, which is much the higher, 198 ft., is an irregular mound, rather elongated to the westward.

South-east Island, 60 ft. high, bears from North Rock S.W. $\frac{1}{2}$ S. $4\frac{1}{4}$ miles, and is $1\frac{1}{2}$ mile S.E. by E. $\frac{1}{2}$ E. from the lighthouse. Three high rocks lie between S.E. island and Kung-kung tau, but no hidden dangers near them have as yet been discovered.

Finger Rock, the shape its name denotes, is half a mile North of Kung-kung tau lighthouse. *Stick-up Rock*, of similar form, lies to the North of the western islets of the group. *Mount Islet*, where was situated from 1861 to 1867 the British Naval coal store and depôt, is the second islet from the westward. These three are useful leading marks for clearing East Sand-spit, and approaching the anchorage under the islands.

Cape Chifu, about 60 miles westward of Alceste Island, is the eastern extreme of a mountainous peninsula connected with the mainland by a low neck of land of considerable extent. This peninsula, which is 5 miles long, E.S.E. and W.N.W., and extends in a narrow ridge parallel to the coast

line, is high and steep, and when seen from the distance appears like an island. *Chifu Peak*, at the centre of the ridge, is 980 ft. high, and has a double top. One cable S.E. of Chifu Cape is *Sentry Rock*, which may be closely rounded in 9 fathoms, and the cape is equally bold.

CHIFU or **YENTAI HARBOUR**, a treaty port, and the only one between Shanghai and Tientsin, is formed in a bight of the coast between the peninsula of Chifu and the Kung-kung group of islands, which, being 3 miles in extent, constitute a magnificent natural breakwater to the harbour, sheltering the various anchorages from North and East. The anchorage space in the harbour, comprising a depth of from 5 to 7 fathoms, is 4 square miles, and for a depth exceeding 4 fathoms, 9 square miles, whilst a depth of 21 ft. can be carried up to within 300 yards of Tower Head, which bears W. $\frac{1}{2}$ S. $5\frac{1}{2}$ miles from Kung-kung lighthouse. The harbour, although affording ample depth of water for all classes of ships, is exposed to the disadvantage of violent north-westerly and northerly gales which prevail through half the year, particularly in the winter months, but its safety as well as its capacity have been now fully proved by experience. During the last China war the French squadron laid between Kung-kung tau and Tower Point during a whole winter, and not a single ship dragged her anchors.

The town of Yentai, where the foreign settlement is, stands on the sandy shore of a small interior bay westward of Tower Head.* It is built without design or regularity. On the slope of the hill, facing landward, are some European houses, the highest of which is the British consulate. The summit of Town Hill is occupied by a Chinese fort and *signal station*. There is a Chinese customs' establishment, which is in all respects similar to that at Shanghai.

Supplies.—Contractors supply excellent beef and fair mutton, and there is an abundance of vegetables of good quality. *Coal* can be obtained from contractors, the naval depôt at Mound Islet having been removed. It is now imported direct from England and Australia, as well as from Formosa and Japan. A correspondent of the North China Herald, writing from Chifu in 1877, says that there is a scheme afoot for working coal-mines. Some 120 miles West of Chifu there is a fine level plain, under which, at no great depth, is a thick seam of coal, but little worked by the natives, as they have no means of pumping the water out of the pits. There are some nearer coal-fields, it is proposed to connect with Chifu Port by tramway.

Water is the great want here, as it is along the whole of this part of the coast of Shantung. Water brought from the interior is 2 to $2\frac{1}{2}$ dollars a ton, but the water obtained near the shore is unwholesome, and produces diarrhoea and dysentery. When water is required it is customary to hoist

* Off the N.W. point of Tower Head or Yentai Hill, with the tower E. by S. $\frac{1}{2}$ S., is a sunken rock of 7 ft. at low-water springs. On it stands a beacon, an iron rod with cage.

signal-flag No. 1 at the fore. At Mound Islet there is a well, but the water is brackish, and at the village inside Chifu Cape there are wells, but the water is of very inferior quality. Accounts are kept in taels, and petty transactions in cash. The clean Mexican dollar passes current, but at a considerable discount, viz. 8 to 15 per cent. The standard of Sycee silver accepted at the Chinese custom-house is 4 per cent. higher than that prevailing at Shanghai.

The exports consist chiefly of peas, beancake, silk, prawns, drugs, dates, oil and wheat. The imports of cotton and woollen fabrics, metals, opium, seaweed, &c. The position of Chifu is highly advantageous for trade with the northern ports of Japan, Korea, and the Russian possessions. It is the only harbour open in the North of China from December to March. There is regular steam communication about two or three times a week with Tientsin and the southern ports, but chiefly with Hong Kong and Shanghai. The voyage to Shanghai occupies about three days, that to Taku about one day.

In point of climate this port is undoubtedly the most salubrious of all those open to the residence of Europeans on the coast of China. The winds in a general manner follow the courses and periods of the monsoons. The summer winds are chiefly from the south-eastward, and light but very changeable; the winter winds are from the north-westward, strong and often violent, but although they are intermittent they are more constant.

Tides.—It is high water, full and change, in Chifu Harbour at 10^h 34^m; springs rise about 8 ft., neap 6½ ft. For information concerning the tidal streams, see p. 1138.

Directions.—If bound to Chifu from the eastward, after rounding Cape and Eddy Island, the course and distance to the Kung-kung Islands is West 25 miles. The high hill over Knob Point, 3 miles eastward of Yentai, kept on a W. by S. ½ S. bearing, will lead well clear to the eastward of these islands, giving S.E. Island a berth of three-quarters of a mile. This mark should be followed, in order to clear the East sand-spit, until Stick-up Rock comes on with the eastern part of Mound Islet (the second from the West), bearing N.N.W., when the course may be altered for Mound Islet, until Finger Rock, which is conspicuous, comes on with the West extreme of Kung-kung tau, then haul up about N.E. by N. or N.N.E., if wishing to anchor close under Kung-kung tau, where the depth will be 4 fathoms, or continue N.N.W., if of light draught, or N.W. if of heavy draught, and anchor in 4 to 7 fathoms as convenient. The bottom is mud, the holding ground is good, and there is sufficient space for a large number of vessels.

If wishing to run on for the anchorage in Village Bay under Chifu Cape, when the mark for clearing the East sand spit has been reached, Chifu Peak bearing N.W. will readily be distinguished. Steer N.W. ¾ W. for the head of the bay, and anchor in 4 to 5 fathoms, mud, with the extreme

of the cape bearing about N.N.E. or N.E. by N. H.M.S. *Actæon*, in 1860, anchored here in $3\frac{3}{4}$ fathoms at low water, with Chifu Peak N.W. by N.; Sentry Rock N.E. by E. $\frac{1}{2}$ E.; the lighthouse E. by S. $\frac{1}{2}$ S.; and Knob Point S.S.E.

If working in for this harbour from the eastward, North Rock, Double and S.E. Islands may be safely approached to half a mile on the one side, and the mainland on the other, until the soundings decrease to $4\frac{1}{2}$ fathoms, the water gradually shoaling as the shore is approached. Between the islands and Knob Point is the Kung-kung Flat, having in one or two places 4 fathoms at low-water springs, rather near to the island, but a general depth of $4\frac{1}{2}$ and $4\frac{3}{4}$ fathoms.

As the East sand-spit extending from Kung-kung tau is approached, remember the bearing of the hill over Knob Point, W. by S. $\frac{1}{2}$ S., and do not go northward of that bearing until the clearing mark, Stick-up Rock and the Mound, comes on. When the spit is cleared a longer stretch may be made on the port tack, taking care not to approach the Mound nearer than to bring S.E. Island E. $\frac{3}{4}$ S., when it will be seen over the sandy flat between the two portions of the island. This line will clear the West sand-spit, the South extreme of which bears from the centre of Mound S. by E. $\frac{1}{4}$ E. nearly three-quarters of a mile, and W. $\frac{1}{4}$ N. from the lighthouse.

Approaching from the westward Chifu Peak, 980 ft. high, and the land of the peninsula will show out conspicuously, appearing from a distance like an island, the low sandy isthmus connecting it with the mainland not being visible. There are no hidden dangers known in the vicinity. Three or four detached rocks are dotted along the face of the peninsula, but they are all well within half a mile of it, and above water, so that a course a mile off and parallel to the shore clears everything. Sentry Rock, lying off the cape, may be rounded at 2 cables distance in 7 fathoms, and the anchorage steered for.

If intending to anchor under the Kung-kung Islands, after rounding Sentry Rock, steer for Knob Point until the clearing mark for the West sand spit (the lighthouse bearing East) comes on; then run in southward of that line and anchor as convenient.

The Coast westward of the bold sea face of Chifu peninsula falls back southward, forming a sandy bay, terminating at Sloping Point, 11 miles N.W. by W. $\frac{1}{4}$ W. At 11 miles farther in the same direction is Low Point, distinguished by a conspicuous nipple or small mound upon it, 250 ft. high; and between the points are two other bays. At 8 miles westward of Low Point is Teng-chau Head of about the same height, around which are steep cliffs. In 1875 a light was falsely reported to be shown on this head.

Teng-chau, a city of the second class, is commanded on three sides; the rising ground of Teng-chau Head overlooking it on the West. An opening

in the sea face of the city wall forms the entrance to a small camber, in which a fleet of small junks lie closely packed and sheltered from all winds. The little camber is a scene of bustling activity in summer, some junks taking in cargoes of grain. *Coal* is occasionally imported from Fu-chau. No supplies or water of good quality can be obtained here.

Teng-chau Bank extends in a W.N.W. direction 7 miles from Teng-chau Head, with a general depth of 2 to 4 fathoms on it. It is apparently of sand and rock, with several small knolls and large shelves of shallow water.

If intending to anchor off Teng-chau, after rounding Low Point steer W. $\frac{1}{2}$ N., and when Teng-chau Head bears W.S.W. stand in and take up anchorage in 3 to 6 fathoms. But if running westward be careful not to bring the nipple on Low Point to the eastward of E. by S. $\frac{3}{4}$ S., to avoid a dangerous rocky ledge extending nearly a mile off a low point of the shore, and the extremity of which is $2\frac{1}{4}$ miles East of Teng-chau Head.

The Miau-tau or Meih-shan Islands, in all fifteen, exclusive of small rocks, extend 35 miles in a northerly direction from Teng-chau to within 22 miles of the extremity of the Liau-ti Shan promontory on the North side of Pe-chili Strait, and they separate the Yellow Sea from the Gulf of Pe-chili. The four northern islands form a group, the peak of the northernmost being in lat. $38^{\circ} 23' 37''$ N., long. $120^{\circ} 55'$ E. The southernmost islands form a compact group, 9 miles in extent, enclosing the anchorage known as Hope Sound, where the British fleet, under Vice-Admiral Sir James Hope, K.C.B., assembled in 1860. The intervening islands and rocks are isolated and scattered.

Anchorage.—Hope Sound can only be considered as a summer anchorage, at which season ships of any draught and in almost any number may lie quite sheltered.

Charybdis Harbour, at the N.W. end of Changshan Island, may be entered from North or South; it affords a secure anchorage at all seasons of the year, and is protected from all winds by the surrounding islands and rocks. There is sufficient room for two large vessels and four small vessels to lie at single anchor. It is advisable to moor, however, as vessels are generally tide rode, and seldom swing to the wind.

In *Chief Bay*, on the South side of Toki, there is anchorage in 6 to 9 fathoms, well protected from the northward and westward.

H.M.S. *Wellesley*, in 1840, anchored in 12 fathoms under Kao-shan or Quoin Island during a strong northerly wind, with the island bearing from North to N.N.E. $\frac{1}{2}$ E. about a mile distant.

Ta-chu-shan, or Great Bamboo Island, the easternmost of the Miau-tau group, is 480 ft. high. *Chang-shan*, or *Long Island*, is the largest of the Miau-tau Islands, and divided into two parts by a narrow isthmus of shingle nearly a mile in length. Its East and North sides, bold and cliffy, are steep-

to. The southern part of Chang-shan is also hilly, its South and centre hills being each 490 ft. high. *Chang-shan Tail*, a sandy spit, extends South upwards of half a mile from Spit Point, its South extreme. *Ta-hi-shan* and *Siau-hi-shan*, or Great and Little Black Islands, are to the westward of Chang-shan, and between them is the small island *Miau tau* or *Temple Island*, 310 feet high, on the N.W. side of which is *Hope Sound*, which, as before stated, is the best and most sheltered anchorage among the *Miau-tau* group. The western point of *Ta-hi-shan* is a stupendous bluff, with cliffs 600 ft. high.

Toki-tau, 10 miles northward of Chang-shan, and readily distinguished by its peak, 613 ft. high, is in the form of a right-angled triangle. *Kao-shan* or *Quoin Island*, 650 ft. high, lies nearly 5 miles W.S.W. of Toki. *Houki Island*, on which it is proposed to build a *lighthouse*, lies 4 miles to the southward. It is 310 ft. high, has a reef extending some little distance from its northern side, and another off its eastern end.

Hesper Rock, about 30 yards in extent, dries from 4 to 6 feet at low-water springs. From the rock the West extreme of *Ta-kin* bears N.N.W. $\frac{1}{2}$ W.; the summit of *Kao-shan* West; and the highest part of *Ta-chu-san*, S. by E. Great caution should be used in approaching this locality at high water. Lieutenant Bullock remarks—"We were much struck on passing, the day being calm, with the treacherous appearance of this rock, which looked like a brown floating log, and might easily have been passed unnoticed."

Fisherman Rock, lying nearly in mid-channel between Toki and *Ta-kin* Islands, is seldom visible. From the rock, the East extreme of *Takin* appears just touching the West extreme of North *Hwangching* N.N.E. $\frac{3}{4}$ E.; *Kao-shan* is just seen over the North extreme of Toki, S.W. by W.; and the western side of *Sha-mo* is in line with the centre of *Siau-chu-shan*, S. by E. $\frac{1}{2}$ E.

Directions.—Vessels bound to the *Pehi ho* or other ports in the Gulfs of *Pe-chili* and *Liau-tung*, are recommended to use the *Chang-shan* channel on the North side of *Chang-shan*, the course and distance from 2 miles outside of *Alceste Island* to the middle of which, is W.N.W. 100 miles. The channel between Toki and *Ta-kin* cannot be recommended to a stranger on account of the *Fisherman Rock*.

There is a narrow, deep channel between North and South *Hwangching* Islands, but at its East entrance, nearly in the centre, is the rock which dries 6 ft. at low water, and is therefore nearly always visible.

From *Miau-tau Strait* the southern coast of the Gulf of *Pe-chili* trends in a south-westerly direction for 60 miles to *Lai-chau*. The coast is low, lying under a mountain range, the crests of which are from 10 to 15 miles inland. Low spurs break through the otherwise even coast-line, and, projecting at some points far from the shore, constitute dangers, which should be approached with extreme caution in bad or thick weather, more particularly in

northerly or north-westerly gales, when at night the reckoning may be in error on account of the current.

East of Lai-chau the mountains turn abruptly to the South, the coast bending westward round a large shallow bight, 30 miles across. Thence it continues in a N.W. direction for 120 miles to within 30 miles of the Pei ho. This part of the coast, the margin of the Great Plain, is low, sandy, and almost a desert. Scantly populated, its inhabitants live in small wretched hamlets, in mud hovels built on banks elevated a few feet above the plain, and in a state of extreme poverty.

The **Ta-tsing ho** or **Li-tsin ho**, the present outlet of the Yellow River, has its entrance in lat. $37^{\circ} 52' N.$, long. $118^{\circ} 35' E.$ Tsi-nan fu, the capital of Shantung, stands 4 miles South of the river, at about 135 miles from the sea and 75 miles from the canal, but there is little known concerning it. The waters of the river are laden with yellow mud or clay, caused by the irruption of the Yellow River into its bed, and that torrent now fairly occupies its channel, having established the Ta-tsing as its outlet since 1851.

The Bar, when surveyed in 1860, was 3 miles from the entrance of the river, and had a depth of from 2 to 3 ft. on it at low water springs. The depth over the bar at high-water springs would therefore be 12 to 13 feet. In 1868 the bar had only .4 feet over it at high tide, but had a channel on either side, that on the South carrying 7 ft., and that on the North 5 ft.

The **PEI HO** or White River, called also the Tientsin ho, is the great highway to Peking, the capital of China. The important city and treaty port of Tientsin also stands on this river at its junction with the Grand Canal, of which it is the northern terminus. No peculiar difficulties in its navigation, from the entrance up to Tientsin, are met by vessels drawing from $10\frac{1}{2}$ to 11 ft. In fact the navigation of the river is too simple to require directions; a mid-channel inclining into the bends and slightly avoiding the points being the best. With long vessels there are some points which will require considerable care and skill in turning. If the vessel is drawing more than 8 ft. there are two places that must be passed at high water. One of these shoal places, having only 7 ft. at low tides, is off the brick-kilns about 9 miles below Tientsin; the other, of $6\frac{1}{2}$ ft., is in the long broad reach, 3 miles below the city.

According to a recent regulation foreign vessels are only allowed to remain at anchor at the mouth of the river, and at Tientsin; they must there occupy berths assigned by the custom-house officials. Vessels anchoring on the route to Tientsin are required to anchor as close to the bank as possible, and to buoy their anchors. No foreign vessel is allowed to anchor in any narrow part of the river, nor in the bends. Persons infringing these regulations are liable to a fine.

TIENTSIN is a treaty port, and has a consular establishment. It is the

sea port of Peking, and the largest and most important city in the North of China. It has trade with Siam and Cochin China, as well as with all the ports of China. Both strategically and commercially it is the key of the capital. The river is 200 ft. wide at Tientsin; above this it soon contracts and becomes too shallow even for gun-boats.

The foreign settlement or concession is about 2 miles below the city. That of the British is at Tz-chu-lin on the South bank of the river, where is the consular establishment. It has a fine bund, where is a jetty at which steam vessels can lie and unload. About a quarter of a mile below the British concession are two large and strong earth-forts on either side the river.

The chief foreign articles of import are cotton goods, cambrics, woollens, silk, opium, metals, needles, and matches. The trade is by no means unimportant, but it is fast merging into the hands of native merchants, who avail themselves of every facility which is at the disposal of the foreigner, and procure their goods direct from Shanghai. The native imports are hemp, paper, teas, sugar, silk, sea-weed, bêche de mer, camphor, and ginger. The chief exports are cotton, soap, skins felt, wool, grain, drugs, and fruits.

The native currency is confined to taels, copper cash, and a sort of bank note current on the spot. Dollars pass at either Tientsin or Peking, but on the road copper cash are more useful. Tientsin cash are not current in Peking. The northern Chinese now accept small silver coins, such as ten and five cent pieces and sixpences.

Supplies.—At Tientsin and along the river ample supplies of bullocks, sheep, and poultry can be obtained. Sheep are cheap and plentiful, and fatten to a great size on oil cake. Vegetables are rather scarce. Water from the river, if taken sufficiently above the entrances at low tide, and cleared by alum, which may be bought at any of the villages, is wholesome. Slack lime can also be procured. Drinking water is supplied by the compradors.

Climate.—Off the river's mouth it has been found both agreeable and healthful during the summer months, the sea breezes which then prevail tempering the heat; at Tientsin the summer heat is intense, and the diseases, typhus, cholera and small pox, which are so rife, are rather attributable to want of sanitary precaution than to climatic influence.

The Bar of the Pei ho, the Chinese name of which is Lan-kiang sha, is about 2 miles in length, in a N.W. by W. and S.E. by E. direction, and consists of hard mud. Being now well buoyed there is no difficulty in crossing it, and there are also beacons on the flats near the forts which serve as leading marks. The channel is wide.

The shoalest part of the bar is three-quarters of a mile in extent, commencing at 4 miles below the outer forts. About the middle of the channel, at $2\frac{3}{4}$ miles S.E. by E. $\frac{1}{2}$ E. of the South Cavalier of the South fort, there is an elbow or bend in the fairway, at which part there are only $1\frac{1}{2}$ feet at

low tides, but the bottom is very soft mud. Farther out there are 2 feet, but the bottom is hard mud, or sand, so that vessels than can cross this can also pass the elbow, although in less than their own draught. At the entrance to the bar, the northern banks, like those of the Peh-tang, are of hard sand, and like them also tail away to the southward.

At high water springs from 11 to 13 feet may be carried over the bar, the height of the tide being much influenced by the direction and force of the winds; at neaps, there is at times as little as 6 or 7 ft. at high water. In November, the channel of the bar becomes somewhat shallower, and the river is generally frozen over early in December, and remains so till early in March. The banks are not always easily distinguished when covered, for at high springs the ripples over them are not visible.

Buoys and Beacons.—There is no light at present to mark the approach to the Pei ho, but it is proposed to erect a *lighthouse* on Sha-lui-tien Island. There are three buoys to mark the passage over the bar, and five beacons to mark the banks of the river, three on the North side and two on the South. *Entrance Buoy* is a *red* iron buoy, on the outer edge of the bar, to mark its commencement and the entrance of the channel. *South Buoy* is a *black* iron buoy, on the South side of the bar, to mark a bend in the channel. *Inner Buoy* is a *red* and *black* striped iron buoy, on the inner end of the bar, to mark the entrance to the channel. This buoy is about one mile S.S.E. of North Fort. *Mud Beacon*, painted *white*, is on the North bank at the mouth of the river. *North Bank Marks* are two 30 feet poles with cages, on the North bank at the mouth of the river. *South Bank Marks* are two poles 30 feet high with cages, on the South bank near the mouth of the river.

These buoys are removed before the river becomes frozen up, and the channel is re-buoyed every spring. They are often washed away.

Anchorage.—Vessels of large draught, say 24 feet, may lie in nearly their own depth about $8\frac{1}{2}$ miles from the forts, the mud being very soft, so that they may ground at low water. The best position is at that distance, S.E. by E. of the South Cavalier, the left and largest of the five seen. This will be about $4\frac{1}{2}$ miles from the bar. Vessels of less draught can choose their own depth upon the same bearing, finding 15 feet at $1\frac{1}{2}$ miles from the bar. A vessel anchoring in 8 feet more than her draught at half tide would have from 2 to 3 feet to spare at low water springs.

The holding ground at this anchorage is excellent. A heavy gale brings in an unpleasant sea, yet with good ground tackling and plenty of cable out it is considered that a sailing vessel ought to ride out a summer gale. The anchorage seems to be a wild one in winter; in the gales of November, some boats only were lost. At a later period ships cannot anchor there at all, owing to the ice.

⋄ Sometimes vessels anchor in their own draught of water, for the mud is

very soft, and if the wind sets in from seaward the level of the sea is raised, whilst with off-shore winds which diminish the depth of water the sea is always smooth. The difference of level between high water spring tides with a south-easterly wind, and low water springs with a north-westerly wind is $12\frac{1}{2}$ feet, the spring rise being 10 feet.

The anchorage, called officially the Outer anchorage extends from the Customs' junks to 3 miles outside the bar seaward.

Pilots certified by Her Majesty's Consul, are usually on the look out for vessels entering during the open season. The rate of pilotage to Tientsin is about 8 dollars per foot of draught.

The native divers are very skilful. They have been able to recover boxes of specie from a depth of 25 feet. As gales sometimes come on in a few minutes without the slightest warning, boats alongside are liable to be stove or damaged.

Tides.—It is high water, full and change, outside the Pei ho Bar at $3^h 30^m$; ordinary springs rise about 10 ft., neaps 7 to 8 ft. The actual time of high water sometimes varies as much as $1\frac{1}{2}$ hours from the computed time, but seldom at springs. As soon as the flats are covered, the tide sets across the bar along the coast, nearly parallel thereto, the flood running northward, the ebb southward, about 2 knots at springs, and 1 knot at neaps. On the bar the tide is always weak. The influence of the direct tides in and out is not felt on the bar except towards low water, when the stream is confined within the mud banks. Outside the bar, the flood sets North, the ebb S.S.E. The tides are subject to great irregularities. North and N.W. winds retard the flood and diminish its rise; East and S.E. winds increase the rise and retard the ebb. Slack water sometimes lasts 3 to 4 hours at the neaps. The rate of the tide in the river is 2 to $3\frac{1}{2}$ knots, its maximum $4\frac{1}{2}$ knots.

At Tientsin it is high water, full and change, about $7^h 0^m$; it is estimated to be about 4 hours later than Ta-ku, but varies very considerably. The average rise and fall is 3 to 4 ft., and the greatest range 6 ft. When the snows melt, the river is said to rise 2 to 3 ft. higher. The times of high and low water are irregular; the water will sometimes remain at its high level for 3 or 4 hours. The tide takes 6 hours to rise and the same period to fall, but at the forts which stand some miles below Tientsin, the flood stream ran only $4\frac{1}{2}$ hours at springs; the ebb therefore must have run 8 hours. At the above forts it is high water, full and change, at about 5^h . The tide ceases at Yong-tsun, 23 miles above Tientsin.

The flood tide has a velocity of about one knot and continues to flow up for an hour after high water; the ebb has a velocity of 2 knots and runs out until two hours after low water. At times when it has been blowing from the northward, there is scarcely any rise of tide and the stream is then always making down.

Tide Signals.—The following signals are made from a flagstaff with yard to

show the depth of water on the bar, the starboard yard-arm being the northern one.

At masthead:—

Ball	signifies	-	-	-	-	Slack water.
Red flag	„	-	-	-	-	Rising tide.
Two balls	„	-	-	-	-	Falling tide.

At starboard yard-arm:—

Triangle over ball	„	-	-	-	-	8½ feet on bar.
Ball over triangle	„	-	-	-	-	9½ „

Triangle hoisted alone at starboard yard-arm, in conjunction with the following signals at port yard-arm, signifies an additional half foot of depth.

At port yard-arm:—

Triangle	signifies	-	-	-	-	10 feet on bar.
Triangle over ball	„	-	-	-	-	11 „
Ball over triangle	„	-	-	-	-	12 „
One ball	„	-	-	-	-	13 „
Two balls horizontal	„	-	-	-	-	14 „
Two balls vertical	„	-	-	-	-	15 „
Three balls	„	-	-	-	-	16 „

Directions.—Having passed the entrance *red* buoy, steer to pass to the northward of the South *black* buoy at the bend of the bar channel, and thence towards the inner *striped* buoy, and from that for the mouth of the river between the forts. A steam-tug is always in readiness at Taku to tow sailing vessels up the river.

The beacons, before described, have been erected for landmarks in case of the displacement of the buoys, and are used when the buoys are removed on the approach of winter and until the channel has been re-buoied in the spring after the breaking up of the ice. The beacons are on the mud-flats below the forts. To enter, keep Mud Beacon (*white*) just open southward of the North cavalier of the North fort, and this will lead in southward of the entrance buoy and up to the South buoy; then the two South Banks marks (poles with cages, black and red), on the South beach kept in one will lead up to the inner buoy, leaving the South buoy to the southward. Pass South of the inner buoy, steering for the mouth of the river.

The river from Taku to Tientsin is not difficult to navigate, yet owing to its winding course great care is necessary. Steam vessels of nearly 12 feet draught, and 200 ft. in length, have reached Tientsin at the period of spring tides almost without a check, but some of the bends are very sharp. The most difficult portion of the passage is a bend known as Double Reach, about 20 miles below Tientsin, where many vessels have stuck fast, and on some occasions the cargoes have had to be discharged before the vessels could be floated. Conveniently placed warping posts are now erected at the worst.

places, so that check lines can be made fast. Twin screw vessels do not require these aids.

As in some parts of the river the channel is very narrow, and barely of sufficient width to allow two vessels to pass each other, it has become customary for that vessel which is proceeding against the tide to run her bow aground so as to make way for the other.

Taku Forts, commanding the entrance of the Pei ho, leading to the capital, are an important military post, and were deemed by the Chinese impregnable till they fell before the British squadron on the 20th May, 1858, and were captured a second time by the British and French allied forces on the 21st August, 1860. The land is so perfectly low and flat about them as to make it difficult for a stranger to detect the entrance of the river, and there is nothing to denote its position, except the shipping and the five elevated cavaliers of the two principal forts which, from their yellow colour, are sometimes discernible with difficulty.

A British vice-consul is stationed at Taku, who receives the papers of all British sailing vessels bound either for this port or Tientsin, those of steamers being retained on board until their arrival at the latter place. The vice-consulate is situated up the river, almost 2 miles above the forts, and about a quarter of a mile from the river's bank. Here also are the Chinese customs' establishment, pilots, &c.

Koku, 17 miles above the forts, is the port at which all the southern junks from Amoy, Swatow, &c., discharge their cargoes. *Double Reach*, about 20 miles below Tientsin, is the most difficult part of the river to navigate. Most vessels frequenting the port have, at one time or another, stuck fast in this awkward spot, and on more than one occasion have had to discharge cargo, in order to lighten sufficiently to get afloat. In the event of thus grounding, boats are despatched from Tientsin as quickly as possible.

SHA-LUI-TIEN ISLAND, distant 120 miles N.W. by W. of Teng-chau, and 30 miles E. $\frac{3}{4}$ S. of the outer anchorage off the Pei ho, stands at the S.E. extreme of an extensive group or mass of sand-banks, the outer edge of which is 20 miles in length in an E.S.E. direction, at a distance of 12 miles from the coast. These banks, some of which dry at low waters must be approached with caution, particularly in thick or foggy weather. The island is low, but it has a small joss house on it, which, standing alone and upon an elevated spot, is conspicuous. It is covered with long grass, and, unlike the banks which are of dark river sand, is of bright sea sand. It is steep-to on its South side. It is proposed to establish a *lighthouse* on the island.

Tides.—It is high water, full and change, off the western part of the Sha-lui-tien Banks, at 2^h 50^m, and neaps rise 8 ft. Near the banks the flood takes a W.N.W. direction along their edge at the rate of 4 $\frac{1}{2}$ knots at springs,

and the ebb to the S.E. at the rate of 3 knots; on their western side the flood sets to the northward, but its velocity is not so great.

A strong N.W. wind drives the water out of the head of the gulf of Pe-chili, reducing the depth a little; but a southerly wind raises the level of the water.

GULF OF LIAU-TUNG.—About 10 miles N.E. from Sha-lui-tien Island is the south-eastern point of the Province of Chili, which defines the limits of the gulfs of Pe-chili and Liau-tung; from thence the coast bends to the N.E. by N. 70 miles to the Great Wall of China, to within a few miles of which it continues to be quite low.

The *Ching ho* entrance to which is 16 miles N.E. by E. of Sha-lui-tien Island, is through a break in the extensive banks which here skirt the coast for many miles, and across a bar on which there are only 2 ft. at low water. The *Lau-mu ho* entrance, 16 miles to the N.E. of the Ching ho, has a narrow bar, with 3 ft. over it at low water. *Hsin-shai-kau*, about 2 miles S.W. of the Lau-mu, is a bar creek, into which junks sometimes run for shelter in bad weather.

MIRAGE on this coast is very deceptive, giving an appearance of water to the dry sand, and distorting the objects on shore considerably, small huts sometimes appearing, when first seen, to be large forts.

From the Lau-mu the coast runs 10 miles N.E. by N. to Sha-ti Point, where the formation of the coast changes. This point is the southern extremity of a ridge of sand hills 30 or 40 ft. high, extending to the N.N.E. in a straight line for 17 miles, as far as the Pu ho.

The *Pu ho* enters the sea through the sandhills, in lat. 39° 40' N. The bar is nearly dry at low water. The rise and fall is about 6 ft.

From the River Pu, the ridge of sand hills, 30 ft. high, continues N.E. 8 miles, and 1 mile beyond their termination is the entrance of the *River Yang*, which is very shallow, and though a few junks pass a short distance up it at high water, the greater number discharge their cargo just within the entrance, whence it is carried into the interior in carts. The depth is 1½ feet over the bar, and the rise and fall 6 ft. The small river *Tai-cho* enters the sea 1 mile eastward of the Yang. The anchorage off *Liu-sia-kwang*, 1½ mile N.E. of the *Tai-cho* entrance, is open from N.E. by E. to S.W., at a quarter of a mile from the sandy beach. The passage into the beach near *Liu-sia-kwang* is between two sand-banks, the one running out from Rocky Point, the other from the mouth of the River *Tai-cho*. Horses and bullocks are abundant. There are two wells of good water at the village near the beach. *Ning-hai* is a walled city, 2 miles from the sea, along the West side of the Great Wall. The anchorage off it, near the extremity of the Wall, is open from N.E. (round southerly) to West.

The **GREAT WALL** of CHINA abuts on the sea on the western shore of

the Gulf of Liau-tung, in lat. $39^{\circ} 58' N.$, long. $119^{\circ} 51' E.$ It originates at the edge of the beach, to which it descends in broad terraces and massive flights of steps, now much ruined, and having a masonry pier jutting out into the sea. The wall rises generally from 20 to 30 ft., in sections similar to the walls of Chinese cities, and with a thickness of 15 to 25 ft. After running round and enclosing a portion of ground close to the sea side, thus converting it into a fort, it runs obliquely inward to the West, and at a distance of about $1\frac{1}{2}$ mile from the beach embraces the city of Ning-hai.

North of the Great Wall the western coast of the gulf is mountainous. The ranges run in an E.N.E. direction far beyond the head of the gulf, and nearly parallel to those on the eastern shore, from which they are distant about 80 miles, and either can be seen in clear weather from the opposite side of the gulf. Although appearing at a distance as continuous ranges, many of them are distinct groups separated by extensive plains, whilst their marked and peculiar forms render them excellent, as they would soon become familiar, and useful landmarks, when steering an off-shore course, which would generally be the case when bound to Newchwang.

From the Great Wall, the coast trends E.N.E. 6 miles to *Temple Head*, and after bending North for 3 miles round the head, it continues in the former direction 26 miles to Sand Point, off which lie the extensive *Cruizer Shallows*. It then turns abruptly to the N.N.E. All this coast is low, along the edge of an undulating plain, 10 miles in breadth from the foot of the mountains, and broken by low headlands on the sea shore, off which are reefs.

The **LIAU HO**, at the mouth of which lies the treaty port of Newchwang (Yingtze), now open to foreign commerce, drains an enormous area of country, consisting of the western half of the Province of Shing-king or Liau-tung. It flows through a plain 70 miles in breadth, and elevated only a few feet above the sea, and about its entrance the lowland, covered with trees, is not visible at the distance of 7 or 8 miles from a ship's deck, although it may be seen from the masthead. Vessels of 18 ft. draught can cross the bar during the summer months, but after the 1st of October, in consequence of the prevalence of northerly winds, which lower the water level of the gulf, it is recommended that vessels abstain from loading over 16 ft.

The river is frozen up during four months an a half, or from the middle of November to the end of March, and the only means of communication is then overland, by couriers *via* Peking at irregular periods. The tide affects the stream for many miles. Small junks ascend to Tie-ling, 205 miles from the sea, and good sized junks to Tien-chwang-tai, 30 miles from the bar. It is 150 years since large junks went up to Newchwang.

NEWCHWANG LIGHT is exhibited from a lightvessel moored off the entrance of the river in $5\frac{1}{2}$ fathoms at 10 miles from the entrance points, and $3\frac{1}{2}$ miles outside the bar. It is a *fixed bright light*, elevated 40 ft. above the

sea, and in clear weather should be seen from a distance of 11 miles. The illuminating apparatus is catoptric. The lightvessel is painted red, with *Newchwang* in large letters on each side, has three masts, and one ball on her mainmast only.

A gun will be fired when vessels are observed running into danger, and the course that should be steered signalled by the Commercial Code. In thick weather blasts from a steam *Fog-horn* are sounded at intervals of 10 seconds. If the light is being trimmed, a small bright light will be hoisted, and a blue light burned at the half interval of time between lowering and rehoisting, that is to say, at 7 minutes after lowering and 7 minutes before rehoisting. This lightvessel is only in position from about the 1st of April to the 1st of November, on account of the ice, and her position ordinarily is, Tower Hill S. by E. $\frac{1}{2}$ E. 16 miles, Ruined Tower on Kae-chu Point S.E. $\frac{1}{2}$ E., direction into the river about N.E. by E.

BUOYS and BEACONS.—There are two buoys to mark the channel over the bar, also five beacons to mark the passage into the river. Both the buoys can be seen from the lightvessel, the entrance buoy with the naked eye, the inner buoy with a telescope.

Entrance or Outer Buoy is an iron nun buoy, painted in *black and white vertical stripes*, and surmounted by a black rod and ball, visible 4 miles; it is in 3 fathoms, oaze, on the western edge of the fairway channel of the bar. From it the lightvessel bears S.W. by W. $\frac{3}{4}$ W. $2\frac{1}{2}$ or 3 miles, and inner buoy, N.E. by E. $\frac{1}{2}$ E. $2\frac{3}{4}$ miles. Good anchorage will be found 2 cables from it, with the buoy bearing between S.S.E. and N. by E.

Inner Buoy is a spar mounted with a bamboo pole, painted *black and white in horizontal bands*, visible 3 miles. It is in 10 ft., hard sand, on the inner edge of the bar, close to the S.E. edge of West bank, and about $2\frac{1}{4}$ miles N.E. by E. $\frac{1}{2}$ E. from outer buoy. It must be left to the westward on passing.

Another small spar buoy, surmounted by a basket, is moored about a mile S.S.W. of beacon No. V., and marks the East bank and the position of Deep Hole.

Fishing Stakes at Deep Hole.—During the winter months the Liau River is closed by ice. While the navigation is open the fishermen have three sets of stakes off Deep Hole; one set on the western side, and two on the eastern, all situated below beacon No. V. As these have proved good marks for the fairway channel, it has become necessary, on their removal previous to the setting of the ice, to leave the outer stake of each set standing.

East Spit or No. V Beacon is a pole 38 ft. high, surmounted with two black balls, with the figure "V" painted in white on the lower ball. It is N.E. $\frac{1}{2}$ E 3 miles from inner buoy, and stands on the East spit, a shoal that projects to the southward from the bank of the river at its East point of

entrance, and is left dry at three-quarters ebb. This beacon marks the edge of the bank, and with the inner buoy forms one of the leading marks in going out or coming in.

Nodding Tommy or No. IV. Beacon is a white pole, 28 ft. high, mounted with a red joss-pole box, on which its number "IV" is painted in black figures. It is on the East bank of the river, at low water mark, on the South side of a small creek, and about 2 miles from beacon No. V. It marks the Whale's Back, a dangerous shoal on the opposite bank from which it bears East.

Middle Bank or No. III. Beacon is a red pole, 28 ft. high, mounted with a black joss-pole box, on which is the figure "III" in white. It is on the East bank of the river, at low water mark, about $2\frac{1}{2}$ miles from No. IV. beacon, and it marks the centre of the Middle Ground Shoal, of 9 ft. water, from which it bears East, and also points out the channel line.

Flagstaff or No. II. Beacon, mounting two trellised frames or basket balls, one above the other, is 50 ft. high; pole and frames black, lower part white with its number "II" in black figures. It is on the East bank of the river, planted on dry ground, $1\frac{1}{2}$ mile from No. III. beacon.

West Bank or No. I. Beacon, also called Fish-house beacon, is a black pole mounted with a red joss-pole box, with the figure "I" on it in black. It is on the West bank of the river, near some fishing houses, a short distance from the bend that leads to the harbour, and is used as a leading mark to No. II. beacon, on the East bank, from which it is three-quarters of a mile distant.

Pilots.—Pilot vessels, having competent licensed pilots for the Liau ho, will be met on nearing the bar. They carry the pilot flag, yellow over green, horizontal, and the words "Licensed Pilot," with number, on the head of the mainsail. There are twelve pilots, who are under the control of the harbour master, under whose direction, also, vessels are berthed, and are not allowed to shift without his permission. The pilot boats cruise within a radius of 5 miles from the lightvessel, except in bad weather, when they take shelter in Deep Hole.

Tides.—It is high water, full and change, at the Liau ho Bar, at 4^h 0^m; springs rise 11 or 12 ft., neaps 7 or 8 ft. At Yin-koa, at 5^h, and springs rise 12 ft. The rise, especially at neaps, is much influenced by the wind, a southerly breeze causing a rise above the normal height, while northerly winds cause a fall below the same.

The BAR.—The channel into the Liau ho flows through the mud flat which extends from 4 to 6 miles off the coast. The eastern point of entrance to the river is 3 or 4 miles South of the western. The bar begins at 7 miles S.W. of the eastern point, and carries for 2 miles depths of 7 to 9 ft., but in its centre is a bank 1 mile in length, of only 4 ft. Thence the channel takes a north-easterly direction towards the East point of entrance, gradually

deepening to 5 and 6 fathoms, but shoaling again to 18 ft., which depth may be carried up to Yin-koa. The bar has somewhat altered since the survey of 1860.

The bar is difficult of approach, especially in cloudy weather or when no ships or junks are lying outside, owing to the low land and the extent of the flats. A vessel should not stand nearer in than 4 fathoms. When in 6 fathoms, soft bottom, Tower Hill bearing S.S.E., she is in anchorage outside the bar, when she must wait for a pilot; or if drawing 10 to 12 ft., and it being 3 hours flood, she may follow, on a course about N.E. by E., the large five masted junks going in, which keep strictly in mid-channel. But as soon as the vessel has passed the first fishing stakes, and having $4\frac{1}{2}$ fathoms, soft bottom, good holding ground (the bar is hard sand), she is inside the bar, and ought to anchor.

Anchorage.—Vessels arriving off the port, if requiring to anchor, should bring-to near and to the eastward of the lightvessel; or, if preferred, they may proceed up to inner buoy, and anchor with the buoy bearing between S.S.E. and N. by E., at 2 cables' distance.

Caution.—Vessels that have been kept too far off shore, in order to give the Bittern Shallows a wide berth, have been run amongst the dangerous shoals, at the head of the gulf, westward of the Liau ho.

Crossing the Bar at slack water of the last of the flood, steer from the lightvessel N.E. by E. $\frac{3}{4}$ E., and pass half a cable to the north-westward of entrance buoy. From this steer N.E. by E. $\frac{3}{4}$ E., which will lead $1\frac{1}{2}$ cable eastward of inner buoy, and stand on, on the same course, until you have brought the latter buoy to bear W. by S. $\frac{1}{2}$ S. about $1\frac{1}{2}$ mile distant. Thence a N.E. course for about 1 mile will bring you to Deep Hole (between the fishing stakes), where there is good and secure anchorage in $6\frac{1}{2}$ fathoms.

The tides set obliquely across the bar, the flood about N. by E., the ebb about S. by W., at the rate of 2 to 4 knots. With this knowledge the mariner will be able to steer so as to make good the courses above given. When on the bar, to avoid the middle ground, do not bring inner buoy to bear to the northward of N.E. $\frac{1}{2}$ N.; and to avoid the dangerous spit on the western bank, do not bring it to bear to the eastward of E.N.E. When above inner buoy, in order to avoid another projection from the western bank, do not bring the same buoy to bear to the southward of S.W. by W. $\frac{1}{2}$ W. until your distance from it exceeds $1\frac{1}{4}$ mile. The western bank is steep-to; the eastern bank shelves gradually.

