ENTERED AT STATIONERS' HALL.

PREFACE,

THIS volume may be considered as a sequel to our Sailing Directory for the Indian Ocean, which describes all the coasts and islands between the Cape of Good Hope and the Straits of Malacca and Sunda, the great westward portals of the vast archipelago which is described in the present work. Although each book is complete in itself, still they may be taken together as the modern representative of our old "Oriental Navigator," which was first issued from this house by the predecessors of the present publisher, in 1775, a fourth edition being completed in 1808. The arrangement of that quarto volume is very much the same as that now followed in these two works; and, as is stated in the Preface to the Indian Ocean Directory, was copied, with most of its matter, from the Oriental Navigator, by the late Captain James Horsburgh, in the first edition of his work, published in 1809—11. Captain Horsburgh died in May, 1836.

This Directory completes the series of those drawn up or edited by the writer. Those for the North Atlantic and South Atlantic Oceans, embracing all the area northward, between Cape Horn and the Cape of Good Hope; those for the Indian Ocean and Indian Archipelago giving all the countries between the Cape of Good Hope and the North of China, while the circuit is completed by the Directories for the Pacific Ocean. These last named works were designed by the author 20 years ago; and, with the exception of this book, all have been before the world for some years, and, it is hoped, have done good service. They were drawn up from materials scattered over a wide range of literature, and the collection of which involved much labour and research.

This book differs in some degree from the others, for a considerable portion of it is taken from the "Pilots," published by the Hydrographic office, so carefully compiled, chiefly by Commander John W. King, R.N., and embracing all the information given by former works, combined with the recent observations of many naval officers.

For the China Sea and Coast of China we are thus indebted to these Admiralty works, and we fully acknowledge our indebtedness to them. In

many parts we have somewhat curtailed the details, without, it is hoped, impairing their utility to the Mercantile Marine.

The other portions of this book have been derived from various and numerous sources, the chief of which we may briefly indicate, proceeding in the geographic order in which the book is arranged.

The Strait of Malacca was partially surveyed, by direction of the East India Company, by Captains Moresby, Ward, and Moore, and part of the Sands by Captain Daniel Ross. The labours of these zealous officers, in the early days of hydrography as at present understood, have been alluded to in the introductory remarks to the Indian Ocean Directory. The northern part of the Sumatra coast was re-examined by Commander Fell, under the same auspices, in 1851—8. Subsequently to this the Sumatran side was surveyed by Lieutenant Jackson, in 1860.

The second great entrance to the Indian Archipelago—the Strait of Sunda—has been well surveyed by the Dutch; and it is to this nation, and the zeal and talent of their officers, that we are largely indebted for our exact acquaintance with the hydrography of the archipelago; and, also, it may be at once stated, that larger portions of the ensuing work are derived from the same sources.

Subsequent to the cession of Java, and other possessions, to the Dutch nation, after the vigorous policy inaugurated by Sir Stamford Raffles during the British occupation of that fine island, the queen of the archipelago, very much attention was paid by the Netherlands officers to the acquisition of knowledge in almost every branch of science relating to their extensive territories; and, however much may have been said as to their exclusive policy, it is certain that a vast amount of knowledge, and the records of the experience of a large number of most competent observers, was given to the world; but their memoirs being too frequently in the Dutch language, one not universally understood, they were left unheeded by those most interested in them, and thus it became a general opinion that this enterprising nation desired to keep the information that was acquired under these auspices to itself. Of late years this opinion has been fully met, and it is now accorded that no country has done better service to science.

For hydrography, the establishment of the Commission for the improvement of the Indian sea charts, at Batavia, under the enlightened Governor-General, the Baron Van der Capellen, in 1821, a period when our nautical surveys were first being commenced on a more extended scale, has led to great results. They are detailed generally in the ensuing pages; but it is desired that every acknowledgement of our obligations to the labours of this commission should be given. They are continued to this day, and are constantly adding to our stock of information. The works of Capt.-Lieut. Baron Peter Melvill van Carnbee have been alluded on page 150 hereafter. It is to this young officer, perhaps, more than any other individual, that we

owe a connected view of the labours of the commission to which he was secretary, as well as one of its most active surveyors.

The Strait of Sunda, as before said, was surveyed by Lieuts. Rietveld and Boom, in 1848, and since that time many additional observations have been added for its improvement. Of the North Coast of Java we have surveys of some minuteness, executed by Lieutenants Escher, Eschauzier, Staring, Rietveld, Boom, and others, which are generally sufficient for navigation.

A portion of the Java Sea is still incomplete on the charts, and is imperfectly described, and dependant on old observations; but the part between the Straits of Sunda, comprising the Thousand Islands, &c., has been more recently examined. Banka Strait has been excellently surveyed by Lieuts. Stanton and Reed, R.N., in H.M.S. *Saracen*, in 1859-60; and this important service has discovered a more direct and open channel through this great highway. The charts and directions for the strait leave little to be desired. Gaspar Strait, as now shown, is from the survey by the U.S. officers, in 1854. Carimata Strait, the easternmost of the western passages between Sumatra and Borneo, is still unsurveyed, although many of its dangers and features were fixed by Captains Ross and Maughan.

The labyrinth of islands and passages to the north-westward, the channels leading to Singapore, have not been completely and systematically surveyed, but the charts and directions are now so far complete that the main routes are quite sufficiently known and described for safe navigation. Lieutenants Melvill van Carnbee, Blommendal, and Edeling, have executed considerable portions, and their charts have been improved, especially Rhio Strait, by the examination of Lieuts. Reed and Stanton, R.N.

Singapore Strait was surveyed by a very zealous officer, J. T. Thompson, Esq., F.R.G.S., the government surveyor at Singapore, and the constructor of those excellent monitors the Horsburgh and Raffles Lighthouses, which mark its East and West entrances. A portion of this important strait has since been re-surveyed by Lieuts. Reed and Richards, R.N.

The Gulf of Siam, which has been very imperfectly laid down on our charts, was well surveyed, and its dangers and main features accurately delineated in H.M.S. *Saracen*, commanded by Staff-Commander J. Richards, a coast line of 1,000 miles in extent in the short space of twenty months, in 1856-8, a work which reflects much credit on its author. Cambodia, or Lower Cochin China, was also surveyed by the same officers. Of the coast of the Annamite empire, which now belongs to the French, our knowledge is less perfect. The Gulf of Tong King and Hainan Island are also mainly dependent upon the former surveys of Daniel Ross and other officers, improved by the observations of Mr. Kerr, R.N.

The western shores of the great island of Borneo are well laid down and described. A large portion of it was surveyed, minutely and excellently, by Sir Edward Belcher, and other parts were completed by Lieut. D. M.

Gordon, partially so by Capt. Drinkwater Bethune, and of late some points have been revisited by the Admiralty surveyors, conducted by Commander Ward.

Palawan, and some of the islands North of Borneo, were elaborately surveyed and profusely described by Captain Bate. The western coast of the Philippine Islands have been generally laid down from the surveys of various Spanish officers.

The China Sea is perhaps the locality where hydrography has made the greatest changes of late years. Up to 1862 the charts of this great highway exhibited a labyrinth of detached shoals, scattered about without order or connection, laid down from the isolated observations of zealous officers of the East India service, many of which are now difficult of recognition, from the vague manner of their announcement. The increasing importance of the China commerce, and the advance in the sailing powers of the ships employed in it, caused this great sea to be much more frequented than in former years. Since the year above named, Commander Reed, with a moderate staff, in H.M.S. *Rifleman*, has examined the outer line of dangerous shoals which limit the two great channels, which are separated by a vast range of dangerous coral reefs and shoals, leaving the clear main channel to the north-west, and the Palawan Channel to the south-east of them perfectly free from danger for those vessels which beat up or down the China Sea by either passage in the opposite monsoons. In the work these dangers are fully described and enumerated.

The Eastern Passages are less known, and their hydrography, generally, is less advanced than in other parts. A great portion of the islands, claimed by the Dutch, are, with the exception of their noble possessions in Java, more or less under the control of native chiefs, and therefore their commerce, in a European sense, is of minor importance; therefore they have attracted less attention. Still very much has been done by the Dutch officers.

Of Java we have before spoken. Of the volcanic range, to the eastward, the coasts have been surveyed by various officers, under the direction of the Commission at Batavia; and the account of its navigation was drawn up by Mr. J. Swart and Melvill van Carnbee.

The remarkable island of Celebes is, in many parts, very vaguely represented, but its main points are well fixed and delineated. Thus Makassar, its chief port, was surveyed by Sir Edward Belcher, as were the ports at its N.E. end. The remainder of its coasts rest on the more vague authorities of Dutch travellers and voyagers, and, for the great Southern Gulf of Boni, on the single voyage of Rajah Sir James Brooke. The groups to the eastward of this are also but indifferently known, although there are several tracks of eminent voyagers which have served to correct the main points and features. Of these, the surveys of Lieut. Gregory of the Dutch navy, with those of M.M. Kolff, Modera, Müller, and other Dutch officers, may

be enumerated. The celebrated Dumont D'Urville also made a cruise through a portion of the archipelago and settled many of its points. To these may be added the names of Sir Edward Belcher, Owen Stanley, and other British officers, so that although as a whole our charts and directions may be somewhat defective, they are still sufficient for the general purposes of navigation.

The coast of China is of vastly greater importance to commerce now that its ports and coasting trade are open to the world. The British Government, alive to the importance of this, commissioned those two well-known officers (now Admirals) R. Collinson, C.B., and Kellett, to replace the vague outlines left to us by the Jesuits in the first part of the last century, as alluded to on page 940 hereafter. The most important result of this extensive and difficult enterprise has been to give to every one a complete picture of the labyrinthine coast of this great empire, as perfect as of any other portion of the globe. Many minor features have been added to this great achievement, a portion of which was attained under difficult and perplexing circumstances. The directions drawn up appeared at first in the Chinese Repository, but have been followed implicitly in this work.

The foregoing brief and imperfect enumeration of the authorities upon which the physical portion of this book rests, will show how laborious and extensive must be the operations which can bring together such a mass of materials as is here given.

The Editor feels it due to his readers to state, as has been before alluded to, that a large portion has been already found to his hands and purpose, and he has only to unite these scattered memoirs into one more complete work by filling up the vacancies from the many sources which it is hoped, as it is intended, are acknowledged throughout.

London, March 1, 1869.

The foregoing preface to the FIRST EDITION was written before a description of the Japanese Archipelago was added to this work. For this description we are indebted to the China Sea Directory, Vol. IV., and recent reports from H.M. surveying vessels. Previous to 1867, the shores of Japan were represented in our charts from the descriptions of its own ingenious geographers. In the year 1867, Commander Brooker commenced an examination of its coasts in H.M.S. *Sylvia*, and was succeeded in the year 1869 by Commander St. John, who continued the survey without interruption till the year 1872, when the *Sylvia* was ordered home for repairs,

and did not return to Japan till July, 1874, since which time she has remained as a surveying ship on the Japanese coasts. Of late years some surveying operations have also been carried on by the Japanese government.

New and important information has been gained from the operations carried on in H.M. surveying vessels *Rifleman* and *Nassau*. In the former of these vessels, Staff-Commander J.W. Reed, after carefully examining the dangers in the China Sea, surveyed Balabac Strait and its approaches, and added to the completeness of the survey of Singapore Strait. In the years 1870—1872, Commander W. Chimmo, in H.M.S. *Nassau*, was employed in the Sulu and adjacent seas. The hostility of the natives, however, prevented a complete survey of the Sulu Archipelago. In the year 1877, the *Nassau*, under Commander Napier, R.N., was engaged in examining the many dangers recently reported as lying near the shore by vessels engaged in trade between the treaty ports of China.

H.M.S. *Challenger*, with the Deep-sea Exploring Expedition on board, between August, 1874, and March, 1875, was some months in the archipelago; and from several books edited by the officers, and from official reports, much has been taken to add to the completeness of the ensuing descriptions. The places visited in the passage from Torres Strait to Hong Kong were the Arru and Ki Islands, Banda, Amboina, and Ternaté in the Molucca Sea; Samboangan, Iloilo, and Manila in the Philippines. In returning, the vessel passed through the Philippine Archipelago eastward of Mindoro and Zebu, and westward and southward of Mindanao, thence to the Admiralty Islands N.E. of New Guinea, before proceeding to the northward to Yokohama.

The above labours of our own government, and those of the Spanish and Dutch governments, have afforded most of the newly incorporated information in this book; but no trouble has been spared to make the work complete up to the date of issue by the careful examination of all other available sources of information.

London, September, 1878.

PART II.

DESCRIPTION OF THE COASTS AND ISLANDS.

CHAPTER III.

THE STRAIT OF MALACCA	106
Eastern Coast, 107; Pulo Penang, 107; Perak, 112; Salangore, 119; Malacca, 130; Carimon Islands, 136; Coast of Sumatra, 137; Pulo Brasse Lighthouse, 138.	

CHAPTER IV.

THE STRAIT OF SUNDA	150
The Java Coast; 151; First Point Lighthouse, 154; Anjer, 162; The Coast of Sumatra, 165; Krakatoa, 173; S.E. Coast of Sumatra, 179; Directions, 179—180.	

CHAPTER V.

EAST COAST OF SUMATRA AND BANKA STRAIT.....	181
Sumatra Coast, 181; Banka Strait, 187; Lucipara Island, 192; Palembang, 196; Coast of Banka, 199; Kalian Point, 210; Mintok, 210; Stanton and Lucipara Channels, 215; Directions, 217; Lucipara Channel, 219; Northern Coast of Banka, 224.	

CHAPTER VI.

	PAGE
GASPAR STRAIT	227
Choice of Banka or Gaspar Strait, 227; Dangers Southward of Gaspar Strait, 229; Macclesfield Channel, 234; Directions, 239; Clements Channel, 244; Stolze Channel, 249; North-east Coast of Banka, 260; Dangers North and N.W. of Gaspar Strait, 264; Directions, 268.	

CHAPTER VII.

CARIMATA STRAIT	271
South Coast of Billiton, 273; Islands and Dangers in the Fairway, 275; West Coast of Borneo, 281; Directions, 293.	

CHAPTER VIII.

BANKA TO SINGAPORE	295
1. DETACHED ISLANDS and ROCKS. Detached Islands and Rocks, 295; Islands, &c., between Borneo and Singapore Strait, 304.	
2. RHIO STRAIT	312
General Description, 312; West side of the Strait, 313; East side of the Strait, 319; Directions, 326.	
3. VARELLA and DURIAN STRAITS	334
Coast of Sumatra, &c., 334; Southern Entrances, 344; Directions northward, 350; Directions southward, 353.	

CHAPTER IX.

THE STRAIT OF SINGAPORE	357
North side of the Strait, 358; Raffles Lighthouse, 361; South side of the Strait, 362; Directions, 364; Singapore, 366; Singapore New Harbour, 374; Singapore Strait, Eastern Part, 381; Horsburgh Lighthouse, 388; Directions, 390; South side of Eastern part of the Strait, 392; Directions, 395.	

CHAPTER X.

THE GULF OF SIAM, ETC.....	400
East Coast of Malay Peninsula, 400; East Coast of the Gulf, 412; Bangkok, 425.	

CHAPTER XI.

	PAGE
THE COAST OF COCHIN CHINA, TON-KING, ETC.....	428
1. Cochin China, 428; Cambodia River, 430; Don-nai or Saigon River, 432; Saigon, 437; Directions, 438.	
2. The Gulf of Ton-King, 456; River Lacht Huen, 461; Haiphong, 462.	
3. Coast of China and Hainan Island, 468; Pakhoi, 468; Hainan Island, 471; Hoihow, 473.	

CHAPTER XII.

NORTH-WEST COAST OF BORNEO	481
Tanjong Datu, 481; Sarawak or Kuching, 482; Bruni River, 490; Labuan, 494; Victoria Harbour, 496; Ambong Bay, 506.	

CHAPTER XIII.

BALABAC STRAIT AND THE ISLANDS NORTH OF BORNEO, INCLUDING PALAWAN.....	513
Balambangan, &c., 513; Banguey South Channel, 517; Balabac Strait, 522; North Balabac Strait, 536; Palawan West Coast, 539; North Coast, 566; East Coast of Palawan, 567	

CHAPTER XIV.

NORTH-WEST COAST OF THE PHILIPPINE ISLANDS.....	585
Calamianes, 586; Mindoro West Coast, 589; Luzon S.W. Coast, 594; Manila, 595; Cape Bojeador, 605; Pratas Island and Reef, 606.	

CHAPTER XV.

THE CHINA SEA, WITH ITS ISLANDS AND DANGERS	531
Anamba Islands, 610; Natuna Islands, 613; Shoals on eastern side of Main Route, 621; Islands and Dangers in the Fairway of the Main Route, 631; Paracel Islands and Reefs, 641; Macclesfield Bank, 645; Palawan Passage, 648; Dangers on its western side, 654; on the eastern side, 656; Shoals near the Main Route, 662; Shoals near the Palawan Route, 664.	

PART III.

THE EASTERN PASSAGES.

CHAPTER XVI.

	PAGE
JAVA AND THE JAVA SEA	670
Java, 670; North Coast, 672; Batavia, 677; Samarang, 693; Sourabaya, 696; Madura Island, 705; Madura Strait, 711; Probolingo, 715; South Coast of Java, 718; Tjilatjap, 724.	
The Java Sea, 735; Thousand Islands, 736; South Coast of Borneo, 739.	

CHAPTER XVII.

ISLANDS AND PASSAGES EASTWARD OF JAVA	742
Baly Island, 742; Baly Strait, 748; Banjoewangie, 751; Lombok Island, 754; Allas Strait, 759; Sumbawa Island, 761; Sapi Strait, 766; Mangarai Strait, 769; Floris Island, 769; Sumba or Sandalwood Island, 775; Strait of Floris, 778; Solor Strait, 779; Allor or Maurissa Strait, 780; Strait of Pantar, 781; Ombay Passage, 782; Wetta Island, 782; Island of Timor, 784; Rotti, 787.	

CHAPTER XVIII.

ISLANDS AND PASSAGES EASTWARD OF BORNEO.....	793
The Strait of Makassar, 793; East Coast of Borneo, 794; Island of Celebes, 801; Makassar, 803; North Coast of Celebes, 809; Boeton Island and Strait, 813; Salayar Island, 817; Postilions and Pater-nosters, 819.	
Molucca Islands, 820; Amboina, 825; Banda Islands, 829; Gunong Api, 832.	
The Banda Sea, 834; Serwatty Islands, 836; Tenimber Islands, 840; Arru Islands, 841; Ki Islands, 846; Arafura S-a, 848; Ceram Laut, 851; Western part of the Island of New Guinea, 855; Mysole, 858; Pitt Strait, 860; Waigiou, 861; Dampier Strait, 862; Pitt's Passage, 865; Gilolo Passage, 867; Gebi, 869.	
Malmaheira or Gilolo, 871; Morti, 873; The Molucca Islands, 874; Ternate, 874; Molucca Passage or Sea, 879.	

CHAPTER XIX.

	PAGE
ISLANDS NORTH OF THE MOLUCCAS	881
Sangir, 882; The Sulu Archipelago, 884; Sulu, 889; Basilan, 892; The Strait of Basilan, 894.	
The Philippine Islands, 895; Mindanao, 896; Samboanga, 896; Samar, 902; Strait of San Bernardino, 903; Ticao, 904; Masbate, 905; Zebu, 906; Negros, 908; Panay, 909; Iloilo, 910; Directions, 913.	
The Sulu Sea, 916; Sandakan Harbour, 917; Cagayan de Sulu, 918; Mindoro, 924; South Coasts of Luzon, 926; East Coast of Luzon, 929; Babuyan Islands, 936; Bashi Islands, 937.	

CHINA AND JAPAN.

CHAPTER XX.

THE COAST OF CHINA BETWEEN HAINAN AND HONG KONG	940
Now Chow, 942; Namoa, 946; Canton Rivers, 949; Macao, 952; La- drones, 954; Lema Islands, 960; Hong Kong, 963; Cap-Sing-Mun Passage, 969; Lintin, 970; Directions for Canton River, 971; Canton River, 979; Boca Tigris, 980; Whampoa, 983; Canton, 988; Si-kiang or West River, 990.	

CHAPTER XXI.

EAST COAST OF CHINA, BETWEEN HONG KONG AND THE RIVER MIN	992
Tathong Channel, 992; Mirs Bay, 995; Bias Bay, 999; River Han, 1010; Swatow, 1011; Namoa Island, 1012; Chapel Island Light, 1017; Amoy, 1019; Quemoy Island, 1023; Chinmo Bay, 1024; Ockseu Lighthouse, 1027; White Dog Islands, 1030.	

CHAPTER XXII.

FORMOSA AND THE PESCADORES ISLANDS	1032
Islands South of Formosa, 1033; East Coast of Formosa, 1034; West Coast of Formosa, 1036; Ta-kau-kon, 1038; Tamsui, 1043; Kelung Harbour, 1045; Islands N.E. of Formosa, 1047; Meiacu Sima Group, 1048; Ykima Island, 1051.	
Pescadores, or Ponghou Archipelago, 1051; Ponghou Harbour, 1054.	

CHAPTER XXIII.

	PAGE
RIVER MIN TO SHANGHAI	1056
River Min, 1056; Fuchau, 1060; Double Peak Island, 1064; Namquan Bay, 1066; Sheipu Road, 1073; Kweshan Islands, 1075; Chusan Archipelago, 1077; Chusan Island, 1083; Tae-shan Island, 1091; Volcano Islands, 1092; Gutzlaff Island, 1096.	
Yung River, 1098; Ningpo, 1099; Chapu, 1102; Hang-chu fu, 1103.	
The Yang-tse Kiang, 1103; Main or Shaweishan Channel, 1106; South Entrance, 1108; Directions for Approaching, 1112; Wusung River, 1117; Shanghai, 1122; Wusung to Hankow, 1126.	

CHAPTER XXIV.

FROM THE YANG-TSE KIANG TO THE LIAU-TUNG GULF.....	1128
General Description, Winds, &c., 1128; The Yellow River, or Whang Ho, 1131; Shantung Peninsula, 1138; Chifu, or Yentai Harbour, 1142; Teng-Chau, 1144; Strait of Pe-chili, 1145; Tatsing Ho, 1147; Pei Ho, 1147; Tientsin, 1147.	
Gulf of Liau-tung, 1153; Great Wall, 1153; The Liau-ho, 1154; New Chwang, 1154; Bittern Shallows, 1158; Quang Tung Peninsula, 1159; The Korea, 1161; Port Hamilton, 1162.	

CHAPTER XXV.

THE JAPANESE ARCHIPELAGO	1163
1. GENERAL DESCRIPTION	1163
Treaty Ports, 1165; Climate, 1165; The Japanese Current, or Kuro Siwo, 1167.	
2. SOUTH AND EAST COASTS OF THE ARCHIPELAGO.....	1168
The Luchu Islands, 1168; Van Diemen Strait, 1171; South and East Coasts of Kiusiu and Sikok, 1171; South-East Coast of Nipon, 1172; The Bay of Yedo, 1182; Yokohama, 1187; Volcanic Islets S.E. of Japan, 1192; The East Coast of Nipon, 1195.	
3. THE SETO UCHI OR INLAND SEA.....	1201
The Boungo Channel, 1202; The Kii Channel, 1202; Isumi Strait, 1207; Hiogo and Kobé, 1209; Harima Nada, 1211; Bingo Nada, 1213; Misima Nada, 1216; Iyo Nada, 1217; Suwo Nada, 1218; Simonoseki Strait, 1218.	
4. THE GOTO ISLANDS AND WEST COASTS OF KIUSIU AND NIPON ...	1224
Goto Islands, 1224; Meac Sima Group, 1229; Kosiki Islands, 1229; Kagosima Gulf, 1231; Simabara Gulf, 1233; Nagasaki, 1239; Directions from Nagasaki to Simonoseki, 1241; West Coast of Nipon, 1244; Port Niegata, 1246; Tsugar Strait, 1248; Hakodadi Harbour, 1250; Yezo Island, 1253.	

APPENDIX.

NAMES, MONEY, WEIGHTS, MEASURES.

THE INDIAN ARCHIPELAGO

showing the WIND SYSTEMS

in the N E and N W Monsoons

THE
INDIAN ARCHIPELAGO,
ETC.

CHAPTER I.

I.—WINDS AND SEASONS.

THE Great Archipelago, which lies between Asia and Australia, by far the largest of the insular regions of the world, covering, as it does, an area of about six millions of square British miles, has been vaguely termed, by various authorities, the East India Islands—the Asiatic, or Eastern, or Oriental Archipelago, or the Malay Archipelago; but, following its great historian, Mr. John Crawfurd, we prefer to designate it as the *Indian Archipelago*, a name, also, by which it is generally recognised.

The Equator passes nearly through its centre, and thus much of it lies on the division between the meteorological systems of the North and South hemispheres, the general particulars of which have been recounted and described in our former works. This peculiar physical condition renders the attempt to define the characteristics of its climatology somewhat complicated and difficult.

It might be supposed that along this neutral line of separation, under the great cloud-ring, as it has been termed by Captain Maury, that there would be some uniformity of wind and weather. Not so, however, for the relative influences of the vast land of Australia, on the one hand; those of the continent of Asia on the other; the direction of the evaporating winds blowing over the Indian Ocean to the West, or over the Pacific Ocean on the eastern side, cause the climate and characteristic weather of the eastern or western portions of the Archipelago to be very different from each other.

For these reasons the changes in the monsoons, the alternation of the wet and dry seasons, in some parts, are very puzzling and difficult of explanation; a fact, also, due in some degree to the want of long series of accurate observations which would be required to elucidate them.

A large portion of the islands thus lies in what has been termed the "doldrums" of mid-ocean, and on the line of the maximum rain fall. This latter arises from the trade-winds in passing over the ocean, evaporating so much from the surface, that on their reaching this central line, or before that occurs, the winds become surcharged, and great deposition follows. It will be manifest that the case is altered when the wind has to pass over great breadths of arid land, and thus arises the complication caused by the reversed monsoons.

The disturbing effect of land influences on the great aerial currents, is more apparent in the Indian Seas than in any other part of the world. The result is a complete reversal of the N.E. trade, and in a minor degree of the S.E. trade wind, producing the well-known phenomena of the monsoons—winds which blow one-half the year in one direction, and in the other half in the opposite.

In the northern winter, when the sun is *South* of the Equator, and the great Asiatic continent is cool, the regular N.E. trade-wind prevails over the whole region North of the Equatorial calms, and is generally known as the *North-east Monsoon*, which is only liable to local deflection consequent on the direction of the land, its mountains, or the channels which separate the islands. To the South of the equatorial calms, the S.E. trade prevails throughout the season of October to April, when the sun is in southern signs; and therefore, in the western portion of the area now under consideration, the winds pursue their ordinary courses.

But when the sun enters into North latitude, or in the northern summer, and especially about the northern solstice, it is vertical over an immense area of land South of the Himalaya Mountains, the desert regions of Arabia, the burning plains of Western India, countries where the earth is fire, and the wind flame; and when this intense heat is extended to the southern portions of China, the S.E. trade-wind, receiving a *northern* impulse, follows up the retreating N.E. trade to the foot of the Himalayas, towards the northern tropic, drawn thither by the intense heat of the vertical sun, receiving this northern impulse, and that impulse carrying it into a region of less rotatory velocity than that which it has left, it assumes a relative S.W. direction, and is called the *South-west Monsoon*.

The features and seasons of this wonderful wind have been recounted in our volume on the Indian Ocean, pages 32—58; and it is there shown that it has a progressive course northward, in its greatest strength, along the African coast, reaching Bombay nearly a month later than it sets in in the commencement.

The effects of this S.W. monsoon are felt very far beyond the coasts, upon which its first furies fall in the burst of their commencement. The high temperature it brings advances so far to the North, that over ground per-

petually frozen at the depth of a few feet, the limit of arboreal vegetation extends in Siberia, even to 72° N. latitude.

While this deflected S.E. trade-wind, in the form of the S.W. monsoon, North of the Equator, is blowing between May and October, the S.E. trade proper prevails over all that part of the Indian Ocean which is not skirted to the South by large tracts of land. Where this is the case, as in the Java Seas as far as New Guinea, which lie North of the great Australian continent, there is again a double maximum temperature in the sea and the land, and the phenomenon of a N.W. monsoon taking the place of the S.E. trade.

The monsoons, therefore, of the Indian Archipelago are not *two* in number, but are *four*—the N.E. and S.W. to the North of the equator, and the S.E. and N.W. to the South of the line. To the two first the northern parts of Sumatra, Borneo, and Celebes, the Philippine Islands, and the Malay Peninsula, as well as the whole of the China Sea, are subject. To the two latter the southern parts of the above-named islands, with the range between Java and New Guinea, and the northern part of Australia, are subjected.

There is one natural indication of this superabundant rainfall in the exuberant vegetation manifest in most parts of the Archipelago. The greater portion is covered with one vast ever-verdant forest, clothing the land and the mountains from the shore to the summits of their loftiest peaks. In some parts this dense and gloomy jungle is not seen, and in its place are arid hills and plains, scantily covered with shrubs and trees.

The naturalist, Mr. Wallace, has well defined these and other characteristics, which need not be detailed here. A few words will suffice. Sumatra, New Guinea, Borneo, the Philippines, and the Moluccas, are all forest countries, except a few small and unimportant tracts. To this there is one important exception in the island of Timor, and all the smaller islands opposite, in which there is absolutely no forest, such as exists in the other islands, and their character extends in a lesser degree to Flores, Sumbawa, Lombok, and Bali.

In Timor and the islands between it and Java the vegetation is of the same character as that of Australia. This peculiar character is most probably owing to their proximity to that great continent. The S.E. monsoon which lasts for about two-thirds of the year (from March to November) blowing over the northern parts of that country, produces a degree of heat and dryness which assimilates the vegetation and general aspect of the adjacent islands to its own. A little farther eastward, in Timorlaut and the Ki Islands, a moister climate prevails, the S.E. winds blowing from the Pacific through Torres Straits; and, as a consequence, every rocky islet is clothed with verdure to its very summit. Farther West, again, as the same winds blow over a wider and wider expanse of ocean, they have time to absorb fresh moisture, and we accordingly find the island of Java possessing a less

and less arid climate in the dry season, till on the extreme West, near Batavia, rain occurs more or less all the year round, and the mountains are everywhere clothed with forests of unexampled luxuriance.

Mr. Wallace continues—Speaking generally, the whole south-western part of the Archipelago, including the whole range of islands from Sumatra to Timor, with the larger half of Borneo, and the southern peninsula of Celebes, have a dry season from April to November, with the S.E. monsoon. This same wind, however, bends round Borneo, becoming the S.W. monsoon in the China Sea, and bringing the rainy season to northern Borneo and the Philippines.

In the Moluccas and New Guinea the seasons are most uncertain. In the S.E. monsoon, from April to November, it is often stormy at sea, while on the islands it is very fine weather. There is generally not more than two or three months of dry, hot weather, about August and September. This is the case in the northern extremity of Celebes and in Boruru; whereas, in Amboyna, July and August are the worst months in the year. In Ternate it is difficult to find out which is the dry and which the wet season. The same is the case at Banda, and a similar uncertainty prevails in Menado, showing, perhaps, that the proximity of active volcanoes has a great disturbing meteorological influence. In New Guinea a great amount of rain falls more or less all the year round. On the whole, the only statement that can be made seems to be that the countries within about 3° on each side the equator have much rain, and not very strongly contrasted seasons, while those more South or North in latitude have daily rains during about four months in the year, while for five or six months there is almost a cloudless sky and a continual drought.

There is one evidence of the uncertain nature of the aerial currents, and of their varying direction and intensity in the frequent occurrence of waterspouts in some localities, as in the Malacca Straits. These columns of vapour or water, formed by a small vortex, are described at length hereafter, as seen in that strait, and are probably in some measure due to the peculiar configuration of the transverse line mountains crossing the normal line of direction of the prevalent winds.

These brief, general remarks will suffice to give a notion of the meteorology of the central or equatorial portion of the Indian Archipelago North and South of these limits. The remarks that have been given in the introductory chapter of our Indian Ocean Directory, will be equally applicable to this portion of the world.

Storms are of rare occurrence, and typhoons are unknown. They only occur beyond the limits of the equatorial calms, and are seldom felt so far South as the northern part of the Philippine Islands. On the coast of China they are experienced in both monsoons, as further alluded to hereafter.

In the Gulf of Siam, in the China Sea, and on the coast of China, the alternating monsoons prevail. In the Gulf of Siam they are comparatively feeble and of short duration. Farther to the East and N.E. they are more decided. The S.W. monsoon commences about the middle or end of April in the China Sea, a little after it is felt in the Gulf of Siam and Tongking, and before it reaches the northern part of its area. It also lasts longer in the southern part of its course than it does in the northern. It is at its height in June, July, and August. The N.E. monsoon or the bad weather season, sets in in the northern part of the China Sea about the end of September or early in October, and lasts till February or March. It sets in with a burst of stormy weather, lasting about a week or ten days, and is in its strength in November, bringing much rain and a turbulent sea. In a subsequent page a further notice of the monsoons will be found.

The ensuing remarks on this branch of our work, derived from various sources, is arranged in a geographical order, as being most convenient for reference. The foregoing introductory portion being sufficient to elucidate the general subject. In them there is necessarily some repetitions. The same topics having to be discussed in each case, necessarily involves this repeated allusion to one subject.

MALACCA STRAIT.—Although the Malacca Strait is within the region of the N.E. and S.W. monsoons, yet the winds are very variable within its limits. There are various reasons for this; the one is, that it lies almost within the limits of the equatorial calms, and therefore the monsoons reach it with diminished force; another is the high land of Sumatra, which impedes the course of the S.W. monsoon, and the N.E. monsoon being the fine season here, the wind is never very strong.

The land and sea breezes are regular on the West coast of Malacca, and also on the N.E. coast of Sumatra which limit the Strait. The monsoons are not always regular, except when they are at their height in the surrounding seas, and at the same time the winds are only moderate in the channel, and only last a part of the day.

The *north-east monsoon*, which, as before stated, is the fine season, lasts from November to May; the S.W. monsoon, bringing rain and thunder, generally commences at the end of April or the beginning of May, and ceases in October. In November the winds often come from the West, and during this monsoon the weather is in general cloudy and rainy, especially during the period that it is strongest. In October and November, at the end of the S.W. monsoon, the winds often vary from N.W. to W., but when the monsoon sets in from the N.E. they are regular in November. The winds are very strong till the month of March, but principally during December and January. Sometimes they vary to N. or N.W., and always during the months of the N.E. monsoon the breezes from the West last during one or two days. During the season of the N.E. monsoon the winds

vary between the N.N.E. and E.N.E. Towards the end of February and March, and sometimes also in the beginning of April, the breezes from the N.E. veer towards the North, and are light and variable. It is found also that the breezes are interrupted by calms during the middle of the day, but during the night and at sunrise they are fresh. The coast of Malacca is much less subject to calms during this monsoon than that of Sumatra.

The *south-west monsoon* is at its height in June and July. During the four months from May to September the winds in the Strait blow principally from S.W. to S., that is, when the S.W. monsoon is at its greatest height in the open sea. During this monsoon calms occur on the N.E. coast of Sumatra, but less frequently there than on the coast of Malacca, and they are rarely of long duration. In general it is calm in the middle of the day, and fresh breezes in the night and at sunrise. It is only in the northern part of the Strait of Malacca that the monsoons are regular.

During the S.W. monsoon sudden and heavy squalls come off the Sumatra coast, generally during the early part of the night. From their direction they are called *Sumatras*, and are accompanied by loud thunder and heavy rain. They are probably occasioned by the mountains on the Pedir coast, and blow sometimes for six or eight hours at a time, strongest at their commencement. In Malacca Road they generally set in at 7 or 8 p.m., and are at their height at midnight, and have caused many ships to part their cables.

The wind does not often come from the N.W., but at times it blows right through to Singapore. They come on very suddenly and violently, but do not last long. They are generally preceded by a black cloudy arch, rising rapidly from the horizon toward the zenith, which only allows sufficient monition to reduce sail as quickly as possible, and should a ship be at anchor, she should immediately weigh, or the burst of the storm will not allow her to do so.

Water Spouts.—In the very excellent and graphic account of the Horsburgh Lighthouse and its erection in the Strait of Malacca, by J. T. Thomson, Esq., F.R.G.S., are some interesting remarks on this curious phenomenon, which, as before stated, is somewhat frequent in these seas. The opportunities afforded during the progress of the works in 1847—1851 gave many unusually good opportunities for observing the peculiarities of their action, of which the following good account is given :—

The curious phenomenon, popularly known as the water-spout, was frequently seen in the Straits, and on two occasions I was fortunate enough to observe them in full action, at a distance of little less than half a mile. On the first occasion, when on board the gun-boat *Charlotte*, off Barbukit Point, at 4 p.m. on the 29th May, a heavy cloud, with rain about to fall from it, was observed to be approaching, driven by the S.W. breeze then blowing.

To the southward the atmosphere was observed to be damp and hazy, while to the North it was clear and dry. On the rain reaching the sea a vapour tube was seen to protrude in the midst from the cloud downwards, gradually lessening in its diameter till it reached two-thirds of the distance between the cloud and the sea, and below which point the tube did not descend. The altitude of the cloud was judged to be about 1,000 feet above the surface. A small attenuated column of white vapour was now noticed to rise out of the sea with a hissing noise, and which was soon surrounded by white vapour disengaged therefrom.

This column quickly effected a junction with the large and heavy vapour tube depending from above, into the centre of which it seemed to be received. The water-spout played for about five minutes, during which time the depending tube appeared alternately elongated and shortened, and the vapour surrounding it maintained a spiral motion. The day was hot.

Again, on the 1st of July another was seen from Pedra Branca, bearing S.W., and approaching the rock. This was at 4.15 p.m. The height of the spout seemed to be nearly 1,000 feet, and its diameter halfway up 50. The depending tube revolved with the hands of a watch, or from West by the North to East, &c. In this one, which was of very large diameter, two columns or tubes of vapour seemed to be in action, one within the other. The depending one, whose massive and opaque vapour was derived from the cloud, enveloped the other, which was thin and attenuated and rose from the sea, with the noise above described, and entered the lower end of the depending tube, through which it seemed to ascend up to the cloud.

The ascending column, as usual, disengaged much white vapour from the surface of the sea, and with which its lower end was surrounded. This water-spout depended from a nimbus, and rain was falling all round it. The nimbus was travelling N.E., and the water-spout was on the advanced edge of it. At 4.25 the depending tube gradually wasted away, until it vanished, when the white vapour of the ascending column parted from the surface of the sea and ascended, like the curling of smoke, up towards the cloud, at the same time the hissing noise ceased, and the surrounding minute spray entirely disappeared.* The atmosphere was clear and dry to the N.E., but rainy and threatening to the S.W., from whence the nimbus travelled. Probably twenty others were seen during the season, but at too great distances for satisfactory observations.

It was invariably remarked that water-spouts formed themselves in rain-clouds, or nimbi, at a time when the rain was about to fall or had fallen for a short time; the state of the atmosphere favourable to their formation

* In this one I observed what was entirely new to me, viz., that the particles of vapour contained in the outer and dependent tube, besides being driven in the helical curve round the inner or ascending column, revolved also round the threads of the helix.

would therefore appear to be just when the capability of the air to support the cloud was in a balanced state.

Squalls.—The larger atmospherical disturbances of squalls formed also interesting objects of observation, the frequency of their occurrence in the Straits of Malacca, and the force with which they sometimes press on the sail, render them of too much consequence to the frequenter of these seas to be lightly considered.

The squalls may be divided into local and general, the first forming in the isolated hills, and influencing the immediate districts only, and the latter termed the "Sumatras," as they invariably come from that island, affecting hundreds of miles on the same day.

The local squalls were observed to form on the only high hills within view from Pedra Branca, viz., Bintang and Barbukit. During the calm months of May and June, should the day be more than usually hot, by noon the moisture of the atmosphere was invariably seen to condense on the cool tops of these eminences, and form into high accumulated masses of vapour, by one or two o'clock the atmosphere being refrigerated and rendered dense in the process would rush down from the summits, displacing the hot and rarified air of the plains, and cooling with its accompanying showers the parched soil. At the change of the monsoons, before either had set in to blow regularly, the local squalls would be seen to spread themselves out from the locality of their formation equally in all directions, upon the surrounding plains. But when either monsoon was blowing, they would be carried in the direction of the prevailing wind,—during the S.W. monsoon towards the N. and N.E., and during the N.E. monsoon towards the S. and S.W. Even during the height of the N.E. monsoon, which blows more steadily than the S.W. one, at night its under current of air would always moderate, if not cease, though, as might be seen by the travelling clouds above, the upper current was not arrested in its progress. At the latter end of the monsoon it has not power to overcome the density of the air overspreading the peninsula, created during the cool of the night, until 10 and 12 and even 4 o'clock of the following day. On such occasions, if the weather be fair and hot, the atmosphere will have condensed its vapour on Barbukit Hill, and from whence heavy squalls will proceed across the Straits of Singapore, assisted by the monsoon. Of this we had many instances, heavy N.E. squalls having taken the gun-boats inside of the Straits, while at the same moment, 10 miles distant, an agreeable and permanent N.E. breeze has been experienced out at Pedra Branca.

The laws that have been observed to generate and direct the local squalls may be safely assumed to operate in the same manner, with regard to the general squalls or "Sumatras" that in the Straits come from the direction of that island during the S.W. monsoon. In Sumatra the regular prevailing wind may be supposed to meet obstruction in the high range of mountains,

that intersect the island in a longitudinal direction, and not having strength at all times to overcome the barrier, is curbed, until, as has been seen to be the case with the local squalls, condensed air has been formed on the highlands, which, with its accompanying vapours, rushes down to displace the heated and rarified atmosphere of the valleys and plains on the lee, and being at the same time urged on by the pent up force of the monsoon now let loose, stretches itself far and wide over the Malacca Straits and the generally low-lying surface of the Malayan Peninsula.

These "Sumatras" were found to arrive at Pedra Branca between the hours of 3 and 8 a.m., and if we be allowed to infer with regard to their time of origin that it is the same as obtains in local squalls, viz. from 11 a.m. to 4 p.m., assuming the distance travelled to be 300 miles, their rate of progression will be 19 to 20 miles an hour. This was corroborated by watching their arrival at distant high points of land seen from the rock, and noting the interval of time consumed in their coming to the rock. A storm or gale is generally estimated to travel at the rate of 32 miles an hour; but it is only for the first few minutes that a "Sumatra" assumes this character, and this only in sudden puffs; they soon decrease in force to a high wind, which is said to travel at the rate of 16 or 17 miles an hour. The approach of a "Sumatra" has much to attract the attention of the student of nature. The most imposing characteristic is in the immense arch that it forms, stretching from the zenith to opposite points of the horizon and below the arch, which is of the darkest hue, there are suspended dark grey vapours, about to descend on the surface of the earth. Above the dark arch will be seen light grey fog banks, over which a slighter arch will be spanning, and which is again crowned by white fleecy clouds, contrasting, if the squall approach at daylight, strongly with the blue sky above and the dark masses below.

SINGAPORE.—The following remarks on the climate, &c., of Singapore are by Dr. R. Little, derived from tables furnished him by Captain Elliott, M.E. They are very important, being based on adequate and well digested data. They are therefore given more at length than in other cases:—

Singapore, though within 80 miles of the equator, through its abundance of moisture, either deposited by the dews or gentle refreshing showers, keeps its atmosphere cool, prevents the parching effect of the sun, and promotes continual verdure. It never experiences furious gales. If more than ordinary heat has accumulated moisture and electricity, a squall generally sets in, followed by a heavy shower of rain; these squalls never exceed one or two hours in duration. According as the monsoon blows, you will have them rising in that direction. In 1841, during the N.E. monsoon, there were four squalls from that direction; but the most severe and numerous are from the S.W., which are called Sumatras, and they most frequently occur between 1 and 5 in the morning. The N.E. monsoon blows from

November to March, and after which the wind veers round to S.E., and gradually sets into the S.W., between which points it continues in May, June, July, and September. The N.E. monsoon blows more steadily than the S.W. one. The temperature of Singapore is one or two degrees cooler during the former than the latter, which also brings more rain. It is further remarked that the wind always lulls at night, during the height of either monsoon. During the S.W. monsoon a wind from the South prevails at times, which is termed by the natives Angin Jawa, or Java winds, because it comes from the direction of that island. This especially exists in September, which is attributed to the usual cooling land breeze being replaced in the mornings during that month by the hotter breeze from the sea; as we advance into the interior this hot breeze is not felt.

TABLE OF THE WINDS.

MONTHS.	Number of Hours in which the Wind is in each Quarter.					
	N.W.	S.W.	N.E.	S.E.		
January	1,389	94	2,097	126	} These observations were taken during five years.	
February	645	105	2,154	277		
March	422	276	2,145	537		
April	746	1,213	1,106	655		
May	524	1,070	356	1,028		
June	343	1,627	286	1,549		
July	456	2,142	185	925		
August	661	1,737	210	1,080		
September	481	1,332	287	704		} Four years.
October	941	1,048	726	347		
November	1,085	412	431	231		Three years.
December	1,207	237	1,370	162		Four years.
Total	8,899	11,293	11,347	7,621		

How beautiful an illustration, exclaims the writer, of the little variation we find in the general laws of nature; though how often do we remark how changeable is the weather. From these observations, carried on nearly five years, the wind blows from the N.E. during 474 days 9 hours, from the opposite direction, S.W., during the contrary monsoon, 470 days 13 hours; another deduction is made, that during the months of December, January,

February, and March, the wind blows more continuously from the N.E. than any other direction; while in the months of June, July, August, and September, the wind is principally to the S.W. During November the prevailing wind is N.W., while its antagonist, S.E., blows in the month of June. Another fact is elicited, viz., that in April we have the winds blowing from the direction of N.W. and N.E. 1,852 hours; and from the S.W. and S.E. 1,868 hours. In October we have them blowing from the N.W. and N.E. 1,567 hours; and from the S.W. and S.E. 1,395 hours: thus the wind, in changing from the N.E. monsoon to the S.W., seems to do so gradually from N.E. to N.N.E., then N.W. to West, then S.W.; and, in changing from the S.W. to the N.E., retraces its progress by retaining its westerly direction, and not reaching the N.E. by S., then S.E. and E., but adopting the same direction, by which it reached the S.W. from N.E., viz., a westerly.

In the same paper the following facts are announced with regard to the fall of rain and quantity of moisture in the atmosphere. In 1820, rain fell on 229 days; in 1821, on 203 days; in 1824, on 136 days; and in 1825, on 171 days; giving an average on 4 years of 185 rainy days, and 180 dry in a year. The quantity of rain that falls is well illustrated in the following table:—

FALL OF RAIN AT THE SINGAPORE OBSERVATORY.

SHOWN BY THE NUMBER OF INCHES.

MONTHS.	1841	1842	1843	1844	Total of 4 years.	Average of 1 year.
	Inches.	Inches.	Inches.	Inches.	Inches.	Inches.
January	3.750	22.585	18.070	10.219	54.624	13.656
February	6.750	10.900	3.050	6.923	27.623	6.905
March	5.009	7.220	8.045	4.150	24.424	6.106
April	3.010	10.071	5.645	12.300	31.035	7.758
May	6.095	9.003	9.000	7.775	31.873	7.968
June	7.490	6.320	2.270	6.025	22.105	5.526
July	7.228	5.098	8.500	5.890	26.716	6.679
August	7.095	6.025	5.545	5.750	24.415	6.103
September	4.220	4.250	4.055	5.075	17.600	4.400
October	4.070	21.005	12.145	10.200	47.420	11.855
November	12.225	9.420	9.560	6.060	37.265	9.316
December	6.175	4.350	3.415	8.750	25.690	6.422
TOTALS	73.126	116.244	92.300	89.117	370.790	92.697

It will be observed, from the above, that the greatest fall of rain during these four years occurred in January, 1842, and the least in June, 1843. The year 1841 was unusually dry, 73 inches only having fallen, while the succeeding was unusually wet, 116 inches having fallen. This was caused by the unusual dryness of January and October, in the former year; and the unusual wetness of both in the latter. By examining the average for each month, the seasons will be found to be very equable, the least average being for September and June, which respectively have 4.400 and 5.526 inches, and the greatest being, for January and October respectively, 13.656 and 11.855 inches. During the other months the rain averages from 6 to 9 inches. The annual average fall is 92.697 inches, a quantity which is about 2 inches less than the average fall for the latitude of Singapore, as stated by Humboldt, who gives 96 inches as the average fall at the equator.

With regard to the temperature of the atmosphere, in 1841 to 1845, the mean was $81^{\circ}.247$, the lowest mean of a month being, for January, $72^{\circ}.55$, the temperature increases to May, June, and July, which have $82^{\circ}.30$, $82^{\circ}.29$, and $82^{\circ}.24$ respectively. It is concluded, from the above, that the temperature of Singapore is $2^{\circ}.90$ less than other localities in similar latitudes, and that the range between the mean temperature of May and January extends over $2^{\circ}.76$, and adding up the mean temperature of each month of each year, we have the mean temperature as follows:—

Of 1841	1842	1843	1844	and	1845
As 81.28	81.6	81.09	80.82	and	81.66

From which this inference is drawn, that in five successive years the mean temperature did not vary one degree.

Deduction made from other tables gave the maximum temperature for five years at $87^{\circ}.5$, and the extreme minimum $74^{\circ}.7$; the former occurred in June, 1842, and the latter in January, 1843, giving the greatest range as $9^{\circ}.8$. To this I may add, that I have seen the thermometer down to $68^{\circ}.5$ in January of the present year, at Bonny Grass, the residence of Dr. Little, where the thermometer was hung in a building, well protected from the sun, but open on all sides.

From observations taken by Captain Davis during six years, the mean temperature was—

In 1820	1821	1822	1823	1824	and	1825
As 79.5	79.5	80.2	79.8	81.0	and	81.4

These observations were taken at 6 a.m. and noon, and the following taken at Singapore Observatory, during the same hours, gives—

In 1841	1842	1843	1844	and	1845
As 82.0	82.08	81.58	83.7	and	84.04

Thus showing that, in 20 years, the temperature of Singapore Town has increased $2^{\circ}.48$. The cause of this advance of the temperature is assigned to

the country, within 3 miles of the town, being now clear of jungle, and cultivated, which formerly was covered with primeval forest.

Dr. Little concludes his remarks by stating the mean annual solar radiation to be $121^{\circ}.50$, the mean terrestrial $66^{\circ}.10$, and the hourly mean reading of the barometer 29.884 inches, which never varies more than the twentieth of an inch.

Thunder showers frequently occur, particularly at the breaking up of the monsoons. That interesting and wonderful atmospherical phenomenon, called a water spout, is often to be seen in the seas and straits adjacent; they would more properly be called whirlwinds charged with vapour. They occur generally in the morning, between eight and twelve o'clock, and rise to the height of half a mile, in the distance appearing like large columns, supporting the heavy masses of Cumuli above them. I noticed, in October, 1841, six of these attached to one cloud, under action at the same time. In August, 1838, one passed over the town and harbour of Singapore, dismasting one ship, and sinking another, and carrying off the corner of the roof of a house in its passage landward. No other atmospherical disturbances of any moment occur. The typhoons of the China Sea, or Bay of Bengal, do not reach these parts, nor are there hot winds to parch the land. The equable and quiet state of the atmosphere and seasons of these regions consequently create analogous properties in the face of indiginous vegetation. Evergreens abound, few trees shed all their leaves at one time, and many of fruit trees produce all the year round; such that have their seasons of fruit will frequently produce their crops out of season, having small irregular ones at intervening times. This continual verdure is perhaps more grateful to the eye of the stranger than to those who have been accustomed to it; to the former it bears the pleasant appearance of exuberance and fecundity, where the lofty forest not only hangs over the beach, but clothes the mountains to their tops, so unlike the sterile bareness of higher latitudes; while to the other, the continued sameness palls the senses, which lack variety and call for a sterile winter only that they may renew, with doubly keen conception by the contrast, their acquaintance with the beauties of returning summer that here always reigns.

STRAIT of BANKA, &c.—The winds in Banka Strait follow the direction of the coasts, though with slight variations from the influence of the land and sea breezes; and fresh breezes may always be expected when working against the monsoon.

During the shifting months of the S.E. monsoon, sailing vessels are often five and six weeks in making the passage from Singapore to Bauka Strait. In the month of September H.M.S. *Saracen* had the S.E. monsoon strong, with much rain; about the equinox there were several heavy squalls. This monsoon is generally supposed to shift about the beginning of October, but during the whole of this month the wind was only 4 hours from the north-

ward, there being a succession of calms, light southerly airs, a close muggy atmosphere surcharged with electricity, and frequent heavy Sumatra squalls or south-westers. On the 9th of November the monsoon shifted with furious gusts.

These squalls at this season generally take place at night, accompanied with heavy rain, thunder, and lightning. They are of short duration, and it was noticed that when one occurs about the time of full and change, another may be expected an hour later every night till the next change of the moon.

In the **Strait of Sunda** the winds vary between S.S.E. and E.S.E. from April to October, and are then called the eastern monsoon. They are generally W.N.W. and N.W. during the western monsoon, which succeeds the preceding one. This monsoon comes in November, and brings bad weather. There are alternate breezes in this strait; they blow from the South before noon, and from the North in the afternoon, and are separated by an interval of calm.

On the *South Coast of Java* the wind blows from the N.W., while the N.E. monsoon is blowing to the North of the line, from October to April: it ceases in March. In April the winds are variable; and in May are settled in the East. The weather is fine, and the winds are strongest from June to August. In October the S.E. monsoon becomes weaker; and, till the return of the N.W. monsoon, the winds are variable. In May and November a great deal of rain falls on this coast. In February and the first part of the month of March, as well as in October, that is when the monsoon changes, the land and sea breezes are alternately regular; they are weaker in October, February, and March. In these two last months, and also in April, the land breezes commense with squalls, or at times with a heavy storm. After this has passed, the breezes from the land are moderate till the return of the sea breeze. In April and May, on this coast, the sea breeze commences with a heavy squall, or a storm, which does not last long.

JAVA SEA.—The following summary is by Captain Jansen, as quoted by M. Krecke:—

During the month of February the westerly monsoon is still strong and steady: in March it is interrupted by calms and squalls, which become less frequent and less violent in April. Now the easterly winds burst in suddenly; clouds collect and darken the sky, while there are incessant thunderstorms by day and night, and waterspouts are very common.

If the wind changes again to West or North, the sky clears again; but this wind does not last, and the clouds soon re-appear. The rain gradually ceases during the day time, and the S.E. winds prevail throughout the month of May. At the time of the reverse change of the East to the West monsoon, the calms last for a shorter period, as the wind assumes a decided N.W. direction at once, and the showers of rain, accompanied by violent squalls,

are felt only for a short time. Thunder storms are abundant, but only on land, or close to the coast. Toward the end of November the N.W. monsoon is again permanent.

On the *North Coast of Java*, from May to July, the winds blow from the S.E. with a return of the opposite winds, which vary to the N.E. near the West point of the island. During the S.E. monsoon, the winds are S.S.E., varying to E.S.E., and it is fine weather. In October the winds are light, weak, and variable. The N.W. monsoon generally commences in October, but sometimes it occurs in September, or is retarded till November, and ends in March. This is the season of the heavy rains. In the month of December the West winds predominate. Towards the middle of February squalls and tempests occur, accompanied by rain. At Batavia, from April to November, the weather is tolerably fine; but, after that, rain ensues till the end of the year.

On the *Southern Coast of Borneo*, from the Pulo-Laut to the Strait of Sunda, the S.E. monsoon prevails from May to September, like the West of Java. At the same time, in the Indian Ocean, the S.W. monsoon is found to the North of the line. From September to April the West winds blow on this coast, the rains are constant, and the weather often very bad. During the S.E. monsoon the weather, though still humid, is less rainy than during the N.W. monsoon.

Observations carried on for a series of years (1850—1856) at *Palembang*, on the N.W. coast of the south-eastern part of Sumatra, have led to the following results:—From November to March the prevalent winds are westerly and north-westerly. This is the regular rainy season during the West monsoon. April is the month of the change of the monsoons, when thunderstorms are most frequent. From May till September, easterly and south-easterly winds (of the East monsoon) are permanent, and the change comes in September or October.

From this it appears that the wind shifts pretty regularly round the compass, for its mean direction for each month in rotation, counting from South to West, is—

Jan.	Feb.	March.	April.	May.	June.
S. 7° W.	S. 20° W.	S. 30° W.	W. 25° N.	W. 79° N.	W. 85° N.
July.	August.	Sept.	Oct.	Nov.	Dec.
N. 6° E.	N. 21° E.	N. 18° E.	N. 25° E.	E. 30° S.	S. 4° W.

At *Banjermassing*, on the South coast of Borneo, the S.W. monsoon prevails from December to March; the S.E. monsoon from April to October. The change seems to be of short duration. Rain is most abundant from July to October, while thunderstorms are more frequent in the months of November, December, and May, at times consequently later than the changes of the monsoons. There is, however, in this respect, a considerable variation be-

tween individual years. In 1851, eighteen thunderstorms were observed, while eighty-three took place in 1857.

A close examination of the direction of the wind leads to the following results:—The predominant direction of the wind in December is S.W. and W.S.W., and it becomes more westerly in January and February. In March the direction during the day is less constant. In April the S.E. wind becomes prevalent, and increases in steadiness up to August and September. In October it gets round to the southward. In November this is the case, in the morning hours, in a still higher degree; in fact, in the afternoon the wind goes somewhat past the South towards the West. At last, in December, the S.W. monsoon is definitely established.—(*Krecke.*)

GULF of SIAM.—The following account of the winds and weather is by Lieutenant John Richards, R.N., who surveyed the gulf in H.M.S. *Saracen*, in 1855-8. The *N.E. monsoon* in the Gulf of Siam sets in early in November. It is usually preceded by a month of squally, variable, and uncertain weather.

In the months of November, December, and January, the wind blows between N.N.E. and East; generally strong breezes, with the temperature occasionally as low as 65°. Along the eastern shore of the gulf at this time the sky is frequently unclouded for a week together, but on the opposite coast the weather is wet and stormy.

In November and December, strong squalls, with heavy thunder and lightning, are occasionally met with near Pulo Panjang.

Towards the end of January the wind blows more from the eastward, is steadier, and abates in strength.

In February the wind is more constant from E.S.E. than from any other point; it veers between S.E. and N.E., with occasional calms and squalls. Fine weather and smooth water now prevail all over the gulf.

In March the monsoon cannot be depended on. In the middle of the gulf calms prevail; with southerly winds near the shore, and occasional land and sea breezes. Towards the end of the month the weather becomes hot and sultry.

April is the hottest month of the year; calms may be expected near the middle of the gulf; land and sea breezes near the shore, and occasional slight squalls. From the 2nd of April until the 15th of May, 1856, the *Saracen* remained at anchor off the Bangkok Bar, during which interval the river was surveyed, and the four-mile boundary line round the town of Bangkok defined. Towards the middle of April the weather changed, and became gloomy and threatening; at the latter end of the month there were several days continuous and heavy rain, after which the weather became snowery, and continued so during the remainder of the above period. On the 15th the *Saracen* sailed for Singapore, and in the upper part of the gulf had calms and light winds from the eastward, drawing round to the

southward as the Redang Islands were neared. A southerly current was experienced the whole way down to Pulo Aer.

S. W. Monsoon.—In May clouds begin to bank up, and an occasional shower relieves the intensity of a vertical sun. The S.W. monsoon sets in about the middle of the month, sometimes preceded by light flaws of wind and fine weather, but usually with squally weather, and occasional heavy falls of rain. In June, July, and August the S.W. monsoon blows strong, with occasional showers, but generally very fine weather along the western shore of the Gulf; out in the middle a rough sea, and along the eastern shore strong breezes with much rain, and occasionally a fresh gale.

In September the wind is very unsteady, veering between S.W. and W.N.W. in strong gusts. Heavy and continuous rain may be expected in this month.

In October the wind veers between West and North, and abates considerably in strength; the rain squalls are less frequent. Towards the end of the month the wind settles in the North, and the cold weather and fine season set in. Vessels bound to the Gulf from Hong Kong will not profit much by leaving China earlier than the middle of this month.

At the bar of Bangkok River land and sea breezes generally prevail, veering by the East or West according to the monsoon.

The S.W. monsoon is scarcely felt close in shore, between Cape Patani and the Redang Islands, its course being interrupted by the high land in that neighbourhood. To the southward of Pulo Kapas it takes the direction of the coast, veering a few points on or off shore by day or night, under the influence, alternately, of the sea and land breezes.

White squalls are said to prevail in the Gulf, particularly in the month of May.

Black squalls are frequent in the S.W. monsoon; they rise in the westward, accompanied by a heavy bank of clouds, and blow with great violence for a short time, and are frequently accompanied by heavy rain.

Heavy gales are unknown in the Gulf.

Cambodia.—On the coast of Cambodia, in June, July, and August, there are heavy rains, accompanied by S.W. winds. The monsoons are not regular on this coast, and land and sea breezes are met with when the prevailing monsoon is weak. The breezes do not last more than five or six hours during the S.W. monsoon, and are not so fresh as those which prevail at the end of the N.E. monsoon. In Pulo Timoan and Pulo Condore the N.E. monsoon is established towards the 15th of October with fine weather. The S.W. monsoon brings rain, and lasts during eight months. Near these islands, in November, there are alternately calms, storms, accompanied by rain, and typhoons. At Pulo Condore the rains last for a month after the N.E. monsoon is established, and at Pulo Timoan the wind becomes unsettled in September, and the change of monsoon brings bad weather. In

November the weather is fine. On the coast which extends between the Gulf of Siam and Cape Padaran the S.W. monsoon blows along the shore. Sometimes, near the land, during the night, a light land breeze is found succeeded by an interval of calm, which is followed by the wind of the monsoon, which blows fresh during the rest of the day. On the same coast the N.E. monsoon is established from the end of September or beginning of October to the middle of April.

Cochin China.—On the coast of Cochin China wintry weather is found with cold northerly winds and rain, which prevail from December to February. Heavy rains occur in the months of September, October, and November. During the N.E. monsoon easterly winds are frequent. Between the Paracels and the coast the same wind is found as far as Cape Varela; and in this channel calms are frequent, while on the offing from this bank the monsoon blows fresh and regularly. During the S.W. monsoon, on this coast, the land and sea breezes are tolerably regular, the sea breeze being replaced by a land breeze every evening, which blows every night, followed by a calm light wind, although not always commencing at the same time. This wind generally lasts till noon, when the S.E. wind again sets in. On the coast of Cochin China the winds are variable during the whole year, and the monsoons generally light. The leeward coast is not dangerous with the N.E. monsoon.

The EASTERN PASSAGES.—The foregoing remarks refer to the great highways which lead directly into the China Sea from the Indian Ocean, and are taken by most ships during the favourable monsoon.

The following will describe the winds and weather of that part of the Indian Archipelago to the eastward of Java, among the islands and channels which are sometimes called the eastern passages, those used during the adverse monsoon. Some of these remarks are extracted from the late Captain de Kerhallet's work on the meteorology, &c., of this region.

Around the islands East of the Strait of Sunda, as far as Timor, the monsoons are the same as have been described before; that from the East commences in May, and the winds vary from East to S.S.E. These winds are strongest in June and July. This monsoon is finer than that from the West, which brings bad weather during November and December. The rains commence in this month, accompanied by squalls and winds. The western monsoon commences in November, and attains its greatest force in January. The rains fall from December to the middle of February, accompanied by storms and tempests. Then the monsoon gradually weakens till March; in April the winds are variable, and the weather is fine.

Among the Archipelago and the intervening seas to the South and East of Borneo there are usually two monsoons, generally called the North or West monsoon, and the South or easterly monsoon, some saying that the wind hangs more to North than to West in the former and more South than East

in the latter. The first corresponds with the N.E. monsoon North of the equator, and the second with the S.W. monsoon. But from the configuration of the islands, the direction of their mountain chains, and the effect these have in causing the rain clouds to deposit their moisture, these alternating monsoons are much less regular than they are in the open ocean, far from these disturbing causes. In general, it may be remarked that to the South of the equator, as far as the parallels of 10° or 12° S., the direction of the wind differs ten or twelve points from that prevailing to the North of the equator at the same period; that is, to the North of the equator if the wind or monsoon is from North, that to the South of the line will be N.N.W.; and if the southerly monsoon is blowing North of the equator, in the Eastern Passages, it will be from E.S.E. or East.

In the *Strait of Bali* the wind often blows from the North with much violence, and in that of Sapy there are alternate breezes from land and sea. They blow from the South in the morning, and from the North about two hours after noon. There is often an interval of calm between them. In the other straits, to the East of Java, the winds are of a singular nature, and also very variable.

In the *Java Sea*, as in the neighbourhood of the Moluccas, the N.W. monsoon commences in the first part of November, but does not attain its greatest force till near the end of December. It lasts till the end of March, when the intervals of calm commence, with variable winds, squalls, and rain. The S.E. monsoon commences in April, and gets gradually stronger till May; it ends in October, during which month the winds are variable. This is the law generally observed in these two seas, except that it must be remembered that there are variations in the direction; it draws sometimes to the North and West, and sometimes to the South and East. Besides this, the changes of the monsoons do not take place at settled times; that of the S.E. is subject to calms, and the wind is less stormy, while it lasts, than during that of the N.W. monsoon.

Arafura Sea.—In the sea lying between New Guinea and Timor, the easterly monsoon commences in April, and continues until the beginning of October, when, after a few weeks of variable winds, the westerly monsoon sets in, and continues without intermission until the beginning of March. In the southern part of the Indian Archipelago generally, the easterly monsoon is attended with fine weather, but on the S.W. coast of New Guinea, and among the islands to the westward, as far as the East coast of Celebes, frequently squalls, with heavy rain, are experienced at this season, often accompanied with considerable swell from the southward, while, during the remainder of the year, the weather is fine. This rule, however, does not extend farther to the westward, for from Celebes to the western extremity of the Archipelago, and also on the North coast of Australia, the westerly is the rainy monsoon. The monsoons, when at their height, usually blow in

an E.S.E. and W.N.W. direction ; but towards the change they draw round more to the southward, sometimes continuing several days at S.W.

The easterly monsoon brings rain, on the eastern part of the Archipelago, as far as Celebes ; beyond this, to the westward, the westerly monsoon is the rainy season. The effect of this on the vegetation of the different islands has been before alluded to. It would seem to be only accounted for by the fact that the monsoons are deprived of their rain-cloud soon after encountering the land. The easterly monsoon, blowing over the Pacific, breaks over New Guinea, the Moluccas, and the eastern side of Celebes, the high mountains of the first-named keeping the rainfall off the North coast of Australia and Timor. The southern part of the latter and northern Australia are open to the westerly rain-bearing winds of the Indian Ocean.

On the *West Coast of New Guinea* two monsoons occur, one from the S.E., which lasts from April to October ; and the other from the N.W., which commences at the end of October, and terminates towards the end of April. In January the wind near this island varies from N.N.W. to N.E. ; in the spring the weather often changes ; and in March, April, and May, the weather is squally. From June to September a great quantity of rain falls ; and from October to May the weather is fine and calm, without clouds or fogs.

To the *North of Bourou and Ceram* the S.E. monsoon varies between S.S.E. and S.S.W., and at the Isle of Amboyna from East to S.E. In the same isles the N.W. monsoon varies from W.S.W. to N.W. This last, which is often called the westerly monsoon, is during the stormy season in these isles, and ends in April. The S.E. monsoon commences in March, and lasts till November, and is the rainy season. During this monsoon violent storms occur in the Moluccas, and rain falls abundantly over the largest islands of the Archipelago. This monsoon ceases in November. The North and N.W. monsoon does not set in till some time after ; for, during two months, the winds are alway variable in these seas towards the end of the monsoons. From October to April the weather is moderately fine.

In the Moluccas, which occupy a space between 5° North of the equator, and 1° South latitude, the winds are much less regular, because there is a great difference between the monsoons which exist in the two hemispheres at the same time.

In that part of the *Arafura Sea* between New Guinea and Australia, during the month of January and the commencement of the western monsoon, the winds are generally from the N.E. to North, occasionally drawing to the westward. Near the N.E. coast of Australia, as far as the parallel of 14° S., winds which vary from N.E. to W.N.W. prevail, and more to the South they come from East and E.S.E.

Between these two monsoons there are frequent calms of long duration, and the time of the change from the S.E. to the N.W. monsoon is the period

when these long calms mostly prevail. When the monsoon is about to be established, westerly winds blow for five or six days; then they cease, and are sometimes succeeded by light variable winds for a month. Then, at the following syzygy, the monsoon becomes established, accompanied by gloomy rainy weather, and sometimes squalls, for two or three days. The weather then clears, and there is a moderate breeze for some time, producing clearer and finer weather than is felt during the S.E. monsoon. Two or three days wet weather is to be expected at the time of the syzygies, although sometimes for five or six weeks continual fine weather may have prevailed. Near the land the weather is always more stormy and rainy than it is farther out at sea, although at the limit of the monsoon in the parallel of 15° S. latitude the weather is generally wet and stormy. The mean direction of the wind is nearly W.N.W., varying to N.W. and S.W. at the time of the syzygies; during these periods it is often W.S.W.

In the *Timor Sea*, and that part of the sea situated between the Arru Isles and the North coast of Australia, as well as in the vicinity of Torres Strait, the S.E. monsoon blows with much regularity. Towards the middle of it, from May to August, it varies from E.S.E. to S.E., and is then very strong. The Malays call this the white season. In the beginning and near the end of this monsoon the wind is due East, sometimes veering to E.N.E. During this monsoon the breeze is generally fresh and steady when the moon quarters, and we find calms and unsettled weather at the time of the syzygies. This fact has also been remarked in the trade wind of the eastern coast of Australia. In Torres Strait easterly winds prevail. The westerly monsoon does not blow steadily, but is often modified by the East wind, which is then light and variable, lasting several days, till it strengthens to a fresh breeze.

On the *North-west Coast of Timor*, in September and March, the N.W. monsoon, varying to N.N.W., is in force. In April or May it is followed by that from S.E., varying to S.S.E., which ends in October. The N.W. monsoon, as before stated, is the bad weather season, and the winds in December are very violent. This monsoon is only well established at the end of November or December, and heavy winds, accompanied by rain, blowing between West and North, continue till February. At the end of April, or beginning of May, the wind returns to East, varying to South; they are very strong on the North coast of the island, where it is then the fine season. The strongest winds vary West by South and N.N.E. On the opposite coast of this island there is a great difference between the winds. The S.E. monsoon is very feeble on the South coast, and strong on the North. On the South coast there are storms during the first part of October; while on the North these are only felt in December. During the fine season the land and sea breezes are strong on both coasts. On the South the land breeze varies from N.E. to North, the sea breeze from S.S.E. to S.S.W.

The *Island of Celebes*, like that of Borneo, is divided into two parts by the equator, and the same remarks given previously for the monsoons at Borneo, are applicable here. On the South coast the S.E. monsoon is established from May to October, and the S.W. monsoon prevails on that part of the island which is North of the equator at the same time. The S.E. monsoon, which lasts from May to October, on the coast of Celebes, situated South of the equator, brings the driest season. The N.W. monsoon replaces the S.E. towards October, and continues till April, when rain is almost perpetual, and the wind strong. During the two months when the sun is vertical over the island, and near to the syzygies, there are invariably northerly winds and rain. On that part of the island situated North of the equator, the N.E. monsoon in October replaces the S.W., making the fine season. In the North part of the Strait of Macassar, from May to October, a S.E. monsoon is found on the East coast of Borneo; also between Celebes and Gilolo, it is succeeded by the N.W. monsoon, continuing from November to April. In the South part of the Strait the wind is N.E. in April, May, and June; but there is less in August and September. During October, November, December, and following months, fresh breezes prevail from W.S.W. to W.N.W. in these latitudes. Near the West coast of Celebes, from May to October, we find land and sea breezes, while on the opposite coast of Borneo the wind is steady from the South. From November to April, on the western coast of Celebes, the wind varies from W.S.W. to W.N.W.; in April, May, and June, it is from N.E., but is light during the month of August. It has been remarked that when the S.W. wind prevails on the Celebes coast, about 6 leagues off the coast it becomes W.N.W. and N.W. on the coast of Borneo. During the S.E. monsoon, from May to October, a vessel cannot contend against it on the low coast of Borneo; and on this coast, in this season, light land breezes are found, while on the corresponding coast of Celebes, which is elevated, a fresh land wind blows during the night, followed during the day by a sea breeze. In December we generally find alternate winds near Celebes. In August and September the winds are light; but sometimes off this coast storms from the S.W. occur, and long calms.

In the *Celebes Sea and Sooloo Archipelago* easterly winds prevail in October, but are not regularly established till November. In May they are replaced by westerly winds, and in a month become established to terminate in October; the climate is then made up of rain, squalls, and tempests, which take place generally in July and August. In September a heavy mist hangs about the coast of Mindanao. At the commencement of the westerly monsoon the winds are light for some time, with heavy rain, during which the wind blows in an opposite direction, sometimes lasting from the eastward more than a week. Occasionally heavy storms happen until the westerly wind becomes established. During this monsoon the weather is cloudy, rainy, and sometimes stormy; and in this season we find between Mindanao

and Celebes that heavy storms take place from N.W.; the westerly winds sometimes last till November.

In the *Sooloo Sea* the East and N.E. monsoon is not a steady fresh breeze, but often varies. In the neighbourhood of Mindanao the northerly winds never blow fresh, but are often displaced for several days by light changeable winds, which again occurs at the end of January, and it is considered that the same winds prevail from the Sooloo Archipelago to Manila.

The *Island of Borneo* forms the N.W. and western boundary of the China Sea, and is intersected by the equator, and the result is as in Sumatra, that the monsoons of the N.W. coast do not take place at the same time as those on the West coast. The S.W. monsoon prevailing on the N.W. coast from May to October, at the same time as the S.E. monsoon is on the West coast, and the N.E. monsoon blows on the N.W. coast, while the N.W. monsoon prevails on the West coast. On the northern part of Borneo the S.W. monsoon is not established till between the 15th and 30th of May, when there is continual rain. The weather is not so bad in September, and the dry season sets in with the N.E. winds, varying to the East. However, this can hardly be called the dry season; for, in consequence of its position under the equator, the island is incessantly inundated with rain. On the West coast the S.E. monsoon prevails towards the end of May, and fine weather then sets in. From September to April the West or N.W. monsoon occurs, with continual rain and heavy gales.

The weather at *Labuan*, on the N.W. coast of Borneo, is generally very fine; the land and sea breezes are seldom interrupted. A large quantity of rain falls annually, but this generally comes off the coast of Borneo in squalls, which most frequently occur between 8 p.m. and midnight, and blow heavily, especially in June and July. In the S.W. monsoon the land breeze, which usually commences with these squalls, lasts until 7 or 8 a.m., and is a steady, fresh breeze, whilst in the N.E. monsoon it is light and variable, and, if blowing hard in the China Sea, it is not felt at Labuan.

The sea breeze in the S.W. monsoon usually commences at noon, and lasts until 4 or 5 p.m., seldom exceeding a royal breeze; but in the N.E. monsoon it commences earlier, and lasts until 7 or 8 p.m., hanging well to the northward, and blowing fresh. January, February, and March, are the dry months; only 2.2 inches of rain fell in those months in 1865.

The monsoons on the coast of *Palawan* are so subject to interruption, being influenced by local circumstances and other causes, that it is difficult to say at what period either fairly sets in. The barometer is of little use in prognosticating the changes; the difference in the column of mercury for the whole year, seldom exceeding two-tenths of an inch. In general the mercury rises to N.E. and easterly winds, and falls to S.W. and westerly.

In January to April moderate N.E. and easterly winds prevail on the coast of Palawan, and on the coast of Luzon land and sea breezes have been

experienced with considerable regularity. May, and the early part of June, appear to be the finest period of the year on the coast of Palawan, when land and sea breezes prevail with tolerable regularity, the former coming fresh from the South and S.E. in the morning, and the latter from the North and N.W. in the afternoon.

Towards the end of June, and throughout July, unsettled weather, generally commencing about the change of moon, may be expected. A slight depression of the mercury, after a succession of fine weather, frequently indicates the approach of strong W.S.W. squalls, which are usually accompanied by dark cloudy weather and much rain, lasting for a week or ten days. These are generally succeeded by a period of fine weather, with N.W. and S.W. winds, which draw to the southward and eastward in the mornings. If June or July have been unsettled, it may be expected that August generally will be fine, with moderate S.W., but more frequently westerly winds, particularly in the afternoon. If, on the contrary, June or July has been tolerably fine, very unsettled weather may be expected in August.

In September and October the wind generally blows strong from the W.S.W., with dark, cloudy weather; and off the S.W. end of Palawan squalls, which veer to W.N.W. and N.W., sometimes blowing with great violence, succeed each other rapidly, and are accompanied by rain. Between the squalls the wind very often shifts to S.E. In November and December the weather is variable; N.E. and easterly winds, changing at times to S.E., more frequently prevail.

Among the *Philippine Islands* the two regular monsoons prevail, which are met with in the China Sea. These monsoons sometimes extend as far South as the Mariana Islands in the Pacific Ocean, and as far North as the coast of Japan. The Philippine Islands, lying North and South, their high lands naturally intercept the course of the wind; and the result is that at forty or fifty leagues from them much bad weather is encountered, which becomes much worse as the islands are approached. The N.E. monsoon commences about October, with fine weather, lasting till April, with winds varying from North to N.E. If it should occasionally veer to N.W. it blows hard. The S.W. monsoon is not observed here till between the commencement and end of May, and does not become regular till June. During this monsoon the weather is gloomy, cloudy, and very wet. About this period severe storms sometimes occur, called "collas tempestados," which are generally accompanied by thunder and rain, the wind changing about and blowing from all points of the compass with the same force. These collas and bad weather take place at the end of July, or middle of August, and sometimes in October. They are not unlike the typhoons. In September the wind loses strength, the rain is less, and the sky is fine; but in the morning there is a thick fog, which lasts till noon. At the change of the monsoons bad weather is sometimes felt, as in the China Sea. During

February and March, about the end of the N.E. monsoon, on the coast of Luçon, the wind varies, often with a tendency to follow the course of the alternate land and sea or solar breezes. The alternate winds are well established in April; and from June to October, the period of the S.W. monsoon, the wind brings rain, which blows on the coast at right angles.

II.—CURRENTS AND TIDES.

It will be manifest that if it be difficult to define exactly the direction and seasons of the monsoons which blow over the Indian Archipelago, it will be still more difficult to describe the currents. Ocean currents are induced, in a great degree, by the prevalent direction of the wind, which having free scope over both land and sea, has a much more persistent character than that of the surface water, driven through tortuous channels, often lying transverse to the normal direction of the wind.

Again there are anomalies arising from the tidal streams, the flood tide from the Pacific, and that from the Indian Ocean, both being directed to the same quarters, produces many apparent complications.

As a general rule, the *true* current sets to leeward, impelled by the trade wind or monsoon prevailing at the period, and when the waters have to pass through the narrow straits between the islands it often rushes past with great velocity.

But then this true current is frequently overcome or accelerated by the tidal streams reaching it in opposite directions; and, therefore, each strait requires special exemplification, and this will generally be found in the description of the coasts which follow these preliminary chapters.

One general remark may be made. A large portion of the archipelago lies between the two great tropical drifts to westward; in other parts of the world, as on the Guinea Coast, and in the Gulf of Panama, a *counter* current is found near the equator running to *eastward*, between these westward drifts. It cannot be said that such a counter current is found in the Indian Archipelago; but the same causes, difficult to define, which produce this equatorial counter current, will help to make the movements of the waters here more complicated and difficult of comprehension. North and South of this central belt on the eastern coasts of Asia and Australia, the equatorial streams recurve and form streams analagous to the Gulf Stream in the Atlantic; and this is especially the case in the stream flowing through the Formosa Channel past the Japan Islands. This was first defined by the Editor in his Pacific Directory as the Japanese Current.

The temperature of the ocean in the Archipelago is high, as might be expected; and, from its peculiar condition, it may be looked on as the head waters of that great circulatory system, which reaches every portion of the ocean in its course, and gives one universal character to the waters of the ocean. Sea water, as is well known, possesses the same characteristics in every known part of the world, and from the surface to its bed. This can only have arisen from the entire circulation and intermingling of the whole mass of the waters of the ocean, which has passed over every portion of its bed. A few brief remarks on each locality will suffice to give a more particular notion of the movement of the waters in its vicinity.

MALACCA and SINGAPORE STRAITS.—The great island of Sumatra, from its lying directly across the line of direction of the two monsoons, causes the currents which enter, or run out of the China Sea by the Malacca Strait, to be much modified by tidal influences. As a broad rule, it may be stated that the waters flow to West and N.W. during the N.E. monsoon, between November and March, and set in the opposite direction with a lesser velocity during the S.W. monsoon, which blows the water into the Bay of Bengal. In September, while the S.W. monsoon still lasts, a strong current sets eastward around the South part of Ceylon, and thence directly for Acheen Head in Sumatra, where it is divided, a portion running down the West Coast of Sumatra to S.W., and the other as a weak current down the Strait of Malacca. In October this drift is weak and uncertain, but in November, when the N.E. monsoon is in full force, the current to N.W. and along the North Coast of Sumatra runs at the mean rate of a mile an hour. From December to February this current still moves to leeward, and in March and April is sometimes very strong. When the S.W. monsoon sets in, in May or June, the reverse current commences, and in July and August attains considerable strength, and thus continues, with some fluctuations, until September or October.

But all these movements of the waters are much mixed up with the tidal streams. The flood tide enters the Strait of Malacca from the N.W., and is met somewhere in the Strait of Singapore by the flood stream coming from the China Sea.

In the Strait of Singapore the true current streams become still more marked by the tides. During the construction of the Horsburg Lighthouse at its eastern entrance, and therefore open to the influences directly coming from the China Sea, Mr. Thompson made the following observations:—The tidal currents set through the Middle Channel, that is, to the North of Pedra Branca, in a N.E. and S.W. direction, through the South Channel, between

Pedra Branca and the Bintang shore, in an E.N.E. and W.S.W. direction, and through the North Channel between Romania shoal and islands, in a N.N.E. and S.S.W. direction. The currents are much affected by the prevailing winds; they set strongly into the straits during the continuance of the N.E. monsoon, and in a contrary direction during the S.W. monsoon. This is particularly the case during neap tides. It is high water at full and change at Pedra Branca at 10^h 35^m a.m. The flood runs into the Straits and the ebb outwards, but the current does not generally turn till half ebb or half flood, that is, if low water be at 6 a.m. the current will run ebb till 9 a.m., although the water be rising on the rock. At 12^h noon it would be high water, after which the tide would fall, but notwithstanding this the current would run flood till 3^h p.m. before turning; but there are frequent exceptions to this rule, for I observed during the months of May, June, and July, when the morning ebb tides fall strong out till three hours after the tide began to rise on the rocks, and then continued slack water all day; while in the months of October and November, when the evening ebb falls much lower than the morning one, the tidal current would set strong out all night and continue slack inwards during the next day. At full moon, in August, 1851, I found the perpendicular rise and fall of tide was only 2 ft. 9 in., but three days afterwards it was 6 ft. 7 in., which was the greatest during three springs. In July the greatest rise was 7 ft. 9 in. The neap tides only rise and fall 1 ft. 7 in.

Again he says:—The current at times is not less than 4 miles an hour, and probably nearer 5, though this is unusual, and 2 to 4 knots may be taken as the usual strength, though much variation was observed during different months. Strong ebbs prevailed during the mornings of May, June, and July, and on the evenings of October and November strong ebbs also prevail. During the S.W. monsoon the floods do not run so strong as the ebbs.

STRAIT OF SUNDA.—The currents in this Strait are more of the nature of tides, although very much affected by the winds. During the S.E. monsoon the ebb tide on the South side of the Strait frequently sets to westward at from 1 to 2 knots, and lasting for fourteen hours, succeeded by a slack water or weak flood for six hours. In the middle of the Strait the velocity is greater, from 2 to 3½ miles per hour. When the winds are light, the flood to N.E. and the ebb to S.W. succeed each other regularly, and their rate is about equal, but at spring tides and in the middle of the Strait they attain a rate of 3 or 3½ miles an hour. In the opposite season of the westerly monsoon the ebb and flood are generally regular, but during strong gales the flood lasts longest. In February and March a strong set to the W.S.W. is sometimes met with on the North side, reaching a velocity at times of 4 to 4½ miles an hour. In the description of the Strait in a subsequent page, this topic will be again alluded to.

IN BANKA STRAIT and the adjacent passages there is much complication in the movements of the waters, arising from two causes, the one is the meeting of the flood tides from the China Sea and from the Indian Ocean, and the other is from the peculiarity of the monsoons, which, as explained in our Indian Ocean Directory (pages 29—36), are here an intermediate belt between the northerly and southerly monsoons on either side of the equator. Occurring during the southern summer months, November to March, and coming from the N.W. is called the middle or cross monsoon. During its greatest strength, January to March, the current or ebb tide sets to southward for fourteen to eighteen hours at a time, with a rate of 2 to $3\frac{1}{2}$ knots, and the flood from South is then scarcely perceptible. The reverse occurs during the S.E. monsoon, the flood stream setting with great velocity to the northward, while sometimes the ebb runs out weakly for eight or ten hours. To the northward the N.W. monsoon has more effect than the S.E. monsoon, and the reverse is the case in the opposite season. Between the monsoons the tidal streams are regular, but when the monsoons are blowing strongly, a constant surface drift is found setting to leeward on the Sumatra shore.

GULF OF SIAM.—The following is by Lieutenant Richards, who surveyed the Gulf:—

The currents in the Gulf of Siam, near the middle, are generally weak and variable, but near the land, in the strength of the monsoons, strong sets may be expected. In the S.W. monsoon a strong northerly current was found, from Lem Chong P'ra to Sam-roi-yot Point. In the N.E. monsoon there is frequently a strong set across the head of the Gulf to the westward.

In the neighbourhood of the Redang Islands and Pulo Obi, the strong currents prevalent in the China Sea may be expected. The China Sea current does not appear to enter the Gulf further than a few miles, but is said to set across its mouth in both monsoons.

The flood tide from the China Sea appears to meet the western shore of the Gulf, and divides somewhere near Cape Patani; for at the Redang Islands the flood sets to the southward, and at Singora and Koh Krah it was found setting to the northward.

CHINA SEA in the SOUTH-WEST MONSOON.—The currents in the China Sea are very changeable, their direction and velocity depending much upon local circumstances. Late in April, or early in May, they generally begin to set to the northward, in the southern and middle parts of the sea, and continue to run in a north-easterly direction until September, while the S.W. monsoon is strong; but they are not constant in this monsoon, for at times, when the wind is moderate or light, they are liable to change and set in various directions. After the strength of the monsoon has abated, there is often little or no current in the open sea, running to the north-eastward; but sometimes its direction is to the southward.

Along the coast of Cochin China, from Pulo Obi to Cape Pandaran, the current sets mostly to the E.N.E., parallel to the shore, from April to the middle of October; and during the same period its direction is generally to the northward along the East coast of the Malay peninsula, from the entrance of Singapore Strait to the Gulf of Siam. To the northward of Cape Padaran there is but little current in the S.W. monsoon, near the Cochin China coast; for, from thence to the Gulf of Tong King, a small drain is sometimes found setting northward, at other times southward. When a gale happens to blow out of the latter gulf from the N.W. and westward, the current at the same time sets generally to the S.W. or southward, in the vicinity of the Paracel islands and reefs, or where these gales are experienced; and this current running obliquely, or contrary to the wind, a turbulent and high sea is thereby produced.

On the Southern Coast of China the current is much governed by the wind; when strong S.W. winds prevail, it runs along shore to the eastward, but seldom strong. Near and amongst the islands, westward of Macao, there is generally a westerly current, occasioned by the freshes from Canton River, which set in that direction; frequently sweeping along the islands from Macao to St. John between W.S.W. and W.N.W., about 1 or 2 knots per hour. This westerly current is, however, not always constant in the S.W. monsoon, for it slacks at times; then a weak tide may sometimes be experienced running eastward.

On the coasts of Luzon and Palawan, the current generally sets northward in the S.W. monsoon, but frequently there is no current, and near these coasts it seldom runs strong. Near the Bashi Islands it sometimes sets eastward when strong westerly winds prevail; but generally strong to the northward, or between N.N.W. and N.E.

In the NORTH-EAST MONSOON.—The current in the China Sea during the N.E. monsoon generally runs south-westward, with a velocity depending on the strength of the wind. When the force of the monsoon is abated, or during moderate and light breezes, there is often little or no current.

In the western parts of the sea, along the coasts of Cochin China and the Malay Peninsula, the current generally begins to run to the southward about the middle of October (sometimes sooner on the former coast), and continues until April. During the month of March its direction is constantly to the southward about Pulo Aor, with light easterly winds and calms at times. On the coast of Cochin China, and adjacent to Hainan Island, a current varying from South to S.W., commences sometimes about the middle of September; near the land, from lat. 15° N. to 11° or $11\frac{1}{2}^{\circ}$ N., it increases in strength; but its rate decreases in proportion as it flows southward. During the prevalence of the N.E. monsoon, from about lat. 14° N. to Cape Padaran, the current near the coast frequently runs 40 or 50, and sometimes 60 miles to the southward in 24 hours; the rate, however, is variable, and it is only

in the limits above mentioned that it is occasionally so strong, for its strength abates at Cape Padaran, and runs with less velocity to the S.W., towards the entrance of the Gulf of Siam.

On the Southern Coast of China the current, during the N.E. monsoon, runs almost constantly to the W.S.W., nearly parallel to the land; and sometimes with inconceivable rapidity, when a typhoon or a storm happens. At the distance of 70 or 80 miles from the coast, it seldom runs so strong as near it; and in 30 or 40 fathoms soundings there is much less current than in shoal water, near the shore and amongst the islands. The westerly current sometimes slacks, and, contiguous to the land, is succeeded by a kind of tide.

Between Formosa and the China coast the current runs to the southward during the N.E. monsoon. When strong N.E. winds prevail, its direction is generally to the S.W. or southward, between the South end of Formosa and the North end of Luzon; but here, in light variable winds, it often sets to the northward. On the West coast of Luzon the current is changeable, sometimes setting southward along the coast, at other times northward. On the coast of Palawan it is also mutable, governed by the prevailing winds, but seldom runs strong in any direction, unless impelled by severe gales. To the eastward of Formosa, about Boteltobago Island, it frequently runs strong to the northward and north-eastward, so early as the 1st of March; and although changeable at times, it sets mostly in that direction during the S.W. monsoon; and in the opposite direction during the N.E. monsoon.—(*China Sea Directory.*)

EASTERN PASSAGES.—The currents in the passages East of Java are very various, and, like the monsoons, do not seem to be reducible to any fixed laws, a feature doubtless due to their geographic relations, lying as they do between the wind systems of the northern and southern hemispheres. But as their action is frequently of importance in endeavouring to make a passage against an adverse wind, they require much attention. The following imperfect notes, derived frequently from the Dutch, are given as a guide to their general character.

SOUTH COAST OF JAVA.—The monsoons here are liable to great deviations, although they frequently shift about the middle of April and November. This is owing in some degree to the mountainous character of the island; and there are some remarkable reverse currents experienced when within a degree or two of the coast. The Dutch officers, Lieutenants Rietveld, Eschauzier, &c., say that during the easterly monsoon, April to November, a constant *easterly* current is encountered, or running against the monsoon at times so strong as to ripple, but on an average of 10 to 12 miles per day. The drift is frequently to S.E. two-thirds of a mile an hour. Captain M. H. Jansen has stated that in the eastern monsoon the current sets to the westward from full to change of the moon, and either to the eastward from the

change, or that there was no current. It is also certain that there is a considerable set to the westward in this monsoon, especially near the shore. In the westerly monsoon the current is sometimes to the S.S.E. and South, decreasing in force to between 11° and 15° , and then ceases, and a strong westerly current is encountered increasing in velocity as the Strait of Sunda is approached, amounting at times to 42 miles per day.

BALI STRAIT.—The currents or tides run through the Narrows of Bali Strait with great velocity, some say 6 knots, and cause great rippings, eddies, and a boisterous sea, particularly near the Bali shore during the eastern monsoon, when the S.S.W. winds blow so strongly that it is often impossible to manœuvre a ship. The flood runs to the northward and the ebb to the southward, and at full and change of the moon it is high water there between 12 and 1 o'clock. About quadrature of the moon, and particularly near the last quarter, the tides are very irregular; they change first on the Java side of the strait, and only $1\frac{3}{4}$ or 2 hours later on the Bali shore. During the eastern monsoon the flood is often found only near the Java shore, and even there not to the northward of Batu Dodol, but during the western monsoon the northerly currents prevail. A tide lasts often for 7 or 8 hours.

TIMOR, ETC.—The currents are strong, with great rippings, in the Ombay passage, and the Straits to the northward of Timor, generally setting to the N.E. during the western monsoon, and during the opposite to the south-westward; but in some places, close in-shore, a kind of weak tide has been experienced. Near the entrance of the Straits of Alloo and Pantar the current takes a northerly direction during the eastern monsoon, but during the western monsoon it sets out S.S.W. The strong current in the Ombay Passage seems to cause a strong easterly current along the North coast of Ombay during the eastern monsoon.

In June the S.W. or westerly currents in the Ombay Passage seem to have attained their greatest strength, amounting to 72 or 82 miles in twenty-four hours.

Near the end of the eastern monsoon (in August and September) strong easterly currents take place in the Ombay Passage, though in October they often run with great velocity to the south-westward.

Ships from Java or Macassar, bound to Amboina, during the eastern monsoon, work along the North coasts of Sombawa, Flores, &c., till they have reached the N.W. or North point of Wetter; or further to the eastward, if bound to Banda; and the voyage is often much accelerated by favourable currents.

NEW GUINEA, ETC.—During the easterly monsoon, the current sets to the N.W. along the western coast of New Guinea and between the Ki and Arru Islands, and thence eastward along the South coast of Ceram, at the rate of a mile or a mile and a half an hour, according to the strength of the wind,

the velocity being greatest along the coast of New Guinea. At this period an easterly current prevails on the North side of the islands, extending from Timor to Timor-Laut, so that a moderately fast vessel would experience no difficulty there in beating up against that monsoon. In the westerly monsoon the current in these seas usually sets with the wind, but its velocity is not so great as during the other season.

Of the currents on the North coast of New Guinea we have but few particulars, and these chiefly from D'Urville, who sailed along it in August, 1827, where he found strong westerly and N.W. currents of more than a mile an hour. It is probable that this westerly drift is constant, and that, arriving at the Moluccas and Philippine Islands, it is diverted more to the northward, and finally assumes the N.E. direction along the coast of China, which has been previously adverted to.

III.—TIDES.

But little can be said here to give a general view of the tides in the Indian Archipelago. Each particular locality and strait would require a special exemplification, which as far as we have the means, is given in the local descriptions in a subsequent part of the work.

The flood tidal wave from the Indian Ocean, proceeding in a N.E. direction, is mainly obstructed by the line of islands which it encounters in its whole breadth. It passes through the various channels with considerable rapidity when favoured by the monsoon, or is almost annihilated by the contrary season. In the former case it passes on till it meets that which comes from the Pacific and China Sea, thus neutralizing each other, and occasioning much complication, and the phenomena of double tides. In the different seasons the tides from this cause are in some cases quite reversed, the high water hour corresponding in one case with the low water period of the other.

Free from the entanglements of the Archipelago, the great tidal wave pursues a normal course in the Pacific, and, according to the China Pilot, it strikes upon the eastern coast of China, from Hong Kong to the Yang-tse kiang, nearly at the same period; it being high water on full and change days in the neighbourhood of the Lema Islands, at about 8^h 30^m, and at the outer islands of the Chusan Archipelago it is an hour later. The rise and fall, however, increases considerably to the northward; probably owing to the obstruction which the wave receives from the Philippine Islands; and in some instances the diurnal inequality is great. By the Tide Table it will be perceived that to the eastward of Hong Kong, and as far as Breaker

point, the tides are irregular and weak, the current occasioned by the monsoon overcoming them.

After passing Breaker Point, the coast trends more northerly, and the flood stream will be found useful to vessels bound to the northward. The rise and fall increases, passing from 7 ft. at Namoa Island to 12 ft. at Tongsang, and 20 ft. at Amoy. Between Amoy and the River Min, the rise of the tide varies from 16 to 18 ft. at springs, and the flood enters on the North as well as on the South side of Hai-tan Strait.

To the northward of the Min, the flood sets more determinately to the North; it seldom, however (unless off headlands or in narrow channels), overcomes the current caused by the monsoon, but has the effect of slackening it.

Throughout the Chusan Archipelago and the estuaries to the North, great care and attention to the tides is necessary. Particular instructions for this purpose will be found in the body of the work; and it only remains here to caution the navigator that, as his vessel approaches the coast to the northward at Chusan, the tides increase in rapidity, and unless precaution is taken, she will be set among the small islets of this rugged archipelago.

The following Tide Table, extracted from that published by the Admiralty, and drawn up by Commander Burdwood, R.N., will give the times of high water and the ranges of the tides.

TIDE TABLE.

* At Sarawak River the highest tides occur at the change of the monsoons, viz., May and November. In the N.E. monsoon the higher tides occur at the new moon, and those of the day are higher and more regular than those of the night; while during the S.W. monsoon the contrary takes place, and the higher tides are then at full moon.

† In the N.E. monsoon.

* In the River Seoul, spring tides rise from 16½ feet at the entrance, to 6½ feet at Séoul.

† With southerly winds the tide rises about 2 feet higher.

I V.—T E M P E R A T U R E.

*Remarks on the Temperatures of the China, Sulu, Celebes, and Banda Seas, by Staff-Commander T. H. Tizard.**

The temperatures obtained in the seas partially enclosed by the Indian Archipelago, prove that they have, each of them, deep basins cut off from the general oceanic circulation by ridges connecting the islands which surround them; for although in each sea soundings of over 2,000 fathoms were obtained, in no case did the temperature decrease in a regular curve from the surface to the bottom, as is usual in the open ocean; in every case, after attaining a certain depth, the temperature below that depth remained the same: thus, in the Banda and China Seas the temperature remained the same from 900 fathoms to the bottom, in the Celebes Sea from 700 fathoms to the bottom, and in the Sulu Sea from 400 fathoms to the bottom.

In the China Sea three temperature soundings have been obtained, one by Commander Chimmo in H.M.S. *Nassau*, in lat. $12^{\circ} 53' N.$, long. $110^{\circ} 31' E.$, the depth being 1,546 fathoms; and two in the *Challenger*, one of which is in lat. $17^{\circ} 54' N.$, long. $117^{\circ} 14' E.$, the depth being 2,150 fathoms, and the other in lat. $16^{\circ} 42' N.$, long. $119^{\circ} 22' E.$, the depth being 1,050 fathoms. In these three soundings the minimum temperature, which varied from $36^{\circ}.1$ to 37° , was found at a depth ranging between 600 and 1,050 fathoms.

In the Sulu Sea three temperature soundings have been obtained, one in lat. $8^{\circ} 5' N.$, long. $119^{\circ} 45' E.$ of the depth of 1,778 fathoms, by Commander Chimmo; one of 2,550 fathoms in lat. $8^{\circ} 32' N.$, long. $121^{\circ} 55' E.$; and one of 2,225 fathoms in lat. $8^{\circ} 0' N.$, long. $121^{\circ} 42' E.$ The latter soundings were obtained by the *Challenger* in October 1874 and in January 1875.

In each of these three soundings the minimum temperature of $50^{\circ}.5$ was reached at the depth of 400 fathoms. From that depth to the bottom the temperature remained unchanged.

In the Celebes Sea three temperature soundings were obtained in the *Challenger*, one in lat. $2^{\circ} 55' N.$, long. $124^{\circ} 53' E.$, in October 1874, the depth being 2,150 fathoms; a second in lat. $5^{\circ} 44' N.$, long. $123^{\circ} 34' E.$, also in October 1874, the depth being 2,600 fathoms; and the third in lat. $5^{\circ} 47' N.$, long. $124^{\circ} 1' E.$, in February 1875, the depth being 2,050 fathoms. In each of these three soundings the minimum temperature of $38^{\circ}.5$ was reached, at a depth of from 700 to 800 fathoms, from which depth to the bottom the water remained unchanged.

In the Banda Sea three temperature soundings were obtained in September 1874, one in lat. $5^{\circ} 41' S.$, long. $134^{\circ} 4' E.$, the depth being 800 fathoms; a second in lat. $5^{\circ} 26' S.$, long. $133^{\circ} 19' E.$, depth 580 fathoms; and the third in lat. $5^{\circ} 24' S.$, long. $130^{\circ} 37' E.$, depth 2,800 fathoms.

* Extracted from the "Geographical Magazine" for March 1876.

In the last sounding, 2,800 fathoms, the minimum temperature of 37°.5 was reached at the depth of 900 fathoms; from thence to the bottom no alteration in the temperature of the water was detected.

In the Molucca Passage, which connects the Banda Sea with the Pacific Ocean, one temperature sounding of 1,200 fathoms was obtained in lat. 0° 41' N., long. 126° 37' E., in October 1874, and the temperature was found to decrease regularly from the surface to the bottom, the minimum temperature at the bottom being 35°.2.

Two soundings and temperatures were also obtained in January 1875 in the waters of the Philippine Islands, which separates the water of the Sulu Sea from that of the Pacific Ocean. One of these soundings (700 fathoms) is in lat. 12° 21' N., long. 122° 15' E., in the basin formed by the islands of Panay, Tablas, Romblon, Sibuyan, and Masbate; and the other (375 fathoms) in lat. 9° 26' N., long. 123° 45' E., South of Bohol Island, in the channel leading from Suriago Strait to the Sulu Sea. In the first sounding the minimum temperature of 51°.5 was reached at the depth of 220 fathoms; and in the second, the minimum temperature of 54° was reached at the depth of 230 fathoms.

A temperature sounding of 2,550 fathoms was obtained, in February 1875, in lat. 4° 19' N., long. 130° 15' E., in that part of the Pacific Ocean adjacent to the Celebes Sea and Molucca Passage. Here a minimum temperature of 34°.6 was reached at 1,300 fathoms.

An examination of the chart of these regions will show that the deep basins of the China and Celebes Seas are alone in communication with the Pacific Ocean, and that consequently their temperature must be greatly dependent on the temperature of that part of the Pacific immediately adjacent to their openings into that ocean, for although both seas are in communication indirectly with the Indian Ocean, they are cut off from the deep basin of that ocean by a large tract of shallow water, which, in the China Sea, exceeds a breadth of 600 miles, and in the Celebes Sea is apparently about half the length of the Macassar Strait.

The Sulu Sea receives its waters from the China and Celebes Seas and Pacific Ocean; its temperature depends, therefore, to a great extent on the temperatures of those seas.

The isotherm of 80° is found at a depth of 20 fathoms in the Sulu Sea; at 40 fathoms in the Celebes Sea; and at 22 fathoms in the Banda Sea. In winter the China Sea has a large range of surface temperature from 64° at Hong Kong to 84° at Singapore, while the surface temperature of the other three seas varies only slightly all the year round. The specific gravity of the water in the Celebes, Sulu, and Banda Seas, was found to be less than in the Pacific Ocean: this may be accounted for by the excess of rainfall over evaporation in the area occupied by them.

V.—MAGNETIC VARIATION.

In the older works which described the navigation of this Archipelago, the important element of the compass variation was disregarded, because the magnetic meridians so nearly coincide with the geographic meridians, that they are in most parts practically the same.

The isogonic lines, as shown on the illustrative chart, have a great peculiarity in the eastern seas. A line of no variation passes across the Coast of China and down through the Philippine Islands, while another, traversing the Bay of Bengal, passes southward of, and parallel to, the Island of Java. Between these lines the amount of easterly variation does not exceed 2° in the western, and 4° in the eastern parts of the area. The chart will best explain this.

But there are other considerations respecting the compass, apart from the amount of its deviation from the true meridian. This is the amount of the different terrestrial and local magnetic forces which act on the compass needle. The lines of equal dip will give one of these elements, but the works specially devoted to the subject will show how important it is that the commander should be aware of the effects of those varying magnetic changes he will have to pass through in his long voyage to the field of the present work.

The epoch assumed in the chart is 1878, but there has been no appreciable change in the amount shown since magnetic observations have been conducted with accuracy, so that, for the present at least, it may be taken as correct for a long period, sufficiently so to draw attention to any unsuspected change in the magnetism of the ship, should the compass show a different amount to that given on the chart.

CHAPTER II.

PASSAGES.

ONE general principle may be laid down for ships traversing the Indian Archipelago, and that is that during the S.W. monsoon, April to September, ships approaching China must go by the channels *westward* of Borneo, and in the opposite season they will take one of the passages to the eastward of Sunda and of Borneo; the return voyage being also reversed in these particulars.

Therefore the passages through the Archipelago, which lie westward of the great island of Borneo, are termed generally the *Western Passages*, being the Straits of Sunda and Malacca; and those which pass eastward of Java and Borneo are called the *Eastern Passages*. To these may be added what was termed the *Great Eastern Passage*, or that to the southward and eastward of Australia and Van Diemen's Land, and which was first followed by Capt. Butler, in the *Walpole*, in the northern monsoon of 1794. Of this route Captain Maury says—This now is never or very seldom used, and should never be attempted except for very special reasons.

An exception may be made to this absolute conclusion in favour of clipper or well handled ships, which sometimes have successfully attempted to beat up the China Sea against the N.E. monsoon. Of this more will be said hereafter.

The Strait of Sunda is then the great portal of the Archipelago and China Sea, and is used in all seasons for the ports South of China, and frequently in all seasons as an entrance to the Eastern Passages. In the remarks as to the most advisable routes, which will follow, the passages from the Atlantic through the Strait of Sunda will be first considered.

1.—THE ATLANTIC TO THE STRAIT OF SUNDA.

In the volume on the navigation of the Indian Ocean, to which this is a continuation, full descriptions of the winds and currents of that ocean are given, so that by reference to that work an insight will be gained into those influences which affect a vessel's course in crossing it. On pages 158, 159, of that work, too, some brief remarks on the best track for approaching the

Strait of Sunda, or the passages eastward of it, are given: but as this topic has more especial reference to the scope of this book, some further observations will be given.

Notwithstanding all the long discussions which have ensued since the vast extension of Oriental commerce, and the consequent accumulation of experience, it is still a disputed point as to which is the best parallel for crossing the Indian ocean in sailing eastward round the Cape of Good Hope. On the one hand it is contended that by not going too far southward, better weather, and as much advantage otherwise, is gained. On the other hand, it is said that by keeping more approximatively to the great circle course, that is in higher latitudes, the "brave West winds" are more constant and of greater force, and that the distance to be sailed over is proportionately shortened. The following will illustrate this. The first remarks are taken from the Admiralty Sailing Directions, advocating a comparatively low parallel.

On leaving the cape, steer boldly to the southward, so as to run down the easting in lat. 39° or 40° S., where the wind blows almost constantly from some western point, and seldom with more strength than will admit of carrying sail; whereas in a higher latitude the weather is frequently boisterous and stormy, with sudden changes of wind.

Some navigators prefer making their easting in a higher latitude than 39° or 40° S., whilst others steer a more direct course for Java Head than is here recommended; but the above directions are those usually followed in H.M. ships, and are generally believed to be the best.

Now, respecting this choice of the parallel of about 39° , on which to run eastward, the distance to be traversed, or the approximate 75° of longitude from the offing of the cape to the point where you must bear off to the northward, is about 3,508 miles, a distance of nearly 600 miles would be saved if the latitude of 50° were taken.

On this point Captain Maury, who differs from the Admiralty, says as follows:—

A vessel bound through the Straits of Sunda, after crossing the equator, usually holds her wind, hauling up to the eastward as the S.E. trades of the Atlantic will allow, until she gets into the calm belt of Capricorn. Here, though she may not find long continued calms, she finds, nevertheless, those light winds which are always found to prevail in that sort of debateable ground which is always between any two systems of winds. This calm belt is between the S.E. trades on one side, and the variables, or "brave West winds," of the southern hemisphere, on the other.

Having cleared the trades, the present practice of mariners is to edge off a little to the East of South until they gain the parallel of 35° — 37° ; crossing this, they haul up due East, between the parallels of 37° and 39° , and run between them—the place of all others where the southern edge of the cy-

clones which traverse those parallels is most apt to be felt adversely—from the prime meridian to longitude 80° — 85° E. Now, if any one were seeking to find a route that passes through the regions most beset with light and baffling winds, this is the route to which I should point. The idea of sailing 5,000 miles along the borders of the calm belt of Capricorn, as many East Indiamen do, when there is sea room for the Great Circle route, with the “brave West winds” “following fast,” is simply absurd.

Having run along this “debateable ground,” and reached the meridian of 80° or 85° E., another mistake is committed by crossing this calm belt in the Indian Ocean again obliquely, which should never be done. These calm belts should always, whenever the land and dangers will admit, be crossed as directly on a meridian as the winds will allow; for the sooner you cross them, the sooner you will get winds that will drive you along.

Such is the course of the present route, as the Dutch crossings abundantly show, and has been shortened for the Dutch, and may be shortened for the Americans and all others, ten days or more, by all vessels that will follow this course.

(1) After crossing the parallel of St. Roque, stand through the S.E. trades with a rap full and topmast studding sail, as if you were bound to Australia. not caring to make better than a S.S.E. course good, until you lose the trades, clear the calms of Capricorn, and get the “brave West winds” on the polar side of them. Vessels that do this will generally clear the calms, and get the “brave West winds” by the time they reach latitude 35° — 40° , finding themselves at this juncture somewhere between the meridians of 20° and 30° W. Now shape your course per Great Circle for the intersection of parallel of 40° , with the meridian of 80° — 85° E., or any other near which it may be deemed advisable, with the changing seasons, to enter the region of the S.E. trades of the Indian Ocean.

The following route, from 30° W. 35° S. to the intersection of this parallel, with 85° E., differs so little from the Great Circle, that the difference becomes practically of no moment.

(2) Suppose you clear the calms of Capricorn in latitude 35° , longitude 30° W., now steer for the meridian of 10° E., at its intersection with the parallel of 48° or 50° S.; then run on between these parallels to longitude 50° . From this point steer for the intersection of 85° E. and 35° S. The total distance to be run South of the parallel of 35° being 5,000 miles, the distance by the present route being 5,500 miles; so here is one day’s sail gained by the “short cut,” and certainly better winds.

(3) But suppose you have good luck in the South Atlantic, and can clear the calms of Capricorn in 20° W. instead of 30° W., but in the same latitude, your course then is to aim to strike the parallel of 50° in 20° E., and then run along it as before to 50° E., the distance South of 35° by this route being 4,900 miles.

But suppose the winds favour you still more, and you be in 10° W. before you reach the parallel of 35° ; in this case you should run between the parallels of 45° — 46° till you come to the meridian of 50° E. You should so shape your course from 10° W. as to get between these parallels, near the meridian of 20° E. The distance South of 35° , by this route, is 4,400 miles; in other words, the distance from the usual place of crossing the parallel of St. Roque to Java Head is—

By present route, 9,200 miles; by (1), 8,940 miles; by (2), 8,730 miles; by (3), 8,520 miles.

There is no part of the world where the master of a sailing vessel can turn his knowledge of the principles of Great Circle sailing to more advantage than he can when his course is East in that great expanse of ocean on the polar side of the calm belt by Capricorn. Here, when his course has easting in it, the famous westerly winds of that region will drive him ahead with the force and velocity of steam power.

Suppose, therefore, a navigator, bound for the Straits of Sunda, should, instead of heading up East on crossing 35° S., near 30° W., after having crossed the equator near this meridian, proceed to 40° S. before heading up East, how much would his distance from the equator in the Atlantic to the crossing of 40° S. in longitude 85° E. be increased? Answer, 100 miles. His gain in time to off-set this increase of distance would be a quicker run through the calms of Capricorn by reason of going straight across them, and the further advantage of strong winds along the more southern route.

The best course, under all circumstances, is as a rule, to do thus:—Run from the equator in the Atlantic to the South as fast as you can, caring little for easting until you have cleared the calms of Capricorn, and caught the “brave West winds” on the polar side of that belt; then shape your course so as to cross 20° E. between 47° and 52° S.; leave these parallels about the meridian of 60° E., and then steer thence for the parallel of 40° S., near its intersection with 85° E.

This description of the course to be run, and the points of intersection to be gained, is given only for those navigators who may be unable to get out of the true Great Circle routes and courses.

It is well to remark that most ice has been seen along this route, between 20° and 40° E., and that much is to be gained by running down your easting as near to the South as ice and safety will permit. So impressed have I been with the gain to be made by running well to the South in this part of the ocean, that I formerly said, with regard to the route to Australia—

“In further proof that the route recommended in the Sailing Directions of the Admiralty is too far to the North, and as an illustration of the advantage of the route which I advise, I have prepared some tables, and it appears from them that there is no longer room for difference of opinion as to the advantages of going farther South than 39° — 40° ; how much farther, though,

still remains to be decided. But so far as the facts before us go, they justify the assertion that for every degree you go South of the Admiralty route to Australia, you gain three days on the average, until you reach the parallel of 45° — 6° , for the averages of the table are not below this parallel; and I believe it will turn out that the best streak of wind, in the long run, is to be found between 45° and 50° S. It seems to be almost as steady, between these parallels, from the westward, as it is anywhere to the East, between the trade wind parallels of 15° and 20° . The average "vertex" of those that go South of 41° is $53^{\circ} 33'$; the average "vertex" of those that go North of that parallel is $39^{\circ} 7'$ S. The mean parallels upon which the latter run down their longitude is $38^{\circ} 52'$, and the former $43^{\circ} 59'$; for this difference of 5° , the average gain of those who take the more southern parallels is 14 days, which comes very near to an average of 3 days' gain on the voyage to Australia for every degree you go South of the Admiralty route. As far as 80° E., the Admiralty route to Australia and the old route to Sunda are the same. The average speed to Australia by the Admiralty route is 134 miles a day against 154 by the new route; so that the route well to the South has in its favour not only better winds, but shorter degrees and longer daily runs.

If the winds were fair all the way, the nearest route to Java Head from the fairway off St. Roque would be via the Cape of Good Hope; indeed, the Great Circle from St. Roque to Java runs through the unexplored regions of Africa. But both the winds and the land render such a route in navigation impracticable; for the former generally compel the outward Indiaman, in spite of herself, to cross the meridian of 25° W. as far South as the parallel of 30° — 33° S.; and the Great Circle thence to Java Head passes some 8° or 10° South of the Cape of Good Hope. Moreover, the winds in the Indian Ocean render a departure from the Great Circle again necessary. The winds, however, are such as to admit all four of the routes on pages 42, 43, ante.

The route No. 3 is 600 miles shorter, and has better winds than the present route. But, after clearing the S.E. trades of the Atlantic, the present route runs about 1,000 miles obliquely across the calms of Capricorn, where the average rate of sailing is not over 100 miles a day. Now, by going straight across these calms as by route (1), you will clear them generally in two days, and then get those "brave West winds," which will waft you along at the rate of 200 or 300 miles a day, according to the heels of the ship.

The navigator, therefore, will act most wisely who will wait, and let things as he may find them govern him as to where, after clearing the S.E. trades, he will begin to shape his course for the Great Circle to the meridian of 85° East, or for the meridian near which he proposes to cross the calms of Capricorn in the Indian Ocean. Suffice it to say, he may begin to do it any-

where South of 30° , and between the meridians of 30° and 10° W., and reach Java Head several days sooner, on the average, than he would by continuing to follow the present route.

In attempting to follow these Great Circle routes, navigators should recollect that the greatest saving of distance, as compared with the rhumb-line route, is always along those arcs that lie nearly East and West, and are farthest from the equator; and that, so far as distance is concerned, he might as well be out of his way on one side of these arcs as the other. As illustrative of this route, I may refer to the track of a ship whose log I have, and with regard to which I only say that, if she had stood on from lat. 28° to 35° S., at that season, in long. 20° W., and then shaped her course per Great Circle route, she would probably have done better; as it is, she crossed the meridians as follows:— 0° in $36^{\circ} 20'$ S.; 20° E. in $38^{\circ} 20'$ S.; 40° E. in $38^{\circ} 35'$ S.; 60° E. in 38° S.; 70° E. in $38^{\circ} 20'$ S.; 80° E. in 36° S.; 90° E. in $33^{\circ} 0'$ S.; which is a fair representation of the average June route of the Dutch.

“Arriving in lat. $28^{\circ} 0'$ S., long 22° W., I projected,” says her master, “on my chart, the Great Circle course thence to Java Head, the vertex being in lat. 44° S., and long. about 25° E. I adhered to this course as far as practicable, having in view the favourable sailing points of the vessel, and being compelled to run her before some of the heavy seas of the high latitudes until reaching the parallel of 30° in long. about 69° E., when I deemed it prudent to keep to the eastward of the Great Circle course, and approach the meridian of Java Head farther South, to forelay for the chance of there being considerable easting in the trades. I crossed the tropic in about $94^{\circ} 30'$ E. long., and fetched Java Head, sailing upon an easy bow-line (which is a good sailing point of the vessel, and, I believe, of most sharp vessels). I will remark here that I could find nothing explicit in ‘Horsburgh’ regarding the direction of the wind in the S.E. trades; but, after many unsatisfactory remarks, the whole is summed up on page 161, vol. i., 5th edition, thus:—When the sun has great North declination, it may not be absolutely requisite for ships which sail well to reach the meridian of their port so far southward, the trade wind then blowing more from S.E. and E.S.E. in general than from East and E.N.E.

Accompanying my abstract is an abstract of the log of the ship *Minstrel*, of Boston, which vessel (commanded by my brother) pursued the Admiralty route in running up her easting; and, although he crossed the equator in the Atlantic 12 days before me, yet I made Java Head the day before him, and there was not much difference in the sailing of the vessels. Where I gained on him most was in high latitudes. Although I made a fair passage by pursuing the circle course so far as the latitude of 33° , yet I would not again adhere to it farther than the vertex; thence, I would sail East on, or near, that parallel until reaching the longitude of 90° , or thereabouts; then

hauling North across the belt of variables to the southward of the trades, at right angles, and be upon the safe side, after reaching the trades, at any season of the year.

A good passage could, perhaps, be made by sailing on a circle course from the Atlantic to a good position relative with Java Head, in the Indian Ocean, say 95° E. and 33° S.; but the vertex should be far South of 53° , or thereabout. And I should not feel justified in attempting to pursue such a route, until we have some definite information relative to the existence of danger from ice, against which Horsburgh cautions navigators.

Navigators, by taking the old route, are liable to meet with another difficulty, especially when they attempt to run down their longitude near the parallel of 35° — 6° S. About this parallel is a famous place for circular storms—cyclones. They revolve with the sun, and the parallel of 35° — 6° is frequently traversed by the southern edge of them; consequently, as these storms travel East or West, the wind on the southern edge of them is generally from the eastward."

Thus far Captain Maury, to which two remarks may be appended, the one on the dangers from ice in high southern latitudes, the other on the occurrence of cyclones in the lower parallels.

The frequency of ice and its peculiarities in the Southern Indian Ocean is dwelt upon in our Directory for the Indian Ocean, pages 86—91, and it is there shown that the drifts attain a lower latitude in the southern winter than at other seasons, nearly approaching the Cape of Good Hope in July to September, but then it is considered that they leave a clear space to the southward. In January to March they are not frequently encountered northward of 55° S.

In the same work the question of the occurrence of cyclones on the parallels indicated is discussed, and to those pages the reader is referred.

There can be no doubt but these revolving storms do sometimes attain these latitudes after recurring from the northward, and passing to the eastward. Should the well-known indications of these meteors be clearly ascertained, of course it behoves the commander to seek that edge of the disk (the northern edge), which will help him forward on his voyage, rather than be opposed by the contrary gales on its southern margin.

But it is argued by some that these gales are generally not revolving, but are right lined winds, or so slightly curved in their paths that they cannot be classed as cyclones. Upon this topic see pages 12, 13, of the Indian Ocean Directory—the whole subject and its application being given in pages 3 to 17, and 151 to 159.

To the two opinions given above, as to the best parallel for running down the easting after passing round the Cape of Good Hope, we may add that of Mr. Towson, whose labours on this subject are well known. It is true that his object was to shorten the road to Australia, and therefore the tracks lie

to the southward of that great continent; but they will hold good equally for that which diverges to the northward before reaching this eastern extension. He chooses the parallel of 51° S. for passing across the Southern Indian Ocean to the southward of Kerguelen Land.

With all deference to these great authorities, may it not be that all are right, if their views are followed in different seasons. It would seem to be quite natural that a lower latitude would carry all the advantages during the winter season that a high parallel does in the summer. The limits between the trade winds and the westerly anti-trades certainly vibrates in latitude with the progress of the sun in the ecliptic; and therefore, during the inclement winter, the Admiralty parallel of 39° — 40° may be quite as advantageous (except as regards the distance to be run) as the probably more boisterous but shorter course in higher latitude. Again, in the summer months the parallels advocated by Maury and Towson may certainly be safely followed; but in this, also, some other considerations may enter. The sailing powers of the ship, the nature of her cargo, and the health of the crew and passengers (especially if the latter be an important item in the account) would lead the commander to hesitate before he would carry his vessel into climates very much colder than that he has recently left, and which he will soon enter again, and where he will probably meet with heavy winds and turbulent seas.

As has been said above, the point does not appear to be entirely decided, nor can it be so when each ship may, from motives of expediency, require different handling. The above facts and opinions are given, and the commander must make his own choice of them. For pursuing the voyage to the northward, the following is given in the Admiralty Directions.

In the South-east Monsoon, i.e., from the middle of April to the middle of September, vessels, having passed the island of St. Paul, should not edge away too quickly to the northward, but should endeavour to reach first as far to the eastward into the S.E. trade wind as the meridian of Java Head, crossing the southern tropic in about 102° E. In this season a westerly current runs along the South coast of Java, and in the months of June, July, and August, when it is at its greatest strength, it will be indispensable to be well to the eastward, or otherwise the ship will be liable to fall to leeward of Java Head. In the vicinity of Java the S.E. monsoon also veers sometimes to East or E.N.E.

In the North-west Monsoon, i.e., from the middle of October to the middle of March, but especially in December and January, the southern tropic should be crossed several degrees to the westward of the meridian of Java Head, when a direct course can be steered for Sunda Strait, or to make Engano Island, or the land about Flat Point, the southern extreme of Sumatra. Great care must be taken during this monsoon not to fall to leeward of Java Head, for the westerly winds blow with great violence along the South coast

of Java, and their strength, united with the strong current setting to the eastward, make it impracticable to beat up along this coast; a vessel may thus have to steer to the southward, and re-enter the S.E. trade, in order to make sufficient westing to fetch Flat Point. When nearly on the parallel of Java Head, and one or two degrees to the westward of it, a direct course may be steered for the Strait, with an allowance for a probable current setting to the southward.

If contrary winds are met with shortly after leaving St. Paul Island, in November, December, or January, a vessel may steer at once to the northward, and cross the tropic in 80° or 90° E., when she will meet with westerly winds to carry her to the strait.

Shifting of the Monsoons.—During the period when these changes occur, i.e., from about the middle of September to the end of October, and from about the middle of March to the end of April, the winds are variable and uncertain. It is advisable at those times to make sufficient easting in the S.E. trade to bring Java Head nearly North, and then to steer direct for it, borrowing a little to the eastward or westward, when it is approached, as may be required by the prevailing wind or other circumstances.

2.—SOUTHERN INDIA TO THE STRAITS OF MALACCA.

IN THE S.W. MONSOON.—In this, the fair wind season, there is no great difficulty in making a passage around the South end of Ceylon, or from Madras, or any of the Coromandel ports. Having passed Ceylon, steer so as to pass, in lat. $6^{\circ} 20'$ N., through the channel between Pulo Rondo and the South end of the Great Nicobar. If the monsoon be strong from southern quarters, and the weather overcast, so that there may be some uncertainty in the latitude for want of observations, keep southward towards Acheen Head, to guard against the chance of a northerly current. But great caution is necessary in such weather, because, should the wind have had much westing in it, it may have caused a south-westerly current down the West coast of Sumatra. Such a contingency must be guarded against when it is neared in dark, stormy weather. Acheen is generally best made from the southward at this season, passing with great precaution either through the Surat Passage within the islands, or, which is better, northward of Pulo Brasse, by the Bengal Passage.

Bound through the strait, and having passed the islands off Acheen Head, which is then best to be avoided, stand on towards Pulo Bouton, on the eastern side of the Strait of Malacca, because, as has been before explained, the high land of the Pedir Coast, intercepting the monsoon, causes light baffling winds all along the Sumatra side. When Pulo Bouton is made bearing to eastward, you may be able to carry brisk westerly winds up to Pulo Penang. Should the winds be light, a northerly current may be

encountered setting out of the entrance to the strait, and this may set the ship to northward of Pulo Bouton; but when once the islands on the Malay coast are made, there will be no difficulty in getting along that coast to the S.E. Keep within a moderate distance of the coast, in 35 to 20 fathoms, making for the Sambilangs, carefully avoiding the mud bank off the coast between Penang and Pulo Dinding, in lat. $4^{\circ} 14' N$. The outer edge of this, as is shown in the subsequent descriptions, is steep-to, shoaling suddenly from 10 and 8 fathoms to 9 ft. in some parts, and it must therefore not be neared into less than 12 to 15 fathoms. Passing between the steep, rocky Sambilangs and the isolated Pulo Jarra, in the middle of the strait, which is perfectly clean with the deepest water in the strait around it, you make for the West end of the North Sands, those dangerous shoals which run parallel with the coast, but which danger is much diminished by the lightship on the One-fathom Bank, between the North and South sands. Should you meet with an adverse wind when up with the Sambilangs, keep along the Perak coast in moderate depths, not less than 10 or 11 fathoms, as there may be a useful counter-tide and good anchorage in doing so. Having arrived at the One-fathom Bank and its lightship, and sighted the Arroa Islands, there will be no difficulty in getting up to Singapore, as shown in the subsequent descriptions.

IN THE N.E. MONSOON.—The passage to the eastward against this fine weather monsoon is tedious and lingering. Having passed Ceylon, it is best to keep to the northward, passing between the Nicobar Islands and the Little Andaman; or, if from Madras, through the Sombreiro Channel. Those from Ceylon should keep well in with the South end of the Great Nicobar, if the wind will permit, in entering the strait. But should you get drifted to leeward of Pulo Brasse, enter it by the Surat Passage, around Acheen Head. When past Acheen Head, a westerly current will be encountered running along the coast between that and Diamond Point; but in the offing and on the Malay side it sets more or less to the northward throughout the year. Therefore, when within the strait, get away from the Sumatra coast, and try to gain the Malay side, where there are more favourable winds, tidal streams, and the alternating land and sea breezes by which you may work to the S.E.

3.—STRAITS OF MALACCA TO SOUTHERN INDIA.

IN THE S.W. MONSOON.—It is best to keep on the Sumatra side of the Malacca Strait in going westward during this monsoon, because there is an eddy current at its entrance on that side, especially along the Pedir Coast. Having, by means of every shift of wind and this favouring drift got up to Acheen Head, pass between Pulo Way and Pulo Brasse by the Bengal Passage, keeping close to the latter island and around the islets at its North

end. If bound to Madras the passage will be very tedious, and every slant of wind must be zealously taken advantage of.

If bound for Ceylon or the western ports, and having cleared Acheen Head, make for the southward, keeping off the islands along the West coast of Sumatra as far as possible. Having crossed the equator, and got into the S.E. trades, run down your westing till up with the meridian of the port of destination. Then bear up northward, and if bound to Point de Galle, make the land of Ceylon to the westward; or, if to Trincomalee or the East coast, make the S.E. part of the island, for strong westerly winds and very violent easterly currents prevail about the South part of Ceylon at this season.

This passage to the eastward, during the adverse monsoon, is seldom attempted if it can be avoided, and unless a vessel can keep well on the wind it may be very difficult.

IN THE N.E. MONSOON.—There is do difficulty in this passage. Keep on the Malay coast until up with Junkseylon, and then steer so as to pass between Car Nicobar and the South end of the Little Andaman, if early in the season. If bound northward of Madras, either the above or the Sombreiro Passage may be chosen, taking care to make the coast to the northward of the destined port.

4.—SUNDA STRAIT TO BANKA STRAIT.

Having passed through Sunda Strait, for which directions will be given in the subsequent pages, and bound to Banka Strait, it is usual to steer a direct course for the Two Brothers. With a working wind, it will be prudent to keep within a moderate distance of the Sumatra coast; 11 or 12 fathoms is a good depth. A good mark in daylight is, when standing in-shore, to tack when North Island is just on with the highest Zutphen Island; the soundings will then be generally 7 or 8 fathoms, and a large ship should not risk a less depth when working between North Island and the Swallow Rock, which she will pass eastward of, if the South Brother is not brought eastward of N. by E.

Although the space between the Thousand Islands and the Two Brothers can be navigated with more confidence since its partial examination by Commander Bullock, in H.M.S. *Serpent*, in 1865, yet, as no complete survey has been made, the mariner is recommended to proceed with caution. The Brothers may be passed at a prudent distance on either side. On passing to the eastward, take care to avoid the Lynn and Brouwers Reefs; and when passing between the islands and the Shahbundar Banks, a vessel should not keep farther from the islands than 3 miles, and not nearer the coast of Sumatra than the depth of 9 fathoms.

Having passed the Brothers, steer to the northward towards Lucipara,

keeping the Brothers to the westward of South, to avoid the reported position of the Clifton shoal, and endeavouring to keep in soundings from 9 to 12 fathoms, as a direct course cannot be depended upon, on account of irregular currents or tides setting out from the rivers. Neither can the soundings in this track be implicitly trusted to, being irregular, from $8\frac{1}{2}$ to 11 or 12 fathoms in some places, particularly contiguous to Tree Island bank, and the edges of the other banks projecting from the coast of Sumatra, also in the vicinity of the Arend and Boreas banks in the offing. It will be, however, prudent to borrow towards the main if the depths increase to 12 or 13 fathoms; and to haul off from it if they decrease to $8\frac{1}{2}$ or 9 fathoms towards the banks that line the coast. Near these the soundings are generally hard and more irregular than farther out from the land, in 12 or 13 fathoms; but, in the latter depths, a ship will be too far off the coast with a westerly wind.

When the weather is clear, during the day, it may be proper to get a sight of the coast from the poop of a large ship at times, edging out occasionally in the night, or when the depths decrease to $8\frac{1}{2}$ or 9 fathoms. Having passed the bank off Tree Island, the coast may be approached with greater safety, and the depth will decrease, regularly steering northward for Lucipara, to $5\frac{1}{2}$ fathoms, when it bears N. $\frac{1}{2}$ E. about 10 miles.

If at night a vessel should come into shallow water between the Two Brothers and Lucipara, and not being certain whether she is on either the Arend or Boreas banks, or the bank off the coast of Sumatra, it is advisable to anchor immediately, and to wait for daylight, for the depths are moderate, and the bottom throughout this track generally favourable for that purpose.

5.—BANKA STRAIT TO SUNDA STRAIT.

When bound from Banka Strait to that of Sunda, the proper course will be about S. by E., keeping in from 9 to 13 fathoms; but the currents are too variable to trust implicitly to any course, and the depths also are too irregular to depend on them alone, for the 5 and $4\frac{1}{2}$ fathoms Boreas and Arend banks may be easily mistaken for those south-eastward of Tree Island, which are very dangerous. It will therefore be advisable in day-time to keep on the Sumatra side in 8 or 9 fathoms, from which depths that shore is generally visible from the deck, and at night to keep off shore when the water shoals to less than 9 fathoms, and to approach it when it deepens to more than 13 fathoms, as that depth with westerly winds would be too far off.

Having arrived in about $3^{\circ} 40'$ S., or about 30 miles distant from the Two Brothers, keep as nearly as possible in 9 or 10 fathoms, so as to get sight of these islands bearing South, but not to the eastward of that bearing in order to avoid the Clifton Shoal; otherwise, if made when in 11 fathoms, it would

be difficult to weather them with a westerly wind, especially as the current runs to the south-eastward during the western monsoon. When passing to the eastward of the Two Brothers, recollect the Brouwers and Lynn Reefs.

Coming from the northward the Two Brothers appear like one island, and hence some vessels have been led into danger by mistaking Mound Imbong, or Knob-hill, in Sumatra, when seen in the twilight, for these islands. Sailing past these islands at night, the vessel's position should be well ascertained before dark, or else it would be better to anchor.

Having passed on either side of the Brothers, the safest bearing to bring them upon appears to be N. $\frac{1}{2}$ E. After losing sight of them upon that bearing, a course about S. by W. may be steered for the entrance of Sunda Strait.

Captain Stephens, of the ship *Harkaway*, says:—"In May, approaching Sunda Strait from the eastward the Java side should be steered for, and kept aboard, as then the winds are light, those from S.E. prevailing at night, and from N.E. during the day; this precaution will prevent the vessel being carried by the current to the westward of the Button Islet; this current runs constantly to the S.W. in the middle of the strait, it is checked by the short flood, but runs strong with a long ebb."

6.—BANKA STRAIT TO SINGAPORE.

Vessels bound from Banka Strait to Singapore seldom adopt the Outer route to the eastward of the islands of Linga and Bintang, most vessels preferring to proceed by Rhio Strait; it, however, forms part of the main route into the China Sea, and is therefore of great importance.

OUTER ROUTE.—The ordinary route for vessels bound northward is between the Toejoe Islands and Pulo Taya; they may, however, pass on either side of Pulo Taya, which, being high and bold, is very convenient to make in thick weather or at night.

At night, or in thick weather, the lead will be very useful in detecting the drift caused by cross currents between the Toejoe Islands and Sumatra, for the depth decreases generally towards Sumatra, and increases towards those islands; but care should be taken in approaching them, as the remarkable irregularities of the currents have brought many vessels into the danger of being entangled among them. Near Sumatra a mud bottom mixed with sand prevails, and near the islands mud only.

The Castor Bank, lying to the N.E. of Pulo Taya, carries not less than 5 fathoms water, but a vessel will pass eastward of it by not bringing Pulo Taya South of S.W. $\frac{1}{2}$ W., and westward of it by keeping that island South of S.S.W. $\frac{1}{2}$ W. The East point of Linga (which, with a point to the westward of it, appears at a distance like two islands) bearing N.N.W. will lead from 4 to 5 miles to the N.E. both of the Castor Bank and the Ilchester Shoal. But in order to avoid the last-named danger, if the channel between

the Castor Bank and Linga is used, take care not to bring the East point of Linga to the East of North.

Having passed eastward of Pulo Taya, a course may be steered to cross the equator in 20 or 21 fathoms, or in long. 105° 30' E. From the equator steer about North until past the Frederick and Geldria shoals, observing in the night not to come under 23 or 24 fathoms between lat. 0° 30' and 0° 50' N. to avoid those dangers; if it be day when Pulo Ruig or Ragged Island is seen, keep it westward of N.W., and it will lead eastward of these shoals. When abreast of Pulo Panjang, and in soundings of 24 or 25 fathoms water, a N.W. or N.W. by W. course, according to tide, will lead to the entrance of Singapore Strait.

The INNER ROUTE, by the Strait of Rhio, will be noticed in connection with the description of the coast of the strait hereafter given, as the various marks, &c., will be best understood by referring to those descriptions.

Vessels bound from Banka Strait to Singapore during the strength of the N.E. monsoon frequently adopt the Inner Route by the Varella and Durian Straits. During the prevalence of strong northerly winds in the months of December and January, sailing vessels will save much time by doing so, for here they will have smooth water, good anchorage, and but little tide, whereas on the eastern side of Linga, at this season of the year, there is generally a heavy sea, and a southerly current sometimes running at the rate of 3 knots an hour. In Varella Strait they will also be greatly assisted by the squalls from the Sumatra coast.

Varella, or Brahalla Strait, is situated at the southern part of this route, and Durian Strait at its northern part; the intermediate portion has not received a specific denomination. The entire route is about 120 miles in length from Pulo Varella to the Carimon Islands, and is bounded on the western side by the coast of Sumatra, False Durian, Sabon, and the contiguous islands; and on the eastern side by Sinkep and the other islands off the South and West coasts of Linga, and by Great and Little Durian, and the adjacent islands.

The STRAIT OF MALACCA and STRAIT OF SINGAPORE, and their navigation, will be also described in subsequent pages.

7.—SINGAPORE TO HONG KONG.

IN SOUTH-WEST MONSOON.—When June approaches, and the S.W. monsoon is set regularly in, the track from Singapore to China by the main route, eastward of Pulo Sapatu and over Macclesfield Bank, is preferable, the winds being more steady in the open sea than near the coast. About full and change of the moon, and as early as April, a westerly breeze will sometimes be found blowing out of the Gulf of Siam to carry a vessel to Macclesfield Bank, and afterwards easterly winds to run her to Hong Kong.

This route becomes precarious if a sailing vessel is not up with Pulo Sapatu early in October; for near this island, about the middle of that month, strong southerly currents begin to prevail with light northerly winds, variable airs, and calms, by which many vessels have been delayed for several days, and have made no progress to the northward. Fresh winds from the southward have been met with, even so late as 1st of November, but these instances are rare.

Some vessels proceeding by the main route have carried strong S.W. and southerly winds, when others taking the inner route have at the same time experienced N.W. and westerly gales blowing out of the Gulf of Tong King, with dark weather and rain, and have been in danger of being driven among the Paracel Reefs; the inner route ought, however, to be chosen in the strength of the S.W. monsoon if the vessel is weak and making much water, for the sea will be smooth, and being near the land she may reach an anchorage if required. The gales out of the gulf are not frequent, and the land may be kept in sight nearly all the time.

Taking the inner route, steer from Pulo Aor along the coast to the Redang Islands, thence across the Gulf of Siam, and along the coasts of Cambodia and Cochin China, keeping the latter aboard to Cape Touron. From thence steer for the S.W. part of Hainan, coasting along this island, and passing between it and the Taya Islands; then cross over to make the coast of China about Tien-pak, or Hailing Island. The islands from thence to Hong Kong may be coasted along at discretion, or shelter may be found amongst them on an emergency. If this route is taken before the middle of March or 1st of April, the passage will be tedious unless the vessel is a good sailer.

Bound to Hong Kong in the strength of the S.W. monsoon, with the wind steady between S.E. and S.W., endeavour to make the Great Ladrone Island bearing about North, then steer between it and the Kypong Islands, and between Lingting and the Lema Islands, for the West Lamma Channel. After the middle of August, when easterly winds are likely to prevail several days together, as they are more or less at all seasons, it will be necessary to make the N.E. head of the Lema Islands, and proceed in by the Lema Channel, towards the West Lamma Channel. The East Lamma Channel is also safe in both monsoons, for although the water is deep, if the wind falls light it is safe to anchor in, and there is little or no tide.

IN NORTH-EAST MONSOON.—Sailing vessels leaving Singapore for China in February, March, and part of April, may expect a tedious beating passage, if they adopt the main route. In March, April, or May, they can proceed by the inner route along the Coast of Cochin China, which is generally the most expeditious route in these months.

The passage to China by the coasts of Palawan and Luzon may be followed late in the S.W. monsoon; without much difficulty in October and

November; and it is now often made in December, January, and at every period of the N.E. monsoon.*

In December, January, and February,† sailing vessels should not leave the entrance of Singapore Strait, in strong N.E. winds, but anchor on the northern shore, under the Water Islands, in 9 or 10 fathoms. In those months gales often occur at new and full moon; the weather is then thick, the rain lasting two or three days, and the current outside accelerates to the S.S.E. $\frac{1}{2}$ E. from $2\frac{1}{2}$ to 3 knots an hour. A vessel leaving the strait then, instead of fetching St. Barbe Island, would fall bodily to leeward, and have to work up the West coast of Borneo. Fine weather follows, the wind backing round to North and N.W.; the current in the offing decreasing in strength to about $1\frac{1}{4}$ knot.

Leave the Water Islands with the first of the ebb, and keep clean full. Stand to the north-eastward to go through the channel between Subi Island and the Great Natuna; a passage that may without much difficulty be made, in these months especially, at full and change, when the wind, after

* It was formerly the general custom for the clipper vessels employed in the opium trade between India and China to beat up the middle of the China Sea in the strength of the N.E. monsoon, keeping as close to the western edges of the reefs as possible, where the current was found to be generally in their favour. Many commanders who have been accustomed to make their passages in that way are strongly of opinion that it is the best route for vessels later in the season than the month of November, whilst others who have been accustomed to proceed by the Palawan have just as strong opinions in favour of that route. The following remarks of Mr. T. B. White, who was for many years in command of clipper vessels engaged in the opium trade, appear to be exceedingly valuable, inasmuch as they furnish a balanced opinion on the respective advantages of these routes. He says: "I am sorry I cannot say much from experience in beating up the Palawan in a sailing vessel, for during the entire period of my command of the *Laurick* I never once went that way, but always along the western edges of the shoals. I am, however, now quite certain that I should have often made much quicker passages, and saved much wear and tear, by going up the Palawan. In the *Fiery Cross*, although a powerful steamer, I found it preferable to take the Palawan, and always did so during the strength of the N.E. monsoon (November to February), saving fuel and wear and tear; and, though a longer route, made better passages by getting smooth water and often favourable currents. I believe nearly all heavily laden ships now take the Palawan from October until the end of February in preference to the outer passage, and a current to the north-eastward is generally felt the nearer the Borneo coast is kept aboard, and usually the weather is moderate, with a rolling beam swell on; at least that has been my experience when going up in the steamer. Mr. Reynell, in the clipper *Waterwitch*, usually took the Palawan in the N.E. monsoon, and made some very good passages. Now that it is so thoroughly well surveyed, I consider it quite as safe as the outer passage."

† These directions (as far eastward as the Natuna Islands) apply with equal force to vessels bound either to the Gulf of Siam or the River Saigon. They have been compiled chiefly from "Sailing Directions between Singapore and the River Saigon, by Mr. A. J. Loftus, commanding the ship *Kensington*," by Commander J. W. King, R.N.

a few hours' calm, frequently hauls to the westward with squalls and rain, and then veers round to S.W. and South, blowing moderately for 24 hours.

By taking advantage of these slants, Subi may be easily weathered, and the intricate channels between it and the N.W. coast of Borneo avoided. After fetching Low Island, in long. $107^{\circ} 48' E.$, if the wind continues easterly, take the starboard tack to the northward, passing westward of Low Island, keeping not less than 3 miles from the south-western side, to avoid the shoal water as far as 2 miles from its shore. Give Haycock a berth of 3 or 4 miles in passing, as the coral shoal about that island extends fully 3 miles from its S.W. side. Large ships should not pass eastward of Haycock at night, as this locality is said to have hidden danger.

After passing Haycock there will be no difficulty in working up to the S.E. point of the Great Natuna, as that island, when approaching it from the S.W., shelters against the strong N.E. current of the monsoon. Off its southern shore at night, in fine weather, the wind is off the land, which should not be approached nearer than 2 or 3 miles without a good breeze, as the water is deep close in-shore, and no good anchorage.

Vessels fetching to leeward of Subi with a northerly wind should take the Koti Passage, between Pulo Panjung and Sirhassen Island. The Sirhassen Passage is also a good channel, and quite safe when the South side of Sirhassen Island is kept aboard. The currents among these islands are more regular; but not so in the Api Passage, where they set in various directions, and with great velocity to the S.W. from 16 to 19 hours at a time; for large ships any of the other passages are preferable to this, for great caution and perseverance are requisite in working through, as the Borneo coast in from 10 to 11 fathoms water must be kept aboard to avoid the current and profit by the land winds.*

In taking the Koti Passage, give Pulo Panjung a good berth to avoid the

* For steam vessels (especially those of small power) proceeding to China by the Palawan passage against the N.E. monsoon, the route by the Api Passage and the coast of Borneo presents the following advantages: first, light, variable winds and smooth water will often be found close to the Borneo coast, when a strong monsoon is blowing a hundred miles off it; and next the Api passage route affords convenient landmarks to lead a vessel safely and expeditiously to the entrance of the Palawan; whereas by the ordinary route much difficulty and delay frequently occurs in making Low Island, and in passing between the Royal Charlotte and Louisa Shoals.

Steamers leaving Singapore should pass southward of Victory Island, then steer to sight the small island of St. Pierre (carefully observing and allowing for the set of the current), and afterwards for the Api Passage, keeping over towards Marundum Island rather than Api Point. Having passed Marundum and Data Point, the course is clear up to the entrance of the Palawan, passing between the South Luconia shoals and Barram Point, and keeping as close to the Borneo coast until abreast of that point as circumstances may make convenient.—Navigating-Lieutenant J. W. Reed, commanding Her Majesty's surveying vessel *Rifleman*, 1866.

dangerous reef which surrounds it. The winds amongst these islands, and as far eastward as the meridian of Cape Sirik, are generally from North to N.N.W. The passage cleared, proceed to the north-eastward; endeavouring, if not certain of the longitude, to make the Royal Charlotte or Louisa Shoal, whichever is the weathermost, by running on its parallel of latitude; and as the currents appear to be influenced by the prevailing winds, vessels should be prepared to anticipate a set in the direction in which it is blowing, the velocity of the current being proportionate to the force of the wind.

Having made either the Royal Charlotte or Louisa Shoals, on passing mid-channel between them, steer E. by N. 100 miles, and then about N.E. for lat. 8° N., long. $116^{\circ} 15'$ E., when Balabac Peak will probably be seen bearing about east-southerly, and making like a rather flat-topped island, with a small peak rising in the centre; when about 40 miles distant from the island, the low hills may be seen on either side of the peak, having at first the appearance of detached islands.

Having brought Balabac Peak to bear about E.S.E. at the above distance, a N.N.E. $\frac{3}{4}$ E. course should be steered, when the high land of Bulanhow will soon be discernible, bearing about N.E. by E. $\frac{3}{4}$ E. This course should lead about 6 miles eastward of the reported Roger Breakers, 10 miles westward of the elbow of the bank of soundings fronting Palawan Island, and midway between the Royal Captain Shoal and the edge of the bank (the most dangerous part of the channel). When Bulanhow Mountain bears S.E. by E. $\frac{1}{4}$ E. the vessel will be in line with it and the Royal Captain Shoal, and in the narrowest part of the channel, which is $27\frac{3}{4}$ miles wide, and the high land of Mantaleengahan will then bear E. $\frac{1}{4}$ S.

If the wind be well to the southward, and the weather thick, Balabac Island may be approached nearer, in order to get well hold of the land, but extreme caution should be taken not to go within 12 miles of it, as soundings of 26 and 20 fathoms extend that distance off, in a westerly direction from the peak, having shoal patches immediately inside them.

If the wind be to the westward, with thick cloudy weather, Balabac Island should not be approached nearer than 36 miles, for these winds usually force a strong current through the straits to the eastward, and when off the S.W. end of Palawan, it is not unusual for them, particularly in squalls, to veer to W.N.W., and sometimes N.W., blowing with great violence, and placing the vessel on a lee shore with respect to the shoals inside the edge of the bank. It generally so happens, that about the time, September and October, when vessels adopt the Palawan route, this weather prevails off the S.W. end of Palawan, rendering it uncertain and difficult to hit the narrowest part of the channel, owing to the land being obscured, especially if neither the Royal Charlotte nor the Louisa Shoal has been made, and the longitude corrected.

Under these circumstances, it is advisable to advance with caution, regu-

lating the speed of the vessel so as to be in the fairway, viz., lat. 8° N., long. $116^{\circ} 15'$ E., for making the channel at daylight. Horsburgh recommends lat. $8^{\circ} 30'$ N., and long. $116^{\circ} 30'$ E., but this may be running too close at night, unless confident of the accuracy of the reckoning.

If not certain of the vessel's position, endeavour to get soundings on the edge of the bank to the north-westward of Balabac Island, and the safest part to approach for this purpose is that about the elbow, on the parallel of $8^{\circ} 30'$ N., or immediately to the southward of it, for it is believed the portion of the bank which is embraced by the bearings of Balabac Peak, S.E. by E. $\frac{1}{2}$ E. and S.S.E., comprising a distance of 25 miles, is free from danger. If the peak be obscured, the same bearings of the body of the island will, if taken with care, answer. Or should the North extreme of the island be discernible (showing like a hillock, with a low double hill to the southward), the part of no danger will be included within the lines of bearing of it, East and S.S.E. $\frac{3}{4}$ E.

During the period in which the *Royalist* was engaged upon this survey, experience led to the belief that in the thickest weather the land is seldom totally obscured for any length of time.

Having obtained soundings, which will be about 90 fathoms, if close to the edge of the bank, and from 45 to 55 fathoms, sand, if inside, haul off to the north-westward, to give the edge a berth of about 10 miles, then steer the channel course N.N.E. $\frac{3}{4}$ E. When Bulanhow Mountain bears eastward of E. by N. $\frac{1}{2}$ N., the elbow has been passed, and the bank then trends N.E. by N. It is between the elbow and the parallel of $9^{\circ} 15'$ N. (a distance of 60 miles) on the East, and the Half Moon, Royal Captain, and Bombay Shoals on the West, that the most dangerous part of the Passage lies.

When Montaleengahan Mountain bears S.E. $\frac{1}{2}$ E., or the Pagoda Cliff, (generally seen when the more elevated land is obscured), S.E. $\frac{1}{2}$ S., the vessel will be on the line of the Bombay Shoal, where the channel is 28 miles broad.

Having passed the Bombay Shoal, abreast of which the bank trends N.E. $\frac{1}{2}$ N., steer a course parallel with its edge, preserving a distance of 8 or 12 miles from it, and 27 or 30 miles from the land, or nearer, if convenient, and the peaks on Palawan are sufficiently distinct to get good cross bearings. It is, however, not desirable to get too close, as the edge of the bank in about the parallels of $9^{\circ} 30'$ and 10° N., is not uniform in its outline, and several rocky patches lie within a mile, and in some places only 3 cables' lengths from the 100 fathoms line.

This N.E. $\frac{1}{2}$ N. course, edging a little more to the northward when abreast of Ulugan Bay, where the bank extends 28 miles from the shore, will take a vessel through the passage clear of every known danger.

Vessels working through the Palawan Passage, having conformed to the directions given for making the S.W. end of Palawan, should, in fine weather, endeavour to make their inshore boards in the afternoon, for the

sun then being astern of the vessel, the patches lying near the edge of the bank will generally be distinguished from the mast-head in ample time to tack off. In squally weather, also, during heavy rains, these patches have been observed imparting a yellowish hue to the surface of the water.

It is almost needless to remind the seaman (when the land is obscured) of the desirableness of getting hold of the edge of the bank before dark, in order that he may have a good departure for the night; and on making his inshore board, it must also be borne in mind, that the probability of coming *suddenly* into soundings is great, as the approach on this tack will generally be at right angles to the edge of the bank. He should therefore be prepared to go round immediately on getting indication of soundings.

Proceeding northerly from the Palawan Passage, it is customary to beat up the West coast of Luzon to Piedra Point, and thence direct for Macao or Hong Kong, passing leeward of the Pratas. But if bound to any of the ports northward, much time might be saved by passing along the eastern coast of Formosa, thereby avoiding the heavy labour, wear, and loss of time, by the attempt to work against the monsoon along the coast of China, which even a clipper sometimes fails in effecting.

In working along the Luzon coast, particularly about dawn or sunset, less sea, and much lighter winds, and at times even land breezes will be experienced by hugging the coast by short boards; but great caution should be observed, particularly between Piedra Point and Cape Bojeador, as several coastline dangers do not find a place in the charts.

The first strong gust of the monsoon will be experienced on clearing Cape Bojeador, but this should not induce the navigator to stand further westward than will enable him to make his eastern stretch to weather it, when he will at once experience less wind. This generally is the case on all lee shores backed by mountains, either resulting from obstruction, reaction, or the effect probably, after sunset, of counteracting land winds. Among the groups northward of Luzon there are no dangers which are not easily avoided, and no continuous strong breezes will be experienced, at all comparable in force, or attended by high sea, similar to those which prevail between Piedra Point and Hong Kong. On the contrary, good working breezes, and at times light winds prevail, enabling a sailing vessel of moderate speed to make the range of 6 degrees northing in 8 days. Typhoons are likely to happen in both monsoons between the North coast of Luzon and Formosa.

8.—HONG KONG TO SINGAPORE, ETC.

IN NORTH-EAST MONSOON.—Ships bound from China to Singapore, or to the Straits of Gaspar and Banka, should in March and April adopt the main route by the Macclesfield Bank, which is the most expeditious in these

months, keeping to the eastward on leaving the China Coast; and also in passing Pulo Sapatu they ought to borrow to the eastward towards the shoals, where the winds are more favourable in these months than farther to the westward. In April, the *Vansittart*, by keeping about 3 degrees more to the eastward than the *Herefordshire*, made as much progress in one day as the latter did in ten.* At all other times, the inner route by the coast of Cochin China seems preferable; for it is the shorter, and the ease afforded to ships by steering from the Grand Ladrone immediately before the wind, when blowing strong at N.E., is a great advantage; whereas, by the main route, a S.S.E. course is shaped for the Macclesfield Bank, often bringing the wind and sea before the beam, which strains a deeply-laden ship. Many have strained so much, that, in order to gain upon the pumps, they were forced to bear away for the inner route; others, by persevering in the main route, have laboured excessively, and some of them at last foundered with their crews. Some of the ships which, after leaving China, have been missing, have probably suffered from the same cause. Had those ships, on leaving Canton River, steered S.S.W. $\frac{1}{2}$ W. or S.S.W. $\frac{1}{4}$ W., the direct course for the inner route, they probably would not have strained in the least, but have reached their ports of destination in safety.

Vessels may, according to circumstances, pass either to the eastward or westward of the Catwick Islands and Pulo Ceicer de Mer, or through any of the channels between them; but since the Rawson Shoal is known to have no existence, it would seem advisable, in thick weather, to pass 20 or 30 miles eastward of Pulo Sapatu, especially at night: from thence, passing westward of the Charlotte Bank and the Anamba Islands, steer to make Pulo Aor.

Should the weather be thick, and a fresh breeze blowing, when near Pulo Aor, round to under its lee, and wait a convenient time to bear up for the

* Captain Stephens says:—"Vessels leaving the coast of China or Manilla, and bound towards Sunda Strait, in March, April, or in the early part of May, may expect a tedious passage down the China Sea if proceeding by the old route which passes Pulo Sapatu, particularly if they do not sail before the 5th or 10th of April. Whereas, if the track be taken along the coast of Luzon, down the Palawan Passage, along the coast of Borneo, past Direction Island, round Soruetou, and through the Carimata Strait, passing close round the North Watcher, and on for St. Nicholas Point on Java, they are likely to carry easterly winds, with fine weather and a smooth sea, the whole distance, thus making a direct course, and will avoid calms. The current will also be more favourable than otherwise until May is well advanced. To prove the advantages of the eastern route, it may be stated, that in April, 1861, two American ships sailed from Fu-chau-fu; one proceeded by Pulo Sapatu on the West side of the China Sea, the other by the Palawan Passage and Carimata Strait; the latter ship passed Anjer twenty days before the other. The *Harkaway*, on her passage in April and May, 1862, carried an easterly wind the whole way down, and had no occasion to anchor."

strait.* The current between this island and the East point of Bintang sets about S.S.E., by which it often happens that vessels leaving Pulo Aor steer too much southerly, and are swept with the current and the ebb tide coming out of the strait, so far to leeward of Bintang, that they have been obliged to proceed round it, and come up through Rhio Strait.

In March, during the latter part of this monsoon, the winds are steady from the eastward, the weather settled, and the current weak. In April the prevailing winds are also from the eastward, and are much lighter and accompanied with calms and squally weather; from the latter end of this month to about the middle of May the monsoon gradually breaks up.

In SOUTH-WEST MONSOON.—Captain Blake, of H.M.S. *Larne*, remarks:—

Although formerly considered impracticable, it is now a common practice for ships to work down the China Sea at all periods of the S.W. monsoon. After leaving Hong Kong, the usual course is to stand towards Hainan, which will be often fetched without tacking, as the wind frequently blows for days together from the S.E. or eastward in that part of the China Sea; from thence across the Gulf of Tong King to the Cochin China coast. Land and sea breezes and smooth water generally prevail close to that coast, for which reason it is usual to work down as close to the shore as possible, taking advantage of every slant of wind, but being careful not to get too far off the land. It is sometimes possible to get as far to the southward as Cape Padaran in this way, but generally after passing Cape Varela the monsoon is found blowing very fresh, with frequent hard squalls out of the Gulf of Siam, rendering it impossible for a ship to do much to windward. From Cape Varela, or from Cape Padaran, if a vessel has been able to fetch it, stretch away to the southward—making a tack, if necessary, to weather the West London or other shoals—till the coast of Borneo is reached, along which work, and pass out through any of the South Natuna channels. Stand across to Singapore, keeping well to the southward before closing Bintang, to be sure of your landfall, as the currents run very strong, sometimes 2 miles an hour to the northward.

9.—SINGAPORE TO GULF OF SIAM AND TO SAIGON.

In NORTH-EAST MONSOON.—Sailing vessels bound from Singapore to the Gulf of Siam in the N.E. monsoon generally pass eastward of the Natuna Islands. Smart sailing vessels proceed between the Anamba and Natuna Islands, and endeavour to make Pulo Obi; they then steer for Pulo Dama, if bound to Kamput, in the Gulf of Siam; or outside Pulo Panjang and Pulo Way, direct for Cape Liant, if bound to Bangkok. In February and March it frequently happens that vessels fall in with an easterly wind off Pulo Aor, that takes them right up to Pulo Obi.—*Captain Loftus*.

* Since the establishment of the Horsburg light on Pedra Branca, there is really now no difficulty in making Singapore Strait at any time, with proper attention.

The directions given on page 55 for proceeding from Singapore to Hong Kong apply also to vessels bound to the Gulf of Siam or to Saigon, until they have arrived to the eastward of the Natuna Islands, either by passing between the Great and South Natuna, or by the Koti Passage, when—

If bound to the Gulf of Siam, proceed to the north-eastward to about long. 111° or 112° E., which can easily be done, as the wind here is invariably from North to N.N.W. as far as the meridian of Cape Sirik, when it generally hauls to the north-eastward; then with a full sail stand on the starboard tack towards Pulo Obi. Little or no current will be experienced until lat. 6° or 7° N. is gained; when it will be found setting strong to the S.W., governed considerably by the prevailing winds.

In April and May the best passages to the gulf are made by keeping the Malay coast aboard; but expect squalls, calms, and rain. The current will also begin to set weakly to the N.E.—*Lieut. J. Richards, R.N.*

If bound to Saigon, proceed to the north-eastward to about 112° E., when stand over with a full sail on the starboard tack, to make Cape Tiwane. From lat. 7° N. until the mouths of the Cambodia Rivers bear West, distant about 70 miles, strong currents will be found setting to the S.W., governed considerably by the prevailing winds, for when strong gales blow in the early part of this monsoon, the south-westerly current is stronger, and often runs 3 knots an hour. The tides are regular, and set pretty strong in-shore on the Cochin China coast during both monsoons.

In the latter part of March and April an easterly wind is often found to the eastward of the Anamba Islands, that will take a ship to the Brothers, W. by S., about 24 miles from Pulo Condore; and afterwards she may work up to Cape St. James inside that island, keeping close to the Cambodia coast, which is very low, and can seldom be seen at night.

After opening out the mouths of the Cambodia Rivers, strong ebbs will be found setting to windward, greatly assisting ships on the in-shore tack; but they should not stand near these mouths during the flood tide, and on no account shoal the water to less than 12 fathoms in the night. The lead should never be neglected when standing towards this low land, which may be seen about 10 miles off on a fine clear day.

N.E. and N.N.E. gales often blow in the latitude of Pulo Sapatu, and between it and the Cochin China coast, in December, January, February, and sometimes March. They continue for two or three days with a heavy sea and strong current. A gradual rise in the barometer is a sure indication of one of these gales; while at their height the mercury fluctuates about $\frac{1}{100}$ of an inch during the twenty-four hours, and commences falling before the gale is over, the sky being generally thick and hazy throughout.

After sighting the land, the vessel should gain the meridian of Cape St. James in one of these gales, bear up for Pulo Condore, and anchor either in

the Great Bay, or in Pulo Condore Harbour, where good shelter will be found; otherwise the vessel will be drifted to leeward of that island, and require several days to beat back to regain her former position.

IN SOUTH-WEST MONSOON.—In this monsoon the winds prevail between S.E. and West in Singapore Strait, and vessels will have no difficulty in sailing through to the eastward.

If bound to the Gulf of Siam, having cleared Singapore Strait, shape a course to make the Redang Islands; and from thence keep the western shore of the gulf aboard, passing inside Puly Lozin and Koh Krah.

If bound to Saigon, steer to pass to the westward of Pulo Condore, making allowance for a current setting out of the Gulf of Siam, whilst crossing the entrance of that gulf. When the body of Pulo Condore bears about South, steer North, or N. $\frac{1}{2}$ W., if an easterly current prevail; which will soon bring the vessel on the edge of the bank that fronts the mouths of the Cambodia Rivers, and extends to the entrance of Saigon River. Steer then northward along the edge of the bank, keeping in 8 to 12 fathoms; if the water shoalens under 7 or 8 fathoms, haul to the eastward, and it will immediately deepen, the soundings being regular on the edge of the bank.

Directions for making the land about Cape St. James, and for proceeding up the Donnai River to Saigon, are given hereafter.

10.—GULF OF SIAM TO SINGAPORE.

IN NORTH-EAST MONSOON.—From Bangkok the passage down the gulf will frequently be shortened in the N.E. monsoon, by sighting the Kusrovie Rock, and passing between the Tanqualah group and Koh Tron. Keep well to the westward of Pulo Panjang, and if bound to Singapore, the passage will be made quicker by hauling well out into the China Sea; passing about 20 miles outside Pulo Brala, outside Pulo Aor, and then steering for Barbukit Hill, so as to allow for the southerly current setting across the strait.

Approaching Pulo Timoan at night or in thick weather, a good lookout should be kept, and allowance made for the current setting to the south-westward, as vessels have several times found themselves close to the North end of that island when their reckoning has placed them well to the eastward of it.

IN SOUTH-WEST MONSOON.—From Bangkok to Singapore keep the western shore of the gulf aboard, passing inside the Redang Islands, Pulo Kapas, and Pulo Brala. Below Pulo Kapas, everything depends on keeping in shore out of the current, and taking advantage of the land and sea breezes. (*Lieut. J. Richards, R.N., 1858.*)

11.—SAIGON TO SINGAPORE.

IN NORTH-EAST MONSOON.—From Cape St. James shape a course to pass to the eastward of Pulo Condore, and from thence direct to make Pulo Aor. From Pulo Aor to Singapore proceed according to directions previously given.

IN SOUTH-WEST MONSOON.—Many good passages have been made by keeping the Cambodia coast aboard as far as the Brothers or Pulo Obi, and then crossing the Gulf of Siam with a strong north-westerly wind until the Malay coast is reached, and afterwards working with the tides, keeping close inshore, by passing inside of Timoan group, Siribuat, and Pulo Sibū,* and thence to the Strait of Singapore, taking advantage of the regular tides and the land and sea breezes which prevail during settled weather in this monsoon.

This route is generally adopted by ships from Siam, and sometimes from Saigon; but the passage to the eastward of the Great Natuna is considered the best, particularly for large vessels.

Vessels leaving Cape St. James should take every advantage of the North and N.E. winds, which frequently blow at night, and in some parts of the day, within a short distance of the coast, by running to the south-westward, until the regular monsoon breaks them off to the S.E. These local winds often carry ships 40 or 50 miles to the south-westward of Pulo Condore without any interruption.

While standing over to the S.E. the full strength of the north-easterly current will be met with about the Charlotte Bank; it gradually decreases and becomes slightly favourable when the Great Natuna is brought to bear S.W. Hereabouts S.E. and easterly winds will generally be met with, and smart sailing ships frequently pass through the channel between Subi and Low Island, and fetch direct into Singapore Strait.

Strong westerly winds with rain frequently happen during the early part of this monsoon, and from this cause or by fetching 2° or 3° to the eastward of the Great Natuna with scant southerly winds after leaving the Cambodia coast, dull sailing vessels have often made the northern part of Borneo about the meridian of Cape Sirik. When this is the case, make for the Api passage, keeping the N.W. coast of Borneo aboard from Tanjong Datu until the Boerong Islands are reached.† This will be accomplished without

* The inside channel, extending from Pulo Sibū to Siribuat, and formed by a chain of islands and rocks parallel to the main, is a good and safe one, having but few hidden dangers, and good anchorage all the way through.

† Many vessels, through leaving the coast of Borneo too soon, have fetched no higher than Pulo Aor or Pulo Timoan.

difficulty, for strong land and sea breezes prevail, and the current is weaker near the coast.

The current in the offing runs strong to the northward and through the Api passage. Ships coming through this passage should never shoal their water to less than 12 or 14 fathoms between Tanjong Datu and Tanjong Api, and never pass them nearer than 2 or 3 miles, but should be ready to anchor in it off any other part of the coast, as the tides are greatly influenced by the currents, which often change without warning.

Leaving the Boerong Islands, pass either northward or southward of the Tambelan group. Should the wind be scant from the S.W. after leaving these islands, steer as high as possible, and endeavour to make Pulo Pantang, off the East side of Bintang Island. (*Captain Loftus.*)

EASTERN PASSAGES.

12.—EASTERN ROUTE TO SINGAPORE.

Captain Mc Kenzie gives the following remarks on this passage:—The passage to Singapore, &c., through Balli and Lombok, and the Eastern Straits, late in the S.E. monsoon is often tedious, as the S.E. currents begin to prevail in October, and light winds, which frequently haul to West and N.W. after passing Pulo Mancap. After leaving the Straits of Lombok or Balli, easterly winds will carry you past Pulo Mancap. The best track thus far will be between Pondy and Galion (safe in the night time), and then to the southward of Lubeck, going well to the westward of the Mancap Shoal, and just giving the Discovery Bank, and other dangers on the West side of the passage, a fair berth. Steer for the Eastern Montaran Island, passing between it and the next westerly one, the passage is quite clear; steer then to the W.N.W. along the coast of Billiton. It is best not to go inside the Montaran Shoals, as the wind there at that time of year is seldom more westerly than S.W., consequently a vessel will lie up high enough, from the East Montaran, to pass South of Pulo Dogan, Taya, and Sinkep (if possible to weather the last), if not the Straits of Dasse are quite safe, and quickly passed through with the tide.

After passing through either of these straits, run for Singapore by Durion Straits.

As to beating down the Carimata against the S.E. monsoon, I believe the best plan is to go through Rhio Strait, then stretch over to the Borneo coast, and work down it close in, anchoring for the tides. From Rendezvous Island make for the Java shore, and if bound easterly work along it. This passage is easily made to Sourabaya in fifteen to twenty days. But it is beating up

from Balli, Lombok, or the East end of Java, in the West monsoon, that requires some remarks ; and for vessels usually deeply loaded with rice, it is a difficult thing to beat up against a strong monsoon and lee current. Two routes have been generally adopted, one to the southward of Java, and the other by beating up the Carimata. By both these routes I have known some vessels get to Singapore in forty days, and some have been fifty, sixty, and eighty days. I should say sixty was an average passage from Balli or Lombok ; and the vessel much strained, sails worn, and cargo probably more or less damaged. I should, therefore, confidently recommend an eastern route, which I have no doubt has been by this time followed by the commanders of Balli vessels, at my suggestion. This is, to go through the Molucca, or even Gillolo passage, and then with the North and N.E. winds through the straits of Balabac into the China Sea, and thence to Singapore. A fair wind would be secured all the way, and the passage made in twenty-five or thirty days, with ease and comfort to the vessel. This may seem a very circuitous track, yet I am certain that it is the quickest way to Singapore. And any one who had once tried either of the other routes would find the difference, when comparing with the eastern route, the harassing work from Pulo to Singapore, and the strong rush of current from the China Sea that begins so early as October before the N.E. monsoon has set in.

13.—EASTERN ROUTES TO CHINA, ETC.

The passages hitherto described are those which are entered by the Straits of Malacca or Sunda, the two principal highways into the China Sea. But during the adverse N.E. monsoon it may be thought preferable to take one of the channels *eastward* of Borneo, and thus avoid the wear and tear of beating up the China Sea in the teeth of the monsoon. In this case, the former universal practice was to follow one of the eastern straits, passing to the East of Borneo, and taking the Strait of Macassar, which leads into the Celebes Sea, from thence, according to circumstances, from this sea proceeding North, and passing East or West of the Philippines. A vessel can also, in this season, take Pitts passage to the East of the Celebes, crossing the Moluccas, and entering the Pacific Ocean by Pitts Strait, Dampier Passage, or that of Gilolo, then keep to the eastward of the Philippines, entering the China Sea by the Strait of Formosa.

Thus, in a general way, it may be taken as a rule, that when the monsoon is favourable in the China Sea, ships must pass to the West of Borneo, but with a contrary monsoon must pass to the East of that island.

October and November are considered the two most favourable months in which to pass the Strait of Macassar quickly. This is the first of the eastern routes. In the other months it is more advantageous to take Pitts Passage, especially from the middle of December to February.

On arriving at the eastern straits in the latter part of January or in February, the Strait of Lombok is generally taken, and generally in passing it, cross the channel East of Banditti Island. You can also round this island to the West, but the channel is very narrow. The channel between Lombok and Banditti Island is generally preferred, and then the East coast of this strait is soon reached. From there ships pass to the strait of Macassar, by passing to the East of Hastings Island and Little Pulo Laut, then the coast of Celebes must be passed in order to enter the strait of Macassar. If instead of taking Lombok Strait that of Balli is chosen, with the intention of passing in the Macassar Strait, ships return to the North by passing by the channel between Pundy and Galion Islands; then round to the West at a good distance from the islands and banks of Kalkoon, and pass the little island of Pulo Laut on whichever side seems best.

On coming from Allas Strait a vessel would steer for Hastings Island, and pass East of it, the same as if coming from Lombok Strait. On arriving from Sapy Strait during the months of September and October, a ship would, according to the prevailing winds, pass to the East or West of the Postillions, and proceed to the North between Tanakeke and the Tongu Islands; then pass at a good distance the isles and banks of Spermonde, which are N.W. of Macassar Bay, and enter the strait and keep on the Celebes coast to pass through. A vessel going out of the strait in March or April off Cape Donda must cross the sea of Celebes, and steer for the extreme East of Bassilan.

A vessel making for the channel between Basilan and the West point of Mindanao, must take care to keep well to the East, if the winds will permit, so that she may not be drifted among the Sooloo Islands by the westerly currents. If she gets to leeward of them, she will find good channels between the isles situated to the West of Sooloo; and then crossing the sea of Mindoro, keep near the coast of the Philippines (Mindanao, Negros, Panay, Mindoro, and Luzon). At the opening of the channel between Mindanao and Negros, and also between Panay and Mindoro, strong winds from the N.E. and westerly currents are generally encountered. A ship must guard against these currents in passing from one island to another, so as not to be set to leeward.

If a ship leaves Basilan Strait with steady winds from S.W. and South, she may steer directly for Point Naso, or keep rather to the East of its meridian; but if the winds are variable or uncertain, she should keep close to Mindanao till Point Galera is reached, and then cross to Naso Point, taking care to keep near Negro Point in crossing from one point to another.

From Naso Point steer North along the coast West of the island of Panay, taking every precaution against the dangers which lie to the West of this coast. Then passing the islands lying near the S.W. point of Mindoro, she will enter the channel either East or West of them and the Apo Bank.

With easterly winds in entering the eastern channel, keep 2 or 3 leagues from the coast of Mindoro ; but with a westerly wind, take care not to go more than 9 or 10 miles from the coast until you are North of the Apo Banks, thus clearing the Strait of Mindoro ; and after having doubled the promontory of Calavite, and passed Luban and Goat Island, you must follow the coast of Luzon as far as Cape Bolinao. Having reached this cape, you may be pretty sure of passing East of the Pratas and reaching Macao. However, it is more prudent to steer North as far as Cape Bojeador before crossing for the coast of China. Also, at this season, a vessel may enter the Pacific Ocean by passing South of Mindanao, when the sea of Celebes has been reached. For which, if the wind permit, steer direct for the Serangani Islands, passing between them and Mindanao, or else South of the former. From thence pass between the Meangis and Tulour Isles, in order to double the North cape of Morty Island with the wind at N.E. If any difficulty arise in taking this route, the channel between the Tulour and Sangir Islands may be adopted.

But after having proceeded from the Strait of Macassar, and passed between Siao and Tagolanda, or one of the neighbouring Sangir Channels, steer to the East, so as to double the North cape of Morty. For the same reason, ships that have passed South of Siao must run N.E. if the wind will permit. When she has entered the Pacific Ocean from the Philippine Islands, passing to the West of the Pelew Islands, afterwards sail towards the North, so as to enter the China Sea by the Formosa Channel.

Pitt Channel, which leads, as has been already stated, into the Pacific Ocean by either Pitt, Gilolo, or Dampier Channels, is preferable to the Macassar Strait during the months of December, January, and February. On arriving, at this season, at the Strait of Sunda, on the way from Bengal, or at the eastern straits on the way from the Cape of Good Hope, I would adopt this channel when bound to China. This is the *Second Eastern Route*.

If, as often happens, a ship, in coming from the Bay of Bengal, passes through the Strait of Sunda instead of along the South coast of Java, in going out of this strait she should pass North of the Thousand Isles, and then steer to the East, leaving the Watcher Isle to the North, on her way to the Strait of Salayer. In case of touching at Batavia, after having passed Edam Island on leaving this port, she would steer so as to leave Burakin Island to the North, and after having passed it, would steer for Salayer Strait. With a N.W. wind the best course through this strait is to pass South of Mansfield Shoal. At night, or when the wind is not steady, it is better to keep to the North of it, along the coast of Celebes. From the Strait of Salayer make for Bouton Strait ; or, if the wind is West, it would be better to pass South of this island, keeping the S.W. point well on board, with the view of avoiding the rocks off it to the southward of Tonkan Bessy. You then pass along the eastern coast of Bouton Island, and having reached the N.E. end

of it, if the wind is fresh from N.W., steer North from the island of Waigiou, and from thence for the Xulla Bessy Island. This is an indispensable precaution for slow sailing vessels in December and the early part of January, because about this period the wind becomes variable, and veers to N.N.W., causing strong southern currents. The winds and currents in Pitt Channel are very variable, and it may be crossed almost anywhere. It is prudent, however, when northerly winds prevail, to keep the weather shore.

In the case of a vessel falling to leeward of the N.W. point of Bouro Island, every exertion should be made to pass it quickly. Instead of working to windward to do this, it is better to run southward of the island, and pass into Pitt Strait to the eastward of it. During the N.W. monsoon vessels which leave Amboyna make to the northward along the East coast of Bouro, where the wind is variable, and squalls come from off the land. Strong currents are rare, and are sometimes favourable for the run northwards; while beyond Manipa and the channel which separates it from Ceram, southerly currents prevail in this season. Having reached Pitt Passage by the foregoing routes, a vessel will be guided by the directions hereafter given.

A vessel wishing to pass through Pitt Strait should take either the strait of Bally, Lombok, Allass, or Sapy, and make for that of Salayer on leaving them; crossing the eastern part of the Java Sea, afterwards steer for Pitt Channel. In coming from the Cape of Good Hope the Ombay Strait is preferable, it being the most direct and more open than those farther West, and the winds being generally less variable there.

In making for Ombay Strait, pass either North or South of Sandalwood Island; but it is better to pass South of it, and then between Ombay and Timor, and after having steered to the eastern extremity of the first of these islands, then steer North, keeping to windward, so as to pass West of Bouro Island; but if this is impracticable, pass to eastward of this island, between it and Manipa, and then take the Pitt Channel. After having entered Pitt Channel steer East, passing between Xulla Bessy and Bouro; but in case you should pass to the West of this island, if no current be found, then steer direct through Pitt Strait; if the current sets northward, keep off the islands which border the northern side of this strait.

When near the meridian of the East point of Oby Major, and wishing to take Dampier Strait, keep on to eastward. This strait seems favourable for good sailing vessels, especially in January and February, when N.E. winds are getting more easterly. In March, when the N.E. winds become weaker, the Strait of Gilolo is preferable for entering the Pacific Ocean.

This last strait is wider, and a ship can work both night and day in it, and the currents are seldom very strong. On leaving Pitt Strait, and also that of Dampier, you must take great care not to be drifted on the North coast of New Guinea, and should therefore contrive to round Point Pigot

close, looking out sharply for Buccleugh Bank, which lies to the East of the East coast of Waigiou.

Pitt Strait should only be taken when it cannot be avoided. In this case, a ship should keep in the middle of the channel to avoid being set to either side by the tides, and should therefore make short boards, not approaching either shore, and should try to make Jackson Isle, and pass 5 miles to northward of it. When a ship has passed the reef, which lies to the northern extremity of Batanta Island, she must steer northward for Point Pigot.

To enter Dampier Strait on passing the meridian of the East point of Oby Major, steer East, to pass between the Canary Isles and Pulo Popo. Sometimes vessels pass between the Bou Islands and Pulo Popo. This last channel is advantageous with the winds from the N.W., and then run for Fisher Island and Mabo Cape, and from thence pass between Pigeon Island and Foul Island, always keeping a good lookout for the dangers which exist on the North shore of Dampier Strait. In coming out keep nearer Pigeon Isle than Foul Island, and steer so as to sight Pigot Point, so as not to be horsed on to the coast of New Guinea by the northerly swell which prevails in the offing. Vessels should always carefully avoid the Buccleugh Bank. The tides are very strong in Dampier Strait, and the currents very irregular, their rate varying from 1 to 5 miles an hour. In the height of the N.W. monsoon, in the narrow part of the strait between Pigeon Isle and Foul Isle, the ebb at the time of the spring tides runs 4 or 5 knots to the E.N.E. for six or eight hours, and between 1 and 3 miles in neaps. The flood sets S.W. for three or four hours, but is weak. During the height of the S.E. monsoon in this part, the flood runs to the West for eight or ten hours at a time, and turns successively to W.S.W., S.W., and S.W. by S.; it then attains its greatest velocity, which at springs sometimes exceeds 5 miles an hour, and is reduced to 4 miles an hour in neaps. The ebb at this season runs to E.N.E. or N.E.; it is not strong or of long duration.

On leaving Dampier Strait, when a ship is in the Pacific Ocean, she should run down her easting quickly, keeping in a low latitude, or between the parallels of $1^{\circ} 30'$ and 3° N., which she can easily do. Sometimes even in December and January easterly currents are frequently found in that track, being that eastward counter current on the equator which has been spoken of in the chapter on this subject. She will thus be enabled conveniently to pass either East or West of the Pelew Isles, but this depends upon the sailing powers of the ship, and the strength of the N.E. monsoon. A vessel must not go too far to eastward, for fear of falling in with the islands of Goulou and Guap, near which, in November and December, heavy squalls from the westward are encountered. From the Pelew Islands, steer for the Bashee Islands, allowing for the westerly currents, which run at a rate of 12 or 15 miles a day. From December to the middle of February it is most prudent to pass to the East of the Pelew Islands.

Should a vessel leave Dampier Strait towards the end of the N.E. monsoon, she should not run far East into the Pacific Ocean. At the end of February and in March ships can pass to the West of the Pelew Islands, as the winds at this time often vary and shift to E.N.E. When the North part of Luzon is reached the China Sea can be entered by either of the great routes, or the channel of Balingtang, or any of the good channels formed by the Bashee Islands and the Babuyanes. However, with the winds from the N.E., and at the commencement of the monsoon, it is necessary to pass to the North of the Bashee Islands, and either North or South of the Cambrian and Gadd Rocks. The South point of Formosa is thus approached, and it is best with daylight and the weather fine to pass between this point and the Vele Rete Rock. During the night, or in bad weather, if prevented from taking this route, a vessel should pass to the North of the Bashee Islands, keeping close to them. Whichever may be the channel by which she enters the China sea, a course should be adopted to sight, if possible, Ty-Sing-Cham, or Pedro Blanco, and enter the Canton River by the Lema Channel.

The Strait of Gilolo, the *third* which connects Pitt Passage with the Pacific Ocean, is divided into two parts by the island of Geby, and the part between this island and that of Gilolo takes the name of Gilolo Strait. That part between Geby and Waigiou has been called the Bougainville Strait, as that officer passed through it in 1772. All the channels leading from Pitt Channel to the Strait of Gilolo are free from danger; but during the N.W. monsoon that between Pulo Gass and Kakik Island is preferable, as being the widest; for the other broad channel between Pulo Pisang and the Bou Islands is too much to leeward at this season. To enter the Gilolo Strait, passing, as we have already said, between Pulo Gass and Kakik, sail closely round the southern point of the first of these islands, so as not to get to the eastward of the channel by the current which often prevails there. After having passed Pulo Gass to eastward or westward, according to the channel taken, continue on between Cape Tabo and Geby Island; and if at night, give a good berth to the Fairway Bank and Widda Island; however, it is prudent, if the wind is light, to keep as close as possible to the islands on the West coast of the strait, on account of the N.E. and easterly currents. Should the winds be contrary, no time should be lost in trying to pass North of Geby; afterwards, passing South between this island and Gagy, and entering the Pacific by one of the channels near Syang. However, when it can be done, the West channel between the coast of Gilolo and the Shampi Isles, or one of those comprised between these islands and Syang is preferable, as with a northerly wind a ship would be able to pass to windward of the Aiou and Asia Islands. Should there be any difficulty in passing to the West of Asia Isles, the channel, which is formed by them and Aiou, can be

adopted, or even between this latter and the North coast of Waigiou. Having gained the Pacific Ocean, a vessel should endeavour, as soon as possible, to make her easting in the zone comprised between the parallels of $1^{\circ} 30'$ and 3° N., as southerly and S.E. currents are found there, and she must not pass North of the parallel 3° N., and she will thus attain the latter part of the route which we have previously indicated from Dampier Strait to the China Sea.

14.—CHINA TO THE BAY OF BENGAL, ETC.

The foregoing remarks refer chiefly to those routes through the Archipelago which lead to the different ports for vessels bound from Europe or India. The reverse, or homeward voyage, is generally subject to the same influences, and requires the same consideration, in reference to the seasons, that is called for in the outward voyage.

As a first principle it may be stated that a vessel bound to an Atlantic port should endeavour to gain the S.E. trade wind as soon as possible, by which she may gain the coast of Africa, Mauritius, or Madagascar, and thence proceed round the Cape of Good Hope. This portion of the subject and that relating to the passage from the Strait of Sunda to Aden is detailed in our Indian Ocean Directory, pages 162—166 and 201—202.

A vessel bound to the Bay of Bengal should take the readiest course for the straits of Singapore and Malacca, and thence as directed in the Indian Ocean Directory, pages 179, 184, &c.

These remarks refer to both monsoons. The best way of reaching the Strait of Malacca, or the Southern Indian Ocean, necessarily requires a different route in the opposite seasons. For the China Sea and the Strait of Sunda this reverse voyage has been considered in former pages; but a few remarks from Capt. Kerhallet may be here appended.

When a ship leaves China during the N.E. monsoon for Europe or India, she should make for the Straits of Banka and Gaspar, or for that of Singapore. In March and April the outer route is the quickest by the Macclesfield Bank. She ought, during these two months, to keep out to sea as far as the latitude of Pulo Sapata, or take the route proposed by Capt. Stephens down the West coast of Luzon, Palawan, and Borneo, as described in a foot-note on p. 62. Some useful remarks by Capt. Polack will also be found on p. 86.

On the contrary, during the other months than March and April, a vessel should take the inner channel, which is comprised between Hainan and the Paracel Islands, when she would without difficulty reach the Straits of Singapore, Banka, and Gaspar. From these two latter a course should be steered for the strait of Sunda. On leaving this strait the parallel of 10° N. should be crossed in 100° E. longitude, and then shape a direct course for the South point of Madagascar, as is described in the Directions for the Indian Ocean. This route crosses the area of the course of hurricanes; consequently they are often encountered by vessels from the eastern seas.

The INNER ROUTE is the most direct for reaching the straits leading from the China Sea ; it has also this advantage, that vessels have the wind aft as soon as the Great Ladrone has been passed. A ship taking this route should steer from the Great Ladrone, so as to pass near the islands of Taya and Paracels at a convenient distance to the West. It is estimated that the current sets westward at the rate of 15 or 20 miles a day, for the currents are strong near the coast of China, although it may not be the case out at sea. If it should be observed that the ship is drifted much towards the West, she must shape her course to allow for it, until she has reached the parallel of 17° W., and entered the channel between the Paracels and Cochin China. Having reached the parallel indicated, and the meridian of 106° , a course should be steered so as to sight Cape Varela, or the Pagoda. With clear weather and an E.N.E. or N.E. wind, a ship may sight Pulo Canton (also called Callao Kay) or the coast situated South of this island, and then keep a moderate distance from the shore ; if the weather be cloudy, and the wind has a tendency to become easterly, it would be more prudent not to approach the coast till she is in the latitude of Cape Varela, nor enter the Bay of Phouyin to the North of this cape.

In case the conical mountain be visible on the North shore of this bay, it will indicate the position of the cape, for as night approaches, the pagoda on the height, which commands it, is obscured by clouds. Having passed to the South of the parallel of 15° N., it will be found that the current sets southward near the land ; for between $14^{\circ} 30'$ and $11^{\circ} 30'$ it often sets at the rate of 40, 50, and even 60 miles a day ; but it is very variable. It is indispensable to make for Cape Varela when land has not been seen to the North of this point, from whence the coast may be kept at a distance of 12 or 15 miles. When a ship is East of Cape Varela, distant about 4 or 5 miles, she can steer along the shore by day ; but at night must be careful to avoid Pyramid Isle, and those near to it. If the night be fine, she can sight these islands, as they may be made out at a few miles distant. Water Islands should then be steered for, which are 21 miles to the southward, and can also be seen. When these islands are reached, if the land is more than 12 miles off, it will be necessary to approach it, to sight the mountain of False Cape Varela, which can be distinguished among the high lands of the coast by its elevation and gentle slope towards the sea.

In order to keep inshore and pass to the West of the Dutchman Bank, a vessel should cross Padaran Bay as soon as she is abreast of the high lands of Cape Varela. This is necessary, because the currents in this part take a S.S.E. direction, and it is very difficult for ships out at sea to approach this coast. When a vessel is in a good position for crossing the bay, the soundings will be found to be 40 and 50 fathoms. Then, during the night, Cape Padaran should be made on the starboard bow. On recognizing this cape, great care should be taken, as it is difficult to distinguish it from the high

lands in the bay. On having sighted Cape Padaran, it may be passed at about 3 or 6 miles; and Pulo Ceicir may be doubled at the same distance on keeping this island to the West. In case ships are only 1 or 2 miles from the cape, a course should be steered to pass at a convenient distance from Pulo Ceicir. When this island is doubled in the day, at 4, 5, or 6 miles to seaward, it should be brought to bear N.N.E. $\frac{1}{2}$ N. before being lost sight of from the deck, and then steering 18 or 21 miles between W.S.W. and S.W. by W., as most convenient, will pass West of Dutchman Bank, when a South course may be steered for Pulo Aor.

This route is not dangerous when the night is clear enough to admit of distinguishing the cavern of Padaran. In this case, when a ship is 3, 4, or 5 miles from the cape, she must take the most convenient route till she sights the Cavern; and when it bears N. by E., she will be off Pulo Ceicir. If in this case soundings are found at 11 or 20 fathoms, she should stand off from it a little, because the island is too low to be seen at night, and in this part of the channel the soundings are too irregular to serve as a guide. The Cavern bearing N. 16° E., Pulo Ceicir is in the same direction; and by running 18 or 20 miles nearer between W.S.W. and S.W. by W., Dutchman Bank may be passed on the West, and then steer for Pulo Aor. If the night should be dark when near Padaran, and the Cavern not to be distinguished, the vessel must be kept between South and West till she is about 12 or 13 leagues from the cape, and in this case it is best not to approach the coast or Pulo Ceicir with less than 6 fathoms of water, and Dutchman Bank should not be approached in less than 18 or 20 fathoms. Between the western edge of this bank and the eastern edge of Britto Shoal, which is nearest to it, there is a distance of 14 or 15 leagues, between which there is a large channel, which may be taken in the night. A ship should keep in soundings of 15 or 16 fathoms, until she is 5 or 6 leagues more to the South of Pulo Ceicir; and when she is 13 leagues to the S.W. of Cape Padaran it will be best to run again between the South and West to the distance of 2 or 3 leagues, so as to give a wide berth to the Holland Bank. A vessel should not take more than 20 fathoms depth, till she has passed this bank, nor less than 16 fathoms when she is near Britto Bank, if she is a little to the West.

In taking the route between these two banks the soundings will be found to vary between 10 and 11 fathoms; and when the western part of the Holland Bank is passed a vessel should keep in 10 or 11 fathoms, and steer towards Pulo Aor. The route between Pulo Ceicir and Holland Bank cannot be taken in the night, except by captains who are well acquainted with these parts, consequently, often while waiting for days, a vessel is obliged to lay off Cape Varela. Besides the loss of time which is thus occasioned, a ship has to contend with a heavy sea, when the breeze is strong; and for this reason mariners generally prefer passing through the passage outside

Pulo Ceicir and Pulo Sapata. When a vessel finds herself near False Cape Varela at nightfall, with a wind too strong to haul up to, or bad weather, and not wishing on account of the darkness to pass between Holland Bank and Pulo Cecir de Mer, she should steer a course to the East of Pulo Cecir de Mer, and then outside Pulo Sapata the next morning. She may run far enough out to sea if the weather is gloomy, after passing a good distance from these isles. When the wind is strong the currents run to the S.W. and W.S.W. with great rapidity, and sometimes towards Pulo Sapata. A ship would then be obliged to pass the night in the narrow channel between this island and the Little Catwik.

In the day, in fine weather, a ship may keep as near as she likes to Pulo Cecir de Mer, and pass between Pulo Sapata and the Large Catwik; she can also pass between the two Catwicks, only it must be remembered that the Paix Rock is in the channel formed by these two islands; from there she may steer direct for Pulo Aor. On arriving at Pulo Timoan during a fog, you must keep in soundings of 28 or 30 fathoms, afterwards passing East of this island for Pulo Aor. As these islands are often concealed in the fog, great care must be taken to avoid them, and attend to the reckoning, especially during the night. Near the Anambas, and to the North of them, a vessel generally has 36 to 44 fathoms. When she is between $5^{\circ} 30'$ and 5° N., these depths decrease in the western part of the channel, and 26 to 28 fathoms on the meridian of Pulo Timoan. Having passed East of Pulo Aor at a distance of 2, 3, or 4 leagues, bound to the Strait of Banca, steer to the eastward of South, according to the wind and prevailing currents, and pass outside the Geldria Bank, which she may avoid by keeping in a depth of not less than 10 or 11 fathoms when between the parallels of $0^{\circ} 56'$ and $0^{\circ} 40'$ N. When this bank has been passed, a course should be steered so as to cross the equator, and pass 4 or 5 leagues from the East point of Lingin, if the current will admit. In all cases a vessel should guard against westerly currents, which are sometimes encountered in these parts.

OUTER ROUTE.—When the outer channel is adopted in coming from China towards Pulo Aor, a vessel ought to pass at a short distance West of the Ladrone and neighbouring islands. In general, strong winds and a heavy sea with strong currents are found on leaving Great Ladrone, and a vessel should steer to eastward of South for the Macclesfield Bank; and when the winds are moderate she should endeavour to reach the East part of it. When 20 leagues East of the meridian of the Great Ladrone, and a vessel has difficulty in obtaining soundings, she may consider herself East of the Macclesfield Bank. When a vessel has adopted the outer route in November and December, with strong winds and no observations for several days, she should endeavour to strike soundings on the Macclesfield Bank; but if she is certain of her position, these may be neglected, because from East to West on the

bank being very wide, and the soundings being very irregular, the depth can only be an uncertain guide as to her real position. On leaving the Macclesfield Bank, she should steer for Pulo Sapata, and should have soundings on that bank, and it being on the same parallel it would be well for her to shape her course for that of Pulo Sapata. If she should not sight this island, she should steer West, so as to obtain soundings in 32 or 37 fathoms. With thick weather, when ships are uncertain of their position, it would be dangerous to run straight for Pulo Sapata and round the island in the night, as it is difficult to distinguish. As a general rule, they should keep well to the East of Pulo Sapata until on the parallel of 10° N., and by standing West by South to obtain soundings. Some captains, on leaving the Macclesfield Bank, run as far as the parallel of Pulo Sapata, keeping well off to the eastward of the island; this can be done in March, April, or May. However, in adopting this route care must be taken to allow for the S.E. currents which might set a ship on the banks to the E.N.E. and East of Pulo Sapata. When a vessel has reached the parallel of 10° N., she would steer between West and South until soundings are found in 30 fathoms; then steer a course for Pulo Aor or Pulo Timoan. If she is bound for the Strait of Singapore, to avoid the Charlotte Bank, the soundings should not be more than 26 or 28 fathoms when in latitude $7^{\circ} 6'$ N. In March and April vessels returning to Europe should keep well to the eastward, so as to pass between the Natunas and Anambas Islands, and take the Strait of Gaspar.

Further remarks on these passages have been given on pp. 62 and 85, as has been alluded to.

15.—PASSAGES BETWEEN AUSTRALIA AND CHINA.

A more full description of the passages between Australia and China will be found in our Directory for the South Pacific Ocean. As described by Captain Allen, harbour-master at Newcastle, N.S.W., there were four principal routes in use by vessels between the years 1869—1873:—1. The Eastern Route, passing eastward of New Caledonia, the New Hebrides, and Santa Cruz Groups, and crossing the equator in 166° E. 2. The Middle Route, westward of New Caledonia, and between the Santa Cruz and Solomon Islands, crossing the equator in 159° E. 3. The Western Route, N.E. from Newcastle to the 157° meridian, thence North on that meridian to the Pocklington Reef in 11° S., crossing the equator in 153° E. 4. The Torres Strait Route, also from Newcastle, N.E. to the 157^{th} meridian, then North on that meridian to the latitude of the Mellish Reef, and N.W. for Bligh's entrance to Torres Strait. When through Torres Strait the route is between the Tenimber and Arrou Islands, and by the passage between Ceram and Bouro into the Molucca Channel, then round the N.E. end of

Celebes Island into the Celebes Sea, through the Basilan Channel into the Sulu Sea, and through Mindoro Strait into the China Sea. The distance from Newcastle to Hong Kong by this route is 5,300 miles, and it has been taken by one ship, between the years 1869 and 1873, the *England*, which made the passage in 41 days, in the month of July. Some further remarks as to the best route through the Archipelago will be found below.

Much depends on the sailing qualities of the vessel, but as a general rule, ships leaving Australia in the months of January, February, or March, for China or Japan, should adopt the Middle Route, and may expect to make the passage in about 40 days; leaving in April, May, or June, they should adopt the Western Route, and may expect to make the passage in about 36 days; leaving in July, August, or September, they should, if they can reach Torres Strait before the end of August, take that route; and if not, either the Western or Middle Route, and may expect to make the passage *via* Torres Strait in 40 days, and by the other routes in 55 days; and, finally, ships leaving in October, November, and December, should adopt the Middle Route, and may expect to make the passage in about 44 days.

FROM SYDNEY TO YEDO.—Vessels bound from Sydney to Japan during the S.W. monsoon should pursue, as far as lat. 8° N. and long. 160° E., the same course as those bound for Hong Kong; from that position a course should be shaped to pass to the northward of the Mariana Islands and to the south-westward of the Volcano Islands, after passing which, steer to make O Sima lights, remembering that the ship must pass the strength of the Kuro Siwo, and will, when in its stream, be set to the north-eastward from 2 to 3 knots an hour.

NORTH COAST OF AUSTRALIA TO CHINA.—The following remarks are by Mr. George Windsor Earl:—

A ship proceeding from the North coast of Australia to China, from April to September, when the S.E. monsoon prevails to the southward, and the S.W. monsoon to the northward of the equator, should pass to the southward of Timor and Sandalwood Island, and through the straits of Allas or Lombok into the Java Sea; and from thence through the Carimata Passage, and up the China Sea to Canton, by which course she will have a stronger monsoon and a clearer sea than by passing to the northward of Timor, and through the Flores Sea; or than by running at once to the northward, through the Molucca Passages. By this latter route, instead of a fair and steady wind all the voyage, difficulty would be experienced in passing between Borneo and Palawan into the China Sea, from the variable winds, and from the numerous shoals which lie to the westward of the Balabak Passage. The passage by the North of Palawan to China is also often attended with difficulty during the S.W. monsoon; and an additional inconvenience of these routes is, that the navigation of the Molucca Sea will be performed during the bad monsoon.

Ships returning from China to the North coast of Australia during this season should pursue the track frequently adopted by ships bound to Europe, namely, by standing to the eastward, round the North end of the Philippines into the Pacific, and so to the southward towards New Guinea. When past the parallel of 5° N., S.E. and S.S.E. winds, with a strong current to the westward, will probably be felt, by which she may easily pass through Dampier Strait, or the Gilolo Passage, into the Molucca Sea. She may then pass between Ceram and Bouro, and across the Banda Sea to Wetta, when no difficulty will be found in getting to the eastward along the North side of the Serwatty Islands, as the current there sets to the eastward during the S.E. monsoon. When off Baba, she may stand to the southward for the coast of Australia, and if she should fall to leeward of her port, she may easily gain her easting by taking advantage of the land and sea breezes.

Again, if a vessel is bound from the North coast of Australia to China from October to March, when the western monsoon prevails to the southward of the equator, and the N.E. monsoon in the China Sea, she should, on leaving the coast, keep close to the wind, and as the monsoon often blows S.W. and even S.S.W. between Australia and Timor, she may be enabled to pass between Timor and the Serwatty Islands and through Pitt Passage into the Pacific, and thus pursue the eastern route to China adopted by ships at this season. If unable to get far enough to windward to pass between Ceram and Bouro, she may run at once to the northward, between Ceram and Ceram Laut, and from thence into the Pacific by Pitt or Dampier Straits. The only difficulty that an indifferent ship would be likely to encounter in this route would be on the passage between Ceram Laut and the N.W. end of New Guinea, where the winds would probably be from the N.W.; but even then she would have the advantage of fine weather. The route from the North coast of Australia, through the Flores and Java Seas, and up the China Sea to Canton, would be impracticable at this season, even for a fast sailing vessel, as she would have a dead beat and a lee current the whole way.

A ship returning from China during this season may steer a direct course through the Mindoro Sea, and thence by the Molucca Passage, and past the N.E. end of Timor to the North coast of Australia.

16.—BETWEEN THE NORTH COAST OF AUSTRALIA AND SINGAPORE.

A vessel bound to Singapore from April to September may pursue the route recommended above for ships bound to China at this season, namely to the southward of Timor, through the Straits of Allas and Carimata, and thence through Rhio Strait to Singapore. The return voyage at that season, through the Java Sea, against the S.E. monsoon, would be tedious and diffi-

cult, even for a smart ship; it would, therefore, be most advisable to run across the China Sea, and round the North end of Borneo, where she would probably have the advantage of S.W. and S.S.W. winds, to traverse the Sooloo Archipelago. When near the Molucca Passage, though the winds will be mostly from the southward, yet but little difficulty will be experienced in passing through it; and when through, the route to the North coast of Australia, already recommended for vessels returning from China at this season, should be adopted.

From October to March, the passage to Singapore through the Java Sea, against the N.W. monsoon, will be tedious and difficult; a ship bound there during that season should therefore proceed to the northward by the Molucca or Gilolo Passage, where she would have the advantage of fine weather, and when to the northward of Gilolo the wind would probably come from the northward and eastward, with a westerly current, which would enable her to proceed round the North end of Borneo, and so with the N.E. monsoon, down the China Sea to Singapore. A ship returning at this season should pass through the Carimata Passage, through the Java and Flores Seas, and then to the southward of Wetta, and between Timor and the Serwatty Islands, to the North coast of Australia. It would be advisable to proceed through the Strait of Allas, and to the southward of Timor, as light airs and calms, with squalls from the South and S.S.W., are often encountered to the southward of the islands East of Java, while in the Flores Sea the N.W. monsoon blows steadily.

17.—FROM CHINA HOMEWARDS.

IN THE S.W. MONSOON.

The adverse voyage against the S.W. monsoon is best followed by adopting one of the ensuing routes, according to the time when the southern part of China is left.

FIRST EASTERN ROUTE.—Quitting Macao, or Hong Kong, in the end of April or beginning of May for the first Eastern Route, that is, the Mindoro Strait, a ship should run to the South as far as the Macclesfield Bank, if the wind allows, so as to reach the N.W. extreme of Mindoro without tacking in case of the wind shifting to S.W. From near the Macclesfield she should stand S.E., holding her wind if it is at all to the S.W., and should it not admit of her weathering the point of Calavite she should work along the coast of Luçon with the variable winds, with which she will come up to the N.W. extremity of Mindoro.

The channel to the East of the Apo Bank should be chosen for crossing the Mindoro Strait, giving the Mindoro coast a berth of some miles, if the wind is variable; a distance of 9 or 10 miles is necessary if the S.W. wind is

steady; she will then pass the islands of Ambolon and Ilin at a distance of about 15 miles.

Should the wind allow, she may cross the Strait of Mindoro, passing West of the Apo Bank, in the Northumberland Channel, formed by this bank and the Calamianes. Then keep along the coast of Panay, working, if necessary, at some distance from this island, according to circumstances, and approach the island of Quiniluban, so as to pass the dry sandbank between this island and the coast of Panay.

Having reached Cape Naso, stand for the strait of Basilan, making it well to the southward and westward, when the wind is from these quarters: but steering direct for it if the wind is easterly. The S.W. extreme of Mindanao being gained, it will be better to take the strait of Basilan than those formed by the islands to the S.W., the former route being the shortest; the Celebes Sea will thus be entered, and the ship will make for the strait of Macassar.

Instead of persevering in working at the entrance of the strait of Basilan against S.E. winds, it may be better to steer West, in order to pass West of the Sooloo Archipelago, between the point of Unsang and the island of Tawee-Tawee. There are two small islands close off the S.W. point of this island, bearing S.W., near Sibutu Island, and forming a good channel leading direct to the Celebes Sea. This channel is safe, and easy of navigation both by night and day, four hours sufficing for passing from one sea to the other by it, while under similar circumstances it has sometimes occupied four days in going from one sea to the other by the strait of Basilan.

To leave the Celebes Sea, a vessel may either take the Macassar Strait or the Molucca Channel. Some navigators prefer the latter when the S.E. monsoon prevails North of the equator. In fact, it is difficult, without a tedious passage to windward, to reach Allass Strait from the strait of Macassar; while by taking the Molucca Channel the S.E. monsoon is found in a latitude sufficiently to the eastward to enable you to take whichever eastern channel is preferred. But vessels bound to Batavia, or the strait of Sunda, will find the strait of Macassar the best.

On leaving the strait of Basilan, if the easterly wind is well established, a vessel should steer so as to make Cape Donda to the S.S.E. or South; but most generally, from the winds veering westward near the northern entrance of the strait, and the current setting eastward, it is prudent to keep as much as possible to the westward, in order to sight Point Kanneeungan. A ship off Cape Rivers is sometimes set to the eastward by the current along the coast of Celebes, and after fruitless contest with it, is sometimes obliged to take the Molucca Channel.

A ship having entered the strait of Macassar, should keep along the West coast of Celebes, passing East of the Little Paternosters, being very cautious, on account of the dangers North of the islands of Nusa Seras, in passing be-

tween them and the Great Pulo Laut. From thence she should steer for the strait of Allas, or one of the straits leading into the Indian Ocean. If bound to Batavia or the strait of Sunda from the strait of Macassar, she should steer South, if the wind will permit, and pass North of the Little Paternosters for the coast of Borneo, keeping along this coast and guarding against the dangers off it, as well inshore as to seaward. She would then enter the Java Sea, and reach Batavia or the strait of Sunda without difficulty; and thence the Indian Ocean, and make for the Cape, or the western coast of India, by the routes before alluded to.

A ship taking this route, and meeting with contrary winds from the strait of Basilan, so as to be unable to reach the strait of Macassar, may take the Molucca Passage, and should then steer for the islands near the N.E. end of Celebes; and passing between the islands of Banka and Bejaren, will clear the N.E. point of that island, and then steer to the southward, through the channel formed by Lissa Matula and Oby Major, which is the most frequented; or, if the wind should not permit her reaching it, should take the Greyhound Channel, between the islands Albion and Hammond (West of Nulla Tallyabo).

When it is difficult to get to the southward in the Molucca Channel, dull sailing vessels might try to do so by keeping near the West coast of Gilolo; thence they might enter the strait of Patientia, between Gilolo and Batchian, or the strait of Batchian, formed by the island of this name and Tawally and Maregoland.

However, a ship having reached the northern extremity of Gilolo or Morty in the height of the S.W. monsoon, should rather pass through the Gilolo Channel than that of the Moluccas, because it leads more directly to Pitt Channel, by which she can gain the eastern straits.

On leaving the Molucca Channel the Timor Strait or the strait of Ombay may be adopted if desirable. A ship should then pass close to Oby Major, in order easily to round the East coast of Bourou, and so pass between this island and that of Manipa. She would then run to the southward into the Banda Sea, where the winds are generally from E.S.E.; on leaving Manipa she would endeavour to pass to the East of Ombay, and having crossed the channel formed by this island and Wetta, would follow the West coast of Timor, and enter the Indian Ocean between Semaou and Savu. This is the shortest route during this season from Pitt Passage to the Indian Ocean.

SECOND EASTERN ROUTE.—The second eastern route for the Cape or West coast of India from China, with the S.W. monsoon, is adopted from the middle of May to the end of July. This route is by taking the Pacific Ocean East of the Philippines, and passing through Pitt Passage. In August it is too late to adopt this route, and a ship obliged to leave the S.W. of China then, should follow the coasts of Cochin China and Cambodia, as before di-

rected, unless from being a bad sailer it may be better to defer her departure until September.

With southerly or S.W. winds, a ship to pass East of the Philippines should steer South in order to enter the Pacific Ocean with tacking. If the wind admits, the channel between the Bashees and Babuyanes should be adopted. Having reached the Pacific Ocean, S.W. winds at this season will generally be found, with easterly or N.E. currents; she should then steer S.E. in order to avoid Cape Engano and Luçon, tacking if necessary so as to pass neither too far out nor too close, and taking care not to round the Pelew Islands farther to the eastward than is necessary.

The best route for making southing is then East of the isles of St. Andrew, Current, Mariere, Lord North, and the dangerous Helen Shoal. If the easterly drifts of the equatorial counter current are met they will not be strong as far as the Pelew Islands; but between lat. 5° and 2° N. they set at the rate of 30 or 60 miles per day. This part must therefore be crossed as quickly as possible if the wind is West, as it frequently is; and if the wind is light, a ship may be set far to the eastward by this current. But from the lat. of 2° N. to the equator a westerly current will be found, while near Dampier Strait it is again running to the eastward.

Having rounded to the eastward the island of St. Andrew, a ship should endeavour to keep between the meridians of 132° and 133° E., and when in 1° N. lat., if Dampier Strait is to be taken, she should make for Point Pigot.

The strait of Gilolo being broader than that of Dampier, is often preferred for that reason, and it has few difficulties to overcome in reaching Pitt Passage.

When Gilolo Strait is to be adopted, on leaving the parallel of 2° N. a ship should steer for the Asia Isles, and round them on the North, if the wind permits, unless she passes between these islands and Ayou.

Having passed the islands of Eye and Syang, she would then go North or South of the island of Geby, and if the weather be not favourable, instead of the strait of Bougainville she might take that of Gilolo, which is North of it; and in crossing this strait she should keep near the eastern coast, and enter Pitt Channel between Pulo Pisang and the Boo Isles, or else, according to circumstances, between Kekek and Pulo Gass.

A vessel entering *Dampier Strait* should round Point Pigot at a distance of 6 or 12 miles, and then steer for King William Island, keeping it West of her; when about 9 miles from it she should steer for Pigeon Island, and pass 2 or 3 miles South of it; she may then cross the strait, taking care to avoid any dangers in her way.

On leaving Dampier Strait she would go close round Cape Mabo, so as if possible to pass South of Pulo Popa; or she may pass North of this island

and enter Pitt Channel between the Boo Islands and Pulo Popa. In Pitt Channel she should keep mid-channel, borrowing rather on the southern than on the northern side. Having reached West of Pulo Popa, and cleared Pitt Passage, passing between Ceram and Bourou, the Indian Ocean may be entered by the strait of Ombay or one of those westward of it.

The strait of Ombay is the most direct route to the Indian Ocean in the S.E. monsoon. If intending to take the strait of Salayer, or those of Allas or Sapie, the N.W. part of Bourou should be gained, and thence the most northerly of the Toukan Bessy group should be rounded at 2 or 3 miles distance; and from thence enter the strait of Salayer.

18. CURRENTS AND PASSAGES AGAINST THE MONSOON, IN THE CHINA SEA.

In pages 28 to 30, are given some remarks on the currents experienced in the China Sea; and in pages 55 to 63 are directions for the various routes, according to the season, between Singapore and Hong Kong.

The following important notes are the result of the experience and observation of Captain A. Polack, master of the Hamburg barque *Madeira*, gained during thirty-five voyages up and down the China Sea, previous to November, 1867. They appeared in the Nautical Magazine for June, 1861, and are here given for the benefit of the mariner.

Although there is a fast and still increasing trade from China to Saigon, it is astonishing how very little this voyage up and down the China Sea *against the monsoon* is yet known and understood in general, for the greatest difference of arriving in China (as to time) exists in this little Saigon voyage of only about 1,100 miles distance. Ships which are acquainted with the voyage here make it in nineteen to twenty-three days, while the greater part not being well acquainted with it, require between thirty and forty-five days. A barque in 1865 took one hundred and ten days, and worse than all, another actually returned this year to Hong Kong, after having been out about sixty days, declaring it impossible to reach Saigon in the S.W. monsoon. As I have made now fifteen voyages from Hong Kong to Saigon and back, and traversed the South China seas up and down, and in all seasons of the year, thirty-five times, I hope you will hold me competent enough, and will allow me to give my brother sailors, who do not know the voyage, a little of my experience.

Leaving Hong Kong in the S.W. Monsoon, our first object ought to be to make southing, and try to reach the North Danger of the Palawan Shoals as soon as possible. But as the wind is most generally between S.S.E. and S.S.W. at starting, I nearly always stood W.S.W. and S.S.W. between Isle

Hainan and the Paracels even to the East coast of Cochin China, and worked along this coast as far as Cape Varela (*not False Varela*), always trying to be a good distance, say 40 miles off shore at noon, to stand in with the S.S.E. winds generally blowing in the afternoon, until 7 or 10 p.m. Then stand off with the wind, then veering a little off land, or about South and S.S.W. (*solar winds*). From Cape Varela I invariably stood to the south-eastward over to the Palawan Shoals, never thinking of going about, for here my greatest endeavour was to cross the Padaran stream of 40 to 70 miles a day to the N.E. as quickly as possible. I then worked along the shoals down to 7° N., and 111° or 110° E. long., and between 7° and 8° N. lat.

I worked from two to four days to the westward, until St. James bore N.W. by N., which I then generally reached in one or two days in one tack. In this track my longest voyage was twenty-three and my shortest nineteen days, at same time when other vessels took fifty and eighty-five days. In this route I generally had the current from Hong Kong (Taytang Channel) and Macao, to the South coast of Hainan from ten to twenty-four miles a day to the N.W.; from there to the East coast of Cochin China the current varies between North, N.W., and West, from 15 to 25 miles a day, but on the West side of the Paracels an East current of 12 to 30 miles will be found. On the East coast of Cochin China it runs from 10 to 20 miles a day to the N.N.W. and N.N.E., but there is often no current at all. From Cape Varela to the shoals I generally had the first day when right in the Padaran stream from 30 to 50 (one voyage 70') miles to the N.E. by E., but from 12° N. and about 112° E., its set is from 12 to 40 miles a day to the south-eastward.

On the shoals there is about 20' to the S.E., and sometimes to the South, but often no current at all. Between 7° and 8° N. lat., and 110° to 108° E. long., there is little or no current, sometimes even a slight drain to the westward. But standing over to Cape St. James a strong N.N.E. and N.E. by N. current of 36 miles a day will be found, while South of St. James it runs E.N.E. along the coast from Pulo Obi to Cape Padaran.

Should the wind at starting from Hong Kong be from the S.W., stand down S.S.E.; never think of going about till in 15° N., unless the wind should break off too much. In this track in the open sea, there is generally not over 20 miles a day of a N.E. current, especially after the strong E.N.E. China coast current, extending 60 to 75 miles South of Hong Kong, is crossed.

South of 15° N. lat., and in 115° E. long., or to the East of it, is very little current. I always give the preference to the inside track, for here the winds are more variable, the sea smoother, and getting the chance of a West or N.W. squall from land. Besides this, a vessel reaches the Palawan Shoals 60 or 80 miles farther West, and westing is very difficult to make

there, especially after July, when the S.W. monsoon blows from W.S.W. or West.

This voyage, as explained here, is quite plain and simple, but if asked, "Where were the other vessels who took from fifty to eighty-five days in their passage?" There is but one general answer. They tried to round Cape Padaran. Here they were lying for forty consecutive days, sometimes with a dozen and more ships together. This year a barque took thirty-five days from Japan to Padaran, but sixty days from there to Cape St. James, running short of everything, and had to be provisioned by other vessels. They sometimes go as far as Sapata, but never thinking that, bound to St. James in $10^{\circ} 10' N.$, they ought to go due South as far as $7^{\circ} N.$ lat., and even ships on the shoals in 9° or $10^{\circ} N.$ and about $111^{\circ} E.$, get tempted to stand W.N.W., intending to pass between Pulo Sapata and Pulo Ceicer. But when making the land, they find themselves between Padaran and Varela.

I know several instances of this. Or that a ship made a N.N.E. course sailing W.N.W. Although some vessels did make Padaran, and made a good passage (assisted perhaps by a N.W. squall), they form an exception, and may not do the same again in ten more voyages. Whereas the track along the shoals, and although about 300 miles longer, is pretty certain.

My short advice, therefore, is, go either East or West of the Paracels, and make the shoals of Palawan as soon as possible. A ship taking the inside route should work between the Cochin China coast and 40' off it, but should not remain there in the night, as there is seldom a land breeze, but much calm. Having reached the shoals as aforesaid, work along them, standing to 60 miles off. Never think of Padaran or Sapata, and do not leave the shoals unless in 8° or $7^{\circ} N.$ lat., as stated before, or you will surely be disappointed.

Bound from Saigon to China in the N.E. Monsoon.—Stand out to the S.E. and tack, even if the wind should be from East 40' off the land. The wind will haul up to E.N.E. and N.E., then try to pass the S.W. current (which runs the first day at the rate of 30 to 40 miles) as fast as you can; for about 150 miles S.E. by E. from St. James, in about $8^{\circ} 30' N.$ and $109^{\circ} E.$, the current runs already to the East and E.N.E. Working along the shoals, between them and 60 miles off from lat. $9^{\circ} N.$, as far as North Danger, about 75 miles off, will be right in the fair N.E. and northerly current (right against the wind), but I am inclined to believe that a ship should not go nearer the shoals than about 20 miles from them, because the northerly current extends not so far East, for I have often found there no current at all. From North Danger to about $119^{\circ} E.$, an easterly current from about 10 to 40 miles will be found. But in the early part of October the current off the North Danger runs from 10 to 15 miles to the S.E.

Along the West coast of Luçonia the wind is from N.N.W. to N.E. and East, with fine weather and 15 to 24 miles current to the North, but from Bolina it blows generally heavy, with a high, short northerly sea. If the first puff off Bolina is passed, and 100 or 150 miles are made to the N.W., the wind and sea are getting more handy and regular, and change one or two points farther to the East. But the ship wants canvas here, and must be in good and sound condition, for the sea rises here in short and high pyramids, on account of the hitherto uninterrupted northerly current, assuming here a velocity of 52 miles a day to the N.W. by N. and N.W., and running oblique to the N.E. sea. My longest voyage in this track was twenty-two days, and my shortest nineteen days from Saigon to Hong Kong. In February and October, a ship should not go East of the Scarborough Shoal, for in February it is not necessary, and in October there will be nothing but calms and a high northerly sea running.

This voyage against the N.E. monsoon is sometimes very easy, and done in less than nineteen days. But it is in general a difficult task, especially in November, December, and January, and requires a good ship and plenty of canvas on her, especially on the West side of the Palawan shoals, where the sea, running right against a North and N.E. current, is as high and short here as from Bolina to the Pratas. But many ships in this voyage commit a great error in working along the South coast of Cochin China and try to get out of Padaran, which is nearly impossible on account of the strong W.S.W. current and always very short sea.

After reaching Cape Bolina, and finding the above mentioned stiff gale and tremendous high cross sea, and thinking it blows a heavy gale all over to China, ships make a second mistake by creeping under the land again and waiting there sometimes for a fortnight, expecting better weather. And this is the same case with many ships South of Formosa when bound North along its East coast.

My advice, therefore, is stand boldly out, and remember that the current will assist you first with 50, and afterwards with 20 miles a day to the N.W. by N., as far as the Pratas. And at 60 miles from the China coast the wind will be about E.N.E., and sea moderating as you close the South China coast. But keep the first day from Cape Bolina good rap full, even if you head the first day to leeward of Hong Kong, and should a ship really fall to leeward of Taytang Channel, let her proceed in at the Ladrões, from which Hong Kong will be reached in one day. If bound to Swatow, Amoy, and the northern ports of China, work as far as Cape Bayadere, and then stand out N.W. or N.N.W., making long legs to the North, and short ones to the East, especially for the first 150 miles, where the strong N.N.W. current will be under your lee. South Formosa will generally be reached in three to four days, from whence to South Pescadores, and over to Swatow and Amoy, is plain sailing, and will be reached in one tack.

Bound to Fou-Chou-Foo and further North, ships have to pass round the South Cape of Formosa, and work to the northward East of the island, where the Kuro Siwo current will assist them 40 miles a day, decreasing to 20 miles as they advance to the northern boundary of the current in about 28° N. and 125° E. long., from where Shanghae is reached without difficulty. But always remember that the cold water current runs strong to the South on the East coast of China. Bound to Fou-Chou-Foo they may cross over from 26° N. lat., and about $122\frac{1}{2}^{\circ}$ E. long. in one tack.

A voyage up and down the China Sea with the monsoon presents no difficulty, but I would advise captains of ships to pass East of the Paracels, for in the S.W. monsoon the winds there are more steady and fresh than inside, or West of them, and a vessel has more sea room in case of a cyclone. After having passed to the West of Macclesfield Bank, steer a N. by W. or N. by W. $\frac{1}{2}$ W. course, on account of a N.E. current, and the winds blowing often from W.S.W. and West. December and January, and in some years the latter half of November, are the only months in the N.E. monsoon that I would advise to pass inside the Paracels when bound South, but which ought never to be done from February to the end of May on account of calms, and always lighter winds than in the open sea. I never went inside in these months, but gained on ships which did so, from eight days to a fortnight in the months of March, April, and May, bound South, as well as in the S.W. monsoon from June to September when bound North.

Every one who has perused the foregoing attentively will perceive that it is not the wind only that causes the long and troublesome passage, but that we have to consider the current as our greatest enemy. And as it has been my principal object from the beginning to make myself thoroughly acquainted with the subject, I beg leave to trouble you a little longer, and give you a slight illustration of my views about it, founded on the experience of my voyages.

Currents.—In the first place, I am positive when I assert that the whole current of the South China Sea is nothing but a large *circular* stream, in which the waters running from South have to pass North, in order to return down South again. Coming from the North through the Formosa Channel, and from the East by the Bashees, the first getting propelled by difference of specific gravity, and accelerated by the N.E. monsoon, it rushes down to the S.W., without finding material obstruction, until met by Capes Varela and Padaran. Here its waters are turned off to the South, part of them or the northern branch runs W.S.W. along the Saigon coast to Pulo Obi, and crossing the Gulf of Siam to Malacca; the main body, after having passed Padaran, resumes its course to the S.S.W., but the south-eastern part branches off to the South as far as 8° N. and $109^{\circ} 20'$ E., from where it runs to the E. and E.N.E. as far as 9° N. and 110° E. There it turns N.N.E.

and from $10^{\circ} 30' N.$ $111^{\circ} 20' E.$ to the N.N.W. into its own whirl again, to give place to new waters of the great counter stream or whirlpool. This explanation may be new, but it is, I fully believe, quite true, for I found it every voyage, bound North in the N.E. monsoon, only differing a little in force and direction according, perhaps, to the prevailing strange or light original main current. The E.N.E. and N.E. current or the first bend in this whirl runs strongest, and from 20 to 51 miles a day, decreasing as it advances North to about 25 and 15 miles when its direction is N.N.W. I consider this branch 50 miles broad, and the diameter of the whole whirl, from Padaran to its southern extremity, about 180 miles, and from Padaran to the S.E. about 140 miles.

If this whirl did not exist, how should we account for the strong N.E. current against a strong N.E. monsoon (and for the always sharp set about Sapata which we experience, and which Horsburg and the China Pilot mention), sometimes when the China Sea current to the North and S.W. of this whirl runs at the rate of 40 to 80 miles a day to the south-westward. This latter current I had in October, 1866, coming down from Hong Kong with the commencement of the N.E. monsoon, or why is there not a N.E. current in the N.E. monsoon, for instance, on the Macclesfield Bank, or at Pulo Condore as well? After this current of the aforesaid main branch has run down to the Natunas, &c., it gets obstructed again on the coast of Borneo, by which a slight drain to the East is caused, running along the North coast of Borneo, through the Palawan Passage (assisted perhaps by a part of the aforesaid eastern counter current of the Palawan whirl), and along the West coast of Luçonia, to run from Capes Bolina and Bayadere N.N.W. in the great China circular current, and commence its round via Padaran again.

This circular whirl-current about Padaran is the same in the S.W. monsoon, but in a contrary direction, but not so constant and regular as in the N.E. monsoon. H.B.M's. surveying vessel the *Rifleman* found the same amongst the Palawan shoals, where the commander says, "The stronger the monsoon, the stronger the current to *windward*," and this is according to the whirl theory quite conclusive, for the greater and stronger the counter current and the larger the whirl (and the stiffer the monsoon, the stronger is the China Sea current). I have often seen and noticed in the Saigon River, where the ebb tide runs at the rate of 5 knots an hour, in the middle of the river, after turning a sharp corner it causes a great counter current or whirl, in which the waters run 2 or 3 knots up the river close alongside the 5-knot ebb tide, so that a boat, and often my own vessel, when in it, drifted up the river at the above rate. And when a small river can produce such a strong whirl, what may not the mighty mass of the China Sea current be able to do? At all events I never found it necessary with the above N.E. current in the N.E. monsoon to take the Palawan Route, and

my results have shown that I never was behind, but generally ahead of those vessels which did take that dangerous Palawan Route.

This whirl current to the West of the Palawan shoals may also account for the different currents found by vessels which are working there at the same time, where one ship beats right in the counter stream, whilst the other is too far West or inside the whirl, or too far East and out of its influence altogether. And these little whirls are to be found around all the shoals in the China Sea, and although Horsburg recommends passing to leeward of all shoals, I have great reason from my own experience for cautioning captains even there. To leeward of the Pratas I found on two voyages the current setting East, or right on the shoals, against a stiff N.E. monsoon in the months of December and January. Although this is the general current it is nevertheless liable to irregularities and changes, in force and direction, and perhaps more than anywhere else, which is not at all surprising in a small sea like this, full of islands and shoals, and entirely enclosed by land, causing different winds on either side of it, and on which the current so much depends. For sometimes it blows a stiff N.E. gale to the North, while it is calm South of the Paracels, and commanders expecting perhaps a slight current are surprised to find one sometimes of 50 miles by observation, but in eight cases out of ten the above explained current will be found pretty correct.

And lastly, I take the opportunity to caution captains against trusting too much to red or green lights when in the vicinity of the Pratas and Paracels, for they are often exhibited by wreckers and pirates, especially at the Pratas. I once observed a green light to windward of me on the West side of the Pratas. I kept four points off, and being a clear night, I went aloft with my glass, and saw two junks, one of which carried the light.

CHINA AND JAPAN.

The following remarks on the passages along the Coast of China and between China and Japan are taken chiefly from the China Sea Directory, and are supplementary to those previously given which describe the best routes for approaching the southern ports of China.

19. PASSAGES ALONG THE COAST OF CHINA.

PASSAGE EAST OF FORMOSA.—When bound from Hong Kong to Ning-po, or Shanghai, or even to Fu-chau fu, during the N.E. monsoon, a vessel should be in good condition for contending with rough weather and for carrying sail. The best plan appears to be, to work along the coast as far

as Breaker Point,* and then stretch across to the South end of Formosa, and work up eastward of that island. By remaining in with the coast of China, she will have the advantage of the land wind at night, of smoother water, and the ebb tide out of the deep bays, which will generally be under her lee on the starboard tack, and in the event of its blowing too hard to make way, there are numerous convenient anchorages. It will be prudent to keep within 10 miles of the coast, to avoid being swept to the southward whilst standing off the land; but as this cannot be done at night without risk, a vessel should, if possible, anchor in the evening, and weigh in the middle watch, when the wind, generally coming more off the land, will enable her to make a good board on the off shore tack. By passing eastward of Formosa, also, a heavy short sea in the Formosa Channel will be avoided, as well as the constant set to the southward during the season.

After rounding the South end of Formosa, off which there is generally a troublesome sea, a vessel should make short tacks, if requisite, to keep within the influence of the Kuro siwo or Japan stream, which has sometimes been found running northward at the rate of 30 or 40 miles per day.

There are no harbours on the East coast of Formosa, except Su-au Bay, towards the North end of the island, and deep water will be found close to the land. The mountains rise almost immediately from the sea; their sides in some places are cultivated, and a good many houses will be seen. H.M. brig *Plover* anchored on an uneven bottom in Black Rock Bay, the vessel swinging from 13 to 22 fathoms, and rode out a gale from the S.W.; but it is by no means to be recommended.

Having weathered the North end of Formosa, it will be still advisable to keep to the eastward, and not approach the continent until the parallel of lat. $30\frac{1}{2}^{\circ}$ N. is gained. Should, however, a vessel be driven to the westward, she may always calculate on smooth water, and be able to tide it through the southern part of the Chusan Archipelago; and if disabled and in want of

* Towards the close of the N.E. monsoon, and still later, it would seem preferable to cross over towards Luzon rather than beat up to Breaker Point against fresh N.E. breezes, as the following remarks of Captain David W. Stephens, of the British ship *Harkaway*, tend to show;—"Ships from Hong Kong, bound through the Bashee or any of the other channels between Formosa and Luzon, from March to June inclusive, but more particularly in March and April, during brisk N.E. winds and a strong westerly current, frequently take a week beating along shore to reach Breaker Point before standing off; whereas, if after clearing the Lema Channel the vessels had stood off on a wind, clean full to the S.E., they would soon have got out of the westerly current, and on nearing Luzon would experience the wind more from the eastward and sometimes from S.E., enabling them to tack to the N.N.E. with a strong current in their favour, and thus would probably get to the eastward of Formosa in less time than it would have taken to reach Breaker Point by keeping along the Coast of China."

spars, she can remain at the southern side of Duffield Pass, and supply herself from the Fu-chau wood junks.

Upon this part of the voyage the following remarks, which appeared in the "Mercantile Marine Magazine" for 1865, will be interesting. They are by Capt. James Turnbull, of the *Glen Clune*, of Glasgow, and relate to an outward voyage made in September, 1864.

The object of nearing Formosa, is to get into an easterly set in-shore, working round and joining the permanent great stream from the Pacific on the East side near Botel Tobago. This set is found as soon as the N.E. monsoon has set down the Formosa Channel, impelling the water, and thus making it perform the entire circuit of the island, down the West and up the East coast. While working off the South coast, wind northing, stood right for the Bashees, there tacked and fetched Botel Tobago, when we were fairly in the Japan current, temperature of water 83° , average daily set 30 to 36 miles N.N.E. and made 70 to 80 miles per diem. From the East cape, too many vessels still commit the mistake of working to the northward, direct for Shanghai, whereas the current sets north-easterly right over the Hoa-pin-su Group. Follow it, drawing for its western edge a curve line from the East cape to 30 miles West of Hoa-pin-su, and on to the East side of the Linschoten or Cecille Group. Its eastern edge cannot be so well defined, but draw a line from Kumi to East of Raleigh Rock, and then past Sulphur Island and West of Lu-chu Group. The reason the western edge is better defined is, that it follows a sudden rise of the bottom, from ocean depth to about 50 fathoms. If you have an atlas on board, you will find the Japan stream placed 2° and 3° further south-easterly, that is just where a vessel would get the back eddies southwards,—any representation that I have seen of it being merely from the guesswork of generalisation, not from actual observation. When the winter has set in the temperature is a good guide on its N.W. side; but in summer and fall, the heat of the water right up to the in-shore set of the China coast is nearly the same, 81° to 82° . From Botel Tobago to off Sulphur Island I beat up in six days, then tacked, heading N.W. by W., and in two days fetched the light-ship. The *Anglo Saxon* and *Sir W. F. Williams* did the same with somewhat similar success, while of those who fought away North of Formosa, one went down, others sought refuge at Amoy to refit, and some came dropping in towards the middle of October, assisted by the southerly winds that often succeed the first six weeks of the N.E. monsoon. The sea is much the same as in the American Gulf Stream, and vessels that cannot stand it ought not to be sent to China.

On making the Barren Islands, as nearly the whole flood tide sets S.W., keep to windward, and do not be tempted to seek shelter under the Saddle Islands. Either work in the open sea under a press of sail; or, if possible, stand on until near the Amherst Rocks, when, if dark, anchor. You will

have rough riding, but the pilot boats and coasters do so at all times in preference to seeking shelter to leeward, as, in spite of the sailing directions, it is difficult to get back. Pilots are now in abundance, and in the N.E. monsoon ships run up to Wusung, and there take steam.

AMOY TO RIVER MIN.—If bound from Hong Kong to Amoy, or the ports between that place and the River Min, a vessel will generally find a difficulty in getting round Breaker Point; for the tide here is of no use, and all there is to assist is the likelihood that the wind will draw off the land after midnight, when, by being in-shore, a good board can be made, and possibly the Cape of Good Hope reached. Haimun Bay cannot be recommended, but still it would be better to anchor there than to be carried round the point. In this case, should West Hill be obscured, run in under the point, lower a boat, and let her find the sunken rock, and then come in with good way to windward of Parkyns Rock—if drawing less than 13 ft.—and shoot up round the boat into Fort Bay.

Having reached the Cape of Good Hope, the flood will assist a vessel to round it, and the ebb out of the Han River will be a weather tide; in the latter case, and not intending to go inside Namoa Island, endeavour to get along the South side of the island, where there is an eddy tide, and anchor in South Bay, should the weather prove too bad to proceed on the flood; both tides will be found strong off Three Chimney Point, and the same may be said of Jakako Point, round which vessels should take the first of the flood on the port tack.

Further northward about Rees Island, the flood tide in strong winds causes an uneasy sea, which will distress a vessel much. Red and Ting-tae Bays will be found good stopping-places; and the latter should be preferred, though at the loss of 2 or 3 miles, to anchoring in an exposed position in the entrance to Amoy Harbour; as when the N.E. winds freshen off here on the flood, they generally bring a mist in with them, which makes it difficult to find the entrance, and at the same time a vessel will have trouble to get out of the harbour against the tide.

To the northward of Amoy or Leeo-lu and Hu-i-tau Bays, both of which afford good shelter. Chimmo Bay is not so good; but with plenty of good ground tackle vessels may ride in it. The current in the monsoon overcomes the tide here; and advantage must be taken of every slant of wind, bearing in mind that it is likely to draw off the land in the middle watch, and in the event of anchoring for shelter, this is the time to start, should the wind moderate; by waiting for daylight vessels lose their offing, and will have to make an off-shore board at a loss. The fogs are at times thick, but the lead is not a bad guide, as the soundings generally change from sand to mud as the shore is approached. There is also fair anchorage under Pyramid Point, but not so good as that under the South Yit; and if the

vessel is looking up North, or anything East of it, the ebb out of Meichen Sound will be of assistance.

From the Lam-yit Islands or the South end of Hai-tan Strait to the White Dogs is beyond doubt the most difficult part of the passage. With steamers the strait will afford the best route; but sailing vessels should decidedly keep outside, and stretch over to the N.W. coast of Formosa, where they are likely to get a slant of wind, and the advantage of a weather tide; and as this portion of the coast has been surveyed, by attention to the soundings no vessel can come to any harm.

RIVER MIN TO CHUSAN ARCHIPELAGO.—North of the River Min the ebb is generally a weather tide (unless the wind is far to the North), and out of the river, and off Ting-hai and Sam-sah Bays, vessels will get a good lift; and with the flood, the indraught into the latter will be sensibly felt as far out as Larne Islet, and increases to 2 and 3 knots as the main is closed. As a general rule, tack for the in-shore tide, when the moon is on the meridian.

Tung-ying Island will be found a strong anchorage, and here the coast should be forsaken (unless the vessel is under 12 ft. draught), and the deep water to the eastward kept in. The tide will afford but little assistance until the vessel arrives at the Chusan Archipelago; the flood causes an uneasy sea in the shallow water, while the ebb has too much southing in it, unless the wind is eastward of E.N.E.; but Nam-ki and Pih-ki-shan Islands will afford good shelter.

On reaching the Chusan Archipelago, take the Beak Head Channel, unless the tide is nearly done, in which case there is Harbour Rouse and the South side of Luhwang Island as anchorages under the lee; and as the first of the ebb runs to the northward through the Foto Channels, the tide through may be saved, and anchorage gained on the Ketau shore. From hence, if bound to Ting-hai Harbour, contrive to arrive at the West end of Tower Hill Island about slack water; otherwise, in light winds, the vessel is liable to be carried on to Just-in-the-Way, and even through the Blackwall Channel.

In working through the North part of the Chusan Archipelago, as the set of the ebb and flood trends nearly East and West, advantage can always be taken of the tide, and vessels may count on feeling the influence of the ebb within an hour of the moon's meridian passage. When in the vicinity of Gutzlaff Island the first of the flood takes a direction to the southward of West, running into Hang-chu Bay.

The eddy tide, generally speaking, will carry vessels clear of the large islands; but when they are approaching detached rocks, great attention is required to prevent being set in amongst them.

IN-SHORE PASSAGE FROM HONG KONG TO THE YANG-TSE KIANG.—These directions for making the in-shore passage from Hong Kong to the Yang-tse Kiang by vessels of moderate steam power, during the N.E. monsoon, are drawn up from a report by Commander C. E. Buckle, H.M.S. *Frolic*, 1876, aided by Mr. T. E. Cocker, commanding the Chinese Revenue Cruiser *Ling-feng*.

A vessel should leave Hong Kong in time to anchor under Tam-tu Island for the night, if necessary, or by leaving earlier, to reach the well sheltered anchorage in Samun Road, between Tuni-ang and Samun Islands; or in Harlem Bay. Leaving Tam-tu at daylight, pass out through Tathong Channel; after rounding Tam-tu Island, steer to the westward of Nine-pin Group for Basalt Island, thence North of Tuni-ang Island for Harlem Bay. If in fine weather, and keeping to the southward, pass near to Single Island. From Harlem Bay, pass on either side of Middle Rock, round Fokai Point, and North of Pauk-Piah; thence steer for Goat Island, where good anchorage may be obtained on the N. W. side of the island.

A vessel may either proceed to the southward of Goat Island and North of Reef Islands for Chelang Point, or pass to the southward of Reef Islands, and thence for Tong-mi Point (good anchorage will be found in Chino Bay). Pass to the northward of Si-ki Island, and South of Tung-ki, thence for Hutung Point and Turtle Rock, from which steer in-shore for, and through, Tungao Roads, tolerably near White Rock and to the southward of Corea Rock.

Having rounded Breaker Point, not nearer than 2 miles, steer to pass near Tong-lae Point into Haimun Bay, South of Parkyns Rock into Hope Bay, where there is good anchorage during the N.E. monsoon. From abreast Swatow, steer to pass about half a mile to the eastward of Fort Island (giving Dove Rock, off Swatow, a good berth), being careful not to mistake either of the cones or hummocks of Fort Island, which appear detached, for the more distant Brig Island. If it be desirable to pass South of Namoa, the best anchorage for small vessels will be found in South Bay. When rounding the S.E. point of Namoa Island, care is necessary to avoid Glen-gyle Rock.

Passing North of Namoa, keep a good look-out for the heavy fishing stakes extending from Clipper Point, and proceed for Breaker Island. From Fort Head, steer towards Chauan Head for Owick Bay, where good anchorage will be obtained, with the rock off Owick Point bearing S.S.E. $\frac{1}{2}$ E., and Jokako Peak, N.E. $\frac{3}{4}$ E. In this bay it will be almost calm when there is a good breeze outside.

From Owick Bay steer for Bell Island; or, if keeping in-shore, haul out when closing this island, and pass to the southward of it. Between Bell and Square Islands a very disturbed sea and tide rip will be experienced; keep towards Jokako Point and into Jokako Bay, gradually hauling out to pass

about half a mile from the rocks off Cone Point, from which steer for Pagoda Island, gradually hauling out to pass close under Thunder Head, thence steer to the southward of Rees Rock. From Rees Pass, steer for the Hutau-shan River bar, and gradually haul out to pass about half a mile off Black Head and Tagau Point; passing tolerably close to and eastward of Hut Islet, thence westward of Spire Islet, and mid-channel between Crab Point and Cleft Islet, which is a desirable channel. Between Spire Islet and Cork Point there is usually a rough sea, and the coast should be followed as closely as Shun Rock will admit. Anchorage may be obtained in Red Bay.

The distance from Cork Point to the outer anchorage of Amoy may easily be run during a fine night, the islands and headlands showing out plainly:— Leaving Red Bay, give Cork Point a good berth, and steer to the westward of House Hill Point, edging out when closing the latter point; thence for Notch Island and along the coast for Table Head (off which some rocks are said to exist), and Chin-ha Point.

Proceeding to the northward, outside Amoy, steer for Leeo-lu Bay, in which, by passing close to Leeo-lu Head, good anchorage will, if required, be found. From Leeo-lu, steer to clear Dodd Ledge thence along the coast, keeping inshore. Safe anchorage may be found under Tongbu in addition to the many good anchorages shown on the chart. Sorrel Rock may be passed either on the East or West sides, and with a strong breeze a vessel may pass North of Loutz Shoal, through Lamyit Channel, and make for Hai-tan Strait. If the weather be fine, pass to the southward of Sorrel Rock, skirt Lamyit Islands, thence for Turnabout Island* and Hai Head. Good anchorage will be obtained under Hai Head, with Turnabout Island shut in.

From Hai Head, steer towards the White Dog Islands, passing westward of that group thence to Matson Diplo, and Spider Islands, between Spider and Cony Islands, or to the westward of Spider Island, and through Seaon Channel, thence to Fuh-yan or through the Chuh-pi Pass, to anchorage in Lishan Bay. From Fuh-yan, keep along the coast, and pass between Tungpwan and Shroud Islands, thence into Bullock Harbour, if necessary. Leaving Bullock Harbour, pass out between Pwan-peen and the northern Tseigh Islands, eastward of Coin Island, and southward of Hea-chu, off the Tai-chou Islands:—With a strong breeze a vessel may steer from Coin Island to pass between Taluk and Chin-ki, thence between San-shi Islands and Stragglers, to good anchorage under Shetung. Proceed between Chikhok and Low Chikhok, West of Squall Islands, and between Fir Coin and

* A sunken rock, on which the S.S. *Sunda* struck, in 1875, is said to be situated from 1 to 1½ mile northward of Turnabout Island.

Chuh-sen, to good anchorage westward of Gau-tau Island. Proceeding to the northward from this anchorage, pass between Kinmen and Gau-tau Islands. In fine weather pass to the eastward of Heroine Rock (the accepted position of this rock, as given by the U.S.S. *Ashuelot*, being S.E. by E. $\frac{3}{4}$ E., 4 miles from the S.W. end of Lea-ming Island) and Twins, or in a strong wind steer for Cape Conway and through Sheipoo Roads.

Fair anchorage in a N.W. wind will be obtained under the northern Kweshan Island, but there is a better anchorage to the N.W. of Castle Rock. It is, however, advisable to get as close to Gough Pass for the night as possible, ready to go through at daylight, or if in time, go through the pass and anchor for the night near Sing-lo Island. After passing Sing-lo Island proceed through Tower Hill and Blackwall Channels; anchorage may be found under Dunsterville or Volcano Islands, both of which should be left to the eastward on passing, thence steer for Rugged Islands.

Care is necessary when navigating this part of the coast, as the tides run strong.

It should be borne in mind, that at all times during the N.E. monsoon the weather is uncertain, and strong breezes set in without any warning, sometimes lasting for two or three days, or even more. Fogs are experienced in the early part of the year in the same manner.

No vessels of small steam power should attempt to proceed northward during the N.E. monsoon, except by the inshore passage, and the same might be said of the typhoon season.

PASSAGES IN S.W. MONSOON.—There will not be the same difficulty in getting to the southward against the southerly monsoon, as there is in going to the northward against the other, as it is not so permanent in its direction, and land and sea breezes prevail; the current has generally been found running strong to the northward in the Formosa Channel, but vessels are not liable to the same detention which they often experience in the northerly monsoon. Care, however, must be taken not to overshoot the port.

Fogs prevail in the early part of the season, and render the navigation at times as harassing as it is in the N.E. monsoon; they, however, generally lift in the vicinity of the land, and a ship's length from where the bowsprit can hardly be seen will carry her into sunshine.

The chief difficulty to overcome in making the passage between the Gulf of Pe-chili and Hong Kong during the southerly monsoon is the strong easterly or north easterly current. After passing the parallel of the Yang-tse kiang, it will be advisable to keep near the China coast; for although a vessel may lie up South or S. by E. on the starboard tack, it should be remembered that she is making little better than a S.E. course in consequence of the easterly set. A stretch to the north-westward, though apparently a loss of ground, will ultimately prove useful.

H.M.S. *Pique*, Capt. Sir Frederick Nicolson, C.B., in making this passage in July and August, was not favoured when close in shore by any land and sea breezes, nor had the least slant, but generally lost the wind. A weather tide was occasionally felt when near the shore in the Formosa Channel.

Although the constant adverse current makes this a tedious passage against the monsoon, there is nothing to prevent a vessel of moderate sailing qualities making the passage at this season. The *Pique* had seldom more than single-reefed topsails, and the sea was generally smooth; she made the passage from the Gulf of Pe-chili to Hong Kong in 31 days.

It would appear that North of the tropic to the parallel of 30° N., North and N.E. winds prevail during the greater part of the year, but alternating with calms, variables, and S.W. winds during the summer months.

20.—PASSAGES BETWEEN CHINA AND JAPAN.

DURING THE NORTH-EAST MONSOON.—HONG KONG TO YEDO.—A vessel bound from Hong Kong to Yedo at this season, should work up the Coast of China as far as Breaker Point (or see note, page 92), taking care to be always under the land at nightfall, the wind during the night always hauling to the northward (off the land), when she may make a long tack off, standing in again in the morning when the wind shifts to the N.E., and frequently more easterly still. From Breaker Point the vessel may then stand across with the wind free for the South end of Formosa, experiencing a southerly set whilst in the Formosa Channel; but on nearing the island she will lose it, and on passing South Cape fall in with the Kuro Siwo setting to the N.E.

Having passed South Cape Formosa, the vessel may work up the coast of that island, passing between it and the Meiaco Sima Group, and to the westward of the Liu-Kiu Islands, having the current with her as far as the parallel of 26° N., beyond which parallel she will experience no current until 30° N., where a strong current will be found setting to the eastward, the wind also being more from the North and West. She may then pass through any of the channels between the islands lying off the South point of Japan, after which, keeping at about from 50 to 10 miles from the land, in the strength of the Kuro Siwo, she may make the lights at Oo Sima (entrance of the Kii Channel), and passing them at a distance of from 5 to 10 miles, may steer to pass just outside Mikomoto (Rock Island).

FROM YEDO TO HONG KONG.—On leaving the Gulf of Yedo, stand to the south-westward as far as 28° S. and 135° E., whence a course may be shaped to pass northward of Kakirouma, one of the Liu-Kiu Group, thus avoiding the influence of the Kuro Siwo. After passing Iwo Sima, a straight course may be steered for Tung Ying, on making which island stand down the China coast for Hong Kong.

FROM SHANGHAE TO NAGASAKI.—At this season, if the wind is to the eastward of North, it would be well on leaving the Yang-tse to stand to the north-westward on the starboard tack, and when the wind hauls round to the north-westward, which it will as the ship advances northward, tack, and steer a straight course for Nagasaki, making allowance for the south-easterly and easterly set from the Yellow Sea and Korea Strait, otherwise the ship may be swept to the eastward through Van Diemen Strait. During the periodic easterly winds (variable between E.N.E. and S.E.) which prevail on the China coast in the vicinity of the Yang-tse, from March to June inclusive, with a sailing vessel, every opportunity must be taken to make easting, even with a fair wind, which it may be almost surely inferred will be but of short duration. In May and June, however, the set of the current will be changed, and will be found running to the north-eastward; under these circumstances there is a probability that a vessel kept on the starboard tack would be set over to the Korean Archipelago. With these considerations the navigator must act on his own judgment, there being only difficulty in making the passage, when baffling winds, and thick, rainy, and squally weather are met with in the vicinity of the Meac Sima, the Pallas, or the Goto Islands, or they are passed on dark nights. If not, therefore, sure of the vessel's position, it would be well to make them in the daytime, unless the nights are moderately fine.

HAKODATE THROUGH KOREA STRAIT.—If bound on to Hakodate at the same season, or even as late as the end of June, it will be found difficult with a sailing vessel to make easting at all along the West coast of Nipon. It will be advantageous in April, May, and June, to pass well East of Tsu Sima in the strength of the Japan stream, which sets N.E. by N. through the Korea Strait, attaining at times, although not constant, a velocity of 2 knots an hour. Should a S.W. wind occur at this season, it may be expected to last only 24 hours, unless it follow an easterly gale with depressed barometer. During the winter, gales from North and N.W. are very frequent in the Korea Strait, lasting three or four days, and are sometimes violent. A rapidly falling barometer indicates their approach, the wind increasing in force after the mercury commences to rise, and not attaining its height until 24 hours after. In such weather, if making for Nagasaki on the port tack, beware of being blown to leeward into Van Diemen Strait, for if set through by the Japan stream it will take a long time to regain the lost ground against the current (one vessel having been nearly three weeks endeavouring to beat round Cape Chichakoff); and if on the starboard tack, there is probability of being set up the Korea Strait to the northward of Ose Saki. As both cases have happened to vessels, it is recommended that they should endeavour to make the land in daylight, and find anchorage, or secure a knowledge of their position.

In winter, when N.W. and West winds prevail, a direct course should be

steered from the Korea Strait when bound to Hakodate; but if bound from Hakodate southward, it is necessary to endeavour to make westing when possible, and keep a long offing, for the coast of Nipon is a lee shore. After passing Korea Strait as well to windward as possible, the winds will be found more liable to change when arrived at lat. 32° N., long. 125° E., but sometimes they continue so steadily between N.W. and W.S.W. as to set a vessel to leeward of the Yang-tse.

SHANGHAE TO YEDO.—On leaving the Yang-tse, the wind will be rarely found as far to the eastward as N.E.; it is best, therefore, to keep the ship on the starboard tack, remembering that she will be set to the eastward towards Van Diemen Strait, after passing which, pursue the same route as directed in the passage from Hong Kong.

DURING THE SOUTH-WEST MONSOON.—HONG KONG TO YEDO.—A vessel bound from Hong Kong to Yedo should run up the China coast as far as Tung Ying, then shape a course for Akusi Sima, one of the Linschoten group. On passing the meridian of 125° E. the set will be strong to the north-eastward. Pass through any of the channels between the islands South of Japan in preference to Van Diemen Strait, as the dense fogs which hang over the coast at this season render the navigation of this strait difficult, whilst farther seaward, when in the warm stream of the Kuro Siwo, the atmosphere is bright and clear. After passing the channel steer to make the lights at Oo Sima, remembering the current sets along the coast of Japan to the north-eastward at this season from 2 to $4\frac{1}{2}$ knots an hour. After passing Oo Sima at a distance of from 5 to 10 miles, steer for Mikimoto (Rock Island) light. If bound from Hong Kong to Nagasaki, after leaving Tung Ying steer for Meac Sima, passing between which group and the Pallas Rocks, a course E.N.E. 80 miles will place the ship off the lighthouse on Signal Head (the North point of Iwo Sima) at the entrance to Nagasaki Harbour, on nearing which it should not be brought to bear northward of E.N.E.

FROM YEDO TO HONG KONG.—This passage is so seldom made by sailing vessels that very little is known of the best route to be pursued; the following, however, is recommended:—

On leaving the Gulf of Yedo shape a course to the south-eastward, to cross the parallel of 30° N in about 145° E., and, passing East of St. Margaret's Island, cross the meridian of 140° E. in lat. 21° N., thence steer (with a favourable current) for the N.E. point of Luzon, on passing which enter the China Sea, when a direct course may be shaped for Hong Kong, taking care to allow for the drift-current setting to the N.E. at this season. It may here be remarked, that this route lies directly across the paths of the typhoons, which are prevalent in the tropics at this period.

This voyage is rarely made, as sailing vessels so take advantage of the monsoons that they leave Hong Kong for the northern ports and Japan at

the commencement of the S.W. monsoon, and, remaining at the ports of the latter islands until the monsoon takes off, leave for the South at the commencement of the N.E. monsoon.

Steamers, however, run at all times between the two places, and at this season usually on leaving Yedo Gulf, and, passing Mikomoto, keep well in shore to Oo Sima, passing which they keep up the Kii Channel through Isumi Strait and the Inland Sea. On passing Simonoseki Strait, if not bound to Nagasaki, they keep to westward of the Goto Islands, and making the Saddle Islands off the Yang-tse, keep close to the shore, and from thence pursue the same course to the southward as vessels bound from Shaghae to Hong Kong.

FROM SHANGHAE TO NAGASAKI.—On leaving the Yang-tse, steer to pass between the Pallas Rocks and Meac Sima (Asses' Ears), which last is visible in clear weather at a distance of 30 miles. The current will be found setting to the north-eastward through Korea Straits; care must be taken, therefore, to avoid being set to the northward of Ose Saki, the South point of the Goto Islands, as the current during the S.W. monsoon is often strong in this locality. Passing the Amherst Rocks, a course E. $\frac{3}{4}$ N. 390 miles will lead midway between the Pallas Rocks and Ose Saki (Cape Goto).

The foregoing is a general account of the tracks most usually followed in traversing the Indian Archipelago or the China Sea. The more particular instructions for each locality will be found in their respective places hereafter.

In such a variety of routes there is necessarily some diversity of opinion as to which is best, and this has not been lessened of late years by the increased variety in the build and trim of the vessels employed in oriental commerce. The route practicable and advantageous to the swift sailing clipper cannot be followed by the heavy-laden and slow-sailing ship of former years. In what is here given, these different routes are each given, some from older authorities, some from recent experience. Some of the best tracks have been avoided from our ignorance of their nature, and their supposed dangerous character. This is fast disappearing before increased knowledge, and it may be predicted that some settled system for the navigation will be established in the course of a few years.

PART II.

DESCRIPTION OF THE COASTS AND ISLANDS.

In the succeeding pages will be found a detailed description of the shores and seas of the Indian Archipelago and China, commencing with the Strait of Malacca, and proceeding thence southward and eastward in regular succession. This arrangement has been preferred to that of following a particular voyage in one direction, as the present exigences of Oriental commerce require the subject to be considered in such varied aspects, that no other than a strictly geographic arrangement can be applicable to every case. The plan of the future pages will be thus readily understood.

Physical Geography.—The Indian Archipelago presents many remarkable features, worthy of the consideration of the passing navigator, as some of its peculiarities will thereby become better understood. This subject was well treated by Mr. Geo. W. Earl, and more recently, in its relation to animal and vegetable life, by Mr. Alfred Russell Wallace.

The first great feature of its constitution is the line of active volcanoes which encircle the whole of the north-western and most extensive area. A line of spiracles and rugged mountains from which they issue may be followed from Cheduba, in the Bay of Bengal, to the Andaman Islands, passing through the entire length of Sumatra, nearer to its S.W. coast; is continued along the southern part of Java, and passes through the chain of islands to the eastward, which are separated by narrow but very deep channels. Thence past the North part of Timor towards New Guinea, where it is met by another chain running from N.N.W., where it may be traced along Kamschatka through the Kurile Islands, Japan, Loo Choo, and the Philippines, after which it divides into two branches, the western passing down to the Moluccas, &c., past Celebes, and joining the first-named line at the West end of New Guinea, and hereabout its greatest effects are evident, in the fantastic forms it has given to Celebes and Gillolo and other islands. These rise abruptly from immense depths,* and to this and other causes may be attributed that want of fertility which characterises them: the rich soil caused by the decomposition of the rocks and vegetation being washed away from their arid surfaces into the deep ocean. The two lines of volcanic action

* H.M.S. *Challenger* found a depth of 2,150 fathoms between Celebes and Gilolo, 2,550 fathoms off the S.W. end of Mindanao, and similar depths in most parts of her track from Torres Straits through the Molucca Passage, Celebes and Sulu Seas, to Manila.

thus united may be followed to the eastward along the North coast of New Guinea, along the Louisiade Archipelago, to New Ireland along the Soloman Group towards the New Hebrides, and may be seen in detached spots as far as New Zealand, and the islands South of it.

This volcanic band is of a totally distinct character in its productions to the other parts of the Archipelago. As in all other parts of the world, the volcanic rocks, which are easily and rapidly decomposed by atmospheric influences, form a soil of unparalleled fertility when cultivated, although there are few useful natural productions, unless the nutmeg be so considered. This feature has attracted the numerous European settlements which are scattered along the bases of these chains, where the sugar and coffee plantations of Java, and the spice groves of the more eastern islands, afford such materials for commercial enterprise, which would seem to be almost illimitable. Mineral treasures are not to be hoped for in these ranges; the action of the volcanic heat has so altered the character of the superimposed rocks, that they afford nothing to the metallurgist.

The second great feature which may be noticed are those parallel lines of primary rocks which trend in a N.N.W. and S.S.E. direction across the archipelago, as well as in the countries of Asia to the northward, and across the continent of Australia to the southward. The chain which forms the backbone of the Malayan Peninsula is perhaps the most conspicuous of these; it may be traced southwards through Banka, &c. It is in this formation where the great deposits of metal are most abundant, or at least most easily worked, as in the famous gold and tin mines of Malaya, and the Banka tin mines. Sumatra, apart from its volcanic ridge, affords another example of these primary ridges. A third traverses Cambodia, &c., showing itself at Pulo Condore and the Natunas, and then reappears at the N.W. end of Borneo, and is lost on the North coast of Borneo. Another passes along the coast of Cochin China, traverses a portion of Borneo and the southern part of Celebes. One feature of these ridges is the existence of the teak tree, which only flourishes on them. When this important tree is transplanted on to the rich volcanic soil, it languishes.

A third feature is the great banks which extend from Asia and Australia, but do not join. This was first pointed out in their relation to their productions by Mr. Windsor Earl. He says: These banks of soundings, which extend from the continents of Asia and Australia, form very remarkable features in the geography of this part of the world, and, as such, are deserving of more attention than has hitherto been bestowed upon them, since it will be found that all the countries lying upon these banks partake of the character of the continents to which they are attached; while those which are situated on the deep sea which separates them are all of comparatively recent volcanic formation, with the exception of a few small coral islands, which are in all probability constructed upon the summits of submerged

volcanoes. The depths on these banks average about 30 fathoms, deepening rapidly as the edge is approached, and shoals gradually toward the land. The great Asiatic Bank extends into the archipelago to a distance of nearly 1,000 miles; in fact, to within 50 miles of Celebes, and perhaps farther.

The great bank which fronts the North and N.W. coasts of Australia commences near the N.W. cape, and extends in a N.E. direction to New Guinea, where it terminates at the base of the high but narrow mountain range that unites the western with the eastern part of that great island, and separates the Banda Sea from the Pacific. It is at this point that the edge of the bank is most remote from Australia, its edge being 400 miles distant from it. It appears again on the South coast of New Guinea, near Torres Strait, and extends along the N.E. coast of Australia.

The Arru Islands and New Guinea are thus united to Australia, and possess in common some features hitherto supposed to belong exclusively to Australia, such as the kangaroo, &c.

The volcanic islands between these great shoals appear to have a world of their own, different from the countries on either side. This remarkable feature cannot be dilated on, but may be followed in the excellent papers given by Mr. A. R. Wallace. It would seem as if the animal life especially belonged to a different order generally from that found on the neighbouring continents, and is even different between adjacent islands, so that these anomalies have given rise to some interesting speculations.

Respecting our knowledge of the coasts and seas, it is of varied character. Although much more perfect than it was a few years since, there are some serious defects in the hydrography of the archipelago, especially in the eastern portion of the area. The surveyors of the East India Company in former years, and our Admiralty hydrographers in later times, have examined the principal passages leading into the China Sea, as the Straits of Malacca and Singapore, Banka, &c. The Dutch Government have given charts and directions for the countries adjacent to these possessions, such as Sunda Strait and the coasts of Java, and the nautical world owes much to the Dutch commission for the improvement of charts and navigation. Under the auspices of this body a fine series of charts, of various and extensive portions of the archipelago, were published. These have since been mostly copied by our Admiralty. For the Spanish possessions in the Philippine Islands, &c., we have the older and modern surveys of that nation. The coast of China has been excellently surveyed by our Admiralty. All these authorities will be generally enumerated in the course of the ensuing pages.

Before proceeding with the descriptions, we must make our general acknowledgement of indebtedness to the *China Sea Directory*, published by the Admiralty. This work, derived from many sources, gives a correct picture of our present knowledge, and is therefore deserving of all confidence.

CHAPTER III.

THE STRAIT OF MALACCA.

This great highway into the China Sea may be considered to be limited on the N.W. by a line joining Acheen Head and the South point of Junksey-lon, which would be about 225 miles in length; and from this limit to the Carimon Isles, at its S.E. end, is 500 miles, so that it has more the character of an inland sea than a channel between Sumatra and the Malay Peninsula. In a more contracted sense it may be said to commence at Diamond Point on Sumatra, and Pulo Penang on the Malayan side, and these are 164 miles apart East and West.

The monsoons, interrupted by the high land of Sumatra on the one hand, and that of the Malay Peninsula on the other, each crossing the line of their normal direction, are only felt for a short distance within the respective en-trances, and from its position so near to the equator, the strait is subject to baffling and light winds and calms. In a former page the peculiarities of the winds and seasons have been referred to.

Its coasts have not been completely surveyed, but partial examinations have been made by Lieuts. Woore, W. Rose, and Capts. Moresby and C. Y. Ward. The charts, it is believed, are sufficiently complete for the safety of its navigation, which, under proper precaution, is free from danger.

The *British Possessions*, called the *Straits Settlements*, are the *Province Wellesley*, a strip of coast on the Malay Peninsula, about 10 miles broad and 35 miles long, at the back of *Pulo Penang*, also a British possession, a patch of country, 22 miles in length from North to South, with the island of *Pancore* lying off its southern portion, as hereafter described. The territory of *Malacca*, about 40 miles in length, and 25 miles in mean breadth, with its capital of the same name, and the great commercial emporium *Singapore*. These form a governorship, which, till the year 1851, was sub-ject to the jurisdiction of Bengal. In that year it was placed under the Indian Board; and on January 1st, 1867, it was transferred from that of India to the Colonial Office, and some changes were made in their constitu-tion. Each of these settlements is largely peopled with Chinese immigrants, who are the most industrious of the people. The Malay States from North

to South are named as follows—Quedah (Wellesley), Perak (Dinding), Salangore (Malacca), and Johore. The maritime population of these would be formidable pirates, were it not for the vigilance of the states cruisers, and gun-boats of light draught, which can follow the delinquents into the shelter of their rivers. Notwithstanding this, small vessels and boat parties should be on their guard, as among a population of this character, where morality is at so low an ebb, it is only a fear of being overpowered in the attempt, or found out and punished after the act is committed, which deters them from similar acts of violence to those committed in years gone by.

In recent years British Residents have been placed as advisers to the rulers of the different native states, and it is hoped by these means to increase the trade and otherwise improve the government of the peninsula.

The greatest mineral production of the country is tin, which seems to be met with in almost every part of the interior, and in very great abundance. The tin districts which have been most worked of late years are situated at Klang, in Salangore; at Laroot, in Perak; and at Linghie, near Malacca. "The mines in these districts," says Mr. Braddell, in 1874, "are so rich, and the profit of working them has been so great, that, notwithstanding the difficulties in dealing with the Malay chiefs as to the royalty to be paid, and notwithstanding the oppression of the chiefs, and the frequent massacres of the Chinese miners, they are still attracted to the place, and succeed yearly in sending large quantities of tin to Singapore and Penang."

THE EASTERN COAST.

Province Wellesley extends from the state of Queda, or Keddah, on the North to the river Krian, or Karian, S.E. of the South point of Penang. In 1851 its population was 64,801, a number five times as great as in 1824; and in 1873 it had reached to 160,000, of whom about 450 were Europeans. It resembles Penang in its geological structure, granite, over which is found the cellular clay iron-stone, so abundant in these regions, and known by the name of laterite.

The settlement produces sugar, rice, and coconuts in abundance, and among many other products a great variety of delicious fruits. Its chief importance, however, arises from the fact, that the capital of the island is a great emporium for the manufactures of Britain, and for the products of the countries of the Malay Peninsula on the one hand, and of Sumatra on the other.

PULO PENANG, or Prince of Wales Island, is about 14 miles long and 9 miles broad, and separated from the Malay coast by a channel from 2 to 5 miles broad. It is intersected by a range of granitic hills, the highest peaks

of which are Government Hill, to the West of the fort, 2,550 ft. ; West Hill, 2,713 ft. ; and Mount Elvira, near the centre, 2,384 ft. It was ceded by the King of Quedah to the East India Company, July—August, 1786, for a naval station. It has answered every expectation of its founder, Captain Light, and is, like the other straits settlements, entirely free from any impost on shipping.*

Pulo Penang, or Prince of Wales Island, is justly termed the Eden of the East, and the northern part especially is an immense spice garden. Fruit and vegetables are in great abundance, and in fact all Eastern delicacies, not forgetting the water, which may be considered the best in or out of the straits.

The N.W. part of the island is lofty and irregular, but seen from a distance, as far as 20 leagues off, it has a regular oblong appearance. The West coast forms a slender bay, with low wooded land reaching to the foot of the interior hills. The southern part of the island is lower. The town is on the East side. The climate is hot, but considered healthy.

The exceeding magnificence of its mountain views, the richness and variety of their component parts, and the coolness and transparency of the atmosphere which this country enjoys, give a freshness and elasticity to the mind never experienced in the sultry plains of India. It is almost inconceivable how nature, in so small a compass, has contrived to crowd such a wonderful diversity of pleasing objects.—*Logan.*

Tanjong Puchat Muka.—The N.W. point is in lat. 5° 28' 40" N., long.

* PORT RULES, 1872.—The limits of the Port of Penang are as follows:—From an obelisk built at Klarwey in a straight line to Bagan Jermal, along the western shores of Province Wellesley, to an obelisk at Bagan Luar, and in a straight line to Penang Bridge, thence along the eastern shores of Prince of Wales Island, to the obelisk at Klarwey, including the mouth of Prangin River, as far as the second Teetee Papan Bridge.

The limits of the South Channel are as follows.—From the North bank of the Penang River to Nos. 8 and 5 red buoys, from thence along the eastern bank of Pulo Perajah to the south-easternmost point of Pulo Rimo, thence in a straight line to No. 9 white buoy, then passing close to Nos. 8, 7, 6, 4, and 2 white buoys, and in a straight line ending at the obelisk built at Bagan Luar.

Signals in case of fire.—In the daytime, the Commercial Code signal of distress indicated by "NC:" at the same time, when possible, two guns should be fired, at an interval of one minute ; at night time, two rockets fired, and two blue lights burned alternately at an interval one one minute, and two guns fired as in the daytime.

Requiring the assistance of the Police.—In the daytime, the national ensign to be hoisted at the main-masthead ; at night, one gun to be fired, and one blue light burnt.

Masters of vessels are prohibited from anchoring abreast of the jetty, or in any place within 250 yards on either side thereof.

Vessels remaining upwards of 24 hours are to moor and keep a clear hawse. No sailing vessel is to be unmoored or shifted about without permission from the harbour-master, and on no account after dark, except in case of emergency.

100° 13' E. It is bold-to on the westward, and has 4 fathoms close-to. From it, on the eastern side, a shoal bank skirts all the North end of the island for 11 miles to the point on which George Town stands, the 3-fathoms edge being from 1 to 2½ miles off shore. At 3¼ miles East of Muka Point is the *Feringi Rock*, close in-shore, and at 3½ miles farther is *Pulo Tikus* (or Tee-coos), a rocky islet with some rocks around. Between this islet (on which is a white obelisk) and the Malay shore is the shoalest part of the channel which insulates Penang, not having more than 4 fathoms.

George Town, or Penang.—The chief place of the island stands on its eastern point, the extremity of which is occupied by *Fort Cornwallis*. It contained probably nearly 60,000 inhabitants in 1873, of whom a very large proportion are Chinese—many of them merchants and shopkeepers. It is situated on a low plain stretching out in a point into the sea, on the side of the island next to the mainland, and its harbour, which is simply the almost landlocked strait between the island and the mainland, is of great extent and unrivalled calmness. It has always a large fleet of vessels of every rig, from the finest British steamer to the Chinese junk.

The distance from the fort to the mainland opposite is about 2 miles, and this forms the harbour. The Fort Point is steep-to, having 9 and 10 fathoms near to it. In the middle of the strait are from 12 to 15 fathoms, and 6 to 7 fathoms on the Malay side. The best berth for anchoring is about a quarter of a mile South of the fort, in 9 or 10 fathoms, or less for small vessels. The tides are more regular here than close to the point, where they cause eddies. It is high water off the fort at 12^h, at full and change, but the flood runs southward till 3 o'clock in the main stream. Springs rise 9 ft., and neaps about 7½ ft.

Channels.—Mr. J. G. Maddock remarks:—"Both the northern and southern channels are safe, the northern shallows being well marked by fishing stakes, numbers of which are in 4 to 5 fathoms water. I have often passed between them, but a stranger having any regard for his copper ought to give them a good offing, as there are many old stakes broken off 2 or 3 ft. under water. The southern entrance is well buoyed, and also marked by beacons; but unless you have a good commanding breeze from the southward or S.W., which is not often the case except in the first of the rainy season (August and September), and if coming from the southward, I should always prefer the northern channel. I recollect once coming up with the *A. J. Kerr*, from Singapore. I had a good stiff breeze from the southward and westward, which I made available for the southern entrance. I had got to within half a mile of my anchorage when I was met by a northerly wind. I gave orders to clew up and anchor, and left the two winds to battle the match how they liked; in the morning I found the northerly wind had gained the day: this is not an uncommon occurrence in the southern channel."

The best route to reach the anchorage, as above stated, is by the North

channel. The southern one is intricate and also dangerous without an intimate knowledge, and with a large ship. With westerly winds, steer for the North end of the island, or with the wind from N.E. or northward, make for the mainland to the northward, and approach Pulo Bunting from N.W. by W. or W.N.W. The *Bunting* (or *Boonting*) Isles are four in number, with an islet between them, lying about 12 to 15 miles North from Penang. The largest is the northernmost, and is opposite to the peak of Quedah; and the southernmost is *Bidan*, or *Biddan*, which is nearest to the shore, and has only 2 or $2\frac{1}{2}$ fathoms inside of it. By night these islands may be neared to within depths of 14 or 15 fathoms; by day there is no danger but what may be seen. When past them, steer about S.S.E., with Pulo Bidan bearing about N. by W., keeping about midway between the North part of Penang and the main to avoid a flat extending off the Malay shore, and also that which encircles the North end of Penang, as before mentioned. The bar, or shoalest part of the channel, will be found when abreast of Pulo Tikus, and is only 24 ft., barely sufficient if there be any swell, which seldom occurs, if the draught be more than 20 ft.

The Fort Point is $3\frac{1}{2}$ miles to the S.E. of Pulo Tikus, which, as before stated, has some rocks around it; but having passed it, the water deepens towards the harbour. The N.E. shore of the island forms a slender bay, filled with a muddy shoal, which suddenly drops from 2 to 5 fathoms. The lead is not a sufficient guide in thick weather, or at night, in passing over the flat between the N.E. point and the Malayan shore, as the depths are nearly the same all across until within $1\frac{1}{2}$ mile of either shore. The shore of the main land is low, and covered with trees, so that it is not so conspicuous as the high land of Penang, which will thus appear the nearest when in mid-channel. From within Pulo Tikus to the fort, stand off again when $5\frac{1}{2}$ or 6 fathoms is reached. By daylight there is no difficulty in thus reaching the harbour, as the rocks of Pulo Tikus are bold-to. In the N.W. monsoon which sets in in August, there may be some difficulty in beating out by this North channel, but at all other times it is preferable for large ships. A good leading mark is to keep the West end of Pulo Jerajah, which lies off the East coast of Penang, clear of, or just open of the point on which Fort Cornwallis is built. This will carry you clear of all danger, the least water being $4\frac{1}{2}$ fathoms, mud and sand. Should you not see Pulo Jerajah, owing to hazy weather, the long leading mark is as before mentioned, Pulo Bidan, the southernmost of the Bunting, bearing N. by W. until you get sight of Pulo Jerajah.

The South Channel, though intricate, is very serviceable during adverse winds, as it affords a ready outlet in fine weather to the southward for ships drawing under 17 ft. water. Pilots are stationed at Pulo Jerajah. It is bounded on the West side by the Middle or Long Sand, marked by three buoys along its eastern side, which begins about three-quarters of a mile

South of the Fort Point, and stretches nearly to the North point of Pulo Jerajah. On the East side it is bounded by the northern spit of the *Great Kra Flat*, or as it was termed the Praya (or Pry) Sand. It is a bank of soft mud, which stretches from the Malay shore for 10 miles, when to the South of Penang.

Pulo Jerajah, or *Jeraga*, is 5 miles S. by W. from Fort Point, and is 734 ft. high. It has a narrow channel of 3 to 5 fathoms between it and Penang. Off the S.E. point of Penang is *Pulo Remo*, or *Ramio*, close to the South of which the channel passes.

Buoys.—The South Channel is marked by ten buoys, numbered from North to South, each placed red on the western, and white on the eastern edge of the channel, in about 2 fathoms of water. Of these, three painted red mark the eastern edge of the Middle Bank; and six, painted white, the western edge of the Great Kra Flat; a fourth red buoy lies S.W. of Remo Island. No. 1, a red buoy, is moored on the North end of the Middle Bank, a mile southward of Fort Cornwallis. No. 2, white, S.S.E. $\frac{1}{2}$ E. $1\frac{1}{2}$ mile from No. 1, marks the eastern side of the channel, which is here quite clear, and nearly three-quarters of a mile in width. At $1\frac{1}{4}$ mile below No. 2 buoy the channel is marked on either side by red buoy No. 3 and white buoy No. 4, which are two-thirds of a mile apart; hereabouts the soundings suddenly decrease from 6 to $2\frac{3}{4}$, 3 and 4 fathoms, the deepest channel being nearer to the white buoy. At about three-quarters of a mile below Nos. 3 and 4, Nos. 5 red and 6 white, three-quarters of a mile apart, mark the opposite sides of the channel. The deepest part of the channel here is towards No. 6, as a spit projects out from the red buoy. No. 7 white buoy, $1\frac{1}{2}$ mile S. by W. $\frac{1}{2}$ W. from No. 6, marks the eastern side of the channel opposite the highest part of Pulo Jerajah. Hence to the southward the channel is broad and deep. No. 8 buoy, white, marks its eastern side, and lies S. by E. $1\frac{1}{4}$ mile from the South end of Pulo Jerajah. No. 9, red, marks the western side of the channel, 2 miles S.W. of Pulo Remo; and No. 10, white, marks the eastern side at its South extremity, and lies $1\frac{1}{2}$ mile southward of No. 9 red buoy.

In *leaving* Penang Harbour by the South channel, get under weigh about half flood, and steer S. by E. and South to enter the channel between the Middle Sand and the Pry or Praya Sand. When the bar is neared, keep near the eastern edge of the Middle (or Long) Sand, the depth in crossing it is nearly 5 fathoms, between the North end of Pulo Jerajah and Kra Flat. When the North point of Pulo Jerajah bears to the northward, the soundings will decrease to 6 and 7 fathoms, then haul near to that island, and these depths will continue through the channel in steering out to S.W. seaward, past the S.E. point of Penang and Pulo Remo. The greatest depths are near the East sides of these islands, which are steep-to, but on the East side of the channel the water shoalens suddenly upon the edge of the Kra Flat. After passing Pulo Remo close on the East side, the course is

about S.S.W., or S. by W., according to the set of the tide, to proceed through the channel fairway between the Kra Flat on the port hand, and the mud bank off the South end of Penang to starboard. The leading mark is to keep the body of Pulo Jerajah on with the East end of Pulo Remo, if Pulo Jerajah is shutting in with Pulo Remo, a ship will be on the West side; and if entirely open with it, she will be on the East side of the channel.

The mouth of the *River Krian* is in about lat. $5^{\circ} 16' N$. This river serves as one of the roads down which the tin is brought from the mines in the interior.

The State of Perak,* extends along the coast from Wellesley Province to the State of Salangore, or from 1 to 2 miles southward of the mouth of the Kutong River to the mouth of the Bernam River, a distance of about 100 miles. A portion of this coast line, however, belongs to Great Britain, having been ceded in the year 1826, and the cession again ratified in the year 1874. This includes the Island of Pancore, or Dinding, and coast of the mainland at the back of the island, and thence for about 20 miles to the northward. The Bruas and Dinding Rivers enter the sea within its boundaries.

The district of *Laroot* is situated to the northward of this British territory, and is bounded on the North by the Krian River. The physical aspect of the district is thus described by Mr. Birch:—"From the sea-shore to some 20 miles inland, Laroot is a great level; here it begins to rise in uplands until it reaches a mountain-range rising to an altitude of some 3,000 ft. above the level of the sea. This level or plain is well watered and well suited for the cultivation of sugar, tapioca, tobacco, &c. Rice is the only cereal now cultivated. The whole of the land, comprising a strip of about 50 miles long by 6 miles broad, along the Laroot Range, is more or less stanniferous, and the supply of tin is inexhaustible. At present (1872) about 4 square miles are occupied for mining purposes, and there are 120 mines open. It is unskilfully worked, and only about 600 tons were exported in 1874. Of the Laroot Range, *Gunong Buboo*, or the 'Wild Mau,' is said to be the loftiest. It is said to be the most conspicuous landmark to mariners beating up the Straits for the mouth of the Perak River, which is several miles South of this mountain."

The population of the State of Perak, which extends eastward as far as the Malayan chain of mountains, was estimated to number 25,000 in 1874, mostly established near the shores of the Perak River, which passes through the country in a direction from North to South at a distance of about 30 miles from the coast. It is from this River Perak or Pera (silver) that the country takes its name. The country is plentiful in fruit-bearing and timber-

* Pronounced like "Pera," the terminal k in Malay words being scarcely sounded at all.

producing trees, among the latter class being the teak. India-rubber and gutta-percha trees are also found. In minerals, iron, saltpetre, and gold, are found, besides the tin before mentioned.

Pry River enters the sea on the southern side of the point, lying E.S.E. of Penang. Here it is high water, full and change, at 12^h. Springs rise 9 ft., neaps 7½ ft.

The *Kutong River*, in lat. 5° 6' N., is merely a southern outlet to the River Krean, and flows along the South side of the North Mound.

The *River Laroot*, rising in the neighbourhood of Gunong Hijau in the Laroot Range, falls into the Sea in 4° 44' N., 28 miles to the S. of the Krean River. Mr. Irving says:—"Compared with other rivers on the coast, it is an inconsiderable stream, as the range of mountains which forms the watershed of the peninsula, at this place, approaches the coast. The colonial steamer *Pluto*, drawing only 6 ft. of water, was not able to do more than enter the river; but the small steamers belonging to the Tunku Mantrie, or headman, are able to get up to the town, a distance of 2 miles from the coast." The town, in 1872, was surrounded with stockaded positions, and Mr. Irving observed that there was an excellent road all the way to the mines in the Laroot Range, about 10 miles from the town. The coast of Laroot between the Kurow, 20 miles northward of the Laroot River, and the Jurom Mas (or Gold Needle), 12 miles to the southward, is a perfect network of rivers and rivulets, and indented by endless creeks and bays, which afford countless sheltering places for pirates. Most of these creeks and inlets have been explored by the boats of the *Thalia* and the *Midge*, when in search for pirates in 1872, under Captain Woolcombe.

The Kurow River enters the sea in 5° N., and 10 miles south-eastward of it is the mouth of the Silensing. This latter river is connected with the six outlets to the sea between it and the Jurom Mas River, in lat. 4° 33' N. These outlets are named in order, Besar, Kechil, Larut, Trong, and Jurom Mas. About 1 mile South of the Jurom Mas is the mouth of the small river Hut. Between this and the mouth of the Bruas River, which is situated 4 miles to the south-westward, is the northern boundary of the British Territory.

At 16½ miles S.E. by E. from the S.E. end of Penang is a hill, called the *North Mound*, which is 5 or 6 miles South of the Krean River, and at 13½ miles further to S.E. by E. is another called the *South Mound*. Further inland high mountains are seen, which extend to the southward.

The Coast is fronted by an extensive shoal, which commences in the strait insulating Penang, and which, South of that island, is called the Great Kra Flat, the 5-fathoms line being as much as 12 miles from the beach. This extensive mud-bank, the produce of the many rivers, before mentioned, which enter the sea from the adjacent coast, gradually shoalens to the shore,

leaving a wide space, which covers and uncovers with the tide, and continues with varying break for 54 miles, till its outer edge comes close to the land at *Pulo Tallong*, near the hills known as *False Dinding*, or *False Suggur*. The outer edge of the bank is steep-to, decreasing suddenly from 13 to 12 fathoms to 2 or 3 fathoms, so that it would be imprudent to stand nearer than that depth, even with the lead kept briskly going, especially in the night. There is some advantage in keeping in with the coast, for by doing so the westerly current usually prevailing in the offing will be partly avoided. The winds will also be more favourable, and anchoring easier than in deeper water.

DINDING ISLAND, or PULO PANCORE, before mentioned as forming a portion of British Territory, was examined together with the channel on its eastern side by Commander Napier, in H.M.S. *Nassau*, in 1876. The island is of irregular shape, 5 miles long N.W. by N. and S.E. by S., and 2 miles broad. Off its S.W. end is *Little Dinding Island*, sheltering a bay; off its N.W. end runs a narrow promontory, $1\frac{1}{2}$ mile long; and midway between the promontory and *Little Dinding Island* a narrow island $1\frac{1}{2}$ mile long juts out on its western side. The highest part of the island is 1,318 ft. high, and situated about 2 miles S.E. of the N.W. point. On the North and South extremes are two hills, respectively 748 and 992 ft. high. Two other mountains rise near the centre of the island, and attain a height of more than 1,000 ft.

Great Dinding Island is densely covered with jungle. The woods consist of ebony, sandal wood, several varieties of gum, india-rubber, and palm-trees, bamboo, and several native woods, some of which are similar to mahogany; coffee and cotton are also grown here. The whole of the woods are farmed out by the colonial government at an annual rental. The population in 1876 consisted of about 250 Bataks or Malayan native hill tribes, and 100 Chinese. A Dutch fort formerly existed on the East side of the island. Poultry, eggs, and occasionally pigs, may be procured at most of the native villages at reasonable prices. Fish and fruit are plentiful; turtle in the season. Fresh water of good quality is plentiful at almost all the villages, but owing to want of proper conduits can only be obtained in small quantities.

North Entrance.—The passage between the North side of Pulo Pancore and the main is divided into two channels by the *North Bank*, which shows breakers in places. This bank is 4 miles long in a N.W. and S.E. direction, and from half a mile wide at its southern end, opposite the mouth of *Dinding River*, on the mainland, to $1\frac{1}{2}$ mile wide at its North end, near which lies *Wedge Rock*, 3 ft. above water, N. by E. $\frac{1}{2}$ E., $1\frac{2}{3}$ mile from *North West Islet*, which lies 5 cables N. by W. $\frac{1}{2}$ W. from the North point of Pulo Pancore, is wooded, 100 ft. high, and difficult to discern until close. A 3-foot rock lies nearly a cable off its West side, otherwise it is steep-to all round.

A small islet, 7 ft. high, lies in the channel nearly midway between North West Islet and Pulo Pancore.

Between the North Bank and the bank skirting the shore there is a channel, suitable for vessels of not more than 10 ft. draught of water; but the passage is difficult, and should not be attempted without local knowledge. Pass Tanjong Hantu, a projecting point, 11 cables N.E. by N. of Wedge Island, at about 2 cables distant on a S. $\frac{1}{4}$ E. course, after which steer S.S.E. $\frac{1}{2}$ E.; this course will lead direct to the centre of Dinding River passage, and in not less than 4 fathoms water. H.M.S. *Nassau*, drawing 13 feet, passed through the channel at three-quarters flood.

The channel westward of North Bank is not recommended for vessels of large draught, for although with care and attention not less than 4 fathoms water will be obtained, the passage is narrow, being only 2 cables wide in the narrowest parts, and the leading marks are not of the best description. The eye, however, is the surest guide.

Give a wide berth to North bank, the western limit of which bears North from the N.W. point of Pulo Pancore. To clear this and the outlying 3-fathoms patch 7 cables W.S.W. of Wedge Rock, the North peak of Pulo Pancore should not be brought to bear southward of S.E. $\frac{1}{4}$ S. North West Islet will be sighted ahead on this bearing, and passing it on the starboard hand at half a cable distant, steer E. by S. $\frac{3}{4}$ S. for *Offlying Rock*, 2 ft. high, near North Point. Between North-west Point and North Point, which are 3 cables apart, a rocky bank projects $1\frac{1}{2}$ cable to the northward, at the extremity of which is Grasshopper Islet, 120 ft. high and wooded. Pass Offlying Rock also on the starboard hand, at half a cable distant; then alter course quickly to starboard, and bring the summit of North West Islet to bear W. by N. $\frac{3}{4}$ N., and midway between Offlying Rock and North Point. This mark will lead a cable North of *Bower Patch*, and 1 cable South of a projecting part of North Bank. When *Scorpion Point* (which forms the eastern entrance point of the large bay indenting the North side of Dinding Island) bears S.W., alter course to starboard, and bring *Table Rock*, lying near a point, and 22 ft. high, to bear S. by E. $\frac{1}{4}$ E.; then steer 6 or 8 cables to pass the latter one, or $1\frac{1}{2}$ cable distant; and thence, preserving the same distance from the island, to the anchorage off Port Pancore.

Charybdis Rock, a pinnacle having a depth of 2 ft., lies North $1\frac{1}{4}$ cable from Scorpion Point. The 2-fathom bank surrounding it extends a quarter of a cable farther North. The ground is foul between Charybdis Rock and Scorpion Point.

Shoal water of 10 to 17 ft. extends a distance of $2\frac{1}{2}$ cables to the N.E. and East of Scorpion Point, and also fills the bay formed to the N.E. of Table Rock.

Bower Patch, having a depth of 15 ft., is nearly circular, about half a mile in diameter, and lies N. by W. $\frac{1}{4}$ W., 3 cables from Scorpion Point. The

summit of North-west Islet, in line with North Point, leads on to Bower Patch. The summit open of North Point, and bearing W. by N. $\frac{3}{4}$ N., leads North of Bower Patch in 4 fathoms least water.

If bound to Dinding River, keep North West Islet bearing W. by N. $\frac{3}{4}$ N., and when Scorpion Point bears S.W., sheer out a little to the southward, to give the S.E. extreme of North Bank a wider berth, and bring the leading mark on again before the tongue of South Bank is approached.

The South Channel lies between the eastern side of the island, which is almost steep-to, and the bank which extends about a mile off the main.

Fairway Rock, 27 ft. high, lies S. by W. $\frac{1}{2}$ W. $3\frac{3}{4}$ miles from the S.E. point of Pulo Pancore; a sunken rock, having less than 6 ft. water, lies half a cable from its North side, and a depth of 4 fathoms near the West side of the rock. There are 9 to 16 fathoms water between the rock and the mainland, and 10 to 23 fathoms between the rock and Pulo Pancore.

Pulo Katta, N.E. by E. $3\frac{1}{2}$ miles from Fairway Rock, is a small wooded islet, 114 ft. high, standing on the edge of the bank near Tanjong Katta, and is separated from the mainland by a shoal and rocky passage 3 or 4 cables wide.

To reach Port Pancore from the southward, having passed Fairway Rock and Pulo Katta, steer to bring Table Rock in line with Tanjong Hantu bearing N. by W. $\frac{1}{4}$ W.: keep these marks in line, which will lead nearly mid-channel to the anchorage off Port Pancore.

If wishing to enter Dinding River, steer from the anchorage to pass Table Rock 2 cables distant, and thence midway between East Bank and the island, until the North summit of Pulo Pancore bears S.W. $\frac{1}{2}$ S.; then bring the summit of North-west Islet bearing W. by N. $\frac{3}{4}$ N. open of North Point, and proceed on that course to the entrance of the river.

Abreast of Port Pancore there will be found secure anchorage for vessels of large draught, and sufficient space for several vessels to moor. The best berth is with the shore end of the pier bearing W.N.W., distant 3 cables, in 8 fathoms, mud. In this berth the vessel will be distant 3 cables from the edge of East Bank, the shoal which skirts the mainland adjacent. Bathing is unsafe on account of the numerous alligators which swim across the channel.

It is high water full and change in Dinding Channel at 3^h 15^m; springs rise 9 ft., neaps 5 ft. The flood stream in the North entrance sets fairly through the channel. In Dinding Channel and South entrance the ebb sets N.N.E., and flood S.S.W., at the rate of 2 to 3 knots at springs.

To the S.W. of Pulo Pancore the flood sets S.E., and ebb N.W., and sets through the narrow passage between Pulo Pancore Laut and Pulo Pancore at the rate of 2 to $3\frac{1}{2}$ knots at springs.

There is anchorage in the bays on the western side of Dinding Island.

Dinding River, perhaps the only river without a bar in Malacca Strait,

has a deep and clear entrance, which between Mehegan and Motts Points is 8 cables wide. A channel 3 cables wide, and having 5 to 9 fathoms, extends 3 miles up the river, the farthest point reached by the surveying parties. The water shoals more gradually towards the North shore than towards the South, which is rocky. Yellow Cliff, 14 ft. high, and Red Cliff, 26 ft. high, both on the South side of the river, are conspicuous. On the North shore of Dinding River, at the West side of the entrance of Sungie Sumpit (small river) is situated a police station, a conspicuous bungalow standing on a spit, and easily recognised by the palm trees westward of it. On the South shore of Dinding River, opposite the police station, is a native village. The flood and ebb tides set at the rate of $3\frac{1}{2}$ knots at springs, and 2 knots at neaps. Directions for approaching it from the Dinding Channel are given previously.

The southern boundary of the British territory is in the bay 2 miles East of Pulo Katta.

The Sambilang Islands are 8 miles South of Dinding. They are so called from the Malay word for nine, their number. They are generally high and bluff, covered with trees, and visible 20 miles off.

The *White Rock*, 15 ft. high, is the south-westernmost of the Sambilangs, and is in lat. $4^{\circ} 0' 10''$ N., long. $100^{\circ} 32' 15''$ E. The *Black Rock*, not very high above the water, is 1 mile North from it. The Sambilangs are quite bold-to, with very deep water, 15 to 46 fathoms, and very irregular bottom, so that the lead is no guide in approaching them. There is a safe channel inside them.

The RIVER PERAH, or Perak,* is an extensive stream, and is much frequented by the country vessels trading for tin. Mr. Birch, in one of his last speeches made at Singapore, speaks about this river in these terms:—“The river is a very magnificent one. At least 150 miles from the mouth, it is over 400 ft. wide, and, as the tidal influence extends a very short distance from its mouth, it may be well imagined what rich and fertile lands are to be found along its valley. The greatest resources of this fine district lie in its soil, which is remarkably rich and suitable for the cultivation of tobacco, sugar, or indigo.”

A vessel entering Perah River should close the North coast, and having passed Pulo Katta, bring the South point of Pulo Pancore, or Great Dinding, to bear N.W. by W. $\frac{1}{4}$ W., and nearly touching the North point of Little Dinding Island. This mark will lead over the bar in 11 ft. at half-tide neaps, and 17 ft. at high water springs, and past the outer clump of

* It was at Passir Salah, a town on this river, about 70 miles from its mouth, that Mr. Birch, the British Resident, met his death at the hands of the natives. The murder took place in November, 1875, at a time of great excitement, caused by the struggles of two rival claimants for the throne of Perah, after the death of Sultan Ali.

fishing-stakes at about three-quarters of a mile on the starboard hand ; the bar is (January, 1876,) situated N.E. by E. from these stakes.*

Keeping the same marks in line, a second clump of fishing stakes is passed on the starboard hand about a quarter of a mile distant ; then alter course gradually to starboard, and pass between this clump and another large clump bearing E. by S. Passing the latter at a quarter of a mile distant, the vessel should steer along the bank for the point on the North side of the entrance, keeping about a half or three-quarters of a mile off shore, and passing outside some small fishing-stakes moored close to the bank, until the mouth of the river is reached. Avoid the first point on the port hand, as there is a long spit extending off it, and steer over to the South or left bank of the river, keeping it at a distance of 50 to 70 yards, as there is a shoal in the centre of the river.

Between the entrance of the river and Kota Striah, distant 25 miles from the bar, on the route recommended, soundings of $2\frac{1}{2}$ to 5 fathoms will have been obtained. There is anchorage off Kota Striah, in $3\frac{1}{2}$ to 4 fathoms, stiff mud, at $2\frac{1}{2}$ cables from the shore.

Durian Sabatang, a town of eighty or ninety houses, the highest point which may be reached by gun-vessels drawing 11 ft., is 43 miles from the entrance. The trade, which is chiefly in tin, is in the hands of the Chinese, and is carried on entirely by junks.

Bandar Bahru, the site of the British Residency, is estimated to be 19 miles above Durian Sabatang. Kota-Lumut is the highest point steam launches can reach.

Bernam River, 12 miles southward of Perah River, is the boundary between the States of Perah and Salangore. It has been for years the resting place of pirates, but in 1870, after some severe fighting, they were dislodged, and it is hoped that by an occasional visit of one of H.M. gunboats, the practice may be checked for the future. The river extends about 150 miles inland.

PULO JARRA lies in the middle of the Strait of Malacca, bearing S. $\frac{1}{2}$ W. 78 miles from Penang, and $26\frac{1}{2}$ miles W. by S. from the Sambalang Islands. It is about 300 ft. high, very small, covered with trees, and may be seen in all directions for 20 or 25 miles. It is very steep-to, the lead affording no

* In June, 1876, the *Ringdove* crossed the bar at high water neaps with the same marks, and had 22 ft. least water. Also H.M.S. *Maggie*, crossing on the 26th of December, 1876, had 25 ft. least water at one hour before high water ; the outer fishing-stakes bore S. by E. The channel of deepest water is probably very narrow, and it may shift. Navigating-Lieutenant Pownal Aplin, H.M.S. *Modeste*, 1876, remarks, that vessels of 9 ft. draught may always enter at high water. Ships of greater draught should not attempt it except at springs, unless in cases of urgency. The best channel in 1861 was 1 mile South of Pulo Katta.

indication of its proximity. The depths around it are from 14 to 48 fathoms, with 25 to 30 fathoms in the channel between it and the Sambilangs; and from 30 to 40 in the channel between it and the Brothers, 39 miles to the S.S.W. It is best to pass to eastward of it, because the current often sets strong to the N.W. in the middle of the strait, and calms are more prevalent there than nearer the coast. It is in lat. $3^{\circ} 58' 20''$ N., long. $100^{\circ} 8' E.$

SALANGORE,* the capital of the Malayan State extending from Bernam River to Langat River, lies within the entrance of a small river at 60 miles S.E. from Pulo Sambilang. The town was founded at the commencement of the last century by a colony of Bugis from Celebes, and was at one time frequented for tin, for which the Dutch had here an establishment and monopoly. The fort on the South side of the entrance to the river is in lat. $3^{\circ} 19' 50''$ N.; there are also some forts on the northern shore. The river is navigable at high water for vessels of some burden, and H.M.S. *Rinaldo*, draught 15 ft. 4 in., entered here in July, 1871, to punish the natives for a piratical attack which had been made in a junk from Penang, when thirty-four persons were murdered. They found the bar 2 miles in width at high water, and grounded at low water when anchored in front of the town. Captain Bloomfield, who examined the river in 1871 up to where it ceases to be tidal, at 22 miles from its mouth, reports that vessels drawing more than 10 ft. water should not attempt to enter the river until more accurate surveys are made. H.M.S. *Pluto* ascended the river 13 miles, or to 1 or 2 miles above Quedah. The spring tide was running very strong, with a rise and fall of 15 ft. There is anchorage abreast of the river at $3\frac{1}{2}$ to 5 miles off shore, in from 4 to 7 fathoms, with Cape Caran bearing N.W., and Pulo Anza bearing S. by E., or S. by E. $\frac{1}{2}$ E., about 9 miles distant. It is high water, at full and change, about 5 hours.

The False Parcelar Hill, or *Bukit Jerom*, is close to the shore, and 7 miles from Salangore. It is sometimes called the *Hill of Salangore*. In passing it, it scarcely seems higher than a clump of trees. Its sides are covered with cocoa-nut trees, and its summit by a grove of senna trees. Off it lies a line of islets and rocks, running to S.W. by S. for $3\frac{1}{2}$ miles. They were formerly called the *Botel* (or *Bottle*) *Islands*. The innermost is *Pulo Besar*, and the outer one is *Pulo Tekolo*. At a mile, or further from it, is a rock, on which the *Calcutta* brig was lost. It bears S.W. $\frac{1}{2}$ S. from it, and should not be approached too nearly; there are 5 fathoms water close to it.

From the outer reef (sometimes also called the Sail Shoal), *Pulo Anzas*, on

* It is probable that within a few years more trade may be done on the coast of Salangore. Under the advice of the British Resident, the Sultan issued a proclamation in March, 1876, declaring it illegal for any, save those properly authorized, to levy taxes on merchandize. Hitherto vessels passing up and down the river have paid heavily to different chiefs, who converted the money to their own use.

the opposite side of the channel, bears W. by S. 3 miles. There are two of them standing upon the eastern edge of the shoal which limits the strait to the westward. (They are the Mudancoos, or Mud and Goose, of the old charts.) The bank and the islets are steep-to. The bank extends for 13 miles to N.W. by N. from them, and gradually shoalens from 2 and 3 fathoms up to *Pulo Colong* (or Callam), the North point of which is 10 miles S.E. by E. from the *Pulo Anzas*.

At 80 miles from the *Sambilangs*, and 30 miles from *Salangore*, is a projecting point, formed by the islands of *Colong* or *Callam* and *Lamaut*, formerly called *Cape Coran*, or *Tanjong Awat*, or *Mud Point*. A shoal bank fronts it for $2\frac{1}{2}$ miles from it, and therefore caution is necessary. This bank of sand and broken shells stretches for 15 miles to N.N.W., and is $6\frac{1}{2}$ miles from shore. On its edge and between it and the shore, the depths are 5 and 4 fathoms, and as they decrease the bottom becomes hard. After the *Sambilangs* disappear, the *False Parcelar*, or *Hill of Salangore*, will come in sight to the S.E. by E., or rather more eastward. The ship will then be in 10 fathoms, green mud, and should steer along the coast to S.E. in not less than 8 or 9 fathoms. When *Cape Caran* bears East, the beach may be neared with safety, but should have a berth of 2 miles, after which the lead will be a sufficient guide.

Pulo Colong, with *Pulo Lumaut* to the South of it, forms a channel called the *Strait of Callam*, or *Colong*, which was formerly used by ships of moderate draught in order to avoid the dangers of the North and South Sands. It is still used by the local steamers. To the eastward of *Pulo Lumaut* two rivers enter the *Lumaut Strait*. The *Callang* or *Klang* is said to be navigable for vessels of light draught, 15 or 20 miles, as far as *Damar*, and for boats by poling as far as the neighbourhood of the tin mines. *Langat River* enters the strait at about 6 miles to the southward. To the northward of *Parcelar Hill*, in $2^{\circ} 50'$ N., the river bifurcates, near *Langat*, the residence of the Sultan and of the British Resident; and a second mouth is formed on the coast S.W. of *Parcelar Hill*, and named the *Jugru River*. Mr. Braddell was on this river in 1874, and says that following the river from bight to bight they found 3 and 4 fathoms wherever they went. Mr. Irving, speaking of the district says:—"It is a magnificent country, with a fine soil and great mineralogical resources. It is watered and opened up by fine navigable rivers, which run up within easy distance of the richest tin districts, situated in the watersheds of the *Salangore*, *Klang*, and *Langat Rivers*. It only wants security for life and property, and a few easily constructed roads, to make it burst out into exuberant life."*

* For further particulars, see a Paper in the *Journal of the Royal Geographical Society*, vol. xlvii, 1876, by W. Barrington D'Almeida, on "The Geography of *Perah* and *Salangore*."

The Strait of Colong, or *Callam*, is about 15 miles in length between the islands, and has sufficient depth for moderate ships. It is not much used now, the less so, as it is said that pirates have been found lurking in its creeks.

Mr. Logan says:—The strait is like a large river or canal. The islands between which it lies are merely flats, and formed of black mud, covered with mangrove thickets. In steaming through it you see nothing but a wall of thick mangroves on either side. Towards the northern extremity of the thickets one place of considerable extent was quite naked, and covered with flying foxes, which have settled here for many years. The strait is (or was) used by the local steamers in passing between Singapore, Malacca, and Penang.

The following are the old directions for those who would wish to follow it:—

To run in for Salangore and the Straits of Colong, after you have rounded the Sambilangs, steer away to the eastward E.S.E. or E. by S., and rise the low land, coming no nearer than 8 or 9 fathoms, but do not rise the beach from the deck. As you lose sight of the Sambilangs, you may see the hill of Salangore, or *False Parcelar*; steer in for it, keeping the above depth, you will soon after make the true hill, which appears like a grove of trees; when you come nearer you cannot mistake it, as it is the only hill near the water side. In observing these directions, you will not meet with the shoal of broken shells that lies to the N.W. of Salangore, and those which follow will enable you better to avoid it.

When you can just discern Salangore Hill from the deck, bearing S.E. by E. or S.E. by E. $\frac{1}{2}$ E., you will have 10 or 11 fathoms, green oaze, with small broken oyster-shells, at 5 or 6 miles from the nearest shore. The course along shore is about S.S.E. 14 or 15 miles. The soundings on the shoal are from 6 to $3\frac{1}{2}$, 5, 4, and $6\frac{1}{4}$ fathoms, with overfalls of 1, 2, and 3 fathoms at a cast: as you deepen you will have soft ground, and the contrary as you are shoaling. When you have sailed the above mentioned distance, allowing for the tides, Parcelar true Hill will be seen from the deck bearing S.S.E. $\frac{1}{2}$ E., distance from the nearest shore 7 or 8 miles, in 14 or 15 fathoms, soft ground.

When you see the False Hill bearing S.E. by E. or S.E. by E. $\frac{1}{4}$ E. from the deck, steer off shore to the southward, until you lose sight of the white sandy beach from the taffarel; then steer to the S.E. along shore, taking care not to raise the white beach, and that will carry you clear without the shoal, in soundings not less than 8 or 9 fathoms. When you have run the above mentioned distance to the S.S.E., you may then with safety raise the beach, or borrow on the shore; but come not under 8 or 7 fathoms, soft ground, as it shoals very fast from that depth until you are past Tanjong Awat.

But to resume our instructions for sailing into Salangore. After you have seen the low land beyond Tanjong Awat, you may be guided by the lead, giving that point a berth of a mile, or $1\frac{1}{2}$ mile, to avoid the shoal which stretches from it. To run into Salangore Road, you keep the hill a little open to the southward, and anchor a little to the northward of it, in 4 or $3\frac{1}{2}$ fathoms, soft mud, as there is a shoal to the southward projecting $1\frac{1}{2}$ mile.

Going to the Straits of Colong, steer for Pulo Anzas, and to the eastward of them you will then see the entrance, or North mouth of the straits. The Pulo Anzas are bold-to, but the islands, which are on the eastern side of the channel, are the reverse. Off the southern or outermost island, Pulo Tekolo, lies a dangerous rock, bearing from it S.W. $\frac{1}{2}$ S. a mile distant, and with 5 fathoms close to it. On the S.W. of the channel there is a sand-bank, but on the other side it is mud. When you are past the above islands, approach nearer the sand-bank than when you leave hard soundings; on the opposite part stand on at pleasure.

A little to the northward of the North entrance of the straits lies a shoal, to avoid which, as well as to keep in the best channel, you are to keep the Middle Botel Island in one with Salangore Hill, observing not to open the hill to the eastward; another leading mark is to keep Parcelar Hill on the West point about its own breadth. After passing this shoal you may be guided by the lead on this side, keeping in from 5 to 9 fathoms. There is also another shoal in a line of direction from Mud and Goose Islands to the West point, but of no great extent.

In working up the first reach there is no danger, having good water from side to side, which at the upper end of the reach is very deep, with irregular soundings from 12 to 22 fathoms. The opening that is on the port hand at the bottom of this reach is the River Colong or Klang; opposite to which is Deep-water Point, the South point on the starboard hand, of the first reach.

The second is Bar Reach, which is clear while abreast of a creek on the port side, opposite to which is the shoalest part of the bar; before you come up to this creek, you meet with another, which it is necessary to avoid, as there is an indraught. It will be best to anchor about a cable's length, in 6 fathoms, before you cross the bar, as it shifts very much, and of course it is requisite to sound. On our sounding we found 3 fathoms at low water the greatest depth, which is a little more than a third over from the S.E. side: you will carry 3 fathoms about twice the ship's length after being over. A good leading mark is some low land just open with the first point; you may stand till it is two sails' breadths open, and close it on the other shore; but the best and safest mark for crossing the bar is to bring Deep-water Point to bear N.E. $\frac{1}{2}$ E.; you may also be guided by the lead, which cannot be done on the opposite side, being a bank steep to that extends along and across

about one-third over to the western point of the Third Reach, and from thence up to the northern extremity of a creek, in that reach, your soundings are from 3 to 9 or 10 fathoms.

The bar is narrow, and begins at the entrance of the first creek, on the S.E. shore, having the least water about half a cable's length to the S.W. ; you then deepen it from 3 to 5 fathoms gradually, and will be abreast of the second creek.* From this you carry not less than $5\frac{1}{2}$ fathoms, about a large cable's length from the port shore. Keep nearly that distance till you pass Point Anna Grabs (so called from a small ship wrecked here), as it is shoal on the starboard side, hard ground, with overfalls. Indeed, you must avoid for the same reason, the starboard shore, until you are beyond the second opening to the sea.

The tide flows about 9 ft. in the springs.

PARCELAR HILL, or Bukit Jugru, a great leading mark, stands in lat. $2^{\circ} 50' N.$, long. $101^{\circ} 26' 10'' E.$, $26\frac{1}{2}$ miles E. $7^{\circ} S.$ from the lighthouse on the One-fathom Bank, and 10 miles eastward from the southern entrance of the Colong Strait. It is 890 ft. high, of oblong form, sloping at each end when viewed from the westward, with the summit a little to the westward of its centre ; but of a regular pyramidal form when seen from the southward or S.S.E., with very gentle declivities in each direction. It is darker in appearance than the neighbouring hills. In front of it, to the S.W., is the Jugru mouth of the Langat River, before mentioned.

The **NORTH SANDS**, which lie off the Malay coast between Salangore and Parcelar Hill, are extensive and dangerous. Their north-western edge is steep, and drops from 5 fathoms to 15 or 30 fathoms in 3 or 4 miles. They have been surveyed by Captain Ross, and his chart shows them as several parallel ridges of sand, trending from N.W. and N.N.W. to S.E. and S.S.E., with deeper water, from 8 to 14 fathoms, between them. The north-western edge of their most dangerous part lies $21\frac{1}{2}$ miles W.S.W. from Salangore. These patches have from 4 to 18 ft. water, with 7 to 10 fathoms on either side. They extend south-eastward for 18 miles, leaving a channel, 3 miles in width, between their extremity and the shoal which extends from Pulo Colong, and which has from 5 to 14 fathoms of water. The chart is the best guide for their position and character, and the various patches need not be enumerated, as it is difficult or impossible to give clearing marks for them.

* After you pass the bar, Captain Elmore advises to "steer direct for the South point of the Sea Reach, until the North point of that reach bears West by North, to avoid the wreck of a large Portuguese ship, which bears West from that point, and lies on the eastern shore, between Anna Grab Point and the bar ; when these bearings are on, and you are 2 cables' lengths off shore, it is best to keep the eastern shore on board, to prevent the flood tide from horsing you through the opening to seaward (which I call Sea Reach), where there is no passage, being entirely choked with sand banks, dry at half ebb."

The **Blenheim Shoal** is one of the most dangerous of these shoals, and lies on their western edge. It nearly occasioned the wreck of H.M.S. *Blenheim*, when it was first discovered. It bears from One-fathom Bank light N. 15° W. 11 miles, and from Parcelar Hill W. 23° N. 31½ miles; Salangore Hill bears from it N. 56° E.; and another hill to the S.E. of it N. 66° E., lat. 3° 3' N., long. 100° 56' 15" E. It has only 6 ft. least water, and there are several dangerous patches to the East and N.E. from it. It is cleared so long as Parcelar Hill does not bear northward of E.S.E.

It is high water at the N.W. head of the North Sands, on full and change, at 6^h 30^m. Springs rise 12 ft., neaps 12½ ft.

When the Round Arroa (presently described) is seen from the mast-head (being 31 miles off), bearing S.S.W. to S.S.W. ½ W., you are on the N.W. edge of these sands, and will pass over spits of 8 and 10 fathoms. As these spits, which form the N.W. part of the North Sands, have 9 to 12 fathoms on their outer edges, it is advisable, when bound to the southward in contrary winds, to keep near the western edges of the sands in working, making short tacks to the westward, and standing in to 10 or 11 fathoms, in a large ship, or to 8 and 9 fathoms in a small one. By this means moderate depths will be found for anchoring during the ebb, with the tides more regular and more favourable than further out in deep water. For here, during S.E. winds, a current is often found to set W.N.W. and westward when tides are prevailing along the edge of the sands. The strength of the ebb generally sets between N.W. and N.W. by N. 2½ miles an hour, the flood in the opposite direction, about S.E. ½ S., standing a little on the western edges of the sands, or running nearly parallel with them, but it is not so strong as the ebb.

The **ONE-FATHOM BANK**, which forms the S.W. part of the North Sands, and is also on the North side of the channel between the North and South Sands, was considered as the most dangerous shoal of the vicinity. According to Lieut. Ward's survey, it is about 1½ mile N.N.E. to S.S.W., and 1 mile broad E.N.E. and W.S.W. It has 6 ft. least water. By keeping Parcelar Hill E. ¼ S., the North end will be cleared, and E. ¼ S. the southern edge will be passed safely.

The **Lighthouse**, on screw iron piles, is painted in stripes of red and slate-colour. It is placed on the centre of the bank, in 15 ft. water, half a mile S. by E. of the position occupied by the lightvessel previous to May, 1874, when a *revolving bright light*, attaining its greatest brilliancy every minute, was first exhibited from the lighthouse. It is shown at 61 ft. above the sea level, and visible 13 miles off. Its position is in lat. 2° 52' 8" N., long. 100° 59' 2" E.

A *red buoy* marks the North end of the bank. It lies in 14 ft. water, at 1½ mile N.W. from the lighthouse.

There is a safe channel between the One-Fathom Bank and the Blenheim Shoal, but there is a small 21-foot bank midway between them, with 7 to 16 fathoms around it. It lies $6\frac{1}{2}$ miles N. by W. $\frac{1}{4}$ W. from One-Fathom Bank lighthouse; and a second bank of similar depths lies 2 miles S.E. of it, and 4 miles N. $\frac{1}{2}$ E. of the lighthouse. Parcelar Hill bearing E. by S. $\frac{1}{4}$ S., nearly, is the best course to pass between these banks and the One Fathom Bank. This channel has not been used by large ships, as the tides run in strong eddies over the sands during spring tides. A better course is to steer so as to pass southward of the lighthouse.

The **ARROA ISLANDS** form the western side of the main channel of the Strait of Malacca past the North Sands. They are a group of small islets and rocks on an extensive shoal which lies in the middle of the strait. The northernmost of the cluster is the *North Rock*, in lat. $2^{\circ} 55' 20''$ N., long. $100^{\circ} 36' 5''$ E. It is of considerable height above the water, with regular soundings very near the rocks that front it of 8 and 9 fathoms mud.

East Rock, or *Batu Mandi*, is a flat black rock, very little above the surface of the sea. It has deep water close on its eastern side. It lies somewhat off the mud bank, as it has a deep channel of 17 fathoms three-quarters of a mile wide to the West of it, between it and a line of *sunken rocks*, covered at half flood, on which the sea breaks at times.

The *High Rock*, or *Batu Balia*, lies 2 miles West from the sunken reef just mentioned. It is surrounded by other rocks, and there are 9 fathoms in the space between, with 7 to 10 fathoms in the channel West of it.

Pulo Jummur, the *Great* or *Long Arroa*, is the largest of the group. It consists of two islands nearly joined, is covered with trees, flat, and is nearly 3 miles S.W. by S. from the North rock. It is nearly a mile long, and the shores appear to be lined with rocks, and a *reef* extends to the N.E. from it for about three-quarters of a mile. The Malay fishermen come here for fish and turtle. Boats landing should therefore be on their guard. Water can be got in a cove with a good sandy beach, on the East side of the South isle. Several springs of good water fall into the deep valley. The *Western Arroa* is a group of islets and rocks lying about a mile to the westward of the Long Arroa, and on the same rocky bank.

The *Round Arroa*, or *Pulo Tukong Simbang*, the chief mark for the channel to the eastward, is very small, high, round, and has a tuft of trees on each side of it. It may be seen 18 miles off. It has several rocky islets near it, two of which are visible 12 miles off; one of these lies to the northward, the other to the southward, with straggling rocks around. The *South Rock*, or *Pulo Tukong*, the southernmost islet or rock, above water, is $1\frac{1}{2}$ mile S.S.W. from the Round Arroa.

The Arroa Islands should not be approached by night, as there is now no necessity for it, since the light on the opposite side of the channel is

established. The currents and ebb tides set very strongly here, and might horse you among them. Should a vessel be working near them against a heavy N.W. swell, there is shelter from N.W. or westerly winds by anchoring under the Long Arroa, guarding against the reef which projects a mile to E.N.E. from its North end.

In sailing down the Malacca Strait from the northward, and having got in mid-channel between Pulo Jarra and the South Sambalang, keeping to the eastward to guard against the easterly tendency of the current, steer about S.S.E. or S. 20° E. to keep well to N.E. of the Arroas, but not too far on the North Sands. Excepting a shingly spot of 13 fathoms in lat. 3° 20' N., bearing South from the Sambilangs, the soundings are tolerably regular on this track generally between 34 and 40 fathoms in the direct line. Should the winds hang to the eastward or E.S.E., keep in with the Malay coast in from 20 to 30 fathoms, until 8 or 10 leagues past the Sambilangs; then steer more southerly to get soundings of 16 to 18 fathoms on the N.W. face of the North Sands, which may be rounded close, provided you do not come into less than 14 or 16 fathoms, and then either the Arroa Islands or the light-vessel, or Parcelar Hill, will come in view, and will be a further guide.

The **SOUTH SANDS**, like those forming the North Sands, are a series of parallel spits which run E.S.E. and W.N.W., or more southerly in the same direction as the Malay coast, and 13 or 14 miles distant from it. The main channel on the North side of them having that breadth, and a depth of from 20 to 40 fathoms (with some exceptions), extends for 60 miles from the One-Fathom Bank Light to Cape Rachado. The South Sands vary in width from 2 to 6 miles. The *northernmost* dangerous patch, with 16 ft. water, is 10 $\frac{3}{4}$ miles S. by E. $\frac{1}{2}$ E. from the lightvessel, and the south-easternmost is a small patch of hard sand, named on the chart the *Pyramid*, with 6 ft. least water. From it Cape Rachado appears like an island, bearing E. $\frac{1}{2}$ S., and from 5 to 9 miles further S.S.E. are several patches of 15 to 4 fathoms. These eastern patches are the most dangerous part of the shoal of Malacca, and require all caution. On the North side of the channel is the *Bambek Shoal, awash*, which is 21 miles from Parcelar Hill, and 14 miles from Cape Rachado.

The space between the Sumatran shore and the South Sands is full of shoals and dangers, and should never be attempted.

It is high water at full and change at the One-Fathom Bank at 6 o'clock. Springs rise 15 ft., and neaps 12 ft. The tide runs strongly at springs, and then there are eddies on the spit which projects from the One-Fathom Bank. Between the sand heads the strength of the ebb runs nearly N.W., but the commencement and end of it run very irregularly. The flood is more regular in its direction, and runs with less velocity. The light is found to be most useful in these strong tide ways, when, if the land

be not visible, the navigation would be as formerly, very embarrassing.*

The CHANNEL between the North and South Sands, which has been known by the name of the *East and West Channel*,—a term probably derived from the fact that the leading marks through it lay East and West of each other. It is about 10 miles wide between the northernmost danger of the South Sands and the lighthouse; and there is a 21-foot patch at $7\frac{1}{2}$ miles S.W. by W. from the lighthouse, which requires caution.

In passing through this East and West Channel, having passed the Round Arroa and brought it to bear W.S.W., there is no danger from the North Sands, so long as it can be seen from the deck. Then steer an easterly course away from it bearing W. $\frac{3}{4}$ S. When the Round Arroa sinks out of sight, the lighthouse will come in view, as will also Parcelar Hill, bearing about East. Bring the latter to bear about E. $\frac{1}{4}$ N., and you will pass safely to the South of the One-Fathom Bank. A course with Parcelar Hill bearing E. $\frac{1}{2}$ S. will clear the bank. Having passed this, the channel within the South Sands is open to the south-eastward. Parcelar Hill may at times be obscured by clouds, when the low land at the entrance of the Strait of Colong may be seen. If this piece of low land be kept N.E. by E. $\frac{1}{2}$ E., or its East end be brought to E.N.E., you will clear the banks in coming from the eastward. This low land comes in sight when abreast of the One-Fathom Bank, and from aloft the tops of the trees may be seen as far as Parcelar Hill.

* Several wrecks having taken place on the South Sands, the following extracts from remarks by Mr. G. J. Maddock (pilot) will prove useful;—"I will now endeavour to give an account of the chief cause of ships being lost on the South Sands. First, with respect to the loss of the *John Curry*, Captain Tucker, in January, 1854. From the wreck, Parcelar Hill bore N.E. by N.; when conversing with Captain Tucker, and informing him that the current and tide out of Calam Strait had been the cause of the loss of his ship, he acknowledged that such must have been the case from the set which he noticed after the ship had struck. About two months afterwards, a large Dutch Indiaman, the *Menado*, got on shore under similar circumstances in the night, and, strange to say, within a cable's length of the spot where the *John Curry* was lost. I also met the captain of the *Menado* in Singapore, and he acknowledged that my version of his loss was correct, as he could not account for it in any other way. Some time afterwards, strange to relate, one of H.M. ships, the *Andromeda*, came to grief in the same locality. In passing up and down the straits some time before, I noticed this set of the tide, or perhaps rather an under current, and always kept correct bearings of the Parcelar, and on a dirty night or when dark, was invariably able to pick out an anchorage in 7 to 10 fathoms; but these observations are nearly useless now, for there is a light on the One-Fathom Bank (North Sands), and if the Government place a second light on the South Sand Head, the principal dangers can be easily avoided. There are nights, however, when all these advantages will be found useless—at short intervals during the north-westers and Sumatras."

The Malay Coast about Parcelar Hill forms a slight bay, instead of a convexity, as was shown on the old charts, an error which led to some disaster. This bay, at the head of which the southern mouth of the Langat River is situated, is filled with a shallow bank, and at about 9 miles southward from the hill is a slight projection named *Parcelar Point*, not easily distinguished on the *low land of Parcelar* of the old charts. It continues low and woody to the E.S.E. for 15 miles, to the N.W. limit of a bight, of which *Tanjong Kamuning*, 7 miles farther on, is the S.E. point. Above the head of this bay is the *South Hummock*, 973 ft. in height, and further inland are seen some other high lands towering above the trees on the coast. This bay is filled with shoals, and a line of detached shoals lies off its mouth. These shoals are formed by the debris brought down by the River Lukut, which enters the head of the bay in lat. $3^{\circ} 35' N$. A few miles up the river, on its left bank, is the town of Lukut.

The *Bambek Shoal* lies midway between *Parcelar Point* and *Cape Rachada*, on the line joining their extremities, and 3 miles off the N.W. point of the bay just mentioned. This shoal was much dreaded by the early navigators, and several ships were lost on it. It is rocky, and nearly awash in the centre, and has several heads of $2\frac{1}{2}$ to 3 fathoms over a space of $2\frac{1}{2}$ miles E.S.E. and W.N.W., dropping to 7 and 8 fathoms at each end, and having 10, 12, and 15 fathoms close outside it, so that the lead by night does not afford a very safe guide on approaching it. The dangerous *Pyramid Shoal*, the south-easternmost of the *South Sands*, is also difficult to avoid by the lead, as the soundings are deep close up to it, the depth of the strait being very irregular throughout its breadth. This danger is not lessened by the strength and irregularity of the tides, which set in various directions among the channels between the *South Sands*. The ground is all oaze, except about the middle of the channel.

The shoal which runs north-westward from *Tanjong Kamuning* is $2^{\circ} 32' N$. above mentioned, has an opening through it abreast of that cape, upwards of a mile and a half in width, and the shoal continues in a direction parallel with the coast as far as *Cape Rachada*, 8 miles to the south-eastward, and at from a mile to $1\frac{1}{2}$ mile from it, leaving a channel inside it, having a depth of from 6 to 12 fathoms. A small island, *Arrang-Arrang*, lies to the S.E. of *Tanjong Kamuning*.

CAPE RACHADA, or *Tanjong Tuan*, derived its Portuguese name from its rugged, cleft character. It is 28 miles S.E. by E. from the point abreast the *Parcelar Hill*, and comes in sight just after passing that point. It is perpendicular toward the sea, and is something like *Mount Dilly* on the *Malabar coast*, but not so lofty.

It projects to seaward in a long narrow point of land, which forms a deep bay on each side of it, with a small rock or islet near its extremity. When first seen coming from the northward it makes like an island, for the neck

of land which joins it to the main is much lower than the cape itself. There are two wells of fresh water under the cape.

The **LIGHTHOUSE** on Cape Rachada, completed in 1863, is a circular white stone tower, 78 ft. in height to the top of the lantern, in lat. $2^{\circ} 24' 30''$ N., long. $101^{\circ} 51' 10''$ E. It shows a brilliant fixed light over half the horizon, or when bearing from S.E. by E. round eastward and northward to N.W. by W. The light is elevated 446 ft., and may be seen 25 miles off.

The tides are very strong off Cape Rachada, and pass it in noisy rippings, especially at springs, the flood to southward, and ebb to northward. This is the narrowest part of the Malacca Strait, the opposite point of Sumatra, Ujong Bantam being only 21 miles from it.

In sailing down this portion of the strait, do not pass within a line joining Parcelar Point and Cape Rachada, nor bring Parcelar Point, the South extreme of the land to northward, to the southward of S. 60° E. to keep clear of the shore bank, giving Parcelar Point a berth of 3 or 4 miles in passing it. When Cape Rachada or the light is seen, keep to the eastward of S.E. by E. $\frac{1}{4}$ E. to keep clear of the Bambek Shoal. Cape Rachada brought to bear E.S.E. is a fair mid-channel bearing throughout, standing off to the southward to E. by S. $\frac{1}{2}$ S. It would be dangerous to exceed these bearings when the cape appears as an island. When approached within 10 or 12 miles the low neck comes in view, and the channel then becomes wider, and the boards may be continued further to the southward. Cape Rachada light kept in sight clears Bambek Shoal in the night time.

Lingey River.—The coast continues somewhat to the North of East from Cape Rachada for 5 miles, and then turns to E.S.E. for 3 miles more to the mouth of the *Lingin* or *Lingey River*, a large stream visited for tin, and tutenague, the white metal alloy used by the Chinese to imitate silver. This river is the boundary between the native state Sunghy Ujong and the British state of Malacca. Off the point to the South of this river are some small detached rocks, and the whole of the coast to the N.W. is skirted by a shoal bank and straggling rocks. A buoy marks the eastern side of the *Battoo Mandi*, a small shoal, which lies $1\frac{1}{2}$ mile S.W. by S. from the southern entrance point of the river. E.S.E. of the buoy lies the Battoo Tinga Rocks, at half a mile from the shore. At 10 miles from the mouth of the *Lingin* is the *Diana Rock*, a large rock always above water, and $1\frac{1}{2}$ mile from the shore, with 15 to 19 fathoms irregular bottom close outside it.

Tangong Kling is 22 miles S.E. by E. from Cape Rachada, and may be known by two or three trees on its extremity, more elevated than the others near the sea. The shore hereabout should not be made too free with in the night, as the soundings are deep and irregular, affording but little guide.

On the opposite side of the strait is the *Quin Shoal*, discovered by Admiral

Quin, in H.M.S. *Raleigh*. It has $3\frac{1}{2}$ to 4 fathoms on it, and is about $1\frac{1}{2}$ mile long from N.N.W. to S.S.E. It bears from Cape Rachada S. $\frac{3}{4}$ E. $17\frac{1}{2}$ miles. Mount Ophir peak bore from it E.N.E., the North end of Pulo Roupat, Ujong Bantam, on the Sumatra side, West, and the South end of Pulo Roupat S.S.W. $\frac{3}{4}$ W.

MALACCA (or Málaka), the capital of the British Province to which it gives its name, stands on both sides of a small stream, at 27 miles from Cape Rachada, and 5 miles from Tanjong Kling.

Malacca was occupied by the Portuguese in 1511, and in 1641 was taken from them by the Dutch, who surrendered it to the British in 1795. It was occupied by us till 1818, when it was restored to the Netherlands Government, by whom it was again surrendered to us in exchange for Bencoolen in 1825. In 1826 it was incorporated with Singapore.

The State of Malacca extends from the River Lingey, on the N.W., to the Cassang, on the S.E., having a coast line of about 40 miles in length, with a mean breadth of 25 miles, which includes the interior territory of *Nanning* or *Naning*, so that it has an area of about 1,000 square miles. In 1865 the state had a total population of 71,600, chiefly Malays. At the census in 1871 the Malays numbered 57,474, the Chinese 30,456. The trade has been considerably reduced since Singapore has risen into pre-eminence, but tin and gold are still sent to that emporium in large quantities. In 1871, imports were valued at £503,326, and exports at £526,428. It has no direct trade with the United Kingdom. In 1875, 651 vessels, of 101,476 tons, entered the port.

Malacca derives its name, according to Malay history, from the Malacca tree (*Phyllanthus Emblica*), and was founded in the thirteenth century.

The town of Malacca is divided by a small river into two parts, connected by bridges, one of which was given by a munificent native merchant. On the left or southern bank rises the verdant hill of St. Paul, surrounded by vestiges of the ancient Portuguese fort. Around its base lie the barracks, lines, and most of the houses of the military; the stadthouse, courthouse, gaol, church, civil and military hospitals, the site of the old inquisition, convent, the police-office, school, post-office, and the master-attendant's office. On its summit stand the ruins of the ancient church of Our Lady del Monte, erected by Albuquerque, the Portuguese conqueror of Malacca, and the scene of the labours and supposed miracles of that apostle of the East, St. Francis Xavier; also the lighthouse and flagstaff. A little to the South rises the hill of St. John's, and in the rear that of St. Francis. On these eminences are still the remains of batteries erected by the Portuguese and Dutch, commanding the eastern and southern entrances to the town. Smaller knolls intervene, covered with the extensive cemeteries of the Chinese.

The view of Malacca from the roads is extremely picturesque. It has the appearance of being situated in the bend of a crescent or bay; the southern

horn of which is formed by a chain of beautiful islets, called by the Portuguese the Aguadas, or Water Isles, stretching out seawards from the coast. On the South side, the shore trends to the West, terminating in an elevated and well wooded point called Tanjong Kling. A few other islets stud the shore. The first objects that strike the eye are a cluster of trees crowning the summit of St. Francis, the Star fort on St. John's to the South, the lighthouse and ruinous church on St. Paul's, and the white edifices that skirt its base, stretching along the sea shore, and gradually lost in the thick groves of cocoa-nut trees that cover the dwellings of the Portuguese, Chinese, and Malays, in the suburbs of Bauder Ilir, and Ujong Passir. In the back ground of this pleasing view rise the hills of Bukit Bertam, Bruang, Panchur, &c. To the North, in the distance from the mountains of Rumbawe and Srimenanti, and far away to the East, the triple peak of Ophir, celebrated for its gold, shoots into the sky with softened outline.—(*Lieut. T. J. Newbold*, vol. i., pp. 109—111.)

The Lighthouse is a turret on St. Paul's Hill, as above stated, and is in lat. $2^{\circ} 11' 15''$ N., long, $102^{\circ} 15' 30''$ E. It shows a bright fixed light, elevated 146 ft., seen 12 miles off. When seen to the northward of N. by W. $\frac{3}{4}$ W. it will lead clear of the Water Islands.

A red light is also shown on the pier-head at Malacca, visible 6 miles off in clear weather.

The roadstead of Malacca is perfectly safe. It is neither visited by the hurricanes of higher latitudes, nor within the influence of the monsoons; as was said in the sixteenth century, "it is the beginning of one monsoon and the end of another.

The Road is limited to the North by *Fisher Island*, a small islet known formerly as Pea or Woody Island, surrounded by a shoal and foul ground, which joins with the shore. This is nearly 3 miles westward from the entrance of the river. It ought not to be approached within 9 or 10 fathoms, which is near to the edge of the shoal. With the extremes of the island bearing from N. by W. to N.N.W. and the body of it N. by W. $\frac{1}{2}$ W. half a mile distant, there is a small circular shoal, having only 18 ft. on it at low water. Near to the city is *Pulo Java*, or Red Island, on the edge of the shoal water. To the S.E. of this is *Pulo Panjang*, a rocky reef or flat, projecting $1\frac{1}{2}$ mile from the shore, and extending along it to Pulo Java. The church and flagstaff on the hill bear N. $\frac{1}{2}$ E. from the West end of Panjang Reef $1\frac{1}{2}$ mile distant, and from its East end N.N.W. $\frac{1}{4}$ W. $3\frac{1}{2}$ miles distant. There is a depth of 18 or 19 fathoms within 2 cables' lengths of its southern edge, similar to that in the offing, therefore the lead is no guide to clear it. From 20 fathoms in the offing the depths decrease regularly over a bottom of soft mud towards the road, where the best anchorage is under 10 fathoms, with the church on the hill N.E. by E., Fisher Island N.W. $\frac{1}{2}$ W., and the tuft of trees East, the town $1\frac{1}{2}$ or 2 miles distant. When the depth exceeds

10 fathoms, the bottom is generally a stiff tenaceous clay, which holds the anchors very firmly; under that depth it is generally of soft mud.

There is no danger going into Malacca Road; if you are in the offing, in 20 or 23 fathoms, you shoalen your water gradually to 7 fathoms, as you run in for the road. A large ship should not go into less than $7\frac{1}{2}$ fathoms; for it shoalens suddenly from 7 to 5 and 4 fathoms. And they should be still more careful not to go too far to the southward, or to the S.E. part of the bay, for there the ground is foul and rocky, and shoalens suddenly from 8 to 3 fathoms. Off Fisher's Island there is no danger; and it is found that a ship, upon occasion, might go within half a mile of it, in 16 fathoms water, or have 10 fathoms within a quarter of a mile, and 20 fathoms within 1 mile of it. You may anchor in Malacca Road from 13 to $7\frac{1}{2}$ fathoms, oazy ground, Malacca church on the N.W. part of Mount Moar, E. $27^{\circ} 30'$ N.; the S.W. part of Fisher's Island W. $36^{\circ} 15'$ N.; and the outermost of the Four Brothers, or Water Islands, E. $50^{\circ} 20'$ S.; distance from Malacca $1\frac{1}{2}$ mile. The flagstaff bearing N.E. or N.E. by E.; Fisher's Island N.W. by W.; and the outermost Water Island S.E. $\frac{1}{2}$ S.; you have 8 fathoms. The flagstaff N.E. $\frac{1}{2}$ N., and Fisher's Island N.W. by W., you are in 10 fathoms. The flagstaff N.E., and Fisher's Island N.N.W. $\frac{1}{2}$ W., you have 14 fathoms, all good anchoring ground.

Ships should not anchor on the East side of the road, near Red Island, for the bottom is foul and rocky, the depth suddenly decreasing from 8 to 3 fathoms, on the North end of Panjang Reef.

During the period of the S.W. monsoon, sudden hard squalls frequently blow into the road from the Sumatra side in the night, accompanied with much thunder, lightning, and rain. It is high water full and change at $7\frac{1}{2}$ hours; springs rise 11 ft., neaps $8\frac{1}{2}$ ft. The rate is about 2 knots. The ebb and flood tides continue to run for 2 hours after high and low water by the shore, and boats cannot enter the river after half ebb. The proceed into the river soon after quarter flood, steering for the church on the hill, keeping it rather on the starboard bow; and when the bar is approached, the channel may be discovered by the stakes in the entrance.

Malacca stands on low ground, but within, the country rises into undulating hills, moderately elevated, among which is that called *Bukit Barong*, 4 miles inland, in a N.E. direction.

Mount Ophir, or *Gunong Ledang*, may be better distinguished than the rest, as it is much higher, 3,840 ft., and lies 24 miles to E.N.E.

The **WATER ISLANDS**, or **Four Brothers**, are a cluster of four small islands and one larger, lying 6 miles south-eastward from Malacca. The outer ones are small round islands covered with trees, and the innermost, *Pulo Bessar*, has excellent fresh water on its eastern side, and thus gives its name to the group. This can be procured at all times, but near low water, when the shore reefs are dry.

The outermost island, *Pulo Undan*, is $1\frac{1}{4}$ mile South of the next, *Pulo Nanka*, and this half a mile South of the third, which has a channel above a mile wide between it and *Pulo Bessar*, but nearly in mid-channel there is a sunken rock. This channel may be used by ships if pressed, by carefully avoiding this rock. This may be passed in 10 to 12 fathoms water, by keeping close to the middle Brother, or to the South end of *Bessar*, for the rock is nearly a mile from the S.E. end of the latter, and one-third of a mile from the middle Brother. Coming from the eastward, keep the South end of *Bessar* N.W. until the southernmost Brother is shut in with the two others.

The *Rob Roy Bank*, so named from a ship which grounded on it during the survey, a very dangerous 6-foot shoal, $3\frac{1}{2}$ miles in extent, lies on the Sumatran side of the channel, opposite the Water Islands and Malacca, from which it is distant 20 miles in a S.W. direction. It is therefore much best to keep in with the Malay shore hereabout, and not to stand off more than 10 or 12 miles, guarding against the uncertain set of the tides. The depth rather increases towards the *Rob Roy Shoal*, which is steep on its northern face.

The coast south-eastward from the Water Islands is low and clean, covered with trees, and intersected by several rivers, the most noticeable of which is the *Sung-ei Moar*, or *Kassang*, 20 miles from Malacca. It is the S.E. boundary of the state. *Bakit Moar*, or *Mora*, an isolated hill covered with trees, lies 9 miles to the S.E. of the river, and is just visible from Malacca Road. The coast, which slightly recedes, is skirted by an extensive shoal, and therefore must be avoided. *Tanjong Tor*, a low level point, is about E.S.E. 33 miles from Malacca, and here the shore bank appears to be much narrower, a moderate depth being found close to the point, while the edge of the bank N.W. and S.E. of it trends in a straight direction, the land recedes into slender bays on each side.

Mount Formosa, or *Gunong Batu Pahat*, is more distinguishable than *Mount Moar*. It is the highest summit, 1,480 ft., of a long ridge of undulating hills near the shore, which are seen to extend inland to the N.E. Its S.W. slope forms a bluff point, *Tanjong Seginting*, on the western side of which is the entrance of the *Sung-hei Batu Pahat*, or *Formosa River*. A small island, *Pulo Sheilo*, lies off the pitch of the cape.

The strait opposite this part becomes more embarrassed with shoals, long narrow spits trending in a N.W. and S.E. direction, some of which are 30 or 40 miles long within the 10-fathoms line. On the Malay side of the strait the more dangerous are not more than 4 or 5 miles off shore, but on the Sumatran side they reach to 18 and 25 miles off. The *Hannah* or *Formosa Shoal* is the most formidable on the northern side. It lies off the foot of *Mount Formosa*, extending thence 7 or 8 miles, and having only 12 ft. water on its shoalest spots. Its S.E. end is $2\frac{1}{2}$ miles from the point of *Mount*

Formosa, and its N.W. end is 5 miles from the adjacent shore. There is a channel between the shoal and the shore, but there are some dangerous spots of 18 ft. in it, one of which is about 2 miles due West of Pulo Sheilo, the islet off the Mount Formosa Cape.

The main channel of the strait abreast of the Hannah Shoal is about 10 miles in width; beyond that distance there are the dangerous patches of the S.W. banks, which have nevertheless deep water channels between the spits. The southern edge of the Hannah Bank and the northern face of the Sumatran Banks are steep-to, but if the lead is very carefully and briskly used, it will indicate their proximity. A long and narrow bank runs along this fairway channel with depths varying from 5 to 12 fathoms, having depths of from 15 to 25 fathoms on either side. All over the eastern and middle parts of it you have soft clay with 8 to 12 fathoms; towards the East end it becomes harder and shoals to 5 and 7 fathoms. This bank was formerly known as the *Pisang* or *Fair Channel Bank*.

The coast south-eastward of Mount Formosa, for an extent of 40 miles, is low and wooded, with nothing remarkable except a small mound near the sea, *Batu Balu*, about 15 miles from Formosa. It is all fronted by mud banks from $2\frac{1}{2}$ to 6 miles in breadth, the edges of which are very steep. This feature is also found in all other banks of this part of the strait, caused probably by the strong currents, and is on that account a dangerous feature in its navigation. It is especially so near Pulo Pisang.

In sailing down the fairway channel from abreast of Mount Formosa at 7 miles distance to Pulo Pisang, the direct course should be S.E. by E.; the distance is between 9 and 10 leagues. Having doubled Formosa Bank, when the mount bears N.E. between 3 and 4 leagues, you will raise this island bearing E.S.E. $\frac{1}{2}$ S., or S.E. by E., you will then have soundings from 20 to 22 or 23 fathoms, oazy ground. In turning to windward on this course, the Pisang Bank is of the greatest service both for anchoring on during the ebb, and for the purpose of keeping on, either in the night or day, during the squalls, which are generally accompanied with rain; for by steering along its verge, on either side, you may run the whole length of the bank without fear or danger, and upon deepening off the end of it may steer for mid-channel, between the Carimons and Pulo Cocob. By keeping in 11 or 12 fathoms on either edge, if you deepen your water, you know which side to steer towards; whereas, by running along the top of the bank, if you deepen, it is uncertain on which side.

PULO PISANG or **Pesang** is a tolerably large and woody island, 200 ft. high, and a mile in diameter, which lies at 2 leagues distance from the main, and there is a channel between it and the main, in which there are not less than 4 fathoms water; on the West side of it lie three small islands, the largest of which sometimes affords good water, and boats may land there commodiously at high water, in a bay on the N.W. part; this island may be

seen in clear weather 9 or 10 leagues off; then it makes in three small hummocks, like boats turned bottom upward.

The Lighthouse constructing (1877) on Pulo Pisang is to show a light, visible between S.E. by E. $\frac{1}{2}$ E. through South and West to N.W. $\frac{1}{2}$ N.

It is high water at full and change at Pulo Pisang at 9 o'clock. The flood tide generally sets fairly through the channel from the Water Island to the Carimons at the head of the strait, and the ebb also, in the contrary direction; the rate about 2 miles at spring tides.

Pulo Pisang bears S.E. by E. 65 miles from the Water Islands, and when abreast of the outer island from 1 to 4 miles off, a S.E. by S. course will carry you about the same distance outside the Formosa Bank, if not drifted out of it by the tide.

When Mount Formosa is brought to bear about N.E., keep within 3 or at most 4 leagues of the Malay coast, to keep well clear of the middle bank on the Sumatra side, so as not to get to the southward of its N.W. end.

If the weather is clear, and Pulo Pisang be discerned, keep it between E. by S. $\frac{1}{2}$ S. and S.E. by E. $\frac{1}{2}$ E., until Mount Formosa is brought to bear North or N. by W. in working between the North side of the Middle Bank and the Malay coast. In passing the Formosa Bank in the night, if it is found that the ship has got too far to the southward so as to be southward of the Middle Bank keep along the southern side, or you may work against a contrary wind, in the channel between this and the next bank to the southward, the breadth of this channel being about $2\frac{1}{2}$ miles, with 16 to 19 fathoms water. But it should be remembered that these long narrow banks, as they get nearer to the Sumatra side, have less water on them, and therefore the most prudent course would be to cross the Middle Bank by some of the numerous channels between its shoaler parts, rather than risk being drifted to the southward into less water. This may be done when Pulo Pisang is brought to bear about N.E. by E., when a depth of $5\frac{1}{4}$ to 7 fathoms will be found on the ridge. Pulo Pisang may be brought to bear S.E. by E. when standing towards the edge of the bank which skirts the coast between it and Mount Formosa, excepting at about 5 miles to N.W. of that island, where it forms an elbow, and should not be approached too closely. When Mount Formosa is brought to bear N. by W., Pisang may occasionally be brought to bear E. $\frac{1}{2}$ S. or East in standing towards the Middle Bank. The channel is about 10 miles broad; during the night stand into 10 fathoms on the shore bank, and off to 18 or 20 fathoms. By day, when abreast of Mount Formosa, and Pulo Pisang is visible, bearing E.S.E. or S.E. by E. $\frac{3}{4}$ E., steer for it; either of these bearings will carry you in mid-channel. When near to the island, its western side and the two islets may be approached within half a mile, as they are bold close-to, with 13 to 15 fathoms within a cable's length of them. In standing off shore about 10 miles from the island you will be close to, or upon, the S.E. part of the middle bank, where

there will be $4\frac{1}{2}$ to $6\frac{1}{2}$ fathoms. In working past Pulo Pisang, tack about $1\frac{1}{2}$ or 2 miles from it in 14 to 17 fathoms, and do not stand off from it more than 3 leagues.

Pulo Cocob (or *Cocops*) is 12 miles S.E. from Pisang Peak. It is a long flat island close to the Malay coast, between which and the shore is a narrow boat channel. It is covered with trees, those at the N.W. end being mangrove bushes, and more like grass; and at the S.E. end they are tall, upright grown trees, like those on the adjoining coast. The island is 2 miles in length. At low water it is surrounded by a dry sand-bank, which extends off the N.W. extreme $1\frac{1}{2}$ mile. Vessels may approach it within three-quarters of a mile.

Tanjong Bolus, or *Buru*, or *Peie*, the southern extremity of the Malay Peninsula, may also be taken as the western limit of the Strait of Singapore. It is in lat. $1^{\circ} 17' 15''$ N., long. $103^{\circ} 27' 20''$ E., and is a low point of land, covered with tall trees, bearing from the South point of Pulo Cocob E.S.E. $5\frac{1}{2}$ miles. At low water it is fronted by a dry sand-bank, and shoal water extends 1 mile from the point, which is very steep. Vessels, therefore, should be careful not to approach too close.

The **CARIMON ISLANDS** form the southern side of the strait opposite Tanjong Bolus, and consist of a cluster of one large and several smaller islands and rocks.

Little Carimon extends furthest to the North. It is a high island, $2\frac{1}{2}$ miles in length N.N.W. and S.S.E., and 1 mile broad. It rises in two peaks, which are ill defined and difficult to distinguish, covered with thick wood. The North end bears from Tanjong Bolus S.W. $\frac{1}{2}$ W. 9 miles, the breadth of the strait, which is free from dangers (except the flat off Tanjong Bolus, before mentioned). The N.E. side of the Little Carimon having deep water close-to.

The **Brothers** are two small rocky islets $2\frac{1}{2}$ miles to the N.W. of the Little Carimon. They have deep water close to them; but at 400 yards to the W.N.W. of the eastern islet there is a *dangerous rock*, just awash at low water. South by East of the East Brother, and West of the North point of the Little Carimon, is another islet of singular appearance, called the *South Brother*; and S.W. $\frac{1}{2}$ S. of this is a rock above water, named the *White Rock*.

Great Carimon is a high island, separated from the Little Carimon by a narrow strait, and lying to the S.W. of it near its North end; it rises to two high peaks, 1,376 and 1,474 ft. high respectively, which are well defined and conspicuous objects, and may be seen 36 miles off. The lowest, or North peak, bearing S.E., clears the danger on the Long Middle Bank, before mentioned. To the westward of the island are several islets and rocks, both above and below the water, but which are entirely out of the track of ships.

The description of the *Strait of Singapore* will be given in a future section.

We now return to the northern entrance describing the Sumatran coast of the strait.

The **COAST of SUMATRA**, between Achin Head and Diamond Point, was surveyed by order of the East India Company, by Commander Fell, I.N., in 1851-8, and later by the Netherlands Government in the years 1872-4, and the N.E. coast of the island thence southward by Lieut. Jackson, I.N., in 1860. These excellent surveys, combined with the previous observations of Captains Moresby, Rose, and Ward, have given us a very perfect representation of the shores of this otherwise little known island.

This side of Sumatra may be described, generally, as a vast alluvial plain, but very little above the sea level, unbroken by any great bays or inlets; but formed at the narrowest part of the strait, of low islands. This great level expanse is 600 miles in length, and from 60 to 120 miles in breadth; an area more than half of the extent of Great Britain. It is intersected by numerous rivers, some of considerable magnitude, which, rising in the great mountain chain, lying nearer to its S.W. side, or the few lakes at their base, afford almost the only clear space for cultivation and the habitations of the people, which are all derived from one stock—the Malayan, but divided into several families or nations, some of which have made considerable progress in civilization, in the arts and agriculture, as well as writing, &c; others are of a very rude and wild class, those living in the mountainous portion of this vast island. Altogether they are estimated by Mr. Logan, the best writer on the subject, to amount to 898,650 souls.

The whole island, except the kingdom of Achin, is nominally under the Dutch Government; but very little power is, or can, be exercised by the few European or native representatives of that nation. The Sumatra shores of the Strait of Malacca belong to the kingdom of Achin, or Acheen, at the North end; the Batak nation, next to the south-eastward; then the Siak State, traversed by the finest river of Sumatra, bordering the narrowest and upper part of the strait.

Achin, or *Acheen*, the northernmost state, is of some interest, as the spot which the earliest English navigators visited in 1602. Its chief feature is the Golden Mount, or Ya Muria, rising 7,546 ft. in height to the S.E. of the capital town, and to be seen 92 miles off. The town in early times rose rapidly to eminence and great commerce; and when Dampier came here in 1688, it had 45,000 or 50,000 inhabitants, a number equal to the whole present population of the state. Its fall, subsequent to this, was equally rapid, and the sovereignty is now passing from the native rulers to the Dutch Government, who commenced the war on Achin in 1871. Previous to this, all the island, except Achin, was under Dutch Government, this

state being protected by the treaty of 1824 between England and Holland, by which treaty English rights in Sumatra were exchanged for Dutch possessions, in Malacca and in the Peninsula of India, with the proviso that Achin should remain unmolested. In 1871, however, when the Dutch Government gave up to us their possessions on the Guinea Coast of Africa, this part of the treaty was cancelled, and the Achin war began; the pretext for the war being the many acts of piracy committed by the Atchinese. Up to October, 1875, the Dutch had lost 5,144 men in this war. Achin is now very unimportant, and rice is one of its chief products. A portion of it is known as the *Coast of Pedir*, the produce of which is the areca nut and a little pepper.

Batak, the next nation to the S.E., the country of the Bataks or Battas, has been partially conquered and explored by the Dutch. It is singularly unlike most other parts of the Malayan Archipelago. A considerable portion of it consists of a dreary, treeless, and sterile plain. The people are more strange than their country. They have a knowledge of letters, but undoubtedly are cannibals. The Dutch authorities say that those under their sway are readily dissuaded from this dreadful crime. There is very little commerce.

Siak, the third division, is but little known. Its great river has been ascended for a considerable distance, and is navigable for vessels of considerable burden for 90 miles to the town of Siak, and for those of 200 tons for 100 miles, but it is almost closed by a sand bank.

The portions of these states unoccupied by man, or lying on the borders of the rivers, is one vast primeval forest, to clear and cultivate which is far beyond the powers or wants of its small and puny population. Its cultivated portion is the chief source of the sago of commerce; camphor and benzoin are also produced. Coffee cultivation has largely extended; besides these, there are other and minor objects of trade.

ACHIN HEAD, the N.W. point of Sumatra, and the islands and passages lying off it, have been described in our Indian Ocean Directory.

Pulo Brasse Lighthouse, 120 ft. high, on the N.W. point of the island, completed in 1875, is a white tower, with its upper part painted red. From it is shown a *revolving light*, elevated 525 ft., and visible 32 miles off to the northward and eastward between W. $\frac{2}{3}$ S. and S.E. $\frac{1}{2}$ E. An *auxiliary red light*, to indicate the shoals which lie to the N.W. of the lighthouse, is shown between N. by W. $\frac{1}{2}$ W. and W. by S. $\frac{1}{2}$ S. from the same tower, at an elevation of 430 ft., visible 8 miles off.

Eastward $1\frac{1}{2}$ mile from Pulo Brasse lighthouse is a projecting point, which shelters an anchorage in Lembalei Bay, to the southward of it. The best anchorage is in about 9 fathoms off the village of Ujong Poneng, S. by W. nearly half a mile from the extremity of the projecting point. There is also

anchorage in *Rots Bay*, a small bay, about a mile wide on the eastern side of Pulo Nancy. It has an islet, forming its South entrance point, in lat. $5^{\circ} 38' 5''$ N., long. $95^{\circ} 11' 25''$ E. At half a mile South of this islet is a stream of fresh water.

Achin Head, the North part of which forms the eastern side of the Surat Passage, is in lat. $5^{\circ} 34' 10''$ N., long. $95^{\circ} 15'$ E., is steep-to, and has a high cliff land on its North side. At three-quarters of a mile E. by S. from the eastern extreme of the head is *Pulo Tuan*, a small circular islet, surrounded by dangerous rocks, which also lie between the islet and the head. A mile E.S.E.-ward of Pulo Tuan, is a shallow inlet, which receives the waters of the *Maraksa River*. Achin or *Atjeh River* entrance, in $5^{\circ} 35' 35''$ N., $95^{\circ} 20' 45''$ E., bears from it E. by N. $\frac{1}{4}$ N. 6 miles; there is no flagstaff, or any conspicuous object, to point out the entrance of the river. The anchorage is in 9 or 10 fathoms, with the eastern extreme of Pulo Way bearing N. 20° E.; Achin Head, S. 69° W.; the shore between Achin Head and River may be approached to 5 or 6 fathoms.

Pulo Burroo, or *Malora*, N. 36° E., $6\frac{3}{4}$ miles from the entrance of Achin River, is a small rocky islet, with a tree on it. It is $2\frac{3}{4}$ miles off shore, with soundings of 13, 9, and 12 fathoms between it and the mainland, from which the eastern extreme of Pulo Way bears N. 5° W., the bluff entrance near Point Pedro S. 41° E.

In working along this part of the coast, attention ought to be paid to the tides, and be sure not to go out of soundings should the wind be light and unfavourable, as the soundings extend but a short distance outside Pulo Burroo. Three miles to the East of it there is no ground at 275 fathoms.

PULO WAY (*i.e.* Water Island), which forms the N.W. side of the Bengal Passage, is steep-to on all sides; the nearest part of it is distant from Pulo Burroo $5\frac{1}{2}$ miles. Off the South side there is a rock, situated a short distance from the shore, on which the sea breaks, and is dry at low water. On its S.E. side there is a deep bay, with 70 fathoms water at its entrance, and 25 fathoms close to the sandy beach at the head of it.

Point Pedro, in lat. $5^{\circ} 39' 10''$ N., long. $95^{\circ} 27'$ E., bears E. 22° N. from Achin Roads, distant nearly 9 miles; it is low, with a few trees on it, and may be approached to 9 or 10 fathoms. It is $7\frac{1}{2}$ miles to the E.N.E. of the bluff formed by the high land, which terminates in a gentle slope. Off this point the bottom is rocky, and the soundings do not extend more than $1\frac{1}{2}$ or 2 miles from the shore. At a mile W.S.W. of it, and S.E. of Malora Island, is a small river named the *Tjankul*, and S.W. 3 miles from this is another small stream entering the sea, and called on the charts *Gigchen River*.

Krang Ryah Bay, in which there is anchorage sheltered from E. and S. winds, lies 6 miles S.E. from Pedro Point. On its eastern side a cliffy coast commences, and off its eastern entrance point is a small islet, Batu Kapal. At 6 miles eastward of Batu Kapal is *Tanjong Batu Putie*, a cliffy point bear-

ing N. by W. from the western slope of the Golden Mountain. Thence the coast takes a general E.S.E. direction to Pedir Point. There is, however, a slight bay between Tanjong Batu Putie and Tanjong Segie, $8\frac{1}{2}$ miles E.S.E.-ward from it, on the shores of which are the few small villages, Lanteba, Bihu, Powad, Lawang, and Kalore. There are no dangers marked on the charts at more than half a mile off shore hereabout.

PEDIR POINT, or *Batu Pedir*, is a table land of moderate elevation. Off Pedir Point, with the exception of a few rocks close in, the shore is steep-to, there being 112 fathoms water 1 mile distant from the shore. From this point the coast is cliffy for $3\frac{1}{2}$ miles, and runs to the southward, thence it takes a general S.E. by E. direction for 16 miles to *Endjung Creek*, a few miles up which is the village of *Sawang*. Six creeks, with sand banks off their mouths, are found on the coast between Pedir Point and Endjung Creek. *Batu Creek*, the first, lies 4 miles southward of Pedir Point. *Bungala Creek*, a mile N.E. of which is anchorage in 9 fathoms, lies $1\frac{3}{4}$ mile E.S.E. of Batu Creek. *Pedir Creek* is $2\frac{1}{2}$ mile E.S.E.-ward of Batu Creek. The village is not visible from the anchorage, which is abreast this creek in 10 or 12 fathoms. *Gichen Creek* is $2\frac{1}{4}$ miles E.S.E. of Pedir Creek. Between this and *Burong Creek* the distance is $1\frac{1}{2}$ mile. Burong may be known by a flag-staff in the centre of the village. The creek is very narrow, and the bar at its entrance very shallow, and only passable at high water. The anchorage is abreast of the village in 15 or 18 fathoms water. From Burong Creek to Ije Labu Creek, which enters the sea at a slight projection of the coast, the distance is $3\frac{1}{2}$ miles. Endjung Creek is $3\frac{1}{2}$ miles beyond this. Sawang entrance, before mentioned, may be known by a high grove of trees near to it.

At E. $\frac{1}{2}$ S. $7\frac{1}{2}$ miles from the entrance of Sawang or Endjung Creek is *Merdu Point*, low and sandy, with a few small round trees on it. *Beradjang Creek* lies 2 miles westward of the point, another creek enters the sea at the point, and *Ulim Creek* 2 miles south-eastward of it. Between Merdui Point and *Rajah Point*, lat. $5^{\circ} 14' 30''$, long. $96^{\circ} 28' 30''$, the distance is $13\frac{1}{2}$ miles, and midway between *Samalangan Creek* enters the sea. Rajah Point may be known by a high grove of trees near its extreme. There is a depth of about 15 fathoms, at a mile off shore, between Merdui and Rajah Points. To the eastward, *Pedada Creek* is in long. $96^{\circ} 35'$; *Djimpa Creek*, $96^{\circ} 39' 45''$; and *Passangan Creek* in $96^{\circ} 48'$.

Passangan Point is in lat. $5^{\circ} 18' N.$, long. $96^{\circ} 51' E.$, and bears from Oujong Rajah E. $\frac{3}{4}$ N., distant 23 miles, between which the shore may be approached to 12 or 14 fathoms, excepting when near to Passangan Point, which is steep-to, having 30 fathoms within half a mile from the beach. Passangan Point is low and sandy, with a few cocoa-nut trees near to its extreme, and is in one with *Elephant Mountain*, bearing S. $42^{\circ} W.$

East 4° South from Passangan Point, distant $9\frac{1}{2}$ miles, is *Agum-Agum*, or *Goma Goma Point*, the coast between is slightly concave, and halfway between

there is a high square grove of trees, near which the *Klumpang Dua Creek* enters the sea. *Manéh Creek* enters the sea a mile eastward of Passangan Point. The shore may be approached between these points to 8 or 10 fathoms, but not when abreast of Agum-Agum, which is low, with a little jungle on it, as two sunken rocks lies off this point, one a mile W.N.W. of the point, and another, the *Sumatra Rock*, at a mile off shore and 2 miles eastward of the point. Do not shoal the water under 25 fathoms when in the neighbourhood of the Sumatra Rock, if you wish to pass outside of it. From Goma Goma Point the coast takes a general E. by S. $\frac{1}{2}$ S. direction for 12 miles to *Telok Samoi*, or *Teles Amoi Point*, S.S.W. from which is a table land of moderate elevation, with a few conspicuous trees on it. The point may be rounded at any convenient distance, as there are soundings of 7 and 10 fathoms within 100 yards of the beach. *Krang Guku Creek* is $4\frac{1}{2}$ miles eastward of Goma Goma Point. At Telok Samoi Point the coast recedes and forms a bay, open to the North and East, with a river flowing into its S.W. corner; and two villages on its shores, *Telok Samoi* on its western, and *Maraksa* on its South side.

From Maraksa, just eastward of which a small creek enters the sea, the coast runs in an E.N.E. direction to Diamond Point, and may be approached to 7 or 8 fathoms, except when approaching Diamond Point, there is a shoal of hard slaty clay, with 2 fathoms on it; it is not more than 20 yards in extent, with 7 and 8 fathoms close round it. From the shoal, Diamond Point bears E. 1° N., distant $5\frac{3}{4}$ miles; a small gap in the jungle S. 1° E.; and Curtoy Creek (which is situated $8\frac{1}{2}$ miles to the westward of Diamond Point, at the West extreme of the belt of thick jungle), S. 22° W.

Passier or *Passey*, now an unimportant place, about 25 miles south-westward of Diamond Point, is frequently mentioned in old Malay annals as being a place of some note, at one time rivalling Malacca. It attained its notoriety as an *entrepôt* for trade carried on between the countries East and West of it. Between Passey Creek and Legabatang Creek, $8\frac{1}{2}$ miles eastward of it, are the *Kerti* or *Kertoy*, *Tyankoy*, and *Pidada Creeks*.

DIAMOND POINT, or *Jambie Ayre*, or *Tanjong Goere*, forms the eastern extremity of the coast of Pedir, the trees on it being of unequal height, and higher than those of the contiguous land, make the land appear like a low sloping island, when viewed at a considerable distance, although the ground is very little elevated above the sea at high water spring tides. A reef extends from the point about $1\frac{1}{2}$ mile in a northerly direction, having 3 fathoms sand on its outer edge, and shoaling gradually to the point. A ship should come no nearer the latter than $2\frac{1}{2}$ miles, nor under 12 fathoms in passing it and the shoal to the westward; for the water shoals quickly under this depth to the westward of the point. This place is frequented in the fair season by fishermen from the coast of Pedir. Inland to the S.S.W. there is a high Table Mountain, visible from the offing in clear weather.

Tides.—Although the tides along the Pedir coast are weak, and only perceptible near the shore, there being a current usually setting to the westward in the offing during the S.W. monsoon, yet they begin to run strong at Diamond Point. The flood here sets to the S.E., and the ebb to the N.W., about 2 miles per hour, with a rise and fall of 9 or 10 ft. on the springs. At the western part of the coast of Pedir, it is high water at about 10½ hours, on full and change of the moon, and at 12 hours off Diamond Point. The soundings are not very regular in the offing, the depths being from 20 to 35 or 40 fathoms, about 3 miles, to 45 and 60 fathoms at 5 or 6 leagues from the point; and soundings extend from hence across to Pulo Pera, and from the latter to the Ladda Islands, and to Penang. A little outside of Pulo Pera there are no soundings.

The coast to the south-eastward has been surveyed by Lieut. Jackson; but the directions of Commander Fell are adapted to this later chart.

Adie, 20 miles South of Diamond Point, claimed Dutch protection in 1874, and a coal depot has been established here. Between Diamond Point and Adie are several rivers and creeks. On the western side of Diamond Point is *Djambu Ayer Creek*, and on its eastern side *Mentui Creek*. In lat. 5° 14' N. is *Bekas Creek*. *Pareh Busuk*, in 5° 13' N., is an entrance between two islands. *Ringin Creek* is in lat. 5° 11' 30"; *Belas Creek* in 5° 11'; *Simpang Olim River*, in 5° 9' 30", has its entrance marked out by stakes on the sand banks; the town is about 6 miles from its mouth, and there are some pepper grounds on its banks. *Malikan River* is in 5° 8' N. *Arakun Dur River*, in 5° 6' N., has a town, *Telok Sintang*, 1½ mile from its entrance, and some pepper grounds higher up. In lat. 5° 4' 35" is the mouth of the *Djolokh River*, a mile below it the *Buging River*; a mile S.E. of Buging River is *Bagan River*, and in lat. 5° 2' 45" the mouth of the *Bagan Panas River*.

Edie Besaar River has a fort and flagstaff on the South side of its entrance, in lat. 4° 58' 40" N., long. 97° 46' 35" E. Some stakes mark the entrance, which lies between sand banks that extend off either point and form a channel, running N.W. and S.E., and open to the northward.

Prauhilah Point, in lat. 4° 53' 15" N., long. 97° 53' 30" E., bearing from Diamond Point S.E. ¼ E. 11 leagues, has a reef projecting North and N.N.W. from it about 4 miles, near which the soundings are very irregular, although between it and Diamond Point they are regular at a short distance from the shore. There are 4½ fathoms, mud, 2¼ miles from Prauhilah Point. On the North side of the point is the entrance into the river, which is almost dry at low water; but inside of it there are 2 fathoms for several miles up, with a small fishing village at a considerable distance from the entrance. Off this part it is high water, at full and change, at 12^h.

Raija River, the North entrance point of which is in lat. 4° 44' 38" N., long. 97° 57' E., has an extensive sand bank lying off its entrance. Along the South side of this sand bank the channel into the river carries a depth of

2½ fathoms, but there is less water outside, as little as 4½ ft. being found at 1½ mile S.E. of the North point.

LANKSA BAY, 20 miles S.E. by S. from Prauhilah Point, formed by Ujong Byan to the N.W., and Ujong Kwala Lanksa to the S.E., is about 4 miles wide, containing numerous shoals, with narrow channels leading into the different rivers, which fall into this bay. Near Ujong Kwala Lanksa lies *Pulo Laga Tojoo*, a small island, about a mile in extent, having a channel about 300 yards wide, with 6 and 7 fathoms water between it and Ujong Kwala Lanksa.

The entrance into Lanksa River bears from it about South, and there is a safe but narrow channel on either side of the island; the best channel, however, is from the N.E., between the island and Ujong Kwala Lanksa, having 2½ fathoms least water. In the entrance of the river there are two small islands, and the town is said to be at a considerable distance inside, containing a number of inhabitants, who cultivate rice, pepper, and rattans. There are only 3 fathoms, mud, about 6 miles distant from the bottom of the bay, and the reefs extend 3½ or 4 miles from the nearest land. Five leagues S.E. of Lanksa Bay is *Ujong Tannang*, or *Tamiang*, with *Ujong Roquit* midway between them. The coast in this interval is safe to approach, having from 15 to 20 fathoms about 2 miles off shore, excepting at Pulo Roquit and at Ujong Tamiang, where there are reefs of breakers, which project out a mile. It is high water at full and change here at 12^h 30^m.

Lunkat River, or *Kwala Bubon*, in lat. 4° 1½' N., long. 98° 29½' E., lies at the S.E. extremity of a deep bay, formed between it and Ujong Tamiang. The bay is not easily perceived from the offing, as *Pulo Tampelu* and *Pulo Sampatuan*, two large islands fronting the bay, appear, unless close in-shore, as part of the mainland. Between these islands there is said to be a safe channel for small vessels, that leads to *Kaya-la-pun River*.

From the mouth of the Lunkat a bank extends about 6 miles to the northward and N.E., having dry patches on it, with breakers in some places. About 5 miles off the entrance of the river the depth is 3 fathoms, mud, and the tide rises and falls about 2 ft. on the springs; high water at 3½ hours, on full and change. About 4 leagues S.E. of Lunkat River there is *Lankat-tuah Island*, close to Ujong Lankat-tuah, which is safe to approach, and which forms the northern extremity of the concavity of the land, where Dehli River is situated.

Balawan and Dehli Rivers are separated at their entrances by a low island, covered with jungle, 2½ miles long from East to West, and 1¾ mile wide, the eastern extreme of which is in lat. 3° 47' N., long. 98° 48' E. The importance of these rivers arises from the fact that the Dutch Government have recently established a *coaling station* on the shore which faces the western end of the island before mentioned. Up to the coal sheds the least depth (8 feet at low water) is found between the outer dark wooden cross and outer

white beacon. The entrance to Balawan River is about 300 yards wide, and much deeper than Dehli River. At 3 miles to the northward of the East extreme of the island which separates Balawan from Dehli River are the outermost of some fishing stakes, which lie 2 miles off the low wooded shore to the westward, and mark the western side of the entrance to the channel, which thence extends to the S.S.W., and is marked on its western side by white basket-topped beacons, and on its eastern side by crosses of dark wood. About $3\frac{1}{2}$ miles up the channel branches off to the westward, between the island and the main, half a mile beyond a beacon marking a projecting shoal on the port hand it turns to the southward, a mile up which reach there is anchorage off the coal sheds. Dehli Town is reached by a channel to the S.E., in which there are $1\frac{1}{2}$ and 2 fathoms water. Here the rise and fall of the tide is from 8 to 9 ft., high water at 3 hours on full and change of the moon.

South of the entrance to the Balawan River a depth of 3 fathoms is found at 4 miles off shore, and for 3 miles eastward of the East point of the island the sand nearly dries. The mouth of the Dehli River is about a quarter of a mile wide, having 4 ft. at high water on some parts, but inside it deepens to 2 fathoms; about 3 miles from the entrance is the town of Dehli or Labuan. A mile up from the entrance the channel separates into two branches, one leading N.W. towards the coal sheds, and the other leading S.W. towards the town. There is only 3 or 4 ft. water in some parts of the channel, and abreast the town the river is only 40 yards wide, with a fresh stream always descending.

From Dehli to Tanjong Mattie, which forms the northern part of Batu Barra Bay, the coast extends about S.E. by E., 55 miles, having regular soundings to $4\frac{1}{2}$ fathoms, within 2 miles of the low sandy beach that lines this part of the coast.

There are some dangerous shoals off this part of the coast, as shown by the survey of Lieut. Jackson.

The Dehli Shoal is the first of these, and lies 17 miles East by North from the mouth of the Dehli River, and nearly 12 miles from the nearest shore. Its least water is 27 ft., and it is surrounded by depths of 6 and 7 fathoms; just outside it there are 10 and 13 fathoms. No marks are given to avoid it.

The Bungan Banks, or Varela Reef, are still more dangerous. They lie from 6 to 9 miles from the nearest land, *Point Bungan Bungan*, 25 miles W. by S. from Pulo Varela, and are two in number. The outer one is a narrow spit, extending $3\frac{1}{2}$ miles N.W. and S.E., with only 9 ft. least water on some parts. A channel, with 7 to 9 fathoms, nearly 2 miles in width, separates it from the inner bank, which is also narrow, and extends in the same direction for 4 miles. Between it and the coast, the channel, 4 miles wide, has a depth of from 7 to 11 fathoms. The Peak of Pulo Varela,

bearing E. $\frac{1}{4}$ S., just clears their northern edge; the same peak, E. by N. $\frac{1}{4}$ N., clears their southern part; and a high tree on the main land, bearing S. by E. $\frac{3}{4}$ E., will lead clear of their eastern face.

PULO VARELA, in lat. $3^{\circ} 46' 20''$ N., long. $99^{\circ} 29' 15''$ E., and 22 $\frac{1}{2}$ miles off the Sumatran coast, is very high, and may be seen 8 leagues off, although it is not more than a mile in circumference. It is wooded, and clear all round, with very deep water, 24 and 25 fathoms, close-to. A small rock or islet off its N.W. point, and another off the South end. There are some small sandy bays, the largest of which is to the S.E. On the South side is a small cove, in which at some seasons water may be procured. It runs down the hill slowly into a small well. The island is visited by the Sumatran people for the purpose of catching turtle and preserving their eggs, fish-roe, &c. As these people are sometimes treacherous, boat parties landing for fire-wood, fishing, or water, should be on their guard.

A bank of 6 to 9 fathoms water lies to N.N.W. of Pulo Varela. It is 7 miles in length, its S.E. end being 7 miles from Pulo Varela. Although the above depths were only found on the survey, it is reported that there are only 2 fathoms over some parts. There is another bank with 8 and 9 fathoms at 4 or 5 miles to the S.W. of Pulo Varela.

Point Mattie is 25 miles due South from Pulo Varela; off it is the *Mattie Shoal*, nearly awash in parts, and 9 miles in extent, parallel with the coast, between which is a channel of from 15 to 5 fathoms water, from $1\frac{1}{2}$ to $2\frac{1}{2}$ miles wide. It is high water here, at full and change, at 3 hours, rise from 7 to 10 ft.

Off Tanjong Mattie, to the northward, the depth increases to 12 and 14 fathoms, and shoals suddenly to 5, 3, and 2 fathoms, on a sandy spit which projects about $1\frac{1}{2}$ mile from that point, and $6\frac{1}{2}$ miles to the eastward of it, and the same distance to the northward of Batu Barra there is an extensive and dangerous sand-bank, having only $1\frac{1}{2}$ fathom, with a safe channel between it and the mainland, 3 miles wide.

BATU BARRA RIVER, in lat. $3^{\circ} 14' N.$, long. $99^{\circ} 35' 30'' E.$, and the coast for some miles eastward, is fronted by an extensive mud flat, from 2 to 4 miles off shore, having regular soundings, and projecting out to within 5 miles of the South Brother. The river is about 300 yards wide, with regular soundings to the dry banks at its mouth, where a little way inside it divides into two branches, one to the eastward, and the other to the westward. About a mile up the western branch is the town where the chief rajah resides. On the banks of the eastern branch stands another town, and there are said to be other towns further up the river. The people on the coast are generally Malays; those in the interior are Bataks. European vessels discontinued visiting this place for many years, owing to the perfidious conduct of the Malays, who formerly cut off several vessels that touched here to

trade. Nevertheless the people of Batu Barra appear more industrious and better inclined to trade than is usual with the other inhabitants of this coast; and they carry in their own proas, to Penang and Malacca, the rattans, pepper, or other articles produced here. Goats and poultry are plentiful, at reasonable prices.

The **BROTHERS**, two small islets, lie off Batu Barra, at $10\frac{1}{2}$ and $15\frac{1}{2}$ miles respectively, to the N.E. by E. The northernmost, *Pulo Pandan*, or *Quandan*, is much lower than Pulo Varela, from which it lies S.S.E. $\frac{3}{4}$ E. $25\frac{1}{2}$ miles distant. It is covered with wood, and surrounded on all sides by a reef to a considerable distance off it. Therefore it should not be made free with. The southernmost, *Pulo Salanama*, is larger, and much more bold-to, although there are some rocks stretching from its North end for above half a mile, and another rock or islet lies to the East of its South end. The channel between the two islets, 4 miles in width, is perfectly safe with 20 to 30 fathoms water; and there is also a channel inside Pulo Salanama, about 3 miles in width, but then it should be borne in mind that the Sumatran coast is here bordered by an extensive shelf, which extends for nearly 5 miles off the point to the southward of the southern Brother. From this circumstance, it should not be used except under great necessity, seeing that the course outside it is so much preferable. There are several other spots shown on the charts, which will demonstrate the necessity of caution, should a vessel get too far over to the Sumatran side. The best course is, as before directed, to the eastward of Pulo Jarra.

The **COAST** of Sumatra south-eastward of Batu Barra is laid down on the charts from the surveys of Lieuts. Rose and Moresby, I.N., and has not been so minutely examined as that to the north-westward; but this is of the less importance, as a great portion of it is unapproachable to shipping, in consequence of an extensive mud flat which stretches off it for many miles.

Assarhan River, in lat. $3^{\circ} 1\frac{1}{4}'$ N., long. $99^{\circ} 52\frac{3}{4}'$ E., has a mud flat, extending from its entrance 8 miles to the N.E., upon which the soundings regularly decrease. From hence to Reccan River care is required not to approach too near the coast, as several mud flats extend to a considerable distance, upon the verge of which the water shoals suddenly; particularly about 5 or 6 leagues to the S.E. of Assarhan River, fronting the bay of Lidang and its contiguous rivers, where the flat extends $3\frac{1}{2}$ leagues from the shore at the bottom of that bay.

RECCAN, or **Rakan River**, has at the entrance two islands, *Pulo Lalang Besar*, in lat. $2^{\circ} 12'$ N., long. $100^{\circ} 36\frac{1}{2}'$ E., and *Pulo Lalang Kechel*; the former is the largest, from which the other bears S. by E. $\frac{1}{2}$ E., about $2\frac{1}{4}$ miles; and there is a shoal channel between them leading into the river. They are low and woody, and not discernible above 10 miles. Having passed between these islands, and being a little to the eastward of them, the entrance to the river bears S.E. $\frac{3}{4}$ E., and extends in this direction about 30

miles; then a small and shoal bank projects to the westward, called *Banka*; but the main branch takes a S.E. direction, and is called *Tanah Putie River*, having a town of the same name at the mouth of this branch, which is here about $1\frac{1}{2}$ mile wide, and is said to take its rise from the mountains. It is shoal and dangerous, from the rapidity of the tides; but several large and populous villages are said to stand on its banks, subject to the Rajah of Siak. The greatest breadth of the mouth of Reccan River is about 15 miles, decreasing about 8 or 9 miles up to 4 miles, afterwards 2 miles, and then continuing this breadth till it forms the two branches mentioned above. It is almost dry at low water spring tides, and is rendered exceedingly dangerous by their excessive rapidity of 7 miles per hour, producing a bore on the springs, and having a rise and fall of 30 ft.

At the mouth of the river it is high water at 6 hours on full and change of the moon; the rise and fall of tide about 26 ft.; and here the velocity of the stream is about $5\frac{1}{2}$ miles per hour, but it becomes much greater a few miles up. On the bank of the river the *Nautilus* found a straggling village, whence the inhabitants came off in great numbers, and entreated to be admitted on board, under pretence of friendship, which was refused excepting to a few of them. They afterwards, without the least provocation, endeavoured to cut off one of the boats, which had got adrift by the rapidity of the tide.

The *Arroa Isles*, described previously, lie off the mouth of the river, 40 miles to the northward.

From Reccan River the land on the eastern bank projects to the N.W., forming the headland called *Ujong Perbabean*, in lat. $2^{\circ} 16\frac{1}{2}'$ N., from which a mud flat extends to the N.W. and N.N.W. about 10 miles, and upon this flat the soundings decrease regularly. When clear to the eastward of this bank, and having *Ujong Perbabean* bearing S.W., and *Parcelar Hill* N.E., you enter upon the most dangerous part of this coast, its various sand banks extending from it over to the *South Sands*, with gaps and narrow channels of mud soundings between them. As the soundings afford no guide in approaching these banks, the depth decreasing suddenly upon them, it is necessary for a vessel intending to pass between them to have a boat ahead sounding, and a good lookout kept from the fore-yard, for the shoal banks are plainly seen when the sky is clear in the daytime.

PULO ROUPAT, the North point of which is called *Ujong Bantam*, is in lat. $2^{\circ} 8'$ N., long. $101^{\circ} 40\frac{1}{2}'$ E. It is bold to approach, having 30 fathoms within $1\frac{1}{2}$ mile of the shore. The eastern side of this island is bold until the entrance of *Brewers Strait* is approached, where a mud bank extends out from the shore of *Pulo Roupat* about 5 or 6 miles between the North point of *Pulo Roupat* and *Ujong Perbabean*, the coast forms a deep bight, which is fronted by an extensive sand bank; this bank, together with those in the

offing, mentioned above, render this part of the Sumatra side of the strait very intricate and dangerous.

BREWERS STRAIT, or Salat Panjang.—The North entrance of this strait is formed between the mainland of Sumatra and *Pulo Bucalisse*; *Tanjong Jati*, the North end of the latter, being in lat. $1^{\circ} 36\frac{1}{2}'$ N., long. $101^{\circ} 59'$ E., a shoal bank, extends 8 miles to the northward from the point.

The northern navigable part of this strait is about 5 miles wide, with soundings of 8 to 15 and 20 fathoms, mud; and 8 miles from the entrance, on the western shore, is the town of Bukit Batu, upon the banks of a very narrow river of the same name. The town is not easily perceived, the houses being scattered among and hid by the trees; but it may be known by a tree, formed like an umbrella, near the entrance of the river.

At *Ujong Ballai*, a point of Sumatra, $3\frac{1}{2}$ leagues to the S.E. of Bukit Batu River, the strait becomes contracted to 3 or 4 miles in breadth; and opposite to the point is the entrance to the narrow strait called *Salat Padang*, affording a safe passage for boats; it is formed between Pulo Bucalisse and Pulo Padang. From Ujong Ballai, Brewers Strait turns from a S.E. to a South direction, till opposite the mouth of the Siak River.

From the entrance of Siak River, Brewers Strait extends S.S.E. to the western end of Pulo Rantow, where it contracts to 1 mile in breadth, with regular mud soundings from 8 to 10 fathoms. Between Pulo Rantow and Pulo Padang is formed a channel leading to the sea, called *Salat Ringit* by the natives, and said to be used only by boats. From the western end of Pulo Rantow the strait takes an easterly direction about 20 miles, with depths from 10 to 15 fathoms, till a small island in mid straits is approached, on each side of which the passage is practicable, taking care to avoid the stream of the island, as a mud flat extends from it to the westward $2\frac{1}{2}$ miles in the middle of the strait. From hence the direction to the strait is to the S.E., and, after passing three small islands on the port hand, the southern entrance opens, off which there are a great number of islands. The safest channel out appears to be between Panton Point and Pulo Senappu, having regular but shoal soundings of only 1 fathom at low water in some parts.

SIAK RIVER, the entrance of which is in lat. $1^{\circ} 11\frac{1}{2}'$ N., long. $102^{\circ} 12\frac{1}{2}'$ E., on the western side of Brewers Strait, is about three-quarters of a mile wide, having a sandy spit, nearly dry at low water, extending almost across, but leaving a safe, although very narrow channel, close to Ujong Liang, the eastern entrance point; the river becomes narrow, with deep soundings inside, and is said to have its source in the mountains.

The town of *Siak* stands at 65 miles from the mouth of the river. The *Nautilus* anchored in 6 fathoms, mud, within a quarter of a mile of the mouth of the Siak River, and found the time of high water at full and change of the moon to be 9 hours; rise and fall of the tide about 12 ft., and the velocity $2\frac{1}{2}$ miles per hour.

Campou River, in lat. $0^{\circ} 43' N.$, long. $103^{\circ} 0' 30'' E.$, is fronted by an extensive mud flat, almost dry at low water; and it is little frequented on account of the rapidity of the tides, occasioning a bore at times similar to that of Reccan River, which it resembles in several respects. In approaching the southern entrance of Brewers Strait, the tides are greatly influenced by this river, producing a strong eddy round some of the islands, so that, while the tide is running to the southward on one side of an island, it may be often found running to the northward on the other side.

The rise and fall of tide near the southern entrance of Brewers Strait is about 15 ft. in some parts, with a velocity of about $3\frac{1}{2}$ miles per hour, but much greater when near the entrance of Campou River. The three islands, Pulo Bucalisse, Padang, and Rantow, which form Brewers Strait, and also Pulo Panjore, ought not to be approached but with great caution, at their eastern sides, as they are fronted by an extensive mud flat, with dangerous sand banks, in some places having only $1\frac{1}{2}$ fathom water on them. These form what is usually called the Sumatra Bank, or third bank in the Malacca Strait to the N.W. of the Carimons, which has been before alluded to. The Carimon Islands, which form the head of the Strait of Malacca, have been described on page 136.

CHAPTER IV.

THE STRAIT OF SUNDA.

THIS important and remarkable passage, the great portal of the Indian Archipelago, has been surveyed by the Dutch officers, Lieutenants Rietveld and Boom, in 1848, and their survey has been improved by the observations of many officers, especially by the late talented Melville Van Carnbee, of the Dutch navy, who drew up an excellent hydrographical description of Java, &c., which has been mainly followed hereafter.*

The Strait of Sunda is a singular break in the continuity of that great chain of volcanic mountains which runs from N.W. to S.E. through Sumatra, and is continued eastward through Java. This depression in the mountain chains is not very much below the sea level, for the general maximum depth of the strait is not more than from 30 to 50 fathoms. But this slight depression, geologically speaking, has produced a great contrast in the islands

* The fine surveys and charts of great portions of the Indian Archipelago, which have been executed by the Dutch officers attached to the Indian Possessions of that nation, have only been known and justly appreciated in this country within a few years. The "Commissie tot Verbetering der Indische Zeekarten" was instituted by the enlightened Governor General of Dutch India, Van der Capellen, in 1821, and since that period the commission has been sedulously and zealously occupied in surveying and collecting information in all the surrounding seas. Captain-Lieutenant Baron Peter Melville van Carnbee became the secretary to the Dutch Commission, in 1850, and among numerous other works he was the author of the "Zeemansgids voor de Vaarwaters om Java," which was soon translated into the French and English languages, the latter being done by Dr. Norton Shaw, Secretary to the Royal Geographical Society. Besides this, he drew up a fine series of charts from the many scattered surveys and observations made by the Dutch officers under the commission; these charts were published by the respected house of Wed. G. H. Van Keulen, of Amsterdam, and were afterwards copied in their main features by the English Admiralty, as the basis for all subsequent charts. Young Melville van Carnbee died in 1856, in his fortieth year, while engaged on the excellent "Algemeene Atlas Van Nederland's Oost Indie."

To the works above quoted, very much is owing in the subsequent pages.—EDITOR.

STRAIT OF SUNDA

H.W.F.S. at Revolution VII^h

Springe rise of 4^h stages not perceptible

on either side of it. Each has a distinct class of animal and vegetable life. Thus the elephant and tapir of Sumatra have no existence in Java. The wild hog and rhinoceros of Sumatra are of different species to those found in Java. The orang-outang is found in Sumatra, but not in Java. The birds are also quite different; many important families belong to each, without having them in common. These curious contrasts are also found to exist between the islands further to the eastward. These remarkable facts in the distribution of life on the earth have been much discussed by naturalists, especially by M. Temminck and Mr. A. R. Wallace.

The strait derives its name from the western portion of Java, which is peopled by the *Sunda* nation, who speak a different language, and are less advanced in civilization than the rest of the Javanese.

In its widest sense, the Strait of Sunda embraces a very large area. Between the western extremity of Java and the south-western end of Sumatra, the distance is 68 miles, and the bearing N.W. $\frac{3}{4}$ N. and S.E. $\frac{3}{4}$ S. ; and from this line to another at its N.E. limits, between St. Nicholas Point on Java, to the opposite side on Sumatra, the distance is 74 miles. The narrowest part of the strait is between Fourth Point on the Java side, and Hog Point in Sumatra, 13 miles apart. There are numerous islands in it, which separate the strait into several channels, of which that along the Java coast is the most used; the lofty and conspicuous island Krakatoa being the great land-mark from the westward, all the headlands being more or less grand in their character.

The Dutch nation holds the sovereignty of the shores on either side, and being the surveyors of the strait, have the right to give the names and orthography to the points and islands, but as their excellent and expressive language is not so generally used, it will be preferred to give these common names in an English form (adding the Dutch), and the spelling in the ordinarily recognized form for pronunciation.

THE JAVA COAST.

The south-eastern side of the Strait of Sunda is formed by that portion of Java which gives its name to it, as before mentioned. The state extends eastward to Cheribon, and includes Batavia, the capital, embracing nearly one-third of Java. It is a mountainous country, but containing some rich valleys, and is said to bear the same relation to Java proper that Wales does to England, or the highlands to the lowlands of Scotland. It is more thinly populated, and the people less advanced than in the rest of Java.

The volcanic ranges which traverse it, in continuation of that extending

throughout the length of Java, give it a peculiarly bold character. Many of the peaks visible from sea attain to great elevation. *Karang*, in the rear of Anjir, is the loftiest, 5,943 ft. ; and a few miles to the South of it is Pulusari, 4,183 ft. ; several others reach to between 2,000 and 3,000 ft. The peak at the southward of Krakatoa Island is 2,623 ft. ; and Bezee, to the North of it, is 2,600 ft.

The coast is deeply indented, and has some sheltering bays, but Anjir Roads is the chief stopping place. Here is a *Signal Station*, at which an officer will reply to and forward answers to signals to Batavia, &c., the telegraph system being perfect in the Dutch possessions. Lighthouses are shown on the chief points, and the following directions in connection with the chart will carry a ship through in safety.

Java Head, the western extremity of Java, and the S.W. point of the Strait of Sunda, is a noble promontory, a fitting portal to that great entrance to eastern countries. But as it is frequently prudent to make the land to the eastward of the strait in approaching it from the Southern Indian Ocean, the features of the southern coast of Java for a short distance will be briefly described first.

Trower Island, or *Pulo Tinjil*, is $3\frac{1}{2}$ or 4 miles in length, and its East end is about 35 miles East of the meridian of Java Head. It is surrounded by a reef. On the North and West sides of it there are from 13 to 19 fathoms water, and at the S.E. and South sides, at some distance, no bottom at 50 and 100 fathoms. A mile to the northward of the island there is a *rock*, on which the native proas have sometimes struck. Everywhere else round the island from 13 to 19 fathoms will be found, and at a short distance to the southward more than 100 fathoms.

Klapper Island, or *Breakers Island*, called by the Malays *Pulo Deli*, 8 miles distant from the nearest shore of Java, 13 miles West by South from Trower Island, and about 18 miles E.S.E. from Cape Sangian Sira, the S.W. point of Java. It is 148 ft high, covered with large trees, those along the beach being cocoa-nut, and is surrounded by a reef, which in many places stretches off a mile ; but on the N.W. side there is a good watering place in the S.E. monsoon, as boats can enter a little river through a channel with reefs on both sides, and ships may anchor in 18 to 24 fathoms, clay bottom, 2 miles distant from the island, close to those reefs which partially dry at low water. The depths are from 30 to 40 fathoms at 4 miles off the South shore of the island.

Sodon Point, on the South coast of Java, is, as before said, 8 miles North of Klapper Island. The head of Welcome Bay, on the North side of the island, reaches to within 3 or 4 miles of this southern coast.

Along the coast to the northward of Klapper and Trower Islands, as far as Cape Sangian Sira, there are rocks which in some places lie $1\frac{1}{2}$ and 2 miles off ; and no shelter whatever can be found there from S.W. and S.E.

gales. A shoal lies to the eastward of Sodon Point, about $1\frac{1}{2}$ mile from the shore. It bears N. $\frac{1}{3}$ E. from the East point of Klapper Island, and N.W. by W. $\frac{3}{4}$ W. from the West point of Trowers Island.

When making Java Head in hazy weather, the appearance of the land to the eastward of Cape Sangian Sira, between it and Sodon Point, bears much resemblance to the high land of the West point of Java, with the adjacent hills on Princes Island; and the low land in such circumstances not being distinguishable at a distance, the position of it is often mistaken for the entrance to Princes Channel.

From Java Head the coast runs S. by E. $\frac{3}{4}$ E. about $4\frac{1}{4}$ miles to Palembang Point, which is $1\frac{1}{4}$ mile northward of Cape Sangian Sira.

CAPE SANGIAN SIRA, the most southern point of this part of Java, is in lat. $6^{\circ} 52' S.$, long. $105^{\circ} 14' E.$ It is the S.W. point of an irregular mass of mountains, which rise abruptly from the sea to a height of 1,050 and 1,300 ft. on the eastern side, and to 618 and 1,400 ft. on the western side. From this cape, and $1\frac{1}{2}$ mile to the southward, several rocks project, some of which are above water. Captain Newby, in passing close round by Palembang Point, thought he saw a clear but narrow channel inside these terrific pinnacle-shaped rocks, which might be used by keeping the point on board, but it should not be tried. The soundings are very deep close to these rocks, and along the shore as far as Java Head there is no bottom with 100 fathoms; but as the breakers which line the whole coast seem to indicate that there are rocks under water, it will be advisable to give the shore a berth of at least 2 miles in passing.

From Cape Sangian Sira the soundings decrease in the direction of Klapper Island to 40 and 20 fathoms; while farther eastward, between this island and Trower Island, they decrease from 20 to 12 fathoms.

Palembang Point is the N.W. point of the promontory of which Sangian Sira is the South extreme. They are a mile apart, and the reef of pointed rocks around the land here comes close up. The coast to the northward, for a distance of $4\frac{1}{2}$ miles to Java Head, is formed by the steep-sided mountains before described, which are dark, covered with trees, some of which on the summits are very large. No signs of any inhabitants. Under these dark frowning hills is a belt of green herbage, and then a sandy beach of dazzling whiteness, with several detached steep rocks, some of which would look like a boat under sail.

JAVA HEAD.—The West point of Java is in lat. $6^{\circ} 46' 40'' S.$, long. $105^{\circ} 12' 22'' E.$ Being frequently the first land made after a long voyage across the Atlantic, and round the Cape of Good Hope, its lofty and majestic character strikes those who approach near it with greater force than even its natural features would command. Captain Newby was much struck with its grandeur. He says:—It is composed of a confused mass of cliffs jumbled together. Two hundred yards North of it is a splendid arch or chasm,

in a high detached rock, through which the surges roll their white foam. Through the arch on the main you behold the most luxuriant green vegetation, contrasting with the white surge, the sombre cliffs, and the variegated surface of the ocean. This arch resembled the cloisters of some ancient cathedral. Three hundred yards to the North of this first-named arch is another, but smaller one, of similar character. Through this is seen the white sand and shells on the beach, and between the water is of a light green shade; outside, between us and the arch, the water being deeper, is of a darker green. Sailing on, the projection, or point, called the *Capuchin*, appeared, and soon after the *Friar*, for which, as the wind was rather scant off, I hauled up, and the water being very smooth, I passed it at not more than one cable's length distance, at 5^b 15^m. I could not see any hidden danger or rock under water in my track. When we had passed the *Friar*, and neared Mew Island, he appeared conspicuous. But as the land between is very high, and very thickly wooded, the *Friar* could not be very well made out as seen from a vessel in the offing, unless she was well to the eastward. From W.S.W. it did not appear to me to be an island at all; there seemed to be dry rocks between it and the hill to the South, which connected the *Friar* with the higher land to the southward. Round the pitch of the *Friar* there is a very fine spacious-looking bay, called Mew Bay. There seems to be a low black detached rocky islet, a mile or so beyond the *Friar* to the S.E., but it is nearer the West than the East side very much. This bay seems very snug and convenient for anchoring in with a wind any way from the E.N.E. round by the southward to S.W.

FIRST POINT (*Eerste Punt*), and the *Friars Rocks*.—The coast between Java Head and First Point forms a bight, and is fronted by high rocks, stretching out a considerable distance in some places. First Point, or *Tanjong Along-Ajang*, the South point of entrance into Princes Channel, has a conspicuous rock lying abreast of it, called the *Friar* (*De Monnik*), before alluded to, which rises abruptly out of the sea, and is steep-to, so that with a steady wind a ship may pass close to it. Close to the northward of First Point there is another rock above water, which together with the former are properly called the *Friars*.

The **LIGHTHOUSE** on First Point was first illuminated in June, 1877. It is a stone tower, painted white, from which is shown a *revolving light*, exhibiting a flash of six seconds' duration once in every half minute. The light is elevated 305 ft. above the sea, and should be visible 25 miles off in clear weather.

PRINCES ISLAND (*Prinsen Eiland*), or *Pulo Panatan*, separated from the West part of Java by Princes Channel, is the largest island in Sunda Strait. Its greatest length, between the West and N.E. points, is 12 miles, and its breadth about 8 miles. It is of an irregular form, projecting to a point on the N.E. side, and having a large bay on the S.W. side, the horns of which

form the West and South points of the island. The middle and eastern parts of the island are hilly, the highest peak, 1,450 ft. above the level of the sea, being on the eastern shore; but in some parts, particularly at the West end, the land is level and low from the sea; all parts of the island abound in wood.

A ship in want of water may anchor on the eastern side of this island in 35 fathoms, soft ground, about half a mile from the shore, with the peaked hill bearing about N.W. by N. Here is a small sandy bay, and at its eastern part a run of fresh water, where the casks must be filled about 100 yards up, the higher the better, otherwise the water will be brackish.

It is, however, only in the N.W. monsoon that water can be procured here, for in the S.E. monsoon all the springs are dry from want of rain, and there is, moreover, no safe anchorage in this monsoon along the East side of the island, as it is a dead lee shore.

Kasuaris Bay, on the S.W. side of the island, is 4 miles deep, and has at its entrance soundings varying from 30 to 50 fathoms, decreasing inside to a convenient depth for anchoring; but, being open to all winds between the West and South points, it is not frequented, and cannot be recommended.

The Carpenters (*Timmerlieden*) are a large group of rocks about a mile in extent, projecting from the South point of Princes Island. Most of the rocks are above water; they are black and pointed, looking very dangerous, and the sea is usually breaking over them. There is no bottom with 50 fathoms a short distance from these rocks.

The West point of Princes Island is fronted by a reef to the distance of about $1\frac{1}{2}$ mile, several rocks of which are seen above water.

On the N.W. and North sides the island is steep-to close to the fringe of reef which edges those shores.

A fringe of reef extends from the N.E. point of the island, and along the shore on each side.

A similar fringe extends about a third of a mile off the S.E. point of the island; nearly 2 miles W.S.W. of which, close inshore, and near a conspicuous white rock, is a coral reef, upon which the sea is always breaking.

PRINCES CHANNEL, between the Carpenters Rocks off the South end of Princes Island, and the Friars Rocks off the First point of Java, is 3 miles broad at its narrowest part, and possesses the great advantage of affording anchorage to vessels when becalmed, which the Great Channel does not. Light baffling winds and calms are very common about the entrances to Sunda Strait, occurring even in the strength of the S.E. monsoon, and vessels, when not able to anchor, are liable to be set back by adverse currents.

The depths in this channel are much greater on the Princes Island shore than on the opposite coast. Close to the Carpenters there is no bottom

with 50 fathoms; with Peaked Hill, on the S.E. part of the island, bearing from N. $\frac{1}{2}$ W. to W. by N., there are 10 to 30 fathoms, coarse sand, shells, and coral, little more than a cable's length off shore; with the same hill bearing from N.N.W. to S.W. there are 36 to 44 fathoms about a mile distant from the shore. Towards Mew Bay the depths decrease to 20 fathoms and less.

Directions.—In the S.E. monsoon, when proceeding either way through Princes Channel keep closer to the Java coast than to Princes Island.

In the N.W. monsoon it often happens that vessels outward bound get very quickly to the westward by proceeding through Princes Channel, while those using the Great Channel are detained by heavy squalls and adverse currents. Indeed, instances have occurred in which ships have worked through this passage in a remarkably short time in a westerly gale, by carrying a heavy press of sail, and tacking between the squalls, at times when it was impossible for any ship in the Great Channel to beat against the current and heavy sea.

Proceeding through Princes Channel in this monsoon, keep near Princes Island and the Carpenters, especially when working out against westerly winds, for a current will then sometimes be found setting to the westward. It is moreover very important to keep close to the Carpenters when working out, to avoid being set upon the rocks near Java Head and Palembang Point by the heavy swell, for, being once outside anchoring ground, and in a calm, a ship would have much trouble to clear the coast of Java. The S.E. coast of Princes Island must not, however, be approached within a mile.

GREAT CHANNEL lies between the North point of Princes Island and the South point of Krakatoa Island, which are 23 miles apart; and although too deep for anchorage, it is much frequented, being the widest passage into the strait, and is considered to be, with the exception of the doubtful Hoedeken Rock,* clear of danger. If the strait is entered by this channel, keep Princes Island aboard, and when farther in the strait, keep on the Java shore.

MEW ISLAND (*Meeuwen Eiland*), or *Pulo Kanti*, lying about $2\frac{1}{4}$ miles eastward from First Point, is nearly 2 miles in extent North and South, and 1 mile East and West. The island is hilly, and abounds with wood. Between it and First Point, close inshore, is a small islet or rock above

* *Hoedeken Rock* is said to lie about 5 miles S.W. $\frac{3}{4}$ S. from Krakatoa. Captain Drury, R.N., is reported to have examined a rock S.S.W. of Krakatoa some years ago, and found it to be near the water's edge. The *Abdul Hassim*, drawing 14 feet, is also said to have struck upon a rock, from which the peak of Krakatoa bore N.E. $\frac{1}{2}$ N., distance from the nearest part of the island 6 miles. There is, however, reason to believe that no rock exists in this locality, for Mr. Richards, commanding H.M. surveying vessel *Saracen*, carefully sounded over it in 1854.

water, called the *Mew Stone*. The shore is rocky on the outside of Mew Island, but safe to approach. The soundings decrease gradually to 8 or 9 fathoms.

Between Mew Island and the main there is a narrow but safe channel, with depths from 10 to 5 fathoms, sandy bottom. When taking this passage, keep close in towards Mew Island, as a shoal, called the *Watson Bank*, lies near the Java shore. Sometimes the sea breaks upon this bank, but between it and Mew Island there are depths of 3, 5, and 10 fathoms, clay bottom.

To the eastward of Mew Island, on the Java shore, there is a good watering place in the S.E. monsoon; the water is excellent, and is poured by a cataract upon the beach. Large boats may approach this spot at high water through a narrow channel in the reef, and fill the cask by a hose. At low water they will require a great length of hose to reach the boats.

A little to the northward of the watering place lies a reef of coral, about a cable's length in extent, and about half a mile from the Java shore. Upon its shoalest part there is 1 fathom water, and all round from 5 to 6 fathoms. A ship standing in for the watering place, must steer between this reef and the island, or rather nearer towards the island, and anchor in 9 or 10 fathoms.

In the S.E. monsoon there is also a good anchorage a little farther out, with the North point of Mew Island about W. $\frac{1}{2}$ S., and the East point S. by W., in 16 to 19 fathoms water, sandy bottom.

Plenty of wood may be got upon Mew Island or the main land. Shore parties should be on the guard against any hidden assaults from the natives.

At Mew Bay it is high water, full and change, at about 6^h.

SECOND POINT (*Tweede Punt*, or *Tanjong Gukulang*, consists of a low foreland, somewhat broad in appearance, the western extremity of which lies about N.E. by E., nearly 9 miles distant from First Point, and its northern extremity—which is usually known as Second Point—about 3 miles farther to the north-eastward. It may be approached without danger to the distance of a mile or even half a mile, and in from 26 to 20 fathoms water, the reefs projecting a little way off shore.

From Mew Island towards Second Point reefs project half a cable's length from the shore, having very near them 5 to 6 fathoms water, which increases speedily to 10 and 20 fathoms; but with due care and attention to the lead, a ship may approach the shore in order to anchor. On the coast there is scarcely any population, but sometimes proas may be met with having turtle, fowls, and cocoa-nuts for sale.

WELCOME BAY (*Welkomst Baai*).—N.E. by E., distant 20 $\frac{1}{2}$ miles from Second Point is Third Point, and between is a deep bight, named Welcome Bay, which in the S.E. monsoon affords good shelter, but should be avoided in the S.W. monsoon. There is, however, good anchorage in the S.W.

monsoon, when the wind is not too northerly, behind Second Point in 9 or 10 fathoms water; but this anchorage should be approached with great caution, as the soundings decrease very suddenly near Second Point, and a shoal, with 12 ft. water on it and 6 fathoms close-to, extends half a mile off shore between Second Point and Tambing Point.

The West side of the bay takes from Second Point a direction about S.S.E. $\frac{1}{2}$ E. for a distance of 11 miles, but about the middle of it the beach forms a small bight, with 4 fathoms at its entrance, but only 1 fathom further in. The whole of this side of the bay is skirted by reefs, some parts of which are a mile distant from the shore.

Lieuts. Rietveld and Boom, D.R.N., surveyed Welcome Bay in 1841, and determined the positions of the shoals and islands given below. A large portion of the bay inside Panter and Rocky Ridge Reefs has not been examined, but it is supposed to be dangerous.

Two small islets, named *Andellan* and *Little Andellan*, lie contiguous to the S.W. shore of the bay, about 8 miles from Second Point, and 5 miles from Rocky Ridge. Three sand banks, each surrounded by a sunken reef, lie from half to three-quarters of a mile off these islands, in a N.N.E., East, and S.E. direction. Between these banks and Andellan are from 4 to 6 fathoms, mud; and between that island and the shore from three-quarters to $1\frac{3}{4}$ fathom. Near the head of the bay, to the eastward of a small islet named *Rongit*, is a fourth bank.

The distance across from the southern shore of Welcome Bay to the South Coast of Java is not more than 3 miles, and the sound of the surf on the South coast may be distinctly heard across the isthmus.

The eastern shore of the bay is 22 miles in length, from the head of the bay to Third Point, in a direction about N.N.E., and the general depths off it are 15 to 24 fathoms at some little distance from the coast. Several islets and dangers lie off this shore. *Baddu* (Baddoe) is a small islet, surrounded by a reef, lying about 5 miles from the head of the bay, and about $1\frac{1}{2}$ mile N.W. of a point named *Tankyngi Parrie*. Between this point and the islet are many coral rocks, for the most part dry at low water, and with depths of 7 to 9 fathoms between them.

A large coral rock above water, usually covered with a heavy surf, and appearing of a bright white colour, lies W. $\frac{1}{2}$ N., about $1\frac{1}{2}$ mile from Baddu; and near it appear to be several reefs. Between the rock and the island are 6 to 12 fathoms water.

Five or 6 miles north-eastward of Baddu is *Plaggan Point*, or *False Hook*, with some islands off it, the southernmost of which is called Mangir, and the others *War*, *Umang* (Oemang), and *Sumur* (Soemoer). These islands, as well as Plaggan Point, are surrounded by reefs, a cable in breadth, but at a mile outside there are 15 fathoms, over mud bottom.

Rocky Ridge is an extensive reef mostly above water, and always covered

by breakers, by which it may be distinguished at a great distance. It lies about halfway between the western shore of the bay and the Panter Reefs; and from it Second Point bears N.W. by W. $\frac{3}{4}$ W., the South point of Baddu S.E. by E. $\frac{3}{4}$ E., and the East point of Andellan S. $\frac{1}{2}$ E. That part of it which remains dry at low water is about 100 yards in length, and the breadth of the surrounding reef the same. The soundings round it are 10 and 12 fathoms, increasing at some distance to 18 and 19 fathoms.

Panter Reefs are the outermost of the known dangers which encumber Welcome Bay, and they lie nearly midway between Second Point and Plaggan Point. From their North extremity, in 11 fathoms, Second Point bears W. $\frac{3}{4}$ N., Third Point N E. $\frac{1}{2}$ N. 16 miles, the East point of Andellan Island S. by W. $\frac{1}{4}$ W., and the S.W. point of Baddu Island S.E. $\frac{1}{2}$ S. They consist of four different patches, lying in a N.N.E. and S.S.W. direction from each other, the whole being from half to three-quarters of a mile in extent. The shoalest patch has $1\frac{1}{2}$ fathom water, rocky bottom, but between and close round them are 9 and 10 fathoms, mud.

East and West of these reefs are 17 and 18 fathoms, and to the northward 20 and 25 fathoms.

Welcome Bay appears to be full of dangers not surveyed, and should be entered with *extreme caution*.

THIRD POINT (*Derde Point*), or *Tanjong Lussong*, like Second Point, is very low, although sharper, and fronted by rocks to the distance of 2 cables, from which the depths increase to 10 and 18 fathoms. The peak of Krakatoa Island bears N.W. by N. from it, and is distant about 21 miles.

PEPPER BAY (*Peper Baai*).—N.E. by E. $\frac{1}{2}$ E. 11 miles from Third Point is *Papolle Island*, and between is Pepper Bay, which is formed by the coast trending away from Third Point to the southward for a distance of nearly 5 miles. Its shores are fronted by reefs, which near the points project about half a mile, increasing their distance from the shore towards the depth of the bay, where they extend $1\frac{1}{2}$ mile. The bay is also encumbered with two dangerous reefs known as the Coral Bank and Paniang Reef. The soundings in the bay generally decrease uniformly from 14 to 10, 5, and 4 fathoms; the latter depth will be found 2 miles off shore. In the eastern monsoon there is safe anchorage N.E. of Lawvengan Isle, in 6 or 8 fathoms, soft bottom.

Coral Bank.—Nearly 2 miles East from Third Point is a coral bank, the greater part of which is above water, and readily distinguished by its bright white colour. The direction of this bank is S.E. by E. and N.W. by W., about 3 cables in length, and from it Third Point bears W. $\frac{1}{4}$ S., the N.E. point of Lawvengan S.E. $\frac{1}{2}$ E., and the West point of Papolle N.E. by E. Between this bank and Third Point there is a channel of 4 to 9 fathoms water, and the depths increase quickly from 7 to 15 fathoms at the distance of a mile.

Lawvengan Islet, lying in the depth of Pepper Bay, E. by S. $\frac{3}{4}$ S., distant $3\frac{1}{2}$ miles from Third Point, is about three-quarters of a mile long, a N.W. $\frac{1}{2}$ W. and S.E. $\frac{1}{2}$ E. direction, a quarter of a mile broad, and is surrounded by a reef, which projects farthest at the North side, where it reaches the distance of $1\frac{1}{2}$ cable's length.

Three-quarters of a mile to the north-westward and to the westward of Lawvengan Islet are two reefs, partly dry at low water, and usually breaking. To the southward, and mid-channel between Lawvengan Isle and the shore, is a reef with only 3 ft. water upon it, between which and the island there is a narrow channel with 3 and 4 fathoms; but between it and the shore are several small coral reefs that dry at low water.

Paniang Reef is a ledge of rocks, the N.W. point of which bears W. by S. $\frac{3}{4}$ S. $1\frac{1}{2}$ mile from the N.W. point of Papolle Island. It is a mile long, in a N.N.W. and opposite direction, and half a mile in breadth, and the shoalest water upon it is 3 ft., and on some parts from 1 to 3 fathoms are found. This ledge is very dangerous, as the sea does not often break upon it, and it cannot be approached by the lead, the depths very near it being 6 and 7 fathoms; but by keeping a good lookout it may be distinguished by the light colour of the water, and its brown patches.

Between Paniang Reef and Papolle Island, the soundings are 7 to 4 fathoms, mud bottom; and on the East and S.E. sides of the reef 5 to 3 fathoms, towards the shore.

Papolle Island, small, round, and about half a mile in diameter, lies within a mile of the shore, with which it is connected by a reef; there is, however, a channel of $1\frac{1}{2}$ fathom through this reef, fit for the navigation of proas.

Tyringin or Tjeringie Reef, lying 5 miles North of Papolle Islet, and two-thirds of a mile off the shore near Tjeringie, is of coral, partly above water, and generally breaks. It is half a mile in extent N.N.E. and S.S.W., and very steep, having close outside of it 6 fathoms water, increasing to 9, 12, and 15 fathoms at 2 miles distance from the shore.

Between this reef and a small rock near the shore there is a channel of 3 fathoms, often used by large proas.

Anchorage.—Supplies may be obtained at Tjeringie, and a convenient anchorage will be found to the northward of Tjeringie Reef, at $1\frac{1}{2}$ mile off shore, with Papolle bearing S. by E., and the flagstaff at Tjeringie E. by S. or E.S.E., in 7 fathoms, clay bottom.

The **COAST** from Tjeringie runs N. by E. and N.N.E., and may be approached, with due attention to the lead, to 2 miles distance, in 18 fathoms, without danger of striking upon the Catharine Reef. The general appearance of the coast is low, though occasionally interrupted by hills and conspicuous rocky points.

Catharine Bank, lying about 4 miles to the southward of Fourth Point,

and half a mile off shore, is a quarter of a cable in extent, N. by E. and S. by W., with some rocky points even with the water's edge, and in other places only half a fathom water; with a little breeze the sea breaks upon it. From its outer edge Fourth Point bears N.N.E. $\frac{1}{2}$ E., Krakatoa Peak West a little southerly, and the West point of Thwart-the-way N. $\frac{1}{2}$ W.

Outside this reef are 4 fathoms water, increasing to 10, 14, and 18 fathoms, the latter depth being within a mile of it; the channel between it and the shore has $3\frac{3}{4}$ and 4 fathoms, and is used by proas.

Directions.—With a steady and commanding breeze a ship may steer N.N.E. from Third Point for Thwart-the-way, which is distant 30 miles; or a N.N.E. $\frac{1}{2}$ E. course for 26 miles, which will place her 2 or 3 miles off Fourth Point, when she may either proceed on her voyage or haul in for Anjer Road. Very often, however, the winds become light and variable there, and she may be compelled to anchor, in which case these courses would lead too far from the land. For these reasons it is better to keep on the Java shore, avoiding, however, the dangers in Pepper Bay, which should not be approached under a depth of 14 fathoms.

When the current is running to the westward in the middle of Sunda Strait, an eddy will be experienced near the land, besides which, a vessel may be anchored anywhere along the shore, except near Fourth Point, where the bottom begins to get foul and rocky. When beating up, therefore, with a contrary wind, it is advisable not to keep too far out in the offing, in order to make the eddy available, and not to lose favourable anchoring ground, and perhaps be compelled to anchor in deep water.

Along the coast to the northward of Tjeringie there are numerous villages (campongs), the inhabitants of which frequently come on board ship with fruit, fowls, eggs, &c., and often with turtle.

FOURTH POINT (*Vierde Punt*), or *Tanjong Tykorang*, bearing N.N.E. $\frac{3}{4}$ E., distant nearly 27 miles from Third Point, is low, but easily discerned from its numerous cocoa-nut trees. From it the nearest point of Thwart-the-way bears N.N.W. $5\frac{1}{4}$ miles, and Krakatoa Peak W. by S. nearly 27 miles.

LIGHT.—In 1865 a stone lighthouse was erected on Fourth Point, near to the old tower. It is coloured white, 35 feet high, and exhibits, at 151 feet above the level of the sea, a *fixed* white light of the second order, visible in clear weather at 20 miles off. A second light, visible 8 miles off, is shown in the direction of the *telegraph cable*, and vessels are warned not to anchor with both the lights in sight, or in the day time with the lighthouse bearing between S.E. $\frac{1}{4}$ S. and E. by S. $\frac{3}{4}$ S.

A *signal station* is attached to the lighthouse, from which signals by the Commercial Code will be answered or transmitted.

Caution should be observed in approaching or rounding Fourth Point, for a reef projects from it more than half a mile, with soundings of 20 fathoms

close-to. Outside, or to the northward, the depths increase quickly to 25 fathoms, and at 2 or 3 miles off the point to 30 fathoms. The point should not, therefore, be approached any nearer than $1\frac{1}{2}$ mile when rounding it. The telegraph cable between Fourth Point and Anjer is marked by three white *buoys*.

ANJER.—At 2 miles E.N.E. from Fourth Point is the flagstaff at Anjer, in lat. $6^{\circ} 3' 10''$ S., long. $105^{\circ} 54' 50''$ E. The town is not easily perceived in coming from the westward, being situated in a bay where the houses are scattered amongst the cocoa-nut trees, and nearly obscured by them, and by a spur of a chain of hills inland. The easternmost of these is a sharp peaked hill called Anjer Peak, directly over the town, and is on with it bearing S.S.E.

A *red light* is shown on the extremity of the western pier of the boat creek at Anjer Point. It is elevated 23 ft., and visible 4 miles off.

The Road or anchorage is N. by W. from the fort in from 12 to 19 fathoms water, soft ground. From a position in 16 fathoms, three-quarters of a mile off shore, the flagstaff of the fort bears S.S.E., Fourth Point S.W. $\frac{1}{4}$ S., the Cap N.N.E. $\frac{1}{2}$ E., and the Button N. $\frac{1}{2}$ E.; and from thence the soundings decrease uniformly to 9 and 8 fathoms at about a cable's length from the reef which fringes the shore. This is but an indifferent roadstead in the N.W. monsoon, and landing is dangerous on account of the high surf. At this season the anchorage near North Island, on the Sumatra shore might be found more convenient.

In the S.E. monsoon, ships, both outward and homeward bound, generally call here for water and refreshments, unless they are content to purchase the latter from some of the numerous native boats usually to be met with on the look out for vessels passing through the strait. Buffaloes, poultry, vegetables, and frequently hogs, sheep, and turtle are to be procured here: water may be had by applying to the shore boats.

There is a *signal station* at Anjer for communicating with passing vessels. A *telegraph cable* crosses the strait from Anjer round the West end of Thwart-the-way, close by Hog Point, and up the eastern coast of Lampong Bay, to the coaling station near Telok Betong. Vessels should avoid anchoring in its vicinity.

Light.—Two lights, each elevated 35 ft., are exhibited on the piers forming the boat creek at Anjer Point.

Caution.—Ships should approach the anchorage of Anjer Road with great caution, especially at night, paying particular attention to the lead. They should not attempt to bring up in less than 15 or 13 fathoms, or they will probably get too near the reef fronting the shore, very close to which are 8 and 7 fathoms water.

“In weighing from Anjer Road with a westerly wind and flood tide, a vessel should cast as quickly as possible with her head off shore, and shoot

well into the strait, where she will have room and time to pick her anchor up; it being dangerous to keep a ship drifting in the road while heaving it close up, in consequence of a steep rocky point to leeward, called Lenning. A large ship was recently totally lost upon it, having drifted on while getting her anchor to the bows.

“Ships have frequently found themselves in dangerous proximity to this reef from anchoring in too small a depth of water, and with no room to veer in the event of sudden and violent squalls, which, as in most tropical countries, are very common in this strait.”—*Capt. J. B. Caldbeck.*

THWART-THE-WAY (*Dwars in den weg*), or *Pulo Renjang*, lying in the middle of the narrowest part of Sunda Strait, is 450 ft. high, and easily recognized by its irregular shape. It is $2\frac{1}{4}$ miles long N.N.W. and S.S.E., and very steep all around, except at its southern extremity, where a reef projects 2 or 3 cables' lengths, on which a rock above water is visible. *Capt. J. B. Caldbeck* states that the reef projects a greater distance out than is generally supposed from the southern end of Thwart-the-way; and that at low water the sea breaks more than a mile from the island. The highest part of the island bears N. by W. $\frac{3}{4}$ W., $6\frac{1}{2}$ miles from Fourth Point, S.W. by W. $\frac{3}{4}$ W. from St. Nicholas Point, and N.E. by E. $\frac{3}{4}$ E. from Krakatoa.

The West side of the island forms a small bay, in which there is temporary anchorage in 16 or 17 fathoms pretty close to the reef, with the N.W. point bearing North to N.N.W., and the South point from E.S.E. to S.E. by E. A 5-fathom patch lies about a mile off this part of the island, with irregular depths, 10 to 26 fathoms, around it.

CHANNELS.—The channel between Thwart-the-way and Java is the most convenient for sailing vessels, owing to the depths of water being but from 20 to 30 fathoms, whereas the channel between Thwart-the-way and Sumatra has 40 to 50 fathoms. The latter channel, described hereafter, is moreover encumbered with the Stroom Rocks, in dangerous proximity to which ships are liable to be set by rapid currents, and unable, from the great depth of water, to bring up by anchoring.* The narrowest part of the channel between the rocks off the South point of Thwart-the-way and the reef off

* “With regard to the respective merits of these channels, being bound either way through the strait, the preference may be decidedly given to that between Anjer and Thwart-the-way, in consequence of the great rapidity and uncertainty of the tides in the neighbourhood of the Stroom Rocks, rendering their proximity very dangerous, and unless in a strong breeze a ship is almost unmanageable. The depth of water on the Stroom side is almost double that on the Anjer shore, except in a S.W. line from the Button to Thwart-the-way. Instances have lately been known of ships which, being drifted dangerously close to the Stroom Rocks, let go their anchors and run their cables out to the clinch; they were of course still whirled on until by a lucky chance they barely went past the rocks and no more.”—*Capt. J. B. Caldbeck. Naut. Mag., 1843.*

Point is a little more than 4 miles; and the distance is the same between the S.E. end of Thwart-the-way and the Cap.

The Cap (*Brabands hoedje*), or *Pulo Ular*, is a small round-shaped island, only about a cable's length in diameter, lying N. by E. 3 miles from Anjer, and about E.S.E. 4 miles from the S.E. end of Thwart-the-way.

A shoal is said to lie between the Cap and the main land of Java, from which Fourth Point bears S.W., and the Cap N.W. by W. $\frac{1}{3}$ W.

BROUWERS SAND is a dangerous bank, lying between the Cap and Merak Island, nearly 2 miles off the Java shore. It is composed of very hard sand, and extends nearly 3 miles along the coast in a N.E. $\frac{3}{4}$ N. and opposite direction, its breadth being only 2 cables. There are three shoal patches on the bank, the least water being $1\frac{1}{2}$ fathom at low tides, and the general depths $3\frac{1}{2}$ or 4 fathoms. Its southern limit is $2\frac{1}{4}$ miles N.E. from the Cap; and its northern end forms with Merak Island a channel 2 cables wide, with depths of 18 to 10 fathoms water.

Between this bank and the shore there is a channel a mile wide, with 6 to 10 fathoms water, which increases in the direction of the Cap to 15 and 20 fathoms. But in this channel a rock called Kroenjo, which partly dries at low water, lies at $1\frac{1}{2}$ or 2 cables off shore, with the Cap bearing S.W. by W. $\frac{1}{3}$ W., the Button N.W. $\frac{1}{3}$ N., and the West point of Merak Island N. $\frac{3}{4}$ W. To avoid it, when standing in shore, the Cap should be kept inside of Fourth Point, for the Cap in line with Fourth Point leads just outside the edge of the bank.

GREAT MERAK ISLAND, or *Pulo Merak Besar*, lying N.E. $\frac{3}{4}$ N. $5\frac{1}{2}$ miles from the Cap, is of considerable height, nearly round, and about half a mile in diameter. The island is bordered by a reef, which on the N.W. side projects nearly a third of a mile.

Little Merak, or *Pulo Merak Ketchil*, lies near the shore, abreast the North end of Brouwers Sand, about half a mile to the south-eastward of Great Merak. It is connected to the main by a reef of rocks, which is just under water, and consequently cannot be passed by laden boats.

MERAK HARBOUR is between Great and Little Merak Islands and the main coast of Java. It is nearly half a mile in extent, but in mid-channel between the islands there is a rocky bank called *Tarremboe*, which partly dries at low water. The harbour may be entered by the channel on either side of this bank, as they carry from 5 to 10 fathoms water. The channel into the harbour North of Great Merak is the best, as it is more than a cable in breadth, and carries 6 to 14 fathoms. Entering by the southern channels, keep nearer to the Merak Islands than to the Tarremboe Bank; entering by the northern channel, keep Great Island shore aboard.

The anchorage with S.W. winds is East from the highest part of Great Merak, and North of Tarremboe Bank, in 6 or 11 fathoms water, soft ground. The Java shore is steep-to. Sometimes a heavy swell sets into the harbour,

for which reason it is not to be considered safe for ships in the N.W. monsoon, but small vessels will always find good shelter under Great Merak.

The **COAST** from Merak Island takes a north-easterly direction for about $4\frac{1}{2}$ miles to St. Nicholas Point. About midway between is a small islet, named Tempoza, lying close in shore. A reef fronts this coast, extending a third of a mile from it, and passing just outside Tempoza. Close to this reef are depths of 10 and 15 fathoms. The shore should not be approached nearer than half a mile, or in less than 20 or 18 fathoms water. The soundings increase regularly from the shore to 30 fathoms; at a distance of 4 miles there are 40 to 50 fathoms.

The **BUTTON** (*Toppers hoedje*) is a high and steep little island covered with trees, and about the size of the Cap, lying well out in the fairway of Sunda Strait, 5 miles to the north-eastward of Thwart-the-way. It has 34 and 30 fathoms close-to, and bears from St. Nicholas Point W. by S., distant nearly 7 miles, and from Hog Point E. $\frac{1}{4}$ N., $12\frac{1}{2}$ miles.

The *Anna* anchored, to wait a tide during the night, in 28 fathoms, E. 3° S. from the Button; and on another occasion she anchored for the night in 37 fathoms of water, with the Button bearing S.W. $\frac{1}{2}$ S.: here, however, a hard bottom was found.

ST. NICHOLAS POINT, in lat. $5^{\circ} 52' 33''$ S., long. $106^{\circ} 2' 10''$ E., is the extreme end of the high bold promontory forming the northern point of Java. Dangers extend about a third of a mile off the point, and close to them are 11 fathoms, and 32 to 35 fathoms at a distance of from 1 to 2 miles.

Directions.—When proceeding to the northward from, or being abreast of, Anjer Road, steer to pass outside the Cap and inside the Button, at any convenient distance from either, taking care not to borrow too close to Brouwers Sand in passing. When clear of that shoal and the Button, steer about N. by E. for the Two Brothers, if bound to Banka Strait; or to pass St. Nicholas Point at about 2 miles if bound to Bantam or Batavia.

THE COAST OF SUMATRA.

The western coast of Sumatra, terminating at the N.W. point of the Strait of Sunda, is described in our "Directory for the Indian Ocean." The deeply indented southern coast of this great island forms the northern side of the strait.

It is occupied by the *Lampungs*, or *Lampongs*, a distinct people from the other nations of Sumatra, resembling in this respect the people of Java on the other side of the strait, and is, like them, subject to the Dutch Government. The geologic formation is of the same character as that of the Sunda country of Java, a mass of volcanic mountains, some of which rise to great

elevation, as those of Lampong and Tanjamus, 7,500 ft. The people are, compared with the rest of the Sumatrans, rude and unpolished, though having a written language. Their country is far from fertile, and much of it incapable of being cultivated. The chief product for exportation is black pepper, next to this are rattans and dammer or resin. It was formerly the dominions of the King of Bantam. It has been surveyed by order of Admiral E. Lucas, by Lieutenants J. A. G. Rietveld and E. H. Boom, 1841. The correct Dutch orthography can scarcely be followed, as many of the names have for so many years been recognized as they will be given, that it has been thought advisable to retain them.

The South coast of Sumatra, between Flat Point on the West and Hog Point on the East, a distance of 70 miles, is indented by two large bays, named Keyser and Lampong, the shores of which are fronted by numerous islands and rocks.

FLAT POINT (*Vlakke Hoek*), in lat. $5^{\circ} 59' S.$, long. $104^{\circ} 32' 37'' E.$, is the southern extremity of Sumatra, and the north-western boundary of Sunda Strait. It is properly the western extreme of the low projecting tongue of land which separates Keyser Bay from Blimbing Bay, and the East point of which is usually, though improperly, called *Chinna Point*, its correct name being *Rada*, another point 3 miles more to the westward being Chinna Point. *Rada Point* bears East a little northerly, and is distant 9 miles from Flat Point. A small reef fringes the shore about Flat Point, but at a mile off shore are 7 to 10 fathoms.

At $2\frac{1}{2}$ or 3 miles S.W. of Flat Point there is a narrow bank, with 8, 13, and 15 fathoms water on it, about 5 miles in length, W.N.W. and E.S.E., and about a mile in breadth, partly consisting of reddish sand. The soundings outside this bank increase rapidly to 30, 40, and 50 fathoms, and inside of it there is a channel, about $1\frac{1}{2}$ mile wide, with 14 and 15 fathoms.

LITTLE FORTUNE ISLAND (*Klein Fortuin Eiland*), or *Pulo Batu Ketchil*, lies in front of Blimbing Bay, just outside Sunda Strait, N.W. by W. 9 miles from Flat Point, and about 5 miles from the main; it is low, woody, about a mile in diameter, and surrounded by a reef also a mile in extent.

BLIMBING or **Billimbing Bay** is inside Little Fortune Island, and northward of Flat Point. At its entrance ships may anchor in 7 or 8 fathoms, and find a good berth with S.E. winds, but not with those from the N.W. Small vessels will be sheltered from all winds by anchoring further inside in 3 fathoms, behind the projecting reef.

There is also anchorage off the East side of Little Fortune Island, in 9 or 10 fathoms. In some charts two reefs are placed in this bay close in shore; it is very probable they do not exist, but it will be advisable to be careful.

On the East side of this bay is a small river, but its water is brackish ; a fresh-water spring, however, may be found inside the S.W. point, from which a reef projects a quarter or half a mile to the northward.

Approaching Sunda Strait by night, the soundings will be a good guide in passing Little Fortune Island and Flat Point. At 6 miles off shore the depths are 40 and 30 fathoms, and, with a commanding breeze, ships may venture into 20 or even 15 fathoms ; but when too dark to distinguish the land, it is advisable not to shoal to less than 20 fathoms.

KEYSER or SAMANGKA BAY runs inland in a north-westerly direction about 30 miles, and is about 20 miles wide at entrance. Its western shore is steep, affords no shelter from south-easterly winds, and has 20 or 30 fathoms water within half a mile of it.

Tampang Bay, just round Rada Point, on the western side of Keyser (properly Keizers) Bay, is only an open bight, but has good anchorage ground in depths from 12 to 15 fathoms, a mile off shore. A ship will be exposed here to south-easterly winds, and will have much difficulty, on account of the rocky shore, in getting water from the shallow rivulets that discharge themselves into the bay.

The village of *Borne* is in the N.W. part of Keyser Bay, at the mouth of Samangka rivulet, the water of which is good, but boats will find it difficult to enter. The land is low, and fronting the sea marshy. The best anchorage is East, or E. by N. from the mouth of the rivulet, 1 or 1½ mile distant from the shore. Ships lie here usually without danger from south-easterly winds, which seldom throw a very high swell so far up the bay. Near *Betong Point*, the southern extremity of the bay near Borne, there is a rocky shoal which projects more than a mile in the offing, with 10 fathoms very near it.

The eastern side of Keyser Bay, North of Kalang-bayang Harbour, is not so steep as the western side, and affords good anchorage about 2 miles off, in 20 or 30 fathoms ; but it is also exposed to south-easterly winds.

KEYSER ISLAND, or *Pulo Labuan*, lying nearly in the middle of the entrance of Keyser Bay, is high and steep-to all round, and affords but one spot fit for anchorage, a very indifferent berth in the western monsoon, which is on the N.E. side in 25 to 30 fathoms, sand, and very near the shore. There is fresh water, but the high surf renders landing very troublesome. The island is inhabited, well cultivated, and produces large trees fit for masts.

Kalang-Bayang Harbour, or *Koloembyan Bay*, on the eastern side of Keyser Bay, and about East from the North point of Keyser Island, is small, but safe, and affords good shelter from all winds, with sufficient depths of water for large ships. It may be easily recognised by the high and rocky island of Eyoe, which lies about a mile outside, and can be seen 15 miles off. Half a mile north-westward of Eyoe there is another island, or rather rock, called

Pulo Klappa, with a single cocoa-nut tree upon it. There is a safe channel with 25 fathoms water between these islands.

This harbour has been said to be well adapted for a fleet in want of refreshments, as every supply may be obtained; but the Java Guide says that refreshments are very scarce. Water may be obtained from a small rivulet in the north-eastern part of the bay.

In the N.W. monsoon, enter the harbour by the western passage between *Pulo Klappa* and the North point called *Tanjong Napal*, and when the latter bears about West, or W. by S., anchor near the eastern beach in 10 fathoms, soft ground, or anywhere in the harbour, there being no hidden danger.

In the S.E. monsoon, steer in about N. by E., between *Eyoe* and *Klappa* Islands. With a commanding breeze a vessel may pass eastward of *Eyoe*, between it and *Pulo Batu Kabu* on a N.N.W. course. These channels lead close to the *Rover Rocks*, which are, however, easily avoided, and left to the eastward, as most of them are above water.

Kiloang Bay lies 5 miles to the south-eastward of *Kalang-bayang*, and also affords safe anchorage. It may be known by *Tongkalie Island*, which is visible 12 miles off, and lies off the East point of the bay, being separated from the main by a small channel only fit for boats. This bay, as well as *Kalang-bayang Harbour*, contains all sorts of wood.

Coming from the westward or southward with a leading wind, steer for *Tongkalie* till it bears East, distant 2 or 3 cables' lengths, when three groups of black rocks will be seen, the southernmost of which bears N.N.W. from *Tongkalie*, and S.W. from the others. Steer N.E. and E.N.E. past these rocks in from 30 to 20 fathoms, for the eastern side of the bay, which is very high, till *Kiloang Island* bears West, where a good anchorage may be taken in 13 fathoms between it and the beach, and sheltered from all winds. *Kiloang Island*, which is small and not very high, lies near the eastern beach of this bay, with some rocks at its northern and southern extremities, a large reef to the eastward, and a smaller one on its western side. Although the bay is spacious, yet pass close to the westward of *Tongkalie*. Everywhere else in the bay anchoring ground may be found in 16 to 18 fathoms, but accompanied by a heavy swell.

MOUNTAINS.—The land of *Sumatra*, eastward of *Kalang-bayang Harbour* and *Kiloang Bay*, is very high, consisting of the *Kalang-bayang* or *Kamantara Mountains*, 3,418 ft. high; and 3 miles farther to the northward the *Ratth Mountains*, the southernmost peak of which is 5,097 ft. above the sea. More westerly, and not far from the shore of *Keyser Bay*, the *Lampong Mountains* rise to the height of 6,560 ft., and *Joukamoe*, or *Keyser Peak*, situated 11 or 12 miles farther to the north-westward, and near the head of the bay, reaches to 7,412 ft.

Pepper Bay is on the North shore of *Lagundy Strait*, on the West side of *Tikus Point*, the S.W. point of entrance of *Lampong Bay*. It has a huge

three-cornered rock in the middle, and is very limited ; but the native proas row up behind the high western beach, where there are 18 fathoms water close in.

LAMPONG BAY, formed between Tikus Point on the West, and Rajah Bassa on the East, is very extensive, being about 20 miles wide at entrance, and stretching northward into the land nearly the same distance. At its entrance the Lagoendy Islands, hereafter described, extend 8 miles to the eastward from Tikus Point. Other islands line the western shore of the bay inside, between which and the main there are several good roads or places of shelter. In every part of the bay, from North to South, will be found from 10 fathoms, mud, to 20 fathoms, clay bottom.

If a vessel keep outside the islands on the western shore of the bay there are but *two dangers*, both of which may be easily avoided. The first is a sandbank, dry at low water, surrounded by a reef, which rises from 17 fathoms, mud, and bears E.S.E. $1\frac{1}{2}$ mile from Kalagian, and N.E. $\frac{1}{4}$ N. 2 miles from Little Pokowang. The second is a reef with 2 and $1\frac{1}{2}$ fathoms upon it, bearing S.E. $\frac{1}{2}$ S. $1\frac{1}{4}$ mile from the easternmost of the Choondong Islands.

Pedada Bay, the first bight to the northward of Tikoes Point, on the western side of Lampong Bay, is $1\frac{1}{2}$ mile wide at entrance, and $3\frac{1}{2}$ miles deep.

When running into this bay in the direction of the southern end of the Kalang-bayang Mountains, on a W. $\frac{1}{2}$ N. course, the soundings will be 20 to 15 fathoms, clay and mud, and the three small islands of Pedada, Penarian, and Lalanga will be seen. *Pedada* is the easternmost and highest, but N. by E. from it half a mile there are two detached reefs, usually covered with breakers ; and a third reef N.E., which bears W. by S. from the North point of the bay. Keeping this last reef on the starboard bow, and the other two on the port bow, will lead to an anchorage in 15 fathoms water, very near the village of Pedada, bearing W. $\frac{1}{2}$ N. This village is to the westward of *Lalanga Island*, and stands on a clear fresh-water stream. The high rocky islet of *Klappa* is connected with Pedada Point by three groups of rocks above water, leaving, however, between each of them a passage for small craft. North-eastward of Klappa lie also three patches of rock, with 17 and 16 fathoms, clay, between them ; to avoid them, keep Lalanga Island to the westward of North. This small island is also high, with a reef extending about 2 cables from its N.E. point.

Poono Bay, lying 4 or 5 miles to the northward of Pedada Bay, is 2 miles wide and 3 miles deep, with 10 to 7 fathoms water. Across the entrance lies *Pokowang*, the largest island in Lampong Bay except Lagoendy, with a peak on its northern side, and to the eastward a small island, to which it is connected by a reef.

Poono Bay may be approached on either side of Pokowang. When

taking the northern passage, which is preferable, the white coral reefs are seen at some distance, but avoid the reef projecting 3 cables' lengths N.E. from the island, with 15 fathoms close to it. There is also a detached coral reef close to the N.W. point of Pokowang, which must be kept on the port side, while the four coral reefs, lying mid-channel N.W. and W.N.W., from the centre of Pokowang, should be kept on the starboard side.

Rateh Bay comes next to Poondo Bay. It is 3 miles in extent each way, with 16 to 18 fathoms, mud bottom, and at the entrance lies Kalagian Island, which is high, and has a small island separated from its South point by a boat channel of 3 to 8 fathoms water.

Not quite a mile S. by E. from Kalagian lies a *coral reef*, showing at low water like a black speck, and bearing W. by N. $\frac{3}{4}$ N. $1\frac{1}{2}$ mile from the above-mentioned coral reefs, between which is 17 and 14 fathoms, mud.

Ratteh Bay may be approached on either side of Kalagian; and the two reefs, which dry at low water, to the westward of the island, may be discerned at some distance, and consequently easily avoided.

Mahitam Island lies off the North point of Ratteh Bay, with which it is connected by a reef. There is good anchorage on its North side, in 13 fathoms, mud bottom.