From Deep Hole, the Admiralty chart and a careful use of the lead will enable you to reach the Yin-koa anchorage. Feel your way along the eastern bank, passing within a cable of Nodding Tommy and Middle Bank beacons, on which side the deepest water is to be found, until Flag-staff beacon is reached, then strike across for Fish-house beacon, on the western shore, in order to clear the shoal water off Everlasting Point. Then (still guided by the

lead) follow the North shore around the bend, until you are well above Everlasting Point below Yingtze, when steer for the anchorage off the town.

At $12\frac{1}{2}$ miles South eastward of the lightvessel is *Kae-chu Point*, low, with a ruined tower on it. Some 10 and 12 ft. patches lie at 6 miles westward of the point. *Tower Hill*, 9 miles S.S.W. of *Kae-chu Point*, is 420 feet high, and has a conspicuous tower on its summit; bearing S. by E., it clears the *Kae-chu* patches to the westward. *Vansittart Saddle*, 10 miles to the S.W. of *Tower Hill*, is a group of hills on a projecting angle of a great plain. A large square tower stands to the eastward of them. *Sandy Head* is a hill 440 feet high, 5 miles S.S.W. from *Vansittart Saddle*. It is conspicuous, and a good mark for the Bittern Shallows. *Maxwell Point*, in lat. $40^{\circ} 2' N$, long. $121^{\circ} 50' E$., is 6 miles S.W. from *Sandy Point*. It is the western extreme of a hilly promontory, 4 miles in extent, rising from the extensive plains of this part of the coast in varying heights to 970 ft., whilst 12 to 13 miles inland mountains of 2,000 to 3,000 ft. run parallel to the coast for 30 miles. At 5 miles below *Maxwell Point* are the *MacGowan Cliffs*, and the same distance S.W. from them is *Schooner Rock*.

Bittern Shallows are a collection of banks of coarse sand, 22 miles in extent, fronting the coast, and marked by heavy breakers in N.W. and West winds. Their most projecting point is 9 miles N.W. $\frac{1}{4}$ W. of *Sandy Head*, where the most dangerous cluster lies. These outer banks carry 12 to 16 ft. water, several of the inner from 1 to 10 ft., and others 15 ft. The lead will be the best guide to avoid these banks. Their most projecting point, with 2 fathoms on it, has 13 and 14 fathoms close to, whilst the sea outside has an uniform depth of 12 fathoms, mud; in other parts the banks are safe to approach to 10 fathoms, mud. A very conspicuous mountain, 2,880 ft. high, in line with the small cliffs East of *Vansittart Saddle*, S.E., will lead over the North tails of the banks in $4\frac{1}{2}$ to 5 fathoms.

Glacis Point, 7 miles W.S.W. from *Schooner Rock*, is the termination of a gentle slope from a hill 500 ft. high. *Fort Head* is 5 miles S.W. from *Glacis Point*, and 4 cables off its S.W. side is the *Cocked Hat*, an islet 60 ft. high. *Fu-chu Point*, the North point of *Fu-chu Bay*, is 4 miles S. by W. of *Fort Head*, and between them is a shallow bay. Extending from it 1 mile to the westward is a reef.

Fu-chu Bay is 11 miles across between *Slaney Head* and *Fu-chu Point*. The approach has from 15 fathoms at 12 miles, to 5 fathoms at 3 to 5 miles from the head of the bay, the soundings generally regular with mud bottom, except off *Slaney Head*. The passage up to *Fu-chu*, at the head of the bay, is between *Square Island*, a flat-top isle 110 ft. in height, on the North, and *Table Point*, a projecting rocky head, on the South. The small town of *Fu-chu* commands but little trade. It produces coal of little worth.

Hulu Shan Bay, the next bay southward of *Fu-chu Bay*, affords anchorage in depths under 9 fathoms, good holding ground of sand and clay, inside

its entrance points, which are $5\frac{3}{4}$ miles apart. Small vessels can find shelter from N.W. on the North side of the bay, or from S.S.W. on the South side. There are no supplies.

Society Bay is 37 miles wide at its entrance, between the North point of Hulushan Bay on its North side and Cape Collinson on its South. To the N.N.E. of Cape Collinson, between the distances of 10 and 17 miles, are *Milne* and *Murchison Islands*, and numerous shallow patches. At the N.E. head of the bay is *Port Adams*, 18 miles in depth, which can be entered by vessels drawing 20 to 21 ft. at high-water springs. A few supplies can be obtained at the villages on its shores. *Kinchan Bay* is shallow, and forms the S.E. part of Society Bay. At its head is the small walled town of the same name.

Quang Tung Peninsula forms the South side of Society Bay. Its N.W. extreme is Cape Collinson. At 6 miles W.N.W. of Cape Collinson is *Si-hau-shan* or *Iron Island*, 750 ft. high. Between Cape Collinson and Liau-ti-shan Promontory, 13 miles to the southward, two bays are formed on the coast; the northern of these is named *Louisa Bay*, and has good anchorage in its entrance in 6 fathoms, outside the small islands. At $4\frac{1}{2}$ miles westward of the entrance of Louisa Bay is *Reef Island*, 400 ft. high, with some rocks off its western side. *Pigeon Bay*, 5 miles to the southward of Louisa Bay, has anchorage in 4 fathoms. The mountain on Liau-ti-shan promontory is 1,500 feet high. *Port Arthur*, 5 miles E.N.E. of this mountain has rocks on either side of its entrance, and a military station on its N.E. shore.

Encounter Rock, in lat. $38^{\circ} 33' 50''$ N., long. $121^{\circ} 40'$ E., is about 70 yards in length East and West, has 24 and 26 fathoms close to. From the eastern or largest rock, which is 11 ft. above high water, the Cap bears N. $\frac{1}{2}$ W.; the summit of Sanshan tau N.N.E. $\frac{3}{4}$ E.; Prominent Peak N. by W. $\frac{3}{4}$ W.; Sampson Peak, N. by E. $\frac{1}{2}$ E.; Liau-ti-shan summit, N.W. by W. $\frac{1}{2}$ W.; and Round Island, E. by N. 25 miles.

Cap Island, 17 miles eastward of Port Arthur, and 5 miles off shore, is about 400 ft. high, and slopes towards the East. *Round Island*, in lat. $38^{\circ} 40'$ N., long. $122^{\circ} 11'$ E., is small, round-topped, 200 ft. high, and is generally sighted when bound to Ta-lien-whan Bay from the southward. The soundings at half a mile from it are 25 fathoms, mud and shells.

Ta-lien-whan Bay is an extensive inlet, square in form, being 6 miles wide and 6 deep, with three smaller inlets, named Victoria, Junk, and Hand Bays, branching from its head; there is also a small bight, Odin Cove, on its eastern shore. The holding ground is excellent, the eastern side of the bay affording the best sheltered anchorage in summer. Its principal approach is 5 miles wide, between the West Entry Point and the two Sanshan Islands. There is also a passage 1 mile wide between these islands; and another 2 miles wide between the northern island and the eastern point of entrance. Both of these channels, and the main entrance, appear to be clear

of danger; but in passing between the two islands it would be prudent to steer a mid-channel W.N.W. course through, so as to clear the 6-fathom mud-banks, one lying S.E. by S. 8 cables from the North Island, and the other East 8 cables from the North hill of the South Island, which have not been examined, and on which there may be less water.

The flat country at the foot of the hills surrounding Ta-lien-whan, appears to be good arable land, well cultivated. Large quantities of a kind of dwarf Indian corn, millet, and wheat (kaouliang) are grown on it. Vegetables are scarce, and from the latter grain above mentioned a spirit is distilled.

Odin Cove lies 3 miles North of the North Sanshan Island, and just within the north-eastern entrance point of Ta-lien-whan Bay. In approaching it care should be taken to avoid a rock lying a mile off shore, and 3 miles N.E. of North Sanshan Island. The best anchorage is on the South side of Odin Cove, the northern shore being dangerous to approach. A few supplies may be obtained, and on the northern shore of the cove water may be got.

The Blonde Group, or Wai-chang shan, lying about 45 miles eastward of Ta-lien Bay, consists of one large island and four smaller islands north-eastward of it. They are all much the same in character; undulating ridges with deep ravines, bordered with high cliffs or ragged shores, but destitute of any prominent feature when seen from a distance. *Shi-siau* is a remarkable rock 40 ft. high, which appears as a junk under sail, and lies 5 miles southward of the Blonde Group. *Hai-yun tau*, 15 miles eastward of the Blonde Group, 5 miles in extent North and South, lies isolated at the S.E. part of the Blonde archipelago. The summit of this island is a gently sloping peak, 1,320 ft. high.

The Ta-hu-san or *Ta-yang ho*, has its entrance in lat. 39° 47' N., long. 123° 40' E. At 12 miles above its mouth is the town of Ta-hu san, the sea-port next in magnitude to Yingtse (Newchwang), and like that place possessing many large native warehouses.

The approaches to the river are shallow, and large vessels can only approach to within 6 miles of the entrance. About 4 miles off the entrance are two small islands, namely, Ta-lu-tan on the South side and Sian-lu-tan on the East side. The channel into the river lies between these two islands; the channel West of Ta-lu-tan is not practicable even for boats. The German vessel of war *Ariadne* was piloted to an anchorage in 4½ fathoms, 1½ mile S.E. by S. from the peak of Ta-lu-tan; shoal water extends South and West of Ta-lu-tan a distance of over 3 miles. A depth of 4 fathoms is found at 4½ miles S.W. of the island.

The boats of the *Ariadne*, in July 1876, ascended this river without difficulty as far as the town of Taku-schan. A depth of 1½ ft. was found on the bar at low water, but it is considered possible that the bar may dry at low water spring tides. Inside the bar the least water found was 7 feet, with a

general depth of 8 ft. At the anchorage off the town there is a depth of 8 feet at low water, bottom soft mud, on which vessels drawing less than 10 ft. may ground. The banks of the river from the entrance to the town of Taku-schan are low, and in some places submerged at high water; the stream is 330 yards wide at the town. Spring tides rise 20 ft.

The population of Taku-schan consists of 30,000 or 40,000. Commerce with Korea, prohibited previous to 1873, has commenced, and is at present very active. The exports consist chiefly of bean cake and timber. Silk of a coarse inferior quality is exported in small quantities.

The KOREA is separated from China on the N.W. by the *Yulu kiang*, the estuary of which river is in about lat. $39^{\circ} 50' N.$, long. $124^{\circ} 10' E.$ Some trade commenced in the year 1876 between Japan and the port of Fusan in Corea.

The coast eastward of the Yalu kiang appears to trend to the S.E. as far as Ping Yang inlet, and is skirted by numerous islands, the whole of which are as yet unexplored. Banks with shoal water on them extend a long distance to seaward of these islands, and vessels navigating in this locality should use great caution, as banks of rock and sand rise precipitously from the water.

The S.W. coast of Korea and the islands lying off it are but little known. The passages between the islands have been traversed by many vessels, and all the outer groups fixed with tolerable precision.

Quelpart Island, about 40 miles long E.N.E. and W.S.W., and 17 miles wide, is of considerable height, and detached from the islands which face the S.W. coast of Korea. Its general outline is that of an oval, with few deep indentations to affect its regularity. Its general appearance, as viewed from the sea, is inviting, there being a pleasing variety of hill and dale, and on the northern and eastern sides much cleared land, cultivation rising probably to the level of 2,000 ft. Rock reported in lat. $33^{\circ} N.$, long. $126^{\circ} 13' E.$

Quelpart, throughout its extent, has but one safe anchorage, and that is at its East end, off the southern bay of Beaufort Island, which here forms a channel with Quelpart, about 2 miles wide, and through which the current sets strong to the southward. The second temporary roadstead is off the city on the northern shore of the island, but a vessel would be compelled to seek an offing at the first symptom of a N.W. breeze.

The third anchorage, at the western extreme of Quelpart, within Eden Island, affords shelter from North (round East) to N.W., and offers an escape to leeward if requisite. A fourth temporary but dangerous anchorage is off Hooper Island, near the city on the southern shore; but this is open from West to S.E., and is too confined to admit of beating out, should wind and sea come in suddenly.

Off the *South coast of Korea*, between Maisonneuve Island and Kuper

Harbour on the West, and Castle Islands and Herschel Island on the East, are about 100 conspicuous islands, from 300 to upwards of 2,000 feet in height, more than two-thirds of which are inhabited; and including the smaller islands, the whole number, more than 200, are contained in a space of between 1,500 and 2,000 square miles. Speaking generally of this archipelago, it is bold, presenting very few hidden dangers. All these off-lying islands have been examined, but the mainland of the South coast of Korea is yet unsurveyed.

Port Hamilton, lying about N.N.E. $\frac{1}{2}$ E. 38 miles from the N.E. end of Quelpart, consists of two large islands, deeply indented, the northern points of which nearly meet, and which, with a third and smaller island, *Observatory Island*, situated between their south-eastern points, form a spacious and well-sheltered harbour, named Port Hamilton, the main entrance to which is at the S.E. part of the group. These islands may be readily distinguished from the numerous clumps of islets and rocks in the neighbourhood, by their greater size and massive bold appearance, as well as their peculiar position. Except at a great distance from the south-eastward, they invariably make as one island.

Within Observatory Island a vessel may be safely hove down for repair. Wood is scarce—fresh water is plentiful and good, and easily embarked. Fish may be caught with the seine.

On entering the port, the only danger that does not show is the Saracen Rock, with 7 ft. on it, lying at the entrance, 2 cables eastward of the East end of Observatory Island. Vessels may anchor anywhere within the port. The holding ground is so good as to render it difficult to trip the anchor after a few days.

Chosan or Tsau-liang-hai Harbour, is formed on the S.E. coast of Korea, in lat. $35^{\circ} 6' N$. The entrance is between Cape Young on the North and Cape Vashon on the South, which bear from each other N.N.E. $\frac{1}{2}$ E. and S.S.W. $\frac{1}{2}$ W., and are 3 miles apart; from thence the harbour trends in a N.W. direction $4\frac{1}{2}$ miles, and is from 1 to 2 miles wide. At 3 miles within the entrance there are some rocks always above water.

No perceptible trade is carried on in the harbour. A few boats were occasionally seen moving about, but their cargoes generally consisted of fire-wood and straw. The Japanese of the garrison, some 250 or 300 men, have but little intercourse with the natives, and apparently hold them in supreme contempt.

The coast of the Korea will be found fully described in the China Pilot, published by the Admiralty. To give a full description of a coast seldom or never visited by European vessels is thought to be beyond the scope of this work. We therefore give the above brief description, and proceed to describe the coasts, &c., of the Japanese Archipelago.

The coast to the northward is described in the North Pacific Directory.

CHAPTER XXV.

THE JAPANESE ARCHIPELAGO.

THE celebrated and long mysterious traveller, Marco Polo, was the first to announce to the western world the existence of the rich and powerful island of *Xipangu*, now known to be Japan. In 1542 a Portuguese, Mendez Pinto, was cast by a storm on its shores, and a Portuguese settlement from Malacca was soon afterwards made on Kiusiu. In June, 1598, some citizens of Rotterdam fitted out a small fleet of five ships to trade in the Indian Archipelago, and injure, as much as possible, the commerce and power of Spain. Among several Englishmen in this fleet, were William Adams, of Gillingham, near Rochester, and Timothy Shoter, who had accompanied the famous Cavendish in his circumnavigation. The venture was pre-eminently unfortunate. Only one ship, and that the smallest, the *Joyous Message*, commanded by Siebold de Weert, returned to Holland. Two of the others were destroyed, and the fourth, in which were these two Englishmen, reached Japan a mere wreck. They were taken prisoners, and, after some confinement, Adams was taken into the confidence of the Emperor; the rest departed; He was raised to great honours; became of first importance in the political and commercial affairs of the empire; but did not succeed to the extent of his intentions, having gained privileges only for the Dutch, who have studiously avoided mention of his part in their establishment. Some extensive privileges were also granted, at his instigation, to the English East India Company, to establish a factory at Firando.*

As is well known, the only port allowed to be open to foreigners, and this permission was limited to the Dutch and Chinese, was the Port of Nagasaki, or rather for the Dutch, the Island of Dezima, lying before it. But the Japanese maintained a rigid exclusiveness, and but little was known to Europe about the country. Without enumerating the older authors, the principal work on Japan was the collection from the notices of the Dutch presidents, by Dr. Ph. Fr. van Siebold, who visited the country in the period between 1823-30, a magnificent work, worthy of any nation.

In the year 1853, July 8th, Commodore Perry, U.S.N., appeared off

* The first English who visited it were with Capt. Saris, who came to the relief of Adams from England, in 1611, arriving at Firando June 9th, 1613.

the entrance to Yedo Bay, with two large steam frigates and two sloops of war. He ostensibly sought at first only to abolish the barbarous Japanese laws, which consigned shipwrecked seamen to death, and their vessels to destruction. The steady resistance to any intercourse, overawed, however, by the presence of this formidable force, gradually gave way, and some concessions were granted before the departure of the fleet, which left with a promise, or menace, from Commodore Perry, that he intended to return for a more definite answer with a "larger fleet" in the following year. Accordingly, on February 12th, 1854, a squadron of nine war vessels appeared in the Bay of Yedo, and after skilful negotiation a treaty of friendship was concluded between the Tycoon and the United States, and permission was granted to locate a consul at Simoda, an insignificant place at the South extreme of the Idsu Peninsula, on the West side of Yedo Bay.

The second stage of this international negotiation was reached by Mr. Harris, the U.S. diplomat, who, by unremitting zeal, contrived to enter Yedo at the end of 1857, not to leave it till April, 1858, with the treaty of commerce framed. This great step was followed by similar concessions being granted to the principal European powers; and that with Great Britain was ratified at Yedo, July 11th, 1859. After all these apparent victories, it was discovered that these treaties were illegal, having been made with the Tycoon of the period, whereas they should have been ratified by the Mikado, but this was remedied by the appearance of the allied fleet from China and the subsequent full recognition of the rights of the external world to trade at various ports. Of the subsequent troubles nothing can be said here. The works of Sir Rutherford Alcock, Captain Sherard Osborn, R.N., &c., &c., will supply all that can be required.

The empire of Japan is composed of four large islands, Kiusiu, Sikok, Nipon,* and Yezo, and numerous smaller islands. Nipon, the largest and most important of these, and that which gives its name to the whole empire, is more than 700 miles in length N.E. and S.W., and its breadth varies from 50 to 150 miles. South of Nipon, and separated from it by a narrow channel, is Kiusiu. Lying N.E. of Kiusiu, and eastward of the South extreme of Nipon, is the island of Sikok, about 130 miles in length. It is separated from Kiusiu by the Bounjo Channel, and with Kiusiu and the western part of Nipon forms a basin or inland sea named Seto Uchi. North of Nipon, and separated from it by the Strait of Tsugar, is the large island of Yezo, a conquest and colony of Japan. Its form is that of an irregular triangle.

* *Nipon* is applied in Japan to the whole empire. In the two words of the Chinese characters which compose it, *Jih Pun*, it means the place or rising of the sun. The Japanese soften the letter into *n*, and so make it *Ni Pun*, the Dutch spelling it *Jeh Pun*, their *j* corresponding with our *y*. The English, giving the harsher sound to *j*, call it Japan; so *Jeddo* should be produced *Yedo* for the same reason, and is hereafter spelt so.

The chief towns of Japan are now all joined with each other and with Europe by electric telegraph; railways are springing up near the chief ports, and coal is being worked on European principles. A good indication of the progress made by Japan in the last few years is afforded by the rapid lighting of the coast. Of the 39 lights now exhibited not one was shown previous to the year 1869, a few coal fires only marking the coast at night. The population of the empire numbers about 33,000,000, and there are about 3,000 foreign residents in the country, nearly half of whom are English. Imports at the various treaty ports in 1876 amounted in value to about £5,000,000, and exports to £5,500,000, chiefly silk (including eggs and cocoons), tea, and miscellaneous produce.

Treaty Ports.—The following are the ports opened to British subjects by treaty, between Her Majesty the Queen of Great Britain and Ireland and the Mikado of Japan:—Kanagawa (including Yedo and Yokohama), in the Gulf of Yedo; Nagasaki, on the West coast of Kiusiu; Hiogo and Oosaka, in the Isumi nada (eastern part of the inland sea); Niigata, on the N.W. coast of Nipon; and Hakodate, on the South coast of the Island of Yezo.

Climate.—The following observations upon this subject, connected with Japan, are made by Van Siebold:—“In speaking of ice, frost, and snow, within 32° of the equator, we should consider the geographic position of the Japanese Islands, and cite an observation which has been more than once made, and at last confirmed by Alex. de Humboldt. The eastern part of Europe, and the immense continent of Asia, are vastly more cold, under the same latitude, than western Europe, making allowance for the greater or less elevation above the sea level. The climate of islands being much milder than that of continents, it can scarcely be comprehended that the temperature should be lower in Japan than those European countries under the same latitude. But the cause of this contradiction is found in the low temperature of Asia, which, surrounding the Japanese and Kurile Islands on the West and North, has a very decided influence on their climate. From the proximity of the continent, and the winds blowing off that coast during a portion of the year, the cold arises which prevails in Japan, particularly in the North and N.W. Thus in lat. 32° N. the thermometer descends on the coast to 30° and 29° Fahr. It freezes to several lines in thickness, and snow falls that remains on the ground for several days. In lat. 36° the lakes, as those of Suwa on the Sinano, are covered with a bed of ice, which, between 38° and 40°, becomes thick enough for the river to be crossed on foot. In the island of Tsusima (lat. 34° 12' N., long. 126° 55' E.) rice will not grow; near Matsmae, in the Island of Yezo, wheat returns but a very poor harvest; and on Cape Soja (lat. 45° 21' N., long. 140° 29' E.) the wild Ainos, a vigorous race, are obliged to retire into caverns, to preserve themselves from the intolerable rigour of winter. On the other hand, the S.E. and eastern sides, protected from the freezing winds of Asia by high chains of mountains,

which traverse these great Islands of Kiusiu, Sikok, and Nipon, in a direction parallel to the continent, have a more fertile and more temperate climate. In those parts of the country between lat. 31° and 34° , the palm, the banana, myrtle, and other plants of the torrid zone, are found. In some parts the sugar-cane is successfully cultivated, and they gather two rice harvests each year. The environs of Sendai, a city in lat. $38^{\circ} 16'$ N. long. $138^{\circ} 36'$ E., near Niegata, produce this grain in such abundance, that, notwithstanding their northern position, they are in reality, as they are called, the granaries of Yedo, the most populous city of the country. But it is more particularly in the rigorous season, which lasts from the commencement of January to the end of February, that this difference between the western and eastern shore of Japan becomes most remarkable. At Dezima (Nagasaki) for example, in lat. $32^{\circ} 45'$ N., long. $127^{\circ} 31'$ E., the thermometer marks 45° Fahr.; while at Yedo, in lat. $35^{\circ} 41'$, long. $137^{\circ} 22'$ E., it rises to 56° ; so that the position of the capital, more easterly by $9^{\circ} 51'$ than the factory, raises its temperature higher by 11° , although it is only 3° nearer the pole. Thus in the two months of winter in which these observations were made, the coasts facing the Asiatic continent were exposed for thirty-seven days consecutively to the freezing winds from N.W. and North. This circumstance explains, besides, why the white mountain (*Siro jama*), which is on the western coast of Nipon, in lat. 36° is covered with perpetual snow at 8,200 feet above the sea; and why *Fusi-jama*, at the eastern extremity of the island, with its summit at 12,450 feet, remains without snow for months together.

“During the hot weather in July and August, when the winds blow from South and S.E., this disproportion in the temperature disappears, and the mean height of the thermometer for this season is 79° at Dezima, and 76° at Yedo. On the South and S.E. coasts, then refreshed by these winds, it hardly exceeds 85; nevertheless in the South and S.E. parts of Kiusiu, and chiefly in the bays sheltered from the breezes, it often rises to 90 and 98° , and sometimes even to 100° .”

At Hakodadi, the climate in winter is variable. In the winter of 1859— 60° , the greatest depression of the thermometer was 12° . The character of the winter season is uneven, and acts prejudicially on the health, in consequence of the great variability of the atmosphere, thaws and sharp frosts alternating. North-westerly winds blow for four months, and snow fell in the winter of 1859 daily for six weeks. Sir R. Alcock says the winter is almost Siberian, with long continued and heavy falls of snow, the thermometer standing many degrees below zero.

Fogs are very prevalent on the coasts of Japan, especially in the northern parts, and thunderstorms are frequent. In June and July, they occur frequently in the Korea Strait; further to the North they envelope the coasts of Manchuria till the middle of July.

Earthquakes.—The whole region of the Japanese Islands is volcanic, and

many of the eruptions are fraught with extreme danger to ships. At Yedo, one occurred in August, 1783, exceeding in its horrors and wide spread desolation that of Lisbon. Another occurred at Yedo on the 10 Nov. 1855, which is said to have caused the destruction of 100,000 dwellings and 54 temples, and the death of 30,000 persons.

In 1854 the town of Simoda was reduced to ruins, and the Russian frigate *Diana* nearly wrecked in the harbour, being whirled many times round her anchors, at one time aground, at another in many fathoms depth. She was then greatly injured, and was subsequently lost in an inexplicable submarine tornado, whilst in tow of a multitude of Japanese boats which deserted her suddenly at some, to them, well known warning.

Simabara, in Kiusiu, is also a locality of terrible earthquakes, one of which is said to have altered the whole feature and coast line of the neighbouring province.

The Japanese Current, or **Kuro Siwo**, as it is called by the Japanese in one point of its course, is an immense stream which rushes part the southern coasts of the Japanese Archipelago towards the N.E. and is exactly analogous to the Gulf Stream in the North Atlantic. It has been observed by every voyager in these regions; and, like the Atlantic Stream, may be traced to a great distance to the eastward, and evidences of this drift have been frequently found on the American coast, as in the remains of junks, or of these vessels with their crews being drifted on to the American territories, as has been previously related.

But the Pacific current differs from the Atlantic Stream in not being confined in a narrow channel at its outset, and in the strongest part of its course. Hence its velocity and direction are not so constant, and some great variations in the current have been experienced, and these, too, without any apparent cause. Thus there can be no dependance placed on its rate or direction, and inshore it is certainly controlled or altered by tidal action. In the North Pacific Directory this remarkable stream will be noticed more at length, in the section specially devoted to currents.

Survey.—The Japanese Archipelago has never been properly surveyed. Some portions have been minutely examined, especially the vicinities of the treaty ports where European commerce has hitherto been allowed. In addition to the surveys made by the officers of the American squadron in 1853-4, and the British fleet in 1863, there are various portions derived from the surveys of Commander J. Ward, R.N., in the *Rifleman*; of Commander Brooker, R.N., in the *Sylvia*; and especially of Commander C. Bullock, R.N., in the *Serpent*; and of Captain St. John, in H.M.S. *Sylvia*. All these and others have been connected together by a most remarkable map. During the political negotiations this perfect representation of the empire was delivered to our representatives, and it was found to be a regular trigonometrical survey of 6 miles to an inch, and so accurate that, when tested by the

surveyors, it was found that very great reliance could be placed on it. Such a geographical work deserves especial mention.*

The Luchu, Loo Choo, or Liu Kiu Group lies to the north-eastward of the Meiaco Sima's (see pages 1048—1051, about 120 miles from the northern island of the latter group to the southern island of the former. It consists of three large islands—Okinawa sima (Great Lu-chu), to the S.W.; Kaki-rouma, in the centre; and Oho sima to the N.E., between which and in their vicinity are numerous smaller islands, some of which form clusters, the whole, with some outlying rocks, lying between the parallels of 26° N. and 28° 46' N., and the meridians of 126° 42' E. and 130° 16' E.

The inhabitants of the Liu-kiu Islands are both friendly and hospitable; their chief resides at Sheudi, the capital, and formerly paid tribute both to China and to Satsum, a powerful Japanese Daimio. They have but little commerce, except amongst the neighbouring islands of the group.

Okinawa Sima (Great Lu-chu Island, the largest of the group, is about 56 miles long, N.E. and S.W., preserves a tolerably uniform breadth of about 10 or 12 miles. *Napha-Kiang*, on its S.W. side, is the principal seaport of the island, and perhaps the only one possessing the privileges of a port of entry.

There are three passages leading into Napha-Kiang Road, viz., the South, the Oar, and the North channels. When sailing into this anchorage great care should be used to avoid the numerous reefs and rocky patches which surround it.

Heber Reef, reported as a rock about 5 feet above water, surrounded by reefs, lying 6 or 8 miles W.S.W. from Cape Yakimu, the South end of Okinawa, has been inserted on the charts in lat. 26° 2' N., long. 127° 34¼' E. Its existence is doubtful, as its description agrees in every particular with Hall's Reef.

Hall's Reef is a large, circular, rocky patch, a part of which is above water; it lies 7 miles W. by N. ½ N. from the S.W. point of Okinawa sima.

Komisang is very irregular in shape, about 6 miles long, and the same in width; its northern peak is 1,108 feet in height, and that to the southward 1,028 feet; the western side of the island being fringed with reefs. *Eliza-*

* There is a sad story in connexion with this map. It is related in Commodore Perry's "Narrative," page 88. The story is thus told by a modern writer on Japan;—"Von Siebold had been with Colonel Struler, the Dezima chief, to Yedo; the Japanese astronomer, *Takahasi Lakusaimon*, had, in violation of the law, furnished him with a copy of a recently made map of Japan. The draughtsman who made the copy having become, from some cause, offended with the astronomer, denounced him to the authorities. An investigation followed, which lasted a year. Von Siebold was banished from Japan; and Takahasi and the draughtsman who accused him, both committed suicide." This occurred prior to the commencement of the American expedition in 1853.

beth Reef, very dangerous, extends 6 miles to the eastward of Komisang. *Tu sima*, in lat. $26^{\circ} 35\frac{1}{2}'$ N., long. $126^{\circ} 51'$ E., lies N. by E. $\frac{1}{2}$ E., $13\frac{1}{4}$ miles from the North peak of Komisang. It is a rocky islet about 60 feet high, one-quarter of a mile in extent, with a reef surrounding it.

Germantown Reef.—The U.S. ship *Germantown*, in 1859, struck on a coral reef said to lie in lat. $28^{\circ} 16'$ N., long. $129^{\circ} 58'$ E. From the shoalest spot found, 6 feet, the highest terrace on Kikai sima bore N.E. $\frac{1}{4}$ E. 6 or 7 miles. The reef is about a mile long in a N.N.E. and S.S.W. direction, and half a mile wide.

Another shoal spot was found lying North 2 miles from the centre of this reef, with apparently a clear passage between. Reefs were also seen from aloft, extending from one to two miles from the S.W. and S.E. points of Kikai sima.

In the American chart Germantown Reef is placed $2\frac{1}{4}$ miles S. by W. $\frac{3}{4}$ W. from the S.W. extreme of Kikai simai, or in lat. $28^{\circ} 14\frac{3}{4}'$ N., long. $129^{\circ} 53'$ E.; and there is another danger, named Marsh Reef, $1\frac{1}{2}$ mile southward of it.

Marsh Reef, placed on the charts in lat. $28^{\circ} 14'$ N., long. $129^{\circ} 55'$ E., was reported by Mr. Marsh in 1853 as lying 7 miles S.W. of Kikai sima, extending N.N.E. and S.S.W. about 3 miles, with 12 ft. on it at high water.

Sandon Rocks, about 33 ft. above the sea, and surrounded by sunken dangers, lie in lat. $28^{\circ} 45'$ N., long. $129^{\circ} 47\frac{1}{2}'$ E.

The **LINSCHOTEN ISLANDS**, or Cecille Archipelago (so called in the French charts after Admiral Cecille, by whose directions the islands were examined), extend from lat. $28^{\circ} 49'$ N. to $30^{\circ} 6'$ N., and from long. 129° to $130^{\circ} 3'$ E. They consist of 12 islands and rocks, some of which are inhabited, and there appears to be many safe channels between them. The mariner is, however, cautioned not to place too much dependence either on their configurations or positions as shown on the chart of this part of the ocean, for they are by no means correct; they are from the Japanese as collated by Siebold, and from detached surveys and corrections by English, French, and American navigators. The French corvette *La Sabine* examined them in the year 1846. As their character will be readily understood from the chart we give only a description of a few of the islands near which dangers exist.

Yoko Sima, rising to the height of 1,700 ft. above the sea, is an extinct volcano, the highest part of which is in lat. $28^{\circ} 48'$ N., long. $129^{\circ} 2'$ E. The bank on which the Pacific mail steamship *Oregonian* is supposed to have struck is E.N.E. $\frac{1}{2}$ E. distant 300 yards from the South point of Yoko-sima.

Kutsino Sima is 4 miles long N.N.W. and S.S.E.; its peak, which is 2,230 feet above the sea, is in lat. $29^{\circ} 59'$ N., long. $129^{\circ} 56'$ E. There is probably no safe passage between Kutsino and Naka, the next island to the southward. *Breakers* are reported 7 miles N.N.W. $\frac{1}{2}$ W. from N.W. point of Kutsino.

Firase, or Blake Reef, consists of several islets and rocks, extending about 3 miles in a N.E. and S.W. direction; the highest islet, 92 feet above the sea, is in lat. $30^{\circ} 4' N.$, long $130^{\circ} 3' E.$

Henty Reef, on which the sea was seen breaking heavily, has been reported as lying N.W. $\frac{5}{8} N.$ $3\frac{3}{4}$ miles from the North point of Kutsino sima, and about $10\frac{1}{2}$ miles to the westward of Firase.

COLNETT STRAIT, which separates the Linschoten group from the group to the northward, appears preferable to Van Diemen Strait for vessels bound from China to Japan; Yakuno sima, being lofty and steep-to, is an excellent mark; besides which better weather is generally experienced in this strait than in the latter.

Medusa Reef, reported as being indicated by discoloured water and high breakers, 2 miles in extent North and South, and lying 8 miles to the northward of Firase, is inserted on the chart in lat. $30^{\circ} 13' N.$, long. $130^{\circ} 4' E.$; it has not since been noticed, but if it exists it is a dangerous impediment to the navigation of Colnett Strait.

Tanega Sima, the most eastern of this group, is 32 miles long, and off the S.E. point of the island is a conspicuous detached rock, 80 feet in height, named S.E. Rock.

A reef of rocks showing above water, and a shoal about 2 miles S.S.E. from them, are reported as lying nearly 7 miles from the S.E. point of Tanega sima. This reef has been inserted on the charts 5 miles South of the S.E. Rock, in lat. $30^{\circ} 15' N.$, long. $131^{\circ} 2\frac{1}{2}' E.$, but its position is very uncertain.

Vincennes Strait between Yakuno sima and Tanega sima is 10 miles wide in the narrowest part.

Seriphos or Omuru Rock is marked on the French charts as a rock under water, in lat. $30^{\circ} 49' N.$, long. $130^{\circ} 45' E.$

Take Sima (Apollos Island), in lat. $30^{\circ} 48\frac{1}{2}' N.$, long. $130^{\circ} 26\frac{1}{2}' E.$, is about 2 miles in circumference and 816 feet high. A rocky spit extends $2\frac{1}{2}$ cables from its East extremity, and a dangerous shoal has been reported a short distance North of the island.

Iwoga Sima (Volcano Island on French chart), is an active volcano; its highest peak, 2,469 ft. above the sea, is in lat. $30^{\circ} 47' N.$, long. $130^{\circ} 19' E.$ A pinnacle rock, marking the centre of a reef, a mile in extent, lies a mile North of the centre of Iwoga Sima. Some rocks and reefs extend about three-quarters of a mile from the East and N.E. points of the island, and about half a mile off its S.E. side lie two rocks, estimated as 50 and 40 feet high respectively.

Cowose or Powhattan Reef, a dangerous reef in lat. $30^{\circ} 41' N.$, long. $130^{\circ} 19' E.$, was discovered by the U.S. frigate *Powhattan* in January, 1860. From the centre rock, about 18 ft. above the sea, the S.W. point of Iwoga sima bore N.W.; the East point N. $\frac{1}{2}$ W., and the East point of Take sima N.E. $\frac{1}{2}$ N.

Other rocks were seen awash, or a few feet above water, stretching out about three-quarters of a mile from the centre rock.

Use or *Trio Rocks* are three distinct islets of about an equal height; the centre islet, 206 ft. above the sea, is in lat. $30^{\circ} 45' N.$, long. $130^{\circ} 7' E.$

Kuro Sima (St. Clair Island on the French chart), is about 3 miles long (East and West). It is an active volcano, and its peak rises to the height of 2,160 feet above the sea, and its centre is in lat. $30^{\circ} 50' N.$, long. $129^{\circ} 56\frac{1}{2}' E.$

Kusaki Sima (*Ingersoll* or *Morrison Rocks*) are eight in number, and extend N.E. and S.W. about $5\frac{1}{2}$ miles; the highest, in the centre, 468 ft. above the sea, is in lat. $30^{\circ} 51' N.$, long. $129^{\circ} 26' E.$, and visible in clear weather at 25 miles.

VAN DIEMEN STRAIT lies between Kiusiu Island on the North, and Iwoga sima, Take sima, Make sima, and Tanega sima on the S.W. and South. It is clear of shallows, with the exception of a shoal spot of 8 fathoms, reported about $2\frac{1}{2}$ miles to the southward of Satano misaki, the South point of Kiusiu, and consequently safe. Making this strait from the westward, Mount Horner, on Kiusiu, 3,069 ft. high, and the peak of Iwoga sima, 2,469 feet high, form two conspicuous landmarks. The only drawback to the navigation of this channel is the heavy weather and thick atmosphere usually met with off Satano misaki; the Japan stream setting strong through this strait at all times causes the latter to become a serious disadvantage, which is, however, somewhat lessened by the light now exhibited on the above cape.

SOUTH AND EAST COASTS OF KUSIU AND SIKOK.

SATANO MISAKI or Cape Chichakoff, the southern point of Kiusiu and of the Japanese empire, is situated in lat. $30^{\circ} 58' 45'' N.$, long. $130^{\circ} 40' 15'' E.$ It is about 650 ft. in height, the mountains at the back, from which it is a spur, rising to a considerable elevation, at some points between 2,000 and 3,000 ft. A small island and several small detached rocks lie off it. This cape is well known to vessels trading to Japan, and has attained celebrity from the fact that almost constant bad weather is experienced in its vicinity, violent gales with a thick murky atmosphere rendering the passage through Van Diemen Strait at times somewhat perilous. At about $2\frac{1}{2}$ miles S.S.W. from the cape a shoal spot of 8 fathoms has been reported. Heavy tide races occur off the cape.

LIGHT.—Situated on a small island about 300 yards from the cape, exhibits, at an elevation of 200 ft. above the sea, a *fixed bright light* of the first order, obscured landward between N.N.W. $\frac{1}{3}$ W. to N.E. by E. $\frac{3}{4}$ E., and is visible in clear weather from a distance of 21 miles. The lighthouse is 35

feet in height, constructed of iron, octagonal shaped, and painted white, and is in lat $30^{\circ} 58' 30''$ N., long. $130^{\circ} 40'$ E.

The **COAST** for 140 miles to the north-eastward, comprising the whole of the East coast of Kiusiu, is very little known.

Osprey Breakers (1864).—The position assigned to these breakers is lat. $31^{\circ} 27'$ N., long. $131^{\circ} 40'$ E. Captain Edmond has frequently passed this locality, but has not seen the breakers; he therefore considers that the appearance of breakers was caused by a current overfall.

Nelly Rock, reported in 1863 by the British barque of that name, was afterwards unsuccessfully searched for by Commander Bullock, in H.M.S. *Serpent*, in 1866. It has, however, again been reported 2 miles westward of its first assigned position by Captain W. B. Andrews, of the Peninsular and Oriental Company's steam-ship *Avoca*, in 1873. The rock is locally known by the name of *Ogo*, and lies 3 miles E. by N. from Cape Cochrane, in lat. $31^{\circ} 48'$ N., long. $131^{\circ} 35'$ E. It is very steep-to, and breaks in bad weather.

Numa Sima or Hosō Sima Harbour, (lat. $32^{\circ} 23'$ N., long. $131^{\circ} 43'$ approx.) is a secure and well sheltered anchorage for a large number of vessels. The entrance is open to the N.E., and thence extends in a westerly direction about a mile to the head of the harbour. During typhoons the winds at East and S.E. are usually the strongest; Hosō Sima Harbour would thus afford shelter during the season when those storms occur. At the head of the bay a vessel in distress might safely be beached. The harbour is apparently clear of danger.

The **SOUTH COAST** of **SIKOK**, from Isa saki at the eastern entrance to the Boungo Channel to I. sima at the western entrance to the Kii Channel, is also as yet unsurveyed. This coast is about 150 miles in extent, and is divided by the projecting peninsula, of which Murato saki is the extreme point, into two bights, that to the westward being the deepest, broken in outline, with several deep indentations which may, when examined, prove useful harbours of refuge; four have been mentioned, two only of which are described as good harbour.

The coast of Sikok between Ootzu saki and Ko sima no hana forms a deep bight $3\frac{1}{2}$ miles wide between these points, and $2\frac{1}{2}$ miles in depth. From it two inlets extend farther to the northward and eastward, forming the harbours of *Susaki* and *Nomi*, the latter in lat. $33^{\circ} 23' 18''$ N., long. $133^{\circ} 17' 48''$ E., in the S.E. part of the bight. Vessels entering Nomi Harbour should keep the northern shore on board.

SOUTH-EAST COAST of **NIPON**.—From Siwo Misaki, the southern point of Nipon, the coast trends to the north-eastward for 75 miles as far as Cape Sima. The whole of this coast is bold and mountainous, the high coast ranges attaining an altitude of 2,000 ft. The hills are thickly wooded and very undulating, those immediately in the vicinity of the coast being steep

and conical shaped. Several good harbours of refuge are found, which have been described as follows :—

OO-SIMA HARBOUR is formed between Oö sima and the East side of Siwo misaki, the extreme South point of Nipon, which, with its lighthouse, is described hereafter, and which is connected to the mainland by a low isthmus. The harbour has two anchorages, one in the bay on the S.W. side of Oö sima, completely sheltered, but the water rather deep; the other in 4 to 6 fathoms, muddy bottom and good holding ground, off the village of Hasingui on the mainland in the northern part of the harbour.

This very eligible harbour is largely resorted to by windbound junks, and it offers every facility for repairs and replenishing supplies. There are three villages, two on the mainland and one on the island. Water is easily obtained from the latter village.

Oo Sima Island, which forms the eastern shores of the harbour, and is about $3\frac{1}{2}$ miles long (East and West), and $1\frac{3}{4}$ mile at its widest part, is irregular in shape and outline, hilly, and the greater part under cultivation, being only thickly wooded in the ravines. Its summit is 535 ft. high.

LIGHT.—On the East point of Oö sima is exhibited, at an elevation of 130 ft. above the sea, a *revolving bright light*, which shows half a minute, and is eclipsed for half a minute, visible in clear weather from a distance of 18 miles. The position of the lighthouse is lat. $33^{\circ} 28' N.$, long. $135^{\circ} 52' E.$

Double Rocks, above water, lie 2 cables to the north-eastward of the East point of Oö sima.