Tagal Island, flat-topped and conspicuous, bears N.E. $1\frac{3}{4}$ mile from Mahitam, and about W. by S., $3\frac{1}{2}$ miles from the Choondong Islands, and is visible throughout the whole of Lampong Bay. When coming in from the eastward, a vessel may steer for it on a N.W. bearing, and pass it in 15 fathoms; if entering from the southward it is a mark for Lagoendy Strait.

In the bay north-westward of Tagal there are the two villages, *Ringong* and *Oerong*; and near the South point of the bay is the small island Laho, connected to the shore by a reef, and throwing out another to the northward.

Tankel Island is 3 miles North of Tagal. The North side is low, but the South side high.

The *Head of Lampong Bay*, northward of Tankel, narrows, so as to be scarcely 4 miles wide, but it contains four islands:—*Pomogotang*, $1\frac{1}{2}$ mile North from Tankel, is all sand, but has some trees, and is surrounded by a large reef. *Little Pomogotang* is a bank without trees, 1 mile W.N.W. from the former, and also begirt by a broad reef. *Koeber Island*, lying S.W. from Pomogotang, is separated from the main by a 5-fathom channel, and a reef runs out 2 cables' lengths from its eastern side. A black beacon *buoy* marks the eastern side of a reef; it lies N. 39° E. from Koeber Island, and South from a white beacon buoy, with the harbour office at the mouth of the river, N. 43° W., and the foot of Mount Apen N. 7° E. The fourth is the low island of *Passarang*, in Telok Betong Road, S.E. from the river. Besides these islands there are some coral reefs.

Telok Betong, situated in the north-western part of the bight, is the chief town of Lampong Bay. Its population consists of natives of Sumatra and

Bugis, with a Regent from the Dutch Government as their chief. They trade with the Javanese in Lampong tobacco, which is highly esteemed. A *telegraph cable* connects Telok Betong with Anjer. The Dutch Government have a coal store at or near here, but fresh provisions are reported as difficult to be obtained. A *red light*, elevated 39 ft., is shown from an iron column.

The eastern side of Lampong Bay, between Telok Betong and the Choondong Isles, is high, free from danger, and may be approached in safety to 14 and 15 fathoms, close to. From the Choondong Islands to Rajah Bassa the coast, at 2 or 3 cables' lengths distance, is fronted by a line of rocks.

The Choondong Islands are three in number, of which the northernmost is a steep rock, and the two others are larger, but not so high. A detached 6-ft. reef is reported $1\frac{1}{2}$ cable E. of the southernmost of the Choondong Isles.

To the northward of the Tiega Islets the Sumatra coast forms a deep curve, called *Blantong* or *Lobogh Bay*, with 4 or 5 fathoms, mud, and a salt-water river. The points of the bay on each side are covered with rocks and a high surf.

Tiga or *Tiega Islets*, three rocky islets lying 3 miles off shore, appear as one when coming from the eastward, and do not begin to open until Rajah Bassa Road is approached.

Rajah Bassa Road.—The land forming the south-eastern part of Lampong Bay is high, and rises to two conspicuous peaks, 3 or 4 miles inland, named *Rajah Bassa Mountains*. The height of the N.W. peak is 4,398 ft., and that of the S.E. peak 4,093 ft. Rajah Bassa Road, which lies directly off the high land, was frequently visited by the China ships, it being an excellent place to obtain good water with facility, and other refreshments, although Anjer is still better.

There are three villages on the shore of Rajah Bassa Road. The first is *Kalinda*, bearing N.N.E. $\frac{3}{4}$ E. from the Tega Islets, and having in front of the white sandy beach some large rocks above water, between which are the openings that make it easy to land. The anchorage is in 7 to 10 fathoms, mud, West from the village, and a mile off shore. The second village is *Tyanti*, which lies E.N.E. from the largest Tiga Islet, and abreast that part of the road where is the best anchorage, and the best watering places. The third village, called *Rajah Bassa*, is just to the northward of Cocoa-nut Point, and about East from the Tega Islets; it is the largest one of the three, but the watering there is very difficult, at least much more so than at Tyanti, and the landing dangerous with westerly winds.

KLAPPA, or *Cocoa-nut Point*, or *Rajah Bassa Point*, is low, covered with cocoa-nut trees, and bears N.W. by W. nearly 8 miles from Hog Point, and E. by S. $\frac{1}{4}$ S. from the Tiga Islets. Between Cocoa-nut and Hog Points the coast curves in to the north-eastward 2 miles, and at the bottom of this bight are the two small *Bight Islands*, surrounded by reefs.

About $1\frac{1}{2}$ mile north-westward of Hog Point, and about $1\frac{1}{4}$ mile off shore,

is the *Tims Klip* or *Collier Rock*, 6 or 7 ft. above water, and 56 ft. in circuit. It is fringed by a reef, which on the N.E. side projects about 50 ft. Another rock above water lies about a cable's length westward of Hog Point, with deep water all around it.

The **LAGUNDY** or **LAGOENDY GROUP**, lying in the S.W. part of the entrance to Lampong Bay, consists of seven islands, viz., Lagoendy, Round, Saka, Soengal, Tims, Sussarat, and Mangoman. They are uninhabited, but produce good timber, deer, and wild hogs. Along the southern shores of the first four islands the sea in the western monsoon is very violent.

Lagoendy, the largest island of the group, is nearly 5 miles in length, E.N.E. and W.S.W., and close to the southward of its West point are two high, round-shaped rocks, covered with verdure, N.E. $\frac{1}{2}$ E. and S.W. $\frac{1}{2}$ W. from each other, with a boat channel between them. On the S.E. side of Lagoendy there is another rock or islet of the same character.

On the North side of Lagoendy there is a small but safe bay, *Nangga Harbour*, with depths of 15 to 7 fathoms. In the middle of the entrance is the small island *Patappan*, behind which a ship may find good shelter from wind and sea. There is room for ten or twelve ships, and fresh water is found on Lagoendy, S.E. from Patappan.

Mangoman Island, lying a little outside Nangga Harbour, has 15 to 22 fathoms, clay, all round it, except on its eastern side, where there are only 10 to 15 fathoms. When coming from the eastward or northward, a mistake may occur between this island and Patappan, but the latter is lower and smaller than Mangoman.

LAGOENDY STRAIT, between Tikoes Point and the Lagoendy Islands, is 2 miles wide, and may be recommended to ships working out of Lampong Bay in the N.W. monsoon. About mid-channel is the high island of *Sussarat*, with 10 fathoms, sand, close-to, and 30 fathoms farther off. Near its West point there are some rocks, but they are high above water. Although this island is in the middle of the channel, yet in a calm ships need not be alarmed by the current which seems to set towards it. The passages on either side of Sussarat are equally good.

A *Coral Reef*, carrying only 2 fathoms water, and having 13 fathoms around it, lies northward of Mangoman Island, and from its N.E. side the highest point of Sussarat bears S.W. by W. $\frac{1}{4}$ W.; the West point of Lagoendy S.W. $\frac{1}{4}$ S.; the North point S.E. $\frac{1}{4}$ E.; and the middle of Mangoman S. $\frac{1}{2}$ E. The reef is about 75 yards long, and cannot be distinguished by discoloured water.

A rock awash, which breaks in moderate weather, has been discovered in Lagoendy Strait, S. 24° E. from Tanjong Blantong (?).—*Naut. Mag.*, June, 1877, pp. 622-3.

Round Island lies off the East end of Lagoendy, its length being about $2\frac{1}{2}$ miles, N.W. and S.E., and its breadth nearly a mile. *Saka* lies about

one-third of a mile off the S.W. point of Round Island; and *Soengal* about the same distance off the S.E. point.

The passage between Lagoendy and Round Island cannot be recommended, nor that between Round Island and *Soengal*, for although the water is everywhere deep, the ground is foul and the current strong.

Tims Island, lying 3 miles eastward of *Soengal*, is very small and low, consists chiefly of red clay, and is surrounded by a broad reef with heavy breakers; but the channels on either side of it are quite clear.

KRAKATOA ISLAND (or *Krakatou*). lying in the middle of Sunda Strait, is about 5 miles in extent N.N.W. and S.S.E., and 3 miles broad. Its fine conical peak, rising boldly up to the height of 2,623 ft., may be seen at a considerable distance, and serves as a fairway mark for ships entering the strait from the westward. It is in lat. $6^{\circ} 9\frac{1}{2}'$ S., long. $105^{\circ} 27' 20''$ E. A range of high land runs from the peak in a northerly direction for $1\frac{1}{4}$ mile, when it turns to the north-westward, and, gradually diminishing in height, disappears at the N.W. point of the island; the outline of the range is marked by several prominences or peaks. The North coast of the island consists of rocky hills, without any vegetation whatever. The West and South coasts also consist of a steep and rocky shore, and it is only on the eastern coast that there is any level land.

There is a small spring of fresh water on the N.E. side of Krakatoa, opposite the South end of Lang Island, but it can only be approached by boats at high water, and ships should not depend upon watering there. A short distance to southward is a hot spring, in which the thermometer rose to 154° .

A bank of soft mud extends from the East side of Krakatoa and Lang Island about 3 miles, with the peak bearing W.S.W. to S.W. by W., affording excellent shelter from westerly gales, by anchoring in from 20 to 23 fathoms about $1\frac{1}{2}$ or $2\frac{1}{2}$ miles off shore. The peak bearing S.W. by W. is the best berth; but a ship should not anchor with the North end of the island to the southward of West, or she will be exposed to a heavy sea rolling in from the westward between Krakatoa and Pulo Bezee, during a westerly gale.

A submerged rock, hereafter described, is marked on the chart nearly East from the peak of Krakatoa, and a quarter of a mile off shore.

On the 21st February, 1829, the Russian corvette *Moller*, commanded by Captain Lütke, although only drawing 14 ft., touched on a coral patch, said to lie $1\frac{1}{4}$ mile from the nearest point of Krakatoa, and S.E. from the isle lying off its N.E. point; but the description of its position, being rather ambiguous, is not satisfactory.

Verlaten (or *Forsaken Island*), 2 miles long, and half a mile broad, lies close off the N.W. end of Krakatoa, from which it is separated by a narrow channel with numerous reefs, which make it dangerous for boats to pass through. A white rock 60 ft. high, and another rock 80 ft. high, lie about

three-quarters of a mile off its S.W. end; and about a mile East of that end of the island, between it and Krakatoa, is a rock or islet, with a rock awash a short distance to the southward of it.

Lang Island, about $1\frac{3}{4}$ mile long North and South, and about half a mile broad, is separated from the N.E. side of Krakatoa by a channel barely 2 cables wide at its narrowest part. A reef stretches out from its N.W. side nearly half a mile, and encircles its North and East sides at an average distance of half a mile, terminating off its South point. The West side of the island is bold and cliffy, with deep water close to. The *Polish Hat* (*Poolsche hoed*) is a round islet, lying off the West side of Lang Island, between it and Krakatoa; a reef projects about half a cable's length from its N.E. side.

The Channel between Lang Island and Krakatoa is from one-half to one-quarter of a mile wide. The shore of Krakatoa, forming the West side of the channel, is fringed with a reef extending about a cable's length from it, except at the point nearest Lang Island, where it projects only about a quarter of a cable. The soundings in the channel are deep, 30 and 28 fathoms, but they are very irregular, decreasing towards the Polish Hat from the southward.

A *shoal* lies a mile S.S.E. from the South point of Lang Island, and about a quarter of a mile from the shore of Krakatoa. It extends about $1\frac{1}{2}$ cable in the direction of the channel, and has a rock which is sometimes awash, and others just under water, upon it. The West extreme of Lang Island in line with the East extreme of Krakatoa leads between this shoal and the reef extending off to the S.E. point of Lang Island, although it passes very close to both.

BEZEE, or *Tamarind Island*, bearing about N. by E., nearly 12 miles from Krakatoa Peak, is nearly 3 miles in extent North and South, and $3\frac{1}{4}$ East and West. This island has also a high peak, named *Sebezee*, sharper than that of Krakatoa, and resembling a sugar-loaf, which rises abruptly to a height of 2,825 ft. from the southern extremity of the island, and slopes gently down to the northward. A reef projects about a third of a mile from the West side of the island, some rocky points of which are visible above water; and off the N.E. side there are three small islets called *Huisman*, *Little Tamarind*, and *Gorts*, all of which are surrounded by small reefs having banks between them; the islands and reefs extend a little over half a mile from the shore. Bezee Island produces a certain quantity of pepper, and is inhabited by natives belonging to the villages in Lampong Bay. The village is on the East side, opposite Little Tamarind Island.

All around this island there is good anchorage in 15 to 25 fathoms water; and at a mile from the N.E. side there is an excellent roadstead, even in S.W. gales, with 13 fathoms water.

Bezee Channel, between Krakatoa and Bezee, is 7 miles wide, and frequently used by ships working out in the N.W. monsoon, in preference to

the Great channel, because here they have regular soundings from 18 to 30 fathoms, and may anchor when convenient.

Boom Rock, lying nearly half a mile off the South point of Bezee Island, is a few feet above water.

Hindostan Rock is the only known danger in this passage. A ship of that name is said to have struck upon it in 1791, and found on its summit, which was only 6 or 8 ft. in diameter, 15 ft. water, and 10 fathoms close-to. Krakatoa Peak bore from it S. by W. $\frac{1}{3}$ W.; the West extremity of Verlaten Island S.W.; the East extreme of Lang Island S. $\frac{1}{4}$ W.; Bezee Island from N.E. to N. $\frac{1}{4}$ W.; the peak of Keyser Island W. by N.; and the Zeeklip W. $\frac{1}{2}$ N., well open to the southward of Keyser Island.

Lieutenants Rietveld and Boom tried to discover this rock, but without success, though they found a shoal with $5\frac{1}{2}$ fathoms least water, consisting of hard rock and coral, and having all around 6 to 13 fathoms, soft mud and clay, and at some distance 19 fathoms. From this shoal Krakatoa bore S. by W. $\frac{1}{3}$ W.; West extremity of Verlaten Island S.W.; South point of Zeeklip West; and the angle between the two extremes of Bezee Island was $68^{\circ} 30'$. Some of these bearings agree exactly with the former, and it is more than probable that it is the same rock; but, if not, the true Hindostan rock must be very near to this shoal, possibly a little to the north-eastward or eastward of it. To avoid the Hindostan rock or rocks, keep at least 2 miles from the South side of Bezee Island. The best mark for proceeding through this channel, is never to bring Gap Rock open to the southward of Keyser Island, W. by N. Between Hindostan Rock and Boom Rock there are 10, 16, and 20 fathoms water, rocky bottom; but between this latter rock and Bezee there are 8, 9, 13, 11, and 8 fathoms, with foul bottom. Lieut. Rietveld saw here different patches of light-coloured water, owing, apparently, to an eddy current, and although they much resemble sunken rocks, all the casts of the lead indicated 16 to 19 fathoms.

Zee-Klip (*Sea Rock*), bearing W. by S. 6 miles from Sebezee Peak, consists of three pyramidal rocks very near each other, and showing above water; the southernmost is the largest, and is often called the *Gap Rock*, on account of a cleft in it. They are visible at a considerable distance, bearing N. $\frac{1}{2}$ E. and S. $\frac{1}{2}$ W. from each other, and are connected under water by reefs, upon which the sea continually breaks. They are steep-to and inaccessible; and near them are 26 and 30 fathoms, mud and clay.

SEBUKO ISLAND (or *Seboeko*), N.N.E. a mile distant from Bezee, is not so high as the latter, and consists mostly of craggy hills. It is inhabited by natives of Rajah Bassa, who cultivate some pepper plantations. Its extent is $3\frac{1}{2}$ miles North and South, and about 3 miles East and West.

Close to the East side of Sebuko is *Beschutter Islet*, which is high on the East side, has a reef on its South side, and forms with Sebuko a small bay, with 15 to 19 fathoms water, affording good anchorage for proas. A coral

rock, lying mid-channel between the East point of Sebuko and North point of Beschutter, renders it dangerous to enter this little bay from the northward with westerly gales; but there is a good road for large vessels in 11 and 13 fathoms, 1 or $1\frac{1}{2}$ mile from Sebuko, near the East side of Beschutter.

Reefs project from the numerous points of Sebuko, and in some places they either show above water, or the sea breaks over them, but they do not seem to extend far off, except from the West point, from which a reef stretches off nearly 2 miles; it is very steep-to, but not dangerous, because the westernmost rock on it rises to a considerable height out of the water, and has a slight resemblance to Zeeklip. This rock lies W.N.W. from the South point of Sebuko; S.W. by W. $\frac{1}{2}$ W. from its N.W. point; N. $\frac{1}{3}$ E. from the West point of Bezee, and $1\frac{3}{4}$ mile from the West side of Sebuko.

The Channel between Sebuko and Bezee Islands is not quite a mile wide, with soundings from 19 to 23 fathoms, hard sandy bottom; the passage northward of Sebuko, between it and the Tega Islets, is $1\frac{1}{2}$ or 2 miles wide, and has 20 to 34 fathoms. A sandbank lies West $1\frac{1}{2}$ mile from Tiga Isles, and N. by W. from the North end of Sebuko.

HOG POINT, or Varkenshoek, *Tanjong Toka*, bearing S.E. by E. $7\frac{1}{2}$ miles from Cocoa-nut Point, is the south-eastern extreme of Sumatra, and between narrowest part of Sunda Strait, across which the Telok Betong *telegraph cable* is carried to Anjer. The point has a round hilly appearance, and is easily distinguished when approaching it from the eastward; but, coming from the westward, it has been mistaken for one of the Zutphen Islands. The soundings a mile distant from it are from 40 to 60 fathoms.

it and Fourth Point on the Java coast, which bears S.E. $\frac{1}{4}$ E. 13 miles, is the

The **ZUTPHEN ISLANDS** front the coast of Sumatra to the north-eastward of Hog Point. Four of them are large, and the remainder are very small, the whole extending N.E. and S.W. about 4 miles, and within $2\frac{1}{2}$ miles of the main. There are several shoals in the passage between them and the coast, amongst which there is said to be anchorage in some places. This passage is generally used by proas, and might be taken by large ships with a commanding breeze, there being sufficient depth of water, but great caution is recommended. The islands are steep-to on their South side, having 40 and 50 fathoms water very near them.

Kandang, the south-westernmost island of the Zutphen Group, is about a mile long N.E. and S.W., and half a mile broad, of considerable height, and covered with large trees. Off its N.W. side are two coral rocks, visible above water, and steep-to on their western sides. Near these rocks, on the N.W. side of Kandang, there is a small bay that affords a safe anchorage to proas in 11 or 12 fathoms water, close in-shore, and even large vessels would find safety there; very often it is frequented by pirates.

High and Hout Islands (*high and woody islands*), lying to the eastward of

Kandang, are of considerable height, rocky, and covered with trees. They are about half the size of Kandang, the three islands being separated by narrow channels. Between Kandang and High Island is a small islet, with some cocoa-nut trees upon it.

A reef of rocks lies 2 cables' lengths from the N.E., East, and S.E. sides of Hout Island, with 10 or 12 fathoms in the narrow gut between it and the island. The soundings eastward and south-eastward of Kandang, and High and Hout Islands are very deep, there being 40 to 50 fathoms a short distance off them.

Cocoa-nut Island, lying westward of Kandang, is small, very low, and surrounded by a reef, which is very steep-to. *The Brothers*, two small islands lying to the northward of High and Hout Islands, are low and sandy, covered with small wood, and surrounded by a narrow but steep reef, with 15 and 18 fathoms water close-to.

Remoa Island, the northernmost and largest of the Zutphen Islands, is also the highest, being elevated 300 or 400 ft. above the sea. To the N.W. there is a low neck of land, which at 2 cables' lengths from the ground begins to rise; the South end is the highest. Part of the low neck is a sandy beach, which affords a good place for boats, it being very difficult to land anywhere else. Remoa is covered with trees, large and small, as also are the other islands belonging to this group.

The South side of Remoa is fronted by a reef, partly above water, with a very narrow channel between it and the island; it is called *Boompjes Reef*, and carries some small brushwood; from its South point the N.E. point of Thwart-the-way bears S.E. $\frac{1}{2}$ E.

Fatal Islet and Reef.—Close to the N.E. point of Remoa is a high rocky islet, called Fatal, and from thence a reef projects to the North and N.W., on which is a separate coral rock, dry at low water, and all stretching off about half a mile, with depths of 11 and 12 fathoms close to them, so that the lead gives but little warning. From the northern point of this reef the North point of Fatal Island is on with the Button; and from its western edge the West point of Remoa is on the West point of Kandang Island. *Toempal Island*, lying westward of Remoa, is small, very low and woody, and surrounded by a reef, which is steep-to.

South of Toempal, and nearly in mid-channel, are two steep *coral rocks*, with 2 or 3 ft. water upon them at ordinary tides, and sometimes dry. They lie in the line of the Boompjes Reef and the N.E. point of Thwart-the-way in one, S.E. $\frac{1}{2}$ E. A little further South lies a small but steep coral rock, sometimes dry at low water, from which Boompjes Reef is on with the North point of the Button, E. by S.

On account of the rapid currents experienced at times near the Zutphen Islands, in the westerly monsoon, ships ought not to approach their South

and S.E. parts nearer than $1\frac{1}{2}$ or $1\frac{1}{4}$ mile, particularly in passing Hout Island, where the current runs with great velocity, sweeping to the S.W. and W.S.W. round Hog Point.

Lieut. Prins, in 1844, discovered an excellent anchorage for a dozen or more large vessels between Hog Point and the Zutphen Islands. He says, if in either of the monsoons a vessel cannot beat through, or is detained by calms or currents, she may bring Kandang Island to bear N.E., and Sindo Island North, and to the westward of that line she may choose her berth in from 30 to 5 fathoms, sand; and from thence the land wind will enable her on the following morning to pursue her voyage. Moreover, just to the westward of Sindo there is a small river, with good water, near Pagatan village.

Vessels are strongly advised not to try the intricate and dangerous passage inside the Zutphen Islands, especially as there is no reliable chart of it yet published.

The Channel between Thwart-the-way and the Zutphen Islands is but $3\frac{1}{2}$ miles wide, and encumbered with two dangers, viz.: the Stroom Rocks off Thwart-the-way, and the Winsor Rock off the Button. Owing to the great depth of water in it, 40 to 50 fathoms, it is not so convenient as the channel between Thwart-the-way and Java, where the depths being only 20 to 30 fathoms, much greater facility is afforded for anchoring in calms. The channel between Thwart-the-way and Sumatra is much frequented in the westerly monsoon by ships bound to the westward.

STROOM ROCKS, lying N.N.W. $\frac{1}{3}$ W., $1\frac{1}{2}$ mile distant from the West point of Thwart-the-way, are a group of three or four rocks very near each other, with some of their tops visible above the sea at high water, and then only discernible in fine weather at a short distance; at other times they may be seen at a considerable distance by the breakers on the reef which connects them under water. They are steep-to, having 40 and 50 fathoms very near them.

The currents which meet about here from the North and East are very strong, and with the opposite wind there is, near these rocks, such a boiling and eddying of the water all around, that it almost appears as if they are connected to Thwart-the-way, the light-coloured patches between them appearing like rocks under water.

Winsor Rock, on which the American ship *Claudius*, Capt. Winsor, struck in May, 1837, was examined by Lieut. B. G. Escher, D.R.N. From it the middle of the Button bears S.E. by E. $\frac{2}{3}$ E., distant $1\frac{1}{2}$ mile; the S.E. point of Thwart-the-way, S.S.W. $\frac{1}{2}$ W.; its N.W. point, S.W. $\frac{2}{3}$ W.; and the South point of the southernmost Zutphen Island is just in one with the northernmost visible point of Bezee Island. The least water on it is 16 ft., the depths increasing suddenly in every direction. Other rocks were seen in the eddy on the lee side of the rock.

The COAST of SUMATRA from the Zutphen Islands runs N.N.E. $\frac{1}{2}$ E. for the distance of 3 miles to a point, not named on the charts, where it trends away to the northward. This part of the coast is fronted by rocks.

Pulo Logok is a small but very high island, lying 1 mile North of the above-mentioned point, and 4 miles N. by E. from the Zutphen Islands; the coast near it is rocky and steep. Lieut. Kolff found there 15 and 20 fathoms hard sand; but further to the southward towards the steep point near the Zutphen Islands, a mud bank projects from the shore; the lead is there a sure guide, for the bottom in 9 and 10 fathoms is hard, while in 7 and 6 fathoms it becomes soft.

The Sisters (*De Gezusters*) are three small islands, lying about N. by E. 3 to $4\frac{1}{2}$ miles from Logok Island. S.E. nearly a mile from them is a small reef with only 2 fathoms water, on which a ship was aground, with North Island bearing N. $\frac{1}{4}$ E., and the middle of the Sisters W.N.W. Another in the same predicament had the East point of North Island N. by E., and the outermost Sister N. by W. $\frac{1}{4}$ W. to N.W. It is, therefore, advisable to give the Sisters a berth of 2 miles, where irregular soundings of 16, 12, and 8 fathoms will be found.

North Island, in lat. $5^{\circ} 40\frac{1}{2}'$ S., long. $105^{\circ} 50'$ W., is small, bushy, and a full mile distant from the coast of Sumatra. There is a small islet, called *Sina*, at its southern extremity; and extending to the S.E. of it is a shoal of $3\frac{1}{2}$ fathoms water. The island therefore requires a berth of at least $1\frac{1}{2}$ mile; its North and S.W. sides are steep-to.

Lieut. Riddle, R.N.R., recommends North Island as a suitable stopping-place during the westerly monsoon. He anchored his vessel in 13 fathoms, with North Island bearing N. by E. 2 miles distant, and found a deep ship channel between the island and the main; but a spit, steep-to, extends 100 or 200 ft. from the N.W. end of the island. Between *Sina* Island and North Island is a narrow and deep channel, bounded on either side by coral reefs. The natives of North Island were friendly, and showed where the best water could be obtained: **this was easily shipped**, while at the same time at Anjer the surf was too violent to allow boats to come off with water.

Between North Island and the Sisters the coast bends in a little, and is edged by a mud bank; so that 2 miles from the shore will be found good soft ground for anchoring, in 8 to 12 fathoms, with North Island bearing N. by E. Small vessels will find good anchorage between the Sisters and the main, in 2 or 3 fathoms water. Abreast of the Sisters there is a fresh water spring, but Lieut. Kolff found its contents detrimental to the health of his crew, although it was clear, and free from any unpleasant taste.

The Winds experienced in the Strait of Sunda have been briefly described on page 14.

The Currents are also described on page 27.

DIRECTIONS.—The brief instructions for passing along either coast of the

strait, before given, will be sufficient for passing it with a fair wind. The following is for the return voyage.

WORKING OUT OF THE STRAIT IN THE NORTH-WEST MONSOON.—The best way is to pass between the Zutphen Islands and the Stroom Rock, and give the Zutphen a berth of at least $1\frac{1}{4}$ or $1\frac{1}{2}$ mile on their eastern side, and beat up by short tacks along the coast of Sumatra between them and Hog Point. Afterwards, passing either North or South of the Tega Islets, as the strong currents and hard squalls may allow, try to get westing in Lampong Bay, to the northward of Tims Island, and to pass between it and Soengal, or through Lagoendy Strait. In this manner a ship will make a quick passage through the strait, if the wind be not too variable, besides having the advantage of anchoring behind Sebuko Island, or in Lampong Bay, if the currents or winds are too strong.

There are, however on record many instances of vessels having beaten out of the strait along the coast of Java, during the western monsoon, with more ease and celerity than could have been effected by stretching into Lampong Bay, in consequence of the westerly current having at those times developed its chief strength along the former side of the strait.

It has been generally supposed that the currents at both ends of Java are regulated by the monsoons; but, according to Captain M. H. Jansen, of the Dutch Royal Navy, who has had great experience in the Indian Archipelago, it appears that most part of the year a westerly current sets out of Sunda Strait. It is much to be wished that this important element in Indian navigation should no longer be left a matter of doubtful opinion.

Some remarks on this subject will be found on page 54.

CHAPTER V.

EAST COAST OF SUMATRA AND BANKA STRAIT.

The **EAST COAST** of **SUMATRA**, between Sunda and Banka Straits, has never been regularly surveyed. The coast is generally low, and covered with wood to the water's edge, and does not therefore present much variation in aspect. It is fronted by some very extensive shoal banks, which in some places project 14 or 15 miles from the shore, but their exact boundaries are uncertain.

The **Winds** of the Java Sea are described on pages 14—16 *ante*.

The **Currents** in the Java Sea are for the most part influenced by the prevailing monsoon. They incline to the northward or southward, according to the influence of the currents of the straits of Sunda, Banka, and Gaspar; for during the western monsoon they run to the eastward, or more southerly according to the set of these which come from the straits; and in the eastern monsoon they run to the westward or more northerly from a similar cause. Through a succession of tides which were observed, chiefly during the eastern monsoon, it was found that those which followed the direction of the monsoon were stronger and of longer duration, so that a daily allowance from 8 to 12 miles may be made in the eastern monsoon, and from 20 to 24 miles in the western monsoon.

The **COAST** trends from abreast North Island with a slight curve inland, nearly North for 13 miles, to a point at which is the entrance of a small river named *Nihoung*. Two other rivers, the Sakampang and the Niale, also appear on the chart of this part of the coast. From the Nihoung River, the coast line runs nearly straight, N. by W. for another 13 miles, where it forms a small bay, and from thence it assumes for a distance of 20 miles a rather irregular outline, in a general direction about N. by E. $\frac{3}{4}$ E. to Tanjong Supong.

Mount Imbong, in lat. $5^{\circ} 20\frac{1}{2}'$ S., generally described as, and sometimes named, *Knob Hill*, is the most prominent hill on the coast near the Brothers,

but the latter name tends to mislead. It is of low elevation, of very gradual ascent, and clothed with trees. There is a hill to the N.W. of it, of hummock form.

SHAHBUNDAR BANK and SHOALS.—Abreast of Mount Imbong and of Tanjong Supong, the bank fronting the Sumatra shore projects about a mile only; but between these points it stretches 10 miles in the direction of the Two Brothers; the channel between the bank and those islands being about 6 or 7 miles wide. Upon the outer edge of the bank are several shoal patches, upon one of which the Dutch ship *Shahbundar* narrowly escaped destruction. As the depths decrease gradually towards this bank, the lead, if attended to, will indicate its proximity.

From Tanjong Supong to a point $1\frac{1}{2}$ mile north-eastward of the river named *Kali Saputi*, the bearing is North a little easterly, and the distance 13 miles, the coast between forming a bight $3\frac{1}{2}$ miles deep. From thence the coast line runs N. $\frac{1}{2}$ W. for 11 miles, and then a little more westerly for 11 miles further, to the large river *Kali Tulang Bawang* or *Toelang*. The bank, fronting the coast between Tanjong Supong and the entrance of the *Kali Saputi*, extends a little more than half a mile from the shore. The *Kali Saputi*, the mouth of which is in $4^{\circ} 44' S.$, may be approached as near as 3 or 2 miles out.

Tulang Bank.—Northward of the *Kali Saputi*, the extensive hard sand-bank of *Tulang* projects as far as 14 miles from the shore; but its South side, bending in to the northward, forms a kind of bay.

Kali Tulang Bawang.—The mouth of this river, in $4^{\circ} 21' S.$, may be closely approached. Near its entrance there is a small village; and three days' journey up the river, according to the natives, is a town called *Mangala*, where the Rajah resides. Pirates sometimes hide themselves there.

The *Coast* from the *Kali Tulang Bawang* to *Tree Island*, 37 miles to the North, curves inland 3 or 4 miles, and about the middle of it is the mouth of the *River Masudyi*. *Tree Island* is in about lat. $3^{\circ} 41' S.$, and close to a point of land, to which it is joined at low water. From thence the coast curves round to a point N. by E., distant 17 miles; from which *Lucipara Point*, at the entrance of *Banka Strait*, bears about N.E. by N., distant 15 miles, the coast between forming a bight 3 miles deep.

Between the *Toelang* and the *Mesudji Rivers* the bank extends from the shore about 3 miles only, but a little northward of the latter it again projects to the distance of 14 or 15 miles; from thence it edges away towards the coast in a N. by W. direction to about 7 miles northward of *Tree Island*, where it approaches the shore within 3 miles; it then runs N.E. for 16 or 17 miles, where its edge is 11 miles distant from the land; here it falls back again towards the coast, and takes a northerly direction to *Lucipara Point*, from which it projects but 2 miles. On this bank between the *Mesudji*

River and Lucipara Point, are many *dangerous*, and occasionally dry patches.

Some of the dangers supposed to exist between the Thousand Islands and the Sumatra shore, known as the Dolphin, Antelope, Banterer, and Paulowna, were searched for in vain by Commander C. Bullock in H.M.S. *Serpent* (1865), and expunged from the chart. The position of the Lynn Bank, as well as that of the Coventry Reef, both of which uncover at low water, were accurately determined. The positions of several other dangers in this route were also rectified, but as no complete survey has been made, vessels navigating this locality are recommended to proceed with caution.

Jason Rock, searched for in vain by Commander Buckle in 1865, was found about 2 miles out from its original position in 1870 by the master of the English ship *Tewkesbury*. It is described as 40 ft. in diameter, with 12 ft. least water and 10 fathoms around it. The Netherlands Government steamer *Borneo* afterwards examined it, giving the following bearings:—North Watcher, N. 40° E.; Pulo Doea, S. 89° E.; and W. Island or Pulo Pablokan, S. 62° E.

Helens Rock.—The barque *Helens*, Captain Inkster, on a voyage from Bangkok to Melbourne, struck on a rock 6 miles E.N.E. of the position assigned to Jason Rock. The lead was immediately hove, and got 5½ fathoms in starboard gangway, and suddenly deepened to 10 and 15 fathoms. The bearing of several islands were as follows:—North Watcher, N. by E. ¾ E.; West end of North Island, just open to the westward of Doea Island; Rangat, S.E. by S.; Peblakan, S. ¼ E.

WEST ISLAND, or Pulo Peblaken, in lat. 5° 28½' S., long. 106° 23' E., is a quarter of a mile in length, and low, but the trees on it may be seen 13 or 14 miles from a vessel's deck. It is steep to on all sides at half a cable distant, except round its N.E. sandy point, off which a coral reef extends a quarter of a mile.

COVENTRY REEF, of coral, dries at low water, and was seen always to break in the calmest weather. The shoalest part is S.S.W. 1 mile from West Island, and is about a cable in extent, but it appeared to shelve off to the S.W. for a quarter of a mile, which would agree with the account given at the time of its discovery by the *Caroline Coventry*, in 1858. It is probably the same as that stated to have been seen by the *Anna Paulowna*. Pulo Doea kept open West of West Island will clear it to the westward; and Pulo Gosong Rangat in line with any part of North Island will clear it to the eastward.

NORTH ISLAND and **PULO DOEA**, the two north-westernmost of the Thousand Islands, stand out very conspicuously from the group. They lie respectively N.E. by E. ¼ E. 6¾ miles, and N.E. ½ E. 6 miles from West Island. In the channel 1 mile wide between them, Mr. Ross, proprietor

of the Keeling Islands, reported a detached reef, which was seen breaking from the mast-head of the *Serpent*. It lies nearer to North Island.

The **NORTH WATCHER** and **LIGHTHOUSE**.—The North Watcher is a narrow island, half a mile in length, the N.E. part covered with high trees, the S.W. part with low trees, visible in clear weather 18 or 20 miles off. A coral reef, with only 6 ft. water in some places, stretches about half a mile round the South end of the island, with a rock in one place above water.

The *lighthouse* on the North Watcher is a white iron tower, in lat. $5^{\circ} 13' 30''$ North, long. $106^{\circ} 26' 30''$ East. The light, first exhibited in June, 1869, is a bright light, *revolving* once in every minute, elevated 159 ft., and visible 20 miles off.

The *wreck* of the *War Eagle* was reported in the last edition of this work to lie S.W. by W. 5 miles from the S.W. point of the North Watcher, in 12 fathoms, mud bottom, her topmast heads showing above water. A blue flag was placed on the main topgallant mast-head. She is alleged to have struck on a reef 2 miles to the N.W. of the North Watcher, for which a Netherlands vessel was sent to search.

OMEGA ROCK, on which the American ship *Omega* struck in 1835, lies about E. by S., distant three-quarters of a mile from the North Watcher. According to her captain, it is composed of coral, about 150 to 200 yards in extent, N.N.E. and S.S.W., and about 60 or 70 yards broad, is steep-to, and has not more than 9 to 12 ft. on the shoalest parts. It should be given a wide berth by a vessel passing eastward of the North Watcher, from which it is separated by a narrow channel with 11 and 12 fathoms water.

EDELING SHOALS.—Between Pulo Doea and West Island lie some patches of rocky ground, named the Edeling Shoals, to avoid which it is recommended that vessels of heavy draught should not pass eastward of a line joining the two islands, unless South of Pulo Gosong Rangat, the small island surrounded by a sand beach, which lies $2\frac{3}{4}$ miles E.N.E. of West Island.

These shoals consist of two coral patches East and West of each other, and half a mile apart. On the eastern shoal there may be as little as 3 fathoms at low water; on the western, $4\frac{1}{2}$ fathoms. They lie directly between Pulo Doea and Rangat; from the latter they bear N.E. $\frac{3}{4}$ N., and N.N.E. $\frac{1}{4}$ E. $1\frac{3}{4}$ and $1\frac{1}{2}$ mile respectively. There were found two other patches of 9 fathoms, and so many indications of sandstone bottom, that vessels should approach this vicinity with caution.

E. $\frac{1}{2}$ N. from the South point of Peblakan or West Island, distant about $3\frac{1}{4}$ miles, is a reef of coral and stone; this reef extends about 1 cable North and South, and $2\frac{1}{2}$ cables East and West. There is about 4 ft. water over the shoalest part, and from 4 to 5 fathoms around the reef; from it the extremes of Rangat Island bore N.W. $\frac{1}{4}$ N. and N.W. by N. respectively.

A reef also, on which the sea breaks heavily, extends a distance of about 2 cables (by estimation) from the North and N.E. sides of Rangat Island.

The **TWO BROTHERS** are low islands, which together extend 1 mile in a N. $\frac{1}{4}$ E. direction. The North Brother is small and round, with high trees; the South Brother is 4 cables long, and two of its trees are very high and conspicuous, and may be seen in clear weather 20 to 23 miles off. Broad coral reefs surround the South Brother; round the North Island they are narrower. There is a passage between the islands 2 cables wide, carrying 7 to 5 fathoms over an apparently regular bottom. To the East of the islands is good anchorage in 9 to 10 fathoms. The South point of the South Brother is in lat. $5^{\circ} 10' 25''$ S., long. $106^{\circ} 6'$ E.*

SWALLOW ROCK.—In April, 1866, Mr. Wilds, Master Commanding H.M. surveying vessel *Swallow*, succeeded in finding the rock marked on former charts at about 8 miles S.S.W. of the Brothers. Its position is in lat. $5^{\circ} 17' 40''$ S., long. $106^{\circ} 3' 50''$ E., the South Brother bearing N. 17° E. (true), distant $7\frac{3}{4}$ miles. There are only 22 ft. water on the rock, and vessels of heavy draught should be careful to give it a wide berth, as there was neither ripple, break, or swell over it to indicate its position. At half a mile S. by W. $\frac{1}{2}$ W. from the rock, soundings in 5 fathoms were obtained on a small patch of sand and shells, with 9 fathoms between it and the rock. The depths around the rock and patch were 9 to 10 fathoms, sand.

LYNN BANK is composed of coral, a cable's length in extent, N.N.E. and S.S.W., and half a cable in breadth, carrying general depths over it of 3 to

* **DOUBTFUL DANGERS.**—The dangers said to lie in the track of vessels sailing direct between Sunda Strait and the North Watcher were searched for by the *Serpent* during several days. The hand and deep-sea leads were kept constantly going, and the sharpness of the mast-head man's eyesight was stimulated by the offer of a reward for their discovery.

A short time was also devoted to the Antelope and other shoals, reported to lie South and S.S.W. of the Brothers, but nothing was seen of them. A 9-fathom bank of fine speckled sand was found $2\frac{1}{2}$ to $3\frac{1}{4}$ miles S. $\frac{1}{2}$ E. of the South Brother. This bank, which showed of a pale green colour, visible 2 miles, would prove at times a convenient anchorage; the Brothers just touching lead over the shoalest part. There are not more than 10 fathoms between this and the Brothers.

The Dolphin Rock, on which the ship *Dolphin* was said to have been aground, was searched for by the *Serpent* during part of two days. It was described as nearly even with the water's edge, and to lie about 6 miles S.S.E. from the South end of the Two Brothers, but it does not appear ever to have been seen by any other vessel. The distance from the Brothers is precisely that of the Lynn Bank, and a change in the bearing from S.S.E. to E.S.E. (such an error being not an uncommon one), would make it the Lynn. If it were not for some indication of sandstone bottom, no credibility need be attached to the statement which records its existence.

Pruisen Bank, sometimes placed in lat. $5^{\circ} 17'$ S., long. $107^{\circ} 9'$ E., does not exist, nor does there appear to be any authority whatever to place it in that position.

4 feet, with some rocks that dry at low water. There are 8 fathoms close to the rock, deepening to 13 and 14 fathoms at a cable's distance. It is in lat. $5^{\circ} 12' S.$, long. $106^{\circ} 12' E.$, and from it the North extreme of the North Brother bears N. $68^{\circ} W.$ $6\frac{1}{2}$ miles, and the South extreme of the South Brother, N. $77^{\circ} W.$

These extremes of the islands subtend an angle of 9 degrees; if, therefore, they be made, whilst passing on (or within a point or more of) the above bearings, to subtend an angle of 8° , a vessel will pass about a mile outside the bank; and if an angle of 10° , half a mile inside it. In calm weather the shoal, from its dark colour, is extremely difficult to see until close upon it; the above method as a safeguard will then be invaluable, and may be used with confidence. A sharp lookout should always be kept, as the shoal may only be detected by a slight ripple. At night it is recommended to close the Brothers and pass them at 1 to 2 miles.

BROUWERS REEFS are two dangerous coral shoals, separated about half a mile from each other, with a dry patch of sand and coral upon each. They are together a mile in extent, and a quarter of a mile in breadth, with depths of $4\frac{3}{4}$ to 15 fathoms in the swatch between them. Hard ground stretches out from their North and South ends; at a short distance to the eastward and westward the bottom is soft, and the depths $1\frac{1}{2}$ mile eastward are generally $14\frac{1}{2}$ and 15 fathoms, regular soundings.

The *Serpent* anchored near the N.E. part of these reefs. No astronomical observations were obtained, but the position of the North reef, by careful magnetic bearings, was made to be in lat. $5^{\circ} 4\frac{3}{4}' S.$, long. $106^{\circ} 15' E.$, the North Brother bearing S. $60^{\circ} W.$, distant 10 miles, and the North Watcher S. $58^{\circ} E.$, 15 miles. This is rather nearer the Brothers than the commonly received position.

A vessel passing eastward of the Brouwers and Lynn Reefs should keep nearer to the North Watcher than to the Two Brothers. The high mountain seen to the southward is Mount Karang, South of Anjer, and in lat. $6^{\circ} 15' S.$, but from the above reef and islands the round hill over St. Nicholas Point is more often visible, and is a good landmark. The latter is named Mount Agoeng on some charts, but is called by the Dutch Gedeh, and its height is 2,100 ft.

Clifton Shoal.—The ship *Clifton*, of Bristol, is reported to have grounded, in November, 1850, on a shoal with $2\frac{1}{4}$ fathoms on it, lying N. $\frac{1}{2} W.$, $10\frac{1}{2}$ miles from the Brothers. It is now marked on the Dutch charts with 18 ft. and 24 to 27 ft. to seaward, about 9 miles to the eastward of Cape Scopong or Supong, in lat. $4^{\circ} 56' S.$, long. $106^{\circ} 3' E.$

Comara, a shoal danger of doubtful existence, with 7 fathoms close-to, placed on the Dutch Government charts about 9 leagues to the N.W. of the North Watcher, and 7 leagues from the coast of Sumatra, in lat. $4^{\circ} 49' 30'' S.$, long. $106^{\circ} 14' 30'' E.$

Ocean Mail, marked on the Dutch Government charts with 18 ft. and 7 and 8 fathoms all round, is situated 11 leagues to the eastward of the Toelang River, in lat. $4^{\circ} 18' S.$, long. $106^{\circ} 26' E.$

A patch of hard ground, about 2 miles in extent, having but $4\frac{1}{2}$ fathoms least water over it, appears on the chart in lat. $4^{\circ} 11' S.$, long. $106^{\circ} 8' E.$ The soundings around it are irregular, 6 to 11 fathoms on the East side, and 6 to 9 on the West.

Arend Bank, in lat. $3^{\circ} 45' S.$, long. $106^{\circ} 16' E.$, is 2 miles in length, and the same in breadth, consisting of fine gray sand and broken shells. It has $4\frac{1}{2}$ to 6 fathoms water over it, and is surrounded by a depth of 6 fathoms, which rapidly increases, over a soft bottom.

Boreas Bank lies E. by N. $11\frac{1}{2}$ miles distant from the Arend Bank, in lat. $3^{\circ} 44' S.$, long. $106^{\circ} 27\frac{1}{2}' E.$ It is also composed of a fine gray sand, and the least water upon it is 5 fathoms. Around it the depth increases rapidly to 10 and 13 fathoms, except on the N.W. side, where the soundings are regular for some time with 5 and 6 fathoms. Between the Arend and Boreas Banks there are irregular depths of 8 to 14 fathoms.

City of Carlisle Patch.—A ship of this name, in 1861, reported a patch of 16 ft. to exist in lat. $3^{\circ} 46' S.$, long. $106^{\circ} 20' E.$, or S.W. by W. $\frac{1}{2}$ W., $3\frac{1}{2}$ miles from the Boreas Bank. Its North end is now marked on the charts in lat. $3^{\circ} 27' S.$, long. $106^{\circ} 24\frac{1}{2}' E.$, whence the bank extends $2\frac{1}{2}$ miles to the S.E., with 5 and $4\frac{1}{2}$ fathoms.

CAUTION.—Vessels in this neighbourhood unexpectedly shoaling their water at night ought to be very careful, for many that considered themselves to be upon these banks were in fact upon those off the coast of Sumatra, near Tree Island, and consequently in great danger. These two banks consist of fine gray sand, while those near Tree Island are of coarse sand with gravel.

The depths in that part of the sea which lies between the North Watcher, Two Brothers, and Lucipara, are, except the banks of Comara, Ocean Mail, Arend and Boreas, tolerably regular from 10 to 16 fathoms; but nearer to Sumatra, about 22 or 24 miles from the coast, they become irregular, changing often, and suddenly, from 10 to 5 and 6 fathoms. Towards Lucipara, in the usual track towards Banka Strait, the water shoals gradually to 6 and $4\frac{1}{2}$ fathoms.

BANKA STRAIT.

GENERAL DESCRIPTION.—The Strait of Banka separates the islands of Banka and Sumatra, and trends with many bendings to the north-westward.

In the ensuing account of it we have followed entirely that given in the *China Sea Pilot*, as the features of this important passage have been carefully and recently surveyed by our officers.

The coast of Sumatra is very low, densely covered with wood, and offers no other variation than a few points, or rather roundings, which are only clearly distinct at short distances, and are easily mistaken for the so-called false points, which are observed immediately after rounding the real points. The shore being inundated at high flood, the distance from it is generally over estimated.

The Island of Banka is covered with hills and mountains, varying from 930 to 2,320 ft. in height; and it is remarkable that, notwithstanding their comparatively small height, their summits are generally covered with clouds, which accounts for the erroneous heights given to these hills by various authors, who have estimated them at upwards of 9,000 ft.

On the Banka Coast are prominent points, sandy beaches, and in some places deep bights, as on the Sumatra side; as a rule, wherever sand occurs casuarina trees will be found; the other trees are principally pine, teak, and aspen. Near the western point of Banka stands the capital of the colony (or residency) of that name, called Mintok, and its roadstead is much visited by the coasters that supply the Chinese miners with rice.

The whole coast of Sumatra is bordered by a mud flat, which is narrower off the points, but in some of the bights from 2 to 4 miles wide. Towards the Banka side the bottom becomes gradually harder, and even rocky. Besides the few small islets and rocks in this strait, there are the group of Nangka Islands, where vessels sometimes proceed to procure fresh water and wood. Many rivers discharge themselves into the strait, of which the principal are the Soensang and the Assing, both navigable to a great distance for vessels of heavy burden.

The entrance to Banka Strait is encumbered with numerous long and narrow banks of sand, having various depths of water over them, and deep channels between. Only two of these channels, however, are available for the ordinary purposes of navigation, as it is not possible to give any directions which would enable vessels to use the others with safety; but in the event of a vessel from accident or other cause finding herself amongst the banks, she would be enabled, by careful attention to the Admiralty Chart, to extricate herself without much difficulty.*

Until the survey of this strait by Mr. W. Stanton, assisted by Mr. J. W. Reed, Masters R.N., in H.M.S. *Saracen*, during the years 1859 and 1860,

* CAUTION—*Buoys and Beacons*.—The Captain of the French transport *La Correze* reports, in 1873, several of the beacons and buoys in Banka Strait as out of position, while others have disappeared. Captain F. G. Petersen, also, in a letter to the "Nautical Magazine" of February, 1875, says—"In the Admiralty charts are mentioned a lot of beacons and buoys, which can never be seen in reality. I saw only one buoy in the whole strait on the Fredrik Hendriks Rock. In the same charts are many conspicuous trees mentioned, which are all or most of them gone. On the points of Sumatra should be some beacons and fishing stakes, but anything of them was not to be seen.

very little was known of the banks at its entrance. The Dutch had published a chart compiled from the observations of the officers of the Dutch men-of-war employed at various times on the station, which furnished a pretty correct outline of the coasts on both sides the strait, and showed the positions of the prominent dangers in the fairway, but the soundings on it were very imperfect, and the space eastward of Lucipara, occupied by the numerous long narrow sandbanks above referred to, was almost a blank.

The ordinary route of vessels up to the time of the *Saracen's* survey, was through the Lucipara Channel, between the Island of Lucipara and the Coast of Sumatra; but the advantages which a navigable channel along the coast of Banka Island would offer to vessels passing through Banka Strait had been long felt by seamen, and Melvill Van Carnbee, in the *Java Guide*, remarks upon this want as follows:—

“The passage between Lucipara and Banka would have great advantages in entering or leaving the Strait of Banka, were it not encumbered so much with shoals and banks, the positions of which are not known correctly, and which render this passage unsafe, at least for large vessels, although Commodore Watson took the *Revenge* by night to the eastward of Lucipara, into the Strait of Banka, and had not less than $5\frac{1}{2}$ fathoms water. For vessels of light burden and beating up against the western monsoon, this eastern channel into the strait is very desirable, as it is almost impossible to make any progress against the strong and continual currents in the Lucipara passage.”

During the *Saracen's* survey, an excellent passage, now named Stanton Channel, nearly 5 miles wide in its narrowest part, and with depths varying from 7 to 20 fathoms, was found between Lucipara and Banka. Mr. Stanton gives the following reasons for preferring this channel to the old one between Lucipara and Sumatra.

“The Stanton Channel will be found to possess many advantages over that of Lucipara, for it is a mile wider, the approaches to it are marked by well-defined hills on Banka Island, and a vessel of the largest draught may pass through it at any time of tide; whereas vessels frequently get on shore in using the latter channel, for the coast of Sumatra, consisting of low muddy mangrove shores about 50 or 60 ft. in height, is unmarked by a single conspicuous object to assist the seaman to clear the mud flat bordering its entire length, and which a few miles southward of Lucipara Point extends 11 miles from the land. The island of Lucipara also is small, about half a mile in length, and no marks can be given to avoid the rocks extending a considerable distance to the southward and eastward of it.

“The water also in the Stanton Channel being much deeper than in the Lucipara, causes the banks, which are mostly of sand, to be easily recognized by the light colour of the water on them. The tide also ebbs and flows more regularly in this channel, and sets directly through it, which enables

vessels even in calms to drop through ; whereas in light winds and calms they are often set over amongst the dangerous banks whilst rounding First Point in endeavouring to get through the Lucipara Channel.

“ The wind in the N.W. monsoon blows off the Banka coast, and throughout the year land breezes generally occur during the night. A strong land wind from the N.E. has been experienced in the Stanton Channel during the S.E. monsoon, when the wind was blowing directly through the Lucipara from the S.W.

“ There is also but little variation in the depth of water between the Sumatra coast and the Lucipara shoals ; and it is stated that during the months of January, February, and March, when the N.W. monsoon is at its full strength, the southern current continues from 14 to 18 hours successively, with a velocity of 2 to $2\frac{1}{2}$ knots, which would make it almost impossible for an indifferent sailer to make any progress against it. It is also said that during the latter part of the S.E. monsoon, it frequently blows hard from the S.W., accompanied with much rain ; this would considerably retard vessels going to the southward through the Lucipara Channel, and offer a fair wind to those proceeding through the Stanton Channel.

TIDES and CURRENTS.—The tides in Banka Strait are strong, but irregular, and are greatly influenced by the monsoons. The flood-tide, entering the strait from the southward out of the sea of Java, meets another flood, about the Nangka Islands, coming from the northward out of the China Sea. The direction of the streams is entirely influenced by the windings of the strait, forming, at their meeting, whirls and eddies in the bights of the land.

In the Lucipara Channel and the southern parts of the strait, sometimes there are two, but generally only one ebb and flood in the 24 hours, the former running to the southward and the latter running to the northward. During the months of January, February, and March, at the greatest strength of the N.W. monsoon, the southern current continues often from 14 to 18 hours successively, with a velocity of from 2 to $3\frac{1}{2}$ knots ; the flood-tide is then very trifling, and sometimes not at all perceptible. On the contrary, during the S.E. monsoon, the stream of flood runs sometimes 14 to 18 hours with great velocity into the strait, and the ebb runs out during the other 10 or 8 hours with but little strength.

In the northern parts of the strait during the N.W. monsoon the southern current or flood remains longer and is stronger than the ebb, and the reverse during the eastern monsoon. The velocity of the tide is sometimes 2 or $2\frac{1}{2}$ knots, and the range from 7 to 12 ft., and sometimes more ; and in the mouth of the rivers the water during the western monsoon, from the heavy rains which prevail at that period, is much higher than during the eastern monsoon.

Between the monsoons flood and ebb succeed each other generally every

12 hours, and the one or the other is then stronger, according to the wind being northward or southward. The rise of an ordinary tide is 5 to 7 ft., and a spring tide 9 to 10 ft., and sometimes 12 ft.; but the average rise seems to be much greater during the eastern monsoon than during the western one.

Mr. Stanton observes, that on the Sumatra shore, when the monsoon is blowing strong, a constant surface current will be found setting to leeward, and extending nearly mid-channel, except between Fourth and Batakarang Points, where it is influenced by the numerous branches of the Palembang River.

On the coast of Banka, owing to the formation of the land, more regular tides will be found; therefore, ships in working should only keep on the Sumatra side between Batakarang and Fourth Points, and when Tanjong Tadah bears N.E. $\frac{3}{4}$ N., work along the Banka coast, as by so doing, and leaving either extremity of the strait at low water, they may carry a fair tide all the way through, and generally have the advantage of a land wind at night.

Throughout the strait, a difference of 12 hours in the tides was observed in the opposite monsoon. It is high water, full and change, in the S.E. monsoon about 8^h 30^m p.m., but in the N.W. monsoon high water takes place at nearly the same time in the morning.

Eddies in the Bights.—When beating through the middle of the strait during the strength of the monsoons, continuous and contrary currents are certain, and the skilful seaman will therefore find great advantage in availing himself of the eddies, as well as of the more regular changes of tide, by standing into the bights and bays in those parts of the strait where he can safely approach the land.

Inshore Tides.—In the Toboe Ali Channel, also in the bay North of the Nangka Islands, and in the passage between Brom-Brom Reef and Banka, we meet, even in the western monsoon, a pretty regular succession in the roadstead tides. It has been often observed, when passing the road of Mintok, that the vessels were lying with their heads in a contrary direction to those at anchor upon the bank outside. In that road the flood comes from the westward, and the ebb from the eastward; but near the mouth of the Assing River the contrary occurs; the flood there runs West, and the ebb East. In the bays between Eerste and Tweede Points, and again between Derde and Vierde Points, there are probably eddies of which vessels of light burden may make use, and heavier vessels may no doubt, in many places, run close enough to the shore to keep out of the influence of the currents.

Freshes.—Between Bata-karang and Fourth Points the ordinary current in Banka Strait, after heavy rains, is considerably accelerated and diverted in the direction of Kalian Point, until it nearly reaches mid-channel, by

the freshes from the many rivers in this vicinity. Vessels sometimes take advantage of this to complete water, as it is frequently quite fresh on the surface.

During the westerly monsoon, which is the rainy season, these freshes set out of the rivers on the Sumatra coast with great force, and they require to be carefully guarded against in the night. Upon one occasion, when H.M.S. *Saracen* was at anchor near Lalarie Point, her decked pinnace, moored at the boom, was fairly pressed under the water and swamped by the force of the current.

LUCIPARA ISLAND, half a mile long, W.N.W. and E.S.E., and a quarter of a mile broad, lies at the southern entrance of Banka Strait, 9 miles East of Lucipara Point, in lat. $3^{\circ} 13'$ S., long. $106^{\circ} 13'$ E., and is visible in clear weather at 14 or 15 miles. It is surrounded by a reef, which from its S.E. end extends rather more than $1\frac{1}{2}$ mile; and around this reef is a bank, with $2\frac{1}{2}$ and 3 fathoms over it, extending about $1\frac{1}{4}$ mile to the north-westward from the island, and 2 miles to the south-eastward of it.

Formerly, the trees on the S.E. end of the island rose to a sort of peak 164 feet high, but all the trees on this peak have been cut down (1875).

Rocky Patches.—Lucipara should not be approached on its S.E. side nearer than $3\frac{1}{2}$ miles, for a rocky patch with $2\frac{1}{2}$ fathoms water over it lies S.E. by E. $\frac{1}{2}$ E., distant nearly $2\frac{1}{2}$ miles from the island; and a mile to the westward of this patch is another of $2\frac{3}{4}$ fathoms.

LUCIPARA POINT, which forms the south-western limit of Banka Strait, is in lat. $3^{\circ} 13\frac{1}{2}'$ S., long. $106^{\circ} 3'$ E. It is covered with trees, the tops of the highest being 89 ft. above the level of the sea.

The **COAST** between Lucipara and First Points is formed of mangrove jungle, and was found in the survey of 1859 to extend considerably more eastward than shown in the Dutch chart. This extension has evidently taken place since their survey in 1818, and it may be attributed to the sediment from the numerous small rivers in that vicinity affording more soil for the growth of the prolific mangrove. The contour of the dry mud was obtained and sounded close-to at the springs, and it will be a guide to show any further extension.

Green Point, so called from the trees on it being of a lighter and brighter green than elsewhere, bears N. $\frac{1}{2}$ W., distant 9 miles from Lucipara Point, the coast between forming a bight about $1\frac{1}{4}$ mile deep. Between these points is a ridge of high trees standing about $1\frac{1}{2}$ mile back from the coast line, with a conspicuous tree, 153 ft. high, near their centre.

EERSTE, or First Point, bears N. $\frac{3}{4}$ W., distant $4\frac{1}{4}$ miles from Green

Point, the coast between forming a bight. The trees on it are of equal height, 60 ft., and present a level appearance.

Mud Bank.—From the southward the coast line approaches Lucipara Point in a north-easterly direction; but the 3-fathoms line, which may be considered the edge of the mud-bank which fronts the whole coast of Sumatra, from a distance of 10 or 12 miles southward of the point, approaches it nearly straight in a N. by W. direction, and passing Lucipara Point about 2 miles off, follows, with a slight curve in towards the coast, the same general direction until abreast of Green Point, from which it extends a little over a mile; it then takes a direction a little more westerly until abreast of the South part of First Point, from which it is distant three-quarters of a mile. In rounding First Point, the bank approaches nearer to it, and on its N.E. side projects only about a quarter of a mile from the shore.

From 10 or 11 miles to the southward of Lucipara Point, to within 2 miles of Green Point, the soundings decrease regularly towards the bank; but just to the southward of, and fronting Green Point, the water shoals suddenly from 6 to 3 fathoms; and, therefore, this part of the flat should never be approached into less water than 7 fathoms. Near First Point the bank is also steep-to, especially on the N.E. side, and should not be approached under 12 or 10 fathoms, those depths extending to the distance of 1 to $1\frac{1}{2}$ mile off the point.

The **COAST** from First Point takes a N.W. by W. $\frac{3}{4}$ W. direction for $6\frac{3}{4}$ miles to False First Point, having a small bight or indentation between, at about two-thirds of that distance from First Point. From False First Point it falls back S.W. by W., about 3 miles, and then forming a deep bay, gradually curves round to a slight point (False Tweede Point of the Dutch), from whence it runs pretty straight about N. $\frac{1}{2}$ W. for 7 miles to Tweede or Second Point.

VALSCHE EERST, or False First Point.—The trees upon this point are more elevated than those on First Point, being 105 ft. high. Lalarie Point, on the Banka side, bears from it N. $\frac{1}{3}$ W. nearly $7\frac{1}{2}$ miles, and Second Point N.W. $\frac{3}{4}$ N. $18\frac{1}{2}$ miles.

The mud-bank projects two-thirds of a mile from False First Point, and more than 3 miles from the shore in the depth of the bay between that point and Second Point. The bank is very steep close-to, and should not be approached under a depth of 12 fathoms near the points, nor under 10 fathoms in the bight between them.

TWEEDE, or Second Point, the trees on which are 81 ft. high, bears from First Point N.W. $\frac{1}{4}$ N. $21\frac{1}{2}$ miles, and from Lalarie Point N.W. $\frac{3}{4}$ W. 13 miles. From this point the coast falls back, and curves round until within 5 miles of Third Point, forming a bay about 5 miles deep; it then runs nearly straight to Third Point.

The mud-bank extends about two-thirds of a mile from Second Point, and being very steep-to should not be neared under a depth of 12 fathoms. Between Second and Third Points it runs very nearly straight from point to point, filling up the bay. The soundings here do not, as a general rule, shoal so suddenly as they have been described to do between the other points, but at 2 or 3 miles South of Third Point the bank curves out considerably, and is dangerous to strangers, particularly when coming from the northward, as they are likely to infer that the bank falls back in the direction of the land. The depths, too, here again begin to shoal suddenly, adding to the danger, so that it is necessary to exercise caution and give a good berth to this part of the bank.

A *Spit* or *Horn* extends $1\frac{1}{2}$ mile from the above mud flat, and then in a south-easterly direction for 2 miles, with depths from $2\frac{1}{2}$ to 3 fathoms, mud, on it, and from 4 to 5 fathoms between it and the flat; from its northern extreme Second Point bears S.S.E. 8 miles, and Parmassang Peak E. by S. $12\frac{1}{2}$ miles; therefore in passing this spit, Second Point should not be brought eastward of S. by E. $\frac{3}{4}$ E. until Parmassang Peak bears E.S.E.

Doubtful Patch.—There is said to be as little as 4 fathoms over muddy bottom, with Little Nangka Island bearing North, and the middle of Parmassang Hill East.

DERDE, or Third Point, bearing N.N.W. $\frac{3}{4}$ W. $20\frac{1}{2}$ miles from Second Point, is 78 ft. high, and has on its North side a *square beacon*, with a *white* top and ball. From this point the coast runs back about W.S.W. for 2 miles to the entrance of a small river, named Songi Kisoegean, which, from native information, is said to connect with a branch of the Palembang River; from thence it curves round in a West and W.N.W. direction for 4 or 5 miles, and then assumes a tolerably straight outline until within 3 or 4 miles of Fourth Point, which it approaches in a N.W. by W. $\frac{1}{2}$ W. direction.

The mud-bank does not extend more than half a mile off Third Point, but is very steep-to, and should not be approached under three-quarters of a mile, or in less than 15 to 18 fathoms water. Between Third and Fourth Points the bank runs pretty nearly straight, the edge of it being distant from 1 to $1\frac{1}{2}$ mile from the shore, except in front of the bight just to the westward of Third Point, where it is 2 miles distant from the shore.

The soundings between Third and Fourth Points are irregular, but vessels may, with careful attention to the lead, stand towards the mud-bank into 7 or 6 fathoms, until nearly abreast of Fourth Point, where the bank gets steeper, having 10 fathoms close-to, and only 8 fathoms a little further off.

Four-and-Three-quarters Fathoms Bank.—A mud-bank, about 2 miles in length, and three-quarters of a mile in breadth, and having $4\frac{3}{4}$ fathoms water over it, lies between Third and Fourth Points, about two-thirds of the distance from the former, and nearly 3 miles from the shore; between this bank

and the edge of the mud flat extending from the shore, is a channel about three-quarters of a mile broad, with 7 to 9 fathoms water in it.

VIERDE, or Fourth Point, bears from Third Point W. $\frac{1}{2}$ N. distant $23\frac{1}{4}$ miles. The trees upon it are 112 ft. high; and a *square beacon*, with *white* top and ball, stands, or used to stand, at the edge of the mangrove.

The coast from Fourth Point stretches westward for 22 or 23 miles, and in this space the different branches of the Palembang River fall into the strait.

Banks off Fourth Point.—A bank of sand and shells, having $4\frac{3}{4}$ to 6 fathoms water over it, lies 4 miles off Fourth Point. It is 3 miles long W.N.W. and E.S.E., about $1\frac{1}{4}$ mile broad, and from its western extreme the beacon on Fourth Point bears S. by W. $\frac{1}{4}$ W. 3 miles; and from its eastern extreme the beacon bears S.W. by W. $\frac{1}{2}$ W. 4 miles. Between it and the mud-bank extending from the shore are from 7 to 9 fathoms.

Another patch, about a mile in extent, and having 6 fathoms water over it, lies nearly 2 miles north-eastward of the last-mentioned bank, with the beacon on Fourth Point bearing S.W. $\frac{1}{4}$ S. $6\frac{1}{4}$ miles, and the dry rocks on the Brom-Brom Reef N.E. by N. 3 miles.

Between these banks the depths are from 8 to 14 fathoms.

The *Mud Bank* from *Fourth Point* takes a W.N.W. direction for 18 miles, where it trends away near South, forming one side of the entrance to the Soengsang River; a spit projecting from the land forms the other side of the entrance to that river, as also the S.E. side of the entrance to the River Assing.

Caution.—This bank, for 6 miles westward of Fourth Point, is composed of hard sand, covered with a thin stratum of soft mud, and is exceedingly dangerous, being steep-to, and many ships, including H.M.Ss. *Himalaya* and *Assistance*, have grounded upon it. The lead cannot at all be relied upon for giving warning in time to avoid it, for 11 fathoms may be had, and the ship be aground the next instant. The safest plan is not to pass the beacon on Fourth Point within 3 miles, and having passed it not to bring it to the eastward of S.E. $\frac{1}{2}$ S. until Monopin Hill bears North.

From 10 to 12 fathoms will be obtained very close to this steep bank, outside of which is a long strip of 8 and 9 fathoms; outside of this strip are 10 to 13 fathoms, so that it is not at all possible for a vessel to discover her position by the lead only. The soundings, however, become more regular off the mouths of the Palembang Rivers, and towards and abreast Batakarang Point the lead will in those localities, if properly attended to, enable a vessel to proceed with ease and safety, as the soundings decrease regularly towards the shore.

Great care, however, is requisite in navigating this part of the strait during the rainy season, for large drifts are then brought down these rivers by the freshes, which set strong over to the West end of Banka; and as the

flood runs strong into them on the springs, a vessel may be driven too near either shore, both sides of which are fronted by dangers.

SUMATRA RIVERS.—To the westward of Fourth Point are the entrances of the Rivers Saleh and Oepan, then the Soensang, and lastly the Assing; the last two are navigable for vessels of light draught as far as Palembang.

SOENGSANG or PALEMBANG RIVER.—Mr. Stanton has furnished the following account of this river and town:—Since the survey of the N.W. part of Banka Strait in 1860, a deeper and more direct entrance to the main channel of this river has been formed, carrying 9 ft. at low, or 22 ft. at high water springs.

This new entrance is marked with beacon poles, similar to those in the old passage, but as, on account of the many floating trees and strong freshes, they will probably not remain long in their position, a vessel of large draught may safely enter at high water by bringing the trees forming the West point of the river entrance S. by W. $\frac{3}{4}$ W., and running for them on that bearing until Pulo Payong (Umbrella Island) bears South; then steer for the island, but take care in approaching it to keep close to the eastern bank of the river, to avoid the spit extending 2 miles off its North end. If a pilot is required, one may be obtained at Kampong Soengsang, the small village on the left bank, but there is no channel available for ships on the West side of Payong.

This branch of the Soengsang at its entrance is upwards of a mile wide, but within, the navigable channel is contracted in some places to the width of a cable's length by the different islands and banks, until close up to the town of Palembang, when the river widens to three-quarters of a mile with 5 and 6 fathoms close to the shore.

Vessels can navigate the whole length of the river up to the town by keeping close to the right bank; but those of large draught are recommended, when passing Pulo Singris and the bank off Kampong Maya, to keep near the opposite shore. Both sides of the river are wooded, and on nearly all the isolated banks there are small trees, and on others fishing slakes, consequently there will not be much difficulty in avoiding them.

PALEMBANG, one of the largest Malay towns in the Archipelago, and the largest in Sumatra, derives its name from the many bridges across the numerous creeks that intersect it. A Dutch resident and other officials reside here, and to support their authority there is a military force, consisting of one European and two native companies. The total number of Europeans in the town is 109, and by the last census the native population consisted of 45,000 Malays, 4,000 Chinese, and 1,000 Arabs. The climate in the vicinity is considered so salubrious that convalescent soldiers are sent here from Banka.

Near the extreme end of the town, commanding the mouth of the Ogan River, is a substantially built fort. It is a square enclosure of masonry,

with walls 8 ft. thick, about 50 ft. high, loop-holed, and at each angle a circular bastion mounting eight guns in casemate embrasures. The fort could easily accommodate 1,500 men, and is surrounded outside with strong wooden palisades, a thick bamboo hedge, and a ditch 20 ft. broad. The fort is in lat. $2^{\circ} 59\frac{1}{2}'$ S. There are several smaller forts some distance up the river.

Covered prahus (called bedahs) daily arrive from the interior, laden with large supplies of cotton for exportation. This useful article grows quite wild some distance up the river, in some places close to the stream, and covering many miles of land. The greater portion of it is sent to Batavia. The total quantity exported this season is estimated at 1,735,500 lbs.

All the necessaries of life are here found in abundance. The country abounds in large game, deer, wild pigs, &c. The river swarms with fish. Beef, fruit, vegetables, &c., are cheap and plentiful. Foreign vessels are not permitted to trade, and Dutch European vessels are not allowed to enter the river unless under special circumstances. The export trade, consisting principally of pepper, rattans, cotton, honey, dye-woods, and gutta-percha, is confined to thirteen European built ships, and numerous country craft, all owned by wealthy natives.

From November to March rains prevail, and the wind varies from N.W. to N.E. At this period vessels belonging to Palembang either remain in port or trade to other places, as it is almost impossible for sailing vessels at this period to make any progress up the river against the freshes. During a stay of five days off the town in January, the influence of the flood was not once felt. The ebb slackened during the day, but at night it often ran 5 knots. After much rain the freshes out of the river are felt in Mintok Bay.

ASSING or SALT RIVER offers the best passage to Palembang, being at all times navigable for vessels of the heaviest burden, but the shallow at its entrance often causes a delay of several days. At its mouth, which was surveyed in the beginning of 1846, Monopin Hill bears N.E. by E., and Assing Point N.W. by N. At the entrance, in mid-channel, there are 8 to 10 fathoms; and close to the poles at the back on the eastern side of the channel from 4 to 5 fathoms. Higher up this river the Pontain and Jarang Channels are just as good as that through the Soensang.

Directions.—To enter the Assing, bring Monopin N.E. by E., and Teloo Point N.W. by N., then steer in a S.W. direction, according to the state of the tide, for the ebb runs strongly over the very shallow outer bank towards Soensang, and the flood towards the inner banks.

Having reached as far as Api Point, take the mid-channel, between the beacon-poles, towards Bayan Point, and then, though still following the middle of the river, keep rather towards the Laga Point side, round which the Pontian Channel is entered. With a flood tide keep on the eastern

shore, as the stream runs with force past that channel; taking care, at the same time, to avoid the shoals which surround the point. In this river we have only to mind the points, as from most of them project small mud banks.

Pontian and other Affluents.—The junction of the rivers Pontian, Kietjar, Gassing, and Sebalick, which last unites the Pontian to the Jarang, causes a part of the ebb to run from the first two rivers through the Sebalick, and compels vessels having come so far with the flood to anchor, and to wait for the ebb. The Pontian is generally deepest on its western side, except near its mouth, where the greatest depth is in the middle; but again towards the western side, higher up, and in front of the shoal off the point, between the Kietjar and the Sebalick. When near its junction with the Sleino and Jarang Rivers, keep close to the eastern shore, in 6 to 8 fathoms, to avoid the reef which projects from the point between the Sebalick and Jarang. When there is no wind, it is necessary to anchor and wait for the flood coming up by the Sleino, in order to proceed up the Jarang, and it will be found that a great part of the flood goes into the Tambangadin River, while that going up the Jarang is very trifling. Having reached the Jarang Ketjil, anchor again till high water, to wait for the ebb from this river, which will soon take the vessel into the Soengsang.

JARANG BANK.—The bank off the Jarang is very shallow, but on the North side there is a narrow passage with 5 or 6 fathoms. Vessels of less draught than 15 ft. can also find a passage on the South side.

The **ASSING**, *always navigable.*—The difficulties in going up the Assing, caused by the narrowness of the rivers Pontian, Sebalick, and Jarang, and the necessity of stopping so often to wait for the tide, are amply compensated by the advantage that vessels of even the greatest burthen suffer no delay at its mouth.

Freshes.—Vessels navigating these rivers, especially during the western monsoon, should be aware that the heavy rains in the interior cause such strong freshes to run out of the river as to reach towards the opposite shore, and that in the spring, especially during the eastern monsoon, very powerful floods pour into the rivers. High up the rivers are seen rippings like breakers, caused by these tides and freshes, which frequently bring down large detached masses of grass and brushwood like floating islands.

BATAKARANG POINT, the N.W. boundary of Banka Strait, is in lat. $2^{\circ} 1' S.$, long. $104^{\circ} 50' E.$, and bears N.W. $\frac{3}{4}$ W. 32 miles from Fourth Point. It may be known by a group of trees, 130 ft. high, which gives it a bluff and jagged appearance.

Valsche or False Point is more sloping and flat, and lies 9 miles to the south-eastward of Batakarang Point; and there is another point about 3 miles in the same direction from Batakarang Point.

The mud-bank projects $4\frac{1}{2}$ miles off Batakarang Point, and 2 miles off

False Point. It then trends away to the south-westward, bounding the entrance of the Assing River on its N.W. side, to Tanjong Kampie, from which it projects not quite a mile.

The soundings off Batakarang Point are regular, and the point may be passed in from 6 to $4\frac{1}{2}$ fathoms water.

COAST OF BANKA.—This coast, which separates the straits of Banka and Gaspar, is treated of here, as being intimately connected with the former, for Mr. Stanton observes, that at the entrance of Banka Strait, in the S.E. monsoon, the ebb tide during the night at springs will be found setting to the south-eastward; consequently many vessels, although steering a course for the strait, get set between Pulo Dapur and Baginda Point.

The **SOUTH COAST**, between Baginda Point and the Dapur Islands, in extent about 14 miles E. $\frac{3}{4}$ N. and W. $\frac{3}{4}$ S., is generally low, and covered with trees; it presents, however, some points sloping down from hills of moderate elevation. It should not be approached under 3 miles, for it is fronted with a mud-bank, extending in places nearly 2 miles from the shore, upon which are many rocks above, and many others below water.

TANJONG BAGINDA, the south-eastern extreme of Banka, is in lat. $3^{\circ} 4' 40''$ S., long. $106^{\circ} 44'$ E. It slopes gradually in a south-easterly direction from a hill 387 ft. high, which rises a mile inside the point. Two miles inside the point, in a N.W. by W. $\frac{1}{2}$ W. direction, is another hill, named Baginda Peak, 521 ft. high.

Tanjong Dua (*Doeya*) bears W. by S. $\frac{3}{4}$ S. $2\frac{1}{2}$ miles from Baginda Point, from which it is separated by a bay about half a mile deep. N.N.W. $1\frac{1}{2}$ mile from the point is a hill, 432 ft. high, from which the land slopes down to the coast.

Rocks, some of which are above water, extend to the southward of this point and for more than a mile along the coast to the westward, to the distance of half a mile. A sand-bank, with rocky patches, commences about $1\frac{1}{2}$ mile S.S.E. $\frac{1}{2}$ E. from it, and extends to the westward until it meets the mud-bank which fronts the coast as far as Tanjong Tanah Roboe.

Tanjong Kejang is 231 ft. high, and bears West-southerly $2\frac{3}{4}$ miles from Tanjong Dua, from which it is separated by a sandy bay about two-thirds of a mile deep.

Karang Layar is a rocky reef above water, lying on the outer edge of the bank above mentioned, and S.W. by W. distant $1\frac{3}{4}$ mile from the East extreme of Tanjong Kejang. Inside these rocks to the north-westward is another bed of rocks, some of which are above water.

Tanjong Bantil, 240 ft. high, bears W. by N. $2\frac{3}{4}$ miles from the nearest part of Tanjong Kejang. The bay between these points seems to be full of rocks; and large and small rocks above water, with others awash, extend to the southward of the point, nearly to the edge of the mud-bank, which projects nearly a mile off shore.

Tanjong Tanah Roboe is $3\frac{1}{2}$ miles W. by S. $\frac{1}{2}$ S. from Tanjong Bantil, and off it, as at Tanjong Bantil, a number of rocks, some above and others below water, project nearly a mile to the southward to the edge of the bank; the bank curves round this point, and terminates just to the westward of it.

Dapur Point.—The coast from Tanjong Tanah Roboe runs West about a mile, and then, curving to the north-westward into a small bay about half a mile deep, runs about S.W. by W. with a rugged outline to Dapur Point, under Toboe Ali Lama Peak, which forms the south-western extreme of Banka. Adjoining Dapur Point is an islet or rock 40 ft. high, with smaller rocks above water on both sides of it.

Dapur Islands * are two islets lying a little more than a mile S. by E. from Dapur Point, and forming a good landmark when approaching from the southward. They form the south-eastern limit of the entrance to Banka Strait by the Stanton Channel, are nearly round, and about a cable's length in diameter, and connected at low water by rocks. The southern one is 120 feet high, resembles a shoe in appearance, and is fronted by a coral sandy beach. Some rocks above water lie about a cable's length to the southward, and a rock under water about 2 cables to the south-eastward of the islet.

There is a narrow channel, half a mile wide, with depths of $5\frac{1}{2}$ fathoms, between the Dapur Islands and Dapur Point; from thence to Nangka Point there are several white rocks lying inside the mud flat close to the shore.

Sand Ridges off the South end of Banka.—H.M.S. *Saracen*, when searching for the coral reef reported by the Netherlands barque *Banka* † (many prominent points offering good objects for fixing her position), was enabled to extend the soundings 20 miles off the land. The soundings were found to be very irregular, long sand ridges, with deep water over a muddy bottom between. None of these banks have less than 5 fathoms on them, with the exception of one lying S.E. $1\frac{1}{2}$ mile from Pulo Dapur, where there are several patches of $3\frac{1}{2}$ fathoms over a sandy ground. At 7 miles E. by S. of these patches, and separated by deeper water, is a bank of $4\frac{1}{2}$ fathoms, coral and sand, extending in an easterly direction for 3 miles; it appears to be a continuation of the Dapur Bank, and from its shoalest part Tanjong Baginda bears N.E. by N. 6 miles.

Overfalls.—At full and change great overfalls were repeatedly noticed, caused by the meeting of the ebb stream from Banka and Gaspar Straits over an uneven bottom.

* Dapur means cooking place. Prahus, in passing, generally land on these islands to catch turtle, as it is the only place in Banka Strait where they are seen.

† This coral reef, about 3 miles in circumference, and probably only 6 ft. water on it, was reported as lying 15 miles from the South end of Banka Island. Its position was given as lat. $3^{\circ} 21' S.$, long. $106^{\circ} 41' E.$, and the land in sight (probably Mount St. Paul, 930 ft. high) bore N.N.W.

TOBOE ALI LAMA is a hill about $1\frac{1}{4}$ mile N.N.E. of Dapur Point. Its peak is of pyramidal form, and rises to an elevation of 512 ft.

NANGKA POINT is 2 miles N.W. from Dapur Point, and the coast between is fronted by rocks extending about half a mile from it. The edge of the bank is nearly a mile from Nangka Point, and has 5 fathoms water close to, so that it must be approached carefully. The point may easily be distinguished by a round hillock over it 264 ft. high, and also the land receding forming Toboe (Tobu) Ali Bay, the shore of which is low, and fringed at high water with sandy beaches inside the mud flat, which here extends 2 miles off the land.

TOBOE ALI POINT, bearing N.W. by N., distant $5\frac{1}{2}$ miles from Nangka Point, has several white rocks near it, and has or had a conspicuous tree on its summit, elevated 213 ft., and visible 14 miles off.

Toboe Ali Fort, with its red-roofed barracks, stands half a mile S.E. of Toboe Ali Point, upon a low mound 40 ft. in height, at the left point of entrance of a small river, on the banks of which is the village of Sabang, situated close to the fort, and containing (in 1860) a mixed population of 600 Malays and Chinese. At low water the river dries to a distance of 3 cables' lengths from its mouth. A Dutch Administrator and a Captain with a small military force garrison the fort.

The anchorage off Toboe Ali Fort is in 4 fathoms, mud, with Toboe (Tobu) Ali Lama Peak S.E. by E. $\frac{1}{2}$ E., and Gadong Peak in line with Toboe Ali Fort N.E. $\frac{1}{2}$ N. Smaller vessels may approach on this bearing nearer the shore, as the soundings decrease regularly. In southerly and south-westerly winds there is a heavy swell here, which makes landing difficult.

No supplies of any description can be procured but water and wood; the former may be obtained at the above river, or at a small stream half a mile to the eastward of it, from half flood to half ebb.

Mount St. Paul, 5 miles E.N.E. from Toboe Ali Point, rises with a gradual acclivity on its south-eastern shoulder to a peak 990 ft. in height, with two others adjoining of nearly the same elevation, the western peak terminating rather abruptly to a lower spur in the direction of Gadong Hill. When to the westward of Puni Island, owing to a projecting spur from the middle peak, the eastern peak of St. Paul is hidden, and the western one then appears the highest, and forms, with the N.W. brow, a saddle hill.

Gadong Hill is a pyramidal peaked hill 593 ft. high, W. by N. distant nearly $2\frac{1}{2}$ miles from Mount St. Paul.

Owing to the land contiguous to these hills and to Toboe Ali Lama being low, they appear as islands at a distance over 15 miles.

Gossong Point bears N.W. by W. 4 miles from Toboe Ali Point, the land between forming a deep bay, with low mangrove trees. From Gossong to Laboh Point the land is more elevated, with numerous rocks close to the

shore. *Puni Island*, lying midway between Gossong and Laboh Points is a small islet, 47 ft. in height, and conspicuous from its white granite rocks. "The small Puni Island and Gossong Point, seen in one, is a good mark for being clear of the banks. Seen from a northerly bearing, this point looks like an island."—(F. G. Petersen, 1875.)

Laboh Point bears N.W. $\frac{3}{4}$ W., distant 12 miles from Nangka Point. There is a hill, 250 ft. high, about a mile to the eastward of it, and another, about the same height, and the same distance, to the northward. This point from the south-eastward presents rather a shelving appearance, with large white rocks extending from it.

Dahun Point is $7\frac{1}{4}$ miles N.W. by W. $\frac{1}{4}$ W. from Laboh Point, and the shore between is low and covered with mangroves; a range of hillocks runs parallel to the coast.

The land at Dahun Point attains a greater elevation, and is faced with sandy beaches and rocky points. At $4\frac{1}{2}$ miles N.N.E. $\frac{1}{4}$ E. from the point is a round woody hill, 315 ft. in height. Close to the coast, 2 miles N. by W. $\frac{1}{2}$ W. from Laboh Point, is a remarkable square tree, 167 ft. high, which is very conspicuous, there being no others of the same elevation near it. In clear weather it may be seen 12 miles off, closely resembling a ship under sail.

Pulo Dahun, 30 ft. in height, is one of a cluster of rocks lying off Dahun Point, nearly all of which are covered at high water. It is or was remarkable by having a solitary tree on it. *Panjang Hill* (or Long Hill) rises close to the coast between Dahun and Banka Points. It had one conspicuous tree on it in 1875. When seen from the south-eastward it shows as a wedge, with its greatest elevation, 316 ft., on the eastern end. A stream of *fresh water* runs close to the North side of this hill.

Banka Point and Hill.—Banka Point is $12\frac{1}{2}$ miles N.W. by W. $\frac{3}{4}$ W. from Laboh Point, and the land to the westward of it recedes into a bay. The point is about the same elevation as Pulo Besar, but at $1\frac{1}{2}$ mile to the northward it rises to *Banka Hill*. From the north-westward it shows with a flat top, having three clumps of trees on its summit, the whole height being 256 feet. *Pulo Besar* is nearly connected with Banka Point by rocks. It is but 3 cables in extent, and 63 ft. high, but shows up well when bearing between S.E. and East.

The Coast, from the foot of Banka Hill, takes a W.N.W. direction for about 4 miles, when it turns more to the northward to the entrance of a small river; from thence it curves round, forming a small bay to Pudi Point, when it runs pretty straight for 5 miles in a W. by N. direction, to Lalarie Point. *Mamelon Hummock* is a small round hill 265 ft. high, standing by itself 3 miles inland, in a N. by E. direction from Pudi Point. Two miles and a half E. by N. of the Mamelon is another small hill; $2\frac{1}{4}$ miles N. by E.

of which is a double-peaked hill, 396 ft. high; about $1\frac{1}{4}$ mile east-northerly of this last, is a hill 471 ft. high.

Lalarie, or *Langkong Point*, 75 ft. high, is very conspicuous. It had a clump of trees on its extremity; those around it (in 1862) have been cut down, and their trunks whitewashed. It is the turning point into the main part of the strait for vessels that have passed through the Stanton Channel. "Round Lalarie Point should be 'whitewashed stumps,' but are not. The point itself is very sharp and good for bearing. From N.E. the point looks at first as if it were an island; from the South the point is very sharp. Clump of trees mentioned in the chart I could not distinguish."—(F. G. Petersen, 1875.)

A mud bank fronts the whole coast just described between Dapur and Lalarie Points. The 3-fathom line may be considered to mark its edge, which in most places shoals very quickly inside that line. The chart will best show its features. It should not be approached under 10 fathoms.

Casuarina Point, so called from a number of casuarina trees on it, is nearly midway between Lalarie and Brani Points; seen from the northward it appears as an island. The coast between is low, with sandy beaches at high water mark.

Brani, or *Bold Point*, 11 miles N. by W. $\frac{3}{4}$ W. from Lalarie Point, is a termination of a spur from the Parmassang range, with a conical peak, 516 feet high, over it, showing very prominently both from the northward and southward.

Timbaga Rocks (or *Copper Rocks*), so called from their reddish colour, are three small rocks, lying East and West of each other, about a cable's length in extent. The highest and westernmost rock is 4 ft. above high water, and from it Second Point bears W. $\frac{1}{4}$ N. $5\frac{3}{4}$ miles, and Brani Point N. by E. 3 miles. With a setting sun their reddish colour, from the contrast to the green verdure of the land, makes them readily identified, but to render them more conspicuous at high water, and in the forenoon when they are not so clearly seen, a white conical *beacon*, surmounted with a ball, was erected on the highest rock, and the whole height being 24 ft. will make it visible in clear weather at 6 or 7 miles. Shoal water, about half a mile in breadth, extends nearly half a mile to the northward of the group, and $2\frac{1}{2}$ miles to the southward, and forms, with the shore and bank of Banka, a channel three-quarters of a mile wide.

Several shoal patches of coral and sand have been found nearly $1\frac{1}{2}$ mile W.N.W. from these rocks, but they are all inside the 10-fathom line, the depth vessels are cautioned not to go within when passing them. These patches are about a cable's length apart, having 2 fathoms least water on them, and 8 fathoms close to. In approaching them the soundings shoal suddenly from 20 to 10 fathoms. As a guide to lead ships clear, a temporary

black buoy has been placed in 4 fathoms on the outer patch, about 2 cables' lengths westward of the shoalest water.*

From the middle patch of 2 fathoms the Timbaga Rocks appear nearly in line with a sharp peak (130 feet high) South of *Bukit Limmaun*, bearing E.S.E.; and the apex of a distant long hill (657 ft. high) is just open West of a white rock off Tanjong Bedaauw, N. by E. $\frac{3}{4}$ E. These patches and the Timbaga Rocks will be avoided by not bringing Lalarie Point South of S.E. $\frac{1}{2}$ S., until Brani Peak bears E. by N. $\frac{3}{4}$ N.

A rocky bank, about a mile in extent East and West, and half a mile North and South, having 7 to 9 fathoms water over it, and 14 to 20 fathoms close-to all around, lies W.N.W. of the shoal patches just mentioned. From its outer edge the largest of the Timbaga Rocks bears E. by S. $\frac{1}{2}$ S., distant 3 miles, and Brani Peak E.N.E. 5 miles. Lalarie Point, bearing S.E. $\frac{1}{2}$ S., which leads clear of the Timbaga Rocks and the above-mentioned patches, also leads just outside the edge of this bank.

Water may be procured at a stream about half a mile to the northward of the Timbaga Rocks, from half flood to half ebb, after which the mud prevents a boat approaching near the shore.

Parmassang Range is a chain of hills running from Brani Point in a N.E. by N. direction for nearly 4 miles, to the highest peak, which rises to an elevation of 1,608 ft.; the range then turns more to the eastward, for a distance of about 3 miles, where it disappears.

Tanjong Bedaauw is a bold headland, N. $\frac{1}{4}$ E. $3\frac{1}{2}$ miles from Brani Point, the coast between forming a bay half a mile deep. A conspicuous white rock 45 ft. high, lies immediately off the point. *Pulo Pemein*, a good sharp mark to be seen 7 miles off, is a small round island, 50 ft. high, lying N.W. by N. 2 miles from Bedaauw Point. *Tanjong Karrah*, 171 ft. high, bears N.N.E. $\frac{1}{2}$ E., nearly 3 miles from Tanjong Bedaauw. Many rocks, some above and others below water, extend more than half a mile off this point.

SLAN BAY.—The coast from Tanjong Bedaauw falls back to the eastward, and between Tanjong Karrah and a point about 9 miles to the eastward of the Nangka Islands is a deep shallow bight, named Slan Bay, into which the Rivers Kotta and Slan disembogue. From the latter point the coast runs, with a slight bend in towards a small river, about N.W. $\frac{3}{4}$ N., $3\frac{1}{2}$ miles to Tanjong Tedong. On the coast line, in the depth of Slan Bay, is a conspicuous tree, 196 ft. high.

Slan is the chief town of a pangkal, or district, and is municipally governed by the administrator of the tin mines. Here, as at all other chief towns of districts, a small number of Dutch troops are stationed.

* Captain Petersen reports that both the beacon and the buoy could not be seen by him in 1875, while passing.

The edge of the Shore Mud Bank is nearly a mile outside Lalarie Point, and from thence its direction is nearly straight, about North by West for $18\frac{1}{2}$ miles, or for $2\frac{1}{2}$ miles beyond Pulo Pemein, passing Casuarina and Brani Points a little less than half a mile. It then assumes somewhat the form of Slan Bay, which it fronts, and surrounding the Great Nangka Island, projects a couple of spits or horns towards the bank extending northward from the middle Nangka. From thence the edge falls back in a north-easterly direction towards Tanjong Tedong, from which it extends little more than a mile.

About two-thirds of a mile south-westward of Tanjong Bedaauw, a narrow inlet, having $3\frac{1}{2}$ to 5 fathoms depths of water, runs into the bank in a north-westerly direction, and turns to the northward nearly as far as Pulo Pemein.

Northward of the Timbaga Rocks the bank may be approached to 8 or 7 fathoms, as far as a mile or two to the northward of Pulo Pemein, when vessels may stand into 7 or 6 fathoms, until near the Nangka Islands, which should not be approached on the West side nearer than 12 fathoms.

The **NANGKA ISLANDS**, three in number, lie about the middle part of the strait, from $1\frac{1}{2}$ to 4 miles distant from the shore of Banka Island, and 8 or 9 miles eastward of Third Point, on the Sumatra coast. *Great Nangka*, 285 ft. high, is $1\frac{3}{4}$ mile long North and South, and $1\frac{1}{4}$ mile broad; *Middle* and *West Nangka* are each about half a mile long, the former being 125 ft., and the latter 205 ft. high.

Great Nangka is nearly half a mile within the edge of the mud-bank which extends from the Banka shore. From the Middle Nangka a bank of 2 to 3 fathoms extends S.S.E. $1\frac{1}{4}$ mile; from West Nangka a similar bank projects to the southward for nearly a mile, and S.S.E. distant three-quarters of a mile from its tail is a $3\frac{1}{2}$ -fathoms patch.

A small flat rock, 6 ft. above water, named *West Reef*, lies about $1\frac{1}{2}$ cable off the West end of West Nangka; and another, 32 ft. high, named *Tree Rock*, lies nearly one-third of a mile south-eastward of Middle Nangka, between it and Great Nangka.

A reef, named *North Reef*, with rocks above and below water, lies a quarter of a mile off the North end of Middle Nangka, the mud-bank extending off in the same direction about a quarter of a mile further.

Between the banks which surround the islands are intricate channels, from 2 to 4 cables broad, having from 4 to 7 fathoms water in them.

Water.—There is a stream of water on the West side of Great Nangka, and another and smaller stream on the N.E. side; but both streams are frequently dry in the S.E. monsoon, and are difficult of approach for ships' boats. H.M.S. *Belleisle* was watering at Great Nangka night and day, and only filled 30 tons in 36 hours. The natives are not to be trusted, but on the contrary much caution is necessary while watering.

In the N.W. monsoon it is high water, full and change, at the Nangka Islands, at 7 a.m., and the rise is about $9\frac{3}{4}$ ft. Many eddies and small races will be met with in the vicinity of these islands. They are caused by the tidal flood wave from the China Sea meeting the flood from the southward.

TANJONG TEDONG, bearing N.E. by E. $\frac{1}{2}$ E., $3\frac{1}{2}$ mile from the West Nangka, is a conspicuous point, 234 ft. high, inside the Nangka Islands, to which it is connected by the mud bank. A large cluster of rocks, some above and others below water, lie about a mile north-westward of the point, only a short distance from the edge of the mud-bank.

The Coast from Tanjong Tedong falls back to the N.E. into the bay, at the bottom of which is the small *River Semboelan*; from thence it curves to the N.W. to *Tanjong Penegan*, from which it again falls back about a mile to the entrance of a small river of that name. The coast line from this river rounds the foot of the higher land sloping down from Mundo Peak, and then forming a small bay, trends N.N.W. to a point bearing E. by S. 2 miles from the largest of the Meddang Islands, when it again bends to the N.E. for $1\frac{1}{2}$ mile to the entrance of the Mundo River.

Mundo Bay.—From the Mundo River the coast trends to the N.W. about 8 miles to Tanjong Jurung-patt, forming the shore of Mundo Bay, with a point about the centre of it projecting nearly a mile. The shore of this bay is low, and covered with trees, which, at the entrance of the Kotta Waringin River, are 121 ft. high. *Tanjong Jurung-patt*, 240 ft. high, is the western limit of Mundo Bay. The land here begins to be more elevated, and continues to be so as far as the entrance of the Jiring River.

The coast from Tanjong Jurung-patt takes a westerly direction for nearly 3 miles to *Tanjong Raya*, where it falls back northerly about a mile to the *Tempelang River*; from thence it takes again a westerly direction for nearly 4 miles to Tanjong Ressam, the eastern extreme of Jiring Bay. This latter point is prominent, and faces the S.W.; it lies N.W. by W. 12 miles from the Meddang Islands.

Jiring Bay is the deep bight between Tanjong Ressam and Tanjong Tadah, the coast trending away from the former point in a N.N.W. direction to the entrance of the River Jiring, and from thence curving round about W.S.W. and S.W. to Tanjong Tadah, which bears from Tanjong Ressam W. $\frac{1}{2}$ S., distant $8\frac{3}{4}$ miles. The shore of the bay is low, with three conspicuous trees 152 ft. high in its N.W. part. *Tanjong Tadah*, 203 ft. high, is readily recognized, the land on both sides being lower, and curving into two bays, giving it a very prominent appearance.

Between Tanjong Tadah and Tanjong Puni, which lie nearly East and West of each other, about 8 miles apart, there are two bays, each about three-quarters of a mile deep, with a point having a hummock or mound, 256 ft. high, upon it midway between.

Tanjong Sukal, 2 miles East by North from **Tanjong Puni**, has a hill 209 feet high upon it, and a small river on its West side. *Tanjong Puni* is low, and the coast line rounds away very gradually on either side of it. From thence to a point $7\frac{1}{2}$ miles to the N.W. by W. $\frac{1}{2}$ W., the coast falls back and forms a bay about a mile deep. From the latter point to **Kalian Point** the bearing is W. $\frac{3}{4}$ S., and the distance nearly 4 miles, the coast between forming **Mintok Bay**.

There are several hills from 100 to 600 ft. high on the part of the coast just described between **Tanjong Tedong** and the **Mundo River**. *Mundo Peak* 512 ft. high, and bearing E. by S. $\frac{1}{4}$ S. 4 miles from the **Meddang Islands**, is the most convenient for fixing the vessel's position.

About three-quarters of a mile to the eastward of the **Tempelang River** is a small hill 263 ft. high; and N.E. 3 miles from its entrance is *Bukit Tempelang*, a hill 412 ft. high; W. by N. $\frac{3}{4}$ N. from **Bukit Tempelang** is *Bukit Pandin*, 585 ft. high, which will be found very useful when in this part of the strait. *Solitary Sharp Peak*, 661 ft. high, is the summit of a sharp cone hill standing by itself, N. $\frac{1}{2}$ E., distant $10\frac{1}{2}$ miles from **Tanjong Tadah**; this is also very useful when brought in line with nearer objects, for giving a correct line of direction.

Four or 5 miles inland from the coast between **Puni Point** and **Mintok** are some hills, one of which, *Bukit Beloe*, 773 ft. high, serves as a mark to clear the **Brom-Brom Reef** and **Amelia Bank**; a little to the westward is another hill 427 ft. high.

About 2 miles north-eastward of **Bukit Beloe** is *Bukit Panjang*, or long hill, 661 ft. high; and nearly 3 miles north-westward of **Beloe** is a hill 454 feet high.

Meddang Islands are three islets lying about 3 miles off the entrance of the **Mundo River**, and forming the south-western extreme of **Mundo Bay**, being joined to the main land by the mud flat. The largest islet is 147 ft. high, and bears North 9 miles from the **West Nangka**. A small island, named **Pulo Antu**, lies about $1\frac{1}{2}$ mile north-eastward of the **Meddang Islands**.

Pulo Sambayang is an islet 175 ft. high, lying about E. $\frac{1}{2}$ S. nearly 3 miles from **Tanjong Ressim**, and $1\frac{1}{4}$ mile W.S.W. of the entrance to the **Tempelang River**.

Karang Sarabu are a cluster of rocks, some above and others below water, extending in a S. by E. $\frac{1}{2}$ E. direction nearly 2 miles from the point with a hummock on it between **Tanjong Tadah** and **Tanjong Sukal**.

MONOPIN HILL, or *Gunong Manombing*, in lat. $2^{\circ} 1\frac{3}{4}'$ S., long. $105^{\circ} 12'$ E., rises near the West end of **Banka**, and its summit being 1,456 ft. high, may be seen at a considerable distance, and serves as a guide in approaching to or departing from the North end of **Banka Strait**. It frequently happens at

the North entrance of the strait, that this hill is the only visible object, especially when a vessel is near Sumatra in 5 or 6 fathoms water.

The edge of the bank, after passing a cable's length outside the rocks off Tanjong Tedong, takes a N.N.W. direction, till abreast of the Meddang Islands, outside of which it extends nearly a mile. From thence it curves round Mundo Bay, projecting 4 miles to the southward of Tanjong Jurungpatt; it then runs to the westward, passing Tanjong Ressam at $4\frac{1}{2}$ miles, and Tanjong Tadah at nearly 3 miles.

Mundo Peak, well open to the southward of the Meddang Islands, leads clear of the edge of this bank between those islands and Tanjong Tadah.

From Tanjong Tadah the bank still follows a westerly direction till South of Tanjong Puni, when it trends away sharply to the north-westward, following the curve of the coast line at an average distance of about $1\frac{1}{4}$ mile, until abreast the East point of Mintok Bay, from which it is distant only half a mile.

Between Tanjong Tedong and Tanjong Tadah, the soundings decrease regularly towards the bank, which may there be approached to 5 or even 4 fathoms, except near the Meddang Islands, where a vessel should not shoal under 9 fathoms. At Tanjong Tadah the bank begins to get steeper to, and abreast of the Karang Sarabu Rocks, there are 9 and 10 fathoms pretty close to its edge.

Caution.—The bank South of Puni Point is very shallow and steep-to, having from 11 to 16 fathoms, almost close to its edge. Tanjong Tadah, bearing E. by N. $\frac{3}{4}$ N., jutt clears this dangerous spit to the eastward, and Monopin Hill N.W. by N., just clears it to the westward.

KARANG BROM-BROM is an extensive shoal of rocks and sand, dry in some places at low water, lying $4\frac{1}{2}$ miles South from the shore between Tanjong Puni and Sukal. It is a little more than 2 miles long in a W. $\frac{1}{2}$ N. and opposite direction, and nearly half a mile wide at its western end, where the rocks are, and from which Monopin Hill bears N.W. $\frac{1}{2}$ N.; the eastern end tapers away to a sandy point. This danger was marked by a temporary beacon, which is said to have disappeared (1875).

A *red buoy* was placed off the southern side of Karang Brom-Brom, in 1875, in 5 fathoms water, with the middle of Monopin Hill bearing N. 40° W., and the East point of Cape Tadah, N. 50° E.

The highest part of the hummock on the point behind the Karang Sarabu Rocks bearing N. $\frac{1}{4}$ E, or the highest part of Tanjong Tadah bearing N.E. $\frac{3}{4}$ N., clears the eastern end more than half a mile; and Bukit Beloe, bearing N. $\frac{3}{4}$ W., clears the western end nearly a mile.

A channel, 2 miles wide, having 7 to 15 fathoms water in it, lies between the Brom-Brom and the shore bank. Notwithstanding that the channel between the Brom-Brom Reef and Banka is only 2 miles wide, a vessel may easily work through it by day, during the western monsoon, because she can

take advantage of the tides; but on the coast of Sumatra a strong easterly current runs with little interruption; she must, however, be very careful in crossing over to the coast of Banka, as the bank is very steep, and she might suddenly fall from 7 to 3 fathoms before there would be time for a second cast of the lead.

Amelia Bank is a small patch of hard ground, with $2\frac{3}{4}$ fathoms water over it, at the S.E. extreme of the Mintok Bank, to the shoal patches of which it is connected by a ridge of 4 and 5 fathoms water. From it the western extreme of the Brom-Brom bears East $4\frac{1}{2}$ miles, and Monopin Hill N. by W. $\frac{3}{4}$ W. 12 miles.

Bukit Beloe bearing N. $\frac{1}{2}$ E. leads a mile to the eastward of the Amelia Bank; and the same hill N. by E. $\frac{1}{2}$ E. leads the same distance to the westward.

Mintok Bank extends from the Amelia Bank in a direction nearly parallel to the shore, for a distance of 10 or 11 miles, to within about the third of a mile of the Karang Hadji Reef, off Kalian Point. It is composed of hard sand, and has several patches with only $2\frac{1}{2}$ and 3 fathoms water over them, and 4 or 5 fathoms between. A 2-fathoms patch lies N.W. by N. $2\frac{1}{3}$ miles from the Amelia Bank. Bukit Beloe, bearing N. by E. $\frac{1}{2}$ E., which clears the Amelia Bank to the westward, also clears the patch to the eastward.

From this last-mentioned patch, other patches of $2\frac{1}{2}$ and 3 fathoms extend N.W. by W. for 5 miles, this part of the bank being about $1\frac{1}{2}$ mile wide. For $2\frac{2}{3}$ miles further in the same direction the bank has from $4\frac{1}{2}$ to 7 fathoms water over it, the deepest water appearing to be with Mintok Fort flagstaff in line with the pier-head, bearing about N. by E. $\frac{1}{3}$ E.

Another 3-fathoms patch lies with the lighthouse on Kalian Point bearing N. $\frac{1}{2}$ E. $1\frac{1}{3}$ mile, from which 5 fathoms may be carried towards the Karang Hadji Reef until very close to it, when the water will suddenly deepen to 11, 17, or 20 fathoms. Monopin Hill, in line with the lighthouse on Kalian Point, N.E. $\frac{1}{2}$ N., leads westward of the 3-fathoms patch, between it and the Karang Hadji Reef.

A ship working through the strait, to keep clear of Mintok Bank, should take care not to bring the lighthouse on Kalian Point to the westward of N.W. by N.

KARANG HADJI is a dangerous reef of rocks and sand lying close to the N.W. end of the Mintok Bank; the rocks on it are all covered at high water, but many of them are visible at half tide. The beacon marked on the chart was not visible in 1875. The reef is $1\frac{1}{2}$ mile long N.W. by W. and S.E. by E., and half a mile broad, and from its western and outer extreme Kalian lighthouse bears E. $\frac{3}{4}$ N. $2\frac{1}{2}$ miles, and Tanjong Oelar and Tanjong Bersiap are in line; its eastern extreme bears S.W. by W. $\frac{1}{4}$ W. $1\frac{1}{2}$ mile

from Kalian Point. Close to it on the North, West, and South sides, the depths are irregular from 16 to 21 fathoms.

A *rock*, with 12 ft. over it at low water, lies about 2 cables northward of the Hadjie Reef, with Tanjong Bersiap, the western point of Banca Island, bearing N. $\frac{3}{4}$ E., and Kalian Point lighthouse E. $\frac{1}{4}$ N.

Tanjong Oelar kept well open of Tanjong Bersiap clears the West end of this reef; the highest part of Monopin Hill in line with the lighthouse clears its eastern extreme; and Tanjong Puni bearing E. $\frac{3}{4}$ S. clears it to the southward.

A *red buoy* was placed off the N.W. side of Karang Hadjie, in 1875, in $4\frac{1}{2}$ fathoms water; from it Tanjong Kalean bears N. 87° E., and Bersiap Hill N. 26° E.

Inner or Binnen Bank, of hard sand, with $2\frac{1}{2}$ fathoms water on it, and 7 or 8 fathoms close-to, extends East $1\frac{3}{4}$ mile from Kalian Point, when it turns to the N.W. for about half a mile, thus forming a spit projecting to the eastward; from thence it curves away and is lost in the sand-bank which extends half a mile from the shore of Mintok.

Two-thirds of a mile E. by S. from this spit is a 3-fathoms patch, from which Mintok pier-head bears N.N.W. $\frac{3}{4}$ W., distant two-thirds of a mile, and Kalian Point lighthouse West, northerly.

KALIAN Point and Light.—Kalian Point, low and sandy, with some trees behind it, is the south-western extreme of the West end of Banka. The lighthouse upon it, in lat. $2^{\circ} 4' 37''$ S., long. $105^{\circ} 9'$ E., is a white stone tower with a red lantern, which shows, at an elevation of 170 ft., a *fixed* white light, visible in clear weather at 20 miles.

About three-quarters of a mile N.W. from the lighthouse is *Tanjong Batubrani*, the trees immediately behind which are 127 ft. high. *Kalian Ledge* is a small reef, with only 6 to 9 ft. water over it, lying a little more than a mile to the N.W. of Kalian Point; from it the lighthouse bears S.E. by E., Bersiap Point N. $\frac{1}{4}$ W., and Monopin Hill N.E. $\frac{1}{4}$ E.

Kalian Pass, formed by Kalian Point and Ledge on one side, and the Karang Hadji Reef on the other, is three-quarters of a mile wide, with soundings in it of 25 to 32 fathoms. This channel is generally used by vessels coming from the northward and proceeding to Mintok Bay, and with a fair wind is preferable to the passage outside the Karang Hadji; but the great depth, bad anchorage, and strong currents, render it unadvisable to attempt to beat through.

In using this channel, the sandy point upon which the lighthouse stands may be passed pretty close to; and the lighthouse on the bearing of E. by S. leads through between the Kalian Ledge and the Karang Hadji Reef.

MINTOK.—Two miles E.N.E. from Kalian Point, on the banks of a small

river, is the town of Mintok, the capital of the island,* having a fort upon a hill, and some stone houses close to the shore, the red roofs of which are visible at a considerable distance. The resident and other Dutch officers have houses on the hill near the fort, most of the native houses being lower down nearer the sea. The mail steamers, which run twice a month between Batavia and Singapore, always call here.

A pier nearly half a mile long, and running out to the edge of the bank, has been built, and is of great advantage to the trade of the place; on the extremity of the pier a small *fixed* white light is shown all night.

The best anchorage for large ships is in 10 to 6 fathoms, about $1\frac{3}{4}$ mile from the shore, with Monopin Hill bearing about N. $\frac{3}{4}$ E., and Kalian Point about W.N.W. or W. by N. The ordinary anchorage of the Dutch man-of-war stationed in Banka Strait, and of the merchant vessels trading to Mintok, which are usually of a small class, is in $4\frac{1}{2}$ or 5 fathoms inside the 3-fathoms patch lying off the spit which extends from the Binnen Bank, at any convenient distance and direction from the pier-head.

The usual route to Mintok Road is across the Mintok Bank, between the Karang Hadji Reef and the Amelia Bank. A vessel coming from the northward, and bound for the road, may proceed either through the Kalian Pass, or she may pass outside the Karang Hadji Reef, and then follow the usual track across the Mintok Bank. A good mark for crossing the bank is Monopin Hill in line with the flagstaff on the fort bearing N. by E. $\frac{1}{2}$ E., which will lead over it in 5 or 6 fathoms water; another good mark is Monopin Hill in line with the lighthouse N.E. $\frac{1}{2}$ N. No ship can cross the bank in safety with Monopin Hill bearing to the westward of North; with the hill bearing North, a ship crossing the bank would have 3 fathoms at low water spring tides, the bottom hard sand, coral, and shells. When over the bank, the water will deepen to 18 or 20 fathoms, soft muddy bottom, and shoal again quickly towards the inner bank and the shore.

With a working wind, keep Monopin Hill N. $\frac{1}{2}$ E. and N.N.E.

To enter Mintok Road from the eastward, a vessel must work between the shore and the Mintok Bank, being careful not to bring Tanjong Tadah to the eastward of E. by N. $\frac{3}{4}$ N., until Monopin Hill bears N.W. by N.

A hard sandy bottom and shoal water will show when near the edge of the

* Banka, like the adjacent countries, is now under the dominion of the Dutch, and has been so without dispute since 1821, when it was finally conquered from the treacherous Sultan of Palembang in Sumatra. As is well known, the chief commercial product is tin: a government monopoly, chiefly worked by Chinese, who form more than a moiety of the total population of Banka, estimated at 35,000. The island is comparatively sterile, and the natives rude and treacherous. There are numerous other colonies of Malays and Javanese, in addition to the Chinese immigrants. The chief geological feature is the range of volcanic and granitic hills which runs through the island, parallel to and of similar character to those on the Malay peninsula.

Mintok Bank; while, to avoid the shallow along the coast, Monopin Hill must not be brought more to the westward than N.W. by N., and taking care not to shoal to less than 5 fathoms.

At Kalian Point it is high water, full and change, in the N.W. monsoon, at 8^h 17^m a.m., and in the S.E. monsoon at 8 p.m.; the springs rise 12½ ft.

Tanjong Bersiap, 168 ft. high, bears from Tanjong Batu-brani, the north-western extreme of Kalian Point, N. by W. ¼ W., distant 3½ miles. The coast between curves slightly inland, and is fronted by a bank extending nearly a mile from it, pretty close to which are 7 and 10 fathoms. Inside the edge of this bank, and lying some distance off Bersiap Point, is a cluster of rocks, some of which are above and others below water. *Bersiap Hill*, 336 ft. high, is small, and stands by itself, about 1½ mile N.E. of the point. About 2 miles N.E. of the hill, the extreme of a range running from Monopin to the N.W. forms a conspicuous peak 709 ft. high.

Tanjong Oelar, 156 ft. high, is about 4 miles N. by E. from Tanjong Bersiap; nearly midway between is a remarkable yellow cliff. About three-quarters of a mile northward of the yellow cliff, and just to the South of a point with a rock off it, is a stream of *water*. *Oelar Reefs* is the name given to the rocky and uneven ground, with reefs and rocks above water in places, extending off shore between Bersiap and Oelar Points. From a mile off Bersiap Point, it runs in a N. by W. direction for nearly 3 miles, when it trends away to the north-eastward, passing about three-quarters of a mile outside Oelar Point, immediately off which are several rocks above water.

Transit Rock, on which H.M.S. *Transit* was wrecked, 10th July, 1857, lies at the western extremity of this rocky, uneven ground, at 2¼ miles off shore, and W. ¼ N. 8 cables' lengths from a reef which generally shows, except at high tides, with 6 and 10 fathoms between them. The least depth on the rock at low water springs is 12 ft., and from this spot Oelar Point bears N.E. by E.; the highest point of Monopin Range E. by S. ¾ S.; and Kalian Point is 1¼° open of Bersiap Point S.S.E. southerly, distant from the latter point 2¾ miles. There are 20 fathoms water at a cable's length to the westward of the 12-foot line; the depth around varying from 14 to 12, 7, and 5 fathoms over very uneven bottom.

A rock awash, at low water springs, lies E. ½ N. 2 cables' lengths from the Transit Rock; and there are 4½ fathoms (perhaps less) rocky bottom, at half a mile to the northward of the Transit, with 20 fathoms close-to; the locality of the latter is indicated by strong ripples.

Tanjong Batu-brani well open of Tanjong Bersiap, bearing S.S.E. ¼ E., clears the Transit Rock to the westward; and Tanjong Biat, well open of Tanjong Oelar, bearing E.N.E., clears it to the northward.

TANJONG BIAT bears N.E. ¾ E., distant 3 miles from Tanjong Oelar, and, like that point and Tanjong Bersiap, has rocks above and below water,

extending some distance off it. The line of danger which extends about three-quarters of a mile off Tanjong Oelar, follows the curve of the coast line at about the same distance towards Biat Point, where it projects rather farther off. In the bay between Oelar and Biat Points is a small stream of *water*, with a village close to it.

Rocky Patches, with 20 fathoms close to them, lie off Tanjong Biat, having a narrow channel with 10 and 11 fathoms water in it between them and the rocky ground extending from the coast. From the outer patch of 3 fathoms, Tanjong Oelar bears S. $\frac{1}{2}$ W. 3 miles, and Tanjong Biat S.E. by E., a little over 2 miles.

Tanjong Oelar bearing South leads nearly half a mile westward of these dangers; and *Bukit Batu*, a hill 708 ft. high, about 12 miles eastward of Tanjong Biat, bearing E. by S., leads northward of them.

Caution.—The West coast of Banka, between Tanjong Kalian and Tanjong Biat, is very dangerous to approach, owing to the rocky patches just described and the deep water close to them; ships should, therefore, exercise great caution when in this vicinity, observing that Tanjong Bersiap, if not brought to the westward of South, will clear all the dangers between Tanjongs Oelar and Biat; and they should be careful to regard the marks given to clear the Transit Rock.

FREDERICK HENDRICK ROCKS lie at the northern entrance of Banka Strait, nearly midway between Batakarang Point on the Sumatra coast and Tanjong Oelar on the Banka coast. They consist of two rocky patches, lying North and South of each other, having only 9 ft. on the northern patch, and 3 ft. on the southern. The two patches occupy a space about a mile long, North and South, and half a mile broad.

From the 3-foot patch Monopin Hill bears nearly E. by S. 14 miles; and the lighthouse on Kalian Point S.E. by E. $\frac{1}{4}$ E. $12\frac{3}{4}$ miles.

Monopin Hill E. $\frac{3}{4}$ S. leads about half a mile southward of the 3-ft. patch; and Monopin Hill in line with the remarkable yellow cliff between Bersiap and Oelar Points, E. by S. $\frac{3}{4}$ S., leads 2 miles northward of the northern patch.

Close around the shoal are 16 to 20 fathoms water.

A *red buoy* is moored on the South point of Frederick Hendrick Reef, in 5 fathoms, with Kalean light bearing S.E. by E. $\frac{1}{3}$ E., Bersiap Hill E. by S., and Mount Parrée N E. by E. It is visible about 3 miles off; but as the buoy from the strong tides frequently shifts its position, vessels are cautioned not to place too much dependence on it.

Channels.—The channel westward of the Frederick Hendrick Rocks is the one most generally used, the depths in it being moderate, decreasing regularly towards the bank extending from the Sumatra coast; whereas in the channel eastward of the shoal the water is much deeper, and the depths irregular.

Between the shoal and the 3-fathoms line at the edge of the mud-bank extending from Batakarang Point, the channel is $4\frac{1}{2}$ miles wide, having 16 and 17 fathoms close outside the 10-fathoms line towards the rocks; the depths under 10 fathoms decreasing regularly towards the bank.

The channel between the shoal and the Transit Rock and reefs off the West coast of Banka is 8 miles wide, having 16 to 20 fathoms at 3 or 4 miles eastward of the shoal, and 19 to 25 miles nearer Banka, which depths increase to 24 and 30 fathoms close to the dangers extending from that coast.

Directions for West Channel.—To avoid the Frederick Hendrick Rocks, vessels taking the channel between them and Sumatra should keep in $4\frac{1}{2}$ to 7 fathoms water on the edge of the bank off Batakarang Point, and not keep more to the eastward than in 9 or 10 fathoms, while Monopin Hill bears between East and E.S.E.

In working through this channel a vessel should not deepen to more than 9 fathoms towards the Hendrick Rocks, but the bank off Batakarang Point may be neared to 5 or $4\frac{1}{2}$ fathoms. When Monopin Hill bears E.S.E., the vessel will be northward of the rocks.

In the East Channel, Mounts Punyabung, Parée, and Jerankat, on the N.W. part of Banka, will appear like islands. To pass eastward of the Frederick Hendrick, keep Mount Punyabung N.E., until Monopin Hill bears E. $\frac{1}{2}$ S., when Punyabung must not be more eastward than N.E.; and when Monopin is E. by S. $\frac{1}{2}$ S., Punyabung must not be more North than N.E. $\frac{1}{4}$ N., so as to avoid in the first case the Hendrick Rocks, and in the second the Transit Rock. When Monopin bears southward of S.E., Mount Punyabung must not be brought to the northward of N.E.

Soundings in Banka Strait.—In Banka Strait, between Lalarie and Second Points, the depths are from 17 to 25 fathoms, shoaling suddenly from those depths to 10 fathoms on the Banka side of the strait, but decreasing regularly towards the 10-fathoms line on the Sumatra side.

The various banks and coral patches which exist in the strait, having more than 5 or 6 fathoms on them, will be best understood by reference to the chart. The dangerous banks have been described. Indeed, throughout the strait, the soundings cannot alone be relied upon to conduct a vessel safely through; but when associated with careful bearings and frequent references to the chart, a stranger need not run the least risk, or experience any difficulty in passing through the strait for the first time.

STANTON AND LUCIPARA CHANNELS.

The **STANTON CHANNEL**, which was surveyed, or rather discovered, by Mr. W. Stanton, R.N., in command of H.M.S. *Saracen*, in 1859-60, is a most important addition to our knowledge of these entrances to the China Sea. This is the more so, inasmuch as the Lucipara Channel to the westward of it is said to be filling up in consequence of the extension of the low Sumatran coast. His directions which follow will be found precise and sufficient. He also makes the following general remarks: It has hitherto been the custom for all ships to work along the Sumatra coast, where they have not only a strong wind, but a constant current to contend with; consequently sailing vessels have been delayed *two and three weeks*, and instances have been known of vessels being a month making the passage through Banka Strait.

The *Saracen* frequently worked well to windward under fore and aft sails, when the clipper ships could not make any progress, and were compelled to anchor on the Sumatra side. From my past experience, I feel confident that a smart sailing vessel, by taking advantage of the tides and currents, and following the directions hereafter given, may make the passage even in the full strength of the monsoon in *three or four days*.

The *Stanton Channel*, lying along the south-western coast of Banka, is 19 miles long, and nearly 3 miles wide at its narrowest part, with depths, mid-channel, increasing gradually from 7 fathoms at its south-eastern entrance to 20 fathoms near the other extreme. The approaches to it from the southward are marked by the well-defined mountain of St. Paul, and the conical hills of Gadong and Toboe Ali Lama (page 201), and in fine clear weather by the more distant range of Padang, 2,217 ft. high; these cannot fail to point out the entrance, and the water being deep within half a mile of the Dapur Islands (page 200), will give strangers confidence in steering for the land. Prominent points and hills will also be seen along the Banka coast, bearings of which will enable a vessel at any time to ascertain her position.

The channel is bounded by narrow banks extending in a N.W. by W. and S.E. by E. direction, and all partaking of the same formation (sand) in their shoalest parts, with a mixture of mud and sand between. The two marking the western boundary of the channel are named *Smits* and *Melville Banks*, and off the latter a lightvessel would be most useful.

Smits Bank consists of four smaller banks, nearly connected, and forming one long narrow ridge 15 miles in length, with its shoalest part of 3 ft., lying 6 miles, and the next shoalest of 9 ft., 3 miles from the north-western end; two other patches of 3 fathoms and $2\frac{3}{4}$ fathoms lie on the S.E. part of the bank.

Panjang Hill, bearing N.E., leads to the north-eastward of this bank, between it and the Nemesis Bank, in 6 fathoms at low water. Gadong Peak

in line with Toboe Ali Point N.E. $\frac{1}{4}$ E., or Lucipara S.W., clears the south-eastern end in 4 fathoms; and Lalarie Point N.W. by W. $\frac{1}{4}$ W., or not approaching the bank to a less depth than 10 fathoms, clears the north-eastern side.

Melvill Bank, 5 miles long, and nearly half a mile broad, lies a quarter of a mile to the eastward of the south-eastern part of Smits Bank, with a depth of 7 and 8 fathoms between. The shoalest part of this bank is near its north-western extremity, and is about 2 miles in length, with from 2 to 3 fathoms on it. At the North end, in 5 fathoms, Laboh Point bears N.E. by E.; and the bank is cleared to the south-eastward in 7 fathoms by the latter point bearing N. by E. $\frac{1}{2}$ E.; and to the eastward in 8 fathoms, by bringing Parmassang Peak to touch the West side of Banka Hill N.W. $\frac{1}{2}$ N.

Between the above banks and Lucipara, there are many others all trending in the same direction, with narrow deep-water channels between; but as these channels are exceedingly narrow, and no marks can be given to clear the banks, they are not available for vessels.

Eastern Bank.—The bank bounding the eastern side of Stanton Channel is 13 miles long and nearly a mile wide, at 3 miles S.W. by S. of Laboh Point, which is the broadest and shoalest part. It is formed by three smaller banks nearly joined together, with from 2 to 3 fathoms on the north-western and south-eastern ones, and only $4\frac{1}{2}$ ft. on the middle of the centre bank. The north-western extremity is separated from a projecting horn, extending from the shore mud flat at 2 miles S.S.W. of Pulo Dahun, by a narrow channel of 6 fathoms.

Gadong Peak, in line with Toboe Ali Fort, bearing N.E. $\frac{1}{2}$ N., leads to the southward of the south-eastern part of the bank in $4\frac{1}{2}$ fathoms; Dapur Island S.E. by E. $\frac{3}{4}$ E. leads to the westward; and the Mamelon or Hummock, kept open to the westward of Pulo Besar, N.W., clears the West side of the north-western extremity of the above banks.

A small bank of sand lies 1 mile to the westward of the south-eastern extreme of the eastern bank, but as not less than $4\frac{1}{2}$ fathoms were found on it at low water, it is not dangerous to ships passing through.

Inner Channel.—To the eastward of the eastern bank along the coast of Banka, there is an inner channel nearly a mile wide, with 4 to 6 fathoms water in it, but as it is encumbered with shoals it is only navigable for small vessels. Dapur Island, bearing S.E. by E., leads nearly in mid-channel.

There are also two outlets into the main channel over the western bank, in 5 and 4 fathoms; the former with Pulo Dahun bearing N.N.E.; the latter and southern outlet, when Pulo Puni and Gossong Point are in line, E. $\frac{1}{2}$ N.

Nemesis Bank, lying nearly mid-channel between Pudi Point and False First Point, is a long ridge of sand extending 9 miles in a N.W. by W. and

S.E. by E. direction, with irregular soundings of from 3 to 10 fathoms on it. The shoalest part consists of two patches of 3 fathoms, each about 2 cables' lengths in extent, upon one of which the French frigate *Nemesis* grounded in 1857. They lie E.S.E. and W.N.W. from each other, distant half a mile, and from the western patch Lalarie Point bears N.N.W. $\frac{3}{4}$ W. $4\frac{3}{4}$ miles, and False First Point S.S.W. $\frac{3}{4}$ W. $4\frac{1}{4}$ miles.

Casuarina Point kept open of Lalarie Point, bearing N. by W. $\frac{3}{4}$ W., leads to the westward of these shoal patches, in 14 fathoms water; the Mamelon or Hummock, N. by E. $\frac{1}{4}$ E., or False First Point S.W. $\frac{1}{2}$ S., leads to the eastward; and Lalarie Point bearing N.W. $\frac{1}{2}$ N., clears them to the northward. There is another patch of 5 fathoms lying 2 miles from the south-eastern extreme of the bank, with False First Point W. $\frac{1}{4}$ S., and First Point S. by W. $\frac{1}{4}$ W., distant $3\frac{1}{4}$ miles.

Anchorage may be found anywhere in the Stanton Channel, but ships bringing up with their kedge or stream anchor must always be prepared to let go the bower anchor, as there will be experienced, particularly during the change of the monsoons, very dangerous squalls, with heavy rain, thunder, and lightning, which generally last for about an hour.

TIDES.—In the S.E. monsoon it is high water, full and change, at Toboe Ali Point, on the Banka shore, at 8^h 30^m p.m., and at 10 a.m. in N.W. monsoon. The ordinary rise at springs is $10\frac{3}{4}$ ft., but it sometimes reaches 12 ft. The highest tide generally occurs two days after full and change. The rate at springs is $2\frac{1}{2}$ knots. The flood stream sets to the N.W. and runs for about 12 hours, and the ebb the same period in the opposite direction, but they are both sometimes influenced by the strength of the monsoon. When it is blowing strong from the S.E., the flood stream often runs for 14 hours.

A vessel may carry a *fair tide all the way through* by starting from either extremity of the strait at low water, as the tidal waves from the China and Java Seas meet near the Nangka Islands.

At Laboh Point it is high water, full and change, at 11 p.m. in the S.E. monsoon, and the rise at ordinary springs is 10 ft.

After rounding Lalarie Point in the S.E. monsoon the flood sets N.N.W., and the ebb to the S.S.E., along the Banka shore.

The time of high water at Laboh Point being $2\frac{1}{2}$ hours later than at Toboe Ali Point, in the southern part of Stanton Channel, for a few days after full and change the tides will be found (as there is generally 12 hours' flow and ebb) to run in one direction all night, and the opposite direction during the day, with a velocity of from $2\frac{1}{2}$ to 3 knots. The current also setting directly mid-channel, the flood N.W. by W., and the ebb S.E. by E., vessels may take advantage of it in light airs to drop through.

Directions for Stanton Channel from the Southward.—Vessels from the south-

ward, intending to proceed into Banka Strait by the Stanton Channel, cannot fail, in approaching the coast of Banka, to recognise the mountain of St. Paul (page 201) by its flattish top having several nipples of nearly the same elevation, and Gadong and Toboe Ali Lama Peaks by their conical appearance. Should the weather be clear, the distant high range of Pedang will be visible. The highest peak of this range is quoin-shaped, attaining from its western shoulder an elevation of 2,217 ft., with several lower hills of a rounder and more conical appearance adjoining, the two westernmost being about 1,200 and 1,400 ft. high.

After recognizing Mount St. Paul and Toboe Ali Lama Peak, approach the latter on a North bearing, and when about 3 miles to the southward of the Dapur Islands, steer N.W. by W., which will lead nearly mid-channel to abreast Banka Point; recollecting the marks given at p. 216, for clearing the Melvill and Eastern Bank.

When off Laboh Point, the high range of Parmassang will be visible, rising from a gradual slope on its western shoulder to a flat-top peak, with two lower ones adjoining. The three hills, Banka, Panjang, and Woody, will also be seen; the two former may be known by their wedge shape, and the latter by its isolated position.

From abreast Banka Point a course may be shaped along the Banka shore, passing Lalarie Point at a distance not within $1\frac{1}{2}$ mile, and from thence to Second Point. When Pulo Dahun bears North, great care must be taken to avoid the spit which extends in a south-easterly direction from the shore mud flat, between the above island and Banka Point. The Mamelon or Hummock, N.W., well open to the westward of Pulo Besar, clears this spit (page 216); from thence to the Timbaga Rocks the bank may be avoided by not shoaling towards it under a depth of 10 fathoms.

Working through this channel from the eastward, vessels may stand towards the South extreme of the Dapur Islands to a distance of half a mile, as these islands have deep water at 4 cables' lengths from them. Between this and Toboe Ali the shore mud flat may be approached until Pulo Dapur bears S.E. by E. $\frac{1}{2}$ E., and Lucipara may be neared to a distance of 5 miles; but when Gadong Peak bears N.E. $\frac{1}{2}$ N., or comes in line with Toboe Ali Fort, Pulo Dapur must not be brought to the southward of S.E. by E. $\frac{3}{4}$ E. to clear the north-eastern part of the Eastern bank.

Parmassang Peak touching the West side of Banka Hill N.W. $\frac{1}{2}$ N., will clear the Melvill Bank, and when Laboh Point bears N.E. $\frac{1}{2}$ N., by not shoaling under 10 fathoms, all the banks on both sides will be cleared. Lalarie Point N.W. by W. $\frac{1}{4}$ W. will also clear the north-eastern part of Smits Bank.

The shoal patches on the Nemesis Bank should not be approached under a depth of 10 fathoms until Casuarina Point comes open of Lalarie Point, and in rounding the latter point take care not to come into a less depth than 10

fathoms, as the bank is here steep-to. The Timbaga Rocks may also be avoided by following the same precaution, and from thence it is recommended to work up from Second Point along the Sumatra coast.

From the Westward.—Proceeding through Stanton Channel from the westward, when abreast and $1\frac{1}{2}$ mile distant from Lalarie Point, an E.S.E. course will lead nearly mid-channel between the Nemesis Bank and the bank extending from the Banka shore, but when Panjang Hill bears N.E. a more southerly course must be shaped to pass in mid-channel. When Dahun Point bears North, the Mamelon or Hummock open of Pulo Besar N.W. (the clearing mark for the spit off Pulo Dahun, page 216), also leads directly through the channel.

Working through from the westward in the S.E. monsoon, the same precaution must be taken as already mentioned to avoid the shoalest part of the Nemesis Bank, which will be passed when the Mamelon bears N. by E. $\frac{1}{4}$ E.; and should a strong flood tide be then running, it would be advisable to anchor in 8 or 9 fathoms, sand, on the Nemesis Bank, as the water on both sides of it is deep, and wait for a change of tide, or the chance of the land breeze, which blows generally either during the night or early in the morning from the Banka shore. When Panjang Hill bears N.E., Lalarie Point must not be brought to the northward of N.W. by W. $\frac{1}{4}$ W. to avoid Smits bank, and the same directions as already given in not approaching the banks under 10 fathoms until Laboh Point bears N.E. $\frac{1}{2}$ N., will be quite sufficient to enable any vessel to work through.

LUCIPARA CHANNEL.—The South entrance to this channel is between Lucipara Island and Lucipara Point, nearly West, 9 miles distant from it. The western side of the channel (p. 193) is bounded by the mud flat which projects from the coast of Sumatra for 2 miles and more, and its eastern side by various hard and dangerous sandbanks, which narrow the breadth of the passage to $1\frac{1}{2}$ and 2 miles.

Mr. Stanton is of opinion that this channel will, within a few years, become unnavigable for vessels of large draught, owing to the rapid extension of the mud flat projecting from the Sumatra coast on the western side, and to the extension, also of the sandbanks on the eastern side.

Round Shoal.—The southern sandbank in this channel is nearly 2 miles long W N.W. and E.S.E., and about a mile broad, the least water, $1\frac{1}{2}$ fathoms, being near the middle of it. From its southern edge, in 3 fathoms, the summit of Lucipara Island bears S.E. $\frac{1}{3}$ E. $7\frac{1}{4}$ miles, and from the western edge S.E. $\frac{1}{2}$ E. 9 miles. The narrowest part of the Lucipara Channel is between the lightvessel off the western extreme of this bank and the mud flat extending from the Sumatra coast.

LIGHTVESSEL.—In 1870 the Lucipara Channel Lightvessel, showing a *fixed bright light*, elevated 28 ft., and visible 10 miles off, was placed in the position formerly occupied by a buoy, in the narrowest part of the channel,

off the N.W. side of Round Shoal. She is painted yellow, and carries one mast with a black ball on the top. From the lightvessel, Green Point bears N.W. $\frac{2}{3}$ N. $4\frac{1}{2}$ miles nearly, Lucipara Point S. by W. $\frac{1}{2}$ W., and Lucipara Island summit, S.E. $\frac{2}{3}$ E. 9 miles.

Hindustan Bank extends from close to the eastern edge of the Round Shoal N.N.W. $\frac{1}{2}$ W. about $3\frac{1}{2}$ miles. The depths on the southern and middle parts of it are 1 to 3 fathoms, but about three-quarters of a mile from its northern extreme is a patch of hard sand, with only 3 feet water over it.

Merapie Shoal, the most northern of the banks on the eastern side of the Lucipara Channel, is composed, like the others, of hard sand, and is three-quarters of a mile in extent North and South, and more than half a mile broad. The least water on it is $2\frac{1}{4}$ fathoms. From the middle of the shoal, False First Point is in line with First Point.

In the Lucipara Channel the bottom is generally hard sand on the banks towards the eastern side, and soft mud on the western or Sumatra side; yet close to the north-western edge of the Middle sand-bank the bottom is also soft, with $5\frac{1}{2}$ and 6 fathoms. It is, therefore, advisable not to keep in too hard or in too soft bottom, but in the middle of the channel.

Directions for Lucipara Channel from the Southward.—When bound towards Banka Strait from the southward, the Island of Lucipara is generally made between the bearings of N. by E. and N.W., and in $5\frac{1}{2}$ to 8 or 9 fathoms. With westerly winds it is advisable to keep on the western side of the channel in $4\frac{3}{4}$ to $5\frac{1}{2}$ fathoms.

In clear weather, when the Parmassang Range is visible, the highest peak on the western extreme of the range in line with First Point, N. by W. $\frac{1}{2}$ W. will lead up to abreast the lightvessel. This mark should be left when Lucipara Island bears about E.S.E., or S.E. by E.; then, by keeping the Mamelon Hummock (page 202) on a N. $\frac{3}{4}$ W. bearing, it will lead through between the bank off First Point and the Merapie Shoal, until Lalarie Point is seen well open of First Point, when a vessel may begin to edge away to the westward to round First Point, taking care not to approach it nearer than a mile, as the bank projecting from the point is steep-to, especially on its N.E. side. After rounding First Point at not less than that distance, a N.W. $\frac{1}{2}$ W. course will lead midway between False First Point and the Nemesis Bank.

From the Northward.—Entering Lucipara Channel from the northward, First Point must be rounded with great caution, on account of its being steep-to, especially on its north-eastern side, and it must not be approached nearer than a mile; at the same time, if the tide is running to the south-eastward, it will be necessary to use proper care that, in giving a safe berth to First Point, the vessel is not set too near the Merapie Shoal, which the tide will be likely to do unless guarded against. When Mamelon Hummock

bears N. $\frac{3}{4}$ W., keep it so, until Lucipara is S.E. by E., or E.S.E., when Parmassang Peak may be brought in line with First Point, N. by W. $\frac{1}{2}$ W., which will lead clear of the Sumatra Bank; or a S.E. by E. course may be steered, which will lead midway between Lucipara and the main.

Working through this channel, a vessel may stand toward the Sumatra Bank safely by attending carefully to the lead, remembering not to go into less than $6\frac{1}{2}$ fathoms when near the elbow projecting just to the southward of Green Point. Lucipara must not be approached nearer than 2 miles, when bearing to the northward of N.E. by E.; between the bearings of N.E. by E. and E. by S. it may be approached to a mile.

Careful attention to the lead and a good look-out will also give sufficient warning when standing towards the banks on the eastern side.

Caution.—Many vessels passing through the Lucipara Channel have grounded on the mud flat extending from the coast of Sumatra, especially a short distance to the southward of Green Point, where the flat extends farther out, and all have been obliged, before they could get off, either to transship or to throw a part of the cargo overboard, as the anchors which were laid out on the soft muddy bottom to heave them off came home. This part of the flat shoals suddenly from 6 to 3 fathoms, and therefore should never be approached to a less depth than $6\frac{1}{2}$ fathoms.

It will also be necessary to use great caution when working through this channel from the southward, and standing to the eastward, to avoid being set on the banks by the tides, which sweep over them with great strength. In working through this channel from the northward, similar caution is required. With light winds it is very difficult to get into the northern entrance, the tides sweeping vessels away to the south-eastward amongst the banks.

Directions from Lalarie Point through Banka Strait.—Having passed through either Stanton or Lucipara Channels, and brought Lalarie Point to bear about East, distant 3 miles, a N.N.W. $\frac{3}{4}$ W. course for about 10 miles will lead midway between the rocky bank of 7 or 8 fathoms water, lying north-westward of the Timbaga Rocks, and the mud-bank projecting from Second Point. Continuing the same course for 6 or 7 miles further, the vessel will be $1\frac{1}{2}$ to $1\frac{3}{4}$ mile outside the horn or spit projecting from the Sumatra Flat (page 194). Still continuing the same course for another 14 or 15 miles, Third Point will bear S.W., distant about 2 miles.

If a vessel following this track, after having passed Second Point, should shoal the soundings under 6 fathoms, she will be getting too near the Sumatra Flat, and should haul out more to the eastward; remembering that Second Point must not be brought eastward of S. by E. $\frac{3}{4}$ E. until Parmassang Peak bears E.S.E., to clear the spit or horn projecting from the bank.

From the above position off Third Point, a W. by N. $\frac{1}{4}$ N. course may be

steered for about 28 or 29 miles, which, if the vessel be not affected by tides or currents, will place her in a position from which Fourth Point will bear about S.E. $\frac{3}{4}$ S. distant 7 miles, and Monopin Hill N. $\frac{1}{4}$ E. to N. $\frac{1}{2}$ E.

From thence steer about N.W. by W. for Batakarang Point—paying particular attention to the tides, which frequently set strong into or out of the Palembang Rivers (pp. 191-2)—and the vessel will soon pass over a narrow bank of sand, having 7 fathoms on it, and again deepen the water to 13 and 16 fathoms. Having run 15 or 16 miles, the soundings will again decrease under 10 fathoms, and she will be on the edge of the bank extending from Batakarang Point, and may proceed along the edge of it in from 8 to 6 fathoms; the directions given at page 214 must then be followed to pass westward of the Frederick Hendrick Rocks, which channel is recommended as being the best and safest, especially at night.

Through Banka Strait from the Northward.—A vessel having passed the Toedjoe, or Seven Islands, and steering to the southward for the entrance of Banka Strait, will find no difficulty in clear weather in fixing her position which can be readily done by cross bearings of Mount Punyabung or Saddle Hill, and Monopin Hill; under such circumstances the strait can be entered on either side of the Frederick Hendrick Rocks by attending to the directions given at page 214. But in thick weather it often happens that no land can be seen until the vessel has arrived very near to the entrance of the strait, and at such times it is important to get hold of the bank extending from the Sumatra coast, and then proceed along its edge in 8 to 6 fathoms, carefully attending to the lead. Sometimes Monopin will be seen, but no other land, in such case it will be prudent to proceed as before, keeping along the edge of the bank.

Working through Banka Strait.—Directions have been given in pages 217-18 and 220, for working into the strait from the southward, and in page 214 for working into it from the northward by the channels on either side of the Frederick Hendrick Rocks; it may, however, be as well to remark again here that the passage westward of the Frederick Hendrick Shoal is much to be preferred at night, or when the land is obscured and reliable bearings cannot be obtained.

The bank fronting the Sumatra coast may be conveniently approached when well between the points, by common attention to the lead; but off the points and for a few miles on either side of them great attention must be paid to the soundings. The most dangerous part of the bank is from Fourth Point for about 6 miles to the westward of it, which must be approached with the utmost caution.

Mr. Stanton strongly recommends vessels working in either direction through the strait, or proceeding through with a fair wind and contrary tide, to avoid the Sumatra coast and keep on the Banka shore, between Lalarie

Point and Tanjong Tadah. He observes that hitherto it has been the custom for all ships to work along the Sumatra coast, where they have not only a strong wind but a constant current to contend with, consequently, sailing vessels have been delayed two or three weeks, and instances are known of vessels being a month making the passage through Banka Strait, whereas a smart sailing vessel, by keeping on the Banka side, taking advantage of the tides, and following the directions given below, may make the passage even in the full strength of the monsoon in three or four days.

The advantages gained by keeping on the Banka coast are as follows:—

A vessel may carry a fair tide all the way through by starting from either extremity at low water, as the tidal waves from the China and Java Seas meet near the Nangka Islands; prominent hills and points, with a gradual decrease in the soundings, give confidence to mariners when steering for the land; a strong land wind will be generally experienced during the night, when the regular monsoon is blowing in the middle of the strait and near the Sumatra coast; and in the strength of the monsoon regular tides will be met with on the Banka shore, while strong currents will invariably be found setting to leeward along the Sumatra shore.

From the Southward—In working between Lalarie Point and the Nangka Islands, the lead is a good guide, as the soundings decrease regularly, except near Lalarie Point and the Timbaga Rocks, where they decrease rather suddenly from a depth of 10 fathoms; if, however, Lalarie Point is not brought South of S.E. $\frac{1}{2}$ S. until Brani Peak bears E. by N. $\frac{3}{4}$ N., a vessel will keep clear of all danger near the Timbaga Rocks. Having arrived within 3 miles of the Great Nangka, the spit extending from the South end of that island should not be approached under a depth of 7 fathoms; and to avoid the rocky ledges extending from Middle and West Nangka, West Reef (6 ft. above water, page 205), should not be brought to the westward of North after the peak of Great Nangka bears N.E., until the vessel is to the northward of the Nangka Group,

From the Nangka Islands to Tanjong Tadah the shore may be safely approached by the lead, as the soundings are shoal with a gradual decrease. When Tanjong Tadah bears N.E. $\frac{3}{4}$ N. (which clears the eastern side of the Brom-Brom Reef), vessels should cross over towards Fourth Point on the Sumatra coast.

From the Northward.—Coming from the northward, it is merely necessary to reverse the order of the above directions. Vessels should keep towards the Sumatra coast until past Fourth Point, which they should not approach nearer than 3 miles. When Tanjong Tadah bears N.E. $\frac{3}{4}$ N., they may cross over to the Banka side, taking care not to bring that point to the eastward of the above bearing. From Tanjong Tadah to the Nangka Islands they may stand in-shore guided by the lead; but having arrived abreast of the latter, take care not to bring West Reef to the westward of North, until the peak of

Great Nangka Island bears N.E., and not approach the spit off the South end of the island under 7 fathoms. From $2\frac{1}{2}$ miles South of the Nangka Islands the shore may be approached by the lead to any convenient depth of water, but when Brani Peak bears E. by N. $\frac{1}{2}$ N. the vessel will be nearing the Timbaga Rocks, and must not then come under 10 fathoms. Lalarie Point bearing S.E. $\frac{1}{2}$ S. clears all the dangers near the Timbaga Rocks, and the point should not be brought to the southward of that bearing until Casuarina Point bears East. From thence to Lalarie Point the shore may be again approached by the lead; but when nearing the point the soundings decrease more suddenly, and a vessel should not go into a less depth than 10 fathoms, and should round the point at the distance of about $1\frac{1}{2}$ mile. From thence she can proceed to the southward through either the Stanton or Lucipara Channels, according to the directions at pages 217—219 and 222.

NORTHERN COASTS OF BANKA.

BULO, or Jibuse Bay.—The N.W. coast of Banka is 43 miles in extent, from Tanjong Oelar to Tanjong Malalu, the bay of Bulo or Jibuse occupying more than half of that space. From Tanjong Biat (p. 212), the south-western point of the bay, to Tanjong Ginting, its north-western point, the direction is about N.E. $\frac{3}{4}$ N., and the distance $17\frac{1}{2}$ miles; the depth of the bay is 7 miles.

The whole of this bay is shallow to a distance of 3 miles from the shore, except to the southward of Ginting Point, where the shoals do not appear to extend farther than a quarter of a mile. The rivers Bulo and Jibuse disembogue in its N.E. part. The bay is much visited by coasters, and occasionally by larger vessels, for the purpose of loading tin.

The anchorage is in 5 or 6 fathoms, on soft muddy bottom, with Ginting Point N. by E. $\frac{1}{2}$ E., Songi Bulo E. $\frac{1}{2}$ S., and the watering place N.E. by E. $\frac{1}{2}$ E.; or in 5 fathoms off the Bulo River, with the village N.E. $\frac{1}{2}$ E., and Ginting Point N. by W. $\frac{3}{4}$ W., 3 miles from the shore.

Water.—Fresh water can be obtained in a small bay about $1\frac{1}{2}$ mile to the eastward of Tanjong Ginting.—Commander J. W. King, R.N., says it is brackish.

TANJONG GINTING, the N.W. point of Bulo Bay, is a long, low point, having a reef projecting 2 miles from it, close to which are 8 fathoms water. The position of the point may be easily recognized by the three hills, *Paree*, *Punyabung*, and *Jerankat*, which at a great distance appear like islands. The first, 858 ft. high, is the most southern one of the three, and rises 4 miles East of the point; Punyabung, a remarkable saddle-shaped hill, 794 feet high, very conspicuous from seaward, rises close to the coast, about 3 miles

south-eastward of Ginting Point; Jerankat, 657 ft. high, is about 4 miles E.N.E. from Punyabung.

The Coast between Ginting Point and Punyabung Hill forms a small bay, which appears to be nearly filled with rocks. It then trends E.N.E. about 18 miles to Tanjong Melalu. The whole coast between Punyabung Hill and Tanjong Melalu is fronted by a reef which projects 1 or 2 miles from the shore.

Malan Hyu, Malan Doyang, and Malan Guntur, are three rocks lying off the coast between Tanjong Dugong and Tanjong Melalu. Malan Hyu is about the size of a boat, and covered with white guano. It lies about 3 miles North from Tanjong Dugong. Malan Doyang is not much above water, and only the size of Malan Hyu. It lies about 3 miles off shore, with Punyabung Hill S.W. $\frac{1}{4}$ S. Malan Guntur is nearly midway between Malan Doyang and Tanjong Melalu, and about a mile off shore. It is larger than the other two rocks, and lies within the limit of the shoal water projecting from the coast. All these rocks appear to be surrounded to a short distance by sunken rocks; and a sunken rock lies southward of Malan Doyang, midway between it and the shore.

KLABAT BAY.—*Tanjong Melalu*, in lat. $1^{\circ} 31\frac{1}{2}'$ S., long. $105^{\circ} 38\frac{1}{4}'$ E., is the western point of entrance of Klabat Bay, and upon it is a pretty high hill, known as *Mount Melalu*. Here the N.W. coast of Banka terminates, as the coast line on the other side of entrance of Klabat Bay trends to the eastward, and forms the North shore of the island.

Klabat Bay runs up into Banka Island about 27 miles in a S.E. direction, but being encumbered with many rocks and shoals, there is only a narrow passage left, of 4 or 5 fathoms water, by which vessels of heavy burden proceed as far as the mouth of the Lyang River. Over the inner end of the bay hangs the highest of the Banka Mountains, called *Gunong Marass*, or *Maradi*. This beautiful mountain is easily recognized by its three peaks, the summits of which may often be seen when passing through Banka Strait, presenting somewhat the appearance of a crown. The highest of the peaks, 2,320 ft. high, is in lat. $1^{\circ} 51'$ S., and long. $105^{\circ} 53'$ E.

Tanjong Penyusu, the eastern point of Klabat Bay, is a long, low projection, with an islet and some rocks extending nearly 2 miles from it.

Karang Trasseh Laout is a reef with only 2 or 3 fathoms water over it, and 10 and 11 fathoms around it, lying about 3 miles N.W. $\frac{1}{2}$ N. from Tanjong Penyusu. From the reef the West point of Penyusu Islet is in line with the hill near Monkubur Point, bearing S.S.E., Moncudu Islet East, and Mount Melalu S.W. by W. $\frac{1}{4}$ W.

Vessels coming to Klabat Bay for cargoes of tin, usually anchor outside the entrance, between its eastern point and the Trassie Reef, in $9\frac{1}{2}$ or 10 fathoms, soft muddy bottom, having Penyusu Islet in line with Mount

Marass S.S.E. $\frac{1}{2}$ E., Klabat Hill S.S.W. $\frac{1}{2}$ W., Melalu Point W. by S. $\frac{1}{4}$ S., and Moncudu Island E. $\frac{3}{4}$ N.

The Coast from Tanjong Punyusu takes, with a slight curve inland, a direction about E. by N. for 10 miles, to a point abreast of a small islet named *Pulo Moncudu*; and from thence East for $2\frac{1}{2}$ miles to Tanjong Crassok, the northernmost point of Banka, in lat. $1^{\circ} 29'$ S., long. $105^{\circ} 56\frac{1}{2}'$ E. Many rocks lie close to this part of the coast, and shoal water extends nearly a mile from it. From Tanjong Crassok the coast trends to the south-eastward, forming the N.E. coast of Banka.

A reef, having 2 fathoms water over it, lies about 2 miles off shore, with Moncudu Islet bearing East, and Gunong Chundong S.E. $\frac{1}{2}$ S. Rocks are also marked on the chart, one at 3 miles E.S.E. from Tanjong Crassok, and another at $2\frac{1}{2}$ miles farther to the south-eastward, and $1\frac{1}{2}$ mile off shore.

CHAPTER VI.

G A S P A R S T R A I T.

THE channels between Banka and Lepar on the West and Billiton to eastward are collectively known as the Strait of Gaspar. Captain Huddart says that the first ship which passed through was the *Macclesfield* galley, Capt. Hurle, in March, 1702. This is the westernmost channel. The name *Gaspar* is that of the Spanish commander from Manila, who passed through it in 1724. Besides the first-named channel westward of Pulo Leat, there is a second, called the *Middle Pass*, on the eastern side of that island. The third is the *Clements Channel*, named after the Commodore of the homeward bound English East India Fleet, in 1781, which passed through between the islets south-eastward of Pulo Leat; and the fourth, the *Stolze Channel*, to the eastward of these islets, is named after the Dutch officer who first surveyed it. Of these the first and fourth are most used, as will be explained presently.

Banka or Gaspar Strait?—From the earliest times of our China commerce Gaspar Strait has been preferred to Banka Strait, by ships coming from China. But it is of much more dangerous approach, both from North and South, and the new and excellent Stanton Channel in the latter may lead to a preference being given to it. Upon this subject the following is given in the *China Sea Pilot*.

Banka Strait possesses unquestionable advantages over those of Gaspar and Carimata, and is without doubt the best and safest route *into* the China Sea. Although of much greater length, and not so direct for vessels bound to China as Gaspar Strait, yet it is manifestly superior to that strait; for it is easy and safe of approach. It affords convenient anchorage in every part, which enables vessels to avail themselves of favourable winds and tides; and it leads into a part of the China Sea free from danger. Gaspar Strait, on the contrary, is difficult and dangerous of approach, rocks and shoals extending for 35 miles to the southward. The depths of water are too great to afford convenient anchorage; and it conducts into a part of the China Sea

very imperfectly explored, and abounding with hidden dangers, amongst which vessels are liable to be set by uncertain currents. No serious accident has occurred within the last few years to vessels passing through Banka Strait; whereas many fine ships, with valuable cargoes, have been lost in or near Gaspar Strait.

For vessels proceeding to Singapore there can be no doubt that Banka Strait is in all respects to be preferred, and it has in fact become the recognized highway of the trade passing between Sunda Strait or Batavia, and Singapore. But for ships to China, Gaspar Strait being shorter and more direct, is still preferred, and will no doubt continue to be by many navigators, especially those who are anxious to make quick passages, even at the expense of incurring additional risk. It is certain that a vessel arriving off the entrance of Banka or Gaspar Strait in the morning, and favoured with a commanding breeze, would gain some advantage in point of time by passing through the latter; but in calms and light airs, or against the N.E. monsoon, there is good reason to believe that vessels will make quick, and often quicker passages, by proceeding through Banka Strait, and they will always be assured of much greater safety. In thick or bad weather, it is possible to proceed through Banka Strait without risk; but Gaspar Strait can never be approached at such times without incurring considerable danger.

The fast clipper ships, which every season contend for the honour of landing the first of the year's teas in England, usually proceed through Gaspar Strait, as do most homeward-bound ships, to whom saving of time is of the first importance, and there can be no doubt but they will continue to do so in preference to the more circuitous, although much safer, route of Banka Strait. Until, however, the correct positions of the shoals and dangers known to exist to the northward of Gaspar Strait are determined, and this space properly explored, vessels must keep a vigilant lookout when approaching the strait from the northward, and be prepared for the possibility of meeting with some danger not marked on the charts. Nor must they relax their vigilance when getting near to Pulo Leat, and when passing through the strait. No opportunity should be lost of determining the ship's exact position; and the greatest attention should be paid to ascertaining the set of the current, and to guard against its effects. Many fine ships have been lost in Gaspar Strait—not a few on the Alceste Reef, from wrongly estimating their distance from the land; but in the majority of instances from causes which might have been guarded against by the exercise of due care and judgment.

Gaspar Strait was surveyed in 1854 by the officers of the United States Navy attached to an exploring expedition.

The territory on either side of the strait being in possession of the Dutch, the names in strict propriety should be in accordance with that orthography.

But as the strait is a common highway for the whole world, only those names which might be otherwise ambiguous will be thus denoted.

BILLITON ISLAND, or in Malay *Blitung*, is only one-half the size of Banka, but it resembles it in its geographical structure and in the production of tin, which is worked by a Dutch company. This is the south-easternmost extremity of the mining fields for this important metal, the northernmost being at Tavoy, on the Tenasserim coast, a range of 20 degrees of latitude.

The following description of and directions for the strait are taken from the *China Sea Pilot*.

DANGERS SOUTHWARD OF GASPAR STRAIT.

Dangerous shoals extend for about 35 miles to the southward of Gaspar Strait, rendering *great caution* necessary when approaching the strait from that direction.*

Sharpshooter Shoal.—The British merchant ship *Belted Will*, Captain Alexander Locke, in July, 1869, during her passage from Canton to London, slightly touched on a shoal patch lying S. $\frac{1}{4}$ E., 34 miles from entrance point in Gaspar Strait. The ship was going 9 knots at the time, but the state of the weather, occasioned by the monsoon blowing very strong, prevented an examination of the danger beyond two casts of 9 fathoms, which were obtained shortly after the shoal was passed. Observations obtained on the same day, as well as the reckoning carried from Entrance point, place this patch in lat. $3^{\circ} 35' 35''$ S., long. $106^{\circ} 56'$ E.

Near this position the Sharpshooter Shoal, of 12 ft. water, and lying 12 miles W. $\frac{3}{4}$ S. from the Hancock Shoal, was unsuccessfully searched for by Staff Commander Edward Wilds of H.M.S. *Swallow*, in 1866. It is probably the same danger, and the name has therefore been retained on the charts.

HANCOCK SHOAL, in lat. $3^{\circ} 34\frac{1}{4}'$ S., long. $107^{\circ} 4'$ E., is a small patch about a quarter of a mile in extent, but whether composed of sand or coral does not appear on the chart. It has only 1 fathom of water over it, and 6 to 7 fathoms around it.

HIPPOGRIFFE SHOAL was so named after an American ship lost on it. Mr. Wilds, R.N., in H.M.S. *Swallow*, searched for the Hippogriffe Shoal, and found it in lat. $3^{\circ} 23' 36''$ S., long. $106^{\circ} 54' 30''$ E. It is a dangerous

* **DOUBTFUL DANGERS**.—A doubtful rock was marked in former charts at $3\frac{3}{4}$ miles S.W. by W. $\frac{1}{4}$ W. of the Hancock Shoal; a small shoal of 6 feet water, named Mary Goddard, at $4\frac{1}{2}$ miles S.S.E. of the Hancock; but a careful search having been made for these dangers in May, 1866, by Mr. Wilds, Master commanding H.M. surveying-vessel *Swallow*, without the slightest indication of their existence, they have been expunged from the charts.

boulder rock, with only 3 ft. over it at low water, of circular shape, and about 150 ft. in diameter, having large branches of coral upon it. It was not seen until close to, and at the time it was examined there was not the slightest swell or ripple to indicate its position; the weather being fine and clear, and the wind light from the S.S.E. Regular soundings of 8 fathoms, sand and shell, were found around it, and the water in that depth was of a pale colour.

TURTLE SHOAL lies about 2 miles N.E. by E. from the Hancock Shoal, and is of about the same extent; it has but 3 ft. water over it, and 8 to 12 fathoms around it. There are tide ripples over this shoal.

LARABE SHOAL, in lat. $3^{\circ} 33'$ S., long. $107^{\circ} 10'$ E., and distant nearly 6 miles E. by N. $\frac{1}{4}$ N. from the Hancock Shoal, is about a third of a mile in extent, having $3\frac{1}{2}$ fathoms of water over it, and 5 to 8 fathoms around it.

SAND ISLAND is the name given to a small patch of sand, just awash at high water, with 8 to 14 fathoms water around it, lying about 4 miles northward of the Larabe Shoal, in lat. $3^{\circ} 29'$ S., long. $107^{\circ} 9'$ E. At a mile E.N.E. from Sand Island is a shoal patch about a third of a mile in extent, having $2\frac{1}{2}$ fathoms water over it, and 8 to 9 fathoms around it; the tide also ripples over this bank.

There is a danger, named *Padang Reef*, marked on the chart about $2\frac{1}{4}$ miles W. $\frac{1}{2}$ N. of Sand Island, but we have no information about it.

MIDDLE REEF, lying N.N.E. $\frac{3}{4}$ E. nearly $2\frac{1}{2}$ miles from Sand Island, appears to be a rock, just above water, on the North end of a small sand patch having 2 fathoms water over it, and 8 to 9 fathoms around it.

BRANDING SHOAL (*Breaking*, Dutch).—North-west, nearly $1\frac{3}{4}$ mile from Middle Reef, are two small patches occupying a space about two-thirds of a mile in extent, E.N.E. and W.S.W., and with 12 fathoms water between them. The western patch has $1\frac{1}{4}$ fathom water over it, the eastern one only 3 ft.; all around them are 7 or 8 fathoms.

FAIRLIE ROCK, in lat. $3^{\circ} 27\frac{1}{4}'$ S., long. $106^{\circ} 59'$ E., was discovered by the East India Company's ship of that name grounding upon it in 1813. It is of coral, about a cable's length in diameter, nearly awash at low water, and 6 or 7 fathoms close around it. The sea breaks over the rock, and all around are overfalls caused by the rocky and uneven character of the bottom. From it Entrance Point, the south-eastern extreme of Pulo Lepar, bears N. by W. $\frac{1}{2}$ W., distant $26\frac{1}{4}$ miles, and Shoal-water Island N.E. by E. 15 miles, and just in sight from the deck of a large ship; therefore, to avoid this rock, Shoal-water Island must, from the deck of a large ship, be sunk below the horizon by the time it bears N.E. by E., this island being the only land distinctly visible from the rock.

SHOAL-WATER ISLAND and **SHOALS** form a group amongst which it would not be prudent to venture. *Shoal-water* or *Embleton Island*, in lat. $3^{\circ} 19\frac{1}{2}'$ S., long. $107^{\circ} 11\frac{3}{4}'$ E., is a little more than half a mile in diameter,

and from it Middle Reef bears S. $\frac{3}{4}$ W., distant 8 miles. Hancock is a small islet, lying N.E. $\frac{1}{2}$ N., three-quarters of a mile from Shoal-water Island.

Dangerous reefs surround both these islands, among which are some deep but very narrow and intricate channels. From Shoal-water Island a reef extends from half to three-quarters of a mile, on its S.E., South, and S.W. sides; and about half a mile off its West side is a small detached reef, having 10 fathoms between it and the reef bordering that side of the island. Off its East side reefs extend nearly $1\frac{1}{2}$ mile. The reefs surrounding Hancock Island are separated from those around Shoal-water Island by a very narrow channel, with depths of 6 to 10 fathoms on it. On the N.E. side of Hancock the reef extends about a third of a mile, and on its N.W. side about three-quarters of a mile, with some rocks above water on its outer edge.

One-fathom Patch.—A patch having but 1 fathom water over it, and 7 to 9 fathoms around it, lies W. $\frac{1}{4}$ N. nearly 2 miles from Shoal-water Island.

Embleton Rock is just above water on the N.W. extreme of a bank of hard sand, which nearly dries, distant 2 miles N.N.W. $\frac{3}{4}$ W. from Shoal-water Island; there are 12 to 14 fathoms around it.

Bliss Shoal, lying N.E. by E. nearly a mile from Embleton Rock, and N. $\frac{3}{4}$ W. $2\frac{1}{4}$ miles from Shoal-water Island, is about a third of a mile in extent, N.W. and S.E.; it has only a quarter of a fathom water over it, and 6 to 14 fathoms at a short distance from it.

There appear to be no dangers between the reefs contiguous to Shoal-water and Hancock Islands, or between One-fathom Patch, Embleton Rock, and Bliss Shoal, the soundings being from 6 to 14 fathoms; but vessels had better keep well outside, as there is nothing to be gained by venturing among those dangers.

BLAS MATEU ROCK is said to lie right in the fairway track of vessels proceeding through Gaspar Strait by the Macclesfield Channel. The American surveyors searched for it without success, but their chart does not exhibit many soundings in that vicinity, and it would be very unsafe to disregard its reputed existence in the face of the following circumstantial account:—The Blas Rock was first discovered on September 23, 1839, by the Spanish brig *San Joachim*, Captain Blas Mateu. Having anchored in 12 fathoms, coarse sand, he took the boat and found three rocks, each about 10 ft. in diameter. Upon the northern rock he had 9 ft., on the southern 12 ft., and on the western 17 ft. water, and between them passages of $4\frac{1}{2}$ fathoms. Shoal-water Island bore E. $\frac{1}{4}$ N., the opening between the two hills on Lepar Island N.N.W. $\frac{1}{2}$ W., and the latitude determined by the sun's meridian altitude $3^{\circ} 20' 38''$ S. The whole extent of the three rocks is about half a cable's length, and round them the depths were 12, 13, and 14 fathoms; but there was reason to believe that there were more rocks, because the chain parted while the anchor was being weighed.

Another Spanish captain, M Aldon, who examined these rocks afterwards, gives them a similar description, and states that the light colour of the water over them was distinctly visible at a considerable distance N.N.W. of them. He places them in $3^{\circ} 21' S.$, with Fairlie Rock S.S.E. $\frac{3}{4}$ E., Shoal-water Island East, and the hills of Lepar Island N.N.W.

To avoid this danger, Entrance Point must not be brought more to the westward than N. $\frac{1}{2}$ W., when Shoal-water Island bears between E. $\frac{1}{2}$ S. and E. $\frac{1}{2}$ N.

Sand Banks.—At 12 miles South of Entrance Point is a patch of 5 fathoms; and at $2\frac{1}{2}$ miles W. $\frac{1}{2}$ S. of this is another of the same depth; between them the depth is 7 fathoms. These spots appear to be on the eastern end of one of the long sand ridges which lie to the southward of Banka (page 200), probably an extension of the strip upon which is shown the following sounding of $4\frac{1}{2}$ fathoms.

A Bank, in $3^{\circ} 19' S.$, with $4\frac{1}{2}$ fathoms water, lies South from a remarkable hummock in Banka; and there are two other banks of 5 fathoms, from which a hummock upon the low long point of Baginda bears N.N.W. $\frac{1}{4}$ W. To avoid these banks, the low land which unites the hills of Banka must be kept from a vessel's deck below the horizon, till Entrance Point bears N. by W., when a vessel may steer towards the strait; taking care not to bring this point more to the northward than N. by W. or N. $\frac{1}{2}$ W.

VANSITTART SHOALS are a collection of rocky patches divided into groups, lying between the bearings of S.E. $\frac{1}{2}$ E. and E. $\frac{3}{4}$ S., distant about 12 miles from Entrance Point, and extending from lat. $3^{\circ} 10'$ to $3^{\circ} 4' S.$ At their southern part are two patches, lying E. $\frac{1}{2}$ S. and W. $\frac{1}{2}$ N. from each other, their inner edges being about $2\frac{1}{3}$ miles, and their outer edges nearly $3\frac{1}{2}$ miles apart. From the western patch of $1\frac{1}{2}$ fathom water, Entrance Point bears N.W. $\frac{1}{2}$ W. 12 miles, Shoal-water Island S.E. $\frac{1}{4}$ E. 14 miles, and Barn Island N.N.E. $\frac{1}{4}$ E. 12 miles; from the eastern patch of only 3 ft. water, Shoal-water Island bears S.E. $\frac{1}{2}$ S. $11\frac{1}{2}$ miles, and Barn Island N. by E. $\frac{1}{4}$ E. 11 miles.

Nearly the centre of the space occupied by these shoals are a group of patches extending N.E. and S.W. about a mile, some having but 1 fathom over them, and one patch, the north-eastern, dries at low water.

The patches at the northern end of the shoals lie close together, and extend in an E.N.E. and W.S.W. direction, about $2\frac{1}{2}$ miles. One or two of them are dry, and others have but 3 ft. water over them at low tides. From the S.W. patch, which dries, Barn Island bears N.N.E. $\frac{1}{2}$ E., distant $6\frac{1}{2}$ miles; the South extreme of Saddle Island is open of the South extreme of Low Island, N.E. by E. $\frac{1}{2}$ E.; and Pulo Jelaka bears N. by W. $\frac{2}{3}$ W. 13 miles. From the N.E. patch, of 2 fathoms water, Low Island is distant $2\frac{1}{2}$ miles, with its South extreme in line with the middle of Saddle Island, bear-

ing N.E. by E. ; and Sand Island is just open of the East extreme of Pulo Leat, bearing N. $\frac{1}{2}$ W.

The marks to clear the Vansittart Shoals are given hereafter.

GEORGE BANKS is the name given, on the American chart, to four or five patches, under a depth of 5 fathoms, lying southward and south-westward of the western Entrance Point. The southern extreme of one of these patches, which is about $1\frac{1}{2}$ mile long North and South, half a mile broad, and has 3 fathoms water on it, lies S.W. $\frac{1}{2}$ W. 4 miles from Entrance Point. About a mile S.W. of this patch is another, but smaller one, of $3\frac{1}{2}$ fathoms water ; and 5 miles S.W. by W. $\frac{1}{2}$ W. from this last patch, or S.W. $\frac{1}{4}$ W. 9 miles from Entrance Point, is a patch of $3\frac{1}{4}$ fathoms water, but this latter lies quite out of the ordinary track of vessels. All these patches lie within the edge of the 10-fathoms line, which, passing Entrance Point about $1\frac{1}{2}$ mile off, runs with an irregularly curved outline to the south-westward.

A bank, under a depth of 10 fathoms, 9 or 10 miles long, which assumes on the chart the form of a shoulder of mutton, N.E. and S.W., with its small end to the north-eastward, lies nearly 2 miles outside the 10-fathoms line extending from Pulo Lepar. Between it and the shore banks the depths are 13 to 17 fathoms.

Two-and-a-half Fathoms Bank.—About the middle of the above shoulder of mutton bank, and about a mile from its eastern or outer edge, is a patch of only $2\frac{1}{2}$ fathoms water. This was formerly known as the George Bank, because the ship *Royal George* had, in 1813, passed over its edge in $5\frac{1}{2}$ fathoms. It was afterwards explored by Capt. D. Ross. From it Entrance Point bears N. $\frac{1}{3}$ W., distant $6\frac{1}{2}$ miles ; and Baginda Peak, on Banka Island, W. by N. $\frac{2}{3}$ N., $12\frac{1}{2}$ miles. To avoid this bank, keep the high trees near Klippige Point, or Rocky Point Hill, open to the eastward of Entrance Point.

About 2 miles West of the $2\frac{1}{2}$ -fathoms bank is a small patch with 5 fathoms water over it.

Two-fathoms Patch.—It would appear from the following report of Capt. Keay, of the ship *Falcon*, March 13th, 1862, that a patch having but 2 fathoms water over it, lies about 3 miles to the southward of Round Island, off the South point of Pulo Lepar :—

Clear, light, northerly, and smooth sea ; steering towards Entrance Point, Gaspar Strait ; Round Island bearing N. $\frac{1}{2}$ W. by compass, ; apparently 3 miles distant, the *Falcon* drawing 18 ft., ran aground on a small sand patch, with 12 ft. least water over it, the diameter of the shallowest part being about 30 ft. The position of this was not properly ascertained by cross-bearings, but it seems as if it was not one of the previously known shoals off the entrance of the Lepar Strait.

MACCLESFIELD CHANNEL.

The approach to the Macclesfield Channel, the westernmost of those through Gaspar Strait from the southward, is bounded on the eastern side by the Hippogriffe Shoal, the position of the Doubtful dangers (page 229), the Fairlie Rock, and the Vansittart Shoals; and on the western side by the outermost of the George Banks. The Blas Mateu Rock, if it exists, lies right in the fairway.

The Sharpshooter, Hancock, and Turtle Shoals, may be said to form a point, from which the shoals already mentioned as bounding the eastern limit of approach to Macclesfield Channel diverge in one direction, whilst those forming the western limit of approach to Stolze and Clements Channel diverge in another; these last may also be said to form the eastern limits of the southern entrance to Macclesfield Channel, as vessels may stand to the eastward of the Fairlie Rock over towards them, if they should find it convenient to do so.

EAST COAST of BANKA.—From Tanjong Baginda (page 199), the south-western limit of Gaspar Strait, the coast of Banka turns sharp to the northward, and after running 4 miles in a northerly direction, forms a large bay, the northern limit of which is Brekat Point, which is also the north-western limit of Gaspar Strait. There are several rivers upon this part of the coast, the principal of which, the *Medang*, is sometimes visited by coasters, but little is known of it.

LEPAR STRAIT, between Banka and Pulo Lepar, is 6 or 7 miles wide at the entrance, but narrows to less than 2 miles some 4 or 5 miles within. The entrance appears from the chart to be barred, although there seems to be deep water inside. It is said to be so crowded with small islands and reefs, as to be available only for small coasters. The most southern of these islands, named *Sugar-loaf*, is very conspicuous, rising to a peak 650 ft. high.

PULO LEPAR is an irregularly shaped island, about 12 miles in diameter, lying close off the southern part of the East coast of Banka. On its southern part are several ranges of hills of moderate elevation, viz: *Six Peak Range*, 781 ft. high; *Maroon Hill*, 850 ft.; *Four Peak Range*, 750 ft.; and two hills not named on the chart, 650 ft. high; further to the westward is a hill, 700 feet high, named *False Sugar-loaf*.

Entrance Point, the south-eastern extreme of the island, is in lat. $3^{\circ} 1\frac{1}{2}'$ S., long. $106^{\circ} 53'$ E. The land over it is hilly, and the point is bordered by a reef, extending 1 or 2 cables' lengths from it. *Pergam* or *Round Island* is a small islet surrounded by reefs, lying W.S.W. $2\frac{2}{3}$ miles from Entrance Point, and about half a mile off the South coast of the island. *False Rocky Point* bears N. $\frac{2}{3}$ E., distant 4 miles from Entrance Point. Immediately to the northward of it is a small stream named Red River.

Rocky Point and Light.—*Tanjong Laboe, Klippige, or Rocky Point*, the N.E. extreme of Pulo Lepar, is distant $1\frac{1}{2}$ mile N. $\frac{1}{2}$ E. from False Rocky Point. Rocky Point Hill, 522 ft. high, stands $1\frac{3}{4}$ mile to the westward of the point. The light on Rocky Point was first shown in October, 1870. It is a *fixed bright light*, elevated 39 ft., and visible in every direction seaward 8 miles off.

At $1\frac{1}{4}$ mile N.W. $\frac{3}{4}$ W. from the lighthouse is Tree Point, from which the coast runs nearly straight to the north-westward for about 6 miles.

Shore Reef.—The whole coast from Entrance Point to Tree Point is fronted by a reef, which at about 2 miles northward of Entrance Point, just to the southward of the entrance of Fresh-water River, extends off to the distance of $1\frac{1}{2}$ mile; it then runs nearly straight to the northward, and rounding Rocky Point at a quarter of a mile, turns to the north-westward, and beyond Tree Point projects but a short distance from the shore.

Water.—To the northward of Entrance Point the coast forms a bay, in which are two small rivers. Vessels may anchor about a mile to the north-eastward of the point, abreast of which position is a sandy beach. Captain Ross watered here, and found the water a little tinged with a red colour, but it produced no pernicious effect upon the crew.

KLIPIGE SHOALS is the name given to three or four reefs, with rocks above water on them, and deep channels between them, lying off Rocky Point. The outer reef lies E. by N. $\frac{2}{3}$ N. 2 miles from the point; the southern reef, over which is a depth of 4 fathoms, lies E. $\frac{1}{3}$ N., 2 miles from False Rocky Point.

Close to these shoals are depths varying from 9 to 14 fathoms, and there appears to be a channel three-quarters of a mile wide, with 6 to 10 fathoms in it, between them and the shore, but it would be a very unwise proceeding for vessels to venture to use it.

Discovery Rocks appear on the American chart as two rocks lying N.N.E. $\frac{1}{2}$ E. $3\frac{3}{4}$ miles from Rocky Point, with a shoal bank extending nearly half a mile north-eastward of them. Close to the rocks and bank are 6 to 10 fathoms, with 13 to 15 fathoms at a short distance all around them.

Capt. D. Ross, in the *Discovery*, was the first to determine the exact position of these rocks, and he says they have only 2 ft. least water over them.

A rocky Patch, with only 3 ft. water over it, lies about $1\frac{1}{2}$ mile W. by S. from the Discovery Rocks. In the channel between the soundings are from 10 to 16 fathoms.

There is also a 4-fathom patch lying midway between Rocky Point and the rocky patch, and a $4\frac{1}{2}$ -fathom bank $3\frac{1}{2}$ miles N by W. from Rocky Point.

PULO LEAT, or *Middle Island*, which separates Macclesfield Channel from Clements Channel, is about $5\frac{3}{4}$ miles long, North and South, and $4\frac{3}{4}$ miles wide. Upon it are several hills, 400 to 600 ft. high, which appear at a distance like a group of islands.

LIGHT.—*Pulo Jelaka* is a small islet lying about a quarter of a mile north-westward of the West point of *Pulo Leat*, to which it is connected by a reef of rocks. Since the year 1870 a *fixed bright light* has been shown from *Pulo Jelaka* over the *Macclesfield Channel* to the westward from N.E. by N. round by North and West to S.S.E. It is elevated 39 ft., and visible 8 miles off. A *dangerous reef* surrounds both *Pulo Leat* and *Pulo Jelaka*, in addition to which are numerous outlying rocks, in many places extending far from the shore.

The South and S.W. coasts of *Pulo Leat* are fronted by a reef which projects from the shore in a convex form to seaward for the distance of a mile. Off the S.E. point of the island are outlying rocks and dangers extending in a S. by W. $\frac{1}{4}$ W. direction, to the distance of nearly $2\frac{1}{2}$ miles. A rock also lies about three-quarters of a mile South of *Jelaka*, just outside the edge of the reef extending from the shore, but there are no other outlying reefs on the S.W. coast of the island.

When three-quarters of a mile distant from *Jelaka*, outside the reef extending from the shore, is a 3-fathoms patch; and N.W. by W., more than a mile from that islet, is a rock near the water's edge, with 11 fathoms water between it and the shore reef. All along the N.W. shore of *Pulo Leat*, and at little less than 2 miles from it, are numerous outlying rocks and patches of reef, between which and the reef extending from the shore are some dry sand-banks.*

ALCESTE REEF.—The *Alceste* Rock, upon which H.M. ship of that name was wrecked in February, 1817, when returning from China with Lord Amherst and suite, is the outer patch of a coral reef which projects N.N.W. nearly 2 miles from the North point of *Pulo Leat*, and has but 2 fathoms water on its shallowest part. It is the same reef upon which, in 1816, the Portuguese ship *Amelia* was wrecked, the remains of both her and the *Alceste* being still visible, with only a few yards between them, at the time the reef was surveyed by Captain D. Ross. The wreck of the *Alceste* was lying $1\frac{1}{2}$ mile from the North point of *Leat*, with the West point of *Jelaka* in one with the southern sand-bank West of *Leat*; the northern sand-bank in one with a white rock which lies between *Jelaka* and the N.W. point of *Leat* and close to it; and a white rock near the N.W. point open to the eastward of a high tree on the centre of the eastern hill of *Leat*.

Many ships have since been lost on this reef, or on some of the coral patches contiguous to it, and they have generally furnished bearings which

* Captain Joass, of the British ship *Lammermuir*, reports that at 2^h 20^m a.m., December 31st, 1863, when proceeding through the *Macclesfield Channel*, his vessel struck on a rock, the position of which, from bearings taken, is lat. 2° 53' S., long. 107° E. H.M.S. *Rifteman* has since searched for this rock, but could find no danger in the vicinity of the position ascribed to it.

would show them to have been wrecked some distance from these dangers; but the wrecks of several of them have afterwards been found upon, or close to the Alceste Reef; and two such wrecks, the *Cornelius Haja** and the *Memnon*, have found a place on the American chart. There is good reason to believe that there is no danger in the fairway of the Macclesfield Channel in this vicinity.

A reef is placed by Dutch authorities 2 miles E. by N. from Alceste Reef, with only 6 ft. water. From a position three-quarters of a cable northward of the shoal, the northern point of Pulo Leat bears S.W., and the eastern point of Bulo Anak, or Selagin, S. by E. $\frac{1}{2}$ E.

The soundings round Alceste Reef do not by any means afford a certain guide, although to the north-eastward they appear to be a few fathoms shoaler than elsewhere. Close-to on the West side are 17 fathoms, and from 15 to 21 fathoms at the distance of 1 or 2 miles; close-to on the North side 12 fathoms, with 16 to 18 fathoms at 1 or 2 miles; and close-to on the N.E. side 16 fathoms, with 12 to 17 fathoms at 1 to 2 miles.†

KILAPAN and **SENIOR** are two hilly islands lying 2 or 3 miles North of Pulo Lepar. Kilapan is about $1\frac{1}{2}$ mile in extent East and West, and a mile wide, and bears from Rocky Point light, N.W. by N. $6\frac{1}{4}$ miles. Senior is not quite so large as Kilapan, from which it bears W. by N. 2 miles.

Wilson Bank, discovered by Captain Lestock Wilson, of the *Carnatic*, in February, 1787, has but 1 fathom water on its shoalest spot, although Capt. Wilson did not find less than 3 fathoms. From the 1-fathom spot the extreme of Brekat Point, the N.W. point of Macclesfield Strait, bears N.N.W. $\frac{1}{4}$ W. $6\frac{1}{2}$ miles; the hummock just inside the point, which is more conspicuous, bearing N.W. by N. The bank extends about a mile to the northward of the shoal patch, having $2\frac{3}{4}$ fathoms over that part of it; to the southward it extends about a quarter of a mile. Close-to on the East side are 13 or 14 fathoms, but to the N.N.E. 8 to 10 fathoms for about $1\frac{3}{4}$ mile, when the depths suddenly increase to 19 or 20 fathoms. The extreme of Brekat Point bearing

* This vessel was reported to have struck on a rock in lat. $2^{\circ} 44\frac{1}{2}'$ S., long. $107^{\circ} 1'$ E.—*Horsburgh*.

† The barque *Carl Ronneberg*, Captain C. L. Lied, is reported to have struck upon a rock about 6 miles to the northward of the Alceste Reef, in lat. $2^{\circ} 42'$ S., long. $107^{\circ} 5'$ E. It is said to be about a cable's length in circumference, having from 4 to 20 ft. water on it, and surrounded by depths of 19 fathoms. The American chart exhibits many soundings in the locality ascribed to this danger, which were obtained in searching for the rock on which the *Cornelius Haja* was reported to have been wrecked, said to lie W.S.W., distant 4 miles from the reported position of the Lied Rock. Mr. Richards, in H.M.S. *Saracen*, also searched for the *Cornelius Haja* Rock without discovering any danger in that locality: for these reasons the Lied Rock is not placed upon the Admiralty charts, and the wreck of the *Cornelius Haja* (as mentioned above) was subsequently found by the American surveyors upon the Alceste Reef.

N.W. by N., or the hill over it N.W., leads a mile outside Wilson Bank, as does also the eastern extreme of Kilapan Island, bearing S. by W. $\frac{1}{4}$ W. The same bearings also clear the elbow of Brekat Bank.

Brekat Bank.—A long, narrow strip of bank, which appears to have from 3 to 4 fathoms water over it, and deeper water inside of it, runs in a S. by W. direction for 3 or 4 miles to the southward of Wilson Bank, and, passing about $1\frac{1}{4}$ mile westward of that shoal, forms to the northward, about a mile farther on, an elbow projecting to seaward, with $1\frac{1}{4}$ fathom water on it, and a small patch which dries at low water; it then takes a N. by W. $\frac{1}{2}$ W. direction, until it joins the bank extending from Brekat Point, which bears from the elbow N.N.W., distant 4 miles.

The soundings in the channel between Brekat and Wilson Banks are $4\frac{1}{2}$ to 8 fathoms. Near the elbow they decrease suddenly from 10 fathoms; there are 9 or 10 fathoms at $2\frac{1}{2}$ miles eastward of the elbow, and 12 and 15 fathoms at a mile N.E. of it.

BREKAT POINT, in lat. $2^{\circ} 34' S.$, long. $106^{\circ} 50' E.$, has a rock off it 28 feet high, and forms the eastern extreme of Banka, and the north-western limit of Gaspar Strait. The land from the inner part of the projecting point falls away to the southward, and has a hill or hummock 620 ft. high upon it. Immediately off the point are some rocks, and shoal water extends nearly a mile from it to the eastward. The point should not be approached nearer than 2 miles, the soundings off it being deep and irregular, 14 to 21 fathoms.

AKBAR SHOAL.—The American ship *Akbar* struck, in 1843, upon a shoal having only 12 ft. water upon it, in lat. $2^{\circ} 39' S.$, long. $107^{\circ} 11' E.$ In the American chart the position of this shoal is marked doubtful, so that the American surveyors did not succeed in finding it.

The ship *Seawfell* reports that, on March 23rd, 1864, she passed close to the Akbar Shoal, which had apparently very little water on it, though no breakers, as the sea was quite smooth. It appeared to be a narrow ridge of coral, about 2 cables long, North and South, and not half a cable wide. Its position is given as $2^{\circ} 38' S.$, long. $107^{\circ} 13\frac{1}{2}' E.$

This places the shoal 3 miles N.E. by E. from the position ascribed to it by the *Akbar*; in either case it is much in the way of vessels proceeding through Clements or Stolze Channels, and until its exact position is determined, it will be necessary to keep clear of the localities in which it is reputed to lie.

TREE ISLAND (*Boompjes Eiland*), distant 10 miles N.E. $\frac{1}{4}$ E. from Brekat Point, and 7 miles S.W. by W. $\frac{1}{2}$ W. from Gaspar Island, is a barren rock, 40 ft. high, with two or three trees on the summit, giving it the appearance of a ship under sail, and making it visible 15 miles off. It is surrounded by a coral reef, and a rock about as high as a boat lies a third of a mile south-eastward of it. There is a cave upon this island where the Malays

come to collect birds' nests, which are probably found also on the other islands.

A detached coral reef lies more than half a mile N.E. of the island, and another about the same distance S.E. of it; between these reefs and the one surrounding the island are narrow channels, with deep water.

GASPAR ISLAND, or *Pulo Gelassa*, in lat. $2^{\circ} 24\frac{3}{4}'$ S., long. $107^{\circ} 3\frac{1}{2}'$ E., bears N. $\frac{1}{4}$ E. $24\frac{1}{4}$ miles from the North point of Pulo Leat, and N.E. $\frac{3}{4}$ E. nearly 17 miles from Brekat Point. Its centre rises to a peak 812 ft. high, which may be seen in clear weather at a distance of 30 miles, and is the principal mark for avoiding the shoals in sailing to or from the northern part of the strait. It is nearly surrounded by a reef, which projects from the South and East points of the island about a third of a mile. The West and North points are bold close-to. The soundings near the island are variable, 12 to 19 fathoms.

Fresh water is to be found upon this island, but the chart does not point out the particular spot where it may be obtained.

Glassa or Gelassa Rock, 24 ft. high, with some trees on it, and rocks contiguous to it, lies about a mile westward of Gaspar Island. It is surrounded by a reef extending about a third of a mile south-eastward and eastward from it, but not quite so far in other directions.

Gaspar Island, Glassa Rock, and Tree Island, form the northern limit of Gaspar Strait. The Canning Rock, Warren Hastings Reef, Belvidere Shoals, and other dangers, are described hereafter.

TIDES and CURRENTS.—It is high water, full and change, in the Macclesfield Channel, at $2^{\text{h}} 30^{\text{m}}$, and the ordinary rise is only 4 ft. The *Vansittart's* boat is reported to have found at Tree Island a perpendicular rise of 18 ft., between the hours of 8 a.m. and 5 p.m.; but there is probably some mistake in this, as 12 ft. is an extraordinary rise in Banka Strait, into which some very large rivers disembogue.

The currents greatly depend upon the strength of the monsoon. When the monsoon is strong, the current will generally be found setting in the same direction at the rate of 2 or 3 knots an hour, but affected somewhat by the tides. In light winds and calms the tides are seldom very regular.

Directions from the Southward.—Proceeding towards the Macclesfield Channel during the S.E. monsoon, having passed the Two Brothers (p. 185), steer N. by E. $\frac{1}{2}$ E., or N.N.E., keeping midway between the Clifton Shoal and the Brouwers Reefs. The depths in this track are pretty regular, 10 to 15 fathoms, soft bottom. In thick weather, or if uncertain of the vessel's position, the entrance of Gaspar Strait should be approached with great caution, keeping a good lookout for broken or shoal water.

Be also guarded when in the vicinity of the Blas Mateu Rock, for although the American surveyors could not find that danger, yet, for reasons given at p. 231, it would be unsafe to conclude that it does not exist. The Six-peak

range (the first clump of hills to the westward of Entrance Point) kept N. by W., will lead 3 miles westward of this rock, and when Baginda Peak bear N.W. $\frac{1}{2}$ N., and the water has deepened from 8 or 9 to 11 or 15 fathoms, steer to the north-eastward until the highest trees on Klippige or Rocky Point, or Rocky Point Hill, are well open of Entrance Point, which will lead clear of the $2\frac{1}{2}$ -fathom bank.

Being 3 or 4 miles to the northward of the Blas Mateu Rock, a N. $\frac{1}{2}$ E. course—guarding against currents—for 14 miles, will lead about 5 miles eastward of Entrance Point, and in this track the depths will be 13 to 18 fathoms; if the vessel gets too far to the eastward the water will deepen, and if to the westward, it will shoal to 12, 11, or 9 fathoms. From 5 miles eastward of Entrance Point, a North course for about 16 miles will lead nearly midway between the shoals West of Jelaka and the Discovery Rocks. In this track there will be from 14 to 25 fathoms till abreast of Klippige or Rocky Point, when there will be 23 or 24 fathoms, deepening to 30 or 33 fathoms between Pulo Jelaka and the Discovery Rocks, having passed which they will decrease to 25, 19, and 16 fathoms. The vessel will now have arrived in a position with Pulo Kilapan bearing S.W. by W., and the North point of Pulo Leat S.E. by E., and may steer N. by E. $\frac{1}{2}$ E. for Gaspar Island, in which track she will have 16 to 21 fathoms.

Since the survey of the sandbanks South of Banka by Mr. Stanton, it no longer appears dangerous to approach the coast to a less distance than 14 miles, and it might be convenient for a vessel to make Entrance Point on a N. by E. or N.N.E. bearing, and pass inside the $2\frac{1}{2}$ -fathom bank by keeping Klippige and Entrance Points in line.

To work through from the Southward.—During the northern monsoon it is very difficult, almost impossible, to work through Gaspar Strait, even in the latter part of the monsoon, about March, when vessels are obliged to anchor often on account of the faintness of the wind and the rapidity of the southerly current. In the southern monsoon vessels will often meet with light, variable winds, rendering it impossible for them to preserve a straight course.

Macclesfield Channel does not afford convenient objects as marks to keep vessels clear of danger, but the following have been taken from the American chart as being, so far as we are able to judge, the best that can be given for that purpose; as, however, some of the objects are at a considerable distance from the dangers, navigators are cautioned not to depend too implicitly upon having made out, or being able to make out, such distant objects, but rather to rely upon a more general exercise of judgment, paying attention to the soundings, frequently referring to the chart, &c. It is indispensable that the greatest vigilance be observed, and careful regard had to the set of the tides and currents, in order to work a vessel safely through this dangerous channel.

Standing to the eastward.—A vessel having passed eastward of the Fairlie Rock may stand on, keeping a good lookout, until she is about $2\frac{1}{2}$ miles from Sand Island, or 1 mile from Branding Breakers, and will have from 13 to 7 fathoms water. Sand Island is just awash at high water, and Shoal-water Island, bearing N.N.E. $\frac{1}{2}$ E., leads a mile to the westward of the Branding Breakers. Shoal-water Island should not be approached nearer than 3 miles, on account of the 1-fathom patch lying about 2 miles westward of it.

The Java Guide gives the following directions to clear the Vansittart Shoals:—

“To avoid the Vansittart Shoals with a contrary wind, do not bring Entrance Point more to the westward than N.W. $\frac{1}{2}$ N. before the peak of Saddle Island bears N.E. by E., or rather keep Leat Island a little to the eastward of North. When near the N.W. part of these shoals, the West end of Leat may be brought N. $\frac{1}{2}$ W., but not more westerly, until South Island is open to the northward of Low and Saddle Islands. The northern extremities of these two islands, and the southern part of South Island in one, E. by N. $\frac{3}{4}$ N., just clear the northern part of the shoals.”

It appears, however, by the American chart, that Entrance Point bearing N.W., and the peak of Saddle Island N.E. $\frac{1}{2}$ E., will keep a vessel nearly $1\frac{1}{2}$ mile clear of the S.W. prong of the shoals. Leat Island a little eastward of North, seems rather an indefinite mark, unless it be known how much of the island is visible; but, taking it to mean the highest point, viz., Putat Hill, 613 feet high, and which would appear from the southward nearly in the middle of the island, it should not be brought to the northward of N. $\frac{1}{2}$ E., until the peak of Saddle Island bears N.E. $\frac{1}{2}$ E., when it may be brought to bear North. The North extremes of Saddle and Low Islands in line, bearing N.E. by E. $\frac{3}{4}$ E., clears the northern end of the shoals nearly a mile.

Being to the northward of the Vansittart Shoals, Low Island must not be brought South of E. by S. $\frac{1}{2}$ S., or Sand Island West of North, to avoid the shoals between those islands; and to clear the patches lying southward of the S.E. point of Pulo Leat, keep Barn Island East of E.S.E., until Middle Point, or Putat Hill, bears N. by W. $\frac{1}{4}$ W., when Barn Island may be brought to S.E. by E. $\frac{1}{2}$ E., which will clear the reef extending from Middle Point. To clear the reefs South of Jelaka, the S.E. point of Leat should not be shut in by Middle Point, until Pulo Jelaka bears N.N.E.; and to avoid the reefs westward of that islet, keep Middle Point East of E.S.E., until Jelaka bears East. Jelaka bearing East also leads northward of the Discovery Rocks.

Having arrived 2 miles West of Jelaka, and to the northward of the Discovery Rocks, Entrance Point must not be brought West of S.S.W. $\frac{1}{4}$ W.,

nor Klippige Point West of S.W. $\frac{3}{4}$ S., until Pulo Kilapan bears W.S.W., which will lead outside the dangers extending from the N.W. coast of Leat, and $1\frac{1}{2}$ mile to the northward of the Alceste Reef. Rocky Point Hill in line with Tree Point, S.W. $\frac{1}{4}$ S., leads about a mile north-westward of the Alceste Reef.

Standing to the westward.—To avoid the $2\frac{1}{3}$ -fathom bank, keep the high trees on Klippige or Rocky Point, or Rocky Point Hill, well open of Entrance Point, bearing N. by W. $\frac{1}{4}$ W., or keep Entrance Point West of N. by W. $\frac{1}{2}$ W., until Baginda Peak bears W. by N., when a vessel may stand over until Entrance Point bears N. by E. $\frac{1}{2}$ E.

To clear the Klippige Shoals, do not bring Entrance Point South of S.W. $\frac{3}{4}$ S., until the right extreme of Pulo Kilapan bears N.W. by W., Klippige Point S.W. by W., or Pulo Jelaka N.E. by E., leads about half a mile northward of the Klippige Shoals.

When standing towards the Discovery Rocks, do not bring Entrance Point South of S.S.W., or Klippige Point South of S.W. $\frac{1}{2}$ S., until the right extreme of Kilapan bears W. by N. $\frac{1}{4}$ N., or Pulo Jelaka, East, when a vessel will be northward of the dangers, and may stand westwards towards the bank into 10, or even 8 or 7 fathoms, until she nears Wilson Bank.

The Saddles, two hills on the Banka coast, 912 ft. high, bearing W.N.W., or the Padang Hills W. by N. $\frac{1}{4}$ N., lead about $1\frac{1}{4}$ mile southward of the Wilson Bank; and the extreme of Brekat Point, N.W. by N., leads more than half a mile eastward of that danger, and will also keep a vessel clear of the elbow when standing inshore between Wilson Bank and Brekat Point.

Directions from the northward.—In the early part of the N.E. monsoon, northerly and north-westerly winds prevail about the entrance of Gaspar Strait, when strong south-easterly currents will generally be experienced between Gaspar Island and Pulo Leat. It appears certain that the frequent accidents happening to vessels in the vicinity of Alceste Reef arise principally from neglecting to guard against the effects of this current. A vessel, therefore, intending to proceed to the southward through Macclesfield Channel, and having passed a mile or two eastward of Gaspar Island, should steer to the south-westward until Gaspar Island bears N. by E. $\frac{1}{2}$ E., upon which bearing it should be kept until Pulo Kilapan is S.W. by W., and the North point of Pulo Leat S.E. by E., when she will be in the fairway of the channel, and may steer South, carefully guarding against the effects of tides or currents by frequent cross bearings of the North point of Leat, Pulo Jelaka, Rocky Point Hill, or Pulo Kilapan. If a South course be preserved, when Pulo Kilapan bears West, Middle Point, the S.W. point of Leat, will be the breadth of Jelaka open of that islet, and Rocky Point will bear S.W. by S., which latter bearing also leads *close* to the East side of the Discovery Rocks. If, when Pulo Kilapan bears West, Middle Point be not open of Jelaka, the vessel will be too far to the eastward; and if Middle

Point should be more than the breadth of Jelaka open of that islet, she will be too far to the westward.

If, in consequence of light or baffling winds, it be found impossible to keep Gaspar Island N. by E. $\frac{1}{2}$ E., but that as the vessel approaches Pulo Leat it is found to bear N. by E., or N. $\frac{3}{4}$ E., great caution must be observed in passing Alceste Reef, for Gaspar Island bearing N. $\frac{1}{2}$ E. is the line of direction of that danger, and to avoid it Pulo Kilapan must not be brought westward of W.S.W. until Pulo Jelaka bears South.

Being in the fairway, with Pulo Kilapan bearing West, and Middle Point the breadth of Jelaka open of that islet, Entrance Point will be just in sight bearing about S.S.W. A ship may continue the South course, but if there be any doubt of her position, it will be prudent to bring Entrance Point S.S.W. $\frac{1}{4}$ W., which will lead through nearly in mid-channel between the Discovery Rocks and the dangers off Jelaka, the narrowest and most difficult part of the channel. But great care must be taken to preserve that bearing, Entrance Point being at so great a distance, that any error in the bearing would be extremely likely to lead into danger. Entrance Point bearing S.S.W. $\frac{1}{2}$ W., leads about half a mile westward of the dangers off Jelaka, and the same point S.S.W. leads clear of the Discovery Rocks.

When the S.E. point of Leat is open of Middle Point, the ship will be southward of the Discovery Rocks, and if she has been steering for Entrance Point, the course must be immediately altered to the south-eastward, until Entrance Point bears S.W. $\frac{1}{2}$ S.—which leads eastward of the Klippige Shoals—when a South course may be again shaped until Entrance Point bears about W. $\frac{1}{2}$ S.; then steer S. $\frac{1}{2}$ W. for 13 or 14 miles, or until Entrance Point is about N. by W. $\frac{1}{4}$ W., and Baginda Peak N.W. $\frac{3}{4}$ W., when the vessel will be in about 10 fathoms on the outer edge of the bank extending northward of the Blas Mateu Rock, and to clear that rock must steer about S.W. until the Six-peak range of hills on Pulo Lepar bears N. by W., when a S. by W. $\frac{1}{2}$ W. or S.S.W. course may be shaped for the Two Brothers.

To work through from the northward, it will generally be advisable to get over to the westward towards the Banka shore as soon as possible, where a vessel will be more in the fairway of the channel, and will find more convenient depths of water for anchoring, if it should be necessary to bring up.

If, however, when to the southward of Gaspar Island, it should be found advantageous to stand well over to the eastward, it is not advisable that Gaspar should be brought more westward than N. by W., or N. by W. $\frac{1}{4}$ W., when nearing the doubtful position of the Akbar Shoal; and the greatest care should be observed in rounding Alceste Reef, not to bring Pulo Kilapan westward of W.S.W. until Pulo Jelaka bears South.

Standing to the westward.—Tree Island may be approached to about a mile, or until Gaspar Island bears N.E. $\frac{3}{4}$ E., which leads that distance clear of the dangers extending from it. Brekat Point bearing N.W. by N., will

lead about half a mile eastward of the Elbow and of Wilson Bank, and a vessel will be to the southward of those dangers when the Saddles on Banka bear W.N.W., or Padang Hills W. by N. $\frac{1}{4}$ N., and may then stand on to the bank into 8 or 7 fathoms, until the North extreme of Pulo Kilapan bears W. by N. $\frac{1}{4}$ N., which leads northward of the Discovery Rocks. Klippige or Rocky Point, S.W. $\frac{1}{2}$ S., leads eastward of the Discovery Rocks, and also clears the shoals extending from the N.W. coast of Pulo Leat.

Standing to the eastward towards Jelaka, take great care not to bring Entrance Point anything West of S.S.W. $\frac{1}{2}$ W. until Middle Point is E.S.E., which leads southward of the dangers off Jelaka. Jelaka must then be kept East of N.N.E., until the S.E. point of Leat is in line with Middle Point, when it may be brought to bear North. To avoid the rocks off the S.E. point of Leat, do not bring Putat Hill, or Middle Point, West of N. by W. $\frac{1}{4}$ W., until Barn Island bears E.S.E. The East extreme of Pulo Leat bearing North will keep a vessel clear of the dangers extending from Sand Island, and Sand Island, if not brought to the West of N. $\frac{1}{2}$ W., will clear the dangers to the southward of it and of Barn Island. Saddle Island in one with Low Island, bearing E.N.E., leads about three-quarters of a mile northward of the northern group of the Vansittart Shoals; Putat Hill bearing North, or N. $\frac{1}{4}$ W., leads westward of the middle group; the same hill N. $\frac{1}{2}$ E. leads westward, and Entrance Point N.W. to the southward of the S.W. group. Shoal-water Island should not be approached from the westward nearer than 4 or 3 miles; bearing N.N.E. $\frac{1}{2}$ E., it will lead a mile westward of the Branding Breakers.

The Padang, Turtle, and Hancock Shoals may be approached to a mile, if a good lookout is kept when in their vicinity.

Standing to the westward when southward of the Discovery Rocks, the right extreme of Kilapan bearing N.W. $\frac{3}{4}$ W., or Entrance Point S.S.W. $\frac{1}{2}$ W., clears the northern cluster of the Klippige Shoals; but when Rocky Point bears West, Entrance Point should not be brought South of S.W. $\frac{1}{2}$ S. After passing Entrance Point, keep the high trees on Rocky Point, or Rocky Point Hill, open of Entrance Point, or keep Entrance Point West of N. by W. $\frac{1}{2}$ W., until Baginda Peak bears W.N.W., to clear the $2\frac{1}{2}$ -fathom bank.

CLEMENTS CHANNEL.

This channel is much narrower and more encumbered with dangers than either the Macclesfield or Stolze Channels. It is separated from the former by the four small islands, which from their appearance are respectively named Low, Saddle, Sand, and Barn, and by Pulo Leat, which form its western limit. To the eastward, it is only separated from Stolze Channel by South, North, and Table Islands, three small islands lying close together, so

that the entrances to both channels, either from the southward or the northward are common. The entrance to Clements Channel from the southward is, however, understood to lie to the westward of the Doubtful Dangers (page 229), Sharpshooter Rock, Hippogriffe Shoal, Hancock and Turtle Shoals, Sand Island, Padang Reef, Branding Breakers, Shoalwater Island, and Embleton Rock; whilst the entrance of Stolze Channel is considered to be to the eastward of those dangers; and this order will be observed in the description of these channels.

LOW and **SADDLE** are two small islands, a little more than half a mile in diameter, lying in a S.E. by S. direction about $8\frac{3}{4}$ miles from the southeastern point of Pulo Leat. They bear E.N.E. and W.S.W., and are distant a mile from each other. Low Island, the westernmost, is 123 ft. high; Saddle Island has two hills upon it forming a saddle, the western hill being 210, and the eastern 266 ft. high. Both islands are connected and surrounded by reefs, extending nearly half a mile from them.

Three *dangerous patches*, extending a mile in a N.W. and opposite direction, lie between the bearings of E. $\frac{1}{2}$ N. and N.E. by N., distant $1\frac{1}{4}$ mile from the East point of Saddle Island. In the Java Guide a dry reef is said to lie $1\frac{1}{4}$ mile N.E. by E. from Saddle Island, but in the American survey 1 fathom water is shown on the S.E. and N.W. patches, and 2 fathoms on the middle patch. Between the reefs and the island is a narrow channel of 8 to 14 fathoms water; close-to, on the outside of the reefs, are 15 to 19 fathoms.

Sand Island, lying S. by E. $\frac{3}{4}$ E. 5 miles from the S.E. point of Pulo Leat, is very small and low, and surrounded by rocks to the distance of a third of a mile. About half a mile to the northward of it are 12 or 14 fathoms, and from 10 to 23 fathoms the same distance to the southward.

Barn Island, lying about $1\frac{1}{4}$ mile E. by N. $\frac{1}{2}$ N. from Sand Island, is small, about a third of a mile in diameter, 154 ft. high, and surrounded by a reef to the distance of about a third of a mile. Between Barn and Sand Islands are depths of 8 to 14 fathoms.

Dangerous reefs, dry at low water, extend nearly 2 miles between the bearings of S.S.E. $\frac{1}{4}$ E. and S.S.W. $\frac{1}{4}$ W. from Barn Island.

SOUTH ISLAND, one of the islands limiting Clements Channel to the eastward, lies S.E. by E. $\frac{1}{2}$ E. $10\frac{1}{4}$ miles from the S.E. point of Pulo Leat. It is the largest of the islands in this vicinity, being about a mile in diameter; the highest hill upon it is 200 ft. high. It is surrounded by a reef extending from it in most parts about a third of a mile, but off its South end dangers project three-quarters of a mile. Close to the reef are from 5 to 14 fathoms, and 18 and 24 fathoms a short distance to the westward.

Table Island, lying E. by S. $1\frac{3}{4}$ mile from South Island, more properly belongs to Stolze Channel. It is surrounded by reefs projecting nearly half a mile from it, and in the middle of the channel between it and South Island, is a $2\frac{1}{4}$ -fathoms patch.

North Island, lying $1\frac{1}{4}$ mile northward of South Island, is also surrounded by a reef, which extends from it about a third of a mile. At two-thirds of a mile E.N.E. from the East end of the island is a dry bank with 16 fathoms close-to, and 12 fathoms between it and the reef extending from the island. A mile S.E. from the same end of the island is a patch of 3 fathoms.

Sunk Rock is 16 yards only in diameter, with 9 ft. water on it, and 10 fathoms around it. From it Saddle Island bears S. by W. $\frac{1}{4}$ W., $4\frac{3}{4}$ miles, North Island E. by N. $2\frac{1}{4}$ miles, Barn Island W. by S. $3\frac{1}{4}$ miles, a reef near Saddle Island South, the centre of Table Island and the North point of South Island are in one, and Sandy Island is entirely hidden by Barn Island.

From its position as placed upon the American chart, the southern extreme of North Island bears East, distant $2\frac{1}{2}$ miles; the south-western extreme of South Island S.E. by E. southerly; and the northern point of Barn Island W. by S. southerly. A quarter of a mile S. $\frac{1}{4}$ E. from it is a patch of 5 fathoms, with 13 fathoms between it and the rock.

Middle Pass Shoals are three coral patches lying close together, and extending nearly a mile in a N.E. by N. and opposite direction. From their southern extreme Barn Island bears S. $\frac{2}{3}$ E. 3 miles; and the south-eastern point of Pulo Leat bears N.W. by W. $\frac{3}{4}$ W. $2\frac{3}{4}$ miles. Barn Island, bearing S. $\frac{2}{3}$ W., leads about two-thirds of a mile to the eastward of the shoals; the southern extreme of North Island S.E. by E., clears them about the same distance to the north-eastward, and bearing E. by S. $\frac{1}{4}$ S., clears them to the southward; the S.E. point of Pulo Leat bearing W. $\frac{1}{4}$ S., clears them to the northward.

Coral Bank is a small patch just awash, with 12 to 19 fathoms around it, lying $1\frac{3}{4}$ mile north-westward of the Middle Pass Shoals. From it the S.E. point of Pulo Leat bears S.W. by W. $\frac{1}{2}$ W., nearly $1\frac{1}{2}$ mile; and Pulo Anak N. by W. $\frac{2}{3}$ W. westerly, $2\frac{3}{4}$ miles. The S.E. point of Leat bearing W. by S. $\frac{1}{2}$ S., leads to the southward of the bank, but over a $2\frac{1}{2}$ -fathom bank which lies between Rocky Bank and the S.E. point of Pulo Leat. The eastern extreme of Pulo Anak, N.W. by N., leads to the north-eastward.

HEWITT SHOAL, upon which, in August, 1820, the ship *General Hewitt* struck, and remained fast for half an hour, lies 5 miles N. by W. $\frac{1}{4}$ W. from the western extreme of North Island. When aground the western extremes of South and North Islands were in one; the extremes of Leat Island bore from W.N.W. to W. by S. $\frac{1}{8}$ S.; Barn Island S.W. by S.; and the hill on Brekat Point was well open of Pulo Leat. It is about a ship's length in extent, and 16 to 20 yards in breadth. The coral rocks were visible under the vessel with only 14 (or 18) ft. water over them, and near the shoal 12 to 15 fathoms.

The high part of South Island open of the West extreme of North Island leads westward of Hewitt Rock; and the same object open of the East extreme of North Island leads to the eastward.

PULO LEAT.—The western coast of this island and Jelaka light are noticed on pp. 235-6. The eastern coast takes a northerly direction for $3\frac{1}{4}$ miles from its S.E. point, when it runs about N.W. $\frac{1}{2}$ N. $3\frac{1}{2}$ miles to the northern point. The whole of this coast is fronted by a coral reef, which commences about half a mile northward of the S.E. point; in front of the bay, about three-quarters of a mile northward of the S.E. point, the reef extends half a mile, but not quite so far from the eastern extreme of the island. Close to the northward of the eastern extreme, upon the dry reef extending from the shore of the island, is an islet called Pulo Anak, or Selagin.

According to the American chart, *fresh water* may be obtained in the small bay, about half a mile to the northward of the S.E. point of Leat, just where the dry reef begins to project from the shore.

Rocky Shoal, lying N.E. by E. $\frac{1}{2}$ E. $1\frac{3}{4}$ mile from the S.E. point of Leat, is before described on page 246.

Of the N.E. coast of Pulo Leat, besides the reef projecting from the shore, are numerous outlying coral patches, extending nearly 2 miles from it, and rendering this part of the coast exceedingly dangerous. The north-eastern of these dangers—which bound this part of Clements Channel to the westward—lies with the S.E. point of Leat in line with the eastern extreme of the island, distant nearly 2 miles from Pulo Anak; from whence the dangers take a S. $\frac{3}{4}$ W. direction until they join the reef which projects about half a mile East of Pulo Anak.

A vessel will pass eastward of these dangers by keeping the S.E. point of Leat West of S. by W. $\frac{3}{4}$ W.; and North Island bearing S.E. $\frac{3}{4}$ S. will lead to the north-eastward.

Akbar Shoal is noticed on page 238.

The **MIDDLE PASS**, which unites Macclesfield and Clements Channels, is bounded on the S.E. by Sand Island, Barn Island, Sunk Rock, and North Island; and on the N.W. by the dangers projecting from the southern end of Pulo Leat and the Middle Pass Shoals.

To proceed from the Macclesfield Channel through the Middle Pass from the south-westward, steer between Entrance Point and the Vansittart Shoals towards Sand Island, the channel between which and the shoals extending from the southern end of Leat, is clear, with depths of 14 to 20 fathoms; Entrance Point kept bearing W. by S. $\frac{3}{4}$ S., leads through in mid-channel.

In the event of meeting with baffling winds, so that the vessel cannot preserve a straight course, the following may prove useful:—The East extreme of Pulo Leat bearing North, clears the dangers extending from the West side of Sand Island; the North extreme of Barn Island bearing East, clears the dangers extending from the North side of Sand Island; Barn Island E.S.E., clears the shoals projecting from the southern end of Leat; Middle Point of Leat W.N.W., clears the Middle Pass shoals; and the North extreme of Barn Island S.W. by W. $\frac{3}{4}$ W. leads North of Sunk Rock.

The Channel between Low Island and Sand Island is narrowed to the breadth of $1\frac{1}{2}$ mile by the shoals extending to the southward of Barn Island. It is not easy to see what advantage is to be gained by using this channel.

The Channel between Vansittart Shoals and Low Island is 2 miles wide, and may be used by bringing Sand Island to bear N.N.W., which will lead through in mid-channel.

CLEMENTS CHANNEL from the Southward.—Proceeding through Clements Channel from the southward, having passed the Fairlie Rock, steer about N. by E. or N. by E. $\frac{1}{2}$ E., if the vessel has passed on the South side of the rock, or about N.E. by N. if she passed on the North side. When the summit of South Island is made out, bring it N.N.E., which will lead between the Embleton Rock and the Vansittart Shoals; take care, however, not to mistake South Island, remembering that Low and Saddle Islands will be seen to the westward of it. Low Island bearing N.N.E. leads over the south-eastern prong of the Vansittart Shoals.

Approaching South Island on a N.N.E. bearing, the soundings will be 9 to 13 fathoms until well up with Low Island, when they will deepen to 16 and 18 fathoms, and to 24 or 25 fathoms when abreast of Saddle Island. When Saddle Island bears West, steer N. by W., which will lead more than a mile clear of the reefs off the north-eastern end of Saddle Island, and midway between North Island and Sunk Rock, and in this track the soundings will be 22, 24, 17, 24, and 23 fathoms. When the North extreme of North Island bears East, steer N.W. by N. for 5 or 6 miles to pass between Middle Pass Shoals and Hewitt Shoal, in depths varying from 22 to 32 fathoms; when the S.E. point of Leat bears about W.S.W., a N. $\frac{3}{4}$ W. course may be shaped for Gaspar Island.

To pass westward of Sunk Rock, keep the summit of South Island N.N.E., until Saddle Island bears W. by S., when steer N.W. $\frac{1}{2}$ W., which will lead clear of the shoals north-eastward of Saddle Island, and between Barn Island and Sunk Rock, and between Middle Pass Shoals and Hewitt Shoal.

No vessel would from choice attempt to work through Clements Channel, as Macclesfield and Stolze Channels are much better adapted for that purpose; but it is possible that a vessel, embarrassed by light baffling winds, may find it convenient to proceed through some part of this channel.

From the Northward.—For the convenience of navigators, the directions for proceeding through this channel from the southward, with a fair wind, are here reversed; but for working through, it will not be necessary to give other directions than merely to observe the bearings of objects to avoid the various dangers, and which equally apply to vessels proceeding in either direction.

Having passed a mile or two eastward of Gaspar Island, steer to bring it N. by W., and kept on that bearing, steering S. by E., it will lead clear of

the dangers lying off the N.E. coast of Pulo Leat. When the North extreme of Pulo Leat bears West, its S.E. extreme should bear S.W. by S. Continue the S. by E. course until the S.E. extreme of Leat bears W.S.W., when Saddle Island should be seen just on the starboard bow with Barn Island and Low Island to the right of it; South Island should be about two points on the port bow, with North Island close to the left of it. The West extreme of South Island, S.E. by S., will lead between Sunk Rock and the dangers extending from North Island. When the North point of North Island bears East, steer S. by E. to pass between South Island and the shoals off the N.E. end of Saddle Island; and when the South extreme of Saddle Island bears West, bring the peak of South Island N.N.E., and keeping it on that bearing will lead between Embleton Rock and the Vansittart Shoals.

If intending to pass westward of Sunk Rock, preserve the S. by E. course until the S.E. extreme of Leat bears West, when Saddle should bear, or must be brought to bear, S. $\frac{1}{2}$ E., which leads between Sunk Rock and Barn Island. When North Island bears E. $\frac{1}{2}$ N., steer, S.E., taking care that the North end of Barn Island is not brought to the North of N.W. by W. $\frac{3}{4}$ W., to clear the dangers north-eastward of Saddle Island; when the peak of South Island bears N.N.E., steer S.S.W., and proceed as before.

STOLZE CHANNEL.