Kami Seh Rock was examined by H.M.S. *Sylvia*, in 1874. It has 16 feet water over it, and 17 to 19 fathoms close-to. From the rock, Oö sima lighthouse bears S.W. $\frac{1}{4}$ W., distant 19 cables. Itsimo Sima, just touching Omi saki Rock, bearing W. $\frac{1}{2}$ N., leads well South of Kami seh Rock.

Directions.—Approaching Oö sima Harbour from the westward, a heavy tide race is often met with off Siwo misaki, which is skirted by uneven masses of rock, most of it showing at low water, with rocks awash 3 or 4 cables off shore. *Bottle Rock*, lying South a quarter of a mile from the point, has some foul ground $1\frac{1}{2}$ cable outside it; a rocky spit extends about a quarter of a mile off Wedge Head, and there is broken ground at nearly the same distance off Isumo saki.

To clear these dangers, the right extreme of Oö sima, the most southern point seen, must not be brought eastward of E.N.E. until Mioga sima comes well open of Isumo saki N.N.W., when it may be steered for, taking care not to bring it northward of that bearing until within half a mile of it, or until the East extreme of Isumo saki bears S.S.W. $\frac{1}{4}$ W., when steer N.W. $\frac{1}{4}$ N., passing mid-channel between the land and the West side of Mioga sima, which has a small ledge running off its South side; after passing Mioga sima, steer for the anchorage of Hasingui.

If compelled to work in, the Oö sima shore is the clearest, but take care

to avoid a dangerous rock lying nearly 2 cables westward of the N.W. part of Tsuya sima, an island 120 ft. high off the S.W. point of Oö sima. The S.W. bay of Oö sima is clear of danger. In making the starboard board remember the bearing of Mioga sima for clearing the foul ground off the West side of the entrance; to the northward of Mioga the lead will give warning when approaching the mainland, but Oö sima is steep-to.

Approaching the northern entrance of the harbour from the eastward, give the mainland a berth until the Kuro sima Rocks are passed, as numerous rocks, only showing at low water, lie scattered along the coast, some nearly a mile off shore, and a shoal has been reported as lying N.E. $\frac{1}{2}$ N. $1\frac{3}{4}$ mile from the lighthouse on Oö sima. The Kuro sima are two large rocks, with a group of smaller ones off their West side. The South end of the chain of rocks off Hasingui may then be steered for, passing the outer rock at half a cable, and taking up the anchorage off the village.

Koza-gawa is a small but opulent town, situated on the East side of the entrance of a river, $2\frac{1}{4}$ miles N.N.E. of the North point of Oö sima. At high water, which is about 7^h full and change, 10 ft. may be looked for on the bar. It is the seat of an important whale fishery.

Ura-Kami Harbour is an inlet running $1\frac{1}{2}$ mile in a W.S.W. direction into the land at 8 miles N.E. of Oö sima Harbour, and, although small, affords excellent shelter in 4 to 5 fathoms, over stiff muddy bottom. For steamers it offers an admirable haven, but being only a quarter of a mile wide, sailing vessels might experience difficulty. In entering, take care to avoid a spit of rocks projecting upwards of half a mile in a N.E. direction from the South point of entrance, but show sufficiently to render them easily to be avoided. The best anchorage is in 4 to 5 fathoms off the East end of Ura kami village, which stands on the South shore about half a mile from the head of the harbour.

Kada Bay.—From Ura-kami the coast trending N.E. by E. is high and thickly wooded. At a distance of 40 miles is Kada Bay. Good anchorage with from 13 to 3 fathoms, gradually shoaling, may be found at the head of the southern arm, which is perfectly landlocked, and is reported to be clear of all dangers. The entrance to the bay is marked by a rock off the northern point, about a quarter of a mile off shore.

Owasi Bay is a deep inlet on the North side of Kuki saki, about 5 miles northward of Kada Bay. This bay is formed by Kuki saki on the South, and Domakura saki on the North, and is 5 miles wide at its entrance and $4\frac{1}{2}$ miles deep, composed of four inlets, two of which are only suitable as anchorages, the remaining two being much smaller, are only frequented by junks.

Otai-yama, lat. $34^{\circ} 11' N.$, long. $136^{\circ} 7' E.$, a mountain 5,620 ft. high, is a conspicuous object when approached from the eastward, and is apparently the highest land seen from that direction.

The coast for 23 miles trends to the E.N.E., is much indented, and thickly wooded; the mountains, however, are of much less elevation than those to the southward; several islets and rocks skirt the coast, and a near approach is not recommended. At the distance above mentioned from Owasi Bay is an extensive inlet named Goza.

Mura Harbour, $2\frac{1}{2}$ miles West of Goza Harbour, is an extensive inlet, which indents the coast in a N.N.E. direction, and is 4 miles deep. The bay is divided at the head into two large inlets. Anchorage may be obtained in either of these arms, that to the westward (Hazama mura) being preferable, abreast a small village, in 10 fathoms. Mura Harbour is an excellent and sheltered anchorage.

Goza Harbour, in lat. $34^{\circ} 17' N.$, long. $136^{\circ} 46' E.$, affords shelter from all but West winds. Its entrance, which is about 1 mile wide between the two points, has 12 fathoms water. The southern point is a high bluff, and is thickly wooded, and has one or two small rocks lying to the westward of it. From the northern point a ledge of rocks extends some distance. After rounding the South bluff point, keep in mid-channel to avoid some scattered rocks lying $2\frac{1}{2}$ cables off the North shore, and stand in 2 miles to abreast the first inlet on the port hand, and anchor as convenient.

CAPE SIMA is a low wooded headland, lying 9 miles to the eastward of Goza Harbour. East, $3\frac{1}{2}$ cables from the cape, is a conspicuous rock, 35 ft. in height; a rocky ledge extends 2 cables from the point. To the south-westward from the point are the two small islands *O sima* and *Kō sima*, from which long reefs extend in all directions. *Outer Reef*, on which the sea always breaks, uncovers 8 ft. at low water, and lies S.W. $\frac{1}{2}$ W. $7\frac{1}{2}$ miles from the rock off Cape Sima; S. by W. $\frac{1}{2}$ W. 2 miles from *O sima*, and S.S.E. $\frac{1}{2}$ E. $5\frac{1}{4}$ miles from the wooded entrance to Goza Harbour. Numerous tide rips occur outside this reef, but there is no danger. The islands off Cape Sima should not be approached within 3 miles, and it would be only prudent to give this dangerous cape a still wider berth.

Matoya Harbour lies 5 miles North of Cape Sima, and is open only to the East. Its entrance is $6\frac{1}{2}$ cables wide between Tomio saki on the South, and Sungi saki on the North, but a reef of rocks which are nearly all above water, situate just within the South point, contracts the navigable channel to $3\frac{1}{2}$ cables.

Light.—On Tomio Saki, the South point of entrance to Matoya Harbour, a wooden octagonal lighthouse, 44 ft. high, is built, and painted white. From this is shown a *light revolving* every half minute, elevated 102 feet above the sea, and visible 15 miles off. It is shown between S.W. $\frac{3}{4}$ S. and W. by N. $\frac{1}{2}$ N.

The whole harbour is split up into numerous inlets, narrow channels, and bays, and safe anchorage may be obtained in nearly all of them.

Watakano sima, an island nearly three-quarters of a mile long, lies in the middle of the S.W. arm of the bay which it divides into three narrow channels. The town of Matoya is approached by the northern of the above-mentioned channels, which is little over a cable wide.

Haka se, a rocky patch which uncovers at low water, lies $6\frac{1}{2}$ cables within the North point of the entrance; and another patch, connected with Haka se, lies 3 cables to the north-westward from it, the whole surrounding the eastern point at the entrance to the bay on the North shore of Matoya Harbour.

Oki-no se, a rocky patch of considerable extent, lies N.E. $\frac{3}{4}$ E. $3\frac{1}{2}$ cables from the outer rock, seen above water off Miya-no saki (at the North entrance to the channel leading to the town), to which it is joined by a reef.

Supplies are very limited.

On entering Matoya Harbour the reef just inside the entrance projecting from Tomio saki, will be avoided by passing from about $1\frac{1}{2}$ to 2 cables from the extreme rock seen above water, after passing which, to avoid Haka se, steer West for the opening leading to the town, seen South of the cliffs of Miya no saki, and anchor as convenient.

With winds from N.E., North, or N.W., good anchorage may be had in the small bay on the northern shore of the harbour off the village of Adako; but with wind from South or East vessels should either anchor off Matoya in from 5 to 6 fathoms, or between the East side of Watakano sima and the reef which extends off the second point from the entrance on the southern shore.

Toba Harbour.—About 8 miles northward of Matoya is the small harbour of Toba, the residence of a daimio. It is said to be available as an anchorage, but is not of any great extent. The harbour is situated at the western entrance to the bay of Owari.

Light.—On the N.E. point of Suga Sima, the South entrance point of Toba Harbour, is built a brick lighthouse, 28 ft. high, painted white. From it is shown a *fixed bright* light, elevated 176 ft. and visible 15 miles off.

A *thirteen-feet rock* lies in Toba Harbour, about 3 cables distant from the North end of Suga Sima; from it Kami Sima bears N. 61° E., the outer rock, near Suga Sima lighthouse, S. 77° E., and the North end of the small island in the inner part of the harbour, S. 68° W.

OWARI BAY.—This extensive inlet, the entrance to which is between Momotori (an island North of Toba) on the West and Irako saki on the East, is about 35 miles long (North and South) and divided into three separate arms, that to the westward being the largest. The western side shows a high mountain range broken opposite Yokaichi. The eastern coast is low; from Moro-saki to Noma Saki are hills of moderate elevation; North of Noma Saki the land appears level and wooded. Mr. Pendered, in the *Thabor*, 1875, proceeding in a nearly direct line from Kama Sima at the entrance

to Yokaichi on the West shore of the gulf, obtained soundings of 13 to 25 fathoms, at $2\frac{1}{2}$ or 3 miles from the East shore.

According to an examination recently made by the German vessel of war *Elizabeth*, Owari Bay has a general depth of 17 to 22 fathoms, decreasing to 7 or 8 fathoms on the East, West, and S.W. sides of the bay at distances of 2 to $3\frac{1}{2}$ miles from the shore. Large vessels, without local knowledge, should not shoal less than 8 fathoms. Near the mouths of various small rivers mud banks have formed, on which the water shoals to 3 fathoms; in few cases can these banks be discovered by the discolouration of the water.

A shoal of $2\frac{1}{2}$ fathoms, mud, lies about 2 miles from the eastern shore, with Onia Saki village bearing N.N.E., Noma Saki S. by E., Tokoname village E.N.E.

Vessels can anchor in any part of the bay, having due regard to the prevailing wind, for the bay is large enough to produce an inconvenient swell with a strong breeze.

Yokaichi, at the mouth of a small river on the western shore, at the head of Owari Bay, is in lat. $34^{\circ} 58' N.$, long. $139^{\circ} 36' E.$ (approx.). It is the port where all produce from the interior is shipped. Native steam vessels call regularly there, and the place is of rising importance. At the head of the bay, about 8 miles N.E. from Yohaichi, is *Kuwana*. The head of the bay is formed by the delta of the large river Kiso.

The N.E. head of the bay is known as *Miya Bay*, and at its N.E. point is the seaport of *Miwa*, which it is proposed to connect with *Nagoya*, one of the largest and most opulent cities of the empire, by a railway about 4 miles long. This railway is thence to be extended till it is joined with the system described with Hiago hereafter.

Entering this bay, Kami Sima should be left on the port hand; the southern passage, having many dangers on it, should not be attempted. Off Irako-Saki are some detached rocks, and when approaching from the eastward the cape should not be passed too closely. Inside of and to the northward of Irako-Saki, H.M.S. *Frolic* found a safe anchorage in from 7 to 8 fathoms, mud, with perfectly smooth water, though a considerable swell was running outside.

The coast from Irako saki takes an easterly direction for 60 miles as far as Omae saki, *Hamana Inlet* lying midway between. It is fronted by a sandy beach with low sandhills and occasional patches of trees, the whole being steep-to, with no known off-lying dangers.

OMAE SAKI and LIGHTHOUSE, the West point of entrance to Suruga Gulf, is a dark wooded bluff 150 ft. in height. The lighthouse, 57 ft. high, is erected on the sandhill at the South part of the cape. It is painted white. From it is shown a *revolving bright light*, attaining its greatest brilliancy every

half minute, elevated 172 ft., and visible 19 miles off. The light is shown eastward and southward between W. by N. $\frac{1}{2}$ N. and N.E.

Lady Inglis Rocks, half a mile in extent, and covered at high water, lie 2 miles E. $\frac{2}{3}$ S. from the lighthouse.

Portsmouth Breakers, S. $\frac{1}{2}$ E. 25 miles from Omae Saki, were reported by the U.S. frigate of that name. They have since been looked for without success, but a good look-out should be kept while in their locality. Irregularities have been found in the depth hereabout, and the water appeared discoloured. In a S.W. gale good shelter may be obtained under the lee of Omae saki in 7 to 4 fathoms, but no closer in.

Gulf of Suruga (named Tutomi Gulf in former charts) is 34 miles deep and 23 miles wide at entrance.

The western side of the gulf is not so well known as the eastern. It appears less precipitous, but, judging from the soundings obtained off Simidzu, is equally steep-to. At the head of the gulf is *Fusi Yama*, the highest mountain of Japan (p. 1181). *Simidzu* and *Eno ura* are two excellent harbours, one on each side at the head of the gulf.

The four bays *Ena Uru*, *Heda*, *Arari*, and *Tago*, on the eastern side of the Gulf of Suruga will serve as a refuge from S.W. winds, which cause a great swell. Their coasts are wooded and mountainous, attaining the height of 1,000 ft. The entrances may be approached fearlessly, for the high coast conceals them, and the bays only open when within a mile. The whole of the western coast of the Idsu Peninsula is shelving, and may be safely approached to 2 miles. Islands lie off it, but not beyond the distance of a mile. The current is stronger along the shores than in the middle of the gulf.

IRO-O SAKI (Cape Idsu), a fine, bold, rocky headland which cannot be mistaken, is the southern extremity of the mountainous peninsula of Idsu. It will be recognized by a conspicuous white cliff, $3\frac{1}{2}$ miles to the N.W. of it. To the E.N.E. the coast for 3 miles is very broken, and fronted with numerous sunken rocks.

LIGHT.—On the point, elevated 185 feet above the sea, is exhibited a *fixed red light* of the sixth order, visible in clear weather from a distance of 8 miles. The tower is 20 feet high, octagonal shaped, built of wood, and painted white.

Rock Island and Lighthouse.—Mikomoto or Rock Island, about 104 ft. high and a third of a mile of length, with precipitous shores and an uneven outline, bears E. by S. $\frac{3}{4}$ S. about 5 miles from Iro-o Saki lighthouse.

On Mikomoto, at an elevation of 164 ft. above the sea, is exhibited a *fixed bright light* of the first order, visible in clear weather at a distance of 21 miles. A *red ray* is shown between N.W. and N. $\frac{2}{3}$ E., over all the dangers between Mikomoto and the shore; the eastern edge of the ray leading into Simoda

harbour. The tower is 75 ft. high, built of white stone, and is in lat. $34^{\circ} 34' 20''$ N., long. $138^{\circ} 57' 10''$ E.

Between Rock Island and the main land are the Ucona and four other rocks, among which the junks freely pass; but a vessel should not attempt to run inside Rock Island at night unless her distance from it can be accurately estimated, for some of the rocks about Ucona are small ledges and only 2 miles distant from Mikomoto.

Tides.—Regular tides have been observed, the flood setting W.S.W., $1\frac{1}{2}$ mile an hour, the ebb E.N.E., from 2 to 3 miles per hour; thus with the ebb tide the north-easterly current is considerably augmented in force, whilst the flood tide overruns the current close to the shore. To the N.W. and North of Mikomoto there are overfalls caused by the tides passing over a very uneven bottom. The Japanese fishermen deny the existence of any danger there.

The channel between Mikomoto and Ucona Rocks carries irregular soundings of 14 to 30 fathoms, with the exception of a patch of 9 fathoms 3 cables North of the island. An additional reason for not using this channel at night is, that by crossing on a more southerly course towards Cape Sagami, the influence of the indraught on the eastern side of Odawara Bay is not so likely to be felt.

Ucona Rocks, two in number, though they generally appear as one, bear N. by W., distant 2 miles from Mikomoto; the largest is about 25 ft. high. Four other rocks occupy a triangular space of a mile from W.S.W. to N.N.W. of the Ucona. The northern and southern of these are small ledges nearly awash. A reef also extends $3\frac{1}{2}$ cables towards them from Tohadgi Point to the N.W. of the Ucona. There is deep water between all these rocks.

SIMODA HARBOUR, is on the eastern side of the peninsula of Idsu, 6 miles N.E. of the cape. *Vandalia Bluff*, the East point of entrance to the harbour, will be known by a grove of pine trees on the summit of the bluff, and the village of Susaki, which is about a third of the way between it and Sumegi Saki. The town of Simoda stands on the West shore of the harbour, and Kaki-saki village on the East. There is good landing for boats in Simoda creek, and also at the village.

Wood, water, fish, fowls, and eggs, also sweet potatoes and other vegetables, may be procured.

Centre Island, lying nearly in the middle of Simoda Harbour, bears N. $\frac{3}{4}$ E., $5\frac{1}{2}$ miles from Rock Island, and N. by E. $\frac{1}{2}$ E. $3\frac{1}{2}$ miles from the Ucona Rocks. It is high, conical, covered with trees, and a cave passes entirely through it. *Buisaco Islet*, a quarter of a mile N.N.E. from Centre Island, is about 40 ft. high, and covered with trees and shrubs.

There are but two hidden dangers in Simoda Harbour; the first is *Southampton Rock*, which is in mid-channel, S. by E. $\frac{3}{4}$ E., 2 cables from South

point of Centre Island. It has 2 fathoms water on it, and was formerly marked by a *white* spar buoy. The other is the *Supply Rock*, lying S. by W. a short distance from Buisaco or Misana Islet; it is a sharp rock, with 11 ft. water on it, and is marked by a *red* spar buoy.

Anchorage.—In the outer road, or mouth of the harbour, a disagreeable swell is experienced; but inside Southampton Rock and Centre Island vessels are well sheltered. Moor with open hawse to the S. W. It is an unsafe and exposed bay, being open to South and S.S.W., the direction from which the heaviest winds blow.

If intending to anchor at Simoda, pass Mikomoto at a mile, when the harbour will be in full view to the northward. Standing in from this island, a vessel will probably pass through a number of tide rips, but no soundings will be obtained with the hand lead until near the entrance, when the depth will be 14 to 27 fathoms. Should the wind be from the northward and fresh, she should anchor at the mouth of the harbour until it lulls or shifts, or until she can conveniently warp in, as the wind is usually flawy and always baffling.

The Coast from Iro-o saki rounds in a N.E. direction 26 miles to *Futo saki*, its general features being high, rocky, and even, having near Simoda a few sandy beaches. Between Simoda and Futo saki the coast is bold of approach. Over it, the *Amagi Yama* rises to 4,700 ft., and on the N.E. ridge is a conspicuous dome-shaped hill.

From Futo saki the coast trends more to the northward, forming the western coast of Awatsu Bay.

Macedonian Reef lies off the East side of Awatsu Bay, at 4 miles N.N.W. of the lighthouse on the West end of Joka Sima. It dries in many places at low tide. To avoid its western side, do not bring the lighthouse to the southward of S,S.E. $\frac{1}{2}$ E. until the South end of the first range of hills, 700 feet high, North of Cape Sagami, bears E. $\frac{1}{2}$ N.

Vessels embarrassed in the vicinity of the Macedonian reef may find an anchorage about $1\frac{1}{2}$ mile N.E. of it in *Asina Bay*, in 4 to 8 fathoms, good holding ground.

Rocky ground extends from the reef to the South extreme of the bay. There are also some rocks off the North side of the bay, but they show, and are easily avoided by keeping mid-channel.

There are two or three excellent havens for small craft and junks on the West shore of Sagami Peninsula, to the southward of Macedonian Reef.

JOKA SIMA and Lighthouse.—Joka Sima lies off the S.W. point of Cape Sagami, with a channel about 2 cables wide, and encumbered with rocks, between it and the shore. Off its southern shore is a rocky patch of 2 fathoms, 2 cables from the island. The light is a *fixed green light* shown on the western end of the island at an elevation of 106 ft., visible 9 miles off. It is obscured to the eastward between E. by N. and S.E. $\frac{1}{2}$ E. by the land.

In navigating the south-eastern coast of Japan, after passing Satano misaki, in Van Diemen Strait, if the weather be thick, the vessel's position should be well ascertained before she is hauled to the E.N.E., as her course is parallel to the high land for about 20 miles from the pitch of the cape. It should also be borne in mind that the current on this coast (*Kuro siwo*) runs to the E.N.E. at the rate of from 40 to 100 miles a day.

Vessels therefore bound to the eastward must allow for this current, and should keep not more than 30 miles off shore, taking every opportunity of verifying their reckoning, if working up inshore the north-easterly set will be lost, and the ship will be influenced by the tides. Many vessels have under these circumstances reported the current as setting in various directions in the vicinity of the Kii and Boungo Channels, indraughts, and vice versâ, resulting from the ebb or flood tide being experienced at the time. In the summer season the north-easterly current is not to be expected in the vicinity of Iro-o saki (Cape Idsu).

Vessels from the Gulf of Yedo bound for the Kii Channel, after passing Mikomoto (Rock Island), should take an inshore passage, steering for Omae saki, and thence for O sima, thus avoiding the strength of the Japan stream. Following this course, a vessel may carry a favourable current (on the flood), and it has been often observed that there is a back set to the S.W. in the bights between Rock Island and O sima. In following this route, take care to avoid the rocks off Cape Sima.

In approaching the Gulf of Yedo, the remarkable high mountain *Fusi Yama*, a lofty and symmetrical truncated cone of 12,450 ft. elevation, and so different in form from any other land in its vicinity, cannot fail to be of great service in directing vessels either to Simoda or Yedo. In clear weather it is the first distant land seen, and generally to the north-eastward, visible at times upwards of 100 miles. Iro-o saki (Cape Idsu) is in line with it when bearing North. When bound from the southward and westward endeavour to make Iro-o saki, and if the weather is at all clear, the chain of islands off the Gulf of Yedo will at the same time be plainly visible. Omae saki, the West point of entrance to Suruga Gulf, cannot be mistaken for Iro-o saki, the former being low, with a sandy beach and low sand hills, with occasional patches of trees, and the coast is said to preserve this character for 30 or 40 miles to the westward; whereas the cape is high and rocky, has a lighthouse at its foot, its summit being generally hidden in the clouds. Mikomoto (Rock Island) being low, unless the weather is clear, or at night when the light is visible, will not be seen until long after this cape and Vries Island are made.

Between the Kii Channel and Mikomoto, westerly winds are most frequently met with, falling light when the latter place is passed; and often on rounding Cape Sagami a strong N.E. wind is encountered.

THE BAY OF YEDO.

The entrance to the Bay of Yedo, named the Uraga Channel, lies between Cape Sagami on the West, and Cape King, in the province of Awa, on the East, is 15 miles wide between these points, and 35 miles deep. Situated on the N.W. shore at its head is the city of Yedo, now known as Tokei (eastern capital) the commercial as well as political capital of the empire, and on the western shore is the principal seaport and treaty port of Japan, viz. Yokohama. In the year 1876, there were 2,554 foreign residents at the treaty port (p. 1187) of Kanagawa (including those at Yedo). Of these 635 were British, 240 Americans, 161 French, 160 German, and 1,033 Chinese. There were 176 firms, of which 54 were British.

Pilots.—Every master of a vessel entering the port who may engage a pilot is to see that he holds a certificate qualifying him for the pursuit of his vocation as pilot. The following are the signals for a pilot in the day time:—

1. The jack or other national colour of the ship hoisted at the fore. 2. The International Code pilot signal P.T.

At night, the following signals, when used together or separately, are deemed to be signals for a pilot:—

1. A blue light every fifteen minutes, or 2. A bright white light flashed or shown at short intervals just above the bulwarks for about a minute at a time.

URAGA CHANNEL, leading into the Gulf of Yedo, appears remarkably clear of hidden danger. On its West side are the *Ashika sima* or *Plymouth Rocks*, which are always uncovered and easily seen; there are some sunken rocks close around them. In their vicinity, off Senda saki and Uraga, are several rocky patches extending some distance from the shore. The mariner should bear this in mind, and as Kaneda Bay has also some foul ground in it at nearly a mile from the shore, it would be prudent to give this locality a good berth in passing.

Sagami Misaki, the western cape at the entrance to the Uraga Channel is comparatively low, the hills forming in a table flat about 150 ft. in height, and rising, about one mile from the shore, to a saddle peak, having on it two conspicuous clumps of trees elevated 354 ft. above the sea. The shore is clear at less than half a mile, except off the eastern part of the cape, where there is a patch of $4\frac{3}{4}$ fathoms at that distance lying S.E., 7 cables from the North extreme of the cape.

TSURUGA SAKI AND LIGHT.—On the south-eastern point of Cape Sagami, at an elevation of 110 ft. above the sea, is exhibited a *flashing light* of the second order, showing a flash every ten seconds, visible in clear weather from a distance of 16 miles. This light is shown *bright* to the

southward and eastward between W. by S. and N.E. $\frac{1}{4}$ E. To the northward over, and to nearly a mile outside the Plymouth Rocks, a red sector is shown between N.E. $\frac{1}{4}$ E. and N.N.E. $\frac{3}{4}$ E. The tower, 36 ft. in height, is in lat. $35^{\circ} 8' N.$, long. $139^{\circ} 41' E.$

Kaneda Bay, contained between Sagami misaki and Senda saki, affords excellent anchorage with winds from South, round by West and North to N.E., in from 10 to 3 fathoms, as convenient; sandy bottom, good holding ground. *Oki-no sima*, 3 feet above high water, is a black rock in the S.W. portion of the bay, steep-to on the North side, but having foul ground between it and the shore on the South and West sides. *Mits iso* form a cluster of rocks in the centre of the bay that cover at high water. *A shoal* having 6 ft. on it at low water lies W. by S. $\frac{1}{4}$ S. 7 cables from the southern and highest of these rocks; *another shoal*, of 9 ft., lies W. by S. $\frac{3}{4}$ S. nearly one mile from the same rock.

Ashika Sima, or *Plymouth Rocks*, are two dark rocks 5 ft. above high water, lying N.E. $\frac{1}{2}$ N. $5\frac{1}{2}$ miles from Sagami misaki, and S. by W. $\frac{1}{4}$ W. $3\frac{3}{4}$ miles from the lighthouse on Kanon saki. *Kata sima*, a rock awash, lies S.E. by E. $\frac{3}{4}$ E. nearly one mile from the eastern of the two rocks, and is marked by a *red beacon*, surmounted by a ball about 20 ft. above high water.

Senda Saki shows in steep white cliffs the termination of the range from Take yama. It has a dismantled fort at the summit of the cliffs, and is surrounded by detached rocks. The eastern portion of these runs out in a spit, the outer edge, of 21 ft., lying E. by S. $\frac{1}{4}$ S. 6 cables from the point, and leaving only a passage of 3 cables between it and Ashika sima. The outer detached rock awash, steep-to on the South side, lies S.S.W. $9\frac{1}{4}$ cables from Senda saki. On entering Kaneda Bay from the northward, Ashika sima should not be brought to the eastward of N.E. $\frac{1}{2}$ N. until Take yama bears N.W. by W.

Kurihama, the bay North of Senda saki, has a sandy beach at its head, the end of a long plain that is drained by a river running into a lagoon that enters the sea at the North end of the beach. This bay should not be used as an anchorage, the ground being foul in all directions.

Kadzusa Saki, the North point of this bay, is terminated by a conical mound, *Shendora*, 69 ft. above high water, from which a ledge of rocks extends S.E. $\frac{1}{2}$ S. $4\frac{1}{4}$ cables to the outer depth of 5 fathoms. From this to Tomio saki the ground is foul nearly 4 cables from the shore.

Uraga, a thriving village, and clearance port of the junk trade to Yedo, is a capital harbour for vessels drawing less than 9 feet, but should not be entered without a chart.

Tomio saki, the South point of entrance to Uraga is a low point with a Japanese lighthouse and a memorial stone near its extreme. These have been erroneously called beacons; when in line they clear Ka yama. *A shoal* of 12 ft. lies E. $\frac{1}{4}$ S. 3 cables from the light, and there is less than 3

fathoms, three-quarters of a cable S.E. from it. *Miojin saki*, the North point of entrance to Uraga, is a bold bluff surmounted by a battery. From it to Kanon saki the land is undulating, with villages in sandy bays. The whole of this coast is foul for half a mile from the shore, having depths of $1\frac{3}{4}$ to $4\frac{3}{4}$ fathoms on the outer margin. *Ka Yama* or *Elmstone Rock* has only 12 ft. on it at low water, with 4 fathoms, 2 cables to the eastward and southward. It lies S. by W. $\frac{3}{4}$ W., nearly 1 mile from Kanon saki lighthouse. Ashika sima kept S.S.W. $\frac{1}{2}$ W. until Kanon saki light bears N.N.W. will clear all the foul ground.

Kanon Saki and Lighthouse.—Kanon saki is a steep and partially wooded point, within which, 1 cable from the shore, is a conical hill, 272 ft. above high water. On the slope of this hill, at an elevation of 170 ft. above high water, is exhibited a *fixed bright light*, visible 14 miles off. The tower is square, built of stone, and rises from the centre of the keeper's dwelling.

The point immediately East of the lighthouse is steep-to, but the S.E. extreme of Kanon saki has a reef off it, terminated by a rock awash, steep-to, $1\frac{1}{4}$ cable from the shore. From this to Rubicon Point the coast is slightly indented, having sandy bays between the points. From Rubicon Point rocks extend 1 cable, with deep water close to the outer.

O Tsu-no ura is a deep bay with a sandy beach, having numerous villages from the largest of which it takes its name. This bay has shallow water in the eastern portion, the outer shoal of 12 ft. lying N.W. by W. $\frac{1}{2}$ W. $8\frac{3}{4}$ cables from Rubicon Point. In the centre of the bay is a shoal $4\frac{1}{4}$ cables long by 3 cables broad, having 9 ft. on the North and 13 ft. on the South edge, with uneven depths of $2\frac{1}{4}$ to $4\frac{1}{4}$ fathoms between. The North edgelies S. $\frac{3}{4}$ E. 5 cables from the South end of Saru sima, and N.W. by W. $\frac{3}{4}$ W. nearly 2 miles from Rubicon Point.

Saru Sima, 198 ft. high, is clifty, with a wooded flat summit. The S.E. point has a conspicuous single tree; and from the South extreme a sandy spit extends half a cable. This island has shoal water all round, except off the North end.

From the South point, E by S. $\frac{3}{4}$ S. $3\frac{3}{4}$ cables, lies *Kitsne no se*, a rock that covers at high water; and West, 3 cables from the same, lie three rocks awash at high water. Between these and Kitsne no se there is shallow water. No vessel should go between Hana rete and Saru sima.

Hana-rete, 94 ft. high, is a grass-covered conical mound, sloping down to dark rugged rocks. Between it and the western end of O-tsu-no ura the coast is a series of white cliffs, with shingly beaches intervening. Immediately South of Hana-rete is a deep bay, off the South point of which there is a conical islet 78 ft. high, from which, S.S.E. $\frac{1}{2}$ E. $3\frac{1}{2}$ cables, lies a rock that dries at low water, with foul ground between it and the shore.

Beacon.—A rock, awash at low water, having on it an iron beacon surmounted by a cage, and painted *red*, lies N.E. by E. $3\frac{1}{2}$ cables from Hana-

rete; East, 1 mile nearly from Ha sima, at the entrance to Yokoska; and N.W. 4 miles from Kanon saki extreme. It may be approached to a quarter of a mile on the North side, but vessels should not attempt to pass inside it.

YOKOSKA HARBOUR, 11 cables in depth, and with a general breadth of $3\frac{1}{2}$ cables, is the eastern of two inlets, and may be easily recognized by Ha sima, the islet that lies off its N.E. point, and by a remarkable clump of trees, 355 feet above the sea, known as *Azuma*, on the highest hill of the promontory that separates it from Ura-no-go ura, the western bay. It has a series of cliffs and indentations, the points generally being marked by white stone beacons. At the head of the harbour is a dock, with large smith and boiler factories, and all the necessary works for thoroughly repairing and building ships, with houses for the officials, built on a plain that joins O-tsu-no ura. On one of these factories is a clock tower, that may be seen from that bay. The inner harbour is formed by two breakwaters, and is of considerable width at the entrance.

The Dock is 395 ft. in length, 82 ft. broad, and 26 ft. deep. It has no lock, and vessels can pass from the anchorage through the inner harbour direct to the dock. There are three other slips for building purposes.

Off the eastern points of Yokoska there are spits, having 10 to 12 ft. on their outer edges; those off Susu-ga saki extending N.N.E. $2\frac{1}{2}$ cables, and N.W. $\frac{1}{2}$ W. $1\frac{1}{2}$ cable. The outer end of the latter is marked by a small *red cask buoy*. Vessels should not bring Ha sima to the northward of N.E. by N.

Anchorage may be had in 6 to 8 fathoms in any part of the bay, but large ships should not go inside the red buoy, as there the anchorage space has only 2 cables breadth.

Across the promontory that separates Yokoska from Ura-no-go ura, a canal has been cut, through which boats may go, when the tide has risen 1 foot above low water. Hako saki, the N.W. extreme of this promontory, has rocks that show at low water, and shoals off it for $1\frac{1}{2}$ cable. For the better protection of Yokoska Harbour, a breakwater is being constructed, which will be about 600 ft. in length when completed.

Ura-no-goura, 8 cables long, with a general breadth of 4 cables, has excellent anchorage in 7 to $4\frac{1}{2}$ fathoms, mud, as convenient; the water shoaling gradually as the bay is entered. There is no danger in mid-channel. *Yeno-kido* is a deep inlet on the western shore of this bay, with too narrow an entrance for ships, but a fine harbour for junks, running inland 4 cables, and having a general width of 1 cable. From its North point, E. by N. $\frac{3}{4}$ N. $1\frac{1}{2}$ cable, lies *Yabama*, a reef that just shows at high water, steep-to on the outer edge. *Matsu Sima* is a partially wooded island, 300 ft. high, that stands between Ura-no-go ura and the entrance no Kanasawa Inlet. It has a spit of shoal water, with 4 fathoms on its outer edge, extending East 3 cables,

and shoaling gradually towards the shore. *Yeboshi yama* is a conical rocky islet, joined to the shore near Yenokido at low water, and separated by a channel of 1 cable from the S.W. point of Matsu sima.

On passing Matsu sima a creek is seen, which, on entering, winds round in a northerly direction, and at about half a mile from the entrance the channel contracts, passing which it opens into a large shallow lagoon. A narrow channel, marked by stakes and bushes, leads up to the village of *Kanasawa*, situated in the N.W. corner. From this village there is a good road (which lies through a remarkable narrow pass) to the town of Kamakura, celebrated in the history of Japan as being a former opulent town, and also at this time for its ancient temples. Continuing this road for some distance about 2 or 3 miles from Kamakura is the celebrated bronze statue of Daibutsu sama, situated in a beautiful grove at the foot of a valley.

From Matsui sima the coast takes a northerly direction for 3 miles to *Graham Bluff*, is shallow for some distance, and at 2 miles off-shore is skirted by banks of from $4\frac{1}{2}$ to 5 fathoms, with deep water between them and the coast.

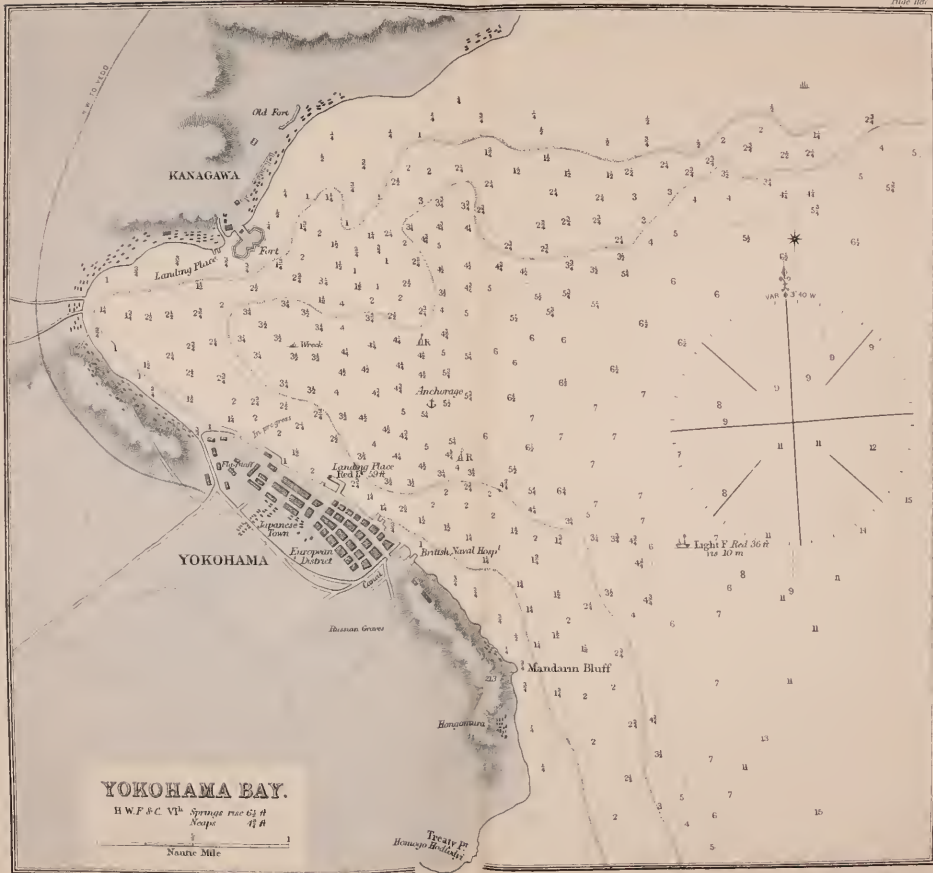

Mississippi Bay (Nigisi), formed between Graham Bluff to the southward and Treaty Point on the North (between which it is 3 miles in width), is well sheltered from the prevailing winds. In anchoring, give the shore a wide berth to avoid a shoal which extends half to three-quarters of a mile from it. Between Matsu sima and Treaty Point the soundings are irregular, shoaling suddenly from 12 to 5 fathoms on banks of hard sand.

Treaty Point, the termination of a ridge of low hills extending into the Gulf of Yedo, about $10\frac{1}{2}$ miles N.N.W. of Kanon saki, forms the southern point of the Bay of Yokohama. The point is formed of a long line of cliffs of a conspicuous yellow colour, the northern bluff of which is called Mandarin Bluff. These bluffs, and a bank which fronts them to the distance of $1\frac{1}{4}$ mile in some places, and which is rather steep-to, protects the anchorage from south-westerly winds, the only ones which blow with sufficient force to send a heavy sea into the bay.

A LIGHTVESSEL, with two masts, carrying a ball at her foremost head, is placed at the extremity of the shoal off Treaty Point and Mandarin Bluff, and lies in 7 fathoms, with the following bearings:—Treaty Point, S.W. $\frac{3}{4}$ S.; Mandarin Bluff, S.W. by W.; and the mouth of the Canal (just northward of the English sick quarters), W. $\frac{1}{4}$ N. The vessel exhibits a *fixed red light*, elevated 36 ft. above the sea, and visible in clear weather from a distance of 10 miles.

A *buoy*, with a cage painted *red*, is moored in 4 fathoms on the northern extreme of the shoal off Mandarin Bluff, southward of the anchorage off Yokohama, with the following bearings:—Mandarin Bluff, S. by E. $\frac{1}{4}$ E.; Mouth of the Canal, S.W. by S. $\frac{1}{2}$ S.; and the centre of the English hatoba (landing place), W. by S.

YOKOHAMA BAY.

Nautical Mile

Treaty of Commerce and Consular Rights between Great Britain and Japan

YOKOHAMA on a plain surrounded by low hills, is environed by a canal which entirely isolates it. It is connected with Yedo by a railway, which forms part of the system described with Hiogo hereafter. The residences of the foreign community occupy the East, and those of the Japanese merchants the N. W. of the town, and the bluff on the South side, on which is situated the camp and British Legation, is being rapidly built over. The English sick quarters are on the northern face of the bluff at the southern end of the town; boats can land there at high water in the canal above mentioned. The position of the square in the sick quarters is lat. $35^{\circ} 26' 30''$ N., long. $139^{\circ} 39' 24''$ E. Yokohama exports tea, raw and manufactured silk, lacquered goods, vegetable wax, oil, antlers, cotton, and rice in small quantities. For the Chinese market, paper, camphor, flour, peas, beans, seaweed, isinglass, beche-de-mer, and dried shell-fish.

At the head of the bay, and on its North side, stands the town of *Kanagawa*,* one of the ports opened to foreigners, but this being an inconvenient situation for a settlement it was changed to Yokohama on the South side, it being a more eligible position for business communication. The water also is deeper for anchorage, and more convenient for the landing of boats and merchandise than at Kanagawa, where it is so shallow that at low tide the sea retreats to a considerable distance from the shore.

Kanagawa is subject to frequent shocks of earthquakes. It is situated on the Tokaido or imperial highway to Yedo. All persons (excepting officers in uniform) passing between Yokohama and Yedo must produce a passport.

A *red buoy*, with staff and cage, is moored in 4 fathoms at low water springs on the point of the spit extending from Kanagawa Fort to the northern side of Yokohama anchorage, and lies S.E. by E. easterly, 1 mile from Kanagawa Fort.

A good *anchorage* for large ships is with Kanon saki just open of Mandaria Bluff, the latter bearing S. by E., and the British Consulate S.W. by W. $\frac{1}{2}$ W., mud bottom. Vessels of lighter draught may, if desirable, take up a position much nearer the town.

All *supplies*, provisions, water, coal, &c., are to be procured in abundance, and ordinary repairs both to ships and engines can be easily executed.

* The limits of the Treaty Port Kanagawa to the North lies along the course of the Logo River, which, after pursuing an easterly direction, enters the sea midway between Yedo and Yokohama. At 25 miles above the mouth of this river the treaty boundary leaves the river and pursues a southerly direction to the coast, which it joins just eastward of Odiwara, in long. $139^{\circ} 10'$ E. The extent of territory open to foreigners is thus, roughly speaking, 25 miles square. There is a strip of land on the western side of Uruga Channel not open to foreigners; its boundary line runs from Susquehanna Bay on the East to Asina Bay on the West.

Tides.—It is high water, full and change, in Yokohama Bay, at 6^h, and springs rise 6½ ft., neaps 4¾ ft. ; with southerly winds the tide rises about 2 feet higher.

The streams in this bay are scarcely felt, but they run strong in the middle of Yedo Bay, and their velocity is much increased off Saratoga Spit, Sarusima, and Kanon saki, particularly off the latter, round which they sweep with great rapidity.

KAWA SAKI, bearing N.E. ½ N. from the lightvessel off Treaty Point, is low and wooded, with shoal water extending 1½ mile from the shore, its edge being marked by Haneda pile lighthouse and two buoys. The southernmost, a *red buoy*, with cage, is moored in 6 fathoms, with Treaty Point S.W. ½ W., Kawa saki N. ½ W., and Bansu hana E.S.E. southerly. The northernmost, a *black buoy*, with cage, is moored in 6 fathoms, with Kawa saki bearing West, Noko gawa entrance N. ¾ E., Bansu hana S.E. ½ E., and the southern buoy S.W. ¾ S.

Haneda Point Lighthouse.—At the extremity of the spit which extends to the eastward of Kawa saki a pile lighthouse was completed in 1875. The lighthouse is 60 ft. high, of iron, painted white, and stands in 7 ft. water, 500 yards in-shore of the black buoy. From it is shown a *fixed green light*, elevated 40 ft. above high water, and visible to South, East, and North, between S.W. by W. ⅔ W. and N.N.W. ⅓ W., 8 miles off.

YEDO, which has lately been named *Takei*, is situated at the N.W. angle of Yedo Bay, along the shore of which it extends, with its suburbs, for 8 miles. Its aspect is not imposing, as large stacks of timber and elevated ground conceal by far the larger part of the city. The suburb of Sinagawa stands on the South of the city, where are seen the low wooded heights of Goten yama, extending 2 miles along the shore. The landing place is on the North side of these and West of the five forts, close to which is the temple occupied by the British legation.

The small River Sdogawa, which flows through the very centre of Yedo, disembogues at the northernmost part of the bay on which the city stands, thence splitting into two streams, up which boats and small junks can pass.

Light.—On the third fort (commencing with the extreme eastern fort) before the city, at the East entrance to the Tsikiji channel leading to the foreign concession at Tsikiji and the city, elevated 53 ft. above high water, is exhibited a *fixed red light* of the fourth order, visible in clear weather from a distance of 9 miles.

Anchorage.—This bay is so shoal all along the shore where the city stands that at low water even a ship's boat cannot approach within a mile. The best anchorage for a large ship is in 5 to 6 fathoms, soft mud, good holding ground, with the south-western of the five forts bearing N.W. ; but recollect that on this bearing the water shoals rather suddenly from 4 to 2½ fathoms. It is better, therefore, to anchor a smaller vessel on a N.W. by N. bearing

of the fort. H.M.S. *Furious*, in 1858, anchored in 15 ft. at low water, with the five forts bearing from N. $\frac{1}{2}$ W. to N.W., Beacon house S. $\frac{1}{2}$ W., and the peak of Fusi yama W. by S.

The Coast from Tonegawa Point round the head of the Gulf of Yedo is low, with shoal water extending a considerable distance from the shore, forming a deep bay with from 6 to 8 fathoms water between the above point and *Bansu hana*, which lies on the eastern shore of the gulf about S.E. by E. 8 miles from Kawa saki; it is very low, and is fronted by shoal water extending 2 miles from the shore in a westerly direction. From *Bansu hana* the coast takes a southerly and then a south-westerly direction for 12 miles, and is low and shoal from $1\frac{1}{2}$ to 2 miles off shore.

Futsu Saki is a low sandy point, having a fort at its high water line, and stretching out in a narrow tongue that forms *Saratoga Spit*. West from this tongue, in 9 fathoms, is moored a *red buoy*, with staff and cage, 13 ft. above the water. East from the buoy there are only 5 fathoms at 3 cables, and 1 fathom at three-quarters of a mile. The bank of 5 fathoms trends N.E. $\frac{1}{2}$ N. and S.E. by E., deepening rapidly to 10 fathoms.

The coast from *Futsu saki* takes an easterly and southerly direction, forming a deep bay, the northern shore of which is sandy and low, but the southern is the termination of the slopes from the high range *Noko-gheri yama*, and is rocky and steep-to. Shoal water extends from $1\frac{1}{2}$ to 2 miles from the shore in the centre of the bay.

Kanaya Point, the south-western extreme of these slopes, is steep-to, and bears nearly East of the *Tree Saddle* on *Sagami Peninsula*; it is at the termination of the sharp well-defined ridge of the *Miogani yama*, a fine dome-shaped mountain, elevated 1,096 ft. The coast from this point takes a southerly direction for $7\frac{1}{2}$ miles as far as *Daibo saki*, between which there are three small bays, the southern of which has several rocky patches.

Ghibu Isi (*Black Rock*), about 20 ft. high, lies three-quarters of a mile West of the latter bay, having several reefs in its vicinity which only uncover at low water. The lofty mountains *Miogani yama*, *Sveno yama*, and *Double Hill*, are very conspicuous, towering above this coast.

The *Peninsula of Awa*, although mountainous, is less so than *Idsu*, and possesses much larger tracts of arable land, all of which is carefully cultivated. Its West coast is more sinuous than the opposite shore of the gulf, but only one of the bays, *Tati yama*, formed in it, affords fair anchorage.

To the northward of these hills the country (*Kadsusa*) becomes much lower, and a few miles north-eastward of *Futsu saki*, the point off which runs the *Saratoga Spit*, it becomes an uninteresting dead flat, encircling the head of *Yedo Bay*.

Tati-yama Bay, formed between *Daibo saki* and *Su saki*, has shelter and good holding ground in southerly and easterly gales, but it is exposed to the westward.

SU SAKI, the East point of entrance of the Gulf of Yedo, when seen from the southward, appears as a block of small hills, rather conical in profile, the highest, *Hazama*, being elevated 650 ft. The point is low, with the exception of a small elevation at the N.W. corner, on which is an old fort. There is a heavy *tide rip* off it, but no dangers at a greater distance than half a mile from the shore, and the point may be safely rounded at a mile.

Mela Head, S.E. $\frac{1}{4}$ S. nearly 5 miles from Su saki, forms the eastern point of entrance to the Uraga Channel and Gulf of Yedo. It is 456 ft. above the sea, the general height of the coast range in its vicinity being comparatively low. An extremely dangerous ledge (*Mela Ledge*) lies $1\frac{1}{2}$ mile off Mela Head, about 5 miles S.E. of Su saki. Extending 3 miles from this ledge in a south-westerly direction is a rocky bank.

NO SIMA LIGHT.—On No sima Point, at an elevation of 134 ft. above high water, is exhibited a *fixed bright light* of the first order, visible in clear weather from a distance of 20 miles. The tower is octagonal shaped, and painted white.

Approaching the Gulf of Yedo from the southward or westward, in clear weather, the chain of islands running southward from it are unmistakeable landmarks, and Cape Idsu can scarcely be mistaken. Omae saki, the point 25 miles westward of the cape, is low, while the cape, as before stated, is high, bold, and rocky. From $1\frac{1}{2}$ mile eastward of Mikomoto (Rock Island) a N.E. $\frac{1}{4}$ E. course will lead 4 miles N.W. of Vries Island, from which position the centre of the entrance of the Uraga Channel bears N.E. by E., distant 22 miles. Care must, however, be observed when approaching Cape Sagami not to be drawn into Odawara Bay by the indraught mentioned. Should Vries Island be visible, this danger is easily guarded against by not bringing that island southward of S.W. by S.

Vessels approaching the gulf from the eastward are recommended not to hug the shore of the South end of Awa too closely, as dangerous shoals are known to exist in that neighbourhood.

To avoid the Mela Ledge and all other *known* danger when rounding from the eastward, do not bring the eastern extreme of land *seen* to bear eastward of E.N.E. until the extreme of Su saki bears N. by W.; and when rounding from the westward do not bring the extreme of Su saki westward of N. by W. until the eastern extreme of land is E.N.E. At night, or in thick weather, when the light on No-sima Point is not seen, soundings of 40 fathoms may be considered as indicating close proximity to these dangers.

In steering for the Uraga Channel the Tree Saddle Hill on the South end of Sagami Peninsula will be readily recognized; and on nearing the channel the Ashika sima (Plymouth Rocks) will be plainly seen on its western side. Give these rocks and the Ka yama a berth of half a mile in passing, or at night keep without the red rays of the lights, and after rounding Kanon saki at a little less than that distance, steer N. by W. $\frac{1}{4}$ W., which will lead

to the westward of the buoy off the Saratoga Spit, and continuing this course when the lightvessel of Treaty Point is seen steer to pass to the eastward of her, taking care not to bring the light to the northward of N. $\frac{1}{2}$ W. The elevated ground above Mandarin Bluff, at one mile northward of Treaty Point, showing to seaward in brown cliffs well wooded to the summit, will be readily recognised; the bluff being the most eastern.

The lightvessel may be passed within a cable's length, after rounding which steer to pass northward of the red buoy with staff and cage moored on the northern edge of the bank off Mandarin Bluff, and anchor as convenient.

A sailing ship will have to make short tacks when working into Yokohama Bay with a westerly wind, as North of Mandarin bluff the deep water channel is narrowed to $1\frac{1}{2}$ miles; the lead here, however, as is the case round nearly the whole shores of Yedo Bay, gives fair warning.

Working through the Uraga Channel.—With a northerly wind a vessel after passing Cape Sagami may stand across and tack close to the opposite shore, as there are no rocks at any distance off it to the northward of Kanaya Point, and to the southward of the point the dangers show. If unable to fetch this point it would not be prudent to stand into the bay between the point and Uki sima, a small rocky island 150 ft. high to the southward, as foul ground exists there. This bay will be readily recognised from a distance, as it is the sea shore of a valley between the Miogani yama and Sveno yama ranges, and two small hills are in the centre of it.

In making the western board, the foul ground in Kaneda Bay, as well as off Senda saki, and along the shore between it and Kanon saki, must be remembered. The shore of Kadsusa Bay, northward of the Miogani yama range, may be approached by the lead, tacking in 5 fathoms.

If unable to fetch Kanon saki on the starboard board, be careful to tack short of the bearing for clearing the Ka yama. Short tacks should be made when to windward of Kanon saki, not shoaling towards the opposite or Kadsusa shore to less than 9 fathoms. When Saru sima bears W. by S., stand no farther eastward than to bring Kanon saki to bear S. $\frac{1}{4}$ E. until Saru sima is S.W. $\frac{1}{2}$ W., when the spit will have been weathered. At night do not bring the light off Treaty Point to bear West of N. by W. $\frac{1}{4}$ W. until Kanon saki light bears S. $\frac{1}{2}$ E. Long boards may now be again made, but do not shoal on either tack to less than 5 fathoms, nor off Yokohama Bluff to less than 7 fathoms. There are some shoal patches of $3\frac{1}{2}$ to 5 fathoms, sand and mud, off the western side of the bay between Saru sima and Mississippi Bay, but none are known at a greater distance off than 2 miles, and they may be avoided by not bringing Saru sima eastward of South.

The Tides are much affected by the winds, but both flood and ebb sweep with great velocity round Saratoga Spit. The flood runs N.W. by W. and

the ebb S.W. by S., about $3\frac{1}{2}$ knots an hour at springs. Generally the flood stream sets a vessel on to the western shore.

VOLCANIC ISLETS, SOUTH-EAST OF JAPAN.

A very remarkable range of detached islets and rocks extends for nearly 300 miles in a S.S.E. direction from the entrance of the Gulf of Yedo. There is no portion of the ocean which has been more misrepresented than this in our older works, and the great number of supposed discoveries rendered the charts so confused that no adequate idea could be gained of their number or arrangement. The author endeavoured, in 1858, to reconcile these vague surmises and great discrepancies, so as to give a more correct representation of their real character.*

This geographical confusion has arisen no doubt from the unsuspected influence of the great Japanese current, which rushes through the group with exaggerated and uncertain velocity, and thus affecting the dead reckoning of many or most of the ships which announced discoveries, most of which are to the *eastward* of the true positions. It will be unnecessary to discuss these varying accounts, since they are now in a great measure reconciled by exact observations; and this is of the greatest importance, seeing that an increasing commerce between China, Japan, and North-Western America, passes through these channels. What follows will, therefore, be confined to a brief description of what is well ascertained, connected with an identification, when possible, with what has been but vaguely surmised.

These islands are all bold-to, some appearing to rise like a wall from the depths of the ocean, and they have but few outlying hidden dangers. The lead therefore in foggy weather will give little or no warning, as in some cases no soundings will be obtained with 150 fathoms line within half a mile of the shore.

The Currents also in this part of the Japan stream are influenced by the prevailing winds at the different seasons, and capricious, heavy current rips being of very common occurrence, have often been mistaken for *shoals*. These rips are more constantly met with *close* to the islands and rocks than otherwise, and in the event of getting into one at night or in a fog, it may be assumed, when the vessel's position is not accurately known, that danger is near. It may be well to bear in mind that in calms, although the stream may appear to be hurrying the vessel on to an island, if the island be steep, it will always turn to the right or left on approaching within a certain distance of the rocks; not so, however, should shallow water extend any distance, when the anchor must be depended on.

* See Transactions of the British Association, 1858.

The usual set of the current through these islands is north-easterly, and the rate ranges from $1\frac{1}{2}$ to 3 knots, but the islands frequently deflect it from its course, and the eddies always found on the margin of great currents are here particularly numerous and active, so that it is not unusual, especially among the northernmost of the islands and in the vicinity of the coast of Nipon, to encounter a set precisely in the opposite direction to that anticipated. Close to Fatsizio and Vries Islands, at less than one-third of a mile off, a regular change of tidal stream was observed, and also between these islands and the coast.

Lot's Wife or Black Rock, in lat. $29^{\circ} 47' N.$, long. $140^{\circ} 22\frac{1}{2}' E.$, is a tall pinnacle rising about 300 ft. above the sea; in clear weather it can be seen at a distance of 25 miles, and bears a remarkable resemblance to a ship under all sail. A cast of the lead within 8 miles of this rock gave no soundings with 160 fathoms of line.

Ponafidin or St. Peter Island, 1,328 feet in height and $1\frac{1}{4}$ mile in length East and West, was discovered in 1820 by Lieutenant Ponafidin of the Russian Navy, and named by him *Three Hills Island*. Lat. $30^{\circ} 33' N.$, long. $140^{\circ} 15' E.$

Smith Island.—H.M.S. *Tribune* passed this island in 1859, and describes it as a high pinnacle-looking rock, in lat. $31^{\circ} 15' N.$, long. $139^{\circ} 52' E.$, about 250 feet in height, three-quarters of a mile in circumference, with heavy breakers extending apparently a quarter of a mile from it, and a small rock close to its North side. A *volcanic disturbance* was noticed in 1870 at 4 miles N.E. by N. from this island.

Bayonnaise, in lat. $32^{\circ} 0' 40'' N.$, long. $140^{\circ} 0' E.$, forms a curve a cable long North and South, with several hummocks on it, its northern summit being about 26 ft. in height; several rocks extend a quarter of a mile off its N.W. and N.E. sides.

Aoga Sima, in lat. $32^{\circ} 37\frac{1}{2}' N.$, long. $139^{\circ} 47\frac{1}{2}' E.$, is 3 miles long, and visible 36 miles off in clear weather. Its coasts are steep, and the only landing place is on the East side, where there is a rock level with the water at a little distance from the land. It is inhabited and cultivated on the North and N.W. sides.

FATSIZIO ISLAND, the most southern of the islands visited by the *Actæon* in 1861, is $8\frac{1}{3}$ miles long, N.W. by N. and S.E. by S., and 4 miles wide at its broadest part. In shape it is nearly an oblong, rounded at the N.W. end, while at its S.E. end a slight curve forms a bay, the spot of observation which (close to some small huts) is in lat. $33^{\circ} 4' 24' N.$, long. $139^{\circ} 50' 24' E.$ Anchorage was obtained off this bay in 16 fathoms, sand and gravel, at less than a mile from the shore, but exposed from S.S.W. to N.N.E., and a vessel would always be liable to experience a heavy swell. There were 30 fathoms, dark sand, at about 2 miles off this shore, but the rest of the coast line

appeared to share the bold features and to be as steep-to as the generality of these islands.

This island is a penal settlement of Japan. Its highest part is the northern, where a mountain reaches an elevation of 2,840 ft. Approaching from the eastward the island appears as two.

At the S.E. end of Fatsizio are two or three small streams of delicious water falling down the rocks, and in fine weather and smooth water, boats may readily obtain an abundant supply.

Kodsine is a small and nearly oval-shaped island 1,820 ft. high, $1\frac{1}{2}$ mile long, and nearly 1 mile broad; it lies westward of the highest part of Fatsizio.

Broughton Rock (Kanawa), in lat. $33^{\circ} 39' N.$, long. $139^{\circ} 18' E.$, is a small inaccessible islet, about 60 ft. high, flat-topped, and so bold that at about a third of a mile from its N.E. side no soundings could be obtained with 180 fathoms line. The north-easterly current in the neighbourhood of this islet was found to be particularly strong, running nearly 4 knots an hour.

Miaki and Mikura.—*Miaki Sima* is 2,690 ft. high, and has a flat summit; the N.E. end of the island is a little more elevated than the S.W. end. The highest part of Miaki is in lat. $34^{\circ} 5' N.$, long. $139^{\circ} 35' E.$, and the highest part of Mikura in $33^{\circ} 52' N.$, $139^{\circ} 37' E.$; the latter lies about 17 miles to the N.E. of Broughton Rock. Mikura is called Prince Island; and Miaki, Volcano Island in former charts.

Dangers.—There is a cluster of rocks about $2\frac{1}{2}$ miles to the S.W. of Miaki, and Broughton says, “there are, in addition, some black rocks 2 or 3 miles from the eastern point of the island.” A cluster of rocks is also marked on some charts at 8 miles S.E. of the East end of Miaki.

Onohara is a small islet W.S.W. 5 miles distant from Miaki, composed of a cluster of high detached rocky pinnacles, the centre one being perforated in two places.

Redfield Rocks (Sanbon-take) are the most western of the chain of islands and rocks South of the Gulf of Yedo, and the most dangerous of the whole group. They consist of two patches of black rocks extending nearly 3 miles N.N.E. and S.S.W. The southern rocks, in lat. $33^{\circ} 56' N.$, long. $138^{\circ} 48\frac{1}{4}' E.$, are the highest, about 20 feet above high water, while the northern are only about half that height. The hand lead will afford no warning until close upon this dangerous cluster.

Kosu Sima, in lat. $34^{\circ} 12\frac{1}{4}' N.$, long. $139^{\circ} 8\frac{1}{4}' E.$ (centre), and elevated 2,000 ft. above the sea, is $3\frac{1}{2}$ miles long N.E. and S.W., and may be recognized by a remarkable snow-white cliff on its western side, and a white patch on its summit, to the northward of the cliff. There is a safe channel 15 miles wide between Kosu sima and Miaki. Two small rocky islets lie close together, about half a mile off the centre of the eastern shore of Kosu sima. About 2 miles southward of the S.W. point of Kosu sima are the *Onghashi*

Rocks, which should be given a safe berth, as their jagged appearance would lead to the belief that there are many hidden dangers in their immediate neighbourhood.

Sikine Sima is low, with a small islet off its North end. It is $1\frac{1}{2}$ mile long N.N.E. and S.S.W., and lies 5 miles N.E. of Kosu Sima. One of the vessels of the American squadron passed between these islands and saw no danger; there is therefore reason to believe that the channel is safe.

Nii Sima is about $1\frac{1}{2}$ mile N.E. of Sikine, and from its broken outline appears from a distance as several islands. Its extent is 5 miles, North and South, and its most elevated part 1,490 ft. above the sea. There is a small low islet a short distance off its S.E. point.

Utone is a conical islet, 660 ft. high, lying N. $\frac{1}{2}$ E., about $2\frac{1}{2}$ miles from Nii sima; detached rocks lie near its shores.

To Sima, bearing N. $\frac{1}{2}$ W. 2 miles from Utone, is 1 mile in diameter, pyramidal shaped, and its summit 1,730 ft. above the sea.

VRIES ILAND (O sima) the largest and most northern of the chain fronting the Gulf of Yedo, is 10 miles N.N.E. of To sima, its south-eastern point being in lat. $34^{\circ} 40' N.$ long. $139^{\circ} 27' E.$ The island is oval-shaped, about 8 miles in extent N.N.W. $\frac{1}{2}$ W. and S.S.E. $\frac{1}{3}$ E., and 5 miles wide, and its summit attains an elevation of 2,550 ft. At its centre is an active volcano, over which a white vapour cloud is generally floating, and frequently, at night, it brightly reflects the glare of the subterranean fires at work in the crater beneath, forming, in clear weather, a conspicuous landmark, visible by night or day for many leagues. *Observation Point*, a bluff forming the N.W. end of the island, is 350 ft. high, and, when seen from the N.E. or S.W., at a distance appears as an island.

There are several villages on the island. On the North side a narrow bank of soundings affords a precarious anchorage in from 12 to 18 fathoms. A junk harbour is situated at the S.E. point of the island. Landing may be effected at the North village, or in the junk harbour. The inhabitants were civil and hospitable, but averse to strangers visiting the volcano.

THE EAST COAST OF NIPON.

Mela Head to Cape Erratatsi and Ohigasi Saki (King and Blanco) is a wild and dangerous coast, skirted by off-lying rocks; the projecting points are generally rugged cliffs of yellow clay or gravel. It is well wooded; the high land ends about Ohigasi saki in a long backed hill, terminating in a couple of thumb-shaped pinnacles, and is fronted by a bold chalky cliff.

The coast, when partially obscured by fog, is difficult to identify when coming from the eastward; a ship thus approaching Yedo Bay is liable to be set considerably out of her reckoning by the Japan stream. The tempe-

perature of the sea is a useful guide, and the soundings will give good warning if attended to. Mela Head sometimes shows out in relief when all the coast eastward is obscured by fog.

INABOYE SAKI and LIGHTHOUSE.—From Ohigasi saki north-eastward to Nakuno saki, a distance of 100 miles, the coast is low, and for the most part sandy. Inaboye saki is a projecting rocky cape, on which is a smooth, bare, and conspicuous hill, about 200 ft. high; reefs extend from the cape fully a mile, but it may be rounded in safety in 40 fathoms water. Shipwrecks are frequent on the sandy beach North of the cape, caused, it is believed, by the effects of the currents, which meet here and set a vessel towards the shore.

The lighthouse on Inaboye saki, completed in November, 1874, is a circular brick building, painted white, 105 feet high. From it is shown a *revolving bright light*, attaining its greatest brilliancy every half minute, elevated 168 ft. above the sea, and visible 19 miles off.

Arkold Rock, originally reported by the Russian frigate *Arkold* in 1859, was considered to lie in lat. $36^{\circ} 15' N.$, long. $141^{\circ} 28' E.$; again reported in thick weather, by the Russian vessel of war *Sibole* in 1870, was said to be 20 feet high, about 11 miles to the southward of the spot in which it was first reported.

H.M.S. *Thistle* on two occasions in 1873 passed close to the last-named position, but saw nothing of the rock, although from the state of the weather a rock 20 ft. high must have been visible. H.M.S. *Ringdove*, in 1874, made a search for this danger under favourable conditions of wind and weather, but without success; good observations had previously been obtained, and the adjacent land, 35 miles distant, was visible. H.M.S. *Modeste*, in 1877, passed over the assigned position of the rock, but without seeing any signs of the danger; good observations had been obtained an hour previously. Arkold Rock has in consequence of these searches and reports been expunged from the charts.

Choosi Point is on the North side of Inaboye promontory. The *Tone Gawa*, a rapid river, flows into the sea on the South side of the point, but owing to the heavy swell from the Pacific its bar can seldom be crossed by ships' boats, and at times native craft cannot attempt it. There is anchorage in 6 fathoms, sand, 1 mile off the bar, but it is not recommended. The soundings deepen gradually to 20 fathoms at 4 miles from the shore.

North from Chöosi Point for 45 miles the shore is wooded; it may be passed along at a distance of a mile, in 9 fathoms. From Machama the shore is bounded by low cliffs, and North of Kawajiri (a populous fishing town) hill ranges commence.

SENDAI BAY lies on the East coast of Nipon, in lat. $38^{\circ} 20' N.$, the land North of it is deeply indented, high, and steep, and apparently thinly

populated, fishing boats being seen only off Simidzu. Most of the bays are open to seaward.

At 10 miles from the coast inland there is a high, easily recognisable mountain, about 4,600 ft. high, in lat. $39^{\circ} 28' N.$, long. $141^{\circ} 41' E.$, approximately.

The group of islands in the N.W. corner of Sendai Bay should not be approached nearer than 2 miles, as reefs and rocks extend off them to a considerable distance, and there is no anchorage even for a small vessel on the western shore of the bay.

Cape Amitsihama, the East point of Sendai Bay, has deep water close-to, and may be passed within 2 cables. Soundings in from 16 to 19 fathoms will be found between the cape and Nagasima Island, and anchorage for the largest ships may be obtained in from 12 to 9 fathoms, sand, off the North end of the island.

On the shore of the mainland, abreast the North end of Nagasima Island, there is a bay half a mile wide, which affords anchorage in from 7 to 9 fathoms, mud. The bay may be recognised by its having the only white sandy beach in the vicinity, and from a wooded islet lying off its northern point.

A single rock, which dries, lies East 2 cables from the southern extreme of Nagasima Island.

Both the above anchorages afford shelter from North and East winds, but a heavy sea is thrown in by winds from East round northerly to N.W.

Matsu Sima Bay.—The southern entrance of this extensive but shallow harbour, in $38^{\circ} 20' N.$, and $141^{\circ} 5' E.$, appeared completely obstructed by low reefs, and according to the fishermen, no channel exists between the sunken rocks. The northern entrance (4 miles to the northward) is very shallow, there being only 4 ft. water over a rocky bar in a narrow channel, but good shelter for two or three vessels may be obtained off it in 5 or 6 fathoms, mud, open only to the East.

Ichinomaki River, of considerable importance, falls into the sea at the North part of Sendai Bay. It is reported to be navigable by junks for 70 miles, and boats can reach *Morioka*, the capital of Nambu, situated 120 miles from its mouth. The town of Ichinomaki at the entrance was not seen in passing. The anchorage is a roadstead, open to the South and S.E., but it is believed that with the wind from those quarters good shelter could be found in the East part of the bay.

Kitakami River enters the bay in lat. $38^{\circ} 26' N.$, long. $141^{\circ} 15' E.$ Kitakami light consists of a lantern similar to a ship's masthead light, and being in front of the town, it can with difficulty be distinguished from the lights of the houses and junks. It is shown from a mast on the East bank of the river, and elevated 52 ft.

Kingkasan, or **Goldmine Island**, dedicated to religious purposes, is resorted to by pilgrims from all parts of Japan; a peak 1,000 ft. high and wooded to the summit, is conspicuous. The deer on the island are numerous and considered sacred. Mica in large quantities is found in the soil.

Between this island and the main a depth of 3 fathoms can be carried by passing at one-third the distance from the island. There is anchorage on the South side of the narrows.

LIGHT.—A granite tower, 28 feet high, was completed in 1876, on the East side of Kingkasan Island, in lat. $38^{\circ} 19' N.$, long. $141^{\circ} 36' E.$ From it is shown a *fixed bright light* seaward between N. by E. and S.W. $\frac{1}{2}$ W. It is elevated 178 ft. and visible 19 miles off.

Aikawa, near Kingkasan, is a safe anchorage, and is the first sheltered spot for vessels bound to the northward from Yedo Gulf. It is easy of access, and the light now shown from Kingkasan Island will guide to its position. The reef projecting 3 cables from the southern cape is dangerous. It breaks only when the wind blows hard, or when there is a heavy swell.

It is not recommended to pass inside Hira Sima, Asi Sima, and their contiguous groups.

The coast to the northward is at present little known to navigators; it presents a deeply indented outline, probably concealing some fine harbours. The shores appear bold.

Kamaishi Harbour, in lat. $39^{\circ} 18' N.$, long. $142^{\circ} E.$ (approximate), is more easy of access to a sailing vessel than Yamada Harbour, which is situated 10 miles to the northward. On the S.W. part of Sangan Sima are some white quartz bolders, and also on the cape N.N.W. of the island. Sangan is steep, well wooded, not distinguishable from the coast at a distance of 6 or 7 miles, excepting when approached from the northward.

There are two rocks near the centre of the harbour, lying North and South of each other, and about a third of a cable apart. On the northern rock there is 6 ft. at low water, and on the southern rock 2 ft. The northern rock is marked by a *black buoy*, surmounted by a circular cage, the top of which is 8 ft. above water; the buoy is moored to the North of the rock in 11 fathoms at low water. The southern rock is marked by a *red beacon*, consisting of a massive stone foundation, on which stands an iron post, surmounted by a cage, which is 19 ft. above high water. Vessel must not pass between the buoy and the beacon.

Kamaishi is not an open port, and at present there is no traffic whatever. At about 10 miles inland is a district abounding in iron ore of good quality, which will probably soon be worked by the Government. A *railway* is in course of construction, also a pier in connection therewith.

Yamada Harbour is a large circular basin surrounded by mountains upwards of 1,000 ft. in height, and is entered by a broad pass or strait running

S.W. between high bold shores, in which there is a depth of from 20 to 50 fathoms. A reef extends nearly 1 cable South from Miojin Saki, the inner North point of the entrance to be avoided by keeping in mid-channel; after rounding this point haul up N.W., and passing a quarter of a mile North of O sima, the larger of the two wooded islands, anchor off the centre of the town of Yama in 6 fathoms. When standing in for the anchorage the water shoals to 7 fathoms, and then deepens to 10, after which it decreases gradually. The eastern part of the bay is deep, rocky, and exposed, therefore not recommended as an anchorage. It is shallow between the two islands at the head of the harbour. The small island Ko Sima is in lat. $39^{\circ} 27' 17''$ N., long. $141^{\circ} 59'$ E.

The town or village of Yamada is populous, and inhabited almost exclusively by fishermen, who appear ignorant, uncouth, and dishonest. The high land on the North may be easily recognized when coming from the northward or southward, in following the coast of which, it forms the most salient point. Outside the port the water changes its colour, but there is no bottom in 38 fathoms at 2 miles from the shore. Yamada is the best anchorage at present known on the N.E. coast of Japan.

It is high water, full and change, in Yamada Harbour at $6^h 30^m$; springs rise 4 ft.

Miyako Port opens at 8 miles North of Yamada, and is a place of considerable trade, situated on the western shore of an inlet about 3 miles deep junks anchor outside in from 7 to 4 fathoms, mud. The anchorage is open to the eastward. About the time of the equinoxes strong N.E. winds occasionally blow, and in the winter strong westerly winds. The point of Tayo-mani that forms it is surmounted by a conical hill.

The coast North of Miyako takes a N.N.E. direction, and is a shelving table land, bordered by broken cliff and backed by high flat ranges, which rise to about 2,000 ft., but the land gradually decreases in elevation towards the North until about *Sanemuva Point*, where it becomes low. *Kuro Saki* stands well out, and may be recognized by its small range of hills about 700 feet high. North of Kuro Saki the cliffs get lower, and the long flat slopes run out into fine tapering points.

Two isolated mountains can be seen behind Hon-na-mi. The land is densely wooded.

Cape de Vries is low and flat, about 330 feet high, and is remarkable from the way it stands out between two bays. The *Dupleix* sailed along this coast from Cape Kiori to Cape Vries, at a distance of from 2 to 4 miles, and saw no danger except close to the shore.

SIRIYA SAKI and LIGHTHOUSE.—At Siriya Saki, the N.E. point of Nipon Island, the coast slopes towards the cape from an elevation of 1,265

feet, and appears like an island at a distance. The lighthouse, completed on the cape in 1876, is a circular tower 94 ft. high, painted white. From the tower, at an elevation of 150 ft., is shown a *fixed bright light*, visible 18 miles off.

A *fog bell* is sounded by machinery in thick weather, 15 strokes in every minute.

Off the cape, at the distance of 3 cables, is a small white rock, 70 ft. high, and at 2 miles to the south-westward is another rather larger than the former, lying 1 cable from the shore. The coast within 4 miles of the cape is studded with rocks, and very foul.

Rattler Rock lies E. by N. $\frac{3}{4}$ N., $1\frac{1}{4}$ mile from Siriya Saki lighthouse, and is a ledge having 5 ft. least water. It rarely breaks, and when it does it is hard to distinguish between the break and the tide rip.

Anchorage.—The *Thabor* anchored 2 miles South of Siriya Saki. This anchorage would be useful to vessels bound West through Tsugar Strait during the winter season, and obliged to anchor. The lead is a safe guide. The bottom at 23 fathoms is fine black volcanic sand, gradually changing to coarse brown, with a few shells. At a depth of 3 fathoms and less the bottom is stony. From a vessel at anchor in 7 to 9 fathoms the light at Siriya Saki is visible. A small vessel might anchor in 4 or 5 fathoms with good shelter. The rise and fall of tide appears to be about 3 ft.

DIRECTIONS.—Vessels bound from the Gulf of Yedo to the eastern entrance of the Strait of Tsugar, will, after passing Su Saki and Cape Erratatsi (C. King) experience the full force of the current setting them to the E.N.E. The land about this cape is high and wooded, and the coast in its locality should be given a good berth, as heavy breakers have been seen some distance off shore.

Caution is requisite in doubling Ohigasi Saki (Cape Blanco), as the American squadron passed over the edge of a reef in 22 fathoms water S.S.E., distant about 5 miles from this cape, and from the heavy overfalls, in which fishing boats were anchored, there is probably much less water upon its shoalest part. As it was near nightfall it was impossible to examine this reef, but its position is about lat. $35^{\circ} 8' N.$, long. $140^{\circ} 34' E.$, and Cape Blanco in lat. $35^{\circ} 13' N.$, long. $140^{\circ} 32\frac{1}{2}' E.$

From this cape to Tsugar Strait, as far as is known, the coast may be approached within from 2 to 3 miles. The Oya Siwo flows to the southward along the N.E. coast as far South as Inaboye Saki, and its average width is from 100 to 200 miles, outside of which the Kuro Siwo flows to the north-eastward. This coast is known to be subject to strong gales and much heavy weather. On nearing the entrance of Tsugar Strait the American squadron experienced a sudden fall in the temperature of the sea of 15°

to 20°, as the squadron ran from the north-easterly current into the cold current setting to the southward.

THE SETO UCHI, OR INLAND SEA.

The great inland sea of Japan, called by the Japanese Seto Uchi (inner strait), is enclosed between the S.W. coast of Nipon, which entirely bounds it on the North and East; and the islands of Kiusiu and Sikok, which bound it on the West and South. It extends somewhat in an East and West direction, in length 240 miles, with a breadth varying from 3 to 30 miles. It has six divisions, called *nadas* or seas, taking their names generally from the provinces, the coasts of which they wash. There is a great maritime trade along its populous shores, as well as the through traffic to Osaka, one of the chief seats of commerce of the empire, and the seaport of its capital, Kioto.

The Seto Uchi can be navigated with safety at all seasons of the year, and even under favourable circumstances during the night, the more particularly now that a correct chart of it has been published from the Japanese manuscript survey, to which has been added the surveys of Commanders Ward, Bullock, Brooker, and St. John, and Navigating-Lieutenant Maxwell. In the winter months, too, when the westerly gales are so prevalent, sailing vessels would probably gain time by tiding through this sea, rather than by endeavouring to beat round Satano misaki (Cape Chichakoff), against the Kuro Siwo or Japan Stream. As an instance of this, a fine clipper ship was nearly three weeks getting round Cape Chichakoff, whilst the *Actæon* sailed through the inland sea in nine days, meeting with one westerly gale, and anchoring every night.

A very destructive species of Mollusk inhabits the Seto Uchi, and might prove very injurious to ships' bottoms. Specimens of new timber were found at Awa sima, the perforations in which were a third of an inch in diameter.

Supplies.—Water of excellent quality can be procured almost at any anchorage in the Seto Uchi or Kii Channel, and is brought off in boats, in buckets, at a very small cost. About 70 tons of charcoal were purchased at the various harbours in the Kii Channel, for fuel for steaming, at from 4 to 11 dollars per ton, superior for such purpose to the best Welsh coal.

Tides.—The tides and currents of the Seto Uchi are as yet but imperfectly known, but are found to be regular at its East entrance; those of the Boungo Channel are quite unknown. The tide wave comes from the Pacific Ocean by the Kii and Boungo Channels; from the latter it branches East and West, meeting the Kii Channel tide at about Awa sima, in long.

133° 38' E., at the eastern entrance of the Bingo nada. The tides run strongly in the narrow channels, especially on the western stream, and whirl about very considerably, so as to render steering difficult.

We first describe the Boungo Channel, then the Kii Channel, and after that the Isumi nada and the different nadas to the westward as far as Simonoseki Strait, by which the Sea of Japan is joined to the Seto Uchi or Inland Sea.

The **BOUNGO CHANNEL**, the western of the two entrances on the East coast to the Seto Uchi, is quite safe to navigate as far as it is at present known, and the projecting points and islands were found correctly marked on the Admiralty chart by the allied squadron under the command of Vice-Admiral Sir A. L. Kuper, K.C.B., which entered the Seto Uchi by it in September, 1864. No dangers were seen in the route they adopted, in addition to those marked on the chart. The western points of the different islands and capes on the eastern shore, from Okino sima on the South to Cape Okanaba on the North, are well defined, and apparently steep-to; so is also the land on the western shore in the vicinity of the town of Kitsiku and along the N.E. coast of Kiusiu.

Okino Sima, forming the eastern point of the South entrance to this channel, is 1,150 ft. high, conspicuous, and may be seen in clear weather from a distance of 35 miles. To the northward of it the space appears to be rocky foul ground.

Euryalus Rock, named after H.M.S. *Euryalus*, is a small rocky islet, 50 ft. high, lying in the middle of the Boungo Channel, 26 miles N.W. of Okino sima. It is surrounded by rocky shoals, some above water, to the distance of half a mile. It occupies a most excellent position for a lighthouse.

Takanaba, the island lying nearly in the middle of the northern entrance of the channel, has two small rocks above water at 2 cables N.W. of it. There appears to be a good passage on either side of this island. The current is not strong.

The **KII CHANNEL**, lying between Sikok and Nipon, is 80 miles across at its entrance from the Pacific, decreasing to 15 miles at 30 or 40 miles within, which width it preserves for 20 miles farther, or up to Awadji sima. The coast of Awa to the West from Muroto saki to Naruto is as yet unknown; but the coast of Kii from Oö sima to Kata, along which vessels pass to and from the Seto Uchi and Yedo, has been surveyed or explored. The fairway from the Kii Channel into the Seto Uchi is by Isumi Strait, but there is a more direct route, by taking which (if not bound to Osaka or Hiogo) a saving of 35 miles is effected, viz., the Naruto Passage, West of Awadji, but this channel should not be attempted excepting under the most favourable circumstances, that is, at slack water or within half an hour of it,

and at neap tides, and even then it is highly dangerous. The coast on the western side of the Kii Channel from Murato saki to the rocky point O-iso at the western entrance to the Naruto Passage is from the Japanese manuscript.

Muroto Saki, the western entrance point to Kii Channel, is a steep headland, 400 ft. high, and when first seen in clear weather from the eastward or westward appears as an island. Another hill, 2 miles to the northward, and 770 ft. high, also makes an island, but may be distinguished from Muroto Saki by the scarcity of trees.

I Sima lies nearly in the centre of the western shore of the Kii Channel at its narrowest part; its southern peak is visible 30 miles. The channels between the reefs westward of I sima should not be attempted.

A rock was reported in 1873, by the steam-ship *Alexander*, at 9 miles S.S.E. of I sima, 10 ft. high. Lat. $33^{\circ} 30' N.$, $134^{\circ} 30' E.$

Wada Sima Harbour, in lat. $34^{\circ} 0' N.$, long. $134^{\circ} 39' E.$, has a good anchorage in from 4 to 6 fathoms water, just inside a low point with trees on it on the East side of the harbour. The South and West parts of the harbour are very shoal.

O-Iso, the projecting sandy point N.E. of Sikok, slopes down from a hill named Shiro-muné yama, 290 ft. high, ending in a bare conical mound. East, 3 cables from O-iso, are some rocks awash, with deep water 1 cable outside them.

NARUTO PASSAGE (literally, gate of the sea which makes a great roaring) has hitherto been considered to be a whirlpool, and not without cause. In its narrowest part it is only 7 cables wide, and this is further narrowed to 3 cables by a reef on its eastern side.

The passage may be taken at the first and second hour before and after change of stream, with the tide, and for the first three-quarters of an hour before or after change, against the tide, in fine weather; but in bad weather it should not be attempted, as the passage then breaks right across, and it is difficult to distinguish the channel.

Vessels must be careful to have the passage well open before approaching it, and at all times great caution must be observed.

Tobi Sima, 93 ft. high, is a conical wooded islet, lying S. by W. nearly three-quarters of a mile from the narrowest part of Naruto Passage. It has shoal water off its North end for $1\frac{1}{2}$ cable, but may be approached on the eastern side to 1 cable. A rock, 1 cable in extent, East and West, with from 4 to 5 fathoms on it, and steep-to, lies S.W. 4 cables from Tobi sima.

Tides.—The tide sweeps through Naruto in about a N. by W. and S. by E. direction, with a velocity at springs of from 10 to 11 knots, but slackening about an hour before and after change either way to from 7 to 8 knots. At springs there is scarcely any slack water, but at neaps about a quarter of an hour.

It is high water, full and change, at Fuk ura, at 6^h 17^m, springs rise 7 ft., neaps (probably) 4½ ft. The north-western stream makes at 2¼ hours before high water at Fuk ura, changing every 6 hours nearly. North of the Naruto Passage the tides are anomalous.

Anchorage—If wishing to wait for slack water, or change of stream, anchorage may be found on the Awadji shore, at Maru yama, on the North side of the Naruto; and at Fuk ura on the South, in 4 to 8 fathoms. There is also excellent anchorage in Minotoye Bay, 5 miles to the westward.

Yura is a town on the S.E. side of Awadji. A low island, 1½ mile in length, with a bluff hill on its North point, and a large granite fort on its South, lies like a breakwater fronting a bay, and forms the harbour, which has narrow entrances North and South. The North entrance has from 10 to 11 ft. at low water springs, and is 120 yards wide; the South is a narrow opening, with 2 to 3 ft. water. The broadest part of the harbour is half a mile, with anchorage in 4 to 6 fathoms, mud. A vessel drawing 16 ft. could enter at high water springs, and lie secure in smooth water for repair. The junks anchor somewhere to the northward of this to wait for tide.

Anchorage may also be obtained in 2 to 5 fathoms outside the island on the sand-bank off it, with the outer extreme of the bluff N.W., or of the fort S.S.W.; but it is very steep on the edge, and the holding ground is probably not good.

Kata is a town on the eastern side of Isumi Strait, on the South side of a bay North of Takura saki, and where there is anchorage in 5 to 8 fathoms. There is a fine landing pier here, 200 yards in length, for the use of the Daimio, who resides at Wakayama, and to whom Kata belongs. Off Takura saki, and in Kata Bay as far as Diyi Island, reefs covering at high water extend about 3 cables off the shore.

It is high water, full and change, at Yura and at Kata, at 6^h 5^m. Springs rise 6½ ft.; neaps, 4½ ft.