STOLZE CHANNEL is rather wider, less encumbered with dangers, and furnishes objects more convenient for guiding vessels safely through it, than the Macclesfield Channel. The southern entrance is 15 miles broad, bounded on the West by the Larabe Shoal, and the dangers described on pp. 229-30, and on the East by the Carnbee Rocks, Naga Reef, Aanvang Bank, Cooper, and Three-feet shoals. These latter shoals are very much against this channel in making it from the southward, for the Carnbee Rocks—the most southern of the dangers—are 20 miles distant from the land, so that in thick or hazy weather, when a ship might be uncertain of her exact position, she would not be able to make Billiton with nearly the same safety that she would be able to make Pulo Lepar or the South coast of Banka. These shoals would appear to form the only drawback to the adoption of this channel, and in fine weather even this would almost disappear, for the hills on Billiton are high, and may be seen at a distance of 30 or 35 miles; and when in the vicinity of these dangers, not only are the hills on Billiton clearly distinguishable, but Kennedy and Otan Islands are well in sight.*

* Stolze Channel is easy for a stranger; but the nature of the bottom, and the depth of water in it is against anchoring, in the event of calms or thick weather. North of Gaspar

Heroine Shoal.—The positions assigned to this shoal, in lat. $3^{\circ} 33\frac{1}{2}'$ S., long. $107^{\circ} 52'$ E., also in lat. $3^{\circ} 37'$ S., long. $107^{\circ} 46'$ E., were examined by H.M.S. *Nassau*, in 1876, when soundings of not less than 15 fathoms were obtained, with no indication of shoal water in the vicinity; the exact position is, however, doubtful, but it is still placed on the charts in lat. $3^{\circ} 37'$ S., long. $107^{\circ} 46'$ E.

Carnbee Rocks, in lat. $3^{\circ} 33' 15''$ S., long. $107^{\circ} 39' 40''$ E., are of coral formation, 400 yards long in a North and South direction, and 300 yards broad. These rocks are covered at high water, and are thus difficult to distinguish, when the water is smooth, from a distance of more than 1 cable; but a portion dries 5 ft. at low water; there are 12 to 15 fathoms 1 cable from them.

Naga Reef is placed on the chart in lat. $3^{\circ} 26\frac{1}{2}'$ S., long. $107^{\circ} 36'$ E., 7 miles N.N.W. from Carnbee Rocks, and S. by E. $\frac{3}{4}$ E. $4\frac{1}{2}$ miles from Aanvang Bank. A rock above water is marked on the Dutch chart at $3\frac{1}{2}$ miles S.S.E. of the Aanvang Bank.

AANVANG BANK (*Commencement Bank*), discovered in 1822 by Lieut. J. Stolze, is half a mile in length W. by N. $\frac{1}{2}$ N. and E. by S. $\frac{1}{2}$ S., and about a cable broad. It consists of large black rocks, some of which are visible at low water springs; close to them are 5 to 13 fathoms, and about $1\frac{1}{2}$ mile westward of them are 22 fathoms. From the western extreme of the bank, Gunong Bolo, on the South point of Pulo Selio, bears N.N.W. $\frac{3}{4}$ W. $10\frac{1}{2}$ miles, and Blantoe Hill N. by E. $\frac{1}{2}$ E.

Cooper Shoals, lying N.N.W. $\frac{1}{4}$ W. $2\frac{1}{2}$ miles from Aavang Bank, have only 2 ft. water over them, and 7 to 10 fathoms close-to. Gunong Bolo bears from them about N.W. by N., and Blantoe Hill N.N.E.

Three-foot Shoal is a patch having only 3 ft. water over it, and 10 to 13 fathoms around it, lying N.W. by W. $\frac{1}{4}$ W. $4\frac{3}{4}$ miles from Cooper Shoals, with Gunong Bolo bearing N. $\frac{1}{2}$ W. $4\frac{1}{2}$ miles, and Blantoe Hill N.E. $\frac{1}{4}$ N. $13\frac{1}{2}$ miles.

Kennedy or Masar is a small island, lying 7 miles to the N.E. of the Aanvang Bank, in lat. $3^{\circ} 19'$ S., long. $107^{\circ} 40' 10''$ E. There is a small islet at $1\frac{1}{2}$ mile to the N.W. of it.

Otan Island is rather smaller than Kennedy Island, and lies about $1\frac{3}{4}$ mile E.S.E. from it. Other dangers and islands lie to the southward of Billiton,

Strait we always found a soft bottom, whereas in Stolze Channel, besides the inconvenient depth, it is of rock or coral. The strength of the current probably prevents the accumulation of mud. High or Hoog Island, off the N.W. coast of Mendanao, shows conspicuously, and is a good distinguishing mark; at night we found it an easy object to see."—Capt. the Hon. C. G. J. B. Elliot, H.M.S. *Sybilie*, 1855.

but they are to the eastward of the track of vessels bound through Gaspar Strait.

‡ The West Coast of Billiton, forming the eastern limit of Gaspar Strait, is fronted by numerous islands, separated by narrow and, for the most part, unnavigable passages. *Pulo Selio*, with the dangers westward of it; the group named the Six Islands; and Pulo Mendanao, the largest of the islands, form the eastern limit of Stolze Channel.

At the S.W. end of Billiton are the *Haycocks*, or Gunong Beginda, two remarkable hills, 496 ft. high, which, when coming from the southward, appear as islands. Five miles north-eastward of the Haycocks is *Blantoe Hill*, 1,166 ft. high; and to the eastward of Blantoe are *Luda*, *Pyramid*, and *South Peak*, all of which serve to determine a ship's position when approaching the strait from the southward.

Seven miles northward of Blantoe are *Kliang*, 1,198 ft., and *Nose* 1,090 ft. high. Ten or eleven miles N. by E. from Blantoe is *Agong*, 1,242 ft. high, and which appears to be the highest hill on the island. Seven miles northward of Agong, in lat. $2^{\circ} 53'$, is *Tadjem*, 1,096 ft. high. The whole of the hills just mentioned are visible from the southward and south-westward. Three miles S.S.E. $\frac{1}{2}$ E. from Tanjong Bienga, a high bluff forming the north-western extremity of Billiton, is *Gunong Tebalo*, the highest part of which, Round Mount, is 541 ft. high.

A little to the northward of Tamelang Point, on the S.W. side of Billiton, there is a small rivulet of *good water*, which may be easily approached by boats. *Fresh water* is also to be found in the northern part of the bay on the West side of Selio.

PULO SELIO is surrounded by a reef, and separated from the south-western point of Billiton by a narrow channel, in the middle of which is the small island of Seriboe; a mile south-eastward of Seriboe is a reef which partly dries. Close to the shore of Billiton are the small islands *Goenting* and *Proet*.

The South point of Selio is in lat. $3^{\circ} 14'$ S., long. $137^{\circ} 30'$ E., and the conspicuous hill, 242 ft. high, upon it, is named Gunong Bolo.

White Rock, 28 ft. above water, stands on the outer edge of a rocky patch, lying nearly 3 miles W. $\frac{1}{4}$ N. from the South point of Selio; a mile S.E. by E. from it are some rocks above water. There is no channel between White Rock and Selio, and shoal water extends nearly $1\frac{1}{2}$ mile southward of that island. A $4\frac{3}{4}$ -fathom patch lies 3 miles S.S.E. from White Rock.

A Shoal, about a third of a mile in extent, having but $1\frac{1}{2}$ ft. of water over it, and 10 to 16 fathoms close-to, lies N.W. nearly 2 miles from White Rock. Between this shoal and White Rock, and between both and the Koerier Bank, are channels of 5 to 8 fathoms water.

Koerier Bank, of sand, about a mile long, and a quarter of a mile broad,

dries at low water at 3 miles North of the White Rock, and 4 miles West of the North point of Pulo Selio.

The 3-fathoms edge of the bank surrounding Selio forms a sort of bay on the West side of that island, where a ship may anchor to fill up water. The entrance to it is between the $1\frac{1}{2}$ -feet shoal and the Koerier Bank; Gunong Bolo bearing S.E. by E. $\frac{1}{2}$ E. will lead into it, midway between those dangers.

Foul ground and shallow water extends to the westward from Billiton, nearly to a line drawn from White Rock to Ross Island, the most southern of the Six-island Group; within this line, $2\frac{1}{2}$ miles N. by W. $\frac{1}{2}$ W. from the Koerier Bank, is *Gull Rock*.

The large bay to the northward of Selio, and eastward of the Six Islands, is crowded with small islands and reefs.

The **SIX ISLANDS**, or *Pulo Lima*, are small, low, and surrounded by reefs, between which are narrow passages having depths of 10 to 20 fathoms water. The southernmost of these islands, named *Ross*, after Captain Ross, I.N., is 42 ft. high, and lies in lat. $3^{\circ} 5' S.$, long. $107^{\circ} 20' E.$ The others are named *Benolo*, 94 ft. high; *Kasengo*, 58 ft.; *Bago*, 146 ft.; *Betong*, 170 ft.; and *Binget*, 158 ft. high. They may be approached to the southward and westward as near as 1 mile; but dangerous patches extend from Ross Island in a S.E. direction for nearly 2 miles; and from Kasengo, the north-western island, reefs, some of which dry at low water, extend in a N.N.W. direction to the distance of $1\frac{1}{4}$ mile, and for three-quarters of a mile in a southerly direction. The western extreme of Mendanao bearing North a little easterly leads *close* to the reef extending N.N.W. from Kasengo, and bearing N. $\frac{1}{4}$ E. or N. $\frac{1}{2}$ E., clears all dangers near the Six Islands.

TABLE ISLAND, 116 ft. high, forms the western limit of the narrowest part of Stolze Channel, the reef extending N.N.W. from Kasengo, forming the eastern limit. The island is about a third of a mile long N.N.W. and S.S.E., and nearly a quarter of a mile broad. It lies nearly 2 miles E. by S. from South Island, and, from its isolated position, serves as an excellent mark to guide vessels in steering for the narrow part of Stolze Channel when approaching it either from the southward or from the northward. It is surrounded by a reef to the distance of nearly half a mile, and at two-thirds of a mile S.W. of it is an outlying patch of 3 fathoms.

SOUTH ISLAND is about four times as large as Table Island, and a hill on its northern part is 200 ft. high. It is bordered by a reef, and dangers extend three-quarters of a mile in a southerly direction from its South point. On its North side are some rocks not far from the shore, and a patch with only 3 ft. water over it lies half a mile N. by W. from its eastern point.

A Two-and-a-quarter Fathoms Patch lies nearly in mid-channel between Table Island and South Island, which makes that passage dangerous; elsewhere are soundings of 14 to 21 fathoms.

A 3-foot patch lies $2\frac{1}{2}$ miles W.S.W. from Table Island, and three-quarters of a mile off the South side of South Island.

NORTH ISLAND, 240 ft. high, is separated from South Island by a channel $1\frac{1}{2}$ mile wide, which, from the reefs projecting from both islands, is narrowed to three-quarters of a mile. The channel is clear, with soundings of 7 to 18 fathoms. The two islands are in one on a N. by W. and opposite bearing. Three-quarters of a mile E.N.E. from the N.E. point is a dry patch; there is also a patch of 3 fathoms lying S.E. $\frac{1}{4}$ E., distant a little more than half a mile from the same point.

PULO MENDANAO, or *Long Island*, lying $15\frac{1}{2}$ miles to the eastward of Pulo Leat, is much the largest of the numerous islands which front the West coast of Billiton. It is about 8 miles in extent North and South, and about the same distance East and West. The island is for the most part low, but has some hills 600 to 700 ft. high upon it.

Pulo Ayam is a very small islet, lying S.S.E. $2\frac{1}{2}$ miles from West Point. There is a rock on the outer edge of the reef extending from Mendanao from which the South point of the island bears E. $\frac{1}{2}$ S. $2\frac{3}{4}$ miles, and Pulo Ayam N.N.W. $\frac{3}{4}$ W. At three-quarters of a mile from the rock in the direction of Pulo Ayam is a dry patch.

Pulo Gala, or Low Island, lies off the S.E. coast of Mendanao, from which it is separated by the Nado Passage, about three-quarters of a mile broad.

The *Nado Passage*, between Mendanao and Gala Islands, is said to be entirely clear, and very deep, but this is doubtful.

A *buoy* is moored on the eastern side of the channel, about a mile wide, which separates the dangers extending from Pulo Gala from those extending westward from the islands which lie southward of Tanjong Roe, off the western side of Billiton Island. The buoy lies $2\frac{1}{2}$ miles south-eastward of the southern extreme of Pulo Gala.

Brown Reef.—The English barque *Victor*, when proceeding through Stolze Channel, struck on a rock with only 8 ft. water on it, and 14 fathoms close to, Pulo Betong (the easternmost of the Six Islands) bearing S.S.E., and Table Island W. $\frac{1}{2}$ S. These bearings would place this reef near the position of a danger named Brown Reef on the Dutch chart.

As there appear to be *other dangers* besides Brown Reef in this locality, a vessel will do well to pass westward of a line drawn between Kasengo Island and the West point of Mendanao.

Hoog Island (*High Island*), or *Pulo Kumbong*, is a small islet, 100 ft. high, and in the form of a sugar-loaf, lying nearly $1\frac{1}{2}$ mile to the northward of West Point; a reef surrounds it, which on the eastern and northern sides projects nearly half a mile.

PULO BATU DINDING lies off the North coast of Mendanao. On the western side of the island is a deep bay, but it is quite filled up with coral

shoals. Half a mile off the north-eastern end of the island is a small round islet.

Rotterdam Island, lying about $1\frac{1}{4}$ mile northward of the S.W. point of Batu Dinding, is small, and more than half a mile West of it is a very small islet, half a mile S.W. of which are some rocks. A bank of sand and rocks surround both island and islet, between which and the reef extending from Batu Dinding is a narrow channel with 6 to 9 fathoms water in it.

The whole coast between Mendanao Island and Tanjong Bienga, the N.W. point of Billiton, is fronted by dangers, and vessels should use extreme caution in approaching it; the outlying dangers only will be described.

Perlak Shoal, or *Kalang Serat*, is a rock nearly awash, with a 2-fathoms patch about a third of a mile north-eastward of it. A monster *buoy*, painted black, is placed in 7 fathoms water on the North side of the bank, and W.S.W. of Tanjong Pandang (Billiton). From it a remarkable tree on Pulo Kalmanbang bears N. $87^{\circ} 20' E.$; the N.E. point of Pulo Sibongkok (on Hoorn Island), S. $75^{\circ} E.$; and the South end of Pulo Kalmanbang on with the North point of Gunong Tadjem.

Pulo Kalmanbang is a small island lying E. $\frac{1}{2}$ N. $6\frac{3}{4}$ miles from the N.E. point of Batu Dinding. It is surrounded by an extensive reef, on the western extreme of which, $1\frac{1}{4}$ mile W.S.W. from the S.W. point of the island, a *buoy* is placed. About a mile North from Kalmanbang, and 2 miles N.N.E. from the last-named buoy, is another buoy, which lies off the middle of a narrow bank, named *Tokul* (Toekoel), which extends 2 miles in a N.E. and S.W. direction, and is separated from the reef lying off the North side of Kalmanbang by a narrow channel. A 5-fathom bank of small size lies 2 miles N.W. from the latter buoy. A shoal, named *Pinang*, lies off the South and S.E. sides of Kalmanbang, distant $1\frac{1}{2}$ mile from it.

Tieroetioep Bay and River.—This bay is to the northward of Kalmanbang Island and the Toekoel Shoal, between the latter and the Karang Panjang, or Bakka Shoal. The river falls into the eastern part of the bay, but reefs extend off its entrance to a distance of nearly 4 miles. The small island of Kalmoa, 150 ft. high, lies directly off the entrance, 3 miles within the reefs.

Pandan, the town on the North entrance point of the river, is joined with Blantoe, 22 miles to the southward, by a railway.

The outer edges of the reefs which lie on either side of the entrance of the river, form a sort of bight, within the horns of which a vessel may anchor in 6 or 7 fathoms. The best anchorage appears to be a little further out, with Kalmoa Island bearing about E.S.E., and Kalmanbang Island S. by W. $\frac{1}{2}$ W. But it is not a safe anchorage in the N.W. monsoon, and even during the N.E. monsoon there are heavy gales from the N.W.

Buoys.—There is a conical buoy lying on the North side of the entrance to the channel between the reefs, at 2 miles W.N.W. from Kalmoa Island. There is also a can buoy lying 1 mile further out, and marking the eastern

side of a rocky 5-fathom patch, which should be avoided by vessels anchoring. It is advisable to lay the kedge out to the northward, as vessels often foul their anchors, either by the currents or winds. To enter and anchor in this bay, having passed the West point of Mendanao at a distance of 2 miles, steer North or N. by E. till Rotterdam Island or the N.W. point of Dinding bears S.S.E., then steer N.E. by E., E.N.E., or E. by N., till Kalmoa Island bears S.E. by E.; steer then direct for that island till Kalmanbang bears S.S.W. $\frac{3}{4}$ W., and anchor in $7\frac{1}{2}$ fathoms, with the mouth of the river S.E. by E. $\frac{1}{2}$ E., 4 miles distant, and the nearest rocks S.E. $\frac{3}{4}$ E., 3 miles. By the American chart, Kalmoa bearing S.E. by E. leads just to the southward of the Bakka Shoal.

When near the N.W. point of Dinding, the wind sometimes flies round to the eastward; and if bound to this bay it is better to anchor and wait for the sea breeze from the southward or south-westward, as the current runs to the N.W. with an easterly wind.

The *water*, which is fetched from a little way up the river, is very good; it may be procured also on the right bank of the river, near the entrance, but it is not so good.

Karang Pandjang, or *Bakka Shoal*, bounding Tieroetioep Bay to the northward, is about three-quarters of a mile in extent, with $1\frac{1}{2}$ fathom water over it. Tanjong Koeboe (Kubu), or Billiton, bears from it E. by S. $\frac{1}{4}$ S.; Kalmoa Islet S.E. $\frac{1}{2}$ E.; and Kalmanbang S. by W.

Argo Shoal, about $1\frac{1}{2}$ mile in extent, with only a foot of water over the middle of it, lies N.N.E. $\frac{1}{2}$ E. $4\frac{1}{2}$ miles from the Karang Panjang, and from its outer edge Tanjong Bienga bears N.E. $\frac{3}{4}$ E. Several shoals are reported to lie westward of the Argo Shoal.

Numerous detached patches lie eastward of the line joining Argo Shoal and Karang Pandjang.

A small *shoal*, with two fathoms water over it, lies $1\frac{3}{4}$ mile N.E. $\frac{1}{4}$ N. from the Argo Shoal, with Tanjong Bienga bearing N.N.E., distant 2 miles; and N.W. Island N. $\frac{3}{4}$ E., $3\frac{1}{2}$ miles.

TANJONG BIENGA is a high bluff point, forming the north-western extreme of Billiton; from this point the coast trends away north-eastward.

Eleven Islands are a cluster of small islands lying off the north-western extreme of Billiton. The names of some of them are the *Sailor's Hat*, *Bamboe*, *Sampit*, and *Burong*; the latter is the largest of the group, and lies N.N.E. nearly 4 miles from Tanjong Bienga.

N. W. Island or *Langwas*, the outer and most north-western of the islands, lies just inside the edge of the coral reef which extends from the shore, and surrounds the entire group. Its North end is in lat. $2^{\circ} 31\frac{1}{2}'$ S., long. $107^{\circ} 38\frac{3}{4}'$ E.

Alwina Shoal.—The ship *Alwina* passed close to a rock lying N.N.W. $1\frac{1}{2}$ mile from the north-westernmost of the Eleven Islands. It appeared to be

a detached danger, with a depth of 6 to 9 feet on it, and deep water all around.

Directions for Stolze Channel.—No soundings appear on the charts for a distance of 7 or 8 miles southward and south-westward of the Carnbee Rocks (p. 250), nor yet close to those dangers, so that a vessel cannot be guided by the lead when approaching them. Between the Carnbee Rocks and the Aanvang Bank are 13 to 18 fathoms. The Aanvang Bank, Cooper Shoals, and Three-feet Shoal appear to lie just within the edge of the line of 10 fathoms, running from a position 4 or 5 miles south-eastward of the Aanvang Bank, outside the shoals just mentioned.

Towards the shoals on the western side of the entrance to the channel the depths are much less, and they decrease more regularly, the 10-fathom line extending some 5 or 6 miles to the eastward of them, so that they may be approached by proper attention to the lead.

The bottom, through the entire length of Stolze Channel, appears to be composed principally of sand and broken shells, with here and there broken coral. To the north-westward of Billiton the bottom is mostly soft, black mud, with sand and broken coral and shells in places.

From the Southward.—As soon as Blantoe, 1,166 ft. high (the highest hill on the South coast of Billiton), can be recognized, it should be brought to bear about N.N.E., and with it just in sight on that bearing, if the weather is clear, a vessel will be about 33 or 35 miles distant from it, in the fairway of the Stolze Channel, with the Carnbee Rocks about 15 miles to the north-eastward, and may shape a course North or N. $\frac{1}{2}$ W. As the vessel proceeds to the northward, Luda Hill will come in sight, and shortly afterwards Pyramid and South Peak, all of which will be seen to the right or eastward of Blantoe. Soon the Haycocks will be visible, at first a little to the left of Blantoe, and by the time they are in line with it, Gunong Bolo, on the South end of Selio, will be well in sight, bearing about N.N.E., and distant 14 and 15 miles. Shoal-water Island will also be in sight, not perhaps from the deck, but from the mast-head, or a little way up the rigging, bearing about N.W. by W., and distant 15 or 16 miles.

From this position a N. by W. $\frac{3}{4}$ W. course will lead up to Table Island. Passing 6 or 7 miles westward of White Rock, Saddle and South Islands will be seen on the port bow; soon Low Island will also rise in sight on the port bow, and the Six Islands on the starboard bow; and as they are approached—if the N. by W. $\frac{3}{4}$ W. course has been preserved—Table Island will be seen right ahead in mid-channel.

Table Island should be approached on a N. by W. $\frac{3}{4}$ W. bearing until the West point of Mendanao bears N. by E. or N. by E. $\frac{1}{4}$ E., which will lead between Table Island and the reefs extending N.N.W., from Kasenga. When the North point of North Island bears W.N.W., either steer N.N.W. for Gaspar Island, which will lead 3 miles eastward of the Hewitt Rock, and

2 miles westward of the western of the two positions ascribed to the Akbar Shoal; or bring North Island S. by W. $\frac{3}{4}$ W., and steer N. by E. $\frac{3}{4}$ E., or N.N.E., which will lead 4 or 5 miles westward of the dangers extending from Rotterdam Island, and into the China Sea eastward of the Akbar and Canning Shoals.

Working through from the Southward.—When standing to the eastward, to avoid the Carnbee Rocks, Blantoe Hill must not be brought North of N. by E.; and to clear the Aanvang Bank and Cooper Shoal, Gunong Bolo must not be brought West of N. by W. When Blantoe bears N.E. $\frac{3}{4}$ N., or the Haycocks N.N.E. $\frac{3}{4}$ E., Gunong Bolo must be kept East of N. by E., to avoid the Three-foot patch.

The dangers southward of Selio should not be approached under a depth of 10 fathoms, or White Rock brought to the West of N. by W. $\frac{1}{2}$ W.; and when Gunong Bolo bears N.E. by E. $\frac{1}{2}$ E. White Rock must be kept to the East of North, to avoid the edge of the bank which lies S.S.E. nearly a mile from it. White Rock should not be approached nearer than a mile, nor to a less depth than 14 or 13 fathoms; when northward of White Rock, it must not be brought anything South of E.S.E. until the North point of Pulo Selio bears E. by N. $\frac{1}{2}$ N., to clear the $1\frac{1}{2}$ ft. patch lying nearly 2 miles N.W. of it. The Koerier Bank should not be approached under a depth of 10 fathoms, or White Rock brought South of S.E. by S.

Gunong Bolo kept East of S.E. by E. will lead clear of the Koerier Bank, and to the S.W. of the foul ground between it and the Six Islands. Ross Island bearing N.N.W. $\frac{1}{4}$ W. leads westward of the foul ground, and also clear of the dangers lying S.E. of Ross Island. Kasenga bearing North clears the dangers extending from the West side of Ross Island; and the hill on the West point of Mendanao, if not brought to the North of N. $\frac{1}{2}$ E., will lead well clear of the rocks which extend more than a mile N.N.W. from Kasenga, and will also clear all danger contiguous to the Six Islands. When Table Island bears W. by N. a vessel will be northward of the dangers extending from Kasenga, and may stand eastward until the hill on the West point bears N. $\frac{1}{4}$ W.

As Pulo Ayam is neared, the hill on West point must not be brought to the West of North, and the islet must not be approached nearer than a mile.

To clear the dangers about Hoog Island, West point should not be brought to the South of S.S.E. until Rotterdam Island bears N.E., when Hoog Island, in line with West point bearing South, will lead clear of the dangers westward of Rotterdam Island. Rotterdam bearing S.W. leads clear of the shoal bank extending from the North point of Batoe Dinding.

The dangerous coast of Billiton northward of Mendanao should not be neared under 5 or 6 miles; the summit of the North range of hills on Mendanao S.S.W., or Taling, the highest hill on Mendanao, on the same bearing will lead well clear of all danger. N.W. Island and Boerong Island should

not be approached nearer than 2 miles, and caution must be observed to avoid the position of the Alwina Shoal (see p. 255).

When standing to the westward, Shoal-water Island, if not brought to the East of North, will clear all danger from the Larabe Shoal to the Middle Reef, and the lead will also give good warning when standing towards them, as they lie some 4 or 5 miles within the edge of the 10-fathom line. Shoal-water and Hancock Islands must be approached with caution, as the lead does not give much warning when nearing their ledges; they should on no account be approached under a depth of 10 fathoms, or within $2\frac{1}{2}$ miles. Hancock Island bearing South leads clear of the Bliss Shoal, between which and South Island a vessel may stand to the westward until the summit of South Island bears N.E. by N., which will lead clear of the Vansittart Shoals and the dangers about Saddle and Low Islands.

Saddle Island bearing W. $\frac{1}{2}$ S., leads southward of the dangers extending from South and Table Islands. When near Table Island, its South point should not be brought to the eastward of North, to avoid the 3-fathom patch lying three-quarters of a mile S.W. of it. The East side of Table Island may be approached to a mile; but the East side of North Island has dangers lying nearly a mile off it, and to clear them Table Island must not be brought eastward of S.S.E. The East extreme of South Island just open of the East extreme of North Island bearing S. by E., leads a mile eastward of Hewett Shoal.

Through Stolze Channel from the northward.—Having passed eastward of Gaspar Island, bring it to bear N.N.W., and keep it so, steering S.S.E., and it will lead into the fairway of Stolze Channel, midway between West point and the Hewett Shoal, and in this track the soundings will be 14, 16, 20, 22, 28, and 26 fathoms. When West point bears East, distant 4 or 5 miles, Table Island will be seen on the starboard bow, with North and South Islands to the right of it. Continuing the S.S.E. course, the Six Islands will soon be visible on the port bow, and, after passing Table Island at about 2 miles on the starboard beam, West point will soon bear N. by E. or N. by E. $\frac{1}{4}$ E.; when an opposite course may be steered to pass between Table Island and the dangers extending N.N.W. from Kasenga.

When Table Island bears N. by W. $\frac{3}{4}$ W., all danger will be cleared near the Six Islands, and if kept upon that bearing it will lead mid-channel between White Rock and Shoal-water Island, having passed which, the most convenient course may be shaped to the southward, giving a good berth to the shoals extending from Branding Breakers to the Larabe Shoal, on the western side of the channel, and to the Aanvang Bank and Carnbee Rocks on the eastern side.

Entering Stolze Channel to the eastward of the Akbar Shoal, between it and the N.W. coast of Billiton, steer to the S.W., giving the Billiton coast a berth of 4 or 5 miles; and as soon as North Island can be made out, bring

it S.S.W., and it will lead well to the westward of the dangers near Rotterdam Island. When Table Island bears a little East of South, a S.S.E. course may be steered until West point bears N. by E. or N. by E. $\frac{1}{2}$ E., which leads midway between Table Island and the reefs off Kasenga; when proceed as before.

Working through from the Northward.—When standing to the eastward, the N.W. coast of Billiton should not be approached nearer than 5 or 6 miles, or the summit of the North range of hills on Mendanao brought westward of S.S.W. (pp. 257-8). Rotterdam Island, bearing S.W., will lead clear of the reefs extending from the North side of Batoe Dinding, and the islet off the N.E. point of the latter island, bearing East, will clear the dangers northward of Rotterdam. West point bearing South will clear the rocks, &c., which lie westward of Rotterdam, and bearing S.S.E. will clear the reef surrounding Hoog Island.

West point and Pulo Ayam should not be approached much under a mile, as a reef extends about a third of a mile outside them. After passing Pulo Ayam, the hill near the extremity of West point, if not brought North of N. $\frac{1}{2}$ E., will keep a vessel outside the dangers between Mendanao and the Six Islands. Kasenga bearing North, leads westward of Ross Island; and Ross Island N.N.W. $\frac{1}{4}$ W., or Gunong Bolo, on Pulo Selio, bearing S.E. by E., leads clear of the dangerous elbow of foul ground to the westward of Gull Rock, and also clear of the Koerier Bank.

To avoid the $1\frac{1}{2}$ -foot patch at 2 miles N.W. from White Rock, do not bring White Rock South of E.S.E. after the North point of Selio bears E. by N. $\frac{1}{2}$ N. White Rock should be passed about a mile off, and afterwards not brought West of N. by W. $\frac{1}{2}$ W., to avoid the edge of the bank about a mile S.S.E. from it. Gunong Bolo N. by E., leads westward of the Three-foot Shoal; and the Haycocks N. by E. $\frac{1}{2}$ E., or Blantoe Hill N.N.E. $\frac{1}{4}$ E., leads westward of Cooper Shoal and the Aanvang Bank. To avoid the Carnbee Rocks, Blantoe Hill must not be brought to the North of N. by E.

Standing to the westward towards Hewitt Shoal, take care not to shut in the East point of South Island behind the East point of North Island; these points just open lead a mile eastward of the shoal. North Island should not be approached on the East side nearer than $1\frac{1}{2}$ mile, or Table Island brought to the East of S.S.E., to avoid the dangers off it; and Kasenga bearing S.E. $\frac{1}{2}$ E. will clear the reef off the East side of Table Island. Table Island should not be brought to the East of North until Saddle Island bears W. $\frac{1}{3}$ S., when a vessel will be southward of the dangers extending from Table Island and South Island; after which she may stand to the westward until the summit of South Island bears N.N.E.

Hancock Island bearing South leads eastward of Bliss Shoal, but Hancock and Shoal-water Islands must on no account be approached nearer than

$2\frac{1}{2}$ miles, or to a less depth than 10 fathoms, which will be not far from the shoals, the lead giving very little warning in this locality. When to the southward of Shoal-water Island Shoals, Shoal-water Island kept to the West of North will clear the dangers extending from the Branding Breakers to the Larabe Shoal; the lead, also, will give sufficient warning, as the 10-fathom line, on the edge of the bank, is 4 or 5 miles to the eastward of them.

NORTH-EAST COAST OF BANKA.

CAUTION.—The mariner cannot be too cautious in approaching this exceedingly dangerous coast. It was surveyed by the late Lieutenant James Robinson in 1819, but many dangers which front it are very imperfectly known, their positions depending for the most part upon the accounts of commanders of vessels who have found themselves too close in and entangled amongst them when running for Gaspar Strait in thick weather.

There are many hills along this coast near the sea, and some mountains inland; one of these, called the *Saddles*, 912 feet high, rises about 9 miles westward of Tanjong Brekat. At 9 miles westward of the Saddles is the conspicuous range of the *Padang Mountains*, the highest summit of which is elevated 2,630 feet. About 21 miles westward of Tanjong Riah, or in lat. $1^{\circ} 50' S.$, long. $105^{\circ} 53' E.$, is the double-peaked mountain *Gunong Marass*, 2,300 feet high, the largest mountain on the northern part of Banka.

The Coast from Brekat Point trends W. by N. 21 miles to *Lanka Point*, 4 miles westward of which is *Koba* village. This part of the shore may be approached as near as 4 miles in 7 to 8 fathoms water, as the shoals are not more than 2 or 3 miles from the land.

About 16 miles N.W. by W. from Lanka Point is the large village of *Koeraw*, from whence the coast trends N. by W. and N.N.W. to the *River Marawang*, near which stands the village of *Pankal Pinang*. The mouth of the river is in $2^{\circ} 4\frac{1}{2}' S.$

Tetawa Bank.—Fronting the coast between the village of Koeraw and the Marawang River is an extensive chain of banks, 15 or 16 miles long, and from 1 to 5 miles broad, known under the general appellation of Tetawa Bank, upon which are several scattered islands. Many of the patches become dry, and but few have as much as 4 fathoms water over them.

Pulo Boear, or *Colowy*, the outermost of the above islands, is very small, and lies near the S.E. end of the bank, in lat. $2^{\circ} 14\frac{1}{2}' S.$, long. $106^{\circ} 11' E.$

Pulo Passir is a small sandy islet lying W.N.W., distant $4\frac{1}{4}$ miles from Pulo Boear.

Pulo Tetawa is about the same size as Boear, from which it bears West-northerly, distant 8 miles. It lies near the S.W. extreme of the bank, the

edge of which is half a mile to the southward and 2 miles to the westward of it.

Pulo Panjang, the largest, lies on the northern part of the bank, N. by E. $\frac{1}{2}$ E., distant 7 miles from Tanjong Poyang, and E.S.E. 8 miles from the entrance of the Marawang River. The bank extends about three-quarters of a mile to the northward of this island, but other shoals, known as the Sullivan Patches, &c., extend to a distance of 5 miles between the bearings of N.E. and N.W., and for the distance of $3\frac{1}{4}$ miles in a W. by N. direction towards Tanjong Bunga, the nearest point of Banka.

Horse, *Mentawa*, and *Goat Shoals*, are to the eastward of Tetawa Bank. The Horse, lying E. $\frac{1}{2}$ S. $3\frac{1}{2}$ miles from Pulo Boear, is a small patch, nearly dry at low water.

The Mentawa Reef, lying about a mile N. by W. from the Horse, and E.N.E. 3 miles from Pulo Boear, is more extensive than the Horse. Goat Shoal lies 3 miles northward of the Mentawa Reef, and N.E. by N. 6 miles from Pulo Boear; 9 ft. is reported upon this shoal.

The Channel between Pulo Boear and the above shoals is shown on the charts to be about $2\frac{1}{2}$ miles wide, with depths of 7 or 8 fathoms in it; but it would appear that either other dangers must lie in the channel at the distance of a mile from Pulo Boear, or that the Mentawa or Horse Reef must extend much further to the westward than was supposed, thus rendering the channel exceedingly narrow:—

Fathool Barie Shoal.—The *Fathool Barie* struck on a rocky bank, with $2\frac{1}{2}$ fathoms on it, in lat. $2^{\circ} 4' S.$, long. $106^{\circ} 28' E.$, with Mount Pouak bearing N.W. $\frac{1}{4}$ W., Pulo Panjang W.S.W., Pulo Tetawa S.S.W., and Pulo Boear S. by E. $\frac{1}{2}$ E.

General Elliott Reefs.—The *General Elliott*, in August, 1811, found herself entangled among some reefs, with Panjang Island S. by W. $\frac{1}{4}$ W., 5 miles, and a point of Banka, being the eastern foot of the hill South of Koba, S.S.E. $\frac{1}{2}$ E., then being in 8 fathoms. More to the northward, this vessel ran over some 7-fathoms banks with probably shoaler spots; they lie in $1^{\circ} 55' S.$, 12 miles from Banka.

Sullivan Reefs, Hillsborough Rock.—The *Sullivan*, on returning from China, December, 1784, and trying to get sight of Banka during thick weather, ran as far in as $13\frac{1}{2}$ fathoms, rocky bottom, and there saw three patches of breakers, one bearing S.S.W. 3 miles; another S.E. by S. the same distance; and the third E.N.E. 4 miles. Between the breakers a few rocks were visible above water. The weather being thick prevented Banka being seen; but it was supposed the rocks were in $2^{\circ} 3' S.$, and North from Panjang Island.

The *Hillsborough*, in March, 1788, returning from China, and steering for Gaspar Strait, struck on a rock having 3 ft. water on its shoalest part, and while the bow was aground there were 13 fathoms under the stern. When

the vessel floated, she anchored in 14 fathoms to the westward of the rock, with the extremes of Banka N.N.W. and S.E., five small islands about South, and in about $2^{\circ} 3' S.$, the reef extended S.E. and N.E. from the vessel. It is manifest that the positions of these dangers are altogether uncertain. The soundings near the Sullivan Patches, where they are placed upon the chart, are but 7 and 8 fathoms.

The *Diederika Shoal*, with 3 ft. water over it, and 13 to 14 fathoms around it, is thought to lie 11 miles north-eastward of Pulo Panjang, and 5 miles to the southward of Palmer Reef, in lat. $1^{\circ} 59' S.$, long. $106^{\circ} 28' E.$

Roberts Shoal lies about $4\frac{1}{2}$ miles to the westward of Diederika Shoal. It has 12 ft. water over it, and 10 fathoms near it.

Between these shoals and Pulo Panjang, and from thence to the coast, there are numerous rocky shoals, with from 7 to 5 fathoms water between them, but, as before stated, their exact positions are unknown.

Palmer Reef, lat. $1^{\circ} 54\frac{1}{2}' S.$, long. $106^{\circ} 27\frac{1}{2}' E.$, is probably part of the northern bank over which the *General Elliott* passed.

Caution.—All these dangers may be avoided by keeping in not less than 16 fathoms, where there is generally a muddy bottom, whereas in 15 fathoms it generally becomes rocky.

TANJONG RIAH, on Banka, in lat. $1^{\circ} 52' S.$, long. $106^{\circ} 14' E.$, is distinguished by two hills, and from its S.E. and South sides an extensive reef projects, which makes it necessary to keep 6 or 8 miles in the offing.

Black Rock Reef, lying $5\frac{1}{4}$ miles to the South and S.E. of Tanjong Riah, is very extensive, with only 3 ft. water over it in some places. *Tate Rocks*, 4 miles S.S.E. from Tanjong Riah, are 14 ft. above water. Other shoals lie S.E. by S. 8 miles from Tanjong Riah; and E.N.E., 4 miles from it, is a patch of 5 fathoms water.

To avoid these dangers, keep Panjang Island to the westward of South, and go no nearer the shore of Banka than 7 fathoms water, when approaching Marawang Road.

Marawang, or *Pankal Pinang*, the chief town of one of the tin districts, is situated a few miles up the Marawang River, the entrance of which lies about W.N.W. 7 miles distant from Pulo Panjang, and can only be approached by vessels with the greatest caution, on account of surrounding dangers. *Good water* can be obtained at Pankal Pinang.

DIRECTIONS.—Vessels bound from Macclesfield Channel to the ports of Pankal Pinang or Roessah, pass between Tree Island and Brekat Point, and to the westward of the Columbian and Dutch Shoals, in 12 to 14 fathoms water, but in not a greater depth—as the Columbian lies in the stream of 17 fathoms—till Boear Island bears S.W. by S., and Panjang Island West; a depth of 16 fathoms must then be kept till Riah Point bears West. From thence steer direct for that point till in 7 or 8 fathoms, having Panjang Island S. $\frac{1}{2}$ W., on which bearing the island may be approached till the

N.W. peak of the Lappa Hills bears S.W. $\frac{1}{2}$ W., which course leads direct to the anchorage.

LIAT BAY, formed between Tanjong Lyang to the N.W., and Tanjong Riah, to the S.E., affords good anchorage with shelter from southerly and westerly winds in 5 fathoms, white stiff clay, about three-quarters of a mile off shore; but in the eastern monsoon the swell is very heavy. The anchorage is in $4\frac{1}{2}$ fathoms, with the mouth of the river W. by N. northerly, Lyang Point N.N.W. $\frac{1}{2}$ W., and Riah Point S.E. by S. From the river, nearly to the S.E. point of the bay, a fine sandy beach lines the shore, with gradually decreasing soundings. The town of Liat, usually known as Songi Liat, stands a short distance up the river, and is a chief town of one of the tin districts.

Fresh water here is very difficult to be procured, on account of the rocks in the mouth of the river, which can only be entered at high water. Wood and spars of any dimensions may easily be obtained on the South side of the bay, within half a mile of the shore.

The three following *dangers* are very much in the way of vessels frequenting this bay. *Liat Reef*, lying E. by S. $\frac{1}{2}$ S. $3\frac{1}{2}$ miles from Tanjong Lyang, has but 6 ft. water over it.

Circe Reef, discovered by H.N.M. schooner *Circe*, has $2\frac{1}{2}$ fathoms over it, and 6 or 7 fathoms around it. From the reef the hill on Lyang Point bears W. by N. $\frac{1}{2}$ N., Simbang Island N.W. $\frac{1}{4}$ W., and the hill on Tanjong Riah S.W. $\frac{3}{4}$ S.

At full and change it is high water in Liat Bay at 5 p.m., and the rise of tide is 9 ft.

Approaching Liat Bay from the northward, $5\frac{1}{2}$ or 6 fathoms will be found at 2 miles from Lyang Point, and in a southerly direction towards the anchorage.

Coming from the eastward, and being in 10 and 11 fathoms, bring Riah Point S.W. by W, and keep towards it till Lyang Point is N.W. by W. $\frac{1}{2}$ W., then steer W.N.W. and W. by N. towards the anchorage. A rock is marked on the charts $1\frac{3}{4}$ mile S.S.E. from Lyang Point and a mile off shore; the anchorage recommended is southward of the rock in $4\frac{1}{2}$ or 4 fathoms water.

The Coast from Tanjong Dyang runs N.N.W. to *Tanjong Tuen*, in lat. $1^{\circ} 35\frac{1}{2}'$ S., which has a hill on it, and there are several hills further inland. Close to the point is *Pongoh Islet*, which can be approached to half a mile. The coast to the southward of it forms a very shallow bay, in which, at about 6 miles S.S.E. from Tanjong Tuen, is a small island named *Pulo Simbang*. This part of the coast may be approached to 13 fathoms, and even less.

The coast from Tanjong Tuen runs about N.W. by W. for $10\frac{1}{2}$ miles to *Tanjong Crassok* or *Moncudu*, the northernmost point of Banka, where it turns sharply to the westward. A reef, with only $7\frac{1}{2}$ ft. water, lies about $1\frac{1}{2}$ mile from the shore, and nearly midway between Tanjong Crassok and Cape Tuen.

From the shoal, Crassock Point bears W. by N. $\frac{1}{2}$ N., Pulo Pongoh off Cape Tuen S.E. $\frac{1}{4}$ S., and Pakoe Point S. by E. A second reef is marked at 3 miles S.E. by E. from Tanjong Crassock. Nearly a mile off shore, distant $2\frac{1}{2}$ miles W. by N. from Tanjong Crassock, is the small island of Monecudu, before described, page 226.

DANGERS NORTHWARD AND NORTH-WESTWARD OF GASPAR STRAIT.

CANNING ROCK, in lat. $2^{\circ} 23' S.$, long. $107^{\circ} 13' E.$, on which, in April, 1825, the East India Company's ship of that name struck on returning from China, lies directly in the route of vessels proceeding towards Gaspar Strait, and therefore is very dangerous, there being only 3 fathoms on it, with 17 to 20 fathoms close-to. From the spot where this ship grounded, Gaspar Island bore W. by S. 10 miles; Brekat Point S.W. by W. $\frac{3}{4}$ W.; the hummock near that point S.W. by W. $\frac{1}{2}$ W.; the summit of Mendanao Island S.S.E.; and Hoog Island S. by E. $\frac{1}{2}$ E.

The danger consists of many coral heads, extending N.E. and S.W. about 100 yards, and East and West 50 yards. As it is greatly in the way of vessels coming from the northward toward the strait, Gaspar Island ought to be made bearing well to the southward, and should be approached within 5 miles, or nearer, before it is brought to bear W.S.W., in order to give a wide berth to this danger.

Sowerby Shoal, seen by Capt. J. Sowerby, of the ship *Montmorency*, April 1st, 1861, with apparently not more than 2 fathoms water over it; by good cross bearings the middle peak of Mount Tebalo (North end of Billiton Island) bore S. $32^{\circ} E.$, and peak of Gaspar Island S. $66^{\circ} W.$, which places it in lat. $2^{\circ} 13' S.$, and about long. $107^{\circ} 35' E.$ (or $107^{\circ} 28'$). This shoal is about 3 miles long N.W. and S.E., and a third of a mile broad, and is very dangerous, as it lies right in the track of vessels beating out of the Stolze Channel to the northward in the northerly monsoon.

Pare Joie Shoal.—A *rock* was marked doubtful on the charts, with the peak of Gaspar Island bearing S.S.E. $\frac{3}{4}$ E. $6\frac{1}{4}$ miles, and Tree Island S. by W. $\frac{3}{4}$ W. 9 miles. It is probably the same as that on which the *Pare Joie* struck in 1869. It is now placed in lat. $2^{\circ} 19' S.$, long. $107^{\circ} 3' E.$, or nearly 3 miles eastward of the position assigned to the doubtful danger. From the Pare Joie Shoal the summit of Gaspar Island bears S. $\frac{1}{2}$ E., distant 5 miles, and Tree Island S.W. by S. 10 miles distant.

Warren Hastings Reef is supposed to extend about $3\frac{1}{4}$ miles N. by W. and S. by E., and to have but 2 to 9 ft. water over it in some places. In 1788 the *Warren Hastings*, returning from China, grounded upon the S.E. projecting point of this reef, having a short time previously had regular soundings from 20 to 22 fathoms. Under the stem there were only 2 ft.

water, 4 fathoms amidships; the high land of Banka bore S.W. by W., the most distant visible land S.S.W. and S.W. by W. $\frac{1}{2}$ W., the centre of Gaspar Island S.E. by E. $\frac{3}{4}$ E., Tree Island, S. by E. $\frac{1}{2}$ E., the latitude by the sun's meridian altitude being $2^{\circ} 23'$ S. On examining the shoal with the boat there were in some places 3 and $1\frac{1}{2}$ fathoms. In 1845 the English vessel *Gondolier* was wrecked on this reef. The French vessel *Joseph* places it in $2^{\circ} 21'$ S., and $106^{\circ} 56' 43''$ E., with the centre of Gaspar Island S.E. by E.; Belvedere Rock, N.N.E.; and the wreck of the *Gondolier* S.S.W.

Chrysolite Rock, said to lie $1\frac{3}{4}$ mile eastward of the southern part of Warren Hastings Reef, is stated by Dutch authority not to exist. The following account is given of it:—"On the 10th of September, 1851, the *Chrysolite*, of Liverpool, while working between the Belvedere and Warren Hastings Shoals, saw a rock, which apparently did not carry more than 4 ft. water, with Tree Island bearing S. $\frac{1}{2}$ E.; Brekat Point S.S.W. $\frac{1}{2}$ W.; and the centre of Gaspar Island E. by S."

Columbian Shoal is marked doubtful on the chart, N. by W. $\frac{1}{2}$ W., distant 14 miles from Brekat Point, from the following report by Capt. G. Wakem, of the ship *Columbian*, who stated that his vessel struck upon it in April, 1845, but without being brought up, although the reef had not more than 10 ft. water upon it. Anchored immediately with Gaspar Island E. by S. distant 16 miles, and Tree Island S.E. by E. $\frac{1}{4}$ E. 12 miles. The next day the vessel was left in a sinking condition.

Belvedere Shoals.—The south-western end of these shoals is a reef under water, in lat. $2^{\circ} 14'$ S., long. $106^{\circ} 59'$ E., and from it Gaspar Peak bears S.S.E. $\frac{1}{4}$ E., distant 11 miles; from thence they extend to the north-eastward $4\frac{1}{2}$ miles. Near their middle is a sand-bank awash; there are besides on them many coral patches with 6 to 10 ft. water, and on their north-eastern extreme a black rock 10 ft. high and 40 ft. long. When there is a heavy swell the sea breaks on them, and by day they may easily be avoided by a good lookout, particularly as some of the patches are dry at low water. However, a vessel from New York was wrecked on these shoals, and shortly afterwards a Chinese junk. It was probably their breakers which were observed from the *Hawk* in 1785, bearing N.E. 6 miles, and E. by N. 3 miles, Gaspar Island S.S.E. $\frac{1}{2}$ E., and part of Banka S.W.

A reef was discovered lying N.N.W. $3\frac{3}{4}$ miles from the Belvedere Rock, also 17 miles distant from Gaspar Island, and 28 miles from Brekat Point, on Banka Island. The position given is in lat. $2^{\circ} 8'$ S., long. $107^{\circ} 1' 15''$ E.

Dutch Shoal (*Vansittart Shoal*), lies in lat. $2^{\circ} 10\frac{1}{4}'$ S., long. $106^{\circ} 44'$ E., with the peak of Gaspar Island bearing about S.E. by E., distant 24 miles.

The *Vansittart*, Capt. Lestock Wilson, struck on this shoal, and was with great difficulty run upon a sandy beach of Banka, to save the lives of the crew.

A shoal of 6 ft. water is marked on the Dutch chart N.W., distant $11\frac{3}{4}$ miles from the Dutch shoal.

Magdalen Reef, discovered in November, 1806, by the American vessel *Magdalen*, is very dangerous in thick weather for vessels bound to Gaspar Strait from the northward, for when the reef was first seen the vessel was only half a cable's length from it. The boat found it to consist of two coral rocks, about 160 yards in length and 30 yards in breadth, with deep water between them, 11 ft. upon them, and at half a cable's length from the shoal 19 to 21 fathoms.

Capt. Ross, in 1818, determined the position of this reef to be lat. $1^{\circ} 59' S.$, long. $107^{\circ} 1' E.$, the peak of Gaspar Island bearing from it S. $\frac{3}{4}$ E., distant nearly 26 miles.

Lanrick or Newland Shoal, with only 9 ft. water over it, lies 8 or 9 miles northward of the Magdalen Shoal. The clipper brig *Lanrick*, Capt. T. B. White, struck upon this shoal in 1852; and the ship *Asia*, Capt. Newland, in October, 1853. Both vessels took great pains to determine its exact position, and the mean of their observations places the danger in lat. $1^{\circ} 52' S.$, long. $107^{\circ} 1' 30'' E.$ Capt. White says:—"It is of very small extent, and exceedingly dangerous, the soundings giving no warning, for the next morning at anchor, and not more than $1\frac{1}{4}$ mile from its position, the boats after a two hours' search could not find, nor did they see any discoloured water, or get less than 17 fathoms." Capt. Newland remarks also that no discoloured water could be seen at the distance of a mile from the shoal.

Atwick Rock was discovered by an English vessel of that name, in August 1831. Its position was given in lat. $1^{\circ} 48' S.$, long. $107^{\circ} 30' E.$, or N.N.E. $\frac{3}{4}$ E. $44\frac{1}{2}$ miles from Gaspar Island.

Pratt Rock, in lat. $1^{\circ} 32' S.$, long. $107^{\circ} 26' E.$, is described as dangerous, extending N. and S. half a mile, and apparently level with the water's edge, having a rock (or dead tree, many of which were floating about) on its northern end.

Catharine Reef was discovered in 1840, by the ship *Catharine*, which anchored at 1 p.m. in lat. $1^{\circ} 31' S.$, long. $107^{\circ} 1' E.$, in 18 fathoms water. They observed breakers in a N.N.E. $\frac{1}{2}$ E. direction, at half a mile distant, on a reef which seemed to extend about 3 miles E. by S. Though the vessel remained at anchor till 5 p.m., it does not appear that any further observations were made. Its position is marked doubtful on the charts.

Actæon Rock.—H.M.S. *Actæon*, when proceeding to the northward through Gaspar Strait, passed Gaspar Island at sunset, July 7th, 1857, and at midnight, running 8 knots, struck on an unknown coral reef, which, when examined the next day, was found to be between 2 and 3 cables' lengths in extent, steep-to, with patches of 7 ft. on it, and 17 fathoms all around. Its position is lat. $1^{\circ} 39' 48'' S.$, long. $106^{\circ} 37' 58'' E.$, or East about 8 miles from the Severn Shoal. The land was observed from the masthead, whereas from the Severn Shoal the hills on Banka are said to have the appearance of separate islands.

Severn Shoal, discovered in May, 1802, by the American ship *Severn*, lies exactly in the track of vessels from Toty Island towards Gaspar Strait. It is placed on the chart in lat. $1^{\circ} 39' S.$, long. $106^{\circ} 30' E.$, but from the following account its exact position is very doubtful.

At sunset, Gaspar Peak bore S.E. $\frac{3}{4}$ S., 14 miles distant. From this situation the *Severn* steered N.W. $\frac{1}{2}$ N. 35 miles, and at daybreak struck on a coral reef, but got off after being lightened of 30 tons of ballast. The reef seemed to extend 2 or 3 miles N.N.E. and S.S.W., but where the vessel grounded there were 10 ft. water. The hills on Banka had the appearance of separate Islands, above which the Marass Mountain was visible, and the nearest land was computed to be about 20 miles distant. The *Columbian*, of New York, was wrecked on this shoal in March, 1824, when returning from China. The crew reached the harbour of Mintok in the long-boat, after having suffered much from deprivation and fatigue.

Ivon Shoal, with $2\frac{3}{4}$ fathoms water over it, appears on the charts at 7 miles West of the Severn Shoal, in lat. $1^{\circ} 39' S.$, long. $106^{\circ} 21' E.$ Like the Severn and Actæon Shoals, it is much in the way of vessels passing between Gaspar Strait and Toty Island. A *doubtful danger* is marked at 3 miles W. by S. of it.

Scheweningen Shoal.—The ship *Scheweningen* struck on an unknown bank in lat. $1^{\circ} 19' 12'' S.$, long. $106^{\circ} 39' 48'' E.$, about 14 leagues E. by N. from Crassock Point, the North extremity of Banka Island. Immediately after the ship struck, a sounding of 4 fathoms was obtained, and a second sounding showed a depth of 15 fathoms.

Celestial Reefs.—The American ship *Celestial* saw a bed of rocks under water in lat. $1^{\circ} 16' S.$, long. $106^{\circ} 50' E.$; sounded in 3 fathoms, but there appeared to be less water on the rocks; the next cast of the lead was 17 fathoms.

Vega Shoal was discovered in September, 1826, by Capt. Jose Antonio de Vega, of the Spanish frigate *Vellos*, which struck on it, but by carrying out an anchor she was hove off. It was described as being not more than a ship's length in extent, with 18 to 21 ft. water over it, and 9, 11, 17, and 22 fathoms around it. Capt. de Vega placed it in lat. $1^{\circ} 10' S.$, long. $106^{\circ} 34' E.$, by chronometers regulated the day previously at Gaspar Island.

The barque *Marquis of Hastings*, Capt. Ingram, grounded upon this bank in May, 1830, who placed it in lat. $1^{\circ} 6' S.$, and $106^{\circ} 31\frac{1}{2}' E.$, by chronometers. Horsburg says that this ship struck on this shoal in April, 1832, and that Mr. Harris made it at the same time in $1^{\circ} 4' S.$ and $106^{\circ} 37' E.$

H.M.S. *Rifleman*, in December, 1863, was employed with her tender for three days in searching for the Vega Shoal, but without success. A small rocky patch, with 7 fathoms water over it, and 13, 15, and 17 fathoms all around, was discovered in lat. $1^{\circ} 5' 30'' S.$, long. $106^{\circ} 35\frac{3}{4}' E.$ Bad weather compelled the *Rifleman* to relinquish the search.

A southerly current, varying from 1 to $1\frac{3}{4}$ knots an hour, was experienced the whole time the *Rifleman* remained in this vicinity.

Hawkins, or *Wild Pigeon Shoal*, we have no account of, and its position is also very doubtful. On the chart three positions are given: the first in lat. $1^{\circ} 8' S.$, long. $106^{\circ} 43' E.$; the second in lat. $1^{\circ} 9'$, long. $106^{\circ} 41\frac{1}{2}'$, with two fathoms marked against it; and the third in lat. $1^{\circ} 11'$, and the same longitude as the second position.

Deva Reef.—The ship *Deva*, Captain J. Pollock, at $5^h 30^m$ p.m. 23rd May, 1859, struck on a coral reef in about lat. $1^{\circ} 9' S.$, long. $106^{\circ} 52' E.$ The reef appeared to be about 60 yards in extent, N.E. and S.W., about 30 yards broad, with $3\frac{1}{2}$ fathoms on it, and 15 and 17 fathoms close-to. At daylight the next morning two reefs were in sight from the masthead; the one the vessel grounded on, and the other, which was much the largest, considerably to the westward.

Caution.—Probably the Deva and the Celestial are the same reefs, but until examined, this neighbourhood must be navigated with great caution; and the whole group of the Vega, Hawkins, Celestial, and Deva Shoals, should be given a berth of 9 or 10 miles.

DIRECTIONS FROM GASPAR STRAIT TO THE NORTHWARD.—Most vessels bound to the northward from Gaspar Strait, prefer passing eastward of Gaspar Island, which is the safest route; but some vessels, especially when bound to Singapore by Rhio Strait, prefer the less safe but more direct route through the shoals westward of that island.

To proceed Eastward of Gaspar Island with a fair wind, as before directed in pages 239, 240, and 256, 257, steer about N. by E. $\frac{1}{2}$ E. if she passed through Macclesfield Channel, or about N. by W. or N.N.W. if she passed through either Stolze or Clements Channels, to pass 2 or 3 miles eastward of Gaspar Island, and 5 or 6 miles westward of Canning Rock. Having passed Gaspar, steer to the northward until it bears S. $\frac{3}{4}$ W., upon which bearing it should be kept as long as it can be seen. A N. $\frac{2}{3}$ E. course from Gaspar will lead midway between Catharine Reef and Pratt Rock, and if Gaspar be brought on the opposite bearing soon after it is passed, it will afford a good opportunity to judge of the effect of the current, by noting the course that must be steered to preserve the proper bearing of the island; and will also assist in forming a judgment as to the proper course to steer to pass midway between Catharine Reef and Pratt Rock, after Gaspar Island has sunk below the horizon, and will no longer serve as a guide.

If the wind should prevent a direct course from being steered, Gaspar Island should not be brought westward of N.N.W., until the vessel is northward of the Akbar Shoal; and, after Gaspar is passed, it must be kept westward of S. by W., in order to avoid the Pare Joie Rock, the Belvedere, and the Magdalen Shoals.

To proceed Westward of Gaspar Island between the Glassa Rock and Tree Island, from a position midway between them, steer to the northward until the peak of Gaspar Island bears S.E.; when a N.W. course will lead be-

tween the Warren Hastings Reef on the port hand, and the Pare Joie Rock and Belvedere Shoals on the starboard hand. When Brekat Point bears S. by W., or the Saddles S.W. by S., a vessel will be westward of the Warren Hastings and Belvedere Shoals, and a N. by W. or N.N.W. course, according to the set of the tide, will lead westward of the Magdalen and Newland Reefs, and eastward of the Actæon Rock. When nearing the Actæon Rock, the soundings should not be shoaled under 20 fathoms; after passing it, a course may be shaped for Toty Island.

Gaspar Island, when 3 or 4 miles distant, kept between S.E. and S.E. by E. $\frac{1}{4}$ E., will keep the vessel clear of the Pare Joie Rock, and of the Warren Hastings Reef.

Brekat Point bearing S. by W., or the Saddles S.W. by S., leads westward of the Warren Hastings and Belvedere Shoals, and Gaspar Island S.E., leads 3 miles eastward of the Dutch Shoal; but when westward of the Warren Hastings and Belvedere Shoals, it will be wise to edge away to the northward—always carefully guarding against tide and currents—taking care not to bring Gaspar Peak to the South of S. by E. $\frac{1}{2}$ E., to avoid the Magdalen Reef.

If proceeding between Brekat Point and Tree Island, the point may be passed at the distance of 3 or 2 miles, and the island at a mile; then proceed to the N.N.W., taking care not to bring Tree Island to the South of S.E. by S., to avoid the S.W. end of Warren Hastings Reef. Brekat Point bearing S. by W. $\frac{1}{4}$ W., leads clear to the N.W. extreme of that reef; and bearing S. $\frac{1}{2}$ E. leads eastward of the reported positions of the Columbian and Dutch Shoals. When Brekat Point bears S. $\frac{1}{2}$ W., a northerly course may be steered, proceeding as before to pass eastward of the Actæon Rock.

Horsburgh states that Capt. R. Scott, in the *Warren Hastings*, after passing Brekat Point, coasted along to the northward, keeping generally in 11 or 12 fathoms water, without any appearance of danger, but a good mast-head lookout was kept. The passage, however, near the Banka coast is so beset with dangers, whose exact positions are unknown, and there may be others of which we at present know nothing, that we would strongly advise vessels to give this exceedingly dangerous coast a wide berth, especially as nothing is to be gained by approaching it. At p. 262 directions are given to proceed along this coast to Tanjoing Riah.

Directions to approach Gaspar Strait from the Northward.—In consequence of the northern entrance of Gaspar Strait being so near the equator, the winds, even in the strength of the monsoon, are very uncertain, producing a corresponding uncertainty in the direction and force of the tides and currents. A vessel approaching the strait from the northward will, therefore, have to be principally guided by the winds and currents which she may herself fall in with, rather than by relying upon experiencing those which are here mentioned as most likely to be met with at certain seasons.

In the early part of the monsoon, that is, from the middle of November to the middle or end of December, northerly and north-westerly winds are said to prevail, but Horsburgh mentions an instance of vessels meeting with strong West and W.S.W. winds in December. As the monsoon gathers strength and becomes more regular, the wind draws to the eastward of North, and late in the monsoon, easterly and south-easterly winds are often met with between Banka and Billiton.

In thick weather it will always be an anxious time for the navigator whilst approaching Gaspar Strait, for unless good sights can be obtained, he can never be certain of his exact position; and we would again strongly advise him, under any circumstances, to steer for Banka Strait, where the soundings on the edge of the bank extending from the Sumatra coast will enable him to proceed with safety, although he may be quite unable to distinguish the land.

Vessels returning from Singapore or China early in the northern monsoon, and intending to go through Gaspar Strait, prefer the Macclesfield Channel, passing between Toty and Docan Islands; but it is better to go 12 or 14 miles to the eastward of the latter, and even more, when the wind is easterly; but early in the monsoon the wind is generally North or N.W.

Having passed Toty Island, steer about S.E. by E., so as to get on the meridian of Gaspar Island before reaching the parallel of $1^{\circ} 50' S.$ Gaspar is visible in clear weather at a distance of 30 miles. Directly it is seen, steer towards it on a S. $\frac{3}{4}$ W. bearing, and, passing eastward of it, steer to the south-westward for the entrance of the Macclesfield Channel.

The above directions apply only to vessels returning from China early in the monsoon. In general, and especially returning late in the monsoon from China, when the S.E. and easterly winds are often met with between Banka and Billiton, it will be better to go 10 or 12 miles to the westward of St. Barbe Island, and endeavour as soon as possible to get on the meridian of Gaspar Island, but not to the westward of it when near the parallel of the Catharine Reef, which should never be passed at night. When Gaspar is seen, bring it on a S. $\frac{3}{4}$ W. bearing, and proceed as before.

Returning from China late in the monsoon, S.S.W. winds are often met in the southern part of the China Sea, and oblige vessels to pass between the islands near the West coast of Borneo. If this should happen in May or June, it would be very tedious to get to the southward; in such case, steer for the north-western end of Billiton, and pass through Stolze Channel.

CHAPTER VII.

CARIMATA STRAIT.

CARIMATA STRAIT, the easternmost of the channels leading between Sumatra and Borneo, is bounded on the eastern side by Carimata, Soruetou, and the other islands adjacent to the southern part of the West coast of Borneo; and on the western side by the East coast of Billiton, with the adjoining islands and dangers. It is often used by vessels from Malacca Strait, proceeding to China by the eastern passages, but although much broader than either Banka or Gaspar Straits, it is not nearly so much frequented as either of those channels by vessels proceeding to and from China by way of Sunda Strait. It is, however, not unfrequently used by vessels returning from China, which, from the effects of winds or currents, find it difficult to get to the westward.

This strait has not been properly surveyed. Capts. Ross and Maughan, of the Indian Navy, determined the positions of many of the dangers on each side of it, but much of the information which we possess has been derived from accounts furnished by vessels that have passed through it. In using it, therefore, a vessel must keep a good lookout, and be as far as possible prepared to meet with unknown dangers.

Besides the Main Channel, limited to the south-eastward by the islands of Soruetou and Carimata, and to the south-westward by the Montaran Islands and Billiton, there are several other channels between the numerous islands lying eastward and north-eastward of Carimata, between it and the Borneo coast, through which vessels have occasionally passed. One of these, known as the Inner Channel, and situated between the islands of Panambungan and Mayang, is much frequented by vessels working through the strait against the monsoon, for a regular tide will be found near the Borneo coast, which enables them to work through the Inner Channel when it is quite impossible to work through the Main Channel against a strong monsoon, and a continuous rapid current setting to leeward.

Currents and Tides.—The currents in Carimata Strait appear to set mostly

to the southward in the northerly monsoon, for many ships have found it almost impracticable to beat to the northward in that season. Captain Ross, in the *Discovery*, found a constant southerly current in this strait; on February 15th he was off Pulo Mankap, and from hence continued beating along the West coast of Borneo, and afterwards on the South and West sides of Carimata and its adjacent islands until March 16th, when he got round the western end of Soruetou. In the southerly monsoon it does not appear to be so difficult to get to the southward, for there are regular tides along the West coast of Borneo, and also off the East coast of Billiton in this season, which seem to extend in some degree across Carimata Strait, the flood apparently setting 12 hours to the northward, and the ebb about 12 hours in the opposite direction. The rise of tide, as experienced by Captain Ross, was about 9 or 10 ft., at full and change of the moon.

A DESCRIPTION of that portion of the dangers southward of Billiton, which lie contiguous to Gaspar Strait, is given at page 250. The following islands and dangers lie nearer Carimata Strait, and are important to vessels approaching it from the southward.

KEBATOE, or SHOE ISLAND, in lat. $3^{\circ} 48' S.$, long. $108^{\circ} 4' E.$, is nearly half a mile long in an East and West direction, and 400 yards broad; it is conical in shape, thickly wooded, 346 ft. high, and visible 18 or 19 miles from a ship's deck in clear weather. The island is steep-to, with a coast or fringing reef extending 1 cable from the North and West sides; and half a cable from the South and East sides. *White Island*, 57 ft. high, having a few stunted trees on the top, lies S.W. 1 mile from Kebatoe Island. A *small shoal*, with 6 ft. water, lies N.E. $\frac{1}{2} E.$, 3 cables from White Island.

Zephyr Rock, supposed to lie W. $\frac{1}{4} S.$, 4 miles from Kebatoe Island, was searched for by the boats of H.M.S. *Nassau* in 1876, when a depth of 14 fathoms (mud bottom) was obtained in that position; but, at three-quarters of a mile W. by S. from Kebatoe, and 6 cables N.N.W. $\frac{1}{4} W.$ from White Island, a rock, on which the sea generally breaks, having 3 feet over it, was found, and this position has been assumed for that of the Zephyr Rock.

A *rock*, said to exist N.W. by W. $\frac{1}{2} W.$, 8 miles distant from Kebatoe Island, was carefully searched for by the boats of H.M.S. *Nassau*, but could not be found. The depth of 14 fathoms, mud bottom, was obtained. From the nature of the examination non-existence of the rock in the position assigned to it is assured.

Karang Kawat, or Grace Reefs, consist of two coral reefs, the centres of which lie N.E. by N. $4\frac{1}{3}$, and $6\frac{1}{2}$ miles respectively from Kebatoe Island.

The *southern reef*, on which the sea breaks heavily in moderate weather, is awash at low water; this reef is $3\frac{1}{2}$ cables long in an East and West direction, and 2 cables broad, with 12 to 17 fathoms at the distance of three-quarters of a cable. The *northern reef* is 3 cables long in an East and West

direction, 2 cables broad, dries 4 ft. at low water, and has 13 to 16 fathoms at the distance of half a cable.

Between Kebatoo Island and the southern Karang Kawat there is a clear channel $3\frac{3}{4}$ miles wide, with depths of 14 to 17 fathoms, mud bottom; and between the southern and northern Karang Kawats there is a channel $1\frac{3}{4}$ mile wide, having also 14 to 17 fathoms, mud; the holding ground in both these channels is good.

A ship ought never to attempt the passage inside Shoe Island, except in very clear and favourable weather.

Heroine Shoal is in lat. $3^{\circ} 37'$ S., long. about $107^{\circ} 52'$ E., or in lat. $3^{\circ} 37'$ S., long. $107^{\circ} 49'$ E.; its exact position is, however, doubtful, and it was not seen by the officers of H.M.S. *Nassau* in 1876. It is reported to be an extensive shoal with breakers upon it. It was passed at about the distance of $1\frac{1}{2}$ mile, when Two-peaked Mountain on Billiton bore N.N.W.; a small island N.E. by E. $\frac{1}{2}$ E.; and shoe Island, seen from the mizen-shrouds, S.E.

Katapang Island, in lat. $3^{\circ} 23'$ S., long. $107^{\circ} 57\frac{1}{2}'$ E., is low and wooded, about a third of a mile in diameter, and surrounded by a reef. Around it are soundings of 8 and 9 fathoms, and the same depths between it and the shore, where, however, no vessel should venture.

The whole of the coasts of Billiton are but very imperfectly known, but it is certain that they are fronted by many dangers, and vessels are strongly advised to avoid them.

SOUTH COAST of BILLITON.—From Karawang Point, the S.W. extreme of Billiton, the coast trends to the eastward for 2 or 3 miles, and then turns sharply to the north-eastward, forming a deep bay, the eastern horn of which is the most southern point of the island, and is distant 21 miles eastward from Karawang Point. This bay is named *Telok Batoh*, which in the Malay language signifies rocky bay, and it appears from the chart to be full of dangers, with others extending some 2 or 3 miles outside its chord. Southward and westward from the eastern horn of the bay are some small islets lying within the margin of the reef which projects from the point.

EAST COAST.—From the eastern point of Telok Batoh Bay the coast trends East-northerly for 6 or 7 miles, to the S.E. point of the island, 9 or 10 miles N.E. of which is a prominent point named *Sakapar*. Between these two latter points is a bay, in which are several islands; and fronting it are also several islands. N. by E. $\frac{1}{4}$ E. 17 miles from Sakapar Point is *Mangar Point*, having a hill upon it, the coast between forming a bay 2 or 3 miles deep. Northward of Mangar Point is another small bay.

The *East and N.E. sides* of Billiton are fronted by several groups of small islands, most of them being surrounded with or connected by rocks, sands, and shoals; the outernmost of these shoals has been recently reported in $25^{\circ} 9'$ S, $108^{\circ} 21'$ E., or $13\frac{1}{2}$ miles N.E. by E. from Sakapar Point.

These dangers are so imperfectly known, that it is not possible to give any accurate description of them here. They do not lie in the track of ordinary navigation, and if a vessel ventures near them she must do so with caution and judgment, and without placing too great confidence in the chart.

SCHARVOGEL ISLANDS are a group of seven islands, the easternmost of which by the chart is in lat. $3^{\circ} 18' S.$, long. $108^{\circ} 28' E.$ The islands are from 90 to 120 ft. high, and thickly wooded, having between them numerous reefs and sandbanks. The relative positions of these islands with each other is uncertain. Between the northern island and the Meray group is a channel 3 or 4 miles wide, with 5 to 9 fathoms water in it. It is bounded on either side by the reefs which extend northward from the islands.

Northern Coasts of Billiton.—From the N.E. point of Billiton the coast rounds gradually to the North, and then takes a general direction about N.W. by W. to the N.W. Hook or Point. The aspect of the coast is high, uneven land, visible in clear weather 24 or 25 miles off.

Outer Dangers off the North Coast of Billiton.—*Pigeon Island*, lying 3 or 4 miles off the coast, with the N.E. extreme of Billiton bearing S.E. by S., and the N.W. hill on Nangka Island E. by N. $\frac{1}{2}$ N., distant 21 miles, is very small, and surrounded by rocks or patches of reef, which also extend 3 miles to the south-eastward of it. About N.E. by E. $\frac{1}{2}$ E. 5 miles from the island, a small *sandbank* was seen by the *Bellhaven* in 1857, probably at high water. A small rock or patch, with 2 fathoms water over it, is placed on the chart, N.N.E., 7 miles from the Pigeon Island, and a second at the same distance E.N.E. of it. At 5 miles eastward of Pigeon Island is the West end of a sandbank, which thence extends for 5 miles to the E.S.E., with an average breadth of $2\frac{1}{2}$ miles. On one spot on its N.E. side, in lat. $2^{\circ} 37' S.$, long. $108^{\circ} 18' E.$, it is reported to dry.

There are other islets and dangers between Pigeon Island and the N.W. point of Billiton; their exact positions, however, are not well known.

Krang Island lies 13 miles West from Pigeon Island, and 3 miles off shore, N.N.W. 2 miles from it, is a sandbank. *Djoeroh Dajong Rocks* lie 2 miles West from the sandbank, and 2 miles N.N.E. from Maleh Island. The *Hydrograf Rock*, of 9 ft., 6 miles off shore, is marked in $2^{\circ} 28' S.$, $107^{\circ} 53' E.$, at $5\frac{1}{2}$ miles N.W. of it is a rock recently discovered in 1877, the outermost off this coast. At 3 miles West of the Hydrograf Rock is a 3-fathom patch, and W.S.W. $5\frac{1}{2}$ miles from the 3-fathom patch is the Seloeting Reef, of 2 fathoms, which lies N.E. $\frac{1}{2}$ E. 8 miles from Cape Bienga, the N.W. cape of Billiton.

ISLANDS AND DANGERS IN THE FAIRWAY.

Discovery West Bank (*Ayer Masein*), in lat. $3^{\circ} 38' S.$, long. $108^{\circ} 44' 30'' E.$, was examined by Captain Ross, I.N., in the surveying ship *Discovery*. It is of coral, about 6 cables in extent North and South, and 2 cables broad, having near its western edge a small sandbank, awash at high-water springs. There are depths of 16 to 20 fathoms around Discovery West bank at a distance of three-quarters of a cable.

Discovery Reef lies N.E. by E. $\frac{1}{2}$ E. $5\frac{1}{2}$ miles from Discovery West Bank, and is in lat. $3^{\circ} 35' 45'' S.$, long. $108^{\circ} 49' 25'' E.$; this reef is 2 cables in diameter, having several coral heads awash at high water, and 14 to 22 fathoms around it at the distance of 1 cable.

Discovery East Bank* (*Mampango*), in lat. $3^{\circ} 34' 40'' S.$, long. $109^{\circ} 12' 35'' E.$, is $4\frac{1}{2}$ cables long in a North and South direction, and $1\frac{1}{2}$ cable broad, having in its centre a decayed white coral ridge 2 cables long, a few yards broad, and 5 ft. above high water; there are 14 to 24 fathoms, sand, around this bank, at a distance of 1 cable. Discovery East Bank is visible from aloft on a clear day at a distance of 7 to 8 miles.

Lavender Bank (*Dyuruh*), in lat. $3^{\circ} 24' S.$, long. $109^{\circ} 1' 30'' E.$, was discovered by Captain Lavender, of the ship *Roman*, who passed it bearing East about a quarter of a mile distant, in soundings from 20 to 26 fathoms. It is 7 cables long in a N.N.W. and S.S.E. direction, and 2 cables broad. It is composed of coral, with several large boulders awash at high water. Around this bank there is a depth of 20 fathoms, sand and shells, at the distance of a cable. During a south-easterly breeze the sea on Lavender Bank has been observed from aloft to break at a distance of 6 miles.

Cirencester Sandbank (*Batuan*), in lat. $3^{\circ} 14\frac{1}{2}' S.$, long. $108^{\circ} 59' E.$, is about half a mile in extent N.N.W. and S.S.E., and 1 cable broad. It is chiefly composed of live coral heads, with 1 to 3 fathoms between them; at $1\frac{1}{2}$ cable within the northern extreme of this bank there is a flat circular patch of dead coral awash at low-water springs, 1 cable wide, having on its western edge a boulder awash at high water. The depth of water increases towards the bank, there being 25 fathoms close off the North end, 32 fathoms off the South end, and 35 fathoms about three-quarters of a mile to the westward; with a good lookout it may be seen from the mast-head about 3 miles at low water, but probably not above 3 or 4 at high tide. Two miles east-

* From the following remarks in possession of Captain Stephen Stocker, R.N., who was mate of H.M.S. *Hecate* in 1813, it would appear that this bank was discovered by that vessel:—"Steering to the southward out of Carimata Strait, we discovered a dry sandbank, 12 or 13 ft. above water, in about lat. $3^{\circ} 40' S.$, long. $109^{\circ} 4' E.$ Passed about three-quarters of a mile eastward of it, and had soundings of 21 to 25 fathoms."

ward of the bank the *Cirencester* had very irregular soundings, from 16 to 20 fathoms, changing at almost every cast of the lead.

Shoal.—Captain Irwin, of the *Arica*, in 1869, intending to lay-to for the night, southward of Scharvogel Islands, came suddenly close to a rock, from 50 to 60 ft. long, the shoalest part having about 6 ft. water, from that to 18 feet over the remainder. Position, South from the South Island and S. by W. $\frac{1}{2}$ W. from the eastern islet, in about lat. $3^{\circ} 31' S.$, long. $108^{\circ} 25' E.$

Bower Shoal, discovered by H.M.S. *Nassau* in 1876, is in lat. $3^{\circ} 28' 45'' S.$, long. $108^{\circ} 40' 30'' E.$ It is a coral patch, three-quarters of a cable in extent, having 9 ft. water on it, and 9 to 11 fathoms close around.

Osterly North and South Shoals were examined by H.M.S. *Discovery*, and afterwards, in 1874, by Lieut W. Pearce, in H.M.S. *Sylvia*. *Osterly South Shoal*, in lat. $3^{\circ} 19' S.$, long. $108^{\circ} 37' E.$, is 2 cables in extent North and South, with 6 to 12 ft. water on it, and 10 to 14 fathoms close around; near the centre of the shoal there is a white dead coral islet, about 40 ft. long, and 3 ft. above high water. *Osterly North Shoal*, situated about 19 cables N.E. from the islet on Osterly South Shoal, is about a quarter of a mile in extent, awash at low water, and has from 10 to 15 fathoms close around. By day this shoal may be distinguished from the greenish tint of the water; but at night it is exceedingly dangerous to vessels passing eastward of the Scharvogel Islands. In the vicinity of these shoals the ebb tide was observed to set to the southward, and the flood to the northward.

The *Discovery* anchored in 11 fathoms, soft ground, with North Shoal East 2 miles, when the boat had from 5 to 7 fathoms rocks on another shoal, bearing S. $\frac{1}{2}$ W. from the ship about a quarter of a mile. From the *Discovery* the extremes of the Scharvogel Group bore W. $15\frac{1}{2}^{\circ} S.$ to W. $15^{\circ} N.$, the nearest island distant about 8 miles, and a high distant hill N.W. When *Discovery* was anchored in the above position, breakers were seen from the mast-head bearing S.S.E. distant about 4 miles (?), on what is named Osterly South Shoal. Many eddies were also seen around.

Cirencester Rock, or *Shoal*, in lat. $2^{\circ} 54\frac{1}{2}' S.$, long. $108^{\circ} 56' E.$, was seen by the *Cirencester* on the same day that she discovered the sand-bank described above. The least depth found upon it was 2 fathoms at low water, and there is probably $3\frac{1}{2}$ fathoms on it at high tide; close around the soundings were 17, 16, and 15 fathoms. The shoal is narrow, and not more than 100 yards in length, North and South. It was not discovered by the boats sounding for it until the rocks were seen under the bottom.

Admiral Protet Reef, &c.—A reef, with about 6 or 7 ft. water, lies near the assigned but doubtful position ($2^{\circ} 58\frac{1}{4}' S.$, $108^{\circ} 34\frac{1}{4}' E.$, or $3^{\circ} S.$, $108^{\circ} 30' E.$) of a shoal named *Admiral Protet*; from it Slandak Island bears W. $\frac{3}{4} S.$, and Liendorg, one of the Scharvogel Islands, S.S.W.; the position given is in lat. $2^{\circ} 59' S.$, long. $108^{\circ} 38' E.$

MONTARAN ISLANDS, lying off the N.E. part of Billiton, consist of three straggling groups, which, with the many dangers that lie near them, are very imperfectly known, and appear to be most inaccurately laid down upon the chart. The navigator is therefore cautioned to be very vigilant when near these islands. Lieut. W. Pearce, R.N., examined East Island, Catherine Reef, and Small Island, in H.M.S. *Sylvia*, in 1874.

Nangka, or *Tokokemo*, the largest and highest of the Montaran Islands, has a high hill on each extreme; and, being low in the middle, appears like two islands till within 8 or 9 miles of it; but it cannot be mistaken when a vessel is 17 or 18 miles to the northward, as none of the low islands near it are seen at that distance. Close to the North point of this high saddle island of Nangka lies an islet covered with bushes, and they are united by a reef which extends about $1\frac{1}{2}$ mile to the northward; a reef projects also about half a mile from the South point of the island.

West Group.—About $2\frac{1}{2}$ miles S. by E. from Nangka are three low islands, named West Group, with apparently much broken water about them, and a dry sand-bank about 4 miles south-eastward of them; there is also a high white *sand-bank* about 4 miles south-eastward of them.

Between West Group and Middle Group the water is shoal, and a dangerous reef very little above water lies midway between them. A second doubtful danger, named High Bank, is marked at 3 miles south-eastward of Gampal, the southern island of the Western Group. *Napier Island* lies 4 miles W. $\frac{1}{2}$ N. from Gampal; it is wooded, and 185 ft. high. Some islets and rocks lie between $1\frac{1}{2}$ and $3\frac{1}{2}$ miles southward of it, and a sandbank a mile long between 1 and 2 miles S.E. of its eastern extremity.

The **Middle Group** consists of four or five islands, lying from 6 to 12 miles to the eastward of the West Group. The southernmost island is in lat. $2^{\circ} 36' S.$, and when approached by the *Fox* frigate, it appeared to be inhabited, and the water very shoal around. It appears to have been upon one of the reefs off these islands that the *Abercrombie* was lost, a fine ship of 1,200 tons burden, belonging to Bombay.

East Island, or *Pesemot*, at the eastern extremity of the group, was examined by Lieut. W. Pearce, in H.M.S. *Sylvia*, in 1874. It is in lat. $2^{\circ} 29' S.$, long. $108^{\circ} 51' 40'' E.$, and about half a mile in extent North and South. The island is of coral formation, thickly wooded, and surrounded by a sandy beach, the trees in the centre forming a sharply pointed summit, 130 ft. high, making the island conspicuous and easily recognised when seen from a distance. On the western side of the island rocks were seen above water about 1 cable from the shore; there is also a sand-bank about 1 mile N. by W. from this island. Skeletons of turtle were seen on East Island, so that it may be assumed they visit to deposit their eggs.

A *sand-bank* is marked at 1 mile N. by W. from East Island.

Luctor Shoal.—The Dutch barque *Luctor* and *Emergo* touched on a reef,

from which Nangka bore West, East Island E. $\frac{3}{4}$ N., and the westernmost island of the Middle Group S. by E., which places the rock in lat. $2^{\circ} 32' S.$, long. $108^{\circ} 44' E.$

Small Island, $1\frac{3}{4}$ mile S.S.W. $\frac{1}{2}$ W. from East Island, flat and covered with trees in the centre, appeared to be about the same length as East Island. The channel between these islands is said to be shallow.

Dangers Eastward of East Island.—A *sand-bank*, having a few patches above water, was seen from the *Sylvia's* boat, about 1 mile E. by S. from East Island; the bank appeared about three-quarters of a mile long, in an East and West direction, but it was not examined.

A *sand-bank*, according to an old report, lies S.E. by E. $\frac{3}{4}$ E. about 4 miles from East Island. About a hundred yards all round this bank the depths were from 10 to 18 fathoms, shoaling suddenly towards it. In the centre of the bank there is a coral rock (3 ft. above water.)?

Catherine, or Evans Reef.—On December 17th, 1840, a ship, commanded by Captain E. M. Smith, was wrecked on a coral reef, in lat. $2^{\circ} 30\frac{1}{2}' S.$, long. $108^{\circ} 59\frac{1}{2}' E.$ In no part was it within a fathom of the surface, and in calm weather no breaker nor any indication of the reef could be perceived, the current running to the N.E. 4 or 5 knots. Again, the ship *Catherine*, Capt. Evans, at 2^h 15^m p.m., struck on this ledge of rocks, with East Island bearing W. $\frac{1}{2}$ N., distant 8 miles, and Carimata Peak N. $4^{\circ} W.$ It is formed of sharp coral rocks, extends N.W. and S.E. a cable's length, and the least water found on it was 2 fathoms. Soundings were obtained in different directions; they were 4 to 9 fathoms about N.W. of the ship, and to the S.E. a little less than a cable distant. Though a strong current was setting to the southward, there was no appearance of broken or discoloured water. Capt. Evans places the reef in lat. $2^{\circ} 31\frac{1}{2}' S.$, long. $108^{\circ} 57' E.$

Catherine or Evans Reef was unsuccessfully searched for by the boats of H.M.S. *Sylvia*, in 1874, in the position given by the master of the *Catherine*, namely with East Island bearing W. $\frac{1}{2}$ N., distant 8 miles, and Carimata Peak N. $4^{\circ} W.$ During the examination, however, a shoal, having $4\frac{1}{2}$ fathoms on it and 8 to 17 fathoms close around, was found at $4\frac{1}{2}$ miles E. $\frac{1}{4}$ S. from East Island, or in lat. $2^{\circ} 31' 30'' S.$, long. $108^{\circ} 54' 30'' E.$ (From this position Carimata Peak bears N. $3\frac{1}{4}^{\circ} W.$) Although $4\frac{1}{2}$ fathoms was the least depth obtained by the *Sylvia*, it was considered probable that less water might be found. Also, that other shoal ground existed in the neighbourhood.

Corsyra Shoal.—The *Coreyra*, Capt. Walison, in August, 1858, discovered a shoal of 15 ft. water, about half a cable's length in circumference, with Round Hill on Billiton bearing S. $57^{\circ} W.$, and the northernmost small island of Nangka, just open of the large one, N. $61^{\circ} W.$; but those bearings will not lay down upon the chart. Reputed position, $2^{\circ} 31' S.$, $108^{\circ} 30' E.$

Maas en Waal Shoal, discovered by the steam ship of that name, has 18 ft.

water over it. From the shoal Pulo Sambilan is in line with the South peak of Pulo Nangka, bearing E. $\frac{1}{2}$ N., distant about 6 miles. The position of this shoal was reported as lat. $2^{\circ} 32' 30''$ S., long. $108^{\circ} 27'$ E. It is marked on the Admiralty chart 6 miles westward of this position.

Condor Reef.—The ship *Condor* struck on this shoal, but did not stop to examine it; the ship, however, made water immediately after she struck. It lies N. by E. $\frac{1}{2}$ E. $8\frac{1}{2}$ miles from Nangka Island, in lat. $2^{\circ} 22' 20''$ S., long. $108^{\circ} 37' 15''$ E. Some rocks lie 8 miles S.W. of Condor Reef.

Ontario Reef, the centre of which is in lat. $2^{\circ} 1\frac{3}{4}'$ S., long. $108^{\circ} 39'$ E., is very dangerous, as it lies in the direct tract formerly recommended to ships when passing between Soruetou and Billiton. It was discovered by Captain Whetten, in the American ship *Ontario*, which was lost on it January 4th, 1799. It is composed of sharp spiral rocks, with the tops of some of them dry at low water spring tides; but the small break against their sharp points cannot be distinguished from the topping of a common sea; and the shoal is steep-to, having 18 and 19 fathoms at a ship's length from the rocks. From the wreck of the *Ontario* the north-eastern end of the Quoin (on the western part of Soruetou) was just shut in with the western end of Soruetou; the East end of Soruetou bearing N.N.E. was open about a quarter of a point from the West end of Carimata. No other land in sight from the reef. The soundings are no guide in the approach to this dangerous shoal, there being 23 and 24 fathoms close to it on the North and East sides, 18 to 25 fathoms nearly close to the rocks on the West side, and 25 fathoms clay, at the distance of a cable's length. The shoal was examined by Capt. Ross, I.N., who found it half a mile in extent W.N.W. and E.S.E.; and one of the Montaran Islands was visible from the main-top, bearing S. $6\frac{1}{4}^{\circ}$ W.

Waller Rock.—There is said to be a coral rock, with 3 fathoms water over it, at 5 miles to the westward of the Ontario Reef.

Rival Reef we have no account of. It is marked on the chart with $5\frac{1}{2}$ fathoms over it, rocky bottom, in lat. $1^{\circ} 47'$ S., long. $108^{\circ} 15\frac{1}{2}'$ E.

Florence Adelaide Reef.—The British ship *Florence Adelaide*, bound from Cardiff to Singapore, in 1863, was reported to have been wrecked on a supposed coral reef, lying in about lat. 2° S., long. 108° E. The reef had 16 ft. water on it in the place where the vessel struck, but its extent and the least depth over it was not ascertained.

Hooghly Rocks.—The master of the French ship *Hooghly*, in 1872, sighted three rocks in lat. $1^{\circ} 35'$ S., long. $108^{\circ} 12'$ E. They bore East and West of each other, and from the westward appeared as a haycock, a sugar-loaf, and a small tree; the haycock, 16 ft., being the highest out of the water. The position was determined by observations of the Peak of Carimata.

SORUETOU ISLAND, about 6 miles long East and West, 2 miles wide, 1,400 ft. high, and visible 28 or 30 miles off, forms the north-eastern limit of the broad main channels of Carimata Strait. The western point of the island

is in lat. $1^{\circ} 42\frac{1}{2}'$ S., long. $108^{\circ} 39\frac{1}{2}'$ E., and on it is a hummock, which has been mistaken for a small island, and called the Quoin, from its appearance. About 2 or 3 miles off the West end of the island the depths are 20 to 26 fathoms.

Breakers are said to have been seen from the mast-head of the ship *Aurora*, bearing S. by W. $\frac{1}{2}$ W., distant about 3 miles, when the eastern extremity of Soruétou bore E. by N. $\frac{1}{4}$ N., the other extreme being obscured by clouds.

At a sandy beach on the South side of Soruétou, and near the East point, there is a good *watering place*, but high tide is required for a large boat to get over a reef. It is said, however, that fresh water can only be got at the West end of the island, at the foot of a hill of moderate height, where a ship may anchor in 10 fathoms.

CARIMATA ISLAND lies north-eastward of Soruétou, from which it is separated by a narrow channel. It is about 11 miles in extent East and West, 7 miles North and South, and near its centre is a peak rising to an elevation of 2,000 or 2,986 ft., which may be seen at the distance of about 45 miles. On the S.W. end of the island are some hot springs.

Reefs and dangers extend off the East and South coasts of Carimata; and at $6\frac{1}{2}$ miles S.S.E. from the South point of the island is a *gravel patch*, having 4 fathoms water over it. Two rocks above water, with others below the surface, appear to lie 3 or 4 miles off the middle part of the West coast; and off the N.W. point of the island are numerous islets and rocks, the outer of which, Tongado Island, is 3 miles westward of the point.

The channel between Soruétou and the reef which extends from the South coast of Carimata is about 2 miles wide, with depths of 10 to 17 fathoms; but no object is to be gained by using it.

Jamsetti Reef, with 19 ft. water over it, lies 7 miles N. by W. $\frac{3}{4}$ W. from the North point of Carimata Island, and N.E. $\frac{1}{2}$ N. $10\frac{1}{2}$ miles from Tongado Island.

Leema Isles are a group of small islets lying North about 18 miles from the northern side of Carimata; near them the soundings are 12 to 14 fathoms.

Wellesley Shoal is said to lie in lat. $1^{\circ} 18'$ S., long. $108^{\circ} 34\frac{1}{2}'$ E., but its position is doubtful. *Crescent Shoal*, also of doubtful existence, is said to lie in lat. $1^{\circ} 10'$ S., long. $108^{\circ} 38'$ E.

Erikson Shoal, of $4\frac{3}{4}$ fathoms, is placed on the chart in lat. $1^{\circ} 5'$ S., $108^{\circ} 29\frac{1}{2}'$ E.

China Reef.—The commander of the *China* reported, in 1871, that his ship struck on a reef, 4 miles North of the last named, on which there is 10 ft. of water. It is about a quarter of a mile long, and stretches out from N.W. to S.E. Its position is in lat. $1^{\circ} 1' 15''$ S., long. $108^{\circ} 30'$ E.

GREIG SHOAL was discovered by Capt. William Greig, of the ship *Lord Minto*, who found it to extend from lat. $0^{\circ} 52'$ to $0^{\circ} 58'$ S., long. $108^{\circ} 37'$ E.; the longitude, however, cannot be relied upon as being correct. Five fathoms

water were found within the extent given above, but on the extremes of the shoal the vessel was often in nearly the same depth of water as she was drawing, 13 feet, and this was in steering between much shoaler spots, with the body of Carimata then seen from the deck, bearing between S.S.E. $\frac{3}{4}$ E. and S.E. by S.; the least water found was 12 ft.; but, in a more recent examination, a spot with 8 ft. water only was found, in lat. $0^{\circ} 55' 30''$ S., long. $108^{\circ} 28'$ E.; from this spot Penambangan Island bears E.S.E., and the peak of Carimara Island S.S.E. $\frac{3}{4}$ E. The shoal is circular in shape, and about $1\frac{1}{4}$ cable in diameter.

Columbus Shoal.—On the 24th of November, 1869, the ship *Columbus*, G. Croot, master, in lat. $0^{\circ} 51'$ S., long. $108^{\circ} 16'$ E., struck soundings in 5 fathoms, hard sand or rock; the ship then tacked and stood to the N.W.; on standing back again, and when about 5 miles S.S.W. of the first position, soundings in 6 fathoms were again obtained; tacked and stood off to 17 fathoms, after which no shoaler water was found. The weather at the time was squally, and no land in sight.

WEST COAST OF BORNEO, ETC.

The southern part of the West coast of Borneo, from Sambar Point (its S.W. extreme) to abreast of the Masien Tiega Islets, is very imperfectly known. Two of its ports Sinkawang and Pontianak, are visited by the Netherlands Indian Steam Navigation Company's steamers, but the trade of the coast is mostly carried on by small vessels, owned and commanded by Chinamen or Malays connected either with the Dutch settlements in Borneo or Java, or with Singapore.

SAMBAR POINT is in about lat. $2^{\circ} 56' 30''$ S., long. $110^{\circ} 15'$ E., and *Mount Minto* in $2^{\circ} 14'$ S., $110^{\circ} 3'$ E., and between them the coast falls back and forms two bays. *Mount Minto* is upon the North point of the northern bay, and about 16 miles S.E. by E. $\frac{1}{2}$ E. from it is a high peak. The islands of Mankap, Laag, Kumpal, and some smaller ones, together with several dangers, lie off this part of the coast, and are described hereafter.

N. $\frac{1}{2}$ W., distant 22 miles from *Mount Minto Point*, is *Bree Point*, the coast between forming a bay 5 or 6 miles deep, in which are several small rivers. Close to the northward of *Bree Point* is the *Pawang River*, which has two entrances, separated by an island 3 or 4 miles in breadth.

From the entrance of the *Pawang* the coast trends with an irregular outline in a general North direction for about 45 miles, to the entrance of the large river *Simpang*. On this part of the coast are several small rivers, and about midway between the *Pawang* and *Simpang* are the islets *Sepadian*, *Tjampedak*, *Dato*, &c., with the islands of *Joanta* and *Batoang*, 7 or 8 miles

in the offing. About 7 miles southward of the entrance of the Simpang is the island of *Palintoan*, lying close to a point of the coast, inside of which on a small river is the town of *Pambarawang*. Two or three miles southward of *Pambarawang* is the town of *Succadana*.

Succadana, or *Sukadana*, "Parrot's Gift," is an unimportant place. It is a part of the Netherland province on the West coast of Borneo, and was once a Javanese state.

There is good anchorage in 3 or 4 fathoms in the roadstead off these towns, with a group of small islands to the southward.

The coast above described is low land, and it has seldom been approached under 12 or 10 fathoms, being fronted by islets or rocky ground in some parts.

From the entrance of the Simpang River, the coast trends for about 40 miles in a W.N.W. direction to a point about 4 miles north-eastward of the *Masien Tiega* Islands. On this part of the coast are several other islands, and separated from it by a very narrow channel is the large island of *Mayang*, which is principally low land, but near its south-western end is a high hill, *Mount Marang*; and near its north-western end a long range fronting the sea, named *Mount Mayak*.

The *West Coast of Borneo*, from a point 10 miles northward of the *Masien Tiega* Islets, takes a general direction about N.N.W. for a distance of 50 miles, when it trends towards the *Pontianak* River. Two or three small islands are shown on the chart as lying close to this part of the coast, and the entrance of the *Sanjavay*, one of the branches of the *Pontianak*, is about 15 miles to the southward of the main entrance of the latter river. The following remarkable phenomenon was experienced by Captain Pearson, of the brig *Lady of the Lake*, in the months of May and June, while sailing along this coast on two different voyages:—

"June 2nd, 1833, at daylight, when sailing along the coast in 10 fathoms water, experienced a singular incident; fresh water on one side the vessel, and salt water on the other, which continued for an hour whilst sailing about 2 miles on the boundary line of salt and fresh water. We filled all our empty casks with good drinkable water on one side of the vessel, when it was quite salt on the opposite side; our distance then $2\frac{1}{2}$ or 3 miles off shore, lat. $0^{\circ} 8' S.$, with the appearance of the mouth of a great river abreast, which must be navigable for large vessels, as the water deepened in crossing its direction." This was probably the *Sanjavay* River, one of the branches of the *Pontianak*, several of which reach the sea between the equator and lat. $0^{\circ} 20' S.$

PONTIANAK RIVER entrance is in lat. $0^{\circ} 2' N.$, long. $109^{\circ} 10' E.$, and distant 35 miles E. $\frac{2}{3}$ S. from *Pulo Datoe*. The anchorage in the road is in $3\frac{1}{2}$ to $5\frac{1}{2}$ fathoms, with the river's mouth bearing E. by S. $\frac{1}{2}$ S., or E.S.E., *Pulo Datoe* W. $\frac{1}{4}$ N. or W. $\frac{1}{2}$ N., and the extremes of Borneo from S. $\frac{1}{4}$ E.

to N.N.W. $\frac{1}{2}$ W., off shore about 4 or 5 miles. A shoal mud-bank projects some distance from the mouth of the river, and although the bar is nearly dry at low water, there are 8 or 10 ft. on it at high spring tides. The town is about 12 miles from the entrance, and has a fort; and at Balu Lagong, about 7 miles up, there is a fort on each side. These two places are sometimes visited by Bengal traders.

Buoys.—Outside the poles which mark the channel of the Pontianak River, two Herbert's buoys are placed. A *white* buoy in 3 fathoms water, with Pulo Batoe bearing W. 4° N., and Pulo Temadyo showing over the low foreland, N. 29° W. The second buoy is *black*, moored in $2\frac{3}{4}$ fathoms water N. 12° E. from the preceding buoy, and with Pulo Datoe bearing W. 2° N., and Pulo Temadyo N. 30° W. These buoys are moored about W.N.W. $2\frac{1}{2}$ miles from the mouth of the river.

Pontianak, a Malay town and state, is the chief place of the Netherlands Administration of their western province of Borneo. There is a considerable trade with Batavia and Singapore. The river is said to be navigable by the light draught steamer stationed upon it, for a distance of 200 miles.

Some bullocks and hogs may be procured at Pontianak, and also at Mampawa; but boats must go far up the Pontianak to procure fresh water during the dry season, which makes watering at this river very inconvenient.

TANJONG MAMPAWA is in lat. $0^{\circ} 19\frac{1}{2}'$ N., long. $108^{\circ} 54'$ E., and bears N.W. 23 miles from the entrance of the Pontianak, the coast between forming a bay. About 4 miles eastward of the point is Mampawa River, which is only navigable for proas; there is a fort at the town of *Mampawa*, a few miles inside the entrance. The anchorage in the road is in 5 to 8 fathoms, about 3 or 4 miles off shore, with the mouth of the river N. by E. $\frac{1}{2}$ E.; or to the westward of the point at discretion, bearing in mind that the soundings decrease rather suddenly under a depth of 10 fathoms.

H.M.S. *Rifleman*, in 1862, anchored off Mampawa Point, but could not find the landing-place mentioned in Horsburgh as being there. Her boats went up to the town of Mampawa, and succeeded in obtaining a few fowls and eggs.

The Tides in Mampawa Road run about 2 miles per hour, nearly E.S.E. and W.N.W.

The coast from Mampawa Point takes a general direction nearly N. by W. for 28 miles, to Tanjong Batoe Blad. At 9 miles from Mampawa Point is *Tanjong Samoedin*, and between these points is a bay, about 2 miles deep, with a small round islet in the depth of it. The western part of this islet was used as an observation spot by the officers of H.M. surveying-vessel *Rifleman*, and its position was ascertained to be in lat. $0^{\circ} 24'$ N., long. $108^{\circ} 56'$ E. At 13 miles northward from Samoedin Point is *Tanjong Sangoa*, having a small islet close to it, and Samassu Island and Kran Islet lying about half a mile off it. On either side of Sangoa Point, the coast line

curves gently back, forming bays, towards which the soundings decrease gradually.

Mountains.—The coast between the Pontianak River and Batoe Blad Point is marked by many remarkable mountains, some rising boldly up near the sea, and others several miles back from it. A long continuous range runs eastward from Tanjong Sedow Malang (5 miles north-eastward of Tanjong Batoe Blad) for a distance of 12 or 13 miles.

Pulo Sitenga, its centre in lat. $0^{\circ} 22' N.$, long. $108^{\circ} 44' 40'' E.$, is small, three-quarters of a mile long N.N.E. and S.S.W., nearly half a mile broad, and moderately elevated. Close around it are 6 to 8 fathoms water, and from 11 to 16 fathoms, clay bottom, at a short distance from it.

Pulo Damar, lying N.E. $\frac{2}{3}$ E., $2\frac{3}{4}$ miles from Sitenga, is a small, round islet, moderately elevated, and covered with large trees. Close around it are $5\frac{1}{2}$ to 8 fathoms, increasing to 10 and 14 fathoms at a short distance to the westward.

PULO TEMADJOE, lying about $2\frac{1}{2}$ miles westward of Tanjong Samoedin, is about $2\frac{1}{2}$ miles long, North and South, and $1\frac{1}{2}$ mile broad. It is considerably elevated, of an irregular shape, forming a point at its South end, and having its greatest breadth on its N.W. side, where are two small bays, with white sandy beaches; there is also a rather deep bay on its West side.

The soundings decrease gradually towards Temadjoe, from 14 and 12 fathoms to 7 and 6, and close to it are 4 and 3 fathoms, except on its East side, where a reef appears to project about a quarter of a mile. The channel between the island and the main is quite clear, with depths of 7 or 8 fathoms, decreasing regularly towards the main, and there is good anchorage anywhere under the lee of the island.

Pulo Baroe, in lat. $0^{\circ} 35\frac{1}{4}' N.$, long. $108^{\circ} 45\frac{1}{3}' E.$, is only about a third of a mile in extent. The soundings are very irregular, 18 to 5 fathoms, close to it, and close to its North end is a patch of $1\frac{1}{2}$ fathom.

A *shoal patch*, of only $2\frac{3}{4}$ fathoms water, and 12 to 16 fathoms around it, lies half a mile N.N.W. from Pulo Baroe.

Pulo Samassu, three-quarters of a mile long N. by W. and S. by E., and a quarter of a mile broad, lies off Tanjong Sangoa, half a mile distant from the coast, but some distance inside the 3-fathoms edge of the bank extend from the shore. The soundings decrease rather suddenly towards this island, which should not be neared under a depth of 8 or 6 fathoms.

About N.W. $\frac{1}{2}$ N., distant one-third of a mile from the North point of Samassu, is a small islet named Pulo Kran.

Four-fathoms Patches.—A shoal patch, having this depth over it, and 8 to 11 fathoms around it, lies with the South point of Samassu bearing East, distant $3\frac{1}{2}$ miles; and the West part of Pulo Kaboen, shut in behind the N.E. part of Pulo Penata Ketchil, bearing N. by W., westerly. There is another 4-fathoms patch at half a mile southward of Penata Ketchil.

BOERONG ISLANDS are a group of five islands lying to the westward of Tanjong Batoe Blad and the coast adjacent to it.

Pulo Landean, the southernmost of the group, is a mere islet, barely a quarter of a mile in diameter, lying about three-quarters of a mile S. by E. from the South point of Lamokatan. Near to it are depths of 4 fathoms, and 10 to 12 fathoms at a short distance westward of it.

Pulo Lamokatan, the largest island of the group, is $4\frac{1}{2}$ miles long N.N.W. and S.S.E., but its greatest breadth is only a little over a mile. It is high, with several peaked hills upon it, the heights of which, however, are not known. The water is deep, 15 or 16 fathoms, close to its West side, and there appears to be a deep water channel between it and Pulo Landean. Shoal water extends about a quarter of a mile from the North part of the island.

There is anchorage in 5 or 6 fathoms abreast of two small bays on the East side of Lamokatan, but it will be necessary to approach the shore with caution, the soundings decreasing rather suddenly from 17 or 16 fathoms.

Pulo Penata Besar, 2 miles long N. by W. and S. by E., and two-thirds of a mile broad, lies about $1\frac{3}{4}$ mile eastward of Lamokatan, the South extremes of both islands being in the same latitude. Close to the East and West sides of Penata Besar are from 4 to 8 fathoms water, except off its North point, where there are but $1\frac{3}{4}$ fathoms. In the channel between these islands the water is deep, 22 to 33 fathoms, but decreasing to 15 and 14 fathoms northward of the parallel of the North point of Penata Besar.

Pulo Penata Ketchil, about half a mile in extent, lies a mile eastward of the middle part of Penata Besar. A point projects in a south-easterly direction from the island, upon each side of which is a small bay. Close to the island are 8 to 13 fathoms, but, as before stated, there is a patch of 4 fathoms at half a mile to the southward, having 6 and 7 fathoms near it.

A *Shoal* or bank, over which the least water appears to be $3\frac{1}{4}$ fathoms, lies (its southern extreme of 4 fathoms) about one-third of a mile N.N.W. from the North point of Penata Ketchil, and from thence extends about N. $\frac{1}{2}$ E. $1\frac{1}{2}$ mile. Close to the West side of this bank are 7 to 16 fathoms, but on the East side, soundings of 5 fathoms extend nearly a mile from it, when the depths suddenly increase to 12 and 19 fathoms.

It would seem necessary to exercise caution when crossing over or passing near to this bank, for the chart does not exhibit sufficient soundings to make it certain that the least water upon the bank has been obtained.

Pulo Kaboen, the N.E. island of the Boerong Group, lies E.N.E. about 4 miles from the North end of Lamokatan, and W. by N. $\frac{1}{2}$ N. nearly 3 miles from Tanjong Batoe Blad. It is a high island, about $1\frac{1}{2}$ mile long, N.E. by N. and S.W. by S., and a mile broad. Close to its South end are $3\frac{1}{4}$ fathoms, and there are depths of 4 fathoms about three-quarters of a mile from it. A

patch of 4 fathoms lies about half a mile off its N.W. point, elsewhere the soundings close to the island are 6 to 8 fathoms.

TANJONG BATOE BLAD, the westernmost extreme of Borneo, is in lat. $0^{\circ} 47' 35''$ N., long. $108^{\circ} 50' 10''$ E. It is a prominent point from the land approaching it from the southward in a N.N.W. direction, and then falling from it in a north-easterly direction, and also from a range of hills behind it, running 12 or 13 miles to the eastward. The point itself appears, from the Dutch chart, to be low, with three hills immediately behind it; some rocks lie off it, and the 3-fathoms line which marks their edge is nearly half a mile from the point.

A *shoal*, of small extent, but over which there are but $2\frac{3}{4}$ fathoms water, lies N.W. $\frac{1}{2}$ N. $1\frac{1}{2}$ mile from Batoe Blad Point, and West-southerly from the North point of Kaboen Island. Around the shoal there appears to be 11 fathoms water, and 8 or 9 fathoms between it and the shore bank; between the shoal and Kaboen are 12 and 15 fathoms.

Directions.—Vessels will frequently find it convenient to keep pretty close to the coast of Borneo, just described, especially when working to windward against the N.E. monsoon, for favourable tides will be found near the shore when a strong current is running to the southward some distance from it. Between the Massa Tiega Islets and Mampawa Point, a vessel may stand towards the coast, guided by the lead, into 7 or even 6 fathoms; farther out, in a line between the Greig Shoal and Datoe Island, the depths are 18 or 20 fathoms. Small vessels may pass in safety between Temadjoe Island and the main, the channel being a mile wide, with depths in it of 7 and 8 fathoms. Large vessels, however, had better pass outside that island. Between Temadjoe and Samassu, vessels of any size may stand towards the coast into 7 or 6 fathoms, and pass on either side of Baroe Island and the shoal near it as convenient. The Boerong Islands may be boldly approached from the westward, and large vessels had better pass outside them; but small vessels may often with great advantage pass inside those islands, taking care to avoid the $3\frac{1}{2}$ -fathom shoal to the northward of Penata Ketchil, and the $2\frac{3}{4}$ -fathom patch about $1\frac{1}{2}$ mile N.W. of Batoe Blad Point.

The *Coast* from Tanjong Batoe Blad takes a north-easterly direction for about 5 miles to Tanjong Sedow Malang, where it falls back East for 2 or 3 miles, and then curving round and forming a long bay, runs in a N.N.W. direction towards Tanjong Biela, the southern point of entrance to the Sambas River.

Several rivers disembogue upon this part of the coast, the most important of which are the *Singkawan*, about 5 miles from Sedow Malang Point, and the *Slakouw*, about two-thirds of the distance between Sedow Malang and Biela Point. The town of Singkawan, situated some miles up the Singkawan, is the principal military station of the Dutch upon this coast, and

there are usually about 500 soldiers, Europeans and natives, quartered there.

SHOAL PATCH.—The soundings along this part of the coast appear to decrease regularly towards the shore, except at one spot which lies S.S.W. $\frac{3}{4}$ W. from Biela Point, and nearly West, distant 5 miles from the entrance of the Slakouw River; upon this spot, which is just inside the edge of the 5-fathom line, there are only $2\frac{1}{2}$ fathoms water.

SAMBANG or **SAMBAS RIVER** has a wide entrance, in lat. $1^{\circ} 11' N.$, long. $108^{\circ} 58' E.$, with some small islets close to the North point, and two hills on the other. The town is about 30 miles up the river on the South branch, which has many windings near the town. The principal branch is wide, running directly eastward, having many lateral branches. The sea flowing into the river makes the water brackish 13 or 14 miles up, so that ships in want of water are obliged to get it from a great distance. The anchorage in the road is with the mouth of the river bearing East or E. $\frac{1}{2}$ N., in any convenient depth, from 15 to 5 fathoms, the decrease being regular over a soft bottom to 4 fathoms about $1\frac{1}{2}$ or 2 miles off shore; the soundings are regular along this part of the coast.

Sambas is one of the places on the Borneo coast formerly visited by ships employed in the eastern trade from Bengal; it was fortified by a piratical Rajah, who was driven to the interior by a British force sent from Batavia in 1812. Since the late treaty with the Netherlands Government, the Dutch have claimed as their right most of the trading ports along this coast, where they have placed commercial residents and some troops.

The *Coast* from the Sambas River trends in a gradual curve to Tanjong Pajang, or Somoet, which bears from Tanjong Biela N.N.E., northerly, 25 miles. The soundings off it decrease gradually towards the shore from 17 or 16 to 8 and 4 fathoms; but shoal water extends more than $1\frac{1}{2}$ mile from Tanjong Pajang.

From Tanjong Pajang the coast falls back 2 or 3 miles to the eastward, and then runs north-eastward 13 or 14 miles to the entrance of the Palo River, from the North point of which it forms a small bay, curving to the northward to Tanjong Api. The coast between Pajang and Api Points has been but very imperfectly surveyed, and must be approached with great caution, for shoal banks appear to extend 6 or 7 miles from it.

TANJONG API, the north-western extreme of Borneo, is described hereafter.

Hector Bank.—Dangerous patches extend many miles to the southward of Sambar Point, the South extreme of the coast just described, the most southern of which is the Hector Bank, which is a $3\frac{1}{2}$ -fathom patch of doubtful position, but placed on the chart in lat. $3^{\circ} 46' S.$, long. $110^{\circ} 8' E.$ Around it are from 6 to 10 fathoms.

Fox Shoal is shown on the chart as two rocks awash N.W. by W. $\frac{1}{2}$ W. and S.E. by E. $\frac{1}{2}$ E. of each other, about $1\frac{1}{2}$ mile apart, with a large patch with only 2 fathoms water over it, to the north-eastward of them, and 9 to 19 fathoms close-to on their West and South sides. The westernmost rock is in lat. $3^{\circ} 32' S.$, long. $110^{\circ} 7\frac{3}{4}' E.$

Aruba Shoal, taken from the Dutch chart, is said to lie 3 or 4 miles N.E. by E. from the Fox Shoal, and to have 3 fathoms water over it.

Clemencia Reef, in lat. $3^{\circ} 24' S.$, long. $110^{\circ} 7\frac{3}{4}' E.$, is nearly dry; around it are 7 to 17 fathoms.

From the Clemencia Reef, shoals appear to extend all the way to Mankap Island, and vessels should be very cautious not to get too near them. Between Fox Shoal and Hector Bank there is a good channel by keeping between lat. $3^{\circ} 36'$ and $3^{\circ} 42' S.$; but when the vessel's position is not correctly known, it is advisable to pass to the southward of the Hector Bank.

Although the bottom near and among these shoals is generally a mixture of red and green clay, with mud, yet the soundings are very irregular, with overfalls, making it prudent not to come under 15 or 16 fathoms towards them.

Den Briel Shoal, reported by the steam-vessel *Den Briel* to have been seen above water, and placed on the charts in lat. $3^{\circ} 23' S.$, long. $109^{\circ} 27' 30'' E.$, was thoroughly and unsuccessfully searched for by H.M.S. *Nassau* in 1876,—depths of 18 to 22 fathoms, mud, having been obtained.

A *doubtful Rock (Euphrosine)* is marked on the chart in lat. $3^{\circ} 25\frac{1}{2}' S.$, long. $109^{\circ} 41' E.$, or S.S.W. 16 miles from Oliviera Reef. It was reported in 1869 by the Master of the English barque *Euphrosine*, who says it is a mile in diameter.

Oliviera Reef, from a Dutch chart of 1842, lies W. by S., $24\frac{1}{2}$ miles from Mankap Island, or in lat. $3^{\circ} 10' S.$, long. $109^{\circ} 47\frac{1}{2}' E.$ H.M.S. *Nassau*, in 1876, passed $1\frac{1}{2}$ mile East, and $1\frac{1}{2}$ mile North of the position assigned, without observing any indication of shoal water; depths of 16 to 19 fathoms, sand, were obtained.

PULO MANKAP or **MANCO**, in lat. $3^{\circ} 5' S.$, long. $110^{\circ} 13' E.$, and distant about 8 miles S.W. of Sambar Point, is a small low island, which may be seen 15 miles from the deck of a large ship. Near to it, to the N.N.E., are three other small isles, which appeared to Capt. Ross, when examining the surrounding shoal, as three bush islets or rocks. It was noticed in the last page that there is shoal water to the southward of Mankap Island, as far as the Clemencia Reef; shoal water also extends far to the westward of it, and vessels must be cautious in approaching the island from both those directions. Captain Ross, in the *Discovery*, with the island bearing East, distant 10 miles, got suddenly into 4 and $3\frac{3}{4}$ fathoms, hard sand, on the shoal bank that encircles the island; when it bore N.E. about 7 miles, the sound-

ings were $3\frac{3}{4}$ fathoms, fine sand; and when bearing N.N.E. $\frac{1}{4}$ E. 10 or 12 miles, seen from the deck, the vessel struck on the ground.

Horsburgh says, Mankap Island ought not to be brought to the northward of N.E. by N. while in sight from the mast-head, for if it bear N.N.E. $\frac{1}{4}$ E., about 18 miles distant, a vessel will suddenly get into shoal water on some of the spits that stretch far to the southward, having from 10 to 17 fathoms, soft bottom, near them.

Gelam or Laag Island (Low Island), is the largest of a group of islands lying north-west 9 or 10 miles from Sambar Point. The whole are encompassed with reefs, and the shoal bank, which extends 10 or 11 miles westward of Mankap Island, also extends 5 or 6 miles westward of the Laag group.

KUMPAL or RENDEZVOUS ISLAND.—The West point of this island, by Capt. Ross, is in lat. $2^{\circ} 44\frac{1}{2}'$ S., long. $110^{\circ} 2\frac{1}{2}'$ E., but Sir Edward Belcher, who visited it in H.M.S. *Sulphur*, October, 1840, places a ledge of rocks on the West point in long. $110^{\circ} 7' 39''$ E., or $6^{\circ} 16' 21''$ East of Singapore, and $9^{\circ} 16' 24''$ West of Macassar.

The *Sulphur* took up a safe berth within 1 mile of the West point of the island; and her tender, the *Starling*, occupied a position within one-eighth of a mile from the shore, but had rocky bottom. A plan was made of the anchorage, and the results of the examination proved it to be much safer and more convenient than the chart or sailing directions led to expect, admirably adapted to replenish fuel or correct chronometers, and with this object in view some pains were taken to connect it with the meridian of Singapore. The rocky portion of the island is composed of a mixture of contorted slaty and sandstone schist, traversed by veins of quartz, exhibiting slaggy indications at the point of contact, apparently ferruginous, but on examination did not affect a very delicate needle. Wood is abundant, but the search for water was unsuccessful.

This island was, in former times, the rendezvous for the China convoys in case of separation. The following is from Horsburgh:—The island extends about 12 miles to the north-eastward, and a chain of small islands and reefs nearly joins it to the main; this chain stretches also southward along the coast to Pulo Mankap, and is fronted with shoal water. About 6 miles S. by W. from the West point of the island is a bank with 3 or $3\frac{1}{2}$ fathoms, which makes it proper in leaving the anchorage at the N.W. part of the island to haul off to the south-westward, to give a berth to this bank. In July land and sea breezes prevailed, the former at East and E.S.E., veering to S.S.E. in a breeze. The island shows in hummocks, but cannot be seen above 16 or 17 miles, and the West point forms in a bluff, when viewed from the S.W. or southward.

The *William Pitt*, in July, anchored in $4\frac{3}{4}$ fathoms, about 4 miles off

shore, with the West point of Pulo Kumpal S. $\frac{1}{2}$ W., its North point E. by N. $\frac{1}{2}$ N., a small isle off the latter part E. by N. $\frac{3}{4}$ N., another isle E.N.E., a third small isle with trees on it North, just visible from the poop, and the North extreme of Borneo N.N.E. The first two isles are united by a coral reef, which extends 2 miles N.N.W. from the second island, having near its extremity a large rock 20 feet above water; from this rock, in a N.E. direction, there is another island about 4 miles long, surrounded by coral reefs.

Although coral reefs, with sharp-pointed rocks visible at low water, project from 1 to 3 miles from most parts of Pulo Kumpal, yet the western side appeared tolerably clear, with a sandy beach. From the West point of the island the land forms an elbow, by which there is shelter from all winds from the eastward, with smooth water.

Water.—Sir Edward Belcher did not find any water on the island, but Horsburgh states that the crew of the *William Pitt* dug wells above high water mark on the sandy beach on the West side of the island, from which very good water was obtained.

The tides were found to be more regular here than at any other part of the West coast of Borneo; the rise and fall was 8 or 9 ft.

Rocks awash.—In a Dutch chart by J. G. Tindal, 1842, some rocks awash are placed in lat. $2^{\circ} 20\frac{1}{2}'$ S., about S.W. by W., 12 miles from Mount Minto.

Gilbert Rocks and Elliot Sand.—In lat. $2^{\circ} 14'$ to $2^{\circ} 16'$ S., and 4 or 5 miles off Mount Minto Point, lie the Gilbert Rocks, or Toekan Mengkoedoe, with Mount Minto bearing about E. $\frac{3}{4}$ N., and High Peak about E. by S. $\frac{1}{2}$ S.

A mile or two S.E. of Gilbert Rocks is a dry bank, named *Elliot Sand*.

BIRDS NEST ISLANDS (Vogelnest Islands), are a group of small islands 3 or 4 miles in extent, and surrounded by a reef. The northernmost island, named Boorong, is in lat. $1^{\circ} 43'$ S., long. $109^{\circ} 15\frac{1}{2}'$ E.

Amur Shoal, of 9 ft., discovered in 1875, is about half a mile in diameter, and lies 3 miles W.N.W. from Boorong Island.

Black Rock (*Zwarte Rots*) is 4 or 5 miles to the S.W. of the Birds Nest group. There is a rock under water about half a mile eastward of it, a rock awash nearly a mile to the southward, and another awash the same distance to the south-westward.

South Island (*Krawang*), about a mile in extent, lies about $4\frac{1}{2}$ miles N.E. from the Birds Nest Islands. A smaller island lies close to its N.W. side, and a rock off its S.E. side. *Ginting*, *Mintano*, *Grisse*, and *Bisi*, are four small islands, the most eastern of which, *Ginting*, is in lat. $1^{\circ} 41'$ S., long. $109^{\circ} 4\frac{1}{2}'$ E.

Bisi is about $3\frac{1}{2}$ miles from Carimata, to which it appears to be almost connected by a projecting reef. *Bold* and *Tongue Islands* form a group of

four small islands. Bold, the most southern and western island of the group, bears North 3 miles from Ginting. The eastern Tongue Island is very small. The North Tongue Island has a reef projecting from it nearly 2 miles in a N.N.W. direction. The middle Tongue is about twice the size of the other two islands. A reef, about a mile in extent, lies 2 miles north-westward of Bold Island.

Pyramid, or *Boan Island*, is about $1\frac{1}{2}$ mile in extent, and its centre is in about lat. $1^{\circ} 29\frac{1}{2}'$ S., long. $108^{\circ} 59'$ E. *Nibong* and *Helinet* are much smaller islands, lying about a mile northward of Pyramid.

The **OSTERLY CHANNEL**, through which the ship of that name passed, lies westward of the Birds Nest Islands, Black Rock, Bold Island, and the reef north-westward of it, Pyramid, Nibong, and Helinet Islands; and eastward of Ginting, the islands and reefs N.E. of Bisi, and the East coast of Carimata. The narrowest part is between Bold Island and the reefs extending eastward of Bisi, where it is but $1\frac{1}{2}$ mile broad, with depths of 5 or 6 fathoms; westward of Black Rock the depths are 10 to 12 fathoms; and from 10 to 13 fathoms between Carimata and Pyramid Island. The *Oosterly* found this route very intricate, and several times had rocky bottom and very shoal water.

PAPAN ISLANDS form two small groups, between which is the Papan Channel, about a mile wide, with 9 to 12 fathoms water. Maleidong, in lat. $1^{\circ} 31'$ S., long. $109^{\circ} 22'$ E., is the largest of the islands, and with two islets near its North side form the eastern group. The western group is said to consist of (three or) four islands, nearly of the same size, the southernmost bearing about South from the one next it; the remaining three are in line when bearing about N.E. by E. and S.W. by W.

Spirit of the North Shoal.—The ship *Spirit of the North*, Charles Wise, commander, September 21st, 1861, was reported to have struck on a shoal lying 2 to $2\frac{1}{2}$ miles N.W. of the middle island of the western Papan group; the shoalest water obtained was 12 ft. There was no ripple on it, but small round white patches were indistinctly seen under the vessel's bottom.

Passage Islands (*Goerong*) are two small islands lying close together, 10 miles N.W. by W. $\frac{1}{2}$ W. from the western group of the Papan Islands.

A rock is marked on the chart in lat. $1^{\circ} 30'$ S., long. $109^{\circ} 5\frac{1}{2}'$ E., 4 miles S.W. of the Western Goerong Island, but its position is doubtful.

Tallack Shoal.—On the 2nd of March, 1871, the British barque *Mary Tatham*, struck on a shoal in lat. $1^{\circ} 21'$ S., and long. $109^{\circ} 6'$ E. On examination of the danger 20 ft. was the least water found, with 20 fathoms close to on all sides. The following bearings were observed from the shoal:—Soeka, the southern of the Melapies group of islands, N.W. $\frac{3}{4}$ N., distant about 2 miles; Pyramid Island, S.W. $\frac{3}{4}$ S.; and Zattak Point, half open of the North side of Meledan or Button Island.

MELAPIES ISLANDS comprise a group about 5 miles in extent, lying to

the S.W. of the high island of Panambungan. Three islands of the group are tolerably large and high, with several contiguous islets, the north-eastern of which, Double Island, lies about $2\frac{1}{2}$ miles from the S.W. extreme of Panambungan.

Rodgers Reef.—In 1857 Mr. Rodgers, master of an English ship, discovered a shoal with probably less than 4 fathoms water on it, the East point of Carimata Island bearing S. $\frac{1}{2}$ W., and the Leema Islands W. by N. $\frac{1}{2}$ N.

Button Island (*Meledan*) lies about 9 miles eastward of the Melapies group, and about $6\frac{1}{2}$ miles E. by S. $\frac{1}{2}$ S. from the S.W. point of Panambungan.

PULO PANAMBUNGAN is high, 5 miles in extent N.E. and S.W., and its western point is in lat. $1^{\circ} 12' S.$, long. $109^{\circ} 10' E.$ There are four small islets off its eastern extreme, the outermost of which is 4 miles N. by W. $\frac{1}{2}$ W. from Button Island; there is also a small islet, named Sirie, lying off its south-western extreme.

There is good anchorage off the north-western side of Panambungan, in $5\frac{1}{2}$ or 6 fathoms, with shelter from southerly winds. *Fresh-water Bay*, at this part of the island, has two runs of good water, the westernmost of which is the largest, where the water is obtained behind a large black rock on the beach, which consists of fine sand. All the watering places are fronted by fine sandy beaches, and easily discerned. There are spars fit for topmasts on the island, but the trees seem to be too heavy.

Baroe and Ananas Islands are the largest and outermost of a group of small islands lying off the north-western extreme of Mayang Islands.

Masien Tiega are three small islands, the outer or westernmost of which is in lat. $0^{\circ} 55' S.$, long. $109^{\circ} 12' E.$ The chart shows a reef extending from them to the S.W.

Greig Channel is the passage between Panambungan and Melapies Islands, and the route by it and among the islands to the south-eastward, although narrow in some parts, has moderate depths with generally good anchorage, and seems preferable to the route westward of Carimata and Soruetou, for ships that have to work along the coast against the monsoon, whether bound northward or southward.

Directions.—Being to the northward of the dangers off Minto Point (page 290), the Borneo coast may be approached to 8 or 9 fathoms of water, and to 7 or 6 fathoms when nearing the Papan Islands. The Birds Nest Islands should not be approached under 10 fathoms, or nearer than 2 miles. A vessel may pass on either side of the two groups of the Papan Islands, observing that the water quickly shoals to 5 fathoms eastward, or inshore of them. If passing westward of them, remember the Spirit of the North Shoal (p. 291). Between South Island and the Papan Islands the depths are 10 to 12 fathoms, decreasing pretty regularly towards the Borneo coast;

and between the Papan and Passage Islands there are 7 to 12 fathoms. Northward of the Papan Island the soundings appear to shoal rather suddenly from 8 to 5 fathoms, but gradually under that depth. The Greig channel appears to be bold towards either shore, with depths from 14 to 20 fathoms in the fairway.

When northward of Panambungan, the Borneo coast may be approached to 9 or 8 fathoms at discretion, but under 8 fathoms the soundings seem to decrease rather quickly. A vessel may stand off to 15 fathoms near the Leema Islands, and to 17 or 20 fathoms when to the northward of them, but remember the Wellesley, Crescent, and Greig Shoals.

The Inner Channel, between the East end of Panambungan and the S.W. extreme of Mayang Island, may be used by small vessels, as it has regular soundings of 3 or 5 fathoms, soft bottom.

Directions through Carimata Strait from the Southward. Approaching Carimata Strait from the southward, a vessel will have to depend principally upon the correctness of her reckoning, for the soundings are so irregular, that they will afford but very imperfect guidance, and the land is too distant to be of service in determining her position. If to the westward of about long. 108° to $108^{\circ} 20'$, a good lookout should be kept to get sight of Shoe Island (page 272), which, if seen, will determine her position, and enable her to steer to pass into the strait, either by the main route eastward of the Discovery, Lavender, and Cirencester Shoals, or by the route westward of those dangers, between them and the Osterly Shoals.

Should the vessel be to the eastward of $109^{\circ} 30'$, and approaching the parallel of 4° S., the greatest care must be observed to keep to the westward of the dangers which extend about 42 miles S. by W. from Mankap Island; and the navigator must be guided by circumstances as to whether he shall proceed eastward or westward of Doubtful Rock and Oliviera Reef. It is often advantageous, on account of the tide, to pass inside those dangers, but it is much better, if possible, to keep the main channel. Having passed Pulo Kumpal (or Rendezvous Island), a course may be shaped to pass on either side of the Ontario Reef. Carimata, Soruetou, and the adjacent islands will afford good objects for determining the vessel's position if she pass northward of the reef, and the Montaran Islands will answer a similar purpose, if she pass southward.

Vessels passing through Carimata Strait and bound to Singapore during the months of December, January, and February, generally keep near the coast of Borneo (where the tides are said to be regular) to avoid the strong southerly current; and pass into the China Sea through Greig Channel.

From the Northward.—Coming from the north-westward towards Carimata Strait, if intending to pass outside or southward of Ontario Reef, having brought Soruetou to bear N.E., distant 25 miles, steer S.E. by E., to give a berth to the supposed rock westward of the Ontario Reef. To keep to the

westward of this supposed rock, it would appear to be necessary to sink the West end of Soruetou from the deck of a large ship before it bears North of N.E. by N. Keep the West end of Soruetou to the eastward of N. by E., until past Ontario Reef, or 25 miles to the southward of Soruetou, or sink the West end of the island from the deck of a large ship, bearing about N. by E.; continuing the S.E. by E. course the Montaran Islands will be seen, if the weather is favourable; pass to the eastward of them at 15 or 16 miles distance. From this position a S.S.E. course will lead in the fair track, between the Cirencester and Discovery Shoals on the West side of the channel, and the Oliviera Reef and Doubtful Rock on the East side. If not certain of the longitude, the best guide is to borrow towards the coast of Borneo, to get a sight of the land, if circumstances admit, and taking a departure from Rendezvous Island, steer to the southward between Oliviera Reef and the Mankap Shoals.

The best track for ships bound to the southward, particularly in cloudy weather, is to pass northward of Ontario Reef, by keeping within 10 or 12 miles of Soruetou, until its West extreme bears N. $\frac{1}{2}$ W.; then observing to keep it to the West of N. $\frac{1}{2}$ W., in steering to the S.S.E., until the reef is passed. Proceeding to the southward, borrow towards the eastern side of the strait, where the soundings will generally be from 17 to 14 fathoms, within from 30 to 20 miles of the coast of Borneo, deepening in some places as the shoals are approached on the West side of the strait, but not always affording a certain guide. To the southward of Rendezvous Island the depths will increase from 19 to 21 fathoms irregular soundings, when about 30 or 33 miles to the south-westward of Pulo Mankap, which is as near as any large ship should approach the shoals that extend far out from it in this direction.

Sailing vessels making the passage from Singapore to the ports in Java during the S.E. monsoon, as a rule, sight Soruetou Island, pass eastward of Discovery East Bank, and thence round Hector Bank.

CHAPTER VIII.

BANKA TO SINGAPORE.

THE routes between Singapore and the western straits, Banka, Gaspar, and Carimata, leading from the Java Sea, pass either eastward of, or within the line of islands and reefs which run generally in a parallel direction to the coast of Sumatra.

This S.W. portion of the China Sea, between Borneo and Sumatra, has not been systematically surveyed; but as it has been the great maritime highway for so many years, it is believed that all its dangers are ascertained, and tolerably well defined. A portion near the coast of Borneo was surveyed by Lieutenant Blommendal, of the Dutch Royal Navy; other parts, including the Tambelan Islands, were surveyed by Lieutenant J. W. Reed, R.N., in H.M.S. *Rifelman*, in 1862, &c. Other portions are by Mr. Stanton, R.N. Rhio Strait, partially surveyed by the Dutch, was afterwards, in the years 1865—1868, examined by Lieut. J. W. Reed, in H.M.S. *Rifelman*; the Linga Islands, also, by the Dutch, by A. C. Edeling, 1863, and afterwards by Lieut. Reed. Lieutenant Melvill Van Carnbee, also executed some portions. From these and many other authorities the following directions, as given in the *China Sea Pilot*, have been derived.

This chapter will include descriptions of the space and the islands between Borneo and Sumatra, including the passages between the groups which lead to Singapore Strait.

1.—DETACHED ISLANDS AND ROCKS.

TOEJOE, or Seven Islands, lie in two groups, between the parallels $1^{\circ} 16'$ and $1^{\circ} 5' S.$, and the meridians $105^{\circ} 13\frac{1}{2}'$ and $105^{\circ} 20\frac{1}{2}' E.$ They are high and woody, and visible 25 or 26 miles, and surrounded by rocks and reefs. They are uninhabited, but occasionally visited by proas.

Pulo Joe, the southernmost of the islands, is very small, but rises to a height of 270 ft.; a short distance N.E. of it is a sunken rock. *Pulo Lalang* is an islet about a mile N. by E. from Pulo Joe; and a mile W.S.W.

from it is another islet surrounded by a reef. *Pulo Sato*, the most western of the islands, is small, 105 ft. high, and bears from Pulo Joe about N.W. by N., distant 5 miles. *Pulo Meranti*, also a small island surrounded by a reef, is 117 ft. high, and lies between Lalang and Sato. *Pulo Tjebia*, the largest island of the southern group, is about a mile in extent, 373 ft. high, and surrounded by a reef which projects a little more than a mile from its S.E. extreme.

Pulo Katjangang, the north-easternmost and largest of the Seven Islands, is 4 miles long N.W. $\frac{1}{2}$ W. and S.E. $\frac{1}{2}$ E., but only half a mile broad, and rises to several peaks, the highest of which is 526 ft. above the level of the sea. It is surrounded by a reef, within the limits of which are some rocks above water, especially off its S.E. end. There are some wells on its West side. About $2\frac{1}{2}$ miles N.W. by W. $\frac{1}{2}$ W. from its N.W. extreme, is *Pulo Tukonkembong*, a small islet, 120 ft. high, and surrounded by a reef. About $1\frac{1}{2}$ mile W.N.W. from Tukonkembong are the *N.W. Rocks*, the middle one of which is above water.

DOCAN ISLAND, in lat. $0^{\circ} 58' S.$, long. $105^{\circ} 39' E.$, is about three-quarters of a mile in extent, surrounded by a reef, and a small islet with some rocks project nearly a mile from its north-eastern extreme.

Two reefs lie off the South point of Docan, the outer one of which, lying S.S.E. distant 2 miles from the point, was discovered in January, 1823, by the ship *Mary* striking on it. There are 2 fathoms water over each of these dangers, and around them 14 to 18 fathoms.

The channel between the Toejoe Islands and Pulo Docan is 21 miles wide, and has regular soundings of 14 to 16 fathoms.

TOTY ISLAND, or *Pulo Laut*, in lat. $0^{\circ} 55' S.$, long. $105^{\circ} 47\frac{3}{4}' E.$, is small, and surrounded by a reef, which on the East side projects half a mile. The passage between Toty and Docan is 6 miles wide, and appears to be free from danger.

When passing between Banka and the Toejoe Islands, the latter should not be approached to less than 10 fathoms water, nor Banka nearer than 4 miles; for its dangers are all 2 or 3 miles in the offing, and nearly awash. Near the Hyu and Doyang Rocks the bottom is rocky, and the depths irregular.

Vessels keeping to the southward of Toty and Docan Islands, in order to cross over to Borneo, must take care to avoid the Mary Rock, lying S.S.E. 2 miles from Docan Island, and also the Vega and other shoals.

From October to March, during the N.W. monsoon, the currents run with force to the S.E., and during the other months to the N.W. It has, however, occurred that vessels going to Banka in June and July have experienced strong southerly currents. Along the North shore of Banka, in regular weather, there are generally two ebbs and two floods in the 24 hours.

PULO TAYA, the centre of which is in lat. $0^{\circ} 44' S.$, long. $104^{\circ} 54' E.$,

rises to a double peak 630 ft. above the sea. Both peaks, when in line on a N. by E. and S. by W. bearing, show as a single triangular peak. The whole shore of the island is steep, and may be approached to a distance of 3 cables. The island is uninhabited, of granite formation, and covered with wood.

There is a spring of *excellent water* on the western side of Taya, and a boat at high tide can approach it to 40 ft., but at low tide rocks extend nearly a cable's length from the sand. The knowledge of this is important to the mariner, as no similar facility for watering occurs between Banka and Rhio Strait. In the fine season, boats come here from Linga seeking turtle.

Castor Bank, lying to the north-eastward of Pulo Taya, is a long ridge of coral and sand, nearly a mile wide, and 13 miles long in a N.N.E. direction. The general depths on it are 10 to 6 fathoms, but on one part, N.E. $\frac{1}{2}$ N. 10 miles from Pulo Taya, there is a ridge about a mile in extent, and its eastern side steep-to, carrying only 5 fathoms. The bank is famous for a red species of fish, called from their colour *Ikan Merah*.†

ILCHESTER, or *Alang Kalem Bank*, on which the ship *Ilchester* struck, was examined by Capt. D. Ross, I.N., who found it to be in lat. $0^{\circ} 26\frac{1}{2}'$ S., long. $104^{\circ} 58'$ E., to extend N. by E. and S. by W. about $2\frac{1}{2}$ miles, and $1\frac{1}{2}$ mile in breadth, and to have but 1 fathom water on its shoalest parts. Pulo Taya bore from the shoal S. $\frac{1}{2}$ W.; Maralie Islet, off the East point of Linga, N. by E.; the East point of Linga, N. $\frac{1}{2}$ E., distant 8 or 9 miles. The depth of water decreases nearly all around from 18, 16, or 15 fathoms, suddenly to 6 and 3 fathoms, on the edge of the shoal.

When passing this danger, Maralie Islet must not be brought to the eastward of North, and Pulo Taya should be kept to the westward of S. by W.

PULO SINKEP, PULO PUNOEBO, and two islands to the westward, appear from a distance like one large island, being separated only by narrow channels. They lie off the south-western part of Linga, and, together with some adjoining islets and shoal spots, cover a space from 20 to 24 miles. Sinkep, the largest island of the group, is of very irregular shape, and of considerable elevation, having on its eastern side a range of hills, with a peak 1,440 ft. high near the centre of the range. It is only the East and N.E. coasts of Sinkep and the dangers off it which will be noticed here: the other

* In old charts a shallow spot of $2\frac{3}{4}$ fathoms, hard bottom, was shown at 22 or 23 miles southward from Taya Island, and W. $\frac{1}{2}$ N. from Toejoë Island, said to have been discovered by the English vessel *Thomas Harrison*, Capt. E. Smith, but it could not be found by Mr. Stanton, in the *Saracen*.

† *Cowman Bank*, said to lie $6\frac{1}{2}$ miles N.E. by N. of the *Castor*, was searched for by the *Saracen* in vain. It is expunged from the charts.

portions of the group belong to the Inner Route, by Varella and Durian Straits, and are described hereafter.

Dangers.—At $3\frac{3}{4}$ miles E. by S. $\frac{1}{4}$ S. from the S.E. point of Sinkep is the South end of a shoal, which from thence extends N.N.E. for 5 miles, but is only about $1\frac{1}{2}$ mile broad. At the South end of the shoal is a patch of $2\frac{1}{4}$ fathoms, and another of $2\frac{3}{4}$ fathoms at the North end; between these patches are depths of $4\frac{1}{2}$ and 5 fathoms. Tanjong Boekoe (the South point of Sinkep), bearing West, leads a mile southward of this danger; and the eastern point of the island bearing North leads about the same distance eastward.

Rocks and shoal water extend nearly a mile from the East point of Sinkep, and the *Saracen's* soundings show a bank projecting 5 miles in a north-easterly direction from it, on the extremity of which there are but 4 fathoms water. As no soundings have been taken near the N.E. coast of Sinkep, it should be approached with caution. There are some rocks awash off the East sides of the small islets lying between the N.E. point of Sinkep and Ponoebo.

LINGA ISLAND, lying about midway between Banka and Singapore Straits, is about 35 or 36 miles in extent, in a W.N.W. and E.S.E. direction. Upon its southern part is a remarkable mountain, the peak of which, rising to an elevation of 3,920 ft., is split in two, forming a sort of double peak, "rising like spires from the summit of the mountain," but which is more generally thought to resemble asses' ears, visible many miles in all directions. Viewed from the sea, this mountain presents a most beautiful and imposing appearance, which is sure to arrest the attention even of the most careless observer.

The north-eastern coast of the island is formed of numerous hillocks, from 200 to 300 ft. high, which give it a uniform appearance; the contour of the coast line is, however, very imperfectly known.

The East extreme of Linga, called by the natives *Tanjong Eung*, from its prominent position and pyramidal peak, 750 ft. high, is very conspicuous, and visible in clear weather 30 miles off. *Tanjong Roe* may be known by a saddle hill, 630 ft. high, near it. The southern coast of Linga, between these points and between Tanjong Roe and the town of Linga, being all low land, both points make like islands when above 13 miles distant.

Pulo Maralie is an islet lying three-quarters of a mile off shore, in a S.E. by E. direction from the hill on Tanjong Eung. *Pulo Kaka*, a larger islet, lying about half a mile off shore in a South direction from the same hill, is surrounded by a reef which off its S.W. point extends a mile.

LINGA ROAD and TOWN.—The bay forming Linga Road is exposed to southerly and easterly winds, and large ships are obliged to lie far out on account of shoal water extending from the mouth of the river around Pulo Colombo and its adjoining islets. Pulo Colombo, the largest of these islets, lies S. by E. $\frac{1}{4}$ E. nearly 2 miles from the entrance of the river. Anto and

Ballang Islets are both small, the former lying about a mile S.E., and the latter the same distance E. by S. from Colombo. W. by S. $2\frac{1}{4}$ miles from Colombo is another small islet named Badas, which is almost connected by reefs to Pulo Mapar, a larger islet about a mile to the northward, with a grove of cocoa-nut trees on it; the village here contains about 300 Malays and Chinese, chiefly fishermen.

H.M.S. *Saracen* anchored in Linga Road in 4 fathoms, mud, Pulo Badas bearing N.N.E. half a mile; Sinkep Peak, 1,440 ft. high, S.S.W.; and Ponoebo Peak, 935 ft. high, W. $\frac{1}{2}$ S. Horsburgh says that the safest anchorage for strangers is 3 or 4 miles off shore, with Pulo Taya S.S.E. $\frac{1}{2}$ E., and the South point of Linga East, southerly. Linga Peak just to the eastward of Colombo, N.W. $\frac{1}{2}$ W. or N.W. $\frac{3}{4}$ W., with Ponoebo Peak bearing about W. $\frac{1}{4}$ S., and the peak of Sinkep S.W. by W., appear also to be good anchorage marks.

The *Town of Linga*, called by the natives *Dyak*, is prettily situated on the banks, and nearly a mile within the entrance of the fresh water river. The high, rugged, fantastic peak of Linga in the background, together with the rakish appearance of the country prahus, all moored to cocoa-nut trees and areca palms, their rich foliage almost obscuring the houses, give to the whole a picturesque appearance.

The town is said to contain (in 1860) about 4,000 Malays, and 1,500 Chinese. The former prefer their usual style of houses constructed on poles, but some of the Chinese have substantial buildings of stone. The produce is rattans, pepper, and gambier, which is carried to Singapore and Rhio by country vessels and prahus. Gold is found in small quantities after heavy rains. Tin has not yet been found, but the neighbouring island of Sinkep produces some. There are no Europeans on the island. The Sultan is nominally under Dutch protection, and the Resident of Rhio pays him an annual visit.

Water.—The *Saracen* obtained good water, but with difficulty, from a well in the interior of Mapar Island.

In Linga Road it is high water, full and change, at 7 p.m., and the rise is 7 ft. The flood runs at the rate of 2 knots to the westward.

Directions.—A vessel proceeding toward Linga Road from Banka Strait, should pass westward of Pulo Taya, and steer for the high land to the eastward of Linga Peak, giving the eastern coast of Sinkep a berth of at least 5 or 6 miles. In working, by not bringing the East point of Sinkep to the eastward of North, will avoid the shoal off the East side of that island; and by not bringing the S.E. point of the island to the southward of S.W. until Linga Peak bears N.N.W. $\frac{1}{2}$ W., will avoid the shoal bank which extends 5 miles in a north-easterly direction from the East point of Sinkep. When standing towards the South coast of Linga, care must be taken to avoid the *De Hes Rock*, with 16 ft. water over it, which lies with the South

extreme of Pulo Singa bearing E. $\frac{3}{4}$ N., distant 4 miles; Linga Peak, N.W. by W. $\frac{1}{2}$ W.; Sinkep Peak, W. by S. $\frac{1}{3}$ S.; and the nearest points of Linga bearing respectively N.E. by N., northerly, distant 2 miles, and N N.W., westerly, distant $2\frac{1}{4}$ miles; close to the rock are 12 or 14 fathoms. The right extreme of Pulo Kaka just open of the right extreme of Pulo Singa, bearing about E.N.E., leads a mile to the S.E. of the De Hes Rock, and Linga Peak N.W. by W. leads to the S.W.

Bound to Linga Road from the north-eastward, round the East point of Linga Island at a moderate distance, and then steer to the westward for the anchorage.—(*Mr. Stanton, R.N.*)

The **NORTH EAST COAST** of **LINGA** is formed of numerous hillocks, from 200 to 300 ft. high, which give it a uniform appearance; but neither it nor the adjacent islets are safe to approach at night, being as yet but imperfectly surveyed. The soundings obtained by the *Saracen* in this locality, were confined to those above a depth of 10 fathoms, as vessels can gain no advantage by keeping close in shore.

EAST DOMINO, or *Selentang*, is an islet lying about 8 miles northward of Tanjong Eung, the East point of Linga. Horsburgh says that this islet is 80 ft. high, and that rocks awash project from it to the southward, to the distance of $2\frac{1}{2}$ miles; but the Dutch chart only shows a reef extending about a mile North and South of the islet, and a smaller islet close to the westward of it; a rock awash is placed about $2\frac{1}{2}$ miles South of it. The soundings close to the eastward of the islet are 14 fathoms, increasing to 16 and 17 fathoms at the distance of 3 or 4 miles.

DOMINO HILL, or *Boediang Island*, is about 2 miles in extent, and a peaked hill near its centre bears W. by S. $\frac{1}{4}$ S., 4 miles from the East Domino.

GREAT DOMINO, or *Kongka Island*, is larger than Domino Hill, from which it bears N.W. $\frac{1}{2}$ N. $3\frac{1}{2}$ miles. It is said to be moderately elevated, and the chart shows a peaked hill on its western side.

Crocodile Rock, about 15 ft. above water, and visible 5 miles off, lies N.E. $\frac{3}{4}$ N. 4 miles off a conspicuous conical hill on the N.E. part of Great Domino.

Brisbane Rock.—The barque *Brisbane*, under the command of Captain Robert Hudleston, grounded on this danger in May, 1876. On examination the rock was found to extend a mile in a S.E. and N.W. direction, with depths of 2 to $2\frac{3}{4}$ fathoms, coarse gray sand. From it, Crocodile Rock bears S.E. by E. $\frac{1}{2}$ E. $2\frac{1}{2}$ miles, and the small island off the North end of Kongka, S.W. $\frac{1}{2}$ W. The rock is steep-to, with depths of 6 and 7 fathoms around it.

Reef.—Captain Hudleston also found a very dangerous reef of coral and sand, awash at low water, with Crocodile Rock bearing E. by N., and Small Island at North end of Kongka Island, S.W. $\frac{3}{4}$ W., by compass. The reef

lies in a N.N.W. and S.S.E. direction, about three-quarters of a mile in length, and one-third of a cable in breadth.

KINTAR ISLAND—Three other islands, with one or two contiguous islets, extend from $4\frac{1}{2}$ to 8 miles in a north-westerly direction from the Great Domino. The large island next northward of Great Domino, named Kintar, has on its southern end a fine bluff, and when coming from the northward, before the contiguous islands to the southward are visible, it much resembles the hill on the East end of Linga.

A rock lies N.W. by W. $\frac{1}{2}$ W., distant 2 miles from Pulo Kapas, which is a small islet surrounded by a reef, and the north-westernmost of the group extending from Kintar.

Fly Bank is a small patch of 2 fathoms, lying N.N.W. $\frac{3}{4}$ W. $10\frac{1}{2}$ miles from Crocodile Rock, with the high bluff of Kintar bearing South a little westerly, distant $7\frac{3}{4}$ miles, and Pulo Kapas W.S.W. $5\frac{1}{2}$ miles; close to it are depths of 9 to 13 fathoms.

Pollux Rock lies N.W. about 4 miles from Fly Bank, with the high bluff of Kintar bearing S. by E. $\frac{1}{4}$ E. 11 miles, and Pulo Kapas S.S.W. $5\frac{1}{2}$ miles; close to it are depths of 10 and 11 fathoms.

RODONG PEAK.—North-westward of Linga Island are many small islands. The most conspicuous of them is *Pulo Rodong*, or *Merodong*, which has a high conical peak, 724 ft. above the sea, the only hill of this feature in the vicinity. This peak is one of the principal objects which will enable a stranger to make out the entrance to Rhio Strait. It may, however, occasionally be useful to vessels working to or from Singapore by the Outer Route.

The Entrance to Rhio Strait between these islands and Pulo Gin to the N.N.E. of them is 23 miles wide. The space between is free from danger. S.S.E. 16 miles from Pulo Gin is the southern part of a bank carrying 7 and 9 fathoms water. It is 17 miles in length, N.N.E. and S.S.W., with its eastern side steep-to, and at its northern end Pulo Ruig bears N.N.W. $\frac{1}{4}$ W., which bearing clears also the Geldria and Frederick Reefs. In the N.E. monsoon much rain and thick weather are experienced, and this bank is a good guide to clear these reefs, and will save anchoring in deep water.

FREDERICK REEF, in lat. $0^{\circ} 37' N.$, long. $105^{\circ} 9' E.$, is awash at low water springs. It consists of two rocks about a cable's length apart, near the middle of a coral bank 3 cables in length North and South, and nearly 2 cables in breadth, having 20 to 22 fathoms all around, except at the N.E. side, where irregular soundings from 10 to 13 fathoms extend half a mile from it. From the centre of the reef Pulo Ruig, or Ragged Island, bears N.W. $\frac{2}{3}$ N. 22 miles, and Pulo Borean W.N.W. $21\frac{2}{3}$ miles.

In the vicinity of this reef in light winds the discolouration of the water is the only guide, and in fresh breezes it is difficult to distinguish breakers from the swell. Breakers on the reef can only be distinguished when the

tide is setting against the wind with a comparatively smooth sea. Off Bintang Island, at the change of the monsoon in April, the flood tide runs for 18 hours, and the ebb 6 hours. In June the tides are reversed, consequently a tide against the wind will only take place a few hours each day.

As this most dangerous reef lies in the direct track of vessels, the utmost care is necessary to avoid it. A vessel will clear it to the eastward by not going into less than 25 fathoms, and to the westward by keeping Gin Peak (a conspicuous hill, 337 ft. high), Gunong Kwas (857 ft. high on Bintang), and Pulo Borean well in sight, until the latter bears W. by N. The high peak of Linga Island, S.S.W. $\frac{1}{2}$ W., or Pulo Ruig bearing from N.N.W. to N.W. by N., will also lead clear.

From a close examination by Mr. Stanton, in H.M.S. *Saracen*, soundings having been taken in every direction to the extent of 7 miles eastward, and from 4 miles southward of the reef to the Geldria Bank, he was led to believe that the other reefs which were said to exist near are identical with it, and that the Frederick Reef is the only danger in this vicinity.

EAST COAST of BINTANG.—Numerous islands and dangers lie off the southern part of the East coast of Bintang, among which no vessel should venture. Vessels making passages between Banka and Singapore Straits should pass outside or to the eastward of the whole of these islands and dangers; and it is, therefore, only necessary here to notice the outermost of them. The whole coast and the islands off it are, as a rule, fringed with coral.

PULO GIN, or *Great Island*, about 4 or 5 miles in extent, lies about 3 miles south-eastward of the S.E. extreme of Bintang. Although appearing as but one island, it is really made up of three small islands separated from each other by narrow channels, which together form the largest Island off this part of Bintang. There are several hills on it from 200 to 300 ft. high, and one, named *Gin Peak*, rising about the centre of the south-eastern portion of the island, is 337 ft. high.

Pulo Terobi, the most southern of a cluster of small islets lying to the eastward of Pulo Gin, is 112 ft. high, and bears E. by S. $2\frac{1}{3}$ miles from the S.E. extreme of Gin. *Pulo Borean*, or *Saddle Island*, is one of the outer islands lying 3 or 4 miles to the eastward of Pulo Gin, inside the Geldria Banks, and bears from Pulo Terobi, N. by E. $\frac{3}{4}$ E. 5 miles. Being saddle-shaped, it is conspicuous and easily recognised.

Pulo Ruig, or *Ragged Island*, appropriately named from the irregular appearance of the trees on its summit, is the outer and easternmost island off the East coast of Bintang. It is about the same size and height, 315 ft., as Pulo Borean, and is steep-to at 3 cables' lengths off.

Geldria Bank is the outermost of a dangerous group of shoals lying 13 or 14 miles eastward of Pulo Gin, well out in the fairway of vessels proceeding between Banka and Singapore Straits, especially such as pass inside Frede-

rick Reef. Its North extreme is in lat. $0^{\circ} 48' N.$, long. $104^{\circ} 58' E.$, from which it extends S.W. by S. about 2 miles, having 2 to 4 fathoms water over it, 19 to 20 fathoms nearly close to the eastern side, and 8 to 12 fathoms, irregular depths, near the S.W. and West sides.

Raleigh Shoal lies W. by S. $\frac{1}{4}$ S. 3 miles from the south-eastern extreme of the Geldria. It has only 2 fathoms water over a coral bottom, from which Pulo Borean bears W. by N. $\frac{1}{2}$ N. 5 miles, and Pulo Ruig N. by E. 11 miles.

A *shoal patch*, with only 2 fathoms water over it, coral and sand, lies S.W. by W. $\frac{1}{2}$ W. nearly 6 miles from the South extreme of the Geldria. It is nearly a mile in length and half a mile in breadth, and from its centre Pulo Borean bears N.W. $\frac{1}{2}$ N., distant $4\frac{1}{2}$ miles.

There are several other knolls, with 4 and 5 fathoms over them, between this patch and the Geldria, of which they are considered to be a continuation; they should be avoided by vessels of heavy draught.

Pulo Terobi, the southern islet off Pulo Gin, bearing W. $\frac{1}{4}$ S., clears the southern extreme of the above shoals; and the Boat Rocks in line with Pulo Borean W. by S. $\frac{3}{4}$ S., or Pulo Ruig N.N.W. $\frac{1}{4}$ W., clears the northern extreme. No good marks can be given to clear the eastern side, which is steep-to, but the high peak of Linga bearing S.S.W. $\frac{1}{2}$ W., is a broad and distant clearing mark, and leads over the large sand-bank, carrying 7 to 10 fathoms, south-eastward of Pulo Gin.

Boat Rocks, lying about $2\frac{1}{2}$ miles N.W. $\frac{1}{2}$ N. from the North end of the Geldria Bank, are three low rocks, visible about 4 miles from a ship's deck.

A *rocky patch*, with 3 fathoms water over it, lies between the northern extreme of the Geldria Bank and the Boat Rocks, the latter bearing N.W. by W. distant 1 mile. A *coral bank*, with 3 to 5 fathoms over it, and about 1 mile in extent, lies W.S.W., $5\frac{1}{4}$ miles from Pulo Ruig. Pulo Borean, or Saddle Island, bearing S.S.W., clears its eastern side.

PULO PANJANG, which in the Malay language signifies Long Island, lies about 9 miles off the East coast of Bintang. It is a large irregular-shaped island, about 5 miles in extent. Rocks extend off its S.E. point, the outer ones of which, named *Bare Rocks*, are 55 ft. high.

On the N.E. side of the island the coral reef is absent, leaving a small sandy bay, where vessels may anchor in 8 or 9 fathoms, about three-quarters of a mile off shore. Wood and water may be procured in this bay, and boats can approach close to the beach at all hours of the tide.

Pulo Ruig, 315 ft. high, lies $3\frac{1}{2}$ miles E. by S. $\frac{1}{4}$ S. from Bare Rocks. It is nearly a mile long in a N.W. and S.E. direction.

Passage Rock, 55 ft. high, lies about three-quarters of a mile to the northward of the N.E. point of Panjang.

Pulo Suto, *Middle Rock*, *Black Rock*, and *Pulo Blanhap*, lying North and N.W. of Pulo Panjang, form a sort of chain, stretching from outside the

dangers off the North coast of that island to the shore of Bintang, and to the southward of which no vessel, except under extraordinary circumstances, should attempt to pass.

North-east Coast of Bintang.—From Tanjong Blanhap to Tanjong Brakit, 8 miles to the N.N.W. $\frac{1}{4}$ W., the N.E. coast of Bintang forms a bay about 2 miles deep, indented with several small bights or coves. Over a point about a mile N.W. of Tanjong Blanhap is a conspicuous tree, the top of which is 252 ft. above the sea; 2 miles W.N.W. of the tree is a hill, 420 ft. high. Three-quarters of a mile northward of this hill, close to the coast line on the deepest part of the large bay, is another, named *Double Tree Hill*, 334 feet high. Two or three small streams of fresh water appear to discharge themselves near the middle of this bay.

Tides.—It is high water, full and change, at Horsburgh Lighthouse, Singapore Strait, at 10^h 10^m p.m.; at Tanjong Brakit, the N.E. point of Bintang, at 11^h 0^m; at Pulo Suto, at 3^h 40^m; at Pulo Panjang, at 4^h 20^m; at Pulo Borean, at 6^h 0^m; and at Pulo Terobi, at 1^h 0^m p.m. The rise is 9 ft., but on extraordinary occasions it is 12 ft.

During the shifting months of the monsoons the tidal streams are regular, but during their strength the surface current will be always more or less governed by the wind.

The flood tidal wave comes from the northward, and runs nearly parallel to the East coast of Bintang, along its southern side towards Abang Strait, and to the northward of Rhio Strait, meeting another tide from Singapore Strait near the town of Rhio.

The flood sets to the southward along the East coast of Linga, and close to Tanjong Eung, its south-eastern extreme; from thence it runs West to Ponoebo Strait, and obliquely across Linga Bay to Varella Strait. From Tanjong Eung to Pulo Taya, and onwards to Banka Strait, its direction is nearly South. Another stream from about 2 miles South of Taya sets towards Varella Strait.

The ebb stream sets in the opposite direction, and the meeting of this stream from Banka and Varella Straits was observed to take place near the supposed position of Smith Bank.

ISLANDS, ETC., BETWEEN BORNEO AND SINGAPORE STRAIT.

PULO DATU, the peak of which, 1,042 feet high, is in lat. 0° 10' N., long. 108° 35' 50" E., is an oblong-shaped island, 1½ mile in extent N.E. and S.W., and three-quarters of a mile broad. It is a conspicuous object when approached from the southward, and is visible from the anchorage in Pontianak and Mampawa Roads. Close to the island are depths of 6 to 14

fathoms; to the westward the soundings are 16 to 19 fathoms, but 29 and 30 fathoms a mile to the eastward of it.

DIRECTION ISLAND, or *Pulo Panecky Ketchil*, in lat. $0^{\circ} 14' 39''$ N., long. $108^{\circ} 1' 53''$ E., is of conical form in the centre, and has a small hill on its North end. The island is 639 ft. high, and visible in clear weather at 30 or 33 miles off.

A small island lies nearly half a mile off the S.E. extreme of Direction Island, and in the channel between are depths of 10 to 17 fathoms.

ST. BARBE ISLAND, or *Pandjangkang*, is high, of triangular form, about 3 miles long, and when first seen appears like two or three islands, being lower at the centre than at the N.E. and West parts. The highest hill on its N.E. end is 762 ft. high, and in lat. $0^{\circ} 8' 6''$ N., long. $107^{\circ} 13\frac{1}{2}'$ E. The hill on the South end is 684 ft. high.

The South point of the island is cliffy and bold, but a reef fills up the first bay on its East side. The West side of the island is divided into two small bays. Off the N.W. point of the island are two or three small rocks a few feet above water, and a reef projects about a quarter of a mile from the point to the northward of it. A small rock above water lies near the middle of the large bay on the North side of the island, and a third of a mile North of this rock is another sometimes awash, with 10 and 17 fathoms close to it. A small rock above water also lies close to the East side of the North point of the island.

Water, wood, &c., may be procured in a bay on the East side of the N.W. point of St. Barbe, and also near the S.E. point. As the shore is fronted by a reef, boats can only land at high tide, at which time fresh water may be rafted off. Water may also be obtained from the bay at the North point of the island, abreast of which is the best anchorage in the southerly monsoon. Wood may also be procured upon the island, and turtle sometimes found upon its sandy beaches.

Welstead Rock was discovered in 1825 by Captain G. Welstead, commanding the ship *General Harris*, which grazed over it. This officer took great pains to ascertain its exact position, which is lat. $0^{\circ} 32'$ N., long. $107^{\circ} 53'$ E.

The shoal extends half a mile in an E.N.E. and W.S.W. direction, its breadth being about a cable's length. It consists of a number of pinnacle rocks, with varying depths of 7 to 3 fathoms; clore around it are 17 to 23 fathoms.

Ebeling Shoal.—Captain Ebeling, commanding the Chilian ship *Mercedeo*, in 1863, reported having sounded in $4\frac{1}{2}$ fathoms upon a coral shoal, and whilst the lead was being hauled in, the vessel passed over one side of a patch upon which there appeared to be as little as 16 or 18 ft. water. The bearings given were:—St. Barbe Island, S. 28° W., middle of St. Esprit group,

N. 79° W. ; Pulo Gigang, or Jarrang (Tambelan group), N. 14° E., which places the shoal in lat. $0^{\circ} 31'$ N., long. $107^{\circ} 26'$ E.

The *St. Esprit Group* (or *Watas Islands*) consists of 13 or 14 small high islands and islets, extending about 12 or 13 miles in a W.N.W. and opposite direction, between the parallels of $0^{\circ} 31'$ and $0^{\circ} 39'$ N., and the meridians of $106^{\circ} 58'$ and $107^{\circ} 11'$ E. ; between the islands are deep and generally clear channels.

S.E. Island, 145 ft. high, in lat. $0^{\circ} 30\frac{3}{4}'$ N., long. $107^{\circ} 8\frac{1}{2}'$ E., is a mere islet, a quarter of a mile in extent, and connected by a reef to a low white rock, which lies a quarter of a mile northward of it.

S.W. Island, 305 ft. high, in lat. $0^{\circ} 33\frac{1}{4}'$ N., long. $106^{\circ} 58\frac{1}{4}'$ E., is a mere islet, bold-to ; close to the southward of it are soundings of 30 to 34 fathoms.

Howqua Shoal is a doubtful danger, said to lie 4 miles S. $\frac{2}{3}$ W. from S.W. Island.

Brace Islands comprise two small islets, about three-quarters of a mile apart, and a third islet, about twice their size, and 572 ft. high, a mile to the N.W. of them. The easternmost island, which is also the easternmost of the group, is in lat. $0^{\circ} 33\frac{3}{4}'$ N., long. $107^{\circ} 10\frac{3}{4}'$ E. A 3-fathom patch, with 7 and 8 fathoms around it, lies about half a mile W.S.W. from the northernmost and largest of the *Brace Islands*.

Head Island, 372 ft. high, lies near the centre of the group, W.N.W. 2 miles from *Round Island*, about a mile in extent. The channels on either side of *Head Island* appear to be clear of danger, and to have depths of 35 to 45 fathoms water in them ; but with the N.E. extreme of *Head Island* bearing S.S.W. $\frac{1}{2}$ W., distant a mile, and the apex of the northern *Brace Island* S.E. by E. $\frac{1}{4}$ E., a little over 4 miles, is the *Royalist Rock*, close to which are depths of 38 and 40 fathoms.

Centre Island is the name of a small round islet, 169 ft. high, lying W. by N. $\frac{1}{2}$ N. $2\frac{3}{4}$ miles from *Head Island*, and about two-thirds of a mile from the S.E. extreme of the largest island of the *St. Esprit* group.

The largest island of the *St. Esprit* group (which is not named upon the charts) is also the northernmost one. It is $1\frac{3}{4}$ mile long North and South, and three-quarters of a mile broad, and the hill on its southern end, 825 ft. high, is in lat. $0^{\circ} 37' 51''$ N., long. $107^{\circ} 0' 50''$ E.

Bush Island, the westernmost island of the group, lies about W.S.W. 2 miles from the largest island. Its apex, 393 feet high, bears nearly North of S.W. Island ; the two islands are a little over $2\frac{1}{2}$ miles apart. An islet, 120 feet high, named *Clump*, lies about half a mile northward of its North point.

Discoloured water has been observed at 20 miles westward of *Bush Island*.

GREEN ISLAND is small, square-shaped, about a third of a mile in extent, covered with trees, and has a white sandy beach. It lies in a direct line between the easternmost of the *St. Esprit* group and the *Tambelan*

Islands, and is surrounded to a short distance by a reef, near to which are from 17 to 32 fathoms; its centre is in lat. $0^{\circ} 44' 43''$ N., long. $107^{\circ} 18' 52''$ E.

Rodger Rock, upon which the ship *Ellen*, Capt. Alexander Rodger, struck in 1845, is of very small extent, and is about 100 yards square; but at low water springs there is but 3 ft. water on it. Its position is lat. $0^{\circ} 41' 15''$ N., long. $107^{\circ} 31' 12''$ E., and from it Tambelan Peak is seen over the right summit of Pulo Gigang, or Jarrang, and bears N. $\frac{1}{4}$ E.; Green Island, W. by N. $\frac{1}{4}$ N., $12\frac{2}{3}$ miles; the eastern extreme of the Tambelan group, N. by E.; and the western extreme N.N.W. $\frac{1}{2}$ W.

This is an exceedingly dangerous rock, for there are regular soundings of 19 to 22 fathoms close to and for miles around it. The *Rifleman* was steaming in its vicinity for four days before it was discovered; it was ultimately found by the weather tide causing a slight ripple.

There is little doubt but this is the rock seen by Mr. Robert Loney, Paymaster, R.N., when in command of the *Rose Ellis*, and marked by that name in the Admiralty charts. The rock is so far from the islands that the least error in bearing would cause the discrepancy in the positions given by Captains Rodger and Loney.

White Rock, about 80 ft. high, lies E. by S., 5 miles from the South end of Pulo Gigang, or Jarrang, the southernmost island of the Tambelan group, and on its S.W. side are two small pinnacle rocks, about 12 ft. above high water.

TAMBELAN ISLANDS lie about 27 miles to the north-eastward of the St. Esprit group, between the parallels of $0^{\circ} 52'$ and $1^{\circ} 7'$ N., and the meridians of $107^{\circ} 21'$ and $107^{\circ} 35\frac{1}{2}'$ E. They comprise a considerable number of islands, and form two groups or chains, each extending N.W. and S.E. about 13 or 14 miles, and were surveyed by Commander Ward, R.N., in H.M.S. *Rifleman*.

South-Western Group.—*Pulo Gigang Besar* (or *Jarrang*), the most south-eastern island of this group, is $1\frac{3}{4}$ mile long North and South, two-thirds of a mile broad, and is bordered to a short distance by a reef. It is a high island, rising to a peaked hill in the centre, and having a lower one near each extreme. *Gigang Ketchil*, an island about a quarter the size of *Gigang Besar*, lies a mile westward of it, and is also fronted by a reef, which, off its North end, projects nearly a quarter of a mile.

A coral shoal, of 3 fathoms (probably the *Constance Shoal*), was found lying off the S.W. end of *Gigang Ketchil*, being separated from that island by a narrow channel of 17 to 22 fathoms water. From its shoalest patch of 3 fathoms water, which is on the western extreme of the shoal, the S.W. end of the island bears E. by S. $\frac{1}{2}$ S., 9 cables' lengths.

Several other shoal patches and dangers were found near the Tambelan Islands, but they lie quite out of the ordinary track of vessels.

Three miles N.W. of the *Gigang* Islands is a group of small islands, the

north-eastern of which, *Harbour Island*, or *Pulo Smot*, limits the narrowest part of the channel between the two main groups of the Tambelan Islands. Two-thirds of a mile westward of it is a much larger island, *Pulo Bedua*, which has four hills upon it, rising N.E. and S.W. of each other, the highest hill, 408 feet, being near its West end. The channel between the Gigang Islands and the Bedua group is free from danger, with soundings of 16 to 23 fathoms.

Bunoa, by far the largest island of the south-western group, is nearly 4 miles long N.W. and S.E., and $2\frac{1}{2}$ miles broad. Its highest part, near its N.E. end, is elevated 915 ft., and there are several other undulating hills upon it, from 300 to 700 ft. high. The North shore of the island forms a bay, in which vessels may anchor in 10 to 16 fathoms, and find excellent shelter in the S.W. monsoon. Close to the East side of Bunoa are two smaller islands, *Selindang* and *Gilla*; *Selindang* is a remarkable cone-shaped island, rising to an elevation of 681 ft.; *Gilla* is about a third of the height of *Selindang*.

The group of ten islands extending nearly 5 miles to the north-westward of Bunoa, are all tolerably elevated, and *Mundaga*, the outermost of them, is 697 ft. high. The channels between them are deep and generally free from danger, but that between Bunoa and *Ebul* (the island next to the north-westward of Bunoa) cannot be recommended as being perfectly safe. A reef extends some distance from the North and N.E. part of *Ebul*, which renders the channels between that island and *Tamban** and *Pening* Islands dangerously narrow. A rock awash lies about a third of a mile from the S.W. extreme of *Leso*, the island lying close to the western part of Bunoa; elsewhere these islands appear free from danger, and may be approached to a half or a third of a mile with safety.

North-Eastern Group.—TAMBELAN, or Great Tambelan, the largest island of the Tambelan group, is of somewhat triangular shape, nearly $4\frac{1}{2}$ miles in extent N.W. and S.E., and about the same N.E. and S.W. Upon its N.E. coast are several hills, the highest of which, *Tambelan Peak*, in lat. $1^{\circ} 1' 5''$ N., long. $107^{\circ} 32' 22''$ E., rises to an elevation of 1,300 ft. *Low Peak*, 643 ft. high, is on the N.W. end of the island; and a short distance to the eastward of *Tambelan Peak* is *Thumb Peak*, a remarkable sloping hill 953 ft. high. *East Peak*, a sharp cone 950 ft. high, rises near the eastern extreme of the island.

Tambelan Island is nearly divided into two parts by a creek, which runs in a north-easterly direction into its western side. The creek is nearly a mile wide, but fringed with reefs and encumbered with several rocks. A breakwater, composed of coral, crosses its upper part, about $1\frac{1}{2}$ mile within the

* The principal observatory station of the *Riflemen's* survey was upon the North point of *Pulo Tamban*, which was found to be in lat. $1^{\circ} 9' 27''$ N., long. $107^{\circ} 24' 10''$ E.

entrance, leaving but a narrow boat channel, through which the tide rushes with great force. Behind the breakwater is a stockade, and a fort stands upon the shore near the West end of the breakwater. The whole of these works have been constructed to defend the village, which is about half a mile beyond the breakwater on the western bank of the creek, from the attacks of the Llanun pirates, who occasionally visit these islands, and carry off into slavery any of the natives they can lay their hands upon.

A reef extends from the East point of Tambelan Island, and upon its edge, half a mile southward of the point, is a rock above water. The N.E. coast is almost free from reefs. A reef, with a rock awash on its extreme, extends about one-third of a mile from the S.W. point of the island, and then trends away, fronting the coast, into Tambelan Creek.

Pulo Bungin, 253 ft. high, is a small island lying $1\frac{1}{4}$ mile westward of the N.W. point of Tambelan. *Sedua Besar*, 860 ft. high, and *Sedua Ketchil*, 650 feet high, are two islands which extend from $1\frac{1}{2}$ to $3\frac{1}{2}$ miles north-westward of Tambelan Island, separated from each other by a very narrow, deep channel; both islands are bold close-to.

Sendulang Besar and *Sendulang Ketchil*, lying 3 miles north-westward of the Sedua Islands, are two small, round-shaped islands, surrounded to a short distance by reefs, and separated by a very narrow channel. *Sendulang Besar*, the western and larger island, rises to a sharp cone 749 ft. high; the smaller island is only 309 ft. high.

Pulo Way, the north-westernmost island of the Tambelan group, is about 2 miles in extent, and rises to several peaked hills, the highest of which, near its eastern end, is elevated 1,057 ft.

Anchorage.—There is good anchorage anywhere between the two groups of the Tambelan Islands, which form an extensive basin or harbour; the depths being generally 17 to 20 fathoms, and the bottom of mud and sand; here and there are places where the soundings are a few fathoms more or less. In the N.E. monsoon a vessel may anchor in the entrance to Tambelan Creek, but she must go but a very little way inside the edges of the reef, on account of a pinnacle rock with 2 fathoms water over it, which lies S.S.E. nearly a quarter of a mile from Suicides Point, the North entrance point to the creek. This position would be unsafe in the S.W. monsoon; the best anchorage at that season being under Bunoa, in 14 to 18 fathoms if in the bay between Pulo Gilla and Bunoa, and in from 9 to 14 fathoms if in the bay on the North side of the latter island, which is the best anchorage.

Supplies.—Ships cannot depend upon procuring supplies at the Tambelan Islands. The officers of the *Rifleman* were only able to obtain a few fowls, and those few with great difficulty. There is a well of good water just to the northward of the mound on the South side of the entrance to Tambelan Creek, and another on the North side about 2 cables' lengths northward of Suicides Point. The village in the creek is inhabited by about 500 Malays,

and the other islands of the group are temporarily inhabited for the purpose of collecting cocoa-nuts. Goats are also bred upon these islands, but at the period of the *Rifleman's* visit none could be purchased.

EUROPE SHOAL is about a mile in extent N. by E. and S. by W., and the least water on it 3 fathoms, is about the middle of the shoal, in lat. $1^{\circ} 11' 19''$ N., long. $107^{\circ} 25' 27''$ E., the Rocky Islets bearing W. $\frac{1}{4}$ S. $12\frac{1}{2}$ miles; Gap Rock E. $\frac{3}{4}$ N. 9 miles; summit of Pulo Way S. by W. $\frac{1}{2}$ W. $5\frac{1}{2}$ miles; western extreme of the Tambelan Group S.S.W. $\frac{1}{4}$ W. $6\frac{1}{2}$ miles; and eastern extreme S.E. southerly $15\frac{1}{4}$ miles.

ROCKY ISLETS, lying N.W. by W. $\frac{1}{2}$ W., 12 miles from Pulo Way, are merely two barren rocks, the resort of sea birds. They are bold close-to, and occupy a space about 2 cables in extent. The northern and larger rock, 134 ft. high, is in lat. $1^{\circ} 11' 9''$ N., long. $107^{\circ} 13'$ E. Between them and the Tambelan Group the depths are 33 and 34 fathoms.

GAP ROCK, in lat. $1^{\circ} 12' 30''$ N., long. $107^{\circ} 34' 20''$ E., and distant $12\frac{1}{2}$ miles N. $\frac{1}{2}$ W. from the eastern extreme of the Tambelan Group, is very remarkable. It consists of two large boulders lying upon a flat rock, the larger of which is 124 ft. above the water. A shoal extends about 2 cables' lengths from its South side.

ST. JULIAN, in lat. $0^{\circ} 55' 40''$ N., long. $106^{\circ} 43' 30''$ E., is a remarkable island, being nearly a mile long E.S.E. and W.N.W., and 200 yards broad. It is low in the centre, rising to a hill 318 ft. high on the South end, and to another, 537 ft. high, on the North end, which latter forms an exceedingly bold cliff to seaward. There is deep water close-to on all sides.

CAMELS HUMP, in lat. $1^{\circ} 11' 46''$ N., long. $106^{\circ} 53'$ E., is about half a mile long, East and West, and a third of a mile broad. It is well named, the highest part of the island forming a sort of hump, elevated 574 ft. above the sea. No danger was discovered in its vicinity.

SADDLE ISLAND, in lat. $1^{\circ} 19' 21''$ N., long. $107^{\circ} 2' 17''$ E., is only half a mile long, and a quarter of a mile broad. This island is also well named; the hills forming the saddle are in line on a S. $\frac{3}{4}$ W. and opposite bearing, the higher one on the North side being 387 ft. high.

BARREN ISLAND is a whitish rock, 80 ft. high, and its summit (by the *Rifleman*) is in lat. $1^{\circ} 31' 50''$ N., long. $106^{\circ} 25' 35''$ E. It is justly denominated Barren, having not the slightest trace of vegetation, and is bold-to, with 10 fathoms close alongside. It appears to be the resort of varieties of sea-fowl, which, in the season of incubation, deposit great quantities of eggs, —the tern, kittiwake, and gulls occupying the summit, the booby, or gannet, the base. The Malay fishermen resort here for these eggs, and from the stores found *en cache* cannot be very particular as to their freshness. Of the eggs, those of the tern were not inferior to plover, and those of the gannet nearly equal to the duck, making very acceptable omelettes and puddings.—

On the N.W. side of Barren Island is a natural reservoir, containing about

10 gallons of water. It is asserted that it is used by the Malays possibly by previous cleansing of the reservoir. Landing is easy on the western side.

VICTORY ISLAND, in lat. $1^{\circ} 34' 46''$ N., long. $106^{\circ} 18' 40''$ E., is densely wooded, and rises to a hill in the centre, 285 ft. high.

HUGHES SHOAL.—The *Rifleman*, in April, 1863, searched for the Doubtful Reef, said "to have been seen in the brig *Bombay Merchant*, commanded by Mr. Hughes, in January, 1825, and was nearly in one with Victory Island, bearing N.E. 5 or 6 miles."

The *Rifleman* anchored on a shoal—the island bearing N.E. $\frac{3}{4}$ E., distant half a mile—in $3\frac{1}{2}$ fathoms, reduced to low water springs, which was the least water found. This shoal is of coral, one-third of a mile long, N.E. and S.W., and a quarter of a mile broad, its outer edge in 8 fathoms lying S.W. $\frac{1}{4}$ W. three-quarters of a mile from the island.

Acasta Rock, lying N. by W. 4 miles from Victory Island, is just under the surface of the water, and in calm weather presents exactly the appearance described in Horsburgh, "the central part of a very brown colour, declining to a pale green around." The least swell breaks on it.

ST. PIERRE ISLANDS are wooded, and appear to be connected by a reef. St. Pierre Rock, South, nearly $1\frac{3}{4}$ mile distant from the southern tree-covered island of St. Pierre, and in lat. $1^{\circ} 51' 44''$ N., long. $108^{\circ} 33' 57''$, ($4^{\circ} 47' 39''$ East of Fort Fullerton, Singapore), is about 30 yards in length, 20 yards in width. It is very steep-to, and is never less than 6 ft. above water, the dry surface being completely blackened. It is, indeed, formed of a close-grained, black basalt, and is not to be confounded with the coralline incrustations about it. Close around its margin are 14, 15, and 19 fathoms. The space between the islands and the rock is safe, having depths of 20 fathoms.

Tides.—The ebb tide between the St. Pierre Group and Tanjong Api sets to the southward. The current of flood, which prevailed during the examination of St. Pierre Rock, set to the N.E. The rise of tide did not exceed 4 ft.

General Remarks.—As the *Rifleman* was constantly shifting her position during the operations of the survey, no good opportunity offered for obtaining a series of tidal observations. Such as were procured were so irregular, that no general conclusion could be formed from them. It was observed, however, that during the S.W. monsoon (from the middle of July to the middle of September), and also during the N.E. monsoon (in the month of December), that the tides set to windward every day against the prevailing current, although they were uncertain as to commencement and time of duration.

The weather was very fine, and the winds generally light. Sailing vessels would frequently shorten their passages through this part of the China Sea, if they kept a kedge ready to let go during light airs and calms, and when

both current and tide would otherwise be setting them back over the ground they had with difficulty gained.

Directions from Singapore Strait to Tanjong Api in Borneo.—Quitting the Romania Islands and Shoals, where there are pretty regular tides, the current off shore will be found to run about N.N.W. in the S.W. monsoon, and having gained 50 miles easting, its greatest strength will be found setting between Pulo Timoan and the Anamba Islands.

In order to obviate the effect of this set or current, it is considered prudent to make good the course for Saddle Island, by which, should light airs prevail, the option will be afforded of steering clear of Victory or Barren Islands, and avoiding the Acasta Rock. This caution may appear as unnecessary, the distance between Barren and Camel Islands being 33 miles. But a very little consideration will satisfy the navigator that, upon the course shaped to counteract the current, running strong in the vicinity of these islands (to the north-eastward as near as could be determined by the lines of scum viewed from the summit of Barren Island), he would not, even with a fair wind, pass more than 10 miles to windward of Victory and Barren Islands. On leaving Barren Island, a course should be shaped to pass well to the southward of the St. Pierre Islands.

In the N.E. monsoon the current will generally be found setting about S.S.E., a few miles outside the entrance of Singapore Strait, taking a more south-easterly direction as the distance from the land is increased. For directions for leaving Singapore Strait during this monsoon, see page 56.

The soundings off St. Pierre Rock, and in the direct course for Tanjong Api, range between 20 and 15 fathoms, and approaching this headland the first cast under 15 fathoms at night should be deemed *the warning*. If in a sailing vessel, deep water to the northward must be sought for. By day, as the land is neared, the vessel's position may readily be determined by the relative position of the coast hillocks, with the mountain range behind, and if clear, the land of Tanjong Datu should be clearly made out before attempting to close, or communicate with, Tanjong Api.—*Sir Edw. Belcher*.

2.—RHIO STRAIT.

General Description.—The route outside Linga and through Rhio Strait, is the one now commonly adopted by vessels proceeding either way between Sunda Strait and Singapore, for the reason that Rhio Strait is “safe, sheltered, and easily navigable, the Dutch Government having placed beacons on many of the dangers; whereas the route outside Bintang is exposed in both monsoons, and the fairway encumbered with many rocks and shoals, which render it necessary for vessels to keep a great distance from the land.”

This route is particularly convenient for vessels leaving Singapore for

The Raffles Lighthouse on Cross Islet Area is a height from high tide 22.25 meters (72.8 feet) not visible from N.W. to W. nor north to E.S.E.

The Borahburg Lighthouse on Pulau Brava is a granite tower 35 feet high, and Area of lighted rock on hill at an elevation of 45 feet above the sea, visible every way at 4.5 miles (7.2)

STRAITS OF SINGAPORE, DURIAN, AND RHIO

Europe in the N.E. monsoon, and few navigators now adopt any other; as by proceeding through Rhio Strait, they avoid the delay and inconvenience frequently experienced during that season in getting to sea by the main channel of Singapore Strait, past Horsburgh lighthouse. In the S.W. monsoon, also, vessels are frequently able to proceed to the southward much quicker by Rhio Strait than by the route outside Bintang.

The following directions are taken from those drawn up by Lieutenant J. W. Reed, R.N., who together with Lieut. Tizard and the officers of H.M.S. *Rifleman*, surveyed the strait between the years 1865 and 1868.

Caution.—As the buoys in Rhio Strait have at times been reported out of position, too much reliance must not be placed on them.

WEST SIDE OF THE STRAIT.

MISSANA ISLAND, which with the opposite island of Talang forms the southern limit of the strait, is somewhat peculiar in shape, consisting of two narrow ranges of hills, moderately elevated, which running in different directions form an elbow; the longer range extends from the South point of the island $4\frac{1}{4}$ miles in a N. by W. $\frac{1}{2}$ W. direction, and the shorter range E. by S., 2 miles from the northern part.

Niamok, a small square-shaped island, lies $1\frac{1}{4}$ mile south-eastward of the South point of Missana, and between them is a rocky islet, and several dangers which block the channel. A small, thickly-wooded islet lies a quarter of a mile south-eastward of the East point of Missana, forming with the eastern side of that island and Niamok a bay, which appears to offer excellent anchorage; but it is treacherous, and must be entered with caution, for a reef extends nearly a mile in a north-easterly direction from Niamok, while the shore of Missana is fronted by a reef which projects in places nearly three-quarters of a mile, and just embraces the small islet off the East point. Vessels may, however, find safe and convenient anchorage anywhere in the bay, in from $5\frac{1}{2}$ to 8 fathoms, by avoiding to bring the eastern part of the small islet to the eastward of N.E. by E. $\frac{1}{2}$ E., and the eastern side of Niamok to the eastward of S. by E. $\frac{1}{4}$ E.; the South point of Missana bearing W. by S. clears the reef which projects from Niamok.

The shore reef extends but a short distance from the north-eastern part of Missana, but from the North shore it projects about half a mile, and a 2-fathoms patch lies some distance outside the edge of the reef, which makes it dangerous to approach that shore nearer than a mile. A mass of rocks above water lies 2 or 3 cables westward of Observation Point, the N.W. point of the island, westward and south-westward of which other dangers extend more than half a mile.

RODONG PEAK, 797 ft. high, bears S.W. by W. $4\frac{1}{2}$ miles from the N.W. point of Missana. Viewed from the southward, it presents a conical appearance, and being the only hill of this feature in the vicinity is very conspicuous. It is one of the principal objects which will enable a stranger to make out the entrance to Rhio Strait, for it can nearly at all times be seen over Missana as the strait is approached. The hill, from the peak, forms a shoulder to the north-westward, and then gradually slopes away in that direction, so that as Missana is passed the conical shape disappears.

BINAN ISLAND, lying W.N.W. $3\frac{1}{4}$ miles from Missana, is easily recognised by a conspicuous hill, 269 ft. high, at the S.E. end. A reef fronts the greater part of Binan, extending a quarter of a mile off the North part, and more than double that distance off the N.W. extreme.

Rifleman Shoal, a patch of hard sand 3 cables in extent, lies about a mile off the centre of Binan; the least water upon it is 2 fathoms, and from this spot the hill on the island bears S.W., and the N.W. extreme W. by N.

Katang Linga lies $1\frac{1}{4}$ mile N.W. by W. from Binan; it is a bold, bluff-looking island, 246 ft. high, nearly a mile long, and half a mile broad; a shore reef fronts the greater part of it, extending off in some places nearly $1\frac{1}{2}$ cable. A *shoal*, having but three-quarters of a fathom water over it, lies three-quarters of a mile W.S.W. from the North point of Katang Linga.

The straits and islands dividing them, which lie to the westward of Missana, Binan, Katang Linga, &c., are hereafter described.

Selanga Islands, three in number, are mere islets, but elevated and conspicuous; they lie to the north-westward of the Tetampan Group, the northern one bearing from the North end of Katang Linga W. by S., distant 3 miles. Vessels working should not stand within a line drawn between Katang Linga and the North Selanga, which will keep them clear of the shoal W.S.W. of the first named island, and of a reef, having a rock with a tree upon it, which lies between the Tetampan Group and the Selangas; and a 2-fathom patch lies 2 cables North of the North Selanga.

Oedek Island is small. It lies N.W. by W. $\frac{1}{4}$ W., $3\frac{1}{2}$ miles from the North Selanga, and E. by N. from the North end of the long island of Pangallap. This island, as well as the Selangas, lies quite out of the track of steamers, or of sailing vessels proceeding through Rhio Strait with a fair wind, but it may sometimes be found convenient when working through to stand so far to the westward, in which cases ships should not pass a line drawn between the North Selanga and Oedek, in order to avoid a rock awash which lies W. $\frac{1}{4}$ N., $1\frac{3}{4}$ mile from the former island.

PULO DUMPO or **RONDO**, 129 ft. high, lies N.W. $\frac{1}{2}$ W. $7\frac{1}{2}$ miles from Katang Linga, and about $1\frac{1}{2}$ mile south-eastward of the South end of Galang Island. It is a remarkable little island, showing very round and bold against the adjacent land, and is one of the most useful objects for recognising the entrance to the narrow part of the strait when coming from the

southward. A patch of 2 fathoms, named *Haai Shoal*, lies a quarter of a mile to the south-eastward of it; and there is a *rock above water* a good quarter of a mile to the north-westward.

Great Bank.—Galang terminates to the southward in a long narrow point. projecting in a S.S.E. $\frac{1}{2}$ E. direction, and half a mile to the eastward are three small islands lying in a line parallel to it; between the point and outer island is a coral patch with 2 fathoms water over it, and 7 to 9 fathoms round about. Between these islands and the large one of Selatan, about 3 miles north-eastward of them, is a deep bay fronted by a bank, named by the Dutch, Groote or Great Bank. This bank has $2\frac{1}{4}$ to 3 fathoms over it, $3\frac{1}{2}$ to 5 fathoms between it and the small islands, and 4 to 8 fathoms between it and Selatan. The anchorage in the bay inside the bank was formerly considered to be good, but large reefs and shoals extend, both from Galang and Selatan, which render it anything but a safe and convenient place for large vessels seeking a temporary anchorage to resort to.

East Bank lies N.N.E. $\frac{3}{4}$ E. $4\frac{3}{4}$ miles, from Pulo Rondo, its outer or northern part being a third of a mile S.E. $\frac{1}{2}$ E. of Tanjong Dempoe, the eastern point of the adjacent islands. It is a little more than half a mile in extent, with $\frac{3}{4}$ to $1\frac{1}{2}$ fathom water over it, and 10 to 12 fathoms near it.

Tjassens Shoal is an extensive bank, with $1\frac{1}{4}$ to 3 fathoms water over it, lying between Pulo Taron (the island close to the northward of Selatan) and the southern part of Great Garras Island; the S.E. extreme, which is nearly in the line between Dempoe Point and the East end of Great Garras, terminates in a reef which dries at half-tide. Former charts exhibited a clear channel on each side of Tjassens Shoal, but the northern one is very narrow at the western end, does not afford a greater depth than 3 fathoms, and is only available for small vessels; the southern channel is good, being nowhere less than three-quarters of a mile wide, with depths of 6 to 13 fathoms. Navigators using it, however, must be careful, when avoiding the shoal, to give a berth to a small patch of reef which lies a third of a mile off the N.E. part of Tarong, and after the West end of Great Garras is brought to bear N.E., that island must be approached in order to avoid the bank extending from the opposite shore, and upon which are some patches of reef; the northernmost of these patches has a small islet upon it, and lies N.W. a little over a mile from the West end of Great Garras.

LITTLE GARRAS ISLAND and **LIGHTHOUSE** marks the entrance of the narrow part of Rhio Strait. It is but a quarter of a mile long East and West, formed of two small hills, and encompassed by a narrow fringe of reef. On the eastern hill is the lighthouse, painted white, from which is exhibited a *fixed bright light*, elevated 114 ft. above the sea, and visible 8 miles. This light is very useful for guiding vessels into the narrow part of the strait by night, and leading them between Pankel and the Moebet Islands, and northward until Sau light comes in sight.

Ditloffs Reef, lying about three-quarters of a mile S. by E. from the eastern extreme of Little Garras, has from $4\frac{1}{2}$ to 10 fathoms water close to it; and between it and that island is a patch with 2 to 3 fathoms water over it.

GREAT GARRAS ISLAND is $3\frac{1}{4}$ miles long W. by N. and E. by S., and three-quarters of a mile broad; it has a flat summit, and terminates with abrupt points. A reef encircles it, and extends in places a quarter of a mile off. A *patch of reef* lies about a third of a mile from the N.W. point of the island, and from that point halfway along the North coast of the island, a bank, with but 2 to 3 fathoms water over it, projects nearly a mile, and for half a mile farther in the same direction the soundings are under 5 fathoms; large vessels should not, therefore, stand inside a line drawn between Little Garras and East Moebet Island.

Tarong Point, the N.E. extreme of Galand Island, bears N.N.W. $\frac{3}{4}$ W. $2\frac{1}{2}$ miles from the West end of Great Garras; it has on its northern side a small bay, in which is a native village. A reef fronts the point at a distance of a quarter of a mile, and outside of it a shoal bank rounds away to the small islet opposite Great Garras.

MOEBOET ISLANDS.—At 6 miles N.W. $\frac{1}{2}$ N. from Little Garras is the larger and higher of the two Moeboet Islands, readily distinguished by its prominent position, and the deep inlets to the westward and southward. It rises to a round peak, with the greatest declivity on the eastern side; whilst the smaller island, or West Moebet, is considerably lower towards its centre. Dangerous reefs and shoals extend from these islands $1\frac{1}{2}$ mile to the southward. The West end of Great Garras bearing S. by W. clears them to the eastward, and the extreme of Tarong Point in one with the extreme of a point a mile westward of it bearing W. by N. $\frac{1}{4}$ N., clears them to the southward. Shoals also extend more than a mile north-westward of East Moeboet. The North and East extremes of Sembolang Point in one bearing about N.W. is a close mark for the eastern side of them, and the South end of Pankel, bearing E. by S. $\frac{3}{4}$ S., clears them to the northward.

SEMBOLANG POINT, the eastern extreme of Rempang Island, is the next prominent object on the western side of the main channel after passing northward of the Moeboet Islands. It is fronted by a reef, close to which are 5 to 9 fathoms. From this point the land trends to the westward, increasing the width of the strait.

TIEMARA BANK lies N.W. $\frac{3}{4}$ N. $3\frac{1}{4}$ miles from Sembolang Point, and about $1\frac{1}{4}$ mile eastward of Tiemara Island; it is about half a mile in extent, with $1\frac{1}{4}$ fathom water over it, and 7 to 9 fathoms near it. A *black* buoy with *white* ring is moored on the eastern side of the bank, in 3 fathoms, with the N.E. point of Tiemara bearing N.W. by W., and the East point of Pulo Loban N.N.E. To avoid the bank, Sembolang Point should not be brought

East of S.S.E., nor the eastern extreme of Little Tiemara Island to the North of N.W.

TIEMARA ISLAND is elevated 341 ft., and when first seen appears like a bold point projecting from Rempang; it is surrounded at a short distance by a reef. *Little Tiemara Island*, lying about a mile N. by W. $\frac{1}{2}$ W. from the N.E. point of Tiemara Island, is about a third of a mile in extent, and surrounded by a reef which on the East side of the island projects a quarter of a mile; near the reef are 12 to 21 fathoms water. Between the Tiemara Islands are several reefs, which render the channel unnavigable.

At $2\frac{1}{2}$ miles N.W. from Little Tiemara is Antu Islet, off the North and East sides of which a reef extends for a quarter of a mile, and forms the southern side of the eastern entrance to Bulang Strait. To the eastward of a line joining Little Tiemara, and a little islet on the reef eastward of Antu Islet, there is a shoal which fills up the bay lying eastward of Pulo Kantylil and Ayer Radya.

Innang Reef bears from Little Tiemara Island N.N.W. $\frac{1}{4}$ W. distant nearly 3 miles. It is marked by a *white* buoy with *black* ring in $5\frac{1}{4}$ fathoms, on its eastern point, with the South point of Pulo Loban bearing E. by S. $\frac{1}{4}$ S., Sau light N. $\frac{1}{2}$ W., and the South point of Pulo Innang W. $\frac{1}{2}$ S. Near it are depths of 10 fathoms, and southward and south-westward of it is a small bank of $4\frac{1}{2}$ and 5 fathoms.

INNANG ISLAND, $1\frac{1}{2}$ mile northward of Ajer Radja, forms the northern side of the entrance to Bulang Strait. A reef fronts the island to the distance of a third of a mile. Sau lighthouse, if not brought to the northward of N. by W. $\frac{1}{2}$ W., will keep a vessel clear of Innang Reef and the tongue of rocks and sand extending from Sau.

SAU ISLAND and **LIGHTHOUSE**.—Sau Island is larger than Innang, and lies to the northward of it. Inside these two islands are several small islands, with channels between them into Bulang Strait. A detached rocky patch lies S.S.E., a quarter of a mile from the eastern point of Sau. The lighthouse, painted *white*, is erected on the East point of Sau Island, from it a *fixed bright light* is exhibited at an elevation of 118 ft., visible 8 miles off.

Little Innang Island and **Van Gogh's Shoal**.—Little Innang is a small island lying off the N.E. part of Sau, opposite West Point, Bintang, from which it is distant nearly 2 miles; it is encompassed by the reef which runs in a northerly direction from the East point of Sau.

Dangerous shoals extend for $2\frac{1}{2}$ miles to N.N.W. from Little Innang Island; and *Van Gogh's Islet*, N.W. by W. $\frac{1}{2}$ W. from the East point of Little Innang, is situated on a coral reef. The East point of Sau in line with the East point of Little Innang clears all these dangers to the eastward, and Malang Yarong (an islet on the opposite coast) bearing E. $\frac{1}{4}$ S. clears them to the northward. The soundings decrease rather quickly under a depth of 10 fathoms near the dangers just described, and in the event of a vessel

standing towards the southernmost of them getting a cast of 10 fathoms or less, she should tack immediately.

Malang Orang Reef.—The N.E. coast of Battam, from abreast Sau Island to *Nongsa* or *Boerong Point*, which forms the western point of the North entrance to Rhio Strait, is fronted by a reef, extending in some places to the distance of three-quarters of a mile from it. The Malang Orang Reef lies nearly three-quarters of a mile from the Battam shore, and about E.S.E. from Malang Orang Point. It is nearly half a mile in extent North and South, with 5 to 8 fathoms near it. It is marked by a *black* buoy with *white* ring on its eastern edge, in 9 fathoms, with Pan beacon bearing N.E. $\frac{1}{4}$ E.

PAN REEF, lying nearly in the middle of the northern entrance of Rhio Strait, is extensive and rocky, and visible at low water, when it appears as a long ridge of black stones. It is half a mile long N.E. $\frac{3}{4}$ N. and S.W. $\frac{3}{4}$ S., and 2 cables broad; and close to it are depths of 5 to 7 fathoms, except at the S.W. end, where it is not so steep. A large *screw pile beacon* is placed near the N.E. end of the shoal, and a *black* buoy with *white* ring, in 8 fathoms, on the S.W. point of the reef, with Sau light bearing South, and Pan beacon N.E. The other edges of the shoal are sometimes marked by small basket beacons, but they are not to be depended upon. There is a safe passage on either side of the shoal, but the native pilots, who generally conduct vessels through Rhio Strait, seldom use the eastern channel, where the depths are inconvenient for bringing up in case of bad weather.

Barbukit kept North, or N. $\frac{1}{4}$ W., leads eastward of the Great Pan, and Johore Hill bearing about N. by W. $\frac{3}{4}$ W. leads westward; but Sau lighthouse in line with the East extreme of Little Innang, bearing S. $\frac{1}{2}$ E., is a good leading mark for passing between the Pan Shoals; and the lighthouse bearing S. $\frac{3}{4}$ W. leads to the eastward of the Great Pan. In passing eastward of the shoal, when Tanjong Nongsa (Boerong Point), the northern extreme of Battam, bears W. by N., or when Pulo Nongsa is just shut in behind Tanjong Nongsa, a vessel will be to the northward of it, and has entered the Strait of Singapore.

Riondo Shoal, said to lie about N.W. $\frac{1}{2}$ W., distant $1\frac{1}{2}$ mile from the Pan Shoal, does not exist; the locality has been thoroughly examined.

LITTLE PAN REEF lies N.W. $\frac{1}{2}$ N., $2\frac{1}{4}$ miles from the Pan Reef. It is a small oval-shaped coral patch, with depths of $3\frac{1}{2}$ to 7 fathoms close around it. It is marked by a *black* buoy with *white* ring, in 3 fathoms, at its northern extremity, with Pan Reef beacon bearing S.E. by E., and Boerong Point W. by N. Pulo Nangsa just open of Nongsa Point leads just clear to the northward; and Sau Point open of the land southward of Malang Orang Point leads close to the eastward.

EAST SIDE OF THE STRAIT.

Talang, or Long Island, may be known by a square hillock over its S.E. end, 350 ft. high, which, with a sharper peak westward of it, forms a saddle; the land from this to the western end of the island is nearly of the same elevation.

Gin, or Great Island, lies 2 miles to the eastward of the northern part of Talang, and forms one of the objects which serve to mark the entrance of Rhio Strait.

Hendrik Jan Rock, on which a Dutch ship of that name struck in February, 1861, is a dangerous pinnacle, nearly awash at low water, and steep-to, having 9 and 10 fathoms close around it. It lies S.E. three-quarters of a mile from the south-eastern point of Talang, with the summit of South-west Hill just shut in by the south-western extreme of Talang.

This rock is of small size, and there was great difficulty in finding it. Several other shoal patches were found in the channel between Talang and Gin; but they all, except the *Hendrik Jan*, lie out of the ordinary track of ships, and are dangerous only in the event of this channel being mistaken in thick weather for the entrance of Rhio. Vessels should give these islands a berth of 2 miles in passing, and not bring Terobi Island eastward of E. $\frac{3}{4}$ N., until South-west Hill is well open of Talang.

SIOLON, or MANTANG ISLAND, 7 miles long, E. by N. and W. by S., and $2\frac{1}{2}$ miles broad, but divided by a narrow channel, lies to the north-westward of Talang, and is separated from it by a channel about $1\frac{1}{4}$ miles wide. On its S.W. end is South-west hill, 267 ft. high, which, when seen from the southward, appears as a double-peaked hill, terminating to the westward in a point, which forms the S.W. extreme of the island; but when viewed from the northward it makes with a peaked top. Four miles eastward of South-west Hill is *Siolon Hill*, 507 ft. high, being the highest hill on Siolon. At a distance of 12 miles to the southward both Siolon and South-west Hills appear as islands, owing to the land between them being low.

The South shore of Siolon Island, between South-west and Siolon Hills, forms a bay about a mile deep, and is fronted by a fringe of reef and a shoal bank, extending out in places nearly three-quarters of a mile. Upon this bank lie two or three detached patches of reef. *Thomas Shoal*, a patch 4 cables in extent, with 2 to 3 fathoms water over it, lies W.S.W. from Segai Islet, distant nearly a mile. There is anchorage under the southern shore of Siolon, between South-west Hill and *Thomas Shoal*, $3\frac{3}{4}$ miles eastward of it, in from 10 to 6 fathoms, with shelter from northerly winds.

There are channels on either side of Siolon which will lead out into the China Sea, northward of Pulo Gin; but as they are quite out of the ordi-

nary track of vessels, they should not be attempted by any one not locally acquainted. The tides in the channels run with great strength, and there are numerous overfalls.

Alligator Island, $1\frac{1}{2}$ mile W.N.W. from the western end of Siolon; seen from the westward, shows as three round lumps, but when approached from the northward, it appears to slope gradually from its northern end, which is 101 ft. high. There is no passage between Alligator Island and Siolon.

Alligator Reef, lying nearly a mile North of Alligator Island, is a quarter of a mile in extent. It is marked by a *white* buoy with *black* ring on its N.W. edge, in 4 fathoms, with West point of Alligator Island bearing S. $\frac{1}{2}$ E.; Topie Island, South point, W. by S. $\frac{1}{2}$ S.; and Blading Island N. by E.

Blading Island, lying $1\frac{1}{4}$ mile to the northward of Alligator Reef, is small and surrounded by a reef which extends in a southerly direction more than a quarter of a mile. Eastward of Alligator Reef and Blading Island are several other reefs and islands, lying off the northern shore of Siolon.

Prins Reef, about a third of a mile in extent, $1\frac{1}{2}$ mile N. by W. from Blading, lies on the outer edge of the shoal bank which fronts Batu Babie Point.

The Topies are a cluster of small round islets and rocks lying about 2 miles westward of Alligator Reef. Topie in the Malay language signifies hat, and when approached from the southward these islets, as they rise above the horizon, certainly present very much the appearance of the round, inverted, basin-shaped topies, or hats, in use among the Malays. The northern and eastern islands are the largest of the group; the former is 134 feet, and the latter 118 feet high. When approaching the eastern island from the northward, it appears of a crown shape, and in clear weather may be seen 10 miles off.

A *rock* lies close off the N.E. end of the eastern island; and a *bank* half a mile long, with $2\frac{3}{4}$ fathoms water over it, lies with its outer edge bearing S.E. by S., distant three-quarters of a mile from the same island.

Rotterdam Reef is a rocky patch, with only $1\frac{1}{2}$ fathom water over it, lying W.S.W. a little more than half a mile from the northern of the Topies group. It is marked by a *white* buoy with *black* ring, in $2\frac{3}{4}$ fathoms, on its West side, with South point of Pankel bearing N.W. by W. $\frac{1}{4}$ W., and Topie Island centre E. by N. $\frac{1}{4}$ N.

There is another reef, with but little water over it, lying N. by W. $\frac{1}{2}$ W., nearly half a mile from the Western Topie; its northern end is marked by a *beacon*. Near these dangers are 6 and 4 fathoms.

Dutch Shoal, a quarter of a mile in extent, with 3 fathoms water over it, and 6 or 7 fathoms close to the western side of it, lies with Little Garras lighthouse bearing S. $\frac{3}{4}$ W., $3\frac{1}{4}$ miles; the northern island of the Topies group E. by S. $\frac{3}{4}$ S., $3\frac{1}{2}$ miles; and the S.W. extreme of Pankel N.W. $\frac{1}{4}$ W.,

1½ mile. The northern Topie bearing E. by S. ½ S., and the S.W. extreme of Pankel N.W. ½ N., will lead a quarter of a mile S.W. of this danger.

This shoal is on the western edge of a bank, with 3 to 5 fathoms water on it, which lies about a mile off the S.E. end of Pankel, and extends 3½ miles farther in that direction from the island. A good mark to keep clear of the entire western edge is the apex of Loban Island in line with the western extreme of Pankel. Between the bank and Pankel the depths are 6 to 10 fathoms.

PANKEL ISLAND, 2 miles long North and South, and half a mile broad, bounds the eastern side of the main channel of Rhio Strait, abreast of Great Garras and the Moeboet Islands; it is belted by a reef which extends from a quarter to half a mile from it. Outside the shore reef at the N.W. part of the island, a bank with less than 3 fathoms water over it, projects to a distance of three-quarters of a mile from the shore. Eastward of this bank, and half a mile northward of the North point of the island, lies Pankel Reef, a patch of rocks about a quarter of a mile in diameter. Pankel, at a distance, makes as two distinct round hills; on a nearer approach a sandy beach will be seen at its South end, from which rocks and fishing stakes extend nearly three-quarters of a mile.

Rupels Reef, about a mile to the eastward of Pankel, has a *black* buoy with *white* ring on its East side, in 5 fathoms, with East point of Soré bearing N. by E.; Pankel, N.W. point, N.W. ½ W.; and Pankel, S.E. point, S.W. by W.

Sore Island, lying E. by N. ¾ N. nearly 1½ mile from the North end of Pankel, is a small, round island, covered with cocoa-nut trees, and surrounded by a reef. A shoal bank, with less than 3 fathoms water on it, extends three-quarters of a mile to the south-eastward, the tail, with 3¼ to 5 fathoms water, stretching nearly a mile farther in the same direction. N.N.W. from the island the shore reef extends more than half a mile, and half a mile farther in the same direction lies a detached reef, nearly a third of a mile in diameter; in the channel between are 5 to 8 fathoms. Nearly a mile from this last, in a N.W. ¾ N. direction, lies the S.E. end of the largest of the Soré Reefs; it is a narrow strip of sand and coral, a little more than 1½ mile long N.W. ½ W. and S.E. ½ E., and marked by a *white* buoy with *black* ring on its N.W. end in 2½ fathoms, with Pitjingit bearing E. by N. ½ N., and Terkolei light N. by W. ¾ W.

The channel, limited on one side by Rupels Reef, Pankel Island and Pankel Reef, and on the other by Soré Island and the reefs and banks adjacent to it, is perfectly free from danger, with depths of 9 to 14 fathoms.

Dompa is an irregularly shaped island; its western extreme, named Dompa Point, bears N.E. by E. 2 miles from Soré, and N. by W. 6 miles from the northern island of the Topies. Two small islands, surrounded by

reefs, lie off the South shore of Dompá. On the outer edge of the reef extending from Dompá Point is a *white* buoy with *black* ring, in 3 fathoms, with Dompá Point bearing N.N.E. $\frac{1}{2}$ E., West end of Basing Island S.E. $\frac{1}{4}$ E., and the end of Soré Island W.S.W.

The channel between the edge of the bank extending from the S.W. side of Dompá, and Soré Island and Reefs, is about 1 mile wide, and is generally used by vessels bound to Rhio from the southward; the depths in it vary from 8 to 19 fathoms.

RHIO ISLAND is about $4\frac{1}{2}$ miles in length East and West, and $2\frac{1}{4}$ miles wide, and, being separated from the manland of Bintang by a very narrow channel, appears to form part of it. The town, which stands on the N.W. point of the island, was formerly a port of much trade; and although its importance has for many years declined, it is still a place of considerable traffic for small vessels. There is a well-built fort on a hill commanding the town.

Tanjong Pinang, N.E. $\frac{3}{4}$ N. $2\frac{1}{2}$ miles from Tanjong Dompá, is distinguished by a *beacon*, consisting of a white square pyramid, 16 ft. high, N. by W. $2\frac{1}{2}$ cables from it.

The usual anchorage is in 3 or 4 fathoms, about 2 miles northward of the West end of Dompá, sheltered from the northward by the island of Pitjingit. The soundings decrease gradually to 4 and $3\frac{1}{2}$ fathoms, but shoal suddenly under a depth of 3 fathoms. It is high water, full and change, at 9^h 50^m; springs rise 7 ft., neaps 5 ft.

Pakko is a small islet lying about half a mile off the western shore of Rhio Island, and N.W. by W. $\frac{1}{2}$ W. three-quarters of a mile from Pinang beacon, in the middle of a rocky bank about half a mile in extent. There is a narrow channel between the bank and the western shore of Rhio, having $1\frac{1}{2}$ to 2 fathoms water in it, and which is marked on the western, or rocky bank side, by three beacons.

Pitjingit, or Mars Island, lies half a mile westward of the N.W. point of Rhio, opposite the town. The island is about a mile long East and West, a third of a mile broad, is surrounded by a reef, which projects from its southern and western sides about a quarter of a mile. *Sengarang Island* projects some 3 miles to the north-westward of Rhio, forming a roadstead or anchorage between it and Pitjingit. Vessels usually enter by the narrow channel between the Pakko Reef and the West shore of Rhio. *Loz, or Loos*, is a small island lying close to the West end of Sengarang, inside the margin of the reef which extends from that island.

Terkolei Island and Lighthouse.—Terkolei Island, lying W.N.W. 4 miles from Pitjingit, is a low, flat island, about half a mile in extent, with a clump of trees on its East end; it is surrounded by a reef, which extends nearly half a mile eastward and a quarter of a mile westward and southward from it. A lighthouse is erected upon its West end, painted white, and exhibit-

ing. from an elevation of 31 feet, a *fixed bright light*, which is visible 6 miles.

Terkolei Island is situated near the middle of a *dangerous shoal bank*, composed of hard sand and mud, $7\frac{1}{2}$ miles long, E.S.E. and W.N.W. nearly, the eastern part of which extends to within half a mile of the reef surrounding Pitjingit. Half a mile South of the island a *black buoy with white ring* is moored on the edge of the shoal, in $2\frac{1}{2}$ fathoms, with Pitjingit bearing E. by S., and Terkolei North. The reef is here steep-to, and S.E. by E. $\frac{1}{2}$ E. $1\frac{1}{2}$ mile from the island is a *beacon*, on the southern edge of a 2-fathom shoal; the 3 fathoms edge of the bank is nearly half a mile southward of this beacon. Pitjingit bearing East clears the S.E. tail, and the apex of Loban bearing N.W. by W. $\frac{3}{4}$ W. will lead clear to the southward of Terkolei and the western part of the bank.

ISABELLA SHOAL lies three-quarters of a mile southward of Loban; it is nearly three-quarters of a mile long East and West, 2 cables broad, and has from 1 to $2\frac{3}{4}$ fathoms water over it. A tail, with $3\frac{1}{2}$ to $4\frac{1}{2}$ fathoms on it, stretches from its eastern extreme nearly a mile in an E.S.E. direction. The 1-fathom patch is near the centre of the shoal. A *white buoy with black ring* is moored in 3 fathoms on the western extreme of the shoal, with the East point of Pulo Loban bearing N.N.E. $\frac{1}{2}$ E., Terkolei light East, and South point of Little Loban N.W.; and a *black buoy with white ring* in 3 fathoms, on the eastern extremity, 3 cables E. $\frac{3}{4}$ S. from the West buoy.

The depths at a short distance from the South side of this danger are 6 to 10 fathoms, but its western edge is very steep, there being 14 fathoms close to it. Terkolei lighthouse, bearing E. $\frac{1}{2}$ N. clears the shoal to the southward, and Sau lighthouse, in one with the West end of Little Loban, leads well clear to the westward.

LOBAN ISLANDS, lying about half a mile off the S.W. part of Bintang, form a group of four or five small islands, separated by channels so narrow that they appear as one island. They may be recognized by the gradual rise the largest island takes from its North end, to a round hummock in the centre, which with Little Loban (the islet off its West end) present to vessels approaching them from the westward, the appearance of three distinct hills. A *reef*, about a quarter of a mile broad, surrounds the group. A small detached patch lies a third of a mile South of the S.W. point of Great Loban. The depths close to the reef fronting the western side of the Loban group are 11 to 20 fathoms. A *2-fathom patch* lies outside the shore reef on the N.W. part of Loban, the western edge of which bears N.N.E. $\frac{1}{4}$ E., three-quarters of a mile from the small islet off the West end of Little Loban.

Dessa is a small islet, conspicuous from having only one tree upon it, bearing N. $\frac{1}{2}$ W. about $1\frac{3}{4}$ mile from the West end of Little Loban, and S. by W. $\frac{1}{2}$ W. about half a mile from Batu Point, the nearest point of Bintang; it is on the southern point of a small shoal three-quarters of a mile in extent. Two patches of reef, together nearly a mile long E.S.E. and

W.N.W., lie with their western extreme about a third of a mile southward of Dessa, and between these and the 2-fathom patch off Loban is a channel not quite half a mile broad, with $3\frac{1}{2}$ to 9 fathoms in it. A *rocky patch* lies off the N.W. side of Dessa, the outer part being distant a third of a mile from it. Little Loban bearing S.S.E. leads westward of all these shoals, as will also West point, Bintang, if not brought westward of N. $\frac{1}{4}$ W. Close to these dangers the soundings are deep, 12 to 23 fathoms.

BATU POINT is $2\frac{1}{4}$ miles northward of Little Loban, the pitch of the point being about half a mile N.E. of the reef lying off the N.W. side of Dessa. At Batu Point the land recedes abruptly to the eastward.

Dua Island, about three-quarters of a mile long N.N.W. and S.S.E., fronts the bay between Batu and West points; a round lump which rises in its centre is lower than the adjacent land. There is a remarkable white rock near its West side. The island is bordered by a reef, and a small detached patch lies nearly a quarter of a mile south-westward of its South point, and a rock awash about the same distance to the south-eastward. This last, narrows the channel between the island and shore to $1\frac{1}{2}$ cable, but the water in it is deep, 7 to 12 fathoms; behind the island the depths are various, $4\frac{1}{2}$ to 11 fathoms, and 3 cables northward of the reef fringing the North part of Dua, and 2 cables from the Bintang shore, is a 3-fathom patch, leaving a patch more than a quarter of a mile broad, with $1\frac{1}{2}$ fathom water in it.

WEST POINT, bearing N. by W. $\frac{1}{2}$ W. $2\frac{1}{2}$ miles from Batu Point, is bold-to on the South and West parts, but on the North part a reef begins to extend from the shore, and trends away from the point in a northerly direction, passing outside by Senggera Islet. West Point is moderately elevated land, presenting a round shelving appearance, and from it the coast line trends to the north-eastward, forming the eastern side of the North entrance of Rhio Strait.

The *Senggera* are a ledge of flat rocks, lying about a quarter of a mile off shore, $1\frac{1}{4}$ mile N. $\frac{1}{2}$ E. from West Point. Detached rocks on the shore reef will be seen nearly as far as West Point.

Malang Yarong is a small islet, covered with trees, lying half a mile North from Senggera Rocks, on the edge of the reef fronting the shore, which here extends more than a third of a mile off.

Pulo Kera, or *Skerrie*, is a small island lying N.E. $\frac{1}{4}$ N. 2 miles from Malang Yarong, and close off Kalumpung Point; it is of an oblong form, about 80 feet high, and will be recognized by the coast near it receding to the E.N.E., in the direction of the Subong River. The reef which fronts the coast from West Point follows the trendings of the coast, and passes a quarter of a mile outside Kera, and then trends to the eastward, fronting the southern coast of the large bight between Kera and Subong Point.

A *shoal bank*, with less than a fathom water over it in one place, and $1\frac{1}{2}$ to 3 fathoms elsewhere, fronts the shore reef above mentioned; the 3-fathom

line which marks its edge takes from Malong Yarong Island a N.N.E. direction for about a mile, where it trends a point more to the eastward and passes about half a mile outside Pulo Kera; from thence it trends away with an irregular outline to Tanjong Subong, passing just outside the Pap and a group of rocks E.N.E. from it. This bank between Malang Yarong and Kera is steep-to under a depth of 8 fathoms, and must be carefully avoided.

Netscher Shoal, the outer part of which lies half a mile outside the shoal bank just described, is very dangerous, for there is less than a fathom water on its N.W. extreme, and less than 3 fathoms everywhere else. It is a somewhat circular shaped shoal, about half a mile in extent, composed of hard sand and coral, and from the outer edge Pulo Kera bears S. by W., distant $1\frac{1}{2}$ mile, and the extreme of Tanjong Subong N.E. by E. $\frac{1}{2}$ E., $4\frac{1}{4}$ miles. Close to the western side of this danger are 10 and 6 fathoms, and the lead cannot be depended upon to give warning in time to avoid it.

SUBONG BAY, the deep bight between Pulo Kera and Subong Point, is nearly filled up with reefs, and is best understood from the chart.

Crocodile Shoal is a small patch of hard sand with 3 fathoms water over it, and is the outermost of the dangers off this part of Bintang. It lies N.E. $\frac{1}{4}$ N. $2\frac{1}{2}$ miles from Netscher Shoal; N.N.E. $\frac{3}{4}$ E. $3\frac{3}{4}$ miles from Pulo Kera; and W. $\frac{1}{2}$ S. $2\frac{1}{2}$ miles from Subong Point. Close to the West and N.W. sides of this shoal are 6 to 8 fathoms, and $4\frac{1}{2}$ fathoms a quarter of a mile from it on the N.E. side. Kera Island bearing S.S.W., leads nearly half a mile westward of the Crocodile; and Pulo Nongsa bearing West, or the islet off Subong E. $\frac{1}{2}$ S., leads half a mile to the northward. Barbukit Hill, N. by W. $\frac{1}{4}$ W., will also lead to the westward.

Sau Lighthouse bearing S.S.W. $\frac{1}{2}$ W., clears the shoal bank N.N.E. of Malang Yarong, as also the Netscher and Crocodile Shoals; it is a good guide for strangers when working near this rather dangerous coast.

SUBONG POINT is the N.W. extreme of Bintang and the north-eastern limit of Rhio Strait. It bears from Kera Island N.E. $\frac{1}{2}$ E. $5\frac{1}{4}$ miles, the coast between forming a deep bight, at the head of which is the entrance of the Subong River. A small islet lies off the pitch of the point, and S.W. by W. a third of a mile from the islet is a sunken rock. Some islets also lie close to the coast S.S.E. from the point.

Tides.—The flood tidal wave in the China Sea comes from the northward, and, being divided by the island of Bintang, sweeps round its shores, and flows into Rhio Strait at both ends, the stream from Singapore Strait meeting that from the southward in the space between Tiemara Island and Rhio. The main body of the southern stream takes a general westerly direction for Dumpo Strait, much of it diverging to the southward through the channels dividing the several groups of islands lying between Missana and Dumpo, and a portion turning off to the N.W., in the direction of Garras;

this last is joined by the streams flowing through the Siolon and adjacent channels, which gradually trend away to the north-westward after they enter the strait.

The monsoons and currents of the China Sea very much affect the regularity of the tides, which are strong, and at the springs rush with great velocity through the channels among the islands, forming numerous eddies, and stirring up the mud. In the narrow part of the strait, about West point, this is particularly the case, the tide running from 3 to 4 knots, and sometimes even $4\frac{1}{2}$ and 5 knots.

DIRECTIONS *through Rhio Strait to Singapore.*—Directions to proceed from Banka Strait outside Linga Island are given at page 54. A vessel intending to proceed through Rhio Strait, and having brought Tanjong Eung (the eastern extreme of Linga Island) to bear S.S.W. $\frac{1}{2}$ W., and Great Domino West, should steer about N.W. $\frac{1}{3}$ N., which, if care be taken to guard against the effects of the tide, will take her to the fairway at the entrance of Rhio Strait, with Pulo Gin—which will be first seen on the starboard hand—bearing about N.E. $\frac{1}{2}$ E., and Rodong Peak about S.S.W. $\frac{3}{4}$ W. In this track, if the course is preserved, the vessel will pass 7 or 8 miles outside Crocodile Rock, and 5 or 6 outside the Fly and Pollux Shoals.

Rondo, the small round island on the West side of the strait, and the peak of Rodong (page 314), the only hill of this feature in the vicinity, with South-west Hill on Siolon (page 319), Talang Island, and the extreme land to the eastward (Pulo Gin, with a flat peak near its centre) will, at a distance of 14 miles, readily show the approach to the narrow part of the strait, while nearer the Topies, Alligator, and other islands, cannot fail to point out the main channel.

Having brought the South end of Pulo Gin abeam, a N.W. $\frac{1}{2}$ W. course will lead to the entrance of the narrow part of the strait, and Table Hill, which is flat on the summit, and stands on the southern part of Galang Island, should be seen a little on the port bow. In entering, borrow towards the islets near Galang, to preserve the deepest water and to avoid the Topies, which latter have shoals extending 1 or 2 miles to the S.S.E., and 1 mile from their western sides.

Having arrived abreast of Little Garras, distant about a mile, a N.W. $\frac{1}{2}$ N. course will lead through the fairway of the channel till the Loban Islands are abeam, a distance of 16 miles. With Little Loban bearing East, distant a mile, a N. by W. course for 7 miles will take the vessel past West Point Bintang, which will bear about S.E.; a N. by E. or N. by E. $\frac{1}{2}$ E. course will then lead midway between the Pan Reef and the dangers off the N.W. coast of Bintang into Singapore Strait.

The mark for passing eastward of the Pan Reef is to bring Barbukit Hill N. $\frac{1}{4}$ W. or North, but not to the eastward of North, and to steer that course until Johore Hill bears N.N.W. $\frac{1}{2}$ W., which will lead north-eastward of both

Pan Reefs. A vessel will be clear of the Little Pan when Pulo Nongsa opens of Nongsa Point, and when the passage between the islands and the point comes open, she may steer N.W. and W.N.W. as necessary for Singapore Road. If the tide is setting to the westward, a sailing ship should be careful, especially in light or contrary winds, to get well over on the northern side of Singapore Strait, otherwise she may be carried by the strong current to the westward of St. Johns, and unable either to fetch into Singapore Road, or, from the great depth of water, to anchor.

The soundings do not give sufficient warning to keep a vessel clear of the Crocodile Rock, but in the event of meeting with baffling or contrary winds or tides, and getting over towards this danger, Domino Hill (the island lying between the Great Domino and Tanjong Eung) should not be brought to the southward of S. $\frac{1}{2}$ W., until the islet off the N.W. end of Great Domino bears S.W. $\frac{1}{2}$ W. The Fly Bank and the Pollux Rock must not be approached to a less depth than 13 or 12 fathoms.

At night, or in thick weather, a vessel, after having brought Tanjong Eung to bear S.S.W. $\frac{1}{2}$ W., and Domino Hill East, should make a N.N.W. $\frac{1}{2}$ W. course for about 23 miles, and then N.W. $\frac{1}{2}$ W. about 28 miles, which courses, if proper allowance has been made for the tide, will keep her 10 or 11 miles eastward of the Fly and Pollux Shoals, and place her in the fairway at the entrance of Rhio Strait, with Pulo Gin on the starboard beam.

Formerly difficulty was often experienced by strangers in making out the entrance to Rhio Strait, from the imperfect manner in which the islands between Missana and Dumpo were laid down on the charts; since, however, these have been correctly delineated, seamen making the strait for the first time will readily recognise any of the islands. The high conical peak of Rodong, the most conspicuous object in approaching the strait, should be made out as soon as possible.

Now that the channel between the two Pan Reefs is known to be clear (the survey of the *Rifleman* having proved that the reputed Riondo Shoal does not exist), no difficulty will be experienced in passing between them, as they are well marked by the beacon and buoy on the Great Pan, and a buoy on the Little Pan; it is only necessary to pass at a reasonable distance from these marks.

To work through Rhio Strait from the Southward.—It seldom happens that a vessel will have to work along near the islands from Missana to Dumpo. It is generally found advantageous to stand to the northward in case of meeting with a north-westerly wind, but it may occasionally happen that a vessel will derive advantage by standing towards them; in which case, when nearing the North side of Missana, in order to avoid the dangers which extend about three-quarters of a mile from that shore, the apex of Binan must not be brought northward of W. by N. To avoid the Rifleman Shoal, which lies about $1\frac{1}{2}$ mile eastward of the N.E.

point of Binan, the eastern extreme of Missana must not be brought East of S.E. $\frac{1}{2}$ E., or the northern extreme of Katang Linga North of W. by N. $\frac{1}{2}$ N. This last also clears the $3\frac{1}{2}$ -fathom patch off the North part of Binan. The East side of Katang Linga may be approached to the distance of half a mile, and the northern part of the island to within a quarter of a mile. The Selangs Islands and Oedik may be approached to within a moderate distance, but care must be taken not to stand within a line drawn from the North extreme of Katang Linga to the North Selanga, or within another drawn from the last-named island to Oedik, for reasons stated in the description of those localities.

In standing to the westward towards the South end of Galang Island, a vessel may approach the Great Bank (page 315) to 9 or 8 fathoms; but between the Great Bank and East Bank should tack at the first cast under 10 fathoms, as a 3-fathom bank projects far out from the island between Selatan and Dempo, and the soundings decrease suddenly towards it. To avoid this bank and also East Bank, the S.E. extreme of Selatan Island should not be brought South of W. by S., until Dempoe Point, the eastern extreme of the group, is West of N.W. by W. Rondo Island bearing S.W. $\frac{1}{2}$ S. also leads outside of East Bank and all other dangers between that island and Dempo Point, and is a safe turning mark.

Between Dempo Point and Little Garras a vessel may stand into 8 or 7 fathoms; but, to avoid Ditloff's Reef, the eastern point of Galang (which projects into the bay) must not be brought South of W. $\frac{1}{2}$ S. until Little Garras lighthouse bears westward of N.W. Little Garras should not be approached nearer than a quarter of a mile, nor Great Garras than half a mile, to avoid their reefs. The soundings near the former are deep, 11 to 22 fathoms, but 8 or 9 fathoms will be found half a mile from the reef of Great Garras.

Between Great Garras and East Moeboet Island a vessel may stand into 8 or 7 fathoms, but a good tacking mark appears to be to keep Little Garras well open of Great Garras; and, if this be attended to, it will keep the vessel clear to the eastward of the banks which extend about $1\frac{1}{2}$ mile southward from Moeboet.

After passing Moeboet, its eastern extreme must not be brought eastward of S. by E., until the southern extreme of Sembolang Point bears W. by S. $\frac{1}{2}$ S., when the vessel will be clear of the bank which extends N.W. of Moeboet; from thence to Sembolang Point she may stand into 8 or 7 fathoms. E. by N. $\frac{1}{2}$ N. $1\frac{1}{2}$ mile from Sembolang Point is a patch of coral, with $5\frac{1}{2}$ fathoms water over it, and 6 to 8 fathoms near it; but half a mile nearer the point there is a run of deeper water, 11 or 12 fathoms, and close to the reef fronting Sembolang Point are 7 and 9 fathoms.

Sembolang Point is fronted by a reef, but the pitch of the point may be passed at a quarter of a mile. The bay between that point and the Tiemara

Bank is free from danger, and a vessel may stand into it as convenient, but be careful not to bring the S.W. extreme of Tiemara Island West of W. $\frac{1}{2}$ N., nor the N.E. extreme of Little Tiemara North of N.W., in order to avoid the Tiemara Bank, over which there is as little as $1\frac{1}{4}$ fathom water.

Little Tiemara should not be approached nearer than half a mile, on account of dangers which extend nearly that distance from it, and close to which are 12 to 21 fathoms, so that the lead cannot be relied upon to give warning in sufficient time. After passing this island, its N.E. extreme kept to the southward of S.S.E. $\frac{1}{4}$ E., will serve as a good tacking mark as far as the buoy on the Innang Shoal, leading outside the Johannes Bank, and clear of all danger.

To avoid the dangerous reef which extends nearly half a mile from Innang Island, the N.E. point of Little Innang must be opened of the eastern extreme of Sau Island (with the lighthouse upon it) after passing the Innang Shoal buoy; and, if this be attended to, a vessel will keep outside all danger as far as the eastern extreme of Sau, which latter should not be approached nearer than half a mile on account of the small reef off it.

After passing Little Innang, in standing to the westward, do not shut in the eastern extreme of Sau Island behind Little Innang; this will lead safely along that side of the channel as far as the buoy on the Malang Orang Shoal, in about 10 to 15 fathoms water. If this buoy should have disappeared, the eastern extreme of Little Innang, if not brought East of S. by E., will lead clear of that danger.

Sau Point, if not brought South of S.W. $\frac{1}{2}$ W., will lead clear of the south-eastern edge of the Pan Shoal; and when passing to the eastward of that danger, care must be observed not to bring Barbukit Hill to the eastward of North, until Johore Hill bears N.N.W. $\frac{1}{2}$ W.; and then not to bring the last-named hill to the northward of N.N.W. $\frac{1}{2}$ W. until Pulo Nongsa is open of Nongsa Point.

In working between the Pan Reefs, after having passed the buoy on the Malang Orang, care must still be taken not to bring the eastern extreme of Little Innang East of S. by E., or to stand inside a line drawn from Malang Orang buoy to the buoy of the Little Pan, in order to avoid the dangerous shore reef which extends from Battam nearly three-quarters of a mile.

In standing to the eastward towards Talang Island, at the southern entrance of Rhio Strait, be careful to give the south-eastern shore of that island a berth of 2 miles, and to keep South-west Hill, on Siolon Island, well open to the westward of Talang, to avoid the Hendrik Jan Rock, which is awash at low water. The S.W. point of Siolon and Alligator Island may be approached to half a mile. When nearing the Topies, South-west Hill kept well open of the southern point of Alligator Island, will lead southward of all danger on that side of the group; and, in order to keep to the westward of Rotter-

dam Reef, the south-western extreme of Pankel must not be brought to the westward of N.W. $\frac{1}{2}$ W.

To clear the shoal water, 4 to 5 fathoms, which extends nearly $2\frac{1}{2}$ miles southward of the Topies, Siolon Hill must be kept open of South-west Hill, which will lead South of it, and the apex of Loban open of the West extreme of Pankel clears it to the westward, as also the Dutch Shoal and shoal bank of soundings south-eastward of Pankel.

It is not advisable to stand over between the Topies and Pankel, on account of the Rotterdam Reef; the reef which lies N. by W. $\frac{1}{2}$ W. nearly half a mile from the northern island of the Topies Group; and the Dutch Shoal of 3 fathoms lying S.E. $\frac{1}{4}$ E. nearly $1\frac{1}{2}$ mile from Pulo Pankel.

The Dutch Shoal, S.E. of Pankel, will be avoided by keeping the S.W. extreme of Pankel to the northward of N.W. $\frac{1}{2}$ N.; and the northern Topie Island, if not brought South of E. by S. $\frac{1}{2}$ S., will lead to the southward.

The S.W. end of Pankel should not be approached nearer than half a mile on account of the shore reef, close to which are 13 fathoms water; the West side may be neared to 7 or 8 fathoms, but the northern end should not be approached within a mile on account of the shoal water extending N.N.W. from it; this shoal water may be avoided by keeping Little Garras lighthouse open of the S.W. extreme of Pankel.

Between Pankel and the Isabella Bank, a vessel may stand well over in depths of 8 or 9 fathoms; but not to bring the North end of Pankel to the southward of S.S.E. $\frac{1}{4}$ E., or Turkolei lighthouse to the westward of N. by W., to avoid the Soré Reefs. Turkolei lighthouse bearing E. $\frac{1}{2}$ N. clears the Isabella Shoal to the southward; and Sau lighthouse in line with the West end of Little Loban leads well clear to the westward.

Little Loban should not be approached nearer than half a mile; and, after passing it, the western extreme should not be brought South of S. by E. $\frac{3}{4}$ E., until Batu Point bears East, which will avoid the dangers near Dessa Island. Batu Point is bold close-to; and both it and Dua Island may be approached to a quarter of a mile, but not nearer the latter, on account of the reef which fronts it, and near to which are 8 and 10 fathoms. West Point of Bintang is bold, and may be approached to a quarter of a mile, but a reef begins at this point which, extending outside Malang Orang and Kera Islands, fronts the whole of the N.W. coast of Bintang. Malang Yarong may be approached to a quarter of a mile, but Kera Island not nearer than three-quarters of a mile. Very close to the edge of the bank which fronts this part of the coast are 7 and 8 fathoms.

After passing Malang Yarong great care must be taken when standing in for the Bintang shore to avoid the dangerous bank which curves away from that island and extends half a mile outside Pulo Kera, and very close to which are 12 or 13 fathoms water; Sau lighthouse bearing S.S.W. $\frac{1}{2}$ W. will lead well clear of this bank, as also of the Netscher and Crocodile Shoals,

If Sau lighthouse cannot be made out after Pulo Kera bears southward of East, Malang Jarong Island—which will be seen well clear of the extreme of the land as Netscher Shoal is neared—must not be brought West of S. by W. $\frac{3}{4}$ W. until the screw pile beacon on the North end of the Pan Reef bears W. $\frac{1}{2}$ N. ; a vessel will then be to the northward of Netscher Shoal, and Pulo Kera may be brought S.S.W. but nothing to the westward, until Subong Point bears S.E. by E., by which means a vessel will avoid all the dangers off the N.W. coast of Bintang, including the Crocodile Shoal.

Through Rhio Strait from Singapore.—The ebb tide from Singapore meets the flood setting through Rhio Strait in the vicinity of the Pan Reefs; vessels, therefore, weighing at high water from Singapore will carry a fair tide through both straits.

The flagstaff on Fort Canning, Singapore, bearing West, leads 2 miles southward of the Johore Shoals; and when Johore Hill bears North, a vessel will be eastward of the shoals. Entering Rhio Strait, pass between the Little Pan buoy and the screw pile beacon on Great Pan; or, pass eastward of the Pan Reefs, and, in doing so, be careful not to bring Johore Hill to the northward of N.N.W. $\frac{1}{2}$ W. until Barbukit Hill bears North.

After passing the Pan Reefs, a course from S. $\frac{1}{2}$ W. to S. by W. $\frac{1}{2}$ W. will lead down the fairway of the strait until the vessel has arrived nearly abreast of the West point of Bintang, when S. by E. is the mid-channel course as far as the Loban Island. From thence a course about S.E. $\frac{1}{2}$ S., making allowance for tide, will lead midway between Pankel and Moeboet, also between the Garras Islands and the Topies, and out of the strait.

To work through Rhio Strait from the Northward.—In working between the Pan Reefs, the screw pile beacon on the North and the buoy at the South end of the Great Pan will point out the situation of that danger; but when standing towards the Battam shore, in order to avoid the dangerous reef extending three-quarters of a mile from the land, care must be taken not to stand inside a line drawn from Malang Orang buoy to the buoy of the Little Pan, nor to bring the eastern extreme of Little Innang East of S. by E. If proceeding by the eastern channel, in rounding the Pan Reefs, take care not to shut Pulo Nongsa behind Nongsa Point, until Johore Hill bears N.N.W. $\frac{1}{2}$ W., and then not to bring Johore Hill to the northward of that bearing until Barbukit Hill bears N. $\frac{1}{4}$ W. or North. The last-named hill must not be brought at all to the eastward of North when on the East side of Great Pan Reefs.

Standing towards the N.W. coast of Bintang, to avoid the Crocodile Shoal, Barbukit Hill should not be brought West of N. by W. $\frac{1}{4}$ W., or in case Barbukit cannot be seen, Kera Island must not be brought West of S.S.W.; or a vessel should tack in 10 or 9 fathoms. When the screw pile beacon on the Great Pan bears North of West, a vessel will be nearing Netscher Shoal, and must avoid bringing the small islet of Malang Yarong (which will be

seen well clear of the extreme of the land) West of S. by W. $\frac{3}{4}$ W., or Sau lighthouse West of S.S.W. $\frac{1}{2}$ W.; this last precaution will also clear the dangerous bank between Kera Island and Malang Yarong. The soundings decrease so suddenly about this part of the coast that they must not be relied on to give warning in time to avoid the dangers.

Kera Island must not be approached within three-quarters of a mile, but Malang Yarong may be to a quarter of a mile. A reef rounds away from Malang Yarong to West Point, having depths of 8 or 7 fathoms close-to, and it must be given a berth from three-quarters to half a mile until up with West point, which is rather bold. Dua Island must not be neared within a quarter of a mile, on account of the reef which fronts it; and all danger between Dua and Little Loban will be avoided by keeping the West end of the latter island East of S. by E. $\frac{3}{4}$ E., or by not bringing West Point West of N. $\frac{1}{4}$ W.

Standing to the westward, when near the South side of Great Pan Reef, Sau Point should not be brought South of S.W. $\frac{1}{2}$ W., which will clear the Great Pan, and also the Malang Orang Reef, in case the buoys upon these dangers should have disappeared. From Malang Orang beacon to Sau Island, keep the East point of Sau open of Little Innang, to avoid the dangers which lie north-westward of Sau.

The eastern point of Sau is bold on its northern side, but on its southern side is a small reef, distant from it a quarter of a mile, which should be given a wide berth; after passing it, be careful to keep the eastern extreme of Little Innang open of the eastern extreme of Sau, to clear the long spit which projects from the latter island, and also to avoid the reef extending from Innang, in case the beacon which marks it should be gone. Close to the reef are 8 or 7 fathoms, and 14 or 15 fathoms about half a mile off.

The same objects in line will serve to guide the vessel past the Innang Shoal buoy, towards which, if desirable, she may stand a little closer, after which, keep the East extreme of Little Tiemara South of S.S.E. $\frac{1}{4}$ E., to avoid the Johannes Shoal. Little Tiemara is fronted by a reef, and should be given a berth of at least half a mile. After passing this island, Tiemara Bank will be avoided by not bringing the N.E. extreme of that island to the North of N.W., until the S.W. extreme of Tiemara is North of W. by N., when she may stand into the bay towards Sembolang Point, as convenient, tacking in 8 or 7 fathoms.

Sembolang Point may be approached to a quarter of a mile in 10 or 9 fathoms. After passing it, do not bring its South extreme to the West of W. by S. until the eastern extreme of East Moeboet bears S.S.E., to avoid a bank which extends N.N.W. of that island. Between East Moeboet and Great Garras a vessel may stand into 8 or 7 fathoms, but a good mark for tacking is to keep Little Garras well open of the East extreme of Great

Garras, and this will also keep the vessel clear of the bank, which lies about $1\frac{1}{4}$ mile to the southward of Moeboet.

Little Garras Island may be approached to a quarter of a mile, but Great Garras not nearer than a mile. After passing Little Garras, the lighthouse must not be brought to the westward of N.W. until the East point of Galang (which projects into the middle of the bay to the southward) bears W. $\frac{1}{2}$ S., in order to clear Ditloffs Reef. Tjassens Shoal, which fills up a great portion of this bay, may then be approached to 9 or 8 fathoms.

Come no nearer than half a mile to Dempoe Point; and, after passing it, do not bring it North of N.W. by W. until the S.E. extreme of Selatan is West of W. by S., which will keep the vessel clear of East Bank and the shoal bank filling up Selatan Bay. Rondo or Dumpo Island bearing S.W. $\frac{1}{2}$ S. also leads outside of East Bank and all other dangers between that island and Dempoe Point, and is a safe tacking mark.

Between Rondo Island and Katang Linga a vessel may stand well over towards Oedik and Selanga Islands, but must avoid standing within a line drawn from the northward of the last-named islands to the N.W. extreme of Katang Linga. The East side of Katang Linga should not be approached nearer than half a mile, and in order to avoid the Rifleman Shoal (which lies about $1\frac{1}{2}$ mile eastward of the N.E. point of Binan), the northern extreme of Katang Linga must not be brought North of W. by N. $\frac{1}{2}$ N. (this also clears the $3\frac{1}{2}$ -fathom patch off the North part of Binan), nor the eastern extreme of Missana East of S.E. $\frac{1}{2}$ E.

Having passed the Rifleman Shoal, if the apex of Binan is not brought to the northward of W. by N., the dangers which extend about three-quarters of a mile from the North side of the Missana will be avoided.

Standing to the eastward, Little Loban should not be approached nearer than half a mile; and, after passing it, Sau lighthouse in line with its West extreme will clear the West side of Isabella Bank. The southern part of the bank will be avoided by not bringing Terkolei lighthouse East of E. $\frac{1}{2}$ N. Between the Isabella Shoal and Pankel, a vessel may stand well over into depths of 8 or 9 fathoms; but, in order to avoid the Soré Reefs, do not bring Terkolei lighthouse to the westward of N. by W., or the North end of Pankel to the southward of S.S.E. $\frac{1}{4}$ E. Little Garras lighthouse open of the S.W. extreme of Pankel will lead clear of the shoal water extending N.N.W. from the North part of that island; its West side may be approached to 8 or 7 fathoms; shoal water extends from the S.W. extreme, close to which are 13 fathoms water; it should not be closed nearer than half a mile. The apex of Loban open of the West extreme of Pankel, will lead clear of the Dutch Shoal, and of the shoal bank of soundings south-eastward of Pankel; this mark will also lead to the westward of the shoal water (4 to 5 fathoms), which extends nearly $2\frac{1}{2}$ miles southward of the Topies, and which will be cleared to the southward by keeping Siolon Hill open of S.W. Hill. The

shoal bank, just mentioned, is not dangerous to small vessels which may stand nearer to the Topies; but in order to avoid Rotterdam Reef, the S.W. extreme of Pankel must be kept North of N.W. $\frac{1}{2}$ W.

To the southward of the Topies, Alligator Island may be approached to half a mile, and a vessel may stand on well into the channel between Siolon and Talang, but must not bring S.W. Hill to the West of W. $\frac{3}{4}$ N., on account of Thomas Shoal. There are many shoal patches between Talang and Pulo Gin, but they all (except the Hendrik Jan Rock, awash at low water), lie out of the track of ships. The S.E. side of Talang should be given a berth of at least 2 miles in passing, keeping South-west Hill well open of Talang, until Pulo Terobi bears E. by N.

3.—VARELLA AND DURIAN STRAITS, ETC.

In the height of the N.E. monsoon, in December and January, when strong northerly winds prevail, it blows much more freely in the open portion of the China Sea, to the eastward of Linga and Bintang, than it does in the straits they form with the coast of Sumatra. Mr. Stanton, therefore, recommends the Varella and Durian Straits for a sailing ship going northwards at this season, as by avoiding the heavy sea, and southerly current, which sometimes runs at the rate of 3 knots an hour, they will save much time, and have smooth water, good anchorage, and will also be greatly assisted by the squalls from the Sumatra coast.

The straits have not been completely surveyed. Lieutenant Melvill Van Carnbee drew up a chart in 1843, to which Mr. Stanton, R.N., made considerable additions in 1860—1, and further corrections have since been made, but still the chart and directions must not be considered as perfect, and the mariner is therefore cautioned not to place too much reliance on them.

The **COAST of SUMATRA** from Batakarang Point (the N.W. limit of the Strait of Banka, described on page 198), trends about N.N.W. towards Jaboeng Point, sometimes known as Cape Bon, in about lat. $0^{\circ} 58' S$. The entire coast, which is very low, covered with wood, and entirely unknown, is fronted by a mud-bank, that may be approached to 6 or 5 fathoms water, except off Jaboeng Point, close to which there are in some places 9 fathoms, but all vessels should keep 3 miles from it. A bank of 4 fathoms was found by H.M. surveying vessel *Saracen*, in 1861, with Jaboeng Point bearing N.W. by W., distant 9 miles; a depth of 6 fathoms also nearer the shore. This is probably a projecting horn or spit extending from the mud flat, and as shoaler soundings may be found, vessels bound to Varella Strait should keep 5 miles off shore until Jaboeng Point bears West.

TANJONG JABOENG, or **Cape Bon**, in lat. $0^{\circ} 58' S$, long. $104^{\circ} 22' E$,

is the south-eastern limit of the Inner Route. Like most other parts of the East coast of Sumatra, it is low land, and has a shoal-water bank extending more than a mile from it.

VARELLA, or **Brahalla**, is a small island, 450 ft. high, which gives its name to the strait, and has a hill on its western part, which may be seen 20 miles off. It lies in the middle of Varella Strait, and bears from Tanjong Jaboeng, N. by E. $\frac{1}{4}$ E., nearly $9\frac{1}{2}$ miles, and from Pulo Taya, W. by S. 30 miles.

There are some islets and rocks near Varella, the largest of which, *Anak Varella*, lies about a mile north-eastward of it; and a mile North from it lies a rock, with 17 fathoms close to it.

There is anchorage on the S.W. side of Varella, and water may be procured; but this only ought to be done in case of necessity, as the lurking piratical proas have been known to assault and massacre the crews of boats sent on shore to procure water at this island. The ship *Hercules* was attacked by seventeen large proas near this place, and narrowly escaped being taken by them.*

Kunst Shoal.—Capt. G. Kunst, of the Dutch barque *Louisa Kroon Prinses of Sweden*, reports having seen a shoal, with but 12 ft. water over it, from which Varella Island bore W.N.W., distant 3 miles.

Middle Rocks lie $4\frac{1}{2}$ miles N.E. by N. from Varella, or nearly midway between the latter and the islets which front the South end of Sinkep Island. Rocks extend halfway across from Varella to the Middle Rocks.

Pollux Rock, with only 4 ft. water over it, lies nearly 2 miles N.E. of the Middle Rocks, and from it the nearest of the islets southward of Sinkep bears N. by W. $3\frac{1}{2}$ miles, and Anak Varella Islet S.W. $\frac{1}{2}$ S., nearly $5\frac{1}{2}$ miles.

The channel southward of Varella Island is wider and more free from danger than the channel northward of it, and is consequently much more frequented. The shoal bank fronting Tanjong Jaboeng projects about 8 or 9 miles north-westward from it, forming a sort of elbow, to avoid which it will be necessary to keep Tanjong Jaboeng to the South of S.E. $\frac{1}{2}$ S., until Varella Island is East of E.N.E. The channel to the northward, between

* Although piracy has very much decreased in these seas since Horsburgh's time, and, as a general rule, but little danger need now be apprehended from piratical fleets, yet Llanun pirate proas have been known to pass through Banka Strait within the last few years. It is still, in fact, very necessary indeed for merchant vessels which have occasion to fill up water in out of the way places to be on their guard against surprise. Natives, not ordinarily pirates, frequently become such if a good opportunity present itself, and merchant vessels offer such rich prizes, that the natives of almost any part of the Eastern Seas would very likely be tempted to attack them, if they saw a favourable opportunity for doing so successfully, when many of the crew were away from the ship watering.—J. W. Reed, Master R.N., 1864.

Varella and the small islands contiguous to the S.E. end of Sinkep is encumbered with the dangers just mentioned.

SINKEP, the easternmost of the three islands forming the North side of Varella Strait, is about 17 or 18 miles in extent, and of very irregular shape, projecting to a point on its East side, another on its S.E. side, and a third on its South side. Between these points are rather large bays, the most southern one, *Baru Bay*, being 3 miles deep. On the eastern side of the island is a range of hills, with a peak 1,440 ft. high near the centre of the range. There is a hill over Boekoe, or Buku Point, and 4 miles to the northward of it, on the West coast of the island, is a sharp peak of moderate elevation. From Boekoe Point the coast line takes a north-westerly direction for 14 miles to *Saboyoro Strait*, which separates Sinkep from the island next westward of it. Rocks above and below water front the whole S.W. coast of Sinkep, to the distance of a mile.

Rawa is the outer of two islands westward of Sinkep, their S.W. coast line following the same N.W. direction as that of Sinkep, the whole distance from Boekoe Point to the N.W. extreme of Rawa being 23 miles. The islands are separated by a channel so narrow that they appear as one. Shoal water extends 2 miles from the S.E. point of the eastern island.

Sinkep Laut is the outermost of four or five small islets lying about $2\frac{1}{2}$ miles off the S.E. point of Sinkep.

Seera, or *Reef Island*, is small, 160 ft. high, and lies E. $\frac{3}{4}$ N. $6\frac{1}{2}$ miles from Boekoe Point, and N.W. $\frac{1}{4}$ N. 14 miles from Varella Island. It is a flat, low island, sometimes mistaken for Varella when coming from the northward. A reef surrounds the island, and extends more than a mile from its East end, and more than 2 miles from its N.W. end. At 4 miles W. by N. $\frac{1}{2}$ N. from Seera is a patch, having 4 fathoms least water over it. *Anak Seera* are rocky islets, lying about $2\frac{3}{4}$ miles N. by E. from Seera, with a safe channel between them and the latter island, and also (with the exception of the $4\frac{1}{2}$ -fathom patch 2 miles eastward of them) between them and the coast of Sinkep. A bank with 2 to 3 fathoms water over it extends from them about 2 miles in a north-westerly direction.

Speke Rock, on which a ship of this name struck, lies W. by N. $\frac{1}{4}$ N., 9 miles from Seera Island, and S.E. $5\frac{1}{2}$ miles from the southern Alang-Tiga Island. It is of small size, and a portion of it uncovers at two-thirds ebb, showing as a small black rock about the size of a boat. Close-to are 10 fathoms water. Boekoe Point kept open to the southward of Seera Island, E. $\frac{1}{4}$ S., leads to the southward, and the southern Alang-Tiga Island bearing N.W. by N. leads to the westward.

Atkin Rock, on which the brigantine *Bob Tail Nag*, Capt. Atkin, struck in May, 1863, is a pinnacle which uncovers at two-thirds ebb. The marks for the rock are, the West extreme of the North Alang-Tiga Island, just shut in

by the East extreme of the Middle Island, and the South extreme of the Southern Island, bearing N.W. by W. $\frac{3}{4}$ W., distant three-quarters of a mile.

Alang-Tiga Islands, bearing N.W. $\frac{1}{2}$ W. 29 miles from Varella, are a group of five small islets, and some rocks above water. The three principal islands are high, and may be seen 24 or 25 miles, and the others 13 or 14 miles from the vessel's deck.

Silensing, or *Green Island*, is an islet 119 ft. high, lying $2\frac{3}{4}$ miles north-westward of Rawa Island, being separated from it by a safe channel, with depths of 10 to 19 fathoms. *Wright Island*, or *Boenta*, is a small islet lying $1\frac{1}{2}$ mile northward of Silensing. Some rocks appear to extend about a quarter of a mile from it.

JAMBI or JAMBIE RIVER.—From Tanjong Jaboeng (page 334), the coast of Sumatra trends in a westerly direction to Jambie Point, from whence it falls back to the south-westward, to the principal entrance of the Jambi River, also named the *River Nioer*, or *Kwala-nur*. There are, however, between this entrance and Tanjong Jaboeng, several other entrances, off the mouths of the two easternmost of which lies an island named Berba. The river is barred, and has a depth of $1\frac{1}{2}$ fathom over the bar, and 4 to 8 fathoms inside. It is one of the principal rivers on this side of Sumatra, and a Dutch expedition under Lieut. Schouw Sautvoort was started in 1876 to explore in its neighbourhood. There are several towns and villages on the banks of the river, the principal of which is *Simpang*, about 20 miles, and *Jambie*, about 50 miles from the entrance. This part of Sumatra is under the Dutch, who have a station and fort at *Moeara Kompeh*, a town 5 miles above *Simpang*. For 30 miles inland the country is a wooded marsh.

Coal.—A fine seam of coal was (in 1860) discovered near the Sultan's house at Jambie. It is said to be 12 ft. thick, close to the river, and at some distance below the surface, quite equal to English Newcastle coal.

BASSO, or Bakauw Point, in lat. $0^{\circ} 20' S.$, long. $103^{\circ} 47\frac{1}{2}' E.$, is the S.E. extreme of Basso Island, which projects in the form of a peninsula from the main coast of Sumatra in an E.N.E. direction about 13 or 14 miles, its breadth being about 5 or 6 miles. It bears N.W., and is distant about $52\frac{1}{2}$ miles from Tanjong Jaboeng, the coast line between falling back into a large bight, 33 or 34 miles deep, the main entrance to the Jambie River, just described, being situated at its head. The eastern face of Basso Island should not be approached nearer than about 2 miles, as a shoal, steep-to, projects nearly a mile from it.

AMPHITRITE BAY and INDRAGIRIE RIVER.—Amphitrite Bay is a large bight about 16 miles deep, formed between the N.E. extreme of Basso Island and Baroe, or Dato Point, 15 miles to the northward. The bay is nearly filled by a shoal, which extends several miles from either shore. It projects in a N. by W. direction (Horsburg says N. by E.) for 5 or 6 miles

from the South point of entrance, but it curves away more gradually from the North point, and between these projections is the deep-water portion of the bay, about 3 or 4 miles broad.

The large River Indragirie discharges itself through several channels into Amphitrite Bay, and also into the bay between Tanjong Jaboeng and Basso Island.

Caution.—The outer edge of the shoal extending from the points of entrance to Amphitrite Bay, especially from the southern, is steep-to, having 10 or 11 fathoms within half a mile of it in some places, then quickly 5 or 4 fathoms, to $1\frac{1}{2}$ or 1 fathom upon it, which requires great attention to the lead when approaching this part of the coast in the night.

All this part of the coast of Sumatra is flat low land, thickly wooded with trees about 120 ft. high.

From the low headland of Dato Point, the coast runs N. by W. and N.N.W. toward the Strait of Durian, and is fronted by a shoal bank from 2 to 6 miles off shore, which may be approached by the lead, as from 10 fathoms upon its edge the soundings gradually decrease to 6, 5, 4, and 3 fathoms.

CHANNELS between SINKEP and LINGA ISLANDS.—*Ponoebo Island*, 5 or 6 miles long, East and West, 2 miles broad, and having a hill 955 ft. high near its centre, lies between Sinkep and Linga, dividing the passage between those islands into two channels, named Lima and Ponoebo Straits.

Lima Strait, between Ponoebo and Linga, is narrow, much encumbered with islets and dangers, and does not, upon the chart, appear to be a very convenient channel for navigators unacquainted with it. Capt. McKenzie, however, says that it is safe and quickly passed through with the tide; and that on its western side, just beyond the narrows, there is a small bay on the Linga shore, with good anchorage, wood, and water.

Ponoebo Strait, between Sinkep and Ponoebo Islands, is, like *Lima Strait*, very narrow and encumbered with islets and dangers. It is said that a vessel of moderate draught may pass through it with safety.

PULO SETJAWA lies close to the N.W. extreme of Linga, from which it is separated by a channel about half a mile broad. Upon the chart it is shown as a long narrow island, 14 or 15 miles long, and 3 miles broad, with hillocks on it from 200 to 300 ft. high; but this island, together with many others near it, are very imperfectly known, not having been even roughly surveyed.

Tiampa Island, separated from the western side of Setjawa by a channel about $1\frac{1}{2}$ mile wide, is about 5 miles long N.W. and S.E., and about $1\frac{1}{2}$ mile broad. *Boeova Island* lies nearly 3 miles westward of the N.W. point of *Tiampa*, and in the channel separating them is a group of islets and rocks. *Boeova* is only 2 miles in extent, but it is a remarkable island, rising to a peak 888 ft. high.

Dian is the easternmost, and *Lobam* the westernmost of a chain of islets fronting the South and S.W. sides of Boeova. The *Leda Rock* is the outermost of a ridge of rocks which extend about $1\frac{1}{2}$ mile in a N.W. by W. direction from *Lobam*.

TEMIANG, RODONG, and DUMPO STRAITS.—To the northward of Boeva Island, the eastern side of the Inner Route is bounded by numerous islands, with deep channels between them. In order to avoid the difficulty and delay sometimes experienced in getting from the northern part of Durian Strait to Singapore Road, many sailing vessels have preferred to pass from the Inner Route by Abang Strait or Dumpo Strait into Rhio Strait. It seems probable that the best passages might be made in this way, for the great depth of water in the western part of Singapore Strait is often embarrassing in light winds.

Temiang Island, which limits the Temiang Group to the north-eastward, is 7 miles long, 3 miles broad, and much the largest of the islands. The island is mostly composed of high hills, and near the West end is some table land elevated 800 ft.

Close off the N.W. end of Temiang is *Pintoe*, an island about $1\frac{1}{2}$ mile long; and off the N.W. end of *Pintoe* is an island named *Kebab*. All the islands are fringed with reefs.

Pompon Island lies S.W. by W., a little over 2 miles from *Kebab*; it is rather more than half a mile in diameter, rising to a hill in the centre 433 ft. high. A rock, awash at high water, lies close off its N.W. point. Some detached rocks lie N.E. by E. three-quarters of a mile from *Pompon*, and N.W. $\frac{1}{2}$ N., the same distance from the N.W. islet of the *Babie Group*, which lie between *Pitoe* and *Pompon* Islands.

Pompon Shoal, N. $\frac{3}{4}$ E., $2\frac{1}{4}$ miles from *Pompon* Island, consists of three or four rocks several feet above water. A detached rock awash lies a quarter of a mile to the westward.

Irene Rock, said to lie W. by N. $\frac{1}{2}$ N., about 7 miles from *Pompon* Island, could not be found by the *Rifleman*, in 1869, in the course of a few hours' search; but the examination was insufficient to disprove its existence.

Allor, a small round island, 139 ft. high, is surrounded by a reef and some islets.

PANGALLAP ISLAND, 3 miles long N. by W. $\frac{1}{4}$ W. and S. by E. $\frac{1}{4}$ E., is moderately elevated and fringed by a reef. The channel between *Pangallap* and the reef extending from *Allor* is 3 cables broad, and from 7 to 23 fathoms deep.

Dedap lies to the westward of *Pangallap*. Off the S.E. end of *Dedap* are three small islets and a rock, the latter being distant a little over half a mile. A mile from the island, in the same direction, are two rocks awash;

from the outer one of these the South end of Pangallap bears N.E. $\frac{3}{4}$ E., and the South extreme of Allor E.S.E. The channel eastward of these, and between Dedap and Pangallap, appears to be free from danger, with the exception of a rock awash a short distance outside the edge of the reef fringing the latter island, and which bears E. by N. $\frac{1}{2}$ N. from the North end of Dedap.

A small islet lies close to the N.W. point of Dedap, and half a mile off in that direction lie two small islets, encircled at a short distance by a reef. These islets form the southern limit of Abang Strait (described farther on).

Rodong Group (see page 314) lies to the westward of Niamok and Misana. The three eastern islands, which form a sub-group, are known as the Desie Islands; the two western ones, lying close together, as the Madang Islands. The channel between Missana and the Rodong group is encumbered with many dangers, and should not be used.

The **Dua Islands**, two rather low islands, lie W.N.W. $2\frac{1}{2}$ miles from the Madangs. Two reefs lie $1\frac{1}{2}$ mile north-westward of the Dua Islands. On the South end of the southern one is an islet, and on the N.E. extreme of the other is *Tree Rock*, a rock about 10 ft. above high water, with a tree upon it. A *coral patch*, with 3 fathoms water over it, and 11 to 14 fathoms around it, lies N.W. by W. $\frac{1}{4}$ W. nearly a mile from Tree Rock, the channel between them is safe.

Tetampan Group, occupying a circular space about 4 miles in diameter, lies north-westward of the Rodong group; it comprises numerous islands, islets and rocks, divided from each other by narrow, intricate channels, encumbered with many reefs and dangers. Tetampan, elevated 390 ft., the highest and most conspicuous of the islands, is situated near the S.W. part of the group; Binan and Katarg Linga form its eastern and northern limits, and the Nopong Islands, with the adjacent islets and reefs, its north-western ones.

TEMIANG STRAIT, leading from the China Sea to the Durian and the other straits adjacent, is about 14 miles long and 2 broad, its direction being N.W. by W. $\frac{1}{4}$ W. and S.E. by E. $\frac{1}{4}$ E.; it is bounded to the southward by the northern islands of the Sebangka group, and by Temiang, Pintoe, and Kemat, and to the northward by Niamok, the Rodong group, Dua Islands, and Tree Rock Reefs.

A *dangerous pinnacle rock awash*, very difficult to make out, lies at the southern entrance of this strait, nearly 1 mile N.E. from a group of small islands south-eastward of Temiang. This danger may be passed on either side, the channel to the southward being three-quarters of a mile wide, but the best plan is to pass to the northward; in doing so, however, be careful to avoid the shore reef, which projects half a mile to the southward of the East point of Desie, and also a rock awash, which lies more than 2 cables from the South point of the Madang Islands.

RODONG STRAIT, between the Rodong and Tetampan groups, is also navigable, but a *rock awash*, which lies N.N.E. $\frac{1}{4}$ E. more than 6 cables off the North point of Rodong, must be carefully avoided; there are also *two patches of reef*, one lying a quarter of a mile south-eastward, and the other about double the distance south-westward, of the southern island of the Tetampan group. Besides avoiding the first-mentioned danger, vessels, when working, should not stand within a line joining the northern extremes of Rodong and Missana Islands.

The channel between the Tetampan group and Dua Island and Tree Rock Reefs is safe, taking care not to stand too close to the S.W. islands of the group between Tetampan and Little Nopong.

PANGALLAP STRAIT is limited on the East by the Tetampan group and the Selanga Islands, and on the West by Allor, Pangallap, and Oedek (page 314). A bank, with from 5 to 10 fathoms water on it, lies in the fairway of this strait, having on the northern end a *rock awash*, from which North Selanga Island bears E. $\frac{1}{2}$ S. $1\frac{3}{4}$ mile, and the apex of Allor Island S.W. by S. $2\frac{1}{2}$ miles; near its opposite extreme is a $2\frac{1}{4}$ -fathom patch of hard sand, with the N.E. extreme of Pangallap bearing N.W. $\frac{1}{2}$ N. $2\frac{1}{2}$ miles, and the apex of Allor Island S.W. $\frac{3}{4}$ S. $1\frac{1}{2}$ mile. Vessels may pass between or on either side of these dangers, but it is better to pass to the eastward of both of them. South of the N.E. point of Pangallap a *hard mud bank*, with 5 to 10 fathoms water over it, extends nearly a mile to the eastward, and the same distance to the southward; and a bank of sand, nearly half as large, with about the same depth of water over it, extends to the eastward from Oedik; elsewhere the soundings are very irregular, 13 to 28 fathoms.

The strong tides near the springs, owing to the uneven nature of the bottom, cause violent whirls and overfalls, which are alarming to strangers; but it seems only necessary to avoid the above described dangers to pass safely through the strait, as none besides those could be discovered, though carefully searched for.

ABANG STRAIT.—Little Abang, about a mile in extent, lies 2 miles N.W. by N. from Dedap, with the Nio Islands, a group of islets and rocks surrounded by reefs, lying nearly a mile from its eastern side. Between Dedap and Little Abang is Abang Strait, narrowed to the breadth of a mile by two islets, which lie half a mile off the N.W. end of Dedap, and by the Sapientoe islets and rocks, the outer edge of which is three-quarters of a mile from the S.E. end of Little Abang. A short distance westward of the fairway of the strait is a deep hole of 25 fathoms, with 15 fathoms round its edge. The depths near the islets are 7 fathoms, with 12 in mid-channel, increasing to 20 or 23 fathoms between the North point of Pangallap and the Nio Islets.

Great Abang, twice the size of Little Abang, lies N.N.W. of it, and between them is a channel with 3 to 9 fathoms, but it is narrow, being con-

tracted by an island near Great Abang and the reefs extending from both islands. A *rock*, with but 3 ft. water over it, lies W. $\frac{3}{4}$ S. nearly a mile from the S.W. point of Little Abang, and S.E. $\frac{1}{2}$ E. the same distance from the South point of Great Abang; near it the depths are 4 to 9 fathoms. Close to the West side of Great Abang is *Tortel Islet*, and W. $\frac{3}{4}$ S. $1\frac{1}{4}$ mile from this islet is *Hippomenes Rock*, a rock awash, with 7 to 13 fathoms around it.

Cameleon Rock was examined in the *Rifleman*; it is a small rock about a foot above high water, with 11 fathoms close to its West side, and some patches of $2\frac{1}{2}$ and 3 fathoms from a quarter to half a mile northward and north-eastward of it. From the rock the apex of Potong bears N.N.W., distant nearly $6\frac{1}{2}$ miles, and the South point of Little Abang E. $\frac{3}{4}$ N., distant about 7 miles. Potong, if not brought to the westward of North, will lead well clear to the westward of both the Irene and Cameleon Rocks.

Potong Island, lying 5 miles W.N.W. from Great Abang, has several hills upon it, one of which is 462 ft. high. The island is surrounded by numerous islets and rocks, which, off its S.E. side, extend three-quarters of a mile. Off the N.E. side the soundings are very irregular and somewhat shoal, $3\frac{1}{4}$ fathoms being found at two-thirds, and $2\frac{1}{4}$ fathoms at one-third of a mile from the shore.

DUMPO STRAIT, 7 miles long N.W. and S.E., and 3 miles broad, is bounded on the southward by Oedik Island and the eastern sides of the Abang group, and to the northward by Dumpo, the S.W. part of Gallang, and the islands Penjaboeng and Somoet, which lie off the West coast of Gallang. Shore reefs, not extending far from most of them, front the whole of these islands, but from the S.W. part of Gallang the reef projects a third, and from Somoet not quite a quarter of a mile.

This strait affords easy and safe navigation, the fairway being perfectly free from danger, and the following rocks lie so near the shore that they may be easily avoided. *Haai Shoal*, a patch of 2 fathoms, lies a quarter of a mile S.S.E. from Dumpo; a 6-foot *rock* E.S.E. half a mile from the S.W. point of Gallang; a *rock above water*, E. by S., a third of a mile from the North point of Great Abang; and *Penjaboeng Rock*, S.W. $\frac{1}{4}$ S., 4 cables from the North point of the island of that name. This last is the most dangerous, and will be avoided if the S.W. point of Gallang be kept open of the S.W. point of Penjaboeng, and the apex of Tafelberg, a table hill on Gallang Island, open of the N.W. end of Somoet. The soundings in the straits are very variable.

We now commence the description of Durian Strait.

THREE BROTHERS.—The South Brother, in lat. $0^{\circ} 33' 20''$ N., long. $103^{\circ} 46'$ E., is the largest and highest of the three islands lying at the South entrance of Durian Strait. It is about a mile in length North and South, and not quite half a mile in breadth; the highest hill near the centre

of the island is 257 ft. high, and may be seen 17 or 18 miles. There is a white cliff or rock on the N.E. side, which makes this island remarkable. The *Middle Brother*, only 135 ft. high, lies about $1\frac{1}{4}$ mile northward from the North point of the South Brother. Between the South and Middle Brother there is a safe passage, about two-thirds of a mile wide, with soundings from 9 to 13 fathoms. The *North Brother*, sometimes called the Round Brother, is smaller and lower than the others, being but 87 ft. high. It lies N. by W. $\frac{1}{2}$ W. $2\frac{1}{2}$ miles from the Middle Brother, and between them there is a safe passage, with 11 to 17 fathoms water, now frequently used.

The **Eastern Bank**, which bounds the channel to the eastward of the Brothers, is composed of hard sand, having irregular depths on it from 1 to 6 fathoms, with 10 and 12 fathoms close to its western edge. A number of low mangrove islands extend from about $2\frac{1}{2}$ miles northward of the Sumatra coast, to a distance of 8 or 9 miles in that direction from it. The south-easternmost of the group is a very small islet, known as South Island, 90 ft. high, and surrounded by rocks. The north-easternmost one, named Long Island, which lies about 6 miles westward of the South and Middle Brothers, is $1\frac{1}{2}$ mile long, North and South; and $1\frac{1}{4}$ mile north-westward of it is a higher island, named Saddle.

A *patch*, having only 2 fathoms water over it, lies with the northern extreme of Long Island, bearing W. $\frac{1}{2}$ S., Saddle Island W. $\frac{3}{4}$ N., and the peak of False Durian N.N.W. $\frac{1}{4}$ W. About a mile north-eastward of the 2-fathom patch is another shoal, with 3 fathoms water over it, and 4 or 5 fathoms around it, discovered in 1861 by Mr. Stanton, commanding H.M.S. *Saracen*. It is about a third of a mile in extent, composed of sand and shells, and lies three-quarters of a mile South from Rocky Islet, off the eastern extreme of False Durian.

All these dangers will be avoided by keeping South Passage Island, or the West end of Little Durian, open eastward of the rocky islet lying off the eastern extreme of False Durian; or by not bringing the latter to the northward of N.N.W. until nearly abreast of it, when it may be approached to 2 cables' lengths.

FALSE DURIAN, or *Pulo Duri*, is a very irregular shaped island, about $2\frac{1}{2}$ miles in extent, and with the contiguous islands, forms the south-western limit of Durian Strait. Near its N.W. end is a peak 604 feet high, which bears West distant 5 miles from the North Brother.

Three or four small islands lie close to the S.E. point of False Durian, the outermost one of which, named Rocky Islet, is very small. A group of islets and rocks, called Rocky Islands, lie off the N.W. point.

As the islands hereabout have a similar appearance, strangers when coming from the southward ought to be careful not to mistake one for the other, for some ships have not been able to discern the proper passage. The

peak of Great Durian being higher than the peak of False Durian, or indeed of any other land, is first discerned in coming from the southward.

Richardson Shoal.—This dangerous coral rock, on which the ship *Hurry Puddemsey*, Capt. Richardson, struck in May, 1863, has lately been examined by H.M. surveying vessel *Rifleman*. It is about 200 yards in extent, has $2\frac{3}{4}$ fathoms on it, and 7 to 10 fathoms around it, and between it and the East side of False Durian Island, at low-water springs. From the rock the peak of False Durian bears W. by N., distant $2\frac{1}{2}$ miles; Rocky Islet S. $\frac{3}{4}$ E. three-quarters of a mile; North Brother, E. $\frac{3}{4}$ N., $2\frac{3}{4}$ miles; and Middle Brother S.E. by E., 4 miles. To avoid this rock, do not bring Rocky Islet South of S. by W., until the peak of False Durian bears West.

GREAT DURIAN, or Pulo Sanglar, about 4 miles N.N.W. of the North Brother, is a larger island than False Durian, being $3\frac{3}{4}$ miles in extent, with a peak near its centre 965 feet high. This peak, as remarked above, is the highest land hereabouts, and is consequently visible at the greatest distance.

The **Tombs** is the name given to some islets and reefs, extending about three-quarters of a mile from the southern part of Great Durian. A small reef of coral lies about half a mile south-westward of the Tombs, and about a mile S.E. by S. from the S.W. point of Great Durian.

Little Durian, 590 ft. high, and about half the size of Great Durian, lies off the N.W. extreme of the latter island, from which it is separated by a channel, only a quarter of a mile wide. *South Passage Island*, 204 ft. high, and about half a mile in extent, North and South, lies three-quarters of a mile from the S.W. coast of Little Durian. It is surrounded by rocks lying close to the shore. *North Passage Island*, 156 ft. high, is about half the size of South Passage Island, from which it bears N.N.W. $\frac{3}{4}$ W. $2\frac{1}{2}$ miles.

PRINCES ISLAND, lying W. by S. $\frac{3}{4}$ S. $2\frac{3}{4}$ miles from North Passage Island, on the western side of Durian Strait, is a coral formation not much above high water. It is covered with trees, and their height being about 100 ft., the island has a round and conspicuous appearance.

SOUTHERN ENTRANCES of DURIAN STRAIT.—Durian Strait may be entered on either side of the Three Brothers. When the peak of Great Durian is seen bearing N. by W., a ship will be in the fair track for entering the strait by either channel, and should steer for the South Brother, which, in one with Great Durian peak, bears N.N.W., nearly.

The channel eastward of the Three Brothers, between them and the Eastern Bank, and between the North Brother and the South shore of Great Durian, is about 4 miles wide, having various depths, from 15 to 10 fathoms.

The channel westward of the Brothers, between them and False Durian, is 3 miles wide, and has from 8 to 14 fathoms water, but near the North Brother 24 fathoms. Both channels are equally safe.

The Strait of Sanglar, to the northward of Great and Little Durian, may also be considered one of the southern entrances to Durian Strait, although it is but imperfectly surveyed, and does not offer any advantages to induce a vessel to proceed through it, but on the contrary is very inferior to either of the other channels.

Monkey Islands, three in number, lie from $1\frac{1}{4}$ to $1\frac{1}{2}$ mile northward of Little Durian. Two *rocks*, or patches of reef, lie off the N.W. point of the westernmost Monkey Island, and a 4-fathom patch midway between the West end of Little Durian and the western Monkey Island.

MURO ISLAND is long, narrow, but high, and forms the eastern side of the middle part of Durian Strait. It extends from about $1\frac{1}{2}$ mile northward of Great Durian in a N.W. by N. direction for $5\frac{1}{2}$ miles. On its East side, between it and Suji Island, is the *Strait of Muro*. The West side of Muro is but imperfectly known.

Dolphin Island, 153 ft. high, lies about a third of a mile off the N.W. end of Muro Island. A *rock* lies a third of a mile N.N.W. from the North extreme of Dolphin Island. A *reef*, of an oval form, 2 cables in extent, steep-to all around, and dry at low-water springs, lies a mile westward of the southern part of Dolphin Island.

Bolombo Island is high, about 3 miles long, N.W. by N. and S.E. by S., and half a mile broad. Its southern end is about a mile E. $\frac{1}{2}$ N. from the North end of Muro, and its North end is about three-quarters of a mile from the Twins. Its North end is fronted by a reef to a distance of nearly half a mile, having a white rock within its margin, off the N.W. point of the island. *Red Island*, or *Pulo Goomeata*, lying nearly 2 miles N.W. of Dolphin Island, is of triangular shape, about half a mile in extent, and covered with trees. Its height is 256 ft., and it may be seen 15 miles off.

The passage between Red Island and Dolphin Island ought not to be attempted, for nearly in mid-channel lie *two dangerous rocks*, one *awash* at low water spring tides, and the soundings near being irregular, afford no guide.

A *rocky patch*, dry at low water, lies rather more than half a mile W. by S. from the S.W. end of Red Island, with deep water all round, and between it and the island. Nearly half a mile northward of Red Island is a *small rocky islet* with a tree on it, surrounded by rocks, dry at low water.

The Twins, or *Pulo Mentegas* are two small round islands, lying a little more than a mile north-eastward of Red Island. They bear N.N.W. and S.S.E. of each other, and are 152 ft. high. Distant three-quarters of a mile north-westward of the North Twin is the North end of a *dangerous* and extensive *coral reef*, dry at low-water spring tides, having from 10 to 17 fathoms all round.

The Western Shore of Durian Strait, from False Durian to the Carimons,

is formed of numerous low islands, covered with trees, the principal of which is Sabon. This land is generally known as the Sabon shore, for the islands forming it are separated from Sabon and from each other only by very narrow channels, and therefore appear as one continuous island.

Pulo Panjang, a large, low, flat island, lies northward of Saddle, and westward of False Durian; off its North coast is a small islet named *Round Island*. *Pulo Torreatep*, the next island named on the chart, is the largest and easternmost of a group of several islands, and bears N.W. by W. $\frac{3}{4}$ W., 5 miles from the N.W. point of False Durian; about a third of a mile from its East side is a patch with 4 fathoms water on it. Two miles N.N.W. $\frac{1}{3}$ W. from Terreatep, is what appears to be rather a conspicuous island. The channel between this island and Princes Island has not been sounded.

SABON ISLAND, or *Pulo Pappan*, is the largest island on the western shore of Durian Strait. Its North point reaches to within 3 miles of the southern part of the Great Carimon, and off its N.E. coast lie the islands of Buru, Paril, and Pandan.

Deep-water Point, the most eastern point of Sabon, lies $2\frac{3}{4}$ miles N.W. from Princes Island. There is another point $2\frac{1}{2}$ miles westward of Princes Island, the coast between forming a bay, fronting which is a reef with some trees upon it, from the outer part of which Deep-water point bears N.N.W. $\frac{1}{2}$ W., distant three-quarters of a mile. To avoid this danger, be careful to keep the peak of False Durian open eastward of Princes Island.

From Deep-water Point the Sabon coast trends N.W. by W., and lying close off it are four islands, the north-westernmost of which is the largest.

Middleburgh Shoal, lying nearly midway between Red Island and the bank extending from Sabon Island, is a reef of coral rocks, 300 yards in extent, of circular form, partly dry, about 1 foot above the sea at low-water spring tides, its sides being almost perpendicular, with 7 and 9 fathoms close to the rocks, and 17 to 20 fathoms about 200 yards off. When on the centre of the shoal, the Passage Islands were in one, their East extremes bearing S.E. by S.; the rocky islet, with a tree on it, off the North end of Red Island, nearly on with the North brow of the North Twin; the Twins open to the northward of Red Island; the South end of Red Island, E. by N. $\frac{1}{4}$ N.; Sabon Hill, W. by N. $\frac{1}{3}$ N.; Clay Island, W. $\frac{1}{3}$ N.; peak of Great Durian, S.E. $\frac{1}{4}$ E., and the peak of False Durian, S.S.E. $\frac{1}{2}$ E.

Passage eastward of Middleburgh Shoal.—The passage between Middleburgh Shoal and the bank extending from the Sabon shore is about $1\frac{3}{4}$ mile wide, with soundings deepening from 6 or 7 fathoms near the bank to 14 and 16 and 20 fathoms near the shoal.

PULO BURU is a low island, $4\frac{1}{2}$ miles in length N.N.W. and S.S.E., crowned with high trees, and having a few inhabitants, who collect great quantities of mangosteins, durians, and other fruits, which flourish here in a wild and luxuriant state. It is the next largest island to Sabon, and its

S.E. part bears N.N.W. nearly 5 miles from Deep-water Point. Off its South end is a small islet, named Clay Island, covered with straggling trees and surrounded by rocks.

The eastern shore of Pulo Buru is fronted by a shoal-water bank to a distance of from 1 to $1\frac{1}{2}$ mile, and rocks partly dry at half tide nearly to the same distance, with Sabon Hill, or Gunong Pappan bearing from W. $\frac{1}{2}$ N. to West. These dangers may be avoided by keeping Deep-water Point South of S. $\frac{3}{4}$ E.

Sabon Hill cannot be easily mistaken, being the only hill on the western side of the channel to the southward of Great Carimon, which island has on it *two* high peaks or hills, and the Little Carimon *one*, as seen from the southward, but has really two high peaks on it also.

Pulo Pandan, the southern of two small islands lying about a mile northward of Pulo Buru, is low, and covered with trees about 100 ft. high. *Pulo Paril* is a much larger island than Pandan, lying to the westward of it, and close to the northern part of Sabon.

Close to the eastward of Deep-water Point the depth is 9 fathoms, and 5 fathoms close to the northern extreme of the point; but from thence a shallow bank extends, with a slight curve into the bight between Deep-water Point and Pulo Buru, as far as Pulo Pandan. Deep-water Point bearing S. $\frac{3}{4}$ E. will lead a mile clear of the edge of this bank.

GREAT CARIMON ISLAND, which divides the Straits of Malacca, Durian, and Singapore, has been described on page 136, *ante*. It is 10 or 11 miles in length in a N.N.W. direction, and near its North end are two high and conspicuous peaked hills, the northern one 1,376 feet, and the southern one 1,474 ft. high; the rest of the island consists of low level land. Its southern part is separated from Sabon Island by the *Strait of Clam*, $2\frac{1}{2}$ miles wide.

LITTLE CARIMON (see p. 136) is a high, bold island, $2\frac{1}{2}$ miles in length N.W. and S.E., and rising to two peaks, covered with trees, the northern one being 1,067 ft., and the southern one 1,026 ft. high.

Sand Banks.—A patch of 5 fathoms lies E. $\frac{1}{2}$ S. $1\frac{3}{4}$ mile from Pulo Pandan; and there are two other patches of 4 fathoms off the same island, one bearing E. by N. nearly 2 miles, and the other about N.E. $\frac{1}{2}$ N. the same distance from it. These patches seem to be the tail of a bank of sand lying about 2 miles off the S.E. coast of Great Carimon, and which nearly joins another bank extending S.E. from the Little Carimon. Pulo Pandan bearing South will lead to the eastward of the $2\frac{3}{4}$ -fathom patch on the southern bank; and the peaks of Little Carimon in line about N.W. will lead close to the edge of the northern bank in 5 or $4\frac{3}{4}$ fathoms. A white Herbert's *buoy* is said to lie off the reef extending from the S.W. point of Carimon Island.

Tides.—Throughout Varella and Durian Straits the tides are very irregular, rendering it difficult to ascertain either their direction or velocity. In

August and September the rise and fall was found generally to be between 10 and 11 ft., sometimes running from 3 to 4 knots per hour during the springs, at other times not more than $2\frac{1}{2}$ knots at the same period. This irregularity appears to be produced by the prevailing winds in the North or South entrance of the straits, forcing the tides through in one direction for 12 or 18 hours at a time, although the rise and fall on the shore was regular. But sometimes the tides run with regularity.

At Red Island, in the northern part of Durian Strait, it is high water, full and change, at 10^h, and the tide rises 10 or 11 ft.

The *rippings* might be alarming to a stranger; they appear to be caused by the uneven bottom, and the resistance the tides meet with from the steep reefs and numerous small islands.

PHILLIP CHANNEL, or the north-eastern entrance to Durian Strait, is formed between the numerous islands fronting Battam and Boelang Islands to the south-eastward, and Long and Round Islands to the north-westward. It appears to be free from danger, with good anchorage, and is a short route for vessels proceeding to or from Singapore.

SUJI, JOMBOL, BOELANG, and **BATTAM**, are four islands lying to the north-eastward of Muro and Bolombo Islands. The two former are about 10 miles long in a N.W. and opposite direction; the two latter are much larger, Boelang being about 15 miles long, in the same direction, and 7 miles broad, and Battam 15 or 16 miles in an East and West direction, and 13 or 14 miles North and South. The northern parts of Boelang and Battam form part of the southern side of Singapore Strait.

Numerous small islands, islets, and rocks lie off the shores of and in the channels between the above-named large islands, the whole of which are known under the general name of the Boelang Archipelago, but in the present state of our knowledge, no vessel should venture among them, and it is therefore only the outermost islands and dangers which concern the ordinary navigator, and those will be next described, after the following brief observations on the channels between the large islands. Muro, Suji, Jombol, and Batu Hadji Straits are the names of the channels separating these large islands.

Muro Strait is bounded on the West by Great Durian, Muro, and Bolombo Islands, and on the East by the eastern bank and Suji Island. There are many islands and rocks in it, and it has been but imperfectly surveyed. It is, however, navigable with proper care; and in 1860 an electric telegraph cable between Singapore and Batavia was laid through it from a large steamer piloted by a Dutch steam frigate.

Suji Strait, between Suji and Jombol, is very imperfectly known, but it is certainly encumbered at both ends with many dangers.

Jombol Strait, between Jombol and Boelang, is also encumbered with many dangers, although apparently not to so great an extent as Suji; it is

but imperfectly known; and at present, like the rest of the straits, is not available for general navigation.

Batu Hadji Strait, between Boelang and Battam, is very narrow, in some places not a quarter of a mile broad. A running survey was made of this strait several years ago by Mr. L. C. Bailey, Master R.N., and it is said to be available for vessels, but we cannot give any directions for it. A short time since it was urged upon the attention of nautical men at Singapore as being a route by which vessels could be speedily towed from Singapore Roads to sea in the N.E. monsoons; but it will have to be properly surveyed before it can be used for such a purpose.

PULO DONCAN, lying N.E. $\frac{3}{4}$ N., distant $6\frac{1}{2}$ miles from the Twins (page 345), is the larger of two low wooded islands, fronting the North entrance of the Strait of Jombol, which is formed by a group of beautiful islands, some of which are inhabited. Pulo Doncan is surrounded by reefs to a distance of a mile, and between E.N.E. and E.S.E. to 2 miles off.

Cap Island, so named from its appearance, bearing N. $\frac{1}{4}$ W. 4 miles from Pulo Doncan, is a rock about 40 ft. in height, with a flat top and perpendicular sides, surrounded by a reef to the distance of about 300 yards.

It would be imprudent to pass to the eastward of Cap Island, between it and Steep Cape, as a reef of rocks lies 1 mile off Steep Cape, and it is quite possible that others may exist, for the chart has very few soundings in this locality.

Round Island, or *Takong Ketchil*, is a small but elevated islet, lying $3\frac{3}{4}$ miles northward of Cap Island, $2\frac{3}{8}$ miles W. by S. $\frac{3}{4}$ S. from Helen Mars Reef, and $3\frac{1}{2}$ miles S.S.W., southerly, from Raffles lighthouse. It is the south-easternmost of a chain of islands and reefs which extend from it in a north-westerly direction for about $5\frac{1}{2}$ miles.

Long Island, or *Takong Besar*, 115 ft. high, and lying nearly half a mile N.N.W. of Round Island, is similarly surrounded by reefs, and a small islet lies close to its North shore. Long Island and Round Island are also known as the Brothers: both are covered with trees.

Red Island, or *Pulo Patampong*, is a mere islet or rock, 20 ft. high, covered with trees, with a beach of red sand, lying two-thirds of a mile to the N.W. of Long Island.

Three detached reefs lie in a south-westerly direction from Red Island, the outer and largest one being distant nearly $1\frac{1}{2}$ mile from it. Raffles lighthouse on Coney Island, in line with the N.W. extreme of Long Island, leads to the eastward of them; Round Island bearing E. by N. leads to the southward; and the northern Tree Island, open westward of the southern one, bearing N.N.W., leads to the westward.

Tree Islands, or *Pulo Angup*, two small islets, or rather clumps of trees, are the outermost of the islands and dangers which extend north-westward from Round Island, and limit the southern side of the western entrance of

Singapore Strait. In passing northward of Tree Island, the Raffles lighthouse (or light) should not be brought to the northward of East, nor the reef neared under a depth of 14 fathoms, which will keep a vessel half a mile northward of its northern edge.

Kent Rocks lie between Red Island and Tree Island Reef, N.W. $\frac{3}{4}$ N. and S.E. $\frac{3}{4}$ S. from each other, and not quite half a mile apart. From the southern rock, which is the larger of the two, and has $1\frac{1}{2}$ fathom over it at low water springs, the North end of Long Island is on with the centre of Red Island, S.E. by E., and Raffles lighthouse bears E. by N. $\frac{3}{4}$ N. From the northern rock, which is about 30 or 40 ft. in circuit, with not more than 3 ft. water on it, the southern Tree Island bears W. $\frac{3}{4}$ S. (or W. $\frac{3}{4}$ N.), distant a mile, and Raffles lighthouse E. by N. $\frac{1}{4}$ N., 4 miles.

HELEN MARS REEF is the outermost of some dangerous reefs, which, together with several small islets, lie off the N.W. point of Boelang. From this reef Round Island bears W. by S. $\frac{3}{4}$ S., distant $3\frac{2}{3}$ miles, and Raffles lighthouse is just inside the left extreme of Barn and Alligator Islands N.W. $\frac{1}{4}$ W., nearly. A short distance from it are 14 and 15 fathoms.

The North peak of Great Carimon in line with Red Island, leads close to the northward of this dangerous shoal; Red Island, bearing W. $\frac{3}{4}$ S., will lead well clear to the northward; and Steep Cape, the bold headland inside Cap Island, if kept to the southward of S. $\frac{1}{2}$ W., will lead to the westward.

The Helen Mars Reef lies at the point where Phillip Channel joins the main channel of Singapore Strait, which at this part is bounded on the North side by Coney Island, on which stands Raffles lighthouse, and the islands adjacent to it; and on the South side by the Helen Mars and adjacent reefs and islands, Long Island, Red Island, Kent Rocks, and Tree Islands, with its surrounding reef.

The description of the Rabbit and Coney, with Raffles lighthouse, and the western part of Singapore Strait, is given hereafter.

Directions Northward.—*Departing from Banka Strait*, and being abreast of Batakarang Point in 7 fathoms, if bound to Varella Strait, a N.N.W. course will lead towards Varella or Brahalla Island, distant about 78 miles. The bank along the Sumatra coast in this space being very flat, the soundings are usually the best guide, and the rule is to keep in from $5\frac{1}{2}$ to 7 fathoms. Recollect, however, that at 9 miles S.E. by E. from Tanjong Jaboeng the bank projects a sort of spit or horn, having only 4 fathoms water over it, and 6 fathoms between its northern part and the shore.

The tides near the shore are generally strong; in the offing they are irregular, and currents sometimes prevail.

In passing through the South channel, between Varella Island and Tanjong Jaboeng, keep in 10 or 12 fathoms towards Varella to give a berth to the bank of hard ground projecting from Tanjong Jaboeng; from thence, working along the coast to the westward.

Standing towards Varella, remember the shoal with only 2 fathoms water over it, reported to lie E.S.E., 3 miles from that island (page 335). Being through the narrow part of the passage between Tanjong Jaboeng and Varella, which is about $6\frac{1}{2}$ miles wide, a N.W. by W. course should be steered towards the Alang Tiga Islands, keeping along the coast in soundings of 9 to 12 fathoms, and carefully avoid the Speke Rock (page 336). In this track attention to the tides is *indispensable*, for they are often irregular, sometimes setting out of the Jambie River to the north-eastward $2\frac{1}{2}$ or 3 miles per hour.

Having passed the Alang Tiga at about 2 miles, a course about N. by W. should be steered for the southernmost of the Three Brothers, bearing from the Alang Tiga N. by W. $\frac{1}{2}$ W., distant 63 miles. In working, be careful not to stand nearer to Basso Island or Dato Point than 2 miles, and also avoid being tempted to stretch into Amphitrite Bay, for the banks off the former, and the shoals in the latter, are steep-to, and the lead cannot be depended upon to give warning in sufficient time.

To enter Durian Strait by the eastern channel, a berth of 1 or 2 miles may be given to the South and Middle Brothers, by passing them in 10 or 12 fathoms; and on nearing the North Brother, give a prudent berth to the reef that projects from it to the south-eastward, taking care also not to stand too far over towards the eastern bank. When the southern point of Great Durian is approached, the three islets near it, called the Tombs, will be discerned, and Sabon Hill, bearing about W. by N. $\frac{3}{4}$ N., making like two islands, which may be mistaken for the Carimons. Having passed the North Brother, at $1\frac{1}{2}$ or 2 miles distance, haul to the westward, giving a berth of about $1\frac{1}{2}$ mile to the southern part of Durian, to avoid the sunken rocks rather more than half a mile south-westward of the Tombs.

To enter Durian Strait by the western channel, when near the South Brother, steer to the westward of it at $1\frac{1}{2}$ mile distance, and proceed to the northward in 8 to 12 or 14 fathoms, about mid-channel between the other Brothers and the eastern part of False Durian, to avoid the foul ground surrounding the Brothers, and the shoal patches which lie to the southward of the rocky islet contiguous to the East end of False Durian (see page 343).

Take care, however, when standing towards False Durian, not to bring rocky islet to the southward of S. by W. until the peak of False Durian bears West, to avoid Richardson Rock.

Having cleared the Brothers by either of the channels, the Passage Islands will be seen to the north-westward on the East side of the channel; and on the West side, opposite North Paasage Island, is a flat island called Princes. There is a channel between the Passage Islands and Little Durian, but it is not frequented, as it is not so convenient as the former; but in a case of necessity a ship may sail between any of these islands, giving them a berth of 1 mile, as off their points there is generally rocky and foul ground.

After leaving the Brothers, steer for the Passage Islands; in mid-channel the depths will be generally from 17 to 26 fathoms. When they are approached, Red Island, about 6 miles N. $\frac{1}{2}$ W. from North Passage Island, will be discerned; it may be known by two islets to the north-eastward of it, called the Twins. With care, the passage is safe in daylight, between Middleburgh Shoal and Red Island; but as a reef, dry at low water, lies W. by S. more than half a mile from the latter, and the depths being from 17 to 26 fathoms, with some overfalls, the channel to the westward is preferable.

There is also a passage close to the eastward of Red Island; but as its eastern side is bounded by the rocks lying about a mile N.W. of the Twins, and by others about three-quarters of a mile E.S.E. of Red Island, it ought not to be attempted by a stranger.

The channel eastward of Middleburgh Shoal, between it and the reef lying W. by S. from Red Island, requires care; the best track is about mid-channel in 19 to 16 fathoms, mud. The peak of Great Durian bearing S.E. a little southerly, or East point of North Passage Island in line with the peak of False Durian, bearing S.S.E., will lead mid-channel between the patch off Red Island and Middleburgh Shoal. In working, do not bring the peak of False Durian above a ship's length open westward of North Passage Island, nor stand nearer, to the reef off Red Island, than to bring that peak nearly on with South Passage Island. The tides are very strong between Middleburgh Shoal and Red Island, the flood setting to the southward, and the ebb to the northward, from 3 to 4 knots on the springs.

The Channel westward of the Middleburgh Shoal is preferable, being about $2\frac{1}{4}$ miles wide, with mostly regular soundings from 16 and 17 fathoms close to the shoal. When clear of North Passage Island, haul to the westward for the Sabon shore, then steer about N.N.W. along it, in 7 fathoms, which will lead in the fair track between that shore and Middleburgh Shoal. When Red Island bears East, or E. by S., edge out a little, about N. by W. or North, and deepen to 10 or 12 fathoms; continuing to keep in these depths, steer to the northward, taking care to give a good berth to the South end of Great Carimon, to avoid the bank of $2\frac{3}{4}$, 3, and $3\frac{1}{2}$ fathoms, sand and mud, which projects 3 miles from the South point of that island. When abreast of this point, the distance of 4 or 5 miles should be preserved from the East side of Great Carimon, and the Little Carimon may be rounded at any convenient distance, if bound to the northward.

In working, do not deepen towards Middleburgh Shoal to above $8\frac{1}{2}$ fathoms, as there are 9 fathoms very near its eastern edge; but the Sabon shore may be approached to $5\frac{1}{2}$, or to 5, or $4\frac{1}{2}$ fathoms, in a small ship.

To pass through Phillip Channel.—If bound to Singapore, having passed between Middleburgh Shoal and the Sabon shore, and brought Red Island to bear East or E. by S., a course about N.E. by N. may be steered guard-

ing against tide, to pass through Phillip Channel to the westward of Doncan Island and between Cap Island and Round Island, neither of which should be approached nearer than three-quarters of a mile, on account of the reefs which project from them.

In this route take care that the vessel is not set too near the dangers which lie at the entrances and near the points of the Straits of Muro, Suji, and Jombol, for the tide rushes through them with a velocity of 3 or 4 knots at springs. Having passed Cap Island, bring it to bear S. by W. $\frac{3}{4}$ W., or S.S.W. astern, which will lead through in mid-channel between Round and Long Islands to the West, and Helen Mars Reef to the East. The soundings in this track are very variable, 15 to 35 fathoms.

In working, if standing westward of the South end of Round Island, do not go farther in that direction than to bring Raffles Lighthouse on with the N.W. end of Long Island.

Standing towards the N.E. sides of Round and Long Islands, to avoid the reefs which extend from them, the Cap should not be brought South of S. $\frac{1}{2}$ W., or Raffles Lighthouse East of N. by E. The Cap, if not brought West of S.S.W. $\frac{3}{4}$ W., or Steep Cape, the bold headland inside Cap Island, kept to the South of S. $\frac{1}{2}$ W., will keep the vessel clear of the Helen Mars Reef; and when the northeru peak of Great Carimon is well open northward of Red Island, a vessel will be northward of that danger, and may proceed to the north-eastward into the fairway of the main channel of Singapore Strait. To proceed from thence to Singapore Road, see hereafter.

Directions Southward.—*Leaving Singapore Strait*, and having proceeded as far as Raffles Lighthouse, and brought it to bear W.N.W., or N.W. by W., distant about $1\frac{1}{2}$ mile, Cap Island will be seen bearing about S. by W. $\frac{3}{4}$ W., or S.S.W., and kept upon either of those bearings it will lead about mid-channel between Helen Mars Reef and Round Island. In working, Cap Island must not be brought West of S.S.W. $\frac{3}{4}$ W., or Steep Cape West of S. $\frac{1}{2}$ W., to avoid Helen Mars Reef. The dangers extending from Round Island and Long Island will be avoided by not bringing Cap Island South of S. $\frac{1}{2}$ W.

Having passed westward of the Cap, which must not be approached nearer than half a mile, a course about S.W. or S.W. by S. may be steered towards the Sabon shore; but, as before noticed, be particularly careful to guard against the effects of the tide in this locality.

With a commanding breeze, the passage eastward of the Middleburgh Shoal may be taken by keeping the East point of North Passage Island in line with the N.W. peak of False Durian, which will lead midway between the shoal and the rocky patch; the water deepens towards the Middleburgh Shoal, it being steep-to all round. To prevent being set upon it in light

winds, caution is requisite, as the tides run here from 3 to 4 miles an hour at times.

A vessel being abreast of Little Carimon, with its northern end bearing West from 2 to $2\frac{1}{2}$ miles, a S.S.E. $\frac{1}{2}$ E. course will carry her clear of the mud-banks fronting the low land of Great Carimon, in soundings from 7 to 8 fathoms, until the North end of Pandan Island is on with the North end of Sabon, when the strait between Great Carimon and Sabon will be open. With a working wind from Little Carimon the soundings are the best guide in standing towards the mud-banks fronting Great Carimon, which ought not to be approached under 6 fathoms, remembering that the peaks of Little Carimon in line, bearing about N.W., lead close to the edges of the shoal banks; the depths in the offing are from 14 to 16 fathoms, mud. The peaks of Little Carimon in line will lead outside the dangers off Great Carimon, as will also Pandan bearing South.

When the strait between Great Carimon and Sabon is open, the soundings become irregular; and here caution is requisite with a working wind, as the tides set strong through this straight to the westward at times. When the North end of Pandan is on with the North end of Sabon, and the vessel is distant from the former 2 miles, in 7 fathoms, a S. by E. course will lead clear of the mud-bank that fronts Buru, and midway between it and Middleburgh Shoal, till the North end of Red Island is on with the South end of the South Twin, and the soundings will be irregular, from 5 to 9 fathoms.

In working, a vessel may stand to the eastward to a moderate distance at discretion, but she must not approach the shore of Buru nearer than $1\frac{1}{2}$ mile in 5 to 6 fathoms. When the South end of Buru bears West, the soundings will decrease regularly on the edge of the mud-bank which extends southward as far as Deep-water Point, and the mud-bank may be borrowed on at discretion. Standing eastward towards Middleburgh Shoal, do not approach it nearer than to bring the West end of North Passage Island to touch the East end of South Passage Island; the North end of Red Island, on with the bluff headland to the eastward, will lead northward of the shoal, and the North end of Red Island, on with the South end of the Twins, will lead southward; the latter transit-line also just clears to the northward, the rocky patch lying to the westward of Red Island.

When clear of Middleburgh Shoal, and of the shoal to the westward of Dolphin Island, as the strait to the southward is free from danger, a direct course may be steered for the East end of False Durian; the Passage Islands may be approached to any convenient distance. Princes Island must not be neared much under a mile, as dangers extend a considerable distance from it. The soundings throughout are very irregular, decreasing towards the western shore, where there is good anchorage. At $1\frac{1}{4}$ mile from the north-western and largest of the two rocky islets off the N.W. end of False Durian,

and it being on with the peak of the latter, there is a bank of hard sand and stones three-quarters of a mile in extent, having $4\frac{1}{2}$ fathoms least water, and from 10 to 6 fathoms close-to; when on it, the East side of South Passage Island is on with the North end of Little Durian.

Standing towards the South end of Great Durian, come no nearer the Tombs than 1 mile, when South Passage Island will bear N.W. by W. $\frac{1}{4}$ W., to avoid the small reef of coral rock lying half a mile from the South Tomb, and near to which are 20 to 29 fathoms. The best anchorage in this part of the strait will be found about three-quarters of a mile from the eastern shore of False Durian, in 12 to 14 fathoms. With a working wind, keep near False Durian, where the tides are much stronger than in mid-channel; but take care to bring Rocky Islet to the West of S. by W. before the peak of False Durian bears West, to keep clear of Richardson Shoal.

To pass westward of the Brothers, between them and False Durian, steer through in mid-channel; but with a working wind, either side of the channel may be borrowed on, when to the southward of Richardson Shoal.

After passing Rocky Islet, off the S.E. end of False Durian, keep it West of N.N.W. until to the southward of the 3-fathom bank, lying nearly a mile South of it.

To pass eastward of the Brothers, after passing the Tombs, steer E. by S., keeping about 2 miles from the North and East sides of the North Brother, where the water will shoal to 12 or 13 fathoms; then steer about S. by E., attending to the set of the tide, to pass the Middle and South Brother at the same distance, not borrowing nearer them than 10 or 12 fathoms. With a working wind, do not stand too far over towards the Eastern bank, but tack immediately, if irregular soundings are got on the overfalls near it, nor so far out as to sink the beach of the Middle Brother from the deck of an ordinary ship. The depths in this channel will be mostly from 10 to 12 fathoms near the Brothers, to 16 or 18 fathoms near the overfalls on the edge of the Eastern bank.

Being abreast of the South Brother, at about 2 miles distance, steer South or S. by W. until it bears N.N.W.; and whether the vessel has passed eastward or westward of the Brothers, after having brought the South Brother to bear N.N.W., steer about S. by E. $\frac{1}{2}$ E. towards the Alang Tiga Islands, and endeavour to keep in from 14 to 16 fathoms. With a working wind the best track is to stand to the eastward until in 17 fathoms, about mid-channel, and into 12 fathoms towards the Sumatra shore, but not under this depth in passing Dato and Basso Points, as the shoal fronting the latter is steep-to, with 8 to 14 fathoms near its edge. After passing Basso Point, the coast may be approached occasionally to 6 or 7 fathoms; but the best track with a fair wind is about mid-channel between it and the Alang Tiga, or pass about 2 or $2\frac{1}{2}$ miles westward of these islands at discretion.

Having passed the Alang Tiga, keep the southernmost island to the North

of N. W. by N., until Seera Island bears East or E. $\frac{1}{2}$ S., to avoid the Speke Rock; the proper track from the Alang Tiga to Varella is to keep along the Sumatra coast in 9 to 12 fathoms, borrowing to 6 or 7 fathoms towards the coast, with a working wind.

Caution is, however, necessary if running here in thick weather or in the night, on account of strong tides setting into or out of the rivers, or you may get set on the extensive sand and mud bank fronting the coast to the westward of Tanjong Jaboeng, opposite the mouth of the Jambie River.

Varella Island may be passed at about 2 miles distance in 10 or 12 fathoms; but the spit surrounding Tanjong Jaboeng is steep from 5 fathoms, and should be approached only with great caution under a depth of 10 fathoms in working.

From a position about 8 miles East from Tanjong Jaboeng to abreast Batakarang Point, at the entrance of Banka Strait, the course is about S.S.E., and the distance 66 miles, and the whole of the bank fronting the coast is in this space very flat, with regular soundings upon it, except the horn or spit with only 4 fathoms on it, lying 9 miles south-eastward of Tanjong Jaboeng. The best guide, therefore, after leaving Varella, is to keep along the coast in from $5\frac{1}{2}$ to 7 fathoms, until Batakarang Point is approached, and $6\frac{1}{2}$ or 7 fathoms are the proper depths to preserve, when passing this point and entering Banka Strait, to avoid the Frederick Hendrik Rocks, on the East side of the channel; with a working wind, the point may be approached to $5\frac{1}{2}$ or 5 fathoms.

CHAPTER IX.

THE STRAIT OF SINGAPORE.

THIS great thoroughfare between India and China is about 50 miles in length from the junction of the Straits of Malacca and Rhio, previously described, to the Horsburgh Lighthouse at its eastern end. The great Malay Peninsula is, as it were, continued in extensive ranges of islands, separated by intricate channels, of difficult navigation, but within a few years the beautiful lighthouses at either end of the main ship channel have rendered the passage easy, with common attention, either by day or night.

Formerly the ships of less draught and smaller tonnage passed through the Old Strait to the northward of Singapore Island, but this is now never used by the larger vessels of modern times—a fact due, in some degree, to the western entrance of this channel, having become much shoaler.

In the earliest days of European navigation, the route followed was around the South side of Singapore island, by the Salat Sambulan and the almost newly-discovered New Harbour. It is exactly described by John Hughen Van Linschoten, in his “Discourse of Voyages of the Portingales into the East Indies,” probably written in the early part of the sixteenth century, and which certainly shows that these early Portuguese pilots were as well acquainted with the channels as we are even now, and their instructions are the best to pursue in the present day. They used Pedra Branca as a leading mark, and went through the middle channel, as now recommended.

The strait was generally, though not minutely, surveyed by J. T. Thompson, Esq., F.R.G.S., the Government surveyor at Singapore, and the engineer to the excellent Horsburgh and Raffles Lighthouses, which form its portals; and the directions which follow are taken from the China Sea Directory, and are based on this survey, as added to by Messrs. Richards, Reed, and Stanton, R.N., in 1858—1862. We have re-arranged the matter

so as to commence at the western end, where it connects with the straits previously described.

The Winds and Seasons are described on pages 6—13, *ante*.

The Currents and Tides are noticed generally on pages 26, 27.

Passages to and from Singapore are discussed on pages 50—67.

The NORTH SIDE of the STRAIT is formed by the southern extremity of the Malay Peninsula, and the southern shores of the Island of Singapore.

TANJONG BOLUS, the N.W. limit of the strait, and the termination of the Strait of Malacca, has been alluded to on page 136, the Carimon Islands on the opposite side being the other boundary. They are also described on page 136.

The Bank, which surrounds Tanjong Bolus, extends across the entrance of the old Strait of Singapore, and is very shallow, having only from 6 to 12 ft. water on most parts. Its outer edge trends about E. by N. for about 9 miles to *Tanjong Gul*, the S.W. point of Singapore Island. The *Old Strait of Singapore*, or *Salat Tambroh*, in early times the great highway, is not now used by large vessels. Its western entrance has shoaled up very considerably.

To the south-eastward of Tanjong Gul is a cluster of islands, of which we have no particular account, which bounds the inner channel, called *Salat Sambulan*. This is navigable, but the strait South of the islands is much preferable, as it is more direct, and its dangers are marked by beacons.

The Coast of Singapore Island, to the eastward of the Salat Sambulan, trends in a straight line S.E. and N.W., and at its South end is the *New Harbour*, a strait presently described, which separates it from Blakan Mati Islands, beyond which, in the same direction, are the St. John's Islands, which form the northern side of the narrowest part of the strait. To the north-eastward of these islands is the roadstead and harbour of Singapore. They will be described together hereafter.

SINKI CHANNEL, or Salat Sinki, by which Singapore New Harbour is approached from the westward, is bounded on either side by reefs, the edges of which are marked by beacons. Its length is 4 miles, and its breadth, at the eastern part, where it is narrowest, is but three-quarters of a mile. The depths in it are very irregular, generally from 9 to 15 fathoms, but in places there are over 20 fathoms. The eastern extreme of the channel is about 3 miles to the westward of New Harbour, and the western extreme about the same distance from the Sultan Shoal, described presently.

North Side.—The first of the reefs, westward from New Harbour, are named the *Cyrene Shoals*, and their S.E. extreme bears from Lots Wife W. by S., distant $2\frac{2}{3}$ miles. They consist of two patches, which dry at three-quarters ebb, extending nearly $1\frac{1}{4}$ mile East and West, and about half a mile North and South. The eastern patch is twice as large as the western one, from which it is separated by a narrow channel. A *beacon* is placed upon the South extreme of each of the patches.

The next patch lies 3 miles to the westward of the western beacon of the Cyrene Shoals; it is very small, and has a *white beacon* on its North side.

Half a mile North of this patch is a small island named *Pulo Laut*, having a smaller island close to the eastward of it. These two islands are the southernmost of an extensive group of islands lying close together, and to the northward of which, between them and the Singapore shore, is the navigable channel named Salat Sambulan.

The outermost reef on the North side of the Sinki Channel, and which may be considered to form its north-western limit, is a small patch lying W. $\frac{3}{4}$ N. $1\frac{1}{2}$ mile from the beacon on the small patch last mentioned; W.S.W. 1 mile from the West end of Pulo Laut, and N.E. by E. $\frac{1}{2}$ E. $2\frac{1}{4}$ miles from the Sultan Shoal; this patch is not marked by a beacon.

South Side.—The South side of the channel is marked by four *red beacons*, the whole of them being nearly in line on a W. by S. and E. by N. bearing, and almost equidistant from each other. The easternmost beacon, bearing S. by E. $\frac{3}{4}$ E., about three-quarters of a mile from the eastern beacon on the Cyrene Shoals, is placed on the northern edge of the reef which surrounds *Freshwater Island*, or *Pulo Bookum* and *Pulo Oelar*. The next beacon, almost a mile distant, is on the edge of the reef which extends from Pulo Bosing. Westward of this last are two reefs, which dry at three-quarters ebb, and their northern edges are each marked by a beacon.

Pulo Salook, a small islet, 90 ft. high, may be considered as the south-western limit of the Sinki Channel. It is surrounded by a reef, which projects nearly a quarter of a mile from it, and other patches of reef lie in a S.S.W. direction, and extend more than half a mile from it. Pulo Salook bears S. $\frac{3}{4}$ E. nearly $2\frac{1}{4}$ miles from the beacon on the reef South of Pulo Laut, S.E. by E. $2\frac{3}{4}$ miles from the reef which forms the north-western limit of the strait, and E. by S. $\frac{3}{4}$ S. $3\frac{3}{4}$ miles from the tripod beacon on the Sultan Shoal.

Directions.—Coming from the westward, and intending to proceed through the Sinki Channel, a course may be steered to sight the tripod beacon on the Sultan Shoal, which may be passed at a prudent distance on either side. But to provide against the chance of the beacon having disappeared, or in the event of thick weather, the safer plan will be to steer for Pulo Salook—which, being a small round islet 90 ft. high, can be readily distinguished—on an East, or E. $\frac{1}{2}$ S. bearing. When the tripod beacon is made out,* and is brought to bear from N.N.W. to N.W., steer from E. by N. to E.N.E., giving Pulo Salook a berth of $1\frac{1}{4}$ mile; after it is passed keep a good look-

* If the tripod beacon upon the Sultan Shoal cannot be seen, a vessel should not proceed until she is quite certain of her position, and assured that some accident must have happened to the beacon. As the mail steamers, both to and from Europe, now pass through the Sinki Channel, great attention is paid to the beacons which mark it.

out for the outer beacons on either side of the channel, when it will be only necessary to steer mid-channel between them.

The same course, E. by N.—always remembering to guard against the effects of tide—will lead to the entrance of New Harbour, which should also be entered in mid-channel, taking care not to get too close over towards Berlayer Point, and to keep the conspicuous red bluff, which will be seen on the South side of the harbour, well open of the P. and O. Company's jetties, to clear the Berlayer Rock. It is very necessary, however, when taking care to avoid this rock, not to get too close over on the opposite side, as has sometimes happened. The best plan is to keep as nearly as possible in mid-channel.

The Tides are very irregular in the passages among the islands, running sometimes 4 miles per hour at springs.

ST. JOHNS ISLANDS, which limit Singapore roads to the south-westward and form the eastern limit of the North side of this part of Singapore Strait, will be described presently.

The **SISTERS** are two small islets, not quite a mile to the westward of West St. Johns Island; the South Sister, named *Pulo Soobur*, is 89 ft. high. They are surrounded by reefs, which in places extend to the distance of a cable's length, and close to their edges are irregular soundings of 5 to 9 fathoms. South from the South Sister the soundings soon deepen to 10, 12, 16, and 18 or 19 fathoms. The channel between them and West St. Johns is free from danger, with depths of 14 to 24 fathoms; but about one-third of a mile West-southerly from the South Sister is the eastern end of a patch, with 18 ft. water over it, which thence extends one-third of a mile to the W.N.W.

MIDDLE ISLAND, or *Pulo Sabaroot*, 78 ft. high, bears W. by S. $3\frac{1}{2}$ miles from West St. Johns, and N.E.-easterly $4\frac{1}{2}$ miles from Raffles lighthouse. It is a green island, with other islands to the north-westward of it. It is surrounded by a reef, which, from its S.E. point, projects nearly a third of a mile.

A **Dangerous Reef** of rocks lies S.E. by E. three-quarters of a mile from the S.E. point of Middle Island. The reef is small, and always covered, except at very low tides, some points of the rocks being then just discernible. From it the South extreme of West St. Johns Island bears E.N.E. 3 miles, Raffles lighthouse S.W. by W. $\frac{1}{4}$ W. $4\frac{2}{3}$ miles, and Buffalo Rock S. by E. $\frac{1}{4}$ E. The chart shows no soundings on the South side of this reef, but there is said to be deep water close to; on the North side it is said to be a steep coral wall, and the chart shows 8 fathoms close to this side.

Pulo Jong, a small round islet 75 ft. high, lying half a mile N.W. of Middle Island, open eastward of Middle Island, leads N.E. of the reef, and the South point of West St. Johns N.E. by E. $\frac{1}{2}$ E., or Raffles lighthouse S.W. by W. $\frac{1}{2}$ W., leads to the southward. The South peak of Carimon

Island, in line with the North part of Barn Island, W. by S. $\frac{1}{4}$ S., also leads to the southward of it.

The North side of the channel between Barn Island and Middle Island is bounded mostly by shoals and coral reefs, partly dry at low water. Nearly $2\frac{1}{4}$ miles S.W. by W. from Middle Island is a reef, the middle part of which is dry.

The **RABBIT** and **CONEY** are two small islets, on the North side of the western entrance to the main channel, nearly connected with the S.E. end of Barn Island, to the North of it, by a reef of rocks partly dry at low water. The Coney, or southernmost, is the smallest, and distant from the point of Barn Island rather less than one-third of a mile. The Rabbit is on with the centre of Barn Island bearing N.W. $\frac{3}{4}$ W.; the Coney is on with it, N.W. $\frac{3}{4}$ N., nearly; and these islets are in one with each other, bearing N. by E. $\frac{1}{2}$ E. A rocky spit, covered at high tide, projects nearly a cable's length to the southward from the Coney; consequently the islet should be given a berth of 2 cables.

RAFFLES LIGHTHOUSE, on Coney Island, was named after Sir Stamford Raffles, the founder of Singapore. It is in lat. $1^{\circ} 9' 51''$ N., long. $103^{\circ} 44' 51''$ E., and exhibits, at an elevation of 105 ft. above high water, a *fixed bright light*, which is visible from a ship's deck at the distance of 12 miles, between the bearings E.S.E. (being obscured over the St. Johns Islands and Middle Island, and its off-lying reef) and N.W. by W., which latter bearing leads 1 mile S.W. of Sultan Shoal. It bears S.W. by W. $\frac{1}{2}$ W. $7\frac{1}{2}$ miles from the South end of West St. John's Island; E. $\frac{1}{3}$ N. nearly $5\frac{1}{2}$ miles from the North end of Tree Island Reef; S.E. $\frac{1}{2}$ E. nearly $7\frac{1}{2}$ miles from the Sultan Shoal; N.W., westerly, 3 miles from Helen Mars Reef; and West, northerly, $4\frac{1}{2}$ miles from Buffalo Rock.

BARN ISLAND, or *Pulo Sennang*, about a mile in extent and 133 ft. high, lies close to the N.W. of the Rabbit and Coney, and E. by N. $\frac{1}{2}$ N. 5 miles from Tree Island. It is of a square, level aspect, covered with trees, and visible at the distance of 15 miles. Its South and West sides are fronted by a reef extending 2 or 3 cables from it, close to which are 9 or 11 fathoms, with 18 and 19 fathoms a short distance off.

ALLIGATOR ISLAND, or *Pulo Runcan*, nearly joins the N.W. end of Barn Island, the space between affording no passage for ships. It is about the same size, but 52 ft. higher than Barn Island, and of a sloping form, the highest part being at its South end. At a quarter of a mile from its South end are 14 and 16 fathoms, but off its West side not more than 6 to 9 fathoms will be obtained at half to two-thirds of a mile.

A mile to the northward of Alligator Island is a small island, *Pulo Soodong*, inside which, between *Middle* and *Freshwater Islands*, are several islands, with numerous coral reefs amongst them, the exact positions of which are

unknown; these islands and dangers lie quite out of the track of shipping. Pulo Salook, the north-westernmost of them, and also the S.W. limit of the Sinki Channel, is described at page 359.

SULTAN SHOAL (*Terumbo Careemon*), which forms the north-western limit of the western entrance to Singapore Strait, is of circular form, about two-thirds of a cable's length in diameter, and the rocks on its shoalest part are about 2 ft. above the sea at low-water spring tides. The ship of that name grounded on it in 1789. Its North side is marked by a tripod *beacon*, painted in red and white stripes, from which the N.W. extreme of Tree Island Reef bears S. $\frac{1}{4}$ E. 5 miles; Pulo Salook E. by S. $\frac{3}{4}$ S. $3\frac{3}{4}$ miles; and Raffles lighthouse, just open of the West extremes of Alligator and Barn Islands, S.E. $\frac{1}{2}$ E. $7\frac{1}{4}$ miles. Captain Ross examined this shoal in 1829, and reported it to be steep-to, 7 fathoms water within a boat's length of the rocks.

Ajax Shoal, on which the steam vessel of that name touched in 1877, lies 1 mile S.E. by E. $\frac{1}{2}$ E. from the Sultan Shoal beacon; this shoal, composed of coral with sharp pinnacles, is about half a cable in extent N.E. by N. and S.W. by S., and has on its S.W. extremity a depth of 19 ft., at low water, spring tides. A *nun buoy*, painted *red*, has been placed by the Master Attendant at Singapore, on the centre of Ajax Shoal; this buoy should be given a berth of 2 cables when passing it, on either side.

The following bearings were taken from the *Grouler* whilst at anchor in 5 fathoms, on the shoal:—viz., Sultan Shoal beacon, N.W. by W. $\frac{1}{2}$ W.; Raffles lighthouse, S.E. $\frac{1}{2}$ E.; and Tanjong Bolus, W. by N.

The line of islands and shoals which lie to the south-westward of these Round, Long, Red, and Tree Islands, &c. which form the N.E. limit of the strait of Durian, has been described on page 349 previously.

SOUTH SIDE of the STRAIT.—The strait between the rocky ledges north-westward of Little Sambo and St. John's Islands (described in p. 371), is $2\frac{1}{2}$ miles wide, with very irregular soundings, varying from 15 or 16 to 40 or 50 fathoms.

Caution.—Owing to the *strong tides* which rush through this part of the strait, and the rocky and uneven nature of the bottom, violent eddies and overfalls, very alarming to strangers, are usually to be met with, more especially on the South side of the channel, towards the Sambo Islands; for which reason, as also because of the dangers and great depths of water on that side, it is advisable to keep on the North side, near St. John's Islands, —a custom, always followed by those accustomed to the navigation of the strait.

The Coast.—That part of the southern side of Singapore Strait between the Sambo Islands and the north-western extreme of Boelang Island, a distance of $7\frac{1}{2}$ miles to the S.W. by W., is formed of numerous islands lying

on either side of the entrance of Batu Hadji Strait, which separates the large islands of Battum and Boelang.

Pulo Sennang, the outermost of the islands at the eastern side of entrance to Batu Hadji Strait, is only about a third of a mile in extent, and bears S.W. by W. $\frac{1}{2}$ W. about $1\frac{1}{2}$ mile from the N.W. extreme of Little Sambo, and S. by E. $\frac{3}{4}$ E. 3 miles from West St. Johns. Westward of this island there are many dangers.

Barren Island, the outer of the small islands on western side of entrance to Batu Hadji Strait, is a mere rock or islet, and bears S.W. by W. $\frac{1}{2}$ W. $2\frac{1}{2}$ miles from Pulo Sennang; S. by W. $\frac{1}{4}$ W. $4\frac{1}{4}$ miles from West St. Johns; and S.E. by E. $\frac{1}{4}$ E. $1\frac{1}{4}$ mile from Buffalo Rock.

Near Pulo Sennang are depths of from 7 to 12 fathoms. Barren Island appears to be free from danger, with depths of 13 to 18 fathoms between it and Buffalo Rock; but, as previously remarked, vessels should avoid getting on this side of the strait.

Buffalo Rock, lying well out towards the fairway of the strait, is of a black colour, about the size of a long-boat, always above water, with 30 and 40 fathoms water near it to the southward, and irregular soundings of 13, 18, and 25 fathoms close to it on the N.W. side. It bears S.W. by S. 4 miles from the South extreme of West St. Johns; S.S.E. 3 miles from Middle Island, and East-northerly from Raffles lighthouse.

Between the Buffalo Rock and the reef off the S.E. end of Middle Island, the strait is $2\frac{1}{2}$ miles, the same breadth as between the rocky ledges and West St. Johns. It is prudent, in working here, to keep nearest the North side of the channel, making short tacks, and not to deepen above 30 or 34 fathoms towards the Buffalo Rock, and the South side of the strait.

Tides.—The flood from the straits of Malacca sets to the eastward, and the flood from the China Sea sets to the westward, meeting between Tanjong Bolus and Tree Island. It is high water at Rabbit Island at full and change at 11 a.m., but the tide does not set to the eastward till about 1 p.m., and it is then about half low water by the shore.

The tides set fairly through the channel about E.N.E. and W.S.W. between St. John's Islands and Raffles lighthouse, frequently very strong, with eddies on the springs. Their velocity, when strongest, is from 4 to $4\frac{1}{2}$ miles per hour, making it unpleasant to anchor here in large ships when the weather is unsettled in the night, particularly if unacquainted. From Raffles lighthouse to the western entrance of the strait the tides cannot be depended on to set as fairly through the channel as they do to the eastward of the lighthouse, but may be expected to draw more across the channel in a north-easterly or opposite direction. Outside the strait between Tree Island and Tanjong Bolus no dependence can be placed upon the set of the tides, for they sometimes run strong down towards the straits of Durian, and at other times to the northward towards the old strait of Singapore.

The flood has been observed in both monsoons to run to the westward 10 or 12 hours at a time, or even 18 hours, strong and weak alternately; at other times the flood sets only 6 hours to the westward, and the ebb the same length of time to the eastward; but the tides throughout Singapore Strait are seldom very regular.

During the strength of the N.E. monsoon at neap tides, the current sets to the westward at times for three or four days, although there is a regular rise and fall by the shore. Staff Commander Richards, R.N., commanding H.M.S. *Saracen*, found the rise and fall in New Harbour to be 10 feet at springs and $7\frac{1}{2}$ feet at neaps.

Temporary Anchorages.—Owing to the strong tides and currents in the western part of Singapore Strait, sailing vessels are frequently obliged to anchor, for which purpose the North side of the channel is much to be preferred. The most convenient spot for the purpose between St. Johns and Raffles lighthouse, are the banks which front the Sisters and Middle Islands. (See page 360.)

Abreast of the South end of St. Johns a ship ought not to anchor if it can be avoided, for the water is deep, and the tides run in eddies with greater strength than in any other part of the strait.

There appears to be fair anchorage, in 12 to 19 fathoms, a mile or two on either side of Buffalo Rock, or between it and Barren Island; also between it and Helen Mars Reef, as well as about a mile or so to the northward and westward of the latter danger; but this side of the strait is usually avoided as much as possible even by those locally acquainted.

To the westward of Raffles lighthouse there is convenient anchorage in 6 to 12 fathoms all along the North side of the strait, while to the southward the water is deep, and the bottom rocky; the South side of this part of the strait is, therefore, very unsuitable for anchoring purposes, especially when it is remembered that violent squalls are common hereabouts.

Caution.—Vessels at anchor, or coming to an anchor during the night, should be careful to ascertain their exact position as nearly as possible, and to have a *good bearing of Raffles light*; they should also keep a vigilant lookout that they do not drag their anchors, and drift into danger.

Directions.—To proceed from *Singapore Roads* or from the eastward, through the western part of Singapore Strait, steer to pass the South point of St. Johns Islands as close as the wind may permit, and then about S.W. by W. $\frac{1}{2}$ W. to round the Rabbit and Coney. It is best to keep nearest the North side of the channel in this track, to avoid the Buffalo Rock, and the deep water and rocky bottom towards the South shore; but remember the reef off the S.E. end of Middle Island. The South end of St. Johns kept N.E. by E. $\frac{1}{2}$ E., or Raffles lighthouse S.W. by W. $\frac{1}{2}$ W., leads clear of this

reef, and either of these are safe bearings to lead along the North side of the channel until Raffles lighthouse is approached, which may be rounded at the distance of 2 or 3 cables' lengths, if the wind is northerly.

After rounding the lighthouse, steer W.N.W. to pass between Tree Island and Sultan Shoal; the lighthouse kept between E. by S. and E.S.E. will lead in a good fairway course, but it must not be brought at all to the northward of East to avoid Tree Island, or to the southward of S.E. by E. to clear the Sultan Shoal; having passed between those dangers, a course West or W. by N., according to the set of the tide and other circumstances, will lead between Little Carimon and Tanjong Bolus.

At Night.—Raffles light (page 361) kept in sight clears all dangers on the North side of the channel, both to the eastward and westward of it.

To proceed from Little Carimon to the eastward through the western part of Singapore Strait.—When in mid-channel between Tanjong Bolus and Little Carimon, in 17 to 20 fathoms water, steer East or E.S.E. as the prevailing wind and tide require, observing to bring the North point of Little Carimon W. $\frac{1}{2}$ S., or draw gradually the North peak of Great Carimon in one with the South point of Little Carimon, bearing about W. by S. $\frac{1}{2}$ S., which will lead about 2 miles northward of Tree Island. If the wind is southerly, borrow towards Tree Island to 14 fathoms, about a mile distant, but no nearer, which will favour the vessel in rounding the Rabbit and Coney.

As before stated, Raffles lighthouse bearing between E. by S. and E.S.E., is the fair channel course between Tree Island and Sultan Shoal, not bringing the lighthouse to the northward of East to avoid Tree Island, nor to the southward of S.E. by E. to clear the Sultan Shoal. Having passed Tree Island, steer to round the lighthouse at from 2 cables' lengths to 1 or 1 $\frac{1}{2}$ mile distant; or if the wind and tides are adverse, or from other circumstances it be desirable to do so, anchor to the westward of Barn Island, out of the strength of the tide. Having rounded the lighthouse, steer to pass St. Johns Islands at a convenient distance—from 2 cables' lengths to a mile—not bringing the lighthouse to the southward of S.W. by W. $\frac{1}{2}$ W., or the South point of St. John's to the eastward of N.E. by E. $\frac{1}{2}$ E., to avoid the danger on the North side of the channel. After rounding St. Johns, and bound to Singapore Roads or through the eastern part of the strait, proceed as directed hereafter.

In working through between St. John Islands and Raffles lighthouse, it is usual to keep on the North side of the channel, making short tacks if necessary, as that part of the strait affords tolerably convenient anchorage along the greater portion of it, and vessels are extremely liable to meet with light baffling airs, which would render it necessary for them to anchor. It is especially requisite to attend to this when to the eastward of Buffalo Rock, for on that part of the South side of the strait the water is deep, and the

bottom rocky and unsafe for anchoring upon, the danger being much increased by rapid currents and tides, with violent eddies and overfalls.

All danger on the North side of this part of the channel will be avoided if the South extreme of St. Johns Islands be not brought eastward of N.E. by E. $\frac{1}{2}$ E., or Raffles Lighthouse southward of S.W. by W. $\frac{1}{2}$ W., but these bearings more particularly apply to the rock which lies S.E. by E. from Middle Island. Vessels may, with proper precaution, stand farther over between the Sisters and Middle Island, and bring the South end of St. Johns as far as E. by N. Take care, however, when nearing Middle Island, not to bring Pulo Jong on with the East extreme of Middle Island until the lighthouse bears S.W. by W. $\frac{1}{2}$ W., or the South end of St. Johns N.E. by E. $\frac{1}{2}$ E. When to the westward of the rock, which may be known by seeing Pulo Jong open of the West side of the island, a vessel may stand to the northward until the South end of St. Johns bears E.N.E., but nothing to the eastward of that bearing. At *night*, Raffles light kept in sight leads clear of all dangers on the North side of the strait, as before stated.

The narrowest part of the channel is when Buffalo Rock bears S. by E. to South, between it and the rock lying south-eastward of Middle Island; and to know in the night when the vessel is in this part of the channel, Middle Island will in general be perceived nearer, and more distinctly than the other islands on the North side of the channel. When approaching the meridian of Buffalo Rock, or when Middle Island bears about N.N.W., be careful to keep Raffles Lighthouse to the southward of W. $\frac{3}{4}$ S.; on no account must it be brought to the westward of W. $\frac{1}{2}$ S. when Middle Island bears N.N.W. When Middle Island bears N. by W., the vessel will be westward of Buffalo Rock, and in daylight may stand farther to the southward, if necessary; but it is much safer and better to keep over towards the Coney. If, however, a board should be made to the southward, take care to keep clear of Helen Mars Reef (page 350).

SINGAPORE.

SINGAPORE, properly Singhapura—*i.e.* Lion City, the great British emporium of the Indian Archipelago, was acquired by purchase in 1819; and in 1826 was formed into one government with Penang and Malacca. It now ranks as the fourth European city of India, being exceeded by Batavia, which the Dutch founded just two centuries previously, in 1619; a century before Calcutta was established, and 50 years before Bombay became a British settlement.

Singapore was the first experiment in free trade. Its success is measured by its progress. In 1819, the population of the island consisted of 150 miserable fishermen; seven years after it amounted to 13,000; in 1850 it

reached 60,000, and in 1865 it was 90,700, among whom were 58,000 Chinese, 13,500 Malays, and about 800 Europeans. In this population the disproportion of the sexes was most startling; to six men there was but one woman, taking the whole inhabitants of the island; but among the Chinese this difference was still greater, only one woman to eighteen men. In the census of 1871 the number of the population was returned as 88,032, but doubts exist as to the accuracy of the returns, and the number is probably much larger. Of the returned number, about one quarter were females; of Malays there were 19,250, and the sexes were about equal in number: Chinese, 54,098, of whom 7,467 were females; natives of India, 11,191, about one quarter of whom were females; Eurasians (half-castes) number 2,164, and the females outnumber the males; the white, European and American population, numbered 1,329. Altogether there are about fifteen nationalities among the people, who, preserving generally their own languages, make use of the liquid, easily acquired Malay, as a common medium of intercommunication. In 1863 its imports reached six and a half millions sterling, and its exports five and a half millions, together twelve millions sterling. In 1875 the imports had decreased to four and a quarter millions, and the exports to four millions sterling, which decrease is accounted for by the fact that goods are now shipped direct to China and other places, instead of being transhipped at Singapore. In 1875, 2,261 vessels arrived at the port, with an aggregate tonnage of 1,283,786 tons, or an average of 568 tons each.

The Island of Singapore is about 25 miles long, and 14 in its greatest breadth; area, 206 square miles, or one-fourth larger than the Isle of Wight. It is separated from the Malay main land by the Old Strait before mentioned, once the great thoroughfare, now abandoned for the more open and well beaconsed passage to the southward. Except on the shore of this strait, the British settlement extends 10 miles inland, while to the southward and with the islands, 75 in number, the whole area of the settlement comprises an area of 223 square miles. The island has the appearance of one continuous forest, with undulating surface, the highest hill being 519 ft. high, and nearly in the middle of the island.

It was ceded to Britain by the Sultan of Johore, on February 6th, 1819, and the city was then founded by Sir Stamford Raffles. He was succeeded by the late talented historian of the Indian Archipelago, Mr. John Crawfurd, F.R.G.S., in 1823, who established the present laud-tenure; he was succeeded, in 1827, by Mr. Murchison.

The following description of the town and harbour is taken, like the foregoing portion of the work, from the *China Sea Pilot*.

The Town of Singapore is built on each side of the Singapore River, a small stream, only navigable for boats, on the S.E. side of the island, about 4 miles northward of the South extremity of the St. John's Islands. The

commercial part of the town is on the South side of the river, the bank on that side being lined with quays and godowns for the landing and reception of merchandise. The river is usually crowded with cargo boats and many other descriptions of small craft on their way to and from the ships in the harbour, presenting a scene of extraordinary bustle and activity. Singapore is a free port; there are no harbour or tonnage dues.

Fort Fullerton, a small battery, stands on the southern part of the entrance to Singapore River. It is important from being the point to which it has been customary of late years to refer the meridian distances of this portion of the Archipelago. The latitude and longitude of Fort Fullerton now used is $1^{\circ} 17' 20''$ N., and $103^{\circ} 51' 18''$ E. A handsome line of godowns is erected to the southward of the fort, upon some land reclaimed from the sea for that purpose. These buildings are conspicuous when approached from the eastward; and in 1867 an extensive system of fortifications was in progress.

The principal landing place is at the Dalhousie Pier, a structure of stone and wood, on the northern side of the entrance to the river, projecting over the flat which extends from the shore some distance to seaward. An obelisk stands near the inner end of the pier, and around it are *four red* lights, which serve to point out the position of the landing place at night. A *white* light is shown on the outer end of the pier. Close to the left of the obelisk (as viewed from seaward) are two fine buildings; the one standing back is the court-house, and that nearer the sea the town hall. Farther to the left is the post-office, a very mean-looking building, and still farther to the left, on the bank of the river, is the office of the master-attendant.

On the right of the obelisk, the esplanade, a grass enclosure surrounded by a carriage drive, extends along the sea front for the distance of a quarter of a mile, and the drive round it is the fashionable resort of the European residents in the cool of the evening. Behind the esplanade are three large buildings, the two farthest to the left are used as hotels, and the third is the masonic hall. To the right of these buildings stands St. Andrews Church, one of the finest ecclesiastical structures in India, built after the model of Netley Abbey; the church has a fine tower, surmounted by a lofty spire, which is very conspicuous when viewed from seaward. To the right of the church is a very large building, the Raffles Institution; extending from which, in the same direction, are a number of handsome detached houses, standing in gardens. Beyond this line of houses is an extensive native town, the greater part of which is hidden by the sandy point, named Tanjong Rhoo.

The above is a brief description of the most prominent objects seen along the shore of Singapore Bay, when viewed from the anchorage.

SINGAPORE ROADS* are on the southern side of Singapore Island, their

* THE LIMITS OF THE PORT OF SINGAPORE ARE AS FOLLOW:—From an obelisk built on Tanjong Catong in a straight line to Peak Island; along the northern shore of that island

limit being defined by a line drawn from an obelisk on Tanjong Catong, $2\frac{1}{2}$ miles E. by N. from Fort Fullerton, to Peak Island. The usual anchorage, however, for ships taking in and discharging cargo, and which is generally known as Singapore Harbour, is restricted to that part of the roads comprised within the limits defined by a line drawn from Malay Point in an easterly direction, until it meets the line drawn between Tanjong Catong and Peak Island, and which includes a space about one-third of the extent of the entire roads.

TANJONG CATONG, or *Deep-water Point*, forming the north-eastern boundary of Singapore Roads, is $3\frac{2}{3}$ miles W.S.W. from the small Red Cliffs. An obelisk, which marks the harbour limit in this direction, stands about a cable's length to the westward of the round of the point.

Sand-Banks.—Lines of fishing-stakes run out from the coast about Tanjong Catong, over the shallow bank extending from the coast, and close to the ends of the stakes are 6 and 7 fathoms water, but these soundings are in a narrow run of deep water, behind the harbour bank, the 5-fathom line at the edge of which is about three-quarters of a mile distant from the point.

Between the deep water close to the point and the 5-fathom line outside of it, are several patches with but $2\frac{1}{2}$ and $2\frac{3}{4}$ fathoms water over them, and two patches with as little as 2 fathoms. One of the latter lies S.E. by E. $\frac{1}{2}$ E. from the obelisk, distant half a mile from the shore nearest to it; and the other S. by W. $\frac{1}{3}$ W. nearly three-quarters of a mile from the obelisk.

These shoals will be avoided by keeping Mount Serapong westward of S.W. by W. $\frac{1}{2}$ W. until the flagstaff on Fort Canning bears W. by N. $\frac{1}{2}$ N.; or by not shoaling under a depth of 6 fathoms towards them.

Tanjong Rhoo, or *Sandy Point*, is the extreme of the land extending $1\frac{3}{4}$ mile West from Tanjong Catong, and forming the northern shore of Singapore Bay. It bears N.E., a little over three-quarters of a mile from the entrance of Singapore River, and is separated from the western shore of the bay by a channel a quarter of a mile wide, in which there are but 3 to 7 ft. water at low spring tides.

to its north-westernmost point, thence in a straight line to its southernmost point of Blakang Mati, thence along the eastern and northern shores of that island to the north-westernmost point thereof, thence in a straight line to a mark placed at Batu Blaayer (Lot's Wife) on the island of Singapore, thence along the shores of the island of Singapore, to the obelisk at Tanjong Catong, including the mouth of the Singapore River as far as the second or Coleman's Bridge, also the mouths of the Rochore and Kallang Rivers as far as the first bridges crossing those streams, and including the public streets, roads, or high-ways, made or to be made along the banks of these rivers to the limits specified and including all public landing-places, stairs, piers, or jetties, made or to be made along the shores of the island of Singapore.

Inside Tanjong Rhoo is an extensive shallow lagoon, convenient for the anchorage of boats and native craft, and very many such are to be seen there at certain seasons. Some shipwrights' yards are now established at this point, and small vessels go there to be repaired.

FORT CANNING.—Rising abruptly behind, and overlooking the town of Singapore, is a hill, 156 ft. high, upon which formerly stood a large bungalow, the residence of the governor; now, however, the crest of the hill is covered by a large fort, which has been named *Fort Canning*, in honour of the late Viceroy of India. Near the middle of the fort is a flagstaff, crossed with two yards, which is used during the day to signal the arrival of ships.

Light.—A *fixed* white light is exhibited from the flagstaff on Fort Canning, at an elevation of 226 ft. above the level of the sea. It is a bad light, but in clear weather is said to be visible at 15 miles. It is only shown over an arc of 90°, or between St. John's Island and Johore Shoal.

A mud flat fronts the whole shore of Singapore Bay from abreast of Tanjong Catong to Malay Point. In front of the esplanade it extends rather more than a cable's length, in front of Fort Fullerton and the new godowns, not more than half a cable, but in the bay to the southward, towards Malay Point, its distance from the shore is nearly 2 cables.

MALAY or **Malang Point**, the south-western limit of Singapore Bay bears S.W. by W. $\frac{1}{4}$ W. nearly 3 miles from the obelisk on Tanjong Catong, and S. by W. $\frac{3}{4}$ W. nearly a mile from the entrance of Singapore River. A mud and sand flat, with several patches of rocks upon it, and which dries at two-thirds ebb, fronts the small bay between Malay Point and Pagar Point. That part of the bank which extends from Pagar Point, and on which the sea wall is built, is known as *Pagar Spit*, and that extending from Malay Point as *Malay* or *Malang Spit*. Shoal water, under 3 fathoms, extends some distance outside the flat, and its edge is marked by several lines of fishing stakes.

BLAKAN MATI ISLAND lies to the southward of the southern part of Singapore Island, from which it is separated by a channel, known as New Harbour. The island is 2 miles long W.N.W. and E.S.E., and a mile broad at its eastern extreme, but its western end terminates in a point. It is fringed by a reef, which from *Berala Point*, its north-eastern extreme, projects a quarter of a mile to the eastward; this part of the reef is known as *Berala Spit*, and from its outer part *Berala Point* bears W. $\frac{3}{4}$ S., and the hill over *Pagar Point* N. $\frac{1}{4}$ W.; from thence it trends about S. by W. for the eastern extreme of the island, from which it projects but a short distance. Off the South point of the island the shore reef extends about three-quarters of a cable's length, and about the same distance along its West side; but a small detached reef, named *Pelawan*, about $1\frac{1}{2}$ cable in extent, lies 2 cables' lengths off the West shore of the island, nearly midway between its southern and western extremes.

MOUNT SERAPONG, rising to the height of 302 ft. near the north-

eastern extreme of Blakan Mati, is conspicuous when approaching Singapore Roads from the eastward, and will assist a stranger in making out the land, St. Johns Islands being seen to the southward of it. There are several other hills of less height than Serapong upon Blakan Mati, but they are more observable in coming from the westward, when they will be seen under the higher land of Singapore Island.

Over *Rimau Point*, the West extreme of the island, is *Mount Siloso*, 170 ft. high, to the eastward of which, and South from *Berdaun Rock*, is *Mount Imbeah*, 202 ft. high. South-eastward from Imbeah is a hill, 168 ft. high, westward of which is another, 160 ft. high.

Buran Darat is the name of an extensive coral reef, which uncovers at two-thirds ebb, and fronts the eastern shore of Blakan Mati Island. It is about a mile long, N.E. by N. and S.W. by S., a quarter of a mile broad at the northern end, and terminates in a point at its southern extreme. There is a detached patch, with $1\frac{1}{2}$ fathom on it, lying about a cable's length to the northward of the North edge of the reef. The north-eastern extreme of *Buran Darat* is marked by a *white beacon*, from which *Berala Point* bears W. $\frac{1}{4}$ N., distant nearly two-thirds of a mile, and the hill over *Pagar Point* N.N.W., westerly.

ST. JOHN'S ISLANDS, three in number, form the south-western limit of Singapore Roads. They lie about N.E. by E. and S.W. by W. from each other, extending nearly a mile in those directions.

Peak Island, or *Pulo Tambakool*, the north-easternmost of the three, is a mere islet, rising to a peaked hill 101 ft. high. From its western part a low, narrow, sandy neck extends, on the extreme of which is a small mound, which at some little distance appears like a separate islet. The island is encompassed by a reef.

The Middle Island, known as *East St. John's Island*, is about half a mile long N.W. and S.E., a quarter of a mile broad, 189 ft. high, and sloping in form. It is also surrounded by a reef.

West St. John's Island is rather larger than *East St. John's*, but not quite so high. Its N.E. extreme is joined to the main body by a narrow neck of lower land, which at a little distance gives it the appearance of a separate islet. Between these islands are narrow channels about half a cable wide, with depths of 6 to 16 fathoms in them.

In the space between Blakan Mati and *St. John's Island* are a few small islands and several extensive reefs. Between the latter are channels of deep water, but they are so narrow and intricate as to be useless for the purposes of ordinary navigation.

Pulo Sikookur, about half a mile long N.W. by N. and S.E. by S., but very narrow, lies nearly mid-channel between *West St. John's* and *Blakan Mati* Islands. *Pulo Ringat* is the easternmost of two small islets which lie close to the north-eastward of *St. John's Islands*.

To avoid all the dangers between St. John's Islands and Malay Point, Peak Island must not be brought to the eastward of S. $\frac{1}{2}$ E., when Mount Serapong bears to the northward of W.N.W. When Mount Serapong is to the westward of W.N.W., a vessel may stand on until the western extreme of West St. John's Island bears S. by W. $\frac{1}{2}$ W., but no farther.

Outer Bank and Shoal.—A mud-bank, with general depths of 10 to 4 fathoms over it, extends across the outer roads of Singapore, from the St. John's Islands to abreast of Tanjong Catong, where it takes the direction of, and fronts, the coast some distance to the north-eastward.

The least water on this bank is about the middle of it, and it is this part which is generally known as the Outer shoal, which is $1\frac{1}{2}$ mile long N.E. and S.W., a cable broad at its northern, and nearly half a mile broad at its southern end, having depths of 4 to $4\frac{3}{4}$ fathoms over the greater part of it, but some patches of $3\frac{1}{2}$ and $3\frac{1}{2}$ fathoms near its southern extreme. *This bank is shoaling rapidly.* From the N.E. end of the shoal, in 5 fathoms, the obelisk on Tanjong Catong bears N. $\frac{3}{4}$ E., Fort Canning flagstaff is just to the northward of the obelisk on the Dalhousie Pier N.W. by W. nearly, and Peak Island bears S.S.W. $\frac{1}{2}$ W.; from its south-eastern extreme Fort Canning flagstaff bears N.N.W. $\frac{1}{4}$ W., and Peak Island S. by W. $\frac{1}{2}$ W.; and from its south-western extreme the same flagstaff bears N.N.W., and Peak Island S. $\frac{1}{4}$ W.

Fort Canning flagstaff open northward of Dalhousie Pier, bearing N.W. by W. $\frac{1}{4}$ W., will lead clear of the North end of the outer shoal; Peak Island S.W. by S. will lead eastward of it; and the southern extreme of Blakan Mati Island S.W. by W. $\frac{1}{2}$ W. will lead westward.

North-eastward of the Outer shoal the bank is not quite three-quarters of a mile broad, with depths of 6, 7, and 8 fathoms over it. South-westward of the Outer shoal the soundings on the bank are not so regular, and a hole of deep water, half a mile long, runs into the bank in a north-westerly direction about three-quarters of a mile from St. John's Islands.

A small patch, about 2 cables in extent, having 4 fathoms least water over it, lies about a third of a mile south-westward of the Outer shoal, and from its centre Fort Canning flagstaff bears N.N.W.-northerly, Peak Island S. $\frac{3}{4}$ W., and Mount Serapong W. by N. $\frac{1}{4}$ N. Mount Serapong bearing W. $\frac{3}{4}$ N. leads between this patch and the Outer shoal, and bearing W. by N. $\frac{3}{4}$ N. leads to the southward of it.

Peak Island bearing S.W. leads just outside the 10-fathom line at the edge of the bank in from 11 to 13 or 14 fathoms; the soundings quickly deepening to 17, 20, 25, and 30 fathoms south-eastward from the middle and southern part; and to 17 and 20 fathoms south-eastward from the northern part of the bank.

Inside the Outer Shoal are 10 to 12 fathoms, mud, decreasing gradually to 7 or 6 fathoms, but shoaling suddenly from a depth of 5 to 4 or 3 fathoms,

when Fort Canning flagstaff bears to the northward of N.W. by W. $\frac{1}{2}$ W., demanding caution in large ships anxious to get as close in as possible. With Fort Canning flagstaff to the westward of N.W. by W. $\frac{1}{2}$ W., the soundings decrease much more regularly. The 2-fathom line extends nearly half a mile south-eastward of Fort Fullerton, and nearly three-quarters of a mile from the depth of Singapore Bay. The extremity of the north-eastern line of fishing-stakes marks the 3-fathom edge of the shore bank, eastward of Malay Point.

Near the north-eastern extreme of the Duran Darat Reef is a run of deep water—12 to 23 fathoms—which terminates about half a mile E.S.E. from Malay Spit.

Anchorage.—The trade of Singapore is now so considerable that a large number of vessels are always to be found anchored in that part of the roads called the harbour, and small vessels may run in, guided by their soundings, and anchor where they can find a convenient berth.

Vessels of large draught must be more cautious, on account of the soundings decreasing suddenly from 5 to 4 and 3 fathoms. Good, safe anchorage, in from 7 to 10 fathoms water, will be found with the flagstaff on Fort Canning between the bearings of W. by N. $\frac{1}{2}$ N. and N.W. $\frac{1}{2}$ N., and with Mount Serapong bearing S.W. by W. $\frac{1}{2}$ W., or the left extreme of Blakan Mati S.W. $\frac{1}{2}$ W.; the latter bearing places a ship a little further in, and is useful when the flagstaff is to the westward of N.W. by W.

Directions.—Small vessels bound to Singapore Roads from the eastward will have no difficulty, as they have merely to proceed to a convenient anchorage. Those drawing between 12 and 16 ft. may pass inside the shoals off Tanjong Catong, by keeping in the run of deep water, pretty close to the end of the lines of fishing stakes which extend out from the point; but vessels of larger draught had better keep outside those shoals.

It is often advisable for vessels, and the usual custom for those belonging to the port, to keep the Singapore shore well aboard when proceeding to the anchorage from the eastward, especially when the wind is off the land and the tide setting to the westward. It will then, however, be very necessary to be guarded as Tanjong Catong is approached, and vessels of large draught must be very careful not to bring Mount Serapong (on Blakan Mati Island), to the southward of S.W. by W. $\frac{1}{2}$ W., until the flagstaff on Fort Canning bears W. by N. $\frac{1}{2}$ N., or to avoid getting under a depth of 6 fathoms towards the Tanjong Catong shoals.

A vessel of large draught will pass north-eastward of the Outer shoal, and not have less than 5 fathoms water, by keeping the flagstaff between the bearings of W. by N. $\frac{1}{2}$ N. and N.W. by W., and she should be prepared to anchor *directly* Mount Serapong bears S.W. by W. $\frac{1}{2}$ W., or the left extreme of Blakan Mati S.W. $\frac{1}{2}$ W., inside of which vessels of heavy draught should

not go; but those drawing not more than 18 or 20 ft. may go a cable's length or so farther in, and have 4 or 5 fathoms.

When bound to the roads from the westward, and having rounded Peak Island at the distance of about 2 cables' lengths, steer N. by E. or N.N.E., according to the tide, across the Outer shoal for the anchorage. A large ship, wishing to avoid the Outer shoal, may steer to the northward with Peak Island bearing between South and S. by E.,—but nothing to the eastward of the latter bearing,—until the left extreme of Blakan Mati bears S.W. by W. $\frac{1}{2}$ W., which bearing kept on will lead north-westward of the Outer shoal, and then steer as convenient for the anchorage.

In *working* towards the dangers between St. Johns Islands and Blakan Mati, care must be observed not to bring Peak Island East of S. $\frac{1}{2}$ E. while Mount Serapong is North of W.N.W.; but when Mount Serapong is West of W.N.W. a vessel may stand on until the western extreme of West St. Johns Island bears S. by W. $\frac{1}{2}$ W. The shoalest spots on the Outer shoal will be avoided by not bringing Peak Island West of South, after the South extreme of Blakan Mati bears W. by S. The fishing stakes will give warning when a vessel is standing towards the Pagar and Malay spits. The South extreme of Blakan Mati, if not brought West of S.W. by W. $\frac{1}{2}$ W., will lead clear of the inner side of the Outer shoal; and large ships, not wishing to stand over this shoal when outside of it, should not bring Peak Island South of S.W. by S.

SINGAPORE NEW HARBOUR.

NEW HARBOUR, between Singapore and Blakan Mati Islands, is about $2\frac{3}{4}$ miles long, in a general direction East and West, and not more than $1\frac{1}{2}$ cable broad in places. The eastern entrance is bounded on the North by the Malay and Pagar spits, and on the South by Buran Darat Reef, and the reefs surrounding the eastern sides of Blakan Mati and Ayer Brani Islands.

As an anchorage New Harbour is but a very indifferent one indeed, for the breadth of the navigable channel is but from 100 to 200 yards, the bottom is rocky and foul, and affords but bad holding ground, whilst the tides rush through it with great velocity; there is, from these circumstances, great risk of vessels dragging their anchors and going ashore, especially during the violent squalls which are common in this part of the world.

Notwithstanding these serious drawbacks, New Harbour has grown into a place of considerable importance, for it possesses facilities for running out jetties and making docks, which render it of the highest possible value to a large shipping port like Singapore, situate in the very centre of eastern commerce. The Peninsular and Oriental Company, together with other steam proprietors and merchants, have erected extensive coal stores, wharves, and jetties, the latter allowing of the largest steamers being lashed alongside in

perfect security. It is the place of arrival and departure of the mail steamers, and all other steamers, no matter how large, proceed here to coal. There are capacious dry docks, with workshops, and all needful appliances for repairing ships.

The whole of the above establishments are situated on the North or Singapore side of New Harbour, but the English and French Governments have coal wharves and jetties on Pulo Ayer Brani, an island lying in the middle of the eastern entrance to the harbour, and dividing it into two channels.

Both sides of the harbour are fringed with reefs which dry at low water, but close to their edges are depths of $3\frac{1}{4}$ to $4\frac{1}{4}$ fathoms, increasing quickly to 5 and 6 fathoms, and to this circumstance New Harbour owes its importance. The deep water at the edges of the reefs allowing the largest vessels to come alongside, it is but a simple matter to run out jetties to secure the vessel to. These jetties, of course, greatly facilitate the coaling of steamers and landing of cargo, which, at the anchorage in the roads, can only be done by means of boats.

The entrance to New Harbour between Pagar Spit and Ayer Brani Island is divided into three channels, by the Timbaga Rocks and Brani Shoals, which are marked by buoys and beacons, as hereafter described. The channel between Pagar Spit and Timbaga Rocks is named the *North Channel*; that between Timbaga Rocks and Brani Shoals the *Middle Channel*; and that between Brani Shoals and Ayer Brani Island the *South Channel*.

NORTH SIDE of NEW HARBOUR.—*Pagar Spit*, which forms the north-eastern limit of New Harbour, extends about S.S.E. $\frac{1}{2}$ E. a third of a mile from Pagar Point, and its extreme is marked by a *red* beacon, and there is another at a cable's length to the north-westward of it. Between these beacons is the head of the sea wall, which is built on Pagar Spit, and off it is moored a *red* nun hauling off *buoy*, in 4 fathoms water S. by E., 150 yards from the end of Pagar sea wall. From the first beacon the edge of the reef trends in a north-westerly direction for rather more than half a mile. The edge of this latter part of the reef is marked by two *fixed white* beacons, and close to it are depths of $3\frac{1}{2}$ to 5 fathoms. The edge then trends about S.W. by W., and for a distance of nearly a quarter of a mile is lined with a row of jetties, with coal stores and godowns behind them. At a cable's length farther to the S.W., on the other side of a shoal bight named Blangah Bay, is St. James's Hill, 70 ft. high, having a house and some trees on its summit, and which is a beautiful feature in the delightful scenery of this harbour. It juts out from the main—to which it is connected merely by a low, narrow neck—close to the edge of the reef, which is there marked by a *red beacon*. Mooring buoys, painted red, are placed off the jetties, to assist in securing the steamers when coaling.

From St. James's Hill the edge of the reef takes a westerly direction, and

at a cable's length from the hill, on the other side of a shoal bight, named Sibet Bay, commence the jetties of the Peninsular and Oriental Company, with extensive coal stores and godowns behind them. The whole of these buildings are on ground that was once a small island, but which is now connected to the main island of Singapore by a roadway. The entire frontage of the jetties is about $1\frac{1}{2}$ cable in extent. A *red beacon* marks the edge of reef between St. James Hill and the jetties, and at either end of the jetties is a dolphin to secure vessels to, with two mooring buoys off in the stream for the same purpose.

From the western end of these jetties, the edge of the reef takes a W. by N. direction for $3\frac{1}{2}$ cables' lengths, a *red beacon* marking it about halfway; it then turns sharply to the N.W., and at about the distance of $1\frac{1}{2}$ cable is the dry dock and works previously alluded to. From the dock the reef curves round to the westward, forming Chermin Bay; it then takes a S.W. direction for about $1\frac{1}{4}$ cable, when it again curves to the westward, and then to the southward, forming another small bay, and finally passes about a quarter of a cable's length round Lot's Wife, at the north-western limit of the harbour.

Hantu, the small round island lying in front of Chermin Bay, is nearly $1\frac{1}{2}$ cable in diameter, 96 ft. high, and covered with trees. Its southern side, being nearly in the same line as the Peninsular and Oriental jetties and Lot's Wife, forms part of the northern side of the main channel of the harbour. A reef surrounds the East, South, and West sides of the island, the edge of which, on the South side, is marked by a *white beacon*. The N.E. side, opposite the dry rock, is free from reefs, with 3 fathoms water close to. On the East side of the island is a ship-yard, with a patent slip for vessels under 200 tons.

BERLAYER POINT, the north-western limit of New Harbour, mentioned previously, is formed of cliffs of moderate elevation, and projects in a S.S.E. direction from the low mangrove behind it to a rather sharp point. From this point the coast trends in a north-westerly direction, and is fringed with a white beach named Pasir Panjang, or long beach, upon which, at a cable's length from Berlayer Point, stands a board, denoting the harbour limit in this direction.

Lot's Wife is a rock about 6 ft. above high water, lying immediately off the pitch of Berlayer Point, about a third of a cable's length inside the edge of the shore reef, which is here steep-to. This rock was formerly much higher, and had the appearance of a pillar, hence its name.

Berlayer Rock, with but $1\frac{1}{4}$ fathom water over it, lies S.W., rather more than half a cable's length from Berlayer Point. H.M.S. *Charybdis* touched upon this rock; it is now marked by a *beacon*.

A *Patch*, having but $3\frac{1}{4}$ fathoms water over it, lies West-southerly, a quarter of a mile from Berlayer Point. It is the shoalest part of a bank

over the greater part of which are 4 and 5 fathoms water, with 7 and 8 fathoms close to its outer edge, and 6 fathoms between it and the shore reef fronting Pasir Panjang beach.

To clear this patch, and also the Berlayer Rock, keep Tereh Point, a conspicuous red bluff on Ayer Brani Island, well open of the Peninsular and Oriental Company's jetties.

MOUNT FABER is the name of a conspicuous range of hills which rise bold up on the northern shore, about the middle part of New Harbour. The direction of the range is about N.W. and S.E., the highest point, 357 feet, being towards its N.W. end. Near the middle of the range is a flag-staff, which, like that upon Fort Canning Hill, is crossed by two yards, used for signalling the arrival of ships from the westward, and repeating the signals made from Fort Canning. The height of the range where the flag-staff stands is 303 ft., exactly the same height as Mount Serapong on the opposite side of New Harbour.

Eastward of Mount Faber, behind the wharves and jetties, are several small hills from 100 to 132 ft. high.

AYER BRANI ISLAND, commonly known as Pulo Brani, lies inside the eastern entrance to New Harbour. It is nearly two-thirds of a mile long, N.W. and S.E., and the same extent East and West; its greatest length is on its north-eastern side, facing Singapore roads, and upon this part are three hills, the middle one, which is the highest, being 168 ft. above the sea. Teregeh Point, the S.E. extreme, and Tereh Point, the North extreme of the island, are both formed by cliffs; those forming Tereh Point are of a red colour, and present a bold, red bluff, which is very conspicuous when viewed from either entrance of the harbour.

This island, like Blakan Mati, is encircled by a coral reef with occasional patches of sand upon it, which uncovers at two-thirds ebb. From Teregeh Point the reef projects about half a cable's length to the southward, and more than 2 cables' lengths eastward, the extreme of the latter part being known as Teregeh Spit, and marked by a white beacon. From this spit the reef curves round gradually, passing about a cable's length from Silingsing Point, the middle point of the island; it then closes the island until at Tereh Point it is distant only about 20 or 30 yards. From Tereh Point it curves slightly in towards Saga Bay, and then runs pretty straight about W.S.W., and forms a spit, the outer part of which is more than $1\frac{1}{2}$ cable's length westward of Risim Point, the West extreme of the island.

Buoys.—Two black nun buoys were placed to mark Brani Reef in 1876, one in 3 fathoms, on the S.E. end of the reef, with Teregeh Spit beacon bearing S.W. by W., distant $1\frac{1}{4}$ cable; and the other on the edge of the Brani Reef, off Brani Bay, in 5 fathoms, with the red beacon on the North shore bearing N. $\frac{3}{4}$ W. distant nearly 3 cables.

The N.W. side of Ayer Brani, between Tereh and Risim points, is the most important part of the island. Between these points is Saga Bay, dry at low water, which offers great facilities for the construction of dry docks. Some years ago a dry dock was commenced by a Mr. Clunis, who had early perceived the advantages possessed by this island for such enterprises. He had made considerable progress with his work when he was stopped by the Government, who took possession of the property, owing to Mr. Clunis having failed to possess himself of the proper legal grant of the land. The Government has since built a temporary jetty and coal stores close to the dock, at the north-eastern part of Saga Bay, but with the dock itself nothing has been done. These coal stores and jetty are at present in a dilapidated state, but they are about to be replaced by permanent structures. Just to the north-eastward of Risim Point the French Government has erected some good coal stores and run out a convenient jetty, off which mooring buoys are placed to secure the vessel to.

SINKI STRAIT is the channel between Ayer Brani and Blakan Mati. To render it navigable, beacons are placed on the edges of the reefs bounding it; even now it is hardly safe for sailing vessels, owing to the uncertainty of the direction of the gusts of wind caused by the adjacent high land.

SILUGU ISLAND lies at the western entrance of Sinki Strait, about a third of a mile West from the extreme of the spit projecting from Risim Point, and fronts a shallow bight, dry at low water, named Imbeah Bay. It is a remarkable little island, almost circular in shape, and moderately elevated, with a small bungalow on its summit. The shore reef projects from the coast a short distance outside this island; close to it are $3\frac{1}{2}$ to 5 fathoms.

On a projecting point of Blakan Mati, a short distance to the south-eastward of Silugu, is a jetty for heaving down ships.

BERDAUN ROCK is a small patch of reef above water, grown over by mangrove trees, distant about $1\frac{1}{2}$ cable westward of Silugu Island, and half a cable from the Blakan Mati shore. A reef, dry at low water, extends about two-thirds of a cable westward, and about a third of a cable northward and eastward from it.

RIMAU POINT, the N.W. extreme of Blakan Mati, and the S.W. limit of New Harbour, is formed of cliffs with patches of shelving rocks projecting from their bases. The shore reef extends only a short distance from the North and West sides of the point, and close to it are $3\frac{1}{2}$ and 4 fathoms, excepting in a W.N.W. direction from the West extreme of the point, where a sort of narrow tongue with but $1\frac{1}{2}$ fathom water projects to a distance of half a cable's length.

Brani Shoals lie at the eastern entrance of New Harbour, between Pagar Point and Ayer Brani Island. They extend, under a depth of 3 fathoms,

about half a mile N.W. by W. and S.E. by E., and from their S.E. extreme Teregeh Point bears S.W. by W., and Pagar Point N. $\frac{1}{2}$ W.; from their N.W. extreme the eastern part of Teregeh Point bears S. $\frac{3}{4}$ E., and Pagar Point N.E. by E. $\frac{1}{2}$ E. The least water upon these shoals is $1\frac{1}{2}$ fathom, this part being near their centre, and in length it is about 2 cables, and from a few yards to half a cable wide. The channel on their eastern side is marked by three *white* buoys, one near their S.E. extreme, one near their middle, and the other half a cable's length inside their N.W. end. A white buoy has also been placed on the S.W. edge of the shoal in 3 fathoms, with the end of Pagar sea wall bearing E.N.E., distant 4 cables.

The soundings decrease gradually towards the shoals, and if the lead be properly attended to, it will show when a vessel is nearing them. The channel between them and Blakan Mati is about a cable wide, with depths in it of 3 to 10 fathoms.

The **Timbaga Rocks**, dry at low water springs, lie between Pagar Point and the shoalest part of the Brani Shoals; they are about half a cable long N.W. by W. $\frac{1}{4}$ W. and S.E. by E. $\frac{1}{4}$ E., but only a few yards broad. Two *red* beacons mark these rocks, one on either extreme.

The **Timbaga Shoal**, about half a cable in extent, and with only $1\frac{1}{2}$ fathom least water over it, lies about a cable's length north-westward of the Timbaga Rocks, and its north-western end is marked by a *red* buoy.

Mæander Shoal, about a cable in extent, East and West, with 6 to 16 ft. water over it, lies on the South side of the main channel of New Harbour, about $1\frac{1}{2}$ cable South of the Peninsular and Oriental Company's works, and a cable to the N.W. of the extreme of the spit extending from Risim Point. The shoal is marked by *two red buoys*, one near its S.E., and the other near its N.W. end; around it, and in the channel between it, and Risim Spit, the depths are $3\frac{1}{2}$ to $4\frac{1}{2}$ fathoms.

A mooring buoy, for the use of the Peninsular and Oriental Company's steamers, is placed 110 yards to the northward of the eastern extreme of this shoal.

Keppel Rock, with 15 ft. water over it, lies W.S.W., a cable's length from the western extreme of the Peninsular and Oriental Company's works. Close around the rock are soundings of 5 and 6 fathoms, and a buoy is placed near its eastern side. The South extreme of Mount St. James on with the eastern extreme of the Peninsular and Oriental Company's jetties leads southward of the rock.

Anchorage.—The general depths in New Harbour are 6, 7, or 8 fathoms, but the bottom is foul and rocky, and very indifferent holding ground. Staff Commander Richards, R.N., who surveyed this harbour in H.M.S. *Saracen*, which vessel remained at anchor there for three months, remarks:—"The holding ground is bad, and great care is necessary to prevent fouling the

anchors; vessels remaining more than a day should moor." The best anchorage is considered to be off the French Naval Coal Stores.

Tides.—It is high water, full and change, at the Peninsular and Oriental Company's Wharf, at 9^h 45^m. Springs rise 10 ft., neaps 7½ ft. The ordinary rate of the tide at springs is 2¼ knots, but it is much influenced by the prevailing monsoon, and often runs 4 knots at the springs. During the N.E. monsoon the stream sets to the westward 18 hours in the 24 hours during spring tides, and almost continuously during neaps.

Directions.—Vessels proceeding from Singapore Roads into New Harbour should steer *about* S.W., according to their draught, not approaching Malang or Malay Point nearer than a mile, nor hauling to the westward until Mount Faber flagstaff is in line with the eastern extreme of the landing jetties, which clears the shoal spit off Malay and Pagar Points. In rounding these points, the fishing stakes furnish a ready guide to vessels, the outer ends of the longest lines of stakes having 3 fathoms water close to them, increasing at a short distance to 5 and 7 fathoms. Having rounded Malay and Pagar Points, steer to the westward until the two *red* beacons on the Timbaga Rocks are in line, bearing N.W. by W. ¼ W., and observing that Teregeh Point, the south-eastern extreme of Ayer Brani Island, must not be brought to the westward of W. ½ S., which clears Berala Spit and the northern part of the Buran Darat, and remembering that the north-eastern extreme of the latter is marked by a *white* beacon.*

To proceed through *North Channel*, north-eastward of the Timbaga Rocks, steer *about* N.W., and passing about half a cable's length westward of the outer or south-easternmost of the two *red* beacons which mark Pagar Spit, open the Timbaga Rock beacons on the port bow, and pass in mid-channel between those beacons and the inner or north-western beacon of Pagar Spit. Continue on a N.W. by W. course, according to circumstances, leaving the *red* buoy on the Timbaga Shoal about half a cable's length on the port hand, and edging to the westward as convenient when Pulo Silugu, a small round island, with a bungalow on its summit, is seen just open of the *red* cliffs of Tereh Point, which mark clears the N.W. extremes of the Timbaga and the Brani Shoals.

It should be remembered, when passing between the north-western extremes of the shoals just mentioned and the coral bank which extends 1½ cables' lengths from the shore of Singapore Island, and which uncovers at two-thirds ebb, that the edge of the latter is marked by two fixed *white* beacons, one North of the *red* buoy on the Timbaga Shoal, and the other

* Staff-Commander Richards observes, that owing to the strong tides and to the hard bottom, the floating beacons frequently break adrift, so that no dependence can be placed upon them; he recommends strangers to take a pilot.

about midway between the *white* beacon just mentioned and the extremes of jetties. Close to these beacons are 3 and 4 fathoms water.

To proceed by the *Middle Channel* to the south-westward of the Timbaga Rocks, after having rounded Malay and Pagar Points, and brought the beacons on the rocks in line, steer about N.W. by W., opening the beacons on the starboard bow, and pass about half a cable's length to the westward of both of them, and also of the *red* buoy on the Timbaga Shoal, about midway between the latter and the *white* buoy on the N.E. extreme of the Brani Shoals, in depths of 7 to $4\frac{1}{4}$ fathoms, deepening to 6 and 7 fathoms as Pulo Silugu comes open of the *red* cliffs of Tereh Point; when steer West and W.S.W., to pass mid-channel between the jetties and Tereh Point, leaving the *red* beacon and mooring buoys on the starboard hand.

The best anchorage is abreast of the French Naval Coal Stores; but if wishing to proceed farther to the westward, or through the harbour to the westward, a vessel may pass on either side of the eastern of the two mooring buoys off the Peninsular and Oriental Company's Wharf, but it is better to pass it on the South side, pretty close-to, giving a good berth to the buoys on the Mæander Shoal, which will then be on the port side. Keppel Rock will be avoided if the South extreme of St. James's Mount is not shut in behind the East extreme of the Peninsular and Oriental Company's jetties.

Having passed between the Mæander Shoal and Keppel Rock, a vessel may anchor where convenient, as nearly in mid-channel as possible. To proceed from thence through New Harbour to the westward, it will be merely necessary to steer about W. by S., and taking care not to get too close over towards the Berdaun Rock, keeping as nearly in mid-channel as possible, and so pass out of the harbour. The conspicuous red bluff forming Tereh Point, if kept well open of the Peninsular and Oriental Company's Works, will lead out clear of the reef extending from the South end of Hantu, on which there is a *red* beacon, and also of the Berlayer Rock and 19-ft. patch just outside the harbour.

SINGAPORE STRAIT; EASTERN PART.

The **SOUTH-EAST COAST** of **SINGAPORE ISLAND**, from *Tanjong Catong*, which forms the north-eastern limit of Singapore Roads or Harbour, to *Changhi Point*, takes a direction first to E.N.E. 5 miles, and then N.E. by N. $3\frac{1}{4}$ miles. A slight indentation in the coast line about 3 miles S.W. by S. from Changhi Point, is known as *Tulloh Mati Ikan* (Dead Fish Bay), just to the southward of which, where the shore begins to round away to the westward, are Tanjong and Tulloh Buddoh.

Red Cliffs.—The South and S.E. coasts of Singapore are level and woody.

The most conspicuous objects are the Large Red Cliff, or Tannah Merah Besar, about S.W. $\frac{1}{2}$ S. $1\frac{1}{2}$ mile from Changhi Point; and the Small Red Cliff, or Tannah Merah Ketchil, in a small bight in the land, just to the south-westward of Tulloh Buddoh.

A *Shoal Bank* fronts the whole of this part of the coast, extending to a distance of more than half a mile in places. The soundings decrease towards it with tolerable regularity, but large ships should not near it under a depth of 10 fathoms.

CHANGHI POINT, the N.E. extreme of Singapore Island, forms the S.E. limit of the Old Strait of Singapore. It is low land, with a white sandy beach, and bears about W. by N. nearly 6 miles from Johore Point. A shoal bank extends about a cable's length from the point, close to which are depths of 6 fathoms.

RED CLIFF BANK is an extensive flat of mud and sand, with some patches of rock and coral upon it, extending from the eastern part of Singapore Island, between Changhi Point and Tanjong Buddoh. The north-eastern edge of the bank projects about S.E. $\frac{1}{2}$ E. nearly 4 miles from Changhi Point, its extreme forming a sort of horn or spit. From Tanjong Buddoh the bank projects in an easterly direction towards the Johore Shoal, which may be considered the outer horn or spit of the bank. These two horns thus projecting from the main part of the bank form a sort of basin between them, in which are depths of 7 to 12 fathoms.

JOHORE SHOAL, or Allang Bau, fronts the entrance of the Old Strait of Singapore, and may be considered as the horn or spit of the outer part of the bank extending about 6 miles eastward from the Red Cliffs at the East end of Singapore Island. The shoal is about 2 miles long East and West, nearly a quarter of a mile broad, and is composed of hard sand, having $1\frac{1}{2}$ fathom on its shoalest part at low water, 3 and $3\frac{1}{2}$ fathoms on its South extreme, and 12 to 15 fathoms very near to it, on the South, East and S.W. sides.

South Romania Island open of South Point leads clear to the southward of this shoal; and when coming from the eastward it may also be avoided by not approaching the North shore under a depth of 17 fathoms after Johore Hill bears North, or Barbukit Hill N.E. $\frac{3}{4}$ E. Coming from the westward, St. John's Island should not be brought to the southward of W.S.W., after Little Johore Hill bears N. by E., or Johore Hill N.E. by N., nor the shoal neared under a depth of 17 fathoms until Johore Hill bears North.

OLD STRAIT of SINGAPORE, the channel between the northern shores of Singapore Island and the Malay Peninsula, was formerly the passage by which all vessels proceeded between India and China, when the strait at present in use was not known to be navigable. Its western entrance has very much filled up; formerly it had $3\frac{1}{2}$ fathoms in it at the least water, but

now a bar of sand, with but 2 fathoms water on it, stretches across from Tanjong Gul to Tanjong Bolus.

No vessels now proceed through this strait, but they occasionally enter by the eastern or Johore Channel to load granite at Pulo Ubin, or to load timber at a small town, about halfway through the strait, close to Tanjong Putri in Johore, and which the present Tumongong is striving to bring into importance, having erected some extensive saw mills there, for the purpose of cutting up the timber as it is brought from the adjacent forests. But these vessels invariably enter and leave by the eastern channel.

TIKONG BESAR and **TIKONG KETCHIL** are the two islands lying north-westward of Johore Point, at the entrance of the Johore River, dividing that stream into two branches. *Tikong Besar*, as its name implies, is the larger island of the two, being in extent $3\frac{1}{2}$ miles East and West, and $2\frac{1}{4}$ miles North and South. *Tikong Ketchil*, or Little Tikong, lying close to the West side of the larger island, is in shape nearly round, its diameter being about two-thirds of a mile. There is a small islet, named *Pulo Sijonkan*, lying close to the S.E. side of Tikong Besar; and another, named *Pulo Sijahat*, at three-quarters of a mile to the southward of Tikong Ketchil.

Kapala Rocks appear to be three rocky heads awash, the outer one lying S. by E. $\frac{3}{4}$ E. rather more than $1\frac{1}{2}$ mile from the South point of Tikong Ketchil, $1\frac{1}{3}$ mile W. by S. $\frac{1}{2}$ S. from the South point of Tikong Besar, and 4 miles W. by-N. $\frac{1}{2}$ N. from Johore Point.

Tikong Bank is the extensive shoal bank which surrounds both the Tikong Islands, and also projects outside the islets and rocks just mentioned. Its edge is distant from Pulo Sijonkan, in the direction of Johore Point, about $1\frac{1}{4}$ mile; and from thence takes a N.N.E. direction, passing about a quarter of a mile outside the East end of Tikong Besar. Southward of Pulo Sijonkan the bank extends farthest, its edge in this direction being distant nearly $1\frac{1}{2}$ mile from the islet.

The eastern side of this bank is rather steep, and must be approached with caution; on the South side the depths decrease more regularly, and it may be approached with proper attention in that direction by the lead.

JOHORE RIVER.—Kwala or Qualla Johore, or mouth of the Johore River, is bounded on the East side by the bank surrounding the South and West sides, and extending to the northward of Pulo Tikong; and on the West side by Red Cliff Bank, by the reef which projects eastward from Pulo Ubin, and by Tanjong Kopo and the coast to the northward of it.

The old town of Johore, once a place of considerably trade, now consists of some wretched huts, built with bamboo and mud, where good water may be procured, but nothing else. It stands about 10 miles up the river, which is navigable for ships the whole distance. It is not at all probable that European vessels will have to proceed to Johore for several years to come yet, although it is quite possible that the energy of the present Tumongong

(the sovereign of Johore), may, in the course of time, again develop some trade there.

JOHORE POINT is a bluff promontory, forming the eastern side of the entrance of Johore River and of the Old Strait of Singapore. The edge of the shore bank and the Malang Berdaun Rocks extend nearly three-quarters of a mile to the southward of Johore Point.

JOHORE HILL, or *Maru Bukit*, 660 ft. high, is of a regular, oblong, sloping form, and covered with trees. Standing but a very short distance inland from Johore Point, it is one of the most conspicuous objects in, and serves as a useful landmark for navigating, the Strait of Singapore.

Little Johore Hill, 749 ft. high, rises N. by W. $\frac{3}{4}$ W. $5\frac{1}{2}$ miles from Johore Hill. Although higher, this hill is not so extensive as Johore Hill, but it is also useful as a landmark.

CALDER HARBOUR is the name given to the entrance of one branch of the Johore River. It lies just round Johore Point, bounded on one side by the bank fronting the coast to the north-westward of Johore Hill, and on the other by the extensive bank which projects from Pulo Tikon Besar. The breadth of the harbour is three-quarters of a mile, with anchorage in $5\frac{1}{2}$ to 9 fathoms,

Tanjong Stapah, about S.E. by E. $\frac{1}{2}$ E. $3\frac{1}{2}$ miles from Johore Point, is a good mark when kept in line with South Point, from which it bears West-northerly, distant $3\frac{3}{4}$ miles, to keep vessels well clear to the southward of all the dangers near the Romania Islands. This point appears to be pretty bold close-to; but vessels are recommended to give it a berth of at least half a mile.

A patch of *dry bank*, with 5 and 6 fathoms water close-to, lies about three-quarters of a mile W. by N. from Tanjong Stapah. It seems, however, to be but part of a shoal bank which fronts the coast to the distance of a mile, between Tanjong Stapah and Johore Point.

The *Malang Berdaun* are a rocky cluster, some above and others below water, the outer rocks of which lie South nearly three-quarters of a mile from Johore Point, and within the edge of the shore bank just described. These dangers are, however, quite out of the ordinary track of vessels as they lie inside the Johore Shoal.

Tanjong Teeram, about $1\frac{1}{2}$ mile eastward of Tanjong Stapah, and bearing W. $\frac{1}{2}$ N. $2\frac{1}{2}$ miles from South Point, has rocks, both awash and below the water, lying off it, and there are also many between it and South Point; but they are all within the margin of the 3-fathom edge of the shore bank.

SOUTH POINT, or *Tanjong Tehimpang*, the most southern point of this part of the Malay Peninsula, bears W.S.W.-southerly 5 miles from Romania Point. The 3-fathom edge of the shore bank which fronts this part of the coast, is distant about a third of a mile from South Point; the soundings near it decrease rather suddenly from 10 or 9 fathoms.

ROMANIA POINT, or *Tanjong Penyusoh*, the S.E. extreme of the Malay Peninsula, and of Asia, with the circumjacent coast, is level land, covered with trees. The S.W. extreme of the point is nearly $1\frac{1}{2}$ mile S.W. by W. $\frac{2}{3}$ W. from the S.E. extreme, and, although it is rather conspicuous, no name has yet been given to it upon the chart. Between the extremes is a middle point, with a small bay on either side.

Many rocks lie off Romania Point, extending nearly half a mile from it in a southerly direction. A *rock awash* also lies a short distance off shore, between the middle point and the S.W. extreme.

A shoal bank fronts this shore and extends outside these rocks, its edge being distant nearly three-quarters of a mile in a S. by W. direction from Romania Point. Southward of the S.W. extreme of the point a tongue projects in an easterly direction from the shore bank, the outer part of which is three-quarters of a mile South of the point. Over this tongue are 3 fathoms water, but inside of it is a narrow gap of 4 and 5 fathoms.

BARBUKIT HILL, 645 ft. high, $4\frac{1}{2}$ miles W.N.W. from Romania Point, and bearing from Horsburgh Lighthouse W. by N. $\frac{2}{3}$ N. $12\frac{1}{2}$ miles, is a regular pyramid rising from the low land, and, being only about 5 miles inland, is a very useful object in making out the entrance of the strait.

FALSE BARBUKIT, 432 ft high, is a low, sloping hill near the sea, appearing like a top of trees a little more elevated than the adjacent coast, which is all rather low and woody to the northward of Barbukit Hill. It bears N.N.E. 6 miles from Barbukit Hill, and N.W. from Horsburgh Lighthouse, and, being discernible during hazy weather much sooner than Barbukit Hill, answers as a guide in coming from the northward towards the northern extremity of the outer shoals.

From the S.W. extreme of Romania Point, the South coast of the Malay Peninsula, trends to the north-westward for about $1\frac{1}{2}$ mile to the entrance of a small river, the *Songie Romynia*. From thence the land curves away to the south-westward for $2\frac{1}{4}$ miles to *Tanjong Romynia*, between which and South Point, which bears from it S.W. by W. $\frac{1}{2}$ W. nearly $1\frac{1}{2}$ mile, is a small bay, and the entrance of another small river, the *Songie Kalarang*.

WATER, or Watering Islands, is the name given to a small round island about a quarter of a mile in extent, with an islet off its West extreme connected to it by a reef, lying N.E. by E. $\frac{1}{2}$ E. from *Tanjong Romynia*, the outer side of the island being distant about three-quarters of a mile from it.

Close around the S.W. extreme of Romania Point is *Diana Cove*, where there is a stream of *fresh water*. The Romynia River, farther to the north-westward, has 2 or 3 ft. water at its narrow entrance at low tide, and is navigable by boats 2 or 3 miles inland.

The **ROMANIA ISLANDS**, fronting Romania Point, are six in number; the westernmost or larger one is composed of two islands very near each

other, joined by a reef; the northernmost and south-easternmost are two barren rocks; but the others are covered with trees. They extend about $2\frac{1}{2}$ miles N.E. and S.W., the largest being within a mile of the point, and the nearest to it. There is a rock, about 12 ft. above water, near the South point of South Island, and a reef of straggling rocks extending to the eastward, which are bold to approach on the South side.

DANGERS.—The following dangers lie contiguous to the Romania Islands:—

Congaltons Carr, a rocky patch, with $1\frac{1}{2}$ fathom water over it, and 8 to 12 fathoms close-to, is the easternmost of the dangers lying near the Romania Islands. From it the middle of the largest island is in line with Peak Rock, the latter distant a mile; North Rock, the northernmost island, bears N.W.-northerly nearly 2 miles, and Horsburgh Lighthouse E.S.E.-easterly $5\frac{1}{2}$ miles.

To avoid this danger, do not bring the southern extreme of the largest Romania Island to the westward of W. $\frac{1}{2}$ N., or the centre of that island in line with Peak Rock, until Tanjong Punji bears N.N.W. $\frac{1}{2}$ W.

Caution.—When the tide is running to the westward, vessels passing through the North channel must be very careful that they are not set too near this danger, of which the lead will not give timely warning.

Jones Reef, having only 1 fathom water over it, and 8 or 9 fathoms close-to, lies N.N.W. $\frac{2}{3}$ W. a little over half a mile from Congaltons Carr, with the Peak Rock bearing S.W. $\frac{1}{2}$ W., distant three-quarters of a mile, and North Rock N.W. $\frac{1}{5}$ W. $1\frac{1}{4}$ mile.

Whale Rock, or *Whales Crown Rock*, lying W. by S. nearly a third of a mile from Jones Reef, is a small ledge of rocks which is particularly dangerous, as it is only at about three-quarters ebb that a small round rock becomes visible, and indicates the existence of the danger. It is steep-to, and the depth in its vicinity is irregular, being from 15 to 8 or 9 fathoms. Peak Rock bears from it S.W. $\frac{1}{2}$ S., and North Rock N.W. $\frac{1}{2}$ N., distant a mile.

A *rock awash* lies a short distance E.N.E., and a 4-fathom patch about a quarter of a mile N.N.E. from Peak Rock. Another 4-fathom patch, with 12 fathoms near it, lies a short distance to the northward of Whale Rock.

A Reef, about half a mile in extent, and dry in places, lies between North Island and North Rock. Its eastern extreme bears North from Peak Rock, distant three-quarters of a mile; and its western extreme rather less than half a mile S.S.W. from North Rock. Upon its north-eastern extreme is the smallest of the Romania Islands—a mere rock; and there is a 5-fathom patch between it and North Island.

Stork Reef, lying S.W. by W. $\frac{1}{2}$ W. about three-quarters of a mile from Congaltons Carr, is about 3 cables in extent N.E. and S.W., and from its S.W. point Barbukit Hill is on with the North hump of the large Romania Island bearing W. by N. $\frac{3}{4}$ N.; Peak Rock N.W., distant a little more than

half a mile; the point of Watering Bay, the S.W. part of Romania Point, West; and Horsburgh Lighthouse E. by S. $\frac{1}{2}$ S. 6 miles.

A **Three-Fathom Patch** lies S.W. by W. two-thirds of a mile from Stork Reef. South Island bears from it N. by W. $\frac{3}{4}$ W. half a mile; the South end of the large Romania Island N.W. nearly a mile; and South Point W. by S. $6\frac{1}{4}$ miles.

A *rock awash* lies with South Island N.E. $\frac{1}{2}$ E., distant one-third of a mile, and the large Romania Island N. by W. $\frac{3}{4}$ W. about the same distance.

A **Four-Fathom Patch** lies nearly a mile W. by S. from the 3-fathom patch just mentioned; with South Island bearing N.E. nearly a mile; the large Romania Island N. by E. $\frac{1}{2}$ E., three-quarters of a mile; and the largest Water Island, West-southerly.

A Shoal with only $2\frac{3}{4}$ fathoms water over it, and which is the southernmost of the dangers near the Romania Islands, lies with the large Romania Island bearing N.N.E.-easterly, distant $1\frac{1}{2}$ mile; Horsburgh Lighthouse E. $\frac{1}{4}$ S. $7\frac{3}{4}$ miles; Romania Point North $1\frac{2}{3}$ mile; and South Point W. $\frac{1}{2}$ S., nearly $4\frac{3}{4}$ miles. There is a patch of $4\frac{1}{2}$ fathoms lying a third of a mile in a south-easterly direction from this shoal.

Clearing Mark.—There is deep water, 9 to 12 or 13 fathoms, very close to the above dangers. Tanjong Stapah, a point $3\frac{3}{4}$ miles to the eastward of South Point, in line with South Point bearing West, will lead clear to the southward of the last-mentioned patch of $2\frac{3}{4}$ fathoms, as also to the southward of all the dangers near the Romania Islands.

The **ROMANIA SHOALS** are a number of detached patches of sand and coral—various as to extent and depths of water over them—stretching in a south-westerly direction from the tail of the bank which extends to the southward of North Patch, towards the rocks and dangers which lie outside the Romania Islands. Between these patches are channels with depths of 8 to 10 fathoms water.

The limits of these shoals, to depths of 4 fathoms and under, lie between the bearings of N. by W. $\frac{1}{4}$ W. and N.W. $\frac{1}{2}$ W. from Horsburgh Lighthouse, the distance on the former bearing being 6 miles, and on the latter 5 miles. The least water shown upon the chart is $3\frac{1}{2}$ fathoms, and this shoal portion lies between the bearings N. by W. $\frac{3}{4}$ W. and N.N.W. $\frac{1}{2}$ W. from Horsburgh Lighthouse, and is about a mile in length, in a northerly direction. But it does not appear that $3\frac{1}{2}$ fathoms is the least water on these shoals, and great caution should be used.

Outside the N.E. limit of the shoal part of these reefs, the patches have depths generally of 6 to 8 or 9 fathoms over them, but there is one patch of 5 fathoms bearing N. $\frac{1}{2}$ W., and another of the same depth bearing N.W. by W. from the lighthouse.

South Island, the southernmost island of the Romania Group, just open of South Point, the southern extreme of the Malay Peninsula, leads to the south-

ward of the Romania Shoals; and Horsburgh Lighthouse kept to the southward of S. by E. $\frac{1}{4}$ E., will lead to the eastward of those patches which have less than 5 fathoms over them.

NORTH PATCH, lying $4\frac{1}{2}$ miles W. by S. from the Eastern Bank, is generally considered the outermost of the Romania Shoals, for the reason that the Eastern Bank, not having less than 7 or 8 fathoms water over it, is not only not dangerous to the mariner, but it is in fact useful to him, serving to determine his position; whereas the North Patch, having but 4 fathoms water over it, is not safe for a large ship to cross in a swell or a heavy sea. The patch is nearly $1\frac{1}{2}$ mile long, North and South, and half a mile broad, composed of mud and sand, and has but 4 fathoms water over the greater part of it. It lies near the North end, and is the shoalest part of a bank about 5 miles long and 2 miles broad, with depths of 6 to 10 fathoms over it, and a 5-fathom spot about a mile from its South end. From the North end of North Patch, False Barbukit Hill bears W. $\frac{1}{2}$ S. $12\frac{1}{2}$ miles; Barbukit Hill S.W. by W. $\frac{3}{4}$ W. 16 miles; and Horsburgh Lighthouse S. by W. $11\frac{1}{2}$ miles.

Bintang Little Hill open to the westward of Bintang Great Hill, leads half a mile eastward of the North Patch.

The **EASTERN BANK**, the outermost of the shoal patches off Romania Point, is nearly $1\frac{1}{2}$ mile in extent, with soundings of $7\frac{1}{2}$ to 10 fathoms over it, and 11 to 14 fathoms close around it. It lies about a mile inside the range of the Horsburgh light, and from its outer edge the light bears S.W. by S., distant 14 miles; Barbukit Hill W. by S. $\frac{3}{4}$ S.-southerly; and False Barbukit W. $\frac{1}{2}$ S.

Vessels getting soundings of 8 to 10 fathoms on this bank, during hazy weather, sometimes think they are on the northern patch of Romania outer reef, and then haul more to the eastward, which renders them liable to fall to leeward of the strait.

PEDRA BRANCA lies nearly in mid-channel of the eastern entrance to Singapore Strait, and as it advances beyond the mouth of the straits considerably into the China Sea, it has for ages served as the principal leading mark to vessels passing out of, or into, the straits. Its Portuguese name, "white rock," was significant of its appearance prior to the erection of the lighthouse, from its being so marked by the dung of the numerous sea birds which lived on it. It consists of a reef of light grey granitic rocks, about 450 ft. long N.E. and S.W., and 200 ft. broad. At high water it had the appearance of a mere heap of boulders loosely piled together, which only afforded two rocks large enough to build the lighthouse upon; the S.W. one was chosen.

The **HORSBURGH LIGHTHOUSE**, which stands on this rock, is a noble monument. It was determined on in 1847, after several years of delay and discussion. The funds were partially raised by liberal subscription in Singapore and China, and the structure was designed and executed by J. T.

Thompson, Esq., the government surveyor, who has given an elaborate and interesting account of the work. It is dedicated to the memory of James Horsburgh, F.R.S., the hydrographer of the East Indies. It is a fine column of dressed granite, the first building so constructed in these countries, is 92 feet 9 inches in height from base to the top of the funnel, with a white spherical dome, and the base of the rock being 16 feet 9 inches above the high-water level, it has a total height of 109 feet 6 inches.

It shows a *brilliant revolving light*, from nine holophotal metallic reflectors, the invention of Mr. Thomas Stevenson, three on each face of a triangular frame, which revolves in three minutes, consequently a bright flash of 15 seconds' duration is produced in every direction once in a minute. The light totally disappears at great distances. It is elevated 95 ft. above high-water mark, and so may be seen 15 miles off from the deck of an ordinary ship.

It is in lat. $1^{\circ} 19' 58''$ N., long. $104^{\circ} 24' 28''$ E., and from it the largest island off Romania Point bears W. by N. $\frac{1}{3}$ N. about $7\frac{1}{2}$ miles. It is the same distance from the shore of Bintang, and is in one with the centre of Bintang Great Hill, bearing S. by E. $\frac{1}{4}$ E.

DANGERS near PEDRA BRANCA.—With the exception of a patch of 4 fathoms, the North and N.W. sides of Pedra Branca are steep-to, there being 17 fathoms close to the rock, and 30 to 36 fathoms near it.

This 4-fathom patch lies about a quarter of a mile northward of the rock, and is the only shoal spot between it and the Romania Shoals, in which space the depths are very variable in mid-channel, 17 to 32 fathoms, but they become more regular, 17 to 14 fathoms, towards the Romania Shoals.

The East, South, and S.E. sides of Pedra Branca should not be approached nearer than a mile, for there are dangerous rocky patches to the distance of half a mile from the East side; and the South and S.E. sides are foul to three-quarters of a mile, at which distance South and S.S.E. $\frac{1}{4}$ E. from the lighthouse are two dangerous ledges, named Middle Rocks, which are but little above the surface at high water. Eastward at a short distance from the Middle Rocks is a patch of 4 fathoms, and North a quarter of a mile from this patch is a rock with only 3 ft. of water over it.

SOUTH LEDGE is very dangerous. It consists of three pointed rocks, very little detached from each other, with 8 and 9 fathoms close to, and 16 or 18 fathoms at a short distance from them in their stream. They are of small extent, not visible until the ebb has been made some time, and are nearly covered before the stream of flood begins to run. Horsburgh lighthouse bears from them N. by E. $\frac{2}{3}$ E., distant 2 miles; the large Romania Island N.W. by W. $\frac{1}{3}$ W. $7\frac{1}{2}$ miles: and the outer hill on Brakit Point E.S.E. $12\frac{1}{2}$ miles.

Between the South ledge and Middle Rocks the distance is about $1\frac{1}{2}$ mile, and the depths 15 to 20 fathoms; and between the South ledge and Diana Shoal the distance is $4\frac{1}{2}$ miles, and the depths vary from 12 to 18 fathoms,

decreasing under 11 fathoms within a mile of the Diana, and shoaling to 8 fathoms close to that danger.

The Tides about Pedra Branca are described on pages 26, 27.

EAST COAST of the MALAY PENINSULA.—The coast from Romania Point turns sharply to the northward, and at the distance of a little over half a mile is a point with some rocks off it, from whence the land falls back, forming a bay about a mile deep, the northern horn of which, named *Tanjong Punji*, bears N. $\frac{2}{3}$ E. $4\frac{1}{2}$ miles from Romania Point. About $4\frac{1}{2}$ miles N. by W. $\frac{1}{4}$ W. from Tanjong Punji, is another point, named *Tanjong Lompat*, which bears about West from the North patch, the outermost of the shoal patches which extend from the Romania Shoals.

A shoal bank fronts the whole of the coast from the point a mile northward of Romania Point to Tanjong Lompat. Abreast of Barbukit Hill it projects $1\frac{3}{4}$ mile from the shore, nearly as far as the meridian of North Rock, which bearing South leads close to its edge. Off Punji Point it extends about half a mile, and off Lompat Point three-quarters of a mile.

Water.—Excellent water can be procured from the river close round the rocky point, about 6 cables' lengths North of Romania Point.

The Inner Channel, between Romania Point and the islands, cannot be considered safe, and we refrain from giving any directions which might have the effect of tempting vessels to use it.

The North Channel is bounded on the East by the shoalest part of the Romania Shoals, and on the West by the dangers which lie to the eastward of the Romania Islands. The channel is about $3\frac{1}{2}$ miles wide; there is one patch of 4 to 5 fathoms and another of 5 fathoms lying in its fairway, but there does not appear to be any less water, and it is now frequently used by those locally acquainted.

Directions from the Northward.—Coming from the northward, and wishing to proceed into Singapore Strait by the North Channel, pass about midway between the North patch and the shore, and by the time False Barbukit Hill bears West, Barbukit Hill should bear S.W. by W., nearly, or in case Barbukit cannot be discerned, the South extreme of Tanjong Punji should bear about S.W. $\frac{1}{4}$ W.; a S. $\frac{3}{4}$ W. course will then lead through the channel by the middle track marked on the chart, which passes over the patch of 4 to 5 fathoms.

A vessel following this track will have soundings from 13 to 10 fathoms, until Barbukit Hill bears about W. by S. or W. $\frac{1}{2}$ S., when they will decrease to 8 and 7 fathoms, and when Barbukit Hill bears West to about 6 fathoms. She will then soon have 5 or $4\frac{1}{2}$ fathoms on the bank, except at low-water spring tides, when there may be as little as 4 fathoms. The depths will soon increase to 8, 9, or 10 fathoms, and then suddenly to 13, or perhaps 15 fathoms, when she will be in Singapore Strait. This 4-

fathom patch may be avoided and the banks crossed in not less than 6 fathoms water, by steering for Horsburgh lighthouse bearing S.E. $\frac{1}{4}$ S. to S.E. $\frac{1}{2}$ S.

Having crossed the banks, the S. $\frac{3}{4}$ W. course should be continued to avoid getting too near Congaltons Carr, over which there is but $1\frac{1}{2}$ fathom. The middle of the largest of the Romania Islands in line with Peak Rock is the mark for this dangerous patch, and vessels should be cautious—extremely so when the tide is making to the westward—not to bring the East extreme of Punji Point to the North of N.N.W. $\frac{1}{2}$ W., until Peak Rock is North of the middle part of the largest of the Romania Islands, or until the South end of the last-named island bears W. $\frac{1}{2}$ N. The vessel will then be to the southward of Congaltons Carr, and may steer S.W., but not more westerly, until Tanjong Stapah comes open South of South Point, when she will be to the southward of all the dangers near the Romania Islands, and may steer W.S.W. or W. by S., according to circumstances.

From the Southward.—In proceeding through the North channel from Singapore, take care, after passing South Point, not to lose sight of Stapah Point behind it, in order to avoid the $2\frac{3}{4}$ -fathom patch and other dangers near the Romania Islands. When the largest of those islands bears N.N.W., steer N.E., to pass about three-quarters of a mile outside Congaltons Carr; but if the tide is setting to the westward, a more easterly course must be steered to avoid that danger, which will be done if the South end of the largest of the Romania Islands be not brought westward of W. $\frac{1}{2}$ N., or Peak Rock in line with the centre of that island, until the right extreme of Punji Point bears N.N.W. $\frac{1}{2}$ W. With these marks on the vessel will be in about 13 or 15 fathoms water, and may steer N. $\frac{3}{4}$ E., through the North channel on the middle track.

In following this middle track, the soundings will vary from 12 to 15 fathoms for the distance of the first mile, when they will suddenly decrease to 9 or 8 fathoms, and shortly after to 5 or $4\frac{1}{2}$, and if at low-water spring tides, perhaps to 4 fathoms. Having crossed this shoal part of the bank—which is only about a third of a mile broad—the soundings will soon deepen to 6, 7, and 8 fathoms, and by the time Barbukit Hill bears W. $\frac{1}{2}$ S., to 10 and 11 fathoms; from thence to the northward they will continue to be 12 or 13 fathoms until past the North patch.

A vessel will avoid the 4-fathom patch and cross the banks in not less than 6 fathoms water, by keeping Horsburgh lighthouse S.E. $\frac{1}{4}$ S. to S.E. $\frac{1}{2}$ S., and steering the opposite course till the banks are crossed.

In working through the southern part of this channel, Horsburgh lighthouse should not be brought to the southward of S.E. $\frac{3}{4}$ S. when standing towards the Romania Shoals; nor to the eastward of S.E. by E. $\frac{1}{2}$ E. when standing towards Congaltons Carr or Jones Reef. The soundings are not at all to be depended upon to guide a vessel near these latter dangers, for there

are 12 fathoms in one direction and 6 in another very close to Congaltons Carr, and 9 or 8 fathoms close to Jones Reef.

SOUTH SIDE OF EASTERN PART OF THE STRAIT.

BINTANG is the largest island on the South side of Singapore Strait; Battam Island, on the West side of Rhio Strait, is also of considerable size, and from it a chain of islands, separated by narrow guts, extends westward, terminating nearly opposite the Rabbit and Coney.

The North side of Bintang is about 16 or 17 miles in length, nearly E. by N. and W. by S., the greater part being taken up by the large bay of Sumpat; several dangers lie off it, which will be described in detail farther on. Like most of the other land bounding the strait of Singapore, it is covered with trees, and, excepting the hills inland, is not much elevated.

Bintang Hills.—*Bintang Great Hill*, in lat. $1^{\circ} 4' 20''$ N., long. $104^{\circ} 29' E.$, bearing S. by E. $\frac{1}{4}$ E., about $16\frac{1}{2}$ miles from Horsburgh lighthouse, may be seen in clear weather 40 miles, being 1,230 ft. high, and is a good mark in approaching the entrance of the strait from the northward. When viewed from that direction it forms a saddle, and adjoining it on the North side, there is a small conical hill, called *False Bintang Hill*, or *Bintang Little Hill*, 762 ft. high, the summit of which is central with the saddle of the large hill bearing S. $8^{\circ} E.$ When the centre of the saddle bears South (*true*), the summit of the Little Hill is just open with the western shoulder of the large hill; and this mark or bearing of Bintang Hill is a safe guide to carry a vessel to the eastward of, but pretty near to the North patch, the outermost of the Romania Shoals.

TANJONG BRAKIT, the N.E. point of Bintang Island, has some hills on its East side 217 ft. high, and others a mile farther to the southward 267 feet high. Reefs and dangers extend $1\frac{1}{2}$ mile from this point, within the margin of which lie the following:—*Pulo Coco*, an island 40 ft. high, narrow, but three-quarters of a mile long, lies close to, and appears to form the eastern side of, Brakit Point; it may be approached to a distance of half a mile. *Pulo Brakit*, 30 ft. high, is an island about half the size of Coco, lying half a mile N.N.E. from the northern part of Brakit Point. It should not be approached nearer than three-quarters of a mile, for the shore reef projects nearly half a mile outside of it.

Black Rocks are a cluster of dark-coloured rocks lying off the North extreme of Brakit Point, the outermost rocks being distant nearly a mile from the shore; and a tongue of sand, with but 3 fathoms water over it, projects a third of a mile from their outer edge.

BRAKIT ROCK, discovered in 1861 by Mr. Stanton, commanding H.M.S. *Saracen*, is a cable in length, N.W. and S.E., and half a cable in breadth, with 2 fathoms over it at low water, and 10 to 12 fathoms close to all round.

It lies N.N.E. $\frac{3}{4}$ E. $2\frac{3}{4}$ miles from Tanjong Brakit, and from its southern and shoalest part the northern extreme of Pulo Sumpat appears in line with the apex of Little Bintang Hill S.W. $\frac{1}{4}$ S., and Horsburgh lighthouse bears W. by N. $\frac{1}{2}$ N. $12\frac{1}{2}$ miles. A conspicuous double tree on a long hill 4 miles from Tanjong Lokan appears just outside the point bearing S. $\frac{1}{2}$ W. This tree kept well open of Tanjong Lokan clears the eastern side; Pulo Panjang peak S.E. $\frac{1}{2}$ S. will clear both the eastern and northern sides. Barbukit Hill, about four times its own breadth open eastward of Horsburgh lighthouse, will also lead a vessel northward; and Little Bintang Hill well open northward of Pulo Sumpat will lead to the westward.

The channel between the Brakit Rock and the point is free from danger. It is not, however, advisable to use this channel except in cases of emergency.

Postillion Reef, composed of coral and sand, and having 2 fathoms water over it, lies nearly half a mile outside the shore reef extending from Brakit Point; between them are depths of 4 to 8 fathoms. Horsburgh lighthouse bears from this reef N.W. by W. $\frac{3}{4}$ W., nearly $10\frac{1}{2}$ miles.

A *shoal*, apparently about half a mile in extent, having $1\frac{1}{2}$ fathom water over it, is marked on the chart S.W. by W. $\frac{1}{2}$ W., $1\frac{1}{2}$ mile from Postillion Reef, W. by N. $\frac{1}{2}$ N., a little over $2\frac{1}{2}$ miles from Tanjong Brakit.

TULLOH SUMPAT or Sumpat Bay, is the extensive bight between the western extreme of Tanjong Brakit and Tanjong Batu Sow, which lie W. $\frac{3}{4}$ S. and E. $\frac{3}{4}$ N. of each other $9\frac{1}{2}$ miles apart. *Pulo Sumpat*, a small island 178 feet high, lying in the eastern part of Sumpat Bay, may be readily known by its saddle shape. It lies $2\frac{1}{2}$ miles South of the shoal last mentioned, and S.E. $\frac{1}{4}$ S. $1\frac{1}{2}$ mile from the western extreme of Brakit Point.

Two Reefs lie near the bottom of Sumpat Bay, the outer of which is nearly a mile distant from a rocky point on the shore, about 2 miles W. by S. $\frac{1}{2}$ S. from Pulo Sumpat, and $2\frac{1}{4}$ miles E. $\frac{3}{4}$ N. from Tanjong Batu Sow.

Diana Shoal, about half a mile in extent, has but $2\frac{3}{4}$ fathoms water over it, and 4 fathoms close around. From its outer edge Tanjong Brakit bears E. $\frac{1}{4}$ S. distant $8\frac{1}{2}$ miles; Tanjong Batu Sow S.W. 3 miles; and Horsburgh lighthouse N. by W. $\frac{1}{2}$ W. 6 miles. A little more than half a mile in a W.S.W. direction from this shoal is a sand patch with 4 and 5 fathoms water.

Langui Shoal, about a third of a mile in extent N.N.E. and S.S.W., lies W. by S. $\frac{1}{2}$ S. $4\frac{1}{4}$ miles from the Diana Shoal. Over its South end there is but $1\frac{1}{4}$ fathom water, and 3 fathoms over its North end. From its North end Tanjong Subong—the N.W. point of Bintang at the entrance of Rhio Strait—bears S.W. $\frac{3}{4}$ W. 4 miles, Tanjong Batu Sow E.S.E. a little over 2 miles, and Horsburgh lighthouse N. by E. $\frac{3}{4}$ E. $7\frac{1}{2}$ miles.

This shoal and bank will be avoided by not bringing the point of Bintang,

which lies a mile W.S.W. of Tanjong Batu Sow, to the eastward of S.S.E., until Pulo Skeree (Doea Island), which lies on the East side of the entrance of Rhio Strait, comes open of Tanjong Subong, bearing about S.W. Horsburgh lighthouse bears from the Langui Shoal N. by E. $\frac{2}{3}$ E. $7\frac{1}{2}$ miles; the lighthouse or light therefore bearing N.N.E. $\frac{1}{4}$ E. will lead about a mile westward of this danger. A *three-fathom patch* lies about half a mile to the southward of the Langui Shoal, and between them are 6 to 7 fathoms water.

The Coast between Tanjong Batu Sow and Tanjong Subong, forms a bay about three-quarters of a mile deep, and off its East point, which is about a mile W.S.W. from Tanjong Batu Sow, are some islets and rocks.

At half a mile S.W. by W. from *Tanjong Pergam*, the West point of the bay, is an islet called *Pulo Pergam*, with a rock awash about a third of a mile N.W. by W. from it. A *rock awash* lies about a third of a mile N.E. $\frac{2}{3}$ E. from Tanjong Subong.

From the above description, it will be seen that the whole of this part of the coast is fronted with dangers; and as it has been but partially explored, and it is extremely probable that other dangers than those marked on the chart may exist, vessels are advised not to attempt to come inside the Diana and Langui Shoals.

Tanjong Subong, the north-western point of Bintang, and the Crocodile and Pan Shoals, in the entrance of Rhio Strait, have been previously described on pages 318 and 325.

TANJONG NONGSA, the most northern point of Battam Island, bears W. $\frac{1}{4}$ N., distant $13\frac{1}{2}$ miles from Tanjong Subong; South, nearly 11 miles from Johore Hill; and S. by E. $\frac{1}{4}$ E. $7\frac{1}{3}$ miles from the eastern extreme of Johore Shoal. The shore reef, which extends a mile off Tanjong Bomban, the N.E. extreme of Battam, decreases in distance from the shore towards this point, and off its eastern part does not extend farther than 1 or 2 cables' lengths.

Pulo Nongsa, a small island a third of a mile in extent, with a high tree upon it, lies $1\frac{1}{3}$ mile westward of Tanjong Nongsa, and about half a mile off the nearest point of Battam. It is rather a conspicuous object when near this part of the strait, and if kept open of Nongsa Point will lead a ship clear of the Little Pan Shoal.

Bollan Bay, lying to the westward of Tanjong Nongsa, is nearly 3 miles wide at its mouth, between *Tanjong Treng* on the East, and *Tanjong Pengair* on the West, and $2\frac{1}{3}$ miles deep, narrowing towards its head. A *detached reef* lies at the entrance of Bollan Bay, a mile distant E. $\frac{3}{4}$ N. from Tanjong Pengair. The best *anchorage* in this bay for vessels of moderate draught appears to be with Pulo Nongsa bearing N.E. by E., and Tanjong Treng about E. by S. $\frac{1}{2}$ S.

BATTAM BAY, the large bight immediately to the westward of Bollan Bay, is nearly $7\frac{1}{2}$ miles wide, and 2 miles deep, being bounded to the east-

ward by the projecting point of which *Tanjong Siquang* is the N.W. extreme, and to the westward by the two Sambo Islands. In the depth of the bay are two islands about a mile apart, the eastern one of which is named Mangrove Island.

The Sambo Islands, forming the western limit of Battam Bay, project from Battam Island in a N.W. by N. direction, towards St. John's Islands on the opposite side of the strait. *Pulo Sambo*, the southern island, is nearly a mile long and about half a mile broad, and is distant a little over $1\frac{1}{2}$ mile from the nearest part of Battam. *Little Sambo*, about half the size of Pulo Sambo, lies about a third of a mile to the northward of it.

A rocky ledge, a third of a mile in extent, lies N.N.W. $\frac{1}{4}$ W., the outer part distant two-thirds of a mile from Little Sambo; and half a mile to the westward of it is another rocky ledge. These ledges are the outermost dangers on the southern side of this part of the strait, and near them are very irregular soundings.

Directions for the Eastern Part of the Strait.—The Middle Channel between Horsburgh lighthouse and the Romania Shoals is the main entrance to Singapore Strait from the eastward. Although the South channel is still recommended as being preferable for sailing through in the night, yet it is so encumbered with dangers, to clear which no good marks can be given, that it is seldom used by those accustomed to the navigation of the strait, more especially since the discovery, in 1161, of the Brakit Rock off Brakit Point, which is extremely dangerous to vessels standing out in the N.E. monsoon. The difficulty and danger attending the navigation of this channel arises from the risk of wrongly judging the distance from the lighthouse when endeavouring to keep clear of the South ledge.

Coming from the eastward or north-eastward in the daytime, the entrance of Singapore Strait may be easily recognized if the weather be fine and clear by Bintang Great Hill, a remarkable saddle hill (1,230 ft. high) on Bintang Island, and the sharp-peaked hill of Barbukit (645 ft. high), on the opposite side of the strait. Bearings of these objects will serve to fix the vessel's position and guide her in shaping a course to sight the lighthouse. In making the entrance at night, if the vessel's position be known, it will be merely necessary to stand on boldly for the light, being careful to make a proper allowance for the set of the current, and when the light is seen, steer so as to pass about a mile to the northward of it. Vessels should not get within about 2 miles of the light until it bears to the southward of W.S.W., on account of the dangers lying off its East side.

It is from the northward, however, that the strait is mostly made (*viz.*, by vessels coming from China), it being now the general custom for vessels from Europe to enter from Rhio Strait.

During the strength of the N.E. monsoon the current sets generally to the southward or S.S.E., between Pulo Aor and the East end of Bintang, by

which vessels running for Singapore Strait in thick weather are liable to fall to the southward of its entrance, if proper allowance be not made.

Departing from Pulo Aor, steer to bring it to bear about North when disappearing; if the weather be clear, Bintang Hill and Pulo Aor may be seen together; but this seldom happens. Do not bring the centre of Bintang Saddle Hill to the eastward of South, until Horsburgh lighthouse is visible from the deck; for with the hill bearing South the vessel will not pass far outside the North patch; but it is a safe bearing if the compass be correct, and will lead down in soundings of 16 to 13 fathoms. Bintang Little Hill, open to the westward of Bintang Great Hill, leads to the eastward of the North patch.

In hazy weather Bintang Hill is seldom visible until the eastern bank is passed, in which case, having Pulo Aor disappearing about North, a course S. by W. to S.S.W. may be requisite to counteract the south-easterly current, or the ebb tide setting out of the strait to the north-eastward. The depths will decrease regularly in steering southward, and the low land will *probably* be seen to the westward, when in 20 or 18 fathoms; if so, coast it along at 10 or 12 miles' distance, until False Barbukit low sloping hill is discerned, appearing a little way from the sea like a clump of trees more elevated than the others. When this hill bears W.S.W., 15 fathoms is the fair track; with it bearing W. $\frac{3}{4}$ S. and W. $\frac{1}{2}$ S., overfalls from 16 to 13 fathoms may be experienced, or probably less water, being then about the parallel of the North patch and the shoal patch, with 8 to 10 fathoms, on the eastern bank.

Having coasted along at 10 or 12 miles distance, with the land distinctly in sight from the deck, and having brought False Barbukit Hill to bear about W. by S., the vessel will be approaching the North patch; and with this hill bearing about W. $\frac{3}{4}$ S., if a cast of 10, 9, or 8 fathoms is got, but uncertain whether these soundings are on the North patch, or on the shoal patch of the eastern bank, haul to the south-eastward until in 14 or 15 fathoms. Steer then South about 2 miles, or until False Barbukit Hill bears West, when the vessel will be to the southward of the shoal patch of the eastern bank, and abreast the North patch; she may then haul in to the W.S.W., and get a cast of 10 or 11 fathoms, and will then be certain that these soundings are on the outer edge of the Romania Shoals, but in doing so, heave the lead quickly, and if there is less than 10 fathoms, haul out directly eastward into 15 to 16 fathoms, and then steer along the S.E. edge of the shoals in 16 or 17 fathoms. If, when the lighthouse is discerned, it bears S.S.W., the vessel will be clear to the eastward of the shoals; but if it is seen bearing S. by W., she will be close to or upon their edge. Having steered round the shoals so far as to bring the lighthouse S. by W., do not come under 16 or 17 fathoms in passing along their southern part; for they are there steep from 16 to 12, and from 12 to 3 fathoms at a cast, on some of

the rocky patches, with the lighthouse bearing from S.E. $\frac{1}{2}$ S. to South. South Island just open to the southward of South Point, bearing about W. by S. $\frac{1}{2}$ S., leads clear to the southward of all the Romania Shoals.

Although Pedra Branca Rock is steep-to on the North side, it should not be approached very closely, for vessels are liable to estimate their distance from it sometimes greater than the truth; and, as the tide runs strong, they are in danger of being drifted quickly towards the rock without warning, if they borrow near it in light winds.

Having passed between the Romania Shoals and Lighthouse, and bound to Singapore Roads, if the vessel be over on the North side of the channel, steer about S.W. or S.W. by W., if in mid-channel about W.S.W., and if near the lighthouse about W. by S., taking care if on the North side of the channel to have Tanjong Stapah open of South Point, before South Island, of the Romania group, is brought to the eastward of N. by E. Having brought the lighthouse to bear E. by N., the opposite course (W. by S.) will lead at a convenient distance from the North shore of the strait until Changhi Point bears North, when steer half a point more to the southward; the ships in the roads will be by this time in sight, and be a guide in approaching the anchorage, and as Tanjong Catong is neared, the flagstaff on Fort Canning Hill overlooking the town should not be brought to the westward of W. by N.

If the tide is running to the westward it is the usual practice for vessels to keep well over on the North side of the channel, especially in light winds, for neglecting this precaution they have often been swept by the rapid current past Singapore Roads and the St. John's Islands—the deep water 45 or 50 fathoms, rendering it difficult or impossible for them to anchor—into the western part of the strait. In doing this, however, they must be cautious not to go too near the Johore Shoal, which will be avoided by keeping South Romania Island open of South Point, or South Point to the northward of E. by N. $\frac{1}{2}$ N.

At Night keep a good look-out for Horsburgh Light (page 388), which being visible in clear weather at 15 miles, will be in sight before the vessel can get too near the dangers at the entrance of the strait.

If entering the strait from the southward or south-eastward, the light is seen bearing to the southward of West, a course may be shaped to pass about 2 miles to the northward of the light, proper care being observed to allow for the set of the tide, so that the light is not neared under 2 miles, on a West or N.W. bearing, to avoid the dangers extending to the East and S.E. from it. Should the light, when first seen, bear about W. by N. or W.N.W., a vessel will be within 2 or 3 miles of the Brakit Rock, over which there are but 2 fathoms water, and from which the light bears W. by N. $\frac{1}{2}$ N. $12\frac{1}{4}$ miles.

If when entering from the northward the light is made bearing anything

to the southward of S.S.W., haul to the eastward until it bears S.S.W., which will lead outside the North patch; approach the light upon this bearing until about 2 miles from it, when a W.S.W. course may be shaped until the light is brought E. by N., when keep it on that bearing, steering W. by S. until the light is lost sight of.

Continuing for 4 or 5 miles farther on a W. by S. course after Horsburgh Light has disappeared, the fixed light at Singapore will soon come in sight, but in case it should not be distinctly made out by the time Johore Hill bears N. by E., do not come under 16 or 17 fathoms towards Johore Shoal, and if a cast of 12 or 11 fathoms should be had haul quickly to the southward, for this shoal is steep, and should not be approached under that depth. Be careful not to mistake Singapore Light, which will be seen some distance above the horizon when first discerned, and high above the lights of the shipping and town as the roads are neared; when plainly seen it may be approached on a West bearing until the eastern extreme of Singapore Island (Changhi Point) bears North, or Johore Hill bears N.E. $\frac{1}{2}$ E., when the light should be brought to bear W. $\frac{1}{2}$ N.; as Tanjong Catong is approached, edge to the southward until the light is to the northward of W. by N.

It is very necessary to observe the precaution of keeping on the North shore of the strait when nearing Singapore Roads at night, for although a vessel may have entered the strait with a strong N.E. monsoon, yet as she nears the roads, the wind will, in the night, generally draw off the land from the north-westward, making it always very difficult and sometimes impossible to fetch into the roads or get into a convenient depth of water for anchoring.

If bound into the strait of Malacca, a W. by S. $\frac{1}{4}$ S. course is the fair mid-channel track from Horsburgh Lighthouse, and when within 5 miles of St. John's Island, the Raffles *fixed* white light on Coney Island will be distinctly seen. A vessel should steer up pretty close to St. John's Island, avoiding the South side of the strait, and proceed through the western part of the strait according to the directions given at pages 364—366; the Raffles Light bearing W.S.W. is the fair channel mark.

The South Channel is sometimes convenient for ships which fall to leeward of Horsburgh Lighthouse during thick weather, as they have no occasion to anchor outside. If the wind be north-easterly, they may run down until within 4 or 5 miles from the Bintang shore, remembering that Barbukit Hill must be kept four times its own breadth open northward of Horsburgh Lighthouse, or the lighthouse kept westward of W. by N. $\frac{1}{2}$ N. to clear the Brakit Rock, then haul to the westward, and pass nearly in mid-channel between the shore and the lighthouse in 11 to 13 fathoms of water. With the wind at N.W. or N., it will be advisable to borrow nearer to the South ledge than to the Bintang shore, observing not to approach too closely to the

South ledge, as it is covered at high-tide. By borrowing towards the weather side of the channel, vessels will be enabled to reach well into the entrance of the strait; and if the wind is scant and the tide against them, they will have smooth water and good bottom for anchorage, until the tide of flood is favourable for proceeding to the westward.

To work through the Eastern Part of the Strait.—No difficulty will be experienced by strangers in working in either direction through the eastern part of the strait. The most prudent plan is to keep towards the North shore, as the depths are more convenient for anchoring on that side of the strait, in case of having to bring up. A vessel should tack towards the Romania shoals, when South Island is seen opening to the southward of South Point; and when standing towards Stork Reef and Congaltons Carr, South Point should not be brought to the southward of W. $\frac{1}{2}$ S. When South Island bears to the eastward of North, Tanjong Stapah must not be shut in behind South Point when standing to the northward; and from thence the shore may be approached into 12 or 11 fathoms. South Island kept open of South Point leads to the southward of Johore Shoal, and when standing towards this danger, if these objects cannot be seen, avoid coming under 17 or 16 fathoms, and on no account under 12 or 11 fathoms, for the shoal is steep. From Johore Shoal to Singapore Roads the shore may be approached to 12 or 11 fathoms; but it is not prudent to go into a less depth.

There are no dangers on the South side of the strait, excepting those fronting the Bintang Coast and the Crocodile and Pan Shoals, &c. But a vessel should not stand so far over as to get near these dangers, for no advantage will be gained by doing so, and the depths there are inconveniently great for anchoring. Pulo Nongsa, a remarkable little island, with a high tree upon it, lying just to the westward of the entrance to Rhio Strait, is very convenient for taking bearings of when getting over to the southward near Rhio Strait, and if kept to the southward of West, will lead clear of all danger at the entrance of that strait.

To proceed from Singapore Roads to the Eastward.—On leaving the roads, steer about E. by S. until past Tanjong Catong, when a course may be shaped about East, and by not bringing the flagstaff on Fort Canning to the southward of West as long as it remains in sight, it will lead well clear of Johore Shoal. When Johore Hill bears North, the vessel will be westward of Johore Shoal, and may steer E. by N. for the lighthouse, and passing about a mile to the northward of it, proceed to sea as convenient.

CHAPTER X.

THE GULF OF SIAM, ETC.

THE Gulf of Siam extends from Pulo Kapas on the Malay coast, 245 miles N. by W. from Point Romania to Pulo Obi, off Cambodia Point, 217 miles in a N.N.E. direction. But in order to complete the description of the coast, that portion of the Malay Peninsula South of Pulo Kapas will be included in the present chapter. A portion of this coast, more than 100 miles in extent, was surveyed in 1849 by Mr. J. T. Thompson, F.R.G.S., the surveyor of the Straits Settlements. The rest is imperfectly laid down, but the Siamese Government have recently made some new surveys.

The Gulf of Siam has not been completely surveyed, but the examination of its shores, more than 1,000 miles in extent, made by Mr. John Richards, R.N., in H.M. surveying vessel *Saracen*, in 1856—8, includes everything required for its safe navigation. The ensuing description of, and directions for the Gulf are chiefly by that officer.

The Winds and Seasons are described on pages 16—17, *ante*.

The Currents on page 28.

The Passages to and from the Gulf, on pages 63 to 67.

The **EAST COAST** of the **MALAY PENINSULA**, from Romania Point, its S.E. extreme, to opposite Pulo Varela, is mostly low and woody, its general direction being about N.N.W. Close to the coast, especially off the points, there are many rocks, both above and below water, but they all, with the exception of the Gading Rocks, near Blair Harbour, appear to lie within the 3-fathom line of sounding; so that when clear of Romania Reef the coast is in most places safe to approach by the lead.

It was formerly a common practice for vessels bound from China to Singapore, or to Banka or Gaspar Straits, to work down close to this coast. Now, however, as has been previously remarked (p. 62), those from China usually stand to the southward as soon as they can weather the reefs. But vessels from Siam bound to the southward against the S.W. monsoon, generally find

it most convenient to keep as close as possible to the Malay coast, where they meet with regular tides, whilst a constant northerly current is found a few miles from the coast.

PULO EU, in lat. $2^{\circ} 7' N.$, long. $104^{\circ} 17' E.$, is the south-eastern of a chain of islets and rocks which lie in a S.E. direction from Pulo Tingy, and East and S.E. of the Sibou Islands; it is described as a round, bluff rock.

Ambong Reef is placed on the chart 7 miles to the N.W. of Pulo Eu; and nearly in a line between them lie four small islets, or rocks above water, named respectively *Chupa*, *Chondong*, *Gantang*, and *Belelei*.

Lima Island, lying about $1\frac{1}{4}$ mile N.W. of Ambong Reef, is nearly half a mile in extent, and there are two rocks above water named Raket, about half a mile E.S.E. from it, another rock just to the northward of its West extreme; and another, named Sangul, nearly a mile W. by N. $\frac{1}{2}$ N. from it. They all appear to be connected, and surrounded to a short distance by a reef.

SIBOU ISLANDS.—Sibou, lying about 5 miles to the S.W. of Pulo Tingy, and the same distance from the coast, is a narrow island, 3 miles long N.W. and S.E., and near its South end is a hill, 553 ft. high. A small island, *Middle Sibou*, and two islets or rocks named respectively *Sibou Kukus* and *South Sibou*, together with other rocks both above and below water, extend in a south-easterly direction from Sibou, for a distance of 2 miles. The western side of the group is dangerous to approach.

Sibou Channel, between Sibou and the main, is about $2\frac{1}{2}$ miles wide in the navigable part between the danger limits on either side, and perfectly clear, with general depths of 6 to 8 fathoms, but of 9 or 10 fathoms near the island.

PULO TINGY, in lat. $2^{\circ} 18' N.$, long. $104^{\circ} 9' E.$, is conspicuous from a very high peak, which, rising gradually from the low land near the sea, terminates at the summit in a sharp spire or cone, 2,046 feet high. The island is nearly 4 miles long, N.W. by W. $\frac{1}{2}$ W., and S.E. by E. $\frac{1}{2}$ E., and 2 miles wide.

A cluster of islets and rocks extend nearly 2 miles southward and south-eastward from Tingy; and on its East side, about half a mile off shore, is a small island named *Ibul*, with an islet between it and the shore, and rocks below water a short distance outside of it. About $1\frac{3}{4}$ mile off the North part of Tingy is a reef, called the *Gebang Rocks*; and to the south-westward of it is the *Siam Knoll*, of 3 fathoms, lying about 1 mile off the N.W. part of Tingy.

Morau Rocks, or *Arethusa Reef*, appears to be a reef under water, extending to the northward and westward of a small islet, which lies $4\frac{3}{4}$ miles N.N.W. from Sibou Island, and W. $\frac{1}{4}$ S. from the peak of Tingy, nearly in mid-channel between Tingy and the main.

BABI ISLANDS.—Babi, or High Island, lying 9 miles N.W. from Pulo Tingy, is $2\frac{1}{3}$ miles long N.N.W. and S.S.E., and three-quarters of a mile broad. On its South end are two peaks, the northern one of which is 911 feet high; some rocks appear to lie close to its southern shore. *Middle Babi*, an island about half a mile in extent, with several islets and rocks close to it, lies nearly $1\frac{1}{2}$ mile north-westward of Babi; and three-quarters of a mile north-westward of Middle Babi, is a rather larger island, named *North Babi*.

Captain Ross, in the *Phlegethon*, in the month of August, having found that the two watering places on the S.W. part of Pulo Tingy had dried up, proceeded to Pulo Babi, and found here three springs of clear fresh water, the principal one on the N.W. point of the island, to the southward of a small patch of mangrove jungle.

Tikus Rocks.—A rock above water, with small detached rocks around it, lies $3\frac{1}{4}$ miles to the eastward of the southern part of Babi. *Sakit Mata* is a rock awash, lying E. $\frac{1}{4}$ N., distant nearly $2\frac{1}{2}$ miles from the North point of Babi.

Rawa is a small island, about half a mile in extent, lying $3\frac{1}{2}$ miles North from Babi, and $2\frac{1}{4}$ miles N.E. from North Babi. From *Rawa* a chain of islets and rocks extend 3 miles to the north-westward.

SIRIBUAT ISLANDS, bearing W. $\frac{3}{4}$ S., 15 miles from the Asses Ears on Tioman, and N.N.W. 7 miles from Gurong, appear upon the chart as two islands, the eastern and larger being about $1\frac{1}{2}$ mile in extent. The western island is a little more than half the extent of the eastern one, but is 748 ft. high. The islands are connected by a reef, upon which are some islets and rocks.

BLAIR HARBOUR.—*Kaban Island*, $1\frac{1}{4}$ mile long N.N.W. $\frac{1}{2}$ W. and S.S.E. $\frac{1}{2}$ E., and but half a mile broad, lies W. by S. $6\frac{1}{2}$ miles from the Siribuat Islands, and the space between its West side and a prominent point of the coast named Peniabong Point, about a mile distant, is known as Blair Harbour. About a mile south-eastward of the South entrance of the harbour, is a small group above and below water, named the *Gading Rocks*; there also appears to be rocks extending from the points on both sides of the South entrance, thus materially contracting the channel. A small island, named *Little Kaban*, lies about a mile northward of Peniabong Point; other islets and rocks lie to the westward of the point. North-westward of Kaban is a group of islets and rocks named *Tonos*, and in the same direction, distant 2 miles from Kaban, is a small island named *Leiar*.

Blair Harbour is safe, sheltered from all winds, with anchorage in 4 and $4\frac{1}{2}$ fathoms, stiff mud. It is easy of access by passing between the North point of Kan and the small islands, where the depths are 6 and 7 fathoms, decreasing to 5 and $4\frac{1}{2}$ fathoms inside. There is also good anchorage under some of the other islands farther out.

Capt. Pridham, R.N., who touched here September 8th, 1830, discovered

a rock in the entrance of the harbour, which uncovers with the falling tide, about half a mile South of Leiar Island.

Plenty of *good water* may be procured on Kaban Island by digging wells 5 ft. deep, about 20 or 30 yards from high-water mark.

The **INNER CHANNEL**, between the Malay coast and the groups of islands just described, is safe for ships of any description by keeping along the coast at 3 or 4 miles distance. The depths in it are 8 to 11 fathoms, in the fair track, usually soft ground. The channel is safe in the day, but in the narrow parts, among the islands, it is prudent to anchor at night, because some of the rocks or islets are very little above water.

Tides.—About 20 miles to the southward of the entrance to the Inner channel it is high water, full and change, at 9^h 14^m, and spring tides rise 6 to 8 ft. Near the Siribuat Islands it is high water at 8^h 50^m, and the rise is 9 feet.

PULO AOR, the southern peak of which, 1,805 ft. high, is in lat. 2° 26½' N., long. 104° 34¼' E., is generally adopted as a point of departure by ships bound to China, and they also steer for it on their returning passage. It is small, but high, and covered with trees. Being formed of two hills, with a gap between them, it has the appearance of two islands when viewed at a great distance, bearing N.E. or S.W., and resembles a saddle on a nearer approach; but when it bears N.W. the hills are in one. The easternmost hill is of round form, like a dome, rather higher than the other, and in clear weather may be seen 45 or 48 miles from the deck; at such times Bintang Hill and Pulo Aor are visible together, when midway between them.

The bay on the S.W. side of the island affords shelter in the N.E. monsoon, when the wind is between North and E.S.E.; and here, persons unacquainted with the entrance of Singapore Strait frequently anchor in dark, hazy, blowing weather, until it becomes more favourable for running into that strait. This has not been a common practice since the establishment of the Horsburgh light at the entrance of Singapore Strait. *Pinang Islet*, covered with trees, lies off the S.E. point of Pulo Aor, and *Lang Islet* lies off the N.W. point; to the N.E. of the latter is *Dyang Islet*, larger than the two others, and separated from the North end of Aor by a narrow gut, having 18 or 19 fathoms water in it.

The depths near Pulo Aor are from 32 to 35 fathoms to the northward and eastward, 24 and 25 fathoms to the westward, decreasing to 16 or 17 fathoms towards Pulo Tingy, and to 21 fathoms close to the South end of Pulo Pemangil.

Supplies.—Pulo Aor is inhabited, and there is a considerable number of huts around the bay; firewood and some cocoa-nuts may be procured, but no other refreshments except water. Ships water with their own boats, for the natives, although shy of strangers, are generally found to be inoffensive; it is, however, imprudent to let the sailors go up into the country.

There is a rise and fall of tide about 5 or 6 ft., although the current in the offing sets mostly with the monsoon.

Directions.—If coming from the northward and intending to anchor in the bay on the S.W. side of Pulo Aor during N.E. winds, pass on the West side of the island, in order to fetch into the bay so far as the watering place, which is a small running stream on its North shore. After rounding the West side of the island, which is steep-to, at any convenient distance, haul into the bay until Lang Island is on with the N.W. point, and anchor in 20 to 15 fathoms, sandy bottom, with the extremes bearing from N.W. to S.E. $\frac{1}{2}$ E., off shore about half a mile; but sail ought to be reduced in time; because from 20 fathoms the bank is steep, and it would be imprudent to shoal under 15 fathoms in a large ship.