Osaki Bay is 1½ mile deep, and open to the W.N.W. The village of Osaki stands on the shore of a narrow inlet on its North side, where small vessels can find good shelter in 5 to 2 fathoms, which they can also obtain in Smotz ura, the innermost bay on the South side of the inlet. The only danger is a rocky patch of 1 fathom 2 cables S.E. of the North entrance head. The South point of Tree Islet should be given a berth of more than 1 cable. Over the village of Osaki is Takadoösi yama, 591 ft. high, a smooth-topped hill, with two stunted trees on its summit, conspicuous from off shore. The South shore is hilly, the South entrance bluff, being about 400 ft. high. Fresh water and small supplies can be readily obtained.

Okino Sima, W. by S. ½ S. 2 miles from the entrance of Osaki, has a round hill, 275 ft. high, and is bare of trees. *Djino Sima*, 1 mile East of it, is 400 feet high, has high cliffs towards the sea, and is wooded. A rock awash lies about 2 cables South of it, and some islets further South.

Miya Saki, 220 ft. high, lies 2 miles South of Okino sima, and may be passed at 3 cables.

Tskahara Bay is 5 miles deep and 6 miles across, between *Miya saki* and *Sirasai saki*, its North and South points of entrance. At its head is the *Bay of Hirowatali*, with anchorage in 7 to 8 fathoms, even bottom and mud, and well sheltered from all winds except W. by S. A pier at the South end of the sandy beach at its head and off a small town, protects small craft in a shallow inner harbour.

Two islands, *Kura sima* and *Taka sima*, lie off the southern shore of *Tskahara Bay*. The *Karamo Group* of small islands, with reefs about their North sides, lie N.N.E. of *Taka sima* and West of *Hirowatali Bay*, with a cluster of rocks E.N.E. of them half way to the shore, the ground about which has not been examined.

Golden Rock, so named from the large amount of property lost there, is a very small patch, nearly awash at low water, and so steep that the lead gives but little warning, there being 17 fathoms at 100 yards on the outside. It lies 3 miles N.N.E. $\frac{1}{4}$ E. of *Sirasai saki*, N.W. $\frac{1}{2}$ W. $1\frac{1}{2}$ mile from *Taka sima Hill*, and S. by E. $\frac{2}{3}$ E. from *Miya saki*.

Sunq-ami, three-quarters of a mile North of the West point of *Karamo*, is a sunken rock, with 6 ft. over it, and equally steep-to; it is also $1\frac{1}{2}$ mile N. by E. of *Taka sima*, and S.E. $\frac{1}{2}$ E. $2\frac{1}{3}$ miles from the point S.E. of *Miya saki*.

Unless desiring anchorage, or working to windward against tide, *Tskahara Bay* should not be entered within a line joining its points, as the two dangerous rocks above mentioned lie in the centre and northern parts of the bay.

Shirasai Saki, or *White Rock Point*, derives its name from the large masses of quartz in its cliffs, and which, with the white pinnacle rock, 200 ft. high, 4 cables E.S.E. of it, show very distinctly from the South.

Fisherman Rock, a small, narrow rock, 4 ft. above high water, and steep-to on the outside, lies 4 cables West of *Shirasai saki*. Some rocks awash extend a cable's length to the N.E. of it. The passage inside the rock carries 14 fathoms in mid-channel.

Oobiki ura is a bay between *Shirasai saki* and *Yura no uchi*, where a vessel might anchor for the night with the wind off shore, in 6 fathoms, at 2 or 3 cables from the beach. The steep little island *Hijiki sima*, 120 ft. high, off its South point, marks the North point of entrance to *Yura no uchi*, a harbour 4 to 7 cables in breadth and 2 miles deep, and being sheltered by the sharp peaked island *Ali sima* and the extensive reefs off the South point of entrance, always above water, and only open to two points, viz., W. by S. and S.W. by W. Winds from these directions cause some swell inside in a gale, but it is nevertheless a secure anchorage. Anchor near the head of the bay in 6 to 7 fathoms, mud.

Hino Misaki, being at the turn of the coast, is the most prominent cape in the Kii Channel. Its terminal hill, *Hino yama*, is smooth-sloped, 675 feet high, and the islet off it may be passed at 2 cables. It is steep-to, but the tide sweeping out of the bay South of it causes an appearance of broken water, especially with a North wind. Thence the coast runs south-eastward for 19 miles to Tanabe, and parallel to the line of the outer capes, but falls back within them from 2 to 4 miles. The shore is hilly, with a strip of low land along the beach; the interior is mountainous.

The *Hidaka kawa*, sometimes entered by small junks, has its entrance 5 miles E. by S. from Hino Misaki. A reef of rocks extends a mile off shore at a mile to the southward from this. Anchorage will be found abreast the sandy beach northward of the river.

The coast to the S.E. has several outlying reefs, the largest of which extends 4 cables off Arari Point. Eastward of Arari Point, $33^{\circ} 45\frac{1}{2}'$ N., is a bay, affording good anchorage in from 5 to 8 fathoms. Reefs extend 4 cables from the cliffs on the northern shore of the bay. North of Arari Point is a round hill, on the summit of which are three spike-shaped monuments; and 3 and 4 miles inland, North and N.E. of this, are two large hill clumps, which are very conspicuous from the offing.

Tanabe Bay is formed in a bight of the coast, 22 miles S.W. of Hino Misaki, its outer parts exposed only to West and N.W. When approaching from the south-eastward, *Itsive misaki*, the most projecting point of the coast, will first be made, and being very similar to Cape Tanabé, the bay between them, in thick weather, may be mistaken for that of Tanabé. *Itsiye misaki* is a sloping point with a low terminating cliff, but the hills over it are much higher than those of Cape Tanabé, and rise to a sharp peak, the outer of a continuous high range. The summit of *Cape Tanabé*, which has a single conspicuous tree on it, is only 539 ft. high, and falls abruptly inland. Outwards a long ridge slopes gently toward the sea, with a dark clump of trees on the brow, from which it falls steeply.

The cliffs which border the cape are bold of approach, but Isaki Point, North of the cape, is very dangerous to three-quarters of a mile off.

In the north-western point of entrance of Tanabé Bay are the *Saito* and *North Bay Reefs*, 4 cables apart, with a deep water channel between them. These reefs are low and quite flat. At 2 cables distance S.E. and North of Saito, the southern of them, are sunken rocks, and off North Bay Reef is a small rock like a boulder. There is also a deep water channel between these reefs and Maruyama Point, off which shoal water extends 3 or 4 cables. Within these dangers there is safe approach for a mile, but farther in is a mass of reefs, rocks, and islets, which must be approached with great caution. In bad weather, with the wind in, all the known dangers would break.

The best anchorage is in the south-eastern arm of the bay, South of

Anchorage Island. This island may be recognised by the dark trees dotted over it, and a tree islet West of it, from which a long uncovered reef extends. The end of this reef may be passed at a cable; then steer to pass the same distance off the N.E. point of Anchorage Island, between it and the sunken rocks of Passage Reef in 6 to 10 fathoms, irregular bottom. Having passed along the East side of the island, stand in S.W. $\frac{1}{2}$ S., anchoring in 10 to 8 fathoms, in a secure and thoroughly sheltered position. There is moderately deep water in the arm to the South, as also in Hosono Bay, but they are too contracted for good anchorage.

Binzli Reef, lying in the centre of the bay, is an extensive reef with several rocks on it, dry and awash at low water. The north-eastern part of Tanabé Bay (only partially surveyed) has many shoals. On the North shore a small river discharges itself, running close under the white loop-holed wall surrounding a residence of the Daimio, the imperial Prince of Kiisiu, hidden among the trees on the left bank at entrance. The village of Tanabé stands on the shore of the sandy bay to the westward of the river, and to the North is a mountain range, the highest part of which rises to the height of 2,650 ft., the ridge curving round to the range which terminates in Itsiye misaki.

SIWO MISAKI.—The shore from Itsiye misaki to Siwo misaki, a distance of 21 miles E.S.E., is very bold, and under a high mountainous coast, terminating in a promontory of table land, which is the extreme South point of Nipon. There is a great tide race and overfalls off Siwo misaki, both on the flood and ebb; they are, however, heaviest on the flood. After a south-easterly gale the sea comes in round this point in immense rollers, such as are rarely seen on any coast.

Bottle Rock lies $2\frac{1}{2}$ cables South of the cape, and foul ground extends $1\frac{1}{2}$ cable further southward.

LIGHT.—On the top of the cape, at an elevation of 163 ft. above the sea, is exhibited a *fixed bright light*, visible in clear weather from a distance of 20 miles. The lighthouse, completed in 1878, is 63 ft. high, built of stone, and painted white. Previous to this there was a wooden tower, now removed.

Passing through the Kii Channel, it is recommended to steer always for Hino misaki.

The coast to the eastward of Siwo misaki is previously described.

ISUMI STRAIT, between the S.E. point of Awadji and Nipon, is divided into three channels by the islands Tomangai and Diyi. The West or main channel is 2 miles wide, but contracted by a sand-bank which extends half a mile off the large fort of Yura, and by reefs stretching 3 cables off the S.W. part of Tomangai. The centre passage is only 1 cable wide, and full of rocks. The eastern channel is a quarter of a mile wide, and said to be clear and safe between the reefs which extend $1\frac{1}{2}$ cable off both shore and island.

LIGHT.—On the western extreme of Tomangai sima, at an elevation of

208 ft. above the sea, is exhibited a *fixed bright light*, visible in clear weather a distance of 19 miles. It is obscured to the eastward between S. $\frac{1}{2}$ E. and N.E. by E. The tower, 21 ft. high, of granite, is in lat. $34^{\circ} 16' 40''$ N., long. $135^{\circ} 0' 30''$ E.

The **ISUMI NADA** at the N.E. extreme of the inland sea, and 35 miles in extent N.E. and S.W., is bounded on the South by a promontory of Nipon, and on the West by the large mountainous island of Awadji. Its shores are in general high and thickly wooded; in some places, however, they are low and sandy. It is singular in having neither an island nor a danger. On the East shore of Awadji the water is deep, with no convenient anchorages except in small bays close in. The coast of Nipon, on the contrary, affords good anchorage along its whole extent, reefs only extending off it 1 or 2 cables.

OSAKA, the place of greatest commercial importance in Japan, stands on the N.E. shore of the sea, on the left bank of the Yodo Gawa, which at the N.W. corner of the city divides into two branches—the Aji Kawa, as the Yodo is here called, continuing directly towards the sea; the other branch, the Kishun Gawa, takes a southerly course, and discharges its waters 3 miles lower down the gulf; these two branches are navigable by junks of moderate size. Osaka is the seaport of Kioto, the capital of Japan, which is situate 20 miles to the N.E., on a branch of the Sedo Gawa.

The Foreign concession, named Ebisu Jimà or Kawa Guchi, occupies the angle formed by the Aji and Kishu branches; its position is indicated by lofty trees; the right of building is confined to this site, but the right of residence extends over the contiguous suburb westward. It is $2\frac{3}{4}$ miles above Temposan, the fort at the river's mouth, and 2 miles below the castle. The population of Osaka is about 400,000.

The River Aji is shallow, but may be navigated by ships' boats as far as the castle; it has a bar, which at unusually low tides would be nearly dry; at exceptionally high tides, 7 ft. might be carried over.

The roadstead of Osaka is open to the West and South. The depths in the roadstead are extremely regular, diminishing gradually over a soft mud bottom; the holding ground is so good that it is considered a vessel could ride out any gale in safety. The shores are everywhere of clean sand (as are the river bars), but it constitutes a fringe only, mud being found at a cable from the low-water line.

Anchorage.—It is not advisable to anchor in less than 4 fathoms, as S.W. winds cause much sea. There are 4 fathoms at 7 cables from the lighthouse, and 7 fathoms at $1\frac{1}{2}$ mile. To the southward it is much shoaler. The best anchorage is West of the Temposan or Osaka lighthouse.

Temposan Fort and Light.—The large Temposan Fort stands on the South point, and commands the entrance of the river; it is a high turfed earthwork, scarpèd with masonry, and is a conspicuous landmark, the shores

being very low. On the parapet of the western salient angle of Temposan Fort, 53 ft. above the sea, is exhibited a *fixed bright light*, shown seaward between the bearing of N.E. by E. $\frac{3}{4}$ E. (round by North and West) to S.W. by W., and is visible in clear weather from a distance of 12 miles. The tower is a square-shaped white wooden building. 30 ft. high.

The Kishu Gawa.—Two miles S.S.E. of Osaka Bar is the bar of the Kishu, at the North point of entrance of which river a small star fort is being constructed at low-water mark a mile from the shore. This bar has not been closely examined, but it is probably a little deeper than that of the Aji, as a larger class of junks ascend this branch to Osaka.

Sakai.—**Light.**—S. by E. 4 miles from Temposan is the mouth of the Sakai River, which enters the sea between two short moles extending from two green batteries; it has no bar, and has 2 ft. at entrance. A light is exhibited from a wooden turret on the North fort.

HIOGO and KOBE.—A treaty port, 14 miles West of Osaka, is a better and more convenient anchorage than the roadstead of Osaka, having slight protection from the South, and being thoroughly sheltered from the westerly or prevailing winds. The shores of Hiogo Bay are steep-to, but low, and rise in a gentle slope from the beach to the abrupt range of hills 2 miles inland, which are of 800 to 2,000 ft. elevation, running parallel to the coast. The bay has an even depth of $4\frac{1}{4}$ fathoms, with good holding ground in a very stiff mud. A *patent slip* is established at Hiogo to receive a vessel 190 feet long, with 13 feet draught forward. A sea-wall and piers, which will also form quays, are also proposed.

The Foreign Settlement is beautifully situated at the head of the northern bay of Kobé. This bay is somewhat smaller than that of Hiogo, but the shores of it are steep, and there is about the same depth of water as in the former, and if less sheltered in S.W. winds it is less exposed to easterly winds.

The railway pier at Kobé was completed in 1876, so that vessels can moor alongside and load from the railway trucks. Moorings are laid down. There is also the old accommodation, which entirely shelters junks of considerable size.

British subjects are free to go wherever they please within 10 *ri* (21 miles)

* A RAILWAY, $21\frac{1}{4}$ miles long, was opened in May, 1874, between Kobé and Osaka (Agi Kawa). From Osaka it is continued in a N.E. direction for nearly 30 miles to Kioto, at the South end of Lake Biwa. It is proposed to extend this railway, so that all the chief parts of Nipon shall be in communication, including Tsuruga and Niigata, on the West coast, and Nagoya, at the head of Owari Bay, and Yokohama on the South coast. Mr. R. Vicars Boyle, C.S.I., has surveyed most of the routes for the intended railways.

A dock was commenced in 1876 at the Osaka station for the accommodation of waterborne traffic, which, when completed, will enable goods to be transported by boat direct to and from that station in place of Ajikawa as heretofore.

of Hiogo in any direction, that of Miako (Kioto) excepted, which city shall not be approached nearer than 10 *ri*. The crews of vessels resorting to Hiogo shall not cross the River Ena Gawa, which flows into the bay between Hiogo and Osaka. During the autumn and winter months small-pox is very prevalent here. The railway borders the bay to the eastward of Kobe.

LIGHTS.—At Kobé a *fixed green light* is shown from a white staff, 34 feet high, on the eastern pier-head of the Foreign Concession. The light is elevated 42 ft., and visible 6 miles off.

On *Wada Misaki*, the S.W. point of Hiogo Bay, elevated 52 ft. above the sea, is exhibited a *fixed red light*, showing seaward between the bearings of N.N.W. (round by East and South) to W. by S. $\frac{1}{2}$ S., visible in clear weather from a distance of 12 miles. The tower is an octagonal-shaped white wooden building, 46 ft. in height.

It must be borne in mind that the ebb tide sets to the westward towards Akashi Strait, and the flood to the eastward towards Osaka, 2 knots an hour at springs, increasing as Akashi Strait is approached. In the bay directly East of Kobé, there is a sandbank of less than 2 fathoms, extending half a mile off shore.

Supplies of all descriptions may be procured in abundance at tolerably cheap rates. Government coal is stored here in charge of a contractor, who also supplies fresh meat, vegetables, and water. Large timber, chiefly cedar (*Sungi*) is also procurable.

Tides.—It is high water, full and change, at Hiogo at 7^h 15^m. Springs rise 5 ft. 8 in.; neaps 4 ft. 3 in.; neaps range 2 ft. 6 in. The range of any day seldom exceeds 5 ft. at springs or 1 ft. 6 in. at neaps.

Taka iso, a rock with 9 ft. on it at low water, lies nearly a cable off shore, 5 $\frac{1}{2}$ cables to the westward of the village of Shiwoya.

Hira iso are the highest pinnacles of a bank of rock and shingle, 4 cables from the shore, having 6 ft. on them at low water. The eastern lies E. $\frac{3}{4}$ N. 3 $\frac{1}{4}$ miles from Matsu-wo-ga hana (the North point of Awadjii sima). South from it, and quite close to, is the wreck of a Satsuma steamer, having 2 ft. on it at low water. To clear them the light on Matsu-wo-ga hana must be kept West, until Ichi-no-tani yama bears N.E. The stone fort at Maiko in sight, N.W. $\frac{1}{2}$ W., clear of the trees on Kara saki, leads to the westward of Hira iso.

AKASHI NO SETO (Akashi Strait), between the North point of Awadjii sima and the coast of Nipon, is nearly 2 $\frac{1}{2}$ miles wide, the above rocks, Taka iso and Hira iso, being the only known dangers when approaching it.

Akashi town, on the North shore of the strait, contains the residence of the Daimio, the four white towers of which show out plainly against the surrounding dark foliage.

In the bay of Yamata ura, between the dark wooded point of Kara saki and the conspicuous granite fort at Maiko to the eastward, and the town of

Akashi to the westward, there is good anchorage, with winds from N.W. round by North to East, in 9 fathoms, sand, good holding ground.

Yamata iso, a rock in the strait having 2 ft. on it at low water, lies N.W. by W. $\frac{1}{2}$ W. $3\frac{1}{2}$ cables from Maiko Fort. Care should be taken not to anchor within 5 cables of the fort. The tides take the line of the coast, and have at springs a velocity of $2\frac{3}{4}$ knots.

From the West end of the town of Ahashi a series of shoals extends to the W.S.W. for 11 miles, the outermost composed of rock covered with sand and shingle, being named *Shika no se*. The South sides of these shoals being steep-to are very dangerous. The South side of the *Shika no se* is marked by a red buoy.

Murozu no se, on the southern side of the West entrance to Akashi no seto, has been thoroughly examined by H.M.Ss. *Serpent* and *Sylvia*, and nothing less than $5\frac{3}{4}$ fathoms has been found.

Directions.—On approaching Akashi Strait from the westward a clear course may be made between the above shoal and *Shika no se*, by keeping the summit of *Ichi-no-tani yama* in line with the lighthouse on the North extreme of *Awadji sima* E. by N. $\frac{1}{2}$ N. or at night by keeping the light on that bearing.

Matsu-wo-ga Hana and Light.—The North point of *Awadji sima* is terminated by a white stone fort, with seven guns “en barbette,” is steep-to, and has a lighthouse erected on it, from which is shown, at an elevation of 158 feet above the sea, a fixed light of the first order, from East round by North and West to S.W. by W. $\frac{3}{4}$ W., visible 18 miles off. The tower is 15 feet high, built of stone.

HARIMA NADA is a comparatively shoal expanse, lying between *Awadji sima* and *Sozu sima*, having about 20 fathoms deepest water, the southern portion of the sea being clear of dangers. The northern portion, however, is said to be encumbered with shoals and dangerous covered rocks, extending from *Ukado Point*, the S.E. point of *Sozu sima* to *Shika no se*, before described. In navigating the *Harima nada* the dotted track should be as closely as possible adhered to, as the northern portion of this sea has not been closely examined. Its southern shore from the *Naruto* passage westward for about 17 miles, as far as *Taka sima*, is also as yet unsurveyed. *Ichi-no-tani yama* (end hill) just seen open of the lighthouse on *Awadji sima* leads between the *Shika no se* and *Murozo-no se*, for the South point of *Sozu sim*.

Sozu Sima, a large island in the western part of the *Harima nada*, is 2,560 ft. high. On its South side the high promontory of *Yosino*, terminating in a bluff 980 ft. high, stretches to the southward, forming a conspicuous landmark throughout the *Harima nada*, and the narrow sea to the westward. There are large bays on either side of it, but they are considered not to afford good anchorage.

Hana Mura, on the Kiusiu shore, S.S.W. 5 miles from Yosino Bluff, is said to be the best anchorage in the neighbourhood, and a fine harbour. A bank, carrying 19 ft. water, lies in the middle of the entrance.

Westward of Sozu Sima the Seto Uchi is studded with numbers of islands, for miles forming numerous channels, of which the most central and southern only have been examined; these, however, are sufficiently clear of dangers to be with ordinary caution quite safe of navigation, the surveys of these narrows having rendered the navigation of the Seto Uchi comparatively easy.

Galatea Shoal, on which H.M.S. *Galatea*, Capt. H.R.H. the Duke of Edinburgh, grounded in 1869, has from 1 to 3 fathoms on it. Its eastern extreme lies $1\frac{1}{2}$ mile W. $\frac{2}{3}$ S. the South point of Kasiwa, and its eastern extreme approaches Odutsi within 11 cables.

Nabae Sima Light.—On the summit of Nabae Sima, it lat. $34^{\circ} 23' N.$, long. $133^{\circ} 49' E.$, at an elevation of 85 ft. above the sea, is exhibited a *fixed bright light*, of the third order, seen between N. $\frac{1}{2}$ E. round by South to W. $\frac{1}{2}$ N.; visible in clear weather from a distance of 15 miles. It is very useful in assisting vessels to avoid the 3-fathom shoal to the southward.

Siyako lies West from Nabae Sima, with a deep channel between. A rocky ledge extends $1\frac{1}{2}$ cable off its South point. *Ushi Sima* lies to the southward of Siyako, between which is a deep channel, 5 cables wide. *Rocks*, which dry towards low water, extend 1 cable off the North point of Usi Sima. They are steep-to.

The Conqueror Bank, steep-to, from the S.W. point of Usi Sima extends $2\frac{1}{2}$ miles in a W.S.W. direction.

Anchorage.—*Hiro Sima* lies to the W.S.W. of Siyako. On its South shore is *Ino Ura*, a small bay, on the shores of which are several small villages. *Ino Ura* is a convenient anchorage for vessels passing through the Seto Uchi, and is generally chosen as a night anchorage, especially when bound from Hiogo to the westward, it being within convenient distance, and can be arrived at before nightfall. Care must be taken not to approach the shore too closely, as the head of the bay shoals very suddenly.

Ten-feet Rock, or *Habushi Iwa*, lies $5\frac{1}{2}$ cables S. by E. $\frac{1}{2}$ E. from the South point of *Ino Ura*; it is 20 ft. high and whitened, and may be passed quite safely on either side at 1 cable distance.

Takami, a very conspicuous island on the South side of the route, is nearly $1\frac{1}{2}$ mile long. A shoal bank extends from the eastern side of *Takami* in an E.N.E. direction, and nearly joins the S.W. extreme of the *Conqueror Bank*.

Sanagi Sima lies 3 miles W.S.W. from *Hiro Sima*. From its eastern shore extending 3 miles in an easterly direction, is an extensive bank of sand, with from half to 2 fathoms upon it.

Nezumi Sima lies $1\frac{3}{4}$ mile to the southward of *Sanagi Sima*, between

which is the channel recommended. Rocks project on its northern side to nearly 3 cables. The channel South of Conqueror Bank is now seldom used.

Anchorage.—*Awa Sima*, on the South side of the western entrance to the channel, joining the Bingo and Harima Nadas, is triangular in shape, having bays on its North, South, and West sides. Anchorage may be had in either of the above bays, that to the South having the deeper water; but in using it *Awa Rock* must be avoided. It lies S.W. by S. $3\frac{1}{2}$ cables from the S.E. point of *Awa Sima*. The northern bay is more convenient for vessels anchoring for the night. Care must be taken not to anchor too near the head of the bay as it shoals a long way out. The bay on the West side of the island is shoal.

The **BINGO NADA** from the channels just described across to the channels leading into the Misima nada is about 80 miles wide, and about 38 miles long in a N.N.E. direction. It is comparatively clear, having only a chain of six islands stretching across it in a N.W. and S.E. direction, and a few others lying near the Kurusima Strait.

Directions.—On passing *Nezumi sima*, steer to pass in mid-channel between *Mutsu sima* and *Akeno misaki*, from whence, if wishing to take the northern route through the channels between the Bingo nada and the Misima nada, a course W. by N. will lead up to mid-channel between the islands of *Hyaku Kuan* and *Yoko*, at the entrance to the *Mekari seto*.

If intending to take the southern route through the Kurusima Strait, a course W.S.W. from *Mutsu sima* will lead up to *Takaikami*, the loftiest of the islands lying in the Bingo nada, and, passing in mid-channel between it and *Oki sima*, continue the same course passing about one mile North of *Kadji*, the northern island of the next group, and when the islands of the South point of *O sima* are seen, haul up and steer to pass them at about a mile, for the Kurusima Strait.

KURUSIMA NO SETO (Kurusima Strait.—The northern shore of the province of *Iyo* forming the southern coast of the approach to *Kurusima no seto*, may be known by two curiously shaped hills, one with a double summit; on one of which is a clump of trees 1,202 feet above high water; the other hill has a lower clump, 363 feet above high water, close to the shore, $2\frac{3}{4}$ miles South of *Imabari*, the coast being a series of sandy beaches between *Imabari* and the spurs from the double hill just mentioned. The large town of *Imabari* is also very conspicuous on this shore, and the islets off the South point of *O sima* on the northern shore of the strait are also easily recognized.

Rocks that cover at high water, and stretch $1\frac{1}{2}$ cables from the shore, lie off this coast N.N.W. $\frac{1}{4}$ W. $1\frac{1}{2}$ miles from the pier at *Imabari*.

Tori ishi, a rock with a temple gate, 13 feet above high water, lies nearly four miles south-eastward from *Imabari Pier*, $1\frac{1}{2}$ cable from the shore.

Obama is a large village $2\frac{1}{4}$ miles to the N.W. of Imabari, having a bluff point at the North extreme, and a conspicuous temple gate near the centre.

Shiroi iwa, 13 ft., is a white topped rock, lying $2\frac{1}{2}$ cables N. by E. $\frac{1}{2}$ E. from the rocky point just northward of the village of Obama, and may be approached to half a cable on the East side.

Amaze, a rock that dries at low water, lies N. by W. $\frac{1}{2}$ W., $3\frac{1}{2}$ cables from Shiroi iwa; and *Hirose*, a patch of rocks that dry, lies S. by E. $\frac{1}{2}$ E. $2\frac{1}{2}$ cables from the same place.

O sima, a large island on the North side of Kurusima no seto, bears evidence of volcanic origin in the remarkable features of its innumerable peaks, deep valleys, and off-lying pinnacle rocks.

Anchorage.—There is a good anchorage off Hangata in 7 fathoms, with the left extreme of the village bearing W. by S. $\frac{3}{4}$ S. distant $2\frac{1}{2}$ cables. There is no really safe anchorage off Obama, the tides being especially strong there. Anchorage, though in a strong tideway, may be had with off-shore winds in from 11 to 13 fathoms, sand, good holding ground, with the pier of Imabari bearing S.S.W. $2\frac{1}{2}$ cables.

From Hashi hama the coast trends to the N.W. to Ozumi no hana, and about midway between is the village of Hangata, near the North end of which is a temple gate, the tide pole datum.

Maru iso lies S.E. $\frac{1}{2}$ S. half a mile from Ozumi no hana and $1\frac{1}{2}$ cables from the shore, and uncovers 5 ft. at low water.

Birose is a ledge of rocks covered at high water, lying off Hangata. Both this and Maru iso are occasionally marked by tree beacons.

Directions.—The channel from the eastward, formerly used between Nezumi sima and Uma sima, is the best; that now frequently taken, known as the Kuru sima or Junk Channel is not recommended. After rounding Uma sima care should be taken to clear the *Perseus Rock* by keeping in mid-channel, with the eastern point of the entrance to Hashi hama Harbour open of Nezumi sima, until a remarkable single tree in the first gap right of the highest sharp hill of O sima, is in line with the North extreme of Mushi sima S.E. by E. $\frac{1}{2}$ E. The northerly stream sets on to the S.E. point of Nezumi sima, and also towards the Perseus Rock.

Approaching from the westward, after passing Kadjitori saki, a course should be steered to pass a quarter of a mile North of the flat rock of Ozumi no hana, when the conspicuous tree in the first gap right of Kiro yama will be seen in line with the North extreme of Mushi sima, S.E. by E. $\frac{1}{2}$ E. This mark should be kept on until the West extreme of the N.E. point of Hashi hama is open East of Nezumi sima S.W. $\frac{1}{4}$ W.; this clears the Perseus Rock (Ko no se). A course may then be steered to pass West of Uma sima, borrowing rather nearer to that island than the mainland, to avoid the Amaze.

Uma sima may be rounded at 2 cables, or continuing the leading mark a

little farther on a course may be steered to pass between Uma and Nagato sima, keeping the latter island close on board.

The other channels should not be attempted.

Tides.—In the Kurusima no seto, from Ozumi no hana, the flood runs towards Nezumi sima and Tsu sima, sweeping over the Perseus Rock (Ko no se) towards the North point of Uma sima, then taking the direction of the channels, diverging into the Hi-uchi nada. The ebb converges from the last-named place to the channels, running with great velocity from Imabari to the North, so that a vessel leaving that place should guard against being swept on to the More no iso. From the South point of Uma sima it runs for the S.W. point of Nezumi sima, and diverges through the channels. The ebb sweeps directly through the channel between Uma and Negato sima, causing on the North side heavy whirls that must be guarded against, their tendency being to turn the vessel's head towards Ko no se. The velocity at springs is from 4 to 6 knots.

It is high water, full and change, at Hangata, at 10^h 36^m; springs range 11½, neaps 5 ft., after superior transit of moon, and at 9^h 52^m. springs range 9, neaps 3½ ft., after inferior transit.

The Northern Route through the Mekari seto and Aogi seto is but little greater distance than through Kurusima Strait, if when off Mutsu sima a course be at once steered for its entrance through the Mekari seto; and it has the advantage of the Kurusima Strait from the fact that the tides are of much less velocity here than in the latter.

Passing westward of Hyaku kuan at about 7 cables, a course N.W. by W. ¼ W., with the bluff fall of Hachi gaune yama (which will be seen ahead 1,405 ft. high), in line with the right extreme of Hosu sima, will lead into the Mekari seto clear of Jarrad Bank, which lies to the northward off the S.E. point of Mukai sima. On passing Hosu sima at about 2 cables distance borrow on the northern shore, which is steep-to, until abreast Ko saki sima, when keep in mid-channel between Saki sima and the coast of Nipon until within half a mile of Ko-ne sima, when the Aogi seto will open, then haul up S.W. by W. ½ W. and bring the distant high peak Higashi on Osaki sima in line with the extreme point of O-mi sima; this mark will lead in mid-channel between Admiral and Captain Banks. On nearing the dark wooded island Kuno sima a rocky islet will be seen off O-mi sima, which may be passed at 1½ cable. Keep in mid-channel between Matsu sima and O-mi sima, rounding Kodono sima at half a mile, when steer to pass in mid-channel between Yoko sima, Niwatori jima, and the shore of Osaki until abreast Noka no hana the S.E. point of Osaki, when haul up and pass in mid-channel between Oge and Ko Oge sima into the Misima nada.

The entrance to Aogi seto from the westward may be readily distinguished by the conical hill and white quartz-faced boulders of Ko-oge sima and the

dark wooded Oge sima, care being taken not to mistake the S.W. point of Okamura, that has also some white rocks at the base.

Mitarai sima, a high wooded island to the westward of the entrance to the Aogi seto, has a flat-topped summit 1,443 ft. above high water, sloping gradually to its West end, when it falls abruptly, has a slightly indented coast line, and an apparently bare double peak at its eastern end, sloping down to a considerable village, with a remarkable white wall at the eastern extreme. South of the village is a Japanese *lighthouse*, merely a lantern, and rarely lit.

Tides.—The tides in the Aogi seto appear to take the line of the channel, running with a velocity of $2\frac{1}{2}$ knots round Noko no hana, 3 to 4 knots in the channel between Kuno sima and O-mi sima, and with an average velocity of 3 knots to the narrows between Mukai sima and In-no sima (Mekari no seto), where they increase their rate to $3\frac{1}{2}$ knots. The flood runs to the eastward and the ebb to the westward.

It is high water, full and change, at Miwara, at 10^h 37^m. Springs range 11 ft., neaps 9 ft. The stream changes to flood at low water, and to ebb three-quarters of an hour after high water.

Directions for Kuruma no Seto.—The directions for Aogi seto should be followed until clearing the channel between Kuno and O-mi sima, when the latter should be rounded at three-quarters of a mile, and a S.E. course steered to pass a quarter of a mile East of Hiotan jima, and the same distance West of the S.W. point of Seto-da jima, bearing in mind that the ebb sweeps strongly towards the beacon on the West side of the channel.

The Seto-da jima shore should be kept about a quarter of a mile off until the islet off the East point of Hakata sima opens of the N.E. point S.E. $\frac{1}{4}$ E., when a course should be steered to pass the latter point at a quarter of a mile, and then for mid-channel between the islets off the East point and Mu sima, taking care to keep the S.W. point of Seto-da jima open of the N.E. point of Hakata sima N.W. $\frac{3}{4}$ W., to avoid the foul ground in the bay between the East and N.E. points.

In the Kuruma no seto the flood runs to the S.E. and the ebb to N.W., with a velocity of $2\frac{1}{2}$ to 3 knots, in the direction of the channel, except off the S.W. point of Seto-da jima, where the ebb sweeps partly across the channel towards the stone beacon on the West side.

MISIMA NADA.—This portion of the Seto uchi is 30 miles East and West, about the same distance North and South, and is studded with numerous groups of islands, islets, and rocks, of which as yet little is known. At its North extreme is the large town of Hiro sima, on the shore of Nipon. Its southern boundary is an extensive chain of islands stretching across the Seto uchi in an East and West direction, of which Yayo sima, Numa sima, Nnku sima, Mosuki, Nokona, and Kosii sima are the largest. The

route recommended lies through the south-eastern part of the Misima Nada, within 2 to 3 miles from the mainland of Sikok.

Tsuri Sima and Lighthouse marks the eastern side of the channel which joins the Misima Nada with the Iyo Nada. Tsuri Sima is highest at its southern end, where the elevation is 150 feet, gradually decreasing to the North and West. The island is wooded. The lighthouse, 21 feet high, is built of granite, and stands 400 yards inshore of the N.W. point of the island. The *fixed bright light*, elevated 186 feet and visible 20 miles off, is obscured to South and East between S. $\frac{3}{4}$ W. and E.N.E.

Anchorage.—Cape Simonamba, $13\frac{1}{2}$ miles north-eastward of Tsuri Sima, is a bluff point of about 250 ft. in height, from which the land rises to the eastward or inland in irregular slopes to three conspicuously sharpened peaks of about 1,000 feet. The bay South of Simonamba Point affords good anchorage in 6 to 9 fathoms with the North point of Kosii bearing W. by S. $\frac{1}{2}$ S., but one mile South of this position is a sandbank, on which there is only 9 ft. water. A sandbank on which there are 14 ft. water, lies in the same bay, about midway between Ka sima and Kosii sima, with the western-most of the two largest elevated rocks which are seen West of Ka sima in line with Cape Simonamba.

Directions.—After rounding Ozumi no hana, Itsuki sima, a comparatively low island with bare ridges of a reddish colour should be steered for W. by S. $\frac{1}{2}$ S., until Kajitori saki bears about S.W. by S., when alter course to S.W. $\frac{1}{4}$ S. for the S.E. point of Nokona, and passing it at about half a mile keep in mid-channel between Mosuki and Kosii sima. Cape Simonamba should not be approached nearer than one mile.

IYO NADA.—This portion of the Seto uchi lies westward of Tsuri Sima, between which and Hime sima its western boundary is about 55 miles. The whole of its shores are as yet unsurveyed, but that to the South appears clear, with no off-lying islands or indications of danger; its northern shore, however, is skirted by groups of islands and rocks. Great caution should always be observed when approaching any of the coast which has been inserted in the charts from the Japanese manuscript only, as the sunken dangers are not often shown on that document. At the S.W. of the sea is a deep bight on the North shore of the island of Kiusiu, which from this, westward, forms the southern shore of the Seto uchi. In this bight are several deep indentations, which are probably good anchorages; several large rivers also flow into this part of the Iyo nada. About 20 miles to the eastward is the northern entrance to the Boungo Channel described on page 1202.

Anchorage can be obtained at Oemura, about E. by S. of the South point of Kosii. There is a large town (Sinhama) in this bay with forts on the shore, and a Japanese man-of-war was seen lying at anchor with a large

number of junks; the bay is open to the westward. In passing through between Kosii sima and the main, where not less than 9 fathoms were obtained, there appeared to be good anchorage in the southern bay on the East side of Kosii; junks were lying there. The shore of the mainland opposite Kosii is skirted with rocks and islets.

Tides.—The tides, both flood and ebb, set across the bay, but their rate does not exceed 1 to $1\frac{1}{2}$ knots. It is high water, full and change, at about 9^h, and springs rise 8 or 9 feet.

Directions.—From Nokono a course may be shaped to pass on either side of Yuri, the South side being preferable, from which a course S.W. by W. $\frac{3}{4}$ W. will lead up to pass about one mile South of Ko Minasi sima, after which alter to W. by S. $\frac{1}{4}$ S. to pass about $1\frac{1}{2}$ mile southward of Ya sima. When Ya sima bears North haul up W. by N. $\frac{1}{2}$ N. This course leads about $1\frac{3}{4}$ mile northward of Hime sima, but according to the tide vessels are either set to the southward towards the Boungo Channel, or to the north-westward towards Iwami sima. Continuing this course from Hime sima will lead through the Suwo nada up to the entrance to Simonoseki Strait.

The **SUWO NADA**, the western division of the Seto Uchi, is the most open but of no great depth, the soundings varying from 15 to 20 fathoms in the centre. It is bounded on the North by the provinces of Suwo and Nagaton in Nipon, and on the South by the province of Buzen in Kiusiu, and on the East by Hime sima, and is about 40 miles in length (East and West). At its western extreme is the strait of Simonoseki, the western approach to the inland sea.

Directions.—Vessels bound from the Boungo Channel or from the eastward for Simonoseki Strait, may steer to pass Moto yama at the distance of 3 or 4 miles. Thence a course should be shaped, N.W. $\frac{3}{4}$ W. for I saki, which is high and bold, as well as steep-to, and may be rounded at the distance of 2 or 3 cables. At night keep I saki *white* light in Sight N.W. $\frac{1}{2}$ N.

I SAKI and **LIGHT.**—Isaki is the eastern promontory of the North point Kiusiu, and South point of East entrance of the strait of Simonoseki; it may be passed at 2 cables.

On its N.E. extreme, elevated 122 ft., and visible 17 miles off, is exhibited a *fixed light*, showing *red* to the northward and eastward between W. by N. and S.E. $\frac{3}{4}$ E., and *bright* to the southward of the latter direction as far as S. $\frac{1}{2}$ W. The junction of the red and white lights bearing N.W. $\frac{3}{4}$ W. clears the shoals off Moto yama. The tower is of granite 31 ft. high.

SIMONOSEKI STRAIT, surveyed during the years 1872 to 1875 by Captain St. John in H.M.S. *Sylvia*, is 7 miles in length, and has a navigable channel varying from 3 to 7 cables in breadth. Both entrances are encumbered with sandbanks, particularly the western, between which and the off-lying islands extensive reefs project in every direction. The eastern entrance to the strait lies between I saki and Kusi saki, between which it is $2\frac{1}{2}$ miles

wide, but is divided into three channels by two extensive sandbanks named the Middle Ground and Tano Bank.

Kusi Saki, the North point of entrance of the strait, has reefs extending 2 cables off it. There is a large military station here, named Choshin, or or Hagi Chiofu.

Kanziu and *Manziu* are two islands E. by N. of Chofu Point. They are both covered with trees, and should not be passed within 2 cables. *Kanziu* is low and flat, with some large rocks and a rock awash off its South end; but *Manziu* is 190 ft. high.

Middle Ground, midway between Kusi saki and I saki, is a shoal bank of sand extending $1\frac{1}{2}$ mile in an East and West direction, being from one-half to 3 cables in width, and has depths varying from 1 to 3 fathoms on it. The eastern extreme is $1\frac{1}{4}$ mile N.N.E. from I saki Lighthouse.

A *black buoy* surmounted by a cage lies in 3 fathoms at the East extremity of the Middle Ground. From it the middle of *Manzui* bears N. by E.; *Mozi Point*, W. by N. $\frac{3}{4}$ N.; and *Isaki Lighthouse*, S. $\frac{3}{8}$ W. There is a shoal spot, with only 6 ft. water on it, immediately North of the buoy. A *red buoy* with staff and ball is moored in 3 fathoms, $8\frac{1}{2}$ cables West of the black buoy, with Kusi saki bearing N.N.W. $\frac{1}{2}$ W., $4\frac{1}{4}$ cables from the western extreme of the Middle Ground.

This bank divides the strait into two channels, that to the northward (North Channel) carrying the deepest water.

Tano Bank, western extreme, on which is 4 fathoms, lies 4 cables E. $\frac{3}{4}$ N. from *Mozi saki*, from which position it extends in an easterly direction for nearly $1\frac{1}{4}$ mile with depths varying from $2\frac{3}{4}$ to 4 fathoms on it.

This bank divides the portion of the strait lying southward of the Middle Ground into two channels. Neither of them is to be preferred to the North channel (North of the Middle Ground), but of the two the channel North of the Tano Bank (Middle Channel) is the best.

A large clump of firs on *Take saki* (the South point of Simonoseki town), in line with *Mozi saki*, W. by S. $\frac{3}{4}$ S., leads between *Kanabuse* and *Tano Bank*.

Anchorage in 5 fathoms may be found on the outer part of the Tano Bank (which shoals suddenly from 7 to 4 fathoms) well clear of the tide race through the strait.

Kanabuse or **Fisherman Rock** lies 11 cables N.E. by E. $\frac{1}{2}$ E. from *Mozi saki*. It is 120 yards long (N. by W. and S. by E.), has only 4 feet on its southern end, 12 feet on its northern end, and 5 fathoms between at low-water springs; the South end has the appearance of two large square blocks of stone 10 yards apart. There are 6 fathoms close to its South, East, and West sides, and 10 fathoms (sandy bottom) about a boat's length northward of the 12 feet patch. A *buoy*, colored *black* and *white* in horizontal stripes and

carrying a staff and ball, is moored in 9 fathoms, half a cable South of the southern rock, with Mozi saki bearing S.W., and I saki E.S.E.