PULO PEMANGIL (or *Pisang* or *Pambelan*) is distant 11 miles N.W. by W. from Pulo Aor, which it resembles when seen in hazy weather bearing to the S.W. or southward; for it is formed of two hills with a gap between them, giving it the appearance of a saddle, but it is not so high as Aor. Its South peak, 1,507 ft. high, is in lat. $2^{\circ} 34\frac{1}{2}'$ N., long. $104^{\circ} 22'$ E. It is said that water may be obtained upon Pemangil; but ships seldom stop here, for it is not inhabited, and consequently affords no supplies.

PULO TIMOAN, the South end of which is in lat. $2^{\circ} 43'$ N., bearing N.W. $\frac{1}{2}$ W. about 22 miles from Pulo Aor, is 11 miles in extent, North and South, and from 2 to 6 miles wide. This island is composed of lofty mountains, the highest of which rises to an elevation of 3,444 ft. and may be discerned 55 or 60 miles in clear weather. On its South end are two remarkable peaks, called from their aspect *Asses' Ears*, standing on one base, and rising almost perpendicularly from the sea to heights of 2,525 and 2,294 feet. There is a village on the S.E. side of the island in a small sandy bay, which has anchorage in 20 or 22 fathoms, sand, and may be used during fine weather; but the bay on the S.W. side of the island affords the best shelter in the N.E. monsoon.

Water; Wood.—There is a small river on the East side of this bay, where boats can fill their casks; but a bar at the entrance prevents their going in and out at low water. At a small rivulet on the N.W. side of the bay, fresh water may be filled at all times. Firewood may be procured in abundance near the shore. Refreshments are not to be had here, the bay seldom being inhabited. Ships seldom touch at this island, and persons landing on it must be guarded against the deceit of the natives, and ought not to penetrate into the interior.

The flood tide sets to the northward, along the West side of Timoan, and the ebb to the southward, 1 or $1\frac{1}{2}$ mile per hour, at times; it is high water, full and change, at 6 hours, and springs rise 7 or 8 ft.

At 3 miles South of the *Asses' Ears* is a small island named *Geeit*, having a small islet or rock close to the southward of it.

Bara and **Burong** are two rocks or small islets, lying in the fairway of the channel between Timoan and the Siribuat Islands. Bara lies 6 miles westward of Geeit, with the Asses' Ears bearing N.E. by E. $\frac{1}{4}$ E., distant 7 miles; some rocks below water extend about a mile to the northward of Bara. Burong is distant 10 miles N.W. $\frac{1}{4}$ N. from Bara, the same distance eastward of Timoan.

Tolie is the largest of the islands lying off the N.W. point of Timoan, from which it is distant nearly 3 miles. It is about a mile in extent, and rocks above and below water extend about a mile to the southward of it. The channel between Tolie and the N.W. point of Timoan is clear, with depths of 22 and 24 fathoms.

The **COAST** from Blair Harbour falls back 6 or 7 miles in a W.N.W. direction to the *Indau River*; it then takes a north-westerly direction for 9 or 10 miles to the entrance of the *Pontean River*; from thence it curves round gradually until it assumes a northerly direction, which it preserves as far as the entrance of the Pahang River, 48 miles to the northward of the Pontean.

Boyah Rock.—Two small islets, named *Duchong*, lie nearly a mile off the coast to the southward of the Pontean River, and about 3 miles eastward of them is the *Boyah Rock*, *awash*, with 4 and 5 fathoms water around. From the rock the entrance of the Pontean bears W. $\frac{1}{2}$ N., $5\frac{1}{2}$ miles; the entrance of the Indau S. by E. $\frac{1}{2}$ E., 6 miles; and the apex of the western Siribuat Island W. by S. southerly.

MARGARET SHOAL, in lat. $2^{\circ} 59\frac{1}{2}'$ N., long. $103^{\circ} 38'$ E.—The brig *Margaret*, in working to the northward along the coast, January, 31st, 1827, shoaled suddenly from 6 to 4 and 3 fathoms, 3 miles off shore. There are two conspicuous little hills on the low land, of regular form, the northernmost of which bore W. by S., and the other S.W. by W., when the vessel was in 3 fathoms.

PULO VARELA, in lat. $3^{\circ} 18'$ N., long. $103^{\circ} 38'$ E., is a barren rock 12 or 13 miles from the main, crowned with a few bushes, which in clear weather may be discerned about 15 miles. There is a ledge of rocks even with the water's edge, about $1\frac{1}{2}$ or 2 miles nearly North from it, on which the sea breaks in bad weather; and about 6 miles North and N.N.E. of it there is a rocky bank with overfalls, probably not dangerous, for the least water on it is thought to be about 5 fathoms. The channel inside Varela is considered safe.

PAHANG RIVER, the entrance to which is in lat. $3^{\circ} 34\frac{1}{2}'$ N., about 20 miles N.W. of Pulo Varela, was formerly a place of great trade, and is still frequented by Chinese junks; but it is small, very shoal, and contracted by sands, which project from the low points on each side. Pahang Point bounds the river on the South side, and has breakers stretching from it to the N.N.E. nearly $1\frac{1}{2}$ mile; a spit of hard sand, with 3 to 6 fathoms, extends about a

mile farther in the same direction, on the West side of which vessels of moderate draught may anchor in $4\frac{1}{2}$ or 5 fathoms, clay and sand, off shore $1\frac{1}{2}$ mile, with Pahang Point bearing South or S. $\frac{1}{4}$ E. about $2\frac{1}{2}$ miles. Large vessels anchor at a greater distance from the shore.

The **COAST** from the Pahang trends about N. by E. for a distance of 33 miles to a point in $4^{\circ} 8' N.$, having high land near it, between which and South Cape, about 14 miles farther to the northward, a bay is formed with some islands close to the shore. From South Cape the direction of the coast alters to about N. by W., as far as *Tingeran*, a distance of about 28 miles: between are several bays, separated by Middle Cape and North Cape, all of which have from 9 to 10 or 11 fathoms water within 2 or 3 miles of the shore, but the projections or capes are rocky.

A chain of mountains commences inland, nearly abreast of Pulo Varela, which converges towards the coast near South Cape, and then extends along it towards Tringanu.

Between Pulo Varela and Tingeran the coast is, in general, safe to approach to 8 or 10 fathoms water; but there are frequently overfalls of 1 or 2 fathoms in the offing, or ridges lying parallel to the coast; and there are some spots of 7 or 8 fathoms, sand and gravel, with 9 fathoms inside of them, but this portion has not been properly surveyed.

HOWARD SHOAL was passed over by Mr. Howard, commanding the ship *Janet Hutton*, in 1823, in lat. $4^{\circ} 17' N.$, long. $103^{\circ} 38\frac{1}{2}' E.$, bearing South (or S. by W.) 30 or 31 miles from Pulo Brala, and S.E. $\frac{1}{2}$ E. 6 miles from the *River Camaman*. Upon this shoal he got 2 fathoms, rocks, and was informed by the Malay fishermen that there was only 1 fathom on its centre.

Tingeran River, the entrance to which is in lat. $4^{\circ} 49' N.$, is formed close under the South side of Rocky Point, the latter being about 12 miles West from Pulo Brala; this river is barred by rocks.

PULO BRALA, in lat. $4^{\circ} 49' N.$, long. $103^{\circ} 38' E.$, distant 12 or 13 miles from the main, is of considerable size, and may be seen 30 or 32 miles off in clear weather; when it bears S. $\frac{3}{4}$ W. its summit is flat, but appears in hummocks when bearing to the S.W. and westward. There is a black rock or islet 1 or 2 miles distant from its southern extreme, and two islets off its north-western extreme, the outer one being distant nearly 5 miles.

Between this island and the coast opposite, about Rocky Point, the soundings are irregular in some places, and the bottom rocky or sandy.

PULO KAPAS is considered as the S.W. limits of the Gulf of Siam. Its S.W. point is in lat. $5^{\circ} 13' N.$, long. $103^{\circ} 16' 4'' E.$; it is $1\frac{1}{2}$ mile long, North and South, three-quarters of a mile wide, and elevated 478 ft. A large rock lies a cable's length N.W. of it. The island is fertile, and inhabited by fishermen, who cultivate a few vegetables for their own consumption. The channel, inside Pulo Kapas, between the island and main, is $2\frac{3}{4}$ miles broad, and quite safe.

TRINGANO HEAD, bearing W.N.W., distant about 3 miles from the North point of Pulo Kapas, and S.S.E. $\frac{1}{2}$ E. 6 miles from the entrance of Tringano River, is remarkable as the only rocky point in the neighbourhood. A *rock awash* at high water lies a quarter of a mile from the beach, and $1\frac{1}{2}$ mile to the southward of the Tringano River entrance.

TRINGANO RIVER.—The entrance to this river may be easily known by the large gap or opening in the coast line, as well as by a remarkable cone, situated about 1 mile to the southward of the town. There is also in the town a small steep hill, 100 ft. high, with a fort, on which the Rajah's flag is displayed when a vessel passes within signal distance of the place.

The river has a bar, with 7 ft. over it low water. Within the bar, and immediately off the town, there is good anchorage in 5 fathoms, but the river itself above the town is very shallow. The Rajah is hospitable to strangers, and the natives of the coast are friendly. Wood, water, and fresh stock can be procured at reasonable rates.

It is high water, full and change, at the entrance of Tringano River, at 8 a.m., and springs rise 7 ft.

EULO ROCKS.—The coast from the entrance of the Tringano trends north-westward, and is low and slightly convex to Eulo Village, where the high land approaches close to the beach. The Eulo Rocks, a small group of 6 ft. elevation, lie immediately off the village, an eighth of a mile from the beach, N.N.W. $\frac{3}{4}$ W. 9 miles from the entrance of the Tringano River.

Seal Rocks consist of three distinct groups, the extremes of which lie North and South, nearly a mile apart. The South Seal is elevated 9 ft., the other two groups only 3 ft.; there are deep channels between them. The South Seal lies nearly $2\frac{1}{2}$ miles from Seal Bluff, and there is a good channel between it and the bluff, with regular soundings. Care, however, should be taken, when standing towards the bluff, to avoid a rock, awash at low water, lying North a quarter of a mile from the bluff. *Bukit Trokit* is a rock, elevated 140 ft. above the sea, lying 4 miles northward of the Seal Rocks. There is a rock, only 5 ft. high, nearly a mile westward of it. *House Rock*, lying N.W. $\frac{1}{2}$ N., $10\frac{3}{4}$ miles from Seal Bluff, is so named from its appearance.

REDANG ISLANDS.—The Great Redang, the peak of which is in lat. $5^{\circ} 48' 16''$ N., long. $103^{\circ} 0' 48''$ E., is safe to approach on all sides. It is surrounded by small islets and rocks, but they are all bold-to, and have generally good water inside them. There is plenty of wood and good fresh water, and turtle may be caught in abundance on a beach at the North part of the island. There is a fine bay on the North side and a small harbour on the South side of the island. The harbour is protected to the southward by Pulo Pinang, and, although small, might be useful to a ship in distress or in want of repairs. There is a village on *Pulo Pinang*, and a few huts

scattered in different parts of the Great Redang. The conical peak of the *Little Redang* is 985 ft. high. All these islands are quite safe to approach.

PRINTIAN ISLANDS.—This group, lying about 15 miles north-westward of the Great Redang, is also safe to approach. The channel between the two large islands, although narrow, is quite safe for vessels with a leading wind. There is good anchorage on either side of the channel, but the most secure is to the southward. The islands are inhabited, but fresh water is scarce.

TURTLE-BACK ISLAND, so named from its peculiar shape, is elevated 346 ft., and bears N.W., distant 26 miles from Seal Bluff. The intermediate coast is low. Between Tringano and Turtle-back Island, at the distance of several miles inland, there are two ranges of high mountains; the northern one and nearest the coast is elevated 3,388 ft. The channel between Turtle-back and the Printian Islands, as well as the passage between it and the main, is safe.

KALANTAN RIVER.—From Turtle-back Island the coast trends N.W. $\frac{3}{4}$ N. 30 miles to the East point of Kalantan River. There are no dangers on any part of it that are not apparent, and attention to the lead will always indicate the distance from the land.

The *Town of Kalantan* stands on the right bank of the main river, 5 miles from the entrance, near the confluence of its delta, which consists of five streams. The main river at the town is about 2 cables broad and 2 fathoms deep: its banks here are very sandy. The town extends about a mile along the river front, and seems to be densely populated. The greater part of the population are Malays; the remainder are Chinese; Siamese were not seen. The Rajah is a Malay, subject to the King of Siam; both he and his people are friendly and courteous to strangers. The whole delta of the river is very fertile and highly cultivated. It produces immense quantities of cocoa-nuts, and a great variety of fruits. Bullocks, sheep, goats, and fowls were plentiful. Dollars are current.

The main branch of the river is the third stream from the eastern one, and was said to have, in 1856, 9 ft. over the bar at high water springs. The delta of the river is said to be continually altering during the N.E. monsoon.

Vessels approaching the river from the south-eastward will be guided to it by three small hills, situated near the coast, 13 miles to the southward. Two of these hills (close together) are called the *Paps*, and are elevated 300 ft.; the third, named *Wedge Hill*, is elevated 400 ft., and separated a short distance. The Paps bearing S. by E. $\frac{3}{4}$ E. will be in line with the sandy point near the main entrance of the river.

The Coast for 25 miles westward from the main entrance of the Kalantan has not been surveyed, but it is believed to be quite safe. It is all low land for the above distance, at the termination of which there is a remarkable conical hill standing on the coast line. This hill is elevated 1,158 ft., and

bears S.E. by S. 17 miles from Baltu Rackil. *Baltu Rackil*, in lat. $6^{\circ} 40' 36''$ N., long. $101^{\circ} 43' 56''$ E., is a white rock, elevated 35 ft., and quite steep-to.

Hilly Cape is remarkable as the northern extreme of a chain of hills, which rising far in the interior, and cutting the parallel of Kalantan 25 miles westward of it, here jut out into the sea, and form an angle of the coast, remarkable from its two steep bluffs. The easternmost of these bluffs bears from Baltu Rackil N.W. $\frac{1}{4}$ W. 15 miles.

Pulo Lozin, in lat. $7^{\circ} 21'$ N., long. $102^{\circ} 1' 48''$ E., is 7 ft. above high water, steep-to all around, and in size and appearance resembles a vessel of about 100 tons burthen bottom up.

The following information of the navigation of this part of the coast is an extract from the Bangkok Calendar, 1873, and derived from the surveys of H.S.M. surveying brig *Enemy Chaser*, Capt. A. J. Loftus.

“From Hilly Cape to Ligor, vessels may safely approach the shore to a distance of 4 miles, giving Cape Patani a berth of at least 2 miles, as there are shoal sand patches, having 10 ft. of water, in that neighbourhood. Patani Bay is quite choked up, and navigable only for small boats at high water. There is no island existing off the end of Cape Patani, as shown on the old charts. The mouth of Patani River lies a little to the westward of the meridian of the cape.

“Midway between Patani and Row Island, and about 3 miles from the shore, is a hard patch of ground, having 10 ft. of water on it. Pulo Ticos and Pulo Kewshan may be approached on their *eastern* side as close as convenient, there being plenty of water and no hidden dangers near them. Inside these islands the water is shoal, and not navigable for sailing vessels of any size. Small vessels will find snug anchorage in $2\frac{1}{2}$ fathoms water, bottom of mud, one-quarter of a mile off the S.W. end of Pulo Ticos. When coming in, or leaving the inner roadstead, keep the South end of the island (Ticos) close aboard. Large vessels will ride comfortably in 5 fathoms water, with the South end of Pulo Ticos bearing westerly.

“The coast from here to the extreme North end of Pulo Tantalum is quite clear, with good depth of water close-to, mud bottom. The coast line is not, however, as represented on the old charts; the extreme end of the Lamcolam Pook being about 4 miles farther South, and $8\frac{1}{2}$ miles farther East, than is there represented. The Pook itself is a narrow, curved spit of coarse sand, being about 6 miles in length, and 300 ft. at its greatest breadth, and having a compact cluster of young fir trees on its extremity, which may be seen at a distance of 12 miles from the deck.

“The water is shoal off and around this point, and continues so to the mouth of Ligor River, which bears from the Pook about W. $\frac{1}{2}$ N., distant $5\frac{1}{2}$ miles, when it gradually deepens to the northward. No hidden dangers have been discovered from thence to lat. $10^{\circ} 7' N.$

“Between the Pook and Ligor Creek the land forms a deep bight to the southward, where a river named Pakinham, $1\frac{1}{2}$ mile wide at its mouth, leads to the inland sea in the same direction. This bight, like that of Patani, is navigable only for small boats at high tide. To anchor in Ligor Roads, round the Pook at a distance of 4 miles, steer to the westward, and bring up according to draught. If coming from the northward, keep inshore, and anchor in suitable water near the inner fishing stakes. Circumstances are frequently favourable near the shore for vessels to beat down against the S.W. monsoon.”

SINGORA.—The town of Singora stands just within the East point of the river, and contains about 2,500 inhabitants. Its position may be known by two small islands off the port, as well as from a remarkable piece of table land at the entrance of the river opposite the town.

The anchorage for small vessels is in 17 ft. water, close inside the inner island, called by the Malays *Pulo Ticos*. The river has a bad bar at its entrance.

Wood and water may be purchased at the town, the latter from a spring just within the bar of the river. Stock of every description is plentiful and cheap.

The **ISTHMUS of KRAW** or **Kraa** (Monkey Isthmus) is probably the narrowest portion of the Malay Peninsula. Its western side has been alluded to in our *Directory for the Indian Ocean*, page 1067. The eastern inlet is the *Champon* or *Tseoompyoon River*, which has a bar with only 9 ft. over it at low water. A large town of the same name lies on its banks, 20 miles from its mouth. The isthmus between this point and the village of Kraw on a branch of the Pakchan River falling into the Bay of Bengal, was traversed by Captains Fraser and Forlong, under the direction of Col. Fytche, with a view to discover whether it was available for a canal or railroad across. But the desirability of this, although it may be practicable, is very questionable, as two transshipments of goods, &c., would be required to save 93 hours between Calcutta and Hong Kong; and, moreover, there are no good ports at either end.

Koh Krah, in lat. $8^{\circ} 24' 47''$ N., long. $100^{\circ} 43' 30''$ E., is half a mile long, a third of a mile broad, and 530 ft. high. Two high rocks, and a rock *awash*, lie to the southward. A small quantity of stagnant fresh water may be obtained on this island, and turtle are so plentiful that 150 have come up in a single night.

The coast between Singora and Champon, 200 miles to the N.N.W., has not been surveyed.

LEM CHONG P'RA, or Cape Chong P'ra, is a remarkable craggy headland of 1,060 ft. elevation, in about lat. $10^{\circ} 54' N.$, long. $99^{\circ} 28' 10'' E.$ A narrow island, called *Koh Buot*, lies 2 miles south-westward of the cape, and within the island is a snug bay named Chong P'ra.

LEM TONG LAN.—From Lëm Chong P'ra, Lëm Tong Lan bears N. by E., distant 18 miles. About midway within the bay, formed by these points, is a level cliffy island, called *Koh Tlu*, 342 ft. high, and nearly $1\frac{1}{2}$ mile long. There is no safe passage for vessels between Sing and Koh Tlu. Lëm Tong Lan is 814 ft. high, and the coast being very low within it, at a distance it makes like an island. At 11 miles northward of Lëm Tong Lan there is a remarkable clump of conical hills, and a low dangerous island lies immediately off them, at the distance of a quarter of a mile from the shore.

From Lëm Tong Lan, Koh Chan, an island 80 ft. high, lying 4 miles off the coast, bears N.N.E., and the distance is 27 miles, and to Koh Luem it is 37 miles, on nearly the same line of bearing.

KOH LUEM, 406 ft. high, is the outermost of several islands which lie off the bays called Ao-ti-bon-lai (?) and Ao-ti-now (?).

Ao-ti-bon-lai, the northern bay, affords the best anchorage for ships. W.S.W. 15 miles within the South horn of Ao-ti-now, is the mountain named *Kow Luang*, elevated 4,326 ft., which is by far the most conspicuous landmark on the whole coast.

KOH TA-KUT, 300 ft. high, is 1 mile long, N.N.E. and S.S.W., and a quarter wide, lying about N.N.E. 28 miles from Koh Luem; the coast between these islands is clear, and the soundings regular.

Samroi-yot Hills.—*Cui Point* (corrupted by Europeans into Cin) is the end of a spur running down from a remarkable clump of rocky hills near the coast, called by the natives Samroi-yot, or 300 peaks. At a distance their appearance is that of a serrated table island; the highest peak is elevated 1,900 feet. Samroi-yot is unlike any other land in the gulf, and all vessels bound to Bangkok in the S.W. monsoon endeavour to make it.

Water.—The only fresh water to be obtained between Chong P'ra and Cui Point is from wells, which have been provided at places convenient for the use of native craft by wealthy benevolent Siamese.

PRAN ROCKS, two in number, and each 100 ft. high, bear N. $\frac{3}{4}$ W. 17 miles from Koh Ta-kut. The village of Pran stands on the shore at the entrance of a river 4 miles southward of these rocks.

Between Koh Ta-kut and the Pran Rocks is a dangerous rocky patch of 1 fathom water, from the centre of which the North patch of Koh Ta-kut bears S. $\frac{1}{4}$ E. 8 miles, and a remarkable head on the coast line W.S.W. 2 miles. Vessels should not approach this part of the coast nearer than $2\frac{1}{2}$ miles, nor stand into less water than 7 fathoms.

A small headland stands out prominently from the coast line at 2 miles N. by W. from the North Pran; and East three-quarters of a mile from the centre of this headland is a rock which covers at half flood.

CHULAI POINT is 34 miles N. $\frac{3}{4}$ E. from the Pran Rocks. At 17 miles N. by E. $\frac{1}{4}$ E. from the North Pran there is much rocky ground, and some

dangerous patches of only 2 fathoms water lie 5 miles off shore; from the outer patch Chulai Peak bears N.W. by W. $\frac{3}{4}$ W.

When passing the neighbourhood of this rocky ground, it is recommended not to approach the coast nearer than 6 miles, nor to stand into less water than 7 fathoms.

The Coast about Chulai Point and to the northward of it is all very low. The edge of the bank extends a considerable distance from the shore and is steep-to, especially off the village of Banlam, 8 miles northward of Chulai Point, where there are only 2 fathoms at the distance of $3\frac{1}{2}$ miles from the shore.

Immediately round Banlam Point the low coast trends to the north-westward, and the soundings in the offing become regular. From this point along the head of the gulf to the bar of Bangkok River the lead will be found a safe guide by day or night.

The town of *Pechaburri* is 8 miles up a river, the principal entrance to which is $5\frac{1}{2}$ miles N.W. of Banlam Point. It is clean, well built, and densely populated, the centre of a great rice-producing district, and evidently of considerable importance. In point of climate it is preferable to Bangkok, and more likely to agree with the constitutions of Europeans. The anchorage off the entrance of the river is far more sheltered in the S.W. monsoon than that off the bar of Bangkok River, and cargo might be safely embarked at all times.

EAST COAST OF THE GULF.

PULO OBI, the main island of the Obi group, lies about 11 miles S.E. by S. of Camao Point, the south-western extreme of Cambodia, which bounds the East side of entrance of the Gulf. The island is nearly $2\frac{1}{4}$ miles long N.E. and S.W., and rather narrow near the middle, the widest and highest part being the S.W., which is elevated 1,046 ft. From its S.W. end *Camao Point* bears N.N.W. $\frac{3}{4}$ W. 12 miles; and Hull Rock S.E. $\frac{3}{4}$ E. 4 miles. There are also two small islands within a mile of the S.E. point of Obi, which contract the channel between them and Hull Rock to little more than 2 miles. The approaches to, and passages between all these islands, are quite safe by keeping at a prudent distance from the shore.

The channel between Pulo Obi and the depth of 3 fathoms on the bank extending from the coast of Cambodia, is rather less than 2 miles wide, has 6 to 15 fathoms in it, and is quite safe to navigate. Marsh Reef, lying N. $\frac{1}{2}$ W. $3\frac{1}{4}$ miles from the North point of Obi, is a dangerous group of rocks awash at low water.

There are two small pebbly bays, one on the N.W., the other on the S.E.

side of Pulo Obi. The best anchorage is directly off these bays, on either side of the island, according to the monsoon, at about half a mile from the shore.

Fresh water is plentiful in the N.W. and S.E. bays, but the shores are not convenient for embarking it. All the islands are densely wooded. No inhabitants were seen.

M. Wüst, commanding the *Alan Prah*, made some examination of Pulo Obi in 1867. He found good anchorage off the S.W. side of the island, and traces of human beings on the coast in the vicinity. The bay on the N.E. side of the island he found to consist of two bays, the southernmost of which has the deepest water, and is most frequented. In the valley extending from the head of this bay was found a small chapel, said to be visited by Chinese sailors at times.

PULO PANJANG, the main island of the Panjang group, is in lat. $9^{\circ} 18' 14''$ N., long. $103^{\circ} 28' 14''$ E. It is 3 miles long, East and West, 2 miles wide, and of a nearly uniform height of 550 ft., making like table land from the sea in every direction. There are two small islands, having deep channels between them, at about a mile from its East end; and one connected with its South point. Besides these there is a large white rock, 75 ft. high, S. by W. $1\frac{3}{4}$ mile from its South point; and two large rocks, named East Island and Table Rock, elevated 110 and 40 ft. respectively, bearing from the N.E. part of Panjang N.E. by E. $8\frac{1}{2}$ miles.

During the N.E. monsoon the bay on the S.W. side of Pulo Panjang affords capital shelter and good anchorage. Fresh water and wood can be obtained in abundance in the bay, and fish may be caught in any quantity with a seine. The anchorage on the S.E. side of the island is very indifferent. The island is not inhabited.

Caution.—Pulo Way, Veer Islet, Koh Prins, the Tanqualah group, and the Depond Reef, were regularly surveyed, and the soundings taken in the neighbourhood seem to denote that the passages between them are safe; but as time would not permit these approaches from the northward and westward to be sounded, caution must be observed when steering for them from those quarters.

The channel between these islands and Koh Tron is believed to be quite clear and safe.

PULO WAY, or *Koh Kwang Noi*, about 50 miles N.W. of Pulo Panjang, consists of two islands about the same size, nearly the same height (250 ft.) each being nearly 2 miles long, E.S.E. and W.N.W., and a quarter to three-quarters of a mile wide. They are distant nearly a mile from each other, East and West, and the channel between them is quite safe. A rock, elevated only 3 ft. above high water, lies E. by S. three-quarters of a mile from the East point of the eastern island; and there is a dangerous patch on which H.M.S. *Saracen* struck, with only 4 ft. on it, lying N. by W. $\frac{1}{2}$ W.

three-quarters of a mile from the N.W. end of the same island. Good anchorage will be found off the North side of the eastern island, but the best berth is off a sandy bay on the N.E. side of the western island.

The natives obtain their *fresh water* from a well about the middle of the eastern island; and from appearance, good water might be obtained in this way on any part of either island at a moderate distance from the shore. The islands are covered with wood; the beaches afford turtle; and a single cast of the seine will generally procure a boat load of fish.

KOH TANG or *Tanqualah Island*, bearing N.N.E. $\frac{3}{4}$ E., $23\frac{1}{2}$ miles from Pulo Way, is $3\frac{1}{4}$ miles long, very narrow, and has a peak rising to an elevation of 440 ft. near its North end. The fine clean sandy bay on its eastern side will afford good anchorage in the S.W. monsoon.

DEPOND REEF, in lat. $9^{\circ} 58\frac{1}{2}'$ N., long. $103^{\circ} 7' 33''$ E., is about half a cable's length in diameter, just awash at low water, steep-to on all sides, and in fine weather might not be noticed until close upon it. From it the peak of Tanqualah is faintly seen bearing N. $\frac{1}{2}$ W., distant $19\frac{1}{2}$ miles; and the peak at the South end of the western Pulo Way is visible over the middle of the eastern Pulo Way, W. by S. $\frac{1}{2}$ S. nearly $14\frac{1}{2}$ miles. The islands forming Pulo Way are well in sight from an elevation of 15 ft.

Condor Reef.*—The Bremen barque *Condor*, 3rd February, 1860, was totally lost on a sunken reef, said to lie in lat. $10^{\circ} 42'$ N., long. $102^{\circ} 48'$ E. The reef was afterwards searched for by Lieut. Ellis, R.N., in the gunboat *Weazel*, but without success, owing to rough weather. A patch of 9 fathoms with 15 to 20 around it was, however, found in $10^{\circ} 41'$ N., $102^{\circ} 51'$ E.

* **DOUBTFUL DANGERS**.—The following dangers may be considered not to exist, as, coupled with the fact that they have been carefully and unsuccessfully searched for, there are hundreds of vessels every year navigating in their vicinity without noticing their existence:—

John Wade Rock.—Commander Fitzroy, of H.M. gun-vessel *Avon*, on a recent passage from Singapore to Bangkok, passed over and carefully searched about the position ascribed to the John Wade Rock, in lat. $10^{\circ} 40'$ N., long. $101^{\circ} 48'$ E., but no sign of danger could be discovered. This very doubtful rock, on which the American ship of that name was reported to have been lost at 3 p.m. on 26th March, 1858, has been frequently looked for in other vessels with the like result, and its existence is altogether discredited by those accustomed to the navigation of the Gulf of Siam.

Emanuel Reef, reported in 1862 by the French ship *Emanuel*, in lat. $11^{\circ} 49'$ N., long. $101^{\circ} 19'$ E., and with Chong Samit bearing N. $\frac{1}{4}$ E., was also searched for in the *Avon* with no better success; nothing like danger could be met with in the locality. Captain Bush, harbour master at Bangkok, reports that after a careful search of nearly three days, under very favourable circumstances, he was unable to discover anything like danger in the vicinity, and is sure that the look-out man was deceived.

A shoal reported, in 1864, to lie in lat. $11^{\circ} 59'$ N., long. $101^{\circ} 10'$ E., was also passed over in the *Avon*; the soundings on and near the spot were 20 fathoms. This doubtful danger appears to have found a place on the chart from very insufficient data.

Captain Thompson, of the brig *Katinka*, in March, 1872, saw the reef, which he placed in lat. $10^{\circ} 43' N.$, long. (by their good sets of observations) $102^{\circ} 51' E.$ The most complete account is by Lieut. Veron, of the French navy, who examined the reef in the steamer *Le Frelon*, who describes it as follows:—Condor Reef is a rocky plateau half a cable in extent, and from 16 to 20 ft. below the surface, except at six points which rise above the general level of the reef to within 6 to $1\frac{1}{2}$ ft. of the surface. The shoalest point is on the S.W. part of the reef; from this point the depth increases in the same proportion toward the North and South; that is, $5\frac{1}{2}$ fathoms at 110 yards, and 13 fathoms at 220 yards. Toward the East the depth increases gradually to 13 fathoms at half a mile from the same point, but it changes rapidly to $16\frac{1}{2}$ fathoms outside of that distance. On the West side the change is more rapid; 6 fathoms of water is found at 55 yards, from thence it increases rapidly to $16\frac{1}{2}$ fathoms, and 22 fathoms water is found at 3 cables West of the shoalest point. From the head of the reef or shoalest spot the bearings *true* are as follows: The western island of the Koh-Samit group, N. $37^{\circ} E.$ The islet situated between the Koh-Kong and Middle Island, N. $76^{\circ} E.$ The highest peak of Koh-Kong S. $88^{\circ} E.$ These bearings give the position of the reef: Lat. $10^{\circ} 43' 40'' N.$, Long. $102^{\circ} 53' 19'' E.$

Hans Reef is marked in lat. $10^{\circ} 43' N.$, long. $102^{\circ} 35'.$

CAMAO or **CAMBODIA POINT**, the south-western extreme of Cambodia, is low and covered with trees, and cannot be seen farther than about 9 miles from the deck of a small vessel. The edge of the bank off the point is very steep-to, the soundings decreasing at once from 8 to 2 fathoms, which latter depth will be found at the distance of 2 miles off shore. Abreast Pulo Obi the edge of the bank is fully 5 miles off shore; it is very steep also to the eastward along its southern edge, and as several rocks have been found within the 5 fathoms line, it will be prudent when passing not to go into less than 8 fathoms water.

To the northward of Camao Point the soundings are regular, and the coast may be approached with safety.

From Camao Point the land trends in an E.N.E. direction 17 miles to the *Camao River* entrance, which is nearly dry at low water. Excepting the scattered huts of a few solitary fishermen, no signs of inhabitants were seen near it.

From hence the coast takes a northerly direction to abreast Pulo Dama. The land is all very low, with the exception of the Paps, two small rocky bluffs, elevated 100 ft. on the coast line, bearing N.E. $\frac{1}{2}$ E. 20 miles from False Pulo Obi.

FALSE PULO OBI, bearing N.N.W. $\frac{2}{3}$ W. 23 miles from Camao Point, is three-quarters of a mile long, half a mile broad, elevated 500 ft., with cliffy sides, and steep-to all round. At 4 miles to the S.S.E. $\frac{1}{2}$ E. is a small rocky island, elevated 167 ft., with a ledge of rocks projecting a quarter of

a mile from its East side. The channel between these two islands is quite safe; and there is a fine safe channel 12 miles wide, between them and the main.

Pulo Dama is $3\frac{1}{2}$ miles long, North and South, 1 mile wide, and near its centre is a sharp peak, elevated 1,077 ft. Three small islands lie off its North point, and there are also several off its S.E. end. No fresh water, and no inhabitants.

Tammassou is a high table island, elevated 1,390 ft., with steep cliffy sides, bearing about E.N.E. 16 miles from Pulo Dama. The island is safe of approach in every direction. A little fresh water was found on it.

Teeksou Island, N.E. $\frac{1}{2}$ E. 13 miles from Tammassou, is of conical form, and elevated 1,380 ft. There is no passage for ships to the eastward of this island.

Teksia Peak is a cone of 810 ft. elevation, bearing N.N.E. 7 miles from Teeksou, and remarkable as the first high land on the main seen on approaching from the southward. Between this peak and Teeksou there is an anchorage for large trading junks, whose cargoes are brought out from the neighbouring town in the flat boats of the country.

TABLE HEAD is a rocky headland, elevated 600 ft., bearing W. by N., 15 miles from Teksia Point. The coast between forms a deep sandy bay, having several small rivers falling into it. This bay is very shoal; and a dangerous rock, awash, lies S.E. $\frac{1}{4}$ S. $4\frac{1}{2}$ miles from Table Head.

TEKERE or **MINGHUE**, a cone-shaped island, elevated 1,120 ft., and bearing S.W. $\frac{3}{4}$ S. 8 miles from Table Head, is the largest of an archipelago of islands and rocks, that extend westward and south-westward from Table Head. There are two islets, named *Outer Island* and *Shark Island*, to the south-westward of Tekere; and there is one also, called *West Island*, lying about midway between Tekere and the Twins, in the fairway channel for vessels approaching Cancao from the southward.

CANCAO RIVER has on either side of its entrance high bluffs, which, together with the gap dividing them, are remarkable from the westward: and from this direction the town of Cancao, which stands at the entrance, may be seen at the distance of 6 or 7 miles. The anchorage off the town is good, and the soundings regular. In working up to it from West Island, care should be taken not to make too free with the islands on either hand; many of them being surrounded by dangerous rocks.

Cancao, named on the French charts *Hatien*, is said to have a population of 8,000. The entrance of this river now belongs to the French, having been recently ceded to that government by the King of Cambodia. There is a large fort in front of the town to seaward to defend the entrance of the river. This river communicates by a canal with the great Cambodian river Makiang, and is the route by which the produce of the interior is brought down to the coast. Some native boatmen assured a French missionary

resident at Kamput that there is a 13-foot channel into the Cancao River. Lieut. Richards only found 7 ft. at high water. Government boats were sent out to warn the *Saracen* off, but it was done with civility. The fort occasionally fires on merchant vessels passing near.

As no European vessel is allowed to anchor off Cancao, they are obliged to rendezvous at Kamput, to which anchorage their cargoes are conveyed in Cancao junks.

Between Cancao and Kep Point, 10 miles to the north-westward, the coast is only navigable for junks. There is no safe passage for ships inside the Pirate Islands; the *Saracen* grounded twice in making the attempt.

Anchorage.—Mr. Brown, commanding the English brigantine *Acis*, January, 1860, recommends the following anchorages to vessels bound to Cancao, the approaches to which are marked on the chart. That eastward of Great Pirate Island will be most useful to vessels trading with Cancao in the S.W. monsoon. The anchorage eastward of North Pirate Island may also be of service to vessels of light draught in the same monsoon, and so may that under the South side of Peaked Island in the N.E. monsoon; but it is to be feared that the channels leading to the two latter anchorages will be found rather intricate. A $2\frac{1}{2}$ -fathom shoal is reported by Mr. Brown as extending $2\frac{1}{2}$ miles W. by N. from North Pirate Island; and he further states that he found a $4\frac{1}{2}$ -fathom channel between Ragged Rock and the nearest Pirate Island, where $2\frac{3}{4}$ and $3\frac{1}{4}$ fathoms are marked on the chart.

The anchorage under the South side of Peaked Island is stated to be the best in the N.E. monsoon for vessels that have sometimes to receive cargo both from Kamput and Cancao. A vessel of large draught should approach this anchorage from the westward, by the main channel about 3 miles West of the Pirate Islands.

East and West Brother are two small islands, 473 and 406 feet respectively in height, lying off the South point of Koh Tron. They bear nearly E.N.E. and W.S.W. from each other, and are 3 miles apart.

KOH TRON, called by the natives *Koh Dud*, is of a triangular form, 26 miles long, North and South, and 14 wide at its broadest part, which is near the North end. Along its N.E. side is a mass of high table land, elevated about 1,600 ft.; farther southward is a remarkable quoin-shaped hill, and there are some remarkable conical hills and bluffs at the South end of the island. There are also some hills of moderate height near the N.W. point; the remainder of the island is low. The eastern shore is dangerous to approach, it being fringed with coral reefs and sunken rocks, but the island is quite clear of danger in every other direction. Fresh-water streams abound, especially along the eastern shore.

Directions for South Channel to Kamput.—The Brothers, with Pulo Dama, are the chief guides when bound to Kamput from the southward. Vessels

intending to take the South channel to Kamput may, if necessary, pass northward of the Brothers, but they should not approach Round Hill Point (the South point of Koh Tron) nearer than 3 miles, as a rocky ridge with $2\frac{1}{2}$ fathoms on it extends E.S.E. $2\frac{1}{2}$ miles from the point.

The eastern shore of Koh Tron, particularly from abreast Pulo Cici to its North point, is very dangerous. In standing towards the Koh Tron shore, always tack when the soundings deepen suddenly. *Pulo Cici*, or the Twins, are two small islets covered with trees, and connected together by a reef of rocks; the northern islet is 213 ft. high. A vessel may pass at a mile on either side of them.

Caution.—Between Koh Tron and Pulo Cici lies the *Rosita Rock*, on which an English schooner of that name struck. It is of coral, half a cable's length in diameter, of only 2 ft. water, and steep-to on all sides, but may be seen at a short distance from aloft by the discoloured water. The high Twin bears from it S.E. by E. $4\frac{3}{4}$ miles; South Pirate Island, E. $\frac{3}{4}$ S.; Gunung Susu or Paps, 300 ft. high (about a mile North of Bumbi Bluff), N. $\frac{1}{2}$ W.; and Byoot Peak, 1,608 ft. high (near the N.E. point of Koh Tron), N.W. by W. $\frac{3}{4}$ W., westerly.

North Channel to Kamput.—For all large vessels the channel northward of Koh Tron is recommended, as the water is deep and the soundings regular. Caution should be used in standing towards the edge of the North bank near the western entrance of the Kamput River, as it is steep-to and rocky. The ground is also foul at the North point of Koh Tron. A number of large rocks 20 ft. high extend about 2 cables' lengths from the point, having others near them under water.

The western entrance of the North channel between Water Island and Koh Tron, is $2\frac{1}{4}$ miles wide, but there is a large flat rock just within it, and lying North half a mile from the N.W. point of Koh Tron; and a rocky island covered with trees lies W. by S. $1\frac{1}{2}$ mile from the same point. There are also two other small rocky islands to the southward of the entrance.

In passing through this channel vessels should not, if possible, pass inside Flat Rock or any of the above small islands, as the ground is foul between them and Koh Tron, and the set of the tides irregular.

The Anchorage off Kamput is in 4 fathoms, with Bumbi cone in line with the Paps, N. $\frac{1}{4}$ W., and Kep Peak E. $\frac{3}{4}$ S. Bullocks, pigs, fowls, ducks, and eggs were purchased very cheap. Of vegetables there were great variety, and the market had a good supply of fruit. Wood was plentiful; water can be obtained from wells near the town, but it is muddy and bad, and procured with great difficulty.

Good anchorage will be found on the N.W. side of Water Island in 4 fathoms water, at a quarter of a mile from the shore; and all vessels intending to remain any length of time at Kamput would do well to anchor here and complete their water. The watering place is in a sandy bay on

the N.W. side of the island; there is a fine running stream, and as the beach is very steep, the water is easily embarked. This bay is also a good place to haul the seine.

BAY ISLAND.—Sailing from Kamput to the westward, after passing Water Island, and a shallow inlet in the bight of the bay to the northward of it, Bay Island will become conspicuous from its position, as well as comparative magnitude. It is $2\frac{1}{2}$ miles in diameter, elevated 380 ft., and its outer or South point bears W. by N. $\frac{1}{2}$ N. 13 miles from the southern extreme of Water Island.

Kapongsom River.—From Bay Island the coast trends to the northward towards the estuary of the Kapongsom River, which is 13 miles wide, and, as far as it was examined, quite safe. The deep water appeared to be along the southern shore.

RONG SAM LEM, the southernmost of a chain of islands that front the estuary of the Kapongsom, is 5 miles long, North and South, elevated 780 feet, and its shores are steep and quite safe of approach. On its N.E. side there is a fine bay, named after the *Saracen*, which indents the island so deeply as almost to divide it into two parts, and affords good anchorage for the largest vessels. Wood and fresh water may be had in abundance at the head of the bay, but it is easier procured just without the bay to the northward, where the beach is steep-to. Between Rong Sam Lem and the nearest point of the main, a distance of 9 miles across, may be considered the proper entrance into the estuary of the Kapongsom.

KOH RONG, lying $2\frac{1}{4}$ miles northward of Rong Sam Lem, is 8 miles long, N.W. and S.E., and 5 broad. The greater portion of the northern end of this island consists of table land, the highest part of which, elevated 1,158 feet, descends with a slope to the southward, and rises again near the southern extreme, where it terminates in a sharp peak. Its shores are generally steep and foul.

There are no inhabitants on any of these islands.

The channel between Koh Rong and Rong Sam Lem is quite safe, although generally rocky ground and unfit for anchorage.

Koh Samit, $1\frac{1}{2}$ mile long, 1 mile broad, and elevated 400 feet, is the southernmost and largest of a chain of islands and rocks that front the coast for 12 miles northward of Samit point. There is a deep-water channel inside all these islands. The highest and most remarkable hill about this part is elevated 1,155 feet, and is named the *Quoin*, from its peculiar wedge shape.

KUSROVIE ROCK, in lat. $11^{\circ} 6' 25''$ N., long. $102^{\circ} 47' 49''$ E., and distant about 17 miles from the nearest part of this coast, is about three-quarters of a cable's length in diameter, and 36 ft. high, without a particle of vegetation on it. Its sides are shelving, and isolated rocks extend half a cable's length from it. The bottom can be plainly seen near it in 6 fathoms.

Ellen Bangka Shoal.—The commander of the Netherlands India barque *Ellen Bangka* reports that his vessel, whilst under sail on the 12th November, 1870, in the neighbourhood of the Kusrovie Rock, struck twice on a shoal, on which there was only 11 ft. water. The vessel was at that time North, 5 or 6 miles from the Kusrovie Rock, which was visible from the deck. The danger has accordingly been placed in lat. $11^{\circ} 11' N.$, and long. $102^{\circ} 47' E.$ (The London and China Telegraph of March 14th, 1871.)

KOH KONG is a level table island, 11 miles long, North and South, 4 miles wide, and elevated 1,500 ft. It has some fine sandy beaches along its western shore, which is steep-to, and quite safe of approach, but the island offers no sheltered anchorages or other advantages to shipping. There are no inhabitants.

Within Koh Kong there is a large shallow bay, into which numerous small rivers disembogue; but they are generally unapproachable.

The main land within Koh Kong is very low as far as visible to the eastward, but it rises to the northward with great regularity until it joins the high table land abreast Koh Kut.

Two rivers of considerable magnitude enter the sea a short distance northward of Koh Kong; the northernmost river is called *Klong Koh Kong*.

The **COAST**, from the Klong Koh Kong, takes a N.N.W. $\frac{1}{2}$ W. direction 40 miles to Tung Yai Bay, and is quite safe to approach with regular soundings. With the exception of two rocky bluffs, the land near the sea is low, and fringed by a straight sandy beach; parallel to the coast, at the distance of 2 or 3 miles inland, a table land rises with great regularity to the height of more than 2,000 ft. One of its highest points was found to be elevated 4,000 ft.

Tung Yai Bay affords good anchorage, but the eastern shore must be approached with caution, as several rocks lie nearly a mile off it. A small stream, the Tung Yai River, falls into the head of the bay, but it is only navigable for boats. *Lem Nam*, forming the western point of entrance of Tung Yai Bay, makes like a low woody island from the southward. From thence the coast takes a W.N.W. direction 20 miles to *Lem Ling*, or *Junk Point*, and is fronted all the way by an extensive flat named *Tung Yai Bank*. A small mangrove islet lies close to Lem Ling, and the ground is foul for some distance off it; but Lem Ling is quite clear to the S.W.

KOH KUT, lying 16 miles off the coast between the parallels of $11^{\circ} 34'$ and $11^{\circ} 46'$, is a high level island, with steep, cliffy sides. There are two small conical peaks near its South end, the highest of which (the northern) is elevated 1,171 ft. The island has no permanent inhabitants. Good anchorage will be found in a bay near the N.W. end of Koh Kut, with a fine stream of fresh water running into it.

KOH MAK, lying 3 miles N.W. of Koh Kut, and S.S.E. 7 miles from Koh Chang, is 3 miles in diameter, and very low, excepting at its West end, which

presents a rocky head to seaward, elevated 300 feet. It is inhabited by fishermen engaged in collecting biche-de-mer.

KOH CHANG, 16 miles long, N.W. and S.E., and 6 miles wide, consists of a mass of peaked hills intersected by rocky and precipitous ravines. The highest part of the island (a table peak near its centre) is elevated 2,446 ft. Notwithstanding the numerous islands and rocks that fringe Koh Chang, no dangers were discovered near its shores but what were apparent. There is a native government station at a low jutting point on its eastern side, with about twenty persons, who are the only inhabitants. Tigers are said to be numerous. Fresh water can be obtained on the western side of Koh Chang, about 3 miles from the North point.*

The Coast from Lem Ling trends N.W. $\frac{1}{4}$ N. 21 miles to *Lem Sing*, which forms the western side of entrance to the Chentabun River. The shore between is low mangrove; but a short distance from it, and 5 miles from Lem Sing, are three small, high islands. There is also a large river at the distance of 6 miles northward of Lem Ling.

ALABASTER ROCKS, in lat. $12^{\circ} 20' N.$, long. $102^{\circ} 14' E.$, $7\frac{1}{2}$ miles S. by W. from the entrance of the Chentabun River, were examined and their positions determined by Mr. Alabaster, of H.M. Consulate, Bangkok, who describes them as two small rocks, about 40 ft. apart, lying N. by E. and S. by W. from each other. The southern and larger one is, at low water spring tides, about 14 ft. long by 5 broad, and 3 ft. above the surface of the sea; the northern one is smaller, and shows but 2 ft. above water. From the Alabaster Rocks Cone Island bears N. $\frac{1}{2}$ W., westerly; the summit of Khao Sabap mountain, N.E. $\frac{2}{3}$ N.; the southernmost of three small islands, N.E. by E. $\frac{1}{3}$ E.; and Table Peak, the highest part of Koh Chang, S.E.

The *Allan Prah*, on her voyage from Saigon to Bangkok, saw a rock in lat. $12^{\circ} 25\frac{1}{2}' N.$, long. $101^{\circ} 39\frac{1}{2}' E.$, which position was determined by bearings.

CHENTABUN RIVER.—The position of this river may be recognized from a distance by a mountain called *Khao Sabap*, which rises to an elevation of 2,090 ft N.E. by E. 9 miles from its entrance; also by Lem Sing, which at a distance appears like an island, and may be further known by a conical islet, named *Cone Island*, 405 ft. high, lying a mile westward of it, as well as by a remarkable white cliff on its eastern face.

The eastern side of entrance begins at Koh Chula or Bar Island, between which and Lem Sing is the channel into the river, with 13 ft. in it at low

* *Doubtful Dangers.*—Some of the old manuscript charts show a sunken rock midway between the Kusrovie Rock and the South point of Koh Kut; and another 24 miles West of the North point of Koh Chang. The *Saracen* passed over these positions without meeting any token of their existence, but caution is recommended to all vessels passing their neighbourhood.

water, but as it is only a quarter of a mile wide, it would be necessary to warp a large vessel in against a head wind. Vessels can ascend the river as far as the fork, which is within 10 miles of the town. A convenient anchorage without the bar is, with Koh Chula N.E. by E., distant about half a mile. Fresh stock is scarce, but an abundance of good water may be procured in a small bay westward of Lem Sing.

It is high water, full and change, at the entrance of the Chentabun, at 10^h 0^m, and the rise is 5½ ft. The highest tide took place on the day after the change.

Koh Samit, 377 ft. high, bears W N.W. 52 miles from the North end of Koh Chang. It lies off Lem Ya, from which it is separated by a channel, called *Chong Samit*, 1½ mile wide, with a depth in it of 3 fathoms.

Mr. Alabaster reports that the native pilots declare a rock exists in Chong Samit, towards the western end of the strait, about mid-channel; their directions for avoiding it are—"It, on entering the strait from the westward, Koh Plateen is sighted, stand over close to the main land; if Koh Plateen is not sighted, keep as near as possible to the island."

LEM YA may be known by a clump of conical hills extending from it 15 miles inland; the highest, which is the northernmost, is elevated 2,470 ft. On each side of this headland the coast is low. The bay to the westward is slightly concave, and fringed with a sandy beach to Lem Sahemsan, or Cape Liant. The bay to the eastward has several small islands in it.

Mr. Alabaster also reports that the native pilots say a rock, named *Hin-ai-eorp*, lies in about lat. 12° 35½' N., long. 101° 46½' E., in a direct line between the island of Mon-Klang and the small bay on the main named Tung Kaben, about 5 miles distant from the latter.

CAPE LIANT or Lem Sahemsan.—On approaching this cape from the southward, the outer islands off it, *Chuen* and *Me-san*, being the highest land in the neighbourhood, will be first seen. *Hin Chalan*, in lat. 12° 27' 46" N., long. 100° 58' 29" E., will not be observed until it is within the distance of 5 miles; it is a white rock 40 ft. high, a cable's length in diameter, very steep-to, and quite safe to approach.

The channel between Hin Chalan and Chuen is 2½ miles wide, and quite clear. The channel between Chuen and Me-san is a mile wide; and there is also a channel between Cape Liant and Koh Riat, but it is only a quarter of a mile wide, and although much used by small vessels, is dangerous during spring tides, and certainly should never be attempted by a sailing vessel, without a fair and commanding breeze. All these channels seem to be remarkably clear of danger.

Sheltered Bay, at 3 miles north-westward of Cape Liant, is about 4 miles wide and 2 deep, with good anchorage all over it. *Koh Yoh*, the outer island off its entrance, is remarkable from its resemblance to an erect triangle. The eastern horn of this bay may be known by a remarkable cone 454 ft. in

height. *Lem Putau*, the N.W. point of Sheltered bay, is a bold bluff headland of 600 ft. elevation, and close round it, to the northward, is a bay, called *Tung Kitea*. Fresh water can be obtained in the S.E. corner of this bay.

Tung Plong Bay lies 1 mile northward of Tung Kitea, and being sheltered by Koh Kram and Koh Ira, offers secure anchorage to vessels detained in the channel.

A remarkable rock, called *Sombrero*, lies three-quarters of a mile from the S.E. side of Koh Kram, and the channel between it and Koh Ira is about a mile wide. The *Sombrero* should not be approached closely to the northward, as there is much foul ground for a considerable distance in that direction.

Koh Kram, lying 9 miles north-westward of Cape Liant, is 3 miles long, North and South, and 2 miles wide. There is a remarkable sharp peak of 704 ft. elevation on its S.E. side, and a bay on its N.W. side; its western shores are quite safe to approach, but reefs extend three-quarters of a mile from its eastern, and half a mile from its southern shores.

KOH LUEM, or **Pilot Island**, bears N.N.W. $\frac{1}{2}$ W. 16 miles from the N.W. point of Koh Kram; along this line runs a chain of small islands, called *Rin*, *Kring Badung*, *Mana Mechy*, and the comparatively large island of *Pai*, which is 2 miles long and 1 mile wide. The channels between all these islands are free from danger.

Koh Luem, three-quarters of a mile long, North and South, and half a mile wide, is as steep as a wall to the southward and westward, and rises from the sea bold and cliffy all around, its peak of a dome-like appearance, and 445 ft. high, being in lat. $12^{\circ} 57\frac{1}{2}'$ N., long. $100^{\circ} 38' 59''$ E. This island, from its conspicuous and peculiar position, has long been considered the principal landmark at the head of the gulf; all vessels bound to the Me-nam make it, and taking their departure from it, run boldly for the anchorage off the bar by day or night.

KOH LAN, lying E. by S. $7\frac{1}{4}$ miles from Koh Luem, is $2\frac{1}{2}$ miles long, a mile wide, and has a remarkable sharp peak, elevated 685 ft. On its eastern side is a village, containing about 200 inhabitants.

The Coast between Tung Plong Bay and Koh Klet-keo, 4 miles to the northward, is high, presenting rocky bluffs to seaward, with sandy bays between. *Lem Pataya* is N. $\frac{1}{4}$ E. 9 miles from Klet-keo, and E. by S. $2\frac{3}{4}$ miles from East Lan, the small island off the East side of Koh Lan. One mile E. by S. of East Lan there is a rocky bank about a cable's length in extent, with 3 ft. on it, which narrows the channel between it and *Lem Pataya* to $1\frac{1}{2}$ mile. From *Lem Pataya*, *Lem Kwan* bears N.N.E. $\frac{1}{2}$ E. distant $3\frac{1}{2}$ miles, and *Lem Kra-bang* N. $\frac{1}{4}$ E. $9\frac{1}{4}$ miles.

KOH SI-CHANG.—W.N.W. 4 miles off *Lem Kra-bang* commences the Koh Si-Chang Group, between which and the coast there is a clear channel. Koh Si-chang, the largest of the group, is $3\frac{1}{2}$ miles long, North and South,

1 mile broad, and its peak, which rises at the North end of the island to an elevation of 697 ft., bears N.E. by N. $15\frac{1}{2}$ miles from Koh Luem. An island named *Kangku*, with a sharp peak 325 ft. high, lies one-third of a mile off the South end of Koh Si-chang, and a rock 10 ft. high, like the hull of a ship, about two-thirds of a mile off the North end; an island, also, called Koh Kam, and three islets, lie off the N.E. side; the western side is quite clear. E. by N. half a mile from the rock 10 ft. high, is a rock with only 4 feet water on it; and there is another with 3 ft. N.N.W. one-third of a mile from the North point of Koh Kam.

The bay on the N.E. side of Koh Si-chang affords anchorage partly sheltered by Koh Kam and the islets to the eastward. The village on the South shore of this bay probably contains about 200 inhabitants, who appear less shy of foreigners than the natives of the coast to the southward.

SI-MA-HA-RA-CHA.*—Koh Si-ma-ha-ra-cha is a rocky islet, about 90 ft. high, lying about a third of a mile from the coast, N.N.E. $\frac{1}{4}$ E. $6\frac{1}{2}$ miles from Lem Kra-bang, and East $6\frac{1}{2}$ miles from the North point of Koh Si-chang. The town of Si-ma-ha-ra-cha stands on the shore about S.E. half a mile from the islet, and contains 500 inhabitants; and the town of Bang Pra, about 3 miles to the northward, has about 1,000 inhabitants. The latter town cannot be approached nearer than 2 miles by a vessel of large draught.

With Si-ma-ha-ra-cha bearing E. by N. half a mile, in $3\frac{1}{4}$ fathoms at low water, or for a large vessel a quarter of a mile farther out on the same line of bearing in 4 fathoms, is apparently the best anchorage at the head of the gulf, for communicating with the shore, for it is better sheltered than any other part.

Supplies.—Fresh water is abundant on shore when the springs elsewhere are dry, and the towns of Si-ma-ha-ra-cha and Bang Pra could furnish large quantities of fresh stock. At the distances of half and three-quarters of a mile southward of Bang Pra are two fine streams of water that run into the sea through the beach, and the natives say that they are never dry, even in the hottest seasons. A boat might fill from these streams at high water, but at low tide the sands dry out so far that they could not be approached within half a mile.

BANG-PASOI.—From Si-ma-ha-ra-cha the coast curves round to the northward, and at the distance of 8 miles is Double Head (native name *Lem Samook*, the Nose Point), a prominent bluff rising from the low land to the height of 270 ft., and appearing at a distance like an island. At 2 miles north-eastward of Double Head stands the village of *Anhin* (a royal watering place), and 4 miles E.N.E. of Anhin, in the depths of a shoal muddy bight, is the large town of Bang-Pasoi, a place of considerable importance. The

* Si, beautiful; maha, great; racha, royal, in Pali.

town is governed by a high noble, and has a good market, but unfortunately it is only accessible from the sea at high water.

The **BANG-PA-KONG RIVER** empties itself into the gulf at 4 miles northward of Bang-Pasoi, and appears to be a fine navigable stream; from hence to the Me-nam entrance the coast is all low mangrove.

ME-NAM CHAU-PHYA or Bangkok River has on the western point of entrance a clump of high trees like a small mound, elevated about 30 ft. above the surrounding mangrove, and this is the first land seen on approaching from the southward. From this mound Pilot Island or Koh Luem bears S. $\frac{3}{4}$ E. $34\frac{1}{2}$ miles; Double Head, S.E. by E. $22\frac{1}{2}$ miles; and Koh Si-chang Peak S.E. by S. 25 miles.

LIGHT.—A pile lighthouse is erected on the western side of a sand-bank, inside the bar of Bangkok River, and from it, in the year 1874, a *fixed bright light* was shown at an elevation of 44 ft., visible 10 miles off. The lighthouse lies 3 miles S. by E. $\frac{1}{2}$ E. from the West entrance point of the river, and in lat. $13^{\circ} 29' 26''$ N., long. $100^{\circ} 35' 20''$ E.

The river is deep and free from shoals for a distance of 60 miles. At about 3 miles within the entrance, on the eastern bank, is *Paknam*, where vessels must anchor to discharge guns and ammunition, and take on board a custom-house officer. Here is a fair market, from which vessels remaining at the bar anchorage can obtain their daily supplies of fresh food, but it is considered better to send to Bangkok for stock for a voyage.

Paklat Lang, on the western bank of the river, 4 miles above Paknam, is the entrance to a canal which saves a circuit of nearly 10 miles to boats proceeding to or from Bangkok; ships must take the circuitous route by the river. The entrance is marked by a guard-house on each side, and its vicinity may be known by a long range of batteries half a mile above on the same side of the river. The canal re-enters the river alongside some floating houses at the small village of Paklat Bon.

BANGKOK, the capital and seat of trade of Siam, is about 25 miles from the sea, following the river course, or about 14 miles direct. The first important objects seen, in approaching the city, are the American consulate on the West, Puddicombe's ship-building yard and Russell and Co.'s godowns on the East. Above these are some handsome temples, the French consulate and cathedral, the custom-house, British and Portuguese consulates, and the godowns of some English merchants, all on the East bank; the only conspicuous object on the other side being a fort nearly opposite the British consulate. Beyond this the river on either bank is lined with floating houses, over which can be seen thick clusters of wooden houses built on piles, and several magnificent temples. The second creek above the British consulate leads to the Sampeng Bazaar, an extensive and well-supplied market. Farther on is the walled city, on the East bank; and in the opposite suburb are

some European stores and lodging-houses, the palaces of the Pra-klang and Kalahome, the old British factory, palace of the Kromma Luang, several European merchants' residences, and some temples, one of them a lofty pyramidal building, above which vessels seldom anchor.

In the city itself are many temples conspicuous for beauty. The palaces of their Majesties the First and Second Kings are extensive buildings, with a long river frontage furnished with elegant and commodious landing-stages for royal use. Floating-houses continue for 3 or 4 miles above the First King's palace, with few interruptions. The population of Bangkok is estimated at 300,000.

"In running for the anchorage off Bangkok River, make Koh Luem, and from that departure steer boldly up, allowing for a westerly set, according to the strength of the N.E. monsoon. The lighthouse will be seen before the land is made, and is an excellent guide for running in; bring it to bear North, and run for it, keeping the lead going, and anchor according to the draught of the ship. During the N.E. monsoon the land is generally obscured by smoke, so that the lighthouse will be the only mark to show the mouth of the river. *Anchorage* during the N.E. monsoon, lighthouse bearing N. 35° W.; during the S.W. monsoon, lighthouse bearing N. 17° E. *Pilot-boats* cruise between Koh Luem and the bar, having competent European pilots on board; they generally anchor vessels in about 6 fathoms water, with the lighthouse bearing as above, according to the season, and distant about 5 miles."—*Lieut. Nichols, U.S.N., 1873.*

Owing to the shifting nature of the bar, it is not safe to enter without a pilot. The pilot boats carry a flag red and white horizontal.

It should be borne in mind that the soundings become hard when nearing the East banks, which are composed principally of sand, and very soft when nearing the West flat, which is all soft mud.

Lieutenant Ellis, in 1868, examined the entrance, and searched in vain for the four piles of stones sunk across the mouth of the river, and said to have as little as 3 ft. over them. He found one mass of stones about two-thirds of the way across the channel on the eastern side, but over which there was 1½ fathom at low water; he could find no less water anywhere about the entrance.

The *best anchorage* off the bar for communicating with the shore is in 3½ fathoms, with the two river points well overlapping, and the West point mound bearing N. ¼ W. or North, distant 6½ miles.

Caution.—Approaching the bar of the Bangkok River from the southward in the N.E. monsoon, it will be necessary, when near the head of the gulf, to allow for a westerly current which occasionally runs with great strength along the edge of the bank, and vessels set to leeward by it have found considerable difficulty in regaining the anchorage. For this reason boats work-

ing out of the river should not attempt to cross the bar before they can make sure of fetching their ships.

The Tides near the entrance are very irregular. It is high water at from 4^h 30^m to 8^h 0^m, and the rise varies from 7½ to 11 ft. At and near the springs there were only two tides in 24 hours, and four tides at neaps. These irregularities, caused by the gradual change from one to the other, are occasionally increased and confused by changes of wind in the gulf.

In the month of April the river is at its lowest level, and the tide observations during this month gave 3 ft. on the bar at low water springs, and 10½ feet at high water. Towards the end of the rainy season (the beginning of October) the river is much swollen, and its banks are frequently flooded and the country inundated. The bar has then 5 ft. on it, at low water springs, and 14 and 15 ft. at high water, and the water is said to be quite fresh at low tide.

Outside the bar and near the anchorage the flood sets to the westward, and the ebb to the eastward, altering its direction occasionally according to the strength of the river stream. Along the eastern shore of the gulf towards Cape Liant the ebb sets to the southward and flood to the northward.

It is high water at Cape Liant about the same time as at the bar of the Bangkok, and the rise is only 6½ ft.

Tachin River.—The mouth of this river lies about 20 miles to the westward of the Bangkok River; it was navigated for about 35 miles by H.M.S. *Teazer*, in November, 1871. This river has a similar bay to that of the Bangkok River, but the entrance is more difficult to distinguish, the land in the neighbourhood being low, and covered with trees.

In clear weather the high land of Bang-Pasoi brought to bear E. by S., will lead to a position off the bar, which may be crossed on a N.N.W. course. Tachin River has about the same general depth, and is of the same general width as Bangkok River.

The *Teazer* anchored off *Maconchisi* in lat. 13° 39' N., long. 100° 11' E., nearly 35 miles from the mouth of the Tachin. At Maconchisi are the new mills of the Indo-Chinese Sugar Company; the sugar is at present sent in barges by canal to Bangkok, but it is expected that vessels will shortly navigate the Tachin River as easily as they now do the River Bangkok, whereby an expensive freight will be saved.

CHAPTER XI.

THE COAST OF COCHIN CHINA, TON-KING, ETC.

THE coast described in the present section borders the empire of Anam, which is 960 miles in length from North to South, and averages about 300 miles in breadth. It is divided into three distinct portions, French Cochin China or Saigon, Cochin China, and Tonquin. The first, of which Saigon is the capital, was ceded to the French (together with the free right of navigating the several arms of the Cambodia River), by the Emperor of Anam, in 1863. Saigon was first occupied by the French in 1857. Subsequently additional territory has been acquired by the French, and several ports have been opened to commerce. Kiung-Chow (Hoi How), in Hainan, is now open; the ports of Haip-hong and Han-oi, in Tonquin, were declared open to commerce in a treaty signed in August, 1874, and the port of Quin-hon in November, 1875. The Empire of Anam contains from 12,000,000 to 15,000,000 of inhabitants, and the French territory 900,000. There were in the latter only 10 European British subjects resident in 1874. The chief export is rice: of this article, 340,000 tons were exported from the French territory of Saigon in the year 1876, chiefly to China and Java. Cotton, pepper, sugar, silk, coffee, fish, &c., are also exported. The trade is chiefly in the hands of Chinese merchants.

The view which the country of Cochin China and Tonquin presents from the sea is that of a varied landscape, composed of bold headlands, picturesque valleys, well cultivated slopes, extensive downs, and low plains, frequently terminating in sand-hills with a back-ground of rather lofty mountains in the distance.

1.—COCHIN CHINA.

The Coast of Cambodia, or Lower Cochin China, from Cambodia, or Camao Point, its south-western extreme, to the Saigon River, is very low land, inundated by the sea at times; and in most parts the trees are just discerned nearly level with the water's edge, from the deck of a large ship, at the distance of 11 or 12 miles. The whole coast is fronted with shoal banks of sand, which project 10 or 12 miles from it in some places, having

2½ and 3 fathoms on them, and 6 to 7 fathoms near their edges. The soundings are regular in the offing, and decrease gradually until the edges of these banks are approached: then from 9 or 8 fathoms the water shoals suddenly in some places; the bottom near the edges, and also a considerable distance seaward, is mostly fine sand and oaze.

As the coast here is very low and destitute of any particular mark, it must be approached pretty closely to observe its bearing, but this must be done with great caution; when its trend changes from eastward to north-eastward, the entrance of the Cambodia River will be abreast.

ROYALIST BANK.—The late Lieut. D. M. Gordon, of H.M. surveying-vessel *Royalist*, sounded on a bank, about S.E. by E. 24 miles from Pulo Obi, which he thus described:—"On January 15th, 1848, we discovered a bank, having 17 fathoms water at each end; and crossing it in a S.S.E. direction, we continued in from 10 to 6 fathoms, sand and hard bottom, for about 1½ mile, where we again deepened to 17 fathoms. Pulo Obi was occasionally in sight through the haze, but no correct bearing could be obtained. I could not see the bottom, and am not positive that it was coral, the lead only bringing up reddish sand. We made it in lat. 8° 12½' N., long. 105° 11½' E."

There is another patch of 6 fathoms upon the Admiralty chart, about E. by N. ½ N., 20 miles from the Royalist Bank.

The **BROTHERS** are two small islands, about 2½ or 3 miles apart, N.E. by E. and S.W. by W., lying about 80 miles eastward of Pulo Obi, and nearly 40 miles from the coast of Lower Cochin China. The westernmost, in lat. 8° 34' N., long. 106° 11' E., is a barren rock, not more conspicuous than Pedra Branca at the entrance of Singapore Strait, and has high breakers on its eastern side during blowing weather. The easternmost is a high round islet, with trees on its summit, bearing W. by S., 18 miles from Pulo Condore.

PULO CONDORE GROUP (called *Con-non* by the Cochin Chinese), lies about 50 miles from the coast of Cambodia or Lower Cochin China, and 60 or 70 miles to the westward of the fair track of vessels bound up or down the Main route of the China Sea, but right in the track of those proceeding between Singapore and Saigon. The principal island is nearly 9 miles in length N.E. and S.W., from 2 to 4 miles in breadth, and the head of the landing place at the village in Great Bay, on its S.E. side, is in lat. 8° 40' 57" N., long. 106° 36' 11" E.* It is encompassed by several islands much smaller, which are mostly all high and covered with trees, and is formed of a ridge of mountains, the summit of the highest of which is elevated 1,954

* The mean of observations obtained in 1862 by the officers of H.M. surveying-vessels *Swallow* and *Rifeman*.

feet, and has been seen 50 miles off in clear weather. The island is thinly inhabited by people from Cambodia and Cochin China, who reside in a village on a plain at the bottom of Great Bay. The French are in possession of the island, which they make use of as a penal settlement.

The approaches to Pulo Condore are safe. The coral banks only occur near the shores, and more particularly in those parts that are sheltered from the N.E. and S.W. monsoons.

The **CAMBODIA RIVER** is of great commercial importance. It has been termed the Me-kong, or Me-kiang, but by the French surveyors it is called the Cambodia River. Taking its source in the mountains of Thibet, it traverses two of the south-western provinces of China, and passing along the entire western frontier of the Annamite empire, enters Cambodia, where it divides into three branches or arms, two of which flow through Lower Cochin China, and are there known as the rivers *Hau-giang* and *Tien-giang*.

This great river, the surveys of which are the result of the labours of M. Manen and other French hydrographic engineers, is navigable for a great distance into the interior. The waters commence to rise in the month of May, attain their maximum in October, and decrease until March. They rise 26 to 33 ft. at Nam Van, and 17 ft. about Chau-doc and the Rach Ong Nu. Tides are only felt during the season when the waters are low, and their height is 10 inches at Nam Van, and nearly $4\frac{1}{2}$ ft. at Chau-doc.

DELTA of the CAMBODIA RIVER.—The several mouths of the Cambodia River form a delta more than 60 miles in extent, in a N.E. and S.W. direction. The land is low, and subject to frequent changes in consequence of the accumulation of the rich alluvial deposit brought down by the different branches of the river. Shoal banks front the whole delta, and extend so far to seaward that the land is nearly always invisible from their outer edges. The 5-fathom line of soundings bounding these banks passes about 30 miles to the westward of Pulo Condore, and imagining a line to be drawn from that island to Cape St. James, the 5-fathom line will be about 8 or 9 miles distant from it at the Co-khien mouth, and about 3 miles at the Cuatieu mouth. Between the extreme mouths of the river, from lat. $9^{\circ} 20'$ to 10° N., lies the most advanced part of the coast, and it is in front of this part that the bank projects farthest. The soundings near its edge decrease suddenly from 10 or 11 to 3 fathoms, and the land, which is here 7 or 8 miles distant, is generally invisible.

Many ships have gone on shore in this locality, on account of the great risk arising from the rapid decrease of the soundings and the absence of any land marks. It is therefore necessary in approaching this coast from the offing to exercise extreme prudence, and the greatest possible caution should be observed when navigating to the westward of the line of Cape St. James bearing N. by E. $\frac{1}{2}$ E. At the first cast under 11 fathoms, or as soon as trees become visible, it is necessary to haul out quickly to the eastward, especially

during the N.E. monsoon, when the currents set strong on to the banks to the south-westward. The direction of these currents vary from West, S.W., and S.S.W., and their rate, which depends a great deal upon the force of the wind, is sometimes as much as 40 or 50 miles in 24 hours. Near the mouths of the Cambodia River the rate of the current increases with the flood and diminishes with the ebb.

The waters of the Cambodia are charged with yellowish mud, and discoloured water may at times be seen 7 or 8 miles out at sea towards the end of the ebb, but it is driven back by the flood. This change of colour indicates the approach to shoal water, and is therefore a limit which it is not prudent to pass.

The formation of deposit is so rapid in these parts, that the limits which we have given may perhaps be altered in a few years. There is so much sea on the edges of these banks, and the currents which set towards the land are so strong, that this coast should be absolutely avoided during the N.E. monsoon.

The mouths *Ba-thac* and *Dinh-nan*, which limit to the westward the delta of the Cambodia River, bear N.N.W. $\frac{1}{2}$ W., and are distant 45 miles from Pulo Condore. The shoal banks fronting them extend about 9 or 10 miles, and are for the most part uncovered at low water. The bar at the entrance of the former has not been completely sounded; upon that of the *Dinh-nan* there are 8 ft. at low water spring tides.

The mouths *Cong-hau* and *Co-khien* are about 20 miles farther to the north-eastward; the shoal banks fronting them extend 10 or 11 miles, and partly uncover. Upon the bar fronting these entrances there are but 6 ft. water, low spring tides. There is a clump of trees on the right bank of the *Cong-hau*, and a fort on the right bank at the entrance of the *Co-khien*.

The *Ben-nhau* mouth, 7 or 8 miles farther to the north-eastward, appears to be more accessible; from 8 to 10 ft. was found upon the bar at low water springs, but the channel is long, tortuous, and difficult. Two torts, one upon each point of the entrance, defend it. It was near this entrance that the *Weser* was lost, the wreck of which is, or was very recently, still visible upon the bank to the southward of the entrance, at a distance of 8 miles.

A few miles farther to the north-eastward is the entrance of the *Ba-lai*, upon the bar of which 9 or 10 ft. water was found at low water spring tides.

The *Cua-dai* and the *Cua-tieu*, the two northernmost mouths of the Cambodia River, are defended by forts built upon the banks at their entrances. On the bar of the former but 5 or 6 ft. was found, and on that of the latter 6 or 7 ft., at low water springs. The shoal banks, near which it is necessary to pass in entering these mouths, are numerous and extensive, the shallow water covering them forming large plateaux of very dangerous breakers.

In the actual state of things it would be useless to give instructions for entering these different mouths, the banks and channels being subject to

change of position; the coast, moreover, is very low, and covered with a vegetation so uniform, that in all probability any bearings we might give here would but have the effect of leading into error. None of these mouths are therefore practicable, in our opinion, unless they be first carefully buoyed, or unless with the assistance of a local pilot.*

DELTA of the RIVER DON-NAI.—Six miles to the eastward of the Dongtranh mouth lies *Cangio Point*, which limits on the West the bay of Ganh Ray, into which flows the Don-nai, as well as the *Viam-tcheou*, the *Viam-kai-mep*, the *Ba-bou*, the *Tchavia*, and the *Rach-lap*.

Caution.—In front of the mouths Cua-dai and Cua-tieu, and to the south-eastward of Cangio Point, the banks are the most numerous and extensive, and as they limit on the West the channel leading to Saigon, it is necessary to be extremely careful that the vessel is not drifted towards them by currents.

When the vessel is abreast of the Cua-dai mouth, or about 15 miles distant from the light on Cape St. James, take care that the light is not brought to the East of N.E. $\frac{3}{4}$ N., upon which bearing at that distance it leads in 4 fathoms about $2\frac{1}{2}$ miles outside the dangerous banks and breakers at the entrance of the river. From thence that bearing of the light appears to be a prudent tacking mark when standing towards the banks fronting the shore; it is however possible, when distant from 5 to 7 miles from Cape St. James, to stand farther to the westward, until the light bears N.E. $\frac{1}{4}$ E., but we consider it advisable not to do so, especially in large vessels.

DON-NAI or SAIGON RIVER.—The *Phuoc-binh-giang*, commonly called the Don-nai, or Saigon River, has not been surveyed higher up than the cascades, situated about 25 miles above *Bien-hoa*, the chief town of a province of that name, and which lies 12 miles to the N.E. by N. of Saigon. It does not become navigable until below the ancient barriers, at the point where the Tay-giang branches off, 6 miles below *Bien-hoa*. From thence it follows a south-easterly direction for 3 or 4 miles, and then trends with several windings to the south-westward, until it receives the Saigon arm and forms the Tam-giang-khau, which runs nearly North and South. At Phami Point it divides into two arms; the one turning to the westward is the Loirap, that turning to the south-eastward reassumes the name of the Phuoc-binh-giang or Don-nai. Four or five miles below the point at which the Loirap diverges, a smaller branch, named Rach-mon-gom, turns to the eastward. This sepa-

* At present the only port useful for trade is Saigon, nor is it probable that any other port will be utilised, for the whole country being intersected with numerous rivers and canals, it is an easy matter to convey its products to Saigon, the river leading to which can be safely and easily entered at any time by the largest class of ships. The Company's ships which traded to Cambodia in the 16th century frequently got aground in the river, and it appears always to have been an intricate navigation for large ships.

rates into two streams, both of which rejoin the main river at one point, and form that part known as the Quatre-bras (four-arms). The Don-nai disembogues at Cangio Point in Ganh Ray Bay, 8 miles below Quatre-bras.

The Saigon arm of the Don-nai is its sole affluent, and, like it, is replenished by the inundations from the great river of Cambodia. It flows from the N.W. to the S.E., leaves on its right the mountain of Badinh, passes by the Cai-cong, Thu-dau-mot, and Dai-thieu, and, pursuing a very serpentine course, passes Saigon, joining the Don-nai about 8 or 9 miles below that city.

CAPE ST. JAMES, bearing from Pulo Condore about N. by E. $\frac{1}{4}$ E., distant 98 miles, and forming the eastern boundary of the entrance to the Don-nai or Saigon River, is the first high land seen when coming from the south-westward, the whole of the coast from thence to the Gulf of Siam being very low drowned land. The mountain forming the cape has at its southern part a low gap, and on its northern part a high gap, which give it the appearance of three islands when first seen at a distance of about 30 miles, but on a near approach the connexion is perceived. The extreme of the cape is a narrow tongue projecting to the southward, and at a short distance to the eastward of it is a small islet.

The village of *Vang-tau* stands in *Cocoa-Nut Bay*, on the western side of Cape St. James, about $1\frac{1}{2}$ mile from its South extreme. The bay is about a mile long and half a mile deep, the beach being lined by a grove of cocoa-nut trees. The shore between the extreme of the cape and the bay is bold, and may be passed at half a mile with safety; but the bay is shallow and affords anchorage only for vessels of the smallest class. At the southern part of the bay the soundings decrease pretty regularly from 5 to 3 and 2 fathoms, but at the northern part they decrease suddenly from 5 to $1\frac{3}{4}$ fathoms; vessels, therefore, intending to anchor off this bay should approach it with caution, and anchor in 7 or 6 fathoms; the bottom is soft mud, and the holding ground good. "Be careful not to drop the anchor on a sunken rock in 7 fathoms of water; the extreme S.W. point of the bay bearing S.E. by E., and the N.W. point N.E. by E."—*Capt. A. J. Loftus*.

Water.—Good water may be obtained from wells, easy of access, at the village of Vang-tau; water may also be found at a village in the Ganh Ray River, a short distance from the point marked in the chart.

Lights.—A *fixed white* light of the first order is exhibited from a light-tower, 26 ft. high, standing on the southernmost of the heights of Cape St. James, and 776 yards within the South extreme of the cape. The light is elevated 482 ft. above the mean level of the sea, and is visible in clear weather at about 28 miles. The position of the light-tower is lat. $10^{\circ} 19\frac{1}{4}'$ N., long. $107^{\circ} 5' 25''$ E.

A *fixed white* light, elevated 32 ft. above the sea, and visible 10 miles, is

exhibited from a lightvessel moored head and stern N.W. and S.E., in 5 fathoms water, close to the right or West bank of the Don-nai River, N.W. $\frac{1}{2}$ W., distant $2\frac{1}{4}$ miles from Cangio Point.

CANGIO or BASSOK BANK, forming the western boundary of the entrance to the Don-nai River, is very extensive, and has but 3 to 4 ft. water over it at low tides. From its southern extreme, in 2 fathoms, the lighthouse on Cape St. James bears E. by N.—northerly, $4\frac{3}{4}$ miles, but shoal soundings of 3 and $3\frac{1}{4}$ fathoms extend from thence to a $2\frac{1}{2}$ -fathoms patch, which lies S.W., from $3\frac{1}{4}$ to 4 miles from the lighthouse. The edge of the bank from the southern extreme in 2 fathoms, takes a north-easterly direction till abreast of Vang-tau, when it trends to the northward as far as abreast of Point A, where the navigable channel is about $1\frac{1}{2}$ miles broad; from thence the bank curves away gradually towards Cangio Point, passing it nearly three-quarters of a mile off.

The edge of the Cangio Bank may generally be known by rows of fishing stakes, the extremes of which are usually close to the deep water; these stakes, however, cannot be depended upon for marks, being occasionally shifted by the natives.

Shoal Banks at the Entrance.—The shoal path, lying about $2\frac{1}{4}$ miles S.E. of the 2 fathoms' extreme of the Cangio Bank, is a hard bank of sand and gravel about half a mile in extent, with 13 to 15 ft. water over it. From its north-eastern extreme the lighthouse on Cape St. James bears N.E. by E., distant 3 miles. Between the shoal patch and the Cangio Bank the depths are 3 and $3\frac{1}{4}$ fathoms; $3\frac{1}{2}$ and 4 fathoms extend a mile to the eastward of it, and irregular soundings of $3\frac{1}{2}$, $5\frac{1}{4}$, and 4 fathoms, about $1\frac{1}{2}$ mile to the north-eastward; from thence to Cape St. James the depths are 6 to 8 fathoms.

The Formosa Bank, the West extreme of which lies S.E. by E. three-quarters of a mile from the South point of Cape St. James, is a mile in extent E. by N. and W. by S., and composed of hard sand and gravel, with but 13 to 15 ft. water over it. About a mile E.N.E. from it is a patch of 3 fathoms, about half a mile in extent.

Two miles S.S.E. from Cape St. James there are shoal patches of $4\frac{3}{4}$ fathoms on a bank of irregular soundings, which extends from thence about E. by N., nearly 3 miles. Between this bank and the Formosa Bank and 3 fathoms patch, are depths of 6 fathoms, and 6 to 7 fathoms in other directions from it.

The Formosa Bank, and the shoal patches to the southward and eastward of it, will be avoided if the lighthouse is not brought to the westward of N. by W.

The Channel at the entrance of the Don-nai forms an elbow to Cangio Point, the first land met with on the left hand when entering. It is 10 miles long, and, between the North point of Cocoa-Nut Bay and the Cangio Bank,

2 miles broad, but gradually narrows to three-quarters of a mile abreast of Cangio Point, where the river is usually considered to begin. The channel is bounded on the West and South by the Cangio Bank, on the East by the cape land, and a mud bank which extends about 2 miles from the East side Ganh Ray Bay, and on the North by a mud bank which extends nearly 2 miles to the eastward of the land opposite Cangio Point; these mud banks are separated by a passage with 5 to 8 fathoms water in it. The bottom of the channel is soft mud; the general depths are 7 to 12 fathoms, and ships may anchor in any part of it.

The entrance of the river at Cangio Point cannot be made out when distant, the land being very low, and covered with brushwood. Should the guard-ship be moored in her proper position at Cangio, the trees and her hull will be seen close together, forming an excellent mark for the entrance of the river.

CANGIO is a small fishing village on the right bank of the river, not far from Cangio Point, but it was, in 1862, nearly deserted on account of the numerous pirates in the river.

Supplies.—Sometimes a few fish, ducks, pigs, eggs, and a small supply of vegetables may be bought at the village, at moderate prices. The native boats are numerous here, and sail very fast, with two and sometimes three triangular sails made of matting, and, if wanted, may be hired for a small sum to go to Saigon or elsewhere.

Guard-ship, Pilots, &c.—A French frigate is stationed as a guard-ship off Cangio, but she is sometimes lying off Cape St. James. All vessels arriving must be brought to an anchor where she is, their small arms and ammunition, of whatever kind and quantity, must be packed up, numbered, and taken on board of her, and the manifest, port clearance, list of passengers, and the ship's draught of water must also be shown to her commanding officer; after which a receipt and pass to proceed up the river will be granted. Printed port regulations may be obtained on board, and also pilots for the river, if necessary. Rate of pilotage 3 dollars per foot.

Caution.—Should the guard-ship be at her station off Cangio, large vessels should not pass on her South side, there being no room between her and a hard bank of sand, extending some distance from the South bank of the river. The best anchorage is midway between the frigate and the North bank, in 8 fathoms, soft bottom. By proceeding farther into the river much deeper water will be found, making it sometimes very awkward for a large ship to get the anchor in the strength of the N.E. monsoon.

Banks and Dangers in the River.—Banks extend from both sides of the river between Cangio Point (B) and the points marked E. and F. considerably narrowing the channel, which must there be navigated with caution; the soundings are irregular, and the banks shoal suddenly. The river from thence to Point P is free from danger, with the exception of a bank pro-

jecting a short distance from Point M, another from the point opposite N, and another from Point O.

Coral Banks.—There is a coral bank in the bend opposite Point P, which extends more than half-way across the river; along its edge are $1\frac{1}{2}$ and 2 fathoms water, with less depths near the shore. There is also a detached bank with as little as $1\frac{1}{4}$ fathom water over it between the southern part of the shore bank, and the shore just to the southward of Point P; and another detached bank, with $2\frac{1}{4}$ fathoms water over it, just to the northward of Point P.

Mr. Phillips, master of H.M.S. *Vigilant*, remarks that these banks are well buoyed; and upon the French charts they are or were* marked as follows:—

Three *red* buoys are placed upon the outer edge of the shore bank.

A horizontally striped *red* and *black* buoy is placed upon the South extreme of the lower detached bank, abreast of the southern red buoy on the shore bank. A *black* buoy is placed upon its northern edge; and a *red* buoy marks its western limit.

A perpendicularly striped *black* and *white* buoy is placed on the northern end of the northern detached bank.

Three trees with their stems painted in *black* and *white* bands, mark the limits of these dangers on the eastern or right hand bank of the river, going up; and a tree, similarly painted, marks the northern limit on the opposite side of the river.

The best channel for large ships appears to be between the *red* buoy on the western edge of the southern bank and the shore on the left hand, going up; and afterwards between the middle *red* buoy of the shore bank, and the perpendicularly striped *black* and *white* buoy on the northern detached bank. The usual plan, however, is to closely hug the shore on the left hand, going up the river.

A shoal bank projects some distance from the shore at Point S at the junction of the Loirap, to avoid which vessels going up should keep over on the left bank or eastern side of the river.

Dangerous Bank commences nearly $1\frac{1}{2}$ mile above Point T, and extends about $3\frac{1}{2}$ miles along the bank on the eastern side of the river, from which it is separated by a narrow channel of 3 fathoms. It reaches about halfway across the river, and is composed of sand and rock, the latter prevailing at its South end; it is also coated with mud and clay. Several ships have been much injured on this bank, and have experienced great difficulty in getting off it. When beating up or down this reach, tack just before getting in mid river, and never shoal the water anything under 6 fathoms.

* We have received no notice of the arrangement of the buoys as above described, having been altered since the French system was adopted of marking channels with *red* buoys and beacons on the starboard side, entering from sea, *black* to port, and *red* and *black* to be passed on either side.

Dangerous bank extends to abreast of Point V, where the river turns sharply from a N.N.E. to a W.S.W. direction; from thence to Saigon the river is free from danger.

The CITY of SAIGON, the capital of the French possessions in Cochin China, stands on the right or West bank of the Don-nai, about 45 miles from Cape St. James. It was formerly the principal arsenal and marine depôt of the king of Cochin-China, who, in 1790, caused it to be extensively and strongly fortified by Colonel V. Olivier, a French officer in his service. Saigon consists of two towns connected by a straggling suburb; Pingeh with the citadel being on the West side of the river, and the commercial town being on a tributary stream navigable by large boats. It is regularly built and intersected by canals, some of which are lined with quays of stone and brick-work. The houses are mostly of earth, one story high, and thatched with palm-leaves. The citadel, fortified in European style, contains barracks, officers' quarters, and the governor's residence. Saigon has also a naval yard and arsenal, a palace, and large rice magazines. It communicates with the Mekong by a canal 20 miles in length, and has a foreign trade with China, Siam, Java, the Philippines, &c. In 1876, there were 317 vessels of all nationalities, and aggregating 234,299 tons register, loaded at Saigon, of which 215 vessels, of 158,151 tons, were British. The markets are well supplied with provisions, especially fish, and the environs fertile and carefully cultivated. Exports, see page 428. A railroad from Cholon to South Fort, a distance of 6 or 7 miles, was determined on in 1875.

The observatory, about half a mile from the principal landing-place, is reached by a straight road. It is, according to the French charts, in lat. $10^{\circ} 46' 40''$ N., long. $106^{\circ} 41' 52''$ E. The observations obtained in 1853 in H.M.S. *Rifleman* agree very closely with this position, viz., lat. $10^{\circ} 46' 39''$ N., long. $106^{\circ} 42' 31''$ E.

Anchorage.—The anchorage for men-of-war is off the city in from 5 to 7 fathoms; merchant vessels are obliged to anchor below the mouth of the Viam-Benghé. Ships' papers must be shown to the harbour master on arrival, and a berth for mooring ship will be pointed out by him.

Supplies.—Captain Loftus says that water is obtained from a well at the Chinese bazaar on the Viam-Benghé; it is brought alongside in boats. The fish are small and black, and inferior eating. Ducks and fowls sell for about three dollars per dozen; vegetables are scarce. There is but a limited quantity of ships' stores, and little variety for visitors.

A plentiful supply of excellent beef was obtained here by H.M.S. *Rifleman*, and also snipe at moderate prices.

Climate.—During the day the heat is very great, the thermometer often rising to 100° in the shade, and during the night also the air is very close and the heat oppressive.

Few strangers escape from what is called the Saigon fever; it seems to

be of a chronic form, and not easily got rid of. Emetics, purgatives, and large doses of quinine are used for its cure. Attacks of cholera and sun stroke are also frequent. Bathing, moderate exercise in the shade, spare regular diet, and ample rest, are the best preventives. Exposure to the sun, indolence, costiveness, irregular diet, and drinking fermented liquors must be avoided.

Tides.—At Cape St. James it is high water, full and change, at 2^h 30^m; * at Cangio Point at 3^h. Upon the bars of all the Cambodia rivers, as far as the mouth of the Ben-nhau, it is high water nearly at the same time as at Cangio. Equinoctial springs rise 13 ft., neaps 9 ft. Spring tides run strong; ebb tides last longer than the floods. Neap tides are feeble and irregular; sometimes strong currents set into the river at that period, and raise the height of the tides a little. On the coral bank up the river it is high water at 3^h 50^m; and the rise is the same. At Saigon the tides are tolerably strong and regular about the springs; it is high water at 4^h 30^m, and the rise is 11 to 12 ft.

“Neaps are weak and irregular, with strong under currents and very little rise and fall. Vessels dropping down during neaps will find great advantage in having a square sail sunk under the stern, with two guys leading forward. From the pitch of the cape the flood sets to the Cangio Bank, almost direct to the mouth of the river; the ebb takes the opposite direction. The passage up the river generally occupies two days.”—*Captain Loftus*.

Directions for making the Land and Entering the Don-nai River.—In the N.E. monsoon ships from the southward should make the land well to windward of the port, or they will be set quickly to leeward of Cape St. James, and too near the Cangio Bank, by the flood tide and the sea current setting about S.W. by W. along the coast. But a strong set in the opposite direction may be expected with the ebb tide, which, at the full and change of the moon, begins to run out of the river about midnight.

Entering the River, the fairway mark is the two points of the cape land northward of Cocoa-nut Bay in one, N. by W. $\frac{1}{2}$ W.; this will lead between the shoal patches in regular soundings of 6 or 7 fathoms.

Cape Bakek just open of Cape Ti-wan, bearing N.E. by E., leads to the southward of the shoal patches which lie south-eastward of Cape St. James, and the lighthouse bearing N. by W. leads to the westward.

The western extreme of the North point of the cape land (A) bearing North, will lead clear of the shoal patch on the western side of the channel, and bearing N. by E. $\frac{1}{4}$ E. will lead between the shoal patch and the Cangio Bank in 3 fathoms least water.

* Mer de Chine, p. 210. Capt. Loftus gives 11^h as the time of high water at the cape, and 5^h 30^m at Saigon.

In the South-west Monsoon, when the East end of Pulo Condore is brought to bear South with a westerly wind and lee current, steer northward, and the vessel will soon gain the edge of the bank fronting the Cambodia rivers, and extending to the mouth of the Saigon River.

Strong freshes run out of these rivers during this monsoon, and join the sea current, whereby vessels are obliged to keep the edge of the bank aboard to prevent being set to leeward of the meridian of Cape St. James.

Continue along the edge of the bank, with the lead going in not less than 10 fathoms, and keep on until Cape St. James bears about N.N.E., then steering direct for it on that bearing, will lead to the fairway of the entrance to the river.

CAPE ST. JAMES to SAIGON.—A steam vessel will have no difficulty in proceeding up the Don-nai River for the first time, guided by the chart only, and without the assistance of a pilot, by keeping as nearly as possible in mid-channel, and being careful in rounding the points. Of course, near the Coral Banks and Dangerous Bank, it will be necessary to be guided by the buoys (page 436) which mark the former, and to keep over to the fort side when passing the latter. A stranger may proceed boldly up to the city, as there is plenty of room to anchor and swing upon the flood tide. It is a different matter however with sailing ships, and the following directions for their guidance are by Captain A. J. Loftus, commander of the barque *Kensington* of Singapore, 1862.

In the North-east Monsoon.—Having rounded Cape St. James at a moderate distance, either with the flood or ebb, keep mid-channel, and steer for point A until it bears East, distant three-quarters of a mile, then steer N.W. $\frac{1}{4}$ W. till the trees on point B. bear W. $\frac{1}{4}$ N., or the guard ship W. $\frac{1}{2}$ N.; at the same time point A must be brought to bear S.E. by E. Then steer W. by N. for the entrance of the river. Take care to make these courses good, attending carefully to the lead. Having arrived at the entrance, bring up midway between the guard ship and the North bank in 9 fathoms water. Do not pass inside the guard ship.

When turning to windward between Cape St. James and Cangio Point, the lead should be kept constantly going, and the water not shoaled to less than 7 fathoms on either side, the banks being steep-to in many places; with a hard bottom the vessel is on the edge of the bank.

Having complied with the regulations of the guard ship, weigh at low water, with a commanding breeze from the eastward, and proceed towards point E, keeping in mid-channel, and giving the small islet lying off point E a good berth.

When near point E,* brace up and luff, run close to it through the next

* Many seamen have mistaken point D for that of E, and having luffed round it have got aground on hard sand.

reach. Should the wind be scant, make a tack and proceed on to point J, keeping it close aboard; then brace up and luff along the South reach, giving the mouth of a river below the point a moderate berth; steer on in mid-channel until near point M, then haul up, and if the ship is handy, work through the East reach, otherwise back and fill, or drop through if the tide be strong. Make sail again at the end of the reach and proceed, rounding point O in mid-channel, as there is a little shoal water off it. Keep very close in to that side of the river until the painted tree that grows out of the water at point P* and the Coral Bank are passed, giving the tree a berth of half a ship's length.

Having passed the bank, run on, keeping clear of the bight Q, which is shoal. When off point T, cross over to U, sailing along that side at a convenient distance. Keep close to point V if the wind be scant, and luff through the next reach; then keep away and brace sharp up at point W, keep a close luff through the South reach, and bring up below the shipping.

In the South-west Monsoon.—Having arrived at Cape St. James, proceed on and anchor in mid-channel off point A if the tide is ebbing; if not, brace up and work to windward in a N.W. direction until point A is brought to bear S.E. by E., and the group of trees on point B W. $\frac{1}{4}$ N., or the guard ship W. $\frac{1}{2}$ N., then work up for the mouth of the river on these bearings, keeping the lead constantly going, and not shoaling the water under 7 fathoms.

This is the rainy season at Saigon, and the prevailing winds are from the West and S.W. Ships are able to partly drop and sail up the river in this monsoon. But when under canvas be prepared for heavy squalls, with rain from the West and S.W., which travel across the southern part of Cambodia from the Gulf of Siam. The tides also are stronger and of longer duration now than in the N.E. monsoon.

Having arrived at the guard ship and complied with the regulations, at a favourable opportunity get away at low water with a westerly or south-westerly commanding breeze, and proceed up the river, making short tacks, if necessary, in the upper part of this reach between points E and D.

When standing over to either side of the river above the branch C, do not shoal the water to less than 10 fathoms; but having rounded point E, in working, approach either side to any distance, as both shores are steep-to.

When close to the Four Arms, the water deepens suddenly from 12 to 17 and 20 fathoms, and it would be advisable to pass these rivers under canvas, until beyond the influence of their conflicting currents, and shoaler water is met with.

In kedging or sailing past these rivers with the flood, keep in or about

* It is doubtful if this painted tree now exists; it is not marked on the latest French charts.

mid-channel, and be guarded against the tide, which sets strong from the N.W. arm into the small river below point J. Having cleared the small river at J, proceed sailing or kedging, according to the size or handiness of the ship. The flood tide at the rivers K and L enter the main branch, consequently ships passing their mouth will be set on the opposite shore.

Having passed point O, if under sail, it will be advisable to take it in, and kedging past the coral bank, with the anchor under foot in the manner formerly mentioned, as it very seldom happens in this monsoon that a ship can luff round point P, and clear the bank.

In passing this bank with a fresh wind and flood tide, take great care to starboard the helm quickly when rounding point P, as the tide sets from that point directly into the opposite bight, and ships from neglect of this precaution would be apt to tail on the West end of the bank. Having cleared it, proceed, and pass the mouth of the river at R closely, as the flood tide sets out of it over to the opposite bank.

When under sail or kedging, pass point S in mid-channel, and make directly over to U, as the flood rushes out of the river at S, and sets over to point T, sweeping the tail of the Dangerous bank. Ships are very apt to be set on the South end of this bank when kedging past, if the point of the river opposite S be not kept close aboard.

Continue on and give point V* a close shave in passing, as the greater bulk of the flood tide runs to the northward, which is apt to carry vessels beyond the mouth of the smaller river, and with a head wind would lose a tide or so in getting back again. Whereas by hugging the point close, a couple of tacks will easily clear the reach, then bear away for Saigon, and drop up to the shipping at leisure.

From Saigon to Cangio Point the ebb tide from the main branch enters the minor rivers and flows in a circuitous direction to the sea; whilst the flood, on the contrary, empties itself into the principal stream, the small river at J being the only exception.

SAIGON to CAPE ST. JAMES.—In the *North-east Monsoon* the average passage of small vessels to the mouth of the river is about five days, while large vessels have taken from fifteen to twenty days. The former have the advantage of being able to beat through nearly all the reaches, whilst the latter have to back and fill or kedge with the anchor under foot.

When unmooring at the city, cat the starboard anchor, keeping the port one down for kedging, and having broken ground, sheer from side to side,

* Ships dropping up or down this part of the river should, if possible, avoid the deep bight to the westward of point V, and keep close to the opposite point, as there are some obstructions in the bottom of that bight, by which vessels have lost their anchors.

lying athwart the tide when convenient, and hugging the points when there is no shoal off them, to prevent being set into the bights.

After rounding point V, keep on the same side of the river as far as U, and from thence sheer direct over to point T, passing it closely, to prevent being set into the river Loirap opposite. The ebb runs very strong into its mouth, and many ships have been hoisted on the soft mud bank lying off point S, through delay in crossing over. Proceed on, and when a short distance from the river R,* change anchors, giving that branch a good berth whilst passing, as the ebb tide sets strong into it. Having passed the bight Q in mid-channel, keep close in to that side, and look out for point P; if the tide runs strong when the painted tree is approached, run out a line and check the ship round it, keeping the bushes close aboard to prevent being set on the rocky patch below the point; this precaution is necessary, particularly during the springs, as the ebb tide runs very strong, setting from point P, directly over the rocky path.

Proceed, passing point O in mid-channel; strong sets will be found in the bight at N and off point M, and also into the rivers L and K, the former of which is nearly blocked up with soft mud. Vessels should hug the points opposite these rivers very closely whilst passing, otherwise they will be hoisted into them, and meet with more or less delay.

Proceeding, take care in passing the Four Arms, as the ebb tide sets strong up the two northern arms, the water also increases in depth at their junctions, making it very unhandy for kedging, and troublesome work for the men at the windlass.

The best way to pass is to keep as close as safety will permit to the mouth of the river at J, which is rather shoal, having but 3 fathoms across its mouth. Having passed it keep very close to point J, where plenty of water will be found, until beyond the tidal influence of the rivers.

Should the ship sheer off the point, carry a line out to the trees at J, and snub her round it, otherwise she will be hoisted into one of the northern arms, and be delayed. Several vessels have been delayed from one to two days through this cause. After passing the Four Arms, proceed, keeping close to point E, as the tide sets strong into the bight opposite. The channel from E to D is much contracted by the extent of the banks on both sides of the river.

Having passed point E, proceed in mid-channel until the small island off point D is rounded, keeping the North shore aboard until arriving at the guard ship. By these means the strong set in the river C and the extensive hard banks which lie on that shore will be avoided. These banks are pretty

Vessels dropping past the river at R, and the Coral Bank should always use the starboard anchor with the ebb tide, and the port anchor with the flood. By these means the river at R and the bank will be passed without much trouble.

steep-to, and vessels tacking or dropping in any part of this reach should borrow, if anything, towards the North shore, as the water shoals there more gradually. The lead at the same time should be kept carefully going, and very short tacks made by vessels working through the narrows at the upper part of this reach.

Having anchored at Cangio, receive the arms, and clearance from the guard ship; then get away with the sea breeze on the ebb tide, and work the vessel through the channel to the eastward, being careful not to shoal the water under 7 fathoms when standing towards the banks.

When the guard ship is brought to bear W. $\frac{1}{2}$ N., or the trees on point B W. $\frac{1}{4}$ N, bring the point A to bear S.E. by E.; work up for the point on these bearings, taking care not to stand too close to the high land of St. James, as the wind is generally puffy and unsteady, causing ships at times to miss stays. Should the tide be nearly done before getting clear of the cape, it would be advisable to anchor off Cocoa-nut Bay until the next ebb makes, for, should the wind fall light outside, the flood tide would in all probability set the ship on the Cangio Bank.

In the South-west Monsoon, ships leaving Saigon will find little difficulty in getting down to Cape St. James, as the prevailing winds are almost invariably favourable for most of the reaches in the river.

When large ships cannot be worked through the smaller reaches, or are obliged to kedge in consequence of foul winds, &c., the directions already given for dropping down in the N.E. monsoon will be applicable. During settled weather in this monsoon the sea breeze sets in from S.W., South, S.E., and sometimes E.S.E. at Cape St. James.

From Cangio work out of the bay with the ebb tide to the cape, following the directions already given for the N.E. monsoon.

CAPE TIWAN, bearing E.N.E. $10\frac{1}{2}$ miles from Cape St. James, is high, and may be seen in clear weather 40 miles off. It is the termination of a chain of hills, which, stretching northward, end in a long slope to seaward, and it is generally the first land made in coming from the southward. When off it, Cape St. James will be seen resembling two islands of moderate height.

The bay between Cape St. James and Tiwan is filled by a shoal bank, the 3 fathoms edge of which is from 1 to 4 miles off shore. Four miles off the entrance of the Cua-lap River, in the middle of the bay, with the lighthouse bearing W. $\frac{3}{4}$ S., and Cape Tiwan N.E. $\frac{1}{4}$ E. $3\frac{3}{4}$ miles, is a patch with $4\frac{1}{4}$ fathoms over it. *Pernambuco Rock*, on which the vessel of that name struck in June, 1875, was afterwards examined by the French ship of war *Surcouf*, and found to lie 8 ft. below the surface of the water, S.E. $\frac{1}{4}$ S., 2 miles from Cape Tiwan, and E. $\frac{3}{4}$ N. from Cape St. James lighthouse. To avoid these rocks, it is advisable for vessels passing between Capes Tiwan and St. James

to avoid coming under a depth of 10 fathoms until they open the entrance of the Saigon River.

BRITTO BANK, named after a Portuguese captain who was wrecked upon it, was examined by Captain Ross, I.N., in 1817, who found it to be a dangerous shoal about $1\frac{1}{4}$ mile in length, E.N.E. and W.S.W., and its breadth does not exceed one-third of a mile. The shoalest spot has but 2 fathoms water over it, and consists of a large patch of rocks near the North part of the shoal, from which the summit of the highest hill over Cape Bahek bears W. $\frac{1}{4}$ N. distant $19\frac{1}{2}$ miles; Cow Island, N. by W. $9\frac{3}{4}$ miles; and the islet close to Kega Point, N.E. $\frac{2}{3}$ N. $15\frac{3}{4}$ miles. There are 3 to 5 fathoms over other parts of the shoal.

Otram Point, formed of yellowish white sand hills, about 120 to 150 ft. high, which render it easily discernible, bears N.E. by E. $\frac{3}{4}$ E. $12\frac{1}{2}$ miles from Cape Tiwan.

Off this part of the coast, at from 2 to $3\frac{1}{2}$ miles distant, are several shoal patches, of from 4 to 5 fathoms water. These banks, from the water shoaling suddenly over a hard bottom, cause overfalls, particularly near the edge of the shore bank. The patches under the depth of 5 fathoms will be avoided by keeping Cape Tiwan to the northward of West, until Cape Bahek bears N. by W.

CAPE BAHEK, or **Ba Ke**, N.E. by E. $\frac{3}{4}$ E. $4\frac{1}{2}$ miles from Otram Point, consists of a hill about 400 ft. high, surrounded by smaller ones, and is connected with Otram Point by a range of sand hills.

The soundings for 12 miles eastward of Cape Bahek decrease regularly towards the shore, but inside the Britto Bank there are several shoal patches, only two of which, however, are dangerous to any but the largest ships.

The first of these patches, with only 3 fathoms water over it, lies about 7 miles N.W. of the Britto Bank, and $3\frac{1}{2}$ miles from the nearest land, which is a point bearing about N. $\frac{1}{2}$ W. from it; the summit of the highest hill over Cape Bahek, bearing W. by S. $\frac{1}{2}$ S. $14\frac{3}{4}$ miles; and Cow Island N.E. by N. 6 miles.

About $2\frac{1}{2}$ miles to the S.W. of the 3-fathom patch is another of 5 fathoms, with 6 and 7 fathoms around it, and from it the summit of Cape Bahek bears W. by S. nearly $12\frac{1}{2}$ miles, and Cow Island N.E. $\frac{1}{2}$ N. $8\frac{1}{2}$ miles. Three miles E. by S. from this patch is another, of $4\frac{1}{2}$ fathoms water.

Vessels passing between the Britto Bank and the shore should not attempt to go inside the 3-fathom patch, for there are no objects sufficiently near to afford safe marks for passing between it and the tail of the spit.

COW ISLAND, bearing N.E. by E. $\frac{1}{2}$ E. $19\frac{3}{4}$ miles from Cape Bahek, is a small round island, with trees upon its summit, lying about a mile from the nearest part of the coast, and $1\frac{1}{4}$ mile westward of the entrance of a small river. It is safe to approach, the soundings decreasing regularly towards it.

KEGA POINT (in lat. $10^{\circ} 42' N.$, long. $107^{\circ} 59' 40'' E.$ by the French chart),

bearing from Cow Island E. by N. $\frac{1}{4}$ N., distant 12 miles, is the extremity of a tongue of low land, the prolongment of a spur from Mount Taiku, terminating in an islet which resembles from a distance a fort in ruins.

The land is low and woody near the sea; inland the country is high, and the regular sloping mountain Tai-ku rises to an elevation of 1,312 ft., at 9 miles N.W. $\frac{1}{2}$ N. from Kega Point. This mountain is visible a great distance from seaward, being the most conspicuous land in this part of the coast, and detached from any other high land.

The shore may be approached by the lead for a distance of 6 or 7 miles eastward of Cow Island, but about $4\frac{1}{2}$ miles W.S.W. from Kega Point, and $3\frac{1}{2}$ miles from the shore, the water shoalens suddenly from 6 or 7 to $3\frac{1}{2}$ fathoms. W. by S. 4 miles from Kega Point is a patch with only $2\frac{3}{4}$ fathoms water over it. A patch with $4\frac{3}{4}$ fathoms water over it, and 6 to 8 fathoms around it, lies E. $\frac{1}{4}$ S., distant 8 miles from Cow Island, with Mount Tai-ku bearing North, and Kega Point N.E. by E. $\frac{1}{4}$ E., distant $6\frac{1}{2}$ miles. About three-quarters of a mile to the south-eastward of this patch is another of $5\frac{1}{2}$ fathoms.

Kega Point is safe to approach, there being 9 or 10 fathoms water close to it.*

VINE POINT, bearing from Kega Point N.E. $\frac{1}{2}$ E. 22 miles, has a small bank on its West side, northward or inside of which there is good anchorage in 5 fathoms, opposite a fishing village in the small bay on the West side of the point. *Phan-thit Bay* is formed by the land trending northward from Kega Point to the Pho-hai River, and from thence eastward to Vine Point. Tiger Island lies close to the East side of Vine Point. Although covered with birds' dung it is not conspicuous, and only perceived when a ship is near the land. The coast hereabout is speckled with alternate patches of sand and verdure.

GUIO POINT, bearing N.E. $\frac{1}{2}$ E. about 12 miles from Vine Point, forms the South point of the bay of *Phan-ry*, and is known by a high, steep sand-hill close to the sea. From Guio Point the coast trends nearly North to the entrance of the Phan-ry River, and is of a reddish colour. Phan-ry is a large fishing village.

LOGAN POINT, bearing N.E. by E. $\frac{1}{4}$ E. 15 miles from Guio Point, is a narrow, low neck of land, projecting a considerable distance into the sea. On its West side there is a small bay with a fishing village. Shoal water appears to extend nearly a mile from the point.

* The description of the coast of Cochin China has, so far, been principally derived from the late French surveys; what follows, with the exception of the more recent descriptions of the Treaty Ports, is chiefly from the surveys made by Mons. Jean Marie Dayat in 1793, and from the remarks of Captain Daniel Ross, of the Bombay Marine, who visited this coast during the years 1806—10.

A bank about a mile in extent, with $4\frac{3}{4}$ fathoms water over it, was discovered in 1862 by H.M.S. *Vulcan*, lying about $2\frac{1}{2}$ or 3 miles southward of Logan Point, with the East extreme of the point bearing N.N.E., and the West extreme N.N.W. Another $4\frac{3}{4}$ -fathom patch, named *Amazon Bank*, lies about 4 miles south-eastward of the point; it is surrounded by depths of 11 and 14 fathoms.

PULO CECIR de TERRE (called *Hon-cau* by the natives), lying N.E. by E. $\frac{1}{2}$ E. 8 miles from Logan Point, is a low island, extending nearly E.N.E. and W.S.W., having near its centre a mass of rocks higher than the other parts, which is visible about 15 miles from the deck of a large ship. When first seen it appears like a small peak or spire, and sometimes like a boat's sail; the whole of the island is rocky and barren, with the exception of a little grass or green moss on the flat part. The two low extremities of the island are encompassed with rocks, which project out above and below water to a considerable distance. There are also some rocks above water on the South side, but as the danger is generally visible, the island may be approached in the day to $2\frac{1}{2}$ or 3 miles; in the night it ought not to be given a wider berth, for then the island cannot be perceived unless it be very near.

Breda Bank.—The coast behind Pulo Cecir de Terre forms a deep and extensive bay, stretching from Logan Point to the land of Cape Padaran; and the high land of Cecir to the N.W. and North of the island is very mountainous close to the sea. Between Pulo Cecir de Terre and the N.E. side of this bay, opposite the Gap of Padaran, lies the Breda Bank, having 2 fathoms, coral rocks, on its eastern edge, and there is said to be much less water to the westward. This danger is not in the way of vessels passing outside Pulo Cecir de Terre, unless with a working wind they stand far into the bay between that island and the land of Padaran.

CAPE PADARAN (called *Muidin* by the natives), in lat. $11^{\circ} 21' N.$, long. $108^{\circ} 58' E.$, is high land, steep and convex to seaward, forming the projecting part of the continent to the S.E. The high land of Padaran is joined to the adjacent mountain of Cecir by a neck of low level land, visible only when near the shore on the North or South side of the cape. The neck of low land forms a deep gap between the land of Padaran and the mountain to the westward; and this gap or chasm in the land is generally called the *Gap of Padaran*, and by the natives *Cana*. It is very conspicuous at a great distance, and serves as a mark to avoid Holland Bank to the W.N.W. of Pulo Cecir de Mer, described hereafter, and to point out the direction of Pulo Cecir de Terre, this island being on with the Gap, bearing from N. by E. $\frac{1}{4}$ E. to N. by E. $\frac{1}{2}$ E.

Soundings do not extend far out from Cape Padaran, it being a steep headland, bold to approach, having from 25 to 30 fathoms very near the shore.

Amazon and Althea Banks.—The soundings about Pulo Cecir de Terre, being in general irregular, are not always a sufficient guide in the night to

show the proximity of the island. The ship *Althea* got on a bank of 8, 7, and $6\frac{1}{2}$ fathoms, with the island bearing N. by E. $\frac{1}{2}$ E. just in sight from the deck, and Logan Point N. by W. $\frac{1}{4}$ W. Lieut. Banare, of the French navy, examined these banks cursorily in 1872, and believes the two banks, *Amazon* (page 446) and *Althea*, to be only one bank, making out from the North point of Cecir Island Bay, surrounding the latter; thence trending out to the S.W., and terminating at about 14 miles distance from the southern point of the bay.

Over an extent of about 16 miles, in a N.E. and S.W. direction, he found but shallow water, at times being able to see distinctly the sandy bottom covered with coral heads.

Although having obtained not less than $5\frac{1}{4}$ fathoms water, he is not positive that there may not be less.

Before a more thorough examination has been made, large vessels should keep clear of these banks, and not approach the coast South of the parallel of Cape Padaran.

PHANRAN BAY and Harbour.—Cape Padaran is the southern boundary of the great bay of the same name, called also Phanran Bay, after a considerable town at its head, where there is a tolerable harbour, formed by a reef, dry at low tide, that projects about 2 miles from the western shore, and shelters vessels from the sea.

After having passed Cape Padaran, if bound to the harbour, steer for the middle of the bay, to avoid a reef and foul ground contiguous to the western shore, then keep to the northward, for the North entrance point of the harbour until the reef on the western side is plainly seen.

When near the entrance, a mass of rocks, one over the other, like ruins, will be perceived close to the shore at the N.W. side of the harbour, and beyond it an isolated hill; keep the highest rock of the mass on with this hill, in steering past the reef at the distance of a third of a mile; 6 or 7 fathoms will be the least water. When inside the reef, steer more westerly, and anchor in 4 fathoms, good holding ground. There is a rivulet at the bottom of the harbour, and a stream of fresh water where the reef joins the shore.

From Phanran Bay to Davaich Head the coast runs about N.E. by N., and is very mountainous and steep. A little to the southward of Davaich Head there is an opening into *Vung-Gang*, a large basin or cove, inhabited by fishermen, which is darkened by the steep surrounding mountains.

DAVAICH HEAD, or *Fulse Cape Varela*,* called Mui-Davaich by the natives, in lat. $11^{\circ} 44' N.$, long. $109^{\circ} 13' E.$, is formed by a high oblong mountain of great magnitude, which, from the steep cliffs that front the sea, rises

* Named from a rock or knob upon the mountain, a little inland, having some resemblance to that over Cape Varela, although not nearly so conspicuous.

with a gentle acclivity inland; it may be known from the other prominent headlands by its great height, its convex outline, and by its regularly sloping to seaward.

CAM-RANH BAY and Harbour.—The entrance to Cam-ranh Bay is bounded on the South side by the land of Davaich Head, and the contiguous isles, and on the North side by the high island *Tagne*: this is called the large entrance, in which there are from 18 to 14 fathoms water. The small entrance is between the North point of *Tagne* Island and the opposite point of the main; it has 7 and 8 fathoms water in it, but it is very narrow, and should not be used except in a case of necessity. The bay carries 10 and 12 fathoms water, and is protected from the sea by *Tagne* Island.

About $1\frac{1}{2}$ mile to the N.W. of *Tagne* Island is the entrance to Cam-ranh Harbour, about three-quarters of a mile wide, formed by a point of land on the North side, and a long neck or narrow peninsula to the S.W. The inner harbour is an extensive lagoon. There are no hidden dangers in either the bay or harbour, and they are safe for ships of any description, the bottom being generally mud, and good holding ground. The harbour is mostly inhabited by fishermen.

FISHER ISLANDS, in lat. $12^{\circ} 2'$ to $12^{\circ} 4'$ N., are of moderate height, and lie $3\frac{1}{2}$ or 4 miles off the mainland to the northward of Cam-ranh Bay. The southernmost island is called *Hon-noi*; the other, which is the largest, and named *Hon-ngai*, has some islets and rocks near it. The channel inside these islands is said to be safe, with 12 fathoms water near the shore, and there is good anchorage opposite to them in the S.W. monsoon, close to the coast at the sandy plain.

The passage inside the Fisher Islands is thought to be safe, and it may be adopted if intending to proceed into Nha-trang Bay by the southern entrance; but caution must be used, for there is to the N.W. of these islands, in the fair track, a rocky patch, on which the ship *Lord Castlereagh* shoaled suddenly, August 18th, 1807.

Capt. A. C. Strode, R.N., H.M.S. *Vulcan*, 1862, reports having seen "what was evidently a *sunken rock*, lying three-quarters of a mile W.N.W. of the southernmost of the Fisher Islands, in lat. $12^{\circ} 1'$ N., long. $109^{\circ} 19'$ E."

Tré Island, in lat. $12^{\circ} 16'$ N., is high, and contains several coves, where vessels may repair damages. The ship *Upton Castle* anchored to the westward of Tré Island, between the inner of the small islands and the main, to the southward of Nha-trang Bay, and found it good anchorage, and convenient for watering.

NHA-TRANG BAY is large, and protected by Tré Island and its adjoining isles to the southward, and by the mainland and Pyramid and Dune Islands to the northward and eastward. The anchorage is in 8 fathoms, good holding ground, with the entrance of Nha-trang River bearing about N.W. or N.W. $\frac{1}{2}$ N., distant 1 mile, and Tré Island E.S.E. The river has a bar,

will only admit vessels drawing 7 or 8 ft. water, and communicates with Nha-trang city, about 5 miles to the westward. This city is the capital of the provinces Nha-trang and Binkang, and has a fort, built in the European manner, by Monsieur Oliver, a French engineer. Here they manufacture some silk and other articles, and carry on trade with different parts of the coast.

A ship in want of wood or water may obtain them by touching at this place.

To proceed into Nha-trang Bay by the South entrance, a vessel may pass on either side the Fisher Islands, then between Tré Island and the two isles to the S.W. of it. Between the West point of Tré Island and the main, the channel is $1\frac{1}{4}$ or $1\frac{1}{2}$ mile wide.

The northern entrance into Nha-trang Bay, although wide, has a coral bank nearly in mid-channel, opposite the large Bay of Binkang, which makes it necessary to keep nearest to Tré Island.

It is high water, full and change, at Nha-trang Bay, at $8\frac{1}{2}$ hours; and the rise and fall is 5 or 6 ft. There is only flood and one ebb in 24 hours.

The **FISHER ISLANDS** are three small barren islands, with some rocks close to them. *Pyramid*, the southernmost island, in lat. $12^{\circ} 19' N.$, is a high regular cone or pyramid, conspicuous as a mark in sailing along the coast. The channel between it and Tré Island is safe.

Dune Island, lying about a mile to the N.E. of Pyramid, is of moderate height, flat on the summit, like the crown of a hat, when viewed in some directions; to the south-eastward of it are some islets or rocks. *Shala* lies 5 or 6 miles to the northward of Dune Island, and about 3 miles to the south-eastward of the peninsula of Hon Cohe.

HON COHE BAY, the next large bight to the northward of Binkang Bay, which is shallow, has several islands in it, the outermost of which, called *Bac*, has, about a mile eastward of it, a rock called the *Button*, and three islands to the westward. Between Bac and the eastern of these three islands there is a safe passage, and also between the latter and the other two islands, which lie much nearer the western shore; but the widest channel is outside Bac, between it and the East point of entrance of the bay. At the head of the harbour is the village of Hon Cohe.

On the East side of the bay are several islands at the entrance of Couabé Harbour, into which ships may warp, and moor to the trees, there being plenty of water and no danger; but vessels do not usually go there, as the harbour is inhabited only by a few fishermen. This harbour or cove is formed by high mountains.

At Hon Cohe it is high water, full and change, at $11\frac{1}{2}$ hours; and the tide rises 5 ft.

The **Three Kings** are three rocks, lying about $1\frac{1}{2}$ mile eastward of the

eastern point of entrance of Coua-bê Passage. They are bold to approach, having 30 fathoms water near them, with a passage between them and the point.

HONE GOME BIGHT.—About 5 miles northward of the Three Kings, and close to a point of the main land, lies the small island *Doi-moi*, at some views resembling a turret or sentry-box. The point, from which this island is separated by a very narrow channel, is the easternmost land of Cochin China, being a little to the eastward of the meridian of Cape Varela. Between it and Cape Varela, the land forms a concavity called Hone Gome Bight, in which the soundings are regular, and there is good anchorage in 8 or 10 fathoms, sandy bottom, at the South side, about 2 miles W.N.W. of the point, near a small island. The sandy flat, which extends from the high land of Coua-be to that of Cape Varela, is a neck of land scarcely a mile broad in some places, separating the head of Hon Cohe Bay from the sea; and the three islands in the middle of that bay may in passing be perceived over the sandy flat.

Water can be obtained at the southern extremity of the sandy flat, but in the dry season wells must be dug in the sand, at some distance from the sea. Fresh water may be procured in this manner on most parts of the coast.

PORT ONG-RO, at the northern extremity of Hone Gome Bight, seems safe at all times. It is about a mile wide at entrance, stretching about 3 miles inland, in a north-easterly direction, with soundings of 8, 7, and 6 fathoms, close to the village at its head. The bottom is fine clay. *Pulo Varela* is a small island near the shore, to the south-westward of the entrance.

Water.—On the West side of the harbour fresh water may be procured in several places, but the best watering place is about half-way up on the same side, to the north-eastward of a little cove.

CAPE VARELA, or *Pagoda Cape*, in lat. $12^{\circ} 55' N.$, long. $109^{\circ} 24\frac{1}{2}' E.$, is formed of steep cliffs, extending nearly North and South $2\frac{1}{2}$ miles, having in the middle of them a small sandy bay, where a stream of excellent water descends from the mountain into the sea. The cape itself may be seen from a distance of 28 or 30 miles, and when first perceived in coming from the northward appears like an island, the gap of low land which joins it to the mountain behind being then depressed under the horizon. This mountain* rises directly over the cape, and upon its summit there is a large perpendicular rock, resembling a pagoda or chimney, called *Da-bia* by the natives, which makes it very conspicuous; and it may be seen about 60 miles distance from the deck of a large ship, either from the northward or southward, in clear weather; but the summits of the mountains are frequently obscured by clouds or vapours, particularly in the N.E. monsoon. The cape may be

* There is a hot spring in the middle of the cape mountain, and there is said to be silver ore in some of the mountains, which form double and treble ridges behind the cape.

approached close to, there being 20 and 25 fathoms water around it at a small distance from the shore.

Directions.—From abreast Davaich Head or False Cape Varela the course is N. by E. $\frac{1}{2}$ E. and N. by E., until Pyramid Island and the other islands adjacent to it are passed, then N. $\frac{1}{4}$ E., and North to Cape Varela. The best track in the night, with a fair wind, is to keep from 6 to 9 miles off the different headlands, which, with the Fisher Islands and Pyramid group, will be visible at that distance in passing along, if the weather be clear. When the weather is unfavourable, edge farther out, to give the islands a prudent berth: and if soundings are obtained, the vessel will not be far from them, or some of the headlands.

From Cape Varela to Cape San-ho the course is N. by W., or N. $\frac{1}{2}$ W., about 50 miles, but soundings will not be obtained in this track unless near the coast. A little inland there is a mount in the vicinity of the city of Quinhon, with a spired pagoda on it; further to the northward there is a mountain, on the summit of which there is a tower crowned with a small spire or funnel; the latter is in about lat. $14^{\circ} 6' N.$, and they are discernible when sailing along the coast at a considerable distance.

PERFORATED ROCK.—About 4 miles North from Cape Varela lies a mass of rocks, some of them level with the water's edge; but the central rock is considerably elevated, with a large stone on its summit, appearing as if placed by art; in passing near it, when abreast, a hole through will be perceived below the upper stone, which has given it the name of Perforated Rock. There is safe passage, with 20 to 25 fathoms water, between it and the mainland.

PHUYEN BIGHT is formed by the land taking a West and N.W. direction from Cape Varela to the Phuyen River, which is distant from the cape about 11 miles. About 18 or 20 miles N.W. from the cape, not far inland, stands a high isolated mountain, which, being a regular cone, is called *Conical Mountain*, or *Epervier*; a little to the S.W. of it there is a sloping piece of land, with a rock or pagoda on it, which is only discerned when near the shore. Here the mountains recede to the westward, a great distance inland, and the Cape Varela chain stretching also to the westward, a large space of low land is formed close to the sea round Phuyen Bight, between Cape Varela and Conical Mountain.

PHUYEN HARBOUR.—The entrance to this great inlet, in lat. $13^{\circ} 23' N.$, is about 2 miles wide, with 10 and 11 fathoms water on either side the small island that lies a little inside, called Nest Island, from the West side of which a reef extends in that direction nearly a quarter of a mile. The country around this excellent inlet, one of the best in the world, is well cultivated, and, together with the houses and huts interspersed along the hills, presents on entering it a beautiful landscape. The province of Phuyen is better cultivated than any other in Cochin China.

The inlet has general depths in it from 12 to 5 fathoms; and three anchorages, *Port Xuan-dai* on its South side, *Port Vung-lam* on its West side, and *Port Vung-chao* in its N.E. corner. The anchorage of *Port Xuan-dai* is in 7 or 8 fathoms, sandy bottom, with the entrance of the river bearing South, and *Nest Island* about N.E. by E. That of *Port Vung-lam* is in 7 fathoms, mud, on the North side of an island that fronts the port, with the village bearing S.W. by W. *Port Vung-chao* is sheltered from every wind by circumjacent mountains, and the anchorage is in $4\frac{1}{2}$ or 5 fathoms, with the houses in the grove of cocoa-nut trees bearing S.E. to S.E. by E. The North shore of this port is fronted by a coral reef, which is visible at low water. In proceeding towards *Vung-chao* the *Buoy Rock* must be avoided which lies nearly awash about a third of a mile from the eastern shore of the inlet. There is a small cove, called *Vung-la*, on the North side of entrance of the inlet, where two or three vessels might be hove down, if requisite.

The *watering place* is in a small bay to the N. by E., in which is a fine cascade close to the beach, and very convenient for watering.

Gain-Ba Point, about 3 miles northward of the entrance of *Phuyen Harbour*, has small bays formed on each side of it. About 3 miles to the northward of *Gain-ba Point* is another point called *Vung-trich*; and $4\frac{1}{2}$ miles beyond the latter is another, named *Vung-mon*; these two points are also bold.

COU-MONG HARBOUR.—Between *Vung-trich* and *Vung-mon* Points is the bay of *Vung-mon*, which is safe to approach, with regular soundings in it towards the shore. On its South side, in lat. $13^{\circ} 30' N.$, is the very narrow entrance of *Cou-mong Harbour*, with 7 and 8 fathoms water in it, 5 and 4 fathoms a little inside, and 3 to 4 fathoms to the southward of the small island, *Cou-mong*, in the middle of the harbour. This is an excellent cove for small vessels, or those of middling size; and there is a little village among the cocoa-nut trees to the northward of the island.

PULO CAMBIR (the centre), in lat. $13^{\circ} 32\frac{1}{2}' N.$, and 4 or 5 miles westward of the meridian of *Cape Varela*, has a regular sloping appearance, and is visible about 18 miles from a ship's deck; it is of considerable size, extending N.N.W. and S.S.E., having a few fishermen's huts on the S.W. side; and at a short distance S.E. from its South end there are some sharp-peaked rocks, called the *Two Paps*. This island is nearly abreast and about 2 or 3 miles distant from *Vung-mon Point*; and the channel between it and the coast is safe.

Date Island, lying about 6 miles N.N.W. of *Vung-mon Point*, and $1\frac{1}{2}$ mile distant from the main, is of round form, and covered with trees. From *Vung-mon Point* to opposite *Date Island* the coast is steep and very mountainous, forming a considerable bight, called *Cambir Bay*.

QUIN-HON HARBOUR, the entrance to which is about North distant 6

miles from Date Island, is bounded on the West by a neck of sand about 4 miles long, and on the East by high steep land. This harbour, once a place of considerable trade, is likely again to become of importance, as it was opened to foreign commerce on November 1st, 1875. It is sheltered from southerly winds by the curved form of the high land on that side of the entrance, and is protected by forts built on the point; but vessels of large draught are prevented from entering it by a shoal bank that extends a long way out from the western point, and which, stretching across to the land on the East side of the entrance, forms a bar, on which there are only 3 and $3\frac{1}{2}$ fathoms water.

The deepest water is close to the eastern point of entrance, where, it is stated, a vessel may carry from $3\frac{1}{2}$ to 4 fathoms on the bar, at high water spring tides; inside of it the depth increases to 7, 8, and 10 fathoms. The western part and bottom of the harbour is a spacious lagoon, with shoal water; several small rivers fall into it, one of which communicates with the city of Quin-hon, situated about 15 miles to the westward, and is the capital of the province of the same name.

CAPE SAN-HO, in lat. $13^{\circ} 44' N.$, long. $109^{\circ} 14' E.$, about $2\frac{1}{2}$ or 3 miles eastward of the entrance of Quin-hon Harbour, is a high bluff headland, forming the eastern point of the Bay of Quin-hon. Close to the land, a little to the northward of the cape, there is an island, called Hau by the natives; and the coast, which extends about 5 miles North from the cape, is steep and high.

Abreast the North point of this high land there are some small islets, one of which, called Cau, is of a round form, and lies about one mile off the point; and nearly $1\frac{1}{2}$ mile outside of this there are some rocky islets, named Hom-Co by the natives, and by Europeans Black Jack.

BUFFALO ISLAND, in about lat. $14^{\circ} 5' N.$, and 4 miles distant from the high land abreast, is a convex rock of sloping form, moderately elevated, but will not be seen in the night until it is approached very close. It lies 15 miles to the northward of the North point of the high land that forms Quin-hon Harbour; from which point the coast is low for some distance, and again becomes high opposite Buffalo Island. The water is very deep outside this rock, and the coast to the westward is bold and safe to approach, having soundings of 14 and 16 fathoms near the shore.

Nucc-Ngol, or *Fresh-water Point and Bay*, lie about 9 miles to the N.W. of Buffalo Island. *Turtle Island*, about 9 miles farther to the northward, and 3 miles off shore, is small, and very little above water; but there is a safe channel between it and the shore. *Tam-Quam River* disembogues in about lat. $14^{\circ} 32' N.$, at the northern extremity of a sandy flat; the bar at the entrance is passable only by boats at high water. *Tiphou River* falls into the sea at 5 miles to the southward of the Tam-quam, in the middle of the sandy flat.

The Coast from Tam-quam Point trends about North 6 miles, and then N.W. by N. about 33 miles to the entrance of the *Quan-gai River*. It is steep and bold to approach. Contiguous to the sea the coast is of moderate height, but the country is very high inland. There is anchorage off the *Quan-gai River*.

Cape Batangan, in lat. $15^{\circ} 16' N.$, about 6 miles to the north-eastward of the river, projects to seaward, and forms on its South side a bay, in which, at about a mile distant from the cape, there are some rocks, called *Rocky Islands*, nearly even with the water's edge; the country vessels sometimes pass between these rocks and the cape. There is also a rock with $2\frac{1}{2}$ fathoms of water over it, in about $15^{\circ} 13' 15'' N.$, a short distance off the coast, on which the French transport *l'Indre* struck in 1875. From it Plat Rock bore S. $28^{\circ} E.$, true, distant $1\frac{1}{3}$ mile. The coast from this cape to Cape Bantam runs about N.N.W. 12 miles, and the soundings are 20 and 25 fathoms near the shore.

PULO CANTON, called *Collao-ray Island* by the natives, in lat. $15^{\circ} 24' N.$, long. $109^{\circ} 6' E.$, is of considerable size, and visible 26 or 27 miles from the deck of a large ship. It has a level aspect when viewed from southward; its West side is inhabited, well cultivated, and fresh water may be procured. A reef projects from its S.E. end; and to the northward there are overfalls and rocky bottom, extending about 3 miles from it, and a low island that lies about 2 miles to the north-westward.

The channel between Pulo Canton and the main is safe, with soundings of 25 to 40 fathoms.

Caution.—It may be proper to observe, that vessels adopting the inner passage to China during the strength of the S.W. monsoon, in June, July, and August, ought not to edge off from the coast of Cochin China until they pass within sight of Pulo Canton, particularly if the winds are light and baffling. On an old French manuscript chart, a reef is placed in lat. $13^{\circ} 58' N.$, long. $110^{\circ} 20' E.$

QUI-QUIK BAY, formed on the West side of Cape Bantam, close to the foot of high mountains, is about 4 miles wide and 6 miles deep, with some islets in it, and small creeks where fresh water may be procured; and it affords good anchorage in the S.W. monsoon. At its N.W. extremity there is a small bay or cove under *Cape Happaix*, said to afford shelter in the N.E. monsoon.

FALSE COLLAO ISLAND.—From Cape Happaix the coast trends nearly N.W. by N. about 45 miles to Cape Touron, and in this space the country is mountainous a little inland. About 9 miles northward from Cape Happaix, and about 11 miles off the coast, lies the island of False Collao, of considerable height, and a reef is said to project from its South extreme.

CHAM-COLLAO (the South part), in lat. $15^{\circ} 54' N.$, long. $108^{\circ} 36\frac{1}{2}' E.$, and 9 miles distant from the main, is a high island, about 6 miles in length

N.N.W. and S.S.E., having some islets adjoining its South end, and others as far as 6 miles westward from its N.W. part. It is inhabited, well cultivated, and the anchorage on the West side, in 4 or $4\frac{1}{2}$ fathoms near the village, may be considered a safe harbour in all winds. Opposite this island lies the entrance of the Fai-foh River, which, by a narrow arm of the sea, communicates with Touron Bay. Near the entrance of this river there is a mass of marble rocks, very conspicuous when sailing near the coast.

TOURON BAY.—*Cape Touron*, or *Tien-Tchu*, in lat. $16^{\circ} 8' N.$, long. $108^{\circ} 21' E.$, is the eastern extreme of the peninsula that forms the East side of Touron Bay (called *Han-san* by the natives); and Collao-Han, or Touron Island, in lat. $16^{\circ} 12' N.$, long. $108^{\circ} 16' E.$, lies close to the point of land that forms the N.W. side of its entrance. The entrance is $2\frac{3}{4}$ miles wide, with regular soundings of 15 and 14 fathoms, decreasing inside to 8, 7, and 6 fathoms. The northern shore of the peninsula must be given a berth, for a reef, on which the sea sometimes breaks, projects about three-quarters of a mile from the third point. A rock awash lies a quarter of a mile off the North point of the peninsula, with a depth of 6 and 7 fathoms between it and the shore. The inner point of the peninsula is also joined to a small contiguous island by a shoal. This small island is in lat. $16^{\circ} 7' N.$, long. $108^{\circ} 17' E.$, and the usual anchorage for ships is to the southward of it, in 4 or 5 fathoms, sheltered from all winds.

This was formerly a great place of trade, and some European nations had factories here; but no trade has been carried on by Europeans to this port for a considerable time past.

In Touron Bay it is high water, full and change, at 3^h, and springs rise 4 feet.

CAPE CHOUMAY, or *Chouway*, in lat. $16^{\circ} 21' N.$, and $22\frac{1}{2}$ miles N.W. by W. from Cape Touron, is the extremity of a round and rugged peninsula of moderate height, which, united to the coast by an isthmus of sand, appears like an island with two summits when seen from the N.E. or S.W. A chain of high mountains with round summits extends almost to the coast. There is good anchorage in a small bay on the West side of the cape, where there is a river. A canal leads from Cape Choumay to Hue, and facilitates the communication between that city and Touron.

The **RIVER HUE**, or *Hue-Fo*, the entrance to which is in lat. $16^{\circ} 34' 50'' N.$, is generally considered the boundary between the coast of Cochin China and Tong King. Between Cape Choumay and this river the coast is formed of sand-hills, the summits of which are covered with numerous villages, surrounded by trees and cultivated fields; a peculiarity which will prevent mistaking this part of the coast for that North of Hue, where the villages are on the sides and not on the summits of the sand-hills. The position of the river is marked by a large fort with a flagstaff, built on the West point of entrance; at half a mile West of this is a small hill with a remarkable

pagoda. There is good anchorage off the mouth of the river in 6 fathoms, muddy bottom; but it is said that there is a heavy swell along the coast during the N.E. monsoon. The bar of the river has only 10 ft. on it at low water,

The city of Hue, situated about 12 miles from the mouth of the river, is sometimes the residence of the king of Cochin China. It is composed of two parts, the inner, and the outer town where the mass of the population resides, which has been estimated at 100,000 souls; the inner town is a large square fortress, built after Vauban, according to the plans of the French engineers. The river encloses it on two sides, besides a canal 130 ft. broad, by which it is entirely surrounded.

2.—THE GULF OF TONG KING.

The **GULF of TONG KING**, or Tonquin, is the great bend of the coast comprised between the parallels of 17° and 22° N., and which is rendered a deep inlet by the peninsula of Lien-chew and the island of Hainan, which protect it to the eastward. The entrance between Cape Lay on the West and the S.W. part of Hainan on the East is about 120 miles wide, which is the general width of the gulf itself. Several islands lie contiguous to the western shore of the gulf, and numerous small islands and shoals at its head. Soundings may be obtained all over it, 45 and 40 fathoms in the middle, decreasing towards either shore; the bottom is generally soft, fit for anchorage. In some parts the soundings appear to be irregular, for the ship *Rolla*, in lat. 17° 25' N., to the northward of Tiger Island, shoaled from 35 and 30 fathoms mud, to 10 fathoms on a bank, steering W. by S.; and soon deepened again to 25 and 30 fathoms, steering W. by N.

CAPE LAY.—From the Hue River a low and sandy coast trends about N.W. $\frac{1}{4}$ W. 47 miles to Cape Lay, which itself is rocky, of moderate height, and covered with several patches of trees. A bank extends a short distance off this cape; within 2 miles of the cape the depth varies from 15 to 20 fathoms.

TIGER ISLAND, distant about 12 miles E. by N. from Cape Lay, was explored in 1831 by Laplace, Commander of *La Favorite*. It is small, about a mile in extent, and its centre rises to a peak about 328 ft. in height, which is visible in clear weather at a distance of 15 to 18 miles. The South point is perpendicular; the North point terminates in a low, narrow neck of land. The channel which separates it from the coast is clear, with 17 to 23 fathoms water.

The Coast north-westward of Cape Lay is sandy and low; it trends first to the N. by W. for about 31 miles, after which it inclines towards the West as far as the entrance of the river Quia Hoy, at which stands a fort; from

thence the coast runs N. by W. for about 30 miles to Cape Boung Quioua, forming a bay of moderate depth.

CAPE BOUNG QUIOUA.—To the northward of Quia Hoy the sand-hills are of a reddish colour, and their summits are covered with brushwood. The coast here is elevated, and forms two bays of considerable depth, in each of which is a small stream. Cape Boung Quioua, easily known by its large red spots, is formed of elevated land. There are two islands near it, and a third at $2\frac{1}{2}$ or 3 miles to the S.S.W.; the latter is named *Boissieux Island*, and it terminates towards the West in a long reef which projects $1\frac{1}{4}$ mile towards the coast.

The anchorage of Boung Quioua is very good for all kinds of vessels during the N.E. monsoon. A vessel can anchor in $4\frac{3}{4}$ to 6 fathoms, sandy bottom, under shelter of the islands.

About 27 miles E.S.E. from Cape Boung Quioua the charts show a *shoal* with 10 fathoms water; its position, however, is uncertain. Lat. $17^{\circ} 50' N.$, long. $107^{\circ} E.$

SOUTH WATCHER.—At $7\frac{1}{2}$ miles E. by S. from the cape, in lat. $17^{\circ} 55' 10'' N.$, is a barren and rugged rock, called South Watcher Island, having 17 fathoms at less than a cable's length from its western side, decreasing to $9\frac{3}{4}$ fathoms near the small islands near the cape.

TSEU or *Goat Island*, also called *Sovel*, lies near a promontory 1,410 ft. high, and is distant 12 miles N.N.W. from Cape Boung Quioua. When seen from the East it appears like two pointed hummocks, with a perpendicular cliff towards the North, and sloping to the South; it is surrounded by a reef which extends more particularly to the South and West. There is an islet at 2 miles N.E. of Sovel. It is a jagged rock with a number of pointed peaks.

Tides.—A short distance to the southward of Sovel, during a period of two weeks, only one tide was observed in 24 hours; excepting for three or four days, during which there were two tides per day. The range of tide was about 10 ft., but this rise decreased in proportion in going southward.

At 6 miles to the West of Sovel is a small port open only from the North to N.W. The bottom is sandy, and it is sheltered from the East and N.E. by a rocky peninsula, connected with the coast by a narrow sandy isthmus, which running to a point projects half a mile from the shore.

The Coast from Cape Boung Quioua has been entirely mountainous, but from the small port just mentioned it trends to the N.W. by W., and alters to a sandy shore occasionally interrupted by isolated mountains, the first of which, called the *Mamelles (Paps)*, is easily distinguished by its two summits, 1,656 ft high, which in coming from the South are liable to be mistaken for those of Sovel.

NORTH WATCHER (marked *Hot Island* on the chart) is a small island, lying 10 miles N.W. from the Mamelles, 21 miles N.W. $\frac{3}{4}$ W. from Sovel,

and 3 miles North of a prominent hill 2,033 ft. high. To the SE. of it is a much smaller island, a short distance southward of which the sea has been seen breaking.

The coast from abreast the North Watcher changes its direction to N.W. by N. for 45 miles, and then runs N.N.E. as far as Bien Shan Island, thus forming a large bay, in which, at 2 or 3 miles from the shore, the depth is $6\frac{1}{2}$ fathoms. A short distance before arriving abreast of the North Watcher, high mountains appear in the N.W. and N.N.W., and in front of this part of the coast lies Matt Island.

Matt Island, formerly called *Frakaki*, in lat. $18^{\circ} 50' N.$, and about 10 miles from the shore, is 1 mile in length, N.N.W. and S.S.E., and precipitous on all sides except the South.

Besides two small islands lying at less than half a mile E. by S. from Matt, there are between Matt and the coast two rocks; the one, distant about 4 miles S.W. of Matt, is 32 ft. above the sea, and at a short distance resembles a junk under sail; and the other, about 1 mile N.N.W. of the former, is low and flat, and consequently dangerous.

GNEU ISLAND, lying about 6 miles West of Matt, and about 2 miles from the coast, consists of two hills separated by a neck of low land; so that from a distance, with the island bearing South, it will appear like two islands.

PORT of LACHT KOUENN.—The coast from abreast Gneu Island advances more towards the sea, and forms a bay, at the head of which are high mountains, with a flat shore at their base. The port of Lacht Kouenn, situated in this bay, in about lat. $19^{\circ} 4' 30'' N.$, long. $105^{\circ} 43' 9'' E.$, is a good anchorage for small vessels; its entrance, which faces the S.S.E. and is not more than a cable wide, has on the West side a large rock, called Dog Rock, which is connected with the shore by a narrow isthmus, only seen at low water.

This harbour, which is the best of those that have been explored on the coast of Tong King by M. E. Ploix, is sheltered from all winds, except those from the West, by rather higher mountains.* It is 2 to 3 cables in width, with about $1\frac{1}{2}$ fathom least water in it at low tide. The river Lacht Kouenn empties itself into it, coming from the W.N.W.

* The size of the rivers of Tong King, which flow into the sea between lat. 20° and 21° North, is shown by the great amount of alluvion that has been deposited, and which is estimated to be about 328 ft. per annum, being the amount which the bank of the river encroaches on the sea. At their entrance the fall of water is about 10 ft., and about 16 ft. during spring tides, if we can believe the inhabitants. The depth varies, no doubt, with the quantity of rain that falls into the basin, the melting of snow on the hills, where the rivers find their source, and the force and direction of the wind on the coast; but 10 ft. rise and fall may always be depended on, and vessels of a certain draught are always sure of being able to penetrate into the country.—*M. E. Ploix.*

Coal is found at the village of Magne Shan, on the East shore of the harbour.

It is high water, full and change, at this harbour, at 10^h, and the range of tide is from 8 $\frac{3}{4}$ to 9 $\frac{3}{4}$ ft.

ME ISLAND, in lat. 19° 21' N., and 8 miles from a projecting point of the coast, is the most northern of a considerable group of islands, about 25 in number, of different forms, and nearly all precipitous. The most western, which is flat and precipitous on all sides, is called *Bong Island*.

BIEN SHAN ISLAND lies to the westward of Mé Island, and rather near the coast. It is about 2 or 3 miles long North and South, and its northern part turns abruptly to the West, and forms a bay, which affords anchorage for small vessels, sheltered from the westward. Larger vessels can anchor at the entrance of this bay.

At Bien Shan it is high water, full and change, at 8^h 30^m, and the rise of tide is about 10 ft.

The *Coast* from Bien Shan Island runs northward, and afterwards N.N.E. At 6 miles North of the island is the river *Keun-bong*, in which the water is very shallow. Here the coast changes its aspect, the hills are at a greater distance from each other, and as the country with which they are surrounded is very low, they appear like islands.

Ne' Island, lying about 3 miles from the shore, and in lat. 19° 52' 30" N., is the last island met with before arriving at the head of the gulf. It affords a temporary shelter from North winds in about 6 $\frac{1}{2}$ fathoms water.

To the S. W. of Né, and upwards of a mile from the coast, is an islet about 13 to 16 ft. high; here the river *Trann* falls into the sea, and on its bar is a depth of 2 fathoms at low water. It is high water, full and change, at the mouth of the Trann River, at 8^h 30^m, and springs rise about 10 ft.

KIAO RIVER.—About 4 or 5 miles to the S. W. of the point before which lies the island Né, and on a low beach, is the mouth of the river Kiao, on the bank of which, and 6 miles in the interior, stands the arsenal of Hamatt, where the king's vessels are built. These pass across the bar without any cargo, with 1 $\frac{3}{4}$ fathom at high tides. This river communicates with the river Trann, which, as mentioned before, falls into the sea opposite Né.

The *Coast* to the northward of Né Island is a chain of serrated mountains, and from them the country, for a considerable distance inland, is entirely flat. As far as these mountains, the depths appeared to decrease in a regular manner on approaching the coast, but on leaving it they were irregular. From these mountains the land forms a great convex bend towards the East; nothing is to be seen but a low shore, relieved at a distance by trees, which here and there appear to rise out of the sea. Fronting this shore are extensive banks, stretching in some places from 8 to 10 miles eastward. Mountains become visible in the N. W., but they are far inland.

Three great rivers, the Dai, Lak, and the Balat, form here a great delta;

they communicate with each other partly by natural means, and partly by canals constructed by the inhabitants. Pilots are also indispensable in order to anchor before their mouth. A line of soundings, of 8 to 11 fathoms, rock and sand, was carried by the *Primauguet* at about 7 miles from the visible coast.

The RIVER DAI falls into the sea to the eastward of the above serrated mountains. The *Pregent*, which anchored off its mouth at the end of December, 1859, found on the bar a depth of $6\frac{1}{2}$ ft., muddy sand, at low water, which would give, according to the tidal observations made along the coast, about 13 ft. at high water, in ordinary weather. After crossing the bar the depth increases to $3\frac{3}{4}$ fathoms at the entrance. The missionaries assert that there are $3\frac{1}{4}$ fathoms water before their house, which stands about 20 miles up the river.

RIVER BALAT.—The *Primauguet* anchored in lat. $20^{\circ} 12' N.$, about 6 miles S.S.E. from the mouth of the River Balat or *Keua-dong*, the deepest of the three rivers, and rather near the banks to the West, having at less than a mile another bank to the N.E., at the West side of which terminates the canal which joins the branch West of Balat (*Keua-dong*), this being the deepest channel to enter the country. The pilots state that there are $5\frac{1}{2}$ ft. at low water, and $10\frac{3}{4}$ to $12\frac{3}{4}$ ft. at high-water spring tides.

At 15 to 20 miles from the mouth of the Balat, and near the junction of a natural branch, which flows to the South and unites the rivers Dai and Lak, the river becomes much broader. The fort Mom-rö is erected here, and opposite to it a toll-bar is established, which seems to be halfway between the coast and Nam-binh, the first town of Tong King after Keicho. Beyond Mom-ro the rivers, which discharge themselves into the sea partly by the Dai and Lak, and partly by the three or four branches of the Balat, unite and become one large river, which is no doubt deep.

Nam-binh does not stand quite on the River Balat, but on a canal of little depth, which joins the river about 3 miles from the town. The other part of this canal enters at Roukbo into the river Dai, a little below the old establishment of the French missionaries, and the important town of Nim-binh,* the second in the province. A little above Nam-binh are the old factories, and farther to the N.W. lies *Keicho*, the capital of Tong King, which it appears can be reached by vessels drawing about $9\frac{3}{4}$ ft. water.

Tides.—From tidal observations made on board the *Primauguet*, at the anchorage off the mouth of the river Balat, the establishment appeared to be 4 hours, and the rise of tide from 6 to 9 ft., the flood coming from the South,

* At Balat, the former limits of the coast, at the time of the commerce with Holland (about 200 years ago), is at present about 4 or 5 miles in the interior. Balat is one of the three ports opened to French commerce by the treaty of Saigon.

and the ebb from the North. It was difficult to determine if there was only one tide every day.

Keicho, or *Hanoi*, hereafter described, the capital of Tong King, is about 28 leagues up the river Balat. It is more than 150 years since European vessels traded to this river, and the knowledge of the navigation of the gulf not having been carefully recorded, it is now almost lost to Europeans. Trade, however, may again open up, but for the present the treaty port of Haiphong, on the Cua Cam River to the northward, will probably absorb the little trade there is. According to M. Ploix, it appears that vessels of about 10 ft. draught can go as far as the capital, but that there are dangerous gravel banks before reaching it. Keicho is in about lat. 21° N., long. $105^{\circ} 47'$ E. It is badly fortified; the houses are constructed of earth and wood, covered with cane, leaves, or thatch. The Dutch and Portuguese had commercial establishments here, but they have been destroyed long ago. The silk and porcelain manufactures of Keicho are the most valued of this part of the East.

The *Coast* North of the entrance of the Balat, as far as Cape Daushon (Too-shan), is low, and its direction is N.N.E. nearly. It appears that there are some rivers within this limit, and a line of soundings, from $3\frac{1}{4}$ to 9 fathoms, was carried at a distance of 5 or 6 miles from the shore.

RIVER LACHT HUEN.—Between Daushon and another projecting point the coast forms a bay with an opening 10 or 12 miles wide, but it is almost entirely filled with banks. Into this bay fall the two principal and numerous smaller branches of the Lacht Huen River (probably the Songka, Sangkoi, or Red River). Up the southern of the principal outlets is the newly-opened treaty port of Haiphong. The coast northward of the bay, into which the River Lacht Huen flows, is steep-to, and is formed by extremely rugged mountains, which determine deep bays, where a vessel drawing 11 ft. water will find safe shelter.

The branches of the river forming the delta of Sangkoi may be navigated by vessels drawing 16 ft. water, but which should not enter without the aid of a local pilot, as the channels frequently change. Between the delta and Hai-Dzeuong, about 50 miles up from the mouth of the Cua Cam branch, there is usually a current running out of the river at the rate of half to one knot. Above Hai-Dzeuong, in a narrow channel leading to Keicho, the current runs $1\frac{1}{2}$ to 2 knots an hour. The water of the river is thick and of a *red* colour, hence one of its names.

Tides.—According to the observations of Lieutenant T. Pepham, of the French navy, the water on the bar of the Cua-cam entrance of Sangkoi River rises and falls as follows:—When the moon's declination is North: On the moon rising the water falls, and again commences to rise as the moon sets. When the moon's declination is South: On the moon rising the water

commences to rise, and again commences to fall as the moon sets. The greatest range of tide is 13 ft.

Hondau Island and Lighthouse lie off the South extremity of Daushon Point, in lat. $20^{\circ} 40' N.$, long. $106^{\circ} 47' E.$, and mark the West side of the entrance to the Cua-Cam branch of the Lach Huen River. The island is small, 100 ft. high, and the light, exhibited at an elevation of 164 ft. above the sea, is a *fixed* white light, visible between the bearings of S. by E. $\frac{1}{2}$ E. and N.E., and in clear weather should be seen from a distance of 8 miles, but it is not a very reliable light.

A European *pilot* is either stationed on Hondau, or is cruising between it and Apowan; he will take vessels up the Cua-Cam branch to Haiphong. Pilotage is compulsory, the charges being 3.05 dollars a foot for steam vessels, and 4.55 dollars a foot for sailing vessels. If no pilot come off, vessels should anchor to the eastward of Hondau Island, and send to Haiphong. Care should be taken not to bring Hondau Island to bear southward of W.S.W., as the water shoals quickly inside that bearing from $3\frac{1}{2}$ to $2\frac{1}{2}$ fathoms.

A vessel drawing 17 ft. can cross the bar at high water ordinary springs; at neaps there are about 14 ft. at high water, but the range of tide is very uncertain, as is also the time of high water, at full and change.

HAIPHONG.—The following description is chiefly extracted from a pamphlet drawn up by N. B. Dennys, Esq., Ph. D., Secretary of the Hongkong Chamber of Commerce :*—

The port of Haiphong, named also Haidong, or Hwafung, recently opened to foreign trade under a treaty made with the Tonquinese, is situated about 16 miles up the Cua Cam branch of the Lacht Huen River. The town, a collection of huts, in about lat. $20^{\circ} 49' N.$, long. $106^{\circ} 40' E.$, is at the mouth of a creek, which enters the Cua Cam on its right bank. It contained, in 1876, a population of about 10,000; of whom 850 were Chinese and 142 French, 120 of the latter being soldiers and marines who have charge of two forts which command the passage of the river. These forts are only to be held until indemnity is paid to the French and Spanish governments. A French consul is resident. Only three steamers and three sailing vessels had visited the port between September, 1875, and April, 1876, which does not look very promising for future trade.

Supplies can be easily obtained. *Water* for drinking purposes is supplied at one dollar per ton, but it can be more easily procured, and of better quality, from the French commissariat; the charge for this is three dollars per ton.

* A most valuable work for captains to have who intend visiting. Its title is, "Report on the newly-opened Ports of Kiung-chow (Hoi How) in Hainan, and of Haiphong in Tonquin (Visited in April, 1876), by N. B. Dennys, Ph. D., etc." Hongkong: Printed by Noronha & Sons, Oswald's Terrace, Wellington Street.

In the narrow creek, on the bank of which is situated the custom-house, are four wooden jetties, two on either side, one of which, on the East bank, is used as a public wharf.

The river at Haiphong is $2\frac{1}{2}$ cables wide and $4\frac{1}{2}$ fathoms deep. Vessels drawing 15 ft. can anchor in mid-channel. Merchant vessels anchor N. and E. of the northern fort; man-of-war vessels N.W. from it.

Keicho, or Hanoi, the centre of commerce (Haiphong being its port), is the capital of Tonquin, and head-quarters of French influence in that country, and is situated inland, upon the river, at the mouth of which lies Haiphong. By the most direct water route, the distance from its port is about 60 miles; but as the water in this channel is frequently too low to float even the lightest draft boats, the usual route taken is by the main river, which extends the journey to about 150 miles. The enormous rise of the upper waters during the rains (some 25 ft.) renders both channels equally available for a short period in each year.

This latter lies through the Tai Bing Canal and Red River, upon the banks of which latter Hanoi lies. It is very intricate, and the sands, which abound in its course, are at times impassable. Vessels drawing only 6 ft. can, however, generally manage to get up, the depth at low water varying from $\frac{3}{4}$ fathom to 2 fathoms. Keicho may be also reached by proceeding up the Balat River as described on pages 460-1.

Hanoi is notable as the place where Lieut. Garnier (whose description of this country, in a splendid work published in Paris in 1873, is so well known), was murdered in November, 1873. The town is situated on the left bank of the river, and is said to contain 60,000 inhabitants, exclusive of 2,000 to 3,000 Chinese and some 175 Frenchmen. Missionaries have long been resident in the district, which is said to contain 20,000 Christians. The houses are mostly of brick. The chief trade is silk. No shipping, except river and cargo boats, is seen at Hanoi. One or two steam launches, however, run weekly between Haiphong and Hanoi. As at Haiphong the French have some land on the river bank at Hanoi, ceded to them and other foreigners, and some buildings are erected on it. So far wines and stores have been the chief imports; further trade is, however, likely to arise, especially as South-Western China can be reached by the Songka River. M. Dupuis was the first to do this successfully. In October, 1873, he conveyed an expedition up the river with arms, &c., for the Chinese, who were then engaged in quelling disturbances. He describes the country as abounding in the precious metals, as well as copper, iron, zinc, &c. The river at Hanoi is 5 to 6 cables broad, and small vessels (probably of 8 or 9 feet draught) may reach this point. There is a rise of 30 ft. in the summer, the river being consequently wider and deeper then. Imports and exports are, as agreed by treaty, taxed 5 per cent. *ad valorem*, salt 10 per cent. The

money, weights and measures will be described in the Appendix at the end of this volume.

Directions for Haiphong from the Southward.— Having passed Hondau Lighthouse (the light from which is not to be depended on), bring Daushon Point to bear S.W. by W. $\frac{3}{4}$ W. distant half a mile, and steer N.W. $\frac{1}{4}$ W. for a distance of $1\frac{1}{4}$ miles, passing between fishing stakes on either side.

When Petit Mirador (a hill over a point lying N.W. from Hondau), bearing S. by E. $\frac{1}{4}$ E., is in line with the western base of Daushon Hill, seen between a group of trees and the hill, steer in with this mark astern, allowing for a strong tide off the mouth of the Cua-Cam River; when Petit Morne Conique, which is easily recognised, bears W. by S. $\frac{1}{4}$ S., the entrance of the Cua-Cam River will be plainly visible to the eastward. Off the mouth of this river, the shores of which are very low, a sharp shoulder of the higher range of hills is in line with a low peak rising from the plain below; from this peak a table land extends westward, terminating in two conical shaped hummocks. From this position a mid-channel course leads to Haiphong.

Or another leading mark is, after passing the fishing stakes, to bring Hondau Island in line with Daushon Point, bearing S. by E. $\frac{1}{4}$ E., and keep it so until Petit Morne Conique bears W. by S. $\frac{1}{4}$ S., when proceed as before. This mark leads close to a sand-bank North 2 miles from Daushon Point, and as this is the shoalest part of the channel, the soundings should be carefully attended to. When a remarkable tree on shore comes in line with Petit Morne Aplati, the sand-bank is passed. In order to keep in the deep water channel, Petit Mirador must be kept open East of the group of trees lying westward of the base of Daushon Hill.

Vessels can anchor off Petit Mirador in 14 ft. water, obtaining shelter from N.E. winds.

PORT OUNONG is on the East side of entrance of the East channel into the River Lacht Huen. Off it is a rock called the *Ninepin* from its shape. W. by S. three-quarters of a mile from the Ninepin is a dangerous rock with about 11 ft. on it, and 8 fathoms close around it at low water.

In 1849 H.M. ships *Columbine*, *Fury*, and *Phlegethon*, entered the East or Main Channel of the Lacht Huen River in chase of pirates. The entrance, in lat. $20^{\circ} 41' 40''$ N., is obstructed by a bar which they crossed at high water, carrying $2\frac{3}{4}$ to 3 fathoms. Inside the bar the water deepens, and the shores are generally bold, except off the West side, where there is an extensive sand-bank. Wood was plentiful, but little water or provisions. The natives said there was coal in the vicinity, but their accounts were vague.

The French ship *Pregent* entered this channel in 1859, and at that period there were 11 ft. on the bar at low water.

During the *Pregent's* stay in the Lacht Huen, there was only one tide every 24 hours; during neap tides, however, there were 3 or 4 days during which

there were two tides per day, but they were weak, and then one tide succeeds the other, so that the establishment at full and change is alternately at 1^h p.m. and 1^h a.m. every 14 days. The rise and fall was about 10 ft.

Apowan Harbour lies about E. by N. 10 miles from Hondau Island. It is reported to be a good typhoon harbour. The soundings inside are from 4 to 5 fathoms (soft mud), shoaling to 2 and 1 fathom towards the village. The entrance is about 500 yards wide N.N.E. and S.S.W., with from 4 to 6 fathoms through it.

The *Egeria* anchored in 3½ fathoms, with centre of village bearing N.E. by E. ½ E.; left extreme of island to the south-eastward S.E. ¼ S.; right extreme of island to the south-eastward S. ¾ E.; left extreme of island to south-westward S.W. ¾ S.

Vessels from the south-eastward, after passing Norway Islands, steer about N.W., until a remarkable high nipple-shaped rock bears East, thence N.E. for a cone-shaped peak which stands on the point at the East side of the entrance. The West entrance point consists of low rugged black rocks which will appear overlapping the East entrance point as it is approached on a north-easterly course.

There is another entrance to Apowan Harbour from the south-eastward by which the *Egeria* entered, having from 9 to 6 fathoms water, and passing between some high precipitous islets about 150 yards apart. This entrance, however, is unsafe, as there are said to be sunken rocks in the neighbourhood. There are 12 hours ebb and 12 hours flood at Apowan. The greatest rise is from 12 to 13 ft., the least about 7 ft.

About 3 miles to the northward of Apowan is the eastern entrance to a channel which leads across the peninsula to the westward. Its western entrance is about 2 miles northward of Ounong.

Chay-le-pi, an extensive group of rocks, some of which are always covered, lie E. ¼ N. 19¾ miles from the Ninepin Rock. At 4 or 5 miles to the S.W. of them is a small group of islands, the Norway Islands of the charts.

Between the Chay and Ninepin Rocks is the entrance of the remarkable bay, called *Fietze-loong*, extending northward, and filled with islets and rocks of limestone formation.

The *North Coast* of the Gulf of Tong King, as far as the strait of Hainan, appears to be little known. It may be said to be bounded by banks and rocks which extend a long distance off shore; some large islands only have been visited by the *Columbine*, *Fury*, and *Phlegethon*, when in pursuit of pirates.

GOW-TOW ISLAND.—There are several islands between the Chay Rocks and Gow-tow Island to the N.E. The *Columbine* passed to the southward of Wuntaun Island and found a good passage 1½ mile broad. There is good anchorage near Fungung, 4 or 5 miles West of Wuntaun.

Gow-tow, or Pirate Island, consists of a group of islands of which Chung-

lan and Gow-tow are the largest; the former is about 4 miles long and 1 to 2 miles broad, in a N.E. and S.W. direction.

A ridge of hills with an average height of about 500 ft., and sloping down to the sea on both sides, occupies the centre of the island and terminates in two or three abrupt precipitous cliffs of a red color, about 200 or 300 feet high. Gow-tow Island is level and much lower, having only one high conical shaped hill near its North end. Its South end has several precipitous cliffs similar to those on Chung-lan, but not more than 100 ft. high.

There is a safe and spacious anchorage for vessels of moderate draught between these two islands, sheltered by Chung-lan to the eastward, by Gow-tow to the westward, and by three or four smaller islands to the northward. The *Egeria* entered it by a channel half a mile wide, which separates the South point of Chung-lan from Gow-tow Island. From the eastward Chung-lan was coasted along about 2 miles distant in 15 and 13 fathoms water, and when the passage between the two islands was well open, a N.N.W. course was steered through it, avoiding the South point of Chung-lan, where a sunken reef on which the sea was breaking extends in a south-westerly direction. The soundings varied from 10 to $7\frac{1}{2}$ fathoms in mid-channel, decreasing to 6 fathoms as the vessel proceeded. The deepest water in this harbour is close along the Chung-lan shore, towards Gow-tow, and to the north-westward, towards a smaller island in that direction, the water shoals to $2\frac{1}{2}$ fathoms fully a mile and a half from the beaches.

The *Egeria* anchored off Chunglan Island, abreast a patch of black rocks on the beach, with a quoin-shaped island bearing N.N.E. $\frac{1}{4}$ E., the North extreme of Gow-tow Island N.W. by W. $\frac{1}{4}$ W., a conical peak on Gow-tow N.W. by W., West side of the entrance S. $\frac{3}{4}$ W., and the East side S. by E. $\frac{1}{4}$ E.; deeper water, however, was found farther to the north-eastward to within 300 or 400 yards of the beach.

There were only a few inhabitants on these islands; pirates make periodical raids and destroy the houses and crops. The ground appears fertile, and has been cultivated in patches; the hills are almost denuded of trees, a feature by which this group may be distinguished from the islands to the south-westward, which are all thickly wooded along their summits.

A reef, awash, nearly $1\frac{1}{2}$ cables long, running N.E. and S.W., lies about 3 miles from the N.W. point of Gow-tow Island; this point may be rounded close to. There is a reef bearing West, distant 4 miles from the anchorage in Sha-pak-wan, the bay on the western side of the island. In the centre of this bay, about $1\frac{1}{2}$ mile from the shore, is a cluster of dangerous rocks awash at low water, bearing S.W. by S. from its N.W. point, and a reef, breaking in bad weather, extends for about $2\frac{1}{2}$ cables to the S.W. from the south-western point of the bay.

There is a channel with 2 or 3 fathoms at low water between Gow-tow and the island three-quarters of a mile northward of it, but a reef runs

along the N.E. shore of Gow-tow, coming close to the beach on its northern side. The best channel is found by keeping close to this reef.

S.W. of Gow-tow is an archipelago of small grotesquely shaped islands and pyramidal rocks, covered with thick jungle interspersed with patches of lawn; they rise to a height of about 130 ft., and are steep-to; numerous caverns are to be found on their shores, in some cases forming natural arches, having a depth of from 3 to 9 fathoms underneath them. There are some rocks awash bearing S.S.E. about $2\frac{1}{2}$ cables from the southern islands of this group.

The main land recedes from the general run of the coast line in the neighbourhood of these islands, forming the bay before mentioned about 13 miles deep, named Fietze-loong.

Gow-tow or Pirate Island has on its western side an extensive bay, which is apparently without danger. Wood and water may be obtained. There are a few miserable huts on its shore. The anchorage is however considered unsafe in bad weather on account of the heavy sea that enters.

The passage from Ching moy-tow Island to Gow-tow by Ye-moon passage N.W. of Gow-tow, and also to Fietze-loong Bay has been frequently traversed by the *Anlan* drawing 8 ft., and is apparently without danger.

Hat Island, in lat. $21^{\circ} 20' N.$, long. $107^{\circ} 45' E.$, is named from its resemblance to a Chinese hat, when seen from the eastward.

Tidal Streams.—Between Gow-tow and Norway Islands, and Hainan Strait, the currents are reported to run 1 to 2 knots an hour in a north-easterly and south-westerly direction. The *Egeria* experienced in April a set of about 23 miles S.W. $\frac{1}{2}$ W. in a run of 24 hours from the entrance of Hainan Strait to Gow-tow Island; there had been a fresh north-easterly breeze during the passage.

Lowseu Island lies 12 miles N.E. of the North extreme of Chung-lan. Good anchorage in 7 fathoms, mud, will be found off a little sandy bay on the S.W. side of this island.

Echun Island, 5 miles S.E. of Lowseu, is small, and lies about 2 or 3 cables North of Tycham Island, to which it is apparently joined; both islands appeared to be foul all round. Between Tycham Island and Chung-lan, there is a group of small islands, the most conspicuous of which, Chusan, is of a pyramidal shape; it is the eastern island of the group, and lies S.W. $\frac{1}{2}$ S. from Lowseu Island.

CAPE PAHKLUNG is the eastern point of a bay in which are situate the town and harbour of Choukshan. It is in lat. $21^{\circ} 31' N.$, long. $108^{\circ} 17' E.$, or about 8 miles to the eastward of the position assigned to it previous to 1876; it is a bold promontory, behind which rises a range of mountains 5,000 to 7,000 ft. high. The harbour, 12 miles West of Cape Pahklung, is on the boundary between Cochin China and China. It is formed by shoals on the East and a low point on the West, has 5 fathoms water in it; pilots

may be obtained. The *Columbine* and *Fury* anchored off the shoals, with the cape bearing N.E. $\frac{1}{2}$ E., distant 6 miles.

Pahklung Rock (Pak-su-hai), lying S. $\frac{1}{2}$ W. 8 miles from Cape Pahklung, is awash at high water, but being so far off the coast it makes the approach to Choukshan Bay dangerous at night. It is in lat. $21^{\circ} 22' N.$, long. $108^{\circ} 14' E.$, or about 7 miles to the eastward of the position formerly assigned to it on the chart. (H.M.S. *Lily*, 1876.)

Guie Chow Island, bearing about S.E. $\frac{1}{2}$ E. 58 miles from Cape Pahklung, is 7 miles in extent East and West, and 400 ft. high. There is an excellent harbour on its southern side. *Chayung Island*, lying 7 miles E.S.E. of Guie Chow, is 4 or 5 miles in length, about 500 feet high, but affords no anchorage.

BACHT-LONG-VI, or *Nightingale Island*, in lat. $20^{\circ} 8' N.$, long. $107^{\circ} 46\frac{1}{2}' E.$, from its position appears to form a good landmark for vessels bound to the northern part of the gulf. It is 2 to 3 miles in length, N.E. and S.W., high, with a flat summit, and its sides are almost everywhere precipitous, except to the S.E., where there are some huts along the shore. Off its low N.E. point are sunken rocks, and breakers to the distance of half a mile. The sea also breaks some distance from the S.E. point of the island.

3.—COAST OF CHINA AND HAINAN ISLAND.

As before mentioned, the boundary line between Cochin China and China reaches the coast at 12 miles West of Cape Pahklung. Of the small portion of coast described in this chapter very little is known, and Hainan Island is only becoming of interest on account of the new treaty port on its North coast recently opened to commerce.

Between Cape Pahklung and Pakhoi, about 45 miles to the eastward, the northern shore of the Gulf of Tonquin recedes, and is formed of the deltas of several extensive rivers, one of which, the *Loong-moon*, has its mouth 12 miles northward of Cape Pahklung.

The directions for Pakhoi are from those drawn up by Commander Cochrane in H.M.S. *Lily*, in 1876, and by Capt. Cocker, of the Chinese gunboat *Feihoo*.

PAK-HOI, opened to foreign trade in April, 1877, is entered between the outer extremity of the fishing stakes off a sandy point $1\frac{1}{2}$ miles N.E. of Quantow, and a large sand-bank, which protects the anchorage to the northward; this channel is less than a cable broad, and to keep in not less than 15 ft. water, the stakes should be rounded as closely as possible, as the water shoals rapidly to the sand-bank. Tikok village, hereafter mentioned, is in lat. $21^{\circ} 28' N.$, and long. $109^{\circ} 5' 5'' E.$ The anchorage at Pakhoi is good and

safe in any weather. The exposed side faces the West, but it is stated that there is no force in the westerly winds here.

The deepest water in this anchorage, 25 feet at low water, is to be found about 7 cables East of the outer extreme of the stakes, with the sandy point bearing S. W. by W. The holding ground is of stiff mud, and should a vessel remain for any length of time, the anchor should be occasionally lifted.

Supplies may be obtained from Pakhoi at moderate prices.

Directions for approaching Pakhoi from Hainan Strait.—The captain of a vessel starting from Haik'ao (Hoi How), for Pak-hoi, ought, before weighing anchor, to ascertain the condition of the tidal current, which runs East and West, and *vice versa*, with great force in the Hainan Straits, and in his subsequent navigation to make due allowance for its effect. It is the simplest and safest plan to leave in the evening, and to steer from the centre of the Hainan Straits West till Haik'ao is 30 or 35 miles distant, so as to keep absolutely clear of any danger off Cape Cami, and to be certain of avoiding a $3\frac{1}{2}$ -fathoms patch of doubtful position, marked on the charts 13 miles West of Cape Cami.

Having gone thus far, a course N. W. $\frac{3}{4}$ W. for 34 miles, and then a course North for 30 miles further, ought to lead a steamer westward of the extensive banks lying as far as 20 miles off the land, and about daylight to the first land, namely, the small island called on the charts Chayune, but known to Chinese as Ch'ieh Yang. This island, which is high and bold, lies about 34 miles S. S. E. off Quantow Head, in lat. $20^{\circ} 54' N.$, and long. $109^{\circ} 13' E.$ About 7 miles to the N. W. of it is the island of Weichow, called on the charts Guiechow. Though larger in area, the latter island is much less elevated than Ch'ieh Yang. It has a Catholic missionary, is apparently well cultivated, and is foul off the North and East sides for a distance of from 1 to 2 miles, and for about half a mile off the West and S. W. sides. At night, when in the vicinity of Guiechow Island, do not shoal the water less than 10 fathoms. After passing Ch'ieh Yanh (Chayune) about half a mile to the East of it, in 9 or 10 fathoms, and keeping well clear of the reef off Weichow (Guiechow), a course to N. N. W. will lead to Quantow Head, which will make as an island.

There are 5 fathoms of water to within a quarter of a mile of this headland. Between the island of Ch'ieh Yang (Chayune) and Quantow Head innumerable heavy fishing stakes exist which render it a very imprudent thing for a vessel to attempt to navigate this distance after dark.

To the eastward of Quantow Head the land is low, and the water shoal for a long distance off shore, to avoid which, when approaching Pakhoi from the southward, Quantow hills should not be brought to bear North of N. by E.

Quantow Head is a bold headland 390 ft. high, forming the western extremity of a narrow peninsula of which the northern extremity is the pro-

jecting beach on which the village of Tikok, one of the limits of the Pakhoi anchorage, is built. To enter the harbour after having reached about a quarter of a mile to the West of Quantow Head, a vessel should steer for the northern end of the fishing-stakes which will now be seen to the N.E. planted athwart the entrance of the harbour in tiers running N.N.W. from the village of Tikok for a distance of 830 yards, taking care not to get into less water than 3 fathoms, as a sandspit runs out in a N.E. direction from the N.N.W. point of the head; at the same time a vessel must not go too far off, as there is a sand-bank running East and West to the North of the fishing-stakes. The fishing-stakes can be passed close alongside (some in fact occupy the deepest part of the channel), after which a course East by South for a short distance takes a vessel to her anchorage.

There is a detached hill to the East of Quantow Head, 130 feet high, known as Tikok Hill. When this hill bears S.W., and the northern end of the fishing-stakes bears W. $\frac{1}{2}$ N., good anchorage will be found in $4\frac{1}{2}$ fathoms at low water.

The tides at Pakhoi are not regular. There is as a rule only one tide in the 24 hours, which varies in its rise and fall from 8 ft. to 17 ft.

The soundings from Haik'ao to Pakhoi are regular, and by attention to the lead notice of approach to land will be given in ample time to avoid accident.

CAPE CAMI, the N.W. entrance point of Haïnan Strait, is a low sandy point backed by sand hills with patches of scrub. *Hoosheak Hill*, at 25 miles from the cape, will be easily recognised from its isolated position. Black rocks extend from the cape for some distance. Strong tide ripples and patches of discoloured water are met with in this vicinity.

The spit of shoal water is reported to extend off the cape in a south-westerly direction for a distance of 2 miles; but there appears to be no danger off the point, outside of the sand-spit. Good shelter from N.W. winds may be found in 7 fathoms, sand and mud, with Cape Cami bearing N.W. $\frac{1}{2}$ W. distant about 4 miles.

About 12 miles West of Cape Cami there is a sand-bank, upon which as little as $3\frac{1}{2}$ fathoms are said to exist, it is apparently a ridge extending North and South for several miles with 13 fathoms on each side of it.

A shoal of 6 fathoms is reported 8 miles W.S.W. from the cape; of 7 to 9 fathoms distant, 15 miles in a W.N.W. direction; and 26 miles W. $\frac{3}{4}$ S. from the cape, is an extensive sand-bank with depths of 5 to 6 fathoms.

Haïan Bay, 15 miles eastward of Cape Cami, may be easily recognised by a white fort (96 ft. above high water), erected on the West entrance point, opposite the village of Haïan. The anchorage is in 5 fathoms, $1\frac{1}{4}$ mile South of this fort, whence the water shoals rapidly to the shore. Sheumen Pagoda, another conspicuous land-mark, lies N.W. from Haïan Fort, distant about

5½ miles. The anchorage is protected from all winds from East round through North to West; the bottom is mud, and affords good holding ground. The greater part of the sugar exported from Hoihow is brought over in junks from Haian.

Baksha Village is situated at the head of a white sandy bay, about 2 miles East of Hian: there is anchorage for junks about a quarter of a mile from the village. Numerous fishing-stakes extend off the East point of Haian Bay, and a reef of rocks stretches off the same point, in a south-easterly direction, for some distance.

4.—HAINAN ISLAND.

Hainan Island, bounding the Gulf of Tong King to the eastward, is about 155 miles in extent, N. E. and S. W., and about 90 miles in breadth. It is in most parts very high uneven land when viewed from seaward, but in the interior there are many level districts, cultivated with rice, sugar-cane, areka or betel-nut trees, and tobacco. These cultivated plains are separated from each other by lofty mountains, covered with impenetrable forests, through which the natives have cut narrow passes in the most accessible parts, to enable them to go from one district to the other. The island forms part of the province of Quang-tong, and is subject to the Chinese, who hold all the places of profit or of consequence, keeping the inoffensive aborigines in a state of abject poverty. Kien-chew or Kiung-chau, the capital of Hainan, is situated at the North side of the island and a few miles from it. Hoi-How, a treaty port, stands on the banks of a river on the North coast of the island.

The N. W. coast of this island is little known to Europeans.

The South and S. E. coasts* are bold to approach, with soundings generally from 25 to 35 fathoms very near or close to the headlands, deepening to 65 or 70 fathoms about 15 miles off; and in some places these soundings extend 18 or 20 miles off shore.

The S. E. coast is indented with several fine bays, affording good anchorage and shelter from the N. E. monsoon. Each of these bays may be considered a safe harbour during that monsoon, but they are partly open to southerly winds.

* The survey of the S. E. coast of Hainan was made by Captain Daniel Ross, I. N., on board the surveying ships *Discovery* and *Investigator*, in 1817. It commenced at Gaalong and Yulinkan Bays, where base lines were measured on the shore; after which a chain of triangles was carried on from the East Brother Island to False Tinhosa Island, and in that space three spaces were measured by sound, and every care taken to render the survey correct. The other coasts of the island are incorrectly delineated, and not to be relied on.

Winds.—*Typhoons or hurricanes*, as some writers term them, have been singularly destructive in Hainan. As at Hongkong, they usually take place between June and October, August and September being the worst months. The Chinese state that the more violent ones give ample notice of their approach, generally occurring every two or three years, though twelve months never elapse without a typhoon visiting the coast. No very heavy storm, however, appears to have happened for about five years (1876), though one of moderate force destroyed a good deal of property last autumn. K'ung-chow is said to have been three times entirely destroyed by typhoons within historic times. The extremely violent typhoons are locally known as *Chü-fung*, the ordinary ones being called *Pao-fung*.

The average *temperature* of Northern Hainan is slightly above that of Hongkong, but the climate is very damp, *fogs* continuously prevailing for long periods. Hr. Taintor describes the spring as dry, but rain fell frequently during my stay of nearly three weeks. The monsoons blow as at Hongkong, viz., the S.W. from April to October, and the N.E. from October to April. Their force is, however, very irregular on the North coast.

Banks at the Eastern Entrance to Hainan Strait.—In the vicinity of Hainan Head there are several dangerous sand-banks, upon which the sea sometimes breaks. There are deep-water channels between them, which, when properly surveyed and defined, may be used by vessels proceeding to the eastward, but an attempt to pass between the banks must always be attended by uncertainty and risk, owing to the strong currents which prevail in this neighbourhood, and the distance of the sand-banks from the land. No reliable directions for the passage in or out can be laid down until the locality is better known. In the directions hereafter given for approaching Hoi-how, some remarks are made on the passage through these banks.

HAINAN HEAD, the N.E. point of Hainan is low and rocky, terminating in a reef, awash at high water, extending North half a mile from the shore. The mound, usually called Hainan Head, lies about three-quarters of a mile S.W. $\frac{3}{4}$ W. from the N.E. point, and when bearing S.W. by S., 5 or 6 miles distant, appears as a flat-topped mound about 180 ft. high, between which and Mount Mofou the land is low. Some black rocks above water extend off the mound to the N.E., and at a distance of 3 or 4 miles there are breakers.

Mount Mofou, S. 41° E., 20 miles from Hainan Head, appears at a distance as an island, and has sometimes been mistaken for one of the Taya Islands, which are, however, much smaller. It is high, with a cleft in its centre, and rises to a height of 800 to 1,000 ft.

The coast West of Hainan Head recedes a few miles, and then trends West for about 5 miles, terminating in a sandy point (Poochin Point), from which it trends South, towards Poochin Lagoon.

Poochin Pagoda, a round whitewashed building with red top, 488 ft. above

the sea, stands on the highest of the sand-hills, 6 miles W.S.W. from Hainan Head. *Poochin Lagoon* is used by small vessels, able to cross the bar, of 7 or 8 ft. A patch of rocks, dry at half-tide, lies half a mile West of Poochin Point, and there are numerous fishing stakes hereabout which require caution.

A *shoal*, on which the water is said to break, is reported to lie N.W. by W. from Poochin Pagoda, about 3 miles off shore. This shoal is said to extend 8 miles in an East and West direction.

The coast from Poochin Point to the entrance of the lagoon is faced with rocky patches, and must be approached with caution. There is said to be a well-sheltered and safe anchorage in the N.E. monsoon, in 4 fathoms, about half a mile S.W. from the point. The coast from the entrance of Poochin Lagoon to Hoi-how Point is low, with no conspicuous objects for the first few miles; it forms a deep bay, which is reported by the native fishermen to have several shoal patches. *Kien-Chew-Fou* pagoda forms a good landmark, but is hidden behind trees when bearing to the westward of South. There appeared to be a junk harbour with Kien-chew pagoda bearing South.

Hoi-How or Backsha Point lies West 17 miles from Poochin Pagoda. It is low and sandy, with fishing stakes extending off 2 miles N.N.W. from it. A village lies 2 miles inland. Hoi-how Bay is included between Backsha Point and Inner Point, 9 miles westward of it. Hoi-how is situated at its S.E. corner, between which and Backsha Point are numerous sand and mud banks extending off shore to a distance of 2 miles.

HOI-HOW BAY.—The following is chiefly derived from the pamphlet mentioned on page 462, which is illustrated with plans, and would be of much use to vessels visiting this port, especially as so little is now known of the coast.

Hoi-How, or *Hai-k'ow*,* may be considered at present as the port to *K'ung-chow*, or *Kien Chew*, which is, however, only important as the seat of government, and is situated upon the river, 14 li or nearly 4 English miles S.E. of it. There is, however, no water communication between the places for anything larger than a canoe, and an amusing method is adopted for the carriage of passengers and goods between the two places. Mr. Dennys says: "The means of transit, irrespective of walking, are threefold—by pony, wheelbarrow, or chair. Very few riders are seen, and the wheelbarrow (which is also largely employed for goods) seems to be the popular vehicle. It is ridden astride by both men and women, the feet being placed in stirrups on either side of the wheel. The whole machine is of the clumsiest

* Captain J. S. Cocker, of the Chinese gun-boat *Feihoo*, says that the name Hoi-how, commonly used by foreigners in China, is unknown in Hainan, where the name *Haik'ao* or *Haik'ow* is used.

description. The chairs are remarkably light and small, being anything but comfortable."

Hoi-how lies upon the shores of a shallow bay and still shallower creek or river (it being the former at low water, though it forms a branch mouth to the main river at high tide), both presenting great impediments to easy trade, its appearance is more thriving than one would expect. The principal industries, visible to the casual stranger, are rope-making, dyeing, junk-building, basket-making, &c., with, of course, numerous rice mills, small silversmith's shops, vermicelli and beancake shops, &c., such as may be seen in any Chinese town. The population of Hoi-how numbers about 12,000.

Supplies are plentiful and prices moderate. Water is brought off in water boats, but it is unfit for drinking or cooking purposes, being muddy and brackish. A large trade in sugar, ground nut cake, bean cake, also oil, coins, and Chinese articles is carried on by junks, between Hoi-how, Swatow, Macao, and other northern ports.

There is a British Consulate and a Custom-house. The former stands about a quarter of a mile S.E. of the southern fort at the mouth of the Hoi-how River, and at high water is practically isolated from the surrounding neighbourhood. The building allotted to the staff of the Marine Customs, which is only accessible to cargo-boats at high water, lies East of the British Consulate, and not far from the edge of the western suburb. A foreign settlement may be formed.

The coinage, &c., is described in the Appendix at the end of this volume.

The Anchorage of Hoi-how is essentially shallow, consisting of a sandy and mud-bottomed bay, slightly protected on its N.E. side by sand-spits, but considerably exposed to all winds, except those blowing from the southward. At a radius of about 3 miles from the mouth of the creek upon which Hoi-how is situated, there is a depth of from 5 to 6 fathoms, but this position is entirely open; and this depth rapidly decreases, so that from 10 to 12 feet only are found at low water when about 2 miles distant from the same point. Vessels drawing 15 ft. of water cannot safely anchor under $2\frac{1}{2}$ miles from the shore. H.M.S. *Egeria*, drawing 14 ft., was anchored at this distance. The *Ling-Fêng* and *Sun-Chi*, drawing 8 feet 6 inches and 9 feet respectively, were anchored at a similar distance from the forts, but nearer to the South shore of the bay; nor did soundings taken justify their moving farther in. A glance at the chart, however, will, better than any description, give a clear idea of the anchorage.

Tides.—According to a note upon the survey of Hoi-how anchorage made by Mr. Henderson (Chief Engineer of the Lighthouse Department), and the Captain of the *Fei-hoo*, the tides are very irregular, they themselves observing only one high and one low water a day.

The range of tide is 7 ft. The flood sets into the straits from the eastward, and into the bay from the N.E.

At Hoi-how, during 37 days in May and June, 1876, when the tides were observed by H.M.S. *Egeria*, the greatest range was found to be $11\frac{1}{2}$ ft., the least 2 ft. At the period of the highest tides, which apparently follow the moon's extreme declination, there is only one flood and one ebb in the 24 hours, the flood making for about 16 hours, the ebb about 8 hours; velocity, $1\frac{1}{2}$ or 2 knots an hour. In like manner, the tidal stream through Hainan Strait was observed to set to the westward for 16 hours, to the eastward for about 8 hours; greatest strength 2 to 3 knots an hour. On the Hainan shore the stream is said to turn an hour earlier than in the offing.

Approaching Hoi-how from Hongkong.—Two routes from Hongkong to Hoi-how are open to vessels; one known as the "inshore," and the other as the "direct" route. The dangers of the inshore route (owing to defective surveys) are somewhat great. The difficulties of the navigation from Now-chow to Hoi-how can scarcely be exaggerated. A vessel missing the tide, owing to fog or other causes, is detained for the day, the southern portion of the anchorage being crossed by a sand-bar, which, at high water, has a little under 3 fathoms on its deepest part. Vessels drawing 16 ft. of water cannot safely attempt it, even in smooth weather. H.M.S. *Egeria*, drawing 14 feet 6 inches, nearly touched on crossing it, in company with the S.S. *Anlan*, when conveying H.B.M. Vice-Consul to Hoi-how—there being then a very heavy sea on. After passing the bar, shoals and rocks, some awash and almost all marked by breakers, abound on either hand, until the extremity of the Lien-chow peninsula has been cleared.

Pilots.—Now-chow furnishes an ample supply of more or less competent pilots for the inshore route, some nine boarding the *Ling-Feng* on her entering the anchorage, all of whom possessed certificates from masters of vessels.

The Direct Route, or that through the banks lying N.E. of Hainan Head, has been several times successfully used. The shoals may be identified by the dark yellow water on them, and by the heavy breakers which exist, even in fine weather. The channels between are 4 or 5 miles wide, and have deep water of a light green tint; there is probably a depth of 5 to 12 fathoms. The tides are strong, and heavy overfalls exist in the vicinity of Hainan Head.

The following directions by Captain Cocker, of the Chinese cruiser *Ling Feng*, should be used with caution, until the locality is better known:—Vessels from the eastward should endeavour to make Hainan Head, bearing S.W. by W. $\frac{1}{2}$ W. and keeping it on that bearing, approach within 6 miles; then steering to the north-westward pass 4 miles North of Hainan Head. Bring Poo-chin pagoda to bear S. 40° W., well open of Hainan Head, and pass 3 miles North of the pagoda, then haul out to pass 8 miles North of the low sandy coast which lies between Poo-chin pagoda and Hoi-how, until the Hummocks (p. 476) bear S.S.W., when the vessel may steer to pass outside the fishing stakes and thence for Hoi-how Bay.

H.M.S. *Lily*, in 1876, found a clear channel to Hoi-how, from a position about 7 miles North of the Taya Islands, passing about 4 miles northward of Mo-fou Point, and rounding the reef, stretching off the N.E. point of Hainan, at a distance of a quarter of a mile.

Mr. Anderson, master, S.S. *Conquest*, 1876, reports the existence of a good channel, free from danger. He recommends, when leaving Hoi-how, to bring the sand spit off Baksha Point to bear South, and from thence an E. by N. $\frac{1}{2}$ N. course, leads between the shoals in about 12 fathoms water.

The Coast.—As before stated, the North, West, and East coasts of Hainan are but little known to Europeans. The following brief description of the North coast is by Lieut. W. H. Stephens, R.N., of H.M.S. *Egeria*, 1876, and of the West coast by Lieut. H. C. St. John, R.N., who carried a line of soundings along it in H.M. gun-boat *Opossum* in 1865.

Jinmee Point, as before remarked, forms the western point of Hoi-how Bay. It is composed of barren sand-hills, the point being made remarkable by a cone-shaped mound, situated half a mile from the beach, and by a village on its western side.

About 6 or 7 miles inland a range of hills rises gradually from the eastward, and terminates to the westward, in two extinct craters, named the *Hunmooks*, which bear S.W. by S. from the end of Backsha Sand Spits and S. by E. $\frac{1}{4}$ E. from Jinmee Point. They are visible about 25 miles distant, and form a conspicuous mark. Numerous fishing stakes extend from Jinmee Point for a distance of about a mile.

Between Jinmee Point and *Sad Point*, 15 miles westward from it is a shallow bay, bounded by low land, which, however, rises in its western part and at Sad Point, cliffs of a dark red colour, and 80 ft. high, are formed. A detached piece lying N.E. of the point is very conspicuous in approach from the westward. West of Sad Point is *Manu Harbour*, on the western side of which the coast is again low, and at a distance of 8 miles inland rises the gently sloping mound called *Laam Koo Hill*. It is in lat. $19^{\circ} 55' N.$, long. $109^{\circ} 39' E.$ A reef extends half a mile off the western entrance point of Manu Harbour.

Pingmar, or *Double Hill*, about 40 miles S.W. of Manu Harbour, is conspicuous from all directions; it rises abruptly from low land, and forms a double-headed hill distinctly separate on N.E. and S.W. bearings, but makes like a round-topped single mount when bearing about S.S.E. 25 or 30 miles distant. Between Laamkoo Hill and Pingmar the land appeared low, forming How-sui Bay; about halfway between the two hills, and some distance inland, is a round-topped, isolated, conspicuous hill, named by the pilots *Koong-chin*, and the volcanic mountains before mentioned are sometimes visible beyond.

The N.W. coast of Hainan, from Hoi-how to How-sui, a distance of 45 miles, is flat and uneven, and the country appeared cultivated with sugar-

cane. At How-sui hills first begin to appear. A small vessel could anchor under the different points of land, but there is no good anchorage.

Off How-sui there is an island of sand (*Stumba* in Chinese), which is the only island between Hoi-how and Yait-chew.

Pingmar, on Double-hill Point, forms the western point of How-sui Bay. About a mile from it there is the remarkable double-coned hill, which has the same double appearance when approaching from North or South.

Pillar Point, 8 miles S.W. of Double Hill Point, is very remarkable, having a peculiar pillar rock on it, and a small mandarin hat-shaped islet joined to it at low water. *Flat Point*, 14 miles S.W. of Pillar Point, is remarkable. There is deep water close off it. Between Pillar Point and Flat Point is *Chappoo Bay*, in which is a good anchorage at Heong-po. Sandbanks lie in the mouth of the bay, as shown by the chart.

At 7 miles westward of Flat Point is the entrance to *Hoita Harbour*, a reef of rocks lying off shore between, covered at low water. Two small conical hills lie at the back of Hoita.

Bluff Point, 21 miles S.W. of Flat Point, is rocky, about 300 ft. high, with anchorage on its South side. From here sandbanks and shoals begin to appear, and continue as far as the S.W. point of Hainan. The *Opossum* passed inside of them. They appeared to extend some 10 miles to seaward, and are invisible from the shore. *Pyramid Point* is very remarkable, having a pyramidal rock shooting out of a low, flat, sandy point. North of it is Back-li Bay, so named from a village about 2 miles inland from its head; it lies to the North of Pyramid Point. The anchorage is off the village, but there is a small reef near it (which breaks only at low water), which must be avoided.

From Back-li Bay the *Bouncer* passed about 3 miles from Pyramid Point, and steering 6 miles off the land kept outside all the sands.

Snake Point, in lat $18^{\circ} 24' N.$, long. $108^{\circ} 54' E.$, forms the West entrance point of Yait-chew Bay, and terminates in two sandy hummocks about 100 feet high, lying N.E. by N. and S.W. by S. from each other. *Mud Island* lies South from Snake Point, distant about $1\frac{1}{2}$ mile. *Button Island* lies W. $\frac{1}{2}$ S., distant 1 mile from Mud Island. There is said to be no safe channel either between these islands, or between them and Snake Point. Maddock Rock, which covers at half tide, lies north-westward of the Button, at the distance of about $1\frac{1}{2}$ mile.

Yait-chew Bay affords good anchorage during the N.E. monsoon in $3\frac{1}{2}$ fathoms, about 2 miles from the beach at the head, from which to the shore the water shoals very gradually. A good position for anchoring is with Yait-chew Fort bearing N.N.E., and Mud Island in line with Button Island, bearing W. $\frac{1}{4}$ S.

Great Cape, at the eastern entrance to Yat-chew Bay, may be recognised by a hill surmounted by a pagoda, which lies about 4 miles E.N.E. from it.

S.W. 3 to 4 miles from Great Cape is a dangerous sunken rock. *Toucon Mountain*, 1,200 ft. above high water, is rugged, with several peaks.

Sama, Sanghia or Samoy Bay, 25 or 26 miles eastward from Yait-chew Bay, has several rocks and islets in it, with anchorage inside for small vessels.

Yulinkan Bay is separated from Sama Bay by a long narrow strip of land, which terminates in Soloman Point, and between it and Paumel or Tomb Point is the entrance, 3 miles wide. About a mile to the northward of Paumel Point, and near the eastern shore of the bay is a small island named *Zonby*. The usual anchorage is in 9 or 13 fathoms, on a mud and sand bottom, about three-quarters of a mile north-westward of *Zonby*, sheltered in every direction, except between South and W.S.W. Several ships, driven from the coast of China by typhoons at the beginning of the N.E. monsoon, have been known to take shelter here until the monsoon was over. The bay cannot be a safe anchorage in the S.W. monsoon.

Good fresh water is to be procured close to the beach in a small bay on the East side of Yulinkan Bay, and the natives are ready and willing to assist in procuring both wood and water.

A dangerous sunken rock lies S.W. from 3 to 4 miles from Great Cape, but the sea breaks over it if there is any swell on.

To the north-westward of the anchorage in the bay is a good channel leading into the creek or inner harbour, which is said to be the resort of pirates. The inner harbour is surrounded by hills, and forms the outlet of a fine river which falls into its N.E. part.

Directions.—A ship may warp in if the weather is fine; or if with a southerly or easterly wind she may sail in, by keeping nearest to the eastern shore until nearly abreast Rocky Point, then steer over for Sandy Point, and round it at a short distance. The best time to enter is at low water, the dangers being then more conspicuous, and 5 or $5\frac{1}{2}$ fathoms will be the smallest depth in the fair channel. Having rounded Sandy Point, and shut it in with the land on the East side of the outer bay, anchor in $5\frac{1}{2}$ or 6 fathoms, within a little less than half a mile of the shore near Sandy Point.

It is high water, full and change, in Yulinkan Bay at 9^h 45^m, rise about $2\frac{1}{2}$ ft. There is one tide in 24 hours during springs, two during neaps.

CAPE BASTION, the South extreme of Hainan, is in lat. $18^{\circ} 9\frac{1}{2}'$ N., long. $109^{\circ} 33\frac{1}{2}'$ E. It is the South point of a high peninsula, 4 miles broad, bold, of rocky appearance, and visible 25 or 26 miles off in clear weather.

GAALONG BAY.—At $2\frac{1}{2}$ miles eastward of Cape Bastion is a black rocky point, named *Cape Rhinoceros*, forming the West extreme of Gaalong Bay, which is about 5 miles wide, and 3 miles deep. In the eastern part of the entrance are two round islands, called the Brothers, and one called St. Peter, or Middle Island, near the middle of the northern part of the bay; in the N.W. part there are some rocks above and under water, and the bottom along the western side the bay is generally foul.

The usual anchorage for ships is between Middle Island and the eastern shore of the bay, in 8 fathoms water, over sand and mud. The *Discovery* anchored with the East Brother S.S.E. $\frac{1}{2}$ E., the West Brother S. $\frac{1}{2}$ W. nearly, and the two extremes of the bay S.E. $\frac{1}{4}$ S. and S.W. $\frac{1}{2}$ W., distant about three-quarters of a mile off the eastern shore. In this position much swell was experienced with a S.E. wind, from which it would appear to be a very unpleasant anchorage during the S.W. monsoon.

Water.—Northward from the usual anchorage there is a white sandy beach, and a rocky part of the shore separates it from the small bay to the eastward. On the N.W. side of these rocks fresh water can be procured from a small run, that terminates in a pool close to the beach. The tide rises here about 4 or 5 ft.

Directions.—The depth of water close outside the Brothers varies from 25 to 21 fathoms, and within them from 15 to 12 fathoms, decreasing gradually to 6 or 8 at the anchorage. With a leading wind the bay may be entered by one of the three channels; that between the East Brother and eastern shore has from 15 to 18 fathoms, coarse sandy bottom; but as a reef projects from the N.E. end of the Brother, it will be prudent to keep in mid-channel, or rather nearest to the main. The channel between the Brothers is safe, but the western channel is the most convenient with a working wind, being nearly 3 miles wide.

LEONG-SOY BAY.—Leong-soy Point, bearing N.E. by E. $\frac{1}{4}$ E. $23\frac{1}{2}$ miles from the East Brother, is formed by several high hummocks, having a sandy plain to the northward, and when seen at 16 or 17 miles distance, it appears like an island. At 2 miles westward of Leong-soy is another conspicuous point, with a hill of a sugarloaf shape; and about 2 miles farther to the N.W. are several dry rocks, steep-to, which extend three-quarters of a mile from another point. At $1\frac{1}{2}$ mile N. by W. of this latter point is a narrow and very shoal passage, which leads between two sandy points into an extensive salt-water lake. The anchorage off the bar is much exposed; the city is 7 miles from the anchorage. Farther to the westward is another considerable town, named Tong-kin.

TIEN-FUNG, or *Sail Rock*, in lat. $18^{\circ} 26\frac{1}{4}'$ N., long. $110^{\circ} 7'$ E., and bearing N.E. by E. from Leong-soy Point, is one of a cluster of large rocks above water, which, from its being higher and whiter than the others, has acquired the name of Sail Rock.

The Coast between Leong-soy Point and Tinhosa Island, about 29 miles to the N.E., forms a large bay, in which may be seen many sandy beaches, and very high land near the shores, but it affords no safe anchorage during the southerly monsoon. On the eastern shore of the bay stands the town of Munchow; and in the vicinity of the coast, near the middle part of the bay, are three prominent peaks of an elevated range of mountains, the centre one being the most pointed, and a little higher than the others; this lies near

the sea, and, at a considerable distance, is sometimes mistaken for Tinhosa Island. Capt. Ross made it in lat. $18^{\circ} 38' N.$, long. $110^{\circ} 7' 15'' E.$, which is about 2 miles inshore, and may be seen 35 or 40 miles off; when it bears W. by N. $\frac{3}{4}$ N. it is over Saddle Island. Farther inland, in about lat. $18^{\circ} 56' N.$, there is another mountain of similar appearance to the former, but more elevated. It was seen bearing W.S.W. nearly 90 miles distant, then forming in three peaks or sugar-loaves.

TINHOSA ISLAND is $2\frac{1}{2}$ miles in extent, in a North and South direction, and is formed by two high hills, united by a narrow sandy isthmus, which covers at high-water spring tides. The southern hill, the highest, is 600 ft. high, and its summit is in lat. $18^{\circ} 39' 45'' N.$, long. $110^{\circ} 27' E.$, determined by angles from the East Brother. The island is just discernible, from the poop of a large ship, at a distance of 33 miles.

False Tinhosa, in lat. $11^{\circ} 49' N.$, long. $110^{\circ} 32' E.$, and 9 miles N.E. from Tinhosa, is an island of small extent and middling height, and when viewed from the southward has a rock like a pillar at its eastern extremity. The island may be seen, in clear weather, from a distance of 23 or 24 miles.* A pagoda stands about 24 miles North of False Tinhosa Island.

The Coast from False Point, abreast of False Tinhosa, extends N. by E. and N.N.E. about 54 miles, to a point under which is shelter in the N.E. monsoon, and close to which, in about lat. $19^{\circ} 37' N.$, long. $111^{\circ} 5' E.$, is a high mountain named *Tongeon* by the Chinese, which may be seen 40 or 45 miles off; and from there being no other high land in its vicinity, may be taken for an island. The point on which the mountain stands is in lat. $19^{\circ} 37' N.$, long. $111^{\circ} 7\frac{1}{2}' E.$, and the depth of water was from 18 to 20 fathoms about $2\frac{1}{2}$ miles off it.

Chun-lan, in lat. $19^{\circ} 29' N.$, is reported to be a good harbour for vessels that can cross the bar. Wood, water, and provisions can be obtained.

The Hainan shore to the northward of Tongeon Point is very low and sandy, without cultivation. To the northward of this low land the coast becomes again high, and safe to approach; the high land projects a little to the eastward, and from lat. $19^{\circ} 43' N.$ stretches northward, forming Hainan Head, the N.E. extremity of the island, in lat. $20^{\circ} 0' N.$, long. $110^{\circ} 54' E.$

The **TAYA ISLANDS**, separated from the high land of Hainan Head by a safe channel about 12 miles wide, consist of two groups of high barren islands, six or seven in number, with some rocks, which may be seen about 12 or 15 miles off. The pilots say there is a safe passage 3 miles wide between the two groups. They extend N.E. by N. and S.W. by S. about 15 miles, the northernmost island being in lat. $20^{\circ} 2' N.$, long. $111^{\circ} 22' E.$ The southernmost island, in lat. $19^{\circ} 52' N.$, long. $111^{\circ} 12\frac{1}{4}' E.$, seems one of the largest, and from it a high sand-bank stretches to the N.N.E., having regular soundings, 20 and 21 fathoms about 3 miles from it on the East side.

CHAPTER XII.

NORTH-WEST COAST OF BORNEO.

TANJONG API is a low spit, forming the north-western extremity of Borneo. It has been referred to on page 287 ante, and the coast of Borneo to the southward of it has been there described. The term *Api*, fire is applied to this point, owing to its having been the principal pirate rendezvous,* where the visitors, upon going away, were accustomed to leave a log burning near the stream for signal to their friends.†

The point may be distinguished from the northward or southward, if showing in profile, by its abrupt termination formed by the stems of large trees, differing from mangrove, as well as by a small hummock within. The beach, also, is remarkable, being composed of very white sand, studded with black basaltic rocks, which project to seaward, showing reefs.

There is an extensive off-lying reef filled in by a sand-bank, which encircles the point, leaving an entrance to the northward. The soundings decrease rapidly from 12, 7, to 2 fathoms. Good anchorage may be found in 14 fathoms W N.W. of *Api Rock*.

Poon, palo-maria, and woods resembling cedar and ebony, adapted for spars and boat planks, were obtained here.

The entire range of *Datu*, presenting a detached mass, clear of the in-

* The active operations undertaken and steadily pursued in the four years, 1843 to 1846, had thoroughly destroyed all the pirate holds whence fleets of rovers had so long spread terror on the coasts of Borneo and many other countries, and the moral influence and example of regular government supplied by the colony of Labuan and the *Rajahship of Sarawak* have completed what was then so well begun, and although on rare occasions acts of violence are still committed, no professional pirate fleet or vessel has sailed along the coast for many years. Shipwrecked crews are treated with kindness, and the smallest trading prahu traverse in safety a coast line extending over more than 700 miles.—*Official Report*, 1875.

† The general observations on the coasts of Borneo are chiefly by Captain Sir Edward Belcher, C.B.

Mr. Logan, commanding the *Rob Roy*, bound from Labuan to Singapore, reported having seen off *Tanjong Api*, the wreck of a vessel ashore on a reef, lying with *Marundum Island* bearing N.E. $\frac{1}{2}$ N., *Haycock Island* N. by W. $\frac{1}{2}$ W., and *St. Pierre Island* W. $\frac{1}{4}$ S.

There is good reason to conclude that Mr. Logan was mistaken in supposing the wreck to be on a reef, as it was fallen in with afterwards by other vessels, drifting about, and ultimately went on shore a short distance southward of *Api Point*, where she was visited by the authorities of *Sarawak*. This danger is now removed from the charts.

Insertion.

intermediate mangroves, will lead to the northward of the dangers near Api Point.

Water.—As this is the only spot where good water can be conveniently obtained in this neighbourhood, it will be necessary to follow these very precise instructions for landing and procuring it with safety.

Tanjong Api is a low, rocky formation, on which the sea forces up the sand by its great exposure to westerly swells, and closes the mouth of a small river which would otherwise flow to the sea. The main stream, thus dammed up by the sand, forms a deep dark-coloured pool of a reddish tint. But nature has again, with a view to purify her supply of this invaluable article, interposed a reservoir, by forming a small strip or pond, running parallel to the beach, and containing about 100 tons of pure water, which is filtered through the barrier of sand, and thus furnishes to the passing traveller this inestimable gift.

Between the rocks there is a safe admission for boats, but due caution is necessary.

The best landing will be found 60 yards to the southward of the great rock on the North, where the beach is clear. Immediately within the beach line will be found the pond before alluded to, into which the engine suction hose may be placed. This supply is of such importance to mankind at large that parties visiting Tanjong Api should be warned from trying any wanton experiments, such as cutting a channel to the sea, by which it might be destroyed.

Tides.—The tide at Tanjong Api was found to rise about 7 ft., the direction of the flood, in 15 fathoms at 2 miles off shore, being E.N.E., and of the ebb S.S.W.

From a position off Tanjong Api to a similar position off Tanjong Datu, the course is E.N.E., and the distance $22\frac{1}{2}$ miles. The dangers within the line between these points have not been satisfactorily examined, and there is some reason to apprehend, from the sudden changes in the soundings, attended with suspicious eddies, that undiscovered rocks lie near the surface.

TANJONG DATU.—Great caution should be observed in approaching this point. The tides are rapid, and the reef which encircles it, at a radius of 2 miles, is studded with rocks, several of which are frequently awash.

There is no inducement of any kind to bring a vessel within 3 miles, therefore no excuse for risking its dangers within a depth of 19 fathoms, where a vessel may securely anchor to await the change of tide.

The entire western coast of this mountainous range is studded with rocks, and the landing is difficult and dangerous. On the eastern side the coast runs suddenly to the southward steep-to, and offers two sandy bays. A coral bank, with detached rocks, being a continuation from the point, extends about 3 miles to the southward, but there is deep water within.

Tides—The flood stream off shore sets East, the ebb nearly West; rate 2 to $2\frac{1}{2}$ knots.

NIGER BANK, discovered in 1858 by H.M.S. *Niger*, and surveyed in 1862 by H.M.S. *Rifleman*, is composed of hard clay, $4\frac{1}{2}$ miles long East and West, and $1\frac{1}{2}$ mile broad. The outer edge of the centre part of the band is about North, distant 5 miles from Tanjong Datu. The bank has 5 to 9 fathoms on it, and is very convenient to anchor upon to await tide; the 5-fathom spots are towards the East and S.E. ends.

Caution.—In the event of detached boats, or a very small vessel, seeking shelter, it may be found at 7 miles southward of Tanjong Datu, in Sleepy Bay (Pirate Bay), but caution is necessary, as rocks near the surface are abundant. Fresh water was not found. The whole space included between a line from Tanjong Datu to Talan Island is very dangerous.

The Coast.—E.S.E. 43 miles from Tanjong Datu is Tanjong Sipang, at the extremity of a high peninsula, the coast between forming an extensive bay, within which are the rivers *Siru*, *Samatan*, and *Lundu*; *Sampadien* and some minor estuaries also discharge their waters, and in the eastern extreme of the bay the Sarawak presents its western embouchure. There are several small islands, the entire spaces between which are safe up to 6 fathoms, but within that depth great caution is necessary.

The Talan or Turtle Islands lie S.E. by S. 13 miles from Tanjong Datu, and deserve notice as affording a rendezvous or shelter under their lee for boats. The northern island is remarkable for the resort of turtle to a small sandy delta on its southern side. *Turtle Rock*, lying S.S.W. about three-quarters of a mile from Little Talan Island, is uncovered at low water, and dangerous by night.

TANJONG SIPANG may always be distinguished from the eastward or westward by two remarkable thumbs or sugarloaf cones, which show out clear next its northern extremity. The southern crest of the range (*Santubong Peak*) 2,712 ft. above the level of the sea, can be seen clearly at a distance of 40 miles.

Samarang or Cruizer Rock, with a $3\frac{1}{2}$ -fathom patch about a quarter of a mile S.W. of it, lies 3 miles North of Tanjong Sipang, and covers at half ebb. It is surrounded by deep water, having 6 or 7 fathoms close to, and is difficult to find. Mantang Peak in line with the western side of Tanjong Sipang, clears it on the East, and the eastern points of Tanjong Sipang in line clears it on the West; the thumb of the point end on leads on it. Probably it is a continuation of the range, this being another outlying sugarloaf.

Sailing vessels navigating this coast must always be prepared to drop a light anchor should calm attend an opposing tide, and particularly between Tanjong Api and Tanjong Sirik. In the depth of 14 fathoms no danger may be apprehended. The flood does not run more than four hours, and the strength of the ebb prevails eight; and where calms are frequent, and steam is not available, no advance can be made without great attention to this subject.

The Santubong Entrance to the Sarawak River was surveyed by Sir Edward Belcher in 1844.

Navigating-Lieutenant H. V. Russell, of H. M. S. *Reynard*, in 1863, remarks "that the Santubong entrance is not navigable in the N. E. monsoon; even the small trading steamer uses the Moratabas entrance when going to Singapore during this season. But at any time the Moratabas is the best channel for a stranger to take. Pilots are not to be found at the mouths of the river, but by sending to the Rajah of Sarawak the assistance of the Europeans in charge of the gun boats may be obtained."

Tides.—It is high water, full and change, at the Santubong entrance, at 4^h, springs rise 10 ft., neaps 6 ft.; at the Sarawak junction at 5^h, at Sarawak city at 5^h 20^m, and springs rise 15 to 18 ft., neaps 9 ft.; and at the Moratabas entrance at 4^h, springs rise 9 ft., neaps 5½ ft.

Lieut. Russell remarks that the highest tides occur at the change of the monsoons, viz., March, April, and November. In the N. E. monsoon the new moon gives the highest tide, and those of the day are more regular, and exceed in height those of the night; while during the S. W. monsoon the contrary takes place, and the higher tides are then at full moon.

Directions.—Making the land from the N. W. or N. E., the position, as regards the two entrances to the Sarawak, may immediately be determined by the inland or coast ranges in connection. Thus Matang Peak, seen clear to the westward of Santubong crest can leave no doubt as to the lead to the western mouth. The thumbs will also show on the left of the profile of Sipang. Another feature is exhibited, which is not visible farther to the eastward; this is the topsail-shaped detached elevation on the right of Matang.

Approaching from the N. E., Matang, seen eastward of Santubong Peak, will afford a satisfactory guide either for Tanjong Sipang, or for finding Tanjong Po, the mark for the Moratabas entrance to the Sarawak, for which latter it is unerring, bearing S. W. by W. ½ W. from a distance.

Matang, when seen to the eastward of Santubong, shields Topsail Peak from view, and the very steep character of Santubong affords on this view a safe leading mark, even as far as the mouth of the Sarebas River.

To ascend this branch of the Sarawak it will be expedient to obtain a good local pilot, or to have boats sounding in advance, as well as immediately under the bowsprit, as there are several dangerous patches of rock, one of which is in mid-channel. A *red buoy*, the position of which, however, is not to be depended on, lies off the entrance of the river N. W. by W. from Mount Santubong. The channel thence extends about S. S. E. 4¼ miles to Royalist Rock beacon, just westward of the entrance point of the river, and on the South side of the channel. There was but 2¾ fathoms on the bar at high water in 1864.

Moratabas Entrance to Sarawak.—From Tanjong Sipang, *Laki*, or *Peile Island*, lying off the northern extremity of Po Point peninsula, bears E. by S. $\frac{1}{2}$ S. $10\frac{1}{2}$ miles; and this course may be safely steered by day or night, if the land can be distinguished, hauling northerly if the depth decreases to less than 5 fathoms; but in bad weather or fogs a depth of not less than 12 fathoms should be risked.

Po Point Lighthouse, of a bright yellow colour, stands on the summit of the point; since the year 1873 a *fixed bright light* has been shown from it, at an elevation of 490 ft. above the sea, and visible 15 miles off. The river is stated to be *buoyed* on its left bank from Moratabas Point, fronting the fishing village, to the village of Sinjinkat.

The entire face of Moratabas sea range to the N.E. is steep-to, and may safely be approached into 8 fathoms; and if intending to enter the Moratabas Channel, this shore should be hugged, passing within half a mile of a white rock or islet off Po Point. The Moratabas Channel begins at this white rock, within half a mile of which is the deep part.

Navigating-Lieutenant Moss, of H.M.S. *Scout*, in March, 1863, surveyed the Moratabas entrance, and found that the banks forming the channel had altered considerably since Sir Edward Belcher's survey, rendering the directions for navigating it given by that officer no longer applicable. Navigating-Lieutenant Russel, of H.M.S. *Reynard*, shortly afterwards made a track survey of the river from Moratabas Point to Sarawak, which is sufficient to enable vessels to proceed up safely. The *Rifleman* twice entered the river, and steamed up to Sarawak, guided by these surveys, finding the soundings correct, and experiencing no difficulty.

The channel of this entrance of the river is bounded on either side by banks, composed generally of sand, with mud in places. The western bank takes from Po Point a direction about S. $\frac{3}{4}$ E. for a distance of nearly 3 miles, when it rounds away S.S.W. $\frac{3}{4}$ W. for a mile, and then S.W. by W. for $1\frac{1}{2}$ mile, where it forms a slight projection; from thence it trends West to Moratabas Point, distant half a mile.

A conical *buoy* painted *red* is (or was) placed off the spit of the Si Jalore Shoal, or western bank, in $3\frac{1}{2}$ fathoms, low water spring tides. Vessels should not attempt to pass to the westward of this buoy, but should pass a quarter of a mile to the eastward of it.

The outer edge of the eastern bank, marked by the 3-fathom line, appears to lie about N.E. by N., distant $3\frac{1}{2}$ miles from Po Point; from thence it takes a southerly direction for 5 miles, and then curves up gradually to Brooke Point, opposite Moratabas Point. But the outline of the eastern bank is somewhat irregular, and a detached knoll of sand, with only 14 ft. water over it, called *Scout Shoal*, from H.M.S. *Scout* having touched upon it, lies with Po Point bearing N.W. by N., and Moratabas Point S.W. southerly.

The deepest water over the bar is between this knoll and the western bank, the distance between them being about a mile. The depths at low water spring tides are $3\frac{3}{4}$ and 4 fathoms, and the bottom is composed of hard sand.

Otter Rock.—The barque *Otter*, on her way down from Quop anchorage, struck and remained some hours on a pinnacle rock, with only 3 ft. on it at low water springs, and deep water all round. The rock lies nearly in the middle of the river, $1\frac{3}{4}$ mile within the entrance points, and E.N.E. about 9 cables from the Belcher Rock. The pilots and small steamers navigating the river always pass to the southward of the rock.

Directions.—Proceeding from abreast Po Point, keep the islet half its breadth open of the point, and steer S. by E. $\frac{1}{4}$ E. until Po Point is distant about 3 miles, and Mount Santubong (2,712 ft. high), distant 13 miles, bears W. by N. $\frac{1}{4}$ N., and is seen in the centre of a break in the hills. The above course will leave Scout Shoal, two-thirds of a mile distant, on the port side, and bring you to a position half a mile E.N.E. of the red buoy. From this position steer S.S.W. $\frac{1}{2}$ W. towards a clump of trees on the South entrance point of the river until Tree Point, the first point northward of Moratabas Point, is in line with the S.W. Sharp Peak, bearing W. by N. $\frac{1}{2}$ N., when steer W.S.W. $\frac{2}{3}$ W. into the river midway between the points. Otter Rock, within the points, has been above described.

Caution.—With strong northerly winds a heavy swell is experienced when about halfway between Po Point and Sarawak River entrance. H.M.S. *Juno*, drawing 18 ft., slightly touched when in mid-channel at half-tide, with 28 ft. soundings, in February, 1877.

Water.—To the eastward of Peile Island is a water-stained cliff, with a minute cascade delivering itself most invitingly into the sea. The ascent to the cliff, about 30 ft. above the sea, is easy. On the summit will be found a series of natural reservoirs of transparent water.

Vessels drawing more than 15 ft. water, or of greater length than 200 ft., cannot go above the Quop without incurring considerable risk; and almost every man-of-war that has gone up has met with some accident.

THE SARAWAK RIVER.—The delta of this river is formed by the several streams which have been briefly described. They unite at the Quop, or Lintang Junction, about 8 or 9 miles above the bar of the Moratabas entrance. Elaborate directions have been given for their navigation, but as it is manifest that in addition to the changes which necessarily occur in the channels, much local knowledge would be required to pass safely up or down, they are not here repeated. Some direction boards have been nailed to the trees at the more important points, and their warnings or guidance should be attended to.

TOWN of SARAWAK or KUCHING.—The principal part of the town is on the South side of the river, where there is a good bazaar and market. The church and bishop's residence are also on this side of the river; and

close to the building, half fort and half house, which stands on Crookshank Point, are the post-office, treasury, and other government offices.

The Rajah's house is prettily situated on a small elevation above the new fort, with one or two bungalows near it for the use of his staff.

In 1871, the total value of exports was £169,826; of imports £172,331. In this year twenty-three vessels entered from Great Britain and her colonies, carrying considerably more than half (in value) of the imports and exports.

Beef and fowls, with sweet potatoes and other vegetables, can be obtained without difficulty.

Directions to pass outside the Moratabas.—Owing to the shifting of the banks at the Moratabas entrance, the exterior line of danger, in 3 fathoms at low water springs, is no longer represented by a line E. by S. $\frac{1}{2}$ S. from Po Point to Curong Island. Unless intending to enter the river, Sipang Thumbs should not be brought to the northward of West, until well past the Moratabas entrance.

LUPAR RIVER, or Batang Lupar, is known also as the Sakarran from the Sakarran tribe of Dyaks inhabiting it. To enter this river, bring Burong Island to bear S.S.E., or equidistant between West Peak and Bliong Hill, passing Burong Island at a safe distance. The mud flat has pretty nearly equal water over it, but it was found to be apparently deeper, and the bottom softer, close to the southern coast line (even with the starboard oars touching the mud).

For boats or vessels of light draught, the Lupar River may be approached from the northward, but it is necessary to be guided by the direction as well as time of tide, particularly as the ebb tide sets westerly on Burong Island.

The young flood brings in a *bore*, which may be avoided by anchoring in 6 fathoms within the Linga entrance, or in 4 fathoms eastward of Aboi Point, until after the first quarter flood.

Sarebas River is 12 or 13 miles to the north-eastward of the Lupar. Its entrance has not been surveyed, but Commander Miall, who, in 1858, in H.M.S. *Mohawk*, proceeded some distance up this river, remarks as follows:—The Sarebas is a larger river than the Rajang. In charge of a pilot, an Englishman in the employ of the Rajah of Sarawak, we proceeded 40 miles, though at night. The soundings are regular and deep. The only necessary precaution is to take the bends of the river (which are numerous), avoiding the spits which run out from the points.

It is high water, full and change, at Burong Island, at 4^h 45^m, and the rise of tide 7 ft. The flood tide off the island sets S.E., 2 $\frac{1}{2}$ knots an hour, and the ebb, N.W. by N., at the same rate; the ordinary rise is 6 ft.

RAJANG RIVER.—In this neighbourhood the land is very low, and a large river, the Rajang, falls into the sea by two mouths, the larger of which

is about 45 miles north-eastward of Tanjong Po, and 40 miles southward of Tanjong Sirik. This river is likely to become of some commercial importance, and it will, under very careful pilotage, admit vessels of 20 ft. or more draught, the following are deduced from what the original chart by Lieut. Gordon warrants.

His anchorage is marked just to the southward of Tanjong Jerri, the North point of entrance, and the leading mark given by him is the Lalang branch of the river open, with the South point of the entrance bearing S.E. $\frac{1}{2}$ E. But it would be preferable to bring Tanjong Jerri to bear East a little northerly, until the inner point, easterly, showed the river open in 5 fathoms. Enter on the first quarter flood with these marks lapping, when the swell of the last drain of ebb will have subsided, and give Tanjong Jerri a fair berth.

Commander Miall, in H.M.S. *Mohawk*, also proceeded up the Rajang. He remarks as follows:—"Steamed up the Rajang to the fort or stockade, a distance of 25 miles. The water is pretty deep, and there are but few dangers; the anchor was let go off the fort in $6\frac{1}{2}$ fathoms. The river at this part is very narrow; we experienced a difficulty in turning under steam on that account, as also from the strength of the tides."

Mr. Consul Ricketts, in his commercial report for 1865, remarks—"From accurate information, I find that there are from $3\frac{1}{2}$ to 4 fathoms over the bar of the Rajang at low water, and at high water probably 6 fathoms. Ships of 1,000 tons and upwards could proceed some few miles up the river and find good anchorage either at the village of Rajang, situated at no great distance from its mouth, or at Mount Sousou, about 12 miles above the village.

Tides.—It is high water, at full and change, at the mouth of the Rajang, at 4^h 45^m; the rise of the day tides is 9 ft., and the night tides 13 ft.; the apparent depth on the bar at low water (at the time of its survey, in 1847,) being 3 fathoms. The tides, both in this river and the Sarebas, are very strong.

Quitting this river, it is advisable to stand to the N.W. into 18 or 20 fathoms before stretching to the northward, to round Tanjong Sirik.

Palo River.—Following the coast line northerly from the Rajang, the Balony River is about 6 miles northward of Tanjong Jerri; it is unimportant, and possibly but an estuary connecting with the Palo River, halfway between the Rajang and Tanjong Sirik. The Palo has a small islet on the sandy tongue of its southern point.

Quitting the Palo River and proceeding northerly, the off-shore soundings, between 12 and 6 fathoms, appear to afford sufficient warning until nearing Tanjong Sirik, which should not be approached under a depth of 12 fathoms.

TANJONG SIRIK, the western point of entrance to the Bruit River, is low and dangerous, and shoals extend from it to the distance of 6 miles.

Vessels should not come nearer this point than 8 miles, nor into less water than 12 fathoms, the soundings decreasing rapidly from that depth to 4 fathoms.

It is high water, full and change, at the entrance of the Bruit River, at 3^h; and springs rise 11 ft. The ebb and flood preserve an E. by N. and W. by S. set off the entrance in 6 fathoms.

The tides in the offing set north-eastward and south-westward, but in-shore follow more closely the direction of the coast, and near Tanjong Sirik they will be found to run North and South with a velocity, according to the prevalence of rain, from 2 to 3 knots an hour. The flood tide will be found to produce a strong indraught into all the rivers, which must be carefully guarded against.

Proceeding northward from the Sarawak, a good off-shore course must be steered, and allowance made for the flood tide, which runs strong to the S.E. on the line between Tanjong Po and Tanjong Sirik, but follows more closely the direction of the coast in shore, setting strong into the mouths of the rivers. It will be well remembered that Matang sharp peak seen over the inner brow of Moratabas Peninsula about W. by S. $\frac{2}{3}$ S., is the danger line for vessels of moderate draught, and Sipang Thumb bearing West, the warning for the off-lying shoals of the Sarawak River.

Shoals extend 6 miles from Tanjong Sirik, the flood tide setting strong upon it with a heavy swell; this point should not, therefore, be neared to a less distance than 8 miles, or under a depth of 12 fathoms, the soundings decreasing suddenly from that depth to 4 fathoms.

The Coast.—From Tanjong Sirik to Tatan Point, a safe course, recommended, is parallel to the chord between these points about E. by N. in 12 fathoms, which will afford an average distance of 10 miles off shore. Proceeding, therefore, on this course in the above depth, if making a passage, or in 6 fathoms if intending to call at the rivers, we first meet with the mouth of the *Ballang River*. The entrance, which appears to be nearly North and South, with the river open, is barred nearly 3 miles off shore. The village of *Oury* is about 2 miles within, on the northern bank.

To the eastward of the Ballang are the rivers *Oyah*, *Panuit*, and *Judah*, but they have not been sufficiently examined to warrant more than the visit by boats. The *Muka* is the next important river in point of trade and population, but as the chart indicates only 3 ft. at low water, it is not likely to be visited by any but boats or native craft. Writing of this region, Lieut. de Crespigny, R.N., remarks, in 1873, that he had been up to Mount Ular Bulu in search of cinnibar, but had found no indication of it or any other metal.

The mouth of the *Neian* appears to have received some attention, off which Lieutenant Gordon anchored in two positions, N.E. and N.W. of its entrance. It is obstructed by a bar, having only 1½ ft. of water. This is succeeded by

the *Tatan River*, nearly 4 miles W.S.W. of Tatan Point. *Mount Tatan* is 1,890 ft. high, and bears S.E. $\frac{3}{4}$ E. distant 10 miles from the entrance of the Tatan River, and S.S.W. distant nearly 20 miles from the entrance of the Bintula River. Farther inland, to the southward of Mount Tatan, is a ridge of hills, the most prominent of which is named *Table Hill*.

The Bintula, also a barren river, was visited by the *Samarang* in 1843. The approach, particularly on the ebb, is dangerous. The cutter grounded about 2 miles off shore, and the swell several times threatened to top. The water deepens suddenly within, and the stream, which was fresh at the last of the ebb, is of a deep reddish hue. The natives, or probably a piratical crew, seen within, did not appear to be well disposed.

The natives' leading mark is a dead tree on Tupak Hill in line with the West point of entrance S.E. by S.

This part of Borneo is now under the Government of the Rajah of Sarawak, by arrangement with the Sultan of Borneo. Trading stations are established both at Bintula and Muka.

It is high water, full and change, at the entrance of the Bintula River, at 5^{*h*} 45^{*m*}, and the rise is 6 ft.

The following notes are from the *Sarawak Gazette*:—Bintula stands on the banks of a river which is easily navigated by vessels of the size generally employed on our coast. During the N.E. monsoon there is generally much less sea at the mouth of the river than at other places on the coast, as it is protected by Kidurong Point. There are 9 or 10 ft. on the bar at the top of the tide, and the entrance is about 60 yards across. The gunboat *Heartsease* and the schooner *Courier* have come in two or three times during the year 1870. From one branch at the head of the Bintula River the upper part of the Rejang can be easily reached by a short journey overland. This route is constantly used by traders during the N.E. monsoon. They find it easier to come from Baloi to Bintula at that season than to descend the dangerous rapids in the Rejang, which must be passed to reach Sibul. Another branch of the upper Bintula River runs in the direction of the Tinga. The journey overland between the streams only consumes a day and a half for loaded men. Tinga traders occasionally bring produce to Bintula by this route. Vessels, as they enter the Bintula River, have to pass the fort, and then reach the bazaar, off which all traders anchor. This bazaar is chiefly built of wood, with bilian ataps, though some of the houses are still roofed and walled with nipa leaves. The Kampong is further up, above the bazaar. New houses are being built here at the edge of the river on bilian posts 9 or 10 ft. high, with plank or bark walls and leaf ataps. These new houses are long buildings with a double row of rooms and a passage between, the people living on either side of this corridor. In front of the house are the platforms on which the raw sago is worked, built on posts or floating on

the river, for the sake of getting the water used in the process of making without difficulty.

The fort, bazaar, and principal part of the Kampong are built on the right bank of the river; there are, however, three smaller kampongs on the opposite bank. The exports in 1870, valued at 172,946 dollars, besides gutta percha and raw sago, consist of camphor, india-rubber, bezoar-stones, and various sorts of canes. The country up the river is laid out in large plantations of the sago palm. There are very few paddy fields, the inhabitants not growing rice enough for their own consumption. Bilian wood grows abundantly on the banks. The greatest obstacle to improvement is the want of population.

The *Acis Patches* were announced in October, 1860:—"Two coral shoals have been discovered off the N.W. coast of Borneo by the brigantine *Acis*. The position of the eastern shoal is given as lat. 3° 45' N., long. 112° 42' E. The other shoal lies on the same parallel, and at a short distance to the westward."

The *Rifeman* anchored near the reported positions of these patches, and searched for them without success. It is possible they may exist somewhere in that locality; but as 9 and 10 fathoms are shown on them in the chart, they were not of sufficient importance to detain her.

Kidurong Bay.—Northerly from the Bintula, at 5 miles distance, is *Kidurong Point*, and about 3 miles S.S.E. from the point is a round hill named Mount Kidurong. To the southward of Kidurong Point is the bay which has been sounded, by Captain G. Heyler, of H.M. gunboat *Heartsease*.

Kidurong Bay is the only place of shelter along 300 miles of coast from Tanjong Sirik to Labuan. In the N.E. monsoon small vessels could run in here, and lie safely at anchor, sheltered from E.N.E. and N.W. gales. The anchorage is good, being soft mud and sand; the soundings vary from 2 to 8½ fathoms; good anchorage could be obtained about a quarter of a mile off the inside point in 3 fathoms of water.

In entering the bay from the northward stand down till the point bears E. $\frac{3}{4}$ N. about one mile distant; then stand in E. $\frac{1}{4}$ N. to 2½ or 3 fathoms of water, and let go about a quarter of a mile from the inside point with the outside point bearing N.W. by N. Entering from the southward or Bintulu side stand out into 5 fathoms, then stand for the point about N.E. by N., but do not come closer than half a mile off the point, then stand in for the anchorage. Good *fresh water* may be obtained here in abundance.

The following are the bearings of the *proposed lighthouse*: Mount Tatu N.N.E., and Kidurong Hill S.S.E.—*China Mail*, 1872.

The coast from Kidurong Point to Breaker Bay and beyond appears to be studded by rocky ledges. Indeed this coast, up to Tanjong Bali, should be avoided within depths of 12 fathoms by day and 30 fathoms by night. The

soundings suddenly decreased from 12 to 6 fathoms, and heavy breakers, with rocks above water, were noticed some distance off-shore.

Lieutenant Gordon observes:—The large bay contained between Sirik and Barram Points, as far as we have examined it, appears to be free from danger. About 30 miles E.N.E.-ward from Sirik Point we found the soundings about 7 miles off shore uneven, varying from 3 to 5 fathom, sand. A rock also exists off Tanjong Bali, about 16 miles southward of Tanjong Barram, but it is only 3 miles off the shore, and inside the 7 fathoms line.

The principal objects along the coasts of this bay are *Mount Tatan*, 1,890 feet; *Mount Silungan*, 1,500 ft.; and *Mount Lambier*, 1,550 ft.

Marabu.—At $2\frac{1}{2}$ miles northward of Tanjong Bali, and 13 miles southward of Tanjong Barram, is the mouth of the *Meri* (or red) River, on the southern bank of which is the village of Marabu, where a considerable trade in bees' wax and camphor is carried on with Borneo and Singapcre. The entrance is barred, and shoals extend some distance from the coast.

TANJONG BARRAM forms an abrupt bend of the coast, and is fringed by a shoal line extending $2\frac{1}{2}$ miles from the shore. Off shore the soundings deepen suddenly, and no dangers seem to threaten; vessels working up may therefore stretch well off this point to the north-westward, so as to make a good beard to the eastward.

The *Barram River* discharges itself into the sea in a W.N.W. direction at the point. The greatest depth over the bar does not exceed 6 ft. at low water, but suddenly deepens within to 4 and 5 fathoms; the stream being fresh nearly at the mouth.

The *Coast* from Barram Point easterly for 45 miles is very low, intersected by numerous creeks, and at 38 miles from the point is the entrance of the *Ampa*, where there appears to be some trade, and whence several prahus were observed to depart.

AMPA PATCH.—N.E. $\frac{3}{4}$ E. 32 miles from Tanjong Barram, and 15 miles off shore, is the centre of a bank termed the Ampa Patch, composed of sand and coral, upon which depths of 5 fathoms was the least water found. It is surrounded by 15 fathoms, and irregular soundings.

SCOUT and VICTORIA PATCHES are two coral shoals lying to the south-westward of the Bruni Patches, the channel between which and the coast of Borneo, heretofore considered quite safe, being thereby rendered very dangerous. Each shoal extends nearly a mile in a North and South, and about half a mile in an East and West direction. These dangers were examined in H.M.S. *Rifleman*, in 1863.

H.M.S. *Scout* passed over the edge of the former patch, in 4 fathoms. The least water found by the *Rifleman* was 2 fathoms, which lies S.S.W. $\frac{1}{2}$ W. $4\frac{3}{4}$ miles from the West Bruni Patch, and W. by S. $\frac{1}{4}$ S. 12 miles from Keti Islet.

The Victoria Patch was discovered by H.M. I.N. steam-vessel *Victoria*, 16th

August, 1860, and the least water obtained upon it was 17 ft. It bears S.S.W. $\frac{1}{2}$ W. 7 miles from the West Bruni Patch; S. by W. $\frac{1}{2}$ W. 2 miles from the Scout Patch, and W. by S. $\frac{3}{4}$ S. 13 miles from Keti Islet.

A $2\frac{1}{2}$ fathom patch, discovered in 1860, lies 2 miles westward of Victoria Patch, and a $4\frac{1}{4}$ fathom patch to the S.W. of it.

The only mark to clear these dangers is a bearing of Keti Islet, which is just visible at a distance of 12 miles.

BRUNI PATCHES.—From the Ampa Patch, steering easterly, the water gradually shoals from 17 to 7 fathoms; when on the parallel of 5° N., and with Bruni Cliffs (above which cleared or bald hills will be noticed), bearing E. by S. nearly 10 miles, a series of coral patches will be found, extending 4 miles East and West, and 2 miles North and South, leaving a channel within of 4 miles free from danger. From these patches, on which 2 fathoms were found, Pisang Mount may be seen bearing East.

Two-Fathoms Rock.—Among the off-shore dangers a single cast of 2 fathoms lies with Bruni white cliffs, bearing S.W. by S. distant 10 miles, and Bruni bluff S.E. by E. $\frac{1}{2}$ E. 7 miles. Woody Peak in line with Bruni white cliffs leads directly on it.

Outlying Shoals.—During the passage of H.M.S. *Iron Duke*, in 1872, from Singapore to Labuan, soundings were obtained in 5 fathoms in lat. $5^{\circ} 5' N.$, long. $114^{\circ} 40' E.$, about $4\frac{1}{2}$ miles N.N.W. of the Bruni Patches, with the eastern extreme of the Bruni cliffs bearing S.E. $\frac{3}{4}$ E.

Colombo Shoal is placed on the chart in lat. $5^{\circ} 13' N.$, long. $114^{\circ} 44' E.$ It has 5 fathoms water over it.

Information was also received from the captain of a vessel trading between Labuan and Singapore, of a similar patch about 16 miles to the N.E. of that found by the *Iron Duke*, reported to be in lat. $5^{\circ} 13' N.$, long. $114^{\circ} 53' E.$ This position was determined from cross bearings of Kuraman Island and Mount Pisang.

GUNUNG MALU, in the interior, is the highest mountain noticed in this part of Borneo. It is in lat. $4^{\circ} 5' 20'' N.$, long. $114^{\circ} 55' 8'' E.$, and rises in a conical form, slightly flattened at the apex, to an elevation of 8,000 ft. It can be seen 90 miles, and is visible from Labuan to 20 miles southward of Barram, a range of 100 miles.

BRUNI BLUFF slopes easterly to Pisang Point, where the sea at times breaks heavily. The land rises to 600 ft. at *Mount Pisang*, which derives its name from pisang, plantain in Malay. It is bare on the crown, excepting a small patch of trees on its summit, and it forms the tail of a long range extending about 12 miles towards the city of Bruni, and exhibits traces of coal throughout. Numerous sandstone cliffs show to the northward.

PELONG ROCKS, lying 2 miles North of Bruni Bluff, consist of four

separate rocks stretching to the northward; the water is deep close-to, and the channel between them and the bluff is safe. W. by N. $\frac{1}{4}$ N. distant 6 miles is the 2-fathoms rock before described, having 5 fathoms immediately surrounding it, outside of which there are 10 fathoms.

The main channel leading to the E.N.E. from the Pelong Rocks may be safely worked, even at night, in fine weather. It is about 4 miles in width, and is everywhere safe in 16 fathoms.

Directions.—Between Sirik and Barram Points, steamers or vessels having a fair wind may steer to pass the latter 4 or 5 miles off. There is nothing in that track excepting the coral patches off the Bintula River (page 487), over which there are said to be 9 and 10 fathoms water. Neither are there any known dangers in the offing nearer than the Luconia breakers. Vessels working against the monsoons will find more regular tides in shore, but they must guard against the effects of the indraught of the flood tide into the several rivers.

Between Sirik and Tatan Points they may stand safely into 8 or 7 fathoms, but between Tatan and Barram Points it does not appear to be safe to stand into less than 12 fathoms, the soundings decreasing suddenly from that depth, and the whole line of the coast is said to be studded with sudden dangers from the instant the trees can be discerned.

From Barram Point to Labuan, or to the entrance of the Bruni River, it is proper, as previously remarked, to keep outside all the dangers between Barram Point and Bruni Bluff.

BRUNI RIVER.—The city and Malay state of Bruni have given their name to the largest island in the world, if Australia is reckoned as a continent. The modern name being synonymous with Borneo, as spelt by older authors. It has been visited by European vessels for the coal which exists in great abundance on the N.W. shore of the river. The trade of the port of Bruni is almost exclusively carried on with the British settlements of Singapore and Labuan, steamers running regularly between these places. The trade is much the same as that described at Labuan. In 1875 exports were valued at £36,663; imports at £36,672. The chief export was sago to the value of £17,835, and the chief import cotton clothes, valued at £13,448.

The port of Bruni lies about 15 miles up the river of that name, the navigation of which is easy, but an artificial bar, which was constructed about 300 years ago for purposes of defence, obstructs the free passage near the island of Cherimon. At this spot, however, the river itself keeps a narrow channel clear, sufficiently deep, at all times, for small craft, but large ships can only pass the bar during high water. The town is called by travellers a "water city," the houses being built on piles driven into the mud on either side of the main stream of the river. Its population, chiefly Mahometan, is estimated to number 35,000. The situation is considered healthy.

The river and its approaches were originally surveyed by Captain Drinkwater Bethune, R.N., in 1845, and this chart, with subsequent remarks, forms the basis of the ensuing description. Brief and later directions will be found on page 493.

The mouth of the Bruni River was especially examined by Lieutenant Gordon, in H.M.S. *Royalist*, and he observes:—"There are no good marks for entering, and I do not think there could be better directions than those given by Mr. Kirton in the old chart.—Thus: 'Do not come within $4\frac{1}{2}$ miles of the S.E. point of Moaro Island until it is brought to bear S.W. by W. or W.S.W., then stand right for it, as the Moaro Reef trends nearly N.E. for 3 or 4 miles.'

"*Moaro Reef* is all sand, and has two or three small rocks near the sea; it is only dry near the island at low water, but the whole of it is very shoal; coming near it may always be known by the soundings changing from mud to sand."

This rule of sand is not always a sure guide, as sand will be found on the Sundar Spit, and at night, or after sunset, a vessel obtaining 4 fathoms, sand may be induced to steer easterly, and thus become fixed for a tide on the Sundar Spit.

Some little experience in this locality, and as far up as the city of Bruni, induce the following: The whole region about the entrance to the Bruni abounds in dangers, demanding extreme caution, and the banks appear to have changed their outline since the old chart was constructed. Entering by the Moaro Shoal, endeavour to keep in 10 fathoms, or until reaching a depth of 5 fathoms, having Mount Pisang open of the northern extreme of Moaro Island on the bearing W. by S. $\frac{3}{4}$ S. Or, running down from the northward, bring it on that bearing and steer for Sapo Point, until having passed over 5 fathoms, sand, depths of 6 fathoms or less, mud, are obtained.

If the bearings can be depended on, and the outline of Moaro can be seen (trees northward), this course should lead directly up to the extremity of Moaro Spit.*

Tree Peak in line with Sapo Point bearing about S.W. by W. $\frac{1}{2}$ W. just clears Sundar Spit in 3 fathoms.

Now, at the present day, when every navigator handles his sextant with ease, let him bring Mount Pisang to bear W. by S. $\frac{3}{4}$ S., and steer for it until Mount Say subtends an angle of 18° . He will then know distinctly his position, and from thence he may be enabled practically to reach the anchorage off Moaro securely.

* Sapo Point is low, with a few shrubs, but there are (or were) high trees about 7 cables' lengths westward of it, which are seen 10 or 12 miles. A stranger would not be able to recognise Mount Say without a good description of it, on account of the numerous hills. It is a sharp cone, having an elbow at right angles on one side, and is seen over the hills close to the sea shore.—Navigating-Lieutenant Russell, H.M.S. *Reynard*, 1863.

Having proceeded as directed, steer now direct for Mount Say and watch the angle of Pisang with Mount Say, until it reaches $22^{\circ} 30'$, when the vessel will be in the fair channel in 6 fathoms, mud.

It is important to bear in mind that the course of the ebb is about N.E. $\frac{1}{2}$ E., whereas that of the flood sets about S.E. across Sundar Spit, on the starboard beam of a vessel entering, and *vice versa* departing. Due allowance should be made for this, and the hand-lead allowed to remain at the bottom a few minutes, if in doubt, to determine not only the set of the ship, but also if she overcomes the tide.

As soon as Sapo Point can be distinctly seen, it should be kept a little open of Tree Peak on its proper constant bearing, but if the flood tide be running it must be kept on the starboard bow. There is no fear of danger on that side, and Sapo Point must be hugged closely, to avoid the Tapayan sands, the flood running with considerable force past Sapo Point. The vessel should be rounded *to starboard*, and the anchor let go immediately on rounding the point, which will ensure the best berth.

The ebb tide strikes into the embayed coast line of Moaro, and forces the tide easterly, until it clears the point; precaution should therefore be observed to prevent the tide setting the vessel on to the eastern tongue.

Such instructions have proved a sufficient guide to enter rivers much more intricate than that of Bruni; and where the safety of a vessel is involved, neither the trouble of pilotage from aloft, nor the practice of the more improved modes, by reliable instruments, should induce any seaman to omit making use of the facilities which correct charts thus afford.

Vessels anchoring here should have an anchor well to the eastward, as night squalls frequently drive vessels from their anchors.

Water may be obtained near the beach, but unless driven by necessity, its use should be avoided. It is of a dark colour, strongly impregnated by peat, and probably affected by naphtha springs, or pyrites connected with the underlying coal.*

* A good channel, beacons with a least depth of 18 ft. at high water, leads up to it. The first and last of these beacons on the starboard or northern side are distinguished by a sort of ball on their summits, the space between and also the port side of the channel being marked by branches of trees. Vessels intending to take this channel may, after rounding Sapo Point, steer along the South coast of Moaro or at a discretionary distance, according to the depth of water, which decreases gradually towards the island, taking care not to open Mount Pisang or Bowong Point until clear of the Tapayan shoals, and when approaching Bowong Point keep a good look-out for the beacons on either hand, between which the vessel is to pass. A tolerable mark through between the beacons is a small elbow on the northern part of Mount Pisang, in line with some white cottages below it, bearing W. by N. or W.N.W. Strangers should procure a pilot, as the beacons are liable to be washed away.—Navigating Lieutenant H. S. Ley, H.M.S. *Cormorant*, 1857.

Sapo Point to Bruni.—The course of the river from Sapo Point to Bruni, the capital of Borneo proper, may generally be discerned by the lines of fishing stakes, which, at the period of Lieut. Gordon's visit appeared to terminate by the fishing stage in deep water, and alternately on either bank, Thus, by leaving the first on the left, second on the right, &c., the channel was easily traced by the boats.

Mount Pisang and Bowong Point (the south-western extreme of Moaro) in line clears both the Tapayan Spits; and Mount Say kept open eastward of Jagar Ridge leads up to the bar.

On nearing the islands Churmin and Ingaran (literally, Churmin, bright like a looking-glass, and Areng, coal), the channel between Ingaran and the main may be taken by boats. But the ship canal has been artificially narrowed by stones laid down, continuous with the reef from Ingaran, so as to compel vessels to pass under the guns of the forts on the North end of Churmin. The result has been to cause the current to cut a deep channel round the point of Churmin, and, entering with the flood, it requires very great caution, from the sudden turn from South to N.N.W., to prevent being thrown on the breakwater to starboard, or the Churmin Rocks to port. Fortunately the channel then leads by a moderate curvature to the western shore, after which a course mid-channel, and moderate attention to the chart, will carry safely up to the city, the anchorage being at the opening leading to the palace in 6 fathoms.

“The Barou Islands may be recognised on approach, the southern being high and rounded, the northern low, with two conspicuous clumps of large trees close together. Mount Say be known by taking its bearing on approach; it appears the northern of three hills of similar elevation, and has a steep notched shoulder on the right, which is the leading mark. If not made out before, after passing Sapo Point it will be the right-hand hill seen over River Point.”—Commander Bullock, H.M.S. *Serpent*, 1866.

“To enter: After passing Sapo Point, steer to the westward, and bring Mount Say to bear S.W. $\frac{1}{2}$ W. open East of Jagar Ridge, until Sapo Point bears N.E. by E. $\frac{1}{3}$ E., when alter course to S.W. by W. $\frac{1}{3}$ W., keeping Mount Pisang astern. When Mount Pisang bears N. by E. $\frac{1}{2}$ E., a stake beacon should be seen, which leave about half a cable on the port hand, then steer S. by W. $\frac{1}{2}$ W., keeping Mount Pisang astern. When Mount Say comes just clear of Jagar Ridge, the vessel should be between two stake beacons lying E. by N. and W. by S. from each other. From the beacons alter course to S.S.W., which should lead mid-channel between the beacons on South Bar bank and Barrier beacon.”—Navigating Sub-Lieut. R. H. Wellings, H.M.S. *Lily*, 1876.

H.M.S. *Lily* in crossing the bar at high water by the above-mentioned channel, had not less than 14 ft. water, bottom soft mud. At spring-tides,

2 ft. more water would probably be found. The flood-tide in the channel sets on to the barrier of stones.

In the river above Barrier beacon, considerably less water was found by the *Lily*, in the month of May, than is shown on the chart. The bank which extends from the North shore of the river, 4 miles above Asing Point, has extended farther out than was formerly marked on the chart.

Tides.—By the chart it is high water, full and change, in the Bruni River at 11^h, and springs rise 12 ft.

Commander Bullock remarks:—"From good information from the best Labuan pilot, the ordinary rise at springs is 8 ft., occasionally 9 ft. There is a greater range in November, December, and January. From January to June the high tides occur at night; from July to December in the daytime. The intermediate high water rises only 1½ ft. above the mean level."

Supplies.—Fresh water may be obtained from a spring near the base of the Kianghi, where the natives will be observed filling their bamboos. The entire range of this mountain, terminating at Bruni bluff, is probably composed of coal, which in many positions crops to the surface. The market of Bruni, carried on by numerous canoes, supplies poultry, eggs, deer, fruit, vegetables, &c. The trade is the same as that (described on page 496) of Labuan.

The water buffalo were used for beef; but bullocks of good quality are to be obtained through the Kadyans or Dyak race of this region, the Malays not being a pastoral or farming race.

The **LABUAN GROUP**, a dependency of Great Britain since 1845, comprehends Labuan, Kuraman, Burong (or Bird Island), Rusukan Besar (or Great Rusukun, supposed to be connected with *deer*), Rusukan Kechil (or Little Rusukan), Enöe, Pappan (or Coolin Pappan), and Daat.*

Labuan, the largest of the group, extends about 10 miles in a N.E. by N. and S.W. by S. direction, forming an obtuse-angled triangle on this base, and having about 5 miles width at the vertex, where it would perpendicularly bisect the base. This supposed division into two right-angled triangles would divide the island into nearly equal portions, the northern being the solid land, and the southern marshy, or intersected by streams.

There is good timber on the north-western point of the island, but it was more easily obtained on the southern portion at the watering place about 1

* The signification of the word Labuan in the Malay language is anchoring-place. In Marsden's Dictionary it is written Labuh-an; but this has eventually, or by the dropping of the h, fallen into its present use.

Labuan was given to the English in 1845 as a port or trading station; and a right was secured for British subjects to reside or trade in any part of the dominions of the Sultan of Borneo. In recent years it has been proposed to bring the government of Labuan under the administration of the Straits Settlements.

mile from Kiamsan Point, the S.W. point of the island. It was used for boat plank, timbers, and knees, being a rough description of poon, varying much in solidity, from the centre, which was very dense, to the outer coating, which resembled cedar. The watering place is well marked by the termination of a range of casuarina trees at a bright sandy beach at the northern bend of the bay. The supply is abundant, landing easy, on a sandy beach, and boats lie safe within convenient distance for hoses. It is almost in connection with a salt-water pool, which may cause some mistake. At low water large and excellent oysters may be found attached to the rocks, then laid bare.

The North end of Labuan is the highest part of the island, its summit, topped by trees, being elevated 460 ft., and appearing, when seen from the North, as two peaks of equal height. It is surrounded by sandstone cliffs, and an extensive reef stretches off the northern point; a continuation of this belts the island, offering occasional breaks admitting boats. The northern portion is worked for coal, and convenient anchorage for vessels of any draught may be found off Koubong bluff. Steam vessels can approach to a cable's length of the beach.

A reef extending from the point off Koubong Bluff affords a good foundation for a jetty, but a heavy sea occasionally tumbles in upon this coast during the N.E. monsoon; vessels should therefore, in that monsoon, anchor well out in a safe position for getting away, and veer in for coaling.

The best spars can be obtained here, and after rain a stream of reddish water flows over the rocks to the sea.

Fresh dangers are frequently discovered off the northern reef, and great vigilance is necessary, the lead affording no warning; the patches, when the sun is visible, exhibit a light green hue, and a peculiar heave of the sea may be detected by a vigilant observer. A breaking patch lies $2\frac{1}{4}$ miles to the N.N.E. of the point.

COAL.—The coal seams extend the length and breadth of Labuan; the mines are at the North end of the island. The coal produces satisfactory results, and is exported to Hong Kong and elsewhere, but it burns rapidly.

In 1848 the value of the coal exported amounted to £600, and in 1874 to £3,451. The quantity raised fluctuates largely from year to year; in 1866 it was valued at £11,995. Recent endeavours have been made to reach an 11-ft. seam, but great difficulty arises from the badness of the pumping machinery, which is not able to cope with the water in the mine. In December, 1874, a depth of 96 fathoms had been reached, and three separate seams of $6\frac{1}{2}$ ft., 3 ft., and $4\frac{1}{2}$ ft. had been discovered. The price, in 1874, did not exceed 5 dollars 50 cents per ton free on board, 15 dollars per ton being the cost in the neighbouring colonies..

The railroad from the mines to the shipping place at Tanjong Kubong,

including a substantial jetty, was constructed in 1862. A new wharf was commenced in 1874.

The *climate* of Labuan closely resembles that of the warm summer months in the South of Ireland. Temperature ranges between 71° and 90°. Rain falls plentifully, but chiefly in the night.

Supplies.—Fresh beef can be procured in Labuan. Vegetation is luxuriant, and the finest fruit is grown; oranges, pummellos, mangoes, mangosteens, pine-apples, bananas, &c., can be got in abundance.

Fish is plentiful and cheap, and fowls can be purchased, but nearly everything is very dear. The water in Victoria Harbour is bad; it can be procured at high tide.

The long continued prevalence of cholera in 1876, and the previous outbreak of small-pox in 1873, had had a very depressing influence on trade.

Labuan may be considered an outpost to Singapore, as here the produce of the neighbouring coasts and of the Sooloo Islands is collected for re-shipment to Singapore, which is distant 707 miles. The total imports into the colony during the year 1875 were valued by the importers at £119,362; of these there came from Singapore £67,105, and from the coast of Borneo £52,257. The exports were in all £114,332, of which £63,229 went to Singapore; the exports to the coast of Borneo, being taken as of equal value to the imports with which they are purchased, represent a total of £51,103. Copper coinage, in 1875, was replacing on the coast of Borneo the cumbrous forms of metallic currency formerly prevalent there.

Exports in 1874, taking them in order of importance, were as follows:—Sago, £30,109; birds' nests, £4,342; india-rubber, £3,867 (decreasing); coal, bees'-wax, specie, rattans, camphor, tortoise-shell, pearls, hides, dammar, gutta-percha, sharks' fins, &c. The principal articles in use at Labuan and adjacent coasts are—brass, brass dishes, wire and other brassware, boxes, candles, cotton cloth, cotton thread, thread for embroidery, earthenware, gambier, gongs, gunpowder, iron bars, empty jars, muskets, opium, salt, sugar, tobacco, &c., &c., all of which are obtained from Singapore by the Labuan traders. A very good breed of ponies might be procured in considerable numbers on the N.W. coast of Borneo, also at Cagayan Sooloo, and more at Sooloo itself.

Tides.—It is high water, full and change, in Victoria Harbour at 9^h 45^m; springs rise 6 ft., neaps 4½ ft. There are two regular tides in the day, but in the S.W. monsoon the night tide does not rise as high as the day tide, and in the N.E. monsoon the night tide is the highest. In the slack of the monsoon the rise of the tides is equal.

VICTORIA HARBOUR, on the S.E. side of Labuan, is well sheltered in both monsoons. The general depths in it are from 4 to 10 fathoms, over a bottom of stiff mud, decreasing gradually as the head of the harbour is approached. Moor open hawse to the S.E., as strong gusts from South to

East occur, particularly at night. The atmosphere here is oppressive, and unless compelled to remain, it is preferable to anchor South of Pappan Island, where the full strength of land and sea breezes will be experienced.

The shores of the harbour are bordered with sand-banks, which dry at low water. On the West side they extend off nearly 3 cables, and are interspersed with patches of rocks and stones. On the North side the bank does not extend more than a cable from the shore. Each side they are steep-to; at half a cable's length from where the sand dries there is deep water.

Rusukan Kechil, one of the group of islands off the S.W. extremity of Labuan, was selected by Sir E. Belcher for the astronomical position, being convenient for the survey, and solid ground. Its eastern sandy tongue is the point on which the observations were made.

Vessels visiting this group, simply for rating chronometers on Little Rusukan, should give it a clear berth to the southward of 3 miles, hauling up when the western extremes of Great Rusukan and Kuraman are in line, and avoiding the $2\frac{1}{2}$ -fathom patch to the south-eastward of the former, by bringing Little Rusukan on either outline of Kuraman, anchor in 11 fathoms about 1 mile East of Little Rusukan, where good landing may be found on the northern beach.

BARAT BANK has 2 fathoms on it, and its outer extremity lies S.W. $\frac{3}{4}$ W. $3\frac{1}{2}$ miles from Great Rusukan, the soundings decreasing suddenly from 30 to 10 fathoms near it. It is therefore prudent not to haul up for Great Rusukan until it bears N.E., preserving the depth of about 15 fathoms on an E.N.E. course until Great Rusukan is open westerly of Kuraman, when the course to Pappan is free from danger. Preserving a depth of 15 fathoms will keep you clear of a $3\frac{1}{2}$ -fathom patch which lies 1 mile South of Great Rusukan, and 4 cables S.E. of a breaking patch.

Lieutenant Gordon observes:—"Between the S.W. point of Labuan and Kuraman is a passage between reefs, but I do not consider it safe."

Formosa Rock lies in the channel between Kuraman Island and Kiamsan Point, with the latter bearing N.N.E. $\frac{1}{2}$ E., and Burong Island East.

Trident Shoal, lying S.S.W. $\frac{1}{2}$ W., nearly a mile from Enöe Island, is a coral patch 2 cables long, N.N.W. and S.S.E., and one cable broad, with only 1 fathom on it at low water. The North extreme of Daat Island just touching the South end of Pappan clears it to the southward, and the flag-staff on Ramsay Point open East of Enöe clears it to the eastward. There is a passage 2 cables wide, with a depth of 6 fathoms, between it and the shoal running off Enöe.

Enoe Island.—The shoal surrounding this island consists of sand, with occasional patches of rocks and stones. It runs off 7 cables to the north-

ward, $3\frac{1}{2}$ to the southward, and 3 cables to the eastward of the island, and on the West side joins the coral reefs stretching out from Labuan. A *beacon* (consisting of stakes lashed at the top) is placed on its N.E. extreme in 4 fathoms water, with the summit of Enöe bearing S.W. $\frac{1}{2}$ S., distant nearly 7 cables, flagstaff on Ramsay Point N.N.E., 1 mile, and extreme of mangrove on Hamilton Point, West, nearly 8 cables. The shoal is steep-to on all sides; at a cable distant from where it dries are from 6 to 7 fathoms water.

Pappan Island is flat, and covered with trees, the tops of which are 124 ft. above the sea level. It is surrounded by a shoal which extends a cable's distance from the North shore, 2 cables from the West, and 3 cables from the South shores, and to the westward it is only separated by a small passage three-quarters of a cable wide from the reefs running off Daat Island and the main coast of Borneo. A *beacon* is placed on the S.W. extreme of the shoal in 4 fathoms, and from it the S.W. end of Pappan bears N.E. $\frac{1}{2}$ N. $2\frac{3}{4}$ cables, the summit of Enöe W. $\frac{1}{4}$ S. $1\frac{1}{2}$ mile, and the flagstaff on Ramsay Point N.N.W. $\frac{1}{4}$ W., $1\frac{1}{2}$ mile.

Outer Shoal, lying between Pappan and Enöe Island, is a cable in extent, consists of coral, and has only 3 ft. on it at low water. A *beacon* with a *black* ball is placed in $1\frac{1}{2}$ fathom on its East side, close to the shoalest part, and from it the flagstaff on Ramsay Point bears N. $\frac{1}{4}$ W. 12 cables; summit of Enöe Island W. by S. $\frac{3}{4}$ S., nearly a mile; Pappan beacon E. by S. $\frac{3}{4}$ S., two-thirds of a mile; and Enöe beacon N.W. by W. $\frac{3}{4}$ W., half a mile. The passage between the Outer Shoal and Pappan beacon is 6 cables wide, and has depths of 12 to 25 fathoms; the passage between it and Enöe beacon is 4 cables wide, and has 9 to 11 fathoms.

Harbour Shoal, lying between Ramsay Point and Enöe Island, is a small coral patch, half a cable in extent, with $1\frac{1}{2}$ fathom least water on it. A *beacon* with a *white* ball is placed near the centre of the shoal, and from it the flagstaff on Ramsay Point bears N. by E. $\frac{1}{2}$ E., distant 6 cables' lengths; Outer beacon S. by E. $\frac{3}{4}$ E., $6\frac{1}{2}$ cables; and Enöe beacon S.W. by S., $4\frac{1}{2}$ cables. Vessels may pass on either side of this shoal.

Columbine Beacon.*—From Ramsay Point the shoal water extends in an E.S.E. direction for 7 cables, when it turns to the E.N.E., and curves gradually to the northward. The edge of this bank is or was marked by the Columbine and Inner beacons.

* CAUTION.—Mariners are cautioned not to put confidence in the arrangement of the beacons as placed on the charts marking the approaches to Victoria Harbour. Columbine beacon and the three beacons on the West side of the bank to the northward of Daat Island do not exist.—Mercantile Marine Magazine, June, 1871.

The Columbine beacon, surmounted by a *black* ball, is in 3 fathoms water, and from it the flagstaff on Ramsay Point bears W. $\frac{1}{4}$ S., nearly a mile; Collier Head N. $\frac{3}{4}$ W., $9\frac{1}{2}$ cables, and the S.W. point of Pappan Island S. $\frac{1}{2}$ W., $1\frac{1}{4}$ mile.

On an old chart of Labuan a rock was placed just to the north-eastward of the position of this beacon, but although searched for carefully, nothing more than a small patch of coral with $1\frac{1}{2}$ fathom on it was found, just detached from the edge of the 2-fathom line of soundings, but inside the line of 3 fathoms. The centre of this patch is N.E. by N., $1\frac{3}{4}$ cable from the beacon, the 3-fathom line of soundings running in a N.E. by E. direction, $1\frac{1}{4}$ cable from the beacon. In the channel, 1 mile wide, between Columbine beacon and the shoal off Pappan Island, the soundings are irregular, from 9 to 20 fathoms.

The Inner Beacon marks the edge of the shoal water halfway between Columbine beacon and Ramsay Point. It is in 2 fathoms at low water, and from it Columbine beacon bears E. by N. $\frac{1}{2}$ N., distant half a mile; the flagstaff on Ramsay Point W. by N. half a mile; and Collier Head N. by E. $\frac{2}{3}$ E., $1\frac{1}{2}$ mile. Between these two beacons the edge of the shoal curves a cable's length to the southward of a straight line joining them, and between the Inner beacon and the flagstaff off Ramsay Point there is a coral patch of 1 fathom and another of three-quarters of a fathom, detached from the edge of the bank, which extends $1\frac{1}{4}$ cable to the southward of a straight line joining the flagstaff and beacon. Both patches are steep-to, and to avoid them keep Columbine beacon open of the Inner beacon, whilst the flagstaff on Ramsay Point is on a bearing westward of North.

Two beacons, with a *white ball on each*, are placed on the western edge of the reef extending from Daat Island to Lubedan Island. The southern one stands about E.N.E., a little more than 2 miles from Collier Head. The northern one is N.E. $\frac{1}{2}$ N., $3\frac{1}{2}$ miles from the same place, and N. $\frac{3}{4}$ E., nearly 2 miles from the South beacon. (See note, p. 498.)

DIRECTIONS for South Channel.—In working into Victoria Harbour from the S.W., Pappan open to the northward of Daat clears the Trident Shoal on one hand, and Burong open of Kiamsan Point gives fair warning of it on the other. The flood tide runs fast near Pappan Island, and from the prevailing winds it was found advisable to hug its western side, making short boards to the N.E. until a free course into Victoria Harbour offered, grazing the northern dangers. Work up under the South side of Pappan until the vessel can weather Enöe. Tack on the first east in 10 fathoms; if the tide should tend to shut Little Rusukan in with Enöe, keep away, as they must be kept open until near Pappan, which is bold-to on the West. Keep rap full, and go round before the vessel is swept past its northern end, otherwise the eddy may bewilder the steerage. Tack again in 10 fathoms

before Great Rusukan Peak opens inside of Enöe. This will clear the 6-ft. patch, on which Burong Island will be seen clear of Hamilton Point. When the northern bluffs are seen open of Collier Head, the vessel will have a free wind into Victoria Harbour. Keep Burong just shutting with Hamilton Point until the harbour beach opens, when the vessel may safely round the 1-fathom tongue, extending $1\frac{1}{2}$ cable's length to the south-eastward of the flagstaff, by keeping in 6 fathoms.

Vessels wishing to sail in or out of Victoria Harbour should always take advantage of the land and sea breezes, instead of attempting to work in. Arriving in the afternoon or at night, the best way is to anchor about half a mile South of the Outer shoal in 10 to 11 fathoms, weighing at daylight the next morning, and running in with the land breeze; and in leaving the harbour wait for the sea breeze between noon and 1 p.m., which carries a vessel with a fair wind past all danger.

North Channel.—As regards the pilotage of this channel, much diversity of opinion seemed to exist, but, it may be remarked, not by those who made the surveys. No difficulty was at any time experienced in beating through with the object of determining the 5-fathom limit. The following, therefore is the result of practical knowledge.

In leaving Victoria Harbour by this passage enter mid-channel between the shoals of Ramsay Point and Daat Island, with Burong Island open of Hamilton Point, and when the S.E. point of Daat shuts in with its S.W. angle, and Malancassan Island opens off its northern point, a N. $\frac{3}{4}$ E. course may be steered, which, with the tide, and edging easterly on any cast less than 5 fathoms, will carry the vessel out in not less than that depth.*

The westerly soundings are all safe, and dangers dependent on sun's bearing, or before 2 p.m. visible.

In approaching from the northward steer for mid-channel, but withal nearer to Lubedan. Nothing less than $4\frac{1}{2}$ fathoms water on that shore will be found until Lubedan opens from the distant tall trees of the N.E. coast; then proceed direct for Pappan Island, and when Burong opens haul in for the town point, and anchor as before.

Route from Labuan to the Palawan.—Sir Edward Belcher makes the following observations on proceeding to sea from the northern part of Labuan:—

As regards off-shore dangers, the patches to the northward rise suddenly.

Gordon Patches.—North, 12 miles from Bethune Head, is a patch of 4 fathoms, with patches of 5, 6, and 7 fathoms $1\frac{1}{2}$ mile to N.W. of it, and one or two detached 7-fathom patches extending as far as $2\frac{1}{2}$ miles westward of it and a mile eastward of it.

Having passed through the North channel, the safest course for vessels of large draught is to bring the high land of Bethune Head to bear S. by W.,

avoiding the dangers extending 3 miles off the Head, and steer N. by E. until past Gordon Patches; this would make a direct course to the North, nearly on the meridian of the high hills of Labuan, until reaching the latitude of $5^{\circ} 45' N.$, in 20 fathoms, when an easterly course may be shaped to make Pulo Tega. This will avoid the Jahat, Winchester, and Nosong patches, and lead to the channel southward of the Tega group, much more reliable than the narrow opening between the Deluar and Tega Shoals, unless good berth be given at 10 miles from the northern Tega Islet, which, simply for making a passage, should be preferred.

Other duties, or inducements, may lead the navigator along the coast line, off which safe anchorage will generally be found.

At 7 miles N.N.E. from the North extreme of Labuan, deep water (15 or 20 fathoms) will be gained. Hence a N.E. by E. course, in depths from 11 to 14 fathoms may be observed, and the Pine Point shoals avoided by moderate attention to the bearings of the elevations marked on the chart. As a general caution for distance from this coast line and limit of shoals, the base of the trees on the beach should not be distinguished when off Pine Point.

On the other hand, similar precaution is necessary not to render them indistinct (which the distances of 5 and 10 miles would vary), which will keep the wary navigator within the limits of the Jahat dangers. Having touched several of these dangers, we may observe that due caution, now their existence is determined, is given by the lead, and the heave of the sea will always warn an intelligent pilot of shoal water. Independent of this, whenever the sun is abaft either beam, or on the back of the observer, the bright green hue of the shoals is distinctly visible.

The preceding remarks especially apply to vessels of great draught; but to small craft, not exceeding 14 or 15 ft., the inner passage within the shoals may be taken at $1\frac{1}{2}$ mile from the coast line. If proceeding easterly, keep Lubedan Islet barely clear of Toulak Point; or, if westerly, the S.E. extreme of Tega and Nosong barely in contact, apparently opening as the vessel recedes from Tega.

Shoals North of Sahat Point.—A 3-fathom patch lies N.N.W. 5 miles from Sahat Point and 6 miles N.E. of Bethune Head. *Nis Shoal* lies 3 miles N.E. of the preceding; and about a mile N.W. of Nis Shoal is a 5-fathom spot, and 2 miles S.E. of it a 2-fathom spot, South $1\frac{1}{2}$ mile from which, and $4\frac{1}{2}$ miles N.N.E. of Sahat Point, is a 2 and 3 fathoms spot, apparently at the end of a spit extending from the shore.

JAHAT SHOALS.—The Jahat (literally bad, or danger) Bank, was examined closely by Lieut. Gordon, and is thus described by him:—"Jahat Bank, the principal and most dangerous reef, is of coral, and horse-shoe form, bearing N.E. $\frac{3}{4}$ N. from the North point of Labuan, and N. $\frac{1}{2}$ E. from

Lubedan. It has 6 ft. water on its eastern, and only 3 ft. on the south-western part; there is deep water all round except on the North side, where depths of 5 fathoms extend for a considerable distance, and there may be less; and there is a passage through the N.W. or centre part of it."

NOSONG SHOALS.—N.E. $\frac{3}{4}$ N. 9 miles from the Jahat Shoals, and West from the South point of the largest Tega Island, is a coral reef, on which are two small sand patches nearly level with the sea, or awash at high water. From these patches, breaking with any ripple, the reef extends $1\frac{1}{2}$ mile N. by E., and the ground is very uneven on the S.W. The following warning lines circumscribe its dangers, and, as will be seen by the chart, afford a very safe passage to the southward.

The North Tega or Burong Island, which is high and conspicuous, clear of the great Tega Island, will lead to the southward; Tangout Rock shut in with Nosong eastern outline leads to the eastward; and Turtle or the second Tega Island open of the great Tega Island leads to the northward of these shoals.

PULO TEGA GROUP, which is composed of three islands, Tega, Turtle, and Burong (which derive their name from *Tega, three*), extend off Nosong Point, but the best authorities, the natives, with whom friendly intercourse prevailed, termed this point Tanjong Pulo Tega, a matter of importance when communicating with the coast people of the Kimanis.

Between Tega, the largest island, and Nosong Point, the channel is quite safe, and the chart itself affords sufficient warning for clearing the dangers off the point. The wind prevailing off-shore prevents vessels from getting near the S.E. spit.

The group stands on a coral bank, extending about 5 miles N.N.E. and S.S.W., with a danger breadth of 3 miles. The largest island is safe-to, and affords good anchorage under its centre in the southern bay; but a shoal with 2 and $2\frac{1}{2}$ fathoms over it extends from its eastern extreme in a southerly direction for the distance of a mile, close to which are 14 fathoms. A shoal patch, with but 2 fathoms on its outer end, also lies W. by S. from the western extreme of the island, the outer part of which is distant $1\frac{3}{4}$ mile; close to this shoal are 7 to 9 fathoms. Navigating-Lieutenant Russell, of H.M.S. *Reynard*, says that a coral rock, with 6 ft. water over it, lies about half a mile to the westward of the S.E. point of the island, and about the same distance from the shore.

Turtle and Burong Islands occupy a patch of 3 miles in extent, and the channel is only passable in light boats.

The northern island received the name of Bird (Burong) from the quantity of birds' deposit. It is high, and bold-to on its S.E. side, where good anchorage was found in 9 fathoms. The trees are useless.

KIMANIS BAY, so retained in compliment to the name given by Dalrymple, as well as to the commercial importance of the river of the same

name, is an extensive bight, and lies immediately to the eastward of Nosong Point, and free from danger.

Kapala River (or *Kuala-panko*, native), in the S.W. bight of Kimanis Bay, is safe, at high water, for trading craft drawing 12 ft., or it can be entered at all times in smooth water by a draught of 4 ft. The *Lama River* is about 3 miles to the eastward of the Kapala. It is barred by rollers in bad weather, but in smooth water may be entered at high water by boats drawing 5 ft. At low water springs it probably would show dry, or possibly offer a very narrow boat channel. The *Membakut* is an insignificant stream in the depth of Kimanis Bay.

Kimanis River, the entrance to which is in the eastern bend of Kimanis Bay, has shoal water extending a considerable distance off its mouth, which, at low tide, is entirely barred to the smallest boats. At high water, prahus of some size, drawing probably 6 ft. water, enter the river by the southern channel.

The Kimanis River forms the boundary of the territory ceded to Great Britain in 1763, as well as the jurisdiction of the Sultan of Bruni, or Borneo Proper; our relations, therefore, with the people are likely to become more important to commerce, as this river is one of the principal trading connections with the interior, as well as with the city of Bruni, to which it sends seed-pearls, camphor, beeswax, vegetable wax, pepper, &c.

Supplies.—The people were found very difficult to deal with. Goats, ducks, fowls, vegetables, fruit, pepper, beeswax, camphor, parrots, &c., were brought down in quantity, and at very low prices. Watering is inconvenient, as the natives must be relied on to fill and bring the casks to the boats.

Watering Place.—At about 4 miles northward of the Kimanis River will be found a space of 20 acres of cleared land, fringed at the beach by a line of casuarinas, and close to the small river Benoni to the northward. The water will be found in a long canal immediately within the trees and parallel to the beach. It is 200 yards long, 30 yards wide, and in general seasons may afford a mean depth of 5 ft. The water is excellent, and is probably in the course of constant filtration to the sea.

Particular stress has been laid in describing this locality, as we found ourselves frequently deceived in replenishing water at places where positive information of its existence was given.

The *Benoni* is probably connected with the above watering place, and during the freshes, floods the neighbouring flat, before described as cleared land. The *Minani*, about 3 miles northerly of the Benoni, is barred, but, like the latter, can be entered by boats at high water.

To the northward of Kinindukan Bluff, the eastern horn of Kimanis Bay, the coast dangers recommence, but are easily avoided by due attention to the soundings. The inland ranges rise suddenly, attaining heights of 1,500 and

2,000 ft. The rivers are insignificant, and do not offer any inducement for trade or other purposes until reaching Gaya Bay.

Caution.—From a general intercourse with all the tribes, Malay, Bajow, as well as the Dyak or mountain races, it was apparent that by kindness and firmness they are disposed to be friendly. Timidity, or too much suspicion on the part of visitors, naturally renders them cautious. But caution, even under the British pendant, is imperative in all transactions with the Malay race.

Pulo Lyang.—N. $\frac{2}{3}$ W. $3\frac{1}{2}$ miles from Kinindukan Bluff, and 2 miles from the nearest shore, lies the island Lyang of the chart (termed *Llanghangan* by the Bajows and coasters). It is high, bold-to, and may be safely passed at 1 mile off by day or night, at which latter period it may be mistaken for a vessel under sail.

GAYA GROUP and BAY.—*Gaya* is a lofty well-wooded island, $15\frac{1}{2}$ miles N.N.E. $\frac{1}{2}$ E. of Lyang, and nearly connected with the main by an extensive reef. To the southward of *Gaya* lie four small islets; within these there is safe anchorage.

Gaya Bay is formed by the northern point of *Gaya* Island and *Tanjong Kaetan*, which is surmounted by a remarkable peak. To the northward of *Gaya*, and parallel to the chord of the bay, are the islands *Sapangar*, *Udar*, *Udar Kechil*, and *Udar Tega*, which form the land-locked harbour of *Sapangar Bay*, the most secure harbour on this coast.

Between *Sapangar* and *Gaya* the main channel is safe. There are also channels between the other islands, but they are unsafe, by reason of the liability to sudden calms, currents, and gusts. The outer navigation is safe, but beware of making too free with the lee side of *Sapangar*, or the vessel will be becalmed.

Within the bays or port just mentioned are the rivers *Inanam* and *Kabatuan*. The *Inanam* is nearest to *Pulo Gaya*, and its entrance is difficult, even for boats.

Kabatuan River is in sight of the eastern bend near the *Udar Kechil*, not within the northern bight or inner bay, but may be at once distinguished, when abreast of its entrance, by a yellow sandstone bluff on its northern, and the abrupt angle of the coast on the southern, shore.

The main or outer bar appears to be composed of coral knolls, being a continuation of the line of reef extending from the *Inanam*. There are gaps in this through which, at high water, small craft might contrive to enter the river. The mouth is nearly closed by a small sand delta, near the southern edge of which the deepest water was found. Water, however, flows in small drains within the delta, furnishing, by perseverance, about 10 gallons in a quarter of an hour. A few miles within the river the water is fresh.

The *Kabatuan* is the principal trading river of this region. Taking into consideration the security of the harbour, as well as the facility of com-

munication in all weathers, added to the character of its governor, this may be considered as the safest and, at present probably, best trading position on the coast.

The deep bight northward of this river is beset with shoals, and possesses nothing worthy of its exploration.

The outer islands are surrounded by deep water, uninhabited, and possess no interest.

Tanjong Kaetan is the inner bluff, near the islands, surmounted by a peak of the same name. The outer bluff has no name, it therefore was designated *Gaya Head*. It is steep-to, and has no hidden dangers outside of it.

Menkabong Bluff and River.—This bluff, about 5 miles N.E. of Gaya Bluff, is a high crowned peninsula, with a sandy beach connecting it with the river of Menkabong, which is about 2 miles to the S.W. The river can be entered by boats or small traders drawing 7 to 8 ft. The inhabitants are apparently friendly.

Directions.—Before proceeding farther along the coast, the observations of Lieut. Gordon, R.N., on the outer navigation, will be recorded. “Vessels working up must not stand too far off, as there are numerous reefs off the East side of Mangalum, which island is W.N.W. 24 miles from the N.W. point of Gaya Island. Off here, at 7 miles from the shore, during the strength of the N.E. monsoon, a strong current was found setting to the north-eastward.”

MANGALUM ISLAND, the S.W. point of which is in lat. $6^{\circ} 10' 40''$ N., long. $116^{\circ} 35' 20''$ E., is nearly round, 4 miles in circumference, and very low, the highest part of the ground being only a few feet above the level of the sea; the tops of the trees are visible from a sloop's deck about 12 miles. It is surrounded by a coral chain, broken only at the S.E. portion, where vessels may enter and anchor close to the shore.

Wood for fuel and other purposes is abundant; the trees grow quite straight, and there is great variety. Mangalum Island is, or was, a common rendezvous for piratical proas.

Tides.—High water about 11 p.m., and low water at 6.45 a.m., the greatest rise of tide being 5 ft. It may be remarked here that, as in other positions on the North coast of Borneo, the night tides greatly exceed those by day, but are yet regular; that this apparent single tide at night may probably be accounted for by the prevalence of strong sea breezes outside, which, failing at sunset, permit the tide to resume its flow, and that two or three sets of tidal observations at this position would upset this theory, as it did that—so long contended for by successive navigators—at Tahiti.

Bank of Soundings.—H.M.S. *Dwarf*, in August, 1876, struck soundings on a bank which lies between lat. $6^{\circ} 22'$ N. and $6^{\circ} 16' 30''$ N., long. $115^{\circ} 51' 10''$ E. and $115^{\circ} 46' 25''$. The vessel was steering S.W. $\frac{3}{4}$ S., and the first

cast obtained was $9\frac{1}{2}$ fathoms, bottom distinctly visible; the shoalest cast was 6 fathoms, sand; the general appearance of the bottom, coral with rocks interspersed. From the North end of the bank Kaetan Peak bore S.E., North extreme of Mangalum Island S.W. by W., centre of Gaya Island S.S.E. $\frac{1}{4}$ E. From the South end of the bank Kaetan Peak bore S.E. by E. $\frac{3}{4}$ E., North extreme of Mangalum Island S.W. by W. $\frac{3}{4}$ W., centre of Gaya Island S.E. The nearest part of the main land, Gaya Head, was thus distant 20 miles.

Off-lying Shoal.—Commander George Robinson, of H.M.S. *Rinaldo*, also reports, that during the passage from Labuan to Manila, when about 21 miles from the coast of Borneo, the leadsman suddenly got soundings in 7 fathoms, decreasing to 5 fathoms, the bottom being distinctly visible, and discoloured water seen from the masthead to the northward. From this shoal water the West extreme of Gaya Island bore S. $\frac{1}{2}$ E., and the mountain of of Kini Balu S.E. by E. $\frac{1}{2}$ E., the depth of 5 fathoms being in lat. $6^{\circ} 26' N.$, long. $115^{\circ} 56' E.$

Tawalan River.—From Menkabong Bluff, which is belted by a reef, the coast runs pretty straight about 4 miles, when the mouth of the Tawalan throws off an extensive sandy flat. The entrance is guarded by a spit, dry at low water, into which boats can enter, from the South, on the first quarter ebb. Within is rather a large village of huts, inhabited solely, it is asserted, by the Bajow fishermen.

Sulaman River.—Two miles beyond the Tawalan or Kawalan is the mouth of the Sulaman. This appears to be a spacious river, running as far as the eye could trace, in a broad sheet inland. The stream is rapid, and the depth at low water about 6 ft. on the bar. Immediately within, it increases to 3 fathoms, the channel apparently deepening on the southern bank.

The Coast from hence to the South bluff, belonging to the Ambong range, is tolerably bold-to, but totally void of interest. Between this bluff and the entrance to the port of Ambong are several patches of rock, but mostly above water. Vessels should not near to less than 8 fathoms, or they will lose the wind.

AMBONG BAY.—The port of Ambong, approached from the northward, may always be recognized by the peculiar projection of high peaks, as it were, into the sea. On the East will be noticed the island of Usukan, showing as a black bushy cone; the mountains near it on the main, exhibiting at the same time smooth, yellowish-green, rounded summits, their bases easterly, falling into apparently level land. In the depth will be seen the high ranges skirting the bottom of the port of Ambong, and, if sufficiently clear, the blue tinted mountain of *Kini Balu* (Chinese widow), 13,698 ft. in height, crowning all in the distance. On the right the Ambong range, clothed with trees from the base to its summit, will stand in the foreground sloping off gradually

towards the Sulaman River, where the high ranges cease, excepting 10 or 15 miles in the interior.

A shoal patch, a quarter of a mile in extent, with $2\frac{1}{2}$ to 3 fathoms water over it, lies with its outer part bearing N. $\frac{1}{2}$ W., distant $8\frac{1}{2}$ cables from Cape Ambong. At 3 cables north-eastward of this patch is another of nearly the same extent, but having only 2 fathoms water over it in places. From a 2-fathom spot near its outer end Cape Ambong bears S. by W. $\frac{3}{4}$ W., distant nearly a mile, and Perunjuk Point S.E. $\frac{2}{3}$ E., distant over a mile.

Supplies.—Ambong, as a place of trade or for refreshments, affords bullocks, goats, fowls, eggs, &c., at very moderate prices. Beeswax, pepper, camphor, birds' nests, and other Bornean produce, were freely brought down to trade.

There are two positions for watering: one immediately to the northward and opposite to Ambong Town; the other, and the most convenient, if cleared above its run beforehand, is at the beach north-eastward of the anchorage. The quantity depends much on the season.

Directions.—The approach to the port of Ambong is so evident on the chart that but few directions are needed. Nevertheless the navigator may find himself hampered by wind or tide, and a few hints may ease his mind, should he find himself on the verge of danger, and he will undoubtedly be led there by too near an approach to Cape Ambong and the consequent failure of wind under the high land.

If coming down from the northward, with Kini Balu visible, bring it to bear S.E. and steer for it, which will lead to Ambong on the deepest line of soundings.

There is no danger in approaching from the westward with a strong leading wind, or under steam, the actual danger being North of the cape, within 1 cable's length of the shore. But trust not the breeze, steer East, or make good that course, at 2 cables' lengths from the cape, until gaining the depth of 8 fathoms, and having the highest peak of the sea range of the western peninsula over the centre of the sandy bay immediately beneath; observing that the first sight of the sand, clear of the rocks, gives warning of the off-lying patches, and the two inner points in line, of having passed them.

A vessel may then steer for Perunjuk Point, and a berth be taken in 6 fathoms, about 2 cables S.E. of it, with the eastern house of Ambong Beach open of Teluk Point.

Large vessels preferring greater security should adopt the outer course, bearing in mind that Usukan open of Sak Point N.E. $\frac{1}{2}$ N. barely clears the patches off Cape Ambong at a good cable's length. This mark will be distinct at all hours, even towards dark. But when objects can be clearly seen the yellow island, Jaga, brought immediately under the highest outer cone, Mount Robertson, also well seen at dawn or dusk, on the bearing of N.E. by

E. $\frac{1}{2}$ E., may be preferred. On this bearing not less than 11 fathoms will be found until the patches are passed, and Perunjuk Point bears S.E.

Ambong Beach, 3 miles distant, will then be clearly seen, and when its western extreme is about to shut in with Perunjuk Point, shape a course immediately for the latter.

In fine weather, by a careful look-out from aloft, all dangers will be clearly visible.

Sak Point.—Quitting Ambong bound north-easterly, Jaga, a very prominent yellow sandstone cliffy island, may be shaved; but within the depth of 13 fathoms northerly of Soundal Point there is reason to believe that dangerous rocks near the surface are yet undiscovered; one, *awash* at low tides, and surrounded by a coral bank, lies W. $\frac{3}{4}$ S. of Sak Point.

USUKAN BAY, about 3 miles to the northward of Ambong Bay, offers not only safe anchorage, but also an excellent watering-place in its bight, and is, moreover, the only convenient spot for communicating with the River Abai. Directions therefore requisite for anchoring and watering will be given.

Passing the rock *awash* off Sak Point, the clearing marks for which are Jaga Island open of Soundal Point, and the second head on the southern side of Usukan Bay open, steer, or work for Slime Rock, which is safe to approach to a cable's length on the S.W. side, and anchor in 10 fathoms, with the apex of the rock bearing N.W. A vessel will then lie secure from swell, and $1\frac{1}{2}$ mile from the watering place in the depth of the bay.

The **Slime Rock** is connected with Usukan Island by a ridge under water. A rock *awash*, with deep water within, but too near the land for safe navigation, lies off Usukan.

Water.—As the driblets of Ambong afford but little, and the detention of more than two days may be involved, it is important to know that here, in safe anchorage, and not incommoded by natives, watering can be expeditiously accomplished.

Usukan Island, fronting the Abai River entrance, is a prominent feature on the coast, standing out clear from the land, and almost a warning for danger when not shut in. It is high, conical, and well clothed with timber, and, indeed, at times of extreme low tides, may be a peninsula.

ABAI RIVER.—It is by this western channel, at the first quarter flood, that boats should visit the Abai, as the entrance by the North, although deeper, is troubled by rollers.

This was formerly the port of Abai, the principal rendezvous of the Illanon pirates, but since they have selected Tampassuk, as better protected by the Sultan, the importance of Abai has fallen. The natives are peaceable, and will furnish bullocks, vegetables, and refreshments, but not so reasonable as at Ambong.

As Abai Port is open by its eastern entrance to vessels drawing 9 ft. at

low, and 12 to 14 ft. at high water, it is proper to caution those intending to enter, that the bottom within is hard sand, and, unless they pass into the river at once, where 3 and 4 fathoms, mud, will be found, they are endangered by the swell and rollers, which would cause them to strike heavily and bilge. They must not, therefore, calculate on anchoring in the outer harbour.

A Dangerous Patch, on which the sea breaks, lies North, $1\frac{1}{2}$ mile from Usukan Island, and exhibits three cones, or pinnacles, at dead low water springs. The marks for it are the points of Abai Port lapping, or the points westerly of Usukan Bay and peak of Slime Rock in line. Abai Port open of Usukan leads to the eastward. The channel within is safe, and to be preferred.

TAMPASSUK RIVER.—The beach from the Abai River to the entrance of the Tampassuk River, a distance of about 3 miles, is nearly straight, sandy, and from the very shelving nature of the whole extent of coast up to the Ant Islands, constantly subject to heavy rollers, rendering landing dangerous, if not impracticable. The 14-fathom line extends far to seaward, and although only two patches have as yet been discovered by the sea breaking over them, it is necessary to caution vessels, not having business at Tampassuk, to give the coast at least a distance, by the lead, of 14 fathoms, or, as before remarked, do not open Usukan Island of the land westerly.

The entrance to the River Tampassuk is barred by a sand-bank, over which, at high water, there is probably 12 ft., but at low water springs, not more than 6 ft.

Caution.—It is necessary at all times to be on the guard when near the Illanon pirates, which frequent Tampassuk. They are all well armed, inclined to be insolent, and are so sudden in their movements, that they may execute much mischief, even slaughter, and escape before they can be overtaken or punished; wherever they are fallen in with, there may not be proof of piracy, but the utmost caution is requisite.

Three-Foot Rock.—At $4\frac{1}{2}$ miles S.W. by W. $\frac{3}{4}$ W. from the outer Ant Island, close to Kranga Bluff, lies a shoal, marked as a 3-ft. rock, but at times awash, on which the sea breaks. The line of direction for it is, Usukan Island clear of the western land beyond; if the objects overlap, it will lead clear outside.

This danger is surrounded by deep water, and shoals suddenly from 14 to 2 fathoms. In this region the 20-fathom limit should be preserved during night.

Ant Islands lie off Kranga Bluff, at the extremity of the sandy bay, the shore of which trends N.E. $\frac{1}{4}$ E. $9\frac{1}{4}$ miles from the mouth of the Tampassuk River. The bay, as before stated, terminates in a river which did not find a place on former charts.

BISA ISLAND, or **Black Peninsula.**—N.E. $\frac{1}{2}$ N. from a safe position off the Ant Island dangers, will lead clear to a Black Peninsula, Bisa Island,

distant $8\frac{1}{2}$ miles. The entire space within is thickly studded with dangers, which about a mile to the north-eastward of Gasap Point extend a mile from the shore. Landing is very difficult.

Mantanani Islands.—Eighteen miles to the northward of Usukan, and about 12 miles W. by N. from Bisa Island, lies the group called Mantanani, consisting of two low islands, and one tolerably high clump, termed Nob Island, the latter covered almost entirely with a species of *pisonia*, the roots of which embrace, and apparently confine together, the loose structure of stones consisting of calcareous tufa, which appears to have been thrown up (or, one would almost say deposited) in the most unaccountable manner. Bird Island of the Pulo Tega group, is of precisely similar formation, but of larger fragments.

There is no inducement, beyond wooding, for any vessels to touch at this island. It is or was much frequented by the pirates.

OFF-LYING SHOALS.—There is reason to believe that many shoal patches may exist in this neighbourhood, and in bringing a line of soundings from the South Furious Shoals towards Labuan, H.M.S. *Rifleman* came on a bank at night, lying S.W. by W. 17 miles from Nob Island of the Mantanani group.

SOUTH FURIOUS SHOALS, a group of coral patches lying a few miles to the north-westward of the Mantanani Islands, were discovered in August, 1859, by H.M.S. *Furious*, and examined, in 1863, by H.M.S. *Rifleman*, which vessel anchored upon a small coral bank barely half a mile in extent, N.N.W. $\frac{1}{4}$ W. nearly 7 miles from the western extreme of the Mantanani Islands. It is in lat. $6^{\circ} 48\frac{1}{2}'$ N., long. $116^{\circ} 14\frac{3}{4}'$ E., and the least water upon it is 7 fathoms.

About 2 miles S.S.W. of the last-mentioned patch is another of 6 fathoms, about a mile in extent; westward and south-westward of which again, are other and more extensive banks. N.N.W. about 5 miles from the western extreme of the Mantanani Islands is a small patch of 8 fathoms; and N. by W. $\frac{1}{2}$ W., $3\frac{1}{2}$ miles, is another spot of 10 fathoms.

NORTH FURIOUS SHOALS are three coral patches lying about 20 miles northward of the Mantanani Islands. These were also examined in the *Rifleman*, and from the vessel's position at anchor in 11 fathoms among them, in lat. $7^{\circ} 3' 19''$ N., long. $116^{\circ} 18' 15''$ E., Nob Island, of the Mantanani group, bore S. $\frac{2}{3}$ E., and Banguay Peak E. by N. $\frac{3}{4}$ N. These shoals extend N.W. by N. and S.E. by S. nearly 2 miles, and the least water upon them is 7 fathoms. The soundings around about are very irregular.

Barton Rock appeared on former charts as awash in lat. $6^{\circ} 52' N.$, long. $116^{\circ} 19\frac{3}{4}' E.$, $9\frac{1}{2}$ miles North of the Mantanani Islands. The *Rifleman* passed over this position without finding the rock; 28 fathoms being the least water obtained, but circumstances did not allow of a further search.

WHITE ROCKS.—Bisa Island (page 509) forms the southern horn of a

great bay, having two large white islets on its chord, with two smaller in its bight. A reef extending $2\frac{1}{2}$ miles in a N. by E. $\frac{1}{3}$ E. direction, and nearly a mile in breadth, surrounds the White Rocks, which are known only by the native fishermen as *Batu Putih*.

The largest rock is in lat. $6^{\circ} 42' N$, long. $116^{\circ} 35' 52'' E$. Within this reef, guided by the chart, good anchorage will be found, varying from 8 to 12 fathoms.

At $4\frac{1}{2}$ miles North from White Rock, 6 miles S. $\frac{1}{4}$ W. from the outer Batomandé, and $1\frac{3}{4}$ mile W. by S. $\frac{2}{3}$ S. from the nearest rocky bluff, Ganda Head, lies a shoal. The whole of this region is unsafe. It should be avoided by vessels drawing above 12 ft.

BATOMANDE ROCKS.—N. $\frac{1}{8}$ E., $10\frac{1}{2}$ miles from White Rock (and visible from each other), lie the two Batomandé Rocks, so named in the old charts by Dalrymple. They are one of the astronomical positions of this coast, and are situated in lat. $6^{\circ} 52' 42'' N$, long. $116^{\circ} 36' 24'' E$.

These conspicuous rocks are of yellow sandstone, 40 ft. above the sea; they lie W. by N. $\frac{1}{4}$ N., 2 miles from Tanjong Agal, with which they are connected by a dangerous reef, leaving a single opening immediately within the inner high rock.

TANJONG AGAL derives its appellation from a species of fucus known by that name in commerce, and is collected on its rocky ledges by the fishermen for sale, similar to birds' nests and trepang.

In sailing to the northward and eastward, a distance of 3 miles from the shore should be observed, the safe course from 10 fathoms off the Batomandé to the Island of Kalampunian being N.E. $\frac{2}{3}$ N., and the distance 14 miles. The space within this line can only be safely traversed by boats.

An unimportant river, navigable for boats at high water, enters at the sandy beach immediately in front of a white cliff, N.E. by E. $\frac{2}{3}$ E., 3 miles from Tanjong Agal. The next river is about 3 miles northerly from the last, and appears to enter at the southern termination of a line of tall casuarinas.

The bay is terminated by a black rocky promontory, which, from its being composed of a blackish compact basalt, containing in its vesicles masses of zeolite, received the appellation of *Zeolite Bluff* (or *Katiga Point*). This bluff is N.E. $\frac{1}{4}$ E. 8 miles from the Batomandé Rock, and S.S.W. $6\frac{1}{2}$ miles from Kalampunian, but it is not seen from the latter.

One stream flows out immediately to the northward of Zeolite Bluff, but it is barred to boats.

No traces whatever of human beings were observed during several days' examination of this angle of Borneo.

SAMPANMANGIO POINT is readily distinguished by the tall casuarinas which rise from its grassy bluff, and by the Island of Kalampunian off its extremity. It is the western point or cape of the great bay of Maludu; but

as Kalampunian is exterior to this, and is the better leading object, it will deserve especial notice. These terms Sampanmangio and Kalampunian have so long been known as beacons for this part of the world, that it would scarcely be prudent to disturb them, whatever their meaning may imply. They are known by these names since Dalrymple handed them to us.

Water.—It is probable, in favourable seasons, that water may be obtained on the western bay, immediately within Sampanmangio Point, where the sandy beach succeeds the cliff termination and the level or marshy ground commences. This is also the favourite resort of deer, wild hogs, &c. Another spot also promises, at the neck of the Peninsula Islet, where a fair leading wind will be found at full or half tide on its southern side.

KALAMPUNIAN ISLAND lies 1 mile North of Sampanmangio Point, and its summit is in lat. $7^{\circ} 4' 17''$ N., long. $116^{\circ} 44' 51''$ E., the nearest point of which island bears N.E. $\frac{1}{2}$ N., distant $11\frac{1}{2}$ miles. It is a sandstone formation, similar to the nearest bluff of Sampanmangio, and rises abruptly, from a flat bed, to the height of 40 ft.

The *Coast* south-eastward for 7 miles from Kalampunian, has been examined, but not beyond. It is dangerous to approach within 2 miles, in consequence of many off-lying coral patches.

MALUDU BAY.—The great Bay of Maludu was not examined by the *Samarang*; but the main channel North of the entrance, between Borneo and the islands of Balambangan and Banguey, is free from dangers, excepting those expressly mentioned in connection with the reefs off their proper shores.

CHAPTER XIII.

BALABAC STRAIT AND THE ISLANDS NORTH OF BORNEO, INCLUDING PALAWAN.

THE line of shoals which lie on the edge of the bank of soundings off the N.W. coast of Palawan, and which form the S.E. limit of the *Palawan Passage*, will be described in a subsequent chapter, in connection with the other dangers in that channel; what follows is a description of the little visited island of Palawan, and those that lie between it and the North extremity of Borneo.

The following directions, from the North part of Borneo to the South part of Palawan, are from those by Staff Commander J. W. Reed, R.N., and have been compiled from the surveys of that officer whilst in command of H.M. surveying vessel *Riflemen* in 1869.

Between the North part of Borneo and the South part of Palawan are several small islands, of which Balambangan, Banguay, and Mallawallé, lying a few miles from the Borneo coast, with many islets and rocks, form a conspicuous group. Northward of this group is Balabac Strait, which connects the China and Sulu, or Mindoro, seas. The elevated island of Balabac forms the northern limit of the strait, and between that island and Palawan are many smaller ones, of which Mantangoule, Bancalan, Bougsook, Pandannan and others form a group separated from Balabac by North Balabac Strait.

BALAMBANGAN ISLAND, 11 miles N.E. by N. from Sampanmangio Point, the N.W. extreme of Borneo, presents in its southern portion a range of hills, the highest of which is 440 ft.; these elevations are bounded on the western sea margin by abrupt cliffy outlines. The northern portion of the island is flat, but thickly covered with high trees. A spur juts easterly at nearly the mid axis of the island, dividing the two inlets known as the North and South harbours; and on the peninsula head forming the southern

horn of the last of these, observations were obtained by Sir Edward Belcher, as the chief eastern meridian for his survey of the North coast of Borneo.

Both harbours afford good water, but the purest was found at the southern one.

Some islets and rocks lie off the South end of the island, and a detached coral patch, with 3 fathoms water over it, E. by S. $\frac{3}{4}$ S., distant a mile from it. Off the S.W. point of Balambangan is the small, round island of *Kalutan*, 278 ft. high, which a vessel should not near under half a mile, on account of a reef projecting from the West side of it. The whole western coast of Balambangan is fronted by reef, which projects, in places, three-quarters of a mile.

Siagut Shoal, a detached coral bank, $1\frac{1}{2}$ mile in length, with less than a fathom water over some parts of it, lies 2 miles off the N.W. part of the island; by keeping in depths not less than 14 or 13 fathoms, all these dangers will be avoided.

Reefs and shoals extend more than three-quarters of a mile from Siagut Point, at the North end of the island, and a 3-fathom patch lies N.N.W., nearly $1\frac{1}{4}$ mile from it; vessels should, therefore, give it a berth of a couple of miles, or not come under 9 or 8 fathoms when rounding it.

The whole of the East coast of Balambangan is also fronted by coral; $1\frac{1}{2}$ mile south-eastward of Siagut Point, separated from the shore reef by a passage 6 fathoms deep, lies a coral shoal, more than half a mile in diameter, having less than a fathom water over some parts of it; and eastward of this danger, in the channel between it and the extensive reef surrounding Tiga Islet, is a small spot of $3\frac{1}{2}$ and another of $2\frac{1}{2}$ fathoms, which should induce great caution in the event of a vessel having occasion to pass through that channel.

The outlines to the eastward of Observatory Head, and along the entire S.E. coast, will be found fringed with shoals, which are not easily discovered, unless the sun be shining on the back of the observer. These shoals will then exhibit a pale green tint, the deeper water being clearly defined by a deep blue.

Tiga Islet, low and covered with trees, is surrounded by reefs, and must be approached with caution.

To enter *South Harbour* requires close attention to the following directions, as well as the customary warning of "lead and look out:"—First, the Cone, the outer islet off Tanjong Kalutan, open of the islets off Observatory peninsula W.S.W., positively clears danger, and on that bearing, if the anchor be let go at the moment the harbour heads open N.W., the vessel will be in 13 fathoms, sufficiently clear of danger. *Water* will be found at a green patch of grassy land cleared from trees, about a quarter of a mile within Raha Point.

The North Harbour, or *Looc Barabok Barabok* (a Bajow name), offers

greater convenience for anchorage than the South harbour, and is of much easier approach, the shoals being better defined.

To clear the shoals off Tanjong Saparoak, do not lose sight of the southern point of Balambangan, or mask it by the islets off Observatory Point, on which line the *Half-Channel Patch* lies, breaking at times, and having 3 feet at low water.

The Banguey Island shore is safe ; work upon that coast until the trees of Tanjong Battang present a decided outline, or the latter bears about W. by N. Two reefs awash lie on the chord of the bay. Enter the bay on a West course, halfway between the northern reef and Tanjong Battang, looking out to avoid a 9-foot knoll, which is on the line of the western extremity of Pulo Kalankâman on with the trees of Tanjong Battang. A shoal *awash*, which bounds the bay entrance on the North, will then be noticed ; it may be grazed, and a position taken up in 10 fathoms, having its centre in line with the trees of Tanjong Battang. The South reef is also awash, and behind it (with a safe channel out S. by E. grazing the reef) the *Samarang* anchored.

It was on the southern point of North Harbour that the English establishment (finally deserted in 1803) was situated. Two streams flow into the sea, one on each side of the ruins. The westernmost is to be preferred for watering. Fuel may be obtained at any part of these islands, and is similar in quality to the woods of Borneo grown on hard soil.

BANGUEY ISLAND—the nearest part $2\frac{1}{4}$ miles eastward of Balambangan—is twice the size of that island ; it is somewhat rhomboidal in form, about 13 miles in diameter, very irregular, and everywhere fringed with reefs. The South coast is faced by small island, between which are deep-water channels, and behind them large concealed spaces formerly, and even now at times the rendezvous and hiding places for the Llanum pirate prows. They form the northern limit, and are included in the description of Banguey South channel. The West coast is included in the description of Banguey West channel, and the North coast in that of Balabac Strait. Offlying for several miles the N.E. and East coasts of Banguey are numerous islands, islets, and dangers, some of which will be included in the description of Banguey South channel, and others, farther on, under special denominations.

There are several ranges, as also some detached hills on Banguey ; the highest, *Banguey Peak*, elevated 1,876 ft., is at the N.W. end of the island, and shows up as a very conspicuous object for more than 30 miles around.

From the peak a long spur slopes in a south-westerly direction to the West coast, and a range of hills extends to the eastward for a distance of 6 miles, *East Hill*, at the extreme of the range, being elevated 1,076 ft. ; thence some smaller ranges take a northerly direction, and terminate near the coast in North Hill, 742 ft. high.

Banguay West Channel, between Balambangan and Banguay, leading from the China Sea into Balabac Strait, is not so free from danger as it was supposed to be, a rock, with 9 ft. water over it, having been discovered in the fairway, and also other dangers off the N.W. coast of Banguay, during the progress of the survey of Balabac Strait and its vicinity, by Staff Commander Reed, in H.M.S. *Rifleman*.

Molleangan, an island 466 ft. high, and Little Molleangan, about one-third its size, together, with some islets and numerous rocks, lie south-westward of the S.W. point of Banguay, the outer rocks being nearly 4 miles off. Dangers stretch off in westerly and north-westerly directions from Molleangan to the distance of three-quarters of a mile, and others in a northerly direction till they unite with those fronting the S.W. coast of Banguay.

Giving the West coast of Banguay a cautious berth of 1 mile on a N.E. and S.W. line, and not decreasing the water to less than 19 fathoms, the coast is safe. A close examination and survey of the coast failed to detect any river. No fresh water was found, and the reefs were unsafe at low water for light boats.

Manyangit Point, the N.W. extreme of Banguay, can be approached to within a quarter of a mile. The N.W. coast terminates at *Samarang Point*, $6\frac{1}{2}$ miles N.E. by E. from Manyangit Point, three-quarters of a mile W.N.W. of which is the outer edge of a patch of dry coral, with a sand cay upon it, so that this part of Banguay must be neared with caution. Two small coral shoals, the north-eastern one having $2\frac{1}{2}$ fathoms water over it, and the other 3 fathoms, lie $1\frac{1}{4}$ mile off shore, with Banguay Peak bearing S. by W. $\frac{1}{2}$ W. The channel between these shoals and the shore dangers is clear, with depths of 6 and 7 fathoms. *Rifleman Rock*, a small coral patch with $1\frac{1}{2}$ to $2\frac{1}{2}$ fathoms water over it, and 5 and 6 fathoms close to, lies in the fairway between the shoals just described and those extending south-eastward from Tiga Islet, distant $1\frac{1}{2}$ mile from the former, and nearly a mile from the latter. From the centre of the patch Manyangit Point bears S.S.W., and the S.W. end of Tiga Islet W. $\frac{3}{4}$ N. Westward of the rock are 6 and 7 fathoms, but eastward of it the soundings are shoaler and more irregular.

Passing through Banguay West channel, Banguay Peak bearing N.N.E., or a depth of 19 fathoms being preserved, will lead you clear to the westward of Molleangan Islands. Manyangit Point to the northward of N. by E. $\frac{1}{4}$ E. will keep vessels clear of the whole of the dangers fronting the West coast of Banguay.

Being to the northward of the Half Channel Patch, haul out a little towards mid-channel, and steer a northerly course until about a mile past Manyangit Point, when bring it to bear S. by W., and carefully keeping it so, guarding against tides, pass between Rifleman Rock and Tiga Islet Reefs. Steering a N. by E. course, and having brought the centre of the highest part of Tiga Islet on the port beam, the rock will be on the starboard

beam, and when past it a vessel of heavy draught may edge more to the eastward, to avoid some 4-fathom patches, the nearest of which lies half a mile north-westward of the rock.

BANGUEY SOUTH CHANNEL, through which vessels may pass from the China Sea into the Sulu Sea, instead of through Balabac Strait, is somewhat intricate, and demands careful navigation, being for the greater part of its length bounded by dangers. The western entrance, about $1\frac{3}{4}$ mile wide, is between Outer Shoal, the westernmost of many dangers which extend off several miles from the N.W. part of Borneo, and the Molleangan Islands off the S.W. part of Banguay. The southern limits of the channel are formed by the dangers off the N.W. and northern parts of Borneo; the South channel dangers; the reefs off the northern part of Mallawallé; and the northern edge of the reefs and shoals extending many miles eastward of that island, and known as Mallawallé eastern dangers. The northern limits comprise the islands which lie close to, and appear to be part of, the southern shore of Banguay; the Carrington Reefs; and by an extensive mass of reefs known as the S.E. Banguay dangers.

Those dangers only will be described which lie outside the mass, limiting the channels proper for vessels to proceed by; the dangers N.W. and North of Borneo will be first described.

Outer Shoal forms the S.W. limit of Banguay South Channel; it is somewhat square shaped, about a mile in extent, with from 1 to 3 fathoms water over the greater part of it, and a patch which dries near its eastern side. The N.W. end is steep, having 13 fathoms close to, and this part forms the southern boundary of the entrance to the channel; from it the apex of Little Molleangan bears N.E. $\frac{3}{4}$ N. $2\frac{1}{2}$ miles; and a small islet close to the N.W. point of Borneo, having upon it a white patch which shows like a boat's sail, bears S.E. $\frac{3}{4}$ S. 5 miles.

A sand cay, on the East side of a coral ledge nearly awash, lies E. by S. $\frac{1}{4}$ S., $2\frac{3}{4}$ miles from the N.E. extreme of Outer Shoal, and S.E. by S. southerly nearly $3\frac{1}{4}$ miles from Little Molleangan.

Between Outer Shoal and the sand cay, but nearer the latter, is a small dangerous coral patch with only 1 fathom water upon it.

Another small sand cay, in the centre of a coral ledge, lies E. $\frac{1}{2}$ N. $1\frac{1}{4}$ mile from that before mentioned, and S.E. $\frac{1}{4}$ E. $3\frac{3}{4}$ miles from Little Molleangan. These cays are very useful as marking the limits of the channel in the direction of Borneo, and being composed of white sand (coral debris) they are very conspicuous.

Nearly 3 miles E.N.E. from the sand cay, last mentioned, is a 2-fathom coral patch, with a couple of ledges which dry a short distance southward of it; from this danger, which is the most northerly of the whole cluster,

Little Molleangan bears W. by N. $\frac{1}{2}$ N., $5\frac{3}{4}$ miles, and the apex of Patanunam N.N.W. $\frac{1}{2}$ W., nearly 4 miles.

About $1\frac{3}{4}$ miles E. $\frac{1}{2}$ S. from the 2-fathom shoal is the outer of two coral ledges lying close together; from it Little Molleangan bears W. by N. $\frac{1}{4}$ N., $7\frac{1}{2}$ miles, Patanunam apex N.W. $\frac{1}{4}$ W. 5 miles, and the highest apex of Mallawallé E. $\frac{1}{2}$ N. 8 miles. A 3-fathom patch lies 3 cables E.S.E., and a ledge of rocks a little over $1\frac{1}{2}$ mile in the same direction from these dangers; this ledge, however, should properly be considered one of the dangers off-lying the N.E. coast, and affecting the navigation of the channel between Borneo and Mallawallé.

South Channel Dangers comprise five coral shoals which lie nearly midway between the Banguay and Borneo coasts, limiting Banguay South channel to the southward, and Mallawallé channel to the northward. It is only necessary to consider these shoals as a dangerous group which the following bearings just clear:—On the North side the apex of Large Molleangan W. $\frac{3}{4}$ S.; on the South side the same object W. $\frac{1}{2}$ N.; on the West side the South apex of Pagassan N. $\frac{1}{4}$ E.; and on the East side, the islet next the Point of Banguay, East of Lampassan, N. $\frac{1}{4}$ W.

Mallawalle Island, 7 miles distant E. by N. from the North extreme of Borneo, is 4 miles long, and about the same distance broad. The island for the most part consists of ranges of hills from 400 to 500 ft. high; but one range, towards the N.W. end, attains the elevation of 562 ft. N.W. islet lies a short distance off the N.W. end; and North Island, low and nearly a mile in length, lies so close to and projects from the North part of the main island in such a manner that it is not easily seen to be detached.

Mallawallé, including the adjoining islands and islets, is encircled by a belt of reef which dries at low water; and at the N.W. point of Mallawallé it curves round and projects a narrow spit more than a mile to the southward, forming a sort of small harbour, with 8 fathoms water in it, where proas, or other small vessels, could easily find anchorage. At the South end of Mallawallé is an inlet about a mile in depth.

Off the North side of Mallawallé, at its western end, the shore reef extends about $1\frac{1}{4}$ mile, and encloses *North Island*, 1 mile long, N.N.E., and S.S.W. A 2-fathom coral patch lies N.N.W. $\frac{1}{4}$ W., nearly 7 cables from North Island, and 5 cables outside the reef encompassing it, and from this patch three narrow strips of reef, dry at low water, extend more than 2 miles to the eastward; the westernmost strip is marked near the middle by a sand cay. Between these dangers and the shore reef is a channel with depths of 10 or 11 fathoms, decreasing to 4 fathoms near the reefs on either side.

Half a mile north-eastward of the snout, projecting from the shore reef at the eastern part of Mallawallé, is a conspicuous sand cay, situated near the West end of a detached reef which extends a mile eastward of the cay; the channel between this danger and the shore reef is blocked by a 2-fathom

coral shoal. About $1\frac{3}{4}$ miles N. by E. from the East end of Mallawallé, and N.N.W., $1\frac{1}{4}$ mile from the cay, is a narrow strip of coral, half a mile in length, which dries; close around it are 12 and 13 fathoms; and S.E. $\frac{1}{2}$ E., $1\frac{1}{4}$ mile from the cay, is another small coral patch, with a spot upon it which dries, and depths of 15 fathoms close to; but these are, in fact, the westernmost of the Mallawallé eastern dangers.

Mallawalle Channel.—Dangers extend off 3 or 4 miles from the N.E. coast of Borneo, and between these and Mallawallé is a safe channel 3 miles broad; but a rock lies in the fairway just outside the southern part, which is the limit of the *Rifleman's* survey in that direction, and, probably, many other dangers will be discovered when the survey is extended.

Mallawalle Eastern Dangers comprise a large number of detached reefs and shoals which extend 10 or 11 miles in directions E.N.E., East, and S.E. from Mallawallé. It is only the northern edge of these dangers, bounding the eastern part of Banguey South Channel to the southward, which require description, for there can be no possible object to induce risking a vessel amongst them, unless it is a gunboat in pursuit of pirates.

About $2\frac{3}{4}$ miles N.E. by E. from the detached cay off the eastern end of Mallawallé Island, is a small coral strip which dries, but surrounded by depths of 14 and 15 fathoms. One-third of a mile southward of this strip is a shoal half a mile in extent, with less than a fathom water over it. A mass of reefs and shoals, occupying a space $1\frac{1}{4}$ mile in extent, with 13 fathoms close to on their northern side, lies a mile eastward of the coral strip, just described; and E. by N. $\frac{1}{2}$ N., $3\frac{1}{2}$ miles from the same danger is a shoal half a mile in length, with only 7 ft. water on its northern end. This last danger, being always covered, is not so readily seen as the others, and it is important to bear this in mind, as the shoal occupies a prominent position, bordering as it does on the deep water of Banguey South Channel.

The Straggler, a small coral islet, with trees 20 ft. high, is a very useful object for guiding strangers into, and assisting them in navigating the eastern part of Banguey South Channel. From it the 7 ft. patch just described lies N.W. by W. $\frac{1}{4}$ W. nearly $1\frac{1}{2}$ miles, whilst westward of the islet are several other dangers. The reef surrounding the islet extends $1\frac{1}{4}$ mile in an E. by N. $\frac{1}{2}$ N. direction. About $1\frac{1}{2}$ mile S.E. from the East extreme of the Straggler Reef, and E. by S. $\frac{3}{4}$ S. from the islet, is the outer edge of a shoal having in some places less than 6 ft. water. This is the north-eastern danger of the Mallawallé group, and half a mile eastward of it is a $3\frac{1}{4}$ fathoms coral patch. Other dangers of the group extend 7 miles further to the southward, which was the limit of the *Rifleman's* survey in a S.E. direction from Banguey.

Fairway Shoal, at the eastern entrance of South Banguey Channel, is a coral shoal, from half to three-quarters of a mile in diameter, having a rock awash near its southern part, and $1\frac{1}{2}$ to 3 fathoms elsewhere; its southern

extreme is N.E. $\frac{1}{4}$ E., $2\frac{1}{2}$ miles from the Straggler, $1\frac{1}{2}$ mile N.N.E. $\frac{1}{2}$ E. from the eastern extreme of its reef, which limits the width of the channel southward of the shoal; the channel between it and S.E. Banguéy dangers is 3 miles wide. From the eastern part of this danger the highest apex of Mallawallé bears W. by S. $\frac{1}{2}$ S., distant 14 miles, and Banguéy Peak W.N.W., westerly, distant $27\frac{1}{4}$ miles.

Islands off the South Coast of Banguéy.—*The Molleangan Islands*, which form the north-western limit of Banguéy South Channel, have already been described (page 516); it is, however, proper to observe here that dangers extend three-quarters of a mile westward and two-thirds of a mile eastward of Little Molleangan; but Molleangan, a high conspicuous island, which points out the entrance of the channel from afar, is free from danger on those sides affecting the navigation of this channel. *Patanunan Island*, three-quarters of a mile eastward of the S.W. point of Banguéy, is 428 ft. high, serves as a useful object for bearings when passing through the channel. *Pagassan Island*, 3 miles eastward of Patanunan, is fringed by a reef which projects 3 cables from the southern part, and a cable farther off lies a rock awash; the island must therefore be neared cautiously. Three-quarters of a mile eastward of Pagassan is *Lampassan*, the southern part of which extends thence $2\frac{3}{4}$ miles in an E.N.E. direction. This island is also high, and from its southern and eastern points some peculiar spits of coral, dry at low water, project nearly three-quarters of a mile. The S.E. extreme of Banguéy is bordered by coral reefs, outside the edges of which, opposite the mouth of an inlet, lie two rather large detached patches, the South end of the outer one being a mile off.

Nearly $2\frac{1}{2}$ miles from the East end of Lampassan is the West end of *Carrington Reefs*, comprising several masses of coral, for the most part dry at low water, extending 4 miles in an E. by N. direction; they are a mile broad, and on the North side, 4 cables from the edge of the mass, is a detached spot of $2\frac{1}{2}$ fathoms. Between this last and the dangers extending from the Banguéy shore is a channel three-quarters of a mile wide, but which, as a matter of ordinary navigation, no vessel would require to use.

The main channel lies between the Carrington Reefs and those off the North part of Mallawalle, and by this channel only should strangers attempt to proceed, taking care not to near the former dangers under a depth of 15 or 13 fathoms; the apex of Pagassan bearing W. $\frac{1}{2}$ N. leads close to the southward, and the East end of Lampassan bearing N. by W. $\frac{1}{4}$ W. leads westward of a $4\frac{1}{2}$ -fathom patch lying 3 cables off the West end of them.

South-East Banguéy Dangers comprise an extensive group of reefs and shoals 10 miles in length, E. by N. $\frac{1}{2}$ N., and W. by S. $\frac{1}{2}$ S., and nearly 5 miles in breadth; they lie south-eastward of Bancawan Island and reefs, being separated from them by Bancawan Channel; the southern part is 9 miles south-eastward, and the eastern part $14\frac{1}{2}$ miles eastward of the S.E.

extreme of Banguey. The West end of the group is defined by two small isolated patches, dry at low water and steep-to; the northern patch lies almost half a mile, and the southern one somewhat more outside the body of the reefs, with depths of 12 fathoms between, so that a sharp look-out is essential when nearing them, and the same precaution will have to be observed when passing through the channel, as the reefs forming the southern edge of the mass are all steep-to. A space, about 2 miles in extent, at the eastern part of these dangers, is studded by a number of coral patches, with $1\frac{3}{4}$ to $3\frac{3}{4}$ fathoms water over them, and from the outer or eastern one the apex of Latoan Island bears N.W. by W. $\frac{3}{8}$ W., $9\frac{1}{2}$ miles; Banguey Peak W. by N. $\frac{1}{4}$ N., 24 miles; and the apex of Mallawallé S.W. by W., 14 miles.

The passage between the S.E. Banguey dangers and Carrington Reefs is nearly 2 miles wide, and perfectly safe.

Bancawan Channel, separating Bancawan Reefs from S.E. Banguey dangers, is three-quarters of a mile wide at its narrowest part, near the middle. The direction of the channel is nearly straight, and a N.E. $\frac{2}{3}$ E. course will lead between the East end of Carrington Reefs and the West end of the S.E. dangers, and through the fairway; but it will be necessary in practice to be guided more by a vigilant look-out for the reefs on each hand bounding the channel than by compass bearings: with proper precautions there will be no difficulty in taking a gun-vessel safely through.

DIRECTIONS FOR BANGUEY SOUTH CHANNEL.—Having rounded Sampanmangio Point, stand over to the eastward for the Molleangan Islands, bringing their apexes in line as they are approached. When arrived within 2 or 3 miles of them open Little Molleangan left of the apex of the larger island, and steer East into the channel; and, in order to keep well clear of Outer Shoal, avoid opening the whole of Patanunan (a black round looking island when viewed from near the entrance of the channel) right of Molleangan, before the apex of Little Molleangan is brought to bear N.N.E. Having passed Little Molleangan steer up more to the north-eastward, keeping a mile or so off Molleangan and Pantanunan; and, being past those islands, bring the apex of the latter to bear W. $\frac{3}{4}$ S. and steer the opposite course through the fairway between the South Channel dangers and the rock off the South end of Pagassan; Molleangan apex bearing W. by S. well clears the former, and Patanunan apex bearing W. by S. $\frac{1}{3}$ S. clears the latter danger.

Continue to steer an E. $\frac{3}{4}$ N. course, by preserving the opposite bearing of Patanunan apex, until the summit of the hill at the southern part of Pagassan bears W. $\frac{3}{4}$ N., when steer East for a mile or so, until the bearing changes to W. $\frac{1}{2}$ N., northerly; when by keeping it so, and steering the opposite course, the dangers off the North part of Mallawallé will be avoided.

When the highest hill of Mallawallé is brought to bear S.W. $\frac{1}{2}$ S., edge away a little to the southward—to give a wider berth to the S.E. Banguéy dangers—until the same peak bears W.S.W., when the opposite course E.N.E., carefully preserving the back bearing, will lead between the outer part of the S.E. Banguéy dangers and Fairway Shoal, and out of the channel into the Sulu Sea.

These directions will serve very usefully to assist in the safe guidance of vessels, but attention to them must be supplemented by a most vigilant and careful look-out from aloft. The best time for proceeding through from the westward is of course afternoon, with the sun astern, when there is seldom much difficulty in making out the various dangers as the vessel advances, which it is almost impossible to do with a glaring sun ahead.

BALABAC STRAIT, leading from the China Sea into the Mindoro or Sulu Sea, is bounded on the South by the islands of Balambangan and Banguéy, and on the North by the island of Balabac. The greater part of the body of the strait is occupied by coral dangers, far too numerous to admit of detailed description. These dangers are delineated upon the chart, the result of the *Rifleman's* survey in 1869.

The high peak of Balabac Island is the most conspicuous object in the vicinity of the strait, and visible from all parts of it. Banguéy and Balabac Peaks lie N. $\frac{1}{2}$ E. and S. $\frac{1}{2}$ W. of each other, $37\frac{1}{2}$ miles apart, and as most of the dangers and channels are to the eastward, and therefore at right angles to that line, these peaks are of the first importance for determining the position of vessels when navigating this dangerous strait.

BALABAC ISLAND, lying off the S.W. extremity of Palawan Island, and about 26 miles northward of Balambangan, is nearly 20 miles in extent North and South, and 9 miles East and West. On the southern half of the island are several ranges of high cliffs, exhibiting great variety in the outline of their summits; only two, however, are of sufficient importance to require particular description. *Steep-fall Range*, the first of these, is about 2 miles from Cape Melvill, the South point of the island; the summits of the several hills composing it form together a semicircular line, convex to seaward, and being of nearly the same elevation, 850 ft., present a somewhat table-like appearance, whence the sides fall in a very precipitous manner; hence the name. These features will enable strangers to readily recognise this range, without confounding it with the small range at the S.W. extreme of the island, the highest part of which is, moreover, but 330 ft. From Steep-fall Range, other hills, less elevated, extend in a north-westerly direction nearly as far as the West extreme of the island; and northward from the same range other ranges, varying in height from 1,200 to 1,300 ft., extend to Dalawan Bay; these last are separated from the still higher ranges of Balabac Peak by a valley which runs in a W.N.W. direction

across the island. *Balabac Peak*, the other object calling for special remark, is a sharp hill near the eastern shore, 5 miles northward of Steep-fall Range, and obtains the greatest elevation on the island, 1,900 ft. Eastward of the peak some ranges slope down to Dalawan Bay and the shore northward of it; and northward of these, separated from them by a valley, other ranges extend along the coast as far as Calandorang Bay; westward of the peak is a range of six or seven sharply marked apexes, running in a N. by E. direction to the inner part of the same bay, and westward of this last are several other ranges, inferior in altitude, which stretch over nearly as far as the West extreme of the island, joining those which extend from Steep-fall Range. On the northern part of the island, joining those which extend from Steep-fall Range. On the northern part of the island, beyond Calandorang Bay, are several detached hills, the highest, 750 ft., being situated near the coast, $1\frac{1}{2}$ mile northward of the bay.

The West Coast of Balabac cannot be closely approached on account of numerous reefs and shoals which extend several miles off. These dangers extend over many miles, and are of two kinds: the first consists of large reefs, most of which begin to uncover at the first of the ebb, the whole of them being dry at low water; whilst the second comprises shoals and shoal banks, none having less than 10 ft. water over them at low tides; these lie outside the reefs which dry, some of them being 7 miles from the shore. Should closer information be required, it will be obtained more readily from the chart than from a written description.

The following is a very brief description of the dangers lying W. and S.W. of Balabac:—

The South extreme of *Gnat Reef*, on which H.M. gunboat of that name was wrecked, lies 2 miles N.W. from the S.W. extreme of Balabac; thence the reef extends $1\frac{1}{2}$ mile to the northward. There is a channel round it with many dangers. N.W., 3 miles from the South end of Gnat Reef, is the South extremity of *Balabac Great Reefs*, which thence extend 8 miles to the northward, and dry to the distance of from 3 to 5 miles from the shore. *S.W. Patches*, a line of shallow water from $3\frac{3}{4}$ to 9 fathoms, lies 2 miles South of the South extreme of Gnat Reef and Balabac Great Reefs. *The Western Shoals*, and numerous detached patches of $2\frac{1}{4}$ to 5 fathoms, extend to a distance of about $3\frac{1}{4}$ miles West from the western side of Balabac Great Reefs. *Ada Reef*, dry at low water, lies off the N.W. side of Balabac Island. It is $2\frac{1}{2}$ miles long E.N.E. and W.S.W., three quarters of a mile broad at its West extreme, and lies a mile outside the shore reef just mentioned, the channel between being full of shoals and patches of reef. From the N.W. extreme of this, the outermost danger off the southern part of Blind Harbour, Balabac Peak bears S.E. by E., $11\frac{3}{4}$ miles, and the apex of the hill over the northern point of Blind Harbour N.E. by E. $\frac{1}{4}$ E. $6\frac{1}{2}$ miles.

Ada Reef is connected by a coral bank, having less than 3 fathoms water,

with the dangers of Blind Harbour, and those extending from the shore thence to Cape Disaster.

North-West Shoal, the last of the Balabac dangers to be noticed, lies about 3 miles north-eastward of Ada Reef, 2 miles distant from the coast northward of Blind Harbour; it is $2\frac{1}{2}$ miles long N.E. by E. and S.W. by W., and half a mile broad. This is a dangerous shoal, having as little as $1\frac{3}{4}$ fathom over some parts, and only $2\frac{1}{2}$ to 3 fathoms over the greater part of its extent: to avoid this danger, the S.W. end of Balabac Peak, must not be brought southward of S.E. $\frac{3}{4}$ S., nor West point South of S. $\frac{1}{4}$ E.; and Cape Disaster, the North point of the island, if not brought to the northward of E. $\frac{1}{2}$ N., will clear the N.E. end.

When standing towards the dangers off-lying the West coast of Balabac in the afternoon, when the sun will be astern, the outer shoals, and also the reefs inside of them, will generally be seen a long way off, but always in sufficient time to avoid them; but if the sun is ahead, more especially if it is low, the outer shoals are sometimes difficult to make out until close to them. The soundings are so variable and uncertain, under depths of 30 fathoms, as to afford little assistance to seamen, and in the daytime a good look-out is of the first importance; but at night the soundings must be carefully attended to if near these dangers, and vessels should not decrease their depths under 40 fathoms off the S.W. and West parts of the island, nor under 50 fathoms off the N.W. part.

Blind Harbour is an opening nearly 2 miles wide on the N.W. side of Balabac, having the appearance of a capacious bay, being $4\frac{1}{2}$ miles in extent. It is, however, blocked up with coral, except near the points at the entrance, where there is a narrow channel between the reefs, with 9 and 10 fathoms water.

From Blind Harbour to Cape Disaster, the North extreme of Balabac, and round the northern extremity of the island, the coast is low, with two small clifty hills a little inland. It is fronted by a reef, which at low water dries from 4 to 5 cables, and off Cape Disaster 7 cables from the shore. Shoal water extends some short distance outside the reef, and near Blind Harbour stretches off more than a mile from the coast.

The Eastern side of Balabac Island is tolerably bold, with deep water close to the shore. From Cape Melville, the South point of the island, the coast to Dalawan Bay trends to the N.E., and is steep-to, except at the cape and the N.E. point of Clarendon Bay, a small inlet near it, off which reefs, dry at low water, extend 2 cables.

The coast northward of Dalawan Bay trends North a little westerly; it is fringed by a reef, which extends from 1 to $1\frac{1}{2}$ cable from the shore, and has three small inlets, the southernmost of which is called Calandorang.

From Candaraman, the northernmost inlet, the coast takes a more westerly

direction for $2\frac{1}{2}$ miles to Encampment Head, a small bushy isthmus nearly a mile to the eastward of Cape Disaster.

From Cape Melvill, the South point of the island, reefs extend off half a mile, and from the S.W. part of the island nearly a mile: some distance outside the shore reefs the ground is foul, with detached shoal spots here and there; from the outermost of these, a 3-fathom patch, the right extreme of the southern part of the island bears N.E. by E. $\frac{1}{2}$ E., $1\frac{3}{4}$ miles, and the S.W. extreme N. by W. $\frac{1}{2}$ W. $1\frac{1}{2}$ mile: vessels should not come nearer than 2 miles to the coast between Cape Melvill and the S.W. point of Balabac.

Clarendon Bay is a small inlet, opening into the coast in a north-westerly direction, with depths of $3\frac{1}{2}$ to 5 fathoms, five cables inside the points; from the southern point the shore reef extends off a very short distance, but from the northern point it projects more than 2 cables in a S.E. direction, narrowing the width at the entrance to barely three-quarters of a cable. Clarendon Bay, after being surveyed by Mr. Doorly, navigating midshipman of H.M.S. *Rifleman*, was used as a place of shelter from S.W. gales by H.M. gun-vessel *Avon*, when engaged in recovering guns and stores from the wreck of the *Gnat*.

Dalawan Bay, convenient for wooding and watering, and affording good shelter with south-westerly winds, has its entrance $6\frac{1}{2}$ miles from the South point of Balabac Island, with Balabac Peak bearing N.W. $2\frac{1}{2}$ miles. When off Dalawan Bay, its locality will be readily recognised by the low land running in a W.N.W. direction from the beach across the island, separating the high land about Balabac Peak from the Transept, a smooth table-topped hill on the South side of the bay.

The bay is about a mile wide from shore to shore at the entrance, and about three-quarters of a mile deep. Reefs, which dry at low water, project from both points at the entrance, contracting the channel to a little less than 7 cables; that on the northern side has a rock at its extremity called Buoy Rock, lying South 2 cables from the shore, but rocky ground extends $3\frac{1}{2}$ cables beyond this in a north-easterly direction, having in some parts only 3 fathoms water, with 5 and 7 fathoms close to the edge.

There is a white rock on the shore in the south-western corner of the bay, $1\frac{1}{2}$ cable to the northward of which is the entrance of the river. A reef of rocks one cable in extent, showing only at low water springs, lies to the eastward of the entrance of the river, upwards of 2 cables from the beach.

The shores of the bay are densely wooded, the entrance on either side being fronted with mangrove. The best anchorage is about the centre of the bay in 9 fathoms, mud, nearly half a mile from the beach. South-eastward about a quarter of a mile from the White Rock, where the mangrove joins the foot of the hills in Dalawan Bay, is a rivulet of *good water*; there are also one or two good streams on the northern shore of the bay, but neither of

them was found so eligible for the purpose of watering as the river; in the dry season the water must be obtained some distance up to be good. The river is navigable for boats on ordinary occasions about a mile, where there are a few houses and some cultivated ground occupied by Malays, who by turns, as opportunities offer, act the parts of pirates or husbandmen. Their character is decidedly questionable, and merchant boats' crews should be on their guard.

It is high water, full and change, at Dalawan Bay at 11^h; and the rise of tide is 5 ft.

Calandorang Bay, or *Puerto del Principe Alfonso*, 6 miles northward of Dalawan Bay, is a Spanish settlement, established a few years ago for the purpose of developing the trade of Palawan and other neighbouring islands; it has not yet succeeded, however, in making any progress, for there is absolutely no trade whatever. It is a naval establishment. No supplies of any kind are to be procured; bullocks, and other necessaries for the use of the garrison, being sent periodically from Manila.

The bay is 6 cables wide at its entrance, and 1½ mile deep. The South point of the entrance is formed by a hill, 110 ft. high, named *Almirante Gill*, upon which is a lighthouse; the North point is mangrove, with hills a short distance inside of it: coral and shoal water extend nearly a cable off both points.

The light on *Almirante Gill* is elevated 268 ft. above the mean level of the sea, and in clear weather should be seen from a distance of 10 miles. The tower is square, white with a red base, and surmounted by a red lantern.

On the South shore, a cable or so inside the lighthouse, is a coal store and small jetty, and further on two bluffs, or heads, project from the higher ranges on to the beach; from the first of these coral, dry at low water, and shoal soundings, extend about a cable, and from the last a coral ledge stretches out rather more than half that distance. Beyond the bluffs, about half a mile from the entrance, is a landing pier, the town being built on the shore of the bay westward of it, and terminating at a third bluff, or spur, protruding from the high range of hills behind. The North shore of the bay is all mangrove; from two points, about half a mile from the entrance, coral, dry at low water, extends off about 1½ cable; and from a point opposite the town, a coral reef, with some rocks above water upon it, extends off almost as far.

A 3-fathom patch, with 3¾ fathoms around it, lies off the first bluff westward of the coal store; from it the lighthouse bears E. ¼ S., and the blockhouse S.W. ¼ S.

The anchorage in the bay is good, the bottom being of mud, and during the S.W. monsoon it is perfectly sheltered and secure; a convenient position for a moderate sized ship to anchor in is just outside a line between the lighthouse and the dry rocks, with the former bearing E. by S. ½ S., the bluff

westward of the town S.W. $\frac{1}{2}$ W., and the block-house fort, a white octagonal-shaped building, S.W. by S. : small vessels can go farther in on the line of bearing of the bluff, just mentioned, and anchor where most convenient. The N.E. monsoon occasionally blows into the bay with considerable force, sending in also a nasty chop of a sea, so that it is better, at that season, to anchor more over towards the North shore, taking care to have plenty of room for veering. At Calandorang Bay it is high water, full and change, at 11^h; springs rise 6 ft.

A steamer will find no difficulty whatever in entering Calandorang Bay guided by the chart. It is, however, very difficult and dangerous of access for sailing vessels, on account of the deep water outside, and of the strong tides and currents which sweep along the East coast of Balabac, in the strength of the monsoon. A sailing vessel bound for that port should be provided with a heavy kedge, and stout hemp, or coir, cable, to enable her to bring up in deep water, in case of missing the port, which she should not attempt to make without a commanding breeze. About 3 or 4 cables off the port the depths are 35 and 40 fathoms, and a mile off they are over 100 fathoms. A vessel coming from the southward should make for Dalawan Bay, if the wind should threaten to fail her, and await there a more favourable opportunity for entering Calandorang Bay; for if the wind should die away when she was a mile or so off the port she would be swept in the most helpless manner towards the numerous dangers to the northward: with a commanding breeze, however, no difficulty will be found in entering, as directed for steam-vessels.

It must be borne in mind that, on account of the very deep water along the East coast of Balabac, sailing vessels bound either for Dalawan or Calandorang Bays must hug the shore, which is pretty bold, the fringe of reef extending but a very short distance from it.

NORTH AND N.E. COASTS OF BANGUEY.—Between Samarang Point (page 516) and the North point of Banguey the coast line falls back into a couple of bays. *North Guhuan*, an islet on the western part of a reef three-quarters of a mile in extent, lies nearly a mile off the North point of Banguey, and $5\frac{1}{2}$ miles E. by N. $\frac{3}{8}$ N. from the sand cay off Samarang Point. In this space, westward of Guhuan, there are no offlying dangers.

Off-lying Dangers are numerous, and extend a long way from the N.E. part of Banguey.

A shoal bank extends from the reef surrounding North Guhuan in an E. $\frac{3}{4}$ S. direction, $4\frac{1}{2}$ miles; from the middle of it a tongue projects half a mile to the northward, having a patch of dry reef near the centre, and a spot of 3 fathoms; E. by N., a quarter of a mile from the extreme. Two sand cays, surrounded by reefs, lie at the eastern end of the bank; and between this part of it and the shore dangers, which stretch off about three-quarters of a mile, is a narrow run, with 4 and 5 fathoms depths of water on it.

Louisa Shoal, coral, with $1\frac{1}{2}$ to 3 fathoms water over it, 8 cables in extent N.W. and S.E., and 4 cables broad, lies half a mile outside the bank, just described; from its North extreme North Guhuan bears S. by W. $\frac{1}{4}$ W., distant $1\frac{1}{2}$ mile, and from its West extreme Samarang Point S.W. by W. $\frac{1}{4}$ W. nearly 6 miles. Nanyangit and Samarang Points in line, bearing S.W. $\frac{3}{4}$ W., lead a good half mile outside this danger.

Maggie Reef, a strip of coral a quarter of a mile long, dry at low water, lies on the northern part of a coral shoal, about 3 miles in circumference, situated E. by N. a little over $2\frac{1}{2}$ miles from Louisa Shoal, and having upon it several rocks, just below water. North Guhuan, bearing S.W. by W., will lead half a mile outside, or N.W. of it; East Guhuan bearing S.S.E. $\frac{1}{2}$ E. leads well clear to the eastward.

Between Louisa and Maggie Shoals are several $4\frac{1}{2}$ and 5 fathom patches, and, outside the line of those dangers, two spots of $3\frac{1}{2}$ fathoms, one bearing N.E. $\frac{3}{8}$ N. nearly 3 miles, and the other N.E. $\frac{3}{8}$ E. nearly $3\frac{1}{2}$ miles, from North Guhuan. A small spot of $5\frac{1}{2}$ fathoms lies on the edge of the bank, and close to the northward of it are 12 fathoms: from this spot North Guhuan bears S.W. $\frac{1}{8}$ S.; the right extreme of South Mangsee island N. by E. $\frac{1}{4}$ E.; and East Guhuan S.S.E. $\frac{1}{4}$ E.

East Guhuan, an islet about the same size as North Guhuan, stands on the West side of a coral shoal which extends nearly half a mile north-westward, 3 cables north-eastward, and nearly a mile South and south-eastward from it. About a mile N.N.W. of East Guhuan, a little to the eastward of a line between it and Maggie Shoal, is a 9 ft. patch, about 3 cables in extent.

Banquey Outer N.E. Dangers are a cluster of reefs lying to the north-eastward of those just described, and divided from them by a clear channel three-quarters of a mile to $1\frac{1}{4}$ mile wide, with depths of 7 to 10 fathoms; they extend $3\frac{1}{2}$ miles in a N.W. $\frac{1}{2}$ W. and opposite direction, and a little over a mile in a direction at right angles to their length. A large reef occupies the centre of the mass, and dries within three-fourths of a mile of each end; upon the N.E. extreme of the reef is a sand cay, which is very useful for pointing out the locality of these dangers, they being 6 miles distant from the shore. Shoal water stretches off nearly a mile eastward of the cay, which must not be neared anywhere to within a mile, except at the West side, where the reef extends off only a short distance. Close to the outside edge of these shoals are 11 or 12 fathoms.

The East coast of Banquey is fronted by dangers which extend off several miles; they consist, for the most part, of extensive reefs, dry at low water, separated from each other by narrow channels—impracticable for navigation; it is only the outer ones that require detailed description.

Kahamkamman is the name of a small islet, 2 miles S.E. of East Guhuan: It lies towards the N.W. end of a coral shoal about a mile in extent, the part surrounding the islet drying at low water. South-westward of this

shoal, separated from it by a $5\frac{1}{2}$ -fathom channel, about half a mile wide, is another, about three times as large, having three islets, a sand cay, and several extensive patches of reef. The S.E. islet is named Balundangan, a mile S.W. of which is an island about $1\frac{1}{4}$ mile long, and rather more than half a mile off the coast.

May Williams Shoal, 9 cables long N.W. and S.E., and 4 cables broad, having from $2\frac{1}{2}$ to 3 fathoms water over it, lies half a mile south-eastward of Kahamkamman Shoal; from its S.E. end the islet bears N.W. by N., distant 2 miles, and the apex of Latoan S.S.W. $\frac{1}{2}$ W., distant $3\frac{1}{2}$ miles; around the shoal are depths of 7 to 9 fathoms.

Sampson Patches, three in number, have $3\frac{1}{2}$ to 5 fathoms water on them; from the outer patch, Kahamkamman bears W. $\frac{1}{2}$ N., distant 3 miles, and the apex of Latoan S.W. $\frac{1}{2}$ S., nearly $5\frac{3}{4}$ miles.

Latoan and Bancawan Islands and Reefs comprise four or five islands, several extensive reefs, and many small detached dangers, the whole forming a group 7 miles long North and South, and $5\frac{1}{2}$ miles wide. Only boats can pass between the various reefs composing the group; but, between them and the reef fronting the Banguay shore, there is a deep water channel, through which it is possible for a gun-boat to pass, although, near the West point of Bancawan, it is narrowed to little more than a cable by a small reef in the middle.

Latoan is an oval-shaped island, a mile long N.W. and S.E., the trees upon it rising to a kind of low apex near the centre. *Bancawan*, $1\frac{1}{2}$ mile south-westward of Latoan, is an irregular shaped flat island, $2\frac{1}{4}$ miles long North and South, and $1\frac{3}{4}$ mile broad. *Outer Latoan Patch* is the name given to the eastern one of three isolated patches which lie close to the N.E. edge of the large reef surrounding Latoan. It is about 2 miles in circumference, with 1 to 3 fathoms water over most parts of it; and a rock, a few feet under water, lies near its eastern margin. From this last, Kahamkamman bears N.W. $\frac{1}{4}$ N., distant $4\frac{1}{4}$ miles, and Latoan apex S.W. by W. $\frac{3}{4}$ W., distant $3\frac{3}{4}$ miles. *East Banguay Patches* are two small coral shoals, lying three-quarters of a mile and a mile, respectively, outside the Bancawan Reefs; the inner one has as little as 2 fathoms upon it, but the outer one not less than $2\frac{3}{4}$ fathoms. From the latter, Latoan apex bears W.N.W. $3\frac{3}{4}$ miles, and the left extreme of the round island, south-eastward of Bancawan, S.W. by W. $\frac{1}{4}$ W., $4\frac{3}{4}$ miles.

Mangsee Great Reef, which forms the northern limit of the main channel through Balabac Strait, lies $4\frac{1}{2}$ miles northward of North Guhuan, and a little over 3 miles, in the same direction, from the Louisa Shoal; its distance from the 10-fathom line at the edge of the shore bank is $1\frac{1}{2}$ mile. The reef is 5 miles long E. by N. and W. by S., and $2\frac{3}{4}$ miles broad. It is nearly everywhere covered at high water, but a sand cay upon the eastern part is

generally visible from aloft when near the edge. At low water the reef presents a vast expanse of coral and sand, with lagoons here and there.

From the West end of the reef shoal water, under 10 fathoms, extends about 2 miles in a W.S.W. direction. The soundings over this part are very irregular, and, although the least depth discovered was 4 fathoms, the locality should be avoided. From the outer part of this shoal water Banguay Peak bears S.S.W. $\frac{1}{4}$ W., and the apex of North Mangsee N.E. by E. $\frac{1}{2}$ E.

The **MAIN CHANNEL** through Balabac Strait is limited to the southward by the 10-fathom line defining the edge of the shoal bank which extends from the shore, encompassing the various dangers and shoal patches lying off the North and N.E. coasts of Banguay; and it is limited to the northward by Mangsee Great Reef, the southern part of which is $1\frac{1}{2}$ mile distant from the edge of the bank on the Banguay side. The depths in the channel are not regular, varying from 14 to 23 fathoms, the deepest water being rather nearer the reef than the middle of the channel.

Vessels coming from the south-westward, and bound through Balabac Strait in the N.E. monsoon, will find the Main Channel the most convenient to proceed by, attending to the following:—When making for the entrance of the strait, and nearing the N.W. part of Balambangan, care must be had not to bring Point Buttun to the westward of S.W. $\frac{1}{4}$ S., nor to come into less than 14 or 13 fathoms, in order to keep clear of the dangers extending from the shore, and of the Siagut Shoal. Siagut Point, the North point of the island, must not be approached nearer than 2 miles, nor under a depth of 8 fathoms. North Hill, on the North part of Banguay, if not brought to the eastward of E. by S. $\frac{1}{4}$ S., will lead a good half mile outside all the dangers off Siagut Point, as also those extending North of Tiga Islet, which last should not be neared to a less distance than a mile, or under a depth of 8 or 7 fathoms. From Tiga Islet the Banguay coast may be approached to 9 or 8 fathoms, until North Guhuan is brought to bear about S.S.E., when it will be well, especially for large ships, not to come inside the 10-fathom edge of the bank extending from the Banguay shore, as the sudden variations of the soundings on the bank are very alarming, and no less perplexing, to strangers. The light green colour of the water over the Great Mangsee Reef will, even at high tides, always enable a good look-out aloft to make out the edge sufficiently far off to permit of a vessel being guided past it at a safe distance; and when over on the South side of the channel, the first cast of 10 fathoms, or under, will denote the edge of the bank. Having brought the apex of North Mangsee to bear westward of North, vessels may stand on to the bank if desirable to do so, but seamen must beware of a scant wind, or lee tide, sagging them to leeward towards Banguay Outer N.E. reefs, and be careful to avoid bringing North Hill anything to the westward of S.W. by W. $\frac{1}{2}$ W. until the West extreme of North Mangsee is shut in behind South Mangsee.

Coming from the Sulu Sea, the Mangsee Islands should be made bearing about West, when a course about W.S.W. will lead up to the entrance of the channel. If, however, the channel should be made more from the southward, and, as the apex of North Mangsee begins to shut in behind the southern island, 14 or 13 fathoms may be had, a vessel will be over towards Banguay Outer N.E. reefs, and care must be taken to bring North Hill of Banguay to the southward of S.W. by W. $\frac{1}{2}$ W. before proceeding further to the westward.

Mangsee Danger Bank* includes within its limits the *Mangsee* and *Salingsingan Islands*, together with the extensive dangers adjacent to them, and Loxdale and Jessie Shoals, besides many other smaller ones. Its length E. by S. $\frac{1}{2}$ S. and W. by N. $\frac{1}{2}$ N. is 10 miles, and its breadth $4\frac{1}{2}$ miles at the eastern end, tapering to a point at the opposite extreme.

South Mangsee Island is somewhat round shaped, about half a mile in diameter; it stands upon a patch of reef which extends from it a mile eastward, 6 cables westward, half a mile south-eastward, and less distances in other directions.

North Mangsee Island is half a mile north-westward of South Mangsee, and, like it, is covered with trees; these rise to a kind of apex near the centre, 130 ft. above the level of the sea. The island is 7 cables long and 3 cables broad, and from its East end reefs and shoals extend—beyond those projecting from South Mangsee—for a distance of $2\frac{1}{4}$ miles, and some patches of 4 to 7 fathoms extend half a mile further in an easterly direction. From the West end a line of reefs and shoals runs off in a W. by N. $\frac{3}{4}$ N. direction, nearly $3\frac{1}{2}$ miles.

Jessie Shoal,† $1\frac{1}{2}$ mile long, E.N.E. and W.S.W., and half a mile broad, lies about 2 to 3 miles E.N.E. of the Mangsees, having as little as 6 ft. over it in places. This danger is situated at the East part of the bank, and some shoal spots run off from it in a south-easterly direction. From 10 fathoms outside these, Salingsingan bears N.W. by W. $\frac{3}{4}$ W., distant $4\frac{1}{4}$ miles, and the left extreme of South Mangsee Island W.S.W., distant $3\frac{1}{2}$ miles.

Salingsingan Island is a mere strip of coral and sand, covered with trees; it is rather more than half a mile long, N.W. by W. $\frac{1}{2}$ W. and S.E. by E. $\frac{1}{2}$ E., and shoals extend 2 miles westward of the island, and three-quarters of a mile eastward.

* The limits of this bank, as is the case with all the other similar banks encumbering Balabac Strait, is defined, on the chart, by a danger line; and as the separate dangers comprising these banks lie too close together for vessels to pass amongst them, they are not described minutely, but only in general terms, and as briefly as possible.

† It must have been on this shoal that the *Black Adder* grounded in November, 1873, as described in a letter to the "Nautical Magazine" of May, 1874.

Lordale Shoal, forming the West end of the Danger Bank, lies $1\frac{1}{4}$ mile westward of the dangers extending from the islands of North Mangsee and Salingsingan, the depths between being from 22 to 34 fathoms. It is a coral shoal, nearly $1\frac{3}{4}$ mile long, E. $\frac{3}{4}$ N. and W. $\frac{3}{4}$ S. From the West end of this danger Banguay Peak bears S.S.W., South Mangsee Island S.E. by E. $\frac{1}{2}$ E., and Salingsingan E. $\frac{1}{4}$ S.

Mangsee Channel, separating Mangsee Great Reef from Mangsee Danger Bank, is a mile wide at its narrowest part, between the shoal water extending half a mile off Great Reef and that stretching off the same distance from South Mangsee; the depths there are irregular, 14 to 17 fathoms near the reef, and 24 to 33 fathoms towards the island, and throughout the channel the depths are greater on the side of the Mangsee Danger Bank.

Ordinary navigators will rarely have occasion to use this channel, but in case of necessity, the following directions may be of assistance:—Coming from the westward, and having sighted the Mangsee Islands, bring the centre of the South one to bear E. by S., and steer for it, carefully preserving the bearing; when the West end of North Mangsee bears N.E. by E. $\frac{3}{4}$ E. steer S.E. by S., passing midway between the islands and Great Reef. With a good compass and a vigilant look-out, no difficulty will be found in following these directions, and passing safely through this channel.

Coming from the eastward, a vessel must be guided by the look-out alone to the entrance of the channel, which, being arrived at, she should pass through the middle, steering a N.W. by N. course; when the West end of North Mangsee bears N.E. by E. $\frac{3}{4}$ E., and the centre of South Mangsee E. by S., steer W. by N. out of the channel.

GREAT DANGER BANK is very extensive, and comprises many shoals, amongst which no vessel should venture. It is 14 miles long in a W.N.W. and opposite direction, and 8 miles broad at its N.W. end, gradually decreasing in breadth towards the opposite extreme; the outline of the entire bank closely resembles the form of a shoulder of mutton.

S.E. Shoals denote several small coral patches situated at that end of the bank; they extend over a space about 3 miles in diameter. From the S.E. extreme of the bank Balabac Peak bears N.W. $\frac{1}{2}$ W., North Mangsee apex S.W. by W. $\frac{3}{4}$ W., and Banguay Peak S.W. $\frac{1}{2}$ W. southerly.

Sand Cay, the only conspicuous object marking any part of the bank, stands at the southern side of it, about 5 miles westward of the S.E. extreme, and $3\frac{1}{2}$ miles northward of the East end of Mangsee Danger Bank. From the centre of the cay the left extreme of South Mangsee bears S.W. $\frac{1}{2}$ S. 6 miles, centre of Salingsingan W. by S. $\frac{3}{4}$ S. 5 miles, and Balabac Peak N.W. $27\frac{1}{2}$ miles.

Middle Shoals are a cluster of coral patches, lying on that part of the bank implied by their name. *North Patches*, two in number, lie along the North edge of the bank, and have nowhere less than $3\frac{1}{2}$ fathoms water over them.

N.W. Shoals lie along the edge of that portion of the bank designated by their name, and near the eastern end of them is a spot with only 9 ft. over it. From the 10-fathom line bounding the north-western extreme of the shoal patches, Banguay Peak bears S. by W. $\frac{3}{4}$ W., Balabac Peak N.W. $\frac{3}{4}$ N., Lumbucan N. $\frac{1}{2}$ W., and Salingsingan S.S.E. $\frac{3}{4}$ E.

MIDDLE CHANNEL, separating Mangsee Danger Bank from Great Danger Bank, is a mile wide at its narrowest part, between the shoals extending nearly three-quarters of a mile eastward of Salingsingan and those extending 3 miles westward of Sand Cay, increasing greatly in width towards both ends.

Middle Channel lies quite out of the ordinary route of ships, but it may be safely made use of, if necessary, by attending to the following directions:— Coming from the westward, shape a course to sight Salingsingan Island between the bearings of E. by S. $\frac{1}{2}$ S. and S.E. The former bearing leads a quarter of a mile northward of Loxdale Patch, and the latter close to 9 fathoms on the edge of Great Danger Bank. Having made out Salingsingan, and being arrived within 4 or 5 miles of it, the fairway course through the channel is E. by S. $\frac{3}{4}$ S., passing a good mile northward of Salingsingan, and bearing in mind that shoal water stretches off nearly a mile in a N.W. by W. direction from that island. Being past Salingsingan the Sand Cay should be seen about three points on the port bow; proceed on the same course, and pass out of the channel, remembering that the centre of Salingsingan bearing W. by N. $\frac{1}{2}$ N. leads close to the Jessie Shoal, and bearing W. $\frac{1}{2}$ S. close to the edge of the Great Danger Bank.

Coming from the eastward, the channel must be approached cautiously, and if near the S.E. part of Great Danger Bank, care must be taken not to bring the apex of North Mangsee to the southward of W. by S. $\frac{3}{4}$ S., and a sharp look-out kept for the Sand Cay and Salingsingan; when the last is sighted, the centre must be brought between the bearings of W. by N. $\frac{1}{2}$ N. and W. $\frac{1}{2}$ S., and a mid-channel course, W. by N. $\frac{3}{4}$ N., steered through the channel, passing a mile to the northward of Salingsingan; when past that island, its centre must not be brought to the eastward of E. by S. $\frac{1}{2}$ S. till Balabac Peak bears N.N.W. in order to keep clear of Loxdale Patch, nor to the southward of S.E. until Lumbucan bears North in order to avoid Great Danger Bank.

Ray Bank, composed of sand, underneath which there is probably coral, is a mile long E. by N. $\frac{1}{2}$ N. and W. by S. $\frac{1}{2}$ S., and half a mile broad, the least water near the centre being 4 fathoms. It lies about $4\frac{1}{2}$ miles eastward of the N.W. shoals on the Great Danger Bank.

Ellis Shoal, 3 miles north-eastward of Ray Bank, is a coral bank, $2\frac{1}{2}$ miles long in an E. $\frac{3}{4}$ N. and opposite direction, and 6 cables broad. The western half, having 9 to 6 fathoms water over it, is not dangerous, but the eastern half is so, there being but $2\frac{1}{2}$ and 3 fathoms over the greater part of

it. From the West extreme of the shoal part, Balabac Peak bears N.N.W. $\frac{3}{4}$ W., and the centre of Lumbucan N.N.E. $\frac{1}{2}$ E.

Simanahan Reef and Channel.—The reef is about $1\frac{3}{4}$ mile northward of North Patches on the Great Danger Bank, situated near the centre of a coral bank 5 miles long, E. $\frac{1}{2}$ N. and W. $\frac{1}{2}$ S., and three-quarters of a mile wide. The part, dry at low water, has a sand-bank near its centre, which is just below the surface at high water; this serves, even when covered, from the light colour of the water over it, to point out the position of the reef from a considerable distance. From the West extreme of the bank the centre of Lumbucan bears N.N.W. $\frac{3}{4}$ W. $5\frac{3}{4}$ miles, and Steep-fall Range, on Balabac Island, W. by N. $\frac{3}{4}$ N. $15\frac{1}{2}$ miles.

The channel between Great Danger Bank and Simanahan Reef is perfectly free from danger with soundings of 24 to 30 fathoms. All that is necessary for its safe navigation is to pass about three-quarters of a mile to the southward of the reef on an East or West course, but occasion can very seldom arise to render this a convenient channel to proceed by.

Doorly Patches are several small coral banks, the centre of them lying N N.E. $\frac{1}{2}$ E., $3\frac{1}{2}$ miles from the centre of Simanahan Sand-bank. The general depths over them are 7 to 10 fathoms, and no less than $6\frac{1}{2}$ fathoms could be discovered anywhere upon them.

Lumbucan Danger Bank, $5\frac{1}{2}$ miles long N.E. by E. and S.W. by W., and $2\frac{3}{4}$ miles wide, comprises Lumbucan Island, with the dangers extending around it, and also some isolated shoals southward and north-eastward of it.

Lumbucan Island, bearing S.E. by E. $\frac{1}{4}$ E. from Balabac Peak, and 9 miles distant from the shore, is small, low, and wooded, with the trees gradually rising from the centre. It is surrounded by a reef and shoal water. *South Shoal* lies $1\frac{1}{2}$ mile southward of the island. It is half a mile in extent, with $1\frac{3}{4}$ to 3 fathoms water over it, and uneven depths. *N.E. Shoals*, some coral patches, with $1\frac{3}{4}$ to 3 fathoms over them, lie a mile north-eastward of the dangers encompassing Lumbucan.

Lumbucan Channel, limited to the southward by Ellis Shoal and Simanahan Reef, and to the northward by Lumbucan Danger Bank, is 4 to 5 miles wide, and perfectly free from danger. Doorly Patches divide the channel at its eastern end, the passage northward of them being 4 miles, and the one southward of them 2 miles wide.

If bound to the north-eastward, this channel, on account of its capaciousness, is a very good one to use; and to ensure a safe navigation, it will be only necessary to keep a proper look-out for the dangers limiting it, and when near them to pay attention to the bearings (previously given) of the different land objects which point out their extremes.

Comeeran Danger Bank, $2\frac{3}{4}$ miles long E.N.E. and W.S.W., and a mile broad, includes within its limits Domeeran Island and two shoals. Natives

from Balabac frequent the island for the purpose of catching turtle, which at times resort here in great numbers.

Comeeran Island, one-fourth the size of Lumbucan, but similar in character, lies N. $\frac{1}{4}$ E. 5 miles from that island. It is surrounded by a reef, extending from 1 to 2 cables off.

A shoal, nearly half a mile in extent, with 2 to 3 fathoms water over it, lies south-westward of Comeeran, its outer edge being distant nearly $1\frac{1}{4}$ mile; and another shoal, about the same size, having $2\frac{1}{4}$ to 3 fathoms over it, lies a little farther off in an easterly direction. Balabac Peak bearing W. $\frac{3}{4}$ N. leads southward of all the dangers near Comeeran, and bearing W. $\frac{1}{4}$ S. northward of them; Lumbucan bearing S. by E. $\frac{1}{2}$ E. leads westward, and the extreme of the trees on the North point of that island bearing S.S.W. leads eastward of them.

Comeeran Channel is $3\frac{1}{2}$ miles wide between the dangers surrounding Lumbucan and the S.W. shoal off Comeeran. The soundings in it are very irregular, with 6 to 10 fathoms over coral patches in places; and a bank, about a mile in extent, lies near the middle, over the southern part of which are $4\frac{3}{4}$ and 5 fathoms—the least water that could be discovered anywhere in the passage; this lies with Balabac Peak bearing W. by N. $\frac{1}{2}$ N., Comeeran Island N. $\frac{1}{2}$ W. This channel is not to be recommended, but it can be used with safety by attention to the bearings, before given, of the extremes of the dangers bounding it.

Nasubatta Island and Reef.—Nasubatta Island, lying N.N.W. $\frac{1}{2}$ W. $7\frac{1}{4}$ miles from Comeeran, is a low cleft rock of sandstone formation, covered with trees, and appearing like two small bushy islets when seen from the N.W. and S.E. It lies from 2 to 3 cables inside the northern edge of a reef, dry at low water, which extends three-quarters of a mile S.W., $1\frac{1}{2}$ mile S.S.W., and more than a mile S.E. by S. from the larger islet; close to this shoal are depths of 40 to 50 fathoms, and 70 to 75 fathoms 3 or 4 cables off.

Roughton Reef lies to the eastward of Nasubatta Reef, separated by a channel $1\frac{1}{4}$ mile broad, in which the depths are very great. On the N.W. side is a sand cay, upon which some bushes have sprung up. From this, Balabac Peak bears S.W. by W. $\frac{1}{4}$ W., Comeeran Island S. $\frac{3}{4}$ E., and the larger Nasubatta Islet W. $\frac{3}{4}$ N. The reef is steep-to at most parts, and three-quarters of a mile northward of the East point is an isolated spot of $2\frac{1}{4}$ fathoms.

Nasubatta Channel is $4\frac{3}{4}$ miles wide between the edge of the reef surrounding Comeeran and the edge of Roughton Reef. It is necessary, when navigating this channel, to carefully guard against the effects of the strong tides and currents which sweep through it in the direction of North Balabac Strait with great velocity.

The soundings on the East coast of Balabac, inside the islands above described, are very deep, owing to a strong current usually sweeping past; no

bottom being obtained with upwards of 70, and in some places 100 fathoms line, within a mile of the shore.

Candaraman Island lies north-westward of Nasubatta, distant $3\frac{1}{2}$ miles from reef to reef. It is a low, flat island, and the reef, which extends from 3 to 4 cables from the northern and eastern sides of Candaraman, and on the edge of which a few detached rocks generally show, forms the south-eastern limit of North Balabac Strait.

North Channel is $4\frac{1}{2}$ miles wide between the North end of Nasubatta Reef and the S.E. part of that extending from Canabungan, and $5\frac{1}{2}$ miles wide between the shoal water off Roughton Reef and the reefs extending $1\frac{1}{4}$ mile from Byan and Gabung Islands.

The soundings, in a N.W. direction from Nasubatta, are very deep, as will be seen by the chart. The only difficulty likely to arise in the navigation of this channel will be caused by the strong tides and currents which rush through it with great velocity during the strength of the monsoons, requiring a strong favourable breeze to enable a sailing vessel to make headway against them. But no danger is likely to occur from this cause if vessels keep over to the northward of the deep water, where they can always bring up.

NORTH BALABAC STRAIT.—About 26 miles N. by E. $\frac{1}{2}$ E. from Balabac Peak, and nearly 16 miles from Cape Disaster, the northern extremity of Balabac, is Cape Buliluyan, the southern point of Palawan; the intervening space being occupied by a cluster of low wooded islands, almost destitute of feature, the largest and easternmost of which is Bugsuk. These islands admit only of one safe channel between them, called North Balabac Strait, which is formed on the South by Balabac Island and Candaraman, and on the North by Bancalan, Mantangule, and Canabungan Islands.

Secam is a low wooded island, $1\frac{1}{4}$ mile long, and only $1\frac{1}{2}$ cable wide, lying in an E.S.E. and W.N.W. direction, at the western entrance of North Balabac Strait, northward of Cape Disaster, and separated from it by *Bate Channel*, $1\frac{3}{4}$ mile wide, where there is deep water, 20 and 30 fathoms, close to the edge of the reefs. The island is surrounded by a reef which follows the contour of the coast-line, and extends $1\frac{1}{2}$ mile from its north-western extreme; and there is a 4-fathom patch near the extreme, and a similar patch $1\frac{1}{4}$ mile West from the West end of Secam.

Bancalan Island, lying 5 miles north-eastward of Secam, is 3 miles long, N.W. and S.E., and $1\frac{3}{4}$ mile wide, and has a small tree on its western side. The island is half encircled by a reef, contracting the channel between it and Secam to the width of 3 miles.

Mantangule lies 3 miles south-eastward of Bancalan Island, and the space between is rendered dangerous by numerous small patches of shallow water. Mantangule is 5 miles long, E. by S. $\frac{1}{2}$ S. and W. by N. $\frac{1}{2}$ N., and $1\frac{1}{2}$ mile broad. It is much larger than *Canabungan*, which lies 2 miles to the south-

westward of it, and which is but $1\frac{1}{2}$ mile long, N.E. and S.W., and about a third of a mile broad.

Reefs also extend $1\frac{1}{4}$ mile to the westward of Mantangule and Canabungan, the two islands being connected by a bank of sand and coral.

To the south-westward of Canabungan, between it and Candaraman, is the narrowest part of the channel, $1\frac{3}{4}$ miles wide, where a strong current is usually setting.

A vessel requiring *anchorage* will find tolerable shelter from S.W. winds on the North side of Secam Island, in 19 and 20 fathoms water, sand and coral, about three-quarters of a mile from the shore, with the eastern extreme of the island bearing South; the reef to the westward affording protection from the swell.

In blowing weather, a second anchor should be let go in time, as the squalls, which often succeed each other rapidly, are sometimes most violent; and, once off the bank in deep water, a vessel would be awkwardly situated as there is no other anchorage for which she could run; and taking the channel, the only alternative at night, would be attended with risk.

Tides and Current.—It is high water at Secam Island, full and change, at $10^h 50^m$ a.m., and low water at $6^h 50^m$ p.m.; rise 5 ft. The flood tide sets to the eastward, and the ebb to the westward; maximum velocity observed $2\frac{1}{2}$ knots. There is only a tide and a half-tide in the 24 hours, the latter occurring in the daytime in the month of November.

The strength of the current through Balabac Strait depends greatly on the prevailing winds. In the months of October and November, after a succession of westerly winds, it was found to set constantly to the eastward, slackening only on the ebb tide; while in July, after a continuance of unusually fine weather, with light East and S.E. winds, it set with the same velocity, viz., from three-quarters to $2\frac{1}{2}$ knots in the opposite direction. The mean velocity observed for thirteen consecutive hours was $1\frac{3}{4}$ knot.

Directions.—If coming from the southward or westward, do not attempt to approach Balabac Island nearer than 12 miles, until its peak bears to the southward of S.E. by E. $\frac{1}{2}$ E.; or if obscured, a low cliff hill, near the northern extremity of the island, bearing East, when an E.N.E. course may be steered for Secam Island, which will show like a small cluster of trees with a flattish summit.

Pass nearly mid-channel to the southward of Secam Island, borrowing a little on its shore, to avoid the edge of the reef which extends about three-fourths of a mile from Cape Disaster, but on which the sea generally breaks.

From Secam Island the channel course is S.E. by E. 6 miles, passing between Candaraman and Canabungan, two low islands, appearing nearly equal in size and elevation; the former having a small island between it and

Balabac, and the latter a few casuarina trees detached from its northern extremity.

Approaching from the north-westward, Secam will appear like a small round island; and in passing to the northward of it, care should be taken not to approach too near the reef off the north-western extremity, as rocky ground extends three-fourths of a mile from it, where there may be shoaler water than that marked in the chart; viz. 6 and 8 fathoms.

Having passed Secam Island about 5 miles, Nasubatta will be seen, distant about 7 or 8 miles, through the channel in the offing to the south-eastward, and soon afterwards Comeeran Island nearly in line beyond it.

If bound to Dalawan Bay, and a S.W. wind, haul close round the reef of Candaraman, and beat down between these islands and the Balabac shore, where there is a safe channel with deep water, but no anchorage.

Islets near Bancalan.—*Patawan* is a small wooded islet, encircled by a reef, lying a mile to the north-eastward of the point of Bancalan. *Patongong Islet* lies 3 miles north-eastward of Bancalan. *Canimeran*, lying $1\frac{3}{4}$ mile north-eastward of Patongong, and 3 miles from Cape Buliluyan, is a small sandy island with trees; a reef extends 8 cables to the north-westward.

Pandannan Island, $3\frac{1}{2}$ miles to the north-eastward of Bancalan, is about $6\frac{1}{2}$ miles in length N.E. and S.W., and about $2\frac{1}{2}$ miles wide. Its southern and western shore are fronted with coral, and off the south-western extreme is a sand-bank, dry at low water.

On the North side of Padannan the land rises a little, on which there are two conspicuous trees. The extremity of the island also terminates in small abrupt heads, more especially at the N.E. point, off which there is a small bushy islet, from which a reef extends $5\frac{1}{4}$ miles in a north-easterly direction, parallel with the coast of Palawan, having 20 and 24 fathoms close to its western edge.

There is also an islet on the N.W. face of the island, midway between it and Palawan, and East $2\frac{1}{4}$ miles from Canimeran, from which an extensive reef projects, contracting the channel round the South point of Palawan to three-fourths of a mile, where there are 7 to 9 fathoms, mud.

Fresh water was found in a small opening on the South side of Pandannan Island, about $1\frac{3}{4}$ mile to the eastward of the point; but the supply, besides being scanty, is difficult to obtain, owing to a reef that extends $1\frac{1}{2}$ mile from the shore, parts of which are dry at low water.

Bugsuk Island, or *Bougsook*, 9 miles long, in a North and South direction, and $4\frac{1}{2}$ miles broad, lies close to the East side of Pandannan, but is separated from it by a long channel, only $3\frac{1}{2}$ cables wide, running nearly North and South, in which there are depths of 10 and 18 fathoms. The southern and eastern faces of Bugsuk are fronted by a reef extending in some parts nearly 2 miles from the shore. The only recognizable feature on the island is a clump of trees near the N.E. extreme. *Bowen* is a small island lying off

the North point of Bugsuk, and a reef, partly dry at low water, extends $3\frac{1}{2}$ miles from it in an easterly direction. *Appo, Gubung, and Byan* are small islands lying in an irregular W.S.W. direction from the S.W. point of Bugsuk, with which they are connected by a reef. *Malinsono Island* lies $1\frac{1}{4}$ mile N.N.E. of Mantangule, and is connected with it by a coral spit. It is small, high, and differs from the rest in character and feature. The ground in the vicinity is foul, and studded with rocky patches nearly awash.

Channels.—To the eastward of Bancalan, limited on the North and South by Pandannan and Mantangule, and on the East and S.E. by Bugsuk, and the small islands Appo, Gabung, and Byan, is an expanse of water, 8 miles in an East and West, and $3\frac{1}{2}$ miles in a North and South direction, where in some parts anchorage, sheltered from all winds, may be found in from 7 to 12 fathoms. The channel into it are, however, intricate, and almost impracticable for sailing vessels, being either close along the edges of the reef, or, where it is wide and inviting, between small detached coral patches, for which it is impossible to give any specific directions.

It must be borne in mind, that in navigating these channels, much depends on a good lookout; for the edges of the reef are generally well defined, and any danger likely to bring a ship up, will under ordinary circumstances, be detected beforehand.

PALAWAN * ISLAND, WEST COAST.

Cape Buliluyan, or Booleelooyan, the southern point of Palawan Island, in lat. $8^{\circ} 20' 25''$ N., long. $117^{\circ} 9' 41''$ E., is low, fronted by mangroves, having on its South side depths of 4 to 8 fathoms close to the shore, and on the eastern side from 28 to 30 fathoms. The western side is fronted by a reef, which is dry at low water.

Coral Patches.—At 2 miles to the westward of Cape Buliluyan, and the same distance northward of the small bushy island of *Canimeran*, is a coral patch three-quarters of a mile in extent, with 2 and 4 fathoms on it, the soundings in the neighbourhood being 18 and 20 fathoms. North, a little westerly, 3 miles from the above and $2\frac{3}{4}$ miles from the shore, is another patch with the same depth, half a mile in extent, from the centre of which the body of Capiyas Island, a little open North of S.W. hill, bears N.E. $\frac{3}{4}$ E., and the southern extreme of Palawan S.E. by S. easterly.

Off Welcome Point, $3\frac{2}{3}$ miles to the northward of Cape Buliluyan, rocky ground, with 2 and 3 fathoms on it, extends about $1\frac{3}{4}$ mile from the shore; and if the *Regent's* bearings be correct, it was on this spot that a vessel of that name was wrecked in October, 1822.

* This island is known to the Spaniards as *Paraguas*.

Capyas, a small, low, woody island, lies 6 miles to the northward of Cape Buliluyan, and 1 mile off shore. The South side of the island is steep-to. Rocky ground extends $2\frac{1}{2}$ miles to the westward of Capyas.

ALIMUDEEN POINT, N. by E. $\frac{3}{4}$ E, distant $8\frac{1}{2}$ miles from Capyas, is a small wooded promontory, which forms the southern extremity of Caneepaan Bay. A low range of hills, which begin to rise abreast of Capyas, runs parallel with the coast, about $1\frac{1}{2}$ mile inshore, of which S.W. hill, with a *small triple summit* 900 feet above the sea, is the highest and most conspicuous.

South Regent Shoal, which appears to be the westernmost of the inner dangers, is a patch of sand and coral, upwards of half a mile in extent, North and South, on which, near its northern extreme, there are only 8 ft. water, with 13 and 14 fathoms all around the edge. It lies nearly midway on the bank, $7\frac{1}{2}$ miles from the shore, and $5\frac{1}{2}$ miles South of the North Regent Shoal.

Kamonga Shoal.—On a line with S.W. hill, E. by S. $\frac{3}{4}$ S. $3\frac{3}{4}$ miles from the South Regent Shoal, and midway between it and the shore, is the Kamonga, a 2-fathoms patch 3 cables in extent.

CANE EPAAN BAY.—Cape *Seeacle*, $2\frac{1}{2}$ miles N.N.E. of Alimudeen Point, is a wooded promontory higher than that of Alimudeen, forming the North extremity of Caneepaan Bay, with a small but conspicuous tree on the flat part of its summit. In the centre of a sandy beach to the southward of this, the Caneepaan River disembogues. It is navigable for boats. Northward of Cape Seeacle, and formed on the East side of that promontory, is a small bay, called *Seemagoup*, with reefs drying nearly across the entrance. The eastern shore of Seemagoup Bay is overlooked by *Caneepahan Hill*, 976 ft. above the sea, rather steep and conical, with two summits when seen from the north-westward.

BULANHOW MOUNTAIN.—To the eastward of Caneepaan Hill, and nearly in the centre of the island from shore to shore (which is here about 13 miles across), the high land of Bulanhow rises, attaining an elevation of about 3,500 ft. above the level of the sea. It is of a reddish aspect.

SE PAN-GOW BAY.—N.E. $5\frac{1}{2}$ miles from Cape Seeacle is Se-pan-gow Bay, in which apparently there are two deep inlets, with Cliff Point, a small red cliff to the northward, and two green islets lying close together immediately under steep hill, the shoulder of a coast-range to the southward. There are 8 and 9 fathoms at the entrance of the bay, but when well within the points, the mud dries across it.

Water.—N.E. $3\frac{3}{4}$ miles from Cliff Point is Rock Point, a long bluff head, with a small rock lying off it. To the southward of this point is a sandy bay, the shore of which is lined with casuarina trees, where, at the western extremity, near Pine Point, there is a good flow of fresh water.

PERIGEE BANK.—The coast between Cape Seeacle and Cliff Point is dangerous to approach, as rocky, uneven ground, with many shoal patches, extends in some places $2\frac{1}{2}$ miles from the shore. The largest of these patches is the *Perigee*, with $2\frac{1}{4}$ fathoms over it, on which the sea breaks in blowing weather, lying to the westward of Se-pan-gow Bay, and N.W. by W. $2\frac{1}{4}$ miles from Providence Point.

Coloby Patch.—N.N.E. $3\frac{3}{4}$ miles from the south-western extremity of the Perigee Bank, and N.W. $\frac{1}{4}$ N. $4\frac{1}{2}$ miles from Cliff Point, is the Coloby Patch, 2 cables' lengths in extent, with $2\frac{1}{2}$ fathoms upon it, and 22 and 25 fathoms water in its immediate vicinity.

Antelope Shoal.—W. $\frac{1}{2}$ N. $3\frac{1}{2}$ miles from the Coloby Patch, and N.E. $\frac{1}{4}$ N. $5\frac{1}{4}$ miles from the Breaker Reef, is the largest of the Antelope cluster. It is a narrow, angular strip of sand and coral, 7 cables in extent in a N.E. and S.W. direction, on which there are only $2\frac{1}{2}$ fathoms water, with 30 and 35 fathoms on either side. It lies 6 miles from the shore, and there are 30 fathoms, green mud, between it and the Coloby Patch. S.W. by W. $\frac{3}{4}$ W. $1\frac{3}{4}$ mile from the centre of this shoal, is a 3-fathom shoal patch; and there is also another with 3 and 4 fathoms, N. by W. $\frac{1}{2}$ W., about $1\frac{1}{2}$ mile from it.

N.E. by E. $\frac{1}{2}$ E. 1 mile from the Antelope, is a bank of sand and coral, 4 cables in extent, with only 2 fathoms water on it.

N.E. Antelope Shoal, the north-easternmost of the Antelope cluster, lies N.E. by E. $\frac{1}{3}$ E. $1\frac{1}{4}$ mile from the latter 2-fathom shoal, and N.E.-easterly, $2\frac{3}{4}$ miles from the Antelope. It is 3 cables in extent, and not less than 3 fathoms were found upon it, and it has 31 fathoms *close* to its outer edge.

The lead does not give the slightest indication when in the proximity of these shoals.

MARASI BAY.—From Rock Point the coast trends to the eastward 4 miles, forming Marasi Bay, off the North point of which, distant 6 cables, is a small bushy islet called Leeta-Leeta, connected with the shore by a reef which also extends the same distance northward of it.

From Rock Point a low ridge extends along the South shore of Marasi Bay, on which is *Balansungain Peak*, 947 ft. in height above the sea. At the back of the above ridge, fronting Bulanhow and running parallel with the coast, is a higher range, called *I-wi-ig*, with a double hill in the centre, 1,814 ft. above the sea.

Balansungain Islands.—In the south-western part of Marasi Bay, a mile from Rock Point, are two islands of sandstone formation, called Balansungain, lying 3 to 5 cables' lengths from the shore; the westernmost (which is flat) being nearly connected with it by a spit which dries at low water.

The distance from Marasi Bay to Rocky Bay on the opposite shore of the island is 10 miles.

PAGODA CLIFFS.—N.E. $\frac{1}{4}$ E. $10\frac{1}{2}$ miles from the summit of Bulanhow, and $5\frac{1}{2}$ miles inland of Marasi Bay, is a remarkable limestone cliff, 2,000 ft.

above the level of the sea, having a table summit with two clefts, which form pinnacles at either extremity; the southern being the sharper, and having a small ninepin rock in the gap, is conspicuous on a N.W. and S.E. bearing. It is called by the natives *Ta-go-ra-ras*, and by the old navigators the *Pagoda Cliff*. It rises immediately above a plain, which here extends in a North and South direction across the island.

MANTALEENGAHAN MOUNTAIN, the summit of which is in lat. $8^{\circ} 49' 22''$ N., long. $117^{\circ} 39' 26''$ E., is the highest on the island of Palawan, attaining an elevation above the sea of 6,843 ft. It is usually of a reddish barren aspect, and when viewed from the westward has a table summit, the North end, where it takes a sudden fall, being the highest part; while a long smooth shoulder, terminating in three small nipples, slopes gradually to the southward.

From Mantaleengahan Mountain a high central range extends in a North easterly direction to the parallel of $9^{\circ} 10'$ N., having on it several remarkable notch saddle peaks with sharp shoulders, the two highest of which are *Lan-dar-gun* (a deep saddle summit), 5,397 ft.: and *Gantung* (a notch peak), 5,868 ft. above the level of the sea. Towards the termination of this range, there is a table hill with a sharp nipple, called *Cal-li-bu-gon*, 1,793 ft.

The Coast from Leeta-Leeta Islet trends to the north-eastward $13\frac{1}{2}$ miles to Pampangduyang Point; it is low, and has small bays, in some of which there are rivulets of fresh water.

Illaan Hill, frequently a useful object on this part of the coast, from the high land being obscured, is a small detached hill, covered with wood, 600 feet above the sea, rising a mile from the coast behind Townsend Point, and S. $\frac{1}{2}$ W. $2\frac{1}{2}$ miles from Pampangduyang Point.

A mile and a half southward of Pampangduyang Point, in the bight of a small bay, is a rivulet, from which in favourable weather a supply of *good water* may be obtained.

Five-Fathom Patches.—N. by W. $\frac{2}{3}$ W. 4 miles from Washington Head, and W. $\frac{1}{4}$ N. from Illaan Hill, is a 5-fathom patch, 2 cables in extent, lying $3\frac{1}{4}$ miles from the shore, with a patch which breaks at low water $2\frac{1}{4}$ miles to the south-eastward of it; the latter lying $1\frac{1}{4}$ mile West of Jervis Point.

Caution.—Vessels should not approach this part of the coast within 3 miles. The lead gives no warning when near a reef, and the water is not always sufficiently clear to see the danger.

The Coast from Pampangduyang Point takes a north-easterly direction for $11\frac{1}{2}$ miles to Eran Point, which, as well as the intermediate land, is low, densely wooded, and fronted by reefs drying from 4 to 5, and in some parts 7, cables' lengths from the shore.

Eran Quoin.—At $7\frac{1}{4}$ miles from Pampangduyang Point is low Point, $2\frac{1}{2}$ miles beyond which is Beecher Point, and on the plain between these two

points is a quoin-shaped hill called by the natives *Pa-le-pie-kan*, rising to an elevation of 518 ft. above the level of the sea. It is in lat. $9^{\circ} 3' 25''$ N., long. $117^{\circ} 38' 56''$ E., and from it Eran Point bears N.E. by N. $2\frac{1}{2}$ miles.

ERAN BAY, immediately to the eastward of Eran Point, is the first bay on the coast, coming from the southward, which affords eligible anchorage in S.W. winds, to obtain wood, water, and supplies. Its locality may be readily recognized by the Eran Quoin.

Gantung Mountain and False Sharp peak (the latter likely to be mistaken when first seen for Sharp or Sal-le-kan Peak), 2,814 ft. farther South, overlook this bay, the spurs from which approach very near the coast.

Eran Bay is 4 miles wide at the entrance, 2 miles deep, and open to the northward; the bottom is bisected by a long head called Truce Head. From this islet the reef projects in a northerly direction three-quarters of a mile, with its extremity East 2 miles from Eran Point. S. by E. $1\frac{1}{2}$ mile from this point, in the S.W. corner of the bay, is the entrance of the Eran River, which, under ordinary circumstances, boats can enter, and obtain a supply of good water without going very far up. There are one or two rivulets of fresh water, called by the natives Eetloose, to the eastward of Truce Head.

The population of this and the neighbouring district, at the period of the *Royalist's* visit, was said to be about 750, chiefly Dusuns, or hill people.

The best place to anchor in Eran Bay is eastward of Eran Point, a mile from the shore, in $6\frac{1}{2}$ or 7 fathoms, stiff mud, with the Quoin Hill bearing S.W. $\frac{1}{2}$ W., and Bivouac Islet S.E. by E., midway between it and the reef off Bivouac Islet, or closer up if necessary.

It is high water, full and change, in Eran Bay, at $10^h 10^m$ a.m.; the rise is $6\frac{1}{4}$ ft. There is a tide and half-tide in the 24 hours.

The Coast to the northward of Eran Bay trends N.N.E. about 4 miles to Elizabeth Point; then N.E. by E. $9\frac{3}{4}$ miles to Hummock Point. *Pu-Lute Range*, which is about $7\frac{1}{2}$ miles inshore of this part of the coast, is 3,067 ft. high, with a deep saddle to the southward, and a high and a low sharp Nipple, the former 2,930 ft. in height, on the slope to the northward.

Malapakkun and Marantao Islands.—Three miles W. by S. of Hummock Point, and $1\frac{1}{4}$ mile off the shore, is Malapakkun, a wooded island 340 feet high, with a small double summit. Fringing reefs extend along the neighbouring coast, increasing in distance from the shore towards Hummock Point, and inclosing a small island called Marantao, 247 ft. high, lying off the coast 1 mile to the westward of the point.

Caution.—Vessels approaching the coast immediately to the northward of Eran Bay, should not shut Malapakkun Island in with Elizabeth Point, as the ground is treacherous thereabouts.

TRIPLE-TOP ISLAND, N.E. $\frac{1}{4}$ E. $4\frac{1}{2}$ miles from Marantao, and N.W. nearly 3 miles from Albion Head, is the outermost of several islands lying from 2 to 4 miles to the Eastward of Hummock Point. It is somewhat flat,

with three summits (the highest being 162 ft. above the sea), and a pinnacle rock at its northern extremity. A reef extends 1 cable's length from the S.W. side of Triple-top.

TAY-BAY-U BAY.—Albion Head, bearing E. by N. $4\frac{1}{2}$ miles from Hummock Point, is a bold perpendicular limestone cliff, with stalactite caves, luxuriantly wooded, and having several summits of nearly equal elevation, the highest being 600 ft. above the sea. It is the extremity of a point projecting from the land, in a north-easterly direction, and forming the western shore of Tay-bay-u Bay.

Tay-bay-u Bay affords shelter in either monsoon, being protected on the S.W. by the projecting point, of which Albion Head forms the extremity, and on the North by a low, flat island, surrounded by reefs. It is, however, difficult of access, and ought not to be attempted by vessels without some previous local knowledge.

A long range of hills overlooks the southern part of Tay-bay-u Bay, the highest part of which is 1,630 ft. above the sea, extending to the south-eastward, two-thirds of the way across the island, where it terminates in the conical mound Ma-la-nut, 1,290 ft. above the sea, but not so high in appearance.

The shore of Tay-bay-u Bay is fronted with mangrove, and in the south-eastern part, at the western extremity of a sand-beach, the *Ma-la-nut River* disembogues, where fresh water may be procured with tolerable facility when the river is swollen.

About $1\frac{1}{2}$ mile up this river there is a landing-place on the right bank, which leads into an open tract of country rather extensively cultivated, where there are a few houses, occupied principally by Illanuns, the chief of whom styles himself Sultan of Ma-la-nut, and exercises almost absolute control over a population of about 3,000 souls. They are in communication with the people of Eran and Caneepaan, and also with other Malay establishments on the East coast of the island.

Supplies.—Goats, fowls, yams, and vegetables of various kinds were procured, for which the natives were willing to take cloth, crockery, and other articles in exchange; and they would stack firewood on the beach (but *would not* embark it) at the rate of one dollar for 100 billets, the average size of each being about 2 feet long and 4 inches thick.

Tides.—It is high water, full and change, in Tay-bay-u Bay, at 11^h 15^m a.m.; low water at 5^h 50^m p.m.; rise 6 feet. The current is hardly perceptible.

Unless the navigator has some previous local knowledge of Tay-bay-u Bay, it is almost impossible to give clear sailing directions for it, as no mark will lead direct in.

TREACHEROUS BAY.—Eleven miles from Albion Head is Deep Bay Point, and midway between is Treacherous Bay, separated from the latter

by a group of four islands, and overlooked by two remarkable peaked hills (called by the old navigators *Devil's Cap Peak*), the foot of which breaks through the mangrove and forms a conspicuous yellow-looking cliff on the shore, three-quarters of a mile to the S. W. of which is a stream of fresh water. *Back Cap*, the highest or inshore peak, is 720 ft. above the sea.

It is recommended not to stand into Treacherous Bay, as the reefs to the northward, as well as to the north-westward of Low Flat Island, extend a long way off, and the water is usually so muddy that they cannot be seen.

The Coast between Double Island and Deep Bay Point is low and thickly wooded, and should not be approached nearer than 2 miles, as the edge of the reef dries half a mile from the points, with rocky ground in some places a mile beyond it. From Deep Bay Point to Long Point, a distance of 18 miles, the general trend of the coast is N.E. $\frac{1}{2}$ N.

VICTORIA PEAK, a sharp double peak, the second highest on Palawan Island, attaining an elevation of 5,680 ft. above the sea, occupies a central position on the intermediate range, from which several lower ranges, of not less remarkable feature, extend on either side, forming ravines and deep gorges, thickly clothed with timber.

VALLEY CONE.—From a range immediately in front of Victoria Peak, a spur runs down to the coast to Steep Point, $4\frac{1}{2}$ miles to the north-eastward of Deep Bay Point, forming on the North side a valley, at the head of which is Valley Cone, a remarkable conical hill lying beneath three sharp peaks on the ridge above.

GAP RANGE.—Immediately overlooking these hills is Brow peak or shoulder, 3,840 ft. above the sea, forming the extremity of a ridge which here takes a sudden trend to the eastward, attaining an elevation of about 5,000 ft. at its highest part, and having two gap peaks on it halfway.

The northern face of this range is a steep slope, with deep ravines and some conical hills at the foot, of which latter *Brow Cone*, 1,180 ft. high, over Bluff Point, is conspicuous.

The Coast.—The bay to the northward of Deep Bay Point is bold to approach to half a mile of the shore; but from Steep Point to Bluff Point the coast is fronted by a reef, extending from 3 to 5 cables off.

Peaked Island, 110 ft. high, with a rock 23 ft. out of water, nearly three-quarter of a mile to the westward of it, lies off the entrance of a fresh-water stream which flows into the sea just northward of a mound 280 feet high, called *Cuckold Hill*.

MOORSOM HEAD, $3\frac{1}{2}$ miles beyond Bluff Point, is rather a prominent headland, moderately elevated, with a small rock out of water half a mile to the westward, and a reef awash—lying a mile from the shore, with 7 fathoms inside it— $1\frac{1}{2}$ mile to the northward of it.

Water.—There is a stream of fresh water at the base of Moorsom Head,

in a sandy bay on the North side, and also one at the extremity of the beach, nearly a mile to the north-eastward.

LONG POINT, in lat $9^{\circ} 38' 8''$ N., long. $118^{\circ} 19' 6''$ E., is densely wooded, moderately elevated, and gradually sloping from the centre, terminating in a rocky coast. The point is steep-to.

APPURAWAN.—Five miles to the north-eastward of Moorsom Head and close to the southward of Long Point, is Appurawan roadstead, where a vessel may obtain a few supplies, such as goats, fowls, vegetables, &c., from the natives, who occupy small farms, scattered over a considerable tract of country inland, and which are approached by a small river that disembogues on the South side of Appurawan Head, $1\frac{1}{2}$ mile from Long Point.

Appurawan is the southernmost of the Christian settlements on this side of Palawan, the natives being chiefly Baquit people, and holding no intercourse with the Malays to the southward. They cultivate rice, maize, sweet potatoes, tobacco, cotton, in small quantities.

Anchorage.—The best anchorage is westward of Appurawan Head, in 17 or 18 fathoms, stiff mud and shells, about 2 miles from the shore, with the extremity of Long Point bearing N.E.

ANIPAHAN PEAK.—East of Long Point are two remarkable sharp peaks, of nearly equal elevation (the northernmost, called Anipahan, being the sharper), from which small table spurs project; they are connected with Long Point by a gradual slope in the range, on which are some round-topped hills, usually visible when the more elevated land is capped. There is a deep valley to the northward, overlooked by a sharp shoulder 3,606 feet above the sea, which is the commencement of another central range broken up into summits of various configuration, extending to Ulugan Bay.

MOUNT STAVELY.—The most remarkable of these are Mount Stavely, 3,930 ft. high (a needle peak rising from the centre of a small table summit immediately to the northward of the sharp shoulder), and two dome-shaped mountains farther northward. The latter, the southernmost, called *Thumb Peak* (4,260 ft.) is the highest part of the range, and has a knob on it; the other, *Mount Beaufort*, has a small hollow in the highest part; and in the afternoon, when the sun is out, a conspicuous red slip, assuming the shape of the letter V, will be seen on a slope in front of a peak to the southward of these.

From Mount Beaufort the range gradually falls, and is again almost separated between *Mount Herschel* and *Mount Peel*, a low ridge only connecting them. Between the former there are two sharp peaks, the northern lying more inland, and having a double hill in the hollow of the range between it and Mount Herschel.

Mount Herschel is 2,316 feet above the sea, and has a smooth summit sloping to the south-westward.

NORTH and SOUTH REEFS.—There is a small bay on the North side of Long Point, to the northward of which are two rocks lying parallel with the shore a mile off, and $1\frac{3}{4}$ miles apart, with 17 fathoms between them. South Reef is 20 ft. out of water and bold to approach, the soundings around it being 18 and 20 fathoms; North Reef is awash at high water. The depths in the bay are 12 and 14 fathoms mud, and 20 and 30 fathoms off the entrance.

There are some streams of *fresh water* in the above bay, but where the best flows the shore is fronted with coral, which extends 2 cables' lengths from it, with 3 and 4 fathoms close to the edge.

ANIPAHAH, about 10 miles N.E. of Long Point, is a small settlement of Baquit people, where there are one or two huts, and a little cleared ground. The shore, 2 miles on either side of this point, is fronted by coral.

Hen and Chickens.—Bluff Point, $12\frac{3}{4}$ miles N.E. of Anipahan Point, is formed by a spur from Mount Herschel, and has a bay to the northward of it, halfway between which and Table Point, 6 miles beyond, is a small group of islets and rocks called the Hen and Chickens, lying $1\frac{1}{2}$ mile from the shore, with 19 and 27 fathoms water between them and Sprat Point to the eastward.

Mount Airy, a double-top summit lying at the foot of Mount Peel, overlooks Hen and Chickens Bay, to the southward of which, between it and Mount Herschel, the ridge is very low.

On the shore are numerous small sand bays, free from coral, with streams of fresh water in some of them, the supply depending on the season.

Mount Peel, 3,600 ft. above the sea, rises immediately at the back of this, and has an abrupt fall in the spur extending towards Mount Airy.

N.W. HEAD.—The coast towards Ulugan Bay is of a bold, rocky, barren aspect, with several high cliffs; and about $2\frac{1}{2}$ miles southward of N.W. Head is a remarkable square grayish patch. The whole shore is bold to approach, having 17 and 20 fathoms close to.

ULUGAN BAY (called by the natives *Banog*), on the eastern side of N.W. Head, is 3 miles wide at the entrance between Cordelia Point and Broken Head, and formed by a deep indentation in the land 8 miles in a southerly direction, half severing the island of Palawan. The coast on the northern part of the eastern shore of the bay is bold, cliffy land, and of reddish barren aspect. *Sangbown*, the North peak, 1,816 ft. high, has a small table summit when seen in a south-easterly direction, and two sharp nipples on the brow in front of it. *Bentoan*, immediately to the southward, and separated from it by a low woody valley, which forms the back of the watering bay, rises to an elevation of 1,730 ft., is sharp, when viewed as above, and has a lower range adjoining it to the southward with four distinct summits.

Three-Peaked Island, or Ca-muong-yan, the highest summit of which is

140 ft. above the sea, lies N. $\frac{3}{4}$ E., $1\frac{1}{4}$ miles from N.W. Head, the northern extremity of the peninsula forming the western side of Ulugan Bay.

A rocky ledge, consisting of sand and coral, extends a mile to the southward of Three-Peaked Island, almost across the passage, on which the average depth is 9 and 12 fathoms, with 19 and 25 fathoms at 2 cables' lengths on either side of it. N.N.E. $\frac{1}{2}$ E., distant $1\frac{1}{2}$ cables from the highest peak of Three-Peaked Island, is a rock which generally shows, with one visible only at low water, half a cable's length to the northward of it.

Reeta Island.—The western shore of the bay is undulating high land, with three inlets, and is fronted by Reeta Island, $1\frac{1}{2}$ mile long, North and South, and barely more than a cable wide in any part; it has a detached rocky head at its northern extreme, 45 ft. in height, called Observatory Rock, in lat. $10^{\circ} 6' 11''$ N., long. $118^{\circ} 46' 26''$ E., part of the base of which shows white on entering the bay. Off Observatory Head, rocky ground, with 5 and 7 fathoms on it, extends in a northerly direction about 2 cables' lengths. The eastern shore of the island is steep-to, having 19 and 20 fathoms within a cable's length of the coral, which fringes it. A reef, dry at low water, extends nearly a cable's length off Tide-pole Point, the southern extremity of the island; the edge of the reef is generally well defined by the discolouration of the water.

The channel to the westward of Reeta Island is about 3 cables wide, and has 13 and 17 fathoms in it, but abreast of South inlet it is choked with coral patches, having 9 and 10 fathoms between them. In heavy northerly gales this channel appears to break across.

Magsiapo Reef, having some spots of only 10 and 12 ft. water on it, extends 6 cables westward and north-westward of Reef Islet, lying nearly 2 cables off Marabay Point on the eastern shore, and has its outer edge one mile from the southern part of Reeta Island. S.S.W. $\frac{1}{2}$ W. $1\frac{1}{2}$ mile from Reef Islet is the centre of a rocky patch, more than half a mile in extent, upon which the sea generally breaks at low water. The high nipple (1,254 ft.) on the brow of Sangbowen open of Broken Head, bearing N. $\frac{3}{4}$ E., leads on the western edge of this. It is, however, too far up for vessels to approach, as the head of the bay is lined with reefs, which project in some places upwards of half a mile from the shore. The above mark also just clears the Magsiapo Reef, and is a good guide to keep vessels to the westward when working out of the bay until they are past the entrance to Tagnipa Inlet.

Oyster Inlet, the southernmost inlet on the western shore, has its entrance 6 cables to the S.W. of Tide-pole Point, and runs back $1\frac{3}{4}$ miles in a W.N.W. direction, being separated from the coast outside by a low ridge 2 cables wide. Reefs, which project from both points, contract the channel at the entrance to one quarter of a mile in breadth; they also fringe the shore inside to the extent of one cable's length, gradually increasing towards the head of the inlet, where a bank of mud and rocks runs off half a mile, on

which good oysters may be found. There are 19 fathoms at the entrance, which depth gradually decreases over a stiff, muddy bottom to 9 fathoms, close to the reef at the head of the inlet.

The two small inlets to the northward of Oyster Inlet are shoal.

East, distant $3\frac{1}{2}$ cables from Coral Point, on the South side of the entrance to Oyster Inlet, and south-westerly nearly three-quarters of a mile from Tide-pole Point, are some small detached coral patches, nearly awash at low water.

Cai-ho-lo and Ba-he-lee Rivers.—Two small rivers disembogue near the S.W. corner of Ulugan Bay, and in the rainy season have fresh water very near their entrance. Cai-ho-lo River breaks through the mangrove between the high ranges of Car-so-glan and Cai-ho-lo, $1\frac{1}{2}$ mile to the southward of Oyster Inlet. It is navigable for boats about half a mile, where a good stream of water is generally running, but owing to the extensive reefs which line the bottom of the bay, neither this nor the Ba-hé-lee River forms an eligible watering-place. The Ba-hé-lee has a small islet at its entrance, which is S.E. by S. $1\frac{1}{2}$ mile from the mouth of the Cai-ho-lo, and is navigable for boats about $1\frac{1}{4}$ mile. A short distance beyond this is a small farm on some rising ground, occupied by a few natives from Baquit, who collect principally bees'-wax, and cultivate the land in a small way.

Between the two rivers is a small islet called Tara-cai-a-wan, nearly half a mile to the southward of which is a white rock, and though small, this generally forms a conspicuous object after entering the bay.

The *Soundings* in Ulugan Bay are from 30 to 35 fathoms at the entrance, gradually decreasing towards the bottom of the bay to 12 fathoms, green mud, close to the edge of the reef.

The *Anchorage* in Ulugan Bay is at the southern extremity of Reeta Island, off the entrance of Oyster Inlet, in 20 fathoms, stiff mud. No experience was had of the anchorage in the northerly monsoon. During westerly gales the swell sets home to the bottom of the bay, breaking heavily upon the reefs, especially on the eastern shore. In the month of November, during one of these, which shifted to the N.W., H.M.S. *Royalist*, riding with a whole cable at this anchorage, was at times pitching fore-castle under.

Water.—Good water can be obtained in a small bay, with a stony beach, to the southward of Sangbowen, N. by E. $\frac{2}{3}$ E. $4\frac{1}{2}$ miles from Observatory Rock, and E. by N. of Three-Peaked Islet. It is not, however, practicable to land there at all times, for, except in fine weather, a heavy swell usually sets into it. The anchorage also is unsafe, having 30 fathoms as close to the shore as it would be prudent for a vessel to lie, and from which it might be difficult to weigh with a westerly wind.

Caution.—Sailing vessels being compelled to water here, should not anchor nearer than one mile to the shore; and they should be prepared to weigh

on the slightest indication of a westerly wind, as the swell is liable to come in suddenly.

The *Royalist*, while at anchor off this bay in the month of November, was caught in a strong westerly wind which brought in a heavy swell, and with difficulty escaped clear, being obliged to slip her cable.

During the fine season, *i.e.* from April to July or August, fresh S.E. winds usually blow over the low land at the bottom of the bay; and in calm weather swarms of butterflies are constantly crossing the bay from the eastern shore.

Tides.—It is high water, full and change, in Ulugan Bay at 9^h 30^m a.m.; low water at 5^h 30^m p.m.; maximum rise (occurring generally three days after), 5½ ft.

No perceptible current was observed in the bay, except after heavy rains, or when westerly winds have prevailed, when there is a light out-draught.

Directions.—Vessels bound to Ulugan Bay, or any of the harbours of Palawan to the northward, should conform to the directions given for navigating the Palawan Channel, and ought not to attempt, except under favourable circumstances, to cross the bank to the southward of the parallel of 10° N.

If coming from the southward, it is recommended to be near the edge of the bank at daylight, with Mount Peel bearing about E. by S., when Three-peaked Island, at the entrance of Ulugan Bay, will bear E. ½ N., distant about 37 miles. Approaching in this direction, the bay will be readily recognised when a considerable distance off by some high rugged land, and a remarkable dome-shaped hill called St. Paul, just seen over a lower range, forming the North point of the bay. At the back of this a very sharp peak rises, named Cleopatra Needle, being the southernmost and highest of a range extending 5½ miles in a north-easterly direction. To the southward and nearer than the above is Mount Peel, already noticed, comparatively an isolated mountain, sloping gradually from the summit to the base, situated S.W. 4 miles from the bottom of the bay, and S. by W. ½ W. 10 miles from Three-peaked Island.

Approaching from the northward the bay is more readily distinguished, apparently by a complete separation between Mount Peel and the high land to the south-westward of the Cleopatra Range, the low land at the bottom of the bay not being discernible until within a few miles of Cape Sangbownen.

If with a S.W. or westerly wind, pass to the southward of Three-peaked Island, not borrowing too much on the Manabure shore, where the vessel is liable to be baffled under the land. Pass at a discretionary distance to the eastward of Reeta Island, in order to avoid being set towards the Magsiapo Reef, the western edge of which is cleared by keeping the high nipple, on

the brow of Sangbowen, to the westward of Broken Head, and proceed to the anchorage.

ST. PAUL BAY.—Eastward of Cape Sangbowen, the north-western point of Ulugan Bay, and separated from it by a low wooded valley, is *Mount Blomfield*, high table land, upwards of 2,000 ft. above the sea, with several small nipples on the summit, and steep watercourses down the side, terminating in a bold barren-looking coast, immediately to the eastward of which is St. Paul Bay.

Overlooking the bay on the South are some very remarkable dome-shaped hills and perpendicular cliffs of limestone formation, the most conspicuous of which is *St. Paul*, 3,370 ft. above the sea, from which the bay derives its name. To the eastward of this is a range, called by the old navigators the Four Peaks, of which *Cleopatra Needle*, 5,200 ft. in height, is the southernmost and highest.

The second peak from the North is 4,730 ft. above the sea, and has a small slip close to the summit.

Cliff Head, bearing N.E. $\frac{1}{2}$ E., distant $9\frac{1}{4}$ miles from Cape Sangbowen, and forming the northern extremity of St. Paul Bay, is a long wooded promontory, terminating in an abrupt fall, 350 ft. above the level of the sea.

The shore of St Paul Bay is bold to approach, having 7 fathoms near the points, and from 12 to 16 fathoms (fine sand and shells) in the centre.

JIBBOOM BAY, the upper part of which is an indentation in the land running 3 miles in a north-easterly direction lies to the northward of Cliff Head. At the entrance, midway between the latter and Peaked Point, $4\frac{1}{2}$ miles to the N.N.E., is a small group of islands and rocks, the centre and largest of which, Bay Island, has a somewhat flat summit, and is 307 feet above the sea. Opposite this group on the South side is a long point, with deep sandy bays on either side, and a remarkable hill (2,015 ft. high), with a nipple shoulder at the back. The shore of the bay is steep-to.

Shelter from N.E. winds will be found in 15 fathoms about three-quarters of a mile to the southward and eastward of Bay Island group, with Zoe, the easternmost islet, and Peaked Point, the northern extremity of the bay, in line bearing N. $\frac{3}{4}$ E. The channel to the northward of the group is a mile wide, and practicable for vessels.

The *Coast* from Peaked Point (which has a detached rock about 100 feet high close off it, with one smaller, $3\frac{1}{2}$ cables' lengths to the southward), trends N.N.E. $2\frac{1}{2}$ miles to a steep bold point, called *Amalingat*, at the foot of which is a nine-pin rock.

From this point the coast takes a sudden trend to the eastward, and off the first point from it are two islands, called Cacbolo and Cabalas, which form part of the western side of May-day Bay.

MAY-DAY BAY, immediately to the eastward of Cabalas and Cacbolo Islands, affords excellent shelter in the S.W. monsoon, and is by far a more

convenient anchorage for wooding and watering than any of those we have described to the southward on this side of Palawan.

It is $3\frac{1}{2}$ miles wide at the entrance, between Cacbolo and Cacnipa Islands, $5\frac{1}{2}$ miles deep, and is formed on the eastern side by a long irregular-shaped promontory, the continuation of a high range jutting out in a northerly direction from the body of the island, eastward of which lies Port Barton.

Cacnipa or *High Island* lies off the extremity of the above promontory, and is separated from it by a channel 4 cables wide, in which is Passage Reef, about 6 ft. out of water. The island is steep and bold, 1,050 ft. high, and $3\frac{1}{2}$ miles in circumference, with two summits, the southern being the higher. There is a remarkable thumb rock off the south-western point, and a peaked rock lies 3 cables' lengths from the shore on the North face of the island.

In the south-eastern part of May-day Bay is a remarkable conical head, with deep sandy bays on either side. The bay on the North side is irregular in contour, and has 14 to 20 fathoms in it, while that on the South side has 19 and 20 fathoms at the entrance, and a similar but smaller conical head in it, with some streams of fresh water breaking through the beach.

The soundings at the entrance of May-day Bay are 25 and 27 fathoms, sand and mud, gradually decreasing to 19 fathoms close to Conical Head. The points in the bay appear to be steep-to, and there is no known danger in it but what shows.

Water.—The watering place is at the head of a small cove, named Watering Bay, 2 miles S.W. by W. of Conical Head. The best anchorage is in 19 fathoms off the entrance of this bay, almost midway between it and Conical Head, with the tangents of Cabalas and Cacbolo Islands in line. The stream falls from the rocks on the South side of the cove, just before coming to the sand beach, where, at high water, or even at half tide, a boat can go almost under it.

Tides.—It is high water, full and change, in May-day Bay, at 9^h 55^m a.m.; low water at 5^h 55^m p.m.; and the rise (only one observation), is $3\frac{1}{2}$ feet.

BOAYAN, lying N.E. $3\frac{1}{4}$ miles from Cacnipa Island, is an irregular-shaped island nearly 5 miles in extent East and West, and $3\frac{1}{2}$ miles N.N.E. and S.S.W., being in some parts less than half a mile wide. Its north-western extremity terminates in a bold conspicuous head, with a double summit 725 ft. above the sea. The highest part of the island is about 910 feet in height, and near it is a flat double summit, apparently of the same elevation.

Two islands lie from $3\frac{1}{2}$ to 4 cables' lengths off Bluff Point, the south-western extremity of Boayan. Shelter from S.W. winds will be found on the N.E. side of Boayan, in about 15 fathoms.

Royalist Shoal is a coral patch with only $2\frac{1}{2}$ fathoms over it, lying E.S.E.

one mile from Saddle Island, with the summit of Cabalas open of the S.E. side of Cacnipa Island S.W. $\frac{1}{4}$ W.

ALBAGUEN, lying 3 miles nearly eastward of Cacnipa, and nearly $2\frac{1}{2}$ miles South of the S.W. extremity of Boayan, is a leg-of-mutton shaped island, 570 ft. high, and nearly $1\frac{1}{2}$ mile in extent, with a conspicuous red stripe (land slip) on the N.W. side.

PORT BARTON.—Albague Island is the extremity and largest of a group of islands stretching in a north-westerly direction from the eastern shore across the mouth of a deep bay, and which, together with the promontory mentioned on page 551-2 as forming the eastern side of May-day Bay, encloses a spacious sheet of water, to which the name of Port Barton has been given.

The entrance to Port Barton is between Riddle Point, the S.W. extremity of Albague, and Bubon Point, the N.E. extremity of the promontory, which is in lat. $10^{\circ} 29' 19''$ N., long. $119^{\circ} 5' 37''$ E. From the latter point the harbour runs $5\frac{1}{2}$ miles in a southerly direction, and near its head is Endeavour Island, three-quarters of a mile in length North and South, having Wedge Islet lying off its south-eastern face, halfway to the shore. There is however nothing to induce vessels to go beyond Middle Reef, nearly 3 miles within the entrance, the harbour affording no eligible watering place, although there are several streams in the mangroves which border the shore, which is apparently rocky in that direction. The soundings at the entrance of the harbour are about 25 fathoms, mud, decreasing gradually to 5 and 6 fathoms close to the edges of the reefs which fringe the shore at the head of it.

If requiring shelter only in Port Barton, and in the S.W. monsoon, anchor in the northern part of the bay in 20 fathoms, stiff mud. In N.E. winds vessels wishing to seek closer shelter for repairs, &c., will find good anchorage in 12 fathoms mud, farther to the eastward, South of the body of Capsalay Island, care being taken in approaching it to avoid Capsalay Reef.

Tides.—It is high water, full and change, at Port Barton, at $10^{\text{h}} 55^{\text{m}}$ a.m.; low water, $3^{\text{h}} 35^{\text{m}}$ p.m.; and the rise of tide 6 ft.

PAGDANAN POINT is a peninsular head of reddish aspect, nearly $2\frac{1}{2}$ miles to the E.S.E. of the eastern extremity of Boayan Island, and has Confusion Rock, white, and about 40 feet high, lying 3 cables' lengths off it. *Niaporay Island*, 354 ft. above the sea, lies in the channel between Pagdanan Point and Boayan, at half a mile from the latter; and S.E. by E. half a mile from the nearest point of Niaporay is the southernmost of two coral patches, which lie nearly in the centre of the channel. There are only 9 ft. over it at low water. There is also a $2\frac{1}{2}$ -fathoms patch, but not so much in the way as the above, lying E.N.E. half a mile from the summit of Niaporay Island. *Pagdanan Rock*, the northern patch of coral just noticed as lying nearly in

the centre of the channel, has $2\frac{1}{4}$ fathoms on it, with 7 and 10 fathoms close to, and lies N.E. by N. one mile from the Niaporay Patch.

PAGDANAN BAY.—At $2\frac{1}{2}$ miles to the north-eastward of Capsalay Island is Betbet Point, with a conical hill near, and a small islet of the same name off it, from which a coral spit projects nearly two-thirds of a mile in a W.N.W. direction.

At two-thirds of a mile in a north-easterly direction from Betbet Point is Reef Point, between which and Pagdanan Peninsula is Pagdanan Bay, $2\frac{1}{2}$ miles wide at the entrance, and about the same distance deep. Reefs lie off the points in the bay, some to the extent of half a mile.

A *fresh water* rivulet disembogues at the foot of a small green cliff island in the centre of Pagdanan Bay; and there are also two others in the South part near Squall Point.

The soundings to the southward of Boayan Island average about 24 fathoms, mud. At the entrance of Pagdanan Bay there are 10 and 12 fathoms. Vessels not wishing to go into Port Barton will find good shelter from S.W. winds to the northward of Capsalay Island; and from N.E. winds in Pagdanan Bay.

MOUNT CAPOAS, N.E. $\frac{3}{4}$ N. $16\frac{1}{4}$ miles from Bold Head (Boayan Island), and in lat. $10^{\circ} 48' 10''$ N., long. $119^{\circ} 16' 56''$ E., is high table-looking land, 3,350 ft. above the sea, with a high and a low sharp nipple at the western shoulder, and a conspicuous land-slip extending two-thirds of the way from the summit to the base, immediately under it.

IMURUAN BAY has its limits formed by Boayan Island and Pagdanan to the southward, and Emergency Point, under Mount Capoas, to the northward, and is about 12 miles wide at the entrance. Its eastern shore is overlooked by a high range of hills, of which Bay Peak, nearly abreast of Imuruan Island, is the most conspicuous. Farther to the southward over Pagdanan Bay the range is lower and assumes a table ridge. From the low neck of Pagdanan Peninsula the shore of the bay for $8\frac{1}{2}$ miles is almost one continuous sand beach, and throughout the bay is bold to approach, having 3 to 5 fathoms close to the beach. At the entrance the soundings vary from 20 to 30 fathoms, mud.

Shelter from the N.E. winds will be found to the northward of these islands, near the foot of Mount Capoas, in 19 fathoms, mud; where also a tolerably good supply of fish may be obtained with the seine, on the sandy beaches opposite.

CAPE CAPOAS, in lat. $10^{\circ} 51' 38''$ N., long. $119^{\circ} 12' 6''$ E., N. by E. $\frac{1}{2}$ E. $16\frac{1}{2}$ miles from Bold Head, and nearly North of Wedge Island, is a bold projecting headland with two summits, and the extreme western point of the peninsula, on which the table mountain of that name is situated, which bears from it S.E. $\frac{3}{4}$ E. distant $5\frac{3}{4}$ miles.

Confagration Hill.—N.N.W. $\frac{1}{2}$ W. nearly 5 miles from Emergency Point,

and 2 miles to the south-eastward of Cape Capoas, lying off one of the points of the several bays with which the coast is indented, is a remarkable steep conical island. It is named *Conflagration Hill*, from an accident having occurred there, which proved fatal to one man, and nearly so to an officer and part of a boat's crew who were ascending it for the purpose of making observations, in consequence of the long grass having been inadvertently set on fire.

Shelter from N.E. winds may be found in the first bay to the eastward of Conflagration Hill, about West of Low Mount Capoas, a peak rising 1,560 feet above the sea, immediately to the northward of the table Mount Capoas, and, next to it, the highest on the peninsula.

To the northward of Cape Capoas, for 6 miles to Diente Point, the south-western point of the entrance of Malampaya Sound, the coast is deeply indented, the bottom of some of the bays being separated from those corresponding to them on the opposite side of the peninsula and in Malampaya Sound, by very narrow isthmuses.

INLULUTOC, the largest of these bays, $1\frac{3}{4}$ mile wide and $2\frac{1}{4}$ miles deep, lies nearly midway between Cape Capoas and Diente Point, and affords good shelter in the N.E. monsoon. It is overlooked on the North by *Saddle Hill*, 1,000 ft. above the sea, which, together with *Chinongab* to the north-eastward, form conspicuous objects to identify the locality. There are no dangers likely to bring a vessel up in any of these bays but what are visible. Outside, the coast is bold, rocky, and very precipitous in some places, with deep water close to.

Anchorage—Water.—The best place to anchor in Inlulutoc (the only eligible bay for vessels to enter) is on the North shore, $1\frac{1}{4}$ mile to the eastward of Wreck Head, a bold rocky cliff forming the North point of it, between Teodore Point and Anchorage Island, in 15 and 16 fathoms, mud, with Saddle Hill bearing about N. by W., where near the foot of it, at the head of the bay, are two streams of fresh water.

MALAMPAYA SOUND, formed on the north-eastern side of the peninsula of Capoas, is about 19 miles deep in a south-easterly direction, varying in breadth from 2 to upwards of 4 miles in the broadest part. It is one of the finest harbours that can be desired, being almost perfectly free from hidden dangers, and containing along its shores bays and deep recesses, capable of giving close shelter to any class and number of vessels. The entrance is occupied by Tukuran Island, leaving only a narrow channel on either side, and at about 7 miles within the entrance the sound is contracted by long projecting headlands from either shore, forming as it were a second strait, containing several islands, which opens into an expanse of water 9 miles deep and 4 miles wide, called the Inner Sound, in which are the Spanish settlements *Panco* and *Baulao*.

Caution.—Merchant vessels entering Malampaya Sound in the early part

of the S.W. monsoon, particularly in the months of May and June, should be on their guard against pirates, for in Pirate Bay, 4 miles within the entrance, H M.S. *Royalist's* gig was nearly cut off in May, 1851, by a fleet of eight Illañon prahus on their annual marauding expedition.

Diente Point, the northern extremity of Capoas peninsula, is the western limit of the principal channel leading to Malampaya Sound. *Notch Islet*, 176 ft. above the sea, lies immediately off it, and at $1\frac{1}{2}$ cable's length to the northward of the islet is a reef of rocks awash.

Tuluran Island, occupying the entrance of Malampaya Sound, is $4\frac{1}{2}$ miles long, North and South, and $1\frac{1}{2}$ mile wide. Two sharp peaks, attaining a height of 1,272 ft., rise in the body of the island, and there are several others of considerable elevation on it; Tuluran Table, the southernmost, being 1,033 feet above the sea, and not unlike Mount Capoas on a smaller scale. The northern and western shores are bold, rocky, and precipitous in some parts, with conspicuous watercourses here and there.

At the north-western point of the island is a remarkable peaked islet, with two rocks awash a cable's length off it.

BLOCKADE STRAIT, the channel to the southward of Tuluran may be said to have its entrance between Diente Point and Bold Head, a distance of $2\frac{1}{4}$ miles. It takes a south-easterly direction, and at about 2 miles within the above line of entrance is the narrowest part, 6 cables' lengths across. Beyond this the strait is about a mile wide for $1\frac{1}{4}$ mile, when it opens into the outer extensive portion of Malampaya Sound.

Entrance Reef.—N.N.E. $\frac{1}{3}$ E. nearly two-thirds of a mile from Notch Islet, off Diente Point, is a cluster of small rocks, of which one is a pillar rock, called Entrance Reef. *White Round Islet* and *Pyramid Rocks* lie off the western face of Tuluran Island. White Round is small, 80 ft. above the sea, and bears W. by N. nearly $1\frac{1}{4}$ mile from Bold Head, the westernmost point of the island and nearest shore.

The Pyramid Rocks are 50 ft. out of water, and one-quarter of a mile in extent N.E. and S.W. The highest rock lies N.N.E. nearly 2 miles from White Round Islet, and three-quarters of a mile to the westward of Triple Head, the N.W. point of Tuluran.

The passage is safe between White Round Islet and Pyramid Rocks, but between the latter and Peaked Islet there is a coral patch with only 6 ft. water on it, N.E. $\frac{1}{2}$ N. one-quarter of a mile from the highest Pyramid Rock.

Cone Islet and Largon Rocks.—A conical islet, 237 ft. above the sea, lies in front of Bolalo Bay, on the South shore of Blockade Strait, and nearly midway between Notch Islet and Parmidiaran Point, a small conical head with a pillar rock over it and the South point of the narrowest part of Blockade Strait. N. by W. $\frac{1}{2}$ W. one-quarter of a mile from Cone Islet, is a smaller islet called Largon, from which rocks out of water extend one-

third of a mile to the northward, their outward extremity being E. by S. $\frac{3}{4}$ S., nearly a mile from Entrance Reef, with Malapina Island S.E. by E. $\frac{1}{2}$ E., $4\frac{1}{2}$ miles.

BOLALO BAY.—There is a small bay immediately to the eastward of Diente Point, and between its eastern limit and Parmidiaran Point, distant $1\frac{3}{4}$ mile, is the entrance of Bolalo Bay, a deep inlet affording good shelter from S.W. winds. It runs $2\frac{1}{4}$ miles in a southerly direction, the bottom being separated by a narrow isthmus from the North part of Inlulutoc Bay. The width inside is about half a mile.

Chinongab, a very sharp peak, elevated 1,216 ft., with a small table ridge adjoining it, rises at nearly two-thirds of a mile within the eastern shores of this bay, and is the same distance from the shores of the bay to the north-eastward, and Pirate Bay to the eastward.

ENDEAVOUR STRAIT, to the eastward of Tukuran Island, has its southern entrance between Pillar Rock Point and Endeavour Point, rather more than three-quarters of a mile to the E.S.E. The strait runs nearly North and South, and is 6 miles in length, and barely a cable wide at the narrowest part.

Coral fringes the shores on either side of the strait, and nearly in the centre of a bay on the West side, immediately under South Tukuran Peak, is a rock awash at low water, with 10 and 12 fathoms all round.

Endeavour Strait ought not to be used by sailing vessels, as they are sure to be baffled, especially in the Narrows, by the very high land on either side of it.

PIRATE BAY.—Between Blockade Strait and the second or inner entrance, the western shore of the sound has three deep bays, in each of which the ground is quite clear, and excellent shelter is afforded from all winds; but the two southern bays have no watering places.

Pirate Bay, the northernmost of the three bays just mentioned, will be found the most convenient to vessels not bound to Pancol, but merely requiring shelter, or wood, or water.

Water.—The watering place, affording a good supply, is in the bottom of Pirate Bay, almost immediately under Chinongab Peak.

Tenabian Island is 325 ft. above the sea, and nearly two-thirds of a mile long in a N.E. and S.W. direction, the N.E. portion of the island having an extreme breadth of nearly half a mile, and the S.W. portion a regular breadth of about a cable's length. The passage inshore of the island is 2 cables' lengths across, but there is a reef in it which covers.

Malapina Island, fronting the inner part of Blockade Strait, is small, 156 feet above the sea, and lies a mile to the eastward of Tenabian, with the northernmost point of Tacbolo Island S. $\frac{3}{4}$ E. $2\frac{1}{4}$ miles.

Boat Rock.—A small rock of this name lies just within the entrance of

N.E. Bay, E. $\frac{1}{2}$ S. $1\frac{1}{4}$ mile from the highest point of Malapina Island, and South nearly half a mile from the South point of N.E. Bay Island.

TACBOLO ISLAND.—In the inner strait, which is about $2\frac{1}{4}$ miles wide, and $3\frac{1}{2}$ miles long in a south-easterly direction, are several islands, the north-westernmost of which is Tacbolo, 300 feet above the sea, partially cleared, and nearly a mile in length N.W. and S.E. It lies exactly in mid-channel between the heads at the entrance of the strait. Between it and Passage Island on the East and Pugguianan Point, a headland with a triple summit 380 ft. above the sea, on the West, is the principal passage leading into the Inner Sound.

Passage, Eniaran, and Durangan Islands.—Passage Island, the largest in the strait, is 3 miles in circumference, and is separated from the S.E. point of Tacbolo by a channel only 1 cable wide, in which there are 5 fathoms, and from Tuluan Hill, the middle point on the eastern shore, by a boat channel, barely three-quarters of a cable wide.

A small islet, called Eniaran, with a flat rock on the West side, lies close off its western point, and off the western point of a small bay on the South side of the island is a white rock called Balolo. Durangan, a round-backed island 386 ft. above the sea, and rather more than half a mile in length East and West, with two small black rocks at the eastern extremity, occupies the centre of the channel between the S.W. face of Passage Island and Bululu Point, the northern extremity of a chain of hills projecting to the northward from the southern shore of the strait.

The channel between Passage and Durangan Islands is nearly half a mile wide, and contains the only danger (the Cancea Rock) we are aware of that is not visible.

To the southward of Durangan the channel is the same width, and has depths of 9 and 12 fathoms, mud, in it; nearly in the centre is Colohogon, the westernmost of two small islands 4 cables' lengths apart in about an E. by S. and W. by N. direction. Bartoc, the easternmost, has a reef extending half a cable's length from its south-western side.

Cancea Rock, the above-mentioned danger, consists of a coral ledge nearly awash in some parts at low water, fronting the head immediately to the westward of the small bay on the South side of Passage Island, from which it extends nearly 2 cables' lengths with 11 and 12 fathoms close to its edge. From its outer extremity, Flat Rock, off Eniaran Islet, is in line with Chinongab Peak bearing N.W., and the outer black rock off the East end of Durangan Island bears S.S.W. $\frac{1}{2}$ W.

Mallaratone and Ibelbel Islands.—S.E. by E. $\frac{1}{4}$ E. nearly a mile from the East end of Durangan, and two-thirds of a mile southward of Canica Point, the South point of Passage Island, is Mallaratone Island, lying N.E. and S.W., in which direction it is nearly half a mile long, with an average

breadth of about a cable's length. A small white pillar rock lies nearly a cable's length off its S.W. point.

Ibelbel Island, about 2 cables in diameter, partially cleared, and having a quantity of bamboo growing upon it, is on the northern shore of the strait at the entrance of a bay of which Passage Island forms the West side. It lies E. $\frac{1}{2}$ S. three-quarters of a mile from Canica Point, and N.E. $\frac{1}{2}$ E. about the same distance from Mallaratone Island, with clear channels between.

DAMAO, MALLAROIS, and VINALO ISLANDS, on opposite sides and marking the south-eastern limits of the strait, are N.E. and S.W., $1\frac{1}{2}$ mile from each other. Damao, 226 ft. in height above the sea, and nearly three-quarters of a mile in extreme length N.W. and S.E., is on the southern shore S.S.E. $\frac{3}{4}$ E. three-quarters of a mile from Mallaratone Island. A peaked islet, 83 ft. high, lies off its northern extremity, and in the channel a quarter of a mile wide, separating the island from a headland on the South, are some small islets and rocks awash.

Mallarois Island, E. $\frac{1}{2}$ N. nearly $1\frac{1}{2}$ mile from the North point of Mallaratone, and S.E. by E. $\frac{1}{2}$ E. three-quarters of a mile from Ibelbel, is 93 feet above the sea, less than a cable in length, and has a precipitous cliff on the South side, with some rocks detached from the East end.

There is a larger island called Vinalo lying 2 cables to the northward of Mallarois, and the channel between them is safe.

ALLIGATOR BAY is the northernmost of two large bays on the southern side of the strait, and, next to Pirate Bay, the most convenient place in the sound for watering. Durangan and Paleocotan Islands are immediately off the entrance, which is between Green Head and Balulu Point. Alligator Island lies on the opposite side of the bay, South of the watering-place, and to the south-eastward of it is a double cone island.

The soundings at the entrance of the bay are 10 and 12 fathoms, mud, decreasing gradually to 3 and 4 fathoms near the shore.

Water.—In the S.E. corner of the bay the main stream from Mount Capoas discharges itself through some low ground, but the watering-place is on the North shore of the bay, in the first small indentation from Green Head.

MALIPU BAY is separated from Alligator Bay by the chain of hills of which Balulu Point is at the northern extremity, and it has its eastern limit at Damao Island. A remarkable hunch hill (545 ft.) rises on the south-eastern side of the bay, and on the western shore is Chinicaran Island, with an isthmus head on the North face, the passage between which and the shore has only 12 ft. water in the narrowest part.

Mount Capoas and the adjacent high land rise directly behind these bays, and it was from the mouth of a small stream just to the westward of Chinicaran Island that the party who ascended Capoas set out; keeping the course of the main stream, they advanced by a steep granite gorge on the

face of the mountain, which is everywhere conspicuous from the North side of the sound.

The soundings in Malipu Bay average about 8 fathoms in the north-western part, 4 fathoms to the south-eastward, and these depths decrease gradually to 2 fathoms towards the shores of the bottom of the bay.

PANCOL.—The Inner sound of Malampaya opens immediately beyond Damao and Mallarois Islands, and in a bay on the northern side, $1\frac{3}{4}$ mile from the latter, is the Spanish settlement of Pancol, prettily situated under the high land, and fronted by a green isolated hill, 65 ft. high, on which is built a stockade in lat. $10^{\circ} 52' 9''$ N., long. $119^{\circ} 22' 56''$ E. The natives are exceedingly friendly, and for supplies it is certainly the best place on the coast. A stream of fresh water runs on either side of the stockade hill, and water can be procured, but not readily in ships' boats. Fish is plentiful.

Vessels can anchor off Pancol in 3 fathoms, stiff mud, within a quarter of a mile S. by W. of the stockade, or in deeper water farther off, as convenient, the anchorage being perfectly safe in all seasons.

Tides.—It is high water, full and change, at Pancol at $9^h 40^m$, and the rise of tide is 6 ft.

The **MALAMPAYA RIVER** disembogues at the bottom of a shallow bay on the eastern side of the sound 3 miles from Pancol. A high round island called Malootone, with a small conical head at the South end, and an island on either side, lie across the entrance of this bay, leaving a channel into it little more than 2 cables wide, in which there are only 13 ft. water. Off the first point inside these islands is a white rock, and across the entrance of the river is a line of stakes commanded by a small stockade in which a guard is usually kept. At low water the mud dries considerably outside this, nearly abreast of two small islands on the South side of the bay.

The river, which is navigable for boats about 2 miles, runs into the body of the island in a south-easterly direction; near its head is a good foot-path leading to the village of Tai-Tai, on the opposite side of the island, a distance of 2 miles.

BAULAO, a settlement similar to that of Pancol, but smaller, is on the eastern shore near the head of the sound, S.S.E. $\frac{1}{2}$ E. nearly $6\frac{1}{2}$ miles from Pancol. It, however, cannot be approached within 2 miles by a vessel drawing more than 12 ft. water, as the sound shoals gradually from 3 fathoms at 4 miles southward of Pancol to the head, where, at low water, the mud dries out nearly to Bay or Bivouac Islet, a mile from the mangroves.

Immediately to the southward of Baulao, the hills at the head of the sound on either side recede, and are separated by an extensive plain which runs through the body of the island, almost to the opposite coast, some of the water of which is discharged into Malampaya Sound by a river having its outlet through the mangrove, close to Bush Head, nearly 3 miles South of Baulao.

There are several detached ranges on this plain; on the West, those overlooking Imuruan Bay, and in the neighbourhood of Port Barton are recognizable.

The western shore of the sound to the southward of Damao Island is indented by bays, all of which are shoal.

The average depth in the centre of the Inner Sound is $6\frac{1}{2}$ fathoms, mud, from which it shoals gradually on all sides, except towards the entrance, where it deepens to 9 and 10 fathoms.

Alleged Danger.—In an old MS. chart, which was seen at Tai-Tai, there is a rock called Coloma, laid down nearly in the centre of the Inner Sound. The late Captain Bate tried for three consecutive days to find it, without success, and the people of Pancol and Baulao denied having any knowledge of its existence. As near as could be ascertained from the Spanish chart, the position of the rock is about 3 miles S. $\frac{1}{2}$ E. of Pancol stockade.

The northern extremes of Mallarotone and Durangan Islands kept in sight, will prevent a vessel going near this position.

Directions.—In making the entrance of Malampaya Sound from the westward, Notch Islet shows conspicuously off Diente Point, White Round Islet will be seen, and on a closer approach the Entrance and Largon Rocks, which are always above water, become visible. The best course is between these rocks and White Round Islet, the soundings in the neighbourhood of which average about 30 fathoms, and the former may be passed on the North side as near as convenient. With a southerly wind, they should be kept close aboard to enable the vessel to fetch through the narrowest part of Blockade Strait, or she is liable to be set over upon the northern shore by shifts of wind from the high land about Chinongab. Having passed Parmidarian Point, proceed just outside the small white rock in the centre of the next bay, and the reef awash off the point under Lookout Hill, having 13 fathoms *close* to, may be shaved without danger; then haul into Pirate Bay, and anchor as convenient.