CHANNELS.—The *North Channel*, northward of the Middle Ground, is, with the exception of the Kanabuse, clear of danger. The *Middle Channel*, South of the Middle Ground, and North of the Tano Bank, carries $4\frac{1}{2}$ fathoms at low water springs. Hino yama kept W. $\frac{1}{2}$ N. until the clump of trees on Take saki comes in line with Mozi saki leads through. The *South Channel*, southward of the Tano Bank, is the narrowest, although the tides here are not so strong as in the North and Middle Channels. It carries a depth of not less than $5\frac{1}{2}$ fathoms at low water.

Mozi Saki.—The strait is narrowed to 3 cables between this point (which is the extreme of a promontory at the North end of Kiusiu), and the eastern end of the town of Simonoseki. *Hino yama*, a peak with three summits, the highest of which is 933 ft. above the sea, is conspicuous on the mainland of Nipon, opposite Mosi saki. Between Mosi Saki and the opposite shore the tide runs with great velocity, but with some interval of slack water between the change of stream.

Whitshed Bay, on the South side of Mozi saki, affords good anchorage in from 5 to 7 fathoms, with Mozi saki and Observation Point in line, or a little open, bearing North; and Mozi village bearing East. Here the heavy ships of the allied fleet anchored after the reduction of the batteries in September, 1864. An extensive shoal bank, with from 3 to 4 fathoms water on it, fills up the whole of the southern part of Whitshed Bay.

SIMONOSEKI is an important town from its position at the entrance of the Inland Sea. It is formed of a single principal street running for nearly 2 miles, at the base of some low steep hills, along the shore of Nipon. Its most conspicuous building is the custom-house, recognised by its tall white gables. A small *light* is exhibited on the shore at the end of a stone balustrade at the eastern quarter of the town.

Supplies of provisions and coal were obtained by the squadron with difficulty, as it was not a treaty port. The *coal*, which is much used here in the forging of nails, was of the worst possible description, and gave 75 per cent. of ash and earthy matter. *Water* of excellent quality was brought off in buckets in large boats.

If intending to anchor off the town of Simonoseki, take a position well below the custom-house in from 6 to 10 fathoms, out of the tides, which are very rapid.

Tides.—It is high water, full and change, at Simonoseki, at 8^h 30^m; springs rise 8 ft., neaps 3 ft. The western stream makes at $2\frac{1}{2}$ hours before high water, and the eastern stream $2\frac{1}{2}$ hours after high water, so that the western stream continues 5 hours and the eastern 7 hours. Off Mozi saki the velocity at springs is from 7 to 8 knots, at neaps 3 to 4 knots; the current is at its

full strength for 3 hours of each tide. There are heavy overfalls in the eastern part of the strait at springs.

HIKU SIMA, lying at the western entrance of Simonoseki Strait, is 3 miles in extent North and South. Its S.W. point, *Entrance Head*, is a wooded bluff, 380 ft. high, to the North of which is a small harbour called *Fuku ura*, where junks anchor in from 9 to 10 ft. at low water. A *fixed bright light* is shown about two-thirds up the hill, on the North point of entrance to *Fuku ura*.

Yodsibi Rock lies E.N.E. $5\frac{1}{2}$ cables from Kibune Point, the S.E. extreme of Hiku sima, and is best avoided by hugging the Hiku sima shore. It uncovers 4 ft. at low water springs, and is marked by a *red conical stone beacon*, 20 ft. in height and 8 ft. in diameter at the base, with a plain rounded top. The rock may be passed on either side, but the western channel is preferable, being twice the width of the other.

Narusi Rock is a quarter of a mile off Kibune Point, and $1\frac{1}{2}$ cable off shore. It uncovers before half ebb, and is very dangerous. A *white conical beacon*, 8 ft. in diameter at the base, 20 ft. in height, and surmounted by a pear-shaped top, has been erected on this rock. To pass outside it, keep Hino yama, the wooded bluff hill over Simonoseki, open of Kibune Point.

Manaita Rocks, lying nearly 2 cables South of Entrance Head, uncover towards low water. A conical *beacon*, coloured *black* and *white* in rings, 8 ft. in diameter at the base, and 20 ft. in height, surmounted by a ball 3 ft. in diameter, has been erected on the largest of these rocks.

KOKURA town and fortress stands on the shore of Kiusiu, South of Hiku sima, at the mouth of a small stream named the Ogawa.

Kokura Ledge is a flat of sand and rock, with shoal patches on it, fronting the low shore of Kiusiu South of Hiku sima. The flat extends from 1 to 2 miles off shore, gradually deepening to 3 fathoms at its outer edge, which is steep-to.

Hiku Flat, lying W.N.W. 1 mile off Entrance Head, is a bank of sandstone rock, 8 cables long and 3 broad, with 13 ft. water on it.

The West extreme of Hiku sima (Cape Sizikuts), in line with the East extreme of Kanasaki sima, N.N.W. $\frac{1}{4}$ W. westerly, leads between Hiku Flat and a small 3-fathom bank, 4 cables N.E. of it (Hamo Bank).

DIRECTIONS.—Approaching the strait with I saki light N.W. $\frac{3}{4}$ W., or at night keeping the *white* light in sight, as before mentioned, pass I saki at half a mile, and when the lighthouse bears S.S.W. $\frac{1}{2}$ W., haul to the northward to clear the eastern end of the Middle Ground, taking care not to bring I saki lighthouse southward of that bearing until Hino yama bears W. $\frac{1}{2}$ S., southerly, when steer for it until I saki lighthouse bears S.E. by E. $\frac{1}{4}$ E., when a small islet will be seen just open North of Kusi saki, bearing N. by E. $\frac{1}{2}$ E. Alter course to S. by W. $\frac{1}{2}$ W. with the above mark on

which will lead between the western extreme of the Middle Ground and Kanabuse Buoy) until the clump of firs on the point South of Take saki is in line with Mozi saki W. by S. $\frac{3}{4}$ S.; keeping this mark on steer for them, rounding Mozi saki at $1\frac{1}{2}$ cable (mid-channel), on passing which haul to the southward, keeping the northern shore on board until Hino yama bears N.N.E. $\frac{1}{2}$ E., when alter course to S.S.W. $\frac{1}{2}$ W., and pass to the westward of the red beacon on the Yodsibi Rocks. Pass Kibune Point at $1\frac{1}{2}$ cable, and take care not to shut Hino yama in with the above point until the Narusi Rock is passed (at about $1\frac{1}{2}$ cable), when alter course to S.W. by S., keeping the hill over Mozi saki open of Kibune Point until Clump Hill (1,778 ft. high) on the southern shore bears S.E. by E. $\frac{3}{4}$ E., then alter course to N.W. by W. $\frac{3}{4}$ W., until the East extreme of Kanasaki sima is in line with Cape Sizikuts (the N.W. point of Hiku sima) bearing N.N.W. $\frac{1}{4}$ W.; haul to the northward with this mark on, which leads to the westward of the Manaita Rock, and in from 6 to 10 fathoms between the Hiku Flat and Hamo Bank, borrowing to the westward as the Hiku Flat is passed, and round Cape Sizikuts at about 3 cables; after which, haul up for the lighthouse on the N.E. point of Rockuren Island, and pass it at from 3 to 4 cables; or at night keep the light in sight, taking care not to bring it to bear eastward of N. by E. $\frac{1}{2}$ E., to clear the shoal extending to the S.E. from Wakura sima and Kanasaki sima.

Caution.—The mariner is reminded that the tidal streams set through this strait with great velocity, and that great caution is necessary for the safe navigation of the ship, to avoid the many dangerous rocks and banks with which it is encumbered. It is therefore recommended that vessels should anchor, if the tide be not favourable on arrival at either entrance, and that the strait should be taken at as nearly at the time of slack water as is possible.

Anchorage may be had at the western entrance to the strait, to the eastward of the Hamo Bank in from 8 to 10 fathoms, with Wakura sima in line with Cape Sizikuts.

The Western Entrance to the Seto Uchi is at its outer part 35 miles across, being formed by the West Coast of Nipon running South for 25 miles from Kado sima, and the North Coast of Kiusiu taking an easterly direction for the same distance, from Kosime no Osima. At the angle where these coasts meet, within 3 miles, is the large island of Hiku sima, above described, South of which is the fairway and entrance to the Strait of Simonoseki.

IWAYA POINT, low and rocky, with projecting ledges, is at the termination of a sandy bay 5 miles wide. A wooded hill, 1,100 ft. high, conspicuous from the offing, with a round gap in its summit, rises 5 miles S.W. by W. $\frac{1}{2}$ W. of Iwaya Point.

The Kiusiu shore eastward from Iwaya Point is generally low, and skirted with sandstone ledges, but the back ranges are from 2,000 to 4,000 feet in height. The shore of Nipon is higher, but its hill ranges lower, or from 1,000 to 2,000 ft.

Siro Islands, two in number and 1 mile apart, lie W. by N. $\frac{1}{2}$ N. 16 miles from the outer point of Kosime no Osima (Wilson Island) and nearly 5 miles N.N.E. from Iwaya Point. The north-eastern one, 400 ft. high, with a wooded summit of rounded outline, has a round rock off its rugged North point and a shoal spit extending 4 cables off its South point. The South island is indented, its eastern sharp peak being 290 ft. high; there is shoal water off its South point; but its North point is steep-to.

To the S.S.E. for a distance of $1\frac{1}{2}$ mile from the eastern end of South Siro Sima are a series of rocky patches and shoals, on the outermost of which is a depth of $2\frac{1}{2}$ fathoms. At $1\frac{1}{2}$ mile southward of this outer patch is a patch of 2 fathoms, and midway between is a rocky patch of $4\frac{1}{4}$ fathoms.

Masui Sima lies N.E. by N. 6 miles of North Siro sima, and 3 miles from the shore of Nipon, off Cape Morotzu, the hills over which are 1,000 ft. high. The channel between is free from known danger.

The northern part of this island is a triple-topped bluff, 900 ft. high; on the West coast (about the middle) there is a very sharp peak; the southern part of the island is lower, and terminates in a bluff. The island is bold-to on all sides, except at its South point, off which reefs extend 1 cable. One mile E.S.E. of the South bluff is a small black rock, 6 ft. high, which should not be approached too closely.

Ai Sima, bearing S. by E., 6 miles from Masui sima, is a low flat island covered with trees, and 1 mile in length. Reefs, dry or sunken, extend 1 mile off its North point, and a spit extends S.E. by S. $1\frac{1}{4}$ mile from the South point; there are also others extending 8 cables East of its South point, and which are marked by a small square rock.

Low Reef or Shirasu and Lighthouse.—To the S.W. of Ai sima is a large detached reef, with a sand patch on it; and in the channel, a mile wide between it and Ai sima, the depths are from 3 to 5 fathoms. The lighthouse, square, and painted in black and white horizontal stripes, 49 ft. high, is situated on the South part of the reef. From it is shown a *fixed red light* at an elevation of 42 ft., visible 8 miles off.

Rokuren Island and Light lie 3 miles S.E. by E. of Ai sima. This island has on its table land a large and conspicuous clump of trees, 390 ft. above the sea, which is visible after rounding Kosime no Osima (Wilson Island), when it will bear about E. $\frac{1}{2}$ N. A spit extends 2 cables from the North point of the island, but the East side is bold. A *fixed bright light* is shown on the eastern extreme of Rokuren, elevated 89 ft. above the sea, and visible 12 miles off. To the westward the light is *obscured* by the high land of Rokuren, between N.W. $\frac{3}{4}$ N. and S. by W. $\frac{1}{2}$ W. The tower is of granite,

25 ft. high. The light when first seen, bearing S.E. $\frac{3}{4}$ S., leads half a mile from the shoal ground North of Ai sima.

U-Ma Sima Group, consisting of Ma sima, Kanasaki sima, Wakura sima, and several smaller islets and rocks, lies to the S.W. of Rokuren.

Anchorage.—There is small anchorage on the S.E. side of Masui sima, with the shore bluff bearing S.W. There is anchorage also along the Nipon shore, East of Ai sima and Rokuren, in 7 and 9 fathoms, but the coast should not be approached within half a mile, as it is fringed with reefs; northward of this the reefs extend a mile off shore. If, however, there be sufficient daylight to get round Rokuren, it is recommended to do so instead of anchoring outside for the night, and bring-to on the bank half a mile South of the U-Ma sima Group, in 6 or 7 fathoms.

Tides.—It is high water, full and change, at the western entrance to Simonoseki Strait, at 10 p.m., and the rise and fall is scarcely 4 ft. At Kokura, on the South side of entrance, it is high water about 9^h 20^m.

If bound to Simonoseki from the westward, pass about 1 mile North of Kosime no Osima (Wilson Island), and steer E. by N. $\frac{1}{2}$ N. for the North point of North Siro sima, which pass at half a mile; then steer East, taking care not to bring the North point of North Siro sima to the northward of West, till the lighthouse on the eastern extremity of Rokuren Island opens out S.E. $\frac{3}{4}$ S., or at night until the light is sighted, so as to clear the reefs marked by the red buoy off the North point of Ai sima. A S.E. course will then lead up to Rokuren, which can be rounded at 3 cables, when steer S. by W. to pass Cape Sisikuts, the West point of Hiku sima, at a distance of nearly half a mile; or at night keep the light in sight, taking care not to bring it to bear eastward of N. by E. $\frac{1}{2}$ E.

The *Southern Channel* only shortens the distance 4 miles, and requires the new survey as a guide. To the S.E. of Shirasu there is but a depth of 2 to 2 $\frac{1}{2}$ fathoms in it.

THE GOTO ISLANDS AND THE WEST COASTS OF KIUSIU AND NIPON.

The **GOTO ISLANDS**, a mountainous chain of many islands, lying between the parallels of 32° 37' and 33° 20' N., is 50 miles in extent in a N.E. and S.W. direction, and from 5 to 20 miles in breadth. The group cannot be said to have been thoroughly examined, but the information relating to it is much more reliable since H.M.S. *Sylvia*, Lieut. Pearce, R.N., made an examination of the more important portions in 1877. Our knowledge previous to this was from visits of H.M.S. *Saracen*, in 1855, and of Commanders Brooker and C. J. Bullock, in 1866-9.

Tides.—It is high water, full and change, in the East Bay (Ojika) at 8^h 40^m; springs rise 10½ ft., neaps 2 to 4 ft. The duration of the tidal streams in the North part of Goto Islands is nearly equal; the main direction of the flood is to the northward, and ebb to the southward. In the vicinity of Hira sima the streams run through the channels at the rate of 3 to 5 knots during springs, causing heavy overfalls.

Ojika Seto or Kosaka Channel is the strait lying southward of Uku sima and Tera sima, the latter 120 ft. high, off the S.W. side of Uku sima. To the eastward of its entrance are the *Kuromo-ze*, a cluster of rocks, 50 ft. high, at 2¾ miles S.E. of Uku sima. There is *anchorage* in a bay on the N.E. side of Tera sima, between that island and Uku sima. There is a bank in the centre of this harbour of 4¼ to 5 fathoms water; the best anchorage is northward of this bank. Some supplies may be obtained from the villages. The harbour should be approached with Tera sima seen just open to the westward of Uku sima, bearing N.W. ¼ W.

The western entrance of the Ojika seto is only 9 cables wide between Tera sima and No sima. Neither the South side of Tera sima nor the North side of No sima should be approached. *Ai-no-se*, 16 ft. above high water, is in the centre of the strait, 2 miles N.E. of No sima; and *Mu sima*, 254 feet high, with dangers extending a quarter of a mile South from its eastern point, lies on the South side of the eastern entrance to the strait, at 3½ miles eastward of No sima.

Nosaki Sima, 1,142 ft. high, is 3½ miles long North and South. Between it and Mu sima to the northward is a strait a mile wide, in which are several dangers. Between the South end of Nosaki sima and the North end of Nakadori is a narrow strait clear of danger; but the islets *Tanji* and *Skinomu*, lying between 1 and 2 miles S.S.E. of it, should be avoided, as many dangers exist near them.

Ojika Island, 3½ miles long East and West, lies South of No sima, a navigable channel separating them. *East Bay*, on the eastern shore of Ojika, is three-quarters of a mile deep, and nearly 7 cables wide at its entrance. The shore of this bay is fronted with shelving rocks that cover at high water. From Tonzaki, the South entrance point, rocks extend 2 cables in a northerly direction, and shallow water half a mile in a south-easterly direction. Kuszukuri, the North entrance point, is marked by a rock above water at the extremity of the shelving rocks. The depths in East Bay are from 4 to 14 fathoms, the best anchorage being in about 8 fathoms, with the North point of Nosaki sima in line with the rock off Kuszukuri Point, bearing E. by N. ½ N.; and the South end of Nosaki sima in line with Tan-ji Islet, S.S.E. ¾ E.

Ko-guro Sima, 57 ft. high, situated 6¼ cables westward of the S.E. point of Ojika, and 2 cables from the shore, is 400 yards long East and West, and

300 yards broad. This island is steep-to, except off the N.E. point. *Anchorage* can be obtained nearly midway between Ko-guro sima and the S.E. point of Ojika, in $7\frac{3}{4}$ fathoms, sand, with the South extremes of Ko-guro sima and Kuro sima in line, bearing W. by S. $\frac{1}{2}$ S., and the hill over the S.E. point of Ojika N.N.E. $\frac{1}{4}$ E. This anchorage is sheltered from northerly winds,, and the depths are even.

For 11 miles to the westward of Ojika there are many islets. The northern of these, named *Hoage* or *Arch Rock*, lies 5 miles West from the West end of Ojika, and consists of two pinnacles, 167 and 120 ft. high. A *dangerous rock*, dry 5 ft. at low water springs, with 5 to 11 fathoms round it, and on which the sea generally breaks, lies to the northward of Hoage, with the summit of Biriyo sima in line with the West extreme of Hoage, bearing S.W. $\frac{3}{4}$ S., distant from the latter $6\frac{1}{2}$ cables, and Aka sima West point S.E. by E. easterly. There is a depth of from 20 to 34 fathoms between this rock and Hoage.

Shiro-se, 105 ft. high, $13\frac{1}{2}$ miles W. by S. from Ojika seto, is the westernmost islet in the northern portion of the Goto Islands. It is divided into two pinnacles, nearly the same height, lying in a N.E. and S.W. direction. Off the islet are several rocks.

Hodge Rock or *Shaku shi*, a rock awash at low water, with deep water around it, lies N. $\frac{1}{4}$ W., distant $4\frac{1}{2}$ cables from *Shiro-se*. The North peak of *Nosaki sima* in line with Hoage, bearing East, will lead 2 cables to the northward of Hodge Rock.

Korai-no-ze Rock, with 18 ft. water, lies near the S.E. edge of a rocky bank; this bank extending N.W. by N., three-quarters of a mile, with a breadth of 4 cables, has from 5 to 10 fathoms. At 3 cables southward of the rock the depth is 20 fathoms; and at half a mile from the depth of $5\frac{1}{2}$ fathoms on the northern edge of the bank there is 38 fathoms. The North point of *Biriyo-sima*, in line with the North peak of *Nosaki-sima* bearing E. $\frac{2}{3}$ N., leads northward of *Korai-no-ze*. South point of *Hira-sima* in line with the North peak of *Nosaki-sima*, bearing E. by N. $\frac{1}{4}$ N., leads southward of *Korai-no-ze*.

Nakadori sima is $21\frac{3}{4}$ miles long between *Sawo saki*, the South extreme, and *Tsua saki*, the North extreme. The coast line of *Nakadori sima*, the greater part of which has not yet been surveyed, is deeply indented with bays. *O-mitzu yama*, a flat peak, 1,446 ft. high, 6 miles from its North end, is the summit of *Nakadori sima*.

Nama ura Bay, situated on the western side of *Nakadori sima*, immediately to the southward of *O-mitzu yama*, may be recognized by *Cone Rock*, 313 ft. high, which forms the South entrance point of the bay. *Nama ura* is 2 miles deep and half a mile wide, with an even depth of about 16 fathoms; from the N.E. side of entrance shelving rocks extend $3\frac{1}{2}$ cables in a S.W. direction.

The best anchorage for large vessels is near the head of Nama ura, in 10 fathoms water, $2\frac{3}{4}$ cables from the shore, with the peak of O sima just open eastward of the Cone Rock, bearing N. by W. $\frac{1}{4}$ W., a patch of red cliff on the West shore of the bay, just North of Nama village, W. by S. $\frac{1}{4}$ S., and Joss Point N.E.

Hira sima, nearly 2 miles from the East extreme of Nakadori sima, and 4 miles westward of Yenoï sima, is 663 ft. high. Its western side is steep-to, and its eastern irregular, with a few off-lying dangers and islets. *Haidomari Bay*, on the N.E. side of Hira sima, is 6 cables deep. It is, however, only suitable for junks. *Komoda Bay*, situated on the S.W. side of the island, affords protection to small vessels from North and easterly winds; near the centre of this bay lies a small wooded islet, named *Kojima*; vessels should anchor to the south-eastward of this islet. *Nanori* is a remarkable rock, 92 ft. high, 6 cables to the south-westward of Komo-no-saki, having rocky ledges surrounding it.

The channels on either side of Hira sima are navigable; the channel between Hira sima and Nakadori sima is clear of danger, but in the channel between Hira sima and Yenoï sima are the *Saracen Reefs*, situated to the southward of Yenoï sima, and S.E. 3 miles from the North end of Hira sima, and the foul ground to the south-westward of Kuro sima (a small islet 120 feet high). The eastern shore of Hira sima is the clearer side of this channel.

Oldham Rock, covered at high water springs, lies nearly $1\frac{1}{2}$ mile E. by N. from *Sawo saki*, the South extreme of Nakadori. An islet, 78 ft. high, half a mile to the westward of Sawo saki in line with it, bearing West, leads to the southward.

The channel between the South end of Nakadori and Kaba sima to the southward is 3 miles wide, and, with the exception of some dangers close to its northern shore, seems deep and clear of danger. On the S.W. side of Nakadori sima is *Wakamatsu sima*, the narrow *Nakadori Channel* lying between. The strait between Wakamatsu sima and Naru sima, a mile wide, has not been examined. It is named *Takigawara seto*.

The **Kuga Channel**, or **Naru Seto**, between Naru sima on the North and Hisakajima on its South side, was examined by H.M.S. *Saracen*, and found to carry deep water, 26 to 32 fathoms, through it. This channel may be approached either around the North or South sides of Kabasima. If using the channel to the North of Kabasima, there is a *sunken rock* to be avoided. It lies West 3 miles from the North end of Kabasima, and about half a mile eastward of the South end of the island ($1\frac{1}{2}$ mile long N.N.E. and S.S.W.), which lies close to the westward of the long promontory forming the South end of Naru sima.

Hardy Harbour, a small inlet, 6 cables in length North and South, and 3 to 4 cables broad, is a snug anchorage, on the S.W. side of Naru sima. It

is entered from the Kuga Channel. On the South side of its entrance is *Observatory Islet*, at 1 cable South of which a shoal, steep-to, with 9 ft. water, extends $1\frac{1}{2}$ cable from the shore. From the N.W. side of the entrance a shoal extends southward halfway across the entrance. The best anchorage is in 6 or 7 fathoms W.N.W. of Observatory Islet, and rather nearer to the opposite shore.

Fukuye or Fukai, the chief town of the Goto Islands, is situated on the shore of an open roadstead on the north-eastern side of Fukuye sima, the southern and largest island of the chain, and southward of the Fukuye Channel, which separates it from Kuga sima. On either side this channel (which is a mile in breadth, with every probability of carrying deep water throughout) there is an anchorage, also several others surrounding the indented coast of Fukuye sima, but neither channel nor anchorages have yet been explored, with the exception of Tama no ura, on the S.W.

Cape Goto, or *Ose Saki*, the S.W. point of Fukuye sima, about 500 ft. high, is exceedingly bold. Behind, or north-eastward of the cape, rise three fine mountains, about N.N.W. of each other, of which the northern and highest is 1,387 feet above the sea. At the extremity of the coast, which extends E.S.E. 3 miles from the cape, is *Otakara Point*. A quarter of a mile S.E. is the islet *Biro Sima*, 150 ft. in height, with a rock $1\frac{1}{2}$ cable off it to the southward. E. by S. 3 miles from Otakara is *Tsutara Sima*, 320 ft. high. Reefs stretch off its East and West points. To the North of this island is a large bay, at the western part of which anchorage may be obtained. Situated centrally in the large bay, at 7 cables N.N.W. of Tsutara, are two islets.

The coast East of Tsutara has not been explored. Kasayama saki, the southern cape of Fukuye, is low and wooded, and separated by a valley from the mountains.

Tama no Ura, the name of a large inlet or arm of the sea, on the western side of Fukuye sima, only partially explored, is finely situated as a port of refuge, and but for its great depth of water would be a magnificent harbour. Its only entrance is $4\frac{1}{2}$ miles N.N.E. of Ose saki, and $2\frac{1}{2}$ miles S.E. of the island *Saga sima*, which is $1\frac{3}{4}$ mile in length, and shows two distinct hills on its North and South parts, which are separated by a valley through the island. In the bay on the East side of Saga there is good anchorage in 7 to 8 fathoms, quite sheltered from all westerly winds.

The entrance to Tama no ura is a mile wide, and must not be mistaken for the blind opening 2 cables wide, only 2 miles North of Ose saki.

The best anchorage for large ships will be found at the S.E. part of the harbour, in 16 fathoms, mid-channel, with the peak of Boshi yama, which is seen ahead when standing up the harbour, bearing from S.W. by W. to W.S.W. There are many parts of the harbour where ships can make fast to the shore in perfectly tranquil water.

From Tama no ura the coast runs North about 5 miles from Algerine

Bluff, falling to a low point, the north-western promontory of Fukuye, which is fronted by shelving rocks. *Hime sima*, 350 ft. high, is separated from this point by a channel a mile wide, in which was seen a rock awash.

Several *sunken rocks* lie off the N.W. side of Fukuye sima, at distances of from 3 to 6 miles. *Nichisone Rock*, a 9-foot patch, lies West $6\frac{1}{2}$ miles from Hime sima, and N. by W. $\frac{1}{2}$ W. $5\frac{1}{2}$ miles from the North end of Saga sima. *Corasone Rock*, of 6 ft., lies N.W. 3 miles from Hime sima. *Decrez Rock*, of 21 ft., N. by W. $\frac{1}{2}$ W., 3 miles from Hime sima. Between the two latter is another sunken rock.

Camono sima is a group of islets, lying 2 miles westward of the western entrance to Tanna ura seto (the channel dividing Fukuye from Hisakajima), N.W. a little more than a mile from the North extreme of these islets is a sunken rock.

PALLAS ROCKS, three in number, lie close together, S.W. 30 miles from Cape Goto. The largest rock, in lat. $32^{\circ} 14' 17''$ N., long. $128^{\circ} 12' 30''$ E., is about 60 ft. high, and very steep-to.

Pallas Rocks are steep-to; fishing vessels, by hooking on to the lee side of the rocks, ride out moderate breezes. During four passages these rocks were passed by the Peninsular and Oriental Company's steam-ship *Orissa*, and the set of the current in this locality was found to be with the wind.

MEAC SIMA GROUP consist of two islands, sometimes called the *Asses' Ears*, with intermediate smaller islands and rocks. *Taka sima*, the N.E. island, is nearly $1\frac{1}{2}$ mile long, and 618 ft. above the sea, and is somewhat level at the top.

Caution.—Reefs a few feet above water were observed by the Peninsular and Oriental Company's steam-ship *Orissa*, in 1875, to extend 2 or 3 miles to the N.E. of Taka sima, and foul ground may possibly extend farther out than was seen. The islet lying N.N.W. a mile distant from Taka sima is about 70 ft. high.

Kusa-kaki, the S.W. island, is less than half the size of the N.E. island, but 100 ft. higher and very craggy. Its remarkable peak probably suggested the name of the group to its first discoverers. *Me sima* and *Wo sima*, the intermediate small islands and rocks, are high and cliffy, the latter partaking generally of the sugar-loaf form. Rocks extend South about a third of a mile from the S.W. island, and a detached rock, 15 ft. high, lies S.W. $1\frac{1}{4}$ mile from the S.W. end of the group.

KOSIKI ISLANDS, consisting of two large and several small islands, extend in a N.E. and S.W. direction from lat. $31^{\circ} 37'$ to $31^{\circ} 53'$ N., and from long. $129^{\circ} 41'$ to $130^{\circ} 0'$ E. They are not high, but their appearance is bold in passing. The *Nadieda Rocks*, off their West side, are considered to be about 4 miles from the shore, and 7 miles North of Haya saki, their westernmost point.

At the South end of Simono ko siki, the southern island is a small bay, in

which is anchorage. A *sunken rock* lies East $1\frac{1}{4}$ mile from the eastern entrance point of this bay and S.E. extreme of the island.

A *reef* is reported (1877) by Capt. Kiljour of the steam-vessel *Kiushu-Mar* as lying in lat. $31^{\circ} 20' N.$, long. $130^{\circ} 10' E.$, about $1\frac{1}{4}$ mile S.S.W. $\frac{1}{2}$ W. from Okino-Akima, and 1 mile from the nearest part of the mainland. The rock has been seen to break in N.W. winds. The reef is said by Captain Davidson, of the *Kiujun Maru*, to lie farther West.

Between *Kamino*, or the northern Kosiki, and the shore, 17 miles distant, are several dangers and rocks. A *conical rock* lies a mile eastward of the N.E. extreme of the island; S. $\frac{1}{2}$ E. $1\frac{1}{2}$ mile from this is *Tsika*, a small rock above water, with a number of dangers just eastward of it. Midway between the conical rock and Tsika is a sunken rock at the West end of a series of rocks above and below water, which thence extends 2 miles to the eastward. *Pinnacle rocks*, a small cluster, lie a mile N.E. of their eastern end. *Pioneer Rocks*, above water, but dangerous from their smallness, are reported as lying S.E. by E. 3 miles from Pinnacle Rocks, and 10 miles W. $\frac{1}{2}$ N. from Kami Saki. A *doubtful sunken rock* is marked 3 miles eastward of the Pioneer Rocks.

Taka Sima, or *Simplegades*, lie S. by E. about $11\frac{1}{2}$ miles from Na Saki, the South point of the Kosiki group. They are described as three rocky islets, forming a triangle, the sides of which are each not more than a cable in extent; to the southward are two small rocks about 7 ft. in height, and a rock awash was observed by H.M.S. *Highflyer*, in 1859, lying a quarter of a mile southward of the group.

The *Tsukarase*, or *Retribution Rocks*, two in number, apparently steep-to, were discovered by H.M.S. *Retribution*, 6th August, 1858. They lie in line North and South, about 2 cables apart, in lat. $31^{\circ} 23\frac{1}{2}' N.$, long. $129^{\circ} 44' E.$ The two southernmost rocks lie in a needle form about 60 ft. above the sea; the northern rock is flat, and only 10 ft. high.

Udsi Sima, or *Roche Poncié Group*,* consist of one island, with some rocks and islets surrounding it. The island is 2 miles in circumference, the western part somewhat flat, but the eastern rising in a precipitous peak to the height of 1,060 ft. above the sea. It is in lat. $31^{\circ} 12' N.$, long. $129^{\circ} 29' E.$ Two and a half and one mile respectively to the S.W. of the island are two small islets; and to the eastward of its peak about a mile is another islet.

"The Udsi Sima are high, and of considerable extent. The easternmost island appeared larger, and its position to be farther North than marked in the chart; no foul ground was near them."—(Stephen Court, Master of H.M.S. *Furious*, 1858.)

The WEST COAST of KIUSIU.—From Satano Misaki, the South point of

* Thus named (and deservedly so, if an European name is admissible), after the Ingénieur-hydrographe of the French Expedition under Admiral Cecille in 1846.

Kiusiu, the coast trends to the northward, forming a large gulf (Kagosima), the coasts of which have only been partially examined.

Anchorage.—H.M.S. *Furious*, in 1858, experienced a strong breeze from the N.E., and being accompanied with a falling barometer, an anchorage was sought for under and to the westward of Cape Chichakoff. The vessel eventually came-to in 13 fathoms, abreast a small village near the centre of the first bay northward of the cape, with the extreme of the cape bearing S.S.W., Horner Peak N.W. $\frac{1}{2}$ N., and Oto Saki N.N.W.; here she was well sheltered. A small but well sheltered inlet in the N.E. corner of the gulf in which the *Furious* anchored (Yama Gawa) has since been examined, and is of great service to small vessels meeting with adverse winds, when bound eastward through Van Dieman Strait.

KAGOSIMA GULF is an arm of the sea 35 miles in length, and from 5 to 10 in breadth, which runs in a North direction into the southern part of Kiusiu. At 25 miles within its entrance the large island of *Sakura* nearly fills the head of the gulf, with channels on both sides leading into an inner gulf or spacious harbour, 6 miles by 9, and quite landlocked.

There is no good anchorage on the eastern side, except on the small bank North of Havock Islands in the North part of the gulf, where there is an anchorage in 7 to 9 fathoms. In *Sata Iras Bay*, about 2 miles northward of Oto Saki, there is shelter from South and S.E. winds for one vessel in $5\frac{1}{2}$ fathoms.

Kami Rock lies in the mid-entrance of Kagosima Gulf, 3 miles off the northern shore. The bearings from it are,—Horner Point, N.W. by W. $\frac{3}{4}$ W.; Horner Peak, N.W. $\frac{3}{4}$ W.; Satano Misaki, S. $\frac{7}{8}$ E.; Oto Saki, S.S.E. $\frac{1}{2}$ E.; and the East head of Tsiring Sima just opening the North and low wooded point of Yama Gawa, N.N.E. $\frac{1}{8}$ E.

Yama Gawa, a small harbour, formed on the West side of entrance of Kagosima Gulf, is the crater of an extinct volcano. Its North part opens East to the sea by a funnel-shaped passage, a quarter of a mile in length, but only 1 cable wide at its inner part, formed by an extensive shoal bank, which extends 1 mile from the shore, South of the entrance. There are $3\frac{3}{4}$ to $4\frac{1}{2}$ fathoms over the lip of the crater or bar, with one patch of 2 fathoms in the centre. No vessel should attempt to enter in bad weather, although a small vessel may lie there at anchor or moored to the shore. Inside the harbour the water is deep.

Two *dangerous sunken rocks*, on the outer of which, named *Waters Rock*, is $2\frac{1}{2}$ feet water, and on the inner 9 feet, lie close together, E. $\frac{1}{2}$ N., 1 mile from the northern point of the entrance to Yama Gawa Harbour. Between the rocks and the shore is a depth of 6 fathoms.

At 4 miles northward of Yama Gawa entrance lies Tsiring sima, on the western shore of the gulf, about 1 mile from the shore, to which it is connected by a reef on which the sea sometimes breaks. It is from 150 to 200 ft. high. On the eastern shore, opposite, a shoal bank called the *Racehorse Shoal*,

extends about $2\frac{1}{4}$ miles from the shore. Between this shoal and Tsiring sima the gulf is narrowed to about 3 miles. Thence the Kagosima Gulf extends for about 17 miles to the northward, with a uniform breadth of about 10 miles to the Island of Sakura.

Seven Rocks is the name of a cluster of small rocks, which lies on the western shore of the gulf at 15 miles N.W. by N. from Tsiring sima. A shoal patch lies just outside them.

The channel at the S.E. end of Sakura is very narrow, and has not been examined. On the western side of the island are several villages, and in the channel dividing Sakura from the shore to the westward is *Parker Shoal*, on which a fort is built. On the S.W. side of this shoal temporary anchorage may be found.

Kagosima.—Facing the Island of Sakura on the West, the Kiusiu shore projects, narrowing the western channel into the inner gulf to 7 cables at its northern part, its length being 4 miles. On this projecting shore stands the city of Kagosima, the fortress of the Daimio, Prince of Satsuma. Battery Point, to the South of the city, is low, and has a spit extending from and around it to 2 cables, and very steep at its edge; a shoal also fills the bay North of this point. Off the centre of Kagosima in front of the Daimio's Castle, is an inner harbour or large camber, gained by entrances between five forts of masonry, which have deep water close up to them. This castle cannot be seen from the gulf. There is a cannon-shot foundry here, worked by Japanese. Two small rivers disembogue, one on the North side of the city with long spits off its points of entrance, on one of which H.M.S. *Racehorse* grounded; the other, South of the city, falls into the shallow bay just North of Battery Point. North of the city the hills reach the sea.

The western shore of Sakura Island is very bold, but anchorage in from 15 to 25 fathoms may be found in Euryalus Bay E. $\frac{1}{2}$ N. of the castle of Kago Sima, very close in. In an easterly gale there is danger of driving off the bank into very deep water and having to slip the cables.

The Coast from Sendai Saki northward to Amakusa, together with the Otentosama Sea, is as yet comparatively unknown. In the middle of the entrance to the Otentosama Sea is Naga Sima, the channel westward of which is foul 10 miles within. The *Kuro-ne-seto*, S.E. of Naga Sima is a safe and clear strait. There is one rock only on the western shore, it is close in, and shows at low water. The tides run with very great velocity through the strait, which should only be used as slack water. The northern part of Otentosama Sea is shoal.

A reef was reported in 1877 as lying $1\frac{1}{4}$ mile S.S.W. $\frac{1}{2}$ W. from Okino-Akima, in lat. $31^{\circ} 20' N.$, long. $130^{\circ} 10' E.$

AMAKUSA, a large island 23 miles in length, lies S.S.W. of the Simabara peninsula; between them is the western entrance to the gulf, only $2\frac{1}{2}$ miles in width. Two harbours, Tomioka and Sagitsu no ura on the western coast of the island, have been examined.

Kotamo Bay, on the South end of Amakusa, is well protected by Kasu sima. A reef lies in the centre of the bay above water, with a passage carrying from 13 to 16 fathoms on each side of it, and three other detached reefs, which always show above water, lie on the eastern shore closer in. The depth in the bay is from 13 to 16 fathoms, shoaling to 8 or 9 fathoms at 1 cable from the shore. In rounding Kasu sima do not approach too near the S.E. rock, as reefs have been observed on which the sea broke heavily outside this rock.

Koto no ura.—This bay has a series of detached reefs in its centre, and there appears to be no anchorage for anything but native craft.

Sagitsu no ura has been recently surveyed, and the channel leading to the narrow passage found rocky and uneven. There are three rocks north-westward of the entrance, the two eastern of which are pinnacles; the western is low. Only 4 fathoms can be carried at low water along the northern shore. *Cormorant Inlet* also is almost closed by the bank of shingle which extends across, and in the channel only 1 fathom at low water can be obtained. *Kami ura* is an inlet on the South shore.

Timioka, about 14 miles from *Sagitsu no ura*, is a lagoon-like harbour, on the eastern side of a small peninsula, which forms the N.W. point of Amakusa. The harbour is formed by a low tongue of land, curving round to the westward and enclosing it, giving complete shelter. The entrance is from the S.E. by a channel carrying 5 fathoms water close along the South side of the low tree-covered tongue which forms the eastern side of the harbour. The deep part of this channel is only 150 yards broad; a vessel should therefore be steered in at that distance from the shore on a W.N.W. course, with the village of *Tomioka* ahead, carrying in $4\frac{1}{2}$ to 5 fathoms, and may anchor in the centre of the harbour in 6 fathoms. It is very shallow off the South shore at entrance, but a flat of 3 fathoms borders the channel, making it for that depth a quarter of a mile in breadth.

SIMABARA GULF.—Of this large gulf, which extends 70 miles into the heart of Kiusiu, little is known. Simabara is a large and broad peninsula, so situated as to make this gulf an inland sea. On the eastern shore of the peninsula there stands a city of the same name. In the centre of the peninsula is an active volcano. The head of the Simabara Gulf is shallow and full of dangers, and vessels navigating it should avoid the very turbulent chow-chow (or disturbed water.)

A rock lies at the entrance of the gulf, and uncovers 5 ft. at low water. It bears N. 20° W. from the East extreme of *Tsuji sima*, and N. 64° W. from East extreme of *Oösima*.

The western passage into the gulf, North of the "5-ft. rock," seems preferable, as it is less exposed in its eastern part to the force of the tide, which here runs with great velocity and produces whirlpools. Great care

is therefore requisite in the steering of the vessel. This rock always shows, except at high-water springs. Southward of the "5-ft. rock," between it and Tsigi-sima, several rocks have been reported showing at low water; the Japanese do not use this channel.

Abreast the town of Simabara a bank, having $3\frac{1}{2}$ fathoms, extends at least half a mile from the shore. There is probably no safe anchorage close to Simabara. To the southward of Do-saki, Ohoye, and Fusinotsu there is probably safe anchorage; and at Fusinotsu is a junk harbour, in which was seen a Japanese barque of 300 tons.

The eastern side of Simabara Gulf seems shoal throughout; but the lead may be considered a safe guide in approaching the bank.

Tsikugo-gawa, situated at the head of Simabara Gulf, is reported to have a depth of 12 ft. on the bar. The foreshore is very low, but the land at the back is high.

Tides.—Springs rise 14 ft. at the town of Simabara; in the southern part of the gulf the range is greater.

About 22 miles of the eastern side of the Nagasaki peninsula has been surveyed. It has generally a bold steep coast, but there are several places on it where a vessel blown to leeward of Nomo saki by West winds will find anchorage and good shelter from them.

Aba Bay is rectangular in shape, $1\frac{1}{4}$ mile deep, and 1 mile in breadth. There is anchorage in the centre of the bay in 7 fathoms, open only between South and S.E. The eastern side of the bay is formed by Maki sima, which has some islets on the reefs on its South side, one of which extends 4 cables. There is a boat camber at the village on the western side of the bay.

On the N.E. side of Maki sima is a small harbour, connected with Aba Bay by a narrow channel. It has from 10 to 12 feet water, but only 9 feet between the reefs at its eastern entrance, which is scarcely a cable wide. There is a road or bridle path to Nagasaki through the valley, only 3 miles distant from the head of Aba Bay.

Mogi Bay is 3 miles S.W. from Aba Bay. Small craft can anchor in from 3 to 6 fathoms, sheltered except from South to East; and larger vessels in from 9 to 11 fathoms off the entrance.

Tameitsi Bay is $5\frac{1}{2}$ miles S.W. from Mogi. Steer for the village at its head, and when Kaba sima shuts in behind the southern point of the bay anchor in 10 fathoms or less, about 2 cables off shore. *Sitsiwura*, a small bay 2 miles farther N.E., has anchorage in from 9 to 10 fathoms, at 2 cables off shore. There is an islet or rock on the reef which extends 2 cables off the South point of the bay; it lies directly under and S.E. of the highest peak of Kawara yama.

Between Sitsiwura and Mogi Bays there is an islet and several large reefs, which extend 2 or 3 cables from the shore.

Misaki Bay, North of Kaba sima and East of the low jutting point and sandy beach where stands the large village of Misaki, affords anchorage in from 7 to 11 fathoms.

Kabasima Bay, between Nomo saki and Kaba sima, affords anchorage at its north-western part open only between S.E. and S.W. Here reefs which dry project $1\frac{1}{2}$ cable from the shore; at 2 cables from the shore there are 8 fathoms, and at 4 cables distance 11 fathoms about E.N.E. of the Nomo Rock. The eastern part of the bay, where a long sandy beach is seen, should be avoided, there being a sunken rock, *Bay Rock*, on which are 6 ft water with 4 and 6 fathoms about it. Its position is E. $\frac{1}{4}$ N. $1\frac{1}{2}$ mile from the Nomo Rock, and N. $\frac{3}{4}$ W. of the West point of Kaba sima, at half a mile from the shores of island and main. Off the South side of Kaba sima are some rocks.