Entering the strait with a N.E. wind, pass on either side of White Round Islet, and conform to the same directions as before, only keeping on the Tuluran shore, but not too close, or the vessel is liable to be becalmed, from the high land there rising more abruptly than on the South side.

The passage through the second strait into the Inner Sound is on the S.W. sides of Tacbolo and Passage Islands, and in using it great care must be taken to avoid the Cancea ledge of rocks under water between the latter island and Durangan.

The Coast to the northward of Tuluran Island, at the entrance of Malampaya Sound, trends northward for nearly 5 miles, where, near Custodio Point, the extremity of a promontory which forms the western shore of Bacuit Bay, is a remarkable quoin hill, 466 ft. above the sea. The intermediate coast is

of a bold rocky aspect, with several land-slips appearing as vertical reddish-looking stripes down the face.

Rugged Limestone Group.—From Custodio Point, the extremity of the promontory above mentioned, a remarkable group of rugged islands, of limestone formation, extends $8\frac{1}{2}$ miles in a N.N.W. direction. The sides of these islands present bare perpendicular cliffs of every variety of tint, with numerous stalactite caves, in which the edible bird's nest is sought. The summits terminate in small clusters of needle peaks, and wherever it is possible for vegetation to take root, they are luxuriantly clothed with foliage, of which the pandanus predominates.

Guntao Islands.—North and South Guntao Islands, the south-westernmost of this group, lie North $8\frac{1}{2}$ miles from White Round Islet, at the entrance of Malampaya Sound, and $4\frac{1}{2}$ miles to the westward of Custodio Point.

Vestacado Rocks, showing like two small boats, lie W. by S. $\frac{3}{4}$ S. $1\frac{1}{2}$ mile from the opening between the Guntao Islands, and on this bearing the bold head of Mantinloc appears in the passage.

Tapiutan, the outer island of the Rugged group, having its summit in lat. $11^{\circ} 12' 50''$ N., long. $119^{\circ} 15' 18''$ E., lies 7 miles from the shore, and N. by E. 5 miles from the Guntao Islands. It is nearly $2\frac{1}{2}$ miles long N.N.W. and S.S.E., the highest part, which is round-topped, being 1,415 ft. above the sea.

Matinloc Island.—East of Tapiutan, and separated from it by a channel $1\frac{1}{2}$ mile long, but only 2 cables wide, in which there are 20 fathoms water, is the northern half of Matinloc, an island formed by a very narrow ridge of limestone, nearly $4\frac{2}{3}$ miles in extent, running in a N. $\frac{1}{2}$ W. and S. $\frac{1}{2}$ E. direction, and almost separated in three places by deep gaps.

The *Horn*, 1,250 ft. above the sea, rises nearly in the centre of the island, and when viewed in a northerly or southerly direction, assumes the appearance of its name, forming a most conspicuous and readily recognizable feature on making the coast.

Ynambuyod Island.—Off the N.E. face, lying parallel with and separated from Matinloc by a deep channel 1 mile wide, is another island, called Ynambuyod, similar in feature but smaller, being only $1\frac{1}{4}$ mile long. Two islets, Cliff and Crown, lie respectively $1\frac{1}{2}$ and 9 cables off its northern extremity, with 17 and 20 fathoms between them. There is also a remarkable rock lying one-quarter of a mile off its south-eastern face, called the Mushroom, from its being poised on a narrow stem about one-third the diameter of the whole base.

Miniloc Island lies to the eastward of the southern part of Matinloc, the channel between, in which there are upwards of 25 fathoms, being $1\frac{1}{4}$ mile wide. It is a remarkable high, rugged island, $3\frac{1}{4}$ miles in circumference, with several summits and precipitous crags, the coast nearly all around being broken up into sharp cliffy heads, and, on the South side, exceedingly

picturesque bays. On the N.W. face are two high, rocky islets, the southernmost and largest of which is cleft in two to the water's edge.

Pacluyaban, Entalula, and Pangutasian Islands.—On the southern side of Minoloc Island, nearly connected with it by a smaller island, which occupies the passage, is Pacluyaban, also of limestone formation, and very precipitous. Between the latter island and Custodio Point are two islands; Entalula, similar in character to the above, and Pangutasian, of entirely different feature.

Pangutasian Island has a double summit, and slopes gradually towards the S.E. point, where there is a sandy tongue, from which a reef projects in a south-westerly direction, contracting the channel between the island and the Custodio shore, off which latter is Flat Rock, to 3 cables across. The depth in this channel is 14 and 16 fathoms.

On the eastern face, 3 cables' lengths from Pangutasian, is Popolcan, a limestone islet 310 ft. above the sea.

Guintungauan Island and Jip Rocks.—Guintungauan Island E. $\frac{1}{3}$ S. $2\frac{2}{3}$ miles from the South point of South Guntao, and W. by N. nearly $1\frac{1}{4}$ miles from Custodio Point, is a quarter of a mile long, and appears like a square block when seen in a North and South direction.

The Jip Rocks are a lump of limestone, 95 ft. high, cleft in two, and lie N.E. by N. half a mile from Guintungauan Island, and 1 mile to the westward of Pangutasian.

Water.—A reef, which always shows, extends 1 cable's length from Custodio Point, and in a small bay fronted with coral between it and Flat Rock, is a stream of fresh water.

BACUIT BAY, formed partly on the West by the islands just described, is 9 miles deep, and 3 miles wide at the entrance between Miniloc Island and a limestone peninsula, the highest part of which, called Bacuit Peak, is tolerably sharp, and attains an elevation of 1,500 ft. above the sea. The eastern shore trends nearly North and South, and is overlooked by a high range, extending in a northerly direction. This range, on which there are some curiously shaped peaks, forms part of a great vein of mountain limestone that here traverses the island in a north-easterly and south-westerly direction, commencing on the West side of Palawan at Tapiutan and Cauayan Islands, just embracing both shores of Bacuit Bay, and terminating on the East coast at Old Castle Point and the islands fronting Tai-Tai Bay, altogether a distance of 30 miles. The average breadth of the vein appears to be about 7 miles.

There are several islands in the bay, all of which are precisely similar in feature and character to the group outside.

Ynabuyatan and Malpacao Islands.—Ynabuyatan, the northernmost island facing the eastern shore of the bay, is a very conspicuous object on

entering, being 1,130 ft. above the sea (somewhat resembling the appearance of an elephant on its haunches), and nearly a mile in circumference.

Malpacao, a remarkable ridge of limestone, with a high boulder detached from it, assuming the form of a double island, lies S.S.E. $\frac{3}{4}$ E. nearly a mile from Ynabuyatan, midway between the southern point of this bay and Lagen Island.

Lagen Island, 1,140 ft. above the sea, the southernmost and largest of the three islands on the eastern side, is of irregular form, $1\frac{3}{4}$ mile in length N.W. and S.E., and presents a bold cliffy shore, upwards of 400 ft. in perpendicular height, with several sandy bays.

Comocutuan and Dibuluan Islands lie on the western side of the bay. The former, a small precipitous island rising 298 ft. above the sea, is S.E. by E. $1\frac{1}{2}$ mile from Pangutasian Island, and between it and the shore abreast, distant upwards of a mile, a spit projects 3 cables' lengths from an islet with a white rock close to it. Dibuluan Island is S.S.E. $\frac{1}{2}$ E. 2 miles from Comocutuan, and about midway between it and Lagen are three rocky islets, the easternmost of which shows like a ninepin on entering the bay.

Manlalec is a small village, situated a short distance up a rivulet, half a mile inside the southern point of the small bay, off which is Ynabuyatan Island, on the eastern shore of Bacuit Bay; the approach is commanded by a stockade at the entrance mounting three guns.

The old and now deserted village of Bacuit is in the extreme south-eastern corner of Bacuit Bay, fronted by a mud flat, dry at low water.

Tides.—It is high water, full and change, in Bacuit Bay, at 10^h a.m.; and the rise of tide is about 6 ft. Little or no current has been observed in the bay.

Directions.—The best channel for small vessels proceeding to Bacuit Bay, if coming from the southward, is between Entalula and Pacluyaban Islands. It is 6 cables wide, and has 25 fathoms in it, with 20 fathoms close to the shore on either side.

The best anchorage in the S.W. monsoon is in 17 or 18 fathoms, stiff mud, about a mile to the south-eastward of Comocutuan Island, off the first limestone head; but as neither fresh water nor supplies are to be had readily, there is little inducement, except it be shealer water, for vessels to go farther up.

CADLAO, or *Table Top Island*, 2,000 ft. above the sea, lies immediately to the N.W. of Bacuit peninsula, being separated from it by a channel barely 3 cables wide, in which there are 17 and 19 fathoms close to the points, and it may almost be considered as a continuation of the North side of Bacuit Bay; while Tapiutan and Matinloc are regarded as forming the southern extremity of it.

The island is $3\frac{3}{4}$ miles in length, in a N.N.W. and S.S.E. direction, with an average breadth of about half a mile. Its features are very remarkable,

and it forms the most conspicuous object when making the northern end of Palawan.

The table rises in the centre of the island, to the eastward of which, and separated from it by a deep gorge, are two remarkable peaks, of nearly equal elevation, called East and West Loggerheads. The island, especially on the southern and eastern sides, exhibits all the characteristic features of the contiguous group, some of the cliffs overhanging the perpendicular to a considerable extent.

There is a bay on the North side of the island immediately under the table, with an islet in it called Mitre; and on the S.W. face, 4 cables distant from the shore, is Ymbalaba Island, three-quarters of a mile in extent, North and South, the channel between the two having 11 fathoms in it.

Shelter in N.E. winds may be found to the eastward of this island, South of the table, in 16 or 20 fathoms, stiff blue mud.

CAUAYAN and CAVERN ISLANDS.—North of Cadlao, and separated from it by a channel about half a mile wide, in which is a peaked islet, is Cauayan Island, 827 ft. in height, and $1\frac{1}{2}$ mile in extent about N.W. by N. and S.E. by S. It is of similar formation to the neighbouring islands, but has a more even summit.

On the N.W. face of Cauayan, and distant a quarter of a mile from it, is Cavern, a small island, the extreme of the group. It is 350 ft. high, and when viewed in an East or West direction has a tall pillar rock rent from the North end.

Good shelter from S.W. winds is to be had on the North side of Cadlao, off Mitre Islet, in 17 fathoms, stiff mud.

Tides.—It is high water at Cavern Island, full and change, at 9^h 30^m a.m.; low water at 5^h 30^m p.m.; rise of tide (one observation only), $5\frac{1}{2}$ ft.

BACUIT.—Cadlao and the islands just described form the western side of a deep bay, in the southern extreme of which is the village of Bacuit, called also by the natives Ta-lan-dac, in a sandy bay on the North side of the peninsula forming the northern extremity of Bacuit Bay. In 1851 it contained a population of 200, exclusive of women and children, all Roman Catholics, under the jurisdiction of the Alcalde at Tai-Tai.

The soundings at the entrance of the bay, and off Cavern Island, vary from 20 to 30 fathoms, decreasing gradually to 12 and 14 fathoms to within half a mile of the shore; towards the village of Bacuit it shoals to 3 and 4 fathoms close to the edge of the coral.

Supplies, such as goats, pigs, fowls, vegetables, &c., in a moderate way, may be obtained from the natives, for which, as usual, they ask an exorbitant price; but a more equitable bargain may be made by giving articles of wearing apparel, crockery, hardware, &c., in exchange.

Water may be procured from a stream at the eastern end of the beach, but not with any degree of facility.

The *Coast* trends in a northerly direction from Bacuit for 8 miles to Crawford Point. A central range, the continuation of that over Bacuit Bay, overlooks both shores of Palawan, and in the parallel of Cadlao, where it attains the greatest elevation, is a high table, the north-western and south-eastern shoulders of which are $1\frac{1}{2}$ mile apart, and are respectively 2,055 and 2,230 feet above the sea.

There is a sharp peak, 1,630 ft. in height to the southward, and several hills of less elevation bordering the coast, the features of which are entirely different from those of the limestone formation, and this is nowhere so evident as at the back of Bacuit village, where a sudden transition occurs.

East peak, attaining a height of 1,890 ft. above the sea, rises $4\frac{1}{2}$ miles to the north-eastward of the high table, but it is not generally observable from the West side until some distance off shore. It, however, forms a conspicuous object when to the northward and eastward of the North end of Palawan.

Emmit, a small wooded island, 170 ft. high, with two remarkable pillar rocks at the North extremity, lies 2 cables' lengths off a projecting point, midway between Bacuit and Crawford Point, and eastward of the channel separating Cadlao and Cauayan Islands.

The coast to the northward, on which is a small sugar-loaf hill, is bold to approach, having 6 and 10 fathoms close to the shore; but that to the southward is fronted with coral, and should not be closed nearer than half a mile.

Water.—Rocky ground extends half a mile from the point opposite Emmit Island, and in the first bay to the southward of it was a rivulet of fresh water in May, 1851.

NORTH COAST OF PALAWAN.—Abreast of Crawford Point the island of Palawan is 8 miles wide, and from this, as well as Darcotuan Point, corresponding to it, on the East coast, the island gradually contracts, forming at the northern extremity a promontory $3\frac{1}{2}$ miles long, and $1\frac{1}{2}$ mile wide. Near the termination of this is a hill 493 ft. above the sea, with some table looking land of greater elevation to the southward.

Off the sandy beach, and N. by W. nearly one mile from Crawford Point, are the *Gemeles*, two white looking rock islets; and N. $\frac{1}{2}$ W. $2\frac{1}{4}$ miles from Crawford Point, and separated from the headland above mentioned by a safe channel $1\frac{1}{4}$ mile wide, in which there are 9 and 10 fathoms, sand, is Lulutaya Island, $1\frac{1}{4}$ mile long, 407 ft. above the sea, and, except on the eastern side, where fronting two small sand bays some coral extends 2 cables, is bold to approach.

Diaphila and Calitan Islands.—Base Bay is immediately to the northward of Pasco Inlet, off which, and $2\frac{1}{2}$ miles N.E. by E. of Lulutaya, is Diaphila Island, lying a mile from the shore, with a safe channel inside. Calitan Island, 256 ft. in height above the sea, lies N. by E. $\frac{1}{2}$ E. nearly 2 miles

from the latter, and nearly half a mile westward of the northern extreme point of Palawan. There is a sharp double rock between it and the shore.

On the South side of an indentation on the coast between these islands, is North Hill, 965 ft. high.

Cabuli Island, the highest part of which is in lat. $11^{\circ} 26' 25''$ N., long. $119^{\circ} 29' 46''$ E., lies off the North end of Palawan, and, except when seen in a N.W. or S.E. direction, appears to form part of that island, the channel separating them, in which there are 7 and 9 fathoms, being only 3 cables wide. It is $1\frac{1}{2}$ miles in extent from North to South, 560 ft. in height, and has rather a flat summit, the northern extremity of the island terminating in a small head, with 17 fathoms water almost alongside. It is also bold to approach on all sides, the soundings in the immediate vicinity being about 20 fathoms.

EAST COAST OF PALAWAN ISLAND.

In giving sailing directions, and a description of the East coast of Palawan, it is to be borne in mind, that, although we believe they will be found sufficiently succinct and accurate to meet the ordinary requirements of navigators, they are, nevertheless, but the result of a few observations hurriedly collected in a run down the coast during the summer, and a beat up in the winter months of 1850, taken with a view to ascertaining the practicability of adopting this route to China, in preference of the usual passage on the West side of Palawan, when late in the monsoon. They are not, therefore, implicitly to be relied upon, as resulting from a well-executed survey; nor are they intended in any way to lessen the necessity of keeping that vigilant look-out which the navigation of coral seas, on all occasions, urgently demands.

The adoption of the regular Palawan Passage, in preference to the route on the East side of the island, is recommended as the result of Captain Bates' experience.

In the strength of the N.E. monsoon, vessels *may*, taking the latter route, reach as far as the parallel of 10° N., or the island of Dumarán, without very great difficulty; but to get beyond this they will experience at least considerable delay, even if they succeed at all, for the current in this season sweeps strong to the southward, between Palawan and the Cuyos Islands, the velocity being almost in direct proportion to the strength of the wind. H.M.S. *Royalist*, in the month of December, was delayed 15 days, vainly endeavouring to get round Dumarán against the monsoon, and had, after all to make the passage into the China Sea, *via* Panay and Mindoro.

The currents on the East coast depend chiefly on the prevailing winds.

The flood tide sets along the shore to the southward, and the ebb to the

northward. The maximum velocity observed was $1\frac{1}{2}$ knots, and the rise 7 feet.

The *Coast* to the northward of Bugsuk Island (page 538) has been only partially surveyed; and that part between Rawnsley and Madripore Points, a distance of 5 miles, is merely sketched in, and no soundings have been taken near it. It is low, consisting chiefly of mangrove.

At $2\frac{3}{4}$ miles beyond Madripore Point is *Deception Point*, and at 5 miles farther to the eastward is *Church Point*, having two wooded hills to the N.E., and a reef which dries off $1\frac{1}{2}$ mile to the S.E. In the coast between the latter points are two openings, with 4 and 6 fathoms water in them.

URSULA ISLAND, in lat. $8^{\circ} 20' 42''$ N., long. $117^{\circ} 29' 56''$ E., lies with the North point of Bugsuk bearing East $12\frac{1}{2}$ miles, and Church Point N. by W. $9\frac{1}{2}$ miles. It is one-third of a mile in length, low, covered with wood, and surrounded by sand. The South side is steep-to; but a reef, dry at low water, extends from the northern half of the island, nearly a mile in a N.E. direction.

N.W. by W. $2\frac{1}{2}$ miles from the summit of Ursula Island, is a $2\frac{1}{2}$ -fathoms coral patch; and there is also one with apparently very little water, N. $\frac{3}{4}$ E. $4\frac{3}{4}$ miles from the same, the soundings between varying from 14 to upwards of 40 fathoms. Vessels should keep outside Ursula Island.

Tides.—It is high water, full and change, at Ursula Island, at 11^h , and the rise of tide $7\frac{1}{2}$ ft.

Wright Shoal, discovered by the *Rifleman* in 1868, is a dangerous coral patch, having but $1\frac{3}{4}$ fathom on the shoalest part; it lies E. $\frac{1}{2}$ S. 9 miles from Ursula Island, and is in lat. $8^{\circ} 19' 17''$ N., long. $117^{\circ} 38' 25''$ E.; the shoal water extends, under a depth of 10 fathoms, $1\frac{1}{4}$ miles East and West, and is half a mile broad. This danger lies in the direct track of vessels proceeding between Balabac and Mindora Straits.

Reef Island.—N.W. $\frac{1}{3}$ N. $7\frac{3}{4}$ miles from Ursula Island, similar to it in character, and $3\frac{1}{4}$ miles from the shore, is Reef Island, from which coral projects in every direction; that to the eastward, to the extent of $1\frac{3}{4}$ mile, where a bank dries at low water.

PIRATE ISLAND, less than 2 cables in extent, lies N.E. $\frac{3}{4}$ E. $5\frac{1}{2}$ miles from Church Point, and $1\frac{3}{4}$ mile from the shore. A reef extends nearly three-quarters of a mile from it in an E.S.E. direction; and there is a patch of coral with 3 fathoms over it, lying S.S.W. $\frac{1}{4}$ W., nearly a mile from the island.

ROCKY BAY is immediately under the Panalingahan range, noticed previously, and has its southern limit about $5\frac{1}{2}$ miles N.N.E. of Church Point. Three small rivers disembogue on the western shore of the bay, the northernmost of which has some houses near the entrance, probably a piratical establishment.

Outer Four-Fathoms Patch.—The shoalest and outermost of the coral

patches that has been discovered has 4 fathoms on it, and lies with Pirate Island W. by N 6 miles; Ursula Island S.E. $\frac{2}{3}$ S.; Church Point E. by S.; Wood Hill, the northernmost and highest of the three that overlook the Pirate Island shore, W. by N. $\frac{2}{3}$ N., and Mantaleengahan Mountain, N. $\frac{1}{4}$ E.

Gull and Egg Sands, nearly 2 miles apart, with dry patches on them, lie in the entrance of Rocky Bay; the former N.E. by E. $\frac{1}{2}$ E., $2\frac{1}{4}$ miles, and the latter N.E. $\frac{2}{3}$ E. nearly $4\frac{1}{2}$ miles from Pirate Island. When inside these sands the depths decrease gradually from 22 to $4\frac{1}{2}$ fathoms, stiff mud, towards the head of the bay.

Off the reef that lines the western shore of the bay there are some rocks and dry sand patches, the largest of which, a mile in extent, lies 2 miles North of Pirate Island, and one mile from the shore.

Segyam Islands are two low islands connected with the shore at the N.E. point of the bay, and have reefs near them, the largest patch lying S.S.W. 6 cables' lengths from the westernmost island, with 8 and 10 fathoms close to it.

Caution.—Vessels having no object in coming into Rocky Bay should not close this part of the coast nearer than 6 miles.

The *Coast* from the Segyam Islands trends about E.N.E. for $13\frac{1}{4}$ miles to Sir James Brooke Point, thence about N.E. by E. for $12\frac{3}{4}$ miles to Nose Point, which is low and wooded, with a small hill at the back of it; the intermediate land is a low, densely wooded plain, well populated, with several cultivated spots, and overlooked by the high range of Mantaleengahan. The coast is slightly indented, and bold to approach to half a mile, the soundings when that distance from it being about 6 fathoms. Several streams of fresh water flow into the bays, and some of the points have projecting reefs; that off Nose Point extending the farthest off, a distance of nearly half a mile. Three miles S.W. by W. $\frac{1}{3}$ W. of Nose Point is a reef awash half a mile from the shore.

TAC-BO-LU-BU, in lat. $8^{\circ} 43' 21''$ N., long. $117^{\circ} 44' 26''$ E., and about $7\frac{1}{2}$ miles E.N.E. of the Segyam Islands, is a Malay settlement, and the district over which a Dato presides. It appears to be well populated. Goats, sweet potatoes, and fruit in small quantities may be obtained; and also water from a rivulet in fine weather, when there is no surf on the beach. There is anchorage in the roadstead off the settlement in from 12 to 16 fathoms, stiff mud, about a mile or upwards from the shore, with Mantaleengahan Mountain bearing N.W. by N., and Addison Peak, a remarkable thumb shoulder at the end of a spur, N. by E. Reefs project 3 cables off both the points forming the bay.

There is also another Malay establishment at Prah Point, about 8 miles to the N.E. It was not visited by the *Royalist's* boats.

The soundings, when from 3 to 4 miles off the coast between the Segyam

Islands and Nose Point, vary from 20 to 30 fathoms mud, deepening as the latter point is approached, with patches of 6 and 8 fathoms, coral, occasionally.

EAST ISLAND, the N.W. extreme of which is in lat. $8^{\circ} 53\frac{3}{4}'$ N., long. $18^{\circ} 13' 56''$ E., is a low coral island nearly half a mile in extent, covered with trees, visible about 12 to 15 miles off, and has a reef extending from the eastern side, on the extremity of which is a small bush half a mile from the island. There is no anchorage near it, the depths in the immediate vicinity being upwards of 100 fathoms.

Cumi-Cumi Island.—The *Rifleman* passed within 3 miles of the position ascribed to an island of this name in lat. $8^{\circ} 57'$ N., long. $118^{\circ} 39'$ E., proving what had long been believed by seamen familiar with the navigation of the Mindoro Sea, that no island exists there. East Island, 24 miles W. by S. of the above position, just previously described, was plainly visible at a distance of 20 miles, and is the only off-lying island in the locality.

The *Coast* from Nose Point trends N.N.E. $\frac{3}{4}$ E. about 11 miles to Crawford Cove, which is a mile deep, and has 5 fathoms at the entrance. Davie Hill overlooks the shore at nearly 2 miles to the southward, and on the North side of the cove is a tree hill, the southern extremity of a coast range.

Immediately to the northward of Crawford Cove are several low coral islands fronting the shore, giving rise to the name of Island Bay to this part of the coast.

ISLAND BAY has been only partially sounded; but sufficiently so, however, to ascertain that several shoal patches exist, and that, close in, it is hazardous for vessels to navigate. It corresponds with Tay-bay-u on the opposite side of the island, the distance across being about 9 miles.

The plain intervening is cultivated in many parts, and broken up into several detached hills of conical form, at the back of which the deep saddle hill of Pu-lute, and Step Cliff on the Ma-la-nut range, are conspicuous.

Relief Point, in the N.E. part of the bay, is in lat. $9^{\circ} 9' 45''$ N., long. $118^{\circ} 12' 1''$ E., and from it coral ground, on which there are patches of 3 ft. and 12 ft., extends $1\frac{1}{4}$ mile to the S.W.

Water.—There is a fresh water rivulet at half a mile to the N.W., or within Relief Point.

Gardiner, Bessie, and Reef, three low islands, upwards of a mile from each other, lie in a N.E. direction from Crawford Cove more than a third of the distance across Island Bay. Reef Island, the north-easternmost, has its eastern side surrounded by coral, which dries half a mile from it, and has 14 fathoms very near the edge.

Another group of islands and sand-banks lies in-shore and to the northward of these, fronting the bottom of the bay; the depth of water between and around them is 6 and 7 fathoms.

On the N.E. island of the in-shore group is the ruin of a Mahomedan temple.

Two and a Half Fathoms Patch lies nearly midway between Reef Island and Relief Point, and 3 miles off shore, with the North extreme of Reef Island a little open of Coast Hill, which rises close to the shore at $1\frac{1}{3}$ mile North of Crawford Cove, bearing W. by S. $\frac{3}{4}$ S.; Steep Cliff, on Ma-la-nut range, W. by N. $\frac{2}{3}$ N.; and the Button, a bush islet near the shore, N. $\frac{2}{3}$ W.

The *Coast* from Relief Point trends in a straight line 6 miles in an easterly direction to Bivouac Point, where a good stream of fresh water breaks through the shingle. There is a rock awash nearly midway between the two points at half a mile from the shore.

In front of this part of the coast, at $3\frac{1}{4}$ miles from the shore, is a 3-fathoms coral patch, with depths of 15 and 16 fathoms, mud, inside it, and which lies with Bivouac Point N.E. $\frac{1}{2}$ N., $4\frac{1}{4}$ miles; Relief Point, N.W. $\frac{2}{3}$ W., $4\frac{1}{3}$ miles; Table Shoulder, the southern termination of the Victoria Range on this side of the island, immediately overlooking the coast N. by W. $\frac{2}{3}$ W.; and the North extreme of Relief Island, nearly in line with Coast Hill, W. by S.

The soundings off Island Bay, and between it and East Island, vary from 20 to 40, and upwards of 100 fathoms, with rocky patches here and there of 6, 7, and 12 fathoms.

FLAT ISLAND, lying $6\frac{1}{2}$ miles E.N.E. of Bivouac Point, is 12 miles in extent, North and South, low, and covered with trees. It is separated from a sandy tongue projecting from Casuarina Point on the main, by a channel 4 cables wide, in which there are 8 fathoms. On its N.E. face a coral spit runs off nearly half a mile.

Together with the main land, a small bay is formed on the western side of the island, where good shelter from N.E. winds may be found in 5 and 6 fathoms, mud, with Crawford Point, the S.W. extremity of Flat Island, bearing S.E., and Emmeline Island, the southernmost of some small islands just detached from the opposite shore, S.W. by W.

Emmeline Island is bold to approach, but off Crawford Point the reef, which fronts the South and western shores of Flat Island, extends 4 cables, and has 8 and 9 fathoms close to the edge.

A reef commencing at the sandy tongue, projects 6 cables' lengths to the southward of Casuarina Point, close to which there are 8 fathoms.

Casuarina Point is in lat. $9^{\circ} 15' N.$, long. $118^{\circ} 24' 16'' E.$

Caution is necessary in going into this bay, as it has been only partially sounded. No watering place was found in it.

Tides.—It is high water in this vicinity, full and change, at midnight, and on the following day at $9^h 30^m$ a.m. Rise of tide $6\frac{3}{4}$ ft.

SAND ISLAND lies E. $\frac{1}{2}$ N. 5 miles from Casuarina Point, and $3\frac{1}{4}$ miles from the nearest part of Flat Island. It is one-quarter of a mile in extent,

covered with wood, and surrounded by a reef, dry at low water, which, on the eastern side, extends half a mile from the island, with from 6 to 12 fathoms close to the edge.

The soundings outside Flat and Sand Islands vary from 20 to 40 fathoms, mud; in their immediate vicinity the depths are 10 and 12 fathoms, mud, decreasing gradually to the shore. Shoaler casts, such as 6 and 7 fathoms of sand and coral, here and there, may always be anticipated.

S.W. $\frac{3}{4}$ W., distant $1\frac{1}{2}$ mile from the centre of Sand Island, is a $5\frac{1}{2}$ -fathoms patch of coral, with 14 fathoms, mud, on either side.

30th of June Island, lying N.E. by N. $8\frac{3}{4}$ miles from Sand Island, and $2\frac{1}{2}$ miles off shore, is similar in all respects to Sand Island, the reef on the East side extending only 4 cables' lengths.

Maltby Island, nearly as large, and of the same description as Flat Island, lies 4 miles to the N.N.E. of the 30th of June Island, being separated from the shore by a channel one mile wide, but which has not been sounded.

Two dry sand-banks with reefs lie between these islands, the depth of water in the vicinity being from 4 to 7 fathoms, and there is a reef awash N.W. three-quarters of a mile from 30th of June Island.

A rocky spit also extends 4 cables' lengths from the S.W. point of Maltby Island.

The Coast opposite these islands partakes of the same features as that farther to the southward, being low and thickly wooded. Victoria Peak, 5,680 ft. above the sea (page 545), overlooks it, and the mountain range, which presents some deep gorges and picturesque valleys, is fronted by an extensive and deeply wooded plain, the hills not approaching the sea until near Table Head, which is low, and nearly 12 miles N.E. by N. of Maltby Island. On the North side of Table Head is a small inlet for boats.

Village Bay, in which are a few huts, 2 miles to the northward of Maltby Island, is small, and a coral patch, 6 cables in extent, N.W. and S.E., occupies its centre. Off the South point of the bay are two islets connected with the shore by a reef, and a reef fronts the coast for a mile from the point on the North side.

Water.—There is a good fresh water stream 5 miles to the south-westward of Table Head, and 2 miles to the southward of S.W. hill, near where the range forms part of the coast line.

The *Soundings* off this part of the coast are exceedingly irregular.

East, 6 miles from 30th of June Island, there is a bank of sand and coral upwards of 5 miles in extent, on which the least water that has been discovered is $6\frac{1}{2}$ fathoms; immediately outside there are no soundings with 80 fathoms; the depths inside the bank vary from 12 to 20 fathoms.

Three and a Half Fathoms Patch.—Rocky ground also extends in a northerly direction from this bank, where, at the extremity, is as little as $3\frac{1}{2}$ fathoms, perhaps less. This patch lies East of Village Bay about $2\frac{1}{4}$ miles from the

shore, and from it the south-eastern extreme of Maltby Island bears S.W. $\frac{1}{2}$ S.; the huts in Village Bay, W. $\frac{2}{3}$ N.; Dome, a conspicuous hill on the ridge which connects Table Head with the Victoria range, N.W. by W. $\frac{1}{4}$ W., and Table Head, N. by E. $\frac{3}{4}$ E.

At $1\frac{1}{2}$ mile to the eastward of this patch there is no bottom with 120 fathoms, but at 4 miles to the north-eastward of it there are 105 fathoms water, $2\frac{1}{2}$ miles from the shore, with 30 fathoms immediately inside. The bottom is distinctly visible when on these banks.

PORT ROYALIST has its entrance $4\frac{1}{2}$ miles north-eastward of Table Head; and Tide-pole Point, the inner extreme point of low land on the North side, is in lat. $9^{\circ} 43' 43''$ N., long. $118^{\circ} 43' 11''$ E. It is formed in an extensive densely wooded plain, fronting a high mountain range to the S.W. of Mount Peel, of which Mount Beaufort and Thumb Peak (page 546) are conspicuous. The latter, when seen from the S.E., appears a remarkable steep conical mountain, with a knob on the summit, and it bears N.W. by W. $\frac{1}{2}$ W. from the entrance of the harbour. The entrance is a strait nearly 3 miles long and 2 miles wide, in a W.N.W. direction, being almost at right angles to the prevailing winds in both monsoons.

Coral spits project from both the outer points, which contract the channel at the entrance to 1 mile in width. The South spit extends 7 cables' lengths from the shore; while the North projects only 4 cables, and parts of both dry at low water.

The reefs forming these spits extend along the coast outside, and have 12 and 13 fathoms close to the edge; that on the North has several dry patches.

In the strait the depth is 25 fathoms, mud, which decreases as the head of the harbour is approached to 4 and 5 fathoms close to the reef.

There are two inlets on the South side of the strait; the eastern has a rock at the entrance lying off a red cliff, which when first seen may be easily mistaken for some native huts. The western and largest is upwards of $1\frac{1}{2}$ mile deep, and has a coral spit projecting nearly 4 cables' lengths from Heron Point, its North entrance point.

There is deep water in both these inlets, but their entrances are very much contracted by coral.

From the inner part of the strait the harbour extends 3 miles in a northerly direction, and is 2 miles wide. The North and western shores are chiefly mangrove, the former being broken up into bays and inlets, all of which are shoal and fronted with coral.

E-wi-ig River disembogues on the western side of the harbour, to the northward of apparently a deep mangrove bay, and has a small island at the entrance, W. by N. 2 miles from Tide-pole Point.

This river is navigable for boats about $2\frac{3}{4}$ miles; half a mile farther up is a small village, which in 1850 contained about forty or fifty persons, chiefly

Bysayans, carrying on a small traffic, beeswax, rice, maize, &c, with some of the contiguous settlements. They were quite harmless, and willing to give ships supplies, but unable to do so, being in a wretched state of poverty and filth.

After heavy rains the river is fresh almost at the entrance; but in the dry season boats must go some distance up to get the water good.

Mud dries at low water nearly three-quarters of a mile from the entrance, through which are two boat channels diverging from either side of the island at the mouth of the river.

Harbour Island lies off the largest opening on the North shore of the harbour; and besides being connected with the shore by reefs, has a rocky spit, and some detached coral patches extending nearly a mile from it in a southerly direction, having upon its extremity a rock nearly awash with 6 fathoms close to.

Anchorage.—Between the end of this spit and Buckle Point, three-quarters of a mile N.N.W. of Tide-pole Point, a distance of two-thirds of a mile, is the best place to anchor in the N.E. monsoon. In the other seasons, vessels may lie farther to the southward.

Vessels bound to Port Royalist, and wishing to remain at anchor outside for the night, will find the most convenient place somewhere abreast of Bryson Point, 3 or 4 miles to the northward of the entrance, in 10 or 15 fathoms water, about 2 miles off shore.

Directions.—The soundings off Port Royalist are deep, there being no bottom with upwards of 100 fathoms of line; and it is not until a vessel approaches within a mile of a line joining the points at the entrance that ground is struck, when from 120 fathoms the depths suddenly decrease to 20 and 30 fathoms, sand. This change is sometimes marked by a ripple line on the surface.

The only part of the harbour that is bold to approach is the shore on the northern side of the strait, from about half a mile inside the point to Buckle Point. There is, however, a spit between the latter and Tide-pole Point, extending 2 cables off, the edge of which is generally well defined by the light green water over it.

In proceeding into Port Royalist do not approach either shore near the entrance within a mile, until abreast of the opening.

When Tide-pole Point is seen midway between Thumb Peak and Mount Beaufort, bearing about N.W. by W., the vessel will be in the fairway, and may then be steered direct for it.

Tide-pole Point in line with Thumb Peak, N.W. by W. $\frac{3}{4}$ W., leads *just* clear of the North spit, and the same point in line with Mount Beaufort, bearing N.W. $\frac{1}{2}$ N., clears the South spit.

Having passed the spits, keep the northern side of the strait on board; and when abreast of Tide-pole Point, in 17 or 20 fathoms, haul gradually to

the northward for Buckle Point, keeping upwards of 3 cables' lengths from the shore, and anchor in from 9 to 12 fathoms, mud, about this distance W.N.W. of the latter point.

It is recommended not to go beyond half a mile to the northward of Buckle Point, as the channel between the reefs gets very narrow, and a $1\frac{1}{2}$ -fathom patch lies 6 cables N. by E. $\frac{1}{3}$ E. of it.

Vessels working in or out of Port Royalist should not approach either the South side of the strait or harbour nearer than half a mile.

During easterly winds a heavy swell sets into the strait, which breaks violently on the reefs, and also across the bay to the southward of the river.

DEEP BAY.—From Port Royalist the coast trends a little to the westward of North for 12 miles, and then E.N.E. for 25 miles, to Bold Point, the angle of the bight forming what the old navigators called Deep Bay.

This bay corresponds with Ulugan Bay on the opposite side of the island, the plain intervening, on either side of which Mount Peel and the Cone are conspicuous, being only 5 miles across; and in approachidg Deep Bay from the westward, Mounts Herschel and Airy appear as two islands between Mount Peel and the range to the southward.

Four low coral islands, covered with wood, lie in a direct line N.E. by E. $\frac{1}{3}$ E. and S.W. by W. $\frac{1}{3}$ W. nearly equidistant across the bottom of this bay, and between these and the shore is another group, consisting of four islands and some reefs and dry sand patches, all of which have been but imperfectly delineated and sounded.

Castle Point, on the North shore of Deep Bay, in lat. $9^{\circ} 59' N.$, long. $118^{\circ} 55' 51'' E.$, probably so called from a small rocky protuberance (a characteristic feature of the Cleopatra range) on the brow of the hill over it, is the commencement of a bold range which borders the coast to Green Island Bay. At $2\frac{1}{2}$ miles westward of Castle Point is a small river, navigable for boats, and there is also a stream of fresh water three-quarters of a mile eastward of the point.

E.N.E., 14 miles from Castle Point is Bold Point, with a double hill immediately over it, forming the N.E. extremity of Deep Bay, and is, as regards both the aspect of the land and depth of water near it, quite what the name imports.

Ramesamey and Mackesy Islands.—Ramesamey, the south-westernmost of the former group, mentioned above, lies in a bed on the western side of Deep Bay, a mile from the shore, and $8\frac{1}{2}$ miles to the northward of Port Royalist. It is surrounded by a reef extending off one-quarter of a mile, and there is a small Tuft Island S.E. by S. three-quarters of a mile from it.

Mackesy, the next island to the E.N.E., of similar form, and $3\frac{1}{2}$ miles from Ramesamey Island, is three-quarters of a mile in circumference, and appears to have no reef round it.

Meara and Fraser Islands, both apparently bold to approach, lie inshore

of the above, fronting the opening in the mangrove, on the West of which, near the coast, is a hill range of reddish aspect.

A reef, partly dry at low water, lies half a mile to the S.E. of the North point of the inlet, and a bush islet close to the shore, a mile to the northward of it.

There are depths of 3 and 4 fathoms inside Ramesamey and Meara Islands, and 10 fathoms near the entrance of the Mangrove Inlet.

Reef Island, lying 4 miles to the E.N.E. of Anchorage Island, is, including the reef that surrounds it, upwards of a mile in extent N.N.E. and S.S.W., and the same distance N.W. and S.E., and there is a small sand-bank, dry at low water, at 3 cables' lengths from its S.W. extreme.

A *rocky bank*, nearly dry at low water, $1\frac{3}{4}$ mile in a N.E. and S.W. direction, lies halfway between the two latter islands, to the northward of which, and between Reef Island and the shore, a distance of $3\frac{1}{2}$ miles, are two of the four islands composing the inner group, with a dry sand-patch off the outer extremity of each. The depth of water between the rocky bank and Reef Island is 11 and 12 fathoms.

Anchorage Island, $2\frac{1}{2}$ miles in circumference, the north-easternmost and largest of the group, has a reef fronting the eastern side, which at low water dries off 3 cables' lengths, and a rock awash at nearly three-quarters of a mile from the N.W. point. The channel inside this island is almost blocked up by two reefs, with dry sand-patches on each, and a shoal spit which extends half a mile from Castle Point.

Between the latter and Anchorage Island are depths of 12 and 17 fathoms.

Soundings.—There is a bank off Deep Bay with 5 fathoms on it, upwards of 2 miles in extent, lying nearly in a direct line between Port Royalist and Bold Point, and S.S.E. $6\frac{1}{2}$ miles from the body of Anchorage Island.

Fronting the group of islands, a little to the southward, the soundings vary from 8 to 12 and 23 fathoms.

A bank with 17 and 27 fathoms over it lies $5\frac{1}{2}$ miles S.E. of Bold Point; but within 2 miles of the coast to the westward of the point, there are no soundings with upwards of 170 fathoms; nor is ground obtained at this depth (unless within 3 cables' lengths of the shore, where there are 30 fathoms) all along the coast, until 3 miles S.E. of Anchorage Island, when it changes suddenly to 6, 9, and then 20 fathoms.

Constancia Shoal, the general extent of which is unknown, was discovered by a Spanish vessel of that name. It had $8\frac{1}{2}$ fathoms on it, sand and coral, where first sounded on, but the depth increased to 11 fathoms about 1 mile to the N.W., and again decreased from that depth in a W.S.W. direction. The shoal part lies about E. by S., 15 miles from Bold Point, which places it in lat. $9^{\circ} 58\frac{1}{2}'$ N., long. $119^{\circ} 24\frac{1}{2}'$ E.

Pasig Shoal, of 5 fathoms, is placed in the chart 9 miles S.E. of Constancia Shoal, in lat. $9^{\circ} 50'$ N., long. $119^{\circ} 31'$ E.

GREEN ISLANDS.—From Bold Point the hills forming the coast range take a northerly direction; and at 3 miles to the northward of the double hill over the point, on the same range, is Bold Peak, upwards of 3,000 ft. above the sea.

The sweep of the current, either round this point or from Green Island Bay, appears to have detached a portion of the low land, which now forms North and South Green Islands, together nearly 4 miles in length, and two smaller islands to the northward, fronting the East side of Bold Peak.

Pascoe Channel, the channel inside the Green Islands, through which the current in the month of June was observed running at the rate of $3\frac{1}{2}$ knots an hour to the northward, is from 1 to 3 cables wide. Reefs lie either side of this channel. Off a point on the mainland to the southward of the entrance, the coral extends 4 cables' lengths, and there is a rock awash with 7 and 8 fathoms close to, immediately in the opening to the northward.

The depth of water about a mile outside North Green Island is 27 and 28 fathoms, but there is a 2-fathom patch E. by S. this distance from its North extreme.

GREEN ISLAND BAY, to the N.E. of the Green Islands, has several low coral islands, with extensive reefs and numerous sand patches in it.

At Cliff Point, 11 miles N.N.E. of North Green Island, a ridge of low hills, called the Barbacan Range, joins the coast, and behind these is a higher range in the body of the island, with some double summits and long table spurs or shoulders.

Barbacan.—A small river disembogues at $5\frac{1}{2}$ miles north-eastward of Cliff Point, and it is shoal off the entrance, where the surf breaks heavily at times. On the right bank, at half a mile up, is the small village of Barbacan. From Barbacan the northern shore of Green Island Bay trends about E. by N. for $10\frac{1}{2}$ miles to *High Point*, a bold headland forming the north-eastern limit of the bay. At 2 miles from the river is Barbacan Point, and close to the sea, at 5 miles beyond, is a conical shaped hill called *Bay Peak*, rising to a height of 1,800 ft.

Mount Baring, in lat. $10^{\circ} 24' 55''$ N., long. $119^{\circ} 32' 56''$ E., and N.E. 33 miles from Bold Point, rises directly over High Point to an elevation of 2,100 ft. *Johnson Island*, the outer of the S.W. portion of the group in Green Island Bay, lies N.E. 19 miles from Bold Point, and $4\frac{1}{4}$ miles from the shore. A *bank*, consisting of sand and coral, $1\frac{1}{2}$ mile in extent, East and West, dries at low water $2\frac{1}{4}$ miles S. $\frac{1}{2}$ W. of the island. There is also some rocky ground with 4 fathoms, and 18 and 20 fathoms, mud, close to, with the island bearing N. by W. $\frac{3}{4}$ W. distant $3\frac{1}{2}$ miles.

Howley, Stanlake, Flat, and Shell Islands lie inshore of Johnson Island; *Howley*, the south-western and innermost, is N.N.E. $7\frac{1}{4}$ miles from North Green Island, and $1\frac{1}{2}$ mile from the shore, with a reef between; and there

is a sand-bank S. by W. $\frac{1}{4}$ W. $1\frac{1}{2}$ mile from Howley Island. *Stanlake* and *Flat* islands are the two largest in the bay.

A sand-patch lies $1\frac{1}{2}$ mile to the eastward of Stanlake. *Shell* island is N. $\frac{1}{2}$ E. 3 miles from Johnson Island, and between it and Barbican. It has a shoal extending one-third of a mile from its north-western side, and a sand-patch at 6 cables' lengths to the south-westward. *Green Island*, the outermost of the N.E. portion of the group, lies E. $\frac{3}{4}$ N. $6\frac{1}{4}$ miles from Johnson Island, and S.W. by S. from High Point.

Reef Island, from the East side of which coral projects three-quarters of a mile, lies W.N.W. $2\frac{1}{2}$ miles from Green Island, and N.W. by W. $\frac{1}{2}$ W. $4\frac{1}{4}$ miles from Johnson Island; midway between it and Shell Island is a sand-bank and reef.

Hog Island, lying 3 miles N. by W. $\frac{1}{4}$ W. of Green Island, and the same distance from the shore, is $1\frac{1}{2}$ cable in extent, with a *rock awash*, East, northerly, 1 mile from it.

The Coast beyond High Point takes a N.E. direction for 12 miles to Endeavour Point, which is low and densely wooded. Midway between is *Squall Point*, from which a range runs nearly North to the coast at the same distance on the other side of Endeavour Point, having *Drake Peak*, a sharp hill 1,300 ft. above the sea, on the southern part, and a double peak 1,400 feet high to the northward of it.

Illan.—Two miles to the northward of High Point is a small river, with a village similar to that of Barbacan, called *Illan*, on the right bank, half a mile from the entrance. The river is fresh at the village.

Dry Sand-banks.—Two reefs lie off this part of the coast. The outer, which is a mile in diameter, and has a dry sand-bank in the centre, is $4\frac{1}{2}$ miles from the shore, and E. $\frac{3}{4}$ N. $6\frac{3}{4}$ miles from High Point. The other is $2\frac{3}{4}$ miles inshore of it, and has also a sand-patch, which, as well as that on the outermost reef, shows at all times. Reefs and sand-banks extend nearly 2 miles off the coast to the northward of this.

DUMARAN ISLAND, separated from Endeavour Point by a channel $1\frac{1}{4}$ mile wide, is about 42 miles in circumference, and not more than 600 feet above the sea in any part. It is of irregular form, and has no very remarkable features by which to distinguish it, the hills being apparently nearly of the same elevation, and, with the exception of a few in the neighbourhood of the settlement on the North shore, and near the North part of the island, are thickly wooded.

There is an inlet on the S.E. face running 3 miles into the body of the island, with 5 fathoms water near the head; and at the eastern extremity of Dumarán is an island connected with the shore by a sandy isthmus, East of which, nearly 6 miles, is a small wedge-shaped island called *Trepang*.

Three small islands front this part of the coast; the S.W. and largest, called *Christmas Island*, lying 4 miles East of the opening of the inlet above

mentioned. S.W. about $1\frac{1}{2}$ mile from the summit of it is a 3-fathom patch of coral, and there is also one with 4 fathoms at 8 cables' lengths N.W. of the same. At $4\frac{1}{2}$ miles S.W. of Christmas Island, abreast of Green Point, the South point of the inlet, is a rocky bank with only 4 fathoms on it. Also S.W. of Green Point, fronting an opening, is a $2\frac{1}{2}$ -fathom patch, lying $1\frac{1}{4}$ mile from the shore.

Barton Point, the S.W. extremity of Dumarán, has a spit with $2\frac{1}{2}$ fathoms water on it, projecting $1\frac{1}{4}$ mile to the westward.

Coral Shoal.—Nearly midway between Barton Point and the inner dry sand-patch already noticed as lying off the coast between High and Endeavour points, is a coral shoal with only 3 fathoms, and perhaps less, over it. From it South Hill, Dumarán, bears E. $\frac{3}{4}$ N. ; Endeavour Point, N. $\frac{1}{2}$ W. ; and Drake Peak, N.W. by W. The soundings in the immediate vicinity of this shoal are 12 and 15 fathoms.

DUMARAN.—The Spanish settlement of Dumarán, next in importance to that of Tai-tai, is $4\frac{1}{2}$ miles to the northward of Barton Point, and in the bottom of a small bay immediately opposite Endeavour Point. The fort stands on a hillock close to the landing place in lat. $10^{\circ} 32' N.$, long. $119^{\circ} 45' 51'' E.$, and in 1850 was in a dilapidated condition, the terre plain, on which a few pieces of old iron ordnance were mounted, being partly constructed of nebang, supported by poles, about 25 ft. from the base of the building. A church forms part of the interior arrangements of the fort. The village is prettily situated in the rear amongst some cocoa-nut trees, and there is a considerable tract of land in the interior under cultivation.

Supplies.—Ample supplies, such as rice, maize, sweet potatoes, tobacco, and cotton are raised, both for the consumption of the inhabitants and for the purposes of traffic. Pigs, goats, and fowls are also plentiful, but an extravagant value is put on them.

There is not any eligible watering-place in the bay.

Anchorage.—Shelter from N.E. winds will be found on the West side of Dumarán in from 9 to 12 fathoms, mud, S.S.W. of the bay where the settlement is.

COOK CHANNEL is the passage between Dumarán Island and the shore of Palawan, and has its southern entrance between Endeavour Point and a rocky spit with a sand-bank on it, dry at low water, extending to the southward $1\frac{1}{3}$ mile from the West point of Dumarán.

The tides set rapidly through the channel, and it should not be attempted by a sailing vessel, unless under peculiarly favourable circumstances.

From Endeavour Point the island of Palawan takes a sudden trend in a N.N.W. direction, and the coast assumes an entirely different character, being fronted by numerous islands and rocks, not one of which partakes of the features of those farther to the southward.

Dampier Point bears N. by W. $\frac{3}{4}$ W., distant 9 miles from Endeavour Point,

and forms the western extremity of the bay mentioned above. *Point Peak*, a sharp peak 960 ft. above the sea, and others of less elevation, immediately over it, joining the range noticed on page 578.

Of the islands in the northern entrance of Cook Channel, the three largest lie on the eastern or Dumarán shore, in a N. by E. and S. by W. direction. *South Channel Island* is 2 cables' lengths West of the southernmost of these three, and is connected with it by a reef awash in some parts at low water.

A rock awash lies apparently in the centre of Cook Channel at 3 cables' lengths from the edge of the reef on the S.E. side of South Channel Island, with the summit of the large island N.N.W. three-quarters of a mile, and Endeavour Point W.S.W. the same distance.

Goat Island, the northernmost on the eastern side of Cook Channel, is N.N.E. $2\frac{1}{2}$ miles from South Channel Island; it is 380 ft. in height above the sea, and has a rocky head just detached from the North extremity.

A 3-fathom coral patch lies W. $\frac{3}{4}$ N. 1 mile from the summit of this island, with 15 and 16 fathoms close to.

Reef and Bivouac Islets.—On the West side of Cook Channel are four small and one larger island. The latter, 200 ft. above the sea, lies nearly West about 2 miles from the centre island on the opposite side, and fronting it are the Reef and Bivouac Islets.

Bivouac Island, 160 ft. high, lies half a mile to the N.N.E. of Reef Islet, is bold to approach, and has a small rocky head on the N.E. side, with 4 fathoms close to it.

North Channel Island is 6 cables' lengths to the N.W. of Bivouac, and from it a reef projects 2 cables in a N:E. direction.

Barren Island, lying to the N.E. of Dampier Point, and separated from it by a channel 2 miles wide, in which there are 23 fathoms, is a narrow island, $2\frac{3}{4}$ miles long, North and South, and 720 ft. in height. It is of a rocky, barren aspect, with comparatively few trees growing upon it.

There is a 3-fathom patch S. $\frac{1}{4}$ E. 8 cables' lengths, and one with the same depth E. by S. $1\frac{1}{4}$ mile from the South extreme of Barren Island, the two being in line with Dampier Point bearing S.W. by W. $\frac{3}{4}$ W.

Water.—A stream in the above-mentioned bay, difficult to distinguish unless close to the beach, was the only eligible place discovered on this part of the coast for watering, which here is a tedious operation if not supplied with long hoses. In the absence of these the natives were found willing to fill the casks and float them off on bamboo rafts, constructed especially for the purpose, at the rate of 75 cents per tun. If the latter expedient be adopted, patience is indispensable.

Tides.—It is high water, full and change, at Barren Island, at 9^h 30^m a.m.; low water at 5 p.m.; rise of tide $5\frac{3}{4}$ ft.

CARLANDAGAN ISLANDS.—The Carlandagan group, lying E.N.E.,

distant 16 miles from the N.E. extremity of Dumaran Island, is composed of two large islands, and three smaller islets or rocks.

Carlandagan, the southernmost island, is 3 miles in extent from North to South, and has a high precipitous conical head to the South.

Maducang Island, 926 ft. high, lies N. $\frac{1}{2}$ E. of Carlandagan, the channel between, in which there are $10\frac{1}{2}$ fathoms, being 6 cables wide. A small island called *Indong* is connected with the shore on the S.E. side, and to the eastward $3\frac{3}{4}$ miles is *Bird Island*, with a remarkable white rock $2\frac{1}{2}$ miles N. by W. of it.

High water, at full and change, occurs at the Carlandagan group the same time as at Barren Island, 32 miles to the westward; rise of tide 6 ft.

The *Coast*.—Immediately opposite Barren Island, and on the North of Point Peak, is an inlet $3\frac{1}{2}$ miles deep, with two islands at the entrance, the largest of which, called *Shadwell Island*, is $1\frac{1}{2}$ miles from the shore.

A *rocky patch*, with 3 fathoms water on it, lies S.E. $\frac{1}{4}$ S. one mile from the summit of Shadwell Island.

SOUTH TAI-TAI ISLAND bears N.W. by N., distant 6 miles from the North extreme of Barren Island, and is separated from the South point of the bay of Tai-Tai by a channel barely a mile wide, with 19 fathoms in it. The highest part of the island is elevated 610 ft. above the sea. A rock awash lies rather more than three-quarters of a mile from the shore on the East side; and at the S.E. extremity of the island is a small spit, with an islet and a white rock near it.

Midway between this island and the North extreme of Barren Island, is a bank nearly a mile in length, E. by S. and W. by N., with 3 and 4 fathoms, coral, upon it.

TAI-TAI BAY is nearly 10 miles wide and 5 miles deep, and is capable of affording good shelter, in the S.W. monsoon. Its western shore corresponds with the eastern side of Malampaya inner sound, the distance across in some parts not exceeding 4 miles.

A high range overlooks both shores, and that portion which separates the N.W. part of Tai-Tai Bay and bottom of Bacuit Bay has an abrupt shoulder 1,680 ft. above the sea, and some remarkable sharp hunch peaks on it, giving rise to the appellation of Shark-fin range. Four islands lie across the entrance of Tai-Tai Bay, extending in a northerly direction from South Tai-Tai Island.

Tai-Tai Fort, lat. $10^{\circ} 50' N.$, long. $119^{\circ} 30' 56'' E.$, in the S.W. angle of the bay, is the principle settlement of the Spaniards on the island of Palawan. From their own account, they first planted themselves here in 1600. The permanent fortress, which now stands on the extremity of a narrow isthmus (nearly isolated at high water), on the eastern side of the small bay where the village is, was commenced in the year 1710, and, as recorded in the interior of the building, finished in 1738. The fort, which had been allowed

to fall into a dilapidated state, was, under the energetic Alcalde, Antonio Gimenez, an officer in the Spanish Royal Engineers, put in an efficient condition. The garrison in 1850 consisted of about 200 soldiers, Manila men, and there were 17 gunboats attached to the station.

The population at the same period was said to be about 600 souls, consisting of Bysayans and half caste Manila people, over whom are placed the Alcalde, or governor of the province, and seven European Spanish officers, including a padre.

Supplies.—The usual supplies, such as pigs, goats, fowls, vegetables, &c., are to be obtained in moderate quantities, and there were some cattle seen in the interior.

Water here, as elsewhere on this coast, is not plentiful, that is, such as can with facility be procured with ships' boats.

From Tai-Tai the shore of the bay takes a northerly direction. At 2 miles is Tai-Tai Head, and $3\frac{1}{2}$ miles beyond is a bush island, just detached from the shore, with a boat channel inside. A reef awash lies $1\frac{3}{4}$ mile off a little to the southward of this.

Polarican.—There is an islet on the North side of a small opening in the reef, 8 miles to the northward of Tai-Tai, which leads to a rivulet of fresh water, and where, on a hill overlooking it, is a stockade and a small settlement, called Polaricon, prettily situated amongst some cocoa-nut trees.

Silanga Bay, which is 2 miles wide and nearly the same deep, has a settlement comprising a stockade and a few houses built upon a small isthmus head in the north-western shore and immediately under a shoulder peak, 1,700 ft. above the sea, called Silanga Peak.

Shelter from N.E. winds may be had in Silanga Bay in 12 and 15 fathoms, West of Smooth Hill, taking care to keep rather on the eastern side, as the shore on which the settlement is, is fronted by coral half a mile off.

Old Castle Point, having the Lion Rock S.S.E. 4 cables' lengths from it, a high precipitous limestone formation, the N.E. limit of Tai-Tai Bay, may also be considered the S.E. point of Silanga Bay. Vessels proceeding into Silanga Bay should haul close round Lion Rock (a steamer may pass into it) in order to avoid the Royalist Reef, and enter to the N.E. of Silanga Islands, keeping a good look-out for discoloured water.

North Tai-Tai, the southernmost island immediately fronting Tai-Tai Bay, is North nearly a mile from South Tai-Tai Island. *Elephant Island* lies about a quarter of a mile to the northward of Castle Island, and has a reef awash at three-quarters of a mile to the eastward. *Snake Rock*, about 60 ft. high, lies to the eastward, distant $3\frac{1}{2}$ miles from the summits of these three islands, which bear respectively S.W. by W. $\frac{1}{4}$ W., W. $\frac{1}{2}$ S., and W. $\frac{1}{2}$ N.

There is a *bank* with 2, 4, and 6 fathoms coral over it, about a mile in extent, N.E. and S.W., lying to the north-westward of Snake Rock.

South Passage Island, $1\frac{1}{2}$ mile in length North and South, lies in the offing

of Tai-Tai Bay, $7\frac{3}{4}$ miles N.E. by N. of South Tai-Tai Island, and nearly 5 miles S.E. by S. of Old Castle Point.

Iguano, the northernmost island in the entrance of the bay, is $5\frac{1}{3}$ miles to the westward of South Passage Island and N. $\frac{1}{2}$ W. nearly $2\frac{3}{4}$ miles from Elephant Island. There is some rocky ground, on which the *Royalist* struck, $1\frac{1}{2}$ miles to the eastward of Iguano.

Dumbell is a remarkable double headed island with a rocky islet a cable off its S.E. point, W. $\frac{3}{4}$ N. $4\frac{1}{4}$ miles from Iguano, and $2\frac{1}{2}$ miles E.N.E. of Polarican. A small double island also lies W. $\frac{3}{4}$ S. nearly 3 miles from Iguano, and between is a rock, with 15 ft. water over it.

A coral patch with 9 ft. on it lies N.N.W. $\frac{1}{4}$ W. nearly a mile from Dumbell Island.

The *Silanga Islands*, three in number, lie off the entrance of Silanga Bay, each being surrounded by a reef barely a cable in extent; but to the S.E. of the centre island there is a patch lying 3 cables' lengths from it.

Tides.—It is high water, full and change, in Tai-Tai Bay, at 9^h 30^m, and the rise of tide is $5\frac{3}{4}$ ft.

Fronting Castle Peak Peninsula is a group consisting of four large and several smaller islands.

Collinson Island, the S.E. and smallest of the four, $3\frac{1}{2}$ miles in circumference, lies nearly East 5 miles from Castle Peak, and has to the N.W. of it *Dome* (1,020 ft. above the sea), and *Montero* Islands, each being separated from the other by a channel from 2 to 4 cables wide.

Gimenez Island, the largest of the group, $3\frac{1}{2}$ miles in circumference, is a mile to the northward of Montero, from which several small islands extend in a northerly direction towards Knob and Triple, and Smith Islands.

Eight cables E. by N. $\frac{1}{4}$ N. of a remarkable red cliff rock on the East side of Dome Island, is a *rock awash*.

It is recommended not to take the passages between the islands forming this group, as they have been but imperfectly surveyed, although the soundings around are deep, viz. 20 and 30 fathoms.

Three-Fathoms Patch.—Some islets lying on the North side of this peninsula have also reefs off them; N.E. $\frac{1}{4}$ N. $1\frac{1}{2}$ mile from the easternmost of which, and S. $\frac{1}{4}$ E. $1\frac{1}{4}$ mile from Pigeon Island, is a 3-fathoms coral patch.

SHARKSFIN BAY, immediately to the northward of Castle Peak Peninsula, is $2\frac{1}{2}$ miles wide at the entrance, and is formed on the North by an island (connected at low water with the shore), 5 miles in extent, on which are two remarkable peaks, called Knob and Triple. Reefs from the northern shore stretch nearly halfway across the entrance.

SMITH ISLAND, $13\frac{1}{2}$ miles to the northward of Collinson Island, and 5 miles north-eastward of Knob and Triple Island, is $2\frac{1}{4}$ miles in extent, having at the South point a remarkable rocky lump, 60 ft. high, three-quarters of a

mile S.E. of which is a rocky islet, resembling in form somewhat that of a bishop's mitre.

ILOC or **AUSTIN ISLAND**, lying $1\frac{3}{4}$ mile N.W. of Smith Island and $6\frac{1}{2}$ miles East of Santa Monica, is 4 miles in extent N. by E. and S. by W., and has, off its N.E. extreme, a smaller island with a rock out of water in the middle of the channel separating them. The western side of this island appears bold to approach, the depths within half a mile being 16 and 17 fathoms. It has, however, been but partially sounded.

CLEOPATRA ISLAND lies North $2\frac{3}{4}$ miles from the eastern side of Knob and Triple Island, 4 miles to the westward of Smith Island, and $3\frac{1}{2}$ miles from the shore. It is $2\frac{1}{2}$ miles in extent, has an undulating summit, and some detached rocks out of water, off the North point. A coral spit projects to the eastward 4 cables' lengths from the South point of the island, to the southward of which, lying respectively at half and one mile from it, are two rocks out of water.

The *Coast* of Palawan between Knob and Triple Island and Santa Monica, about $7\frac{1}{2}$ miles to the northward, is fronted by rocky ground, which in some places extends upwards of a mile from the shore.

North and South rocks, always above water, lie off it, in a N. by W. and S. by E. direction, $2\frac{1}{2}$ miles apart, the latter being 2 miles from the shore, and nearly $2\frac{1}{2}$ miles North of Knob and Triple; in a direct line between these rocks are two patches of 3 and $3\frac{1}{2}$ fathoms, coral, with 10 and 16 fathoms outside.

Santa Monica, the northernmost settlement of the Spaniards on the East coast of Palawan, is situated in a small bay immediately under East peak, (page 566), the stockade being built on a small projecting head, with a few houses at the back amongst some cocoa-nut trees. The population in 1850 was about 100, and in other respects the station is similar to those previously described.

Darcotuan Bay.—Darcotuan Point, forming the South extremity of the bay of that name, is N. by W. $2\frac{1}{2}$ miles from Santa Monica, and has a small rock close to it, from which Cabuli Island, off the North point of Palawan (described in page 567), is distant nearly $5\frac{3}{4}$ miles to the N.N.E.

Bay Island occupies a central position in this bay, about a mile from the shore, and has on the South side some reefs which stretch nearly two-thirds of the way towards Darcotuan Point. Reefs, awash, also extend 8 cables' lengths in a northerly direction from the latter, with 13 fathoms close to.

In the northern part of the bay are the North and South Brother Islets, lying a mile to the S.E. of the opening between Cabuli and Palawan. The depth immediately outside them is 25 fathoms, but in the direction of Bay Island it is only 12 fathoms, mud.

CHAPTER XIV.

NORTH-WEST COASTS OF THE PHILIPPINE ISLANDS, ETC.

IN this chapter the N.W. coasts of the important archipelago the Philippine Islands will be described. The island of Palawan also belongs to the same archipelago. The latter, as before mentioned, has been regularly, though not completely, surveyed by Captain Bate. Our descriptions of the coasts to the northward of this, which form the eastern limit of the China Sea, is chiefly derived from the charts drawn up under the superintendence of Don Antonio Morata, of the Spanish Royal Navy, who was at the head of the hydrographic commission appointed to collect the information upon this portion of the Spanish possessions. To these charts and the resulting remarks some additions have been made by other officers, as quoted and arranged in the ensuing pages, which are derived from the China Sea Pilot, vol. ii.

The general features of the Philippine Islands will be described in a future chapter, only that portion limiting the China Sea being here alluded to.

HASTINGS ISLAND, lying 7 or 8 miles eastward of the North point of Palawan, between it and Linacapan, is $2\frac{1}{2}$ miles in extent N.W. and S.E., and has several summits, the highest being near its South extremity, where, just detached from the point, is an islet head and some rocks awash. Immediately off the N.W. point is a somewhat flat cliffy head, called Base Cliff, and to the northward of the island, between it and Square-top group off Observatory Island, are two peaked islets.

LINACAPAN ISLAND is the largest of an extensive group lying between the N.E. coast of Palawan and the Calamianes, distant 11 or 12 miles from the former. It is about 10 miles in extent, East and West, and has on the North side two deep bays, with several islands and rocks lying off their prominent points. In the eastern bay are several steep conical heads; and

in the S.W. corner is the Spanish settlement of St. Nicholas, comprising a stockade and a few houses. There are 19 fathoms water at a mile from the settlement; but the approach to the bay has not been sounded, and no part of the southern face of the island has been examined.

Several islands and peaked rocks lie between the North side of Linacapan, and Calamion Island; and to the south-eastward there are also some small groups of islands.

Observatory Island, lying E. by N. $\frac{1}{2}$ N. 10 miles from Cabuli, is the north-westernmost of the Linacapan group. It is 758 ft. above the sea, and when first seen, on making Palawan from the northward appears like a conical hill. The island is $1\frac{3}{4}$ mile in extent, N.N.W. and S.S.E., and has at its North extreme a saddle head, with a slip or water-course down it, connected by a low neck of land, on either side of which are sandy bays.

A small rocky point, where observations were usually taken, in the bay on the West side of Observatory Island, is in lat. $11^{\circ} 30\frac{1}{4}'$ N., long. $119^{\circ} 39' 33''$ E.

The channel between Observatory Island and Linacapan is barely $1\frac{1}{2}$ mile wide, and has upwards of 30 fathoms water. A strong current (depending in velocity and direction on the prevailing winds) will be found usually setting through it.

Square Top Group.—Four islands and some peaked rocks, so called, lie off the S.W. face of Observatory Island, S.S.W. 3 miles from the largest of which is Hastings Island.

Base Reef, lying N.W. by N. nearly $3\frac{3}{4}$ miles from the high part of Observatory Island, is about the size of a large boat, and between it and the saddle head are two rocks awash.

Tides.—It is high water, one day after full and change, at Observatory Island at 11^h ; maximum rise observed, $5\frac{1}{4}$ ft. The half tides in the month of May occurred during the day.

The **CALAMIANES** are a group of high islands lying between the N.E. end of Palawan and Mindoro, and extending between the parallels of $11^{\circ} 39'$ and $12^{\circ} 20'$ N., and the meridians of $119^{\circ} 47'$ and $120^{\circ} 23'$ E.

Busuagan or Busuanga, the largest island of the group, is about 34 miles in extent, N.W. by W. and S.E. by E., and 18 miles at its broadest part. It is very irregular in form, being indented with numerous deep bays. The islands and reefs which front its N.E. side, form the western side of Northumberland Strait.

Calamian or Culion Island lies off the S.W. side of Busuagan, from which it is separated by a strait about 3 or 4 miles wide in its narrowest part, and in which are numerous islands, rocks, and shoals. Calamian is 19 miles long, N. by W. $\frac{1}{2}$ W. and S. by E. $\frac{1}{2}$ E., and its greatest breadth, near the middle of the island, is nearly 10 miles. It is also of very irregular shape on the side next Busuagan, but its western side, which alone concerns the

ordinary navigator, is nearly straight, in the direction of the greatest length of the island. Close to the south-western extreme is *Dicabaito*, a small island which is distant nearly 10 miles from the nearest part of Linacapan ; between them lie the numerous small islands and peaked rocks previously mentioned.

Upon the West side of Calamian, in lat. $11^{\circ} 45' N.$, is a small island at the entrance of a narrow inlet or harbour running into the island in a north-easterly direction about 5 miles. A reef, with some rocks above water upon it, projects about a mile to the south-westward of the island. A little over 3 miles N.W. by W. from the island is an islet or rock, surrounded by a reef, which is nearly 2 miles distant from the nearest shore.

Islands and Dangers Westward and Northward of the Calamianes.—*Galoc* is the name of a long narrow island lying close off the north-western extreme of Calamian. It is surrounded by a reef which projects from its south-western end nearly a mile. Close off its northern part, and about a third its size, is an island named *Popototan*, from the western point of which a reef extends more than a mile to the south-westward.

From Popototan a chain of islands and dangers extends across the strait which separates Calamian from Busuagan, and other islands and dangers extend several miles to the northward ; it is, however, only the outer of these that concern the ordinary navigator.

Isla Verde, *Green Island*, or *Nalaut*, in lat. $12^{\circ} 3' N.$, long. $119^{\circ} 47' E.$, and the westernmost island hereabout, is of moderate height, covered with trees, and visible 15 miles off ; it is surrounded by a coral reef, extending about one-third of a mile. About 3 or 4 miles N.W. of the island the *Discovery* got overfalls on a coral shoal, but did not find less than 5 fathoms ; to the eastward of the island 23 fathoms were found, and 9 and 10 fathoms close to the reef.

The *Haycock*, in lat. $12^{\circ} 9' N.$, long. $119^{\circ} 48\frac{1}{2}' E.$, is a high rocky island, about 2 miles off the western part of Busuagan, and may be seen 18 or 20 miles. About $2\frac{1}{2}$ miles West of the Haycock soundings of 26 fathoms were found, with overfalls, 19 fathoms about 6 miles off, and 30 fathoms about 11 miles off.

Elet is the name of a $2\frac{1}{2}$ -fathom patch, which lies close to the westward of two small islets, joined by a reef to a point of the N.W. part of Busuagan, N. by E., distant about 4 miles from the Haycock.

Escollo del Pinnacle, *Pinnacle Rock*, in lat. $12^{\circ} 19\frac{1}{2}' N.$, and about 2 miles West of the North point of Busuagan, is a very sharp rock above water, having 25 fathoms water about 2 miles westward of it, and 12 fathoms about a mile off.

Calavite, *Dimipac*, or *High Island*, in lat. $12^{\circ} 21\frac{1}{2}' N.$, long. $119^{\circ} 53\frac{1}{2}' E.$, by Captain Ross, I.N., lies about 2 miles to the northward of the North point of Busuagan. It is a small island, not quite 2 miles in extent, and the

channel between it and Busuagan does not appear to be free of danger, as some rocks were seen above water eastward of the island.

About a mile north-westward of Calavite Island are rocks above water, one of which, named *Sail Rock*, is very remarkable; and $1\frac{3}{4}$ mile north-westward of this lies a large black rock, named *N.W. Rock* or *Dichilem*, in lat. $12^{\circ} 24\frac{1}{2}'$ N., long. $119^{\circ} 52'$ E. When passing between these the *Discovery* had 38 fathoms, and about 2 miles N.N.E. of N.W. rock, passed over a coral spot in 8 fathoms.

Calocoto, or *North Rock*, in lat. $12^{\circ} 28'$ N., long. $120^{\circ} 1\frac{1}{2}'$ E., is of a dark slate colour, no trees, has two lumps, and when closely approached, appears excessively rugged, having three others a short distance westward of it. It is the northernmost of the islands which lie on the East side of Busuagan, and may be seen 13 or 14 miles from the deck.

Soundings.—The charts exhibit no soundings within 20 miles of the West side of Calamian, but beyond that distance are irregular soundings, 19 to 54 fathoms. In lat. $11^{\circ} 52'$ N., long. $119^{\circ} 26'$ E., is a patch of 9 fathoms, with other patches, 12 to 15 fathoms, within a few miles of it. The soundings near the islands westward and north-eastward of the Calamianes have been given with the description of those islands. They are also very irregular, 17 to 30 fathoms, with patches of 5 and 8 fathoms, and it would appear necessary to be on the lookout for shoal water when navigating in this locality.

A doubtful patch of 5 fathoms is shown on the charts 14 or 15 miles to the northward of the North point of Busuagan, in about lat. $12^{\circ} 35'$ N., long. $119^{\circ} 52'$ E.

Mindoro Strait.—*Dangers in the North Entrance*—Between the parallels of $12^{\circ} 35'$ N. and $12^{\circ} 34'$, there are four banks at the North entrance of Mindoro Strait, which were examined in November and December, 1872, by the Spanish gunboat *Mindoro*.

Hunter Shoal—The most western of the above, named Hunter Shoal, is in lat. $12^{\circ} 40'$ N., long. $120^{\circ} 15'$ E. The part on which the sea breaks is a flat rock about a cable in extent. It trends N.N.W. and S.S.E. for the distance of 2 cables, with 12 fathoms water on it, but at its South end it has but 8 feet at low water. Around it are depths varying from 24 to 64 fathoms. From it Mount Calavite bears N. by E. $\frac{1}{2}$ E., and Apo Islet E. 1° S., which places it in lat. $12^{\circ} 40'$ N., long. $120^{\circ} 9'$ E.

Merope Shoal lies $5\frac{1}{2}$ miles N.E. of Hunter Shoal. From the centre of the bank, Mount Calavite bears N. by E.; Apo Islet S.E. by E.; and Mount Tundalara, S. 2° W.; which places it in lat. $12^{\circ} 43' 29''$ N., long. $120^{\circ} 13' 22''$ E.

Rosamel Bank, 7 miles N. by E. from Merope Shoal, could not be found. It is probably Hunter Bank, for on sounding on its assigned position, and over a radius of 4 to 5 miles, no bottom was found with 90 fathoms of line.

Bajo De Apo or Appo Shoal, lying between the West coast of Mindoro and the island of Busuagan, was examined by the Spanish surveying ships, and also by the British ships *Discovery* and *Investigator*, under the command of Captain Ross in 1813. Its northern extremity is in lat. $12^{\circ} 45' N.$, long. $120^{\circ} 29' E.$; from thence the shoal extends S.E. by S. $7\frac{1}{2}$ miles, where it forms a very narrow spit or East point, in lat. $12^{\circ} 40\frac{1}{4}' N.$, long. $120^{\circ} 34' E.$; from the East point the southern extreme bears S. $35^{\circ} W.$, distant $5\frac{1}{2}$ miles, and between the two points there are several gaps in the shoal, having 9 ft. water. On the western side there are two islands, *Apo* and *Menor*. Apo, the western one is largest, being about half a mile in diameter, and covered with trees; white beaches line its northern and eastern sides, and a surrounding reef projects about half a mile. About $1\frac{1}{2}$ mile E.N.E. of it Menor a small rock on the western edge of Apo Bank was formerly called Little Apo, and is surrounded by reefs; off its N.W. end is an elevated rock covered with trees. Between Menor and Apo is a wide, practicable channel.

Apo is in lat. $12^{\circ} 39' N.$, long. $120^{\circ} 26' E.$; from its centre the North part of the shoal bears N. $24^{\circ} E.$, distant 7 miles; the eastern point E. $9^{\circ} N.$, 8 miles; and the South point S. $56^{\circ} E.$, $6\frac{3}{4}$ miles.

Towards the middle of Apo Bank, at the North end, are two cays, close to each other, and visible some distance.

The whole extent of Apo shoal is 10 miles from its North to the South point, and 9 miles from its East point to the western part of the large island. There are two high black rocks N.E. of the small island, which may be seen about 6 miles off, and the islands in clear weather are visible from an elevation of 20 ft., about 10 miles. At low water many small rocks are dry on the shoal, particularly along its North side.

Ships intending to pass between the coast of Mindoro and the Appo Shoal in the night, should keep about 6 miles off the small islands near Pandan Point, as the eastern point of the shoal is narrow, and should the wind be westerly, it would not readily be perceived, nor would there be breakers to make known the approach to danger.

Discovery Bank.—The centre of this bank is in lat. $12^{\circ} 41' 13'' N.$, long. $120^{\circ} 37' 10'' E.$, with Point Sablayan bearing N.E. by N.; the North islet of Pandan N.N.E. $\frac{1}{3} E.$; the South islet of Pandan N.N.E. $\frac{2}{3} E.$; Mount Calavite N. by E. $\frac{1}{2} E.$; Apo Islet W. $\frac{1}{2} S.$; and Mer or Islet W. $\frac{1}{3} S.$ The bank is very narrow, extending $1\frac{1}{4}$ mile North and South, with 9 fathoms over it, and no change in the colour of the water. The spot was found with difficulty, as the natives knew nothing of it. The *Mindoro* anchored on it, but saw no signs of breaking; there was a slight stream of current visible.

The **WEST COAST of MINDORO ISLAND** has no soundings off it excepting in the bays, or within 1 or 2 miles of the shore in some places. In the interior double and treble chains of mountains extend through the island, and some low points of land project from them into the sea.

GARZA BAY, formed between points Buruncan and Ilim or Ylin, the South extremes of Mindoro and Ilim Islands, affords excellent anchorage and shelter from northerly winds at the mouth of the strait in 10 or 12 fathoms. Garza Island and its extensive shoal also offers shelter from strong easterly gusts. About 3 miles to the W.N.W. of Buruncan Point is a *rock awash*, and $3\frac{1}{2}$ fathoms on its southern side.

The strait between Ilim and Mindoro is free from dangers, but owing to the prevalence of light airs should not be attempted without a fair wind. Caution must be used when entering Garza Bay from the northward by this strait, for the spit off Mindoro shoals suddenly from 10 to 3 fathoms. Keep the channel well open, therefore, borrowing rather on Ylin until Garza is nearly locked in by the eastern point, then haul easterly, anchoring in 12 fathoms.

This neighbourhood, particularly Mangarin, the principal settlement of Mindoro, had been reported, by a Spanish officer who had commanded a gunboat, to abound in stock, water, &c., and much attention was directed to these matters, as likely to be of importance to vessels making this passage from Batavia, Macassar, or Basilan Strait. Indeed, it is immediately off this place that the *Young Queen* was fallen in with, distressed by want of water, which might have been readily obtained at Ylin without inconvenient delay had the coast been known. No inhabitants were noticed in Garza Bay.

MANGARIN or Mangarim Bay.—H.M.S. *Samarang* passed through the strait, between the S.W. part of Mindoro Island and Ylin Island, anchoring off Mangarin Bay, the *Royalist* being moored within the sandy tongue, which is in lat. $12^{\circ} 20' N.$, long. $121^{\circ} 2' 8'' E.$

The interior of the bay is very shoal, and the settlement, $1\frac{1}{2}$ mile N.E. of the spit, only accessible to light boats. There is no inducement to visit Mangarin; little was offered, and that excessively dear, and water fit for consumption was not found; indeed, the marshy, unhealthy location should be avoided.

ILIM or Ylin Island fronts the S.W. part of Mindoro, covering a space of 10 miles in a N.N.W. and S.S.E. direction. The South extreme is bold-to on all its faces. Hence easterly, with the previous warning for the tail of the Garza Shoal, no dangers are known. Northerly, the passage up to the town by the channel is safe, if it can be run with a free wind; but it is safer to pass outside Ambolon, bearing in mind that the tail of the southern shoal, lying off the latter island, is exactly on the line of contact of Ilim and Ambolon extremes at the moment that Ambolon outer point shows clear of the smaller attached island. Indeed, the reef with this warning is so manifestly to be seen that no excuse will warrant the oversight, notwithstanding the deep water between it and the island.

Supplies.—The town of Ilim or Ylin will be found in lat. $12^{\circ} 15' N.$, one mile to the northward of Ambolon Island. A reef extends seaward half a

mile, off which, with the southern large house bearing East, good anchorage will be found in 10 fathoms. A channel, staked by the natives, leads up to the settlement, where a stream delivers itself into the sea; but much sweeter water was found trickling over a cliff just round the town point to the southward, to which the boats had easier access, and from which H.M.S. *Samarang* was readily completed with water. Of the other source, a most excellent run of water was found, but used for all purposes by the people, and difficult to embark, excepting at high tide, owing to the shore being dry at least a cable's length from the mouth of the stream. Fowls, eggs, grain, and vegetables were procured at reasonable prices. Cattle were stated to be abundant at Mangarin, but of this we have already remarked.

AMBOLON ISLAND.—The dangers on the sea-board of this island are all visible, and easily avoided.

On the meridian, or $2\frac{1}{2}$ miles North of Ambolon, a shoal as well as a tongue spitting to the W.N.W. from Ylin must be avoided; and 5 miles North, two coral banks, one dry at low water, cover the entrance to Mangarin Bay.

The safe channel in, will be found by passing the northern dry patch on its northern side, and the next dry patch ($2\frac{1}{4}$ miles easterly) on its South, anchoring the moment the channel between Ylin and Mindoro is fairly open.

Pandan Islands.—The position and configuration of these islands, which lie off the coast of Mindoro, in $12^{\circ} 50' N.$, were verified by the *Mindoro*. During the S.W. monsoon there is shelter to the N.E. of them; but when seeking it, go North of them, or between the two,—never South of them.

Port Sablayan, one of the few harbours on the West coast of Mindoro; has anchorage which may be recommended. Here, vessels of any size can obtain good shelter at all times except with the winds from S.W.; but even with these, small craft can lie under the lee of the reefs, and large and small vessels alike may anchor in safety outside the harbour, North of point Sablayan, between the Pandan Islands and the coast.

PALUAN BAY, at the N.W. end of Mindoro (House Cliff), was examined by the late Capt. W. T. Bate, R.N., of H.M.S. *Royalist*. It affords excellent shelter in the N.E. monsoon, and is also a convenient place for vessels to obtain supplies when passing through Mindoro Strait. The bay is 5 miles wide at entrance, of a semicircular form, running back 3 miles in a northerly direction. There are no dangers in it. Reefs, dry at low water, extend a quarter of a mile from either point of entrance, having deep water close to them. The soundings at the entrance are from 45 to 50 fathoms, half a mile to the southward of which they increase to 200 fathoms.

The best anchorage is in the north-eastern extremity of the bay, in 14 fathoms (to which the water suddenly shoals from 20 fathoms), less than a mile from the beach, and West from a small isolated head, upon which a

hut is erected. There is a black rock close to it, standing a few yards in front of a sandy beach, which shows in good relief. The bottom consists of a black tenacious mud, from which it is difficult to extricate the anchor after it has been down a few days.

Water.—A small river disembogues immediately on the North side of the cliff, where good water can be obtained with facility; and on the beach there is plenty of drift-wood. The coral projects half a mile from the entrance of the river, and has 10 and 12 fathoms close to its edge.

Caution.—Care must be taken when beating into Paluan Bay, for the squalls come violently off the high land, are very sudden, and at night do not give the least warning.

CAPE CALAVITE, the north-western extreme of Mindoro, is in lat. $13^{\circ} 26'$ N., long. $120^{\circ} 18'$ E. Between it and Paluan Bay there are soundings near the shore, which is bold to approach. The few rocks interspersed along this part of the coast, adjacent to the cape, lie close in, and one of them, just above water, has a sandy beach adjoining, upon the projecting part of the coast that forms the cape. Over this point stands Calavite Mountain, which is of regular sloping form, and visible at a great distance in clear weather.

Flying Cloud Rock.—The ship *Flying Cloud*, on the 7th of April, 1854, is reported to have struck on a sunken rock, with from 6 to 12 ft. water on it, and about 30 or 35 ft. in diameter; it is said to lie in lat. $13^{\circ} 28'$ N., long. about $119^{\circ} 34'$ E.

LUBANG ISLANDS.—Lubang, extending about 16 miles nearly N.W. and S.E., is the largest island of a detached group that fronts the S.W. end of Luzon and the N.W. end of Mindoro; it is high in the middle, but low at each extreme. Navigating-Lieutenant Phillips, H.M.S. *Vigilant*, 1863, remarks that the northern part of Lubang is very low land, and when coming from the southward, the northern extreme of the high land in the centre may be mistaken for the end of the island. *Ambil* or *Amul*, to the eastward of it, is a high conical mountain, about 2,500 ft. high. *Golo Island*, a high but long narrow strip of land, 8 miles W.N.W. and E.S.E., with reefs off its N.E., East, and S.E. points, adjoins the south-eastern extreme of Lubang. The northern part of Lubang is lined by a reef, on which the Company's ship *Regent* was driven and wrecked, after having struck on one of the shoals off the S.W. end of Palawan, where she lost her rudder.

Löoc Bay, on the East side of Lubang, is thus described by Sir E. Belcher,—"On the eastern end of Lubang Island, and covered by *Ambil* Island, is the very snug port of Löoc, which affords safe retreat in the event of accident in passing Calavite, or during the passage by the strait of Bernardino. It is pretty free from dangers at the mouth, and good holding ground will be found in depths between 10 and 20 fathoms. Within the former depth it suddenly shoals, and several lines of coral ledge bar the inner depths of the

bay from direct access, although excellent shelter would be found by a vessel moored between these barriers, to which they might easily be conducted. At the village a brisk rivulet supplies most excellent water, but boats cannot fill except at high water.

In approaching the bay caution must be observed, as a $3\frac{1}{2}$ -fathom patch is marked on the chart about $2\frac{1}{2}$ miles to the eastward of the southern horn of the bay. Water, as well as wood, are easily procured, but bullocks, stock, vegetables, &c., are at the same (or higher) prices as Manila.

Another port was indicated on the North side of Lubang. It was cursorily viewed by the *Samarang* in passing, and appeared to be merely sheltered by a reef running parallel to the coast. It might afford shelter to a steamer, but ingress and egress, unless in very favourable weather, owing to its being on a lee shore, is problematical to a sailing vessel. The village is termed *Tagbach*, and may afford supplies to passing vessels which send their boats. It was reported to be a gunboat rendezvous.

Northward of Ambil are some rocks, and the islets of *Mandani* and *Malacatuán*. To the northward of these islets are shoal patches, but the least water over them appears from the chart to be 6 fathoms, the soundings round about being 36 to 50 and 90 fathoms. Westward of Ambil, and 2 or 3 miles from the northern shore of Lubang, are two rather extensive shoals, named *Ambil* and *Afuera Banks*.

Cabra or Goat Island, the south-western extreme in lat. $13^{\circ} 52\frac{1}{2}'$ N., long. $120^{\circ} 2\frac{1}{2}'$ E., is the outer or westernmost island of the Lubang group, and its S.E. point nearly joins the N.W. end of Lubang; it is a low, flat, woody island, about 200 ft. in height, and very even, with a reef of foul ground projecting from its North end. Sir E. Belcher remarks:—"Some doubt existing as to the true position and the dangers reported to extend off this island, a day was devoted to establish this turning point of the navigation of these seas."

"The *Samarang* grazed the island on its eastern side, rounding to and anchoring off its southern face. The distance usually observed in passing land is the only question to be noticed here. No dangers requiring express caution exist. It has also been passed by the *Samarang*, very close on the West side, much within the range that any merchant vessel could try, without the appearance of danger. In the voyage of H.M.S. *Sulphur*, it is observed,— "Both the *Starling* and *Sulphur* shaved the surf-line of Cabra without obtaining soundings; therefore the dangers reported to lie to the northward of this island are incorrectly stated."

The Channel Eastward of the Labang Islands, and also between them and Mindoro, is frequented by the Spanish ships, when going to or coming from Manila. The *Samarang* beat through this channel easterly, and Sir Edward Belcher remarks,— "It is important to remind seamen that from about 4 to

6 a.m. those who frequent this coast state that sudden heavy squalls may be expected off-shore, and as vessels are compelled to carry a press of sail to make progress, they should shorten before they attempt Calavite; and this especially applies to close working to get through the channel between it and Lubang. Even with caution a flurry took two jibbooms in succession between 6 and 10 a.m. The advantage gained by this channel, which is free from dangers as to pilotage, was manifest, as it enabled us, having cleared the channel at 3 p.m., to reach the entrance of Manila Bay with a free wind at 10 p.m."

MINERVA ROCK.—Ships passing eastward of the Lubang group and approaching the S.W. point of Luzon, called Cape Santiago, should be careful to avoid the Minerva Rock, which seems not to have been noticed by navigators, until the *Minerva*, of Alioa, Capt. Robertson, bound from Sydney to Manila, struck on it at 2 a.m., September 10th, 1834, although an American ship had been wrecked on it several years previously. It is said to be a coral rock, having 17 fathoms water near it, and bearing from Cape Santiago S.E. $\frac{1}{2}$ E., distant 4 or 5 miles.

FORTUN ISLAND, in lat $14^{\circ} 2' 45''$ N., long. $120^{\circ} 28' 34''$ E., is shown on the chart as about a mile in extent, with some rocks off its eastern side. Sir E. Belcher observes,—“The island is safe to, and, like Cabra, requires but the seaman’s attention.”

SIMO BANK.—In about lat. $14^{\circ} 4' N.$, long. $120^{\circ} 16' E.$, 14 or 15 miles northward of the Lubang group, and 12 or 13 miles W. $\frac{3}{4}$ N. from Fortun Island, is a bank 4 or 5 miles in extent, with 7 to 11 fathoms water over it, and irregular soundings, 21 to 109 fathoms, near it.

SOUTH-WEST COAST of LUZON.—We have no description of the land between Cape Santiago (the South extreme of Luzon) and Manila Bay, and this part of the coast is quite out of the ordinary track of vessels proceeding up and down the China Sea. The coast line appears by the chart to take from Cape Santiago a north-westerly direction for 4 or 5 miles, when it trends 10 or 11 miles to the northward to San Diego Point, which appears to be low and sandy. This latter part is fronted by a reef which projects in places more 2 miles from the shore.

Fuego Point bears about N. by W. 10 miles from San Diego Point, and just to the northward of the latter is Lian Bay, and about midway between the points is the anchorage and town of *Nasugbu*. Two or three miles southward and south-westward of Fuego Point, fronting a small bay, are several islets and rocks.

From Fuego Point the coast line takes a direction about N. by E. to Limbones Island, which lies close off a point of the main; in this space are some bays and islets, with anchorages off them. From Limbones the coast falls back to the north-eastward, forming the southern part of Manila Bay.

The soundings off this part of Luzon are deep and irregular, 30 to 100 fathoms, and afford but little or no warning when approaching the dangers, close to which are 17 to 60 fathoms; consequently the navigator will have to approach the coast with proper care and caution.

MANILA.

MANILA BAY.—This large inlet is about 30 miles in extent each way, and the land on both sides is high. The city of Manila, standing on its eastern shore, about 25 miles from the entrance, is the capital of Luzon, one of the largest of the Philippine Islands, and the seat of the Spanish Government in the East. The city is large and convenient for trade, the country adjacent producing excellent indigo, sugar, tobacco, hemp for cordage, &c.; but the inhabitants around are indolent. The cigar factories are numerous, several thousand of women working in each. Its chief dependence was formerly on the trade to Acapulco, carried on in two or three ships, which usually sailed in March or April from that place, and arrived at Manila in August or September, but not always regular; now, however, it has a considerable trade with all parts of the world.

The imports of Manila are chiefly British manufactures, linens and cottons, hardware, and articles of British produce; French and German toys and goods, wines, &c. Its exports are sugars, rice, hemp, tobacco, hides, and cotton; a small quantity of coffee, indigo, rhubarb, native cloths, and hats. In 1875, 86 British ships (chiefly from Hong Kong and Australia), or 57,687 tons, entered at Manila; 111 Spanish ships, or 32,316 tons; and 65 foreign ships, chiefly American, or 53,966 tons.

During the months of June, July, and August, the air of Manila is rendered impure by noxious exhalations arising from the swampy land around; and the weather being sultry, with much rain at times, febrile complaints are then likely to appear.

The N.E. monsoon blows strong out of Manila Bay at times, accompanied by a cloud resembling smoke, which is driven out of the bay to the S.W., and forms an arch in that horizon, when the sky is otherwise clear; but sometimes sea-breezes from the S.W. blow into the bay in the N.E. monsoon after mid-day, increasing in strength as you advance into the bay.

The harbour is formed by two piers at the mouth of the River Pasig. A bar lies off the river's mouth covered by 11 feet at low and 14 feet at high water. The harbour itself has as much as 25 feet of water. The channel over the bar runs from the end of the northern mole S.S.W., diagonally across the mouth of the river, and is marked by *two red conical buoys*, which must be passed close-to.

A small *green light* visible seaward between the bearings N.W. and S.E. is shown from a red iron stand on the battery of the South mole head, and a *red light* visible 8 miles from a circular white tower on the North mole head. These lights bear North and South from each other, and that on the North mole head is in lat. $14^{\circ} 36' 7''$ N., long. $120^{\circ} 57' 20''$ E.

Supplies.—Coal of all kinds may be purchased. *Water* can be purchased, but as the water boats have to be sent 5 or 6 miles up the river, timely notice must be given. The water in Manila, excepting the rain preserved in tanks, is brackish and very hard. Fresh beef is or was very bad, being spoiled in the killing. If much be required, the bullocks should be purchased and killed on board. Vegetables are not plentiful.

“The stay at Manila was sufficiently long to prove how very unsuitable a port it is for refitting a ship and recruiting the men; compelled, as the ship is, to anchor at a distance of nearly 2 miles from the shore, with a temperature ranging from 75 to 85 degrees, with an oppressive atmosphere, the temperature of the water being constant at 82 degrees. The public houses open to the crews are dens of infamy, in which the men are hounded, robbed, and turned into the streets, without any chance of obtaining remedy, owing to the insufficiency of the police.”—J. E. Davis, H.M.S. *Challenger*, Nov. 1874.

THE ENTRANCE OF MANILA BAY is divided by some islands into two channels, known respectively as the North and South channels.

Corregidor, or Mariveles Island and Lighthouse, the principal island in the entrance, lies over towards the North shore, and is $3\frac{1}{4}$ miles in length East and West. A Lighthouse 60 feet high stands on its highest point, in lat. $14^{\circ} 23' 5''$ N., long. $120^{\circ} 33' 30''$ E., and exhibits at an elevation of 639 feet above the sea a *white light*, which *revolves every half minute*, and is visible in clear weather at 20 miles. A *fixed white light* is shown from the white tower on the West mole head. There is fresh water to be procured under a steep cliff at the western end of the island, but the landing is on a stony beach, and inconvenient.

Pulo Caballo and Lighthouse.—Pulo Caballo is a high bluff rock 639 feet high, of considerable size, partially covered with verdure, lying about three-quarters of a mile southward of Buri Point, the eastern extreme of Corregidor. A *fixed white light* is exhibited from the low spur on the N.E. part of the rock, 27 ft. above high water mark, and is visible 6 miles. It is *concealed by high land to seaward* between the bearings of S.W. by S. and W. by S., and *screened towards the North shore* between the bearings of N. by E. and N.W. by W. $\frac{1}{2}$ W.

Sangley Point Light.—A *fixed white light* is shown on the eastern shore of Manila Bay, elevated 29 ft. above high water and visible 7 miles off, at Sangley Point, the outer extreme of the low land at the entrance of Port Cavité.

Soundings of 50 to 40 fathoms will be got when within 7 or 6 miles of

Corregidor, decreasing gradually to 27 or 26 fathoms about 2 miles to the westward of it.

Between Corregidor and the North shore the depths are 50 to 48 fathoms within a quarter of a mile of the island, 26 fathoms in mid-channel, decreasing quickly to 16 or 15 fathoms, stony ground, within half a mile of the North shore.

La Monja, the *Nun*, or *Haycock*, is a high rock, bearing from Corregidor Light W. $\frac{3}{4}$ S. distant 3 miles, with 27 fathoms water within a quarter of a mile of it all round. The soundings from it decrease regularly to 29 fathoms within a quarter of a mile of the North shore, and deepen to 29 or 30 fathoms near the N.W. part of Corregidor, close to which there is a perforated rock.

FULTON ROCK.—This danger lies about a quarter of a mile off the northern shore of the entrance, N. by W. $\frac{1}{4}$ W. from Corregidor Lighthouse. There appears to be 6 to 11 fathoms near the rock, and 5 to 6 fathoms between it and the shore. The North shore, several miles north-eastward of it, is fronted by rocks, and about 3 miles north-eastward of the Fulton is or was a *bell buoy* to warn ships to avoid the dangers which lie off Caucave Point.

El Frayle, the *Friar*, rock or islet, which appears like a sail, lies $3\frac{1}{4}$ miles S. $\frac{1}{2}$ E. from Caballo Light, and nearly 2 miles from the South shore of the bay. Close around it are depths of 10 and 11 fathoms, increasing to 17 and 23 fathoms at a short distance to the westward.

A 3 fathoms' patch lies 3 miles N.W. of Point Marijondon, the nearest land, and 4 miles from the Friar.

PORT MARIVELES, on the North side of the entrance to Manila Bay, is about a mile wide and $1\frac{1}{2}$ mile deep, with good anchorage, sheltered from all but S.E. winds. Vessels of any size may moor here, and procure excellent water. Some rocky islets, called *Los Cochinos*, with a rock awash just outside them, project half a mile off the S.W. point of entrance. Vessels may anchor in 17 fathoms, with the village bearing N.W. by W., or they may run farther into the bay if necessary; the bottom being good holding ground and the anchorage safe. This is a convenient place for ships to touch at when in want of wood and water, the former being an expensive article at Manila.

St, Nicolas Banks are two shoals lying midway between Caballo Island and Port Cavité. The outer shoal, nearly a mile in extent, is the larger of the two, and has but 5 feet water on its shoalest part. From its outer or northern edge in 11 feet water, Corregidor Light bears W. by S. $\frac{3}{4}$ S., and Cavité Church E. by N. $\frac{1}{2}$ N. Within a ship's length to the north-westward there are 13 and 15 fathoms water, the soundings being no guide in approaching it, because the bank is so steep. A buoy was placed on this shoal, but had disappeared when H.M.S. *Nassau* was here in 1871.

CAVITE, on the eastern shore of Manila Bay, is the port and marine arsenal of Manila, where ships are built, and to which those are hove down that want repairs, it having excellent conveniences for that purpose. The town is well fortified, and stands on a low point of land, which forms a good harbour or cove, the deepest water in which appears to be $3\frac{1}{2}$ fathoms, soft mud, with shelter from West and S.W. winds. As the water in the wells here is brackish, the inhabitants are supplied with fresh water from the river by Old Cavité.

ANCHORAGE IN MANILA ROAD.—A good berth is in 7 fathoms, stiff mud, with the church of Santo Domingo (white, with two square towers, an excellent mark for entering or leaving the bay) bearing E.N.E. $\frac{3}{4}$ E.; light on North mole, N.E. by E. $\frac{1}{2}$ E.; an isolated cloister to the right of the town, E.S.E. $\frac{1}{2}$ E.; and the light-tower at Cavité, S. by W. This anchorage is only 2 miles from the town, and has the advantage of a fair wind for boats to and from the mouth of the river. Large ships generally anchor at Cavité Harbour. Sir Edward Belcher observes, that anchorage may be taken up anywhere among the shipping, but the best and most convenient is in 5 or 6 fathoms, having the flagstaff of the garrison gate open to the right of the convent dome, which is within the walls. This position enables boats to fetch off under canvas, against the fresh afternoon breezes, when a very unpleasant sea prevails, which not only renders pulling in laden boats laborious, but entails wetting, a matter in tropical climates to be specially avoided, irrespective of damage to light goods.

Tides.—It is high water, full and change, in Manila Bay, at $10^h 40^m$, and springs rise about $2\frac{1}{2}$ ft. The tides are irregular; with an easterly wind, the ebb runs out 18 hours together, between Corregidor and the North shore pretty strong; the flood about 6 hours to the eastward, sometimes weak, at other times with considerable strength.

Directions.—If intending to enter Manila Bay by the North channel,—when about 6 miles to the westward of Corregidor, steer for it; with a fair wind the common passage is between it and the Haycock, afterwards on the North side of Corregidor. From hence to Manila the course is N.E. by E. $\frac{3}{4}$ E., distant 25 miles, and to Cavité E. by N. $\frac{1}{2}$ N. 22 miles. To avoid San Nicolas Shoals, keep the Haycock open of the northern part of Corregidor bearing W.S.W. until the steeple of Cavité Church bears East, and a remarkable hummock, which stands close to the sea upon a point of land on the North shore, W.N.W.; being then clear of the shoals, steer for Cavité or Manila at discretion.

In the fair channel, between the shoals and the North shore of the bay, the depths are 17 and 18 fathoms, decreasing gradually towards that shore to 5 and 4 fathoms; and in steering eastward, the depths also decrease regularly to 5 fathoms off Cavité, where ships anchor a little more than a mile off shore in that depth, the bottom all stiff mud.

In using the channel northward of Corregidor, care must be taken not to near the North shore under a mile, in order to avoid the Fulton Rock and the dangers fronting that part of the coast. It appears from the chart that the Haycock kept to the westward of S.W. $\frac{1}{4}$ W., will lead clear of these dangers.

South Channel.—When the wind is blowing from the eastward, out of the bay, the current runs out through the North channel to the westward; it is therefore proper at such times to adopt the channel between Corregidor and the South shore, there being more room in it to work to windward. To enter the bay by this channel, caution is requisite when the vessel is abreast Point Marijondon, the easternmost high land on the South shore, N.W. of which is the 4 fathoms patch before mentioned. The trail of the St. Nicolas Banks also trends away gradually towards this high land, and the water may shoal suddenly in approaching them from 12 to 7 or 6 fathoms, rocky ground. Do not, therefore, come under 13 fathoms when in their vicinity, and when to the eastward, keep the Haycock open with the northern part of Corregidor. From 15 fathoms water, the east may be 7, and then 8 fathoms on the verge of the St. Nicolas Banks, when the Haycock is shut in with Corregidor.

To avoid the St. Nicolas Banks at night, Corregidor Light must not be brought to the westward of S.W. by W. $\frac{3}{4}$ W.

Within three-quarters or half a mile of the eastern part of Corregidor there are 22 and 23 fathoms; and when it can be rounded, stand over for and work along the North shore, which has 15 or 16 fathoms at a quarter of a mile, and 10 or 12 fathoms about a cable's length off; although, in some places, the water shoals suddenly from 15 to 10, 7, and 5 fathoms, there is no invisible danger, and when past Corregidor, the North shore has good anchorage over a sandy bottom. Farther to the northward and eastward this shore becomes more flat, the soundings decreasing regularly from 10 to 8, 6, 5, 4, and 3 fathoms close in shore.

Sir Edward Belcher remarks, that it is customary to enter this bay by the passage between Mariveles Bay and Corregidor Island, but experience has proved that this practice is injudicious, that the wider channel easterly, where less tide prevails, is to be preferred, where the local or coasting pilot well knows, that by hugging the eastern coast of the bay or wide channel, a fair leading or working breeze will be experienced at times when calms prevail on the western side of the bay. As an instance of this, at 5^h 30^m a.m. on the 16th March, 1844, an American frigate was seen at dawn well to windward, taking the western channel. Fresh working breezes prevailed, and at noon the *Samarang* having beat up by the eastern channel, had brought El Frayle S.S.W. $\frac{1}{2}$ W. and Cavité Lighthouse E.N.E. In 12 hours, viz., at 5^h 30^m p.m. she was moored off Manila. At dawn the next morning the

American frigate was seen becalmed on the West side of the bay, and she did not anchor off Manila before 8 o'clock.

The only reason advanced for the custom before alluded to, is, that it is more convenient for the guard boat to communicate by the western channel, and the officer of the guard boat generally instructs vessels in an authoritative manner to adhere to routine, even to threaten if his directions are not obeyed.

Working up on the eastern side of Manila Bay, the chart furnishes sufficient warning as to where danger may be apprehended. The best leading mark for avoiding the San Nicolas Banks (until Cavité Lighthouse bears E. by N. $\frac{1}{2}$ N.) is never to open El Frayle to the westward of the more distant land to the southward. Nevertheless, it is prudent to hug that shore, on short boards, up to that limit, particularly about noon, or before 2 p.m., as the S.E. sea breeze first makes easterly, then southerly, off Cavité, which affords a fine lead to the anchorage of Manila.

The *Coast* from Mariveles Point, at the entrance of Manila Bay, takes a general direction nearly N.W. by W. $\frac{1}{2}$ W. for about 7 miles to Luzon Point, and is indented with several small bays; it then trends nearly North for about the same distance, and then north-westward for another 8 or 9 miles, thus forming a bight, named Bagac Bay, the town of Bagac being in the depth of it, in lat. $14^{\circ} 35' N.$ From the north-western extreme of this bay the coast line trends to the northward to Port Subig.

The *Coast* from Mariveles Point to Port Subig is in general equally steep, and may be approached to 1 or 2 miles in some parts; but it will be prudent to give it a wide berth, because rocks or foul ground extend 2 miles or more from some of the points.

PORT BINANGA, or Minangas, is the first bight to the southward of the entrance of Port Subig. Small vessels may anchor in 3 fathoms, sheltered from all winds excepting those at West and W.S.W.; the course into it is East and E. by N., about mid-channel between the points, to avoid the shoals projecting from them, and there are 4 fathoms, fine sandy bottom, inside, within a musket-shot of the shore.

PORT SUBIG has *Grande Island* at its entrance in lat. $14^{\circ} 47' N.$, long. $120^{\circ} 12\frac{1}{2}' E.$, to the westward of which is the safe passage into the port; for the passage to the eastward is intricate and lined by reefs. This port stretches 8 or 9 miles inland, and forms two excellent harbours, one on the East side, named Port *Olongapo*, or Olonapo, and the other at the northern extremity, opposite the village of Subig; here ships of any description may be sheltered from all winds in 7 to 10 fathoms, mud.

PORT SILANGUIN, in lat. $14^{\circ} 47\frac{1}{2}' N.$, long. $120^{\circ} 5' E.$, is about half a mile wide at entrance, and 2 miles deep, having tolerable shelter from all winds, but rather exposed to the N.W. and W.N.W. The southern part is formed by a high, round, bare hill, with a reef projecting from it about a

musket-shot to the northward; this must be avoided in steering East into the entrance of the port, where the depth is 30 fathoms, decreasing gradually to the anchorage a little inside, near the beach on the South shore, which is the best berth.

About $2\frac{1}{2}$ miles S.S.W. of the southern point of this port there are several rocky islets, called the *Three Friars*, with a coral reef projecting from them nearly a mile to the north-westward, and between these rocks and the shore there are 40 and 42 fathoms water.

There is a stream of *fresh water* at the bottom of Port Silanguin.

CAPONES POINT, in lat. $14^{\circ} 54' N.$, long. $120^{\circ} 3' E.$, is the most western point of this part of Luzon, and therefore important to vessels proceeding to and from China, and passing close to this coast. It bears from Cabra, or Goat Island, North, distant 60 miles, and is high, bare land, of reddish aspect, having two islands about 2 miles distant to the north-westward of it; the outermost of these, called Great Capones, is about one mile in length East and West, and nearly 3 miles distant from the shore. It has a sunken rock off its North side.

About a mile outside Capones Point the depth is 42 or 44 fathoms; from 40 to 35 fathoms will be found within a mile of the shore, between this part of the coast and the North part of Port Subig, and generally 45 to 50 fathoms about 3 or 4 miles off.

The *Coast* from Capones Point takes a general N. by W. $\frac{1}{2}$ W. direction for 33 miles, to the southern part of Palauig Point. A town named *Cabangan* lies about 7 or 8 miles northward of Capones Point, and another and more important town, named *Iba* or *Yba*, the capital of the province of Zambales, 6 or 7 miles southward of Palauig Point. A reef is also shown as lying about 2 miles off shore, in lat. $15^{\circ} 10' N.$, with several other dangers between it and Palauig Point. At 19 or 20 miles to the northward of Capones Point, is *Playa-Honda*, formed of a small hill, projecting a little into the sea; and the fort is 2 miles farther northward amongst trees, by which it is not easily perceived. The coast between them is of moderate height, with a level space of considerable extent northward of Capones Point; but inland, the country is formed of high double mountains, one of which has a small sharp peak upon it. About 2 or 3 miles off, the depths are 35 and 40 fathoms, and the shore is lined by coral reefs, stretching out nearly a mile in some places; about $1\frac{1}{2}$ mile from the beach there is a small coral bank, bearing S.W. by S. from Playa-Honda Fort, having 2 fathoms water, and close to it 10 or 12 fathoms. From Manila Bay entrance to lat. $15^{\circ} N.$ the land is generally high and mountainous. Here it begins to decrease in height; and near the sea in lat. $16^{\circ} N.$ is not much elevated.

PALAUIG POINT and BANK.—The southern part of this point is in about lat. $15^{\circ} 26\frac{1}{2}' N.$, long. $119^{\circ} 53' E.$; from thence the coast line trends

northward for 5 or 6 miles to the southern point of entrance to Port Masingloc.

Palauig Bank is a danger about 2 miles to the south-westward of the point; from its outer part the West end of South Salvador Island bears N. by E. $\frac{3}{4}$ E., and Mount Yba E. by S. The *Luzon*, a new steamer, commanded by Mr. McGowan, was wrecked upon this shoal in December, 1864; and as, by the same authority, there appear to be several other dangers on either side of the point, it will be prudent to give this part of the coast a berth of 3 or 4 miles.

The *Coast* from Palauig Point to Cayman Point, bearing N. by W. $\frac{1}{4}$ W. 30 miles, is indented with several deep bays filled with shoals, projecting beyond the points that form their entrance. Just round the northern part of Palauig Point, in about lat. $15^{\circ} 31' N.$, is a small port named Masingloc; and 16 or 17 miles farther northward, inside the Hermans or Sisters Islands, is the port of Santa Cruz. Between Santa Cruz and Caiman Point is Bazol Bay, which appears to be encumbered by many dangers.

HERMANAS and CULEBRA ISLANDS.—Hermanas Islands, or the *Two Sisters*, are low and woody, with a conspicuous sandy beach, the northern one, in lat. $15^{\circ} 48' N.$, being the larger, and distant about $2\frac{1}{2}$ miles from the other. *Islote Culebra*, about $5\frac{1}{4}$ miles northward of the North Sister, is small, with trees on it and a sandy beach. These islands have shoals projecting a long distance from them, and it will be prudent to give them a good berth in passing, for they are about 6 miles off shore.

PUNTA CAYMAN, or Cayman Point, in lat. $15^{\circ} 55\frac{1}{2}' N.$, has a reef projecting to the S.S.W.; but the channel is safe between it and Culebra Island, having 30 fathoms water, and the point may be approached occasionally to 10 fathoms on the tail of the reef.

Seno de Bazol, or *Tambove Road*.—The channel between Culebra Island and Caiman Point leads to the extensive bay called the Seno de Bazol, or as formerly Tambove Road, which lies to the eastward of Caiman Point, and is open only to southerly winds. There appears to be many detached reefs in it. Steering for the extremity of the beach, to the eastward of the point, the depths will be 12 to 15 fathoms, coarse sand and shells, near the termination of the beach; the water will then deepen, but until in soft mud it will be improper to anchor, for rocks are scattered over the bottom, where it consists of sand.

Wood and good water may be got here.

The Coast.—From Caiman Point to the entrance point of the Bay of Lingayen, the land is level, of moderate height and sterile aspect, with a steep beach fronting the sea, and may be seen in clear weather about 24 miles. The coast in this space is bold to approach, having no ground at 50 fathoms within a mile of it in many places; there are soundings near the

beach in some of the small bays, where a vessel may anchor occasionally, but there is no safe place of shelter for large ships.

LINGAYEN GULF, or *Pangasinan Gulf*, the entrance to which between *Purra Island* off Bolinao on the West and Punta de San Fernando on the East, is 17 miles wide, and from the line joining them to its head at the town of Lingayen 26 miles in depth, is very extensive, formed by the low land of *Cabaluyan Island*, taking a south-easterly direction about 12 miles; and then the Mongos-Mongos chain of islets and rocks, extending along it nearly S.E. by S., lines the West side of the bay.

The Gulf is about 30 miles deep, and about 20 miles wide across the entrance, from Santiago Island to San Fernando Point, or Balanac. Lingayen River, a place of some trade, disembogues at the bottom of the bay, and into which the small coasting vessels can pass over the bar. The rivers San Fabian and San Thomas are farther eastward, the former directly in the S.E. angle of the bay.

Port Sual.—About $1\frac{1}{2}$ or 2 miles to the southward of the high islet *Calamitian*, which is the last of the Mongos-Mongos chain, there is good anchorage in muddy bottom, at the entrance of a small port, called Sual, into which a ship might be warped, should circumstances render it necessary.

Navigating Lieut. Harvey, of H.M.S. *Magicienne*, in 1859, made a rough plan of Port Sual, and furnished the following account:—

The port is of small extent, the entrance narrowed by rocks and reefs to the breadth of about a third of a mile, while an extensive coral bank, with but 5 ft. water over it, fills up a large portion of the port.

The land about Portuguese Point, the northern point of entrance of the port, appears like an island when viewed from a distance of 7 or 8 miles; the point may be recognized by a small round tower on its bluff, and between it and Calamitian Island the ground is foul, with rocks just awash. A reef extends nearly $1\frac{1}{2}$ cable's length from Portuguese Point. It is always covered, and the sea breaks upon it only when the wind sets in. *Mangos* or *Manzas Point*, the southern point of entrance, has rocks extending some distance from it; but they are always uncovered, and may be approached to half a cable's length. In the S.W. part of the port is the village, which has a church and a small landing jetty. Mr. Harvey made the position of Port Sual to be lat. $16^{\circ} 7' 20''$ N., long. $120^{\circ} 2' 44''$ E., and the rise of tide 6 feet.

When approaching the port, keep about $1\frac{1}{2}$ or 2 miles from Calamitian or Calamitian Island, steering for Manzas Point; pass the outer rock off that point at the distance of half a cable's length, and then steer for the church, taking care to avoid the large coral patch, the southern edge of which lies between the N.E. point of the port and the church, bearing from each other N.E. $\frac{1}{2}$ E. and S.W. $\frac{1}{2}$ W.; anchor in 5 or $4\frac{1}{2}$ fathoms.

DILE POINT, in lat. $17^{\circ} 34\frac{1}{2}'$ N., long. $120^{\circ} 20\frac{1}{2}'$ E., is the most prominent point of this part of the coast, projecting far to the north-westward. Between it and San Fernando Point there are several towns along the coast. The country is formed of high double mountains, with low woody points to seaward in some places, and the direction of the coast is mostly North and N. by E. H.M.S. *Samarang* met with a dangerous patch in the bay near Dile Point, $2\frac{1}{2}$ miles off shore, a church bearing E.S.E.

Vigan or *Bigan Road*, in lat. $17^{\circ} 24'$ N., is sheltered from northerly winds by Dile Point, but exposed to the southward and westward. A patch of $3\frac{1}{2}$ fathoms is marked on the chart about a mile off shore. The anchorage is near the shore, off the river, bearing about East, in 10 or 12 fathoms; the bank shelves suddenly off to no soundings. About 9 miles inland to the E.N.E. of the road there is a *chasm* between two mountains, called *Abra de Vigan*, or *Gap of Vigan*, which is very conspicuous when viewed from the offing, and is a good mark to know this part of the coast.

Lepog or *Salut-Salut Bay*, at 11 miles north-eastward of Dile Point, is sheltered from all winds but those that blow between S.W. and W.N.W. There are good depths in it, and the reefs bounding the entrance, with a rocky bank in the mouth of the bay, will be seen in clear weather. The rocky bank has 1 and 2 fathoms on it, with a passage on each side of 9 or 10 fathoms water; but that to the northward, between it and the North point of the bay, is too contracted.

The coast from *Vigan Road* to this bay should be given a good berth, for *Pingue* or *Pinget Island*, or *Bantay*, surrounded by breakers and foul ground, lies about $1\frac{1}{2}$ mile off the projecting part of the land to the southward of Lepog Bay; and to the northward of it the coast is lined with coral reefs, stretching out a great way, as far as the entrance of Lepog Bay.

PORT SALOMAGUE, adjoining to the northward of Lepog Bay, is separated from it by a point of land encompassed with shoals. West from this point, $1\frac{1}{2}$ and 2 miles distant, are two rocky banks, with $2\frac{1}{2}$ fathoms, or probably less, water on them. This port is more capacious, sheltered from the same winds, and deeper than Lepog Bay.

The North point is also, like the southern one, encompassed with a reef, which stretches to the eastward along the northern side of the port; and an island of moderate height lies about three-quarters of a mile from the point, with a reef projecting off it about a cable's length to the S.W. This place may be known from the offing by a chasm or gap in some high mountains, which overtop the rest of the chain on this coast. It resembles the Gap of *Vigan*, but it is not so large, nor does it approach so near the sea as that gap; it may also be seen bearing about S.E., when a ship is 12 or 13 miles West of Salomague Bay. When the Gap of Salomague bears about E. $\frac{1}{4}$ S., an East course will lead direct towards Salomague Island at the North point of the port, which should be approached in a large ship, bearing about

East; and the reef off its S.W. point ought to be passed close in 25 or 30 fathoms, mud, to avoid the rocky banks that lie to the westward of the South point of the port; she may then steer right in the middle of the port, rather inclining towards the northern shore, and anchor in 8 fathoms. Farther in there is a shoal spot, which will be perceived in clear weather by the discoloured water on it. The best berth to moor is in 6 or 7 fathoms, mud, opposite some rice magazines on the North shore.

The Coast from Port Salomague trends about N. by E. to Cape Bojeador; in the bight to the southward of the cape there is said to be anchorage near the shore; in some parts the coast is low and woody to seaward.

The chain of high mountains inland, which commences near St. Fabian, in the Gulf of Lingayen, extends parallel to the coast, gradually diminishing in height, and stretching more inland about 24 miles to the southward of Cape Bojeador, leaves a spacious plain fronting the sea. Another chain of hills begins about 7 or 8 miles from the shore, and stretches northward parallel to the coast-line.

About 9 miles northward of Salomague is *Badog* or *Sinay Isle*, about half a mile off a point of land, surrounded by a reef; and the coast between these places is rocky, with breakers projecting from it about a mile.

Ilara Hummock stands near the sea, about 9 miles southward of Cape Bojeador; being of middling height, with patches of trees on it, and there being no other of similar appearance, it is a good mark in sailing along the coast. Soundings are got about 3 miles off shore from Salomague to *Ilara Hummock*, but from 4 or 5 miles beyond the latter to Cape Bojeador, none are obtained at the distance of 2 miles from the shore; and the whole of this part of the coast is destitute of shelter for ships, and has rocky patches stretching out above a mile in some places.

CAPE BOJEADOR, in lat. $18^{\circ} 30' N.$, long. $120^{\circ} 34' E.$, is a low point with a reef of breakers projecting off it, which forms the north-western extreme of Luzon. From hence the coast takes a N.E. direction, and at the distance of 6 miles is *Negra Point*, on the East side of which is anchorage with southerly winds. The deep bay between this point and *Dialao Point*, 9 miles to the N.E., has much foul ground on its eastern shore. There is anchorage at the bottom of this bay, near the small port of *Bangui*, which is said to have been long shut up by an earthquake.

Cauagan or *Mereira* or *Mayraira Point*, distant about 20 miles N.E. of Cape Bojeador, has a reef projecting about a mile out. *Caravallo* or *Patapat Point*, bearing about E. by S. 11 or 12 miles from *Cauagan Point*, is a bluff, steep point of white cliffs, having a mass of high mountains, the *Montes Patapa*, contiguous to it. To the eastward of *Caravallo Point* there is a round hill of middling height, called *Pata Point*. The whole of the coast from Cape Bojeador to this place is steep, without any soundings until near the shore.

The land is of moderate height, and in some parts rather low close to the sea, with several rivers; but the country inland is high and mountainous.

SCARBOROUGH or **Maroona Shoal** was surveyed by Nav. Lieut. Wilds in H.M.S. *Swallow*, March, 1866. It is a dangerous coral reef, rising out of deep water, and it affords, and that only in the calmest weather, a single precarious anchorage off the entrance to the lagoon, at its south-eastern extremity. The opening to the lagoon is about 2 cables wide, but it is dangerous from the large jutting pieces of coral extending from point to point, over which there are only 9 ft. water, with 5 and 6 fathoms close to; just within it shallows.

The reef consists of a narrow belt of coral, nearly level with the water's edge, enclosing a lagoon of clear blue water. On the belt are scattered several rocks 3 to 10 ft. above water, visible about 5 miles. The 10-ft. rock is $1\frac{1}{2}$ mile S.W. of the opening. In shape the reef is a right-angled triangle, with the corners rounded off, the western side being nearly perpendicular to the southern, the direction of the three sides being S. $\frac{3}{4}$ E. $7\frac{1}{2}$ miles, S.E. by E. 10 miles, and E. $\frac{1}{2}$ N. 8 miles. The South side and North point are in lat. $15^{\circ} 5' N.$ and $15^{\circ} 12' N.$ respectively, and the West side and East point in long. $117^{\circ} 44'$ and $117^{\circ} 52' E.$

In March, 1866, the current ran strong to the westward; in April, 1853, its direction was very doubtful in the proximity of the reef. It is high water, full and change, about 11^h , and the rise is 5 ft.

The **TRURO SHOAL**, in lat. $16^{\circ} 19' N.$, long. $116^{\circ} 41' E.$, was discovered by Capt. T. J. Duggan, of the ship *Truro*, in September, 1857. He states, "Whilst taking my forenoon observation, distinctly saw the bottom, white coral. Got a cast of the lead instantly at 10 fathoms; again, about half a mile more North, had 19 fathoms; steered North for another half mile, and had 22 fathoms, and the next cast no bottom at 40 fathoms; no shoal patches were visible from the mast-head."

PRATAS ISLAND and **REEF** was surveyed by Navigating Lieutenant John Richards, R.N., April, 1858. Patras Island, the N.E. end of which is in lat. $20^{\circ} 42' 3'' N.$, long. $116^{\circ} 43' 22'' E.$, rises from the West side, and near the middle of the sunken part of the Pratas Reef. It is about $1\frac{1}{2}$ mile long, E. by S. and W. by N., half a mile wide, and 40 ft. high, of which elevation the scrubby bush, with which it is covered, forms about 10 feet. It is composed of sand, not a particle of mould or earthy matter could be found on it, and its shape is that of a horse-shoe, enclosing a shallow inlet or lagoon, which runs into its western side for about half a mile, and must afford shelter to the Chinese fishermen who come here to fish in the early part of the year. Brackish water can be obtained by digging a few feet

into the sand. Gannets are numerous, and may be knocked down with sticks.

The island is visible at a distance of 9 or 10 miles, in clear weather, from the deck of a large vessel; from the westward it will make like two detached but contiguous islets, the centre being lower than the ends. It is visible when near the southern extreme of the reef, but more conspicuous when approaching it from the westward or northward.

The N.E. point of Pratas Reef is in about lat. $20^{\circ} 47'$ N., long. $116^{\circ} 53'$ E., is a coral barrier of nearly circular form, encircling a lagoon of 5 to 10 fathoms water, and thickly studded with coral knolls round its margin, but comparatively clear near the middle. The reef is about 40 miles in circumference, 1 to 2 miles broad, and slightly flattened on the northern side. Nearly two-thirds of it, or the North, East, and South sides, are just dry at low-water springs; the remainder, or western side, forms a sunken barrier, across which are two channels leading into the lagoon, one on each side of Pratas Island. The North channel is about 3 miles wide, between the island and the edge of the breakers, and 3 fathoms may be carried near the middle of it at low-water springs. The South channel is by far the better of the two, from being wider, a little deeper, as well as its comparative freedom from coral knolls.

Tides.—During the survey of Pratas Reef, April, 1858, it was high water, full and change, at about 4 a.m., and the rise was about 5 ft. There was only one perceptible ebb and one flow in the 24 hours at the springs. The highest tide occurred on the third day after the full moon, but the tides were very irregular.

Anchorage.—Although Pratas Reef is steep-to in most parts, there are several spots where, in case of necessity, a vessel might find anchorage outside the breakers, particularly on the West side, abreast the middle of the channels through the sunken part of the reef, and at the distance of about $1\frac{1}{2}$ or 2 miles on either side of the island. At each of these spots there is good anchorage in the N.E. monsoon, in 20 to 10 fathoms, but the position abreast the South channel is considered the best, the sunken reef at this part being deeper and the bottom more even than in the channel North of the island. A vessel of light draught might even anchor in safety on the reef, in the middle of the South channel in $3\frac{1}{2}$ fathoms at low water, or cross it and take up a berth inside the lagoon in 10 fathoms, fine sand.

Captain Ross, I.N., visited this reef in the *Discovery*, with the *Investigator* in company, August, 1813. The first soundings obtained were 74 fathoms, fine coral, about $1\frac{1}{2}$ or 2 miles from the N.E. point; from thence the former vessel steered along the North side, about three-quarters of a mile from the breakers, in soundings of 31 to 38 fathoms; the *Investigator* keeping about a quarter of a mile off, had great overfalls of 10 to 24 fathoms. After rounding the N.W. part of the reef about a mile off in 35 fathoms, rocky

bottom, they anchored in 24 fathoms, about $1\frac{1}{2}$ mile from the West end of the island, with the island bearing from S.E. $\frac{1}{2}$ S. to E.S.E. About half-way between this position and the shore the depths were 4 and 5 fathoms, and then very shoal water.

H.M.S. *Highflyer*, in May, 1857, anchored about 8 cables' lengths from the West end of the island, in 20 fathoms, coral and clay, the extremes bearing S.E. $\frac{2}{3}$ E. and E. by S. She also anchored, with stream anchor, at half a mile from the S.E. edge of the reef, in 32 fathoms, white mud, with the centre of the island N.W. $\frac{1}{2}$ W. distant 10 miles; there were 13 fathoms water at 2 cables' lengths from the edge of the reef, and 7 fathoms at a short distance from the edge. In April, 1859, H.M. steam gunboat *Leven* anchored three-quarters of a mile off shore in 5 fathoms, with the centre of the island bearing E. by N.

Caution —When beating against, or running with, the strength of the monsoon up or down the China Sea, vessels should always endeavour to pass to leeward of Pratas Reef, on account of the invariable set of the current to leeward; for there are no soundings to indicate a near approach, and the weather is frequently thick and hazy in this vicinity. The safest quarter to make the reef is from the N.W., the island being on its western side, and the currents in the neighbourhood invariably running in a N.E. or S.W. direction according to the monsoon. Approaching the reef, a vessel should be coned from the fore-top. The sun should be well above the horizon, and if possible astern or on the beam, as the bottom can then be easily seen in 10 fathoms.

The *Hossack Shoals* were said to have been seen by Mr. Hossack, commanding the ship *Cyclone*, 9th August, 1861. He reports, "When standing to the N.W., wind W.S.W., tacked ship, having seen two patches, the easternmost of which appeared to be very shoal, about 2 or 3 fathoms water, extending about 400 ft., and the water breaking on it. From good observations the position of the reef is lat. $21^{\circ} 31' N.$, long. $117^{\circ} 7' E.$ " These shoals were sought for in vain by H.M.S. *Serpent* in 1866.

CHAPTER XV.

THE CHINA SEA, WITH ITS ISLANDS AND DANGERS.

THE great channel between the continent of Asia on the N.W., and the line of the islands of the Indian Archipelago between Borneo and the Philippines on the opposite side, have been described in previous pages.

The Coasts of Malaya and the Gulf of Siam are described in Chapter X, pages 400 to 427.—The Coasts of Cochin China and Ton King, with the Island of Hainan, are given in Chapter XI, pages 428—480.—The North-West Coast of Borneo, in Chapter XII, pages 480 to 512. Palawan Island and the Philippine Islands are included in Chapters XIII and XIV, pages 513—608.—The South-West part of the China Sea, or that between the North coast of Java and the Coasts of Sumatra and Borneo, is described, with its detached islands and shoals, in Chapter VIII, pages 295—356.

The CHINA SEA, although the main ship route towards the long frequented parts of China, was but imperfectly understood previous to the examination commenced by Lieut. J. W. Reed, R.N., in H.M.S. *Rifleman*. Before this, the charts were disfigured by numerous shoals, which closer examination showed to be either non-existent, or placed so far out of their true positions as to have been announced at different times as distinct dangers, widely separated.

The important results of Lieut. Reed's survey have been to show that there are two clear channels, free from all known danger, the one to the N.W. upwards of 230 miles in breadth between the coasts of Cochin China and a line of reefs and dangers lying along the centre of the China Sea, generally parallel with its limiting coast. The other channel, termed the Palawan Passage, lies between the reefs on the edge of the bank of soundings on the N.W. side of that island and the S.E. limit of that apparent archipelago of reefs which limits the northern channel.

The labours of the officers in command of the *Rifleman* have wisely been confined in the outset in determining the outer limits of this line of dangers,

and the result has been not merely the determining of the exact character of many previously announced reefs and banks, but proving the non-existence or wrong identity of others, and the discovery of several new groups of banks, which are not dangerous, but will serve as excellent points of verification and departure in this troublesome navigation.

The currents of this region, also, do not appear to be well understood, and some remarks by Captain Polack, on pages 85—91, will be read with interest, as giving the result of much experience in these waters, and the best means of utilizing every slant of wind or current in making a direct passage against the adverse monsoon, instead of the very circuitous routes formerly advocated.

From the fact of its dangers having thus disappeared, and those which are determined having shown that there are safe routes under the lee of either shore, it is probable that a great portion of the commerce will pass through this main ship channel, instead of being carried through the distant and imperfectly known passages to the eastward of Borneo.

The S.W. portion of the China Sea, which has been previously described, is separated from the main area by three groups of islands, the Anamba Islands and the two clusters of the Natuna Islands, which have broad and safe channels between them. In describing these, we follow, as heretofore, the compilation published by the British Admiralty.

THE ANAMBA ISLANDS.

The westernmost group, termed by Europeans the Anambas, is not known by that name to the natives. They are mountainous and sterile, and the scanty products of the land and sea are disposed of by the few Malay inhabitants at Singapore. Formerly they had an evil name for piracy, but are now peaceful traders and fishermen, nominally subject to the Dutch, a flag of that nation being shown at Terempa, where a magistrate is appointed.

The approach to the group from the westward is not dangerous, and the French surveys of this part, made in 1828 and 1831, may be used with confidence.

Climate.—From the vegetation and the stout build of the people, the climate must be considered very favourable. While the average temperature in Bangkok and in the Gulf of Siam had been, in daytime in the shade, 93° to 95°, and at night 88° to 90½', it was at the Anamba Islands only, respectively, 84° and 77°. The cause of this low temperature appears to be the frequent heavy rains, preceded by fresh breezes. (Corvette *Nymphe*, June, 1873.)

The **SOUTHERN GROUP** consists of the White Rock, high above water, in lat. 2° 20' N., long. 105° 34' E., and the following islands:—

Pulo Repon, or Saddle Island, in lat. $2^{\circ} 25' N.$, long. $105^{\circ} 52' E.$, the most southern island of the group, is about three-quarters of a mile in extent. Captain Goldsmith, of H.M.S. *Ilyacinth*, states that this island has discoloured water three-quarters of a mile off its N.E. end, with regular soundings of 33 and 35 fathoms, sand and shells, about $1\frac{1}{2}$ mile to the westward of it.

Capt. Laplace, of the French Imperial corvette *La Favorite*, in April, 1831, passed about midway between White Rock and Pulo Repon, carrying depths from 30 to 34 fathoms, muddy bottom.

Baua is a small group, about 11 miles north-eastward of Repon; and about 15 miles N.E. by E. $\frac{1}{2}$ E. from Baua is another small group, called Rittan, in lat. $2^{\circ} 39' N.$ This last group forms the south-eastern limit of the Anamba Islands.

The Riabu Group extends from about 5 to 13 miles N.N.W. of the Rittan group. Pulo Riabu is a high island, about 6 miles in extent, having a much smaller island, named Piling, close to the westward of it, and several islets and rocks off its S.E. extreme.

The **WESTERN GROUP** comprises a high island, called *Djimaja*, about 14 miles in length, with several small islands, nearly joining each other, off its N.W. extreme; their N.W. limit is in lat. $3^{\circ} 5' N.$, long. $105^{\circ} 32' E.$, and the South point of the large island is in lat. $2^{\circ} 50' N.$ Djimaja has a peak on it, and a bay on the North side, with islets and reefs about a mile distant on the western side, and soundings of 24 to 35 fathoms near them.

Courier Rock.—There is a sunken rock, on which the *Courier* struck, in lat. $2^{\circ} 58' N.$, about 3 miles from the western shore of Djimaja, and nearly the same distance S.W. $\frac{1}{2}$ S. from Joulan Point, which projects to the westward near the parallel of $3^{\circ} N.$

Pulo Domar, in lat. $2^{\circ} 45' N.$, long. $105^{\circ} 25' E.$, and the most western of the Anamba Islands, is a high, barren rock, with 34 or 36 fathoms water close to it, 35 to 40 fathoms between it and Djimaja, and 32 to 39 fathoms in the channel between it and Pulo Aor. Sir E. Belcher states it to be 150 feet high, and that in fine weather safe landing may be found on its S.E. extreme.

Telaga Group.—Telaga or Peaked Island, in lat. $3^{\circ} 5' N.$, and about 8 miles north-eastward of the East end of Djimaja, is about 3 miles in extent, and has a high peak on its northern end. Close to its N.W. end is Little Telaga, an island about half its size, and close to its western side are some islets and rocks.

Some groups of small islands lie between Telaga and Riabu, and others between the former island and the northern group.*

* In sailing round the northern group of the Anamba Islands, Telaga or Peaked Island is a most remarkable object, and appeared higher than any land about it. Douraj Island

The **NORTHERN GROUP** of the Anamba Islands is comprised between the parallels of 3° and $3^{\circ} 30'$ N. Its western portion consists of three large islands, and there are numerous smaller ones to the south-eastward, with other detached islets. The longitude of the most eastern islets is $106^{\circ} 29'$ E. The larger islands are inhabited, and abound with fruits and vegetables.

Captain Laplace examined this group in 1831, and he makes the three large islands to extend from lat. $3^{\circ} 9'$ to $3^{\circ} 27\frac{1}{2}'$ N., the two northernmost, called *Mata* and *Mobur*, having a channel about a mile wide between them, called *Selamata* (more properly *Selat-Mata*), with depths of 15 to 28 fathoms in the South entrance and middle part; but the northern part has several isles and rocks, and appears, by the chart of the survey, not to have been examined. Between the South point of *Mobur*, the westernmost island, and *Mangar* Island, fronting it about a mile distant to the westward, is the entrance of a deep inlet, named *Paris Cove*, which extends about 3 miles to the northward into *Mobur*, nearly dividing that island into two sections; the general depths in it are 23 to 17 fathoms, decreasing near the shore at the upper part, and it appears to form a safe harbour. The German corvette *Nymphe*, in June, 1873, anchored in 18 fathoms of water, with a house on the West side of the cove bearing W.S.W., and the S.E. point of the bay S.E. $\frac{1}{4}$ S. A supply of good water was procured, but no provisions.

Siantan, the southern large island, fronts the South end of *Mata*, being separated from it by a channel from 1 to $1\frac{1}{2}$ mile wide, in which the depths are from 10 to 24 fathoms. The eastern entrance of this channel is obstructed by a chain of shoals, but there is thought to be a narrow passage, with from 5 to 9 fathoms water, to the southward of them, by keeping close along the reef that borders the eastern side of *Siantan*. The western entrance of the channel is formed by *Tupinier Bay*, which is 3 miles wide between *Pedasse Point*, the N.W. extreme of *Siantan*, and the South point of *Mangar*, which bear nearly North and South of each other; the centre of the entrance is in lat. $3^{\circ} 16\frac{1}{4}'$ N., with depths from 24 to 32 fathoms.

Terempa.—About $1\frac{1}{2}$ mile inside *Pedasse Point*, is *Terempa* village, at the bottom of a small bay, where a vessel might anchor in from 10 to 15 fathoms, sandy bottom, sheltered from all winds. *Terempa*, containing 300 or 400 inhabitants, is the chief place of the group, and the residence of the native magistrate appointed by the Dutch. The German corvette *Nymphe* anchored here in $20\frac{1}{2}$ fathoms water, with *Rigni Island* bearing N.W. by N. and *Pedasse Point* W. by N.

is high, about the same height as *Paat Island*. *Sendock* is a low rock, and will not be seen till *Namas Island* (which is high and one mass of large rocks) bears about S.E. *Guerite Rock*, when first seen, makes like a topsail schooner; on a nearer approach the stone on the summit appears like the top of a lighthouse, and on a S.W. bearing, like a schooner running before the wind.—Navigating Lieutenant J. W. King, H.M.S. *Vernon*, June, 1847.

Two miles eastward of Terempa a bay is formed in the N.E. part of Siantan, with depths of 10 to 15 fathoms near the reef that borders the shore, where it would appear by the chart ships might anchor completely landlocked.

The following is from the report of the German corvette *Nymphe*, 1873:—

From Terempa we steered southerly around Siantan Island for the southern entrance of Clermont Channel, but we found the chart too incomplete. We therefore proceeded North through Thetis Channel, along the eastern shore of Bougainville Island, for the northern entrance of Port Clermont, which, according to the chart, was to be looked for in a south-westerly direction from a cliff running out to the North. This we found to be correct; but the eastern coast of Bougainville Island proved to be quite different from that represented on the chart, on which it trended first about 2 miles North and South, and then 2 miles N.N.W. and S.S.E., with a small bight midway of the latter part, while in fact there were two bays, the southernmost of which was about a mile deep, with an entrance similar to Port Clermont, with depths of from 11 to 17 fathoms; the northern bay was wider and of less depth. The southern bay is quite foul, and, as the entrance much resembles that of Port Clermont, may be dangerous.

In Port Clermont we found the reefs and shoals to extend considerably into the channel, rendering it quite narrow. The hilly shores are everywhere steep-to; the harbour is quite roomy, and, having three entrances, would be an excellent place of refuge when better surveyed. The water in the creek shown on the chart is in such small quantity that it would hardly suffice for one vessel.

NATUNA ISLANDS.

The name given by Europeans to these groups is entirely unknown to the Malay inhabitants. They own allegiance to the Prince of Johore, who lives under British protection at Singapore. The larger islands only are inhabited, and according to Mr. Crawford, the Great Natuna had a population of 600, the northern group 300, and the southern 400, making a total of 1,300. The islands are rocky and sterile, and the few articles of trade, fish, raw sago, and cocoa-nut oil, are exchanged in the straits of Malacca for rice, clothing, and iron.

The northern groups were examined by Captain Laplace, in the French Imperial corvette *La Favorite*, in 1831, and a survey was made by Lieutenant E. Paris. The South Natuna Islands were surveyed by the late Lieutenant D. M. Gordon, R.N., in H.M.S. *Royalist*, in 1847.

The Natuna Islands extend in a N.N.W. $\frac{1}{2}$ W. direction to the distance of 100 miles from Tanjung Api, the N.W. extreme of Borneo. They may be

divided into three groups,—the South Natuna, near Borneo; the Great Natuna and its contiguous islets; and the North Natuna.

SOUTH NATUNA ISLANDS.—This group extends from the coast of Borneo to about lat. $3^{\circ} 3' N.$; it is subdivided by a safe channel, and the outside channel, between it and Great Natuna, is spacious. The two principal islands are Sirhassen and Subi.

Marundum, the southernmost island of the group, is in lat. $2^{\circ} 4' N.$, long. $109^{\circ} 7\frac{1}{2}' E.$, and bears from Tanjong Api N.W. by W. $\frac{1}{2}$ W., 14 miles. It is about a mile in extent, and 120 ft. high. A reef, which dries, lies about a mile off its West side, and there is a patch of $4\frac{1}{2}$ fathoms about the same distance from its N.E. side. The soundings round about are very irregular.

API PASSAGE, the channel between the coast of Borneo and Marundum, appears to be free from danger, with depths varying from 11 to 23 fathoms. The description of the adjacent coast of Borneo will be found on pages 287 and 480, *ante*.

South Haycock Island, in lat. $2^{\circ} 17' N.$, long. $108^{\circ} 55\frac{1}{4}' E.$, is a mere islet, said to be, however, very conspicuous; it is surrounded to the distance of about a third of a mile by a reef, and there appears to be an islet, or rock above water, close to the southward of it.

Sembuni and Molu Shoals comprise an extensive mass of dangers lying between Marundum and Sirhassen. The Sembuni is the name given to that portion which lies nearer to Marundum, the channel between that island and the shoals being 7 or 8 miles wide, free from danger, but with depths varying from 8 to 16 fathoms. The Larkin Shoal, of Horsburgh, appears to be one of the Sembuni patches.

The Molu Shoals lie to the eastward of Haycock Island, and cover a space about 5 miles in extent; the channel between the island and the shoals is about 5 miles wide, with depths varying from 11 to 20 fathoms.

A rock is placed on the chart 4 or 5 miles to the N.E. of the Molu patches, with Prantou Island bearing N. $\frac{1}{4}$ E. $5\frac{1}{2}$ miles, and the apex of Brian Island N.W. $\frac{3}{4}$ W. 13 miles. To the eastward of this rock is a space 7 or 8 miles in extent, which has not been sounded over, and where it is probable other dangers may exist.

SIRHASSEN PASSAGE is bounded on the South by Haycock Island and the northern part of the shoals and dangers just described, and on the North by Sirhassen and its contiguous islands. Its narrowest part, between the rock N.E. of the Molu Shoals and Prantou Island, is about 5 miles wide, and appears to be free from danger, although the soundings here, as elsewhere in this neighbourhood, are very irregular, 14 to 40 fathoms.

SIRHASSEN GROUP.—*Sirhassen* or *High Island*, is 9 miles long, East and West, and represented on the chart as mountainous, except on its N.E. side,

where the lofty extremes of the island have a low sandy bay between them. Nearly joining the island on its S.W. side are several islets, the largest of which, *Brian Island*, is 760 ft. high. These islets, having but very narrow channels between them, must at a distance appear as part of the main island. The chain of islets running about 7 miles in a N.N.E. direction from the N.E. point of Sirhassen, give a partial shelter from the north-easterly winds to vessels which may anchor in the sandy bay before mentioned, the depths in which are from 10 to 17 fathoms.

It is reported that the ship *Lightfoot*, Pierce, master, from Whampoa to London, struck on a coral shoal the 3rd September, 1854, about $3\frac{1}{2}$ miles to the westward of Sirhassen Island, in lat. $2^{\circ} 32' N.$, long. $108^{\circ} 58' E.$; whilst the ship was on shore, found the current was setting to the eastward 3 knots per hour.

Prantou, a small island, 465 ft. high, lies nearly 3 miles to the southward of the eastern extreme of Sirhassen, with a deep channel of 20 to 40 fathoms between them.

Royalist Haven is on the S.W. and West side of Sirhassen Island. The leading mark in is *Mount Koti* (765 ft. high, on the N.W. part of the island), on with David Point bearing N.N.W. The entrance is about 2 cables wide between Rimell and Wilkinson Rocks, with 7 to 10 fathoms in the channel, and 7 to 11 fathoms in the haven; there are several rocky heads with deep water between them in and near the anchorage, in 9 or 10 fathoms, nearly half a mile within the entrance, though a vessel of large draught may thread her way between the coral heads at least 2 miles within the entrance towards Banff Bay to the N.N.W. The Dutch have or had a small supply of coal on Sirhassen Island.

KOTI PASSAGE is the name of the channel between Sirhassen and Pulo Panjung, dividing the South Natuna group into two divisions. It is 9 or 10 miles wide, and appears, with the exception of the Milton Shoal, to be quite free from danger, although the depths are very irregular, 15 to 30 fathoms generally, with some deeper holes—no bottom 35 to 37 fathoms—near mid-channel.

This passage is often used by vessels proceeding from Singapore to Hong Kong against the N.E. monsoon, and which are unable to weather Subi.

Milton Shoal.—Capt. Le Boutillier, of the *John Milton*, reports a shoal in the Koti Passage, as follows:—"On the 22nd September, 1869, passed over a shoal, where on the chart is marked 20 fathoms water. This shoal is about a quarter of a mile in breadth, the bottom of large round coral stones; found no less than 28 ft. of water, being very smooth at the time, seeing the bottom quite plain, vessel going at the rate of one mile per hour. At the same time took several cross bearings, and found the said shoal to be in lat. $2^{\circ} 37' N.$, long. $108^{\circ} 50' E.$ "

SUBI GROUP.—*Subi* or *Soubi*, or *Flat Island*, the northernmost and largest island of the South Natuna, is about 12 miles long North and South, and 5 miles wide, including an island about 2 miles in extent off its northern end, to which it is connected by a reef. It is also apparently connected with the smaller island of Panjung and its neighbouring islets, lying 7 miles to the S.S.E. by the rocky bank on which both seem to be based.

Subi appears to be surrounded, except on its S.W. side, with shelving rocks, to the distance of 2 or 3 miles, and on their outer edge are several rocky islets, the principal of which is Bucu, on the West side of Panjung, completely detached; and 16 miles south-westward of Subi is the hilly island called *Serai*, or *West Island*, in lat. $2^{\circ} 40' N.$, long. $108^{\circ} 35' E.$, with the Doua Rock $1\frac{1}{2}$ mile north-eastward of it.

Pumunabung Reef, lying about 3 miles West of the Panjung group, is about 2 miles in extent, East to West, by one mile North and South, with soundings of 4 to 15 fathoms near it. There is also a rocky patch, the *Jabak Reef*, at $3\frac{1}{2}$ miles N.N.W. of this; and West of the latter, and North, distant $3\frac{1}{2}$ miles of the Doua Rock, is the *Jaring Reef*, which is a rock with a bank extending about 3 miles to the north-eastward from it. There is also a rocky patch called *Laut Reef*, off the East side of Subi, about $2\frac{1}{2}$ miles outside the reef surrounding the island, from which the hill, 200 ft. high, on the northern extreme of Subi bears N.W. $\frac{1}{4}$ W., and the eastern apex of Pulo Panjung S. by W. $\frac{3}{4}$ W. Vessels should be cautious in approaching the eastern side of Subi.

The *Soundings* round the South Natuna group vary from 10 and 15 to 30 and 40 fathoms, and to the south-eastward extend to the coast of Borneo in average depths of 14 to 20 fathoms.

Current.—The current at times is strong among the South Natuna Islands, according to the prevailing winds. In the Koti Passage it has sometimes been found to run $2\frac{1}{2}$ miles per hour to the northward, during the southerly monsoon.

The *Channel* between Subi and Low Island is ordinarily used by vessels proceeding to China by the Palawan route, during the N.E. monsoon, although, as has been previously remarked, it sometimes happens that vessels are unable to weather Subi, and find it convenient to proceed through the Koti Passage. Low Island lies 60 miles to the westward of Subi, but the channel is narrowed to about 50 miles by reefs which lie eastward and south-eastward of Low Island.

LOW ISLAND, in lat. $3^{\circ} 0' N.$, long. $107^{\circ} 48' E.$, is in extent about $3\frac{1}{2}$ miles North and South, and $2\frac{1}{2}$ miles East and West, having shoal water extending to a considerable distance from its eastern and western sides. The following dangers render great caution necessary in passing to the southward of it:—

JACKSON REEF lies off the S.E. part of Low Island, in lat. $2^{\circ} 56' N.$,

long. $107^{\circ} 55'$ E. The bottom was perceived in 14 fathoms, coral, and the boat in sounding near the ship, had from 5 to 7 fathoms, coral; in one place only $4\frac{3}{4}$ fathoms, with apparently less water on other patches of this coral shoal, which extends about 2 miles in a S.E. and N.W. direction, bearing from the East point of Low Island E.S.E., distant about 6 miles. This shoal ought to be avoided, as well as Hutton Reefs to the northward; they may probably be a continuation of the chain of shoals formed of coral patches, now ascertained to exist in the proximity of Low Island.

Hutton Reefs are thus described in the journal of Mr. Howard:—Observing shoal water to extend a long distance off the East and West ends of Low Island, edged out to give it a wide berth in passing on the South side. From 10 a.m. to noon steered E. by S. 3 miles, and East 2 miles, when discoloured water was seen bearing East; hauled up N.E. by N. to go between it and the island, the extremes of the latter then bearing from N.W. by N. to W. by N., distant about 3 miles, observed lat. $2^{\circ} 59'$ N.

In passing between the shoal and island, the least water was 8 fathoms, rocks, with the East part of the island bearing S.W. by W. $\frac{1}{2}$ W. 3 miles, and the nearest patch of shoal water S.E. This appears to be an extensive shoal, consisting of patches, and formed in the shape of a horse-shoe. After passing between it and Low Island, sent the first officer in a boat to examine the nearest patch, on which he had $3\frac{3}{4}$ fathoms, pyramidal rocks, and there is probably less water on some of the patches, with channels between them. The South or outer patch appeared to lie 4 or $4\frac{1}{2}$ miles from Low Island in an E. by N. or N.E. direction.

Diana Reefs.—This dangerous coral reef, lying to the N.N.W. of Low Island, is thus described by Lieutenant Kempthorne, who grounded upon it in H.M. brig *Diana*:—Saw the bottom, and sounded in $4\frac{3}{4}$ fathoms, but lost the lead, by its getting fixed in the coral. Wore to the eastward, and had $5\frac{1}{2}$, 6, 7, 8, 10, 11, 17 fathoms, then no bottom at 20 fathoms. The boat sent to sound had $3\frac{1}{2}$ fathoms, and several casts of $5\frac{1}{2}$ fathoms on the points of coral, with deep water between them; two spots of discolored water, one bearing South, and the other S.W. by W. about 2 miles, appeared much shoaler than where the boat sounded. The shoal seemed to extend N.E. by E., and S.W. by W. $1\frac{3}{4}$ miles; no broken water was visible upon it, but when the swell rolled over the points of coral, it resembled a shoal of fish.

When the bottom was first seen in $4\frac{3}{4}$ fathoms, the N.E. point of Low Island bore S.E., and the N.W. point, with the S.W. point just open of it, bore S.S.E. $\frac{1}{2}$ E., Haycock Island, N. 43° W., distant from Low Island about 9 or 10 miles. Where the boat sounded, she had nearly the same bearings, but was half a mile more to the N.W., with Haycock Island just in sight from her.

Caution.—The channel between the Natuna and Anamba Islands is wide

and safe in daylight; but as several coral spots with but little water on them have been discovered in the vicinity of the Natunas, a good look-out is necessary, as other shoal patches, yet unknown, may probably exist.

Yong Sabal Bank, is placed on the Dutch chart W. $\frac{1}{2}$ S. 19 miles from the S. W. point of Low Island.

North Haycock Island, in about lat. $3^{\circ} 17' N.$, long. $107^{\circ} 34\frac{1}{2}' E.$ is high, of conical shape, having a reef projecting 3 or 4 miles from it to the S. W. and South, with 30 and 33 fathoms near its edge.

Elphinstone Rock is named after the ship which discovered it in 1844, and is thus described by her commander, Mr. Crawford:—It stands high out of the water, about 69 feet. From the southward a reef projects about a mile, at the extreme of which is a rock which is partially covered at high water. From this a dangerous reef projects a long distance to leeward, and is probably a continuation of the Hutton or Diana Reefs. To the northward of the main rock there appears to be a safe passage. This rock is in lat. $3^{\circ} 23' N.$, long. $107^{\circ} 50\frac{1}{2}' E.$, and in a dark night or thick weather a ship would be on it before it could be seen, as the soundings are no guide; from 40 to 23 fathoms in a cast.

GREAT NATUNA GROUP.—Great Natuna Island, called *Pulo Boong-Ouran* by the Malays, extends from $3^{\circ} 38\frac{1}{2}'$ to $4^{\circ} 16\frac{1}{2}' N.$, and two small islands off the North point, joined to it by a reef, extend about 3 miles farther with 17 fathoms water within a mile of them. The North extreme of the island is in long. $108^{\circ} 11\frac{1}{2}' E.$, and the East extreme in $108^{\circ} 23' E.$, its breadth being about 25 miles.

The interior of the island is mostly high; and on the northern part are two mountains of considerable elevation, *Mount Bedong* or *Quoin Hill*, in lat. $4^{\circ} 3' N.$, and *Mount Ranay*, near Cape Senubing, the East point of the island, in lat. $4^{\circ} N.$; the latter is 1,890 feet high, and may be seen 44 or 45 miles. Some of the projecting parts of the coast are rather low, particularly from lat. $4^{\circ} N.$ to the North end of the island, where there are red cliffs.

Reefs and islets front the eastern coast of this island, rendering it dangerous to approach under 6 or 7 miles in some places, at which distance the depths are usually from 34 to 46 fathoms. Mr. Whiteside, commanding the ship *Sarah*, describes an extensive coral bank in patches, in passing over which the ship received a slight shock, at which time a small island off the Natuna bore S. W. by W., distant about 6 miles. A one-fathom patch, in lat. $4^{\circ} 4' N.$, long. $108^{\circ} 26' E.$, called in the chart *Mieulle Reef*, agrees with this bearing, but it is only half the distance from the island, which is called *Senoang*, and lies close to Cape Senubing.

Devonport Rock is 10 miles distant from the East coast of the Great Natuna Island, and in the neighbourhood of deep water 34 fathoms. It has about 17 ft. water on the part where the *Devonport* struck. From the ship

the following bearings were taken; Senoang Island N.W., and Kamodi Island S.W. by W., which places it in about lat. $3^{\circ} 54' N.$, long. $108^{\circ} 30' E.$

A reef is placed upon the Admiralty chart S. by E. $\frac{1}{2} E.$, distant $3\frac{1}{2}$ miles from Kamodi, the outermost of two islets lying off this coast; and another reef is said to lie 3 or 4 miles farther in the same direction from that islet.

The Dutch vessel *Lamina Elizabeth* struck on a reef lying off the S.E. coast of Great Natuna, with Kamodi and Jantay Islets nearly in one, bearing N. by E. $\frac{3}{4} E.$; Mount Ranay N. by W. $\frac{2}{3} W.$; the nearest high land on Natuna W. by N. $\frac{1}{4} N.$; the South point of the same W. $\frac{1}{2} N.$; and the point of Lagong Island about W. by S. It appears necessary to be cautious in approaching the eastern and south-eastern coasts of Great Natuna.

The western coast of Great Natuna is also fronted by islands, the chief of which are the Duperré group, lying near its S.W. extreme. They are high islands; *Sédédap*, in lat. $3^{\circ} 34' N.$, is the southernmost. *Salaor*, or *Peaked Island*, in lat. $3^{\circ} 53' N.$, is also high; likewise *Seluan*, or *North-west Island*, in lat. $4^{\circ} 9' N.$, long. $107^{\circ} 50' E.$, which has a reef projecting a mile or more from its South point, with depths of 30 to 20 fathoms on its S.W. side; a reef is marked on the chart at $2\frac{1}{2}$ or 3 miles distance from the western side of this island, and one 3 miles S.S.E. of Sededap.

A reef of coral rock, with only 2 fathoms on it, and from 20 to 30 fathoms near it on the West and S.W. sides, lies in lat. $4^{\circ} 3' N.$, about 5 miles S.S.W. from Seluan Island; about 5 miles S.W. $\frac{3}{4} S.$ from this reef, and 10 miles N.W. by W. from Peaked Island, and about the same distance from Seluan Island is another coral shoal in lat. $3^{\circ} 59' N.$, having 3 fathoms, rocks, on it, and from 20 to 30 fathoms, mud, close around. These shoals were explored by Captain Ross, in 1814. There is also a reef named *Semapi*, midway between Seluan and the North point of Great Natuna, 9 or 10 miles off shore; it appears to be of considerable extent.

PYRAMIDAL ROCKS, in lat. $4^{\circ} 3' N.$, long. $107^{\circ} 21\frac{3}{4}' E.$, are in the track of ships returning from China late in the season, when they pass between the Anamba and Natuna Islands, proceeding towards Gaspar Strait. The *Windham* and *Coldstream*, in 1817, passed on the East side of these rocks at 4 miles distance; they described them as a clump, of rugged aspect, elevated about 20 or 25 feet above the sea. The *General Kyd*, commanded by Mr. Nairne, in 1818, passed 4 or 5 miles to the westward of them; when Seluan Island bore N. $85^{\circ} E.$, the rocks were on a transit line with Salaor Island bearing S. $72^{\circ} E.$, distant 4 or 5 miles.

In 1863, H.M.S. *Rifeman* carried a line of soundings from Victory Island to the position of a doubtful rock that was placed on the Admiralty chart 11 miles S.W. of the Pyramidal Rocks. The *Rifeman* passed close to the spot without discovering any danger, and had soundings in 33 fathoms. The

Pyramidal Rocks were also passed within 4 miles, but it was getting too dark to examine them closely.*

A *Doubtful Rock* is placed upon the chart in lat. $4^{\circ} 11' N.$, long. $107^{\circ} 34\frac{3}{4}' E.$, about 15 miles N.E. by E. from the Pyramidal Rocks, and the same distance to the westward of the North point of Seluan Island. The Dutch notice, previously alluded to, states that a rock, 25 ft. above water, was discovered lying N.E. by E. $\frac{1}{4}$ E. of the Pyramidal Rocks. Its appearance was similar to those in the neighbourhood of Pulo Semione, and it is said to be in long. $107^{\circ} 26' E.$

Success Reef is about 2 miles in extent, in lat. $4^{\circ} 22' N.$, long. $107^{\circ} 55' E.$, nearly midway between Semione Island and the North point of Great Natuna. When the breakers on the reef were seen from the ship's deck bearing E. by S. about 2 miles, Semione bore N.W. $\frac{3}{4}$ W. about 12 miles; the eastern extreme of North Natuna N. by E.; and the western extreme of Great Natuna S. by W. $\frac{1}{4}$ W. about 20 miles. The ship afterwards tacked in 35 fathoms, within a mile of the breakers. The *Favourite*, Captain La Place, in March, 1831, passing close to the eastern extremities of these dangers, marked as two patches in his chart, carried soundings of 30 to 20 fathoms, sandy bottom.

Semione or Saddle Island, in lat. $4^{\circ} 31' N.$, long. $107^{\circ} 42' E.$, has a reef projecting from its South end, and another from the N.W. end, with less than 3 fathoms water on it, and 40 fathoms close-to.

There is a rock above water about 4 miles S. by W. $\frac{1}{2}$ W. from this island and between them are depths of 28 fathoms.

THE NORTH NATUNA GROUP are of moderate height, producing coconuts and some other fruits, and are inhabited by Malays. They comprise a long island named *Pulo Laut* (Sea Island), stretching N.E. by N. and S.W. by S. 8 miles, with *Pulo Stokong*, a smaller island, near its northern extreme, and several islets and rocks close to its southern end, upon the reef that fronts the shore. There is also a rocky islet, in lat. $4^{\circ} 39' N.$, about $2\frac{1}{2}$ miles S. by E. $\frac{1}{4}$ E. from the S.E. point of Laut; and S. $\frac{1}{8}$ E., $2\frac{1}{2}$ miles from this islet, a rock touched on by the *Louise and Marguerite*, drawing $14\frac{1}{2}$ ft. water, in 1873. From it the S.W. end of Pulo Laut bore N.N.W. $\frac{1}{2}$ W. *Gloria Reef*, on which the Spanish steamer of that name was wrecked in May, 1877, lies 2 miles N.W. of the *Louise and Marguerite*. From this wreck, lying in 15 feet water, the West extreme of Pulo Laut bore N.N.W., and the South extreme of Semione Island W.S.W. Between the two reefs a depth of 12

* From the Pyramidal Rocks, H.M.S. *Rifleman* carried a line of soundings to the position of the *French Rocks*, shown on former charts as three rocks above water lying N.N.W. $\frac{1}{2}$ W. of Pulo Laut. Their position was approached on a W. by N. $\frac{1}{2}$ N. bearing, and at noon the *Rifleman* was 2 miles North of it. She then steered South $7\frac{3}{4}$ miles, N.W. 9 miles, and N.E. $6\frac{3}{4}$ miles, without discovering any signs of the rocks. The soundings about the spot were from 35 to 40 fathoms.

feet was found, so that the locality must be most carefully avoided until examined properly. About 9 or 10 miles south-westward of the rocky islet is *Cockeran Bank*, with 8 fathoms on it, from which Semione Island bears W. by S. $\frac{1}{4}$ S., distant 11 miles.

The North extreme of these islands is in lat. $4^{\circ} 51' N.$, long. $108^{\circ} 3' E.$ There are 35 fathoms water about $1\frac{1}{2}$ mile N.N.W. from Stokong, but the whole of the western coast of Laut is fronted by a dangerous reef, which extends nearly 5 miles W. by S. and W.S.W. from the S.W. point of that island, having no bottom at 40 fathoms within a mile of its West extreme; but both North and South of this extreme there are soundings of 32 to 36 fathoms, mostly coral bottom.

SHOALS ON EASTERN SIDE OF MAIN ROUTE.

Scawfell Shoal and Charlotte Bank are hereafter described.

Vanguard Bank is crescent-shaped, about 37 miles long, with an average width of 6 miles. It has no danger whatever on it, the least water being 9 fathoms, the general depths varying from 20 to 60 fathoms. The horns of the crescent are respectively in lat. $7^{\circ} 16\frac{1}{2}' N.$, long. $109^{\circ} 26' E.$, and lat. $7^{\circ} 31' N.$, long. $109^{\circ} 57' E.$, the convex curve being on the N.W. side, and reaching to the parallel of $7^{\circ} 36' N.$

Grainger Bank, lying 33 miles north-eastward of the Vanguard, is pear-shaped, $5\frac{1}{2}$ miles long, N.E. and S.W., by $2\frac{1}{2}$ at its widest part. It has only 6 fathoms least water on it, but no danger; the general depths are under 20 fathoms, the bottom coral, quite visible over nearly the whole of it. The centre is in lat. $7^{\circ} 47\frac{3}{4}' N.$, long. $110^{\circ} 29' E.$

Prince Consort Bank (discovered by the *Rifleman*), lies between the Vanguard and Prince of Wales Bank, and extends from $7^{\circ} 46' N.$ to $7^{\circ} 58' N.$, and from $109^{\circ} 55'$ to $110^{\circ} 6' E.$ No danger exists on it; the general soundings are from 30 to 50 fathoms, sand and coral, the least water found being on a small coral patch of 10 fathoms.

Prince of Wales Bank, the centre of which is in lat. $8^{\circ} 8\frac{1}{2}' N.$, long. $110^{\circ} 32\frac{1}{2}' E.$, is in shape an irregular oblong, 12 miles in extent N.E. and S.W., by $7\frac{1}{2}$ miles wide; near its N.W. corner is a patch having 4 fathoms on it, but nothing less was found. It is in character just the same as the other banks in the neighbourhood, coral, having three or four excrescences on it, but no danger, without the 4 fathoms may be considered so; the general depths upon it are under 20 fathoms.

Alexandra Bank, in lat. $8^{\circ} 1\frac{1}{2}' N.$, long. $110^{\circ} 36\frac{3}{4}' E.$, is in shape a full oval, 5 miles in extent North and South, by $3\frac{1}{2}$ miles wide. A small patch with only 3 fathoms water on it was found close to the eastern edge, but no other dangers exist. The average depth on the bank is about 15 fathoms; the bottom coral, distinctly visible.

Rifleman Bank lies between the parallels of $7^{\circ} 31'$ and $7^{\circ} 57' N.$, and the meridians of $111^{\circ} 32'$ and $111^{\circ} 45\frac{1}{2}' E.$ Shoal patches were found round its edges, one of which, of only 11 ft. water and half a mile in extent, lies on its northern edge in lat. $7^{\circ} 55' 20'' N.$, long. $111^{\circ} 42' E.$; with this exception, 4 fathoms was the least depth obtained on the bank. In the centre of the bank, the soundings are from 20 to 40 fathoms, sand and coral; and around its edge, outside, a few deep casts were obtained varying from 300 to 600 fathoms.

Bombay Castle Shoal.—The 11 ft. patch on the North edge of this bank is the shoal seen by Mr. Cameron, commanding the *Orleana*, who obtained a cast of 8 ft., and placed the danger in lat. $7^{\circ} 56' N.$, long. $111^{\circ} 38' E.$ The 8 ft. knoll was not found by the *Rifleman's* boats, but it is quite possible to have escaped the lead, for large isolated rocks are known to exist on coral reefs, though extremely difficult to find. Heavy breakers mark the position of this patch, in any but the finest weather.

The *Rifleman* sounded over the position assigned to the Bombay Castle Reef, in lat. $7^{\circ} 56' N.$, long. $111^{\circ} 51' E.$, but no bottom could be obtained with upwards of 10 fathoms of line; nor could any sign of shoal water be seen from the mast head under most favourable circumstances, when on, and cruising around its supposed position; it is therefore deemed probable that the *Bombay Castle* must have sighted the 11 ft. patch on the Rifleman Bank, as the latitude is nearly the same, though the longitude differs 9 miles.

LADD REEF (*Rob Roy Reef* of former charts), the eastern extreme of which is in lat. $8^{\circ} 40\frac{1}{4}' N.$, long. $111^{\circ} 41' E.$, is a coral bank 3 miles long E.N.E. and W.S.W., and a mile wide at its broadest part, which is at its eastern end. In the centre of the reef is a lagoon with a bottom of clear white sand, which shows up with remarkable distinctness. The surrounding reef uncovers at half tide in many places, and at low water it is almost impossible for boats to cross over into the lagoon. A conspicuous beacon was reported to exist on it in 1868.

Gillies Island, doubtless identical with Ladd Reef, reported to be in lat. $8^{\circ} 38' N.$, long. $111^{\circ} 28' E.$, is now removed from the charts. H.M.S. *Rifleman* found 800 fathoms in its supposed position.

SPRATLY ISLAND, in lat. $8^{\circ} 38' N.$, long. $111^{\circ} 54' 30'' E.$, bearing E. $\frac{1}{2}$ S., distant 14 miles from Ladd Reef, is evidently identical with *Storm Island*, as no other island exists in the vicinity. It is a flat islet, about 8 ft. high, and very small, being in extent but $2\frac{1}{2}$ by $1\frac{1}{2}$ cables' lengths, with a margin of bright white sand and broken coral, which, when the sun is shining on it, is conspicuous from the mast-head at a considerable distance. It was described by Mr. Spratly, commanding the *Cyrus*, whaler, as "a low sandy island, the top appearing to be covered with bushes." Commander Ward says that not a bush or even a blade of grass is to be found upon it,

and the appearance described by Mr. Spratly was no doubt the effect of the mirage, which exaggerates the size and distorts the appearance of the driftwood on the beach and the sea birds which throng it. At a distance of 3 or 4 miles, the birds standing erect look very like small bushes.

The islet is on the West side of a coral bank, which is $1\frac{1}{2}$ mile long N.E. and S.W., and three-quarters of a mile wide. Northward of the islet the bank is shallow, there being only $3\frac{1}{2}$ fathoms close to the edge of the deep water, three-quarters of a mile distant from the islet, decreasing towards the shore. North-eastward of the islet there are 7 or 8 fathoms on the bank, which extends not quite half a mile from it. Rocky ledges, dry at low water, surround the islet, rendering it necessary to be cautious when landing in boats, which during the S.W. monsoon may be effected on the lee side. The bank is steep-to, the sea breaking heavily upon it in the S.W. monsoon, except in very fine weather.

A square *beacon* was erected by Commander Ward on this islet. It is formed of four uprights of rough driftwood spars, 27 feet high and 15 feet apart. The uprights are shored up, and the centre space solidly filled in and built up to the height of 15 feet with driftwood, rubble, &c. The top is at present covered in with canvas—to be replaced by plank if circumstances permit—with black and white sides, and may be seen in clear weather at a distance of 8 miles.

The *Rifleman* anchored in about 6 fathoms on the N.E. point of the bank, but it is so steep-to, that, riding with the wind W.S.W., and 50 fathoms of chain out, the vessel's stern was in 54 fathoms; this position was, however, fairly sheltered from the S.W.; the extremes of the islet bore S.W., $\frac{1}{2}$ S.; and S.W. by W. $\frac{1}{2}$ W., and the extreme of the breakers on the western edge W. $\frac{3}{4}$ S.

In the months of June and July the island swarmed with turtle of a very fine description, and they may possibly frequent it at other seasons. Large numbers were taken, being easily turned over by two or three men on the beach, in the evening or night, and occasionally in the daytime; they are apparently identical with the green turtle of Ascension. Immense quantities of their eggs were found on the S.W. side of the islet. Fish were numerous, but very few captures effected. Sea birds' eggs literally covered the ground. About seventy sprouts of cocoa-nut trees were planted, and at the end of a fortnight exhibited every promise of a vigorous growth.

Tides.—Observations at Spratly Island in the S.W. monsoon showed but one tide during the 24 hours, and in the early part of July it was found to be high water at 9^h a.m., the rise and fall being $5\frac{1}{2}$ feet. No observations up to the present time have been obtained during the N.E. monsoon, which probably creates a great change. The direction of the stream at the N.E. corner of the bank was S.W. during the rising tide, and S.E. to E.N.E. during the falling tide.

The *Ruby Shoal*, a small spot formerly shown upon the Admiralty chart in lat. $8^{\circ} 35' N.$, long. $112^{\circ} 4' E.$, was searched for in 1864 and in 1865 by the *Rifleman* without success; it is now expunged from the chart.

LONDON REEFS.—*West London Reef*, bearing E. by N. $\frac{3}{4}$ N. distant 31 miles from Ladd Reef, is the westernmost of a group of shoals, the London Reefs of the charts. It is a bank $4\frac{1}{2}$ miles long, N.E. by E. and S.W. by W., $3\frac{1}{4}$ miles wide, and almost surrounded by coral reefs, some of which dry at low water. There is a space in the centre of the bank with from 6 to 10 fathoms water in it, but also many shoal spots. The only approach to this central space is from the S.E. side, but so many coral patches crop up that the navigation is extremely hazardous. On the East side of the bank, in lat. $8^{\circ} 52' N.$, long. $112^{\circ} 14\frac{3}{4}' E.$, is a sandy cay, a quarter of a mile in extent N.E. and S.W., but only 26 yards wide, and 2 feet above high water. The *Rifleman* anchored at the middle of the North side of the bank in lat. $8^{\circ} 53' N.$, long. $112^{\circ} 12\frac{3}{4}' E.$

Central London Reef, the centre of which is in lat. $8^{\circ} 55\frac{1}{3}' N.$, long. $112^{\circ} 20' E.$, was discovered by the *Rifleman* whilst sounding between the East and West London Reefs. It is a coral patch, awash, half a mile in extent, with a shallow lagoon inside the belt of coral. On the S.W. extreme of the reef is a sandy cay, 60 or 70 yards in circumference, which is probably covered at high-water springs.

This is in every respect a most dangerous reef, and lies directly in the track of vessels working up or down the China Sea. Being small, it is not marked by great masses of breakers, like those which so readily point out the positions of East and West London Reefs, for one of which it has probably been mistaken, when sighted, as it has doubtless been.

Caution.—Like all other dangers in the China Sea visited by the *Rifleman*, the Central London Reef is surrounded by deep water, thus rendering the lead useless; it is therefore essentially necessary to observe the greatest precaution when in their vicinity, and never to stand towards them with the sun shining ahead, as under these circumstances it becomes almost impossible to distinguish shoal water or breakers.

East London Reef is 7 miles long, East and West, from 1 to 2 miles broad, and its East end is in lat. $8^{\circ} 49' 38'' N.$, long. $112^{\circ} 37' 26'' E.$ The coral round its edges encloses a lagoon, having 4 to 8 fathoms water. No entrance into the lagoon could be discovered, but there were apparently numerous shoal patches inside. The sea breaks heavily on the reef, and on its western extreme are one or two rocks which seldom cover. No soundings could be obtained with 100 fathoms of line at one mile from where the coral dries, nor with 500 fathoms at 2 miles North of it.

Quarteron Reef, named after the Spaniard who discovered it, is awash, and in shape like a crescent, whose chord is 3 miles in length, E. by S. and

W. by N., with the curve to the southward. Its eastern extreme is in lat. $8^{\circ} 50' 54''$ N., long. $112^{\circ} 49' 34''$ E.

This reef was found steeper-to than any yet visited, for although deep water is found close to all of them, there was generally some slope from the rocks awash, on which the *Rifleman* could anchor with safety for a short period, to enable the position to be fixed; here, however, although she anchored in 5 fathoms, with the jib-boom over the rocks awash, the reef was so steep as to cause the anchor to roll down the incline, and run the cable out to the clinch. Captain Ward is of opinion that no vessel should ever venture to sight this reef.

The **Fiery Cross or Investigator N.W. Reef**, which was marked as two distinct dangers on former charts, was found by Lieutenant J. W. Reed in H.M.S. *Rifleman* in 1867, to be but one extensive coral reef, having several dry patches on it, upon most of which the sea breaks even in light winds, or with a light swell. It is 14 miles in length N.E. by E. and S.W. by W., and 4 miles in breadth. Its S.W. end is in lat. $9^{\circ} 32'$ N., long. $112^{\circ} 53'$ E., and its N.E. end in lat. $9^{\circ} 41'$ N., long. $113^{\circ} 4'$ E. The largest dry patch is at its S.W. end, and here were found the wrecks of two vessels, supposed to have been those of the *Fiery Cross* and *Meerschaum*, both of which are known to have been lost upon this reef.

Dhaulle Shoal, reported in the year 1826, by the vessel of that name, which anchored on it in 3 fathoms, is now erased from the charts. Its reported position was 25 miles westward of the South end of Fiery Cross Reef, in lat. $9^{\circ} 32'$ N., long. $112^{\circ} 24'$ E. Here, and in the locality in favourable weather, H.M.S. *Rifleman* was employed a whole day in searching for this reef, but with no success, a depth of 1,060 fathoms being found on the spot. The *Dhaulle* doubtless anchored on the end of Fiery Cross Reef.

DISCOVERY GREAT REEF, the South end of which is in lat. $10^{\circ} 0' 42''$ N., long. $113^{\circ} 51\frac{1}{2}'$ E., is a long, narrow coral shoal, the greater part of which dries at low tides, with several large rocks upon it which always show above water; in the centre is a lagoon, which appeared to be shallow, and to have no passage through the reef leading into it. From the South point the reef trends first North, 5 miles, then N. by E., 5 miles, and it is a mile broad at the South end and half a mile at the North. No bottom was found with 100 fathoms line within a very short distance of any part of the reef except off its North end, where the *Rifleman* anchored in 42 fathoms, nearly half a mile from the rocks; a third of a mile off its S.W. point a sounding of 192 fathoms, sand and coral, was obtained.

The reef reported 10 miles north-eastward of Discovery Great Reef was found to have no existence by H.M.S. *Rifleman*.

Discovery Small Reef, in lat. $10^{\circ} 1\frac{1}{2}'$ N., long. $114^{\circ} 1\frac{1}{2}'$ E., is a small

round coral patch, a third of a mile in diameter, dry in places at low tides, with very deep water all round. Soundings of 174 and 180 fathoms, sand and coral, were obtained very close to its eastern side, and no bottom at 210 fathoms the same distance off the opposite side.

Western or Floral Temple Reef, the centre of which is in lat. $10^{\circ} 15' N.$, long. $113^{\circ} 37' E.$, is the westernmost reef in this part of the China Sea, and very dangerous, having patches of rock just under water at the S.W. part, and but 1 to 3 fathoms in other places. It is $1\frac{1}{2}$ mile long N.E. and S.W., and rather more than half a mile broad at the southern part, decreasing to half that breadth at the opposite end. The *Rifleman*, for the purposes of the survey, anchored in 5 fathoms on its north-eastern extreme, which had to be approached with great caution, as shoal water was seen at a very short distance inside the edge; soundings of 18 to 74 fathoms were obtained close to, but at a short distance off no bottom at 100 fathoms.

The reef upon which the *Flora Temple* was wrecked in 1859 was said to lie 6 miles north-westward of the western reef, but the *Rifleman* passed over that position, and certainly no danger exists there; moreover, the description of the reef given at the time of the wreck applies exactly to the Western reef, where, without doubt, the ship was lost.

TIZARD BANK and REEFS.—From Discovery Small Reef, the nearest part of this bank bears N.E. by E., and is distant 16 miles. It is very extensive and, like the generality of the large coral banks in the China Sea, consists of a lagoon, bordered by shoal patches. Several of the patches up on the Tizard Bank are dangerous reefs, dry at low water, two with islands on them, and a third a sand cay. The bank lies in an E.N.E. and W.S.W. direction, and extends nearly 31 miles; its breadth in the middle being 11 miles, at the S.W. part 7 miles, and at the opposite end $3\frac{1}{2}$ miles.

Itu Abaar, the larger of the two islands, is situated at the N.W. corner of the bank, and is three-quarters of a mile long E. by N. and W. by S., and a quarter of a mile broad. The reef surrounding it extends in some places to the distance of a short half mile, and in others not so far; its limits, however, are generally defined by a line of breakers. The island is covered by small trees and high bushes, together with numerous nests of sea birds. Two or three cocoa-nut and a few plantain trees stand near a small well, but the most conspicuous object is a single black clump-like tree on the North side of the island, which may be distinctly seen 10 miles off; this is in $10^{\circ} 22' 25'' N.$, and $114^{\circ} 21' 45'' E.$

A little more than 6 miles East from *Itu Abaar* is a small *sand cay*, nearly in the centre of a round-shaped reef, three-quarters of a mile in diameter. The island and cay are connected by a line of shoal patches, which form the N.E. part of the bank; and nearly midway between, but nearer the island, is a dangerous reef, entirely covered at half-tide, about the same size as that surrounding the cay. Elsewhere on the northern edge of the bank

there is not less than 4 fathoms, and vessels may safely anchor in from 7 to 11 fathoms about $1\frac{1}{2}$ mile westward of the sand cay, midway between it and the reef last described.

Petley Reef, an oval-shaped patch a little over a mile in extent, lies E. by N. $\frac{3}{4}$ N. $5\frac{1}{4}$ miles from Sand Cay; it forms the extremity of a remarkable strip of coral, $1\frac{1}{4}$ mile wide, projecting like a horn in a N.N.E. direction from the main body of the bank, the edge of which trends E.S.E. from the cay; not less than 6 fathoms was found upon the strip, except within a mile of the southern part of the reef above mentioned, where it shoals to 4 and 3 fathoms, and no bottom could be obtained with 100 fathoms at a short distance on either side of it.

Eldad Reef, the N.E. end of which is in lat. $10^{\circ} 23' N.$, long. $114^{\circ} 42' E.$, forms the eastern extreme of Tizard Bank. It is a peculiarly shaped reef, $4\frac{1}{2}$ miles long, N.N.E. $\frac{1}{2}$ E. and S.S.W. $\frac{1}{2}$ W., the southern and middle parts being about $1\frac{1}{2}$ mile wide, but of irregular outline; and the northern part tapering away in the form of a long, narrow tongue, on either side of which no bottom could be obtained with 100 fathoms of line. A few large rocks are visible at high water, and at low water many smaller ones uncover. Shoal patches extend nearly three-quarters of a mile to the westward of the reef.

Namyit Island lies due South from Itu Abaer, distant $11\frac{1}{4}$ miles; it is very small, being only 3 cables long East and West, and 1 cable broad, and is surrounded by a reef which projects more than a mile to the westward, and about a third of a mile in other directions.

Gaven Reefs are two dangerous reefs, covered at high water, which lie to the westward of Namyit; the first is oval-shaped, three-quarters of a mile long N.N.W. and S.S.E., the island bearing from it E. $\frac{2}{3}$ N., distant 6 miles; the second is a mile long North and South, and nearly three-quarters of a mile broad at its northern end, narrowing to a point at the opposite end; this last is the westernmost danger of the Tizard group, and its outer edge is in $10^{\circ} 13' 20'' N.$, and $114^{\circ} 13' 7'' E.$

Anchorage.—The above comprise all the dangers found upon this great bank, and, with the exception of a small 3-fathom patch which lies N.E. nearly a mile from Namyit Island, nothing less than 4 fathoms was found upon any of the shoal patches surrounding the lagoon; so that vessels of moderate draught can, in cases of necessity and in fine weather, find convenient anchorage, observing always due care and caution in approaching them, so as to guard against possible danger from some shoal spot having escaped detection by the lead.

Hainan fishermen, who subsist by collecting trepang and tortoise-shell, were found upon most of these islands, some of whom remain for years amongst the reefs. Junks from Hainan annually visit the islands and reefs of the China Sea with supplies of rice and other necessaries, for which the

fishermen give trepang and other articles in exchange, and remit their profits home. The junks leave Hainan in December or January, and return with the first of the S.W. monsoon. The fishermen upon Itu Abaer Island were more comfortably established than the others, and the water found in the well on that island was better than elsewhere.

LOAI-TA BANK and REEFS extend 21 miles N.E. and S.W.; its southern part is $5\frac{1}{2}$ miles wide, and its centre 7 miles; from thence it gradually narrows to a point at its N.E. extreme.

Loai-ta Island (South island of Horsburgh) lies N. $\frac{3}{4}$ E., distant 18 miles, from Itu Abaer, its N.W. extreme being in lat. $10^{\circ} 40' 45''$ N., long. $114^{\circ} 24' 54''$ E. It is a low sand island, covered with bushes, and small, being only $1\frac{1}{2}$ cable in diameter; a reef surrounds it, extending, in some places, nearly half a mile.

A reef, about $1\frac{1}{2}$ mile in extent, dry at low water, and having a small sand cay near the centre, lies 5 miles north-westward of Loai-ta. Another and larger reef lies three-quarters of a mile to the south-westward of the one just mentioned, extending in that direction $1\frac{3}{4}$ mile, its width being about a mile. The S.W. extreme of this last reef, which is also the S.W. extreme of Loai-ta bank, is in $10^{\circ} 42'$ N., and $114^{\circ} 19'$ E.; the sand cay bearing N.E. distant nearly 3 miles, and Loai-ta Island E. by S. 6 miles.

From the sand cay above mentioned the north-western edge of the bank trends away E.N.E. 5 miles, and then N.E. 13 miles; no less than 4 fathoms was found anywhere upon this part of the bank.

Lan-Keeam Cay, a coral patch, half a mile in extent, which partly dries at low water, lies E. by N. 2 miles from Loai-ta Island; and E.N.E. $6\frac{1}{2}$ miles from the same island is a larger reef, three-quarters of a mile in diameter, having a sand cay near its centre; this cay, known to the Hainan fishermen as Lan-Keeam, is in $10^{\circ} 43' 20''$ N., $114^{\circ} 31'$ E.

N.E. by E. $\frac{1}{2}$ E. 3 miles from Lan-keeam is a small dry patch, which forms the S.E. angle of the great Loai-ta Bank, and N.E. $\frac{1}{4}$ N. $4\frac{1}{4}$ miles from that cay is another small reef; this last is the northernmost patch which dries.

From the reef just mentioned the south-eastern edge of the bank trends to the N. by E. about 9 miles, when it meets the north-western edge; nothing less than 4 fathoms was obtained on this part of the bank.

SOUBIE REEF, the S.W. end of which is in lat. $10^{\circ} 53\frac{1}{2}'$ N., long. $114^{\circ} 4'$ E., is the westernmost danger in this locality. It is an irregular-shaped coral reef, nearly $3\frac{1}{2}$ miles long, N.E. and S.W., and 2 miles broad, is dry at low water, and has a lagoon, into which there appears to be no passage.

THI-TU REEFS and ISLAND, or the *N.W. Dangers*, consist of several very dangerous patches grouped upon two coral banks, separated by a narrow deep gut. Thi-tu is a low sand island, somewhat round in shape, and

not quite half a mile in diameter. Near its S.W. end is a dark clump tree in lat. $11^{\circ} 3' 9''$ N., long. $114^{\circ} 16' 25''$ E.; in addition to this clump tree the island has upon it some low bushes and two stunted cocoa-nut trees, near to which is a small well and a few plantain trees.

From the island the western bank widens out in directions N.W. and S.W. for a distance each way of $2\frac{1}{2}$ miles; the North side of this part of the bank is marked by a round coral reef, three-quarters of a mile in diameter, between which and the reef surrounding the island are soundings of $2\frac{1}{2}$ to 7 fathoms, the deep water being nearer the island. The South edge of the bank is also marked by a reef, but this is much smaller than the one just described, and the depths between it and the island are more favourable for anchoring upon than the opposite side of the bank, being in no place less than $4\frac{1}{2}$ fathoms. From these two reefs the bank gradually narrows, and terminates in a point in lat. $11^{\circ} 2' 30''$ N., long. $114^{\circ} 10' 30''$ E., the island bearing E. $\frac{3}{4}$ N., distant 6 miles.

On the North edge of the bank is a sand cay, which bears from the island W. $\frac{1}{3}$ N., nearly $3\frac{1}{2}$ miles. This is also on a large patch of reef, dry at low water, and between it and the western extreme of the bank are dangerous reefs, nearly always marked by breakers. There is a passage into the lagoon between the sand cay reef and the one $2\frac{1}{2}$ miles N.W. of the island, with depths of 5 to 12 fathoms.

The South side of the bank is not nearly so dangerous as the North side, and vessels may anchor upon it with the sand cay bearing between N.E. by N. and N.W. by N., or to the eastward of the patch which lies S.W. $2\frac{1}{2}$ miles from the island, with the cay bearing N.W. by W. $\frac{1}{2}$ W., and the island N.E. $\frac{1}{2}$ E. In the lagoon the depths are 17 to 19 fathoms.

The eastern bank is a mass of dangerous reefs and patches; its western extreme is more than a mile eastward of Thi-tu Island, extending from thence $1\frac{1}{2}$ mile East and $3\frac{1}{2}$ miles N.E., with an average breadth of 2 miles.

TRIDENT SHOAL, lying E. by N. 16 miles from North Danger, is a coral bank $7\frac{1}{2}$ miles long and 6 broad, of the shape of a shoulder of mutton, the broad part being to the northward; it is composed of many patches with less than 10 fathoms water over them, two of which are dangerous. These patches lie round the edges of the bank, forming a lagoon, the depths in which are 26 to 37 fathoms; close outside of them, there is no bottom at 100 fathoms.

The most dangerous patch is at the northern extreme of the shoal. This patch extends $1\frac{3}{4}$ mile East and West, and half a mile North and South, and near its centre, in lat. $11^{\circ} 31' 30''$ N., long. $114^{\circ} 39' 15''$ E., is a small spot which dries at low water springs; the depths on other parts of the patch vary from $1\frac{1}{4}$ to 6 fathoms. The other patch is at the eastern extreme of the shoal, and is distant $3\frac{1}{2}$ miles S.E. $\frac{1}{2}$ S. from that just described; it is a small spot of $2\frac{1}{4}$ fathoms, with depths of 3 to 5 fathoms at half a mile around.

it. Some casts of 4 fathoms were had about a mile W. by S. from the dry spot, but not less than 5 fathoms on any of the other patches.*

LYS SHOAL lies 2 miles southward of Trident Shoal, and like the latter is formed of a number of patches under 10 fathoms, with a lagoon in the centre; only one danger, a small spot of 17 ft., was found, and this lies near the S.W. extreme of the bank, in lat. $11^{\circ} 19' 40''$ N., long. $114^{\circ} 34' 24''$ E.; around it the depths are 5 fathoms. Some 5-fathom patches were also discovered near the N.E. end of the bank, but nothing under 6 fathoms was met with elsewhere, the general depths on the patches being 7 to 10 fathoms, and a short distance outside of them bottom was not reached with 100 fathoms of line.

North Danger Reef, of coral formation, is about $8\frac{1}{2}$ miles long, N.E. and S.W., and $4\frac{1}{2}$ miles broad. On its N.W. side are two sandy cays, the north-eastern of which is half a mile long, one-quarter of a mile broad, and 10 ft. above the level of the sea at high water; the south-western cay is only 4 cables long, and $1\frac{1}{2}$ cable broad, but its elevation is 15 ft. above the same level. Between the cay is a passage 1 mile wide, with from 4 to 9 fathoms water, leading into the lagoon of the reef, where the depth is from 20 to 25 fathoms.

Shoal water exists all round the edge of North Danger Reef, and there are heavy breakers over the coral, awash at its N.E. and S.W. extremes. No soundings could be obtained close to the edge of the reef with upwards of 100 fathoms of line, but one cast of 380 fathoms was procured $1\frac{1}{2}$ mile to the N.E. of the breakers on its N.E. extreme. On the eastern side of the reef no bottom could be obtained with 450 fathoms of line.

Both cays are covered with coarse grass, and on the north-eastern of the two is a stunted tree in lat. $11^{\circ} 28' N.$, long. $114^{\circ} 20\frac{3}{4}' E.$ The cays are frequented by Chinese fishermen from Hainan, who collect biche-de-mer, turtle-shell, &c., and supply themselves with water from a well in the centre of the north-eastern cay.

Caution.—Vessels should not attempt to pass through the reefs in this part of the China Sea, as a line of dangerous shoals, extending many miles, is known to exist eastward of the dangers just described.

Currents and Tides.—Whilst the *Rifeman* was at anchor on the reefs, careful observations were taken of the set of the current, which, for 16 hours

* Mr. Lyall, commander of the *Trident*, who discovered the Trident Shoal, placed it 6 miles to the northward of this position. The *Rifeman* was employed five days searching that locality without discovering any danger, and it is certain none exists there.

The Bremen vessel *G. E. Lorenz Meyer* was reported by her commander, Mr. Moller, to have struck at night upon a shoal in lat. $11^{\circ} 25' N.$, long. $114^{\circ} 51' E.$; this position was also examined by the *Rifeman*, but no danger discovered, and there is but little doubt that the vessel struck on the eastern patch of the Trident.

out of the 24, invariably set to windward, generally with the greatest force when the monsoon was strongest.

The rise of tide at springs was about 5 ft., and at neaps 1 to 2 ft. ; one tidal stream in 24 hours.

ISLANDS AND DANGERS IN THE FAIRWAY OF THE MAIN ROUTE.

CHARLOTTE BANK.—H.M. surveying vessel *Rifleman* anchored in 8 fathoms upon the Charlotte Bank, in lat. $7^{\circ} 7\frac{1}{4}'$ N., long. $107^{\circ} 37\frac{1}{4}'$ E. From this position the bank extended North three-quarters of a mile, South $1\frac{1}{4}$ mile, East three-quarters of a mile, and West 3 miles ; the least water found was 5 fathoms. The bank will be avoided by keeping under 30 fathoms water when passing its parallel.

SCAWFELL SHOAL.—Mr. Thompson, commanding the ship *Scawfell*, reports as follows:—"On the 13th of May, 1865, on my passage up the China Sea, just before noon I observed an unusual quantity of fish around the ship, and while taking noon observations, rocks were reported under the bottom. I immediately got a cast of the lead, and had 9 fathoms, the lead trembling off the coral gave half a fathom more. The water was very smooth at the time, the vessel having just steerage way, with a very light air from the N.E. Other casts of the lead gave $7\frac{1}{2}$ fathoms until about the middle of the shoal, when the lead got fast between the coral rocks and was lost ; this part appeared as shoal as any that was visible round the ship. Got another lead ready as soon as possible, when we had 17 fathoms, then losing sight of the bottom, the ship drifting to the N.N.W., with a light northerly current about one knot an hour. On sounding an hour later, the ship going in the same direction at the same rate, had 22 fathoms ; one hour afterwards 20 fathoms, this last being 5 or 6 miles north-westward of the shoal.

"The noon observations taken on the shoal gave lat. $7^{\circ} 19'$ N., and by mean of forenoon and afternoon sights for chronometer, made the longitude of the shoal to be $106^{\circ} 51'$ E.. Made Pulo Condore next day, and by that island, together with observations taken in Sunda and Gaspar Straits, the chronometers appeared to be quite correct."

It will be seen that the position of this shoal is about as far to the westward of the usual track of shipping proceeding up or down the China Sea before a fair monsoon as the Charlotte Bank is the eastward of it. Lying so near the fairway, it appears extraordinary that it has not been before observed.

BANDA SHOAL, discovered in 1871, has a depth of 3 fathoms over it, and lies S.E. 48 miles from Pulo Condore, in lat. 8° N., long. 107° E. It is marken on the charts as a small isolated patch.

PULO CONDORE has been before noticed on page 429. It is 50 miles off the coast of Cambodia, and is to the westward of the main track through the China Sea, but immediately in the way of those going between Singapore and Saigon. It is occupied by the French, who use it as a penal settlement. The approaches to the island are safe. The village in the Great Bay on the S.E. side is in lat. $8^{\circ} 40' 57''$ N., long. $106^{\circ} 36' 11''$ E.

The Great Bay is formed by the projection from the main body of the island of two high points of land, which are about 5 miles apart. Off the southern point a chain of four islets extends nearly $1\frac{1}{2}$ mile to the eastward, and the bay is fronted in that direction by an island, named Haon Bai Kan, having an islet off its South side, named Haon Lap.

There are three passages into this bay; that between the southern point and the islets to the eastward of it, although but a quarter of a mile wide, is quite safe, with depths of 20 and 16 fathoms, decreasing to 9 and 7 inside. The passage between the islets and Hoan Bai Kan is about $2\frac{1}{4}$ miles wide, but is nearly filled up by a bank with depths generally of $3\frac{1}{2}$ to $4\frac{1}{2}$ fathoms, hut having one patch of only $2\frac{3}{4}$ fathoms, and two patches of 3 fathoms upon it. The $2\frac{3}{4}$ -fathom patch lies about two-thirds of a mile N.E. $\frac{3}{4}$ E. from the easternmost of the islets. One of the 3-fathom patches lies nearly a mile N.E. by E. from the same islet, and the other is about half a mile S. by W. $\frac{3}{4}$ W. from the western part of Haon Bai Kan. The passage between the northern point of the bay and Haon Bai Kan is the best for large vessels, being two-thirds of a mile wide, with depths of 10 to 19 fathoms.

The northern sides of the islets off the southern point of the bay are fringed with coral, as is the western side of Hoan Bai Kan; but Hoan Lap islet appears to be bold close-to, the chart, however, has no soundings near its astern side. The bay, inside a line connecting its northern and southern points—which bear from each other N.E. $\frac{3}{4}$ N. and S.W. $\frac{3}{4}$ S.—is encumbered with an extensive shore flat, as also many detached shoal patches having less than 6 ft. water over them. On account of these dangers vessels should not go inside the line connecting the points, excepting at the S.W. part of the bay, where they may stand in until the North point of Haon Bai Kan bears N.E. by E. $\frac{1}{4}$ E., there being nothing outside that line more dangerous than a patch of $3\frac{1}{2}$ fathoms, with $4\frac{1}{2}$ and 5 fathoms near it, which lies nearly half a mile N. by E. $\frac{1}{2}$ E. from the southern point of the bay; and a small patch of $3\frac{3}{4}$ fathoms, with 6 and 7 fathoms around it, which lies N.N.E. $\frac{1}{2}$ E., distant $1\frac{1}{4}$ mile from the same point.

The anchorage in Great Bay is only available during the S.W. monsoon. In order to avoid the sea, vessels should anchor in its S.W. part, where, however, the squalls are heavier, but the holding ground is good, the bottom being gray mud. There appears to be good, safe anchorage, with depths of $5\frac{1}{2}$ and 6 fathoms, inside the $3\frac{1}{2}$ and $3\frac{3}{4}$ fathoms patches, with the South point

bearing from S. by W. to South, and Haon Lap Islet from E. $\frac{1}{2}$ N. to E. $\frac{1}{2}$ S. A good berth for a large ship appears to be in 7 or 8 fathoms, with Haon Tai-leung, the largest islet off the South point of the bay, bearing about South, and Haon Lap East or E. $\frac{1}{2}$ N.

North-East Bay is to the northward of the North point of Great Bay, and would appear to offer convenient shelter in the S.W. monsoon for vessels not wishing to enter Great Bay. It appears to be quite free from danger, but the depths decrease rather quickly from 6 to 5 fathoms. Vessels should therefore anchor in 7 fathoms, or directly the water shoals under that depth.

Haon Cao is the name of a bold island, nearly a mile in extent, lying 2 miles N.E. by E. from Haon Bai Kan. In the channel between them are depths generally from 12 to 15 fathoms, but near Haon Cao the soundings appear to be more irregular, 17 to 29 fathoms.

A barren white rock lies N.E. by E. $\frac{1}{4}$ E. $3\frac{1}{4}$ miles from the N.E. point of the largest island of the Pulo Condore group; around it are 17 to 22 fathoms.

South-West Bay, or Pulo Condore Harbour, called by the Cochin-Chinese Queou Dam Leun, is formed between the S.W. end of the large island and an adjoining high island called Little Condore, or Bae Vioung, the East point of which is separated from the S.W. point of the large island by a narrow gullet, but to the north-westward they are separated about three-quarters of a mile, forming the entrance to the harbour. Here the depths are 9 and 7 fathoms, gravel and mud, decreasing to 5 and 3 fathoms near the flat that occupies the head of the harbour, and which is dry at low water. This bay is well sheltered by the surrounding hills, except from the north-westward, but the wind is seldom strong from that quarter; it affords shelter to seven or eight vessels. The heavy squalls require precaution, but holding ground is good.

Some islets lie off the North point of this bay, to the northward of which is a high island named Haon Trap, having some rocks above and below water extending from its N.W. side.

Haon Tae, another high island, lies about a mile to the north-westward of Haon Trap; off its north-eastern extreme is an islet. Haon Tae Niao is another island lying a little more than 2 miles to the north-eastward of Haon Tae, having a reef and some rocks extending a little over a cable's length from its North and East sides. There is a safe passage inside the two last-mentioned islands, with depths of 16 to 22 fathoms.

Supplies.—At the time of the *Riflemen's* visit, in 1862, the inhabitants were living in a state of great poverty in miserable huts, and subsisting upon yams, pumpkins, fruit, and fish. Horsburgh remarks:—"These islands abound with timber, but there are no articles of trade to be procured; the soil being generally dry and unfruitful, the country unhealthy, and abound-

ing with reptiles, there is no inducement for strangers to visit this place ; consequently few ships touch here."

In the *Mer de Chine*, 1st part, page 197, published in 1865, it is stated that "the character of the inhabitants is very mild. The country, without being rich, yields plenty of fruit, timber for building, and vegetables. The natives rear a large quantity of pigs and poultry."

Water may be procured in the N.E. part of South-West Bay, a short distance to the southward of the landing-place.

Tides.—At the Pulo Condore group it is high water, full and change, at 2^h 30^m, and springs rise 6½ feet.

Soundings.—The soundings 13 or 14 miles outside the Brothers are 17 or 18 fathoms ; 13 and 12 fathoms within 2 miles of them on the East and N.E. sides, deepening to 17, 18, and 20 fathoms close to Pulo Condore. When Pulo Condore bears North, or N. by E., distant about 30 miles, the soundings are 19 and 18 fathoms ; when N.W. about 25 miles, 18 and 17 fathoms ; West 45 or 50 miles, 24 fathoms ; West 60 miles, 27 fathoms. Rounding Pulo Condore on the South and S.E. sides within 2 to 3 miles distance, the depths will be 17 or 18 fathoms.

From 18 fathoms, near the White Rock off the N.E. end of the Pulo Condore group, the soundings continue between 18 and 17 fathoms for a few miles in a direct line to Cape St. James, when they gradually decrease to 15, 14, and 13, with an occasional cast of 17 fathoms, as that headland is approached.

From Pulo Condore, steering direct for the Great Catwick, the depths increase very slowly until within 40 or 45 miles of the latter, then rather quicker from 30 or 34 to 45 and 50 fathoms near the Catwick.

The following accounts of the reefs and dangers to the north-eastward are chiefly derived from the result of a survey made by navigating-lieutenant J. W. Reed, commanding H.M. surveying vessel *Rifleman*, between the 3rd April, and 21st May, 1863.

ROYAL BISHOP BANK.—From near the Great Catwick, the *Rifleman* carried a line of soundings for this bank until she came to a coral patch, 3½ miles long, E.N.E. and W.S.W., and about 1½ mile broad, having 10 fathoms least water upon it, in lat. 9° 40' N., long. 108° 14' E. There are 28 to 30 fathoms all round it.

Circumstances did not permit of a farther search for the 7 and 8 fathoms patches said to be found on the Royal Bishop, and which will probably be discovered to the northward of the bank examined.

Corsair Rock is now removed from the charts. Its existence has been frequently denied, and the *Rifleman* passed so close to its reported position, lat. 9° 54' N., long. 108° 35' E., that she must have seen it if it had been there.

RAGLAN BANK.—The ship *Lady Raglan*, in September, 1858, is said to

have passed over a rocky shoal lying about S.E. $\frac{3}{4}$ S. 39 miles from Pulo Sapatu, in lat. $9^{\circ} 28' N.$, and long. $109^{\circ} 25' E.$; no soundings were tried for, but the rocks were plainly visible under the vessel's bottom; shoal water was seen a short distance off; the direction, however, is not stated. This is another doubtful danger which could not be found by the *Rifleman*, there being upon the spot no bottom with 300 fathoms. The *Lightning* steamer also passed over this position recently without observing any appearance of danger, although circumstances were very favourable for doing so.

In 1875, the French government gave notice that the vessel *Jackmel* had passed near a shoal supposed to be the same as that seen by the British ship *Lady Raglan* in 1858. The *Jackmel* passed close to the shoal, on which the sea was breaking heavily, and the position assigned to it by that vessel is lat. $9^{\circ} 24' N.$, long. $109^{\circ} 26' E.$ The position of this danger must be considered as approximate, and caution is necessary when navigating near it. It will be observed that the position assigned to the danger by the *Jackmel* is 1' to the eastward and 4' to the southward of the spot searched by the *Rifleman*.

PULO SAPATU (or *Sapata*), or *Shoe Island*.—Its summit, 347 ft. high, is in lat. $9^{\circ} 58' 23'' N.$, long. $109^{\circ} 5' 57'' E.$ It is the easternmost of three islands that go by the name of Catwicks. It is a high, barren rock, frequented by numerous birds, one-third of a mile long North and South, about half as broad, and visible in clear weather at 22 or 23 miles. Under very favourable circumstances it is possible to effect a landing upon the rocks at its base; but otherwise it is impossible. When viewed in some directions, it resembles a shoe; at others it seems a large square column; and when bearing to the westward it assumes the form of a pyramid. Ships generally endeavour to sight this island, or to pass within 20 or 25 miles of its eastern side, in proceeding up or down the main route of the China Sea. With the exception of a rock awash lying a quarter of a cable's length eastward of its South end, the island is bold close to; 16 and 17 fathoms were obtained about 2 cables' lengths eastward of it, and half a mile off in that direction 25 to 30 fathoms. On the West side the soundings are a few fathoms deeper.

JULIA SHOAL is a small coral patch about a quarter of a mile in extent, with only $2\frac{1}{2}$ fathoms on it at low tides, lying S.E. by E. distant $3\frac{1}{2}$ miles from Pulo Sapatu.

The Little Catwick in line with the northern extreme of Sapatu, N.W. by W. $\frac{2}{3}$ W., leads nearly half a mile north-eastward of the Julia; the Little Catwick exactly in line with the southern extreme of Sapatu, leads over 10 fathoms water on the S.W. edge of the shoal; and the Little Catwick well open of the southern extreme, N.W. $\frac{2}{3}$ W., leads half a mile south-westward of it.

When the Little Catwick is just lost behind the southern extreme of Sa-

patu, and the angle of elevation of that island is $1^{\circ} 22'$, or more (the height of the eye being 15 feet), ships will be one mile or more inside the Julia. When the angle of elevation is $0^{\circ} 45'$, or less (the height of the eye being 15 feet), they will be one mile or more outside the shoal.

It is strange that no mention of this important danger is made in Horsburgh. In 1836 Mr. Thomas, commanding the ship *Good Success*, observing a rippling, sent a boat to examine it, and found a sharp pinnacle rock, to which the boat was held by a boat hook. In 1847 it was examined in the ship *Julia*, but no less water than 3 fathoms could be found, which is no doubt the usual depth upon the shoal, although it is not safe to depend upon finding more than $2\frac{1}{2}$ fathoms. It is possible that the *Christopher Rawson* knocked off the pinnacle mentioned by Mr. Thomas. She struck with great force, dragging the stern post out of her.

From the examination made in the *Julia* the danger obtained a position on the charts, which position was very nearly the same as that ascribed to it by Mr. Thomas. Lieut. Reed agrees with both in bearing, but makes the distance from Pulo Sapatu (which with them must have been a matter of judgment only) a mile less than they.

This shoal has been the cause of more anxiety, perhaps than any other in the China Sea. In all probability many of the reported positions of dangers in that locality (for instance the Hopkins Bank), have proceeded from this shoal having been seen, and its position wrongly estimated. In the note below* are given Lieutenant Reed's reasons for believing that the *Christopher*

* The *Rifleman* searched carefully for the dangers supposed to exist to the eastward of Pulo Sapatu, but without success. The Rawson Shoal was marked on the charts as a doubtful danger about 20 miles E.S.E. of Pulo Sapatu. It was hereabouts the *Christopher Rawson* was supposed to have struck. But bearing in mind that the accident occurred in the middle of the night, when the ship was running under double-reefed topsails before a strong N.E. monsoon, and that she went down a few minutes after striking, the crew having barely time to save their lives by taking to the boats, it was manifestly impossible under such circumstances to calculate the position of the shoal with any degree of certainty; it must have been a matter of mere conjecture.

It happened that the gunner's mate of the *Rifleman* belonged to the *Christopher Rawson* when she was lost. Overhearing him speak of the wreck in the passage out from England, Lieutenant Reed questioned him as to the circumstances. He asserted that they had seen no land before the vessel struck, but shortly after they had taken to the boats (which were running before the wind) an island was seen upon the starboard quarter about 4 or 5 miles off. If this statement be true, the vessel could not have been lost in the position shown in the charts, for Sapatu is only visible from the bridge of the *Rifleman* at a distance of 22 miles.

The *Rifleman* steamed about the position of the *Rawson* a whole day, but could find no appearance of danger. The soundings upon the spot were 162 fathoms, with similar depths around it. H.M.S. *Saracen* also passed over this spot some years ago and saw no danger. It has also been passed over by many other vessels with the same result.

Rawson (the only vessel heard of striking on a shoal near Pulo Sapatu) was lost upon the Julia; and that from the impossibility of correctly calculating the ship's position at the time of the accident, the navigation of the China Sea was for twenty years encumbered with the Rawson Shoal.

The **PYRAMID**, or **LITTLE CATWICK**, is a small peaked rock 56 feet high, lying N.W. by W. $\frac{1}{2}$ W. $2\frac{1}{4}$ miles from Pulo Sapata. It is steep close to, with no danger near it, and can be seen about 9 to 10 miles.

The channel between this rock and Pulo Sapatu is free from danger, and the soundings in it are deep, 50 to 65 fathoms. The following observations from Horsburgh are very valuable,—“Although this passage seems to be safe with a commanding wind, it ought not to be adopted excepting in a case of emergency, for it is contracted, and the currents are strong and irregular about these islands. Ships passing here in the night, during the N.E.

A day was also spent in searching for the Hopkins Bank, but no sign of danger was met with in this case either.

For these reasons, therefore, and considering also that no authentic account of danger having been seen near the position has since appeared, Lieut. Reed thinks that it may be fairly inferred that the *Christopher Rawson* was lost on Julia Shoal; and that there is no good reason for believing that any other danger exists in that locality.

A day was spent in carefully searching for the Forth, Columbia, and Alexander Shoals, but nothing of the sort could be met with. Upon the positions of the Forth and Alexander the *Rifleman* had no bottom with 500 fathoms; and no bottom with 350 fathoms upon that of the Columbia.

Mr. T. B. White, the late commander of the *Lanrick* and *Fiery Cross*, a gentleman of great experience in the China Sea, in an able paper communicated to the Nautical Magazine in 1853, thus mentions these shoals:—“The Shepherdess, Christopher Rawson, Forth, and Alexander Shoals, I do not believe to exist. The *Rawson* was no doubt bilged on the 3-fathoms patch (the Julia Shoal) lately found a few miles S.E. of Pulo Sapatu. The Forth Rock is said to have been seen at 2 a.m. in a dark squally night, and the *Alexander's* wreck is asserted to have been seen on the Western Reef. Nor need we be much surprised at this latter discrepancy, when it is known that in the strength of the S.W. monsoon, observations are often not to be had for 36 or 48 hours, and the current in that season often runs from 30 to as much as 56 miles in 24 hours, varying in direction from E. by S. to N.E. by E.”

Mr. Crockett, now commanding the steamer *Clan Alpine*, who has had similar experience in the China Sea to Mr. White, also states that he has passed over the positions of all these supposed shoals, and has never seen any sign of danger. Many similar statements have been received from other captains not so well known as those referred to, but in every way worthy of credit.

From the above statements, and from the result of the examination in the *Rifleman*, it may be inferred that the main route to China is not fraught with so much difficulty and danger as it has been hitherto considered to be, and that, with the exception of the Julia and Raglan Banks, there is no reliable report of the existence of any danger between Pulo Sapatu and the western edges of the reefs known to extend from the North Danger Reef far to the south-westward.

monsoon, ought to make proper allowance for a south-westerly current, which is liable to deceive, and to carry them down upon the island, particularly if the wind is strong at the time."

ROUND ISLAND, or **GREAT CATWICK**, is a barren rock 196 ft. high, and about $1\frac{1}{2}$ cables in diameter, bearing W.N.W., distant $11\frac{3}{4}$ miles from Sapatu, and nearly South, about 30 miles from Pulo Ceicer de Mer. It is bold close-to, having 30 to 50 fathoms at a short distance from it in all directions.

LA PAIX ROCK is a small spot with a pinnacle awash lying nearly in the fairway of the channel between Great and Little Catwick, and which may, with this exception, be considered safe to navigate. From the pinnacle the Great Catwick bears west-northerly, distant $4\frac{1}{4}$ miles, and the Little Catwick is seen open to the southward of Pulo Sapatu, bearing S.E. by E.-easterly, $5\frac{1}{2}$ miles. Except in exceedingly fine weather, the sea always breaks upon this rock, but vessels should not attempt the channel at night, unless their position is exactly known, and other circumstances are favourable.

YUSUN SHOAL, in lat. $10^{\circ} 16' N.$, long. $109^{\circ} 2' 15'' E.$, is a small coral patch of 4 fathoms, lying in the fairway of the channel between Ceicer de Mer and the Catwicks. From it the S.W. summit of the former bears N. by W. $\frac{3}{4}$ W. $17\frac{2}{3}$ miles, the Great Catwick S.S.W. $\frac{1}{4}$ W. $14\frac{3}{4}$ miles, and Sapatu S. by E. $\frac{1}{4}$ E. 18 miles, which is very nearly the position assigned to it by its discoverer; close around it are 45 and 50 fathoms, which is the general depth of the middle of the channel; but about a mile W.N.W. of the shoal is a patch of 24 fathoms.

In fine weather the shoal is not easily seen, but when blowing hard in the strength of the monsoons, the sea has been frequently observed to break heavily upon it.

There is good reason to believe that the Yusun is the only danger in the channel between Ceicer de Mer and the Catwicks, which is otherwise spacious and safe. The soundings in the channel are irregular, and will be better understood by a reference to the chart.

PULO CEICER DE MER is $3\frac{1}{2}$ miles long North and South, and $1\frac{1}{2}$ mile broad. There are two small hills towards its North end, and they bear E.N.E. and W.S.W. distant a mile from each other. The S.W. and higher hill of the two is in lat. $10^{\circ} 32' 36'' N.$, long. $108^{\circ} 56' 30'' E.$; it is 360 feet high, has a round top, slopes gradually until it joins the low land. and is visible at 24 or 25 miles. The N.E. hill, 306 ft. high and of a conical form, rises abruptly from the low land, and has several irregular masses of rock near its summit, which give it a somewhat remarkable appearance.

Nearly half a mile off the N.E. end of the island are several masses of rocks with foul ground around them; the most conspicuous is a large black rock 60 ft. high. This part of the island should not be approached by ves-

sels of large draught nearer than $1\frac{1}{2}$ or 2 miles, nor by small vessels nearer than a mile. In a case of emergency it is possible, perhaps, to gain shelter from the S.W. monsoon by anchoring off the N.E. end in 14 or 15 fathoms; but the bottom is rocky, bad holding ground, and by no means to be recommended as an anchorage.

On the East side of the island is a sandy bay which has the appearance of affording convenient anchorage; but a coral reef not only fills it completely up, but projects in such a manner that the 5 fathoms line of soundings forms an arc of a circle convex to seaward more than a mile distant from the depth of the bay, and approaches within a cable's length or two of the N.E. and S.E. points of the island. Vessels should be extremely cautious in approaching this treacherous bay, as the soundings decrease so suddenly from no bottom with 40 or 50 fathoms to 4 or 5 fathoms, that the land cannot be relied upon to give warning of the danger in sufficient time to avoid it.

At half a mile off the S.E. end of Ceicer de Mer is a small island lying in a North and South direction, the highest point of which is 133 ft. above the sea. The S.E. part of Ceicer de Mer is nearly the same height, and both present steep rugged cliffs to the eastward. In the middle of the channel between these islands is a mass of rocks just above water, between which and the small island is a channel for boats. A quarter of a mile S.E. of the small island is a conspicuous black rock 30 feet high, with smaller rocks around it; 2 cables' lengths S.E. of which, again, are two rocks awash. The small island, therefore, should not be approached within a mile when bearing to the westward of North.

Anchorage.—A sandy beach extends along the whole West and S.W. coasts of Ceicer de Mer, the S.W. point being formed by a number of black rocks. There is fair anchorage in 13 to 16 fathoms, with a bottom of sand and shells, all along these shores; but the best is just to the southward of the S.W. point, where vessels may conveniently anchor in 10 to 14 fathoms. It is necessary, however, to be careful in coming to, as shoal water and rocks extend about one-third of a mile from the island, and the depths rapidly decrease from 11 to 4 fathoms.

Supplies, etc.—Pulo Ceicer de Mer is inhabited by poor fishermen and others, and is well cultivated, yet no supplies could be obtained. The natives brought off a few fowls on one occasion, and seemed pleased to receive some empty bottles, biscuit, &c., in return; but they refused all offers of money, and would not be prevailed upon to sell anything. They were much disturbed at the vessel remaining so long in their neighbourhood, and kept up an almost incessant noise with drums and gongs all the time she was at anchor. They always lined the beach, armed with spears and other Chinese weapons, when any boat landed, but did not attempt to molest the crew.

HIGH ROCK, of a white colour, 50 ft. high, and the resort of sea birds,

lies N.W. $\frac{1}{2}$ N. nearly 5 miles from the N.W. point of Ceicer de Mer. Nearly half a cable's length northward of it is a small rock a few feet above water, close to the northward of which is a rock awash.

In the channel between Ceicer de Mer and High Rock the depths vary from 8 to 12 fathoms, and the bottom is coral. Near the rock some patches of 5 and 6 fathoms were found, but no danger discovered. The channel between Ceicer de Mer and Holland Bank is about 12 miles wide. The depths in it are very irregular, varying from 26 to 10 fathoms, the bottom generally sand, or sand and shells, at the deep soundings, and rocky at the shoal ones.