The West Coast of Nagasaki Peninsula.—From 10 miles outside the islands fronting the West coast of Nagasaki the soundings decrease gradually over a bottom chiefly sand, until 30 fathoms is obtained, which will be at a general distance of a mile from all the outer islands; the only exception is an 18 fathoms spit which extends one mile N.W. of the Sotonohirase Rock, and the extremity of which is $1\frac{1}{2}$ mile W.S.W. of the N.W. point of Iwo sima. Within this island, the bottom in the fairway is of mud, gravel, or rock.

IWO SIMA and LIGHTHOUSE.—Iwo Sima lies in a N.W. and S.E. direction, and is of undulating outline, the eastern summit being 400 feet in height. *Signal Head* forms its N.W. point, and on this is established a signal station (for telegraphing the arrival of vessels), and the lighthouse, an iron tower painted white, 38 feet high, from which is shown a *fixed bright light*, elevated 205 feet above the sea. The light is obscured to the South and eastward between S.W. by S. and E. $\frac{3}{4}$ S. *Signal Head* is a good guide for entering the harbour of Nagasaki. It is bold and may be rounded at 3 cables distance in 25 fathoms.

Oki Sima, of much the same height as Iwo, is more wooded, especially its southern summit. There is access to the harbour by the channel East of Oki, between it and Koyaki. Iwo and Oki appear as one long island, although separated by a narrow boat passage.

Hirase Rock, which covers at high water only, is marked by a beacon, painted *red* and 10 ft. high. It lies 4 cables from the eastern shore of Iwo sima, and E. by S. $\frac{1}{4}$ S. 11 cables from *Signal Head*, and although not directly in the fairway, is in the route of vessels beating in and out. There do not appear to be any other dangers near it. If covered, the bluff of Papenburg Island, bearing E. $\frac{1}{2}$ S., leads 3 cables North of it.

Sotonohirase Rock, also covering at high water, is 9 cables off the S.W. shore of Iwo sima, and S. by W. $\frac{1}{4}$ W. $1\frac{1}{4}$ miles from *Signal Head*. *The Kutsnose*, 10 ft. high, lies inshore of the Sotonohirase, at $1\frac{1}{2}$ cable from Iwo

simo. *The Kurose* is a large straggling reef off the South end of Oki, from which it is distant 4 cables.

Taka Sima, at 3 miles S. by W. of Signal Head, has a precipitous ridge about 900 ft. high on its eastern side, and a smaller ridge over the cliffs on its western or sea-face. Reefs extend $1\frac{1}{2}$ cable of its North and West points. Three small islands, about 120 ft. high, Tobi sima to the North, and Futako sima (two islands) on the South, lie in line, North and South of its East face. The latter two are connected and fringed by reefs.

There are *coal mines*, the first in Japan worked on European principles, on the East side of Taka sima, from which coal of a very fair quality is mined. The only anchorage is on the West side of the island in from 2 to 7 fathoms on a bank of coal and sand, which at 3 cables from the shore deepens suddenly to 15 and 20 fathoms. Small vessels might anchor there in fine weather and smooth water, but the anchorage is neither of sufficient extent or protection to be in any way recommended to H.M.'s ships requiring coal.

Hi sima and *Nagano sima*, $1\frac{1}{2}$ and 2 miles S. by W. and S.S.W. respectively from the summit of Taka sima, are smooth-topped islands about 120 feet in height, with rocky shores and with reefs extending more than a cable off their southern points. Nagama sima is 4 cables S.W. of Hi sama, there being deep water, about 14 or 16 fathoms, in the passage between them.

Mituse Rocks, the outermost dangers in the approach to Nagasaki from the South, lie $3\frac{1}{4}$ miles S.W. of Taka sima, and N.W. $\frac{1}{2}$ W. $2\frac{1}{2}$ miles from the summit of Nomo saki. They spread irregularly over an extent of half a mile, the interior rocks of the group covering with the tide. On the northernmost rocks are two pointed islets, 60 ft. in height, with outlying patches on the East and West; the south-eastern of the group is a bare rock about 6 feet above high water. At one cable westward or outside the rocks there are 23 fathoms and no outlying dangers are known, but it would not be prudent to pass between the rocks although the water appeared deep.

NOMO SAKI is the south-western extremity of the peninsula of Nagasaki, and at a distance has the appearance of an island. At 6 cables North of the cape is *Nomo yama Point*, which rises steeply to a wooded summit, beneath which stands a look-out house; the hill slopes towards the cape in two gently descending ridges of small hills: the coast between is broken and rocky, and skirted with dangerous reefs which dry out in patches to a quarter of a mile, but it may be passed at the distance of 4 cables in from 12 to 17 fathoms, gravel and rock. At 2 cables off the cape is an inaccessible islet called *Nomo Rock*, which is surrounded by small low detached rocks, most of which cover.

Nomo ura, the entrance of which is one mile N.E. of Nomo yana Point, is small and perfectly sheltered, 6 cables in length and from 1 to 2 in breadth, with 9 to 10 feet at high water in the deepest part of its narrow entrance. Take care to keep rather along the southern shore in entering.

The coast of the peninsula northward from Nomo yama Point is bold with a few outlying rocks, and should not be approached within half a mile, the ground off it being uneven and rocky.

Suzume, 6 miles north-eastward of No saki, is a bare rock, about 50 feet high, and the north-western of a group of islets. *No sima*, the southern, and all the other islets, are wooded and low, and surrounded by large reefs. There is a 5 fathoms channel between No sima and the coast, but the islet must be closed in passing, as a large reef projects from the shore. *Suzume* may be rounded at 3 cables on its West side in 15 fathoms, rock or gravel, but at that distance N.N.E. there are only 5 fathoms.

Koyaki is the largest island off Nagasaki, and is situated directly S.W. of the entrance, which may be gained by the channels both East and West of it. This island is not high, but very hilly, its two chief elevations being 362 and 403 ft. Numerous reefs and islets border its broken outline. Of these *Joka sima* and *Hodagase*, an islet and a rock, lie about W.S.W. at 5 and 8 cables respectively off Mumenoki, the South point of Koyaki, with from 15 to 18 fathoms inside them. *Hodagase* may be passed at 4 cables on its West side in 26 fathoms. The large bay on the northern side of Koyaki has from 17 to 20 fathoms water, and, besides being too deep for convenient anchorage, is open to the N.W. swell. On the eastern side of Koyaki, there is a mass of reefs in the South Channel.

Kageno.—This island appears part of Koyaki, as it is only separated from its North point by a narrow boat passage. The *Naginato* or *Hungry Rock*, which covers at high water, lies a cable East of its N.E. point, off which is a small islet.

Kamino sima, at 6 cables North of Kageno, is the largest island on the northern side of the fairway to Nagasaki. Its North hill is elevated 330 ft., and on its central hill, which is lower, is a *Signal Staff*. On the East side there is a small boat camber; on the S.W. the small flat island of *Siro sima*, on which there is a battery, is connected with a work on Kamino sima by a causeway of masonry. There are other batteries on Kamino sima, all of which command the passage.

North-westward of *Siro sima* are the two small islands *Aino sima* and *Mats sima*. *Aino sima*, at $1\frac{1}{2}$ cables distance, is a flat table island on a reef, with a conspicuous rock (the observing place of Belcher, in 1843, from which several meridian distances were measured to Lu-chu, Quelpart, &c.) close off its South point; *Mats sima*, at 5 cables, is a small hill 90 ft. high. There is deep water in the passage between *Siro sima* and *Aino sima*.

Barracouta Rock.—Off *Kabuto saki*, the S.E. point of Kamino sima, on which there is a battery, are some small islets. One cable from these, S.W. of the Tree Rock, and W. by N. of the South bluff of Papenburg, is the Barracouta, a sunken rock, which is the only hidden danger in the entrance,

and may be cleared to the southward by keeping the summit of the coast range (800 ft.) over Megami Point open of Papenburg, bearing East.

Papenburg, or *Takaboko*, 2 cables S.E. of Kamino sima, is the small precipitous island covered with dark foliage, which so well marks the entrance to the harbour. It may be passed at half a cable in 18 fathoms. To the N.E. of it, and distant one-third of a mile, is a small flat-wooded island, *Nezumi sima*, lying off the small bay of Kibatsu, East of the large village of Kosedo.

Swinger Rock, with 4 ft. water over it, lies nearly midway between Takaboko (Papenberg Island) and Ogami Point. From it, Signal Head, the N.W. point of Iwo-sima, is in line with Kabuto-saki fort. Centre of Nizumi-sima bears N.N.W. $\frac{1}{2}$ W. ; centre of Takaboko (Papenberg Island), W. by S. $\frac{1}{2}$ S. ; Kosaki Temple, Ogami Point, E. by N. $\frac{1}{3}$ N.

This rock may be dangerous for steamships leaving the harbour when passing another vessel in its vicinity, or for sailing vessels working in, care must be taken therefore to keep Signal Head well open of Kabuto-saki fort when near the locality.

The **HARBOUR of NAGASAKI**, an arm or inlet running in a north-easterly direction, is large and commodious, thoroughly sheltered from all winds, and available for ships of all classes. From its entrance, which is a quarter of a mile wide between Ogame Point on the West and Megami Point on the East, it runs N.E. to the city a distance of 2 miles. The depths decrease gradually from 16 fathoms at entrance to 3 fathoms off the city. A *sunken rock* lies about 70 yards South of the East extreme of Ogame Point. A temple stands on the South extreme of the point.

Megami Point is at the foot of a steep ridge, on which are three batteries, one above the other. Within Megami Point $1\frac{1}{2}$ cables (a small islet lying between them) is another point, on the extreme of which, in a battery, is a remarkable large tree. *The Hishiwo Bank*, which fronts the shore from De sima to the foreign settlement, is a good and convenient place for grounding.

The harbour has three approaches. The principal one or fairway is directly from the N.W., the entrance of which, 4 miles outside the harbour, is between Fukuda saki and Iwo sima light. Vessels entering Nagasaki Harbour should invariably use this channel. The second approach is by the Oki Channel, between Oki sima and Koyaki, but it is only 3 cables in breadth. Neither this channel nor its approaches have been yet thoroughly examined. *The Kurose*, a rocky islet with reefs projecting from it lies in the fairway to the entrance to this channel from the southward. The third approach is by the South channel, between Koyaki and the main, and can only be used by steam-vessels. The whole of this channel is so encumbered with rocky patches that instructions for its navigation would not be suffi-

cient; a local pilot would be necessary, and it should never be taken without one.

NAGASAKI, a treaty port, at present second only in importance to Yokohama, and the only place of trade open to foreigners between 1623 and 1857, covers a broad valley on the eastern side of the harbour, surrounded by lofty hills. Its population in 1858 amounted to nearly 70,000. In December, 1876, there were 134 British residents, 14 German, 31 Americans, 14 Danish, and 450 Chinese. Altogether, including a few of other nationalities, numbering about 700 foreign residents. The exports consist of tea, silk, coal, vegetable wax, gall nuts, copper, gold; also various articles for the Chinese market.

De sima, the historic site of the Dutch factory, projects into the harbour on the S.W. side of the city, with which it is only connected by a stone bridge. At the broad steps at its West end is the best place for landing at the city. The Foreign Settlement is on the flat South of *De sima*, having a water frontage of 730 yards; it also stretches up the valley on the Owara Creek on the South. The British Consulate is upon the bluff South of this creek, where there is a good landing place. The American, French, and Portuguese consulates are on the hills at the back of the settlement.

Provisions are plentiful, cheap, and easily obtained, as also is wood and water; the latter is brought off in boats to the shipping. There is a Japanese government steam factory at Akunora, on the West side of the harbour, and also a patent slip. The *dry dock*, which was reported as completed in 1877, is 460 ft. in length, 89 ft. in breadth, and 28 ft. deep.

Coal is worked at several mines in the neighbourhood of Nagasaki, and, although reported as of inferior quality, is used by vessels of the French, United States, Russian and German navies, also by some of the fast tea ships trading to London. The chief mine is at *Taka sima*, before described; there is also a mine on *Hi sima*, which lies 3 miles S.W. from *Taka sima*. At *Muke*, also, in the N.E. corner of Simabara Gulf, coal is worked.

The best *anchorage* for men of war is just above the British consulate bluff, large ships anchoring in from 6 to 7 fathoms, rather over towards Minage Point, at this the broadest part of the deep water of the harbour. Merchant vessels usually anchor off the foreign settlement in from 4 to 6 fathoms, or even above *De sima* in 3 fathoms. In the hot weather of July and August great relief may be experienced from the closeness of the atmosphere, and it will be beneficial to the health of the crews to spring the ship's broadside to the sea breeze, which, in fine weather, is almost constant from the S.W., and generally very fresh.

Pilots, either Japanese or European, can always be had at a charge of 30 dollars, obtained by requisition through the consul. It is said that they are well acquainted with their business, and that it is their custom to take entire

charge of the navigation of the ship; but great caution should be used in this respect, as some of them have only knowledge of particular localities.

Tides.—It is high water, full and change, at Nagasaki, at 7^h 15^m. Springs rise 9 ft., and neaps about 7½ ft., but they are variable. The current in the harbour is always sluggish. A strong southerly wind is said to raise the level at high water at springs from 10 to 12 ft., or 2 ft. above the ordinary level.

Directions.—When making Nagasaki from S.W. or West, steer to round Signal Head, the North end of Iwo sima, at a quarter of a mile, taking care not to bring the light to bear northward of N.E. by N. (on which bearing it is obscured) on approaching it. By keeping the light in sight, or during the day, keeping the North point of Iwo sima bearing eastward of N.E. by N., will clear the shoal water off the dangerous Sotonohirase Rock. After rounding the head, steer E. ½ S. for the Papenburg Bluff, passing it as closely as convenient, but taking care to avoid the Barracouta Rock; then E.N.E. for the entrance. At night do not bring the light to bear northward of W. ¾ N.

Passing in mid-channel between Ogame and Megami Points, a N.E. course direct for the Dutch flag on De sima will then lead up in the best water, and when the factory of Akunora, on the West shore, opens of Minage Point, N. by W., a large vessel should haul up N.N.E., and anchor in 6 fathoms between it and the British consulate or foreign settlement.

Should a vessel, from calms or adverse winds, be unable to enter, every endeavour should be made to get inside Papenburg, if it be the intention to anchor, for outside this island the water is inconveniently deep, and it would be preferable to stand off and on till daylight, taking care not to decrease the soundings below 30 fathoms.

Anchorage can, however, be found in 20 to 26 fathoms over a bottom of thick green oaze with fine sand, good holding ground, or possibly rock or sand and shells if near the Hirase Rock. There is also anchorage East of Papenburg and Kageno, in from 13 to 17 fathoms, or in 11 fathoms on a bank S.W. of Megami Point; the bottom here is mud, and the shelter good except from West. Towards the eastern shore the ground is irregular, and probably rocky.

Miye no Ura, with good anchorage at its head, is about 5 miles N. by E. from Iwo sima light. It runs N.E. and S.W., is 2 miles deep, and the navigator should be cautious, as it is much encumbered with dangers.

The Coast from *Miye no ura* takes a N.N.W. direction to the East Rock (*Kashe*), with bold points and sandy beaches, and moderately elevated coast range of hills, nearly all the points having off-lying rocks; an isolated rock, with deep water around, lies off the centre of a bay, 6 cables from the shore, and N.W. ½ N. 1½ mile from the outer low flat rock, off the northern point of *Miye no ura*. Vessels creeping up in shore must be careful of this rock;

and nearly 2 miles S.E. $\frac{1}{2}$ E. from Kashe (East Rock) are some rocks and islets, 3 cables off the shore.

Mats' sima, a large and well-cultivated island, with coal mines, is 2 miles long and $1\frac{1}{4}$ mile broad. The whole of the channel between Mats' sima and the main is much encumbered with reefs and obstacles.

DIRECTIONS from NAGASAKI to SIMONOSEKI.—The *coast route* is taken by vessels who know the land, and in thick weather prefer to sight it, and feel their way along from point to point; they steer for the square rock Kashe (East Rock), and pass between it and the arch rock Tengu, or rather Hako sima, which is to the eastward of the arch rock, making for the South coast of Mats' sima, the western coast of the last island being safe at 2 cables distance off shore, taking care of the rock above water off its N.W. shore.

The western cape of Mikoto sima can be approached to 3 cables, and from here, in clear weather, a course may be shaped to the westward of Kata sima, up to Taka sima, passing eastward of Kuro sima, and thence along but outside of the islands which lie off the coast of Kiusiu, and forms the East side of the Hirado Straits.

A more direct course from Nagasaki Harbour is to steer straight for Ko tate (Bonnet Rock), but allowance must be made for the current which in the vicinity of Oö tate, and to the southward sets N.W. and S.E., so that a vessel in thick weather finds herself either to the westward and northward of her reckoning, or to the eastward, and towards the main; but, having sighted the cone-shaped, easily-distinguished Ko tate (Bonnet Rock), she can steer for the bold bluff of Kuro sima, bearing in mind that great danger the *Fukushe*, which lies North $4\frac{1}{2}$ miles from Ko tate. This rock was marked by a beacon, 38 ft. high, in 1876, but it had been partially destroyed in 1877.

The southern coast of Kuro sima is steep close-to, and the perpendicular cliffs at its western end loom up in thick weather. The mariner, however, must remember that off its western end, and separated by a passage of $2\frac{1}{2}$ cables, is a low flat rock, above water, with deep water close to it. After sighting the bluffs, vessels should steer for the South coast of Hirado, which can be boldly approached to 1 or 2 cables, and by keeping it in sight at 2 cables distance, the *Costa Rica* and *Robinett Rocks* will be avoided. Vessels can run along the East coast of Hirado to the North as far as Kawatchi Bay, when it is necessary to steer for the opposite shore, to avoid the *Asama*, before entering the narrow part of Hirado Straits, at the red cliff point, from which the vessel must be guided by the sailing directions (pp. 1242-3).

From Hirado or Spex Strait to the North there are no difficulties in clear weather. A straight course for Mats' sima, passing eastward of Madara sima, and giving the rocks off Hato saki a good berth. The conspicuous

cone islet of Yebosi, or its *fixed bright light* (elevated 182 ft.) at night, is a good mark, which can be steered for, and a course shaped to go outside of Wilson Island, taking care to look out for the Kuri no kami (Swain Reef).

It was formerly recommended to vessels to pass eastward of Oogawa sima (the eastern of three islands lying North of Hato saki), between that island and Hirase Rocks, but a dangerous sunken rock having been discovered in that passage in 1876, the best track from Hirado Strait, steering from it on a N.E. $\frac{1}{4}$ E. course, is to pass between Madara and Kagara, and rounding the N.W. point of the latter at a mile; from this a N.E. by E. $\frac{1}{2}$ E. course will lead up close to the West point of Wilson Island, passing half a mile to the westward of Yebosi, between it and the rock off the Idzumi Islets.

Should the passage have been made by the Korea Strait, after rounding the North point of Iki, an E. $\frac{3}{4}$ N. course may be steered for the Siro simas, at the entrance of the Inland Sea, passing well northward of Oro no sima with a clear run of 55 miles. The tidal streams here are not very well known.

Another route from Nagasaki is to steer for Oö tate, and take the clear channel between it and Yenoï sima, passing up the West coasts of Hirado and Ikutski, and enter the Genkai nada by the channel South of Iki sima. In this route the rock South of the Idzumi Islets must be remembered.

If proceeding outside Hirado, after leaving Nagasaki steer N.W., unless wishing to pass outside Hiki sima. A run of 16 miles will place a ship abreast that island, and a further run of 13 miles on the same course will lead up mid-channel between Oö tate and Yenoï sima, from which position a N.N.W. course for 11 miles will reach the islets off the S.W. point of Hirado. Pass a mile outside these islets, and also of the Aska sima, 3 miles North of them, unless intending to take the Obree Channel, in which case the ship may pass between Ko Azika sima and Kasira, and steer N.E. by N. directly for it.

Coasting Hirado and Ikutski on a N.N.E. course, a run of $13\frac{1}{2}$ miles from Oö Azika sima will place a vessel off the North point of Ikutski; then steer N.E. by E. for 7 miles until past *Use*, the small rocky patch off the north-western face of Atsusi no Osima, which, if not seen, may be cleared by keeping the summit of Madara in line with the summit of Mats' sima E. $\frac{1}{2}$ N. Giving Use a berth of $1\frac{1}{2}$ mile, a course E. by N. $\frac{3}{4}$ N. leads up in mid-channel between the rock lying to the southward of Kami Idzumi and Yebosi, and when the latter island bears S.E., alter course N.E. by E. $\frac{1}{4}$ E. to clear Kuri no kami, and pass northward of Wilson Island, being careful lest the eastern tidal stream into the Strait of Simonoseki, which sets rather strongly through the channels East of Wilson Island, should saddle the vessel on to that reef.

Entering Hirado Channel or Spez Strait from the North, vessels of light draught use either passage, but the western, from being full of rocks and

uneven bottom, with the Vineta Rock to the S.W. 1 cable, and further, subject to much "Chow-chow" water and tidal whirls, is not recommended; the eastern passage, although much narrower, is by far the safest.

The North end of Kuro-ko sima kept midway between the rock and the wooded head of Ushi-ga no kubi (a point a little more than 2 cables South of Hirose) leads clear through the passage, passing the rock at little more than half a cable; three-quarters of a cable outside the wooded point.

Vessels of heavy draught when passing through this passage at the springs, when the strength of the tide is great, must remember the shoal patch of 15 feet, which extends $1\frac{1}{2}$ cable to the north-eastward of Ushi-ga no ubi Point. From the wooded point the Kiusiu shore should be kept at a cable's distance while rounding to Red Cliff Point.

Due North, nearly 2 cables from Red Cliff Point is the Oötaske Rock, 5 ft. above water, and E. by N. $\frac{2}{3}$ N. from the latter, three-quarters of a cable, is a sunken rock, having 15 ft. at low water springs; the precipitous fall from the end of a flat-topped ridge on the Kiusiu shore kept open of the Red Cliff Point will clear the sunken rock.

The Kiusiu shore must be kept on board until abreast Aosa saki, which is $1\frac{1}{4}$ mile S.S.W. from Red Cliff Point, where a course for the extreme South end of Hirado (S.W. by S.) can be shaped, which clears the Asama Bank.

The East coast of Hirado can be kept at from 2 to 3 cables distance.

It has hitherto been the practice to pass down the western shore of Kiusiu to the eastward of Kuro sima, &c., but from the numerous islands, rocks, and outlying dangers off that shore, and from the absence of prominent marks for avoiding the James Rock, the above route is recommended; there being no danger along the Hirado East shore.

As soon as the Costa Rica Rock has been passed (which may be known when the Kuro sima bluff bears S.S.E., with the North Kareki open of the South Kareki), a course can be shaped to pass between Mikoto and Ko tate (Bonnet); this course passes 2 miles to the eastward of the Fukushe, taking care to keep the peak of Sisiki on with or open to the eastward of Ho-age (Sail Rock) until Kata bears East.

Vessels taking the outer passage from Simonoseki, and passing between the Goto Islands and Hirado, can round the cone-shaped islet of Take sima off the South end of Hirado, quite close, and to avoid the Fukushe, must either take the direct route between the islands of Otate and Yenoi, or steer for the Ho-age (Sail Rock), in order to run with it and Sisiki Peak in line till Kata bears East.

Anchorage.—Vessels passing through this strait will often find it convenient to anchor. The places recommended are Kawatchi, on the East side of Hirado, and Taske on the North side, or at Kamada on the Kiusiu shore, immediately North of the entrance to the strait from the northward.

Vessels from the westward, bound for the Inland Sea, and finding bad weather

coming on from the North or West, will find Go no ura convenient and safe. From the westward, steer for the South point of Hira sima (the outer or southern island, which has a smooth top, with black cliffy and rocky shores), giving it a berth of from 2 to 3 cables, then steering E. by N. for the next low rocky islet, giving it a berth of half a mile; haul up N. by E. $\frac{1}{2}$ E., anchoring near the head of the bay in 12 fathoms, remembering the low rock on the port hand, just above water, when passing up the bay. From the eastward vessels must remember, before making the South coast of Iki sima, the 8-foot rock which lies to the southward of the Idzumi Islets, when they can steer for Ka saki (the southern cape), from which the coast should not be approached nearer than half a mile, to avoid the rock above water, and the ledges farther to the northward.

The WEST COAST of NIPON is but little known, and should therefore be navigated with necessary prudence and caution. The only parts at present surveyed are the islands Sado, Awa sima, and Tabu sima, and the strait between Sado and Niägata, by H.M. ships *Actæon* and *Dove* in 1859. The coast from Tsugar Strait to Cape Noto has been partially explored by the *Bittern* and other of H.M. ships, the Russian gun vessel *Djigit*, and H.M. surveying vessel *Saracen*. The latter vessel has also explored the coast between Simonoseki, the western entrance of the Inland Sea, and Taka yama (Cape Louisa), lat. $34^{\circ} 40' N$.

Tsuno or Kado Sima and Lighthouse.—Tsuno sima is of peculiar formation, appearing from the northward as two very flat quoins. The lighthouse a granite tower 100 ft. high, is placed on the N.W. point of the island. From it is shown a *flashing bright light*, showing a flash every 10 seconds, elevated 142 ft., and visible 18 miles off seaward, between S. $\frac{1}{2}$ E. and N.E. by E., in which latter direction the light is intercepted by Square Rock Point, which is 8 miles distant from the lighthouse.

Igama Bay has its entrance E.N.E. from the lighthouse. It has not been explored, but the best anchorage seems to be in its N.W. corner, just within the North entrance point.

Bank.—About $4\frac{3}{4}$ miles in a N.N.W. $\frac{1}{4}$ W. direction from the Tsuro sima lighthouse is situated the tail of a bank, composed of broken shells, sand, and stone, and having at this part a depth of 16 fathoms. In the winter, during N.W. gales, a heavy sea runs on the bank, and many junks have foundered there.

Mino Sima is in lat. $34^{\circ} 47' N$., long $131^{\circ} 7' E$., W. by N. $\frac{2}{3}$ N. distant 20 miles from the northern coast of the province of Nagato. Approached from the northward, at 9 miles distance, it appears much extended, with an undulating outline, its highest part, elevated 492 ft., being in the centre of its West side. A large square rock lies half a cable off its eastern point, and there is an islet on its N.W. side.

Miku ura, in lat. $35^{\circ} 32' N.$, long. $133^{\circ} 24' E.$, affords an excellent anchorage in 9 fathoms, mud; shelter (except with winds from the East, which are of little consequence) can be obtained. Rocks are said to lie off the lagoon opening on the South side.

The **Oki Group**, consisting of one large and a group of three smaller islands, and a number of islets and rocks, lie N.E. and S.W. of each other, and occupy an extent of 23 miles in that direction. There is an open and apparently safe channel between the large islands and the group of smaller ones. *Oki sima*, the N.E. or largest island, about 10 miles in diameter, was estimated at 3,000 ft. elevation, but no indication of a port, nor even the prospect of a tolerable anchorage was observed along its western shore.

Miyadsu, an excellent harbour, completely landlocked, with good holding ground, situated in about lat. $35^{\circ} 32' N.$, long. $135^{\circ} 15' E.$, is easy of ingress and egress, and free from dangers. The town contains about 12,000 inhabitants. Silk is manufactured in the neighbourhood, and this is a great mart for dried fish. In entering with the southernmost of the Okino Islands, bearing N.E. $\frac{3}{4}$ E., steer S.W. $\frac{3}{4}$ W. between Whale Point and Kata sima; then steer S.W. $\frac{3}{4}$ S. until at the mouth of the harbour, when steer direct for the battery, keeping in mid-channel up to the anchorage. The soundings from the mouth of the harbour will gradually decrease from 11 to 7 and 6 fathoms to abreast of the town, with bottom of sticky mud.

Tsuruga Bay, in about lat. $35^{\circ} 40' N.$, long. $136^{\circ} 1' 20'' E.$, is very easy of ingress and egress, and, so far as is known, free from rocks, excepting those supposed to exist well in on the western shore. The town of Tsuruga, at the head of the bay, contains about 15,000 inhabitants, and exports dried fish and rice. Approaching Tsuruga Bay from the northward, steer so as to be distant 6 miles from the North end of Tamagawa when it is brought in line with Ibo Point; then steer S.E. $\frac{1}{2}$ S. until the triangular white cliff seen to the left of the town is opened, when bring it to bear S. $\frac{1}{2}$ E., and then steer for it until the first prominent point on the left of the bay going in is brought to bear E. by N. $\frac{3}{4}$ N.; then steer S. $\frac{1}{2}$ W. to the anchorage.

Mikuni Bay.—The approach to Mikuni Roads, in about lat. $36^{\circ} 13' N.$, long. $136^{\circ} 8\frac{1}{2}' E.$, is bold to within half a mile from the shore, when the soundings vary from 9 to 6 fathoms. The town of Mikuni is said to contain 10,000 inhabitants, and is situated on the right bank of a river. The anchorage in the outer roads is exposed from S.W. round West to North, but completely sheltered from all other winds. On Cape Sakiura, just northward of Mikuni, a light is sometimes shown.

CAPE ROIVEN or NOTO, in lat. $37^{\circ} 28' N.$, long. $137^{\circ} 22' E.$, is elevated about 700 or 800 ft., the land rising 1,200 to 2,000 ft. to the westward of it. At 12 miles W. by S. from the cape is a remarkable white cliff, that shows well to the westward. A reef, which dries, extends eastward 2 miles from

the cape, with much uneven ground in the vicinity, and it is reported that a 5-fathom patch lies at a distance of 3 miles.

A sunken ledge of rocks, with only 3 ft. water, is said to exist between the Astrolabe Rocks and Waisima, $2\frac{1}{2}$ miles from the latter place.

Aroostook Reef lies nearly N.N.W. $\frac{3}{4}$ W., 10 miles from Cape Roiven. From the reef the northern Astrolabe Rock bears W. $\frac{3}{4}$ S., and Isonosu Hill S.W. $\frac{1}{2}$ W.

Yutsi Sima, in lat. $37^{\circ} 50\frac{1}{2}'$ N., long. $136^{\circ} 55'$ E., is 40 ft. high, about two-thirds of a mile in diameter, level, and cultivated; there are a few stunted trees on it, and a small village on its southern side.

Nana Sima (Astrolabe Rock), in lat. $37^{\circ} 35'$ N., long. $136^{\circ} 54'$ E., is 200 feet high, about a quarter or a third of a mile in diameter, and is the largest and highest of a group of five rocks, which extend nearly $1\frac{1}{2}$ mile in a N.E. and S.W. direction, and vary from 200 to 70 ft. in height.

Nanao Harbour, in lat. $37^{\circ} 2'$ N., long. $136^{\circ} 58'$ E., has two entrances, caused by Noto-jima, an island about 3 miles long. The city of Nanao is situated in the extreme western angle of the bay. There are some iron-works here.*

Toyama Bay.—Cape Roiven is the western point of entrance to this extensive bay, which is broadly open to the North and N.E. The shores of this bay appear populous, and at *Fushiki*, in the centre of the head of the bay, a *fixed bright* light is shown. Good anchorage will be found with this light bearing S.S.W. $\frac{3}{4}$ W., distant three-quarters of a mile.

At 15 miles S.W. $\frac{1}{2}$ W. from Niëgata the low shore terminates at *Kadota yama head*, $4\frac{1}{2}$ miles North of a spur of the fine peaks of *Yafiko yama*, which has the appearance of a blunt cone sloping on the West. A mile to the South the peak of *Kauriko yama* rises to a higher elevation.

PORT NIEGATA.—The city of Niëgata stands on the left bank of, for Japan, a rather large river, with 4 fathoms water within the entrance; but a bar off the entrance seals it to vessels of greater draught than 7 or 8 feet ($7\frac{1}{2}$ feet in 1877). In fresh breezes from seaward the sea breaks across the entrance, and at that time not even a boat could cross the bar without risk. The roadstead off the river's mouth is quite exposed, and the holding ground bad.

Niëgata, one of the ports open by treaty to foreign trade, is the most opulent city on the West coast of Nipon. It is said to be more than four times as large as Hakodate, and the population exceeds that comparison. A small battery near the entrance to the river appeared to be unarmed.

The port of Niëgata still (1877) remains unvisited by foreign ships. There is no good harbour, which is much to be regretted, as it is the outlet of one

* The places on the coast between Nanao and Niëgata are described by J. Troup, Esq., in the Journal of the Royal Geographical Society, vol. xlii., 1872.

of the most fertile districts of the country. Imports are mostly brought overland from Yokohama. There is a temporary light-tower (1877) at the mouth of the river.

Anchorage.—Although Niëgata is opened to European trade, no vessel except a powerful steamer could, during the autumn or winter months, remain at anchor off that port, as before mentioned. Under these circumstances, the most prudent course to adopt would be to anchor under shelter of Sado Island, and have the cargo transported from Niëgata in junks or light-draught steamers.

Soundings reach to a considerable distance off the mainland in the vicinity of Niëgata; vessels, therefore, running between Sado and Nipon at night, or in a fog, should keep the lead quickly hove. Should soundings be obtained and decrease gradually, the mainland is being approached. A run of very deep water will be found on the Sado side of the channel.

The town of *Aosima yama* stands near the embouchure of a river, which also has a clear channel carrying only 7 ft. It is said to be 6 miles N.E. of Niëgata, but is but half that distance according to the Japanese manuscript.

Tides.—For the distance of 4 miles a strong indraught, on the flood tide, is experienced off the entrance of Niëgata, greatly to the inconvenience of sailing vessels seeking an offing. The ebb would, of course, assist them off the land.

Sado Island, lying 25 miles westward of the important trading port of Niëgata, is $33\frac{1}{2}$ miles long, N.N.E. and S.S.W., nearly 17 at its widest part, and is composed of two parallel mountain ranges lying N.W. and S.E. of each other, the neck of land joining them being a plain, on the N.E. and S.W. sides of which are formed two extensive open bays.

The bend in the coast-line on the N.E. side of the island forms an extensive bay called *Minato-mats*, which affords anchorage in from 12 to 16 fathoms, sheltered from E. by S. (round South and West) to North. A conspicuous rock, 60 ft. high, called *Siza*, marks Okawa Point, the South extreme of this bay, in which no known dangers exist. At the head of the bay is the town of *Ibesso* or *Yebisu*.

Another eligible anchorage will be found off Oda village, a quarter of a mile S.S.W. of Matsu saki, a low projecting tongue of shingle, bearing S.S.W. $\frac{1}{2}$ W., distant $10\frac{1}{2}$ miles from Okawa Point. The *Actæon* rode out a heavy gale of wind here in 13 fathoms water.

The South part of the East coast possesses several coves and inlets in which small craft will find excellent shelter, but there is no harbour of importance on it.

Nearly every little valley has its stream of excellent water flowing down to the beach, and when the sea is smooth easily obtainable. Coal is not known.

Awa Sima, the N.E. extreme of which is in lat. $38^{\circ} 29' 36''$ N., long. $139^{\circ} 16' 7''$ E., is a narrow strip of land running N.N.E. and S.S.W., and reaching at its southern extreme an elevation of 680 ft.

The S.E. side of the island is fringed with a narrow bank of soundings, but is clear of rocks. Rocks are found off the West side of the island to the distance of a quarter of a mile, and off the N.W. side to the distance of a mile.

The hand-lead will afford but little warning to vessels approaching the N.W. side of this island.

Tabu Sima (Observatory Rock, off the East extreme of which is in lat. $39^{\circ} 11' 53''$ N., long. $139^{\circ} 34' 17''$ E.), is in shape somewhat of a horse-shoe, with a club at its N.E. end. It is on top nearly a flat, varying from 120 to 150 ft. in height. Its greatest length is $1\frac{1}{2}$ miles N.E. and S.W. Except on the S.E. side, the island is surrounded by detached rocks; they all show, and are in no instance more than three-quarters of a mile off shore.

Bittern Rocks.—This group of three small rocks, two above water and one awash, was discovered by H.M.S. *Bittern*, 8th July, 1855. The southwestern or largest rock, in lat. $40^{\circ} 31'$ N., long. $139^{\circ} 31'$ E., and lying W. by S. about 15 or 17 miles from Cape Yokoiso, is about 18 ft. high, and in size and appearance resembles the hull of a vessel of about 200 tons.

TSUGAR STRAIT, separating Nipon from Yezo Island, is about 40 miles in length in an E.N.E. and W.S.W. direction, and $9\frac{1}{2}$ miles wide at its narrowest part.

Winds.—Strong N.W. winds prevail in this strait during the winter months, accompanied by snow and rain, and the weather is very boisterous. In April the wind hauls to the westward, with heavy squalls from the S.W. In May the wind is from the southward, variable between S.W. and S.E., or more easterly or westerly, and fine weather commences, lasting until the middle of September when it becomes unsettled and summer commences to break up with frequent gales; winter fairly setting in in October.

Dense *fogs* prevailed in May and June; after that period they are comparatively rare.

Current.—Through the middle of Tsugar Strait the current sets constantly to the north-eastward, but its breadth varies considerably according to the state of the wind and weather. The shores of the strait are subject to tidal influence, the flood making to the eastward and the ebb to the westward; the velocity of the whole stream on the flood tide being thus considerably augmented; whilst on the ebb it is diminished.

Awomori Bay, a vast interior basin at the North end of Nipon, opens on the South side of Tsugar Strait. The entrance is 5 miles wide, and with high land on both sides. Off the salient part of the West point, some half-tide rocks lie one cable from the shore.

The town of *Awomori*, in the S. W. part of the bay, stretches along the beach for nearly a mile. It appears to have from 15,000 to 20,000 inhabitants. A great quantity of rice is exported to *Yezo*. This anchorage is open to the North; the soundings decrease gradually, and 9 fathoms will be found at 2 cables from the shore, with good holding ground. A considerable river flows into the sea East of the town, but its entrance is blocked by a bar, the outer edge of which projects $1\frac{3}{4}$ cables.

A *fixed red light* is shown at *Awomori* from a pole placed 100 ft. from high water mark in the front of the town.

Toriwi Saki, the most northern point of *Nipon*, lies 26 miles W. by N. $\frac{1}{2}$ N. from *Siriya Saki*, which with its lighthouse is described on page 1199. *Toriwi saki* is a low tapering point, off which, at the distance of a cable, is *Low Islet* or *Omasaki sima*, 40 ft. high. The ground all around this cape and islet is very foul, except to the N.E., where a vessel may anchor to wait tide in 13 fathoms, with the centre of the islet bearing S.W. by S. distant about a mile. This is a useful anchorage for vessels approaching *Hakodate* from the eastward, particularly during the light south-westerly winds common to the strait during the summer months. There is a tide race, near the full and change of the moon, 3 miles North of *Low Islet*, and heavy overfalls with a N.E. swell. On such occasions care must be taken to avoid this locality. There is no clear channel for large ships between the race and the islet.

Singapore Rock, with 6 ft. on it at low water springs, lies N. by E. $\frac{2}{3}$ E., $2\frac{1}{2}$ miles from the centre of *Low Island*, and is at the extremity of a sunken ledge, with from 6 to 17 fathoms on it, connecting this rock with *Low Island*, excepting in which directions the soundings round it vary from 13 to 21 fathoms. This rock is surrounded to a considerable distance by the most conspicuous of the overfalls existing in the vicinity, all of which should be carefully avoided.

NORTH SHORE.—*Cape Sirakami* (*Nadiejda*), the North point of western entrance to *Tsugar Strait*, is a high bluff similar to *Cape Siwokubi*, but not so safe of approach. The coast, for more than a mile on each side of the cape, is bordered with numerous rocks, generally above water, some of which extend nearly 2 cables from the shore. As it is not known whether the dangers extend under water beyond this distance, it will be prudent to give the cape a good berth in passing.

Cape Tsiuka, at $12\frac{1}{4}$ miles N.E. by E. from *Cape Sirakami*, is a high cliffy point, which may be further known by three rocks extending a quarter of a mile from a point one mile north-eastward of it; the outer rock of the three is of a conical form, and 70 ft. high.

Vessels can anchor in the bight of the bay, between *Capes Tsiuka* and *Sirakami*; but as a southerly wind on the western tide sends in a cross

swell, it would not be prudent to anchor far in. The best position is in from 15 to 20 fathoms, with the southern white cliff bearing West about one mile.

HAKODADI HARBOUR, or more properly Hakodate, on the North side of Tsugar Strait, is situated at the foot of the northern slope of a high peninsula which is connected with the mainland of Yezo by a low sandy isthmus. It is an excellent roadstead 4 miles wide and 5 miles deep, and for accessibility and safety is one of the finest in the world. Its entrance is between Hakodadi Head and Mussell Point, which bear East and West of each other, distant $4\frac{2}{3}$ miles. The harbour is in the south-eastern arm of the bay, and is completely sheltered, with regular soundings and excellent holding ground, the best anchorage being over a depth of 5 fathoms, black mud, in a line with the avenue leading to the governor's house. The town of Hakodate stands on the N.E. slope of the promontory, facing the harbour, and in 1854 contained about 6,000 inhabitants. Hakodate exports herring oil; bear, river and sea otter, and deer skins, antlers, and edible seaweed in large quantities; and large junks of from 200 to 300 tons visit the harbour engaged in this trade. There is telegraphic communication between Hakodate and the other Japanese ports.

A *lightvessel* painted red, with two masts carrying a ball at the foremost head and exhibiting a *fixed bright light*, elevated 36 feet above the sea, is moored in $7\frac{1}{2}$ fathoms (at low water spring tides) off the most northern point of the spit, which runs out from Point Anama, the N.W. point of the town, with the mouth of Kamida Creek bearing E. by S. $\frac{1}{2}$ S., and White Bluff S. by W.

Vessels of large draught entering the harbour should pass North of the lightvessel, as there is a bank of stones directly South of her.

At $2\frac{1}{2}$ cables South from the vessel is a *triangular floating beacon* moored in $5\frac{1}{2}$ fathoms. The passage between the lightvessel and the beacon may be taken by vessels drawing less than 18 ft. water.

South of the beacon the bottom is composed of large stones, and is very irregular. The banks on the East side of this bay must be avoided, that extend half a mile from the shore. A vessel can moor at half a mile from the shore in $5\frac{1}{2}$ fathoms mud, good holding ground. In less than that the bottom is gravel, and anchors hold badly.

Water can be obtained, likewise *coal* and wood for steaming purposes. There is a brass and iron foundry on a limited scale. Vessels, even when seriously damaged, can undergo repairs in the harbour.

Pilots.—Vessels entering the bay are boarded by pilots, who charge five Mexican dollars, without any distinction as to the size of the ship. There are no special harbour regulations.

Tides.—It is high water, full and change, in this harbour, at 5^h., and the extreme rise and fall of tide is 3 feet.

Directions.—Entering Hakodate Harbour, after rounding Hakodate Head, and giving it a berth of a mile to avoid the calms under the high land, steer for the sharp peak of Komaga-daki, bearing about North, until the eastern peak of the Saddle Mountain, bearing about N.E. by N., opens to the westward of the round knob on the side of the mountain, then haul up to the northward and eastward, keeping them well open until the centre of the sand hills on the isthmus bears S.E. by E. $\frac{3}{4}$ E. (these may be recognised by dark knolls upon them). This will clear the spit which runs in a N.N.W. direction two-thirds of a mile from Anama saki, the north-western point of the town. Round the lightvessel, passing northward of her, and anchor as convenient in from 6 to 8 fathoms, taking care to keep the lightvessel bearing westward of N.W. to avoid the shoal bank off the town. Should the lightvessel be removed, then bring the sand hills a point on the port bow, and stand in until the above point of the town bears S.W. $\frac{1}{2}$ W., when the vessel will be in the best berth, in $5\frac{1}{2}$ or 6 fathoms water. The upper part of the harbour is generally crowded with small vessels.

At night bring the light to bear N.E. $\frac{3}{4}$ N., and steer for it on that bearing, taking care not to bring it to bear North of that bearing. Round it as before directed, and anchor as convenient. Should the light be removed steer a northerly course on entering Hakadodi Bay to a depth of 7 fathoms, and keeping in that depth on an easterly and south-easterly course the spit will be safely rounded.

Should the wind fall before reaching the harbour, there is good anchorage in the bay, in from 25 to 10 fathoms water.

Cape Siwokubi bears E. by S. 12 miles from Hakodadi Head, and N. by E. $\frac{3}{4}$ E. $9\frac{1}{2}$ miles from Low Islet on the Nipon shore; this is the narrowest part the Strait of Tsugar. This cape is steep-to, and the N.E. current frequently runs with greater strength close to the rocks than out in the stream. The summit of the bluff immediately above the cape is 1,022 ft. high.

Cape Yesan, the North point of eastern entrance to Tsugar Strait, is the East extreme of a bold promontory, with several remarkable dome-shaped mountains in the rear. The cape itself is a steep cliff about 600 feet high; the *volcano* immediately above it is 1,935 ft. high, and frequently capped with a light cloud of steam, and a jet of steam is constantly seen issuing from a hollow on the West side of the hill, but it is not otherwise active.

At $2\frac{1}{2}$ miles E. $\frac{2}{3}$ S. from Cape Siwokubi is *Conical Islet*, 200 ft. high, lying close to the coast.

DIRECTIONS.—Sailing vessels approaching Tsugar Strait from the westward during foggy weather should guard against being carried by the current to the northward past the entrance. Should the weather be clear when nearing Cape Yokoiso, it may be as well to sight it; but if doubtful, shape a course (allowing for the probable current) direct for Oho saki. Should a fog come on suddenly when nearing this cape, recollect that the coast is clear and

sandy, and the soundings are regular to the southward, but rocky with irregular soundings to the northward of it. The cape is steep-to, and standing out prominently from the coast line, forms a good landmark.

No particular directions are required in passing through the strait from the westward, the only dangers being those off Toriwi saki above described, and the Rattler Rock off Siriya saki, and the north-easterly current will always be found strongest in the middle of the stream. After passing Tatusipi saki, if the weather is thick, and the vessel bound to Hakodate, endeavour to make Cape Tsiuka, and proceed from thence to Mussell Point; or giving Cape Tsiuka a berth, feel the way by the lead into the bay, between it and Cape Saraki, and anchor till the weather clears.

Approaching the strait from the eastward, steer for Siriya saki, and endeavour to make it on a N.W. bearing. Pass the cape at not less than 2 miles distance, then haul in to avoid the current and to anchor should it fall calm. In this case, by keeping this shore close aboard, the vessel may probably be drifted up to Low Islet, off Toriwi saki, by the western stream, when the N.E. current is running like a mill stream in mid-channel.

At the anchorage off Low Islet the vessel must wait a favourable opportunity for crossing the strait. During the summer months the winds are generally light from the S.W. for a considerable period; the wind, however, generally freshens a little when the western stream makes, and this is the right time to weigh. Pass about half a mile from Low Islet, between it and the Singapore Rock, and in crossing the current take care not to be set to leeward of Hakodate. If proceeding straight to Hakodate from the eastward, the better course is to cross the strait, and passing about 5 miles off Siriya saki make for Cape Yesan, so as to take advantage of the cold westerly set along the South shore of Yezo.

Proceeding from Hakodate to the westward against S.W. winds, keep well inside Cape Tsiuka, and if unable to round it, anchor with the stream or kedge about 2 miles to the N.E., weighing again when the next western tide makes. Should the wind be very light, a vessel may not clear the strait in one tide; in this case it will be better to wait a tide to the eastward of Cape Sirakami, and take the whole of the following tide to clear the strait, than run any risk of being swept into the strait again by the current. Vessels passing through the strait, particularly to the westward, should have a good kedge and 150 fathoms of hawser ready for immediate use, and must keep the land close on board.

Tides.—The tide in the stream runs about 12 hours each way near the full and change of the moon, and there are two regular tides by the shore in 24 hours. At full and change the flood or eastern stream makes at Tatusipi saki at 6^h 30^m a.m., at 7^h 0^m at Cape Tsiuka, and at 7^h 30^m at Toriwi saki. The western stream begins about 12 hours later. The turn of the stream takes place 1½ hours later every day. With heavy S.W. gales the

north-easterly current swells and fills the strait, attaining a velocity of from 5 to 6 knots an hour, and entirely overcomes the ebb tide.

YEZO ISLAND.—The coast line of Yezo is about 1,000 miles in extent, and its eastern shore appears low from seaward, resembling table-land; its appearance is, however, most deceptive, as the country is a repetition of abrupt hills of a uniform height, interspersed with deep valleys, rivers, swamps, and large lagoons.

The western coast is bold, and ranges of lofty mountains, many of the summits of which are extinct volcanoes, rise in every direction. The highest of these, *Shubets*, a cone-shaped mountain 30 miles inland, is an active volcano, and from its size and grandeur may well be considered by the Japanese as the *Fusi yama* of Yezo.

The island is almost entirely covered with wood, the ground being in many places strewn with the trunks of trees in all stages of decay, and covered with moss, lichen, and rank vegetation; and the coarse bamboo grass is found in some places growing to a height of 15 ft.

There are numerous rivers and streams, the largest of which, the *Iskarri*, is on the West coast, and three or four large lakes are said to exist in the interior. *Coal* is found in several places, but is principally procured from the village of Kamami, near Iwani, on the West coast. Sulphur abounds, and sulphur springs are numerous.

Yezo is a conquest and colony of Japan, and small settlements of emigrants from the South, and of natives are found scattered along the shores. The Ainos or aborigines of Yezo are a race of stunted growth, and are grossly ignorant, wretchedly poor, and filthy both in person and habits; unlike the Japanese, they allow their hair and beards to grow to a great length. They appear to be of a different race to the Japanese.

Little or no agriculture is carried on, both Japanese and Ainos principally subsisting on the produce of the ocean. Salmon and herring fishing on a large scale is their principal occupation, and large quantities of seaweed are collected, dried in the sun, and sent South, finding its way into all parts of Japan and China.

“Want of harbours, or even anchorages, is the great drawback to Yezo. The extent of coast line is about 1000 miles, and along the whole of that distance there are only Hakodadi and Endermo on the S.W., and Akishi on the S.E., that can be called harbours. Hamanaka is an anchorage, Nemoro is but an anchorage, and from Nemoro to Otarunai, a distance of 420 miles, there is nothing in the shape of a harbour. A vessel may anchor at one or two places, provided the wind is off shore; under such circumstances little could be done in the way of exportation should the island become of any importance.

Otarunai is at all times safe, and might be made an excellent harbour.

There is no place between Otarunai and Hakodadi which can be used as an anchorage, except Sutsini and Rogers Island, and there only under favourable circumstances. Considering Otarunai as a harbour, there are then four along the 1000 miles of coast line, namely, Hakodadi, Endermo (in Volcano Bay), Akishi, and Otarunai; and three anchorages possessing good shelter—these are Hamanaka, Nemoro, and Sutsini.

None of the places I visited in the East had ever seen European vessels even pass the coast, except some years ago, when a vessel went once or twice to Nisibets, and a steamer passed into the Straits of Yezo, and proceeded to Nemoro; the *Sylvia* is the first man-of-war, and almost the first ship, that has been round Yezo."—(Journal of the Royal Geographical Society, vol. xlii., 1872, Notes on the East, N.E., West Coasts of Yezo.—Commander H. C. St. John, R.N.

In the same volume will be found a long and interesting description of a journey made nearly around the coast of the island by Captain T. Blakiston, F.R.G.S.

With this we shall close the description of Japan. A description of the coasts to the northward will be found in the North Pacific Directory.

A P P E N D I X.

NAMES, MONEY, WEIGHTS, MEASURES.

Geographic Terms.

THERE is not a more vexed question than the proper mode of representing the sounds of an Oriental language by our European alphabet. Though every language has much in common, there are still those great and important differences in the value of different letters or syllables, that each language, or even dialect, would require a separate alphabetic system, and a great variety of independent letters, or combinations of letters, to represent the specific peculiarities of each. If it be difficult, or impossible, to represent the various local pronunciations of our own tongue, the different way in which many words composed of the same letters would be uttered by a native of Devonshire, Northumberland, or Lanarkshire, how difficult or impossible it will be to carry such a system into a tongue of a totally different construction.

But there would be a limit to some of this confusion, if it were agreed as to what should be a common value for the European alphabet. Formerly every one represented the names of places, difficult to describe the sound of, in that mode which seemed best to him, without heeding what value those of any other nation would give to his orthography. The confusion thus arising is nowhere more evident than in the countries described in this work, where no written language similar to our own exists.

As has been before remarked, certain values should be given to every letter, and this system is now generally adopted by modern writers; and, as far as practicable, has been followed in this work. Briefly, the system is this, that all the consonants are to be pronounced as in English, French, &c., and the vowels as in Italian, *i* as *ee*, and *u* as *oo*, or *ou* in French. In the vocabularies of the names which are given for each principal language hereafter this system is followed.

MALAY, SINGAPORE, ETC.

Malay Vocabulary.

MALAY.	ENGLISH.	MALAY.	ENGLISH.
Amas - - -	Gold.	Gajah, gajah mina -	Elephant, whale.
Anak, anak ayer -	Child, rivulet.	Gosong - - -	Shoal, sand-bank.
Ang-in - - -	Wind.	Gunong - - -	Mountain.
„ durat - - -	Land wind.	„ api - - -	Volcano.
„ laut - - -	Sea breeze.	Jambatan, palamban	Bridge.
Api - - -	Fire.	Jurang, churang -	Creek.
Arang - - -	Charcoal, coal (?).	Kalang-an - - -	Dry dock.
Ayer - - -	Water, river.	Kampong - - -	Enclosure, village.
„ baku - - -	Ice, hail.	Kamudi - - -	Rudder, helm.
„ dang kal - -	Shallow water, ford.	Kapal - - -	Ship.
„ masin - - -	Salt water.	Karang - - -	Coral reef.
„ sung-ei - - -	Rain water.	Karra - - -	Monkey, ape.
„ tawar - - -	Fresh water.	Karsik - - -	Gravel, sand.
Banchah - - -	Marsh, morass.	Kayu, kayu api -	Wood, firewood.
Barat, barat tapat	West.	Kilat - - -	Lightning.
„ daya - - -	South-west.	Korong - - -	Cabin, poop.
„ laut - - -	North-west.	Kota - - -	Fort, castle, tower.
Batang - - -	River.	Kuda - - -	Horse.
Batu - - -	Rock, stone.	Kuku - - -	Fluke of an anchor.
„ barani - - -	Loadstone.	Kuning - - -	Yellow.
„ Bedil - - -	Gun, musket.	Kwala - - -	Mouth of river.
Belantara - - -	Forest, desert.	Labuh-an - - -	Anchorage, harbour.
Bender - - -	Port for trade.	Lama - - -	Former, old, ancient.
Bengkok, Bungkok-	Crooked, humped.	Lamong - - -	Buoy.
Besar - - -	Large, great.	Lang-it - - -	Sky, heavens, roof.
Besi - - -	Iron.	Lang-kong - - -	Arch, crescent.
Beting - - -	Sand-bank.	Lapong - - -	Gap, wide.
Biduk - - -	Boat, Great bear.	Laut, laut besar	Sea, the ocean.
Bintang - - -	Star.	„ salatan - - -	Southern ocean.
„ kutab - - -	Pole-star.	Layen - - -	Sail.
Bras, nasi, imei -	Rice, boiled rice.	Lembah - - -	Valley.
Buah - - -	Fruit.	Lichah, Lumpun	Mud.
Buaya - - -	Alligator, crocodile.	Lima, lima-blas	Five, fifteen.
Bukit - - -	Hill.	Lubok - - -	Bight or recess.
Bulan, bulan baru	Moon, new moon.	Mata - - -	Points of the com- pass.
„ purmana - - -	Full moon.	Merah - - -	Red.
Buluh - - -	Bamboo.	Nang-ka - - -	Jack Fruit.
Burong - - -	Bird.	Negri - - -	City, town, country.
Damie - - -	Peace.	Padang - - -	Plain, open space.
Danau, tasek - -	Lake, small lake.	Padi - - -	Rice in the husk.
Dapur - - -	Cooking place.	Padoman - - -	Mariner's compass.
Datu, datuk - - -	Chief of a tribe.	Pahak, lembah -	Valley.
Da-un, dahan - -	Leaf, bough.	Pakau, pasar - -	Market place, ba- zaar.
Dayong - - -	Oar, paddle, to row.	Palamban - - -	Bridge.
Etam - - -	Black.		
Gading - - -	Ivory.		
Gadong, godong -	House.		

MALAY.	ENGLISH.	MALAY.	ENGLISH.
Panjang - - -	Long, tall.	Salat, sellat - - -	Strait of the sea.
Punchuran, trusan - -	Channel, passage.	Salatan - - -	South.
Pasang - - -	Tide.	„ daya - - -	South-south-west.
„ besar - - -	Spring tide.	Sampan - - -	Canoe, small boat.
„ kadang - - -	High water.	Sapah, sippah - - -	Quid of Betel.
„ kring - - -	Low water.	Sudagan (Ar.) - - -	Merchant trader.
Payang, rawah - - -	Marsh.	Sung-ei - - -	River.
Pendek, korang - - -	Short, wanting.	Tambaga - - -	Copper.
Pikul - - -	Weight of 133 lbs.	Tambang - - -	Mine.
Pinang - - -	Betel nut.	Tanah, benua - - -	Land, country, earth
Pisang - - -	Plantain, banana.	Tanda - - -	Beacon.

Prigi - - -	Well.	Tasek - - -	Inland sea, lake.
Pulau, Pulo - - -	Island.	Teluk - - -	Bay.
Putih - - -	White.	Timor - - -	East.
Rachun - - -	Poison	„ laut - - -	North-east.
Rakil - - -	Raft.	„ tung-ara - - -	South-east.
Rantau - - -	Plain, flat sea coast.	Ubat bedel - - -	Gunpowder.
Rata - - -	Flat, level, low.	Ujong tanah - - -	Promontory.
Rawang, rawah - - -	Swamp, marsh.	Utara - - -	North.
Rumah chukei - - -	Custom-house.	Utang, rimba - - -	Forest.
Rumpak - - -	Pirate.	„ timor - - -	North-east.
Sakat - - -	Bar, barrier.	„ sa-mata timor - - -	North-north-east.
		„ barat-laut - - -	North-north-west.

Money.

The silver coin in general use in Singapore, Penang, and Malacca are the rupee and dollar. Foreign monies, also, are freely used, especially the Mexican and Spanish dollar. All government accounts are kept in £ s. d. The metallic value of the rupee of course depends on the market price of silver. In 1872 it was 1s. 11½d.; in 1874-5, 1s. 10d.; in 1875-6, 1s. 10¼d.; and in 1876-7, 1s. 9¾d.

12 pies = 1 annam = 1½d.	1 cent = ½d.
16 annas .. 1 rupee 2s. (nom.)	100 cents = 1 dollar .. 4s. 3d.
100 rupees = 46½ dollars.	
100 dollars 214 rupees, 1 anna, 5 pies.	

The same denominations for moneys, weights, and measures prevail, with variations throughout most of the Malay States.

The word *picul* is the Malay word *pikul*, which, like the Chinese word *tan*, means a load or burden carried on the back. *Mace* and *tael* are derived, through the Malayan and Javanese *mas* and *tail*, from the Hindu *Masha* and *tola*. *Cash* is from *caixa*, the Moorish name of the tin coin found by the Portuguese at Malacca in 1511. *Catty* or *kati* is the Malayan pound, and *candareen* or *kondrin* is also Malay. *Pice* is the Javanese word *piehis*.

Weights.

The commercial weights in use between Europeans and natives are the Chinese *picul*, *catty*, and *tael*. A little discrepancy exists in the weight of the *picul* and

catty in some places ; and there is a distinction between the Chinese and Malay picul ; the latter is equal at Penang to $142\frac{2}{3}$ lbs. avoirdupois, and is only used to weigh tin and pepper. This discrepancy arises from the use of the *bahr*, which varies considerably in weight, and is divided into 3 Malay piculs ; the *bahr* is equal at Penang to 421 catties. By the Malay picul, goods are purchased from the native vessels ; but they are re-sold by the Chinese picul. By the *coyan*, of 50 Chinese piculs, grain and salt are sold ; a bag of salt weighs 100 lbs. avoirdupois ; but one of grain or rice weighs 164 lbs. The *coyan* at Penang is a measure ; 45 piculs of rice, or 43 of salt, make a measurement *coyan*.

The Chinese *dotchin* is commonly met with ; but among merchants English weights and scales are generally used ; and, in fact, wherever Europeans have colonized or settled in Malaya, they have fixed the imperfect native measures and weights, as thereby making them the standard, or by supplanting them with their own.

Gold dust is weighed by the *bunkal*, equal to 2 dollars or 832 grains, troy, which is divided into 16 *miams* of 12 *sagas* each ; a catty of gold is $1\frac{2}{5}$ of the common catty. In the towns on the eastern side of the peninsula the *bunkal* and catty are found to be about 10 per cent. less than these. Pulse, dhol, and rice from Bengal are sold by the bag of 2 bazar maunds, or $164\frac{1}{3}$ lbs. Piece goods are sold by the *corge* of 20 pieces, and Java tobacco by the *corge* of 20 baskets.

At Malacca the picul weighs 135 lbs. avoirdupois ; and 3 piculs, or a *bahr*, 428 lbs. avoirdupois.

Measures.

The measure of length frequently used by the Malays and other natives is the *hasta* or cubit, equal to 18 English inches ; but among the Chinese, as well as Europeans, the English yard is always used.

The chief measure of capacity for grain and oil is the *gantang*, divided into 4 *chupals*, each about $2\frac{1}{2}$ lbs. avoirdupois ; the *gantang* is equal to 271.65 cubic inches, or $1\frac{1}{4}$ gallon ; 10 *gantangs* make one *parah*, which is merely a nominal measure ; and 80 *parahs* of rice make 1 picul ; 800 *gantangs* are counted to a *cayan*, about 2 tons 7 cwt.

20 taels	- - = 1 catty	$2\frac{2}{3}$	1.20958
50 catties	- - = 1 picul	$133\frac{1}{3}$	60.479

The *Coyan* is a weight which is usually reckoned equal to 20 piculs, but it varies from 18 to 22 piculs. The coyan of paddy (rice in the husk) is reckoned at about $16\frac{2}{3}$ piculs, and is considered equal to $2133\frac{1}{3}$ lbs. av.*

COCHIN CHINA (ANAM.)

Money.

"The every-day money of the country is cash of the Chinese pattern, though bar silver, cast in pieces weighing ten taels each, is also made use of by merchants. Lumps weighing a tael, with Chinese characters on them, as also round silver coins of Chinese origin, are occasionally seen, both finding their way down from Yunnan. Gold is not used as money. The cash are, in one respect, singular, being made of zinc, or what seems like a mixture of lead and sand, and so fragile as to be easily broken between the finger and thumb; 60 cash make one *chek*, 10 *chek* make one *koon*, or 'ligature,' as the French name it; 5 *koons*, on an average, go to the dollar, but the exchange varies daily. On April 14th, 1876, the exchange was 3,300 cash, or 5 *koon* 5 *chek* per dollar; while at Hue, the capital of Annam, the dollar had been commanding 7 *koon* and over. At Hai-phong, foreign silver coins of any denomination are readily taken."—(N. B. Denny, Ph. D.)

Accounts are commonly kept in *quan*, *mas*, and *sapeks*, as follows:—

	1 sapek, or dong, or cash	=	$\frac{1}{2}$ d.
60 sapeks	= 1 mas, or mottien, or heap		$3\frac{1}{2}$ d.
10 mas	1 quan, or string		2s. $9\frac{1}{2}$ d.

* The Merchants' Handbook of Money, Weights, and Measures of all Nations. By W. A. Browne, LL.D. London: Edward Stanford, 6, Charing Cross.

Measures of Length.

			Inches.	Metres.
	1 ly - - -	=	·0192	= ·00048
10 ly - -	= 1 phau - - -		·192	·00487
10 phau - -	1 tac - - -		1·92	·04876
10 tac - -	1 thuoc or cubit -		19·2	·48766
			feet.	
5 thuoc - -	1 ngu - - -		8	2·43835
10 thuoc - -	1 truon - - -		16	4·87670
			yards.	
3 ngu - -	1 sao - - -		8	7·31506
3 truons - -	1 chai vai or that -		16	14·63012
10 saõ - -	1 mao - - -		80	73·15064
10 chai vai - -	1 quo - - -		160	146·30128

The thuoc, which is the chief unit of measures of length, varies considerably in different places; thus there are six different values assigned to it, varying from 15 to 25 $\frac{3}{4}$ English inches, or from ·38098 to ·656209 mètre, but the thuoc, the value of which is given in the Table, is the one in general use. The drapers' thuoc is a little longer, being equal to 25 $\frac{3}{4}$ inches; the tac to 2 $\frac{1}{2}$ inches; the phan to ·256; and the ly to ·0256 inch English.

2 hao - =	1 shita or tao -	$12\frac{1}{3}$	56.541172

“The weights and measures in use for commercial purposes are Chinese, and bear Chinese names, differing from the Canton standard only in being heavier. The *leong*, or ounce, weighs about $1\frac{1}{2}$ ounce English, and the *catty*, 1 lb. 6 ozs. 10 grs. There are several differing standards of length. The ell used for measuring piece goods is $25\frac{1}{2}$ inches. It is in fact necessary in buying articles of any description to agree beforehand as to the length or weight of the denomination used. This especially applies to grain and similar products.”—(N. B. Dennys, Ph. D.)

NETHERLANDS' INDIA.

Money.

The monetary system of Netherlands' India has of late years been assimilated to that of Holland. The silver standard is the Netherlands *guilder*, or *florin*, which is divided into 100 *centen*.

	1 Cent	=	$\frac{1}{4}$ d.
100 Cents =	1 Guilder or Florin	=	1s. 8d.

The gold coinage in Holland was suppressed by law in 1850, and has not since been re-established. It consisted of the 10 *gulden* and 5 *gulden pieces*. These are sometimes met with, but they are not a legal tender; their price rises and falls with the fluctuation of the market. The average price of the 10 *gulden* piece is about 9 *gulden* and 65 cents, and that of the 5 *gulden* piece about 4 *gulden* and 82 cents.

The silver coins are the $2\frac{1}{2}$ *gulden piece* (sometimes called *rix-dollar*), the *florin* or *guilder*, and the $\frac{1}{2}$ *florin*. These are of the fineness of $\frac{904}{1000}$ ths, and the *florin* weighs 866.17 grains troy. There are also in silver of a lower standard the 25, 10, and 5 *cent pieces*. The 5 *cent* piece is often called a *stiver*.

The copper coins are the *cent* and the $\frac{1}{2}$ *cent*, worth respectively $\frac{1}{8}$ d. and $\frac{1}{16}$ d. sterling.

Weights.

The weight for gold and silver is the Dutch mark, troy, divided into 9 reals, each weighing 422 grains, English.

The commercial weights in common use are based on the China weights, thus.—

16 taels =	1 catty	=	$1\frac{1}{4}$ lbs. Dutch troy.
100 catties =	1 picul	=	125 „ = 136 lbs. avoirdupois. or 61 kilogrammes.
3 piculs =	1 small bahar	=	408 „
$4\frac{1}{2}$ piculs =	1 large bahar	=	612 „

In foreign trade, however, the Dutch troy pound of 2 marks is generally used. The proportion of the Dutch and English weights are—

1 Dutch troy pound	=	7576 grains, English.
1 Dutch commercial pound	=	7625 „

The metric weights are as follows—

		Grains Troy.		
	1 korrel	=	1.5432349	= 1 decigramme.
10 korrel	= 1 wigkje	=	15.432349	= 1 gramme.
10 wigkje	= 1 lood	=	154.32349	= 1 decagramme.
			Lbs. av.	
10 looden	= 1 onze	=	.220466	= 1 hectogramme.
10 onzen	= 1 pond	=	2.20466	= 1 kilogramme.

Measures.

The measures for rice and grain are the picul and coyan or koyang, and for smaller quantities the *timbang* and gantang. The coyan weighs at—

Batavia	-	-	-	27 piculs or 3,375 troy Dutch lbs.
Samarang	-	-	-	28 piculs or 3,500 „
Soerabaya	-	-	-	30 piculs or 3,750 „

or about 60 imperial bushels.

The *timbang* contains 5 piculs or 10 sacks; 5 gantangs make 1 *measure*; and 46 measures are equal to a *last*. These measures are principally in use among the natives.

The most general liquid measure in all the Dutch settlements is the *kan*, 33 of which are equal to a little more than 13 English gallons. A leager or legger of arrack is 388 Batavia kans, equal to 133 imperial gallons, or 550 litres.

Of long measure, the *ell* is $27\frac{3}{4}$ English inches, and the foot of 12 *duimen*, or inches, is equivalent to $12\frac{9}{16}$ English inches.

The metric system of measures is as follows—

		Imperial Pints.		
	1 maatje	=	.176077	= 1 decilitre.
10 maatjes	= 1 kop	=	1.760773	= 1 litre.
			Imperial Gallons.	
10 koppen	= 1 schepel	=	2.200967	= 1 decalitre.
			Imperial Bushels.	
10 schepels	= 1 mud or zak	=	2.751208	= 1 hectolitre.
			Imperial Quarters.	
30 mudden	= 1 last	=	10.31703	= 30 hectolitre.

A market schepel contains $2\frac{1}{2}$ schepel, or 25 koppen, and is equal to 5.5024175 imperial gallons, English.

Length.

In 1820, Holland adopted the metric system; and the weights and measures are the same as those of France, but have different names, as will be seen by the following tables:—

		Inches.			
	1 streep	=	0.3937	=	1 millimetre.
10 strepen	= 1 duim	=	.3937079	=	1 centimetre.
10 duimen	= 1 palm	=	3.937079	=	1 decimetre.
10 palmen	= 1 el	=	39.37079	=	1 metre.
		Yards.			
	1 ellen	=	10.936308	=	1 decametre.
100 roeden	= 1 mijle	=	1093.6082 or nearly 5 furlongs	=	1 kilometre.

NORTH-WEST BORNEO.

Memorandum forwarded by H.B.M., Consul-General for Borneo, with regard to Dr. Browne's tabulated series of questions on the Currency, Weights, and Measures of Borneo, &c.

Money.

On the N.W. Coast of Borneo, goods and produce are exchanged for each other, the reckoning being made in so many piculs of brass guns, a picul being worth about 35 dollars.

This is not altogether an imaginary mode of keeping accounts, for the guns are actually cast in quantities at Brunei, and weigh from 2 to 8 guns to the picul. At Brunei fines are levied in piculs of guns. Dollars and cents are also a medium of exchange.

In the South of Borneo, under Dutch rule, the real and guilder are used in reckonings, the real being an imaginary coin worth 2 guilders.

In Lootoo and the territories in Borneo belonging to that country the currency consists of doubloons, dollars, and Pitis, 5,000 of which are equal in value to a dollar. These small zinc coins are made in China and Manilla for the Lootoo market, and are similar to the copper cash used in China, but are much smaller and thinner. In the extreme North of Borneo money is almost unknown, and accounts are kept in pieces of cloth, each piece equal to 1.50 dollar. In the mountains of the same district reckonings are made in bundles of iron for large accounts, each bundle, so far as I could learn, being in weight about 8 lbs. For small accounts they reckon in charges of gunpowder.

The mountaineers (Legai) in the N.E. of Borneo, reckon in cakes of salt for small accounts, and pieces of cloth, each representing 3 dollars, for large accounts.

In the western part of New Guinea accounts are calculated in pieces of black cloth, each valued at 10 guilders.

Weights used at Brunei.

16 taels	=	1 Catty.	
100 catties	=	1 picul	= 133½ lbs.
40 piculs	=	1 koyan.	

Measures of Quantity.

2 pahus or bambus	=	1 chupa.
4 chupahs	=	1 gantang.
10 gantangs	=	1 para.
20 gantangs	=	1 picul.
40 piculs	=	1 koyan.

Measures of Length.

2 jankals	=	1 hasta.
2 hastas	=	1 ella or yard.
2 ellas	=	1 dapa or fathom.

PHILIPPINE ISLANDS.

Money.

The currency of the Philippines is the Spanish dollar divided into rials and cuartos, but for commercial accounts, and to correspond with the American dollar, also divisible into cents. A dollar consists of 8 rials, equal to 160 cuartos, a rial being equal to 20 cuartos.

The coinage consists of the gold pieces of 4 dollars, 2 dollars, and 1 dollar; of the silver pieces of 4 rials (equal to 50 cents), 2 rials (equal to 25 cents), 1 rial (equal to 12½ cents), and a recent emission of 20 and 10 cent pieces; and of the copper pieces of 2 cuartos and 1 cuarto.

The Government accounts are, however, calculated in escudos or florins (2 to the dollar), and in ten-thousandths of an escudo; thus, 1 dollar 6 rials are equal to 1 dollar 75 cents, and to $3\frac{5000}{10000}$ escudos.

Weights.

The weights commonly in use are the picul and its parts. There are also the following Spanish weights:—

8 dram	=	1 ounce.
16 ounces or 2 marks	=	1 pound.
25 pounds	=	1 arroba = 25½ lbs. avoirdupois.
4 arrobas or 100 lbs.	=	1 quintal = 102 „
5½ arrobas or 137½ lbs.	=	1 picul = 148 „

Measures.

The Spanish foot is about $11\frac{1}{8}$ English inches. It is divided into 12 pulgados, each containing 12 lines. The *vara*, or measure for cloth, is three feet, or 4 palmos, or 36 pulgados, equal to $33\frac{1}{2}$ English inches; 100 varas are equal to $92\frac{2}{3}$ English yards. English goods and some other goods are sold by the English yard. The *corge* is 20 pieces. The *caban*, a measure for grain, contains $3\frac{1}{10}$ cubic feet; a *caban* of rice weighs 123 lbs., and of paddy 85 lbs. Sixteen Manila piculs equal 1 ton English weight. One ton weight of hemp measures 2 tons of 40 cubic feet.

CHINA.

Glossary of Chinese Words.

Money.

The only native coin now in use throughout China is the *tsien*, called *cash* by the English, and *sapeque* by the French, who derive it from the Portuguese *sapeca*. It

is circular from $\frac{5}{16}$ to $\frac{9}{16}$ inch in diameter, and has a square hole in the middle for convenience of stringing them. It is cast, not stamped. On one side it bears the name of the province it is cast in, in Mandchu letters, on one side of the hole, with the Chinese word "money" on the other. On the other side is the name of the emperor reigning, on each side of the hole, and above and below it two Chinese characters, signifying "current money." Copper coins of this shape were first cast about B.C. 1120, when Saul was King of Israel, and has ever since been retained as the national currency.

Spanish, Mexican, and South American dollars (though not acknowledged by the government) are employed as a commercial medium throughout the maritime provinces.

The nominal moneys of account are the *liang*, *tsien*, *fan*, and *li*, called by foreigners *tael*, *mace*, *candareen*, and *cash*, the proportion of which, one to the other, is decimal. The candareen is equal, only in accounts, to 10 cash; but, owing to the deterioration of the coin, its actual value in Canton, in 1854, was about the eighteenth part of a candareen, 1900 ordinary cash, or 1800 picked ones, being paid for a tael. Since that time the exchange has risen from various causes, and only 1350 to 1400 can be obtained for a tael. At Amoy, in 1850, a Spanish dollar would purchase 3600 pieces of the poorest kind, but only 1300 selected ones. At Canton, at the same time, the dollar bought 1200 current cash, and at Shanghai 1750. In 1863 a dollar at the same three cities would exchange for 1100, 1050, and 1100 pieces, showing the result of freer intercourse.

The terms tael, mace, candareen, and cash, are merely denominations of weight; the cases in which stamped pieces of silver (other than clean dollars) pass current as coin being few, except in small transactions. It is more convenient, however, to speak of them as nominal moneys.

The circulating medium in transactions with foreigners, at the open ports, is chiefly in whole or broken dollars; the value of the dollar in relation to the tael varies in different transactions. In calculations and accounts between foreigners and merchants, and almost always in bargains between the Chinese themselves—

Taels are converted into dollars at the rate of - - taels 720 per 1000 dollars.
 But payments in *cash* are generally weighed at - - ,, 717 ,,
 Tradesmen paid by compradores receive - - - ,, 715 to 717 ,,

The value of the tael in relation to sterling money was reckoned by the East India Company at 6s. 8d., but its intrinsic value varies according to the price paid for dollars per ounce in London. Hence, to convert taels into sterling money, multiply the price paid for dollars by multiplier 1.208. Thus, if the price of the dollar be 60d. per ounce, the value of the tael will be $60 \div 1.208 = 72\frac{4}{100}$ d., if at 66 it will be $79\frac{7}{100}$ d.

Taels.	Mace.	Candareen.	Cash.	Drs. Avoird.	Grs. Troy.	Grammes.	Tolas.
1	10	100	1000	21.33	579.34	37.796	3.23
—	1	10	100	2.13	57.984	3.779	—
—	—	1	10	0.213	5.798	0.378	—

Commercial Weights.

The unit of the table is the *liang* or tael.

1 kernel of millet	is 1 <i>shu</i> .		
10 shu	= 1 <i>lui</i> .		
11 lui	= 1 <i>chu</i> or pearl.		
24 chu	= 1 <i>liang</i> or tael	=	1 $\frac{1}{3}$ oz. avoird.
16 liang or taels	= 1 <i>kin</i> or catty	=	1 $\frac{1}{3}$ lbs. "
2 kin	= 1 <i>yin</i>	=	2 $\frac{2}{3}$ lbs. "
30 kin	= 1 <i>kium</i>	=	40 lbs. "
100 kium	= 1 <i>tan</i> or picul	=	133 $\frac{1}{3}$ lbs. "
120 kin	= 1 <i>shih</i> or stone	=	160 lbs. "

Chinese weights and grain measures, and the linear long and land measure, all vary in different parts of the country; but, as a general rule, they are largest and longest in the southern provinces.

1 ton	is equal to 16 piculs 80 catties,
1 cwt.	" 84 catties.
1 lb. avoirdupois	$\frac{2}{3}$ of a catty or 12 taels.
4 oz.	is equal to 3 taels.
1 picul	" 1.19047 cwt. or 1 cwt. 21 $\frac{1}{3}$ lbs.
3000 taels	" 302 lbs. troy.

The difference in the values of the weights above a tael as fixed by the natives, and those in common use in China, are as follows—

	British Treaty,	French Treaty,	Common Weights.
Stone - - -	159.99 lbs. avoird.	72.544 kilog.	159.11 lbs. avoird.
Picul - - -	133.33 "	60.453 "	132 6 "
Catty - - -	1.333 "	604.53 grammes.	1.326 "
Tael - - -	1.333 oz. avoird.	37.783 "	1.328 oz. avoird.

Measures.

<i>Length.</i>	1 <i>lih</i> or gran is 1 fun.	
	10 fun - - -	1 tsun or inch.
	10 tsun - - -	1 <i>chih</i> , coid or foot = 14.1 in. Eng.
	10 <i>chih</i> - - -	1 chang or pole = 11. ft. 9 in.
	10 chang - - -	1 yin.
<i>Capacity.</i>	1 grain of millet is 1 suh.	
	6 suh - - -	1 kwei.
	10 kwei - - -	1 tsoh or pugil.
	10 tsoh - - -	1 chau or handful.
	10 chau - - -	1 choh or ladle.
	5 choh - - -	1 yoh or cup.
	2 yoh - - -	1 koh or gill = 0.103 litre.
	2 koh - - -	1 shing or pint = 1.031 "
	10 shing - - -	1 tau or peck = 10.31 "
	16 tau - - -	1 yu.
	5 yu - - -	1 koh = 51.55 "
	2 yu - - -	1 shih = 10.310 "
	16 koh - - -	1 ping.
	1 fu - - -	6 tau 4 shing.

These are taken from the "Chinese Commercial Guide," by S. Wells Williams, an excellent work.

Money.

The coinage now in use in Japan was adopted in the year 1871. The *Yen*, a gold coin weighing 25.72 grains troy, was constituted the fundamental unit of the system. The gold coins are 1, 2, 5, 10 and 20 yen pieces, the latter valued at £4 3s. 4d. The one yen piece is valued at 4s. 2d. English.

Silver and copper coins are as follows. The yen or dollar being the coin used in paying duties and in commercial transactions between Japanese and foreign merchants:—

<i>Silver.</i>		<i>Copper.</i>	
1 yen	= 4s. 2d.	1 sen	= $\frac{1}{2}$ d.
50 sen	„ 2s. 1d.	$\frac{1}{2}$ sen	„ $\frac{1}{4}$ d.
20 sen	„ 10d.	1 rin	„ $\frac{1}{20}$ d.
10 sen	„ 5d.		
5 sen	„ 2 $\frac{1}{2}$ d.		

Weights.

<i>Avoirdupois.</i>		
1 drachm	- - - - =	.4695 Monme.
1 oz.	- - - -	7.5117 „

NAUTICAL WORKS.

— o —

XIII.—NAUTICAL DIRECTORIES, ETC.

The following DIRECTORIES, Nos. 201 to 206, comprise, in Six Volumes, the descriptive hydrography of, and nautical directions for, the whole of the great Oceans. They are uniform in size—Royal octavo; and in their various recent Editions show the present state of our knowledge. They are zealously corrected and improved from all attainable data, and are confidently presented to the sailor as useful and important guides. They are amply illustrated by Diagrams and special Charts.

201. NORTH ATLANTIC OCEAN:

£ s. d.

MEMOIR, Descriptive and Explanatory, of the Northern Atlantic Ocean: and comprising Instructions, General and Particular, for the Navigation of that Sea. By ALEX. G. FINDLAY, F.R.G.S. *Thirteenth Edition*. In one thick volume, 860 pages. Royal octavo, cloth boards. With Eleven Illustration Plates - - - - - 0 14 0

This volume is in some respects introductory to those which follow. The meteorology and hydrography of the North Atlantic have been so much more studied, and its commerce is so much more important than any other of the great oceans, that these particulars are more fully entered into than in the other works. The refined geodetic operations which have not, with the exception of India, been extended to other coasts, are fully described. The same with the Lighthouse system and the List of these useful monitors. The Wind Systems, their causes, and effects, are completely elucidated. The same with the Tides and Currents. The latter topic, almost a new subject, is largely dilated on, as affording a clue to many obscure facts in other parts of the world. The application of these to navigation in directions for crossing the Atlantic by the different routes, is also largely referred to. The islands are fully described, and directions are given for the principal ports of Western Europe and North-eastern America.

202. SOUTH ATLANTIC OCEAN:

A DIRECTORY for the Ethiopic or South Atlantic Ocean, including the Coasts of South America and Africa; with the Islands, &c. By A. G. FINDLAY, F.R.G.S. *Eighth Edition*. In one thick volume, 850 pages, Royal octavo, cloth, boards 0 14 0

A continuation or sequel to the volume on the North Atlantic. Its less perfect hydrography is elucidated in the introductory Chapters, and the more simple meteorology and its application to navigation is fully described. The Islands and Shoals of the open ocean and the Coasts of South America, between the Rio Pará and Cape Horn, are amply described. The same with the African Coast, from Cape Mount; along the Guinea Coasts to the African Bights; and thence to the Cape of Good Hope. The work is Illustrated by Ten special Charts.

203. INDIAN OCEAN :

£ s. d.

A DIRECTORY for the Indian Ocean, with Descriptions of its Coasts, Islands, &c., from the Cape of Good Hope to the Strait of Sunda and Western Australia; including, also, the Red Sea and Persian Gulf; the Winds, Monsoons, and Currents; the Passages from Europe to its various Ports, and the Port Regulations and Charges; Indian Money, Weights, and Measures, &c. By A. G. FINDLAY, F.R.G.S. *Third Edition*. In one thick volume, 1,250 pages. Royal octavo. With Fifteen Illustrations - - - - - 1 8 0

204. INDIAN ARCHIPELAGO, ETC. :

A DIRECTORY for the Indian Archipelago, China, and Japan, from the Straits of Malacca and Sunda, and the Passages East of Java, to Canton, Shanghai, the Yellow Sea, Japan, &c. With Descriptions of the Winds, Monsoons, and Currents, and General Instructions. By A. G. FINDLAY. In one thick volume, 1,350 pages. Royal octavo. With numerous Illustrations - - - - - 1 8 0

205. NORTH PACIFIC OCEAN :

A DIRECTORY for the North Pacific Ocean, with Descriptions of the Coasts between Panama and the Sea of Japan, and of the Islands North of the Equator, including the Japanese Archipelago, with its Winds, Currents, Passages, &c. By A. G. FINDLAY, F.R.G.S. One volume. Royal octavo. 1,000 pages. With numerous Illustrations - - - - - 1 4 0

206. SOUTH PACIFIC OCEAN :

A DIRECTORY for the South Pacific Ocean, with a Description of its Coasts and Islands between Cape Horn and Panama, New Zealand and Australia; its Winds, Currents, and other Phenomena, with Instructions for the Passages. Illustrated by Diagrams and Maps. *Fourth Edition*. By A. G. FINDLAY, F.R.G.S. One volume. Royal octavo. 1,150 pages - - - - - 1 4 0

207. LIGHTHOUSES of the WORLD :

A List and Description of the Lighthouses of the World, giving their Position, Appearances, and the Character of their Lights. By A. G. FINDLAY, F.R.G.S. A new and enlarged Edition. Handsomely bound in cloth. Royal octavo. *Seventeenth Edition* - - - - - 0 4 0

This work is uniform in size—Royal octavo—with the preceding. It has been remodelled; and this Seventeenth Edition has received such amendments as the progress of the subject demands. The Introductory Chapters contain notices of the improvements that have been made in the Lighting and Controlling Apparatus.

Supplements, giving the changes which have taken place within the year, are issued free to the holder of the book for three years from the date of publication.
